AN Augustine Guinoisseau Rose bush which I bought some eight years ago has suddenly reverted in part to a La France, from which I have always understood Augustine Guinoisseau originally sported. The bush is now bearing blooms of both varieties at the same time, which has a curious effect. I do not know if any of your readers have ever experienced a similar occurrence.

Forest Park, Windsor. ARTHUR L. WIGAN.

[We have frequently had plants of this Rose suddenly produce a growth bearing La France blooms, which proves it to be a sport of that old variety. We understand the introducer kept the variety some years before he sent it out, possibly because of its tendency to revert back. However, it is a very lovely Rose, and we do not mind if it does occasionally produce flowers of a deeper colour than its own. Both Roses are deliciously sweet.—Ed.]

### SARAH BERNHARDT.

(HYBRID TEA.)

A ROSE of even more brilliant colouring than Liberty, with semi-double flowers of the size of Bardou Job, will surely be welcome to all lovers of this picturesque type. We have such a flower in Sarah Bernhardt, which should enable the planter to make some very effective groupings this autumn. The variety is semi-climbing and thus must be allowed a freedom of growth such as we accord to Grüss an Teplitz, Gustave Regis, Alister Stella Gray, Gloire des Rosomanes and varieties of that type. One can imagine what a glorious effect will be produced when Sarah Bernhardt is freely planted. It provides a really splendid bit of colour much enhanced with the wealth of golden stamens in the half-open flowers. There are about nine petals composing the flower, so that it is somewhat fuller than Bardou Job. One would do well to plant Sarah Bernhardt on the upright posts of a pergola on the sunny side, or else as a free bush, affording the plant a space of 3 feet each way and looping up a branch or two to a stick if necessary. P.

## THE FRUIT GARDEN.

### PLANTING STRAWBERRIES IN AUTUMN.

THE BEST VARIETIES.

THE amateur who looks through a list of Strawberries is often at a loss to know the best to plant in the garden, as the most reliable varieties are required, at least these should be selected in preference to mere size. At the same time, if both size and variety can be secured so much the better. I have for many years advocated treating the Strawberry more like an annual or biennial, and this done it can be grown in land quite unsuitable, as by deep cultivation it is remarkable what vigour the plant has. It will pay for cultivation if not left too long in one place. Another point amateurs should observe is not to replant from exhausted plants. This is a great mistake, as runners should be secured from strong tufts or new stock from a distance. The soil should have been deeply dug in advance. I have frequently planted after late Potatoes and got excellent results.

Select an open place for the main crop sorts, a south border for early ones and a north for the latest. This gives a long succession. I recently saw in an amateur's garden (the soil very poor) six rows of three varieties, early, mid-season and late, and in soil that he was told would not grow Strawberries, whereas they have been excellent. The land was trenched, the manure was placed halfway down at the digging and there was an excellent return. He will take one more crop and then destroy, and to get fine fruits yearly a new bed will be planted each season and one destroyed, but of course having a fresh site, not planting on the old quarters for at least three years.

PLANTING.

August or September is a good time to plant, though I have done so in November, but prefer the earlier dates, and the soil being prepared as advised. If the land has had a Potato or other vegetable crop, dig deeply and incorporate some decayed manure with the top spit. Much depends upon whether the soil is heavy or light. If the former, any light material, such as spent manure, old Marrow beds or road sweepings, will do good, or a dressing of lime well dug in after being spread evenly over the surface. For light soils more food is required and deep culture is necessary. The plants do well 2 feet between the rows and 18 inches between the plants. I admit this is somewhat close, but it must be remembered that the plants are not long on the land, and this is a fair space, as the first season there is ample room to work between, and the second year, after the crop is cleared, the land is at liberty and gives good results without digging if drills are drawn for such crops as Broccoli, Kale or Savoy.

I fear some of my readers may object to a two seasons' crop only, and this mostly applies to gardens where Strawberries are not a success. Here I advise more frequent planting, and feel sure the results will give satisfaction. Firm planting is important, placing the crown of the new plant quite under the surface of the soil. If above the plants are loose and give poor crops; indeed, after a severe winter it is a good plan to make the new plants quite firm by treading and to draw a little soil out of the rows to the crowns to encourage surface roots. The after management is simple, merely hoe between, keep clean and remove runner growths.

VARIETIES.

In poor land a good grower is advisable, and there are none better than Royal Sovereign. This is early, a good fruit and a splendid bearer. The older President is still a reliable midseason variety, and I am unable to omit Vicomtesse Hericart de Thury, not a large fruit, but a wonderful cropper, and does well where others fail, also a splendid preserving fruit, rich and good, hardy, prolific and excellent. Of newer sorts that have been proved the Bedford Champion is an excellent fruit but very large, and those who object to size would find Reward most suitable. This is a cross between British Queen and Royal Sovereign, and it has the Queen quality with the free growth of the Royal Sovereign; it is a beautiful fruit as regards size, colour, shape and finish, a midseason variety of vigorous growth. Laxton's Latest is also a very fine fruit, a dark coloured variety and of free growth; it is useful for its late supplies. One of the best croppers for poor soils is Pillbasket, of good flavour, also bears enormous trusses.

Givon's Late Prolific is excellent, and does well where others fail. Of the Pine family the Filbert Pine is a reliable fruit, late and excellent and of freer growth than the Frogmore. The Elton is very late, but somewhat acid in flavour. I have named enough varieties for any amateur who has difficulties to contend with and omitted new sorts that have not yet been long in cultivation. There is no need to have too many kinds, but only those that are reliable and of good quality. The new perpetual fruits are most interesting.

I noted these in *THE GARDEN* earlier in the year; they greatly prolong the season and are of easy culture. G. WYTHES.

### ANTS IN THE FRUIT GARDEN.

IN recent issues various ways have been given to destroy ants. Although they are not generally an annoyance, still in some soils and situations they are troublesome. I have found them so on light, dry soils, giving much trouble in Peach houses when in bloom. During the past hot weather I have found them giving trouble on Red Currant bushes, carrying the fine soil on to the berries. As our soil is light and dry, they make their nest in almost any position. In this instance they selected it among some large patches of White Pinks and double White Arabis. These are used as an edging to the centre path of the garden. After trying several things it occurred to me to use Abol White Superior Insecticide. I used two measures to the gallon, then with an Abol syringe and the coarse spray (using the solution at about 100°) forced the liquid into the nest. Every one with which the preparation came in contact was killed. I then lifted up the foliage of the Pinks, &c., and forced it among them, there being a large number of eggs and young ones. After I had made all wet I left it until the next day, when I found only a few left where the solution had not touched them. These received a dose which entirely destroyed them. On the third day not one could be seen. Boiling water is recommended, but in this case that would have killed the plants. Not so with Abol. This may be used in dwelling-houses; it is not poisonous, and is quite safe where animals are kept. J. C. F.

## TREES AND SHRUBS.

### THE DAISY TREES.

**O**LEARIA or Daisy Trees are worthy of more attention than they receive, for they are profuse bloomers and very showy. In many parts of England they will be found quite hardy, but should the frost be very severe must be sheltered in winter. The illustration accompanying this note shows a well-grown specimen of *O. macrodonta*, its silvery grey thorn-pointed leaves and white blooms making an effective foil for the rosy pink Rhododendron growing beside it, as they come into bloom together. S. M. W.

### A WHITE-FLOWERED HONEY-SUCKLE.

(*Lonicera Maaekii*.)

THE species of *Lonicera* commonly known as Honeysuckles are distributed throughout the temperate regions of the Northern Hemisphere, reaching as far north as the Arctic circle, but only in the Malayan Archipelago crossing the Equator, attaining their southern limit in Java. The headquarters of the genus is in Central and Eastern Asia, and recent botanical explorations have added considerably to our knowledge of the species belonging to those regions. Some 150 species are enumerated in Rehder's synopsis of the genus *Lonicera*; of this number 20 belong to North and Central America, 18 to Europe, including the Mediterranean region, and the remaining 112 are Asiatic.

Although previously introduced to this country, *Lonicera Maaekii* was not in general cultivation until introduced by Messrs. Veitch a few years ago through their collector, Mr. E. H. Wilson, who sent seeds of it from China. A small plant in flower was recently exhibited by Messrs. Paul at a meeting of the Royal Horticultural Society at Vincent Square. The plant forms an upright, medium-sized, deciduous shrub, with

slender horizontal branches clothed with oval, lance-shaped, pointed leaves narrowed to a stalk at the base and arranged in pairs on the branches. The trumpet-shaped flowers are produced in pairs in the axils of the leaves along the whole length of the growths; they are white when they first open, but assume a yellow colour before they fall. The stamens are about half the length of the corolla tube, and are furnished with bright yellow anthers.

Being perfectly hardy, extremely floriferous and not particular as to soil, this Honeysuckle should find a place in all gardens where flowering shrubs are appreciated. The only attention it requires after it has become established is a thinning out of the branches after the flowering is over so as to encourage the production of well-ripened growths on which the succeeding flowers are borne. H. SPOONER.

### FLOWERING SHRUBS IN JULY.

IN the majority of gardens there is during the summer months almost an entire absence of shrubs in flower, and very little of interest or beauty is to be noticed from the time when the large number of spring-flowering subjects cease till the autumnal tints appear. Now this is, admittedly, not as it should be, for there are many beautiful shrubs which flower in July and onwards. If for this reason only they deserve much extended cultivation. A want of knowledge of these shrubs is, undoubtedly, the reason why they are not planted, but with the increasing interest now being extended to this most fascinating branch of gardening, one may reasonably expect to see them more extensively grown. To those who are interested in the subject the excellent and exhaustive article in the current number of the Royal Horticultural Society's Journal, by the Hon. Vicary Gibbs, should prove of great value, and may be looked upon as a perfectly safe guide as to what to plant and what to omit.

It is indeed surprising to find how large the number is when one inspects a representative collection, but the undermentioned kinds have been carefully selected, and may be regarded as among the best for garden decoration.

The *Spiraea* family, which contains many of the most beautiful spring and summer-flowering shrubs, is responsible for a number at this season, and nearly all the larger growing ones are to be seen at their best. *Spiraea lindleyana*, the species of largest growth with pinnate foliage and great panicles of creamy white flowers, is a handsome shrub if allowed sufficient room to develop and display its elegant semi-pendulous growth. If it gets a little out of place, hard pruning can be resorted to. This not only improves its appearance, but frequently invigorates the growth. The newer *S. Aitchisoni* resembles the preceding, but is more refined. Its reddish stems and pure white flowers, which appear at the beginning of August, render it possibly more attractive. *S. assurgens* would be worth growing if the fresh green foliage were its only merit, but during July each stem produces large terminal panicles of creamy white flowers. It is of vigorous growth, and as new stems are freely sent up from the base, the old wood can be occasionally removed with advantage. The typical *S. japonica* is a very pleasing shrub with pink flowers, and it has several excellent varieties, including *alba*, *Bumalda superba* and *Anthony Waterer*, all of which are dwarf, compact growers. The last-named is one of our finest coloured flowering shrubs, and should be much more largely planted in gardens. If space will permit of planting a large or small bed of this sort, a telling effect may be produced. The colour of the flowers is rich red, not equalled by any other hardy shrub with which I am acquainted. There are numerous other species and varieties which flower in July and later, but the foregoing is a selection of the most noteworthy, which may be thoroughly recommended.

The *Cytisus* and *Genista* families are responsible for several very beautiful summer-flowering shrubs, but as these do not transplant well after becoming established, it is advisable to select positions when planting where they can be allowed to remain. There is, however, one important exception to this rule, namely, *Cytisus nigricans*, which we have found does not resent being disturbed. A. E. T.

(To be continued.)

ONE OF THE DAISY TREES (*OLEARIA MACRODONTA*) IN A GARDEN IN DONEGAL.

## THE FLOWER GARDEN.

### EARLY SOWING OF CANTERBURY BELLS.

**W**HEN well grown few plants are handsomer or make a finer show than this well-known favourite; it needs little care, growing well in any ordinary garden soil. Seed is generally sown in June or July, but a better result is assured if it is sown either in March or April, for then the seedlings have time to grow into fine plants before autumn. The illustration is of part of a border of Canterbury Bells which gave a striking example of the success of spring sowing. It was planted with self-sown seedlings which came up in various parts of the garden early in the year. These were removed to a nursery bed and grown on there until September, by which time they had become fine strong clumps ready for their permanent quarters. These plants stood the winter well in spite of a damp soil, and flowered profusely, many of the plants being 3 feet in

CANTERBURY BELLS IN SCOTLAND.

diameter. The illustration gives an idea of the wealth of bloom and shows the wisdom of early sowing.  
I. S. TURNBULL.

### BUD-DROPPING IN SWEET PEAS.

I HAVE been troubled with Sweet Pea buds shrivelling and dropping off. I enclose one specimen of shrivelled buds and two of flower-stems from the same plant where terminal buds have dropped off. The Peas are in light, open soil, well manured with soot and stable manure some time before sowing. They are 6 inches apart, and look very healthy apart from this. The flowers are large and well formed in most cases, but many buds on all plants have dropped off. We suffered here from drought some weeks ago, but the Peas were carefully watered during the time. I should be very grateful for your advice.  
J. M.

—I shall be much obliged if you can tell me the cause of the disease that has attacked my Sweet Peas. The buds dry up and fall off; in many cases all, sometimes one flower in three matures. I can see no reason, as they are all

doing the same. The soil is rich, and manure was put in the trench before the seeds were sown. The seeds sown in pots are doing the same. If you can reply to my query in your next number I should be obliged, as, if there is a remedy, I should like to try and save some.  
J. H.

[It is impossible to assign one cause of this trouble that is applicable to all cases. There is little doubt that it is almost invariably due to a check in progress, which may be the result of over wetness or over dryness at the roots or to extreme variations of the temperature affecting the tops. A frequent cause is a check at planting out, but our correspondents do not say whether the seeds were sown in or out of doors. Some varieties appear to be more prone to it than others.—H. J. W.]

### PANSIES FOR SMALL GARDENS.

"SEEING is believing" is one of the wise saws that we have all known since we were children, but whose force and impressiveness only strikes us now and again. I have grown *Violas* off and

summer. She told me her secret was nothing but daily picking and never allowing seed-pods to form.

This brings me to my second point. The picked flowers were not thrown away, but were used for decorating the dinner-table and the sitting-rooms, sometimes arranged with foliage, sometimes as "blobs" of colour, the small vases each filled with just one self variety. It was a case of a fortune in the refuse which many might unthinkingly throw away.

### HOW THIS IS DONE.

The first thing is to get suitable varieties. To be useful for both garden and house purposes long flower-stalks are a prime necessity. Other important factors are freedom of flowering and a not too compact habit. A certain looseness seems more effective and telling when they are not used in geometrical designs or as a carpet for other things. The following is a list of good varieties which will serve as a guide to those unfamiliar with their names. Nearly all of them can be bought at 2s. or 2s. 6d. a dozen. Blues: Archibald Grant, dark; and Admiral of the Blue, medium. Mauves: Blue Duchess, pale blue; Maggie Mott, bright mauve; and Kitty Bell, pale lavender. Whites: Duchess of York, loose flower, rayed; and Snowflake, very pure, rayless. Yellows: Royal Sovereign, deep yellow, rayless; and Klondyke, longer flower, rayed. Purple: Duncan, imperial purple (I hear this was extensively used in the Coronation decorations). Fancies: Countess of Kintore, purple and white; Mrs. Chichester, white, pale purple edge; Ada Anderson, lavender and white; and White Duchess, white, blue edge.

### MANAGEMENT.

*Violas* grow in any good garden soil, provided it is not very light and sandy or very heavy clay. In the former case nothing is better than a good dressing of well-rotted cow manure, well dug in in the autumn before the young plants are put in. In the latter, littery horse manure should be used. In any case it is well to treat the ground with Vaporite or a similar preparation to kill any wireworms, slugs or other depredators that have a weakness for the young tender shoots. If these simple precautions are taken they may be said to grow anywhere but in deep shade.

### PROPAGATION.

They may be increased by seed or by cuttings. In the case of seed, save only from the very best kinds or buy from the best sources. It may be sown thinly in rows out of doors in a shaded position in July or August. In about six weeks' time or a little more the seedlings may be transplanted to the place where they are to bloom next spring. Where no particular colours or types are wanted this system has much to recommend it, for the expectation of "something good" is always exhilarating. I should, however, never advise any one to raise seedlings out of doors in very cold or exposed situations. In the case of cuttings, to ensure a display next year it is best to take them in July or August. Nice short-jointed young lateral shoots of 2 inches or 3 inches in length that have never borne flowers should be chosen and the lower leaves cut off. These should be firmly inserted in a prepared bed of light soil in a semi-shaded position. There they may remain until they are put into their blooming quarters in the following March or April.  
JOSEPH JACOB.

### THEIR UTILITY.

I was recently staying with a friend who has a tiny garden. Speaking from memory I do not think it would be more than 30 feet by 40 feet, but it looked so bright and gay. What was in it? Practically nothing but *Roses* and *Violas*, and it was the *Violas* that made the show, for the *Roses* were not yet out. It had been gay for several weeks, so the lady of the house told me, and she expected to have flowers all the

### NOTES FROM A LONDON SUBURBAN GARDEN.

My garden lies in the south-east of London, six miles and a-half from London Bridge, and, therefore, in no sense of the word can it be called other than a London suburban garden. The situation is an open one, and considering the way in which the present day builder cuts up the

ground for building purposes in and around the great Metropolis my garden may be fairly considered a large one.

For many years before moving into my present house I had a keen desire to have a hardy herbaceous border, and there are probably other readers of THE GARDEN who share this desire. So many owners of town gardens are content with a few bulbs in the spring and the usual summer arrangement of golden Pyrethrum, blue Lobelia, Calceolarias and Zonal Pelargoniums neatly planted in the beds and borders, either by themselves or by contract with the local florist, that I determined when laying out my new garden to have as little to do with such gardening as possible. Not that I despise the Zonal Pelargonium, for in its place it is a valuable adjunct to the amateur's town garden.

My chief desire for a hardy herbaceous border was so that we might have plenty of flowers to cut from for the house and to make up bunches for friends and visitors who, living in the heart of London, have few opportunities to grow flowers for themselves. A little gift of this kind is always highly appreciated, especially when it contains uncommon flowers not to be met with in the florists' shops.

In arranging the plan of my garden provision was made for a terrace at the back of the house about 9 feet in width with a balustrade, where in the pleasant summer evenings we can take tea and enjoy the prospect. A flight of steps at each end leads to the path that runs round the lawn and separates it from the flower border. The lower end of the garden is devoted to fruit trees and vegetables, with a middle path leading directly to a rustic summer-house. It is from this point that the accompanying photograph was taken looking straight up to the house. On each side of the path I planted about eighty varieties of hardy perennials, not in any particular way for artistic or colour effect but chiefly for a supply of useful flowers. They were planted in three rows quite informally and have proved most satisfactory. The front row is necessarily composed of very dwarf plants, the next row consists of plants varying from 1½ feet to 2 feet and the back row to taller ones.

It may be interesting to some readers of THE GARDEN if I mention a few of the principal occupants of these two borders. There have been losses, the soil being very heavy and on clay, but the plants that have done well and

MIXED BORDER IN A LONDON GARDEN.

given us the greatest satisfaction are as follows : Achillea tomentosa, Armeria lanchiana, Aubrietia

graph. There are many others which might be named, but space will not permit.

A CORNER OF A LONDON GARDEN IN SPRING.

deltoidea, A. rosea, Erigeron glabellus, Gypsophila prostrata, C. paniculata, Hepatica triloba, (Eriogonum macrocarpa, Silene maritima, Tiarella cordifolia, Veronica rupestris, V. amethystinum, Arabis alba and Pulmonaria saccharata. I find Campanulas have been of great service, particularly C. persicifolia, C. latifolia, C. pumila alba, C. Hostii alba and one or two others. Middle row plants, of course, include one or two of those already mentioned, but others are Erigeron philadelphicum (essentially an amateur's flower for its easy culture), Stenactis speciosa, Centaurea montana alba and the blue variety, Dielytra spectabilis, Lupines, Rudbeckia Newmanii, Achillea Ptarmica The Pearl, several of the Heleniums and Heucheras, Monarda didyma, Asperula hexophylla, Achillea buglossis, one or two of the Geums, &c.

In the back row generally, for later flowering, we include Michaelmas Daisies and perennial Sunflowers; the white and purple Galegas, which make a fine effect when planted at intervals; Centaurea macrocarpa, a bold golden yellow Cornflower that does not last very long; Echinops Ritro; Doronicums; Rudbeckia submentosa; Spiraea Aruncus, a very useful decorative plant; and Thalictrum glaucum, the foliage of which is, perhaps, more useful than the blooms, are all plants that have succeeded well with us and are shown in the photograph. There are many others which might be named, but space will not permit.

In the other photograph a small rockery is represented when in flower last May. It was built of material supplied by Messrs Doulton and Co., which they call "Grotto," really the breaking up of their kilns. I think it is more like rockwork than bricks or burrs, and is to be had in very large pieces. This little rockery was built to save one corner of my garden being constantly lumbered up with pails and pans, clothes' props and all kinds of odds and ends that our maid did not know what to do with. Its dimensions are 9 feet in length, 5 feet through and about 4 feet in height. Small as it is, it is an object of interest when in flower in the spring-time. The Mossy Saxifrage, a few odd pieces of Stonecrop, London Pride, Aubrietia purpurea, A. rosea, Alyssum saxatile, Linaria pilosa, Sedums, Waldsteinia trifolia and Cerastium tomentosum complete the arrangement. C. H. P.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**THE VEGETABLE GARDEN.**—Vacant ground from which crops have already been gathered this season should be dug and heavily manured without delay, and the same quarters planted with spring Cabbage and Coleworts. So long as the ground is well tilled and treated as we have described, good results are sure to follow. Continue to sow winter Onions; these are so useful for saladings in the dull season of the year. Tripoli and other Onions for next summer's use may still be sown. Sow the seed in rows 8 inches to 10 inches apart and in drills a quarter of an inch deep. It is necessary that the surface soil be well broken up and made friable, and subsequent to the sowing the ground should be rolled over or beaten with the back of the spade. Continue to earth up Celery from time to time, choosing fine days for this work. Cut and dry all kinds of herbs at the present time for winter use. It is not generally known that Parsley can be dried. This should be rubbed fine and placed in wide-mouthed bottles for flavouring during the winter months.

**The Flower Garden.**—The present is an excellent time to plant the beautiful Madonna Lily (*Lilium candidum*). Do not make the mistake of embedding this bulb and covering it with soil, as is common with so many other kinds. We have succeeded with this beautiful flower by simply placing it on the surface soil, where it emits roots very readily. In other cases we have just embedded the base of the bulb in the soil, leaving the upper portion exposed. Plant the bulbs several inches apart, and group them, if possible, in the hardy border at intervals for effect. China and other annual Asters are just coming into flower, and may be improved by frequent applications of manure water at this time. They are

1.—HYACINTH, NARCISSUS AND TULIP BULBS SUITABLE FOR POTTING.

voracious feeders, and readily respond to generous treatment in this respect. Annuals and perennials that have ceased to flower should have the seared heads removed as soon as possible. Those subjects which it is desired to perpetuate by seeds should be carefully gathered and harvested, placing them in muslin or tiffany bags, or, if more convenient, for a time spread out on sheets of paper in the open or under glass for the weather to thoroughly dry. By these means it is possible to obtain an abundant supply of seeds, which in many cases may be sown at once or else next spring for the purpose of perpetuating the different subjects. Dahlias and early-flowering Chrysanthemums in the open border should be

watered freely in hot weather, supplementing this attention by copious applications of liquid manure.

**The Greenhouse and Conservatory.**—For early flowering we are now potting up our Roman Hyacinths, Freesias, double Daffodils and other bulbs for forcing. Five bulbs of the first mentioned in a 5-inch pot will make pretty plants in the late winter. Carefully crock the pots, using light sandy soil, embedding the bulbs so that their apex alone is in evidence. Place them in a cold frame or in cool, darkened quarters to root. The present time is most opportune for lifting the beautiful Calla Lilies. These have been growing outdoors for some time past, and have made strong and vigorous growths in consequence. See that each plant has a pot large enough to accommodate its roots without unduly confining them, and stand in a cool, shaded position for a time to become established. Fuchsias that are going out of flower should be placed outdoors now for the wood to ripen. Water must be given less freely now that the flowering season is practically finished. The beautiful Abutilons that were planted out some time ago should be partially cut back at the present time. They will then make new growths that will bloom through the autumn and winter. Winter-flowering Geraniums should have their final potting at the present time. Raspail Improved is a magnificent variety. We are just now repotting Cyclamens in small pots, using a compost made up of two parts good fibrous loam, one part leaf-mould and sand, well mixed and passed through a sieve with a coarse mesh.

**Trees and Shrubs.**—Privet and other evergreen hedges should be trimmed at the present time, as they must be kept under control if appearances are to be all we desire. Evergreen shrubs and trees may be propagated by cuttings at this period. The useful Bays, Laurels, Box trees and conifers in variety, and many of our choicer shrubs may be raised by inserting the cuttings in cold frames, and in the case of some of the more hardy subjects in a semi-shaded border. The choicer subjects are raised from cuttings about 2 inches to 3 inches in length, the coarser and stronger-growing ones being made rather longer. Dibble in the cuttings a few inches apart, pressing the soil firmly at the base of each one.

**The Fruit Garden.**—Early Apples and Pears should be gathered as soon as they are ripe, and stored in a cool, dry room or shed. In gathering these fruits they should be lifted by the hand to a horizontal position, when they can easily be separated from the branch. Unless this separation takes place easily, it is a sign that the fruit is not ready to be gathered. Runners and elongated foliage on Strawberry plants should be removed with care, thus concentrating all the energies of the roots on the sturdy plants thus retained. Continue to plant new beds of Strawberries with runners layered in pots that were severed from the old plants a short time since. Plants of this kind invariably give excellent results. D. B. C.

## POTTING BULBS FOR GREENHOUSE AND ROOM DECORATION.

THE season is once more with us when we must seriously consider the question of potting bulbs to produce flowers in the late winter and early spring months. Providing a few simple rules are observed there are no plants easier for the beginner to grow, and the main points in their culture are given below. The sooner the work is

done now the better, but if a succession is required, other batches may be potted up at intervals of two or three weeks until the end of November.

As bulbs in pots are grown under more or less artificial conditions, it is absolutely essential that the best only be employed for the purpose; by this is meant the best bulbs of a variety and not the best or choicest sorts. Many amateurs are apt to be led away by size when using bulbs or corms for pot work, but, as in many other things, size does not mean everything. What

2.—THE BULBS PROPERLY POTTED AND READY FOR PLUNGING BENEATH ASHES.

the beginner should endeavour to secure are bulbs of medium size, firm and heavy. A bulb that is both firm and heavy is sure to have been well ripened, which really means that it is well stored with reserve food, and is, consequently capable of producing large, sturdy flowers. In Fig. 1 such bulbs are illustrated. On the left four Roman Hyacinth bulbs are placed, at the back three Narcissus, and on the right four Tulips. It will be noticed that each kind varies somewhat in shape.

The potting of the bulbs is the next question that must be considered. The size of the pots used will vary to some extent according to the purpose for which the plants are required, but generally those measuring 6 inches in diameter at the top are the most suitable. A pot of this size will easily accommodate four Roman Hyacinths, four Narcissus such as Paper White, or six of the small Duc Van Thol Tulips. The best soil for the bulbs now under notice is one composed of three parts good turfy loam, one part sharp sand, with a 6-inch potful of steamed bone-meal added to each bushel. This will, doubtless, have to be varied according to what the cultivator is able to obtain, but these bulbs are good natured subjects, and will do well in almost any soil, providing it is not sour. Each pot should have about 1 inch of crocks placed in the bottom, then three-parts filled with the prepared soil and the bulbs placed in position thereon. Care must be taken not to place the bulbs on a hard bottom, else when roots are formed they will be unable to penetrate the soil beneath the bulb and the latter will be lifted out of the pot in consequence. It must not be surmised, however, that loose potting is desirable; after the bulbs are in position place more soil round them and then make the whole moderately firm. When potting is finished the bulbs and pots should appear as shown in Fig. 2.

The treatment of the bulbs after potting is a stumbling block to many, yet on it depends to a great extent the future display of flowers. The best system to adopt is to plunge the pots outdoors in damp sifted coal ashes, so that the tops

3.—THE BULBS PLUNGED BENEATH ASHES.

of the bulbs are covered with at least 6 inches of ashes. Fig. 3 depicts pots thus plunged. A variant of the method there shown is to place an inverted pot of the same size over each potful of bulbs, so as to prevent the growths being injured by the sharp ashes or any deleterious substances that may be present. The object of plunging the bulbs is to induce the formation of a good root system before top growth takes place to any great extent. Unless the bulbs are thus treated it frequently happens that leaves are formed before any roots have been made, and then failure is practically certain.

After a few weeks' sojourn beneath the ashes, some, at least, of the bulbs will be ready for removal. To ascertain when they have reached this stage it is a good plan to carefully turn the ball of soil out of the pot; it may be returned again without the least harm accruing to the plants, providing reasonable care is exercised. Fig. 4 shows a potful of Hyacinths at the proper stage for removal from the ashes. It will be observed that the roots have thoroughly permeated the soil and crocks and that top growth has just commenced.

When removed from the plunging material the pot should be stood in a cold frame and gradually inured to light and air. When the tops are quite green and in active growth the plants may be removed to the greenhouse or window to develop and open their flowers. When growth is active abundance of water must be supplied, as if the plants are but once allowed to suffer for the lack of moisture at the roots, a serious and irreparable check will be the result.

#### TREATMENT OF RIPENING FRUIT UNDER GLASS.

FRUIT which is ripening under glass in the autumn requires very careful treatment. The recent fine sunny weather has been most favourable. Not only should one study the condition of the present fruit crop, but also the welfare of the trees for future bearing. The wood must have all the assistance possible in maturing as well as the crop of fruit on it. A free circulation of warm air through the house is essential. During bright weather the ventilators must be opened at both the top and front of the house night and day; but the ventilators should be opened wider at the top than at the front. At sunset each evening the volume of air must be reduced by about one-half during the latter part of August and the early part of September, and by one-third during the remainder of the latter month. In October the front ventilators should be closed at night in damp or foggy weather and only left open about 1 inch on fine nights.

*Heating.*—It is false economy to refrain from using the heating apparatus in autumn altogether. On certain occasions, *i.e.*, when the weather is fine, and certainly while it is dull and cool, the pipes should be warmed both night and day in the case of late Grapes, which are somewhat backward in ripening. All late varieties of

Grapes should be ripe by the first week in October if they are to keep well throughout the winter months. If the pipes be warmed in fine weather, and while a nice current of air is passing through the house, the ripening and colouring of the fruit will be hastened and perfected. AVON.

#### TREATMENT OF CLIMBING ROSES UNDER GLASS IN THE AUTUMN.

SOME of the most beautifully-formed blooms are to be had from Roses growing under glass in the autumn. They may not be as large as those that are produced earlier in the year, but the colour is good, and in every way these late blooms are highly satisfactory. But cleanliness is a very important matter. Dead and fading leaves soon accumulate and form bunches in the branches, also they fall to the ground, and not only make the house look very untidy but act as hiding places for insect pests. A vigorous shaking will dislodge the loose leaves, then all should be gathered up and burned. Afterwards syringe the surface of the border with some approved insecticide. Aphides are now collecting on the young Rose shoots; fumigation will quickly destroy these pests, but it is well to do this work directly the insects are observed rather than to wait until they have multiplied considerably and injured the branches.

*Pruning.*—Some pruning or thinning out of the branches should be done forthwith. First cut out some of the older branches which have borne flowers, and then the weakly ones which are not likely to be profitable. The object should be to prevent overcrowding of shoots, so that all young wood retained during the winter months will mature thoroughly and bear blossoms freely next spring. AVON.

#### THE EDELWEISS.

THE Edelweiss (*Leontopodium alpinum*) is perhaps one of the most popular plants of the alpine flora, and the one plant of thousands that the average mountain tourist is most anxious to discover. Interesting the plant is undoubtedly, though beyond this it possesses but few attractions from a decorative point of view. Of course its correct home is the rock garden, where it should be planted in not too rich soil, yet quite firm. The plant is seen always to good advantage if rather freely grouped in colonies in the rock garden. The plant may be grown with complete success when a few strong seedlings are firmly planted in a narrow chink of rock, so placed that a deep fissure of gritty or sandy loam may be assured for the roots to ramble in. Plants in pots may be grown and flowered when the collar is tightly wedged between some pieces of stone or old mortar. At this season of the year we frequently receive parcels of the plant by post merely wrapped in a bit of sphagnum moss and some oiled paper, and in this way they travel well. But whether these collected plants will continue to succeed under cultivation in our lowland gardens depends as much on the way they have been lifted as upon any subsequent treatment on arrival. Assuming such plants do come to hand, and possessing a fair amount of fibrous roots, there is no better way of starting such things than by planting them not too deeply in cocoanut fibre and sand. Many plants that frequently rot, and that rapidly, when placed in soil will start new roots quite quickly when planted in this simple way: Give one good watering when planted, place in a rather shaded place and not a stuffy, ill-ventilated frame, and leave them alone for a week at least without further moisture. In this way scores of rare alpine plants have been treated after a long journey with a good deal of success. On the other hand, those who have no opportunity of obtaining plants direct from their mountain home will find seeds by far the best method of obtaining a stock. Indeed, seeds must be looked to for perpetuating

the stock also, for the plant is not always a success when divided.

#### THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### CARNATIONS.

"Ormonde" sends flowers of Carnations, of which there are several of the same colour. *Pelegia* is the best of them; *Twilight* is the same colour—pink, flaked lavender.

#### FLOWERS OF THE BOTTLE BRUSH TREE FROM KENT.

A correspondent with the signature of "Canterbury Bell" sends excellent inflorescences of the Bottle Brush Tree (*Metrosideros floribunda* or *Callistemon salignus*) from a garden at Encombe, Sandgate, Kent, with the following letter: "I send you two blooms of the Australian Bottle Brush (*Metrosideros*), cut from a bush growing in the open. It is planted on a slight slope facing south-west, backed by high *Laurustinus*. The only protection we give this shrub in the winter is some Bracken placed in its branches. This year there are forty-two blooms, some of which have been flowering since the end of June. I think you may be interested, as I believe *Metrosideros* has never before been flowered in the open in England, except in Cornwall. Even in such a favoured spot as Encombe I was told I should not succeed in flowering this shrub except on a wall."

#### DIANTHUS NAPOLEON III.

We have received a bunch of flowers of this beautiful Pink from Mr. J. Crook, The Avenue, Camherley, with the following interesting note: "A bunch of that fine *Dianthus Napoleon III.* The flowers are from plants that have been blooming in my garden for two months, and promise to continue for some time. This is one of the finest border plants, and should be more grown. I have a group 2 feet across, and in this way it produces a remarkable effect. There is a prevailing idea that it is difficult to manage, but this is not so when it is understood. I had six plants in early spring, and have got forty-eight plants from them."

4.—HYACINTHS AT THE STAGE FOR REMOVING FROM THE ASHES.

## THE TOWN GARDEN.

**FLOWER BEDS.**—The hot and almost invariably over-drained soil of town gardens renders it somewhat difficult to keep the ordinary summer-bedding plants in good progress as long as one would like, but much may be done by the aid of the water-pot and some liquid manure. As far as smartness of appearance is concerned, the most important point is to keep all dead and dying leaves and flowers picked off, while another important cultural point is to persist in loosening the top inch or two of soil. Then will arise the necessity for a generous use of the water-pot or hose, with a view to thoroughly soaking the soil to well down below the roots. As to whether liquid manure will be advantageous or the reverse each cultivator must decide for himself, but it should certainly never be had recourse to until the plants have exhausted the supply of food placed in the ground for them before any planting was done. Should it be deemed requisite it must always be given in a weak condition and following two or three hours after a soaking of clean water. It may be necessary to apply water twice or thrice a week and liquid manure about once a week or once in ten days.

**SEED-PODS.**—The conditions of culture which prevail in town gardens are not generally favourable to the production of good seeds, and amateurs are recommended to leave this task to those who are equipped for carrying it out properly. Apart from the fact that they will thus secure far finer seeds they have the additional advantage of a longer season of blooming, for the plant that has its energies directed towards seed-development will give scant attention to the production of flowers. Immediately a bloom has reached the zenith of its beauty, rather before for preference, it should be promptly removed and placed in water. By the adoption of this method the grower ensures a more protracted display in the garden and has also a constant succession of flowers with which to adorn his rooms.

**FEEDING DAHLIAS.**—There is no disputing the fact that among all our florists' flowers there is none more generally satisfactory in town gardens than Dahlias. Where the soil is too poor to grow the Cactus and show and fancy varieties, the grower can always fall back upon the floriferous Pompons, the neat blooms of which are so charming for decorative purposes; they thrive magnificently in poor soil and do not demand any special attention in the way of feeding. Plants belonging to the other sections, however, and which have been restricted to four or five stems, will now require plenty of water and liquid manure if the blooms are to come of the finest size and colour. First apply abundance of clean water and two or three hours later give weak liquid manure made from any natural manure that may be at command. When the time comes for a second application of special food let it be made up from soot or one of the concentrated fertilisers, so as to afford the change of diet that is as much appreciated by plants as by human beings. Finally, loosen the surface of the soil and mulch with manure. Subsequent applications of water will, of course, have to pass through this dressing and the virtues contained therein will, consequently, find their way down into the soil for ready appropriation by the roots.

**ROOM PLANTS.**—In the holiday season the room plants are apt to come off rather badly, and it is only the almost unkillable Aspidistra that will stand the neglect that is inevitable. If the house is to be left, it is better to place the whole of the plants out of doors in some shady position where they will get the benefit of any rain that may fall and not suffer from the intense heat of the sun; if an arrangement can be made with a friendly neighbour to come in and do the necessary watering. H. J. W.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FLOWER GARDEN AND PLEASURE GROUNDS.

**T**HE beds and borders in the flower garden and pleasure grounds should be kept smart. All the flowers and decayed leaves should be picked off and water given where needed. Now is the time to take cuttings from Pelargoniums and all plants that require this method of propagation. Cut all Box and other edges, and also all kinds of shrubs now that are overlapping their neighbours. These latter should be cut so that they look afterwards as though they have not been touched, and to accomplish this it is necessary to thin out the long growths. A plant or shrub pruned badly is an eyesore for a long time. Now is a good time also to train climbers on walls. Varieties of Vitis have made tremendous growths this season.

In the rock and alpine garden much will now require doing in the way of reducing many plants that have overrun their space. This should be neatly done. Collect seed and clean as this reducing work goes on. Seeds may be sown as soon as they are ripe. Shade all newly-planted seedlings or plants, or the sun will burn them up before they can get established. With regard to

*Carnations*, all borders kinds should be layered by this time or they will not become rooted well enough to go safely through the winter.

#### HARDY FRUIT.

Attention should be paid to the early ripening varieties of Apples and Pears this month. A pot or two of water will often save a tree or crop if used at the right time. Early Apples and Pears must be gathered when ripe or they lose flavour and become mealy. If they are gathered too soon they are insipid. Citron des Carmes and Doyenné d'Ete are two of the earliest Pears, and neither are much good, but should be eaten as soon as ripe. Beurré Giffard and Jargonelle are the first Pears of any exceptional merit, while the Old Windsor and Williams' Bon Chrétien are both good and closely follow. Irish Peach, Beauty of Bath and Devonshire Quarrenden are the pick of early Apples, and do not keep long in good condition. Thinnings of Apples for cooking should be sufficient now. Lord Suffield, Lord Grosvenor, Keswick Codlin and such sorts as Peasgood's and Stone's Seedling I have found cook very well. Apples and other hardy fruits carrying large crops should have a thorough watering. The drying sun of the last week in July and first week of August has penetrated to the roots, and a good soaking should be given. Late Cherries and Currants and Gooseberries should have wasp-proof netting as a covering. Continue to place Figs in muslin bags out of the reach of bees and wasps; the Figs ripened outside are delicious. Tie the growths up neatly so that every portion will be benefited by the sun's rays, including the fruit.

#### KITCHEN GARDEN.

**Brassicas.**—Continue to plant out all the late kinds. Sow now the last batch of Cabbage seed and also Cauliflowers. This will stand the winter and give good supplies next May, June and July. Parsley should be thinned out and the young plants kept well watered. Clear away all crops that have finished, as these look untidy. Take up second-early Potatoes and store: these are good this season. Give abundance of water to Scarlet Runners, Vegetable Marrows and plants of a like nature, or they will soon cease to yield their supplies in hot, dry weather. Earth up

Celery as it becomes ready for so doing, and give thorough soakings previous to this being done.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**PALMS.**—The atmosphere in the Palm house should now be kept drier to give the plants a chance to harden the growth they have made during the summer, and be better prepared for use indoors during the winter months. An occasional dose of weak liquid manure, to which a little soot has been added, will sustain those plants that have their roots confined in small pots in a healthy condition and impart a dark green colour to the foliage. The exceptionally hot weather experienced of late has been very favourable to

*Insect Pests*, especially to red spider. Plants which have been attacked, and which it is not safe to dress with insecticide, should be laid on their sides and vigorously syringed for two or three days in succession, after which the syringe should be freely used in the house containing plants so affected, for if neglected the pest will spread rapidly.

#### HARDY FRUITS.

**Apricots.**—These require copious supplies of moisture, and even when the fruit is cleared there should be no want of attention in the way of food and moisture. The trees should be encouraged to make strong leaders, these being of great help to the trees in the future. The earlier these strong growths are matured the better. Continue to stop foreright shoots. These should be pinched in a small state with the thumb and finger; do not use the knife. Syringing overhead should be continued for some time after the fruit is gathered; this will keep red spider from the foliage, and the young growth will mature sooner if assisted. Late varieties with heavy crops should be liberally fed, and young or newly-planted trees kept nailed to the wall to prevent loss of branches from high winds.

#### KITCHEN GARDEN.

**Winter Turnips.**—This is a good time to sow the first lot of Chirk Castle and Blackstone Turnips for winter use. Sow the seed broadcast and not too thickly, a surface sowing of Ichthemie Guano or some approved fertiliser being given as soon as the crop is thinned. Orange Jelly is a good winter Turnip, and although perhaps not quite so hardy as Chirk Castle, will stand severe frost without succumbing. A second sowing should be made about the first week in September, as even during frosty weather this Turnip will increase slowly in size and come in most useful at the new year.

**Cauliflower.**—The principal sowing of Cauliflowers which are to be planted out in hand-lights as an early batch for cutting in May should now be made. I prefer an east border, as then, should the weather be very favourable to growth, the plants are not liable to get too forward by transplanting time as when grown on a sunny south border.

#### FLOWER GARDEN.

**Seed Gathering.**—Now is a good time to look after the ripe or ripening seeds of all good hardy flowers. By gathering the best seeds of Foxgloves, Poppies, Honesty, Primroses, Scillas, Chionodoxas and Narcissus, and sowing them at once in half-wild places now that the earth is warm and moist, the beauty of the garden may be made to overflow into the woods and walk-sides, the fringes of carriage-drives, or even into hedges near the garden. The sowing of seeds and the rooting of cuttings or layers almost continually are among the most important of all operations in good gardens. T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Wintering Incarvillea Delavayi** (N. G. H.).—With a covering of ashes about 2 inches thick your seedlings of *Incarvillea Delavayi* should winter quite well without lifting, but some kinds of coalashes are injurious to plants under them, and we rather advise straw or peat moss litter about the same thickness. Of course the straw would require to be fastened down to keep it from blowing away. If spruce branches are obtainable more easily, the bed may be covered with these—about two layers over it. But you could lift the tubers and store them in dry sand until spring, and this is safer than allowing them to remain in districts where they perish so readily as they do in yours. Some of the seedlings may give a few flowers next year, but some will hardly do so until the following one.

**Phloxes** (E. G. King).—We could form no idea of the Phlox from the small crushed bit received, but from your letter we take it to be an instance of sportiveness or reversion to more normal conditions. Occasionally indifferent treatment, resulting in deterioration, will produce something very near akin, and in such a case if transplanted and given good cultivation the plants should show signs of improvement. Many plants are inclined to sport at times, and can only be regarded as one of Nature's ways of providing new varieties of plants. At the same time these "breaks" are not always in the nature of improvements, and if in your case they savour of inferiority, your only course is to discard them. This should not be done too hurriedly, and often enough the "sport" is but a thing of a season and may not reappear another year; and the stems being of annual duration only, the sport may exhaust itself as the result of one season's growth.

**Sweet Williams diseased** (Mrs. G.).—Your Sweet Williams are attacked by eel worms in the stems, and by the fungus *Puccinia dianthi* on the leaves. The Larkspurs are attacked at the base of the stems by the bulb mite (*Rhizoglyphus echinopus*) in considerable numbers. Asters frequently go off the same as yours, but the cause is not known; there was not any sign of fungus or other pest. As regards the Sweet Williams and Larkspurs, the only thing to be done is to pull up the plants and burn them, and so prevent the attack spreading. Then give the soil in which they were growing a good dressing of vaporite, apterite or gas lime, either of these being mixed with soil to the depth of 4 inches or 5 inches.—G. S. S.

**Names of plants** (G. B.).—Your plant with the scarlet tube-shaped flowers is a *Pentstemon*, a well-known garden flower of which myriads of varieties can be obtained if a packet of seed be purchased and sown now. The plants should stand the winter freely in North Devon, and then, planted out next spring, flower finely all the summer and autumn. You would get in that way much finer varieties than the one you name. That will seed freely also, but too late for sowing this season probably. If you get seed you may, if you prefer, sow in a shallow box or in pans, keeping them under glass and shaded till growth begins. You may also put in young tops 4 inches long as cuttings into sandy soil under a hand-light or in pots in a frame. The other plant with the creamy edged leaves is *Arabis alba* variegata. Tops of that put in now as cuttings under hand-lights will strike freely. The old plants also may be lifted in October, and divided and replanted.

**Bulbs for hillside** (E. Ch. P. M.).—We cannot specially mention any bulb trader, as all who advertise in our columns offer bulbs cheaply. Your best course would be to write to two or three of those advertisers and ask for their price lists. The quantities of each you may want depends on the area of the hillside to be planted. Narcissi in variety, including Emperor, Sir Watkin, Horsfieldi, Barri conspicuus, Ornatus and many others which any trader will give you a list of. Also Scillas or Bluebells in two or three colours, some May-flowering Tulips, Crocuses, Snowdrops and the blue *Chionodoxa* or Glory of the Snow. The greater the quantity of bulbs ordered the cheaper are they relatively.

### TREES AND SHRUBS.

**Leaves of trees diseased** (B. J. B.). The brown spotting of the foliage sent does not appear to be due to the attack of either fungus or insect, but rather to some condition in the soil that is uncongenial. Either the roots have got into something that is injurious to them or they may be suffering from over-drainage or lack of drainage. Similar appearances on the leaves might be caused by the cold winds in the spring if the trees are in an exposed situation, or even by acid brought down in the rain.

**Canadian Poplar gone wrong** (Reader).—In the shoots sent there is not the slightest trace of any disease proper, such as is caused by parasitic fungi or insects. A microscopic examination of various parts shows nothing but dead tissues. We are inclined to believe that the splitting and decay has arisen from the severe topping soon after replanting and that possibly something may be wrong with the roots or the soil. The nurserymen from whom you bought the plants might be able to explain matters if you mentioned the nature of the topping and your method of replanting, with a hint as to the nature of the soil.

**Cutting a Yew hedge** (Lindfield, Sussex).—You may cut your Yew hedge in April or in August, whichever is most convenient to you. A top-dressing of manure may be put on at any time, and a very light dressing of nitrate of soda well watered in will do good. You could make the wire shapes you require to train the shoots on. Select strong shoots, and while young bend them into the position you require. We do not know of any firms who supply such things, though, doubtless, any firm of horticultural sundriesmen would have them made for you if you wish it. If the Yews are not in good health let them go unclipped for a year or two. The Yews you removed from the hedge are probably dead. If not, syringe them twice a day overhead and well water them at the roots occasionally; this is all you can do for them. It is a bad plan to put a lot of fresh manure about the roots of trees when you are planting them; better by far give a little fresh soil.

### THE GREENHOUSE.

**Salvia leaves for inspection** (J. P. W., Lindfield).—The material sent is insufficient to determine what is the cause of the white spots upon the leaves; they are, however, either the result of the punctures of insects or they are of the nature of the warts which often occur on the leaves of Vines, due to keeping them for a time in an atmosphere too moist and too close for their good health.

**Flowering plants failing in a conservatory** (Lodwig).—We do not entertain the slightest doubt that the failure of flowering plants in your conservatory is caused by it being an unsuitable structure and with most unsuitable surroundings. Light and air, so essential for flowering plants, are almost shut out, and we cannot advise anything likely to give satisfaction there. Such a structure could be furnished in an ornamental manner with Palms and Ferns, which would succeed therein, and this we consider the only possible solution of your difficulty.

**Information about Bougainvilleas** (F. J. Heil).—*Bougainvillea glabra* is so readily propagated by means of cuttings that seedlings are seldom raised. Plants from seed have, however, been brought under our notice, but in no single instance when they flowered did they vary from the ordinary form. There is, however, a variety much cultivated in this country known as *sanderiana*, in which the bracts are of a much richer purple than in the type. Whether it originated from seed or as a sport we are unable to say, as its early history seems to be unknown, it having been found in an old garden in the

South of England. The more vigorous-growing *Bougainvillea spectabilis* varies more than the other in the colour of its bracts, but, with one exception, they are all more or less of a purplish tint. The exception is the variety *lateritia*, whose bracts are in colour a kind of brick red, but in this country at least it is decidedly shy-flowering and is very seldom met with.

**Treatment of bulbs from South Africa** (W. J. Hall).—You did quite right to pot up the bulbs and other plants received from South Africa. Care should be taken not to overwater them till they commence to grow. An average temperature of 45° by night during the winter will not be warm enough for some of them, but if the night temperature at that season does not fall below 45° most of them will succeed therein. Of the plants enumerated *Bowiea volubilis* pushes up a long, climbing flower-spike, but the green flowers, though curious, are not at all ornamental; *Critium Moorei* is a well-known bulbous plant with large white Lily-like flowers; *Cyrtanthus sanguineus*, a pretty little red-flowered bulb not at all difficult to cultivate; *Gladiolus psittacinus* and *G. salmoneus*, two interesting species of *Gladiolus*; *Gloriosa virescens*, a pretty climbing plant with red Lily-like flowers; *Hæmantis Katherineæ* and *H. natalensis*, two pretty bulbous plants with large globular heads of brightly coloured flowers; *Kämpferia natalensis*, a member of the Ginger Wort family with purplish flowers; *Richardia Rehmianii*, the pink-flowered Arum Lily; *Saundersonia aurantiaca*, a climbing plant with yellow flowers; and *Spathoglottis longifolia*, an easily-grown terrestrial Orchid with whitish flowers. Of the others *Cyathea Dregeli* is a Tree Fern and *Encelpharctos brachyphyllus* and *E. villosus* belong to the Cycas family. These last three are evergreen in character and would prefer somewhat more heat, as also would *Stangeria paradoxa*, which is nearly related to the *Encelpharctos*, but they might possibly thrive in a minimum winter temperature of 45°. To stamp out the rust in *Chrysanthemums* pick off all badly-infested leaves and burn them, as in this way the spores are prevented from spreading. Then spray the plants at intervals with a solution of potassium sulphide, made by dissolving 1oz. of potassium sulphide (diver of sulphur) in a quart of hot water, making this up afterwards by adding clean water to 2½ gallons. As the *Amaryllis* root so readily there must be something, we should say, radically wrong either with the bulbs themselves or the soil in which they are potted. On such a subject it is difficult to advise without inspecting the bulbs, but we advise you to turn them out of their pots, shake quite clear of the old soil and repot in some fresh compost made up of two parts good loam to one part of leaf-mould and nearly one part of sand. Then place them in the greenhouse, for they do not need any great heat, and water very carefully. As the season is so far advanced, it is quite probable that they will only make a few leaves this year, but will root and start away next spring. During the winter scarcely any water should be given them.

### ROSE GARDEN.

**Roses for the South-West of Wales** (L. B.).—The conditions you name are not very favourable for Rose growing, but we think your friend would succeed in growing such Roses as the following: *Rugosa*—Blanc Double de Courbet, Conrad F. Meyer, Mme. G. Brunt and Mrs. A. Waterer; Hybrid China—Blairi No. 2 and Charles Lawson; Bourbon—Robusta and Mme. Pierre Oger; Damask—Mme. Hardy, La Vallée de Bruxelles and Mme. Zoetmans; Moss—Crimson Globe; Noisette—Aimée Vibert, Rêve d'Or and Jaune Desprez; Chinas—Armosa, Fellenberg, Mme. Laurette Messing, Common Blush and Fabvier; Hybrid Tea—Cheshunt Hybrid, Mme. Alfred Carrière, Longworth Rambler, Waltham Climber No. 1, Pink Rover, Mme. J. Siegfried, Grace Darling, Gustave Regis, Grüss an Teplitz and François Crousse; Hybrid Perpetual—John Hopper, Clio, Jules Margottin, Ulrich Brunner, Magna Charta and Mme. Isaac Pereire. Most of these are strong growers, and should be afforded a space of about 3 feet apart each way. Procure as many as you can on their own roots and have the soil deeply dug, working in some gritty material or coal ashes with the clays.

**Twelve ramblers to bloom simultaneously** (Enquirer).—As you mention Dorothy Perkins and Hiawatha, we do not know whether you desire a list of sorts to flower at the same time as those varieties. If this should be the case, we recommend the following, which would bloom from the third week in July and through a part of August: *Mandarin's Triumph*, Lady Gay, The Garland, Queen of the Belgians, Flora, Dundee Rambler, Mrs. E. W. Flight, Rivers' Musk, François Foucard, Débutante, Adèle Morelle and Moschata. The following would commence to bloom about the first week in July: *Philadelphia Rambler*, *Félicité Perpetue*, *Leopoldine d'Orléans*, *Bennett's Seedling*, *Queen Alexandra*, *Pink Roamer*, *Edmond Froust*, *Sweetheart*, *Blush Rambler*, *Waltham Rambler*, *Elise Robichon* and *Ernst Grandpierre*. You could make a selection from the

following, which commence to flower about the third week in June: René André, wichuraiana rubra, Gardenia, Virginian Rambler, Psyche, Alba rubrifolia, Paul Transon, Rubin Zepherin Drouhin, Helene, Jersey Beauty, Ne Plus Ultra and Wedding Bells. Or if you desire a still earlier selection the following would commence to bloom about the first week in June: Carmine Pillar, Waltham Bride, Aglaia Ruby Queen, Electra, Alberic Barbier, Trier, Tea Rambler, Grissu an Zabin, M. Desir, Reine Olga de Wurtemberg and Mme. Alfred Carrière. When burnt clay is referred to for potting purposes it is usually understood to be clay that has been burnt in a heap. A quantity of wood is placed together and set alight then clay with a little fine coal is placed upon the wood in a conical shape. As soon as this is burnt through more clay and coal is added, and so on until a large heap has collected. This is excellent material when cool to apply to land that is bad to work. It is spread on the surface and mingled with the other soil. A little of this burnt clay may be mixed with potting soil to much advantage. Burnt garden refuse is also good for similar purposes.

## MISCELLANEOUS.

**Recipe for weed-killer (Ashford).**—The constituents of weed-killers are manufacturers' secrets, but no doubt they are largely composed of powerful poisons such as sulphuric or carbolic acid and arsenic. It is far better to purchase the liquid in tins or drums. This concentrated liquid is mixed with water at the rate advised by the vendors before it is used. You will find in our issue of July 4 advertisements of weed-killers from Joseph Bentley, Limited, Barrow-on-Humber, Hull; and from C. E. West, Higham Hill, London, N.E., both of whom will supply you with the liquid. Great care must be exercised in applying it, using an old water-can with a rose spreader and mixing the liquid in a large wooden tub used exclusively for that purpose. The operator should wear old clothes and leather gloves.

**Names of plants.**—H. Payne.—Roses: 1, E. T. Cook (Hybrid Tea); 2, G. Nabonnand (Tea).—J. B. Read.—The smooth-wooded Rose we take to be the Bour-sault Morlettii, and the other variety Rosa rugosa calocarpa. This should be grown as a free bush, pruning it very sparingly.—G.—Roses: 1, Frau Karl Druschki; 2, Souvenir de Pierre Notting; 3, Grissu an Teplitz. —A. T. King.—Rose Mme. François Pittet. —J. C. A.—Roses: 1, Réve d'Or; 2, Mme. Pierre Cochet; 3, Mme. Moreau; 4, Mrs. Harry Turner; 5, Lady Roberts; 6, Baron Gonella; 7, Prince Arthur; 8 not recognised; 9, Celine Forestier. —An Old Reader.—Quite impossible to name the specimens, which were crushed beyond recognition. Such things should always be enclosed in a wooden box and carefully packed. —W. C. Yates.—The Carnation is doubtless a local seedling; it is not good enough to name, but it was much faded. —H. L. Kenyon.—The flower of the Picotee sent is what gardeners term a "sport." In any large collection of Picotees some of them will annually take this ground colour. It had the petal edge of Mrs. Gorton. —Subscriber.—1, Quercus pedunculata variegata (Variegated Oak); 2, Potentilla fruticosa; 3, Tamarix speciosa, probably T. anglica. Kindly send when in flower. —Devonia.—The prickly shrub is Solanum pyracanthum; the other Feijoa sellowianum. —A. Ralph.—Your Sweet Peas are: 1, King Edward; 2, Countess Spencer; 3, Dainty. —Azara.—1, Cedrus Deodara; 2, Pinus Laricio nigricans (Austrian Pine); 3, P. excelsa (Ehottan Pine); 4, P. sylvestris (Scotch Pine); 5, Sambucus nigra var. laciniata; 6, S. racemosa var. laciniata; 7, Prunus laurocerasus var. colchica. —F. J.—Adiantum formosum. —A. Buckingham.—Ampelopsis Veitchii. —M. F.—1, Physostegia virginiana; 2, Digitalis lutea. —Miss M. H.—Lysimachia punctata. —Indigo.—Colutea arborescens. —Polygonum.—Polygonum baldschuanicum. It flowers best when not pruned at all. Thin out only in winter or spring. —D. R. P.—1, Digitalis lutea; 2, Cimicifuga racemosa; 3, Lysimachia punctata; 4, Genista tinctoria; 5, Symphoricarpos orbiculatus var. variegatus; 6, Geranium pratense var. flore-pleno. —F. A. Bates.—1, Myriophyllum verticillatum; 2, Blanket Weed. They are both common plants, the former reproducing itself from resting buds in winter, while the latter reproduces itself from spores. They may be destroyed by treating with copper sulphate at the rate of 1 lb. to 1,000,000 gallons of water. Care should be taken in estimating the contents of the pond, as an overdose will be fatal to Nymphaeas and other plants. See THE GARDEN, July 7, 1906. —J. Stowe.—Spirea filipendula flore-pleno. —Col. F.—Valeriana officinalis

## SOCIETIES

### STUTTON COLDFIELD AND DISTRICT AND WALSALL AND DISTRICT GARDENERS' ASSOCIATIONS.

The annual outing of the above associations took place recently to the extensive seed warehouses at Wordsley and seed farms and trial grounds at Kinvor, by the kind invitation of Messrs. Webb and Sons, the King's seedsmen, Wordsley, Stourbridge. The party, numbering about 150, included Mr. Joel Cadbury, president of the Amalgamated Associations, Mr. Thompson, Mr. Jeffs and Mr. Grove, was conveyed by special trains from Dudley to Wordsley, where they were met by Mr. Edward Webb and the heads of departments, who conducted them over the offices, warehouses and greenhouses. Adjoining the warehouses is the extensive range of glass; here all the best types of florists' flowers, Calceolarias, Cinerarias, Begonias,

Primulas, &c., are to be seen in their respective seasons. The size and rich colouring of the Gloxinias and Begonias now in bloom, which have excited so much interest at the leading shows of the season, came in for much admiration, as also did the heavy crops of Melons, Cucumbers and Tomatoes. The party had the privilege of inspecting the various types of vegetables which were awarded the only gold medal at the Franco-British Exhibition.

From Wordsley the visitors resumed their journey to Kinvor, where luncheon was provided by Messrs. Webb, over which Mr. Cadbury presided. The party then left for an inspection of the trial grounds, where an enjoyable time was spent in looking over the numerous trials of flowers and vegetables. Some idea of the magnitude of these operations may be gathered when it is mentioned that there are hundreds of trials of Peas, Beans and other vegetables, 240 rows of Sweet Peas and 250 trials of other annuals, but time did not allow of a complete inspection of the seed farms, which extend to 2,000 acres. At five o'clock tea was served, and after a hearty vote of thanks, which was proposed by Mr. Cadbury, supported by Mr. Thompson and Mr. Jeffs, to Messrs. Webb for their hospitality, the party dispersed to visit the rock houses and Roman encampment at the famous Kinvor Edge, a return being made to the Kinvor tram terminus en route for home. It was generally voted that the outing had been one of the most enjoyable ever held by the societies.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The monthly meeting of this society was held at the Horticultural Hall, Vincent Square, Westminster, on the 10th inst., Mr. Charles H. Curtis in the chair. Four new members were elected. The amount of sick pay for the month was £46 8s. 6d., which is heavy for this time of the year. A member was granted 10s. per week for two or three weeks from the convalescent fund in addition to his sick pay to enable him to get a change of air. Arrangements for the annual dinner are being made.

### KIRKCUDBRIGHT HORTICULTURAL SOCIETY.

This society held its annual show in the Town Hall, Kirkcudbright, recently, when there was a good competition in both the open and amateurs' sections, cut flowers in particular, with vegetables, being well shown and of good quality. The show was larger than that of last year, and many things were of better quality than at the preceding exhibition. Non-competitive exhibits of Roses and other flowers were shown from the gardens of Mr. James Brown, Knockbrex, where his gardener, Mr. Bennet, grows Roses exceedingly well; and these flowers were also exhibited by Messrs. T. Smith and Sons, Stranraer, the collection exhibited by that firm being representative of the best flowers of the day. In the competitive classes, Mr. W. McGuffog, Balmac, was awarded the medal presented by Miss Blackburn for a table of cut flowers, with an excellent exhibit. In the class for a circular table of plants, Mr. James Duff, Threave, was first with a good table; Mr. A. Anderson, Barmcle, and Mr. W. McGuffog, Balmac, being respectively second and third. Other leading winners in the show were Messrs. W. Brown, J. Drummond, W. and D. Kelly, R. Webster, W. McCormack, B. Rutherford, R. Middleton, A. S. Murchie, J. Hannah, J. A. Gourlay and Mrs. Gibson. In the ladies' classes for bouquets, &c., Mrs. Blyth, Mrs. Allan and Mrs. Coleman were the first in various classes.

### BISHOP'S STORTFORD HORTICULTURAL SOCIETY.

The thirty-ninth annual exhibition of the above society was held on the 3rd inst., at Silver Leys, and was a great success from all points of view.

#### PLANTS.

The first prize for a group arranged for effect was taken by Mr. J. Vert, gardener to the Right Hon. Lord Howard de Walden, Audley End, Saffron Walden, and was beautifully arranged, having splendid Lilium auratum, Crotons, Dracenas and Humex elegans. The second prize went to Mr. G. Beech, gardener to T. Barker, Esq., M.P., for a very fine group; Mr. Harrison, gardener to Colonel Archer Houlton, Hallingbury Place, Bishop's Stortford, being a close third.

For foliage plants Lord Howard de Walden was again first, and Mr. Woods, Stansted, second. The last-named exhibitor was first for stove and greenhouse plants in flower, also for Ferns.

#### CUT FLOWERS.

It was a trying day for Roses and cut flowers owing to the great heat. The premier award for Roses was taken by F. E. Croft, Esq. (gardener, Mr. G. Longhurst), Stanstead Abbots, Mr. Pritchard being second; and in the smaller class Tresham Gilbey, Esq., was first.

The class for twenty-four bunches of hardy herbaceous flowers is always a great feature here, and Messrs. G. Paul and Son, Cheshunt, were an easy first with grand flowers. This well-known firm rarely fails in the open class, and they had splendid trusses of Chrysanthemum King Edward, Platycodon grandiflora, Aconitum pyrenaicum and Phloxes. Mr. Parker of Hertford was second, and Mr. Woods third. In a smaller class Mrs. W. T. Gee was first, Colonel Healey second, and Mr. W. Holland third. The collections of Sweet Peas were numerous. For the best collection Mr. Barker was first and H. Harrison, Esq. (gardener, Mr. Lee) second. For twelve bunches Messrs. Johnson and Tresham Gilbey won in the order named.

#### TABLE DECORATIONS

These were fewer than usual, but they represented splendid quality. Miss E. A. Spencer, Stansted, was first,

having Carnation Raby Castle and Grass arranged in low glasses. Miss Vert, Audley End, Saffron Walden, was second with choice flowers of Odontoglossum crispum.

#### FRUIT.

For a collection of eight dishes there was some splendid fruit staged, and Colonel Archer Houlton (gardener, Mr. Harrison), Hallingbury Place, Bishop's Stortford, was a good first, having very fine Grapes Muscat of Alexandria and Black Hamburg, Peaches, Nectarines and Melons. Mr. G. Beech, gardener to T. Barker, Esq., M.P., The Grange, was an excellent second. For baskets of fruit M. Glyn, Esq., was first; second, Colonel Archer Houlton; third, Mr. Barker. For black Grapes Messrs. J. Balfour, Mrs. Menet and Mr. G. Barnes won in the order named. For other black varieties Messrs. Balfour, Glyn and Colonel Archer Houlton were successful. Plums and other small fruits were numerous, and Messrs. Barnes, F. A. Taylor and Croft had very fine Cherries.

#### VEGETABLES.

These occupied much space, there being a great number of single dishes. For the collection of twelve distinct varieties J. Balfour, Esq. (gardener, Mr. Jeffries), Moor Hall, Harlow, was a splendid first, having perfect roots, fine Cauliflowers, Onions, Tomatoes and Emperor Beans. Mr. F. E. Croft was a good second and Mr. J. B. Woods third. For six varieties Mr. W. J. Kindell was first, Mrs. Gee second and G. Barnes third. For Tomatoes Colonel Archer Houlton led, Mr. Barker being second.

#### NON-COMPETITIVE GROUPS

Messrs. Paul and Son, Cheshunt, sent beautiful herbaceous cut flowers, Messrs. Bolton and Son, Roses, Mr. Scruby, Roses and Mr. Chaplin, Waltham Cross, herbaceous flowers. These groups added greatly to the decoration of the tents.

\* \* \* Owing to the demand on our space we are obliged to hold over the report of the Royal Horticultural Society's Exhibition until next week.

"Country Life" for August 22 contains, among other articles, an illustrated account of Kirklees Park, Yorks; "Herefords at Evesbatch Court" (illustrated); "The Pochard in Kent," by John Walpole-Bond; "The Fascination of the Trout," by A. R. Haig Brown; "In the Garden" (illustrated).

### Obituary—Mr. Henry Balderson.

The death of the above well-known amateur horticulturist took place on the 12th inst. at his residence, Corner Hall, Boxmoor, Herts, and though for the past two years illness has prevented him taking an active part in horticultural matters, till the last he was much interested in his garden at Corner Hall, and was a warm supporter of all matters appertaining to horticulture. For many years the Royal Horticultural Society found in him a strong supporter, and he was vice-chairman of the fruit committee, and by his presence and help a good friend to the gardening charities. At his Boxmoor residence he grew Grapes well, and nearly fifty years ago was one of the promoters of the present Hemel Hempstead Horticultural Society. In 1900 he was Mayor of the borough, following the late Sir Astley Paston Cooper, Bart. He was till the time of his death an alderman of the borough, chairman of several important committees and of the gasworks, a director of the waterworks, a prominent Freemason, a great friend of the local friendly societies and for over fifty years churchwarden of Boxmoor, also for some time vice-chairman of the Board of Guardians. His last public act was the opening of the new fire station. Mr. Balderson was born at Gadebridge in the year 1830. In his early days he was an ardent Volunteer, being in 1859 second lieutenant when the corps was started. He leaves six daughters and one son, losing his youngest son in the South African War.

### CATALOGUES RECEIVED.

Bulbs—J. Veitch and Sons, Limited, Royal Exotic Nurseries, Chelsea, London; W. Cutbush and Sons' Nurseries, Highgate, N.; Sir Josslyn Gore-Booth, Bart., Lissadell, Sligo; D. W. Thomson, 113, George Street, Edinburgh; E. P. Dixon and Sons, Limited, Paragon Square, Hull; J. A. Laing, Seal Chart, near Sevenoaks; Cooper Taber and Co., Limited, 90, Southwark Street, S.E.; and E. H. Krelage and Sons, Haarlem, Holland. Bulbs and Winter Flowers—W. Paul and Sons, Royal Nurseries, Waltham Cross. Gladioli—H. H. Graff, hybridist, Simcoe, Ontario, Canada.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE GREAT SHREWSBURY SHOW.

THIS, the thirty-fourth meeting of the Shropshire Horticultural Society, is once more past and gone. It opened under pleasant auspices on Wednesday, the 19th inst., in the beautiful Quarry Grounds, the weather, although dull, being pleasant, with a fresh breeze blowing from the east.

The great advance made in horticultural progress during the past twenty-five years is focussed and practically demonstrated at this annual meeting at Shrewsbury as it is perhaps at no other horticultural meeting in the kingdom. High culture is here represented in every department of practical gardening. The only thing lacking to complete its inclusiveness is an important class for Orchids. The season of the year bars this, as there are comparatively few in bloom at the time the show is held.

Of rare, interesting and beautiful plants, not only the best are seen here, but such examples of high culture, combined with the art of artistic arrangement in combination, are brought before the public as is witnessed in few, if any, other shows within the kingdom. The groups of plants arranged for effect and the great specimen plants dominate, no doubt, the exhibition as far as the general public are concerned. The groups were eleven in number, each occupying 250 square feet, divided into two classes—one for ornamental foliage and flowering plants combined and another for ornamental foliaged plants only. Messrs. Cypher and Sons took the first prize of £25 in each class.

It would occupy many pages of THE GARDEN to describe the plant and cut flower treasures of this wonderful show. I must, however, mention an exhibit of hybrid Water Lilies by Mr. Amos Perry of Enfield which interested hosts of the visitors. They included most of the best varieties and were in lovely bloom. The tank in which they were arranged was surrounded by rocky mounds profusely planted with beautiful water plants, producing, I thought, as a whole a delightful picture of this natural style of gardening.

There is one class in the plant section I should particularly like to mention, namely, Class 7. The prizes here are offered for stove or greenhouse plants grown in pots not exceeding 10 inches in diameter, the object being to promote high cultural skill in the growth of plants, and truly its object on this occasion was fully attained. Such grand specimens grown in such small pots conclusively prove that the art of plant growing in England is still well to the

fore. The first prize in this class also went to Messrs. Cypher.

Fruit is a most important section of the show. I can only describe it as simply grand. The new champion class—introduced this year for the first time—for thirty dishes of fruit decorated with flowers proved most successful and popular. Mr. Barnes of Eaton Hall Gardens was the victor, closely followed by Mr. Goodacre of Elvaston Castle Gardens. The Grape and other fruit classes were well filled; but, generally speaking, the Grapes were not so fine in bunch or berry as I have seen them on other occasions at Shrewsbury. Lord Hastings's grand exhibits of former years were absent. To close this brief mention of the fruit exhibits would be incomplete without noticing the magnificent groups of fruit trees in pots exhibited by Messrs. Rivers of Sawbridge-worth and the King's Acre Nurseries, Hereford.

No section of the exhibition has shown greater progress of late years than has that devoted to vegetables. Instead of being considered of minor importance, it now commands the ready homage not only of growers, but of the public generally, by the magnificence and perfection of growth it has attained to. The exhibits in the open class completely filled a large tent. The greatest interest was centred in Class 138, in which the society offered a first prize of £10 for nine dishes. It goes without saying that as the two champion vegetable growers were competing in this class—Mr. Beckett of Aldenham Gardens and Mr. Gibson of Welbeck Gardens—that something worth looking at would be placed before the judges. It proved so, Mr. Beckett's collection being in the estimation of competent judges one of the best and most perfect collections ever put up. It also won a challenge cup value 10 guineas. Mr. Gibson's collection was also superb, but a few points below the first-prize group.

OWEN THOMAS.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

September 1.—Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster. 1 p.m. to 6 p.m.; Lecture at three o'clock on "The History of Garden Making," by Mr. Thomas H. Mawson, A.R.I.B.A.

**East Anglian Horticultural Club.**—"The Cultivation of the Cucumber: its Diseases and Remedies." This was the subject chosen by the president of this club, Mr. J. Powley, for an essay competition open to all members for the August meeting. Three papers were received and read, great interest was taken in the subject, and the three judges, Messrs. T. B. Field, H. Read and H. Goude had a good

lengthy deliberation before making their awards. The prizes were awarded: First, Mr. C. Matthews; second, Mr. F. Kemp; third, Mr. C. H. Fox. The subject brought out a good discussion, and included many practical points. Mr. F. Williams, gardener to Louis Tillett, Esq., M.P., staged some grand Peaches, as also did Mr. W. Shoemith, gardener to F. W. Harmer, Esq. Flowers, pot plants and vegetables were also in strong force in the monthly competition. —P.

**National Dahlia Society.**—The annual exhibition in connexion with the above society will be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Thursday, September 3. Full particulars can be obtained from the hon. secretary, Mr. H. H. Thomas, 68, Shakespeare Road, Hanwell, W.

**National Rose Society's autumn show.**—This promises to be one of the most interesting exhibitions of the year, the recent rains having helped the plants considerably. We always enjoy this display, as Roses in September are as welcome in the garden or at the exhibition as they are in July. There seems a richer depth of colouring in the flowers and the fragrance is stronger. This exhibition is, we feel sure, responsible for much of the interest that is being taken in the raising of new sorts that bloom particularly in the autumn months. Raisers should direct their attention to the autumn-flowering climbers in particular. There is a sad dearth of these as yet.

**The Countess of Selkirk's Cottage Gardens Prizes.**—As in former years, the Countess of Selkirk has given prizes for cottage gardens and climbers upon the estate of St. Mary's Isle, Kirkcudbright, and there were thirty-one entries for the competition. The awards, together with a general report on the gardens, have just been issued by the judge, Mr. R. Service, Dumfries. In the report Mr. Service remarks upon the use so largely made of bedding plants, and urges that the cottagers should devote more of their gardens to hardy border flowers instead of these. He comments, in generally favourable terms, upon the gardens and the taste displayed in their cultivation and arrangement. The leading awards are as follows: Gardens within a two-mile radius of Kirkcudbright. Best gardens—First, Mrs. Kelly, The Stell; second, Mrs. C. Dorrance, The Stell; third, Mrs. M'Coull, The Stell; fourth, Mrs. Anderson, Auchenfleur. Best creeping plants—First, Mrs. J. Dorrance, Mutehill; second, Mrs. Graham, Auchenfleur. Gardens and creepers outside the two-mile radius—First, Miss Dickson, The Doon; second, Mrs. Graham, Low Newton; third, Mrs. Kelly, Burnfoot of Borgue. Balmae district, gardens and creepers—First, Mrs. M'Kie, Little Balmae; second, Mrs. Welsh, Dromore.

#### **Dundee Parks Superintendent.**

Mr. James Carnochan, who has been for a number of years superintendent of the Dundee City parks, having intimated a desire to have an assistant on account of his advancing years, the parks committee came to a satisfactory arrangement with him for the appointment of an assistant and successor. There were some sixty candidates for the appointment, and it was finally given to Mr. Alexander MacRea, gardener to Mr. Gilroy, Balumbie, who was appointed unanimously. Mr. MacRea, although a comparatively young man, has had a long gardening experience, beginning at Geddes, Nairn. After passing through a number of good gardens for experience, he was for some time with Mr. A. F. Burk, Adderley, Monifieth, whence he went to Balumbie, where he has been for eight years. Mr. MacRea's long experience and knowledge of the district give confidence for the belief that his régime will be a great success.

#### **Dundee Horticultural Association.**

The members of the Dundee and Broughty Ferry Horticultural Associations had

on the 15th inst. an opportunity, of which a number availed themselves, of visiting The Tower, Wormit, the property of Mr. George Duncan, for the purpose of seeing the rock garden there. This is a successful piece of work, executed by a Dundee firm of landscape gardeners, one of whom accompanied the party and explained the construction, while Mr. Duncan was most assiduous in entertaining the visitors. As the rock garden was formed about three years ago, the plants have had time to establish themselves, so that the success of the undertaking was proved by the flourishing condition in which the plants were found.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**"The Garden" Flower Show.**—As one who saw much of this novel and excellent exhibition, and who critically examined a large number of the exhibits staged on the occasion in question, I should like to endorse in the fullest possible manner all that "One of the Judges" at page 381 has said concerning one of the most remarkable exhibitions I have seen. Those of your readers who had no opportunity of seeing the very fine collections of fruit and flowers staged on the occasion in question will gather much from the detailed report of the show, and not a little also from the excellent series of pictures. Several of these pictures reveal in a way that is otherwise impossible the superb character and excellence of a few of the winning groups, and will further assist in bringing into closer touch that larger body of readers interested in gardening who for many reasons were prevented from seeing the display for themselves. The very widespread interest taken in the show may be gathered from the report itself, and it will be seen that exhibitors from Gloucester, Derby, Cambridge, Herts, Sussex, Lanark, Maidstone and Market Harborough were among the most successful. The freshness of the exhibits, apart from their high quality, was a matter of frequent comment during the day, and reflects the greatest credit upon those responsible for their preparation, packing and staging. Many exhibits from long distances, unattended by their owners, were staged with care and skill, losing little or nothing in consequence. In short, the occasion, like the display, may well be regarded as unique, and for this extremely gratifying result the contributors thereto, in common with the promoters, have every reason to be satisfied with the results of their efforts. —VISITOR.

**Popular confusion in nomenclature.**—Your correspondent P. Clapham, page 395, is very severe upon the nurserymen and seedsmen for the inaccuracies to be met with in some catalogues. That grievous mistakes are sometimes made cannot be denied, but the greatest sinners in this respect are the botanists, who are continually chopping and changing the names about without any apparent reason, except that of self glorification, in order to pose as the authority for some new name. I might quote many instances, but one will suffice to illustrate the troubles to which we gardeners are subjected in an attempt to get the correct name of any particular plant. In the forties of the last century William Lobb, when travelling in Brazil for Messrs. Veitch, sent home an exceedingly pretty flowering climber, to which the name of *Manettia bicolor* was given. As the tubular-shaped blossoms are in colour red and yellow, the specific name of *bicolor* is a decidedly appropriate one. By this name the plant was always known till about seven or eight years ago, when it was named at Kew *Manettia luteo-rubra*, and as such it is given in the "Kew Hand List," with that of *bicolor* as a synonym. Some little time after that it was figured in the

*Botanical Magazine* as *M. bicolor*, the old name being there retained. Yet another indignity has fallen to this unfortunate plant, for it is, I see, at Kew now labelled *Manettia inflata*. It is easy to understand that the compiler of a catalogue is at his wits' end to know which to take as his authority—the name the plant has been known by for half a century and supported by the *Botanical Magazine*, the "Kew Hand List" or the present-day labelling at Kew. We are sometimes told to take the "Index Kewensis" as our authority, but the price of such a work is beyond the means of many. There is another point connected with catalogue nomenclature, and that is many names are too firmly fixed in the popular mind to omit them from a nurseryman's catalogue, even if they are according to the botanist's dictum incorrect. For instance, Indian *Rhododendrons* would leave many in doubt as to the plants intended; but Indian *Azaleas* are understood by everyone, yet botanists tell us that with the exception of our little *Azalea* or *Loiseleuria procumbens* all plants known as such in gardens are *Rhododendrons*. Granting this to be the case, it is absolutely necessary for a nurseryman to retain the name of *Azalea* in order to render the plants recognisable to many. Exactly the same applies to the *Hippeastrums*, which are still generally known as *Amaryllis*. A great number of instances might be quoted, but enough has been given to show that the compiler of a trade catalogue is not the only sinner.—H. P.

**Notes from County Down.**—The seasons this year have been very variable, the spring cold and late, difficulty being found in starting bedding plants and Vegetable Marrows out of doors. Many early seeds were failures, and Peas and Sweet Peas had to be sown twice to provide proper supplies. Everything has, however, improved since, a fine supply of Cucumbers and Melons in frames being forthcoming, and, by the way, there is nothing like a large supply of dead leaves for keeping up long heat in the frames. In our rambles by the shore and through the woods here, we picked up the Sea Starwort, the Willow Herb and the Bog Pimpernel, all beautiful flowers of the field.—WALTER SMYTH, *Holywood, County Down*.

**Keeping Vineries free of wasps.** I have been much troubled with wasps in the Vineries here, and although all ventilators were covered with butter cloth and bottles of syrup hung about they still managed to get in and do considerable damage. The beginning of last week an idea occurred to me, and I cut small branches of common Laurel and hung them up in the houses, and since the leaves began to wither I have not seen a single wasp. I hope this may be of use to others similarly situated.—H. TOMLINSON, *Gardener, Cossington, Bridgwater*.

**Sweet Pea Countess Spencer.**—Since reading the remarks of Mr. G. Clapham re the above under "Sweet Pea Prospects" in THE GARDEN of the 25th ult., and those of Mr. J. F. Barwise in the issue of the 8th inst., I have devoted some time to a careful study of this variety. I am of the same opinion as Mr. Clapham as regards sports, but in even worse plight, for out of a score of plants I have only four giving true flowers. After reading Mr. Barwise's theory of possible cross-fertilisation by means of "insects, wind, or any other agency," I went straight away to my plants and examined scores of blooms, and I must say I found the Spencer varieties, at the stage when fertilisation takes place, with stigma quite as carefully protected by keel and wings as in any of the "old-fashioned Eckfordian type." I do not say Mr. Barwise has not seen flowers with stigma exposed, for I have seen such myself at various times and on plants of several varieties, both old and new; but the peculiarity was always due to some malformation of the bloom, brought about by an uneven development of wings or keel. For my part I am inclined to think Mr. Clapham has got nearer

the true cause than Mr. Barwise, because to any observant student of the Mendelian theory of cross-fertilisation the whole gist of the matter lies in the supposition that the variety Countess Spencer, being a new "break" among Sweet Peas, is an impure dominant, and therefore likely to retain that character generation after generation; and to my thinking—but I may be wrong—it is only by using it as one parent in a new cross and getting it bred as a pure dominant that fixed varieties having the same conformation and colouring can be obtained; and if one knew the history of any similar variety—Audrey Crier, for instance—since raised, possibly that is the course that has been taken.—WILLIAM BOOTH, *Howsham, Lincoln.*

**Cross-fertilisation of Sweet Peas.**—Mr. J. F. Barwise's account of his seeing the stigma of some Sweet Peas protruding outside the keel before the stamens were ready to fertilise came as a surprise to me. Since then I have examined several hundreds of blooms, but have failed to discover one where the stigma was in such a well-developed state as Mr. Barwise says. If such a state of things does occur, we can at once account for the number of rogues which appear every year among the modern Sweet Peas. My experience has been that before the flower is half developed pollination has taken place, and by the time the stigma appears outside the keel fertilisation is effected. I quite agree with Mr. Barwise that the wings do not lie so closely over the keel in the modern Sweet Pea as in the older sorts, but that does not in the least, in my opinion, alter the cause of so many rogues appearing. When I wrote that out of fifteen plants of Countess Spencer only six were true, this has been my average for at least four years, and when Mr. Barwise says that his packet did not contain a rogue I forthwith broke the Tenth Commandment. I shall watch with great interest during the remainder of the season for the appearance of the stigma before the pollen sac has burst, for this to me is a point which should not be lost sight of, and I thank Mr. Barwise for mentioning it.—P. CLAPHAM.

**Cervantes' Daffodil.**—With reference to the Rev. Joseph Jacob's remarks over this "first of all" early trumpet variety, allow me to mention that it is as far apart from a relationship with Princess as John o' Groats and Land's End in England. There is no possible affinity, as I know all about it, being its introducer at the start twenty years since. It is a wonderful increaser and succeeds in any soil, the lighter the better. We usually flower it here before Christmas. We are sorry that the stock is very much run on this season by market growers, this on account of the wants of our private customers.—W. BAYLOR HARTLAND, *Ard Cairn, Cork.*

**Growing Carnations.**—I notice your correspondent, C. Ruse, gives some useful hints on growing Carnations in your issue of the 15th inst. On one point I do not quite agree with him. When layering he advises giving an upward cut for about 1 inch through the stem. I find it is much better to stop the knife at, say, from a quarter of an inch to half an inch, so long as the cut is made clean through a joint. The drawback to having such a long tongue is that it is apt to snap off when taking them up for planting out, however carefully the work may be done. When this happens the plant is useless, as the roots are emitted at the joint which should be near the tip of the tongue. I have had these mishaps happen myself when planting out, but by making a short tongue it is avoided. Of course, they will root just as well from a long tongue and may be taken up all right with extra care, but where one man has a few thousands to plant out it is a case of quick handling when suitable planting weather comes round.—A. CHILDS, *Brown Candover, Alresford, Hants.*

**A remarkable crop of Peas.**—In these days of intensive cultivation and heavy cropping I think it may interest your readers to

hear about a remarkable crop of Peas (Duke of Albany) which we have just marketed from our small holding in Kent. Early in May we planted one-eighth of an acre with half a bushel of the above Peas. Between August 1 and 8 we picked from this plot 36 bushels and there are still quite 4 bushels to gather; therefore, forty multiplied by eight would give a yield of 320 bushels to the acre. Is not this a record yield, as the average crop is computed at 150 bushels to 170 bushels per acre? The price obtained has been 3s. a bushel, or £6 for the crop, which works out at £48 to the acre. The seed was supplied by Messrs. Harrison of Maidstone. We attribute this heavy crop to two things—thin sowing and constant hoeing, added to a favourable season. Our market garden has only been under cultivation for four months, and the whole gives returns approaching these figures. I think we shall be able to prove an axiom which I have propounded for many years, namely, that "Agriculture can be made a paying profession for women."—EDITH BRADLEY, *Greenway Court, Hollingbourne, Kent.* [No doubt a crop of Peas working out at 320 bushels per acre was a record one. Yours being 40 bushels for twenty rods runs to about 3 bushels per rod, which, after all, for deep-worked, well-manured ground, of

A FINE GROUP OF PEONIES IN DR. MCWATT'S GARDEN, MORELANDS, DUNS, N.B.

such a Pea as Duke of Albany is far from being exceptional. Presumably the Peas were not staked. If they were, while materially adding to the cost, the produce would have been heavier. We assume, however, the Peas were grown field fashion, that is, lying on the ground, in rows 2½ feet apart. Thus treated we have had a bushel of ripe seed per rod from Senator. A very interesting addition to your note would have been rent of land, cost of manure, of labour, of seed, of gathering, of baskets, of marketing and other small items of expenditure to set against your £6 receipts, that a balance of net profit might have been shown. Also, while you claim that agriculture may be made a paying vocation for women, will you please say how much of the labour of trenching or deep digging of the soil, getting on manure, &c., was done by women.—E.O.]

#### PEONIES IN SCOTLAND.

THE above illustration is from a photograph kindly sent to us by Dr. McWatt of Morelands, Duns, N.B. The Peonies are growing in Dr. McWatt's garden, where the soil and climate are evidently very suitable for these handsome plants.

## THE FRUIT GARDEN.

### GOOSEBERRIES ON NORTH WALLS FOR LATE SUPPLIES.

THE value of the Gooseberry on a north wall is often overlooked by amateurs who like these fruits over as long a period as possible, and, once the wall is furnished, the trees give very little trouble indeed. A few years ago I advised an amateur to make a trial of Gooseberries, and double cordons were planted. The wall, being only 7 feet high, was quickly furnished and has never failed to bear a good crop, though the plants get rather rough treatment, shears being employed to keep the growths cut back, and only a nail here and there to keep a main growth in position. I have seen a good crop from north walls when the earlier crops in the open were quite ruined by frost in consequence of their early flowering.

Another point that should not be overlooked is to plant several sorts, as variety is liked for dessert purposes. At the same time I do not advise all the Lancashire Prize Gooseberries for wall work, on account of their peculiar growth, but most of them are much better grown thus, as, having a spreading growth, they will repay the support of a trellis or north wall. They give a splendid return and fruits of delicious flavour, and the buds are protected much easier from birds early in the year and when the fruits are ripe, as a net or thin tiffany hung over the trees is easily placed in position.

Trees are grown purposely for this work, and their training is a simple matter. It is necessary to continue the growths of the main shoots and stop all breast wood to within a short distance of the shoot—that is, continue the terminals and stop all side shoots not required. I have mentioned the large-berried varieties, and in addition would advise a large percentage of the small-berried sorts, as I consider these even superior to the larger ones. These latter bear so freely and make a much closer growth, so that the wall is much sooner covered. Autumn planting, as soon as the leaves have fallen, is best, as the purchaser will secure much stronger trees, which will grow much better the next season and give less trouble. As regards the distance to plant, so much depends upon the shape of the trees at the start. A fan-trained requires more room than a double cordon. Those with three shoots, or triple cordons, are best, and they may be planted so that each tree has at least 1 foot to 1½ feet clear from the side growths when planted. A great deal depends upon the size of the tree and height of wall to cover. On a low wall, single cordons planted 1½ feet or 2 feet apart soon furnish the wall and give a crop the first season. The trees should, late in the autumn each year, have a liberal mulch of decayed manure at the foot of the wall.

The following varieties are suitable for this system of culture: The new Langley Gage, a recent introduction from Messrs. Veitch's Langley nurseries, is a splendid white berry for flavour, and the plant has a free habit. Golden Gem is also a delicious fruit, small, but of the best possible flavour. Langley Beauty is a large yellow fruit of great excellence. Among the older sorts of the smaller berries worth noting are Golden Drop, Yellow Champagne, Sulphur, White Swan, Whitesmith, Cheshire Lass or Shiner, Glenton Green, Greengage and Hedgehog, and the well-known reds such as Keen's Seedling, Crown Bob, Red Champagne, Warrington (very late) and Industry. There are so many large varieties that I will only note a few. Greens: British Queen, Shiner, Glenton, Stockwell and Telegraph. Reds: Crown Bob, London, Dan's Mistake and Speedwell. Whites: Alma, King of Trumps, Swan, Transparent and Lancer. Yellows: Drill, Keepsake, Leader, Leveller and Trumpeter. The above include early and late sorts, and are noted for their flavour. G. W. B.

## THE KITCHEN GARDEN.

### AUTUMN SALADS FOR AMATEURS.

**A**MATEURS are at times at a disadvantage, as the seasons vary so much that a sowing on a given date is not always reliable. Dates of sowing, however, are not the most important points, as the soil, situation and other details so much influence the crop. At the same time it is by no means a difficult matter to get good salads from October to Christmas, and this may be done at a small cost by growing in good land, by not crowding the plants, thinning freely and transplanting when necessary. It may be thought that to do this glass protection is a necessity, but this is not imperative, though if a cold frame is available this is a great help, as Lettuce, one of the best salads, is the most tender, and is always a valuable adjunct, but not by any means a necessity.

*Endive*.—This is one of the most useful salad plants grown; it is harder than Lettuce and of easy culture. Seeds should be sown in August, and if the plants are given ample moisture they will give a good return at the season named. The Moss-curl variety is the best looking, but not so hardy, and for late use I would advise the Round-leaved Batavian; this is very hardy and superior to the white. Sown very thinly in good soil on an open border the plants grow quickly, and the thinnings planted out 12 inches apart give a later supply. It is important to give plenty of room, as a crowded plant is very tender and is soon injured by frost. In transplanting do the work in dull or showery weather. Care should be taken to preserve the roots, and, if possible, to get some soil attached, as this greatly assists the plants. There is another very good hardy Endive, the Winter Curled, a large leaf and very hardy also, and Carter's Oval-leaved, a new plain-leaved Endive, is specially good for winter salads. I have had this on an open border well into the spring. There is also a distinct salad plant known as Sutton's Winter-leaved Lettuce which is well worth amateurs' attention. The leaves are of excellent flavour and hardy, and the plants stand a long time.

*Lettuces*.—I am unable to advise these with the same remarks as I have the Endives, as owing to their tenderness they are not so reliable, but some are more suitable than others, and if a frame is available my remarks as regards their good keeping are applicable. Even without glass it is an easy matter to lift Lettuce at the approach of frost and put them in boxes in a place of shelter, where they remain good for a considerable time. There is a very hardy Lettuce named Sutton's Little Gem, which is well worth a trial. It is a Cos variety, but very dwarf, and it certainly stands severe weather where others fail. It is small, crisp and good. The hearts are very solid, and when sown in August or September is one of the best winter varieties I have ever grown. Of older sorts the Stanstead Park and Hammersmith Hardy Green Cabbage are excellent autumn and winter varieties. These sown thinly on an open quarter, and well thinned out afterwards, will be found the most hardy of this section. I have referred to cold frames, and where these are available it is a good plan to lift full-grown Lettuce at the approach of frost and place therein, leaving the smaller plants for succession.

*Chicory*.—This plant is a valuable addition to the salad bowl, and to get the best results should be grown somewhat like Beet, the roots lifted and stored; the new leaves are the portion used for salad, but amateurs can get good results by sowing now and leaving in the row and cutting the plants over as required. Of course the leafage is much smaller, but it is plentiful, hardy and the plants continue to grow for a long time. The older roots sown early in the season should be placed in a cellar or dark shed, where they

will give a quantity of blanched leafage all through the winter.

*Corn Salad*.—This is a hardy green salad not grown nearly as much as it should be. It is often known under the more popular name of Lamb's Lettuce, and is of great value for salads from October to March. Several sowings should be made, on good land, very thinly in an open quarter and cut over as required. Sown in August, September and early October there will be a good winter supply and a quantity of green sweet leaves that are most useful; indeed, with this and Endive, Lettuce may be dispensed with. The best variety is the Broad-leaved Italian.

Other aids that help to make a good salad are the useful Chives, a hardy perennial early in the year, also the small green Onions. Dandelion is also useful, and Watercress early in the year is most welcome. This can be grown from seed in a moist soil, and Mustard and Cress are too well known to need describing. G. WYTHES.

## THE ROSE GARDEN.

### THE ASHFORD ROSE.

**T**HIS is the only known name for a most beautiful Rose of tall or climbing habit which is now to be found in a few Irish gardens, but which is nowhere to be found more beautiful than in the gardens of the Right Hon. Lord Ardilaun, at St. Anne's, Clontarf, Dublin. This is as it should be, as the Rose was first observed on the walls of Lord Ardilaun's other mansion at Ashford in County Galway, where it had probably been for many years before its merits were again recognised when a renewal of the taste for such Roses set in. At St. Anne's it is freely used, and its great trusses of fine flowers of a charming pink are of the greatest service on wall, trellis and arch. The Ashford Rose is evidently a form of Rosa Pissarti, and has even more vigour than its allies, while the foliage is of a healthy green, and its rapidity of growth renders it of the utmost value for places where free-growing Roses are required. It soon covers a great space, runs to a considerable height if required, and gives for a long period an abundance of its large trusses of flowers. One of its great advantages is the freedom with which it strikes from cuttings, and it is being multiplied at St. Anne's and the other Irish gardens into which it has found its way. It is a great favourite with Lady Ardilaun, whose taste has done so much in transforming the fine walled garden at St. Anne's, in which the Ashford Rose is cultivated; and it responds to the liberal treatment given to it by Mr. Campbell, Lord Ardilaun's gardener. S. A.

### ROSE COUNTESS OF GOSFORD.

This lovely Hybrid Tea, which one might call a glorified Mme. Laurette Messimy, has been very fine this season, and it will certainly rank very high as a decorative Rose for the garden. There is nothing of the formal shape about it, the flowers being of those huge loose types we have learned to admire so much; it is a pleasure to see such Roses in the early morning or late in the evening. There is a richer suffusion of salmon in its blossoms than we have in Mme. Laurette Messimy, otherwise there is a great similarity in style. Messrs. McGredy and Son, the raisers, have obtained some excellent novelties, and they exhibited several at the National Rose Show this year, which will be heard of in the near future. Perhaps the thin loose flowers are being introduced rather too plentifully, for one might say that two-thirds of the novelties now sent out are of this character. Obviously they must possess special merits in either colour or form, or they will not be wanted, for have we not now a collection already overburdened with sorts that are too much alike? P.

## DAFFODIL NOTES.

### THE CUTTING BED AND ITS OCCUPANTS.

**N**O one who can avoid it likes to spoil their show in the garden, but many who want flowers in the house are more or less obliged to do so just for the want of a little foresight in the autumn in making a bed or beds in the kitchen garden, or in that very useful border which surrounds the outside of the wall, and filling it with Daffodils. This is really as necessary an adjunct of a well-planned scheme of gardening operations as are Daffodils themselves.

And how useful it is! Here the flowers that are to be cut for the house are grown. Here, too, new sorts may be tried, and here expensive varieties may find a home and be looked after until a little stock has been got together. Although the present series of notes are not cultural in the strict sense of the word, I must allude here to the importance of doing the cutting bed well. I strongly advise double digging, and in old gardens a good application of slaked lime or the newer form of ground lime. Gardening papers are just now full of articles and notes on the value of lime in the soil, and as far as Daffodils are concerned I can thoroughly bear them out. After the beds are dug I cover them with a coating of lime on a calm day, and then fork it in immediately. The bulbs can then be put in at any time. If ground lime is used I would only half cover the ground, and then would leave it about a week before planting. Four feet wide is a convenient width, and the bulbs are best planted in rows across the beds, the rows being about 8 inches apart. I have dwelt on these cultural matters because it is important to have as good flowers as possible in the house. They are then admitted to a closer companionship, and, both for their own sake and for our own, ought to be in their "best." Out in the garden we may leave them in their everyday clothes. One great desideratum, from the strictly cut flower point of view, is length of stem, and nothing helps so much to this end as good culture. It is the only substitute we can offer for the ideal climatic conditions of Cornwall, where such is the growth that who knows but that the Daffodil of Cornwall will one day rival the Cabbage of Jersey in providing the astonished visitor with a walking-stick. Another desideratum is elegance. The Daffodil above all others for cutting is Frank Miles. Its graceful perianth is a sort of standard yard which we may use as our basis of comparison. Maximus is its counterpart in the long trumpets; but, sad to say, it is a shy bloomer. Citron and Duchess of Westminster among the Leedsii and Princes among the long trumpets, Almira and Eyebright among the small cups, are flowers that have that undefinable something that lends them specially to vase decoration. Not but what all Daffodils are beautiful, and doubtless there are some who would prefer the stiffer type of Tenby and Emperor, or Mme. de Graaff and J. B. M. Camm, or Autocrat or Crown Prince.

A third desideratum is succession. Those who can give both a north and a south aspect have a distinct advantage. Wherever it is possible it is best to divide the bulbs for cutting, and put some in an early aspect and others in a late one simply to extend their flowering season. If, in addition to this, we choose early and late varieties, it is surprising the time that they are available. The earliest section are the large trumpets, and the latest the Poets; between the two come the large and small cups. I will now give two lists of suitable sorts, arranged, as far as possible, in their order of flowering. The first and longest contains only old and cheap varieties, and the second and shorter a few of the newer and more expensive which might be used to supplement or extend the other, as the case may be.

Old varieties: Golden Spur, Princes, Queen Bess, Sir Watkin, Campenelle Jonquils, Glory

of Leiden, Orphee, Emperor, J. B. M. Camm, Empress, Frank Miles, Minnie Hume, Mrs. Langtry, Beauty, Autocrat, Duchess of Westminster, Flora Wilson, Barri conspicuus, Crown Prince, Citron, Falstaff, Vanessa, Mabel Cowan, ornatus, Elvira and Klondyke.

Newer sorts: Blackwell, Golden Bell, Duke of Bedford, Mme. de Graaff, Ariadne, Eyebright, Dorothy Wemys, Comus and Horace. I have not put maximus in the list, because it is a shy bloomer in most gardens, nor Almira, because it is not a good doer as a rule, but, all the same, they are beautiful flowers. JOSEPH JACOB.

## NEW PLANTS.

**PINK PRINCESS CHRISTIAN.**—A useful addition to the perpetual-flowering border Pink. The flowers are blush coloured at the margin of the petals and heavily coloured a dark maroon at the centre. The variety is exceedingly floriferous and of considerable vigour, the flower-stems reaching to nearly 2 feet in length. Shown by Messrs. B. Ladhams and Co., Limited, Southampton. Award of merit.

*Thalictrum dipterocarpum*, shown by Messrs. James Veitch and Sons, Limited, will be described and illustrated next week.

*Sophro-Cattleya-Lælia Marathon.*—This plant is interesting as well as beautiful, owing to its being a reputed cross between *Sophro-Lælia Psyche* and *Cattleya Empress Frederick*. The flowers are of nearly true *Cattleya* form, of medium size and very showy. The lanceolate sepals and ovate-lanceolate petals are of a uniform bright rosy purple colour, the labellum being of the richest velvety purple, with golden striation in the throat. The edges of the labellum are much crimped, thus adding to its beauty. Shown by Messrs. Charlesworth and Co., Bradford. Award of merit.

*Odontoglossum Zenobia.*—This is a new hybrid of more botanical than garden interest. The plant shown had a long, branching raceme, bearing in a sparse manner medium-sized flowers of a deep maroon colour, the edges and tips of the segments being yellow. The labellum also has yellow markings at its base. Shown by Mr. de B. Crawshaw, Rosefield, Sevenoaks. Award of merit.

*Odontoglossum wiganianum superbum.*—As its last name implies, this is a really superb form of a good Orchid. The plant exhibited possessed one raceme composed of nine large and handsome flowers. The sepals and petals are of a rich yellow colour, dotted on the lower portions with good-sized, brownish crimson dots and blotches. The labellum is very large and spreading, the white ground being regularly marked with crimson. All the segments have crimped or wavy edges. The plant was a most vigorous one and attracted much attention. Shown by Sir Trevor Lawrence, Bart., Dorking. First-class certificate.

*Cypripedium Rosetti.*—This is a reputed cross between *insigne sanderianum* and *Maudiae*, and partakes of both parents in character. The flower is very large, the dorsal sepal being remarkably broad and heavily edged and tipped white. The petals are very long, lanceolate, with beautifully crimped edges. The labellum is of large size, pointed and of a shiny greenish yellow hue, a colour that predominates in the flower. Shown by Lieutenant-Colonel G. L. Holford, Westonbirt, Tetbury, Gloucestershire. Award of merit.

*Sophro-Lælia-Cattleya Medea vinicolor.*—In addition to a beautiful outline this Orchid possesses a colour that is almost unique, this being a self bright plum colour. The flowers are of medium size, and are borne on stont, almost erect stems, thus showing them to the best advantage. Shown by Lieutenant-Colonel G. L. Holford. Award of merit.

*Pilumnus nobilis alba.*—This is a pure white form of an Orchid that is none too well known.

The sepals and petals are very small and inconspicuous, the labellum being the most prominent segment. This is very broad and spreading, and of the purest white. Shown by Messrs. Charlesworth and Co., Bradford. Award of merit. All the above were shown before the Royal Horticultural Society on the 18th inst., when the awards were made.

## THE FLOWER GARDEN.

### INCARVILLEA DELAVAYI.

**H**ARDY in all but the coldest soils, *Incarvillea Delavayi* is one of the midsummer flowers which yearly greet us from their accustomed places. Introduced from China some fifteen years ago, the merits of this plant were early recognised, consequently it became much sought after; and where the plants have been allowed space to develop and their requirements understood, the result has been the establishment of splendid clumps, which

quality, as the plant succeeds in the natural chalky soil of this district. Generally the trouble with *Incarvilleas* is to winter them, so that it is always good practice to give abundant drainage, and on heavy soils this is absolutely necessary. Where the plants are of doubtful hardihood it is safest to place over each crown before winter a spadeful of cinders or a similar quantity of moss litter. *Incarvillea Olga*, from Turkestan, makes a splendid second to the first-named species: the flowers are larger, but the foliage is more sparse and growth is less vigorous, rarely exceeding 1 foot in height.

*Incarvilleas* are easily raised from seed sown in light sandy soil in a cold frame as soon as it ripens in autumn. Probably the best results follow spring sowing in boxes or frames, as then satisfactory growth is made the first season and the plants attain a size which enables them to withstand the trials of winter. Once the seed germinates and the plants are fairly growing they are transplanted 6 inches or 9 inches apart either in frames or a half-shaded position outside (spring sowing) in light rich soil. No further attention is necessary save weeding and hoeing until autumn, when the roots are dug up and

INCARVILLEA DELAVAYI PLANTED AMONG OTHER SUBJECTS IN THE BORDER.

amply testify that such confidence has been singularly well placed. *Incarvillea Delavayi* has distinctive features which commend it to amateurs. It is of free growth and very easy to establish, to which may be added its stately appearance; then the leaves are particularly beautiful, forming a pleasing and effective accompaniment to the soft colour of the trumpet flowers.

I think that *Incarvilleas* are specially adapted for grouping with such subjects as accentuate rather than compete with its own beauty, for nothing detracts more from its effectiveness when in flower as being placed in association with gaudy and high-toned flowers. Planted in informal groups as seen in the illustration, where the neutral grey tints of *Retinospora plumosa argentea* have been employed, against which the bright and pleasing shade of the rose flowers stand out with telling effect, then, as a carpet, the *Viola Wm. Neil*, the effect is certainly good.

The *Incarvillea* is a Bignoniaceous plant, an order sparingly represented in gardens. The rootstock is swollen, and often tapers to a length of 15 inches to 18 inches, consequently it can only be successfully grown in a good depth of soil. This need not necessarily be of special

stored in moist sand in a frost-proof structure till spring. The following year they are planted in their permanent positions, prepared on the lines indicated, where they will flower and continue to increase yearly.

Walsgate Gardens.

THOMAS SMITH.

### SAVING SEED OF SWEET PEAS.

I HAVE lived abroad for many years, and on my return to England this year have grown my first Sweet Peas with very satisfactory results, owing to advice read in your columns. I wish to save some seed from Gladys Unwin and Mrs. H. Philbrick; is it advisable to do so? At what time should I allow pods to form? Is any special treatment required during such period? How am I to know when the seed-pods are ready for picking?

EAST ANGLIAN.

[There is no special reason why you should not save seed of the two varieties you name if you particularly wish to do so, although, speaking generally, seed of Sweet Peas is so cheap that it is hardly worth while to trouble about gathering and storing at home. No special treatment is needed. You may let seed-pods form at any time, and gather them when they shrivel.—ED.]

## A RARE AND BEAUTIFUL IRIS.

(IRIS GATESII.)

AFTER the excellent article on the "Culture of the Cushion Iris," with accompanying illustration of *Iris iberica*, which appeared in *THE GARDEN* on the 18th ult., the photograph of *I. Gatesii*, another member of the *Oncocyclus* section, may be of interest to any who intend to grow, or have already grown, any of these beautiful plants. The species, which hails from Armenia, should be included in every collection, as it is as easily grown as any other of the same section, while its flowers, which have a ground colour of creamy white, dotted on the falls and delicately netted on the standards with faint purple, are larger than any other of the same section. The plant illustrated possessed originally four flowers, instead of three, as in the illustration, a snail having destroyed one by eating through its stem during the night. The height of the flower-stems were nearly 2 feet. A good way to grow them where the soil is retentive of moisture is to lift them as soon as they have died down, which takes place shortly after the flowering period, and store them in dry sand till about November, when they may be potted up, using abundance of sand in the soil. Keep them in a cold house during the winter, during which time very little water is needed. When March comes, if weather permits, plant in their flowering quarters, sheltering with some light material if necessary during cold spells of weather, taking care they are not overgrown at any time by any other more vigorous plant near them.

*Bathaston Lodge.*

A. E. PORTER.

## A BORDER OF HARDY FLOWERS.

THE border represented in the illustration was very effective during the latter end of June and the beginning of July. The idea was to make as effective a show as possible with large masses of a few very free-blooming plants. The narrow border on the left-hand side is composed of *Pentstemon Newry* Seedling and the yellow *Calceolaria*. These are raised each year from cuttings inserted in a cold frame during September, and are planted out the following April. Only a few *Calceolarias* are used along the edge to brighten up the *Pentstemons*. These two begin flowering in June and continue well into October. On the right-hand side the *Pinks* are very beautiful; they have been there about five years and are constantly increasing. The most striking *Campanula* used is *C. grandis*,

the clumps of which are from 6 feet to 8 feet across, while large masses of *Canterbury Bells* are also very effective. These want to be studied closely. There are all possible shades, with also some very pretty splashed forms. Not quite so readily seen in the picture is *Campanula persicifolia* in various forms. The *Roses* at the back are the common *Cabbage* variety. Among other occupants the border contains *Sweet Williams* in various shades (white, pink and red), *Delphiniums*, various forms of the *German Iris*, perennial *Asters* varying from 1 foot to 6 feet, *Solidago*, *Chrysanthemums*, *Meconopsis Wallichii*, *Aquilegias*, also various annuals such as *Godetias*, *Clarkias*, *Coreopsis*, *Larkspurs* and *Statice sinuata*. The border is rearranged every two years, owing to the number of strong-growing plants in it.

W. P. WOOD.

*St. Peter's, Kent.*

## THE CULTURE OF VIOLETS.

## SEASONABLE NOTES.

IN a sense the culture of Violets continues throughout the year, but in the beginning of September plants from the border are to be

A BEAUTIFUL IRIS FROM ARMENIA: I. GATESII.

A PRETTY BORDER OF HARDY FLOWERS IN A KENT GARDEN.

lifted for winter "blooming" under glass, and pot plants are taken into the greenhouse or sunny window for the same purpose. If there is a healthy Violet plantation in the garden, the plants of which have not been allowed to throw all their strength into runners, it is certainly advisable to lift some of them and encourage them to produce plentiful blossoms during the flowerless season of the year, when their fragrance and beauty will be most delightful. Supposing an empty frame to be at the gardener's disposal, let this be filled up with old hot-bed manure to within 12 inches of the glass, making the material rather firm so that it will not sink much afterwards. Upon this decayed manure 6 inches of good loam and leaf-mould should be placed, and I find it best to add a little road-grit and some pieces of charcoal, as the former keeps the soil in a friable condition and the latter mitigates the danger of its turning sour.

In this soil the lifted Violets are to be firmly planted 7 inches apart; their top foliage will then be about 2 inches below the glass when they are well established and the flower-buds will rise rather higher. It is essential for success that flowers and glass should be close together, as if more space is given leaf-production will be over-vigorous and the blossom harvest very scanty. Sometimes it happens, even when best measures have been adopted, that the buds grow too tall, so are injuriously pressed against the glass, but if a thorough watering is given to the soil it will be possible to press the plants down lower into it

without disturbing their roots. It is more risky to raise plants that are too low, yet this can also be done with care. A hand-fork should be thrust down beside each to its fullest depth, some good soil being piled up all around the plant, and, as the fork slightly lifts the plant, the left hand of the operator should press the soil firmly down, so as to fill up any space left beneath or around the roots. If all is made firm and a thorough watering is given then—not before the work—the lights being kept closed for a day, it is improbable that any of the foliage will suffer.

Plants lifted from the border can be potted, but this is not generally very successful, as Violets should be grown in pots from April plantings, and the pots be sunk out of doors in a shady place during summer. I have had plenty of good Violets during winter, however, by planting lifted plants in deep boxes of the suitable compost and ranging these on such a high shelf of the greenhouse that their foliage almost touched the glass. To grow free-blooming Violets in pots or boxes in a sunny window is quite possible, but best results are obtained by covering each plant with a small bell-glass.

The Violets planted in frames should not be watered again for a very long while; indeed, authorities state no watering should be done during winter; if they are kept moist, there will be few, if any, flowers. The frames should occupy a sunny position, failure often being due to having them in shade. It will be necessary to ventilate very freely, or sickness and insect pests will result, and I find that foliage sprinklings do good in dry spells of weather, especially when gales are blowing dust about freely. The plants must be protected from any touch of frost, so mats should be laid over the glass and also hung over the wooden sides in severe winter. A perfect soil for potting Violets consists of two parts loam to one each of river sand and leaf-mould; as many as six roots can occupy a 6-inch pot, and the plants will require watering occasionally, as pottery does not retain moisture as the earth or frame-bed would do.

Outdoor Violets are too often neglected, allowed to form runners and given no extra nourishment. Throughout summer they should be given liquid manure every second or third week, and if liquid cow manure is objected to, there are several chemical forms in which suitable food can be administered. Soot water can be alternated with other manures, such as those made of an ounce of guano in a gallon of water and a quarter of an ounce each of sulphate of ammonia, superphosphate of lime and sulphate of iron to two gallons of water. Outdoor beds can have supplies of liquid manure right up to the end of November.

Violets do not thrive on sandy gravel soils unless the borders are prepared first by a copious mixture of stiff loam and cow manure; a clay soil needs to be lightened by plenty of road grit, and the ashes from vegetable bonfires should be added to them as well as manure. Excellent

Violets can be grown at the base of fruit trees, because the manure given the trees will benefit them as well, and the partial shade will also be advantageous to their welfare.

#### LONG-STEMMED VIOLETS

are beautiful for dinner-table arrangements and bouquet making; they should never be gathered short and packed together in the tight market posy which used to be the only form for bunches of Violets. Double as well as single Violets can be cultivated well if the above rules are carried out, but it is seldom that the former thrive perfectly except in southern counties and sheltered warm gardens.

An old writer on this subject states: "White, dull red and deep blue scented varieties grow wild; there are also double white, red and dark blue garden sorts. The Parma Violet has very

## COLOURED PLATE.

PLATE 1355.

### POLYANTHUS PRIMROSES.

WHEN asked to write a few notes about these flowers one finds it is rather difficult. They are merely the result of careful selection and cross-fertilisation for a number of years. The ideal plant is one which throws up a good firm stem of sufficient length to carry the flowers well above the foliage and has sufficient bloom to furnish a compact head; the individual flowers should be round, of good size but not necessarily very large, I have measured some over 2 inches in diameter, but these are exceptional and perhaps too large; the colours should be clear and bright and the dark varieties should have a well defined and clean eye. They are essentially garden flowers, but how long they will remain so one cannot say. There is plenty of scope for the keen florist to devote his energies to them and then we might have a long string of named varieties. The increase by division of *Polyanthus Primroses* tends to weaken them, the little fibrous roots suffering considerably by the process. By far the best method is to raise a fresh lot of seedlings when the old plants have run their course; they need not, however, be destroyed after blooming the first time; if

planted in a sheltered position in good cool soil they will go on for several years. They are easily raised from seed and require little attention; the great secret of success, if one can call it a secret at all, is to give them good soil and a position sheltered from rough winds in the winter and from too much sun in the summer. Sow the seed in boxes or pans, keep them well watered and the seedlings should appear in about three weeks from sowing. Plant them out when strong enough about 10 inches apart. They are perfectly hardy, but if a few selected plants are potted in the winter they flower earlier under glass. W. A. WATTS.

SOPHRO-CATTELEYA WARNHAMENSIS VAR. J. M. BLACK. SHOWN BY R. G. THWAITES, ESQ.

(Natural size.)

light blue double flowers, exceedingly pleasing, will flower under a frame from October till spring. The Bruneau Violet has double flowers, with the outer petals dark blue, the inner ones mottled with white, red and blue. Some Violets have a greater tendency than others to commence flowering in autumn, and to continue, under favourable circumstances, throughout the winter. Such are the Russian and the Neapolitan Violets among the singles, and the double red, and the Champlatreux, double white, or Four Seasons Violet." There is always interest in learning olden ideas and methods of flower culture. E. D.

### SOPHRO-CATTELEYA WARNHAMENSIS VAR. J. M. BLACK.

(SOPHRONITIS GRANDIFLORA × CATTELEYA AMETHYSTOGLOSSA.)

THIS is a very beautiful bigeneric hybrid of a distinct and novel shade of colour. The plant is of dwarf habit, and when exhibited on the 4th inst. bore a two-flowered scape, one flower only being expanded. The sepals and petals of the comparatively large flower are of a ruby red tone, the drooping tip of the acutely-pointed lip shaded crimson and carmine, the disc and throat deep yellow. This charming novelty was exhibited by R. G. Thwaites, Esq., Chessington, Streatham (gardener, Mr. J. M. Black), and received a first-class certificate.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**G**REENHOUSE AND CONSERVATORY.—The present is an excellent time for potting up a batch of the beautiful sweet scented Freesias; the more popular variety of this plant is *Freesia refracta alba*. In late August and September the potting up of the bulbs may take place. Suitable soil is light loam with the addition of a little well-decayed manure and plenty of sand. These soils should be well mixed and placed in 5-inch pots. Seven or eight of the larger bulbs, or nine or ten of the smaller ones should be arranged the same distance in the pots. After potting, they should be stood in a cold frame until growth begins, subsequent to which introduce them into the glass structure where a temperature can be maintained at from 45° to 55°. It is a good plan to remove the pots into the glass house in successive batches. If wanted in flower at Christmas they should be introduced into heat in the early part of November, maintaining the temperature at from 60° to 65°. Remove dead flowers and foliage from all plants in these structures. It is not necessary yet to place winter-flowering Zonal Pelargoniums under glass; they should be allowed to remain a little longer outside in a warm and sheltered aspect. As Hydrangeas go out of flower remove the old flower-heads, and where the plants are root-bound place them in pots of larger size. Embed the pots to the rim outdoors in some cool material, such as sifted ashes, coke breeze or Cocoanut fibre refuse.

*Vegetable Garden.*—For winter supplies we have just been lifting and transplanting a few young roots of a good form of Parsley. These, if planted out at the foot of a south wall, should provide a supply of this useful subject in the dull months of the year. Autumn Giant Cauliflowers that are now beginning to turn in will be benefited by an application of liquid manure, and this may be applied frequently until the crop has matured. Turnips sown some little time since should not be left too long before they are thinned out. Allot a square foot to each root if results are to be all that the grower desires. Celery is growing vigorously just now, and growth may be still further promoted by frequent applications of liquid manure. Where blanching has not already been done, plants that are ready should receive this attention now. We prefer to blanch Celery by wrappings of brown paper cut in strips 6 inches in width. If this be bound round and tied securely, blanching will proceed apace, and the work may be expeditiously done. It may be necessary to draw soil just round about the stems to assist the blanching. Should the weather be dry at the time the earthing up is done where this method of blanching is not followed, the plants should have copious applications of water.

*Hardy Flower Garden.*—The beautiful Brompton and intermediate Stocks for next summer's blossoming may now be sown in an open position outdoors. Thin sowing is essential to success, and that the seeds may germinate satisfactorily water the ground before sowing the seeds, subsequently proceeding to sow thinly as

above suggested. Should the weather be warm it is a good plan to shade the quarters thus sown until the seeds give evidence of germination, which will not be very long. As soon as they are large enough to handle transplant the seedlings in a cold frame, or if preferred in a sheltered and warm border outdoors. Pansies are now providing an abundant supply of fresh young shoots with which to make cuttings. These should be detached about 3 inches in length, the lower leaves trimmed off and cut through immediately below a joint. If these cuttings be inserted in light sandy soil in the open border or in a cold frame and shaded from the bright sunshine, they will soon root and provide plants for the late autumn, or, what is better, fine tufts for planting out in their flowering quarters next March. These same subjects may be raised from seed at the present time, as these germinate very readily at this period. Useful little seedling plants may be pricked off before the hard weather sets in, from which we may anticipate a glorious display in late spring and early summer. We are still prolonging our display of Sweet Peas by removing spent blossoms and seed-pods, and in the case of the less vigorous shoots cutting back these to within 3 feet of their base.

*Window Gardening.*—Very pretty effects are secured at the present time from plants of the beautiful Clematis Jackmani that were shaken out of their pots and plunged in the end of the window-boxes. These have been trained round the window and have made a charming picture. Spent blossoms and decaying foliage should be rigorously removed from all plants in window-boxes to maintain them in health, and later on, as the growths of some of the more robust begin to run into the foliage, instead of into the flowers, we should be disposed to remove them and plunge other flowering plants that are in season in their place. Foliage plants arranged in the inside of the windows need constant attention if they are to be maintained in health at the present time. A weekly sponging of the foliage contributes in no mean measure to their pleasing appearance and healthful condition. The plants should be turned round from time to time that their growth may not become drawn. Those who desire a winter display of the beautiful Roman Hyacinth and the Paper White Narcissus should make a planting of these subjects at the present time. Three or four of the former bulbs placed in 5-inch pots and three of the latter in 6-inch pots will give excellent results. They may also be planted in boxes 3 inches deep, and by these means will provide cut flowers for winter use. After potting, the pots and boxes should be placed in some plunging material and covered to a depth of 6 inches or 8 inches, until shoots are emitted from the crown of the plants fully an inch in length. They may then be removed from the plunging material and placed in a sunny window, where their progress should go on unhindered. Where it is intended to grow Hyacinths in vases of water, the present is a

1.—SHOOT OF BOX TREE SUITABLE FOR A CUTTING.

good time to place a few of the earliest bulbs in position. The vases should be stood in a dark cupboard until roots have formed. D. B. C.

### PROPAGATING EVERGREEN SHRUBS BY CUTTINGS.

EVERGREEN shrubs in great variety are increased by varying methods, each of which has something to commend it. At the present time we are in a position to propagate some of our choicer evergreen shrubs by means of cuttings, and should take advantage of the opportunity to raise a stock of the different subjects by these means. In the present instance we will deal with just two subjects. The first is that of the popular Box tree, botanically known as *Buxus*. This is a hardy evergreen with ornamental foliage. Of this hardy shrub there are two species cultivated, and the height varies from 6 inches to 20 feet. The character of the plants is pleasingly varied, some being green, while others are golden or silver variegated, each having a beauty peculiarly its own. They are not fastidious as to soil, but will do well in any good garden soil that has been well tilled. The Box may be propagated by cuttings of young shoots in August and September, this being the generally recognised time for the work. Cuttings should be made from young shoots such as are depicted in Fig. 1. Here, it will be observed, the growth is vigorous, giving evidence of the fact that there are suitable shoots from which we may safely anticipate good results. These same shoots should be shortened to about 3 inches and the lower leaves trimmed off, in which case we have ready for use ideal cuttings, from which we may expect a satisfactory rooting process.

The illustration in Fig. 2 shows the cutting properly prepared and ready for insertion in prepared quarters. Readers will note that it is cut through immediately below a joint, from which the roots will be emitted. Such cuttings should be inserted in the shady border in rows 3 inches apart, and each individual shoot 1 inch or 2 inches from its neighbour. In Fig. 3 we give an illustration of a few cuttings inserted in light sandy soil in the shady border above referred to. It is important to remember that the soil should be pressed firmly at the base of each cutting, otherwise they will fail to root and our labour will be in vain. Under no circumstances should these plants be coddled, as they are quite hardy.

3.—CUTTINGS OF BOX INSERTED IN A BED OUTDOORS.

4.—SHOOT OF CUPRESSUS FROM WHICH CUTTINGS CAN BE PROCURED.

The other subject we propose to deal with in the present instance is one of the beautiful conifers. This is known as the Cupressus, and the variety illustrated in Fig. 4 is the well-known *C. lawsoniana*, and there are few more interesting members of this family of shrubs. Unlike many other conifers, this subject does extremely well in town and suburban gardens, and does not seem in the least particular as to its aspect or the soil in which it is cultivated. We know of plants used as a screen in the front gardens of many of our suburban residences with an eastern aspect, and we also know of the same subject used as an individual specimen growing in the centre of a lawn in some of the smaller gardens, in the rear of houses of a London suburb, with a warm aspect.

This Cupressus may be raised from cuttings procured from a spray such as is represented in Fig. 4. Here will be seen a shoot on which are numerous little branchlets 2 inches or 3 inches long, which make ideal cuttings. The little branchlets may be torn off with what is known as a "heel," which is really a small portion of the main stem adhering to the branchlets. We prefer, however, to make cuttings such as are represented in Fig. 5. Here, it will be observed, the lower pieces have been trimmed off and the stem cut through immediately below a joint. These little pieces should root easily and readily if prepared in the manner we have described. As we said before, the cuttings should be about 2 inches long, and be inserted in sandy soil made up in a cold frame. Those without a cold frame may, perhaps, have a spare hand-light or a bell-glass with which to cover the small bed of prepared soil in which these cuttings may be inserted. They must have protection, however, as these plants are less hardy than some of the other evergreen shrubs with which most gardeners are familiar. September and October is the period during which the propagation of the Cupressus by cuttings should take place. This will, therefore, enable readers to prepare their cold frames with special beds of soil, so that the cuttings and everything may be dealt with at the proper time. The surface soil must contain plenty of sand; the cuttings inserted about 2 inches to 3 inches apart, and in the rows 3 inches apart. Special care must be taken to press the soil firmly at the base of each cutting, in order that the soil may adhere to the roots and thus ensure a satisfactory rooting process. The cuttings should be watered in as soon as they are adjusted in position, and the frame-lights or hand-lights kept close for a time while rooting takes place. Many lovers of gardening feel more than ordinary interest in plants and shrubs raised by themselves, and, as this is a somewhat unusual thing for a beginner to take

in hand, the interest in raising plants by these means will doubtless prove fascinating.

#### SOWING WINTER ONIONS.

It frequently happens that the sowing of these plants made during the early part of August partially or even totally fails, as the weather often experienced during that month is very hot and dry, and not at all conducive to the growth of small seedlings. Where such failure has been experienced, there is still time to make another sowing, providing the work is done at once. A bed of fine soil must be prepared, and it is best to sow in flat-bottomed drills 1 inch deep and 1 foot apart, watering each drill thoroughly before sowing the seeds if the soil is at all dry.

The seeds may be scattered more thickly than is advisable for spring-sown crops, but even at the autumn sowing it is well to be sparing with the seed. As soon as the plants are well up, much good will be done by running a Dutch hoe between the rows, thus keeping down weeds and allowing air free access to the roots. Although transplanting in spring is successfully adopted by many growers, the best results are obtained from plants set out the latter end of October. These generally get well established before very severe weather is experienced, and will usually produce larger bulbs than those moved in the spring. In addition to the Giant Rocca and Tripoli the White Lisbon is an excellent variety for sowing now, and its bulbs are of decidedly better quality than those of the two first-named sorts.

#### WORK IN THE HERBACEOUS BORDER.

THE aim of every gardener, whether amateur or professional, should be to retain the herbaceous border in as bright and floriferous condition as far into the autumn as possible, and although a great deal will naturally depend upon judicious arrangement and planting at the outset, much may be done to prolong the floral display and make the most of the plants, even at this late date.

Where annuals have been used for filling up spaces not occupied by permanent subjects, they will probably by this time be nearly over and their removal imperative. Such removal naturally means blank spaces, and the beginner in gardening will probably be puzzled over the task of filling them so as to maintain the border in at least presentable condition for a few weeks longer. Fortunately there are a few subjects that lend themselves to removal at this period, and foremost among them come the early-flowering Chrysanthemums. This race of our favourite autumn flower has been so much improved in colour, form and habit during recent years, that with these alone any blanks in a border may be filled without any fear of monotony.

Where a good supply of these plants has been grown in the reserve garden it will be a comparatively easy matter to remove them to the places where they are required to flower. It is a good plan to tread the soil firmly round each plant to be moved a few days beforehand, then one evening give each plant a good soaking of water at the roots and lift and transplant the next evening. Before lifting the plants, however, holes must be prepared for their reception, as it is imperative that a good ball of soil be retained intact with each plant. Each hole should be at least 9 inches square and the same in depth. In moving the plant cut round it at least 4 inches away from the stem with a sharp spade, thrusting the tool in to its full depth, then lift the plant bodily out and carry it on the spade if possible to where it is to flower. Of course where a large number of plants have to be dealt with and conveyed any considerable distance this method would take far too long, and a truck or barrow will have to be employed. The great thing, however, is to avoid disturbing the soil that is in immediate contact with the roots.

When the plant is placed in the hole fill up any cavities round the roots with fine soil, tread

the whole firmly and then give a thorough soaking with clear water. This will settle the soil among the roots, and the plants will suffer little by removal. The soil must be kept moist for a week or two until new roots have been formed. African Marigolds also lend themselves well to this treatment, and last season the writer successfully removed a number when in full flower. Dahlias may also be removed when in flower, but more care is needed with these, it being necessary to syringe the foliage daily for some days after removal. Where old specimens of Coleuses, Fuchsias, Celosias, Geraniums and similar subjects are available in pots these may be successfully employed to fill up gaps for a few weeks previous to the advent of serious frosts.

The perennial Sunflowers, *Chrysanthemum uliginosum*, Michaelmas Daisies and similar plants will now be giving us their flowers in abundance, and where it has not already been done mulching, staking and thinning the growths should be attended to at once. Michaelmas Daisies especially pay for a 4-inch thick mulching over the roots with well-decayed manure, and copious supplies of water will do much good where it is possible to apply them. Any growths that are too weak to give good flowers should be cut clean out and those that remain staked out so that each has room to develop properly. Several shoots may be loosely looped up to one stake, taking care to avoid the tying up in tight bundles so often seen, and which does more harm than no tying at all. Any stems of herbaceous plants which have finished flowering and are at all shabby should be removed and burned, as once the leaves have turned brown they are of little use to the plants. H.

#### WINDOW AND ROOM PLANTS.

WITH the approach of shorter and cooler days less water will be required by the general run of plants used for room and window decoration, and much good will be done by paying particular attention to this item. As much light as possible should be afforded the plants now, this applying even to Ferns, and an abundance of air without excessive draughts will do much towards ripening up the growths for the winter. The foliage of plants treated thus will be much hardier and far more suitable for withstanding the rigours of winter than those that have been coddled and kept away from the light. Generally speaking, feeding must soon cease, using only clear water. All foliage plants must, of course, be sponged at frequent intervals to free them of dust that is sure to accumulate. Geranium and Fuchsias will derive much benefit from standing outdoors during the daytime in September, taking care, however, not to stand them direct from a more or less shaded room into bright sunshine.

5.—SIDE SHOOT FROM FIG. 4 PREPARED READY FOR PLANTING.

## THE TOWN GARDEN.

**ROSES ON WALLS.**—Although Roses are not usually regarded as satisfactory plants for cultivation in town gardens there are one or two extremely vigorous varieties which thrive fairly well, provided that they receive proper attention. Failures are generally ascribed to lack of fresh air, and no doubt this is the principal cause, but in the case of plants on walls and arbours neglect of watering accounts for many, for the plants grow weakly, and when they are attacked by green fly or other pest they suffer far more than they would do if they were in robust health. A satisfactory condition can only be ensured by paying close attention to watering, especially in the direction of giving abundant supplies, and also in the judicious use of weak liquid manures. Before the soil about the roots becomes as dry as dust it should be heavily watered, and if it is thought that liquid manure will prove advantageous, apply it a few hours later. For some time it will not be wise to tread upon the soil at all, but as soon as the surface becomes dry enough to warrant it, loosening should be carefully done with a fork, and if it is possible to spread on a dressing of long manure so much the better, as it will convey a little food to the plants and at the same time conserve the moisture in the soil. If the plants are infested with any insect pest, turn the full force of the nozzle of the hose upon them occasionally in the evening.

**WEEDS.**—The most attractive aspect of the flower garden will soon, alas! be on the wane, but this is no excuse for the neglect to which it is sometimes subjected. Of course, it is still holiday time with many people and they have then some excuse for having a few weeds in their gardens, but I have seen others of late which were decidedly dirty and the owners had not been away. This is never permissible. If the weeds are not sufficiently numerous to affect the present plants, they will reduce the prospects of success with those that are to follow them, for they are always taking food out of the soil which should go to the legitimate crops and not to the robbers and interlopers. Do not begrudge the time devoted to keeping the garden perfectly clean, as it is well spent and generously repaid.

**THE LAWN.**—The grass plot is a constant source of pleasure to its owner, even though it does cause him many hours of worry and hard work to keep it in satisfactory condition. At this time of the year the principal work lies in watering abundantly and in cutting, while next month it will be necessary to put in hand the work of renovation, so as to leave all well for the winter. Mowing and rolling should proceed regularly, according to necessity, as these operations favour a close, firm turf. If there are bare patches, such as usually occur on small areas, seeds should be purchased from one of the several firms of high repute advertising in *THE GARDEN* ready for use as soon as it is required. The work of renovation should commence about the middle of September. In those places where the grass is simply thin it may suffice to scratch them over with an iron-toothed rake, and subsequently scatter seeds rather thickly on the loosened soil, afterwards beating or rolling down very firmly. Where, however, the patches are bare it will be advisable to thoroughly loosen the soil, incorporating with it some sweet manure and then working it down until it is quite as firm as the surrounding ground. When this is completed rake it and sow the seeds, covering with fine soil and rolling in as before. The new grass should not be cut with the machine in the ordinary mowing for a short time, but dealt with by the aid of shears or a scythe, either instrument being used having the keenest possible edge; the ordinary rolling of the whole of the lawn will assist materially in improving the newly-moved areas.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**SOUVENIR DE LA MALMAISON CARNATIONS** layered in July should now be ready for severing from the parent plant. The best method is to sever them with a sharp knife and then in a day or two lift them up carefully and place in small pots—3-inch or 4-inch—according to the size and variety. Use soil composed of good loam, sand and leaf-soil, and bone-meal or Carnation manure and a small quantity of Velthea, after which place the pots in a frame or low span-roofed house, and shade for a few days till the plants have become established. Water very sparingly and spray with Carvita or some fungicide in order to prevent an attack. Old plants that have been potted up for providing large plants next season should be watered most carefully and have plenty of air.

*Primulas*, *Cinerarias* and similar plants should be potted into larger pots and stood on a cool bottom. Prick out *Calceolarias* into pans or seed-boxes, the former for preference, as they are cooler than boxes. Ferns should now have a somewhat drier atmosphere.

*Plumbago rosea* ought to have the points pinched out once more to ensure charming plants in the autumn. Afford them a little soot water occasionally.

*Freesias*.—If these are not at hand, they should be secured and potted at once, as they are much better when started early, so as to have a long season to grow in. Seven to ten bulbs are not too many for a 4½-inch pot.

#### FRUITS UNDER GLASS.

**Late Grapes.**—If it is desirable to have Grapes over as long a season as possible, they must be thoroughly ripened, and if the nights are cold a little more fire-heat must be given, especially to *Muscats* of *Alexandria*. The late lateral growths must be removed regularly, so that they do not obstruct the light and air. The borders must have a sufficient supply of moisture. Manure should not be used after the Grapes are ripe.

#### HARDY FRUIT GARDEN.

**Autumn-fruiting Raspberries** must be afforded water, and the canes thinned in order to strengthen those left for fruiting. As soon as the fruits show signs of ripening nets must be placed over them, or birds will soon eat them.

**Fruit Gathering.**—All fruits should be gathered at this season as soon as ripe. Early fruits do not improve by being kept. Water trees that are carrying heavy crops, going over the trees a second time so as to enable the water to soak in. Remove the nets from Cherries and Gooseberries, and clean the ground from weeds. Stir the ground with the hoe. Nail all growths of Pear and other trees to the walls. If nailed in position now they can be finally arranged with much more effect in the winter; but if not done now the wood becomes old and tough and cannot be got into position without much trouble and, perhaps, many broken shoots.

#### KITCHEN GARDEN.

**Cabbages and Cauliflowers.**—The last sowing of Cabbages should have been made by this time, and, if the earliest sowings have got too far advanced to stand the winter, the later sowings will come on and do well. These plants are quite early enough if planted out in the first or second week in October. A small sowing of Cauliflowers of several successive varieties, such as *Purity*, *Favourite*, *First Crop*, *Magnum Bonum*, *White Queen* and *Universal*, should be made now.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**MIGNONETTE** for flowering at midwinter should be sown at once, using 3-inch pots for the purpose, and a mixture of loam, leaf-soil, well-powdered lime rubble and sand. A little well-decayed manure mixed with it will be beneficial. The seeds should be sown thinly, and the seedlings finally thinned to three plants in each pot. Put the plants close up to the glass in a cool, well-ventilated pit.

**Kalosanthes.**—As these go out of flower select those that are worth saving for another season, and cut back the growths to within 2 inches or 3 inches of the base in the case of the young stock. Older plants do not require such severe pruning. Place the plants when cut back in a cool, airy frame, and keep rather dry at the roots until growth begins, when the balls of soil should be reduced so as to enable them to be placed into the same size pots again. Cuttings may now be inserted, putting four to six in a 3-inch pot, subsequently transferring them without dividing into 6-inch size.

#### THE FERNERY.

Remove shade from the glass, but before doing so endeavour to harden somewhat the growth of the Ferns by reducing the supply of water to their roots as well as the moisture previously occasioned by syringing their surroundings.

#### HARDY FRUIT.

**Strawberries.**—Newly planted Strawberries have had a rather trying time, as there have been few showers to help them on, and artificial watering never appears to do so much good as one would wish from the amount of water used. The greatest help appears to be given by keeping the surface open. Use the Dutch hose and keep the runners cut hard back.

#### FRUITS UNDER GLASS.

**The Early Vine.**—Too often Vines are sadly neglected once the crop is removed. Borders filled with roots should not be allowed to become dry; indeed, occasional applications of manure, either artificial or natural, will enable the Vines to store up material for a vigorous start in the new year. Superfluous laterals should be checked early, shortening the fruiting laterals gradually, so that the basal buds may derive all possible benefit from autumn sun.

#### KITCHEN GARDEN.

**Spring Lettuce.**—This is a very important crop, and in many gardens it is needed in quantity. No matter how carefully plants are treated when sown in heat, they fail to turn in so soon as those sown in autumn. Now is a good time to sow for keeping through the winter. Many sow on a warm south border, but this I do not advise. I would recommend an open quarter for winter Lettuces, and sow sufficiently thin to give each plant room to develop. There is no need to be too niggardly with the room. Far better give a bed or beds double the size than cramp the seedlings. Cabbage Lettuces are the most serviceable, as they stand frost well and turn in earlier than the Cos varieties, which are valuable for a succession.

#### FLOWER GARDEN.

**Lavender.**—No flower garden is complete without its Lavender bushes. Fortunately, it grows freely in almost any kind of soil, and old bushes continue to give a display for many years; but when they get old and straggling they are easily converted into young dwarf bushes again, as even good-sized branches cut off and planted deeply in the soil root freely, and soon form flowering plants again. In any garden a few good-sized bushes are decidedly ornamental, and the flowers are always acceptable.

T. B. FIELD.

(Gardener to Baroness Berners.)

*Ashwellthorpe, Norwich.*

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

## A SEEDLING CARNATION FROM KEIGHLEY.

Mr. F. White, Cemetery House, Keighley, sends flowers of a beautiful deep crimson seedling Carnation, the flowers of which are large, possess good calyces and are very fragrant. He writes: "I am sending for your table a few blooms of a Carnation which I raised three years ago from seed supplied by Mr. James Douglas. The plant is a strong grower and blooms very freely. From a layer planted last October I counted fifty blooms and buds. It rarely bursts its calyx."

## DELPHINIUMS AND HEATHS FROM SCOTLAND.

We have received from Dr. McWatt, Morelands, Duns, N.B., a most interesting series of Delphiniums and Heaths; of the latter no less than thirty-five forms. The Delphiniums are exceptionally fine, but as they are under numbers we cannot refer to them individually. All we can do is to congratulate the sender on varieties of such beautiful colouring and strength of spike. We must thank Dr. McWatt for the collection of Heaths, a family we take the greatest interest in; they deserve far more extended culture.

## COLLECTION OF INTERESTING AUTUMN-FLOWERING SHRUBS FROM MESSRS. J. VEITCH AND SONS, LIMITED, KING'S ROAD, CHELSEA, S.W.

It will interest our readers to know which shrubs are very beautiful at this time of the year, when more attention should be paid to those that bloom at this somewhat dull season. One of the most beautiful things of all sent is *Eucryphia pinnatifolia*, which reminds one of a very beautiful white single Rose. It is one of the loveliest shrubs we know of. Another very beautiful plant sent is *Astilbe Davidii*. It is one of Messrs. Veitch's introductions through their collector Mr. Wilson. The colour is exquisite. When the plant is good, one sees a sea of mauvy purple. We like to see it by a lake side. The other plants sent are as follows: *Colutea arborescens*, *Hypericum Androsæmum*, *Hydrangea mandschurica*, *Amorpha canescens*, *Buddleia variabilis veitchiana*, *B. v. magnifica*, *Corylus purpurea*, *Hedysarum multijuga*, *Sambucus canadensis*, *Hypericum kalmianum*, *H. floribundum*, *Indigofera floribunda*, *Fuchsia americana elegans*, *Cornus alba Spathii*, *Polygonum baldschuanicum* and *Potentilla Friedrichsonii*, all of which are of great interest.

## GLADIOLI FROM MESSRS. KELWAY AND SONS.

It is a pleasure each autumn to receive a boxful of the new hybrid Gladioli from Messrs. Kelway and Sons of Langport, Somerset, who have done more to popularise these flowers through their beautiful introductions than any one we know of. Among the most beautiful sent on this occasion were Mrs. J. M. Skittery, a noble spike with flowers a soft sulphur yellow, the lower segment marked with crimson: Duke of Richmond, rose, with central line of white down each segment, the spike of great height and strong growth; Hawick Pageant, another

brilliant flower, scarlet, with half the lower segment creamy white; Esser, a very large flower of almost a self scarlet, with a central line of white down each segment. Kelway's White: We have seen this on previous occasions, and it is the most beautiful Gladiolus in existence. The flower is pure white, except for just short stripes of scarlet colour in the centre. We congratulate Messrs. Kelway on having raised such an exquisite flower.

## VIOLAS FROM OLD SOUTHGATE.

A correspondent at Old Southgate, signing himself "An Old Reader," sends beautiful flowers of the Tufted Pansies. The blooms are large, of excellent form and colouring, and for so late in the season are admirable in every way. He writes: "I am sending you a few of our Violas for your table. We have them all named, but will not bother you with these, as I dare say you are acquainted with most of them. We take cuttings of same in October, keeping them in a cold frame and planting them out in early spring under Roses in beds, where they are grand, making a nice carpet for the Roses."

## A RARE CAMPANULA FROM STEVENAGE.

Mr. Clarence Elliott, Six Hills Nursery, Stevenage, Herts, sends flowers of the pretty little *Campanula Zoysii*. He writes: "I am sending for your Editor's table a few blossoms of the rare little *Campanula Zoysii*, which is just now in flower on my rock garden. I consider this and *C. pulla* the loveliest of all the very dwarf bell flowers. *C. pulla*, with its low slender stems, arched at the neck and bearing solitary bells of a glorious deep glossy purple, rather large for the height of the plant, flowers in June, July and August, according to locality. I find that it flourishes in yellow loam, with sand and some humus added. A drift of this *Campanula* several feet across is very lovely indeed. *C. Zoysii* flourishes in the same soil. Its height is 2 inches to 3 inches. The blossoms, which are tubular and about three-quarters of an inch in length, are of a soft delicate blue and most curiously and beautifully puckered together at the mouth, quite unlike any other member of the family. This odd puckering of the flower is rather suggestive of a *Kalmia* blossom. It is a rare, very choice gem for the rock garden."

## CARNATIONS FROM NORTH WALES.

Mr. Watts sends from Bronwyf, St. Asaph, North Wales, beautiful blooms of Carnations, among them being The Master, a very fine scarlet; Mrs. Kearley, blush; George Maquay, one of the best whites we have for the open garden; and John Guy, yellow. One of the most notable things about these Carnations is their delicate scent and strong growth, and the flowers do not burst their calyces.

## LEGAL POINT.

## Master and Servant (Regular Reader).

A head or sole gardener, unless expressly engaged "by the week," is entitled to one month's notice or one month's wages in lieu of notice. As regards what occurred prior to notice of dismissal, for we presume you treated it as such, the £2, in our opinion, amounted to a personal present from one who was a stranger to the contract of service, and the temporary arrangement interfered in no wise with your established engagement, which ran on in the ordinary way. If your master had made it clear that your work and remuneration there had to be in lieu of your wages with him, and you had assented to it, there would have been something in your master's present contention. The proper tribunal for enforcing a small claim of this kind is the county court.

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Rock garden (Puzzled).**—It is not at all an easy thing to say what might be done in the way of a rock garden without seeing the spot itself, and it would depend greatly upon circumstances and what you desired to spend in the erection of the structure as to what may be eventually accomplished. So far as the position is concerned—altitude and the like—the spot is an ideal one, and apart from this everything resolves itself into the single item of expenditure. You say nothing about stone in your near district, whether difficult to obtain or otherwise. Limestone or sandstone are both good for the purpose. The interesting series of photographs sent reveal, so far as we can determine, a flat area, and the cheapest and simplest way, when you have determined the extent of the proposed rockery and roughly fashioned its outline, is to erect a bank of earth and out of this form your rockery. A rockery is possible in almost any position the garden affords, but for the cultivation of good alpine plants should not be in the near vicinity of trees, which would quickly rob the soil. A selection of plants could be made for any position, but the structure should be arranged with a view to growing certain plants.

**Fernery (M. F. W.).**—If the bank has long been occupied by the *Rhododendrons*, your best plan will be to dig it all over and give a light dressing of manure. By digging the soil deeply and adding manure as above, it should then grow the ordinary Ferns quite well, while the addition of leaf-soil and loam would materially assist matters. This done, you must sink your blocks of stone two-thirds their depth in the soil of the bank, and in such a way that the flat surface of the stone will act as a receiver for the plant for the washed-down soil and for moisture. Avoid placing the stones like almonds stuck into the top of a cake, but deeply bury them in the soil, so that the Fern roots will presently get into contact with them. In this way, and by planting the Ferns not too erect, the bank may soon be furnished. Avoid all formality in the setting of the stones. If the bank is very steep you must set the stones with a view to retain the soil in position. Any arrangement for the Ferns will naturally depend upon the size of the plants and the varieties you intend employing. The work may be undertaken during autumn or winter, planting being done while the Ferns are still dormant.

**How to propagate *Achusa italica* (Mrs. Gurney).**—If you desire to increase any variety of the above-named plant, there is no better way than by root cuttings. The species and its varieties produce seeds, but the plants from these do not come true, hence the value of the root-cuttings. The best time to take the work in hand is from November to the end of January. At this season lift the plant and detach a few of its larger roots, cut them into lengths of from 1 inch to 2 inches, and arrange them around the

interior of a well-drained pot in very sandy soil. A greenhouse temperature of 45° or 50° will suit quite well. Beyond a good watering at the start not much water should be given till growth is apparent at the apex of the root-cuttings. When the cuttings are in free growth transfer them to boxes or pot them singly in readiness to plant out, an operation best done in April or May. The stature of the original plant will be somewhat reduced by the treatment referred to, but the plant, as well as the best of the root-cutting plants, will flower the same season. You might also try dividing the plant when you have lifted it, and by potting the divisions and giving cold frame treatment for a few weeks good established plants would be assured for planting out in due season.

**Cutting down Delphiniums** (A. H. P.).—To induce a second flowering it would be necessary to cut the stems of these plants down to near the ground level, the second flowering depending upon the starting into growth of the latent eyes or buds at the base of the first flower-stem. These secondary spikes, however, are rarely of good quality, and it is a moot point whether much or anything is gained by the second flowering. D. Belladonna is, however, a notable exception, and this beautiful plant frequently flowers twice and sometimes thrice in one season, the growth being well nigh perpetual in this case. It is, as perhaps you are aware, a rather dwarf-growing plant of about 3 feet, the colour being a clear and beautiful deep sky blue.

**Flowering climbers for a very shady position** (Miss A. C.).—There are no flowering climbers that would be likely to give satisfaction in such a position as that indicated by you. Such being the case, it will be necessary to fall back on climbers with ornamental foliage, such as the Dutchman's Pipe (*Aristolochia Sipho*); the Virginian Creeper (*Vitis (Ampelopsis) hederacea*); *Vitis Thunbergii*, a handsome large-leaved Vine; *Vitis vinifera apiifolia* (the Parsley-leaved Vine); and *Actinidia chinensis*, a rapid-growing climber with large, heart-shaped leaves. These are all deciduous, and if you want evergreens the only plants likely to succeed are some of the quick-growing *Ivy* such as *canariensis*, *dentata*, *amurensis* and *agerianiana*.

**Plants for stony bank** (Miss A. C.).—The following subjects would be likely to give satisfaction under the conditions named by you. Herbaceous: *Achillea Millefolium rubrum* (red-flowered Millfoil); *Acanthus candelabrum*, handsome foliage; *Bocconia cordata* (Plume Poppy), noble foliage and panicles of creamy white flowers; *Crambe cordifolia*, large, roundish leaves and loose heads of small white flowers; *Echinops* of sorts, Thistle-like plants, with globular heads of blue flowers; *Eryngium* of sorts, handsome foliage plants, while the roundish heads of flowers are in some kinds of a beautiful metallic blue; *Elymus glaucophyllus*, bluish leaved Grass growing from 3 feet to 4 feet high; *Euphorbia Cyparissias*, *E. pilosa* major and *E. Wulfenii*, different forms of the Caper Spurge, all of a greenish yellow tint; *Fernula gigantea*, a gigantic member of the Fennel family; German *Irises* of sorts, a most accommodating class of plants; *Polygonum cuspidatum* and *P. sachalinense*, two noble forms of Knotweed, but of far too aggressive a nature to associate with delicate subjects; *Phalaris arundinacea variegata* (Gardener's Garters), a well-known variegated-leaved Grass; *Sedum spectabile* and its deep-coloured variety *atropurpurea*. Of shrubs the following can be recommended: *Colutea arborescens* (Bladder Senna) and varieties; *Atriplex Halimifolia* (Sea Purslane); *Berberis vulgaris* (common Barberry); *Caragana arborescens*, yellow flowers in spring; *Broomia* of sorts; *Cistaceae* in variety; *Helianthemum* (Rock Roses) of sorts; *Lycium europaeum* (Box Thorn); double pink-flowered *Bramble*; *Rhus Cotinus* (Venetian Sumach); *Spartium junceum* (Spanish Broom); and the common *Furze* with its double-flowered variety. The *Periwinkles*, too, must not be omitted. The genus *Iris* is such an extensive one that no hard-and-fast rule can be applied to them all, but that set of garden forms known popularly as German *Iris* will succeed and flower fairly well in the shade.

## ROSE GARDEN.

### Yellow Rose for standard (B. W.).

(1) We think you would find *Bouquet d'Or* or *Billiard et Barré* a good sort for the position named. (2) You could not do better than plant *Frau Karl Druschki* for a white, and especially as a standard. As the position is somewhat shaded, you would find *Hugh Dickson* a more satisfactory Rose than either *Liberty* or *General Jacqueminot*. *Commandant Felix Faure* would go very well with *Liberty*. (3) *Caroline Testout* is the best pink for your other bed. We should suggest *Pharisæer* or *Gustave Grünerwald* instead of *Mrs. John Laing*. The other sorts would do well, although *Mrs. Sharman Crawford* is badly addicted to mildew. *Mme. Edmée Metz* would be a better Rose. (4) A good

white Rose for an arch would be *Mme. Alfred Carrière* and *Grüss au Zabern*, the first perpetual flowering and the other flowering the end of June. You could plant the two together. (5) *Climbing Frau Karl Druschki* is quite a disappointment. It will not climb any more than the ordinary sort. The white *Dorothy Perkins* will be fine to plant when it is commoner. (6) You could transplant the *Grüss an Teplitz* if you choose a time after a good rain in October, and lift it with a good ball of earth, having previously prepared its new position. (7) *Maggie Mott* is one of the best mauve *Violas*.

### Roses for Rose arbour (E. H. Dupe).

There would be no objection in steeping the Larch poles in creosote, but we think if you steeped 3 feet of the ends that go into the soil, this would be sufficient. Charring the ends is a good plan in order to preserve the poles. As to the varieties to plant, seeing that you desire them to flower at the same time as *Dorothy Perkins*, you should certainly plant the *White Dorothy*, and *Hiawatha* would be another beautiful sort. *Aimée Vibert* is a grand old white, and *Longworth Rambler* and *Grüss an Teplitz* should fulfil your requirements if you encourage good growth by trenching the soil. *Climbing Cramoisié Supérieur* would also be good. *Lady Gay* is equally as good as *Dorothy Perkins*, in fact it is superior in quality of blossom.

**W. A. Richardson not blooming** (J. A., *Kilmarnock*).—We should advise you to refrain from pruning these vigorous shoots next spring. Nail them out in a palmate fashion on the wall and shorten back any laterals to 3 inches or 4 inches. In order to assist the ripening of the strong growths you could pinch out their points by the end of September. This Rose does not require much pruning beyond shortening laterals and removing old worn-out growth now and then.

**Rose Bessie Brown not opening** (M. P. P.). This Rose has a very bad character as a garden variety. It is really only an exhibitor's flower. When seen so fine at the exhibitions such flowers have been protected with shades and the weak-necked specimens tied up to sticks. This drooping of the blooms is a very serious defect, and it is too double to expand well. If you have some shades put them on sticks and place over your blooms, and we have no doubt they will expand if you give them time. There are Roses now to be had far more satisfactory than *Bessie Brown*. Try such superb sorts as *Pharisæer*, *Joseph Hill*, *Königin Carola*, *Florence Pemberton*, *Mme. Jules Gravereaux*, *Melanie Souper*, *William Shean*, *Mrs. Myles Kennedy*, *Jenny Gillemot*, &c., and we think you can well dispense with *Bessie Brown*, unless, of course, you are an exhibitor, then you will want it.

## FRUIT GARDEN.

### Plum tree leaves diseased

(Cuddon).—The Plum tree, the leaves of which have a silvery appearance, is attacked by the disease known as silver leaf. The cause of this disease has been recently shown to be a fungus, namely, *Stereum purpureum*, the mycelium of which grows in the plant for a considerable time before the fungus produces any fruit. The fungus fruits are produced upon old and dead stems, and the spores which these fruits bear are capable of reproducing the disease. It is therefore necessary that all dead shoots and branches of trees that are attacked should be removed and burnt as soon as possible. No certain cure is known when once the tree is attacked, and it is probably just as well in view of this to cut out all parts at once which show the silvery appearance on the leaf, though good results have followed the use of iron sulphate crystals put into a hole bored in the trunk it is said, and this possible remedy is worth a trial.

**Peach leaves falling** (H. G. S.).—There is no doubt, we think, that watering with sewage water and with chemical manure previously is accountable for the dropping of your Peach leaves. Both want handling with great care and to be used only in a very weak and diluted form.

**Plum tree dropping its fruit** (H. R. P.).—The Plums which are dropping have soft stones, the result of imperfect fertilisation. We hope enough will remain on to make a crop. Japanese Plums have not proved satisfactory in this country. We advise you to bend the tree down next March and graft the stock with a variety named *Reine Claude de Bavay*, a very hardy, heavy-bearing *Grain* Gage. Cut back all the shoots badly

affected with blight, but you must not cut them too low; leave at least twelve leaves from the base on each shoot.

**Strawberries gone black in the stem** (J. M.).—An attack of mildew, we think, is accountable for the destruction of your Strawberry crop. The plants being more or less weakened by the setting of a heavy crop and by the scorching hot weather we have had, would help to make them easy victims to this malady, which often attacks one variety, leaving others alone.

**Vines and Tomatoes** (Beginner).—If you wish your Vines to carry Grapes next year, you must not cut back the shoots or laterals, that is, the season's growths on them, as you suggest; but you may pinch the points of each shoot out beyond the fourth leaf, also any small shoots that may have broken out from them. Unless these shoots become strong and stout and have good leaves they will not create strong buds to carry fruiting shoots next year. If you care most for the Tomato plants below the Vines, then cut away the Vines as you wish. All depends on which is to you the most important. It is very unfortunate that the Tomatoes are in such a position, as to ripen them properly they need all possible sun and air.

## KITCHEN GARDEN.

### Tomato leaves diseased (R. T.).

The Tomato leaves are attacked by the fungus *Cladosporium Tomato*, causing the disease known as Tomato leaf rust. This may be checked by spraying the plants with a solution of potassium sulphide, made by dissolving 1 oz. of the material in 3 gallons of water, or with diluted Bordeaux Mixture. When, as in this case, the disease has existed for some years, the spraying should be commenced before the disease appears.

### Tomato fruits decaying (J. R.).

The Tomato fruits are decaying through the growth of the fungus, *Botrytis cinerea*, upon them. This is an exceedingly common fungus upon all sorts of dead and dying plants, and in the present case the opportunity to attack the fruits has probably arisen from the exceedingly moist conditions you describe under which the plants have been grown. The Tomato does not succeed well under very moist conditions. The frequency with which manure has been applied seems excessive, and this, too, would probably make the plant more susceptible to fungus attacks. The remedy lies in attention to the points indicated.

**Tomatoes diseased** (H. M. C.).—The Tomatoes are attacked by the fungus which causes the disease known as black stripe. It would be well to pick off and burn all the affected parts and spray the plants with potassium sulphide, half an ounce to a gallon of water.

**Maggots attacking the roots of Cauliflowers** (A. D.).—The best preventive we know of is to dip the roots of the plants in the following preparation: One gallon of soot, 1 lb. of saltpetre (or less in the same proportion), add water and mix to the consistency of thick paint.

**Earthing up Celery with bog mould** (W.). There is no advantage to be gained by using pure bog mould for earthing up Celery, and we certainly do not advise you to go to any trouble whatever to procure and use such soil. The chief object in earthing up Celery is to exclude light and thus blanch the leaf-stalks, and any ordinary garden soil serves this purpose well. In the event of very wet weather we think the bog mould would be likely to cause decay.

**Lettuce eaten at the roots** (H. D. Player).—No doubt the damage to your Lettuce plants has been caused by wireworm, which answers to the description of the pale yellow worm-like thing you saw near the injured plants. It is a difficult pest to eradicate, being much like wire. The most effective way is to bury pieces of Carrot, Turnip or Potato just under the surface of the soil, examining them every morning, when many may be found and killed. Another good way of getting rid of them is by applying a liberal dressing of soot and guano to the soil at the time of digging in spring. *Vaporite*, *Kilgub* and *Apterite* are excellent for killing these pests if used according to the directions supplied with them.

**Cabbage or Onions** (Hunslet).—In the South it is the rule to sow Sutton's April and Flower of Spring Cabbage the third and fourth weeks of July to stand the winter when planted out 12 inches to 15 inches apart to heart in April and May. If plants so treated will not stand out the winter it is because yours is a cold, northerly district, where winters are more severe. Your best course then would be to either sow in the middle of August to plant out later on very firm soil, or else to winter the plants in a frame, planting out in March. Frosts rarely harm Cabbage plants southwards. If Onions stand the winter with you sow Record Onion seed in the middle of August in a sheltered place to lift carefully and transplant in April on to good soil, or you may sow seed of that and of *Ailsa Craig*, the finest of all Onions, in shallow pans in a frame in February, to transplant outdoors in rich soil early in May.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## GATHERING HARDY FRUIT.

THE suggestions as to fruit gathering given here are intended only for those amateurs who grow fruit on a limited scale for their own use and who wish to enjoy it for as long as possible in the greatest perfection of ripeness. It has no reference to the gathering of fruit on a large scale for market purposes, when a more rough and ready process has of necessity to be adopted.

*Early Apples.*—To have these in perfection of flavour and juiciness they must not be gathered from the tree more than three or four days before they are eaten; indeed, they are best gathered the same day that they are wanted for dessert. An Apple tree, say, of Mr. Gladstone or Devonshire Quarrenden, can be made to supply perfect ripe fruit over a considerable period by taking particular care to watch for the first fruit to show indication of ripeness. All the fruit does not ripen together, but in succession, and by adopting the plan of plucking the fruit approaching ripeness daily I have known those varieties to give a supply of fairly crisp and sweet-flavoured fruits for three weeks or longer. The same principle applies in a modified degree to autumn-ripening varieties, such as James Grieve, Wealthy, King of the Pippins and others, so that the time these may be had in good condition may be considerably lengthened by adopting the same process. In the case of late Apples the principle is not so pronounced, but even here it is operative, for all the fruit on an Apple tree never ripens quite at the same time.

With *Early Pears* it is even more necessary to watch with diligence the ripening process, and a pleasant and interesting pursuit it is. Even Doyenné d'Été, the earliest Pear to ripen and the quickest to lose flavour and to decay, can be enjoyed in good condition for at least a fortnight by adopting and pursuing this method zealously. In the case of a large tree with a heavy crop it is necessary to watch with eagerness each day for a single fruit showing a tinge of gold on the green surface of the fruit. More will follow every day, when they should be immediately plucked, until all are gathered and consumed. Williams' Bon Chrétien, not to mention other early varieties, should be treated in the same way. The fruit of this fine variety should never be all gathered at the same time, but by a gradual process as the fruit show signs of ripening. In the case of this variety it is better when gathered and stored for a week or ten days before it is eaten. By adopting this method a succession of ripe fruit of this superb variety may be enjoyed for five or six weeks. As in the Apple

the principle applies in a modified degree to later Pears.

*Dessert Plums.*—As regards some of the best varieties the principle does not apply. In those the flavour goes on improving until the fruit is dead ripe, when many of them, such as the Gages and Golden Drop, become perfect sweetmeats, and the stalk of the fruit, unlike the stalk of the Apple or Pear, which casts off the fruit as soon as it is ripe, clings with greater tenacity as the ripening process proceeds; in fact, with some varieties it will not lose its hold until the fruit has perished from long keeping, as in Golden Drop.

*Some Cherries* are the same. For the reason of this tenacity of hold which the stalks of the finer varieties have on the fruits, they should never be plucked by hand, or the pressure necessary to pull them off will bruise the flesh. The stalk should be cut off full length with a pair of scissors. OWEN THOMAS.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### CLERODENDRON FETIDUM FROM DEVON.

Mr. S. C. Stuart, Meriden, Exmouth, Devon, sends fine heads of the nearly hardy *Clerodendron fetidum*. He writes: "As you encourage your readers to send you specimens of anything curious or beautiful relating to gardening, I think you may like to see these blossoms of a handsome flowering shrub, the Japanese *Clerodendron*. It grows 5 feet or 6 feet high, and throws up many flowering stems, but is suitable only for large or moderately large gardens, as it extends itself rapidly. In winter it dies down completely, but is indifferent to cold or wet. I hope the blossoms will arrive in good condition."

### RUDBECKIAS AND COREOPSIS FROM LEICESTER.

A correspondent, signing himself "L. D.," sends flowers of an interesting *Rudbeckia* and *Coreopsis* from Desford, Leicester. He writes: "I am sending you a few blooms of two new annuals, *Rudbeckia superba* Orion and *Coreopsis annua maxima*. The former is a fine vigorous-growing annual, attaining to about the same height and needing similar treatment to *Zinnia elegans*. Seeds were sown in early March and

raised in heat, transplanted and grown on sturdily in frames until planted out in June. They need a fairly rich soil and sunny position to bring them to perfection. The plants commenced to bloom in July, and the individual flowers last for weeks, as they develop very slowly. The *Coreopsis* is a very free-blooming plant, and seems to flourish in any ordinary garden soil. I gave these the same treatment as that for the *Rudbeckia*, and they began to bloom when quite small in June. I should say that it could be sown outdoors and would give satisfaction, although it would be late coming into bloom. The flowers are quickly over, but there are always plenty to follow."

#### GLADIOLI FROM IRELAND.

Miss M. E. Dobbs, Camphire, Cappoquin, County Waterford, sends splendid spikes of this beautiful bulbous family with the following note: "I am sending you a few Gladioli for your table, as I am told that they are fine specimens of their kind. I have grown them for over ten years without renewing the stock in any way; in fact, have grown the hundreds I have now from about two dozen corms I got originally and from seeds obtained from them. They have not deteriorated at all, and some have improved in size and colour. Yet people tell me that why they have good Gladioli so seldom in the ordinary garden is that, however much care they take, the good corms always deteriorate into a dull red, till after a couple of years they all become like an inferior *Brenchleyensis*; so perhaps an account of my treatment of them may be of interest. It is very simple and as follows: Plant them early, not later than the beginning of March, January or February if the ground is fit, in soil manured the year before, and give them plenty of water. In heavy soils they want some drainage, but never so much that the soil gets dry underneath them. They should be from 4 inches to 6 inches below the surface, and they should not be dug before the stalks have withered off naturally. If the largest of the little bulblets, which are found attached to the old root when digging them, are saved—all those as large as a garden Pea—and sown in March in furrows 2 inches deep and 8 inches apart, the larger number of them will flower in the autumn just when flowers are becoming scarce, and all will grow into large corms for the following year. I hope the ones I send will travel well, but they will be two days on the journey I am afraid."

## PRIZES FOR READERS. SEPTEMBER.

### SPRING FLOWER BEDS.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The object of this competition is to bring out the uses of bulbous and other plants for the spring garden, as the autumn is the proper season for planting. Essayists should pay special attention to the combination of bulbous plants with other things, as many of our readers are anxious to know what bulbs to use with such plants as *Forget-me-nots*, *Polyanthuses*, *Wall-flowers* and similar subjects.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than

Wednesday, September 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

September 15.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1—6 p.m. Lecture at 3 p.m., by Mr. Thomas H. Mawson, A.R.I.B.A., on "The Ethics of Garden-making." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

September 17.—Autumn Rose Show, 1—6 p.m. Royal Horticultural Society's tickets admit. Royal Horticultural Hall, Vincent Square, Westminster.

**London Dahlia Union.**—The annual exhibition in connexion with this society will be held in the Royal Botanic Gardens, Regent's Park, London, N.W., on Thursday and Friday, the 10th and 11th inst. In addition to good cash prizes the Hobbies Challenge Cup for Cactus Dahlias (amateurs only) will be competed for. Full particulars can be obtained from the hon. secretary, Mr. E. F. Hawes, Royal Botanic Gardens, Regent's Park, N.W.

**Dying back of Peach shoots.**—The *Key Bulletin* of miscellaneous information (No. 7) contains an interesting article by the well-known fungus expert, Mr. G. Massee, on the dying back of Peach shoots, a disease which has caused Peach growers considerable trouble during recent years. This is found to be caused by a fungus named *Nemospora crocea*, the spores of which are not dispersed by wind but depend upon birds or other animals for their distribution. It appears from experiments conducted that the shoots can only be affected when quite young, but when the fungus has once gained an entrance the mycelium rapidly spreads and infects the entire growth of the season. The spores do not retain their power of germination for more than about three months.

**The Peacherine.**—"One of the most delicate and delicious fruits known to commerce has, after ten years' experiments, been evolved in California by a well-known fruit specialist. It has been named the Peacherine, from the fact that it was obtained by crossing the Peach and Nectarine. The new fruit has been submitted to experts, who declare that it will prove of great commercial importance. The flavour of both the Peach and Nectarine has been combined, with the result that the flesh of the Peacherine is of the most subtle and delightful flavour. At the same time the warm red hue of the Peach has been transmitted to the skin of the new fruit. Although very juicy, it possesses a firm flesh which fits it to travel. It is unusually early, ripening before any known Peach matures in the open air. Already a leading nursery firm has set to work to propagate the new fruit trees for distribution among private and commercial fruit growers." [The above appeared in the *Daily Mail* recently. The fertility of American soil, rich as we know it is, is as nothing compared to the fertility of inventive resource possessed by our American cousins. When directed, as it frequently is, in the way of horticulture, some marvellous creations in the fruit or flower world are evolved, calculated to stagger the British horticulturist. We have heard of many of these creations before, but the "Peacherine" is a great joke. Our contemporary, we are pleased to notice, has of late given prominence to matters

horticultural in its pages. May we suggest the advisability of appointing a horticultural censor? We have had a Nectarine Peach for ages, and a very good Peacherine it is, if we may adopt this new phrase. As most people know, the Nectarine is a form of the Peach, and is distinguished from it chiefly by having a smooth instead of a downy and rougher skin and also by its flavour. So close is the relationship that it is not an uncommon occurrence for a Peach tree to produce a Peach and a Nectarine fruit on the same branch. A case is recorded of a single fruit being half Nectarine and half Peach.—Ed.]

**Grapes at Wisley.**—There is just now to be seen on Vines at Wisley Gardens probably the most complete collection of Grapes to be found in any garden in the kingdom. In a large span house, 30 feet wide, are thirty-eight strong Vines planted three years ago last spring, each one carrying from six to seven bunches, generally very fine ones, the major portion ripe, and a few late ones gradually ripening. There are forty Vines in all, twenty on each side, and of whites and blacks an equal number. Two of the Vines—Mrs. Pince, black, and Buckland Sweetwater, white—have been recently planted, having replaced others that were found to be duplicates. The growth of the Vines has been very strong, and many experts looked for bad breaks from the gross wood of last year. Very happily, such has not been the case, for the breaks have been first-rate, and the bunches really very fine and good, and such a Grape as Prince of Wales is there indeed superb. Those who wish to see this collection of thirty-eight distinct varieties should do so at once.

**Dunfermline Garden Competition.**—The final adjudication of the prizes offered by the Carnegie Dunfermline Trust for flower gardens, flower plots and window-boxes took place on the 21st ult., and the leading prizes were awarded as follows: Single plot in front of dwelling: First, William Ferguson; second, David Wishart; third, George Rollo. Single plot in any position other than facing the street: First, David Adamson; second, Robert Lister; third, Thomas Sinclair. Window-box, single window: First, Alexander Hind; second, Miss A. Munro; third, H. Hynd. Window-box other than single window: First, Mrs. James Anderson; second, James Anderson; third, James Paterson. Flower garden not to exceed two falls: First, R. Boag; second, D. Robertson; third, J. Marshall. Flower garden not exceeding one fall: First, J. Cummings; second, P. Smith; third, James Hamilton.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Autumn-sown annuals.**—Your correspondent "H. M. C.," page 395, asks successful sowers what annuals they sow and when. *Linaria alpina*, *L. maroccana*, *L. multipunctata* and *L. reticulata* aureo-purpurea sown during the next few weeks are infinitely finer than when sown in early spring. The plants themselves are much more bushy and the flowers last much longer. The finest variety of *L. maroccana* I ever saw is now just 2 feet across. It is a self-sown plant and has flowered from early in June.—G. CHARLES BENTON.

**Fruit trees at the Franco-British Exhibition.**—I notice a good deal has been said about the quality of the French trained fruit trees at the Franco-British Exhibition. They are good, it is true; but while criticising them, besides paying compliments, we should say all we see about them, and one looking at the trees now planted there cannot overlook the fact that, besides being well trained, they are also badly affected with American blight, also many of them have died through being moved. This

proves the theory that young trees move much better than older specimens, however often the latter are transplanted.—FREE LANCE.

**Beans damaged by frost on August 12.**—I beg to ask if it is unusual to have a frost on August 12. We had two plots of Beans damaged same as the enclosed leaf.—R. WARDMAN, *The Gardens, Kirby Hall, York.* [The leaf sent had been severely injured by frost.—ED.]

**A remarkable Delphinium stem.** I enclose a section of stem of a Delphinium which measures just over 7 inches in circumference. It is from a seedling sown in the open ground last June twelve months, and transplanted to its present position last September. It was grown among a batch of just over 300 others, the tallest spike of which was 9½ feet.—F. W. SMITH, *The Gardens, The Hollies, Weybridge.*

**Classification of Daffodils.**—It is rather doubtful if a new classification of Daffodils will be a help to either growers or the committees of spring flower shows. According to the wisdom of the Royal Horticultural Society an alteration is wanted; but when people have got accustomed to a certain division of the genus it is rather hard to get them to learn a thorough alteration. Alterations have been made from time to time by Messrs. Barr in their catalogues, from the excellent pamphlet arranged by Mr. Peter Barr in 1884 down to their autumn list of 1907. The variations may easily be seen by the following comparisons. Division I., 1884: Magni-coronati of Baker.—Crown or trumpet as long or rather longer than the divisions of the perianth. Group I., 1907: Large-crowned or trumpet Daffodils.—Tube of flower as broad as it is long, and the crown or trumpet more than three-quarters as long or longer than the perianth segments or petals. Class 1, 1908: Large trumpets.—Trumpets three-quarters as long as the perianth segments or longer. Division II., 1884: Medio-coronati of Baker.—Crown half as long as the divisions of the perianth, but in one or two cases three-quarters as long. Group II., 1907: Chalice-cupped Daffodils or Star Narcissi.—Depth of crown or cup more than one-third and up to three-quarters the length of the perianth segments (petals). Class 2, 1908: Short trumpets.—Trumpets one-half to three-quarters the length of the perianth segments. Group II. (sub-division), 1907.—Depth of cup a quarter to one-third the length of the perianth segments (petals). Class 3, 1908: Large cups.—Cups from a quarter to one-half the length of the perianth segments. Division III., 1884: Parvi-coronati of Baker.—Crown less than half as long as the divisions of the perianth. Group III., 1907: Dolly Cup or Poet's Narcissi.—Depth of cup less than a quarter the length of the perianth segments (petals). Class 4, 1908: Small cups.—Cups less than a quarter the length of the perianth segments. Class 5: Flat cups. Class 6: Double flowered. Class 7: Bunch flowered, i.e., more than one flower on a stalk. Taking the new classes into consideration, it seems to many that taking the larger incomparabilis into small trumpets is a mistake, the general effect of the flowers being very different. Again, classing Poeticus with the small cups is like classing thorough-breeds and hunters as one. The flat cup class is a decided gain, but leaves a great deal in a show to the discretion of the judges. Double flowers have usually been shown in a separate class; but many would be sorry to lose the placing of the doubles with their single relations in catalogues. Bunch flowered seems wrong in name as well as inconvenient in its character. According to the meaning of a bunch, gathered from various sources, it is several things tied together naturally or artificially. "Several" is defined as three or more. Why, therefore, include the two-flowered Narcissi with the Polyanthus? Why include the Tazettas, which have always been a class to themselves, with biflorus, calathinus, Jonquilla, &c.?—(Rev.) G. P. HAYDON.

## THE KITCHEN GARDEN.

### CULINARY PEAS IN SCOTLAND.

THE weather during the present summer has been the very antipodes of that of 1907, and it may be of interest to record the behaviour of the varieties that were so good last season, and to see which are in this cold, late district the really reliable sorts to cultivate. The early part of the spring was both cold and damp, and Peas, like other garden crops, made but slow progress. As is my usual practice, I sowed The Pilot and William I. on an early border, and side by side, for first crop. Last year, and indeed for several years, The Pilot yielded the first picking nearly a week before the

A REMARKABLE DELPHINIUM STEM MEASURING OVER 7 INCHES IN CIRCUMFERENCE.

other. This year both were ready on July 3, which is very early for this locality, and with one exception the earliest date during seven years. In 1905 I picked good Peas on June 30, last year it was July 27 before a dish could be gathered. Gradus and Edwin Beckett, as usual, came in together, and I have now decided to delete the former from my list of suitable varieties.

Boston Unrivalled, which last year matured with Gradus, sown on the same date, was this year ten days later, but produced the finest crop of Peas I have ever seen, and the quality is unsurpassed by any other sort. Senator I tried for the first time, and it produced a grand crop; but it matures very fast, and all the pods seem to be ready at one time. This Pea might be described as an early Gladstone, as the pods strongly resemble that genuine late sort.

Sown on April 27 the old variety Walker's Perpetual Bearer has produced a good crop of fine pods. The new variety The Bell has done first rate, producing a grand crop, but the pods are less in size than last year. On the other hand, Glory of Devon has given a great crop of very large pods, certainly the finest I have seen of this sterling sort. Alderman has grown 8 feet high and given a good crop. Royal Salute, as usual, is very fine, the pods being large and well filled, although at the time of writing (August 15) the earliest row of this variety is hardly ready for picking. The Gladstone is also well up to the average, and I would not ask for a better late Pea except Royal Salute, which here certainly produces a better crop and is of even better table quality. My latest Pea is Carter's Michaelmas, and this year it gives promise of a first-rate crop.

Among dwarf varieties Carter's Daisy is again an easy first. This is the Pea everyone should grow who is at all scarce of room. Little Marvel is also a good Pea for early work. The Sherwood I tried for the first time this year, and am quite pleased with it, as it produces a very heavy crop, but my row of it was seriously damaged by slugs, so that I require another trial before being quite certain about it.

Taking it all through, 1908 has been one of the best Pea years within my experience, and I think it has proved that the list I gave in this journal last spring cannot well be beaten, and I will certainly stick to it for some time yet. I repeat it here: The Pilot, Carter's Daisy, Boston Unrivalled, Glory of Devon, Royal Salute and The Gladstone.

Preston House, Linlithgow.

C. BLAIR.

### FRENCH BEANS IN AUTUMN.

To get good dwarf French Beans as long as possible is worth a trial, as this vegetable is more appreciated when other choice things are less plentiful. There is no difficulty in having a good supply of Beans well into November in a mild season, and even in ordinary seasons a good crop may be maintained till quite late in the autumn. For this purpose I advise the use of land that is in good condition. Poor soil will not give a good return, as to get the best results growth must be rapid. It will be found that deeply-dug land well enriched with food will give the best returns. Many amateurs would get a much better crop if the seeds were sown thinner than usual, as with late supplies of vegetables there must be ample room to prevent damping.

As regards varieties to sow and when to sow, of course a great deal depends upon the quantity required as well as the quality. I do not advise the largest sorts, such as Canadian Wonder, although the latter is one of the best French Beans under cultivation for summer supplies. A dwarf, quick grower is preferred for autumn, and one with a sturdy growth able to withstand extremes of cold and wet. There are some splendid varieties to select from, one of the best autumn varieties I ever grew being Veitch's Progress, a very prolific Bean, and by no means a small pod. It is an enormous cropper, even at the late season named, and of excellent flavour. There is no lack of really good varieties. Veitch's Early Favourite is splendid, having long pods of fine quality and good flavour. This is an early variety, but it is equally good for late supplies owing to its rapid growth. Sutton's Plentiful is also very good, and is a stringless Bean, early and remarkably productive. The pods are long, straight and handsome, and the quality all one may desire. Sutton's Perfection is also a very fine autumn variety and stringless, and from seed sown in August or September I have, by a little shelter on frosty nights, had them in excellent condition well into November. The plant has a branching, free habit, and produces pods freely. There are others, such as Negro Longpod, Ne Plus Ultra (a smaller pod, but

good), Carter's Longsword (a very prolific variety) and the Magnum Bonum.

The seed, as noted above, should be sown in August or early September, and if on the later date select a small Bean or one with a dwarf habit, such as Early Favourite, Early Gem or Ne Plus Ultra. These dwarf growers soon pod, and continue doing so for a long time. Where possible I advise a south or west border under a wall, as there is some shelter afforded by the wall and it is an easy matter to cover the plants on cold nights with mats, canvas or anything that protects, as often only very little shelter is required, as we frequently get one or two sharp frosts and then none for some time. I advise sowing thinly in rows at least 2 feet apart for the small-growing varieties and a wider distance for the taller ones; indeed, 3 feet at the season named is none too much. If the land is heavy or poor, place some lighter soil in the drills, such as burnt refuse, old leaf-soil or spent manure, anything that lightens or improves. The work done in this direction is not lost, as the land will be in a much better condition for crops the next spring. If the soil is dry at the time of sowing, it is well to thoroughly water the drills. G. WYTHES.

## THE FRUIT GARDEN.

### HINTS ON THE MANAGEMENT OF STRAWBERRIES IN POTS.

**S**TRAWBERRIES intended for forcing purposes should now be rooted in 3-inch pots, and the strongest and best plants selected for potting into the final pots. It is desirable to have the pots clean and well crocked before placing the plants therein. If the drainage gets stopped up before the plants have finished fruiting, it is desirable that they should be turned out of the pots and the drainage seen to, and if the pots are not clean the roots of the plants will stick to the inside and be difficult to turn out, and great damage will be done. After the pots are crocked it is advisable to shake a little soot over the crocks, as it prevents slugs and worms from entering the bottom of the pots; it also provides nourishment for the plants when the roots reach the crocks.

Strawberries require a good rich soil, therefore it is necessary that great care be taken in the mixing of the soil used: Take two parts of loam, one leaf-mould and sand, some wood ashes, lime rubble, a little soot and some artificial manure, and thoroughly mix them together. Let the whole stand for two or three days before using. This should serve as a very good soil, and Strawberries will flourish exceedingly well in it. Firm potting is essential, as the roots work their way through the soil very quickly. After they are potted they can be stood along the walks until frost sets in, then they should be plunged in leaves or ashes in the frame ground or some sheltered place where they will be protected from the frost.

The time for putting the plants in to force depends upon when the fruit is required. Strawberries require about two months or ten weeks from the time they are put into heat until they are ripe. When put in the houses they should be placed on shelves close to the glass, and great care must be taken not to let the plants get dry. When in flower they should be pollinated every day. After the fruits are set, they should be thinned out to about six on every plant. Water every other day with a little artificial manure, which will help them to swell and ripen quickly. J. P. S.

### SOME GOOD LATE DESSERT CHERRIES.

THERE are some excellent dessert Cherries which extend the season so considerably that they are worth a note on that account. In the Southern Counties these late varieties do well on a north

wall, but in the North they well repay a west or even east wall if in a somewhat sheltered situation. I have found much better results from trees that have room for extension of main shoots or branches, there being less gumming and decay, and it is surprising what a large space the trees will cover in a short time once the roots have taken hold of the soil.

The Cherry on walls requires much moisture, especially in light land on gravel; but much can be done to assist the trees by liberal mulchings, so that when moisture is given it is conserved. The trees also frequently suffer from black fly if at all dry at the roots, and this pest is difficult to dislodge when the fruits are ripe; it then cripples the wood for another year.

My note more concerns the best late varieties than cultural details, and, though the latter must not be overlooked at this season, much of the work consists in watering and cleansing. The following are splendid black varieties, and worth room in all gardens for a late supply.

SEMELE ANDROGYNA, A CURIOUS FLOWERING GREENHOUSE CLIMBER.

Black Tartarian is one of the best wall Cherries; it is of excellent quality, large and of fine flavour; it is also known under the name of Black Circassian. St. Margaret's is another very fine black variety, known in some localities as Tradescant's Black Heart. It comes in long after the usual season if grown on a cool wall. I think this variety is one of the best of the late section, as it is a good grower and rarely fails, as it blossoms late. In the North I have grown it on a north-west wall and had splendid dishes for dessert in September. Noble, a recent introduction, is also a good late fruit, but not so late as St. Margaret's. It is reddish black, large, with firm flesh and a free grower. It does well as a bush in good land. Of red or lighter-coloured fruits there is less choice. One of the best late sorts is Guigne de Winkler or Belle Agathe. It is a splendid keeping fruit, and I have had it good well into October. It is bright red, juicy and crops well on a west wall.

Of other varieties there are some good types among the Bigarreau section, the Bigarreau Noir de Guben, a variety that should not be overlooked, being a very large fruit of a bright, shining colour. It fruits freely on a wall, being in season in July in the South. Bigarreau Monstreuse de Mexel is also a very large, dark red fruit with splendid flavour; this variety with me did not do so well in the North as Napoleon, but in the South it was superb and a good bearer. Bigarreau Napoleon is doubtless one of the best and most popular of the late white Cherries, and it certainly is one of the most reliable; if only two or three late sorts are required this should be one, as it never fails. Given proper food and moisture it is a large, handsome, pale yellow, mottled fruit, firm, juicy and richly flavoured, a great bearer, and in season in August in the Southern Counties.

Governor Wood is another popular fruit of the white or pale-coloured section, and a good companion to the last named. It is sweet and richly flavoured, but a little earlier than Napoleon, and is also a great cropper and hardy. Emperor Francis is a large, rich, late red Bigarreau with splendid flavour. There are a few others that I could note, but the above are the best, and there is ample variety for a late supply from July to October. G. W. B.

### A RARE CLIMBER (SEMELE ANDROGYNA).

THIS is a native of Madeira and the Canary Isles, and in the first-named island is much used for draping the pillars at the entrances to quintas, where it has a charming effect. It was introduced into this country nearly 200 years ago, and was for long known as Ruscus androgyne. It is but rarely to be met with in the open in this country, but is grown in a few gardens in Devon and Cornwall. The leaves, or rather cladodes, are from 1 foot to 2 feet in length, and are furnished with from twelve to twenty pinnate sections of brightly polished green. As these droop the glossy green is well displayed, and a wall completely covered with the handsome foliage is an attractive sight. The cladodes are very tough in texture, and often remain perfectly fresh for six or seven years. Strong, well-established plants push up vigorous Asparagus-like shoots from the base, which will sometimes attain a length of 40 feet in a season. In young plants these shoots often appear as early as November, but as they become established the shoots do not appear until the spring. Semele androgyne is a noble climber for a large cool house. In the Temperate House at Kew there is a splendid specimen which has reached the roof, a height of over 30 feet. In the summer the plant presents an attractive appearance, since every pinnate section of the cladode bears, along its edge, clusters of small, yellowish flowers about an eighth of an inch across, some of these clusters containing as many as twelve blooms, and ten or more often being borne on one section.

## THE ROSE GARDEN.

## ROSE NOTES FROM SCOTLAND.

**O**WING doubtless to the cold, wet summer and autumn of 1907 Roses have been anything but satisfactory this season, especially in cold, late districts like the one in which these notes are penned. It is satisfactory to note, however, that some varieties seem able to thrive under all kinds of climatic conditions, and it would be well if growers would give heed to this and plant more numerous the sorts that succeed best in their own localities. The best Rose here this year has certainly been Caroline Testout, and as it is equally fine in a cold season one can hardly have too much of this grand variety. I note that it was the premier bloom in the open section at the important Dunfermline show on July 23. The climbing form is also good here on a wall facing east.

That grand Rose Marquise Lita was better this year than usual, but, curiously enough, Clara Watson, which has hitherto been our best light Rose, was very poor. Lady Ashtown gave some very good blooms, as did Killarney, and Kaiserin Augusta Victoria was better than it has ever been. Very good were Mrs. John Laing, Mavourneen and Betty. Mrs. Sharman Crawford (which never failed before), Le Progrès, Mme. Ravary, Pharisæer and Rosomane Graveureux have been very poor. Dean Hole, Prince de Bulgarie, Gustave Grünerwald, Frau Peter Lambert and Liberty gave us some fine blooms, but there seems but little vigour in the plants. M. Paul Lede we have had for the first time, and although our blooms were very limited in number, what we had were perfect in form and colouring. It is an exquisite Rose.

Captain Hayward and Ulrich Brunner were our best dark Roses, all others being very small, although colours were good. Frau Karl Druschki, La France, Margaret Dickson, Jeannie Dickson and Mme. Jules Grolez were disappointing. Quite good were Mrs. W. J. Grant, Exquisite, Gladys Harkness and Paul Neron. Climbers, both on walls and arches, have been very fine. The best are Dorothy Perkins (at its best on the 17th ult.), Mme. Isaac Pereire, Gloire de Margottin, Leucht-tern (extra fine), Climbing Caroline Testout, Climbing Mrs. W. J. Grant, W. A. Richardson and Duchess of Albany on a low wall. This latter has been magnificent. It faces east and gets no sun after midday.

Preston House, Linlithgow.

C. BLAIR.

## NEW TEA ROSE PAULA.

THIS, as may be seen by the illustration, is a beautifully shaped Rose of good depth and substance of petal. In colour it somewhat resembles Mme. Hoste, and it possesses a most delightful fragrance. It is said to be a very hardy variety, and it is safe to predict a brilliant future for such a flower. This variety was shown before the Royal Horticultural Society by Messrs George Paul and Son, The Old Nurseries, Cheshunt, on the 4th ult., when it received an award of merit.

## ROSE MME. SECOND WEBER.

THIS fine novelty is in the way of Mme. Edmée Metz; it is of similar growth and mildew proof, which all will welcome. It is, perhaps, rather early to say whether it will always possess this good character, but so far I have seen no mildew upon its fine healthy foliage. The colour is a most delightful shade of rosy salmon, something of a blending of Mme. Edmée Metz and Mme. Leon Pain. The blooms are of enormous size, having large firm petals. Mme. Second Weber will be sure to become popular, as it possesses all the good points of a decorative Rose, except fragrance; the absence of the latter apparently is the penalty we have to pay for size

and floriferousness in our modern Roses, although I am glad to find some recent novelties are very sweet.

## SWEET PEA NOTES.

**I**HAVE been at Shrewsbury Show this year and seen the wonderful success of Thomas Jones of Penylan, Ruabon. He exhibited in five classes and won five "firsts" with some of the best flowers seen this year. I visited his garden with a kind friend who motored me over in the middle of July and found the Peas at Penylan a mass of flower, and such flowers and such stems. He had then already been to shows and won prizes, and here he is at Shrewsbury on the 20th ult. with tip-top blooms carrying all before him. If there were a Marathon race for who could cut Sweet Peas in the best condition for the longest time, I would back "Tommy," as his friends call him, to be in at the finish. Other competitors may come and go, but, like the brook, he "goes on for ever."

The friend who motored me over was with me at Shrewsbury, and he was so impressed that he at once arranged with the champion to go over again and see if he could find out the secret. My opinion is that he will find it to be persistent and skilful attention to details during the different stages of growth. At Penylan the land, which is stiff loam with a marly subsoil, is undoubtedly a good foundation to build on. The "footings," as I think the builders term the bottom courses of brick, are carefully laid. First, there is adequate room between plant and plant and clump and clump; secondly, there is careful protection from wind and cold and the necessary watering for the young plants when they are first turned out of their pots; thirdly, there is the building up and getting a good strong plant well established before it is allowed to flower (this is done by thinning the side shoots and stopping the main stem with the skill and knowledge that are only learnt from constant attention and practice); and, fourthly, the getting to know the right strength and proper frequency with which to administer manurial nourishment.

These are matters which, alas! cannot be altogether learnt from books, but which need that hard but withal excellent master, "Mr. Practical Experience," to inculcate them. Even then there is still that undefinable something which must exist between the grower and his plants, which Thomas Jones undoubtedly has, and which we may compare with all reverence to that feeling between the Eastern shepherd and his sheep, which Our Lord seized upon

THE NEW TEA ROSE PAULA, SHOWN BY MESSRS. G. PAUL AND SON, CHESHUNT. (Natural size.)

in one of His most beautiful analogues—that something whose outward sign is loving and unremitting care. I heartily congratulate our great cultivator. Long may he continue to put before us at our shows the possibilities of what is undoubtedly the most popular flower of summer.

JOSEPH JACOB.

## SWEET PEAS DROPPING THEIR BUDS.

MR. A. E. WHITAKER writes: "I was interested in your remarks re Sweet Peas dropping their buds, as I have had some experience of the trouble. As far as I can see, it is not check which causes buds to drop, but rather excessive growth. Let your correspondent test this matter by putting some Peas out in poor soil, and he will not find the buds drop. I once grew a row of Sweet Peas in ground so rich that they never bloomed at all, though they reached a height of 9 feet or 10 feet. I always expect this bud-dropping while the plants are making their first strong growth, say, up to 5 feet high, and I find that the plants are stronger and healthier afterwards. This year the excessive heat and drought in June forced the plants into bloom before they had made sufficient growth, thus threatening to ruin their constitution, but the welcome rain in early July caused all the buds to drop, and the plants made excellent growth. Last year, owing to the persistent rain, the plants went on steadily making growth and dropping buds till the end of July, and they were over 6 feet high before they bloomed. Thus it would seem that anything which causes rapid growth will also cause buds to drop. Artificial manure is a well-known cause. I also find that seeds sown in March or April are more liable to this trouble than seedlings from January or February sowings."

## SWEET PEA SPENCER VARIETIES SPORTING.

I READ in your excellent paper last year an account of the pedigree of Countess Spencer Sweet Pea, and since then I have ceased to wonder at its sportive tendencies; indeed, it would be surprising if it were otherwise. Varieties were crossed and the unfixed seedlings crossed again until the poor thing hardly knew what to do; then came the marvel of the century. Is it any wonder that it takes some years to settle down again after such a mixing up? If Mr. Clapham will take a walk as far as Priesthorpe, which is only a mile away from his place, I will show him Countess Spencer without a single rogue. I have fixed the flower in the last four years.—A. E. WHITAKER, *Priesthorpe, Farsley, near Leeds.*

## THE FLOWER GARDEN.

## A NEWLY-MADE ROCK GARDEN IN A TOWN.

THE rock garden which is the subject of this illustration, was commenced in June of last year in a small town garden, and planted about the middle of July. The site was a piece of lawn 18 feet wide by 45 feet long, running east and west and sloping slightly to the north. The turf was taken off and the ground deeply dug preparatory to wheeling in seven or eight loads of good soil from a neighbouring field where building operations were in progress. This soil was placed in heaps like a miniature range of hills, the level ground between representing valleys. The highest of the hills was about 6 feet and the lowest 18 inches. This was allowed to settle for some weeks, and was well soaked with rain before the stones, which were obtained locally, were placed in position. As each stone was laid the soil was firmly trodden behind it to avoid subsequent settlement.

The largest of the valleys was excavated to the depth of 2 feet and the soil replaced by leaf-mould and peat, into which a trickle of water was led. This makes an excellent home for such Primulas as *rosea*, *sikkimensis*, *Munroi*, &c., fringed with *Iris Kämpferi*, *Spiraea palmata* and other moisture-loving plants. By this method of construction, every aspect is obtainable and each plant can be placed in the position which suits it best. One part facing north is completely shaded from the sun for the sake of the *Ramondias* and *Oxalis enneaphylla*, while another for the *Gentians* faces south and gets the full benefit of the sun.

*Chester.*

FRANCIS SKIPWITH.

## THALICTRUM DIPTEROCARPUM.

THIS is a distinct, welcome and beautiful new species from China, introduced by Messrs. J. Veitch and Sons, Limited, of Chelsea, through their traveller, Mr. E. H. Wilson. The persistent

sepals are ovate, reddish violet in colour, and contrast well with the pale refined sulphur tone of the stamens. In some respects the newcomer may be likened to an improved *T. Delavayi*, but the colour is more pronounced and the flowering more abundant. The leaf character is that of a modified *T. aquilegifolium*, while the plant, as judged by the exhibited examples, is possessed of a vigorous habit of growth. Not more than 2 feet in height as shown, it is highly probable that when well established this elegant novelty will much exceed the height named. A delightful plant in every way. It was shown by Messrs. Veitch and Sons before the Royal Horticultural Society on August 18, when it received an award of merit.

## TREES AND SHRUBS.

## THE SPANISH BROOM.

(*SPARTIUM JUNCEUM*.)

AMONG hardy shrubs this is a well-known and old plant, for it was introduced as long ago as 1548. Although we have received innumerable beautiful shrubs since that time, the Spanish Broom is worthily entitled to still rank as one of the very finest of those that flower during the latter part of the summer and extend even into the autumn. It is too well known to need any detailed description, therefore it will suffice to point out that it forms an upright bush, composed of green Rush-like shoots, which are practically leafless. The Pea-shaped flowers are large and of a beautiful rich golden yellow tint.

According to soil and situation it will reach a height of 5 feet to 10 feet, and being somewhat spare in growth it is seen to great advantage when associated with other shrubs, which, being less in stature, are overtopped by this Broom. The roots are stout and of a deep descending nature, with very few fibres, so that, like most of the Brooms, it transplants badly. Even in dry, stony soils it will hold its own, though it does not attain the same stature as when grown under more favourable conditions.

H. P.

## A BEAUTIFUL EVER-GREEN SHRUB.

(*VERONICA TRAVERSII*.)

THE *Veronica* tribe contains plants so different in size and habit that it is rather difficult for the amateur to believe that all can belong to the same family. The greater number are what are known as herbaceous plants, while one or two of a trailing habit are among the best blue-flowered rock plants our gardens possess. Shrubs are few among *Veronicas*, but the few there are have become very popular, and I think *V. Traversii*, which is in flower just now, has come more into favour than any other variety. The flowers are of a pale lilac colour, although in some districts they are almost white. It blooms very freely and is especially at home near the coast. I have noticed some very fine specimens of it in Ayrshire. It does not seem in the least particular regarding soil, as I have seen it thrive in ground which was nearly all sand, while it does equally as well with us here in ground which is of a cold, wet, clayey nature. The best time for planting is from October to the end of November.

JAMES McGRAN.

(Gardener to Sir W. H. Houldsworth, Bart.)

*Coodham, Kilmarnock.*

A TOWN ROCK GARDEN ONE YEAR AFTER ITS FORMATION.

## THE GREENHOUSE.

### GREVILLEA BANKSII.

**A**LTHOUGH "The Dictionary of Gardening" states that more than 160 species of *Grevillea* have been described, very few of them, except *G. robusta*, which is grown as a foliage plant, are ever met with in gardens. Two species (*G. rosmarinifolia* and *G. sulphurea*) are quite hardy in the favoured parts of these islands. Both as a foliage and a flowering shrub for the greenhouse *G. Banksii* merits notice. It forms a rather bold-growing shrub, whose ascending branches are clothed with pinnate leaves 6 inches to 9 inches long and nearly as much in width. The sub-divisions of the leaves are about a quarter of an inch wide and 3 inches long. When young the leaves are quite silvery on the under sides and to a lesser extent above, but when mature the upper surface loses its silvery character and the under side has it less pronounced than when young. The flowers are collected in a cone-like terminal head, which is about 4 inches in width and the same in depth when fully expanded.

As with most of the *Grevilleas*, the showiest portion of the inflorescence consists of the long, prominent styles, which curve in a downward direction. The colour is scarlet, tipped with yellow, the expanded mouth of the flower having the same tints. The exterior of the tube is paler and clothed with pinkish hairs. As many as fifty flowers are borne in a cluster, and they will remain fresh and bright for a considerable time. This *Grevillea*, in common with most members of the genus, is a native of Australia, and was introduced to this country in 1868.

H. P.

### BEGONIA

#### KEWENSIS.

THIS exceedingly pretty *Begonia* was recently given an award of merit by the Royal Horticultural Society, an honour that, in my opinion at least, is well merited. It is one of the shrubby section and forms a freely-branched specimen clothed with neat leafage. The flowers are borne in clusters towards the points of the shoots, which, naturally drooping, become more so with the weight of the blossoms. They are pure white in colour and are borne in great profusion. It has undoubtedly a great future before

it as a basket plant, for which its semi-pendulous habit of growth eminently fits it. The specimen to which the award was given was shown by Messrs. Veitch, so that it will doubtless be more generally distributed before long, as up to the present the only catalogue in which I can find it is that of MM. Lemoine et Fils of Nancy. It was, I believe, as implied by the name, raised at Kew, but reference to the Kew "Hand List of Tender Dicotyledons" does not help one as to its parentage, &c., it being simply described as of garden origin.

H. P.

### FREESIAS.

THESE sweetly-scented subjects are now being put into the grower's hands, and where they are required from late autumn to a late date in spring the first batch should at once be introduced to a

growing temperature. Good fibrous loam will form the staple here, while a little leaf-mould, Mushroom manure and sand may be added in sufficient quantity to give lightness and a free-rooting texture to the whole. A dusting of dissolved bones, too, should be incorporated, the pots being liberally drained and soil put in to within 1 inch of the rim. The bulbs should be fixed firmly into their respective positions and

round pond about 15 feet across, dug out of the lawn to a depth of about 5 feet, cemented and edged with bricks and surrounded by a border of peat and loam. The outer edge of this border was formed of stones cut and faced and left over from the building of the big house. The pump is at a distance of some 10 yards from the pond, and, not being a very picturesque object, is hidden by Honeysuckle trained over small poles.

The water is conveyed from the pump to the pond by the somewhat primitive plan of a wooden trough, removed when not in use, and leaden pipes beneath the lawn connect the pump with the tank. Three plants of Water Lilies (*Marliac's* tribe), white, pink and white tipped with crimson, were sunk in baskets in the pond in April, and flowered the same year, and have proved quite hardy. The border is divided into spaces, half of which are kept wet by holes in the side of the pond quite close to high water, through which the water percolates when the pond is sufficiently full. In these divisions are grown plants that require a boggy soil, such as *Primula rosea*, Water Forget-me-nots and Hoop-petticoat Narcissus. The drier divisions are filled with *Iris Kempferi* in mixed colours, about four groups.

During the summer the water is allowed to flow over the whole border in dry weather when required, and these *Irises* flourish exceedingly, for they require plenty of moisture without actually standing in water and a position in the full sunshine. *Primula japonica* flowers luxuriantly, bearing tier after tier of blossom for weeks at a time, very different to what it does in the mixed border hard by.

A plant of *Astilbe Davidii* and another *Astilbe* of a paler pink shade, with long racemes of blossom, last far into the autumn. The big house is now let and the manor house inhabited, and from the dining-room window of the manor house the water garden is a very charming feature, seen as it is across a Lavender hedge surmounted by Larch poles, connected at the top and covered with pink Papillon Roses, which flower from June till the frost ends their beauty. It may be thought

that not a very large number of plants have been enumerated, but a better effect is produced by masses of one flower than by many isolated specimens. A few Saxifrages are planted to cover the stones and carpet the border. A large flat stone is placed to approach the pond as a sort of step, and should be slightly raised so as to keep the water in when the border is flooded; it is also useful to step on when replenishing the water-cans, as we use this water for watering the border close by. Being exposed to the sun, it is far better for the flowers than what is drawn direct from the tank. A dovecot in the shrubbery close by is the home of some white fantail pigeons, who come down to the water to drink and fly back to sun themselves on the old stone-tiled roof of the manor house.

C. ASTLEY COOPER.

Hambledon Manor, Ruttland.

A NEW *THALICTRUM* (T. DIPTEROCARPUM), SHOWN BY MESSRS. J. VEITCH AND SONS, LIMITED.

(Slightly reduced.)

the final soil added, bringing it up near to the top of the rim. Usually five bulbs are put in a 4½-inch pot and nine in a 6-inch pot. Plunge the pots in ashes, but only lightly cover them, say, about half an inch.

## A WATER GARDEN.

**T**HE full pleasure of a water garden can be enjoyed with very little facility for water and in a very small space. The one I am going to describe is in front of an old manor house, till lately uninhabited, and forming only a picturesque background to rather a retired corner of a much larger garden. A tank, used to water the Rose garden, about 20 yards distant, was utilised by means of a force pump to fill a

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**THE WINDOW GARDEN.**—The present is the proper time to pot Arum Lilies that were planted outdoors some few months ago. They should be lifted, repotted and stood in a shady corner to get established and recover from the lifting. Bulbs of the Chinese Sacred Lilies, known as *Narcissus Tazetta*, should be potted now; they make a pretty display in the window in midwinter and early spring. Window-boxes may be renewed at the present time by removing subjects that are past their best, placing therein dwarf early-flowering Chrysanthemums, which should make the window gay for some time to come. It may be possible that a plant or two can be lifted from the outdoor garden and planted in the window-boxes, which are much better than plants grown in pots.

**Hardy Flower Garden.**—Daffodils planted at the present time will do much better than those planted a month or two hence. These bulbs should never be kept out of the ground longer than can be helped. Hardy Primulas and Auriculas may be lifted, divided and replanted in their flowering quarters at once. The beauty of their display in the late spring justifies the beginner in growing these subjects freely. Hollyhocks, Delphiniums and other plants as they go out of flower should have seared flower-heads removed, as their prospects for another season's display are benefited thereby. Beds of the Lily of the Valley that are so beautiful in the early summer are benefited by a top-dressing of well-decayed manure at the present time. I make this an annual piece of work and the crowns respond in most liberal fashion with stately spikes of blossoms in the flowering season. Manure from a spent hot-bed is the best material to use for this mulching.

**The Vegetable Garden.**—Onions that are now nicely ripened I am lifting, and after leaving them in the open for a few days to dry off,

2.—THE SAME SHOOT PREPARED READY FOR INSERTION.

1.—SUITABLE SHOOT OF THE COMMON SWEET BAY FOR MAKING INTO A CUTTING.

they are placed indoors and carefully stored. It is a mistake to leave these in the beds when they have finished growing, as they soon spoil. Spring Cabbages may be planted now. I plant them about 1 foot apart in rows and the rows about 2 feet asunder. This timely work ensures the early development of useful Cabbages in the early summer. Crops that have finished their yield, such as Peas, Broad Beans and any other subjects should be pulled up, and where there are sticks these should be stored away in the dry, the quarters treated to a heavy dressing of manure, to be deeply dug in ready for other crops. I do not believe in leaving the ground vacant for any length of time, being rather disposed to have this turned over, that the elements may exercise their beneficial influence upon it. Mushroom beds may be made up outdoors at this time, and as this matter was dealt with fully in an illustrated article for beginners a short time since, I would direct readers to the information given therein.

**Trees and Shrubs.**—I am taking advantage of the present time to plant Ivies against walls or fences. Too often beginners are disposed to ignore the fact that this subject appreciates soil that has been well tilled. For this reason see that the quarters are deeply dug, and, if the soil be poor, incorporate a combination of well-rotted manure and leaf-mould. The advantage of this will be seen in the succeeding seasons.

**The Greenhouse and Conservatory.**—What I said regarding the Calla Lilies in the window garden section also applies to plants of this subject that may be required for the greenhouse and conservatory. Continue to pot up successive batches of Roman Hyacinths, the Paper-White Narcissus and Duc Van Thol Tulips for early flowering. Each of these subjects, when nicely rooted, do very well, and should provide an early display of their welcome blossoms. Quite a

number of subjects that were planted outdoors at midsummer, such as *Salvias*, *Bouvardias*, *Solanums*, *Genistas*, *Eupatoriums*, &c., may be lifted at the present time and placed in pots of suitable size. These have their value when there is little else to brighten the conservatory. After being placed in pots they should be stood in the cold frame for a short time until established, and if the weather be bright and sunny they should be shaded during this period. I water my plants in the greenhouse in the early hours of the morning at the present season, and open the ventilators as soon as the glass begins to feel the influence of the sun.

**The Rose Garden.**—There should be no delay in the preparation of borders for planting Roses within the next month or two. It is a good plan to have the quarters prepared early, and that the Roses may do well, we would certainly dig the ground at least two spits deeps, or, if possible, trench the same. Poor soil should be enriched with heavy dressings of manure. Light soils should have well-rotted cow manure added thereto, and soils of heavy texture would be benefited by the abundant supply of good horse manure. D. B. C.

## PROPAGATION OF THE SWEET BAY, YEW AND THE COMMON LAUREL BY CUTTINGS.

THESE subjects are of interest to most lovers of the garden, and as they play such an important

3.—SHOOT OF THE COMMON YEW AS TAKEN FROM THE PLANT ON THE LEFT AND AS PREPARED READY FOR INSERTION ON THE RIGHT.

part in beautifying the surroundings of our homes there may be readers who desire to raise a batch of plants by means of cuttings.

**The Sweet Bay.**—Most of us have been familiar with the Bay tree from our earliest days, and know its value both as a decorative evergreen shrub as well as the usefulness of the leaves for their flavouring. The Sweet Bay, like many other evergreens, is a subject of easy culture, and may be easily increased by cuttings of shoots at this period. The shoots should be from 3 inches to 4 inches long, and similar in every respect to the illustration in Fig. 1. Here it will be noticed

4.—SHOOT OF THE COMMON LAUREL SUITABLE FOR MAKING INTO A CUTTING.

the growth is clothed with leaves from its apex to its base, and that the shoot may be encouraged to root speedily it is customary to trim off a few of the lower leaves, so that it may be possible to insert the cutting properly and that it may root satisfactorily. As an indication of what should be done with the shoot in Fig. 1, Fig. 2 is an apt illustration. The prepared cuttings should be inserted in light, sandy soil in a shaded border outdoors. It is not absolutely necessary, although it is better to acquire the use of a cold frame in order to raise plants of this useful subject, as a cutting-bed made up in a semi-shaded or shady position anywhere in the garden will answer the purpose very well. What we would do, however, in order to encourage a more speedy-rooting process is to place hand-lights over the cuttings at first, or frame-lights arranged over any rough framework; a cold frame may serve the same purpose. The cuttings should be inserted about 3 inches apart and in rows 4 inches to 6 inches asunder, so that in this way quite a large number can be accommodated in a comparatively small area. This propagation of the Sweet Bay by cuttings may take place at any time between the present and the end of October.

*The Yew (Taxus baccata).*—This is a common enough subject in our gardens, yet it is so very useful and ornamental that it has come to be regarded as an almost indispensable occupant of our borders, covering up unsightly quarters, and also serving the purpose of a screen against cold winds and providing sheltered quarters for many of our more tender subjects in the hardy flower garden. The Yew may be raised from cuttings quite easily in September, and readers will be wise to take advantage of the present opportunity to insert a batch of suitable cuttings. These should be made from shoots of comparatively recent growth about 3 inches in length, and are represented by growths as shown in Fig. 3. The leaves are removed from the lower portion of these shoots, so that the cutting may be inserted easily and the prospect of rooting rendered more likely thereby. These cuttings should be inserted in light sandy soil and placed under a hand-light or in a cold frame. The

cutting-bed should be made fairly firm after being properly levelled, and, say an hour or two previous to the insertion of the cuttings, the bed should be given a good watering by the aid of a fine-rosed can. The cuttings should be inserted about an inch deep about 2 inches or 3 inches apart, and in the rows 3 inches to 4 inches asunder. Always take care to press the soil firmly at the base of each cutting, otherwise the rooting process will fail to take place. Keep the cuttings rather close during the rooting process, which should not take many weeks.

*The Common Laurel*, so useful in covering up unsightly quarters of our garden and serviceable in so many respects, may be raised with the greatest ease by the aid of cuttings. We are quite aware that this and many other evergreens are increased by layers, but this subject is so very easily increased by the aid of cuttings that we have taken advantage of the present occasion to give a few directions respecting this matter. Fig. 4 shows a growth of comparatively recent development and in fine condition for the purpose under notice. The cuttings should be about 6 inches long and should be inserted in cold frames during September, after being prepared and made ready for this operation as illustrated in Fig. 5. Here it will be noticed the lower leaves are removed and the shoot cut through immediately below a joint. It is the practice in some establishments to cut out the leading growth, so that as the cuttings root new shoots are evolved in the axils of the leaves, and the young plants subsequently assume a more bushy and branching form. Insert the cuttings to the depth of 2 inches, more or less, and make them quite firm by pressing the soil at the base of each one. They should be 3 inches to 4 inches apart, and the rows about 9 inches asunder. It is astonishing what a number of such shoots may be propagated within a comparatively small frame, and assuming the soil is of a light and sandy nature, and this be kept fairly moist, there is no reason why the roots should not be emitted within a few weeks.

#### LIFTING AND STORING POTATOES.

DURING the months of September and October the work of lifting and storing Potatoes will be in full swing, so perhaps a few hints concerning this apparently simple operation will be of benefit to those who are beginners in gardening. When to lift is a question that puzzles many, and even among professionals there is considerable diversity of opinion on this point. Some growers advocate leaving the plants until the tops naturally die down and others lift them while the haulm is quite green.

A simple test is to lift a plant and examine the tubers found thereon. If the skins are set quite firm there is very little to be gained by leaving the crop longer in the soil, even if the tops are more or less green, and the Potatoes may safely be lifted at any time. The skin may easily be tested by scraping it with the thumb-nail; if it peels off in a flake it is not set and the tubers are not ready for lifting, but if it refuses to peel off it may be regarded as set.

A fine dry day should always be selected for digging Potatoes, and care must be taken not to pierce the tubers with the fork. A flat-tined tool is best for the purpose, but an ordinary garden fork answers very well. It should be thrust in at the side of the plant, not between two plants, and pushed well under the stool, lifting the whole of the tubers bodily out of the soil. Any that cling to the haulm must be shaken off and the stems thrown on one side so as not to shade the Potatoes. The tubers should be allowed to remain exposed to sunshine for a few hours before picking them up, as they are thereby dried and will keep much better.

Grading is best done when collecting the crop, and any that are required for planting next spring must be specially selected and given

different treatment to those intended for eating. All diseased tubers should be burned as soon as possible, and not given to pigs.

The storing of ware and seed tubers, as stated above, will differ considerably. Those for eating must be kept in a dark, cool, but frost-proof place for the winter, and if properly dried may be placed in a thick heap. A cellar is an ideal place where one is available. The system of clamping adopted by cottagers and market growers is a good one if properly carried out. A bed of soil large enough to take the heap of Potatoes is made level and very firm, and the tubers placed thereon in a conical or ridge-shaped heap. Over these good Barley, Oat or Wheat straw is placed to a thickness of 6 inches or 9 inches, taking care to get it as straight and even as possible. It should be put on so that one end of the straw points to the top of the heap and the other to the bottom. Soil is then dug out round the heap so as to form a trench 1 foot to 15 inches wide, and banked on the straw, starting at the bottom and working upwards. Not less than a thickness of 9 inches of soil should be used, and it must be made firm as the work proceeds, leaving the outside as smooth as possible so as to ward off rain. It is a good plan to leave a little space at the top of the heap unearthened for a week or two; then any heat that is generated will escape. Of course, enough Potatoes must be left out of the clamp for the winter supply, as it is not advisable to open the clamp until the middle of February.

Those Potatoes selected for sets ought to be stored in single layers in a cool, frost-proof position and in the light if possible. On no account should they be kept in a thick heap or in a warm place, else weak growth will occur, to the detriment of the crop another season. Only the best-shaped tubers should be retained for planting, and it is necessary to see that each possesses at least one good eye or bud. It is unwise to save Potato sets for planting in the same garden for more than two consecutive years; it is far better to change the stock, buying sets if possible which have been grown in Northern counties. Many of our Southern seedmen now have their seed Potatoes grown in the North.

5.—THE SAME SHOOT AS SHOWN IN FIG. 4 PREPARED READY FOR PLANTING.

## THE TOWN GARDEN.

**BULBS IN POTS.**—Many as are the beautiful flowers which we can grow in our rooms and greenhouses, there is none more delightful for the town residence than those that come within the comprehensive category of Dutch bulbs. In pots, window-boxes, jars containing moss fibre without drainage, and in the garden they succeed splendidly, and there is no single home in London or any town or city in the British Isles where they will not grow, provided that the needful bulbs, soil and pots can be procured. It is to their distinct attractiveness and ease of culture that they owe much of their popularity, and it is highly improbable that they will ever fall from their present high estate. In my next two or three articles I propose to deal fairly exhaustively with the general culture of bulbs in various ways, and the suggestions which will be made will be so simple that they can be adopted by everyone who desires to do so.

**PROCURING BULBS.**—This is one of the most important points in the whole matter, and care in selection goes far to ensure success, whereas hunting the length and breadth of the country to find the lowest-priced—not the cheapest—bulbs often spells failure. The grower who would achieve the most gratifying success must be prepared to procure sound, heavy bulbs from a source of the highest repute, and if they cost a few more pence than others which can be had, he can rely upon it that they are far away the cheapest in the long run, for they bring certain satisfaction if correctly managed. There are several firms advertising in *THE GARDEN* who are so jealous of their fair name that they would not send out an inferior bulb if they knew it, and should a purchaser receive one that is partially rotten or very rough, and unduly light for its size, he need only return it to have another sent in its place. Upon this particular point there is one other thing that I should like to emphasise, and that is the importance of early purchase. The demand is always enormous and the finest bulbs go first, therefore the earlier the order is placed the more probable it is that perfect bulbs will be sent, and they can easily be stored until they are required for potting or planting.

**THE SOIL.**—Simplicity should be the rule in the preparation of the compost, as there is absolutely nothing to be gained by making up elaborate mixtures of numerous ingredients. The principal part of the compost ought to consist of sound, fibrous loam, of which three-parts should be used to one part of sweet, decomposed leaf-mould; to these add one-tenth part of clean, sharp sand, mix them thoroughly, and the result will be a soil that will admirably suit all the kinds usually grown in pots. This material must be turned and re-turned over and over again until the parts are thoroughly incorporated, and if it can be done two or three weeks prior to use so much the better. It is the practice of some growers to add a little concentrated plant food or natural manure to the soil, but I prefer to rely upon plain food at the outset and feed when the plants are well advanced as may be necessary. If manure is used let the quantity be very small.

**THE POTS.**—These will have to be of various sizes to accommodate bulbs of different kinds and in varying numbers, but generally speaking those 5 inches in diameter, inside measurement, are the most serviceable. For single bulbs of Hyacinths I prefer, however, a 4-inch pot (known generally as a small 48), as I think that the spikes are better when the roots are thus slightly restricted, and it is easy to give special food to compensate for the limited supply in such a small bulk of soil. Whatever size is used they should be clean, inside and out, as also must the crocks that form the drainage. Above the crocks should be placed a layer of rough moss or the constant watering will wash the finer particles of soil into the drainage.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CLEANING THE HOUSES.**—Give all houses as soon as possible a thorough clean out, so that they will be in order when housing time arrives. Cleanse the conservatory and fumigate. Paint all iron or open wood work with petroleum, and afterwards hose thoroughly. Oil the ventilating gear and do any repairs that may be necessary. See also that the boiler and connexions are sound.

**Mignonette.**—Thin out the seedlings sown last month to about three or five plants, and take out side shoots or laterals as they become large enough to handle.

**Begonias** of the winter-flowering section, such as *Gloire de Lorraine* (white and pink) and *Gloire de Sceaux*, should be potted on. Let the soil be rich and fairly open, and see that it is well rammed down between the ball and the pot: stake and keep neatly tied. These plants are very useful for winter and spring decoration and cannot be grown too well, but one often finds them overpotted, when the soil becomes sour before the roots have had time to permeate it. Much larger plants can be produced in small pots by judicious feeding and watering. This would also apply to many plants, especially Persian Cyclamen, Cinerarias and Primulas. Many professional as well as amateur gardeners err in doing this.

#### PLANTS IN FRAMES.

**Pot Roses** should be looked over, and if any potting is required it should be done at once. Meanwhile keep the pots plunged in ashes up to the rims. Cleanse the leaves by constant syringing. Prepare frames and pits for the reception of Violets, &c., and keep these plants well supplied with water. Pick off all long runners. Water Salvias, Bouvardias and Chrysanthemums that are to be lifted and keep the roots in a growing medium; they will make much progress in the next few weeks. Take all buds on Chrysanthemums in pots as fast as possible, and any early varieties showing colour should be put in under protection from wet. See that all bush varieties have stakes sufficient to keep them from damage by wind. Give Arums (Callas) plenty of water, as they are now making strong growth. I find that planted-out roots are the best.

#### HARDY FRUIT.

**Watering Fruit Trees.**—In this locality many Apple and Pear trees have had to be watered. The fruits are very good this season. Continue to water any that require it and net early varieties, as birds soon damage them. After the birds' attack wasps and bees become troublesome. Gather all fruits that are ready.

#### KITCHEN GARDEN.

**Leeks.**—Draw more soil up to the stems if very large specimens are wanted, but prevent the soil getting into the hearts or leaves. Those planted later and dibbled into deep holes should now have some fine soil put in and nearly filled up, as the roots will go downward for the moisture that has been supplied.

**Spring Cabbage.**—Prepare the soil for this important crop. These should be put on a plot that has been heavily manured previously. The Onion plot is considered by many to be the best place, and it has much to recommend it, but it must always be borne in mind that the Cabbage is on the ground for nearly a year. The latter, however, should be made ready and fit by manuring.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**HYACINTHS IN POTS.**—The foundation to a successful flowering of these, as well as other spring bulbs, should be made in autumn by potting at the proper time, so that a plentiful supply of roots may form before any kind of forcing is started. September is a good month for potting Hyacinths, and those that are required for forcing should be so treated early, following with later batches. The soil best suited is loam two parts, good dry rotten manure one part (this should be passed through a sieve) and half a part of grit. I often use road scrapings obtained after a heavy storm in preference to sand, because they are coarser and tend to keep the soil open. Four-inch pots are used for one bulb, and three bulbs are put into pots 8 inches in diameter. These latter make showy specimens for the conservatory. Care should be taken to select each of the three bulbs about even in size, so that there shall not be an odd look in the spikes of blooms.

#### FRUITS UNDER GLASS.

**Pot Trees.**—The present is an excellent time for potting on any of the orchard-house trees that may need it and which have been cleared of their fruit. Trees which have reached their limit as to size of pot or other receptacle need to be carefully managed, as the balls must be slightly reduced and the roots carefully pruned in order to make room for new soil. Those which can be afforded more room will only need a slight disturbance of the soil round the outside of the ball. The crocks, too, should be removed carefully so that the ball may be placed low enough in the new pot. Cover the drainage with rough turf, cut thin, and ram the new soil in round the ball as firmly as possible. The old ball should have a good soaking of water some hours before potting takes place.

#### KITCHEN GARDEN.

**Tomatoes.**—Batches of plants bearing fruit in a very small state should now be watered with clear water only, applications of liquid manure tending to promote growth rather than hasten on the fruit. Where any old spare lights from pits or frames are at hand, these may with advantage be placed in a slanting position against the wall in order to hasten on the fruit. In exposed gardens the moulding up of any late planted winter and spring crops, especially Broccoli, must be attended to, as, independent of its steadying the stems, the soil protects them from frost.

#### HARDY FRUIT.

**Apricots and Nectarines.**—At this season Apricots especially need copious supplies of moisture at the roots, and though there has been some rain I find it has failed to reach the roots, especially where the borders are cropped. The trees in many cases are making free growth, needing ample supplies of moisture. I find the more robust the trees the less danger there is of branches dying off. The Apricot does best when the roots are near the surface, hence the need of moisture in dry seasons. A mulch at this time is of great value, as it retains the moisture given and promotes root action.

#### FLOWER GARDEN.

**Michaelmas Daisies.**—These plants should be thoroughly mulched and watered during dry weather, and neatly tied to strong stakes as the growth is made. Care must be taken not to bunch them up too tightly, or much of their beauty will be lost; the shoots should be looped up just sufficiently to keep them from being broken down by wind and rain, thus allowing the habit of each variety to develop, and in most cases they are very beautiful.

(Gardener to the Baroness Berners.)

*Ashwellthorpe, Norwich.*

# ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**September-sown Sweet Peas** (J. F. A.).—Unless your soil is exceedingly heavy and cold, September is too early for sowing, as the probabilities are that the plants will grow rapidly and rankly and will be too sappy to withstand the rigours of the winter. If the soil is of medium texture the end of October will be quite early enough to sow, and to ensure hardiness the position must be open so that they will get unlimited air, and about the middle of December the soil should be drawn up to the plants on each side of the row to a height of about 4 inches. The twiggy sticks will also answer as a slight protection. You will have to thread or otherwise protect the young plants efficiently or birds will do as much harm as frosts.

**Large-flowered white Gladiolus** (Constant Reader, Wynberg).—Kelway's White is a large-flowered Gladiolus, and a very good one it is. You will find that it is rather expensive at present.

**Failure of Romneya Coulterii** (Miss S. R.).—It is not possible to say what is the direct cause of Romneya Coulterii dying off without seeing the plant and conditions under which it is growing. This plant wants a warm, sunny position, deep loamy soil, with perfect drainage.

**Name of Delphinium** (E. M. M.).—We think that the name of the Delphinium is Ustane, but as there are such a vast number of florists' varieties in cultivation it is impossible to say positively without a large collection being available for comparison. Florists' flowers should be sent to a nurseryman who makes a speciality of the particular class of which the name is required. It is hardly and would succeed in Oxfordshire.

**Water Lily leaves for inspection** (J. S.).—The leaves of your Water Lilies are attacked by the caterpillars of the moth *Hydrocampa nymphaeata*, an insect which measures rather more than 1 inch across the open wings, which are of a pale brown colour with white blotches. The caterpillars are now becoming chrysalides. If the tank is not too large, it would be worth while to examine the leaves and destroy the chrysalides or caterpillars which are under the patches of leaves; as the latter are green and the under sides of the leaves reddish brown they are easily seen. The moths emerge in June or July, and may often be found flying about over the water. They lay their eggs on the leaves, and the caterpillars are a year old before they are full grown. It should be quite possible to catch the moths in a butterfly net, but I do not see how you could very well kill the caterpillars with an insecticide.—G. S. S.

## TREES AND SHRUBS.

**Tree leaf-soil** (Susan).—Lime leaves, though of less substance than Oak leaves, still result, when fully decayed, in producing good leaf-mould. But as you have Oak, Horse Chestnut and Willow leaves to mix with the Lime leaves, you should find the whole when fully decayed produce excellent soil. Hard leaves, such as those of Holly and Laurel, are not desirable, but those are shed chiefly in the spring. As you collect leaves spread them out to form a bed 4 feet in width, adding layer on layer as collected, also casting house soaps, water and soot over each layer. When a well-trodden body some 3 feet in height has been formed, slight fermentation follows, and decay is all the more rapid. If the heap be turned in January and more water, if the material be dry, cast over it in the turning and liberal dustings of soot to

kill insects added, in about nine months capital soil is formed. For mixing with potting loam, however, the leaf-soil should have lain fully a year.

**Willow leaves falling** (Mrs. Cuff).—Without seeing the tree itself it is difficult to say what is the direct cause of the leaves falling. It is most probable that the trunk of the tree is infested with scale, which would suck the sap and have such an effect. The trunk should be dressed in spring with a paraffin and soft soap emulsion to kill the scale.

**Trees to shut out view** (Teesdale).—Either the White or the Canadian Poplar, or, if you prefer it, the two planted alternately, would make a quick-growing screen, but both are of course deciduous, hence they are only effective during the summer months. Trees from 10 feet to 12 feet high may be safely planted provided they have been regularly transplanted and are well rooted. The best time for carrying out the operation is in October or November. For an evergreen screen one of the best subjects you can plant is the Austrian Pine, but its rate of growth is slower than the Poplars. Plants of this not exceeding 6 feet in height will give more satisfaction than taller ones. The Douglas Fir is another good screen tree.

**Planting a Yew hedge** (Yew Hedge).—In the first place, the ground must be thoroughly prepared for the reception of the Yews by being trenched about 3 feet wide and 2 feet deep. In trenching, too, the subsoil must be well broken up. Some well-decayed manure should be mixed with the lower half of the dug soil, but not with the subsoil. The ground being thus prepared, the planting is the next consideration. Good, bushy, well-rooted plants about 4 feet in height are the best, and they should be obtained from a reliable source, where regular transplanting every two years is carried out. The planting is best done during the month of October or the first half of November. The distance apart at which the plants are put will depend upon their size, but they should be sufficiently near each other for the side branches to interlace a little, and at the same time undue overcrowding must be especially avoided. After the hedge is planted it will not require clipping until the second year, though any shoots that show signs of straggling may be shortened back. After the second year it may be trimmed annually in May, being just looked over in September for any very long shoots. The common English Yew is the best for the purpose, and when established a growth of 6 inches may be reasonably anticipated. A top-dressing of short well-decayed manure every three years will be helpful.

## ROSE GARDEN.

**Roses in cold frame** (Amateur).—We certainly think you could grow some good Roses in a frame 6 feet by 3 feet with a depth at back of 3½ feet sloping to 2 feet in front. The main thing is to prepare the soil well. Dig it deeply, and add some fresh loam if the staple soil be not very good. About a barrowful of good manure should be incorporated, also an 8-inch potful of half-inch bones. You must see that the drainage is good, if not add 4 inches or 5 inches of broken pots, bricks or clinkers to the bottom. Plant the Roses early in autumn and keep the lights off until February if weather permits, then prune the plants. Bring them on as naturally as possible, merely covering with the lights when frosts threaten; but as soon as new growths appear then you must see that these do not become injured. It may be necessary to cover the lights with thick mats if we get sharp frosts in March.

**Rose for examination** (G. S. L.).—You have evidently a Rose that is not W. A. Richardson. The leaf looks uncommonly like that of a monthly Rose, but we cannot be certain. Could you send us a piece of the growth with bud or bloom? We should discard such a poor specimen and plant a vigorous tree during the coming autumn. Roses are now so cheap that it never pays to have poor enfeebled plants about.

**Rose plants mildewed** (A. H. P.).—This troublesome fungus will undoubtedly survive the winter, and if the plants were badly infected before leaving the nursery, the spores would fall to the ground from the infected branches and reappear in the plants the following spring. It must not be forgotten that certain localities favour mildew more than others, and if one's plants were free one year, the Roses in the hedgerows might disseminate the fungus another season. Much depends upon climatic conditions. When foliage is soft it is more liable to attack. Certain varieties of Roses, by reason of the structure of their foliage, are more susceptible to mildew than others. Thus we have Killarney very prone to it, whereas Mme. Edmée Metz, which has a sort of glazed leaf, is entirely free. If plants are sprayed with sulphuric acid when received, this would prevent the dissemination of the spores. They should be sprayed for three days in succession, using the sulphuric acid at the rate of one part of acid to a thousand parts of water. Mo Effic is also a valuable preparation for combating mildew.

## MISCELLANEOUS.

**Cultivating a small garden** (M. E. D.).—A garden only 13 rods in area would be of no use whatever to conduct French or, indeed, any description of market gardening. Were it eight times the area, it might be made to serve some market uses. French gardening is very costly, and can be made to pay only in the hands of a thorough expert. So far as it has been in use in England, while glowing accounts have been written about the profits, no experienced gardener believes them. As to your Strawberry bed, if it is three or four years old it would be better to clear off the plants and get the ground ready for Cabbage plants in October; but by all means lift the strongest of the runners first and plant them out on fresh, deeply-dug and well-manured soil. If strong and well rooted they will carry some fruit next year. At this time of year, as crops are cleared off, the ground should be trenched 2 feet deep and well manured ready to receive early Potatoes, Peas, Cauliflowers, Dwarf French Beans, Lettuces, Carrots, Radishes, Tomatoes or similar crops in the early spring.

**Names of plants.**—Kate P.—*Pisum elatius*.—Colonel F. Killivan.—*Althea officinalis*.—Mrs. W. A.—*Pisum elatius* ("Mummy" Pea). It is a native of the Mediterranean region, and so called on account of seeds having been found in the Egyptian tombs with the mummies. It is highly probable that the Peas are first placed in the tombs by the guides, to be sold to tourists.

A. L. Ford.—*Picea orientalis*.—E. K. Baker.—*Schizanthus pinnatus*; *Sedum prealtum*.—R. H. Salop. 1. *Saponaria officinalis flore pleno*; 2. *Humulus Lupulus* (Hop); 3. *Helianthus humboldtianum*; 4. *H. corymbosum*.—Miss Wells.—*Celsia Areturus*.—A. W. P., Dublin. —Your Roses are: 1. *Francisca Kruger*; 2. *Mme. Lambard*; 3. *Dr. Grill*; 4. *Freiherr von Maréchal*; 5. *Tom Wood*; 6. *Mme. Pierre Cochet*; 7. *Climbing Cramoie Supérieure*. —H. W.—Your Roses are: 1. *Victor Verdier*; 2. *Perle d'Or*; 3. *Gloire de Margottin*; 4. *Princesse de Sagan*; 5. *Mme. Chedane Guicolsseau*; 6. *Anna Olivier*; 7. *Abel Carrière*; 8. *Baroness Rothschild*; 9. *Crown Prince*; 10. *Dr. Sewell*.—J. E. M. F.—*Alyssum incanum*.—W. E. P.—The Peas inside the edible Pea-pods are gruted and the pods over-ripe, making it quite impossible to identify the variety. If you will send a younger sample with some of the haulm on which it is growing we will endeavour to name it. The blue Sweet Pea was rather withered. It seems of a pleasing shade of blue and worth perpetuating. Sweet Peas have been sporting very freely this year and yours may be a sport, or it may have been a chance seed of a blue variety that had got in with the others. In any case, we would save the seed and see what will come of it next year. —E. S.—1. *Cunrussus pisifera var. plumosa aurea*; 2. *Taxus baccata*; 3. *Cupressus lawsoniana var. erecta viridis*; 4. *Cassinia fulvida*; 5. *Cupressus pisifera*; 6. *Thuya dolabrata*.—Wm. Gregory. —4. *Hebeanthus Katherinae*; 5. *Dracena godseffiana*; 12. *Cypripedium Sedenit*; 13. *Cypripedium sp.*; 14. *C. villosum*; 15. *Oncidium hypomaculatum*; 16. *Cattleya Loddigesii var.*; 17. *Cattleya Harrisonii*. The other numbers were all garden forms of the *Croton*.

**Names of fruit.**—Wm. Mathews.—The shape and colour of an Apple varies so much under different conditions of growth. For instance, the same variety grown in Glamorganshire placed side by side with those grown in Kent would often be hard to recognise as the same sort. Moreover, your fruits in the majority of cases have not finished their growth. However, we have named the majority of them. Send the two Pears again when fully grown, when we shall be glad to name them for you. 1. *James Grieve*; 2. *Red Juneating*; 3. *Stirling Castle* (deformed fruit); 4. possibly a local variety; 5. *Bramley's Seedling*; 6. *Hawthornden*; 7. *Tower of Glamis*; 8. not known, possibly a local variety; 9 and 11, not known; 10, *The Queen*; 12, deformed, possibly a local variety; 13, *Lane's Prince Albert*; 14, not known, small and unripe; 15, *Beauty of Kent*; 16, *Golden Spire*.—E. Harden.—*Ecklinville Seedling*.—A. Ince.—The large cooking Apple is, we think, a small sample of *Duchess of Oldenburg*; the small dessert variety is *Golden Harvey*.—X. Z., *Raspberry*.—It is quite impossible for us or anyone else to name a Raspberry from a description such as you furnish. If you will send fruits, carefully packed, we will endeavour to name it for you. —A. E. Speer.—1. *Pear-good's Nonsuch*; 2. *Cumberland Favourite*; 3. *Newton Wonder*; 4 and 8, *Cox's Orange Pippin*; 5, *King of the Pippins*; 6 and 7, *Claygate Pearmain*; 9, *Stamford Pippin*.

## SOCIETIES.

**KIRKCALDY FLORAL AND HORTICULTURAL.** THE annual show of this society, the thirty-first since its establishment, was opened in the grounds of Raith, the seat of Mr. R. C. Munro-Ferguson, M.P., on the 21st ult. The show was an exceptionally good one, particularly in the section for pot plants, where the entries were seventy in excess of those of last year and the quality of the 570 exhibited was higher than ever before. In the cut bloom classes there was also an increase of about 100 entries. Vegetables were also finer than usual, and the classes for nurserymen brought out many fine exhibits. The winner of the Nairn challenge cup for the most successful exhibitor in the vegetable section was Mr. Alex. Grierson, who had sixty-five points, having won no fewer than eighteen first prizes. The principal prizewinners were too numerous to detail, but in the nurserymen's classes they were Messrs. D. and W. Croll, Dundee; Messrs. James Cocker and Sons, Aberdeen; and Messrs. Morgan and Simpson, Monkrie.

## ROYAL HORTICULTURAL SOCIETY.

At the fortnightly meeting held on the 1st inst. there was a good exhibition, but visitors were comparatively scarce. Fruit was well shown by several of our leading growers, and Dahlias formed a bright and prominent feature. Hardy flowers in general were also shown in profusion, the whole making an exhibition of more than ordinary interest.

## ORCHID COMMITTEE.

Present: Mr. Harry J. Veitch (chairman), Messrs. James O'Brien, H. Little, W. Boxall, Stuart H. Low, A. A. McBean, Walter Cobb, J. Charlesworth, W. P. Bound, F. J. Thorne, W. H. White, H. A. Tracey, Gurney Wilson, J. Forster Acock, F. J. Hanbury, W. Bolton and de B. Crawshaw.

Messrs. Stanley and Co., Southgate, London, N., exhibited four plants of interest. These were *Cynoches chlorochilon splendens*, with a large, curiously-shaped green flower, sweetly scented, two plants of *Cattleya Mionia* and a fine specimen of *Cypripedium A. de Lairese*.

From H. S. Goodson, Esq., Fairlawn, Putney (gardener, Mr. G. E. Day), came a pretty little collection, consisting chiefly of *Cattleyas*, *Odontoglossums*, *Cypripediums* and *Miltonias*, the whole being well flowered and staged in excellent form. Silver Flora medal.

The group from Messrs. J. W. Moore, Limited, Rawdon, Leeds, was a most interesting one, many rarely-seen plants being included. *Masdevallia macrura*, *Cypripedium Andromeda*, *Cattleya Aelandie*, *Bulbophyllum godseffianum* and *Coleogyne corrugata* were a few of the most interesting. Silver Banksian medal.

Messrs. Sander and Sons of St. Albans had a pretty little collection of well-grown plants. Some good specimens of *Vanda cœrulea* occupied the centre, the blue flowers being most attractive. *Cattleyas*, *Brasso*-*Cattleyas*, *Cypripediums* and several others of botanical interest were also included, the whole being exceedingly good. Silver Flora medal.

Messrs. Charlesworth and Co., Heaton, Bradford, put up a small group of very fine plants. *Houlletia antiquensis*, *Brasso-Cattleya Heatonense*, *Sophro-Lælio-Cattleya Marathon*, *Cattleya Iris* and *C. Rhoda* being some of the most noticeable. Silver Flora medal.

## FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, George Woodward, Alex. Dean, E. Beckett, John Basham, James Vert, J. Davis, H. Parr, H. Markham, A. R. Allan, John Lyne, G. Reynolds, J. Jaques, J. McIndoe, John Harrison, Owen Thomass, W. Poupard and A. H. Pearson.

Messrs. Cannell and Sons, Swanley, Kent, staged a really superb collection of hardy fruits, these comprising small Apple trees in pots, grown entirely in the open, Plums and Apples, gathered and shown on dishes and in baskets, Raspberries and the Strawberry-Raspberry. The Apples and Plums were particularly well finished and all the best varieties in season were represented. Silver Knightian medal.

An interesting exhibit of Grape Madresfield Court came from Waldorf Astor, Esq., Cliveden Gardens, Taplow, Bucks (gardener, Mr. W. Camm). This consisted of six medium-sized but remarkably well finished bunches, the produce of a single Vine grown in half a paraffin tub. The berries were of good size and shape, and were evidently the result of very intelligent cultivation. Silver Banksian medal.

Messrs. George Bunyard and Co., Royal Nurseries, Maidstone, put up a remarkably fine group of orchard house trees in pots with dishes of hardy fruits now in season. The trees comprised Plums, Pears, Apples and Peaches all to the finest possible condition, and high-class Peaches, Plums, Nuts, Apples, Pears and Nectarines were included in the gathered fruit, the arrangement of the whole being of a most pleasing character. Gold medal.

From the King's Acre Nurseries, Limited, came a beautiful collection of fruit trees in pots, a fan-trained Peach tree of the variety Sea Eagle attracting many visitors. It was carrying an enormous crop of good-sized and well-coloured fruits. Apples, Plums, Grapes, Figs and Pears all added to the interest of this very fine collection. Silver-gilt Hogg medal.

Messrs. John Peed and Son, West Norwood, London, S.E., were exhibiting a good collection of Apples, Pears and Plums on dishes, these being of very good size and moderately well finished. All the best varieties were included, the colour of some being very good. Silver Banksian medal.

Leopold de Rothschild, Esq., Guonersbury Park, Acton, W. (gardener, Mr. G. Reynolds), staged a very fine lot of Pine-apple Queen, and also some excellent dishes of Peaches, Nectarines and Jefferson Plum. The whole of the fruits were in the very pink of condition, and reflected much credit on those responsible for their culture. Silver Hogg medal.

## FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. C. T. Drury, H. B. May, J. Walker, J. Green, J. Hudson, G. Keuthe, Charles Blick, W. Howe, J. Douglas, J. T. Bennett-Poë, R. W. Wallace, W. T. Ware, W. Bain, G. Gordon, A. Turner, H. J. Jones, Charles E. Pearson, W. Cuthbertson, W. P. Thomson, E. H. Jenkins and W. J. James.

Messrs. Kelway and Sons, Langport, had a particularly fine display of *Gladioli*, the collection occupying one of the long tables. It was noticeable that the spikes were much finer than on a former occasion and the flowers more richly coloured, both of which are the obvious outcome of the more genial weather conditions. In a large grouping we take the following as among the best: *Felicity*, creamy white and yellow; *Mrs. J. M. Skittery*, buff yellow; *Leader*,

rosy buff and primrose; and *Happy Match*, scarlet and yellow. Silver-gilt Banksian medal.

Messrs. Baker, Limited, Wolverhampton, had a nice lot of Dahlias, of which the new Peony-flowered varieties were the chief. These were in many beautiful and distinct shades of colour, while their handsome flowers appealed to a large number. Cactus and other forms of the Dahlia were also largely shown. Silver Banksian medal.

Mr. Amos Perry, Hardy Plant Farm, Enfield, had a very showy group of perennials in the cut state, of which *Papaver Mrs. Perry* (a lovely salmon), a beautiful array of *Delphiniums* and *Pyrethrums* from a second flowering, *Asclepias tuberosa*, *Liatris pycnostachya*, *Stokesia cyanea precox*, a fine lot of hybrid *Pentstemons* and other plants were most noticeable. A central grouping of *Lilies* included all the forms of *L. auratum*. Silver-gilt Flora medal.

Messrs. H. B. May and Sons, Edmonton, staged a very fine lot of Tree Carnations in small pots, groups of two or three dozen plants of each variety being shown in excellent flower. *Elizabeth*, scarlet; *Mrs. Brooks*, white; *Coronation*, cerise pink; *Enchantress*, Mrs. Lawson, Mrs. Burnett, Britannia, White Perfection, Fair Maid and others were extra good. Silver Flora medal.

Messrs. R. Wallace and Co., Kilfield Gardens, Colchester, had a lovely lot of the new hybrid *Montbretias* raised at Westwick, the value of which it is not possible to over-estimate. Some of the gems of the group were *Hereward*, clear yellow; *Lady Hamilton*, orange yellow, a very lovely flower and strong grower; *Ernest Davison*, red orange; *Lord Nelson*, a dark-stemmed variety with orange-red flowers; *Klug Edmund*, deep chrome with orange; *St. Butolph*, clear yellow, a refined flower; *Prometheus*, the giant of the race, dark-stemmed and reddish orange crimson-centred flowers, a really grand plant. Messrs. Wallace also displayed hardy plants in variety, *Phloxes*, *Lilies* and *Gladioli*. Silver-gilt Flora medal.

Messrs. William Bull and Sons staged miscellaneous greenhouse plants in variety.

Messrs. Jarman and Co., Chard, had a most delightful gathering of Sweet Sultans in white, mauve, soft and deep yellow and other shades.

Messrs. T. S. Ware, Limited, Feltham, put up a showy group of hardy flowers and alpine, the former including *Lilies*, *Asters* and a large assortment of seasonal things. *Aster Beauty of Colwall* is the new double mauve-flowered variety, and it is interesting to see it quite fixed and good. Silver Banksian medal.

Messrs. Wells and Co., Merstham, filled a long table with a fully representative collection of early-flowering *Chrysanthemums* interspersed with a few *Michaelmas Daisies*. This firm also had *Pentstemons* of a very fine strain, and a select lot of *Phloxes*. Silver Flora medal.

Messrs. James Veitch and Sons, Limited, Chelsea, staged a group of interesting plants such as *Andromeda arborea*, *Rubus bambusarum*, *Aconitum hemsleyanum* (the climbing *Aconite*), *Magnolia parviflora* (white with crimson anthers), the handsome red-fruited *Viburnum rhytidophyllum*, some very handsome specimens of *Buddleias* and other plants. This firm also had a large exhibit of *Asters*, Sweet Peas and a great variety of other annuals, also a select set of ornamental Gourds. Silver Flora medal.

Messrs. J. Cheal and Sons, Crawley, had a few cut shrubs and fruiting examples of the Siberian Crab and others.

Messrs. Watkins and Simpson, Covent Garden, displayed a variety of *Asters*, a very distinct one being the white-flowered *Unicum*.

Messrs. Hugh Low and Co., Enfield, had *Erica tubæformis* (a very beautiful Cape Heath), *Clianthus Dampieri* and *Chironia ixifera*, the latter studded with pink flowers.

Messrs. Barr and Sons, Covent Garden, had a group of hardy flowers, in which *Lillies*, the white *Agapanthus* and many good annuals were displayed.

Messrs. Carter Page and Co., London Wall, filled the end table of the hall with Cactus Dahlias, the very representative gathering being displayed in a bold arrangement throughout. Gold medal.

## OBITUARY.

## MR. WILLIAM MITCHELL.

THIS talented gardener passed away on Saturday, the 22nd ult., after months of suffering from a painful malady. He had occupied the position of head-gardener at Chilworth Manor, Romsey, for over twenty-five years, first under Mrs. Fleming, and in later years under the only son, J. Willis Fleming, Esq., J.P. Mr. Mitchell's ability as a fruit grower, especially of Grapes, is well known to readers of THE GARDEN, he having had many successes at the London, Shrewsbury and principal provincial shows. That he was greatly valued and esteemed by his employer was evinced by that gentleman's solicitude for him during his illness, providing for him the very best advice and all that skill could suggest to mitigate his sufferings. The funeral took place on the 26th ult. at Chilworth Church, the body being enclosed in a polished Oak coffin, and was attended by the widow, the only surviving son, and many relatives and friends, the latter including representatives of the Southampton Royal Horticultural Society, the Romsey Horticultural

Society and gardener friends from all parts of the county; in fact, the *cortège* was so numerous that the church was barely large enough to hold them. Mr. and Mrs. J. W. Fleming attended the service, which was fully choral, and also at the grave-side.

## MR. GEORGE BETHELL.

THE death took place at his residence, The Firs, South Woodford, on the 27th ult. of Mr. George Bethell, who for many years took an active part in the horticultural world, being a Fellow of the Royal Horticultural Society and for thirty-eight years a subscriber to the Gardeners' Royal Benevolent Institution. The deceased was in his seventy-sixth year.

"Country Life" for September 5 contains, among other articles, "Parnham House" (second article); "In the Garden"; "The Parliamentary Journals of Ireland" (illustrated), by Sir Edward Sullivan; "Wild Country Life"; "Goat Farming and Goat Keeping" (illustrated).

**Pea Quite Content.**—The true and original Pea Quite Content, as sent out by Messrs. James Carter and Co., is a maincrop variety, height 6 feet, foliage and pod deep green, pod 7 inches to 7½ inches long, hanging mostly in pairs, and is quite distinct from all other Peas.

We are requested to make this statement, as we are given to understand that a Pea, which has not all the claims of Carter's Quite Content, has been widely distributed this season by others, either by accident or design, thereby causing much correspondence and annoyance to the growers and Messrs. Carter alike. Messrs. Carter's Quite Content was distributed this season in their sealed packets, and has each year been carefully re-selected.

## Reading Horticultural Society.

The report of this interesting exhibition is unavoidably held over until next week.

## TRADE NOTES.

## THE GAYTON RAKE.

We have recently had an opportunity of seeing and testing this most useful tool, and find it of the greatest help in the garden. For stirring the top soil between plants of all descriptions it is most suitable, the prongs being rounded so as not to injure any small roots with which they may come into contact. The tool is strongly made, and may be had either with or without the good ash handle, which is obtainable in two lengths. The rake is made by Messrs. Norton and Co., High Street, Cheltenham, from whom all particulars can be obtained.

## ESTABLISHED FOR 100 YEARS.

MESSRS. J. WEEKS AND CO. of Fernshaw Road, King's Road, Chelsea, inform us that on the 14th inst. they will open new offices at 72, Victoria Street, S.W. As manufacturers of all descriptions of horticultural buildings, and makers of every kind of hot-water heating apparatus, they are the oldest established firm in the trade. Founded in 1808 they have carried on business at Chelsea for exactly 100 years, and their trade connexion and reputation for good work extends throughout Great Britain, Ireland, the Colonies and the Continent of Europe. Weeks's "Duplex" Upright Tubular Boilers have been supplied for heating glass houses in almost every garden of note throughout the kingdom, also a great number of public buildings, churches, schools, &c., including such well-known buildings as the South Kensington Museum, Canterbury Cathedral, Netley Hospital, &c. Under new management the business has been brought thoroughly up to date.

## SCHEDULES RECEIVED.

North Middlesex Dahlia and Horticultural Society. Exhibition at Alexandra Palace on the 10th and 11th inst. Hon. secretary, Mr. J. H. Crossley, Clarendon Road, Hornsey.

London Dahlia Union. Exhibition, September 10 and 11, at the Royal Botanic Gardens, Regent's Park, N.W. Hon. secretary, Mr. E. F. Hawes, at above address.

## QUESTION.

ROWAN TREE BERRIES AND THEIR USE.—I have a fair number of Mountain Ash or Rowan Tree (*Pyrus aucuparia*) berries nearly ripe. There is a common prejudice that they are poisonous, but I am of opinion this is not so. I shall be much obliged if you will advise me as to this, and also, if you can, give me a recipe for preserving or pickling the fruit.—W. HORSFALL VINT, Willow Field, Idle, Bradford, Yorks.

\*. The Yearly Subscription to THE GARDEN is: Inland, 6s. 6d.; Foreign, 8s. 9d.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## PHOTOGRAPHIC COMPETITION FOR OUR READERS

WE frequently receive photographs from our readers of some pretty spot or corner in their gardens, and it has occurred to us that it would be interesting if prizes were offered for the best examples sent in. We therefore offer a first prize of two guineas for the best photograph of a reader's garden, and a second prize of one guinea. Each photograph must be accompanied by a written description of the garden. Photographs must be sent addressed to "The Editor, 20, Tavistock Street, Covent Garden, London, W.C.," on or before October 31, and the envelope or wrapper must be marked on the outside "Photographic Competition," and accompanied by a coupon, which appears in the advertisement pages. Each photograph must have the sender's name and address plainly written on the back. Rejected photographs will be returned if stamps are enclosed for postage. The Editor reserves the right to use any photograph and description that does not win a prize, and his decision must be regarded as final.

## AUTUMN - FLOWERING ROSES.

(First Prize Essay.)

ROSARIANS were never placed under a greater obligation to the raisers of Roses than when they introduced the race of modern autumn-flowering sorts. True, the old Chinas and Bourbons, together with the so-called Hybrid Perpetuals and the hardier Teas, had done their best to brighten our gardens as the days shortened and the summer flowers departed. But at its best the display was only a feeble effort compared with the glories of June and July, and more calculated to emphasise its own poverty by giving the occasional bloom in contrast with its former abundance.

It was the advent of the race of Hybrid Teas, and the introduction of freer-blooming and more vigorous Teas, that has made a September show of the National Rose Society, instead of the dream of an enthusiast, a glorious reality. Personally, I believe I find a keener enjoyment in my Rose garden in the autumn of the year than in the garish days of summer. The blooms open more slowly, are deeper in colour, richer in perfume and of more lasting properties than those that unfold their petals to the hot bleaching suns of summer.

### CULTIVATION.

It will be readily understood that if a plant is called upon to give a succession of blooms over a lengthy period it must be lovingly tended and

liberally treated. Deep cultivation of the soil is one of the first and most important requirements. If the roots cannot find a cool and moist run during the drought and heat of summer they cannot sustain the strain of continuous flowering, therefore dig deeply and incorporate plenty of rich farmyard manure with the bottom spit. A little artificial in the shape of quarter-inch bones or bone-meal is also a great help.

Another important point to be observed is to remove all spent blooms as speedily as possible, and in cutting them to take a fair length of the flowering stem, but at the same time taking care not to cut low enough to start the basal buds into growth. These lower buds are those from which the shoots for next year will emanate, and it is most desirable to have the early-formed and well-ripened wood to prune back to than that grown later in the year, hence the need for exercising judgment and care in cutting the blooms. Constant stirring of the surface of the Rose bed is also an immense aid to healthy and vigorous growth. It not only aerates the soil, but prevents evaporation, and thus conserves the moisture, a most desirable thing, especially so in a hot, dry summer such as we have just passed through. It is also advisable to give a liberal top-dressing of well-decayed farmyard manure in the spring, immediately after pruning. This may be lightly forked in, taking care not to disturb the roots when so doing. When time cannot be spared for almost daily hoeing between the plants (using a Sproughton hoe for preference) the manure may remain on the surface all the summer, making an effectual mulch and supplying nourishment to the roots after each shower of rain. This may be supplemented with applications of liquid animal or artificial manure at intervals during the season, for the former using that from sheep, horse or cow, the last-named being most suitable for light soils. Soot water is also most beneficial, heightening the colour of both foliage and flower, while Tonk's Manure or Clay's Fertilizer used at the rate of one ounce to the gallon, or sulphate of ammonia at the rate of half an ounce per gallon of water acts as a capital stimulant. These applications should only be made when the soil is thoroughly moist, and not oftener than once a week or fortnight. We now come to the most important question of

### THE BEST VARIETIES

to be grown to provide a really good autumnal display. Varieties have increased so rapidly of recent years that it is needful to exercise a wise discrimination in making a selection. I have therefore endeavoured in the following list to include only those sorts that from practical experience I have found to give the best results, and which are, in my opinion, the pick of their colour for freedom of blooming and habit of growth. First, as to

*Climbing Roses.* In this class there is still plenty of scope for the art of the hybridiser, and a fortune awaits the lucky man who first introduces a perpetual-flowering Dorothy Perkins, Lady Gay or Hiawatha and, shall we say, our old friend Crimson Rambler. Up to the present the best autumn bloomers are: Grüss an Teplitz, bright crimson, sweetly perfumed (a semi-climber, also good as a bush or standard). Alister Stella

Gray, pale yellow. Gloire de Dijon, buff or salmon yellow; will thrive and bloom almost anywhere. Rêve d'Or, buff yellow; blooms freely in the autumn on established plants and when growth is not unduly restricted. Climbing Aimée Vibert, pure white. Climbing Mrs. W. J. Grant, imperial pink; a grand variety. Climbing Caroline Testout, salmon pink; as sterling a variety as the dwarf form from which it sprouted. Bardou Job, glowing crimson, very lovely colour; but only a moderate climber, semi-double. Longworth Rambler, light crimson. Mme. Alfred Carrière, white with yellow base; very hardy. Trier, creamy white; the best autumn-flowering climbing Polyantha. When we come to the question of Roses most suitable for bedding, continuity of blooming is of paramount importance. A good selection of dwarf habit would be: Marquise de Salisbury, bright crimson. Ecarlate, scarlet; a magnificent new variety. Mme. Pernet-Ducher, canary yellow. Cecile Brunner, blush, shaded pale pink; one of the best bedding Polyanthas. Mrs. W. Cutbush, bright pink, flowering in clusters. Baby Dorothy, somewhat similar in colour to the well-known Dorothy Perkins, of which it is a dwarf form; of perpetual-flowering properties. Camoens, an old favourite of glowing crimson colour, yellow at base of petal. Mme. Jules Grolez, bright China rose. G. Nabonnand, pale flesh, shaded rose; one of the very best, but of taller growth than the preceding. Warrior, blood red, opening to scarlet-crimson; a new variety of sterling merit.

To make a selection of the best dozen or so for general garden purposes is no easy matter out of the number now on the market. The following, however, would be sure to please, and being very vigorous would thrive in almost any garden:

*Hybrid Perpetuals*.—Frau Karl Druschki, pure white. Hugh Dickson, crimson, shaded scarlet. Mrs. John Laing, rosy pink.

*Hybrid Teas*.—Caroline Testout, light salmon pink. Mrs. W. J. Grant, bright rosy pink. J. B. Clark, deep scarlet, shaded dark crimson; blooms well in autumn if lightly pruned. La Tosca, salmon blush. Mme. Abel Chatenay, carmine rose, shaded salmon. Mme. Ravary, beautiful orange yellow. Lyon Rose, shrimp pink at edge of petals, centre of flower intense coral red, shaded chrome yellow; one of the best Roses ever introduced. Florence Pemberton, creamy white, tinted pink. Killarney, flesh, shaded white, flushed pale pink; a beautiful variety but addicted to mildew. Countess of Gosford, clear salmon pink, base of petals suffused saffron yellow. Betty, coppery yellow, overspread with golden rose. Joseph Hill, pale salmon pink, shaded yellow, outside of petals coppery yellow. C. J. Graham, dazzling orange crimson. Dean Hole, silvery carmine, shaded salmon.

*Teas*.—Marie van Houtte, lemon yellow, edged with rose. Maman Cochet, deep flesh, outer petals suffused light rose. White Maman Cochet, the white, or, more correctly, creamy white form of above. Mme. Jules Gravereaux, buff white, shaded peach or yellow; splendid for pegging down, or makes a good climber. Mme. Constant Soupert, dark golden yellow, tinted peach pink; fine. Mme. Hoste, lemon yellow. Lady Roberts, rich apricot, base of petals coppery red, edges shaded orange.

Mildew and thrips are often troublesome in late summer and autumn. For the former I find nothing better than Mo-Efic, used according to the directions, and for the latter (which is a pest in dry weather) syringing. W. B. PRICE.

#### FORTHCOMING EVENT.

September 17.—Autumn Rose Show, 1—6 p.m. Royal Horticultural Society's tickets admit. Royal Horticultural Hall, Vincent Square, Westminster.

## PRIZES FOR READERS.

### AUGUST COMPETITION.—AWARDS.

In this competition the prizes were offered for the best essays on "The Best Roses for Autumn Flowering." This proved a most interesting competition, and we received a large number of essays that were both practical and interesting. After most careful consideration the adjudicators have allotted the prizes as follow:

First prize of four guineas to B. W. Price, Trelawney, Podsmend Road, Gloucester.

Second prize of two guineas to Walter Bentley, Field End, Eastcote, Middlesex.

Third prize of one guinea to C. W. Caulfield, Bridgen House, Park Crescent, Erith.

Fourth prize of half-a-guinea to Arthur W. Panton, B.A., Greenmount, Clontarf, County Dublin.

The essays from the following are highly commended: John J. Burton, A. D. Cooper, Thomas Alexander, Miss J. M. Hopkinson, R. M. Munro, Edwin Howes, W. P. Wood and A. M. Durling.

Many of the competitors treated the subject in a too complete manner; that is, they went through the whole routine of cultivation from spring onwards. The competition was designed to show what could be done in the way of summer cultivation to induce an autumnal display. Many competitors appeared to have drawn their replies too glaringly from the books on the Rose published by various authors rather than from their own experience.

## NOTES OF THE WEEK.

**Nurserymen and seedmen's conference.**—The Horticultural Trades' Association of Great Britain and Ireland has just completed its annual congress, the meeting taking place this year in London. The gathering was a record one as regards numbers, over 100 leading members of the nursery and seed trades attending from all parts of the United Kingdom. The three days allotted were devoted to excursions round London, and the evenings to business meetings and the discussion of topics of trade interest. Among the nurseries visited were those of Messrs. Hugh Low and Co., Enfield; Paul and Son, Cheshunt; W. Paul and Son, Waltham Cross; Thomas Rochford and Son, Limited, Turnford; and James Veitch and Son, Limited, Coombe Wood. The generous hospitality shown by the proprietors to the visitors added much to the pleasure of the outing, which was marred only by the miserable weather experienced the last day.

**The Royal Horticultural Society and a colour chart.**—The council of the Royal Horticultural Society have long felt the need of a chart for the international standardisation of colours, but the huge expense of producing it has hitherto deterred them from issuing it. Not long since a most admirable chart, containing more than 1,450 shades of colour between white and black, was published in France at the instance of the French Chrysanthemum Society, the price in England being £1 ls. net, and by it it is now possible to recognise or describe to a friend or purchaser at a distance the precise colour of any possible flower. The cost of this chart has been somewhat prohibitive in the past, but by undertaking to be responsible for the disposal of a large number, the society is now in a position to offer this chart to its Fellows at the reduced cost of 14s. 6d., for which price it can be obtained at the society's offices, Vincent Square, Westminster, or it can be sent free by post for 15s.; but in all cases a cheque or postal order must be sent beforehand.

**Prizes for bulbs grown in moss fibre.**—Mr. Robert Sydenham has offered, and the council of the Royal Horticultural Society have accepted, the following prizes to be competed

for on March 9, 1909. N.B.—For bulbs grown in moss fibre or similar material (not earth) and without drainage. (a) Six single Hyacinths, in separate vases, not to exceed 6 inches in diameter, to be selected from any of the following twelve varieties: Balfour, General Vetter, Grand Lilas, Grand Maître, Innocence, Isabella, Jaques, Johan, Koh-i-noor, King of the Blues, La Grandesse and Roi des Belges. Prizes, 25s., 21s., 15s., 10s., 7s. 6d. (b) Six vases of Tulips, in vases not to exceed 7 inches, but no restriction as to the number of bulbs in a vase, to be selected from the following varieties: Duchess de Parma, Dusart, Pabiola, Joost Van Vondel, Keizerskroon, M. Trésor, Prince of Austria, Rose Gris de Lin, Thomas Moore, Van de Neer, Vermilion Brilliant and White Pottebakker. Prizes, 25s., 21s., 15s., 10s., 7s. 6d. (c) Six vases of Narcissi, in vases not to exceed 7 inches in diameter, but no restriction as to the number of bulbs in a vase, to be selected from the following varieties: Barri conspicuus, Campenelle rugulosus, C. J. Backhouse, Emperor, Frank Miles, Lulworth, Leonie, Mme. de Graaff, Phyllis, Sir Watkin, Victoria and Waterwitch. Prizes, 25s., 21s., 15s., 10s., 7s. 6d.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**The Royal Horticultural Society's classification of Daffodils.**—The little book just published containing a classified list of Daffodil names drawn up by a committee appointed by the Royal Horticultural Society, contains the names of some 2,200 Daffodils, most of which are classified. The old order of classification into Magni, Medio and Parvi-Coronati, with their subdivisions, is all changed, and we now have: 1, Long trumpets; 2, short trumpets; 3, large cups; 4, small cups; 5, flat cups; 6, doubles; 7, bunch-flowered. The long trumpets are, of course, the old Magni; then comes a new class called short trumpets, and I must say it gave me rather a shock to see such varieties as Lady Margaret Boscawen and White Queen classed as trumpets. To call White Queen a trumpet, even a short trumpet, seems to upset all one's ideas about classification. There are large cups and small cups, but there is no separate class for the Poeticus, so they will be shown in the same class as other small cups, such as the Burbidgei. This seems a great pity, and is sure to make judging difficult. Then comes the flat cups. Why flat cups? Surely a cup if it were flat should be called something else! The doubles, Class 6, should be easy, including such flowers as Argent, and, presumably, all flowers with any pretensions to doubling. The double bunch-flowered varieties, such as Jonquilla flore-pleo, come under this class. Last of all come the bunch-flowered, Class 7, and in this are included Biflorus, Tridymus, Jonquilla, Tazetta, Odorus and the new Poetaz varieties. Triandrus, too, comes under this class, so it includes, one would suppose, every variety which habitually throws more than one flower on each stem. We may expect to see some curious exhibits in Class 7. The new list will be indispensable to exhibitors at shows where the classification has been adopted, and as the Midland Daffodil Society has adopted it, we may expect other societies to follow suit. I must say it seems most complete. I even see the name of one of my seedlings, one flower, once shown, but too good for this wicked world. When I came to lift S 24, otherwise Olwen, what had been a bulb was a bulb no more. (Curiously enough it was the only one that had rotted off out of some eighty seedlings marked for lifting.) To show the necessity for a recognised classification I give one instance of the state things had got to: An exhibitor is disqualified after being awarded first in a class for Parvi, because his exhibit contained flowers one thirty-second of an inch too long in

the cup, according to measurements which he had no means of knowing were those accepted as authoritative, these flowers being undoubtedly Parvi, according to the definition given in Bourne's "Book of the Daffodil" and in "The Narcissus: Its History and Culture," by Burbidge and Baker, the leading authorities on the subject. The exhibit placed first and other exhibits in the show contained flowers which, according to the same measurements, were open to disqualification, but were evidently not subjected to the measure test. When things had got to this state it was high time for something to be done, and I am sure we all welcome the attempt to evolve order out of what was fast becoming a hopeless chaos, but at the same time I think the classification could have been made according to the old groups, so familiar to all of us and universally understood and accepted.—W. A. WATTS.

**Lilium auratum in a back garden.**—I am sending a few particulars re the accompanying photograph of *Lilium auratum*, which I think you will agree is rather a fine one, especially as it was grown in a small back garden measuring 16 feet by 40 feet. The plant has had twenty-two blooms, some of which had been cut when the photograph was taken. The buds were  $5\frac{1}{2}$  inches long. Last year it was grown in a pot, and when it had done flowering was planted out in the ground, where it has been ever since. We attribute the quantity and size of the blooms to the fact that last year we only allowed three buds to open. While admitting it is nothing out of the way for house culture, we think it is good for a small back garden.—J. JAMES, Enfield Wash.

## NEW PLANTS.

**ILEX PERRYI.**—A new and distinct species of Holly from China. The plant exhibited was little more than 2 feet in height, hushy, compact and forming a perfect pyramid. The leaves are small, glossy green, and quite unlike any other species known to cultivators. We think very highly of the new-comer, which should prove of great value in the garden. Shown by Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

**Gladiolus Golden Measure.**—A valuable addition to the yellow-flowered section, and a good and vigorous variety withal. Award of merit.

**Gladiolus White Cloud.**—The large and handsome flowers of this variety are of an ivory white tone and well disposed in a compactly-formed spike. Award of merit. Both were shown by Messrs. Kelway and Son, Langport.

**Dahlia Marathon.**—A Cactus variety with a flower of unusual size, well formed and coloured a rosy fawn. The base of the florets is yellow and the tips of a golden hue. Shown by Messrs. J. Stredwick and Son, St. Leonards. Award of merit.

**Dahlia Tom Jones.**—A show variety. This type of Dahlia still appeals strongly to the florist. The variety is a very attractive one, the florets being edged and suffused rose-pink on a creamy yellow ground. Shown by Mr. S. Mortimer, Farnham, Surrey. Award of merit.

**Tritonia (Montbretia) Norrie.**—A showy and good novelty, dwarf growing and free flowering, with much-branched and dark-coloured stems. The colour is yellow, much stained with reddish orange. Award of merit.

**Tritonia (Montbretia) Hereward.**—Another novelty of sterling merit, with palest orange-coloured, widely-opened flowers 3 inches across; free and late in flowering. Award of merit. Both were shown by Major Petre, Westwick, Norwich (gardener, Mr. Davison).

**Kniphofia R. Wilson Kerr.**—A tall-growing and handsome variety with attenuated inflorescences of reddish scarlet flowers. From Messrs. R. W. Wallace and Co., Colchester. Award of merit.

**Phlox General Von Lassberg.**—If we regard this from the standpoint of purity and size of

flower individually, we say at once that it is the finest pure white herbaceous Phlox we have seen. The variety attains to 3 feet high, and when well grown should prove a grand addition. Award of merit.

**Phlox Violet.**—The name here given is suggestive of the colour of this showy and distinct sort, which is the deepest we have yet seen. Award of merit. Both were exhibited by Messrs. Gunn and Sons, Olton.

**Gladiolus primulinus hybrids.**—A charming new and beautiful race, with somewhat small spikes of hooded flowers, which are singularly novel and artistic-looking in their present form. There are varying shades of yellow, primrose and rose and pink, and these are occasionally combined in one flower. Shown by Messrs. R. W. Wallace and Co., Colchester. Award of merit.

**Pteris aquilina Nicholsonii.**—An elegant-looking variety of the well-known Bracken hailing from New Zealand, and probably only hardy in the open in the more favoured parts of Britain. The variety is very distinct from the typical form

Trevor Lawrence, Bart., Burford, Dorking (gardener, Mr. White). Award of merit.

**Cattleya Rhoda.**—This is one of the prettiest Cattleyas we have seen for a long time, and a mere description cannot do it justice. The sepals are lanceolate, long, and of a rich crimson apricot colour. The petals are ovate-lanceolate, partly twisted, and of a somewhat lighter colour than the sepals. In addition they have a distinct edging of delicate primrose colouring. The labellum is very curiously shaped; it is nearly flat and extends abruptly about two-thirds up from the base, thus forming a reniform sort of fan. At the base, in what would ordinarily be the throat, the colour is a mixture of very rich yellow and crimson, but on the broader portion it is rich carmine, daintily edged with pale primrose. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

**Brasso-Cattleya Mme. Charles Maron, Sander's variety.**—This is a large flower with a long and unwieldy name, which it does not deserve, as the bloom itself is very refined. The long, narrow

A GOOD CLUMP OF THE GOLDEN-RAYED LILY (*LILIAM AURATUM*) GROWN IN A SMALL BACK GARDEN.

we know so well. Exhibited by Messrs. H. B. May and Sons, Edmonton. Award of merit.

**Sophrro-Labio-Cattleya Danc superba.**—This is a very pretty Orchid of a mixed parentage, no less than three genera being employed in its production. In form the flower is midway between a *Laelia* and a *Cattleya*, the sepals and petals being a lovely mixture of dull purple and apricot. The labellum is of medium size, with a bright purple edge and a very rich lemon-coloured throat, the whole making a very handsome flower. Shown by Lieutenant-Colonel Holford, C.I.E., C.V.O., Westonbirt, Tetbury, Gloucester (gardener, Mr. H. G. Alexander). Award of merit.

**Catasetum russellianum.**—A curious addition to this interesting family of Orchids. The flowers are borne rather closely on a pendulous raceme and are of medium size. In colour they are a greenish white, with thin green venation over the whole flower. The plant exhibited was in a 3-inch pot, and carried one raceme composed of twelve fully-developed flowers. Shown by Sir

sepals are bluntly pointed and somewhat reflexed at the edges, the sepals being very much broader and slightly crenated. The labellum is quite characteristic of the family, it being very large, broad and highly fimbriated. The colour of the whole flower, with the exception of the throat of the labellum and at the extreme base of the segments, which are primrose, is bright lilac purple. Shown by Messrs. Sander and Son, St. Albans. First-class certificate.

**Labio-Cattleya Elva St. Vincent.**—A very pretty flower of rich yet refined colouring. The sepals and petals are of the usual bright rosy mauve colouring, but the labellum is most distinct. As the ground colour is very deep rich purple, this being relieved by two large dots of pale and deep yellow hues situated at each side of the entrance to the throat, these give the flower a most striking appearance. Shown by H. S. Goodson, Esq., Fairlawn, Putney. Award of merit.

All the above were shown before the Royal Horticultural Society on the 1st inst., when the awards were made.

## TREES AND SHRUBS.

## FLOWERING SHRUBS IN JULY.

(Continued from page 409.)

**C**YTISUS nigricans is one of the most showy of the whole family, in addition to the success with which it can be transplanted. It makes a well-shaped, round-headed bush and produces a very large number of flower-spikes, each in turn carrying fully 100 bright yellow flowers; in fact, on some spikes I have counted almost 200 blossoms. This shrub is very seldom met with, but attracts universal attention when seen at its best, and only needs to have the flower-stems removed when they are over to keep it shapely.

The Genistas are closely allied to the Cytisus, and all have yellow flowers. One of the most striking is *G. aetnensis*, which makes a tall, elegant specimen with very slender, pendulous branches, and flowers freely in a young state. *G. tinctoria* has upright stems about 2½ feet in height, and makes a good subject for planting in a mass on account of its even growth. It is often improved and invigorated by being cut clean to the ground. For the front of the shrubbery there are several very ornamental sorts, especially noticeable being *G. sagittalis*, *G. pilosa*, *G. prostrata* and *G. cinerea*. Perhaps the most showy of all summer-flowering shrubs with yellow flowers is *Spartium junceum*, which deserves a place in all gardens. In addition to the fine display produced in the open, it is also most useful for all kinds of cut-flower work. It will thrive in almost any soil, even of the poorest description, and only requires the Rush-like growths cut back after flowering. To prolong the flowering season, however, it is a good plan to prune back one specimen into the old wood annually.

Another highly ornamental member of the Leguminosæ is *Hedysarum multijugum*, from Southern Mongolia, which is perfectly hardy, but the shoots die back and a profusion of young growth is made, which carries numerous racemes of rosy purple flowers. It looks extremely pretty if the slender stems are tied up to a neat stake.

The Hypericum family comprises many pretty yellow-flowered shrubs, and a selection of the best should always be included. They are all of small or medium-sized growth, neat in appearance and require little attention. *H. androsæmum* is one of the largest growers, and the flowers are succeeded by showy black fruits. *H. inodorum*, *H. elatum*, *H. hookerianum* and *H. prolificum* all make good-sized bushes, which make new stems freely and are improved by having the older ones removed when this appears necessary. The smaller-growing Hypericums are exceptionally pretty and vary much in appearance. *H. aureum*, *H. galioides*, *H. kalmianum*, *H. densiflorum* and *H. Coris* are among the best. *H. moserianum tricolor* is one of the most pleasing of all variegated shrubs, being a charming combination of green, yellow and red. It is a small grower and should be given a well-drained position.

Hardy Fuchsias are common in the warmer parts of the country, but their cultivation might well be extended, for, though they die back to the ground annually, this need be no deterrent. We have grown beds of them for many years, and a very charming display they make if one has room, otherwise single specimens in the shrubbery are very ornamental. I believe there are now some thirty or forty hardy varieties, but can only speak of those which have proved a success with us. *F. Riccartonii*, one of the oldest, is a delightful shrub, and probably the hardest of all, *F. macrostemma*, has long, slender, red blossoms produced with great freedom on pendulous branches. *F. Thomsonii* and *F. corallina* should also be included. A. E. T.

(To be continued.)

## THE FRUIT GARDEN.

## THE ROOT-PRUNING OF FRUIT TREES.

**I**N the culture of hardy fruits there is no operation capable of producing such good results as root-pruning when the task is intelligently and properly carried out, but where the work is performed in a haphazard manner much more harm than good is frequently done. At the outset it may be as well to briefly consider what root-pruning is and for what purpose it is adopted. The operation itself merely consists of shortening back all large, straight roots which have a tendency to go downwards in the soil, but the object of the work will need more explanation. It frequently happens that when young fruit trees have been planted a year or two they commence to grow at a tremendous rate, shoots several feet long being produced in one season. This may at first seem very satisfactory, but when the owner looks year after year in vain for flowers and the subsequent fruit he is inclined to think, and rightly so, that something is wrong. What is happening in such a case is that the tree is devoting the whole of its energies to the formation of wood, and no fruit is the result. It is in such instances that root-pruning is required, the idea being to give the tree a check and thus induce it to form less wood and more flowers.

The best time to carry out the work is the end of September, and it does not matter in the least whether the leaves have fallen from the tree at that date or not. In the case of trees of manageable size, say, those which have been planted three years, it frequently happens that lifting them and replanting them immediately will suffice, the breaking of a certain number of roots in the operation being a sufficient check. With older and better established specimens, however, the above system will not answer, and more elaborate methods have to be adopted. The general practice is to measure a half-circle round the stem of the tree and some distance away. The distance will vary according to the size of the specimen being dealt with, but a good general rule is to make the line one-third the distance from the stem as the tree is high. Thus if a tree is 9 feet high the half-circle line should be made 3 feet from the stem, or in similar proportion. The idea of only going half-way round the tree at one operation is that this will probably prove sufficient to bring the tree into bearing; if not, the other half is done two years hence.

A trench 12 inches to 18 inches wide is next taken out to a depth of 1 foot or more so as to reach all the large roots, these being severed close to the inner side of the trench. A sharp knife must be employed, and the cut should be made from below in an upward yet sloping outwards direction. When 12 inches or 18 inches down it is a good plan to tunnel under the mass of soil and roots towards the bole of the tree, severing all large roots encountered in the course of the work. This tunnelling is probably of more benefit than anything else, as the roots found thus are usually those which take a straight downward course.

To fill up the trench will be the next task, and this requires some care. Where it is easily procured good fibrous loam of a rather heavy character is best, and if Plum, Cherry or other stone fruit trees are being dealt with, the addition of some old mortar, or lime in some other form, will be highly beneficial. The tunnel under the ball of soil and roots must first be filled in, taking care not to leave any hollow spaces and making the new soil firm, then fill in the trench, and make this firm also, so that the new roots which penetrate shall have an opportunity of becoming fibrous.

Many amateurs, and even some professionals, expect to see a good crop of flowers and fruits

the spring and summer following the root-pruning and as a result of the work. This is quite impossible, because any flowers to open next spring are already formed in the bud, hence it is obvious that the operation can have no influence over the crop the summer following the autumn in which the work was carried out. Growth should, however, be less vigorous, and a tree root-pruned in the autumn of this year should, as a result, produce flowers and fruits in 1910.

## A NEW EARLY DESSERT APPLE.

(FELTHAM BEAUTY.)

A GOOD new early dessert Apple is sure of a hearty welcome, as we have none too many which can be included among the very early varieties. Feltham Beauty is stated to be the result of a cross between Mr. Gladstone and Cox's Orange Pippin, two excellent parents as all hardy fruit growers will know. The fruits as shown were rather larger than the average of either of the parents, the colour being deep yellow heavily striped red. The flesh is yellow, moderately firm and crisp, and of a pleasing brisk flavour. Evidently the fruits are in season immediately Mr. Gladstone is over, thus partaking more of this parent than of Cox's Orange Pippin, so far as period of ripening is concerned. The tree is said to possess a vigorous, erect habit, and the variety will, we think, be largely grown in a few years hence. The fruits were shown by Messrs. J. Veitch and Sons, Limited, Chelsea, before the Royal Horticultural Society on the 18th ult., and received an award of merit.

## THE KITCHEN GARDEN.

## SUTTON'S EVERGREEN DWARF BEAN.

**H**AVING grown this excellent Bean for the past three seasons, I am most favourably impressed with it, and consider the variety to be one of the very best that can be grown. The habit of the plant is very dwarf, and the pods are produced abundantly; and if these are gathered as fast as they are ready, the plants will continue to bear during an exceptionally long period. Sown on the same date as the well-known Canadian Wonder, pods were gathered five days before those from the latter variety were ready. I have not personally any experience with this Bean for forcing, but am told by friends who have tried it that it is one of the best for this purpose, making a good succession to that well-known and excellent Bean Sutton's Forcing. Pods of the Evergreen Bean are perhaps hardly large enough from the exhibitor's point of view, but for home consumption, especially for growers with small gardens, it would be difficult to beat, if, indeed, it can be equalled.

Munden Gardens, Watford.

C. RUSE.

## PARSLEY FOR WINTER USE.

MANY persons fail to grow Parsley satisfactorily during the winter months. It is generally rather scarce at that time, and so nice clean leaves are highly appreciated. But Parsley will not always grow freely in some soils; the young seedlings canker and die. In quite another part of the garden the plants will often thrive well, so it is a good plan to transplant some of the best seedlings to various quarters in the same garden during the month of September. A few rows of plants should be in partial shade, while others are in the open; then if one batch fails to grow the other might succeed. The young seedlings should be lifted with the aid of a trowel or hand-fork from different parts of the rows without disturbing the roots of those left. Avon.

## COLOURED PLATE.

PLATE 1356.

### THREE INTERESTING DAFFODILS.

**L**ORD ROBERTS.—This handsome trumpet Daffodil was raised in the Surbiton nurseries of Messrs. Barr and Sons a few years ago, and was the result of a cross between Weardale Perfection and Monarch. The flowers are of enormous size when well grown, with a broad, massive perianth and a noble trumpet. The colour is golden yellow. The plant makes a strong, vigorous growth and attains a height of 23 inches. First-class certificates were awarded to this flower in 1901 by the Royal Horticultural Society, the Midland Daffodil Society and the Cornwall Daffodil Society. At Plymouth in 1905 it also received a first-class certificate.

*Calpurnia*.—This is another new seedling Daffodil which was raised in 1903 at Surbiton, and has been very much admired wherever exhibited. The flower has a white campanulate perianth and a long, straight trumpet of a soft primrose shade; it is a beautiful flower.

*Loveliness*.—This is a seedling raised from the well-known Daffodil Mme. de Graaff, and after Peter Barr was one of the first new seedlings exhibited of the solid white trumpet Daffodils. The flower is of remarkable beauty, having a bold, stiff, snowy white perianth, broad and smooth, and a very elegant white trumpet expanding at the mouth. At the Midland Daffodil Society in 1903 it was given an award of merit, and again at Truro in 1906.

## THE ROSE GARDEN.

### NEW ROSES.

**A** LETTER just to hand from a reader of THE GARDEN asks that the notes I have contributed to your columns dealing with newer Roses for some years past should be published forthwith, giving as his reason for the request that most Rose amateurs order their plants in October, and thus could have the benefit of my experience when so doing. "Had you written before October last year, I would not have ordered some plants that I did and would have ordered other plants that I did not." As there is much force in his remarks I comply with pleasure with his request. At the same time, I must point out that my notes on these new Roses are simply the result of my growing them, often for only twelve months, in my garden, and it does not necessarily follow that because a particular Rose has done well or badly with me it will behave in a precisely similar fashion

somewhere else, possibly 100 miles away, with a different soil, atmosphere, aspect and all the other "matters and things" that affect for good or evil a Rose plant.

It is curious how much seems to depend on these "matters and things." How often one comes across examples of a Rose that does well in your garden, yet positively refuses to grow at all in the garden of a friend whom you know to be possibly a better Rose grower than yourself! I could give many instances, but one will suffice; Betty, for instance. Now I have had Betty in my garden ever since she was obtainable—some three or four years—and, be the reason what it may, I can always grow Betty well. Perhaps it is because I have always spoken well of her that she treats me so kindly; but there are not many Roses that flower like Betty. I cut five good blooms of this Rose from two plants last Christmas Day, and two more flowers subsequently opened on New Year's Day. Those two identical plants were in flower again before June 1, or five months later. I cut a flower in May, so that only left February, March and April out of the whole twelve months that I did not have a

record one. And a record one it has turned out, although not quite in the direction I anticipated. I never remember having so many flowers, such grand colour and perfect shape, but so short lived, here to-day and gone to-morrow would give the majority too long a life, it was more often a case of fine before seven gone before eleven. The season was a curious one in many respects, promising at one time to be very late; the powerful sun of the last week in June turned it into a very early one, and the majority of the flowers, especially those varieties with three or four rows of petals, never had a chance to grow, all of which will have to be borne in mind in consulting Mr. Mawley's analysis, which we all look forward to in October, for Roses like Killarney, Captain Hayward and Betty never had an opportunity, one was afraid to stage them, and so they were left at home. Apart from the exhibition point of view, it must be a good many years since we had such a tremendous quantity of flowers. The aftermath or mid-season has suffered in consequence and so will our autumn display; but the grand rain which is coming down steadily while I write

will help considerably. With me the season has been entirely satisfactory—I have never had better flowers. The plants have made wonderful growth notwithstanding a rather bad attack of mildew, and the new Roses have had an exceptional opportunity to show us what they can do. Some of the old favourites for that matter have taken a new lease of life, practically as well as figuratively, and many a Rose that was marked for the bonfire or the churchyard or a neighbour's

A NEW EARLY DESSERT APPLE, FELTHAM BEAUTY, SHOWN BY MESSRS. J. VEITCH AND SONS, LIMITED.  
(Slightly reduced.)

flower off Betty. This I consider a record for Roses growing out of doors. I admit that, practically, January and May should be added; but (last year only, mind!) I did, as a matter of fact, have flowers on these particular plants of Betty for nine months out of the twelve. My plants are flourishing, 3 feet high and as much through; yet I came across, in a garden of a friend, some miserable plants, and on enquiring what they were I was told, "That's what I wanted to show you! That's your friend Betty! No earthly use!" I told him to burn them and have another try, and he did; but the result was not very much better. Yet he can grow Roses better than I can.

I cannot grow Mildred Grant, yet it apparently is not a difficult Rose to grow, judging from the number one sees exhibited. I have never perhaps grown it in sufficient numbers; it is evidently a Rose that you must grow by the dozen or the score, and I have no room for luxury of that kind. No, we all have a Rose or Roses that do well with us, be it a Betty, a Bessie or a Mildred, and equally we have Roses that do not do well, so that a word in season on this point will not, I hope, be thought out of place.

Talking about the season reminds me that last time I wrote was on the "Prospects of the Rose Season of 1908," and writing in early June I ventured to prophesy that the season would be a

garden has been saved that fate by its performance in 1908.

Purley.

HERBERT E. MOLYNEUX.

(To be continued.)

### PRUNING RAMBLER ROSES.

Now that the majority of the ramblers have passed out of flower no time should be lost before the pruning is completed. Attention to this matter promotes tidiness, and also by removing the old flowering wood light and air is admitted to the young shoots, thereby producing a condition favourable to the thorough ripening of the wood, and consequently a good crop of flowers the ensuing season. C. RUSE.

### ROSE BARONNE PISTON DE ST. CYR.

THERE is something extremely dainty about this charming monthly Rose. It is the nearest approach to a mauve that we have. The lovely clear colouring is most pleasing, and the semi-double blossoms so elegantly borne upon erect tall growths are very attractive. The inner petals are of that delicate flesh pink that we usually associate with sea shells. These monthly Roses are invaluable to our gardens of the present day, many of them being as beautiful as the Tea Roses, a class to which they are related. P.

## THE FLOWER GARDEN.

### DAFFODIL NOTES.

#### OVERCROWDING IN POTS.

**I**N my notes on the best Daffodils to grow in pots I forgot to mention one important item which is worth consideration at planting time if we wish to get the most pleasing results in the spring. It is the question of overcrowding. I used to think that the more flowers I could get a pot to produce the better, and that a regular solid mass of colour was the acme of perfection. It may be if we only consider the floriferousness of individual bulbs or the care required in flowering a tightly packed pot, but if we look upon graceful effect as the main point to aim at we must seriously consider the above question.

The charm of a pot of Daffodils does not consist in making it look as much like a hedgehog as possible, but in so regulating matters that each individual plant can grow in a proper upright way and show the beautiful outlines of its flowers. Not that I like a skinny-looking pot; far from it. It is as bad to have too few as too many. We want the happy mean where the desired colour effect is gained without the obliteration of the outlines of the several blooms.

#### DAFFODILS FOR BEDS AND THEIR ARRANGEMENT.

In considering what varieties are best suited for planting in beds a good rule to follow is large varieties for large beds and small for small. I would also advocate only one variety in a bed; a mass of anything is always attractive. They know how to garden at Glasnevin Botanical Gardens, Dublin, and here I found when visiting them this spring that one variety in a bed was

living mass of coloured gold. Golden Spur comes next in depth of colour, then Golden Bell, Glory of Leiden, Emperor and P. R. Barr. For small beds the early Tenby (*obvallaris*) and the rich yellow Santa Maria are splendid subjects. One bit of advice I would give in respect of planting in beds, and that is, plant thickly. The object of a bed is to give a grand solid mass of colour, and whenever I see a poor and badly covered one I feel that its life has been a signal failure.

#### WHAT TO PLANT IN BORDERS.

If I were asked what might be planted in borders, I would reply, "Any sort"; but if I were asked what I should plant, then I would have to think, for I would want diversity, succession, freedom, constitution and attractiveness to be combined, as far as possible, in my selection. In borders we have only Hobson's choice, for we must all plant in clumps more or less. Individuality appears when it comes to settling their size and arrangement. Personally, I like largish groups of about nine or ten large trumpets, and about a dozen or even more, if the flower is small, of the other types. Then as to arrangement; in a mixed herbaceous border I should have as many sorts as possible, the variety being much more interesting than more clumps of a fewer number. When, however, the border is long and narrow, the conditions are changed, and alternate clumps of good contrast are very charming. For this I would suggest such combinations as Duchess of Westminster and P. R. Barr; Emperor and Empress; Mme. Graaff and Leonie; Flora Wilson and J. B. M. Camm; Barri conspicuus and Citron; and Klondyke and Louise (Poetaz).

For clumps in mixed borders I would start with the following, or, if I could not get them all at once, I would go on adding more until I had them. They combine pretty well all the

P. R. Barr, Seagull, Sir Watkin, Stella superba, Vanessa, Waterwitch and White Lady.

If I wanted to add a few more they would certainly include Cassandra, Duke of Bedford, Dorothy Wemyss, Brigadier, Castile, Golden Bell, Gloria Mundi, Lady Margaret Boscawen, Firebrand, Mrs. Betteridge, Torch, Ariadne and Weardale Perfection. The two lists together contain fifty varieties, and form a collection of good reliable sorts of, on the whole, a medium price.

JOSEPH JACOB.

### THE ADONIS.

THE Adonis form a small group of *Ranunculus*-like herbs with finely divided leafage and glossy bright yellow flowers; they found much favour in old-time gardens, and one often meets with cheery-looking clumps of the native *A. vernalis* in old-established herbaceous borders in association with *Fraxinella*, *Thyme*, *Hepatica*, *Aconite*, *Goat's Rue* and *Celandine*, these having slowly but steadily spread themselves beyond their allotted places till everything of a weaker constitution gave way before their aggressive roots. The Adonis, if old-fashioned, are none the less charming, and their dainty growths, studded with bright flowers, find many admirers in this age. If we are content to leave them to grow at their own limited pace, and carefully avoid disturbing them when rearranging the border, they will not fail to give a good return in plenty of flowers of surprising richness when seen in the mass. There are about six of them, and all will grow in any good garden soil in a sunny position. If the soil is inclined to be damp they will like it so much the better. Planting should be done in autumn, and it is preferable to plant strong seedlings than fragments of old clumps. Most of these plants produce seeds plentifully, and they germinate well if sown in a damp corner and lightly covered; a similar site to that one would choose for *Primula* seedlings is best. The finest Adonis is a new comer

*A. amurensis*, a strong and free-growing plant, 1 foot to 3 feet high, somewhat variable in its leafage and in the colour tint of its flowers. The stems are stout and thickly clothed with elegant leaves, sometimes slightly tasselled but generally flat and fan-like, and there are numerous branches, each of which bears a bright yellow flower, 2 inches across, like a giant Buttercup, but with about twenty petals that are tinted with a warm bronze shade on the outer surfaces. There are semi-double forms and others whose flowers are much paler and without the external bronze colouring, and one hears of many other forms that have been grown in Japan for ages, but which appear to be quite unknown here. It often pushes its first flowers in the new year, and these will expand if the weather is open or await a more favourable opportunity. It is a native of China.

*A. pyrenaica* is an older plant of vigorous and distinct growth. It has pale green leaves which resemble curled Parsley at the base of the stems, and they decrease in size until they become mere mossy tufts about the inflorescence. The stems branch freely when strong, grow 2 feet high, and bear fine, rich yellow, glistening flowers 2 inches to 3 inches across the expanded petals. It seems better adapted for planting on the rock garden than in the border; the roots prefer a stony medium, thoroughly well drained, or the plants will discolour and decay at the collar. It flowers in early summer.

*A. vernalis*, the common Ox-eye, is a well-known border plant. It makes thickets of flexible stems which do not branch freely, clothed with finely-cut, tasselled leaves and bearing a single flower at the top of each coloured a deep yellow, the surfaces glistening, the petals numerous and 2 inches across. There are several varieties not generally separated, of several shades of yellow, and the tint of silvery yellow seen in the flowers of *Ranunculus Ficaria*

A CHARMING POOL IN THE REV. T. S. LINDSAY'S GARDEN.

the rule. A glorious mass of Golden Spur in a large oval bed is famous and attracts visitors every spring. Yes, these deep yellow selfs are the boddera *par excellence* of all Daffodils. How I wish maximus was the free bloomer that Golden Bell is! It would have no rival, and the tears that Linnaeus shed over the golden Gorae of English hillsides would have their counterpart in me in the intoxicating pleasure of looking on that

five points I enumerated above: Agnes Barr, Albatross, Autocrat, Barri conspicuus, Beauty, Blackwell, Comus, Citron, Crown Prince, Campanelle Jonquils, Duchess of Westminster, Elvira, Emperor, Empress, Eyebright, Flora Wilson, Frank Miles, Glory of Leiden, Grandee, Homer, J. B. M. Camm, Klondyke (Poetaz), Leonie, Lucifer, Lulworth, Mabel Cowan, Mme. de Graaff, Minnie Hume, Mrs. W. T. Ware, Ornatus,

is represented in one rare form, and there are several forms with a multiplicity of petals. It averages a little above 1 foot in height in most gardens.

*A. volgensis* is a rare plant with slender stems clothed with bright green Parsley-like leaves, bearing on every one of its branches a rich yellow flower  $1\frac{1}{2}$  inches across the petals. It much resembles *A. vernalis* as regards its flowers; in fact, several forms of *vernalis* are scarcely distinguishable from it. Its leafage is quite distinct, being thinner and flatter than that of *A. pyrenaica*—more resembling Chervil.

*A. walziana*, the only remaining perennial plant, is a hybrid between the last-named and *A. vernalis*. It has stiffly, erect stems above 1 foot high clothed with finely-cut, tasselled foliage, coloured a pale shade of green and bearing narrow-petalled, yellow flowers that expand very fully. This and the preceding plant flower late in spring. G. B. M.

### THE PENTSTEMON AS A BEDDING PLANT.

FORMAL bedding often becomes wearisome to the eye, by reason of its lack of variety and the repeated use of the same subjects year after year. This may be remedied in part by a less frequent use of Geraniums and planting more of those things which are beautiful individually as well as decorative in the mass. A packet of good seed will yield many Pentstemons that will be a joy from the opening of their first blossoms until the frosts of autumn end the display. Treated as annuals they will make a brave show, provided they are given an early start. Growing from cuttings may be desirable to preserve certain varieties, but the longest spikes and the boldest flowers are produced upon seedlings in their first year.

Early in February is a good time to sow the seed, placing it in an intermediate house or upon a gentle hot-bed. The seedlings should be pricked off about 4 inches apart to give them plenty of room to develop. When nicely rooted they may be moved to rather cooler quarters, into a greenhouse or sheltered frame. Unless the weather is very severe for the time of year, they may be placed in the open air to harden about the beginning of April. This makes room for more tender things, and if there is a bed or two that can be cleared of early-flowering bulbs, the Pentstemons may be planted out before the rush of other bedding work. It is not advisable to pinch the seedlings, for if allowed to grow naturally they will produce a magnificent spike in the centre of the plant and a number of smaller ones from the side shoots.

Seeds may be obtained in separate colours, but a mixed bed seems far more interesting, and the various shades of colour do not clash to any serious extent. The plants will often live for several years, especially when they can be left undisturbed in the autumn. To make certain of a supply of approved varieties, cuttings may be put into a cold frame in the autumn, dibbled into boxes, or, better still, into a bed of sandy soil made up in the frame to within 6 inches or 8 inches of the glass. The cuttings should be made from the tips of young shoots about 3 inches or 4 inches long which have not developed flower-buds. They will root very easily and go through the winter without artificial heat; but a covering of mats or straw will be a safeguard in very severe weather. Damp, not cold, is the great winter enemy of the Pentstemon.

By reason of its height—about 24 inches—the Pentstemon is not to be recommended for small beds. To produce a good effect, a round bed for its accommodation should not be less than 10 feet in diameter, and one of any other shape should be proportionately large. It will not take many plants to fill a bed, for the seedlings may be given a space of 15 inches with advantage. Golden Feather or the dwarf white Antirrhinum make a good edging for the bed. Spare plants put into the kitchen garden or herbaceous borders

yield a good supply of long, graceful spikes for house decoration. THOMAS H. WORLD.

### AN IRISH RECTORY GARDEN.

I SEND you a couple of photographs of my garden which you may think worthy of your pages. One represents a portion of the alpine valley which I dug out in a winding line, one side being rockwork, the other lined with turf bricks, in the interstices of which many Saxifrages and Ferns

difference. There's a Daisy: I would give you some Violets." T. S. LINDSAY, B.D.  
Malahide, County Dublin.

### SWEET PEA NOTES.

#### BUD-DROPPING IN SWEET PEAS.

I THINK I can give your correspondents "J. M." and "J. H." a hint from my own experience this season. During the June drought I noticed that

A PORTION OF THE "ALPINE VALLEY" IN THE REV. T. S. LINDSAY'S GARDEN.

find a congenial home. At the end is a circular nook filled with *Ramondia pyrenaica*, which I dug out of the precipitous cliffs near St. Sauveur in the Pyrenees some years ago, and here they are quite happy. In May and June this alpine valley is a very pretty sight.

The other picture is of a pond which I scooped out and lined with concrete. Round the edge is a circle of sunken tubs to retain moisture, in which grow *Rodgersia*, varieties of *Osmunda*, *Ourisia coccinea*, *Kämpferi* Irises and other moisture-loving plants. In the pond are *Nymphaeas*, and around are banks covered with luxuriant *wichuraiana* Roses, such as *Hiawatha* and *Minnehaha*.

There is nothing exceptionally rare or fine in my garden, but that does not hinder it from giving me pleasure, nor have I anything in great abundance; but I have a very good variety. On one side of a brick gate tower between two gardens I have fixed in terra-cotta lettering the inscription *Deus primum hortum fecit*, from Lord Bacon's "God Almighty planted the first garden." On the other side is *Deus incrementum dat*, from 1 Corinthians iii., 6. On another pillar is George Herbert's verse adapted addressed to my successors:

If thou dost find  
A garden to thy mind,  
Without thy cost,  
Serve thou the more  
God and the poor;  
Thy labour is not lost,

while on others I have inscribed Ophelia's words: "There's Rosemary, that's for remembrance; pray you, love, remember; and there is Pansies, that's for thoughts. There's Fennel for you, and Columbines: There's Rue for you; and here's some for me. We may call it herb of grace o' Sundays; you may wear your Rue with a

many plants in one of my rows of Sweet Peas were dropping their buds. Instead of watering them I dug down carefully with a hand-fork near some of the worst plants and found the soil about the roots quite moist enough, but at the same time I saw that some roots were injured by contact with farmyard manure. My reason for proceeding on these lines was the fact that the next row was growing away quite healthily, and as far as I could observe had not dropped a single bud. The healthy row had been treated to a somewhat different method of manuring, the surface soil having been removed, leaving a deep trench, in which the manure was placed and then well dug into the second layer of soil before the upper layer was returned to its place, whereas the manure for the other row was dug in less deeply, thus leaving it in such a position that the roots worked amongst it too early, with consequent injury to them and resultant failure of flower development. However, the whole row soon resumed a healthy appearance and has since produced a mass of bloom without the aid of the watering-can; in fact, I am not aware that either row has been watered since the plants were 1 foot high, and I am convinced that many promising rows of Sweet Pea plants that would otherwise have yielded an abundance of bloom have been ruined by injudicious watering. I am also of opinion that the application of too much manure, manure wrongly applied, not sufficiently decayed, applied too late—before Christmas is better than after—and soil not properly worked are among the chief causes of failure to produce satisfactory results in Sweet Pea growing. How your correspondents above referred to have failed I leave to their own decision after a review of their methods in the light of the above-mentioned conclusions.

Howsham, Lincoln.

W. BOOTH.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE HARDY FLOWER GARDEN.**—The planting of Daffodils must go on apace, and clumps of the double and single forms should be planted forthwith at intervals in the border, where annuals have ceased flowering and where the ground can be prepared for the planting. Dutch bulbs of all kinds should be dealt with as opportunity offers. Wallflowers may be planted in their flowering quarters forthwith. It is well to get these nicely established before the hard weather sets in. In the same way we should be disposed to plant Sweet Williams, Canterbury Bells and other biennials which make such a good display in the early summer. Never crowd these plants, but anticipate the space they will require when they are in bloom and dispose the plants accordingly.

**Roses.**—The present is an excellent time to remove weak shoots from dwarf Roses, thus concentrating the energies of the roots on the strong ones that are retained which are to bear flowers next season. At the same time it is wise to cut away unsightly old growths that are of little or no use to the plant and spoil its beauty. Roses may still be propagated by cuttings outdoors, and we would refer the reader to an illustrated article that recently appeared in these columns for information thereon.

**Vegetable Garden.**—Weeds are developing at an alarming pace just now, and if the well-being of the various crops is to be promoted the weeds must be kept under and the hoe frequently used for this purpose. On no account must weeds be allowed to seed, otherwise considerable trouble will be perpetuated in this way. Sowings of Spinach for spring gathering may still be made. I am just putting in my last batch, although it is somewhat late for this work. Onions that have

1.—A CHARACTERISTIC SPRAY OF FUCHSIA RICCARTONI, SHOWING ITS BRANCHING GROWTH.

ripened should be lifted without delay, as the moister weather we are likely to experience will seriously impair the prospects of keeping them through the winter.

**Hardy Fruit Garden.**—As soon as Apples and Pears are ripe they should be gathered and stored away in a cool room, where they will keep satisfactorily during the recognised keeping period. One of the best Plums for the beginner is the well-known Victoria, as it comes into bearing early and fruits so freely. Unfruitful trees that have been making rank growth for some time I am lifting during the present month, and to ensure satisfactory fruiting in the future the roots are being pruned at the same time. I am making up my last bed of Strawberries.

**Chrysanthemums.**—Hardy early-flowering Chrysanthemums are fast coming into flower; but unless their growths be securely staked and tied there is a risk of many shoots being irreparably damaged. As the first blooms get past their best it is a good plan to remove them at once, so that the buds surrounding them may produce flowers for successional displays, and thus make the beds and borders bright and pleasing. Plants of exhibition varieties, the buds of which are showing colour, I am removing under cover at once. I have always found that the plants left out after the florets are showing colour suffer in consequence of exposure to heavy dews and rains that invariably fall at this period. It is wise to shade the plants when under glass for a time. Abundance of air must be admitted to the greenhouse, and on no account should the doors or ventilators be closed. Those growers who have not yet prepared their glass structures for the reception of these plants should do this at once. Faulty glass roofs should be made secure by painting the rafters, in this way filling up pin-holes and other points where rain comes through. See that the hot-water apparatus is in

good order and the hinges and supports to ventilators are in working trim. Always maintain the buds of these plants in an upright position, and the flowers will then open evenly and be of good form.

**The Window Garden.**—Aspidistras, Palms and Indiarubber Plants that always make the window interesting in the winter months will require less water from this time. All that is needed is to keep the soil just moist, and once or twice a week should meet their demands quite satisfactorily. Fuchsias and other plants that are going out of flower may be stored in a spare room from which frost can be excluded. Here they winter very well, provided the plants are kept dry at the roots during the whole of the period. Hyacinths should be placed in glasses and stood in a darkened cupboard or in any position answering the same purpose until rooted. They will make a welcome display in the succeeding spring. Early-flowering bulbs such as Roman Hyacinths, Freesias, Paper White Narcissi and double and single Van Sion should be potted up freely for window gardening purposes. D. B. C.

### INCREASING THE HARDY FUCHSIAS.

THERE are few plants in the hardy flower garden that are of more value than the hardy Fuchsias, of which we have several very excellent sorts, and for all gardens where they can find ample accommodation they may be recommended for providing a display over many months. They are more or less shrubby plants, and most of them are hardy enough to pass through the winter of the United Kingdom unscathed. In the more Southern Counties of England they are extensively grown as shrubs, also for making an interesting hedge, and one often meets with them on either side of the cottage doorways of humble workers in the South.

An ideal position for these plants is, of course, a southern aspect, and if grown under the base

2.—A SPRAY OF FUCHSIA CORALLINA, SHOWING THE STRONG CHARACTER OF THE GROWTH.

3.—SHOOTS DETACHED FROM OLD PLANTS AND SUITABLE FOR MAKING INTO CUTTINGS.

4.—THE SAME SHOOTS MADE INTO CUTTINGS AND READY FOR INSERTION. NOTE THE FLOWER-BUDS AND LOWER LEAVES REMOVED AND THE STEM CUT THROUGH BENEATH A JOINT.

of a sunny wall or in any sheltered position they undoubtedly give a more than ample return for the trouble taken with them in the first instance.

They are all too seldom seen in our hardy flower garden, and it is because of this fact that we hope to induce beginners in gardening to take up their culture, with which we know they will be more than pleased. Even in the coldest districts many of the hardy Fuschias, if cut down by the frosts, will spring up again and grow away vigorously; in fact, they may almost be placed among the best of our hardy plants. At the recent show for readers of *THE GARDEN* pretty bunches were set up by some of the exhibitors, and, in comparison with many other hardy flowers, they were seen to advantage.

Fig. 1 represents *Fuchsia Riccartoni*. This is one of the prettiest of the hardy sorts, and grows well without any protection in the coldest quarters as well as in the northernmost gardens of the United Kingdom. It possesses a compact and twiggy habit of growth, as the illustration aptly portrays, and throughout the summer months bears in profusion bright red blossoms of a most effective kind. We can recommend this variety as being one of the very best; this is one of the first that should be acquired by those who desire to take this subject in hand. We have seen whole beds of this beautiful variety where they have been grouped for effect, and from all quarters, whether viewed close at hand or from a distance, they make a most effective display.

Fig. 2 represents another hardy variety, but quite distinct in the character of its growth. This is known as *Fuchsia corallina*. It is a very beautiful plant of more slender growth, and rather taller than the others. Its habit also is not so erect as that of some of the other forms, but on account of its distinctiveness and the larger size of its freely-developed blossoms, which are of a showy red colour, it is well to grow this in conjunction with the variety already mentioned. It is a vigorous grower, as the shoot in Fig. 2 aptly portrays. Other varieties which may be mentioned as deserving of notice are: *F. corymbiflora*, scarlet; *F. globosa*, purplish red

and violet; *F. gracilis*, scarlet and purple; and *F. macrostemma*, scarlet.

These plants are increased very readily, and this is a matter of considerable interest to those who desire to raise a batch of their own plants. Cuttings may be procured from any well-known hardy plantsman, who does not, as a rule, charge very much for them. Fig. 3 gives a good indication of the sort of shoots to detach from the old plants. This is shown in the hope that some readers may have a plant in their own garden or may acquire a few pieces from a friend. The period of propagation is either in the spring or autumn, but as there is at the present time such an abundant supply of suitable shoots on every old plant, the present opportunity should be taken to insert cuttings as soon as they are prepared.

Fig. 4 represents cuttings after they are prepared. Here it will be observed the lower leaves have been removed, and the shoot cut through with a sharp knife immediately below a joint, and all shoots on which buds have developed have the latter removed, in which case they are ready for insertion in sandy soil.

The cuttings prepared in the manner we have suggested should be inserted in a cold frame at this season, where they will root readily enough, but where accommodation of this kind is not available, a few cuttings may be inserted round the edge of a 5-inch pot, where the cuttings will root readily enough, and this within a few weeks. Suitable soil should comprise loam, leaf-mould and sand in equal proportions, and if these be well mixed after passing the ingredients through a sieve with a half-inch mesh, the cuttings may be inserted with a sure prospect of a successful rooting process. It is important to remember, however, that the soil should be pressed firmly at the base of each one, otherwise the cuttings may what is known as "hang," which means they will be suspended between the surface and the bottom of the hole made for its reception, and this will have the effect of causing the cutting to decay and fail.

Fig. 5 shows a number of cuttings inserted in a 5-inch pot, and these may be placed under a hand-light or bell-glass, or the pot may be placed in a cold frame and kept close during the rooting process. The soil must, of course, be moistened as soon as the cuttings are inserted, and if suitable conditions are made to prevail it is possible no more water will be required until the cuttings are rooted. Subsequently they may be potted up singly in small pots, and, if exposed to the open on fine days to properly harden off, should be placed in their flowering quarters on the first favourable occasion in the late spring or early summer, where they will grow very rapidly and make quite large and beautiful specimens by the autumn.

#### TREATMENT OF PEACH TREES.

VERY often the trees are neglected after the fruits are gathered; they do not appear so attractive as when laden with the luscious fruit, and the watering-can is not used as much. But I am quite sure that the neglect is not wilful: it is brought about through ignorance of the consequences of neglecting to water the border and thin out the shoots. If the beginner fully realised how much the future welfare of the trees depended upon the keeping of the soil moist during

the autumn there would be no lack of water. But there is a happy medium. It would not do to over-water the border, so we should closely examine the soil at quite 1 foot below the surface and keep it moist there as well as on the top. Surface sprinklings are not of much service; a really thorough watering should take place when it is attempted, then wait so many days again and once more saturate the soil right down to the lowest roots. This treatment, combined with plenty of fresh air, will prevent bud-dropping in the new year when the sap becomes active again. Trees that are bearing ripening fruit should also be watered if the soil at the roots is really dry. It is a mistake to keep the soil excessively dry at such a period. Of course, I am here referring to trees grown under glass. Those in the open air receive rain-water at all seasons and stages of the growth of the fruit, and with benefit, too. It is advisable to keep the ventilators open both night and day while the fruits are maturing, and after they are gathered the ventilators should be opened to their widest extent, so that a regular current of fresh air may pass through the house. The air tends to ripen the young wood. Cutting out surplus shoots also does good at this season, as then more air, light and sunshine can reach those branches retained for fruit-bearing next year. But in doing this early pruning, care should be taken to avoid cutting away too many shoots growing near the base of the stronger branches. Leave the young shoots about 4 inches apart. Thoroughly syringe the foliage occasionally. AVON.

#### COLLECTING WINDFALL APPLES.

ALL Apples which fall from the trees before they are properly ready are regarded as windfalls, yet it is safe to say that 80 per cent. of such fruits do not owe their premature detachment from the tree to the wind, but rather to the larvæ of the Codlin moth. These larvæ are the result of eggs laid in the top ends of the fruits in late spring or early summer, and when they hatch out in the form of maggots commence to eat tunnels in the fruits, with the result that the latter fall from the tree before they are ripe. Shortly after the fruits have fallen the maggots emerge from the Apples, change into pupæ, and in this condition pass the winter in loose soil, bark or rubbish beneath the trees, changing again to moths in the spring and thus completing the life cycle.

Much can be done at the present time towards stamping out this pest by promptly collecting all Apples as they fall and using them in some way so as to destroy the larvæ contained therein. Such fruits are useless for keeping purposes, and it is far better, if they cannot be otherwise employed, to give them to pigs than to leave them lying under the trees until the larvæ have escaped.

5.—CUTTINGS INSERTED AROUND THE SIDES OF A 5-INCH POT. THEY MAY ALSO BE DIBBLED IN SOIL IN A COLD FRAME.

## THE TOWN GARDEN.

**BULBS IN POTS.—POTTING.**—This is an operation to which sufficient importance is not attached by some amateurs. They may procure the finest possible bulbs, use clean, perfectly-prepared pots and then prejudice their prospects of success by carelessness in the actual potting. The great thing to guard against is not to get the soil too hard beneath the bulb. Of course, rooting will be much more satisfactory in a firm than in a loose medium, but if the firming is carried too far the result will be that the roots will not penetrate the soil readily and the bulb will be forced up out of place, and failure will be the ultimate result. As a rule, if the pot is filled to within about 1 inch of the rim with loose soil and the bottom is tapped sharply once or twice on the bench the compost will settle down to the right depth and solidity, and the bulb can be placed in position and surrounded with soil, so that the apex just protrudes through the surface. Immediately upon the completion of potting, and prior to the pots being plunged, the soil should be nicely moistened through a rosed water-pot. The number of bulbs put in each pot will vary according to the kind and the size of the bulbs, but it is never wise to crowd them unduly, as the leaves and flowers then come weak.

**PLUNGING THE POTS.**—This is an exceedingly important part of the business. If we kept the pots in full light and watered them as the soil became dry, leaves would be produced very quickly indeed, but roots would be practically non-existent, with the natural result that the flower-spike would not develop, and the operation would have to be written down as a failure. If, on the other hand, the pots are plunged in suitable beds, or, if this is not convenient, are placed in a dark, cool cupboard, roots will be produced in advance of top-growth, and progress throughout will be entirely satisfactory. The best material of which to form a plunging-bed is Cocoanut fibre refuse, and it is preferable to have it out of doors in some such position that it is easy to cover it with sacking or other material that will throw off heavy rains. In the event of Cocoanut fibre refuse not being available ashes can be requisitioned for the purpose, but there is occasionally a something in them which prejudicially affects the growing point of the plant and sometimes quite ruins the spikes. Failing either of these systems being convenient, success will accrue upon placing the pots in a dark cupboard, where one can gain access to them for watering, which will demand more attention than when a plunging-bed is at command. It is impossible to say definitely for how long the pots should remain in the dark, but usually a period of six weeks answers admirably. The grower must exercise his own judgment upon this point, withdrawing them when it is certain that root-growth is good and some advance has been made in the tops. In the case of Hyacinths the top should be about the same size as a Filbert nut when they are brought into the light.

**AFTER TREATMENT.**—The period immediately after the plants have been brought out of the dark is rather a critical one, for in the desire to bring the process forward one may easily do wrong. In no circumstances must they come directly into full light. When the pots are taken out the growing point will be pale yellow in colour and the action of strong light on this will be unfavourable; therefore, for the first few days cover plants and pots with three or four thicknesses of newspaper, withdrawing them one at a time until after a week or so the last one will be removed, by which time the growth will be hard, green and not at all likely to suffer. It will also be necessary to attend to the watering with the utmost care. The soil must never be allowed to become as dry as dust. It is not wise to commence the use of liquid manure until the flowers themselves are well up in the sheath.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## FLOWER GARDEN.

**M**AKE good any cuttings which may have failed. It is not too late to put in cuttings now, but they should have the shelter of frames. Violas and Pansies may be easily struck in quantity. Take the cuttings from young growths and dibble them in a shaded border which has been prepared by adding a little leaf-soil and sand. If a large quantity be required, they may be put in with a spade. Keep the plants that are being grown for spring decorations free from weeds, and water whenever they appear to be suffering from drought. This applies to Stocks, Wallflowers, Pansies, Lunaria, Canterbury Bells and Forget-me-nots.

**Carnations.**—Dig or trench the ground that is to be filled with these plants. A good layer of cow manure should be put in the bottom of each bed or border, and then let the soil lay up rough till required for planting. The positions for these plants must be varied so that they do not all bloom at the same time.

## KITCHEN GARDEN.

**Potatoes** of all kinds may soon be lifted. Keep all varieties true to name, and select those for table use and place them in the dark. Then choose those for seed and leave them in an exposed position for a few days. Potatoes do well and keep perfectly in cool, dry sheds with some mats or straw thrown over them, or they do equally well in clamps when they cannot be given shed room.

**Carrots.**—Take up and store early varieties in sand or ashes outside or in cool sheds. Continue to thin those sown to stand the winter.

**Radishes.**—Sow seeds of these to draw late. They make a nice addition to salads.

**Cucumbers.**—Prepare the house to accommodate these by giving it a thorough clean. Make a small hot-bed over the pipes with fresh material, and then place on the soil, which should also be fresh and consist of good fibrous loam with a little leaf-soil and decayed manure. Plant as soon as the soil gets nice and warm, and keep the night temperature not lower than 65°.

## PLANTS UNDER GLASS.

**Bulbs for forcing.**—Continue to pot up Tulips and Hyacinths of the early types. Roman Hyacinths are most useful for supplying plenty of cut flowers, and also for conservatory and house decoration. When potted place them in the open under a wall, stand the pots close together and put over them some screened coal ashes to the depth of 6 inches or 8 inches.

**Gloxinias.**—As these cease to flower place the pots in a dry position, reduce the moisture gradually and when the foliage has gone lay them on their sides in a protected position.

## FRUIT UNDER GLASS.

**Vineries** that have been cleared may now be kept well syringed and the laterals cut back. If any insects abound some good insecticide should be used in the water when syringing. A little fire heat must now be kept on all late houses at night, and Muscats not quite finished may be kept up to 70°; but all ripe Grapes must have a low temperature, just enough to keep them dry. If wasps prevail lose no time in tacking on wasp-proof netting. This is much better than putting the Grapes in muslin bags, as in the latter process the bloom becomes damaged and one cannot see to cut out bad berries as they appear.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**SCHIZANTHUS.**—Those who wish to have a bright display of flowers in the greenhouse or conservatory during the early summer months should not overlook the Schizanthus. *S. wisetonensis* is a well-known compact strain, and excellent for pot culture. *S. pinnatus candidissimus* is pure white, and is also an excellent pot plant for greenhouse decoration. To have these at their best seed should be sown now in 6-inch pots filled with a sandy mixture, of which the bulk is composed of good loam with a fair addition of decayed manure. Sow several seeds in each pot, and as the seedlings develop thin down gradually to from three to four plants in each pot. The best place for the seed-pots is a cold frame, and later on as winter approaches they should be moved to a shelf near the glass in a greenhouse or cool vinery, the coolest treatment being the best.

## CHRYSANTHEMUMS.

If not already done, the buds should now be taken. As fast as these form in the points of the shoots they must be examined, and if found of good form, devoid of any irregularity or blemish, they should be taken. This phrase is a common one among cultivators, but to the inexperienced it may be misleading. It really means removing all side shoots so as to concentrate the energy of the whole plant into the swelling of the flower-buds. If the removal of the shoots is deferred for a few days longer than is necessary, they appear to rob the bud of its power of development to such an extent that it seems to lack power to swell to its normal size, and consequently receives a check.

## FRUIT UNDER GLASS.

**Figs in pots.**—Those that were forced early and have since been top-dressed or repotted should now be placed outdoors in a sheltered sunny position. The object of this is to thoroughly mature the young wood. If the top-dressing or repotting of the trees has not been attended to, it should be done before the foliage falls and root action has become inactive.

**Melons.**—Plants bearing fruit nearing maturity must now be carefully watered, giving enough only to keep the soil moist. At the same time guard against permitting it to become dry, for if the plants are allowed to suffer and their foliage flag the flavour of the fruit will be impaired.

## KITCHEN GARDEN.

**Leeks and Celery.**—Both are now growing rapidly and need attention in the way of removing weeds and earthing. Before this is done make sure that they are thoroughly moist at the roots. The appearance of the ground is sometimes misleading, as it looks sufficiently moist, but on examining the soil a few inches below the surface it may be found quite dry. Work the Dutch hoe rather deeply between the rows of Leeks to loosen the soil a little, then draw it carefully up to the necks of the plants, repeating the operation as the plants grow. In moulding up the Celery plants let the soil be broken up finely early in the day with the spade, and mould up the Celery in the afternoon, when both plants and soil are thoroughly dry. Before this is done with late batches give the plants a good soaking of liquid manure. Failing liquid manure or soot, guano may be used.

## FLOWER GARDEN.

**Pentstemons and Choice Antirrhinums.**—Now is the time to propagate these. Choose cuttings from the bases of the plants. These do well inserted in light soil in a cool pit or frame, shaded from bright sun and kept fairly close by placing lights over them until callused, but once rooting has commenced expose them fully during favourable weather.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## BOOKS.

**Kew Gardens.\***—The title of this volume is somewhat misleading, as although the twenty-four excellent coloured illustrations are all of views relating to the famous gardens, the greater part of the letterpress is devoted to a history of Kew as a parish, including, of course, a history of the gardens. Such a history is, undoubtedly, of considerable interest, and the author adopts a pleasant and entertaining style in which to record it. The chapter devoted to "Visiting the Gardens" is of a very meagre character, and might well have been improved and much extended. For the visitor who has a lazy hour or two to spend in the gardens this chapter might suffice as a guide, but to the real plant lover it is useless. The general get-up of the book and the coloured plates are admirable, and as a history of Kew the volume is of value.

**The Perfect Garden.†**—Among gardening books the volume now under notice will, we think, rank as one of the most interesting, unique and instructive that have been published for some years. In addition to providing a mass of instructive, useful and practical matter, the author has adopted a high literary style such as we seldom find in books relating to horticulture, thus proving that a combination of the two is quite possible when in the hands of a skilful writer. Flowers, fruits and vegetables, both outdoor and under glass, are dealt with in a highly interesting manner, the chapters on "The Cost of Gardening," "How to Learn Gardening," "Colour for All Seasons," "When and How to Make the Fruit Garden" and "A Complete Kitchen Garden" being particularly good. In addition to excellent letterpress, six charming coloured illustrations, twenty-four half-tone plates and nineteen plans are given, while the binding is suitable to adorn any bookshelf. An excellent, cheap and reliable work.

**London Parks and Gardens.‡**—The author of this handsome new work is already well known as the Hon. Alicia Amherst, whose "History of Gardening in England" published a few years ago at once established her fame as a student of the literary and historical aspects of horticulture. In the work now under notice it is abundantly evident that the researches necessary for her former work have materially helped in the compilation of "London Parks and Gardens," a work not only full of horticultural matter relating to the open spaces of our great metropolis, but replete with many details of historical and literary interest concerning our parks not to be found elsewhere. The volume is one of the most attractive in binding, printing and illustrating that have emanated from the press in recent years. It is tastefully bound and gilt-lettered, and in size is a large octavo. Thirty-five illustrations in colour from drawings by Lady Victoria Manners adorn its pages, and we notice that the book is rightly furnished with an excellent index. We should exceed our scope if we were to attempt to review in detail the contents of the 376 pages, all of them brimful of interest and written in a style that commands the reader's attention. The most we can attempt is to give just a superficial outline of the subject headings, which are as follow, viz., Hyde Park, St. James's and Green Parks, Regent's Park, Greenwich Park, Municipal Parks, South London Parks, Commons and Open Spaces, Squares, Burial Grounds, Inns of Court, Historical Gardens, Private Gardens, &c. There is a list useful for those interested in town gardening of the trees and shrubs grown in Hyde Park and Kensington Gardens, and also examples of

planting flower-beds in Hyde Park in 1905-6. Some of the full-page illustrations in colour are very attractive. We call our readers' attention especially to Crocuses in Early Spring, St. James's Park, Spring in Regent's Park, The Inner Temple Garden, Herbaceous Border, Lambeth Palace, Chelsea Physic Garden, &c.—C. H. P.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

## AUTUMN ROSES FROM HORSHAM, SUSSEX.

Mr. W. A. Cook, The Gardens, Leonardslee, Horsham, Sussex, sends good flowers of some of our best Roses for autumn flowering. Among others, we specially noticed *G. Nabonnand*, Grand Duc Adolphe Luxembourg, Climbing Niphetos, La France, Fellenberg, Mme. Laurette Messimy, Commandant Felix Faure, Etoile de France, Gloire Lyonnaise, Corallina, Antoine Rivoire, Merveille de Lyon, Charles Wood, Eugène Rêsal and Alfred Colomb. Naturally these flowers do not possess the same depth or substance as those produced in the summer, but the colour and fragrance are most welcome in these shortening days.

## FLOWERING AND ORNAMENTAL FOLIAGE SHRUBS FROM DUNS.

Dr. McWatt of Morelands, Duns, N.B., sends excellent sprays of various hardy shrubs. Among others we noted the handsome Spanish Broom (*Spartium junceum*), *Cytisus capitatus*, *C. nigricans*, *Hypericum moserianum*, *H. m. tricolor*, *Escallonia rubra*, *Ceanothus Gloire de Versailles*, *Buddleia variabilis veitchiana* with inflorescences 15 inches long, *Spiraea japonica* Anthony Waterer, *S. j. ruberrima* and *Cornus alba* *Spathii* with its beautiful golden and green foliage. Many of these are flowering several weeks later than they do with us, and consequently are all the more welcome.

ANSWERS  
TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

## Sweet Peas diseased (J. N. H. G.).

The portions of plants sent are affected by the mysterious disease commonly known as "streak." What it is or how it is caused does not appear to be known, but once it attacks the plant nothing can be done, except to pull up the

affected specimen and burn it. Usually a fungus named *Botrytis cineria* is found on affected plants, but this is probably a result of the "streak" rather than the cause.

**Birds attacking Sweet Peas (E. S. P.).**—We cannot say why the birds are attacking the Sweet Peas, and the meagre details and the crushed blooms furnished do not help us at all. We have never experienced any trouble in this direction. It may be that the birds are after aphides, traces of which we found on the mangled flowers sent. We cannot suggest any remedy unless fuller particulars regarding position, parts of the plants attacked and the presence or absence of other green plants in the garden.

**Caterpillars on Romneya Coulteri (G. B. Savely).**—The caterpillars you found on your *Romneya Coulteri* are those of a moth belonging to the family Geometridæ, and are commonly known by the name of loopers, on account of their hunching their backs into a loop when they walk. The caterpillars are so young that I cannot be certain to what species they belong, but they very much resemble those of the winter moth in appearance and habits. Spray the plant with a solution of arsenate of lead or paraffin emulsion.—G. S. S.

**Rock garden (Miss E. M.).**—It is somewhat difficult to advise in such a case without fuller knowledge of the surroundings, and much will also depend upon what phase of a rock garden you have in mind. If the trees you refer to are quite near the site there would be a possible danger from the roots of the Elms entering the soil and thus greatly impoverishing it. In this way the chances of success are not great. Cannot you give us a few more particulars, and we will do our best to help you. At the same time we think a little expert advice on the spot would be much the best.

**Lilium speciosum (E. M. S.).**—If all the Lilliums are like the one sent for our inspection, it is clear that the bulbs have been attacked by fungus at their bases, and this precluding them from the further producing of main roots exhaustion is the natural result. The bulbs were in all probability imported roots, and the method of preparing these for shipment from Japan, coupled with the long period of confinement in air-tight cases, are chiefly responsible for the trouble. The bulbs in the first year were obviously assisted to the flowering stage by the production of so large a number of stem-roots, the bulbs meanwhile making no basal roots, hence the failure.

**Lawn extension (D. Vandery).**—Sowing seeds, we think, would prove the most satisfactory in the end. If sown from the middle to the end of September, the lawn could be used towards the middle of the next summer, provided, of course, the grass had grown well and that it had been rolled, mown and properly cared for in the meantime. The ground should be dug up as soon as available, leaving it exposed to the sun, in order that the grass and all weeds may be killed. To help to this end the ground should be rolled and harrowed or forked over occasionally. Before the seed is sown the ground should be dug as deep as the gravel bottom will allow, adding 2 inches of new soil and a fair dressing of rotten manure. The surface should be lightly rolled and afterwards raked over before the seed is sown, choosing a dry and perfectly still day to carry out this work. The seed should be sown broadcast by hand at the rate of four bushels to the acre. No clover should be included. The seeds should be rolled in as soon as sown with a fairly heavy roller, in order to fix them firmly in the soil and to prevent the wind blowing them about. They must be protected from birds until they have made about 1 inch of growth, when they will be safe from further depredation. The best way of protecting them is to hire two boys at about 6s. per week, one to go on duty at daylight until mid-day and the other from mid-day to dark. The grass had better not be cut until spring, and then on the first occasion with the scythe and not too low. The seed will require protection for a fortnight or three weeks.

## ROSE GARDEN.

**Roses blighted (S. Krinks).**—Your plants are affected with one of the worst enemies of the Rose, mildew. This fungus is very prevalent just now, owing to the changeable temperatures we have experienced. Mildew can be considerably checked, if not really cured, if the plants are sprayed as soon as the slightest appearance of mildew is manifest. A very good wash to spray with is a solution of Lifebouy soap. Take half a bar and dissolve it in three gallons of soft water, then spray every two or three days, using a fine sprayer for the purpose.

**Roses with green centres (M. S. W.).**—Probably your soil is too rich for Roses. This will often cause the malformed, green-centred buds such as you send. But this year there is much complaint of this malformation, and we consider it arises from cold winds and spring frosts, which chill the embryo flower-buds. Try the plan of pruning your plants later, say, the

‡ "London Parks and Gardens." By the Hon. Mrs. Evelyn Cecil. (Arch. Constable and Co., London.)

end of March, and cut back rather more severely. The variety we believe to be Mme. Isaac Pereire, and, strangely, this sort is much given to produce its buds of the first crop like this. The latter blooms are seldom deformed.

**Training weeping Roses** (R. W. A.).—If the roses you planted last autumn were of the wichuraiana tribe, they will form drooping heads naturally, but if of the multiflora group, such as Crimson Rambler, Aglaia and Blush Rambler, it will be necessary to tie down their growths for the first year or two. We usually prune the latter tribe rather closely the first season in March, but where this was not done the best plan is to remove any old shoots not wanted at once and the young growths which have come mainly from the crown of the head may be tied over. The best method of doing this is to attach a piece of tarred twine to the end of the shoots, then how them over umbrella fashion and secure the string to the stem of the tree. Where the young growths are not numerous some of the old shoots may be so tied over. The shortening back of any laterals we defer until March. The pruning of the wichuraiana group merely consists in removing some growths when overcrowded and shortening back laterals in March. These roses are apt to droop in a very crowded fashion, and in order to avoid this some growers place a hoop beneath the growths to keep them outward. This may be done according to taste. The Ayrshire and evergreen roses should be treated the same as the wichuraiana group.

**Rose-growing for the working man** (Frank S.).—We can assure you that such enthusiasm will enable you to overcome many obstacles. Do not be downhearted because certain books recommend things out of your reach, for you can make your own insecticides and fertilisers in a very inexpensive manner, and as to the knowledge how to prune and cultivate, study these columns carefully and you cannot fail to learn much that will be useful. As to the time taken up for the necessary work, we have known enthusiastic men take a lantern and do their pruning when they had no time by day. Just follow our hints week by week and make notes for future guidance. If possible, make the acquaintance of a clever amateur or gardener and watch him do the work. Gardeners are a very sociable set of men and are always willing to impart of their experience if approached in the right manner. Some of the medal roses have been grown in gravel pits before now, so do not despair because you are near a quarry. Try and gather some soil from the hedgerows or surface soil anywhere close by and mix this with any of the sewage material you have that is not too fresh. About five or six parts of such soil to one part of the sewage should make good material. Throw this all together in a heap and keep it stirred over now and then. This heap could be collected during the summer and would be in readiness by October, when you should plant. Each position where you propose to plant a rose should be excavated out to a depth of 2 feet if you can, more if possible. Break up the bottom so that water can drain away, then fill the holes with the prepared compost. Holes about 18 inches wide each way would do. Tread the soil in firmly and plant about two weeks afterwards. A bag of bone-meal would only cost you a few shillings. This is a splendid manure. Give each plant a large handful each spring and hoe it well into the soil. The labour spent on making the positions will be well repaid. A little tact on your part in securing the help of some carman to collect such soil as we advise should enable you to obtain it without much difficulty. We can recommend the following for the various positions you name. Six good ramblers for your pergola would be: Crimson Rambler, Dorothy Perkins, Hiawatha, Blush Rambler, Gardenia and Alberic Barbier; six bush to grow between the ramblers: Caroline Testout, Ulrich Brunner, Marie van Houtte, Pharisier, Mme. Ravary and La France; climber for arbour to make a dense cover: Felicite Perpetue; six standard roses: Gruss an Teplitz, Mrs. John Laing, William Allen Richardson, Gloire de Dijon, Cheshunt Hybrid and Conrad F. Meyer; six drooping roses for arches: Lady Gay, Rubin, Waltham Bride, Mme. Alfred Carriere, Reve d'Or and Aglaia.

## FRUIT GARDEN.

**Grapes mouldy and splitting** (A. K. M.).—The reason for the splitting of the Madresfield Court Grape and the succeeding mould on the berries is that the vines have been grown in too damp and close an atmosphere. Give more air day and night, and until the mischief is stopped provide a fair amount of heat in the hot-water pipes in order to create a greater buoyancy and circulation of the air; also keep this vine rather drier at the roots. This will arrest the splitting, and by keeping a little artificial heat in the pipes until the grapes are all cut, and by cutting away all bad berries, you ought not to be troubled in this way again. No doubt the Sweetwater Grapes are suffering from the same cause. The dew-like drops on the Black Hamburgs would indicate that the vine is more or less infested with mealy bug, a most undesirable pest.

**Peaches shrivelling** (J. S.).—Judging at various shows this year, we have come across many otherwise fine

dishes of Nectarines which were marred in the same way as our correspondent complains of. Red spider is sometimes responsible for the shrivelling of the skin and the absence of colour in Nectarines, and so is bright, hot sun shining on the young fruit while it is wet, and we should be inclined to think that the latter agent has been the cause in this instance.

**Gooseberries and Red and White Currants denuded of leaves by caterpillars** (A. P. J. S.).—Try Abol. The soot and lime is a good stimulating mixture for promoting growth in the trees.

**Pruning Apple, Pear and Cherry trees** (Apple, Brockley).—We presume that the Apple, Pear and Cherry trees in your garden are in bush or pyramid form, not standards. Each tree will have a certain number of main branches or limbs radiating from the main stem or trunk of the tree. From each of these branches will emanate a large number of side shoots of this year's growth. These side shoots should be cut back at once, or as soon as possible, to within six leaves of their base, and the leading shoot at the end of the main branches should not be shortened at all. This is what is called summer pruning. We presume the cherries are sweet dessert ones and not Morellos, as the latter have to be pruned differently. The effect of this summer pruning will be that the growth left on the trees will be exposed to more light and air, and the buds for next year's fruiting will be better developed and ripened. Winter pruning afterwards will consist in cutting those side shoots still shorter; in fact, to within three buds of their junction with the main branch, meaning their base. The leading shoots on the main branches which have so far not been cut at all may now be shortened by one-third their length. This process of pruning should be repeated every year.

## KITCHEN GARDEN.

**Peas and soil for examination** (Mack).—From what you say it would appear that plants of all kinds die in the soil, and this indicates that the soil itself is at fault, either containing something which should not be there or lacking something which should. A test of the soil shows that there is very little lime present, and it would be well to see whether a dressing of lime put on in the autumn would improve matters. If not, it would be well to have a complete analysis of the soil made, so as to ascertain whether any substance was present in the soil that should not be there.

**Killing the Asparagus beetle** (Hon. Miss P.).—As regards your Asparagus beds, I can only suggest that you should dig in a good dressing of gas-lime or Vaporite where the plants grew and allow the soil to have a complete fallow for some months and to make fresh beds as far from the old ones as possible. The grubs of the Asparagus beetle which have been feeding on the grass will become chrysalides when full grown in small cocoons in the ground. When the beetles emerge in the spring they feed on the young shoots, so that it is desirable to kill the grubs or chrysalides as soon as possible. In case any escape the effects of the dressing, the further the new beds are from the old ones the less chance the beetles have of reaching them. If any of the grubs are now feeding on the grass cut it down and burn it as it lies.—G. S. S.

**Tomato leaves gone wrong** (Norice).—We have closely examined the leaves and cannot trace any disease or even insect pests, but the leaves are very thin and lack substance. We think they have been grown in a very warm place, and, being thin, have got scorched, which accounts for the minute spot. The specimen sent was very small and young, and a thorough examination was difficult. If you had sent a few details as to the soil, culture and other matters, it would have helped us greatly. Kindly say if the plants are in pots or planted out and your treatment, and what food given, if any.

**Onions attacked by caterpillars** (W. Labrum).—We advise you to cut away the tops of the badly-affected plants and burn them, and then spray the plants with the following solution: Dissolve 1 oz. of sulphide of potassium in a quart of hot water, then add enough water to make from two to three gallons. This will destroy the minute pest or larva, or you may get the better-known Bordeaux Mixture and spray with this late in the day, and early the next morning spray with clear water, but you will find the sulphide of potassium most effective, cheap and reliable. By cutting away some of the worst or most affected plants, of course you arrest growth, and if the plants are not had you could try the remedy advised first; but the Onion growth should now be well advanced so that you would not lose much, and you would gain in the end. When the crop is cleared give the land a rest till spring. Grow the Onions as far away as possible another season, but if you use lime this autumn freely you will get rid of the pest, or a thin dressing of

fine gas lime on the surface later on and deeply dug in early in the year will clear the soil.

**Diseased Tomato leaves** (W. M.).—Your Tomato plants are suffering from a bad attack of a disease similar in every respect to the Potato disease. It is generally caused by the crippling of the roots of the plants by the application in too strong a dose of some concentrated manure, or by too much water at the roots in late winter and early spring, combined with cold draughts of wind. There is no cure for it. The best thing to do is to try to help the plants to finish their crops by careful watering, ample ventilation day and night, with slight warmth in the hot-water pipes during cold weather. Root out and burn the plants as soon as the crop is gathered; turn out the soil and burn this also if you can. Do not grow Tomatoes in the same house again for at least twelve months.

## MISCELLANEOUS.

**Preserving Scarlet Runner Beans and Marrows** (H. C.).—Please see the Prize Essay article in THE GARDEN, August 15.

**Sulphate of potash** (A. S.).—An ounce of this chemical manure may be dissolved in a gallon of water and so used. A good way to make liquid manure is to dissolve 1 lb. of the sulphate in 20 gallons of water in a large tub, adding also in a coarse bag a peck of good soot and a few ounces of sulphate of ammonia.

**Judging cottage gardens and allotments** (Reader).—The Royal Horticultural Society have no rules or regulations relating to this matter. You cannot do better than send a stamped addressed envelope to Mr. A. Dean, 62, Richmond Road, Kingston-on-Thames, one of the Surrey county judges, who will, no doubt, readily furnish you with the practice prevalent in Surrey, where many hundreds of such things are judged yearly.

**Fish manure** (T. C.).—We know of no book which deals with the manufacture of fish manure or, as commonly called, guano. To publish such a book would be practically giving away the secrets of the trade. However, what is done apparently is that refuse fish to be so utilised must be thoroughly dried, so that flesh and bone will grind up into a coarse powder. Usually also is added to it some finely-crushed kainit or other potassic manure, and the combination is known as fish potash guano. It is a really valuable manure, especially when used as a dressing of half a ton to the acre, for corn and root crops. Such a dressing follows on a previous one of farmyard manure. Any fish manure dressing should be speedily buried in the soil, as its strong smell attracts dogs and cats. After the dried matter has been ground it should be run through a screen with an inch mesh, to remove any portions of bone too large and which may be better for further grinding.

**Working a small holding** (Norice).—An area of land from six to eight acres is practically a small holding. If you could obtain fairly good land on lease at, say, £3 per acre per year, your rent would, of course, be £18 or £24. To that you would have to add probably £4 per year for rates. If the site was within an easy distance of a railway station, you could get manure from London and carted on to the land for about 6s. to 7s. per ton, and you would need at least 25 tons per acre to grow vegetables and Strawberries. If the land had hitherto only been ploughed, you would have to spend at least £2 per acre to have it deeply dug, and without deep working and liberal manuring the crops would be poor. From £5 to £6 would have to be spent for seeds, and from £5 to £10 for Potatoes to plant. Labour to generally crop and cultivate would be a formidable item. Then, with ever so good crops, the question of how to dispose of them would be of great importance. Not only should a good market be fairly near, but it should be one where there is a fair average demand for such produce. Baskets and getting to market necessitate expense. Generally, therefore, the outlay is considerable and the risk material. A really good, honest, practical foreman would be a great help, especially as you are quite ignorant of gardening, and this is very unfortunate. Your prospects of success, as you see, depend on so many things. If we advised you to do all that is in mind, we might seriously mislead you. Circumstances and general conditions, especially with luck to get good land cheap in a favourable place, might help towards success; but, on the other hand, they may result in failure. It is too serious a matter for us to accept further responsibility than so far has been incurred.

**Names of fruit.**—Miss Parr.—1, Emperor Alexander; 2, Sugarloaf; 3, Schoolmaster; 4, Improved Keswick Codlin; 5, Gasconne's Scarlet; 7, Worcester Pearmain; 8, Potts' Seedling; 9, Dumelow's Seedling, syn. Wellington; 10, Devonshire Quarrenden.—Apple Brockley.—1, is in too unripe and undeveloped condition for us to distinguish it. Please send a specimen again when nearly ripe. 2, the red one, is Worcester Pearmain.—H. H.—We think your fruits are Nectarine Pineapple, Peach Stirling Castle and Apple Lord Derby. The specimens were too poor to name with certainty.

**Names of plants.**—Surrice.—1, Achillea Ptarmica flore pleno; 2, Armeria maritima; 3, Sedum spectabile; 4, Solidago canadensis.—W. G. A.—Euphorbia Lathyris (the Caper Spurge). It is not edible.—Rhapart.—The crushed specimen sent appears to be Salvia splendens, but we cannot name it with certainty.—M. Farrant.—Campanula primulefolia; Gilia capitata.—A. L. Ford.—Pinus Strobus.—C. R. G.—Clematis Viticella rubra.—S. M. S. Moncreiff.—Colutea arborescens.—E. Ballard.—Rhus glabra.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

## PHOTOGRAPHIC COMPETITION FOR OUR READERS.

WE frequently receive photographs from our readers of some pretty spot or corner in their gardens, and it has occurred to us that it would be interesting if prizes were offered for the best examples sent in. We therefore offer a first prize of two guineas for the best photograph of a reader's garden, and a second prize of one guinea. Each photograph must be accompanied by a written description of the garden. Photographs must be sent addressed to "The Editor, 20, Tavistock Street, Covent Garden, London, W.C.," on or before October 31, and the envelope or wrapper must be marked on the outside "Photographic Competition," and accompanied by a coupon, which appears in the advertisement pages. Each photograph must have the sender's name and address plainly written on the back. Rejected photographs will be returned if stamps are enclosed for postage. The Editor reserves the right to use any photograph and description that does not win a prize, and his decision must be regarded as final.

## THE NEW CLASSIFICATION OF DAFFODILS

SOMETHING new seems to have a fascination for most people. Lovers of the Narcissus tribe have for many years been talking of species, varieties, classes, divisions and sub-divisions of their favourite flower. The only persons or firm who have taken the trouble to create a published stud-book are Messrs. Barr. Mr. Peter Barr, working from Parkinson downward, made use of the knowledge collected by Messrs. Salisbury, Haworth, Herbert, Baker, Burbidge and others, and founded the catalogue, which, published by Messrs. Barr and Sons, forms the most complete catalogue which exists of the Narcissus tribe.

There are, however, some people who object to the dog Latin descriptions of plants which are useful to all European nations, and who want everything described in vulgar English, often using words in their own sense of what they mean and not necessarily in the correct sense. The few Latin words used in the above-mentioned catalogue are easy to understand, and those who have been for years accustomed to their use will be sorry to lose them.

There is no reason, however, why the new classification adopted, or manufactured, by the Royal Horticultural Society should be accepted generally, nor need it be taken up by local societies for the regulation of their prize schedules in such a hurry as the Midland Daffodil Society seems to have been. It appears to many

that the old classification should be held to as regards the species, and that cross-breeds between species should form a class of garden hybrids, which might be distinguished by arbitrary divisions. Thus one might have the Pseudo-Narcissus in all its varieties forming the Magni-Coronati section, and all flowers obtained by cross-fertilisation from the members of this section. Then the Narcissus would, with its varieties, form the Parvi-Coronati section, with all flowers obtained by crosses between parents of this section. This would leave the Medio-Coronati for garden hybrids, flowers obtained by hybridisation of Magni-Coronati, and Parvi-Coronati, or by cross-fertilisation of flowers belonging to this section.

The Tazettas or Polyanthus Narcissus would form a class for themselves with all their hybrids. The smell of these flowers, though loved by the Oriental, is not a favourite in England, and as a rule the race does not love the climate. If we look at the unfinished state of the classified list of Daffodil names, we cannot help feeling dismayed at the power left for next season in the hands of the judges at various shows of the Narcissus tribe. There are just 2,200 names in the catalogue and of these 790 are unclassified. One would think it would have been wiser if committees had allowed the new classification to have been completed before adopting it. Many who do not know the ways and customs of the Royal Horticultural Society would expect that a radical change of this sort ought to be carried, not only by the whole Narcissus committee, but also by a vote of the members at the annual meeting.

A DAFFODIL LOVER.

THIS list of names officially appeared about the third week in August, and is an eloquent tribute to the popularity of the flower and the marvellous results that have been attained by the labours of hybridisers. It is a long step from Herbert to Engleheart, and could the former see the creations of his distinguished follower he would rub his eyes with amazement. The classification is intended only for show purposes, and it is to be hoped that it will be always considered in this aspect. The divisions are purely arbitrary, as it was felt that any other system was quite out of the question, and English names have been adopted. These are as follow: 1, Long trumpets; 2, short trumpets; 3, large cups; 4, small cups; 5, flat cups; 6, doubles; 7, bunch-flowered. At present this classification has been adopted by the Devon, Brecon and Midland (Birmingham) societies for their 1909 schedules. Another year, if it is taken up at all generally, various sub-divisions

will be indicated in a second edition. Thus what are called pure Poets will be marked, and bicolor, white and yellow trumpets indicated. The main thing that will make it so useful, if not indispensable, is that every flower is placed in one or the other of the above classes. Naturally, there are mistakes in the present issue; but even with these mistakes it cannot fail to be of the greatest benefit to harassed exhibitors and doubtful judges.

JOSEPH JACOB.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 7 and 8.—National Chrysanthemum Society's early autumn exhibition, Crystal Palace.

**Our Rose number.**—We hope to publish a Rose number on October 10. A coloured plate of the Rose Joseph Lowe will be given, and the number will have illustrated articles and notes from the leading rosarians.

**Another flower show for our readers.**—As the flower show which was held for readers of THE GARDEN in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on July 29 last, was such a splendid success, the publishers have decided to hold a similar exhibition again next summer, which, we feel sure, our readers will do all they possibly can to make an even greater success. The date and place of the show will be announced later, and the schedule will appear in our pages in due course. Any suggestions made by readers at an early date regarding the classes will receive careful consideration. Such an exhibition will, we think, do much to encourage and foster the high class culture of flowers, fruits and vegetables among those who weekly peruse these pages.

**Conference on the spraying of fruit trees.**—With the hearty concurrence of the National Fruit Growers' Federation, the Royal Horticultural Society are organising a conference on spraying on the second day of their annual exhibition of British-grown fruit at their hall in Vincent Square, Westminster. The conference will be warmly welcomed by fruit growers as a means of obtaining and disseminating the latest expert information on this very practical subject. The following is the programme proposed: October 16, 1908—11 a.m. to 1 p.m., Colonel Ward, M.P., in the chair, papers by Mr. George Massee, V.M.H., and Mr. H. F. Getting, F.R.H.S.; 2.30 p.m. to 4.30 p.m., Colonel Long, M.P., in the chair, papers by Professor F. V. Theobald, M.A., and Mr. G. Hammond, F.R.H.S. Discussion invited. Seats will be reserved for anyone making application before October 9.—W. WILKS, *Secretary*.

**National Chrysanthemum Society.**—Three exhibitions are arranged to be held under the auspices of the above society during the coming season, as usual at the Crystal Palace. The early autumn exhibition is fixed for October 7 and 8, the great autumn competition is to be held on November 4, 5 and 6 and the early winter show on December 2 and 3. As usual, some very handsome prizes are being offered, and doubtless the displays will be well up to the average. Copies of the schedule and full particulars can be obtained from the general secretary, Mr. R. A. Witty, St. James's Villa, Swain's Lane, Highgate, N.

**British Gardeners' Association and Kew gardeners.**—The Journal of the above association for September contains an interesting report by the sub-committee appointed to meet the committee of the Richmond branch to consider the alleged grievances of the gardeners at Kew. We are pleased to observe that the report is temperate in tone and that the matter has been dealt with in a reasonable and business-like manner. It is suggested, among other things, that work in the glass houses

should cease at 5 p.m., instead of 6 p.m., in the summer months, that the courses of lectures be rearranged so as to deal with science as applied to horticulture rather than with botany, and, what is more important, an examination be held on the subjects at the end of the session. In the past no real examination has been held, and this has undoubtedly led to much dissatisfaction. A third point worth the earnest consideration of the authorities is the suggestion that a special building or hostel be erected for the young gardeners, so that the necessity for living in lodgings of a more or less inferior character be obviated. In regard to wages, it is suggested that every young gardener should be paid 21s. per week for the first six months, after which, if he has proved satisfactory, he be recommended for an increase of pay. The report is signed by two present and three past Kew gardeners.

**Bulbs grown in fibre.**—As our readers are well aware, Mr. Robert Sydenham of Birmingham has long advocated the growing of certain bulbous plants in fibre, and a most interesting exhibition of Hyacinths, Tulips and Daffodils grown in this way is promised for March 9 next, when the prizes offered by Mr. Sydenham will be competed for. The lists of varieties with the prizes was given in our issue for last week.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Rose Augustine Guinoisseau sporting.**—I have had a similar experience to Mr. A. L. Wigan with regard to this Rose. I planted it about eight years ago, and for the last five years it has borne splendid blooms of La France, side by side with those of Augustine Guinoisseau. Seeing the Rose mentioned in THE GARDEN as one that does well on its own roots, I started some cuttings from that part of the bush still true to name. These have produced fine strong plants, which flower freely and show no signs of sporting. Mr. Wigan might find it worth while to try this plan.—J. A. DOUGLAS, *Balbriggan, County Dublin*.

**A warning about auction bulb sales.**—I have just received my *Irish Gardening* for September. In an article on "Current Topics," by Mr. Peter Brook, occurs the following passage: "Residents in Fermanagh had an experience this spring through an auction of Dutch bulbs held at Enniskillen last September, when Mme. de Graaff was put up and sold at 3s. per dozen, but which on flowering turned out to be Grandis. Mme. Plomp sold at full commercial value, but the contents turned out to be Princeps. Glory of Leiden produced Emperor." Exactly the same thing happened in my local town (Whitechurch, Salop), as a few friends of mine and myself know to our cost, only there was nothing so good as Emperor in any lots that I saw flower. I strongly warn readers against these local auctions of bulbs.—JOSEPH JACOB.

**Pruning wichuraiana Roses.**—As wichuraiana Roses have not been generally grown for long, it occurs to me that my experience as to pruning may be of interest to others and may elicit notes from other growers. I have for some years pruned my ramblers very severely in August or immediately after the flowers had begun to fade, but was doubtful whether the wichuraianas would make sufficient growth of new wood to allow the same treatment. I have just been over my plants, which consist of 7-foot standards of the following sorts: Lady Gay, Dorothy Perkins, Alberic Barbier, Paul Transon, René Andre, Elise Robichon, Débutante, Hiawatha, Leontine Geronis and climbing plants of Dorothy Perkins. I find that they allow of the whole of the old flowered wood being removed, and at present have long growths of new wood,

which by the time the frost checks the growth will be almost too long. On the tall standards I find that it is a good plan to tie small stones to the ends of the long growths, so as to induce a weeping habit and yet free from stiffness engendered by tying. From an experience now of four years I cannot too strongly recommend all lovers of effect in the garden to go in for wichuraianas on tall standards at least 7 feet. I hope to get some 10-foot standards this autumn to bud. Within two years from budding you get a most lovely effect, and by having a variety of kinds such as mentioned above the flowering season is extended for a long time.—C. L. A., *Staffordshire*.

**Fruit trees at the Franco-British Exhibition.**—It would be a great mistake for anyone to believe that training fruit trees is a pure fancy or an ornamental system. It is, on the contrary, absolutely useful, even indispensable in many cases, for several reasons. First of all, by the mere fact of training and pruning we take away all branches or parts of branches which are not useful, so that the good buds may receive more sap, be better fed, and thus able to bear larger fruit. That, however, is not all. The real aim of training a tree is to give it a form which will render it suitable for cultivation under special conditions. Just a word to say that a special form should be used to temper the inclemency of the weather. Everyone knows there is no possibility of obtaining every sort of fruit anywhere; but, nevertheless, it is true we can obtain results which were considered quite impossible to get hitherto. The following example will help readers to understand my meaning: Suppose in a very cold country where it is almost impossible to grow fruit in the open and one wishes to eat an Apple or a Peach, what is to be done? Buy them in the market, of course; but those we gather ourselves are better. Well, then, I choose a wall facing south and plant there the trees chosen. During the winter the wall protects them, and, if necessary, I further protect them with a covering. If, on the contrary, the country is too hot, instead of planting on the south side we do it on the north, west or east, according to the temperature. Trained trees are very useful in every part of the world, even where the climate allows growing in the open, as by using different situations we get different periods of maturity; besides, by methodical and scientific training and pruning, we get fruits exactly where we want them; that is to say, in the most suitable places, and so obtain sweeter and larger fruit. The best forms for wall trees are palmette with oblique branches, several storied, and palmette verrier or palmette with horizontal vertical branches. Another good shape of tree is what we call horizontal cordon, one or two sides; this small form is very productive and does not take much space.—C. VATERE, 108, *Godolphin Road, Shepherd's Bush, W.*

**Rowan berry jelly.**—In answer to the question about Rowan berries in THE GARDEN of the 5th inst., I write to say that we are in the habit of making Rowan berry jelly to eat with roast mutton, hare and kipper herrings. Soak berries in cold water for forty-eight hours. Then take the berries out and boil with enough water to prevent burning, until the berries are soft. Squeeze through a jelly bag and allow 1lb. of sugar to 1lb. of juice and pulp and boil up together till ready to stiffen or pot. It is a darker colour than Red Currant jelly, and, being rather bitter, much nicer with meat.—M. H. MARSHALL, *Lochmalony, Cupar-Fife, N.B.*

—In answer to Mr. Horsfall Vint's question in THE GARDEN of the 5th inst. as to the use of Rowan tree berries, I wish to say they make a delicious jelly; the berries when ripe are boiled till soft in a small quantity of water, then strained through a bag made of cheese cloth, sugar added and boiled with the strained juice till clear and stiff enough to set. Some people put Apple with the berries.—E. H. C.

**The use of Rowan berries.**—In answer to a query in THE GARDEN for the 5th inst. as to Rowan berries being poisonous or not, I can assure your correspondent that they are not. Rowan jelly is used in Scotland with game, the same as Currant jelly is with mutton, &c. The following is a recipe for Rowan jelly: Gather the berries when they are almost ripe, wash them and put in a preserving-pan with sufficient water to cover them. Boil till soft and strain the liquid through a bag. Allow 1lb. of loaf sugar to every pint of juice and boil the latter with the sugar for half-an-hour, skimming carefully. Apple juice added to the Rowans is a decided improvement. To every pint of Rowan juice allow a pint of Apple juice, adding sugar to the latter—1lb. to a pint.—H. INGLIS.

**Fruit Bottling.**—Referring to the first prize essay on "Bottling Fruits and Vegetables," in your issue of the 15th ult., I have no experience in the latter, but I am somewhat at variance with the author in fruit bottling. We have for several years used the bottles of Messrs. C. Lunn and Co. of Kirkburton. We gather the fruit as stated in the essay, when not too ripe, fill the bottles, shaking them as filled, then pour in sufficient cold water to fill the bottles to within half an inch of the rim (top), put on the glass top with its rubber ring, turn the wire clip round and the contents are secure. The bottles are then placed in a suitable receptacle, putting a few split canes on the bottom first, also a few between the bottles to keep them apart; the receptacle is then filled up with cold water, so that the stoppers are quite an inch below the surface, and the receptacle placed on a fire (we prefer a gas stove, as the heat is more easy of regulation) and gradually heated up to 160° Fahr. At this temperature the gas is turned out and the receptacle and contents allowed to get quite cold, then the bottles are taken out, wiped and put away in a dark cupboard. We do not use a particle of sugar, for I believe this often sets up fermentation; anyhow, barring perhaps one bottle a year bursting, which generally takes the form of the bottom coming clean off as it is removed from the receptacle, we keep such fruits as green Gooseberries, Currants, Raspberries, Plums and Greengages for over a year, and their flavour in no way deteriorates. The same bottles do year after year, but I prefer to have new rubber rings every time.—D. HILL, *Herga, Watford*.

I have read with much interest the articles on "Fruit Bottling" in THE GARDEN, and am surprised no one has mentioned Messrs. Fowler and Lee's method, so I enclose one of their advertisements. Their method is very simple and the results perfect. We have used it for ten years, preserving over 1cwt. of various fruits every year, and have never had a bottle become poor. The fruit is preserved without sugar in its own juice or with a little water, and never boiled. The colour and flavour are perfect after twelve months. We also bottle Tomato purée for soups and various other things. I have tried various methods, but none were as simple and effective as this.—(Mrs.) A. R. PHILLIPS.

**Gooseberry mildew in Essex.**—In the interests of fruit growers throughout Essex it is expedient that the greatest possible publicity should be given to the fact that, after extensive ravages in many of the Eastern Counties, the American Gooseberry mildew has at length appeared in our county. A Gooseberry Mildew Order will be issued by the Board of Agriculture as a natural corollary, and growers should see that every effort is put forward to ensure the efficient working of the order on their part. The mildew, as its name implies, is a native of America, and was unknown in Great Britain till 1900, when it was found in two Irish counties; by 1907 it had spread to no fewer than twenty-one counties. In respect to the damage done by the disease, Dr. Pethybridge says: "As regards Ireland, it is no extreme view of the

case to state that the losses have been in many cases most serious, and unless the disease is checked we are threatened with nothing less, practically, than the total loss of the profitable cultivation of the Gooseberry as a bush fruit." What is true of Ireland is true, also, of Essex. I will gladly give any help to Essex fruit growers who care to write me on the subject.—C. A. BALAND, B.A., F.L.S. (Biologist to the Essex Education Committee), *Chelmsford*.

**Layering Carnations.**—Referring to my note on "Layering Carnations," page 397, Mr. A. Childs, on page 419, states that he does not quite agree with me when recommending an upward cut of about 1 inch through the stem, his reason being that the long tongue thus formed is apt to snap off when the layers are lifted for planting out. Personally, I have never experienced this difficulty, although I admit there is the risk if the plants are not carefully handled, especially if the soil adhering to the roots is of a heavy and close nature, but I advise a light, sandy soil to be prepared for use when layering Carnations. Mr. Childs admits "the layers will

A LOVER OF DAFFODILS AND TULIP :  
MR. WILLIAM BAYLOR HARTLAND.

root just as well from a long tongue." Now I have frequently noticed when taking up rooted layers that, in cases where a short tongue had been prepared, the roots were not so abundant as those produced from a longer tongue; therefore, I think, all things considered, the latter should have the preference. I quite agree with Mr. Childs that, when a large quantity of plants are to be handled by one man, it is necessary to lose no time when a suitable day for planting comes round; but, at the same time, the more one has to handle the more proficient he becomes in the work, and the risk of the damage mentioned should be reduced to a minimum.—C. RUSE, *Munden Gardens, Watford*.

**A remarkable crop of Peas.**—I notice Miss E. Bradley's account of a remarkable crop of the Pea Duke of Albany in your issue for the 29th ult., and would inform her that the attributes do not lie in "thin sowings and hoeings" so much as in the vital words "our garden has only been in cultivation four months." There we have the solution of her record crop. Any newly-turned-up soil does and will continue

to yield good crops for three or four years, as it contains all the chemical ingredients for building up good crops of Peas, without resorting so much to nitrogenous manures.—B. LOCKWOOD, *Lindley*.

## WORKERS AMONG THE FLOWERS.

WILLIAM BAYLOR HARTLAND.

THE name of Hartland has long been connected with horticulture in Southern Ireland. The first Hartland in Ireland was one Richard, who came over from Kew and in 1774 settled at Mallow, where he established a flourishing nursery garden called Bellevue, along with two others in different parts of the country. At his death Bellevue passed to the father of the subject of my present notes. Here he was born in 1836. The Cork business was started by two of Mr. Hartland's uncles in 1810, and it is this same business that is being carried on to day by himself and two of his sons. As recently as the middle of August this new partnership came into being. Let us hope that it will be the means of rejuvenating the old business, and that a fourth generation may in due time have the same success that filled the Patrick Street shop with customers in the best days of the old firm's life. So much for the dry facts of history and finance. They do not assimilate with William Baylor Hartland at all. He is, and he always has been, an enthusiast and an idealist, and in this latter spirit he would write history and in the former look on life. Nature has exacted from him her price, and once more the saying of the Old Book has come true, "Whatsoever a man soweth, that shall he also reap."

For some reason or another our friend was attracted to the Daffodil when the efforts of Herbert, Leeds and Backhouse were beginning to be appreciated by that pioneer band of devotees, Peter Barr, Wolley-Dod, Rawson, Nelson, Brockbank, Burbidge, Masters, Baker and (as a young stripling not, as it were, yet out of his teens) Engleheart.

"Worthy of a Hartland's researches" is a phrase that occurs as a casual remark in one of the late F. W. Burlidge's letters written in 1885. It is as the diligent explorer of the gardens of old Ireland, as the great collector of the many lovely forms that but for him might for ever have been lost, that history will register his name. But his sympathies were not limited to one flower only. True to his genius as collector he has accomplished, along with those great enthusiasts of Glasnevin—Burbidge and Moore—a proportionately greater work for an even more famous flower, and found many of the lost ones of the tribe of Tulips, and by careful nursing and cultivating restored them to the gardens of the world.

Mr. Hartland is a widely-read man. You have only to get one of his very original catalogues to feel this, or, better still, buy his "Wayside Ireland," in which he has recorded his experiences and thoughts as he toured through Connemara and Achill Island in 1894. He is full, too, of human feeling, as this same book discloses. He has long seen the importance of agriculture for a prosperous Ireland, and twenty and more years ago urged the growing of early Potatoes in suitable spots, and was the first to institute prizes for cottage gardens in the Emerald Isle. He is proud of his country—witness his gift of Shamrock seed to sow on the graves of the Irish soldiers who fell in South Africa, an action which surely has done much to popularise the wearing of the green on St. Patrick's Day. And now, as "Baylor Hartland Redivivus," may he long live on in his old home at Ard Cairn, where I am sure he will always have a truly Irish welcome ready for his friends.

JOSEPH JACOB.

## THE FRUIT GARDEN.

### SOME GOOD MELONS.

**O**F late years some splendid Melons have been introduced, and some of the new seedlings are noted for their compact growth and free setting, a point that amateurs should not overlook, as I have frequently heard the remark that it was a difficult matter to set the fruit, and amateurs in consequence have given up their culture. It is only fair to add that a great deal depends upon culture; if the roots get too much food at the start the results are disappointing. The variety illustrated, Superlative, is a very fine fruit, of good shape and beautifully netted, as the illustration shows. It is of good quality and a very free setter.

A WELL-NETTED FRUIT OF MELON SUPERLATIVE.

In this note I do not intend to name a large number of varieties; indeed, with so many to select from this would be difficult, and any good varieties omitted are merely left out on account of space, so that my readers will, I trust, pardon the omission, as often growers of these fruits have their own favourites, which they do well to make a speciality of, as by keeping a good type true there is a great gain.

There can be no doubt whatever that during late years these fruits have been grown in greater numbers, and with small forcing houses at command the crop can be cleared so quickly that three crops can be grown where only one was grown previously. This is a great gain, and some of the later introductions are noted for their quick free growth. I have grown them as cordons and fruited them under three months; but this is a mere matter of culture, and I will briefly refer to it later. A strong point with Melons, and indeed the chief one, is, undoubtedly, flavour, and this is a difficult point, as often the fruits, even in the same house, vary greatly. A Melon which was really excellent last year may be second rate this year and *vice versa*, although given the same treatment in every way.

I have referred to pit or small house culture, and this is so well known that I do not intend to dwell on this point; but I would point out other modes which have been most reliable as regards flavour and getting the crops cleared in a given time. Pot Melons are a great success, and as regards getting good flavour it is one of the most reliable methods of culture. With pot culture there is a little more labour at one period of the

growth in the way of watering; but, on the other hand, at the finish the treatment that is most suitable can be afforded. The roots are kept in bounds, early setting is facilitated and feeding at the critical moment can be attended to. Good results are obtained with 12-inch pots, but from 12-inch to 16-inch pots give excellent returns. Many good Melon growers who have to rely on manure as the heating agency place large pots in the manure for the plants, so as to keep the roots under command. The season is now drawing to a close as regards these plants, but with pot culture I have had good fruits in November from August-sown plants.

Another mode of culture not often practised is growing the Melon as a cordon. Years ago in THE GARDEN I noted this, and it is an excellent way to get a quick crop. Very little root space is required, and the small, compact sorts are best. I had splendid crops of Blenheim Orange

grown thus; but, of course, more plants are required at the start. Grown as cordons the soil required is much less, as the plants are from 12 inches to 18 inches apart, planted in about 6 inches of soil, and one (the main) growth trained and the lateral growths closely stopped after the first fruits are secured; in fact, the growth much resembles that of a well-trained Tomato. It is surprising how rapidly the fruits will mature on these plants. In our case we did not top-dress with soil after the planting, but watered freely with liquid manure or used a good fertiliser after the fruits were set.

Invicta, Frogmore Scarlet, Sutton's Al, Best of All, Invincible, Triumph, Windsor Castle, Earl's Favourite, Syon Perfection and Beauty of Syon are all excellent varieties. Of other well-known sorts it would be difficult to omit Melons of

such good quality as Hero of Lockinge, still one of the best, and Blenheim Orange. G. W. B.

## THE KITCHEN GARDEN

### FRENCH BEANS IN FRAMES IN AUTUMN.

**D**URING the next few weeks those who have frames at liberty can get a good return by sowing a small, quick-growing French Bean therein, and even should the frames be now occupied with Melons or other plants the seeds may be sown in pots or boxes and the seedlings planted out as soon as the frames are available. The plants grown thus will prove most useful, as they will give a good crop after the latest in the open ground, and last a considerable time. I have referred to an early variety, and by this I mean a dwarf grower and one that matures quickly. Such sorts as Veitch's Early Favourite, Early Gem, a very free bearer and of splendid quality, and Sutton's Early Forcing, a very dwarf grower, are eminently suited for this work.

The culture is most simple. The frames that have grown Melons or Cucumbers should give a good return. From 4 inches to 6 inches of soil will be sufficient for the plants, and if new soil is put in the frames it may be placed in ridges in rows 12 inches apart, so that a saving is effected. I have, however, had splendid results by merely

levelling the old Cucumber or Melon soil and planting in rows 12 inches apart, as the plants soon make good roots if not kept too moist at the start. Of course, if the soil is dry it is advisable to give a thorough watering before sowing or planting, and if at all poor I advise a small quantity of some quick-acting fertiliser mixed with it to promote rapid growth. A heavy clay soil is not suitable for these plants at this late period of the year, a warm friable soil being required, but the cultivator who can sow or plant after Cucumbers or Melons will find such soil quite suitable. Plants sown for autumn supplies during September and forwarded by early closing and occasional damping overhead will give a supply from October well into November, or even later.

G. WYTHES.

## THE ROSE GARDEN.

### THE NEWER ROSES.

**I**N attempting to deal with the numerous Roses that have been placed before the Rose world in recent years, one is forced to have some method of arrangement, and I propose, therefore, to take first of all those Roses that are likely to prove of some service to the Rose exhibitor, and then to deal with the remainder in the two sections of climbers and dwarfs. In order to avoid repetition, I shall limit these notes to the Roses introduced during the three years 1905, 1906 and 1907, referring your readers to your columns for such other Roses as may not here be mentioned, and to my notes of last and other years.

It is pleasing to be able to note the advance that is being made in the quality of the flowers, in their freedom of flowering, also in the not unimportant question of growth, and last but by no means least, to the great majority being more or less fragrant, some quite pronouncedly so. These facts point to the stiffening of the standard now required by the purchasing public; it is no longer simply a question of being new, pure and simple. Unless the Rose has some marked feature it has no chance of recognition, and its life, seen in the pages of the catalogues, is a very short one. I will endeavour to take them alphabetically.

*Avoca* (Hybrid Tea).—Sent out last year by Messrs. Alexander Dickson and Sons of Newtownards, Ireland. I have been delighted with what I have seen of this Rose; the colour is a good crimson-scarlet, the shapely long pointed buds opening out well, and it is sweetly scented. A good grower, but not so free-flowering as some of this firm's novelties. The flowers are reminiscent in shape of C. J. Grahame; that is to say, they are on the thin side, but do not open to an eye so quickly, and keep their colour well without going off into a bad purple. It is said to be especially good as a cut back, and is undoubtedly one of the best of its colour in this section, which want these scarlet Roses badly. It received the gold medal of the National Rose Society at the autumn show at Vincent Square last year, and is a better Rose than its appearance then led some to think.

*Betty* (Hybrid Tea, 1905).—I referred to this Rose recently; it has not been Betty's year, but some excellent flowers have been exhibited nevertheless. Its colour and the beautiful shape of the young flower will, particularly in a cool season, always make this Rose useful; but it is a garden Rose first and an exhibitor's one afterwards.

*Charles J. Grahame* (Hybrid Tea, 1905).—If only it had a few more petals what a flower this would be; its colour is dazzling, and a good bloom stands out in a quite startling fashion among a long bed of the newer Roses, but it was very difficult to catch it during the exhibition season this year. It has made some wonderful growth, which seems to be a feature of the scarlet

Hybrid Teas as compared with the Hybrid Perpetuals of the same colour. All exhibitors must grow it for the sake of its colour; we shall not always have such a tropical heat as this year during the last week of June and the first in July, and in a cool season C. J. Grahame will be wanted.

*Countess of Annesley* (Hybrid Tea, 1905).—This year the relative value from the exhibition point of view of this Rose was very little. Last year I was inclined to think its large shell petals placed it in front of the *Countess of Derby*, but this year the position was easily reversed. At its best a beautiful Rose with a good scent.

*Countess of Derby* (Hybrid Tea, 1908).—All the Roses I have mentioned so far have been the product of that home of the Rose, the Newtownards Nurseries, and this is one of the best of the many good ones that have left Messrs. Alex. Dickson's hands. Besides being useful for exhibition its free-flowering qualities make it an excellent garden Rose; it is in full flower with me as I write, notwithstanding the rain and the wind of the previous week. Again, a good Tea scent has to be noted.

*Countess of Gosford* (Hybrid Tea, 1906).—A rather thin but large-petalled Rose of beautiful shape that has kept well in a cool season; the colour is a blending of salmon pink and rose with a suspicion of old gold and lasts well. It comes from Messrs. McGredy and Son of Portadown, and is no doubt the forerunner of many beautiful Roses from the same source, if one may judge from the batch of new seedlings the firm exhibited at the Manchester show. It is very free flowering.

*Comtesse Alexandra Kinsky* (Tea, Soupert et Notting, 1905).—This is one of those Roses on the border line, not an exhibition Rose always, but occasionally good enough; creamy white with a deeper centre that is very beautiful in the bud, opening into a full flower. My plants have done well, sufficiently, at any rate, to warrant mention here and to receive a further trial. At the same time it is not such a good Rose as

*Comtesse de Saxe* (Tea, Soupert et Notting, 1905).—This is of very similar colouring, but better shape, that has again been quite good with me. It is perhaps a purer white than *Comtesse A. Kinsky*, and is undoubtedly worthy of more extended cultivation. I recommend it to all Tea growers as a good new Tea for exhibition.

*David Harum* (Hybrid Tea, E. G. Hill and Co., 1904).—A good Rose with reflexed petals, but not a very strong grower with me; the colour is rosy pink. The flowers open well and are occasionally good enough for the front row. It has been well shown on more than one occasion by Messrs. George Paul and Son of Cheshunt.

*Dr. J. Campbell Hall* (Messrs. A. Dickson and Sons, 1904).—I mention this Rose because it has been especially good with me this year. Its colour, always beautiful, has been particularly fine, recalling the superb flowers I saw of it in the nurseries at Newtownards the year it was sent out. It is not possible to accurately describe the colour—deep coral rose suffused pale pink almost to white at edge of petals. It is even better as a garden Rose than most of the exhibition varieties, as it is free flowering and the buds have such long footstalks that it need not be disabused as much as some varieties.

*Dr. William Gordon* (Hybrid Perpetual, William Paul and Son, 1905).—The only plant I have of this has done well; it is a good grower and the flowers look well on the plant, for a Hybrid Perpetual free-flowering, and the blooms last well, being of large size and of the old-fashioned circular shape; fragrant, bright pink in colour. It obtained an award of merit at the

moreover, a good garden Rose that can be recommended for general cultivation.

*Frau Ernst Borsig* (Hybrid Tea, P. Lambert, 1907).—I have seen this Rose strongly recommended to exhibitors, but I should hardly care to go as far as that; at the same time it is a very beautiful variety, robust in growth rather than vigorous, smooth wood and good broad foliage; colour rosy carmine. The best of this raiser's 1907 set.

*General McArthur* (Hybrid Tea, E. G. Hill and Co., 1905).—This is a good Rose of very fine colour with a strong scent; vigorous grower. The raiser, who was over in England this year and was present at the National Show in the Royal Botanic Gardens, seemed to think it was a better flower than Richmond. I have not sufficient plants to speak positively about it, but I am sure it is well worth trying. The Irish growers, who seem to patronise these American Roses more than their English *confrères*, have exhibited this Rose well on several occasions.

H. E. MOLYNEUX.  
Purley.

### NEW ROSE MRS. LITTLETON DEWHURST.

This is a white-flowered sport from the well-known Rambler Rose *Lady Gay*, the pink-coloured buds contrasting well with the purity of the opened blossoms. The general effect is not unlike *Aimée Vibert*, save for the greater display of blossoms. This variety received an award of merit on the 1st inst., when shown before the floral committee of the Royal Horticultural Society by Messrs. J. R. Pearson and Sons, Lowdham, Notts, but was accidentally omitted from the official list of awards.

### NELUMBIUM SPECIOSUM OSIRIS.

This magnificent variety of the Lotus or Sacred Bean is a great advance on the type, the flowers being very much larger and of a deeper clear rose colour, with white at the bases of the petals. The leaves also are very large and of the most pleasing shade of green. It was shown before the Royal Horticultural Society on July 21 by Leopold de Rothschild, Esq., Gunnersbury House, Acton (gardener, when it received a first-class certificate. The flower from which the accompanying illustration was made measured 10 inches in diameter, and created a considerable amount of interest, as it is very seldom that the *Nelumbiums* are exhibited. Visitors to Kew, however, will be comparatively familiar with them, as the plants in the tropical Water Lily houses usually flower well each summer, the graceful, long-stemmed flowers standing well above the foliage.

THE NEW NELUMBIUM SPECIOSUM OSIRIS. (Much reduced.)

Royal Horticultural Society's Temple show last year.

*Earl of Warwick* (Hybrid Tea, William Paul and Son, 1904).—Pale salmon pink, deeper centre, but no vermilion in any of the flowers that I have seen, although I see it so described in the National Rose Society's catalogue. It is distinct and has been often exhibited this year; in fact, I consider it the best exhibition Rose we have had from these raisers for some time, and it is,

Mr. J. Hudson, when it received a first-class certificate. The flower from which the accompanying illustration was made measured 10 inches in diameter, and created a considerable amount of interest, as it is very seldom that the *Nelumbiums* are exhibited. Visitors to Kew, however, will be comparatively familiar with them, as the plants in the tropical Water Lily houses usually flower well each summer, the graceful, long-stemmed flowers standing well above the foliage.

## THE CHIMNEY BELLFLOWER.

WE are indebted to Mrs. G. H. Trollope, Fairmile Hatch, Cobham, Surrey, for the photograph of splendidly-flowered plants of *Campanula pyramidalis*, from which our illustration has been prepared. The photograph was accompanied by the following note: "The photograph does not do the plants justice, but it gives a little idea of their size. They were grown in cold frames entirely up to the last few weeks, when they were placed in a cold greenhouse to keep the bees off them before they were brought into the living rooms, and where they have lasted at least four weeks in perfection. The reason of their size is that they are two year old plants, not having flowered the first year, and consequently we are able to grow them in large pots and feed them well."

## THE GREENHOUSE.

## A NEW BEGONIA (B. PATRIE).

**A**S that most popular of all Begonias, *Gloire de Lorraine*, was raised and distributed by the eminent nursery firm of MM. Lemoine et fils of Nancy, the announcement of the distribution of another variety which is considered extremely promising will be of interest. An illustration just received shows a group of plants of dwarf habit and extreme floriferousness. The variety in question is described as a new winter-flowering Begonia, the result of crossing *B. socotrana* with a variety of *B. Pearcei*, a tuberous species with velvety leaves and yellow flowers. It has the same style of growth as *B. Gloire de Lorraine*, but is distinguished therefrom by its greater vigour, denser habit, more fleshy leaves and, above all, by the brighter colour of its blossoms. Its culture is just as easy and it can be quickly propagated.

The inflorescences cover the plant like a dome and arch over at the tips in a graceful manner. The flowers, nearly all males, have four petals, and are almost as large as those of *B. Gloire de Lorraine*, their colour being a kind of reddish (*grosseille*), coppery salmon with a golden sheen. They are so numerous that a plant 25 centimetres high and the same in width bears several hundreds of them at a time, each flower lasting for a long time. As in *B. Gloire de Lorraine*, the flowers are persistent on their pedicels, remaining fresh on the drooping clusters for more than a month without shrivelling. The flowering season extends from November to April. The fact that *B. Gloire de Lorraine* emanated from the same source would lead one to have high hopes of the newcomer. As might be supposed from the fact that one of the parents is a strictly tuberous species, the variety *B. Patrie* shows a leaning towards Messrs. Veitch's many varieties between *B. socotrana* and some of the Andean tuberous-rooted sorts.

H. P.

## BLUE HYDRANGEAS.

MANY and varied methods, more or less successful, are adopted by those wishing to induce their plants of *Hydrangea Hortensia* to produce blue flowers, while occasionally one may see plants in the open ground with apparently no particular treatment afforded them producing flowers of a lovely blue shade. Sometimes among a large quantity of plants a few will have blue flowers, and

all the rest will retain their usual shade of rose. The reason given by some authorities is "alluvial deposits in the soil" in which the roots of the plants showing the blue flowers are growing. Whatever induces blue flowers outdoors without special treatment I cannot say, but I have never seen flowers produced in this shade from plants grown in pots unless they had received some special attention, or in some few cases where the soil in which they were potted contained some mineral, such as iron. There is a variety (*H. Hortensia rosea*) which I believe is known in Covent Garden as *Otaksa*, which produces the most decided blue flowers. This subject of blue *Hydrangeas* is continually cropping up among admirers of these handsome plants, and an exchange of views is always interesting and instructive.

Munden Gardens, Watford.

C. RUSE.

## SWEET PEA NOTES.

## CLASSIFICATION.

THE floral committee of the National Sweet Pea Society recommends the following varieties as the best in their colours:

*White*.—Dorothy Eckford, Etta Dyke and Nora Unwin.

*Crimson and scarlet*.—King Edward and Queen Alexandra.

*Rose and carmine*.—John Ingman.

*Yellow and buff*.—James Grieve and Paradise Ivory.

*Blue*.—Lord Nelson and A. J. Cook.

*Blush*.—Mrs. Hardcastle Sykes.

*Cerise*.—Chrissie Unwin.

*Pink*.—Countess Spencer and Constance Oliver.

*Orange shades*.—Helen Lewis and St. George.

*Lavender*.—Lady Grizel Hamilton and Frank Dolby.

*Violet and purple*.—Rosie Adams.

*Magenta*.—Menie Christie.

*Picotee-edged*.—Evelyn Hemus.

*Fancy*.—Sybil Eckford.

*Mauve*.—Mrs. Walter Wright and the Marquis.

*Maroon and bronze*.—Black Knight and Hannah Dale.

*Striped and flaked* (red and rose).—Jessie Cuthbertson and Paradise Red Flake.

*Striped and flaked* (purple and blue).—Prince Olaf.

*Bicolor*.—Jeannie Gordon.

*Marbled*.—Helen Pierce.

## TOO-MUCH-ALIKE VARIETIES.

The National Sweet Pea Society brackets the following varieties as too-much-alike. "Not more than one of the bracketed varieties shall be shown on the same stand at any exhibition of the National Sweet Pea Society." Priority is given to the first name.

Etta Dyke	John Ingman
White Spencer	Paradise Carmine
Paradise White	Spencer Carmine
Queen Alexandra	George Herbert
Scarlet Gem	E. J. Castle
Her Majesty	Rosy Morn
Splendour	Rosie Sydenham
Duke of Sutherland	Mrs. W. King
Monarch	Phyllis Unwin
Lottie Eckford	Dora Breadmore
Maid of Honour	Miss Bostock
Ivy Miller	Clara Curtis
Black Knight	Primrose Spencer
Stanley	Evelyn Hemus
Boreatton	Mrs. C. W. Breadmore
Lord Rosebery	Countess Spencer
Cyril Breadmore	Paradise
James Grieve	Enchantress
Mrs. Collier	Pride of St. Albans
Mrs. Felton	Olive Bolton
Dora Cowper	Codsall Ros
Devonshire Cream	Gorgeous
Ceres	Miss B. Whitley
Yellow Dorothy Eckford	Mildred Ward
Captain of the Blues	Countess of Lathom
Bolton's Blue	Coral Gem
Lady Grizel Hamilton	Marbled Blue
Countess of Radnor	Hester
New Countess	Mrs. Henry Bell
Princess May	Sutton's Queen
Flora Norton	Kitty Lea
Miss Philbrick	Romani Ronni
Modesty	Mrs. Hardcastle Sykes
Duchess of Sutherland	Princess Victoria
Sensation	Pink Gem

WELL-GROWN PLANTS OF THE CHIMNEY BELLFLOWER (*CAMPANULA PYRAMIDALIS*).

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**THE COLD FRAME.**—This is already proving invaluable. I am just now lifting and placing in pots Carnations layered some time ago, and which are now well rooted. Later batches will be dealt with as they are ready. Three-inch pots are large enough at the present time, and the soil should comprise good loam, free

1.—A FIRM IVY SHOOT OF THIS YEAR'S GROWTH AND SUITABLE FOR MAKING INTO A CUTTING.

from wireworms, leaf-mould and sand. I am just about to insert my first batch of shrubby *Calceolaria* cuttings. They are now abundant on the old plants. Insert the cuttings in light sandy soil, in rows in the frames, or if more convenient use boxes for the same purpose, placing these in the cold frame subsequently. Cuttings are obtained from side-shoots about 3 inches in length.

**The Vegetable Garden.**—I am planting out Cabbages to provide supplies next spring and early summer. Lettuces, too, are receiving attention. A batch of young plants is being planted in a warm aspect for early use. In gardens where winter greens have been planted between rows of Potatoes, the latter had better be lifted as soon as possible. Make up Mushroom-beds in the open when the weather is not unsuitable. This matter was fully dealt with in a recent issue. Cauliflowers that were sown a month or more since should be quite ready for pricking out in cold frames. Plants raised during the period under notice invariably do well and

provide supplies in the succeeding early summer. A pinch of seed sown at this period will make up for any shortage that may arise and ensure successional supplies.

**The Hardy Flower Garden.**—Anticipating pretty floral displays next spring, I am now planting several varieties of the quaint bulbous Irises. The Netted Iris (*I. reticulata*) and its varieties are beautiful and should be in all gardens. The Persian Iris (*I. persica*) as well as *I. histrioides*, *I. alata* and others should each find a place in beds or borders, where they make a welcome display in the spring. The Spanish Iris, too (*I. Niphon*), should be planted at this period, and for pleasing effects may be grouped in masses of distinct varieties. The once-popular laced and other hardy Pinks I am planting freely at the present time. Many of these plants may be numbered among the best of our hardy flowering subjects. Bulbs of all kinds may be planted during the present month. Snowdrops I plant in gritty soil about 2 inches to 3 inches deep. The small bulbs of the charming Winter Aconite (*Eranthis*) should be scattered about and planted where they lie, some 2 inches deep. They do well in semi-cultivated areas, and are much appreciated in early spring.

**The Greenhouse and Conservatory.**—Tuberous Begonias and other flowering plants will need less water at the roots in future, gradually reducing it until the leaves turn yellow, when the waterings should be discontinued. I am moving into the cool greenhouse the earliest batch of the Chinese Primulas, where protection from frosts may be obtained for them. Later batches and Primula obconica may remain in the cold frame for some time yet. Cacti must be kept rather dry at the roots until February next, Epiphyllums, however, being an exception to this rule.

**Chrysanthemums.**—Hardy varieties in the open border must have considerable attention given to them at this period. I make it a rule to look through the collection pretty frequently, staking and tying cumbersome and unruly growths and removing spent blossoms before they rot. Apply liquid manure to plants that have their buds well set and those also that are partially open. The large-flowered, mid-season sorts need persistent attention just now. Buds that are not yet retained should be dealt with as soon as possible, and in the case of earlier buds showing colour the plants must be placed in a cool glass structure for protection. D. B. C.

## HOW TO INCREASE THE IVY BY CUTTINGS.

OF all the hardy evergreen climbing plants we doubt whether there is any subject that will compare with the Ivy for real lasting usefulness. Owing to the great and pleasing diversity of its form and habit, varieties of the Ivy may be used on pergolas, garden arches, stumps of old trees, the walls of either dwelling-houses or outhouses, and in almost every conceivable way where a permanent covering is desired. *Hedera* is the botanical name of the Ivy, and all the forms now in cultivation have originated from one species, viz., *H. Helix*, which is a native of Great Britain and other parts of Europe. The green-leaved climbing varieties with black or yellow berries will grow in almost any aspect, but to do them well preparation of the soil in which they are to be planted amply repays the trouble taken. The ground should be deeply dug and heavily manured, and if old mortar rubbish is incorporated therewith the Ivy will revel in this, as it prefers a soil

with lime in it. On the other hand, the beautiful variegated sorts give better results in soils of a poorer nature, rich soils invariably causing the variegation to die out. These variegated sorts are not so robust, and for this reason should be planted in the warmer aspects. In south-west, west or south aspects they are seen to advantage.

When planting the Ivy see that the soil is made firm round about the roots, and for the first season the growths should be loosely secured to the walls or fences. We plant our Ivies from plants in pots in April, and they go ahead from the commencement. There are no doubt readers who would much prefer to raise a batch of plants themselves, either from stocks in their own garden or else from suitable shoots acquired from gardens of their friends. These plants may be propagated at any time between September and November quite successfully, although when raising plants in pots we prefer to insert the cuttings in October. Generally speaking, however, we prefer to make up a cutting-bed outdoors in a northern or western aspect. Those who prefer to raise these plants under glass may do so, where the temperature can be maintained at from 50° to 60°. We may mention here that these remarks apply especially to the green-leaved climbing sorts. Tree and variegated Ivies are usually increased by grafting on the common stocks in February.

The cutting-bed is our first consideration. This should be dug over at once and the surface soil well broken up, incorporating plenty of sand or gritty matter at the same time. Rake over and make fairly firm. This done, proceed to acquire a sufficient supply of shoots of the current year's growth. Fig. 1 gives a very good idea of the kind of shoot that it is intended to take in

2.—THE SAME SHOOT MADE INTO A CUTTING READY FOR PLANTING.

3.—A ROOTED GROWTH SEVERED FROM AN OLD PLANT.

hand. This is of a firm nature; soft shoots should be rejected. The cuttings when prepared should be from 6 inches to 8 inches in length. Fig. 2 shows how the cuttings should be prepared. Here it will be noticed that the shoot in Fig. 1 has been reduced in length and the lower leaves trimmed off close to the stem. To complete the operation, the stem has been cut through immediately below a joint, as it is from the base of the latter that the roots are emitted. Fig. 3 represents a shoot that has been severed from the old plant with roots adhering. Pieces of this kind may frequently be obtained, and with such material we may proceed at once to plant either in specially-prepared quarters or in permanent quarters, where their future well-being is practically assured.

Fig. 4 shows a number of Ivy cuttings inserted in a box of sandy soil. In this case they are dibbled some 3 inches to 4 inches apart in rows, and the latter rather farther asunder. Fig. 5 illustrates a number of prepared cuttings inserted in a 6-inch pot. Note how that portion of the stem from which leaves have been removed is inserted, so that the cuttings have quite a natural appearance. Always press the soil firmly at the base of each cutting, otherwise it will fail to root satisfactorily. Water the cuttings in after the operation is completed.

Should the cuttings be rooted in prepared beds outdoors or in cold frames take out a small trench some 3 inches to 4 inches deep and sprinkle in the bottom some coarse sand if the soil be of heavy texture. Place the base of each cutting firmly on the sand in the bottom of the trench, then fill in the latter, treading the soil to make it firm round the bases of the cuttings. The cuttings should be 4 inches apart and the rows about 8 inches asunder.

#### PLANTING SNOWDROPS.

The present is the best time of the whole year for planting the bulbs of this charming and

popular little flower, and no time should be lost in carrying out the work. It is true that good results can be and are secured from later plantings; but nothing is gained and much may be lost by any delay in getting the bulbs into the soil. Wherever they are planted they should be placed in masses, as the effect is then much better than when a bulb is placed here and another there. For planting in grass or the fronts of shrubberies, or for carpeting a bed of deciduous shrubs, the Snowdrop is eminently suited, while clumps dotted about in nooks in the rockery are most pleasing in the early days of spring.

The plants are not at all fastidious as to soil, as they will thrive in almost any, except that of a very wet and close character. Two inches is a good depth to plant the bulbs, taking care that each one is placed quite to the bottom of the hole. Other bulbous subjects which form excellent companions to the Snowdrop are the pretty little *Scilla sibirica* and the *Glory of the Snow*, as *Chionodoxa Lucilia* is popularly called, the bright blue colour of these contrasting in a pleasing manner with the pure white of the Snowdrop. In addition to the common and double-flowered Snowdrops there is a large-flowered and handsome one named *Galanthus Elwesii*, which should certainly be included in every collection. In addition to their uses in the open garden, all the plants mentioned above

4.—CUTTINGS PLANTED IN A BOX 4 INCHES DEEP.

are splendid for window-boxes, where they will flower with little trouble if planted now.

#### WHEN TO GATHER HARDY FRUIT.

The beginner in gardening who possesses a few fruit trees which are carrying good crops is naturally anxious to secure these with as little loss as possible, and frequently his or her anxiety on this point leads to the removal of the fruit before growth is anything like completed. This applies particularly to Apples and Pears which do not ripen until some time after they are ready for gathering, and the result of this premature removal from the trees is fruit that is shrivelled and comparatively flavourless a few weeks after gathering. As implied above, these fruits need not be ripe at the time when they are ready for collecting; indeed, only very early varieties are, and one is led to make this statement because the two phases are so frequently confused by amateurs. Apples and Pears will ripen perfectly after they are removed from the tree, providing such removal is not premature.

The exact time when such fruits are ready for picking is easily understood by those who are used to the work; but the beginner will often experience a difficulty in determining this point. A general and fairly reliable guide is to take a good average sound fruit and cut it in two, so as to expose the seeds. If these are brown the crop may be regarded as ready for picking, although a few fruits on the tree may not be quite far enough advanced. A better test is to gently lift

each fruit until its natural position is nearly reversed. If it is ready for gathering, the stalk will then part from the spur quite easily without any pulling whatever. Where sufficient energy is required to remove the fruits with leaves adhering to the stalks, the crop is not ready and should be left a few days or a week or two longer.

#### PLANTING OUT YOUNG CARNATIONS.

WHERE layering was done early in July the young plants ought now to be in excellent condition for removal from the parents, and the sooner the work is done the better. It is a good plan to go over them a few days previous to lifting and sever the layers from the old plant with a sharp knife. Removal is then felt less than when the young plants are severed and lifted at the same time.

During the last decade there has been a growing tendency among cultivators to treat the Carnation as a half-hardy plant, the rooted layers either being potted up and stood in a cold frame or house, or else planted out in a prepared bed in the cold frame, there to remain until the spring before being transferred to their flowering quarters. How far this system has tended to discourage the culture of Carnations by amateurs would be difficult to ascertain, but it is certain that many now regard a cold frame as essential for the culture of these plants. This is a great pity, because the Carnation is a perfectly hardy plant and, except in the wettest and coldest of soils, will stand the winter outdoors unharmed. Even where the natural soil is cold and wet it may be considerably improved by the addition of road scrapings, old mortar, wood ashes, burnt earth or similar lightening material, this being thoroughly mixed and deeply dug into the ground at once, breaking any large lumps encountered.

Lift the young plants with as much soil adhering to their roots as possible and transfer them to the prepared bed without delay, taking care to avoid deep planting, and make the soil moderately firm around the roots. Birds are frequently a great source of trouble during the winter, and the plants must be protected from these and rabbits by placing netting over them almost as soon as planted. Where birds only are to be feared, black cotton is less conspicuous and equally as effective if stretched from sticks a few inches high placed at intervals over the beds.

5.—CUTTINGS PLANTED ROUND THE EDGE OF A 6-INCH POT. IF THE POT IS PLUNGED IN SOIL IN A COLD FRAME THE CUTTINGS WILL FORM ROOTS MORE QUICKLY.

## THE TOWN GARDEN.

**RULES IN MOSS FIBRE.**—If we give, as we all desire to do, honour to whom honour is due, then we shall credit the versatile Mr. Robert Sydenham for having made this form of bulb culture so enormously popular. Mr. Sydenham wanted to sell his bulbs, but he was wise enough to see that the use of soil and pots would not commend itself to all ladies, so he told them how to cultivate bulbs in moss fibre and shell, offered to sell them the necessary material, and lest they should have trouble in finding suitable receptacles, he secured some most artistic jars and listed them in his catalogue. This should have been sufficient to satisfy the most fastidious; but in case there were sceptics who doubted the possibility of what Mr. Sydenham promised, he grew bulbs in jars and showed them at various exhibitions; at this everyone capitulated and sought to do likewise. All these things were done years ago, but Mr. Sydenham is still willing to do them, as our American friends would say, "right now." On behalf of my fellow town gardeners and myself I tender thanks to the genius from Birmingham.

**PREPARATION OF THE MATERIAL.**—One of the principal points in this form of culture is to have the material in proper condition at the time of use. It should be borne in mind that it is perfectly clean, and that if a newspaper is spread on the drawing-room table all the processes in connexion with it can be done there. Assuming that the mixture of moss fibre and shell is procured, it will remain only to bring it into the correct condition of moisture prior to use. This is ensured by adding a little water and thoroughly turning; it may be necessary to apply three or four quantities of water, but judgment must be used in this matter to have the material just pleasantly moist when it is put into the jars in advance of the insertion of the bulbs. My own experience goes to prove that this is the greatest element towards success or failure, and that when once the knowledge to decide the correct condition has come, the whole matter becomes exceedingly simple and failures will be few and far between.

**THE RULES AND THEIR INSERTION.**—In saying that the chief element to success lies in the condition of the material, I was regarding the question from a purely cultural point of view, for the use of the finest quality bulbs is even more imperative. If the bulbs are poor, no excellence in preparatory work or subsequent management will produce perfect flowers; therefore, procure sound, solid bulbs which have been selected with precisely the same care as those for glasses. This done, the potting (if I may use the term) should proceed on the same lines as in the case of ordinary soil, and throughout the treatment should be identical with that already advised for those grown in pots. It will, however, be essential to use even greater care in watering, as the fact that there is no drainage predisposes the receptacle to stagnation and souring which are fatal to success.

**RULES IN GLASSES.**—This is another delightful way in which town gardeners can grow bulbs. The water should not actually touch the base of the bulb, but it must be so close that there is only the thickness of a piece of paper between; in each receptacle there must be one or two knobs of charcoal, as although it will not yield food it will help materially to keep the water sweet. The bulbs for this purpose must be specially chosen for their good shape and solidity, and the bulb merchant should be apprised of the purpose for which they are to be used when the order is given. These will require a sojourn in the dark, just the same as those in pots of soil or jars of moss fibre.

**SELECTION OF BULBS.**—Neither for pots, jars nor glasses has a selection of varieties been given for the simple reason that most readers will prefer indulge their own tastes. H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**B**OUVARDIAS that are planted out should now be carefully taken up and potted. See that the plants are moist enough before taking up, then a much better ball of soil can be secured and the plants will scarcely feel the check. When they are potted place them in a pit and shade rather heavily for a few days. Syringe well until the roots take hold of the new soil. Solanums, Salvias and Libonias will need similar treatment, though they need not be put under glass for another week or ten days.

**Violets.**—I have noted in a previous calendar the necessity for preparing the frames for Violets. These plants may now be taken up and put in the frames. Use good soil (fresh and rich) around the roots, take away any runners that may be on the plants, and allow a fair amount of room between the plants; but above all keep them near the glass. After planting is completed, thoroughly water and shade lightly, if necessary, for a few days.

**Chrysanthemums.**—Those early varieties which are showing colour should be placed under glass or the night dews may ruin the blooms. Keep a sharp look-out for earwigs. Carnations of the winter-flowering section that have stood outside must now be placed in the houses, which should have been made scrupulously clean.

#### KITCHEN GARDEN.

**Parsley.**—This is always in demand, and some plants should be pricked out into a frame or two-light box. Plants from the June sowing will suit this purpose well, and choose the finest curled varieties.

**Lettuce.**—Continue to prick out those varieties which are to stand the winter. Plant rather close in the rows as the plants can with advantage very often be used as thinned in the spring; in fact, they should be planted close with this idea. Plant out also quick growing varieties in frames for use in October, November and December. Golden Ball and All the Year Round are good varieties for this purpose.

#### HARDY FRUIT.

**Apples, Pears and Plums.**—The protection of these will be necessary against the ravages of the birds. Nets should be cut up and placed over choice varieties, and if these are kept in a dry place, when finished with they will last for the same purpose for several seasons. Unfasten the ties of grafted trees and see that the shoots are secured to stakes to keep them from blowing out. Get a good stock of soil ready for top-dressing trees, and mark all those that require lifting or root-pruning, as this work can be proceeded with as soon as the fruit has been gathered.

#### FRUIT UNDER GLASS.

**Early Peaches** should have the surplus wood taken out now so that the fruiting wood which is left may have the benefit of light and air and have ample room for development. Keep the roots well supplied with moisture.

#### ORCHIDS.

**Odontoglossums** should be looked over during the next week or two and potted or top-dressed as required. Many plants will be making fresh roots, and the cool, refreshing nights now will enable them to make very speedy progress. Dendrobiums which have completed their growth may be kept somewhat drier.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**USEFUL WINTER PLANTS.**—*Begonia fuchsoides* and *B. weltoniensis* are special favourites among those who have much indoor furnishing to do in winter. They do best when potted in fibrous loam, a little peat, leaf-mould and silver sand or road grit, preferring, like *Libonias*, a warm, moist pit during the summer, where they can be treated to early closing and gentle syringings overhead. They will also bear a little weak liquid manure once a week when the pots have become well filled with roots. *Eupatorium odoratum* and *E. riparium* are of very easy culture, rooting freely into a compound of loam, well-rotted manure and rough sand. Plants which have grown one year should be cut hard back and repotted, cool treatment throughout suiting them best.

#### KITCHEN GARDEN.

**Spring Lettuce.**—In many places this is even more important than the winter crop, and there are very few who grow Lettuce all the year round, as the losses from December to March are so great. Frost, of course, injures the plants, but damp and fogs are equally fatal, and large plants suffer more than smaller ones at this period. For spring supplies I advise sowing in the open about the middle of this month. Thin sowing is most important, as crowding means weak plants, and if necessary thin early before the seedlings touch each other. Grown thus, with a favourable winter, there will be good plants for putting out in February or March, leaving the large ones to mature for early cutting. Such hardy sorts as Stanstead Park, Sutton's Winter Green and Lee's Hardy Green are among the best winter varieties.

#### FRUIT UNDER GLASS.

**Vines.**—Young planted-out Vines will by this time have made their growth, and attention should be directed to the ripening of the wood. The front ventilators must never be quite closed now, and should there be any suspicion of green wood keep the hot-water pipes slightly heated. The laterals may now be allowed free extension. Succession Vines must be encouraged to ripen their wood, so that they may be in fit condition for pruning at the proper time. All growths should be kept in check, and if the foliage is at all crowded the wood may be shortened a little, so that light and air are admitted.

**Pot Roses.**—Now is the best time to lay in a stock of these for winter blooming. Many lovers of Roses have not the convenience to produce plants of the same quality as the nurseryman, and it pays better to purchase plants than to attempt the rearing one's self. Bought specimens are now in the right condition to go on growing in a gentle heat. I find it best to start the plants almost as received, excepting that it is best to remove the twiggy shoots and cut back the next growth to a plump eye. Mistakes are frequently made in pruning these pot Roses hard at first. Tie them out as much as space will allow, and out away but very little of the growth. Soon after starting the dormant basal eyes will begin to swell, and will eventually throw up growths which will yield some beautiful blooms.

#### FLOWER GARDEN.

**Bedding Plants.**—From now onwards every effort should be made to keep the beds and their contents as neat as possible by picking off all dead and dying leaves and flowers. If further stock is required, it is better now, in the case of *Geraniums*, to depend on lifting the youngest and least ungainly of the plants in the beds before they have become much injured by frost, trimming them into shape and boxing them up to go through the winter under glass.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich

## NEW PLANTS AT WISLEY.

The joint sub-committees of the floral committee of the Royal Horticultural Society and the National Dahlia Society met at Wisley on the 4th inst. to examine the Dahlias, a number of which are this year on trial. The generally inclement weather and continuous rains for some days previously had been most unfavourable for the development of the flowers, not all of which were in a condition to judge of their merits. The following, however, each received three marks as judged from the garden or decorative point of view.

*Dahlia Emily Habgood*.—This belongs to the decorative class. Flowers pure white, freely produced on sturdy, erect stems; height 4½ feet.

*Dahlia Brightness*.—A member of the Pompon Cactus section, but the flowers are somewhat above the usual size. Colour scarlet, growth and flower heads erect; height 3 feet.

*Dahlia Avoca*.—A free and profuse-flowering Cactus variety. Colour crimson, shaded scarlet, the tips of the incurving florets being of a reddish hue. A showy plant, 4 feet high.

*Dahlia Miss Willmott*.—A plant of good garden value, free in growth and flowering. The colour is yellow, shaded with orange; height 4 feet.

*Dahlia Stahwart*.—A variety of good Cactus type. Flowers bright crimson, with maroon centre. The plant is free flowering and not more than 3½ feet high.

In addition to the Dahlias, the following plants were also awarded three points each.

*Phlox Prosper Henry*.—A dwarf-habited, free-branching variety of much promise. The pure white flower has a conspicuous lilac centre, and is of excellent form; height 1½ feet.

*Phlox Comtesse de Jarnac*.—This variety was not in flower, but its silvery leaf variegation was conspicuously good, and it was regarded from this latter standpoint. The plant is about 2 feet high.

*Zea japonica gigantea quadricolor*.—The varietal names of this strikingly-beautiful Maize are fairly descriptive, the plants presenting a handsome appearance.

## THE EDITOR'S TABLE.

APPLE THORLE PIPPIN.

Mr. William Baylor Hartland writes: "I send you a nice early Apple named as above, and am drawn towards dropping you this note on account of what is being said over the value of that over-estimated fruit Worcester Pearmain. Thorle Pippin has character and quality, and bears in thick, overcrowded bunches; then it will keep as a dessert fruit until Christmas, and is a great bearer. The Worcester Pearmain, to my mind, has nothing to recommend it but colour and constant fruiting, and its rich tone catches the public eye and the coster's barrow. The great fault now with many of our committees is that the great aim is to please the barrow of the coster and ignore merit in other directions."

[This is a variety of excellent flavour, with a pleasant acidity that would be much liked by some. It is also of attractive appearance.—ED.]

AUTUMN FLOWERS.

Dr. McWatt sends from Morelands, Duns, N.B., many interesting autumn flowers which, as he rightly says, are rarely seen in our gardens. They comprise *Chrysanthemum arcticum*, a branch of the beautiful *Spiraea Aitchisonii*, which, as our correspondent mentions, is fit to be planted among good flowering shrubs. Then also is sent *Senecio tanguticus*, which is a good plant for the more southern counties of the British Isles. We were very pleased to see some flowers of *Anemone japonicum* Queen Charlotte, a very pretty double form of a rose colour, and splendid inflorescences of the Swallow Wort or

Willow Gentian (*Gentiana asclepiadea*) and the white variety *alba*. As our correspondent remarks, these are very beautiful plants which are not very often seen. At Kew a fine effect is produced by growing them among hardy Ferns on a steep bank at one end of the rockery. Many other interesting plants were sent, but we think these were the most worthy of notice. We thank our correspondent for so interesting a collection of autumn flowers.

ABELIA RUPESTRIS (CHINENSIS) FROM LOWESTOFT.

The Rev. M. Made, Lound Rectory, Lowestoft, sends flowering sprays of the pretty shrub *Abelia rupestris*, or *chinensis* as it is now called, the sweetly-scented, bell-shaped flowers and glossy green foliage being most pleasing. He writes: "I enclose some sprays of *Abelia rupestris* from my rockery. The plant is growing well in a sheltered sunny spot (south aspect) in a raised position. The soil is partly leaf-mould and sandy loam. The *Abelia* was planted last spring."

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Twelve best Carnations for exhibition (Burnbob).**—Agnes Sorrel, maroon; Ann Hathaway, yellow; Charles Martel, scarlet on white ground; Erl King, buff, marked rose; Hidalgo, yellow, red and maroon; John Pope, deep rose; Lady Hermione, salmon pink; Liberté, yellow, maroon and crimson; Miss Willmott, coral; Hildegard, white; Robert Berkeley, scarlet; Rony Buchanan, terra-cotta and rose.

**Single Hollyhocks (North Lanes).**—It is possible that your single Hollyhocks are of an inferior strain, but all the same, as the strains ordinarily grown are so good, it is still not probable. The cultivation seems to have been too rich, and it is possible that it has created long stems and large leaves at the expense of the flowers. Very possibly if the plants be kept through the winter several stems will break up next year, less gross in growth, and you may have well furnished spikes and fine blooms. It is very possible that the strong manuring you have given your plants has enabled them to withstand an attack of the Hollyhock fungus. Probably next year you will find the fungus present, but may have a fine display of bloom all the same. In any case cease giving the plants further manure, liquid or solid.

**Plants for beds (Springtime).**—The end of May is rather late for good effects with Cottage Tulips generally, unless you purposely defer the planting of them till the end of the year. You might do this with absolute safety with both Cottage and Darwin Tulips, provided the bulbs are kept in a perfectly cool and dry place. At the time stated there are no other plants capable of the same bold effect as these late May-flowering Tulips, and the number of suitable carpet plants is not large; that is to say, whose colours would not clash with the Tulips, for we presume you require the twain to be in flower at the same time or nearly so. Two very fine yellow-flowered and cheap Tulips are Golden Crown and Golden Eagle, carpet plants for which might be golden yellow Polyanthus or Red Polyanthus. For a crimson and scarlet Tulip use *Gemeriana spatulata*, the surface to be carpeted with double white

*Arabis*. *Macrospella*, another scarlet, may have a carpet of single white *Arabis* or white *Alyssum*. Flambeau, Herschell and Glow are fine varieties of Darwin Tulips with richly coloured flowers, for which carpet plants are scarcely necessary. *Doronicum Harpur Crewe* makes a fine bed of yellow for the same season.

### THE GREENHOUSE.

#### Plants for flowering in the house during December and January

(*Susser*).—Of bulbous plants to flower during the period named may be especially mentioned Roman Hyacinths, which potted at once and brought on in a greenhouse temperature will flower well. The same also applies to Freesias. The varieties of Polyanthus Narcissi, such as double Roman, Paper White and Early Snowflake, potted now, stood out of doors and covered with ashes till they are rooted, and then gently forced, will also be available, and Tulips of the Duo Van Thol section of different colours are equally valuable for flowering in the depth of winter. With regard to Arum Lilies, your better way will be to purchase plants showing flower at the proper season. Strong clumps of the Christmas Rose bristling with flower-buds can be obtained, and these if potted will make a goodly show. There is no need to obtain these before the latter part of November. Retarded bulbs of *Lilium longiflorum*, which need to be potted about three months before they are required to bloom, are very desirable, and so are the varieties of *Lilium speciosum*, that need about eighteen weeks to develop their blossoms. *Spiraeas* and *Lily of the Valley*, too, give great satisfaction from retarded crowns. As it is very difficult, indeed practically impossible, to actually time the flowering of these without a good deal of experience (for the weather is such an important factor in the matter), it will be much better to purchase them from the large growers just as the blossoms are on the point of expanding. Of hardy shrubs *Azalea mollis* and *White Lilacs* might be flowered within the time named, but they need to be hard forced. You could obtain flowering plants of American Carnations in December, and greenhouse Heaths, Indian *Azaleas*, *Begonia Gloire de Lorraine*, *Primulas*, *Cyclamen*, *Solanum capsicastrum* with its red berries, *Poinsettia pulcherrima* and a few other lesser-known plants.

***Lonicera hildebrandiana* (B. H.).**—The plant appears to be infested with spider, which may be cured by fumigation or by syringing with insecticide. The house has probably been kept too close for it, and more air should be given. Cutting back should be left till the plant has made full growth, when all surplus shoots may be thinned out.

***Odontoglossum leaves spotted* (J. W.).**—The tiny spots on the very youngest leaves of *Odontoglossum grande* are not caused by any insect or disease, but are simply the normal condition of the plant. As you say, the spots gradually disappear as the leaves develop. This feature is by no means confined to *Odontoglossum grande*, for several other *Orchids* behave in the same way.

### ROSE GARDEN.

**Roses by the sea (E. W.).**—Tea Roses are very suitable to grow by the sea. Some of them are more robust than others. You would find the following thrive excellently: Yellows and creams—Marie van Houtte, Mme. Hoste, Mme. Charles, Mme. Ravary, Souvenir de Pierre Notting and Billiard et Barré. Pinks—Mme. Abel Chatenay, Caroline Testout, Grace Darling, Mme. Leon Pain, Killarney and La France. Reds—Griess an Teplitz, Marie d'Orleans, Marquise de Salisbury, Betty Berkeley, General Schablikine, Richmond, General McArthur and Papa Gontier. The *Rugosa* and Chinese or monthly Roses also do well, of which there are several sorts, and also the dwarf Polyanthus, which are especially lovely. You could also grow some of the flowering shrubs by the sea, viz., the hardy *Fuchsias*, *Altheas*, *Hydrangeas*, *Lilacs*, *Guelder Roses*, *Tamarisks*, *Hypericums*, *Spiraeas*, *Philadelphuses* and *Weigelas*. Most of these are tall growing. Of tall-growing herbaceous plants *Tritomas*, *Delphiniums*, *Asters* or

Starworts, Sunflowers of sorts, Ox-eye Daisies. Anemones and Aaron's Rod would do well; and of low-growing kinds choose Phloxes, Paeonies, Pyrethrums, Poppies, Geums and Potentillas.

**Rose to name** (*Mrs. J.*).—The Rose you send is the Persian yellow Briar. The green centres are probably the result of early frosts, although this variety being so double will often come malformed in this way. It would make a pillar Rose, growing to a height of some 4 feet to 5 feet in course of time. The variety Harrisonii would make the better pillar Rose. It is not so rich in colour, but far easier to grow.

### MISCELLANEOUS.

**Exhibiting Ten-week Stocks** (*F. E. P.*).—As your schedule so strictly confines the number of spikes of Stocks to be shown in a vase to six, it will be wise to read that condition literally and set up six of the best spikes of each variety you have. If the centre spikes are over, use the best of the side spikes. If you have given the correct reading of the schedule, it does not say each vase must contain a distinct variety, and therefore no one can be disqualified if, having six spikes exactly in each, the varieties are mixed. All the same, we advise you to set up one variety in a vase only, because some judges do odd things. Probably that is what is wanted; but the schedule does not say so. At many shows we have found the Stock class to be "six plants as pulled" the best way to show them. Your schedule says "spikes," not "plants," so adhere to spikes.

**Names of plants.**—*H. E.*—The shrub is *Symphoricarpos racemosus*, and the perennial is *Artemisia vulgaris*.—*C. Jones.*—*Vitis inconstans*, synonymous with *Ampelopsis Veitchii*.—*W. A. Macgregor.*—*Pyrus lobata*, synonymous with *Mespilus Smithii*.—*O. G.*—*Coronilla Emerus*.—*C. S. S. J.*—*Crinum Moorei*.—*Mrs. B.*—*Rhus Cotinus*.—*E. Bunbury.*—*Crinum Moorei*.—*Lord C.*—*Molnecia spinosa*.—*T. C.*—*Asplenium bulbiferum*; *Amorphophallus Rivieri*.—*Lady Davis*—*Magnolia acuminata*.—*H. G. Cole.*—The Sweet Pea we do not recognise, but it is very poor and, commercially, useless.

**Names of fruit.**—*O. N. J.*—1, Hawthornden; 2, Potts' Seedling; 3, Cellini Pippin; 4, White Transparent; 5, Queen Caroline.—*E. Barror Jones.*—Purple round, Cox's Emperor; red oval, Victoria; yellow, spotted red, Jefferson; green oval, Lawson's Golden Gage; green round, Green Gage. Please number fruits when sending again.—*Glasgow.*—1, Orleans (kitchen); 2, Egg Plum (kitchen); 3, Braham's Late Gage (dessert); 4, Late Prolific (dessert); 5, Washington (dessert); 6, S and 9, Victoria (kitchen); 7, Wyedale; 10, Dove Bank; 11, Prince Englebert; 12, all smashed up; 13, Green Gage.—*R. U.*—1, Mr. Gladstone; 2, Golden Spire; 3, Gascoyne's Scarlet Seedling; 4, unable to recognise, probably a local variety; 5, Crimson Queen (Herefordshire).—*H. G. Cole.*—1, Blenheim Orange; 2, New Hawthornden; 3, Sugarloaf; 4, Prince Englebert; 5, Plum Belgian Purple; 6, Pear Jargonelle.—*R. E. D.*—Apples: 1 and 9, Yellow Ingestre; 2, Pearson's Plate; 3, Round Winter Nonsuch; 4, Lady Sudeley; 5, Bess Pool; 6, Cox's Orange Pippin; 7, Braddick's Nonpareil; 8, Pear's Pippin; 10, Blenheim Orange; 11, Hambledon deus Ans.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY.

The fortnightly meeting in connexion with the above society, held on the 15th inst., was well attended, and both the quantity and quality of the exhibits was good. Dahlias were naturally very prominent, the magnificent bank staged by Messrs. Dobbie and Co. attracting much attention. Other flowers were well shown, and several interesting fruits were to be seen.

#### ORCHID COMMITTEE.

Present: Mr. J. Gurney Fowler (chairman), Messrs. James O'Brien, Jeremiah Colman, H. Little, W. Boxall, Stuart H. Low, R. G. Thwaites, F. J. Highbury, Walter Cobb, A. A. McBean, C. H. Curtis, F. J. Alcock, W. P. Bound, J. Cypher, Harry J. Veitch, F. J. Thorpe, H. G. Alexander, H. A. Tracy, W. H. White, Gurney Wilson, J. Wilson Potter, W. Bolton, A. J. Foster and de B. Crawshaw.

Messrs. Sander and Son, St. Albans, were exhibiting a small group of plants to their usual high-class style. These comprised good specimens of *Miltonia spectabilis* moreliana, *Odontoglossum grande*, *Cattleya gaskelliana* alba, *Phalenopsis Esmeralda* atro-rubens, *Brasso-Cattleya Doris* and B.-C. Charles Maron. Silver Banksian medal.

From Messrs. Moore, Limited, Rawdon, Leeds, came a nice group of various kinds, a large well-flowered plant of *Vanda cirulea* occupying a prominent position. *Odontoglossum harryanum*, *Trichocentrum albo-purpureum* and the curious green-flowered *Cynorchis chlorochilon* were three of the most conspicuous. Silver Banksian medal.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, put up a nice little group of splendidly-grown plants. Among these a particularly fine flower of *Cattleya Iris*, *Oncidium oblongatum citrinum*, *Cyclopogon Veitchii*, *Stanhopea oculata*, *Dendrobium sanguinolentum* and *Cypripedium concolor* were specially noticed. Silver Banksian medal.

Messrs. William Bull and Sons, King's Road, Chelsea, staged a nice little bank of *Cattleyas*, including several interesting crosses. *C. Harrisonii* × *C. aurea*, *C. velutina* × *C. aurea* and *C. schofieldiana* × *C. aurea* gave some very

interesting results. A pretty little bigeneric hybrid, the result of crossing *Cattleya Harrisonii* with *Sophranitis grandiflora*, was also included, this partaking in an unmistakable manner of both parents.

Messrs. Charlesworth and Co., Heaton, Bradford, exhibited a tastefully-arranged group of well-grown plants, including many interesting things. *Cypripedium Daisy Barclay*, *Zygopetalum Burkii*, *Z. roeblingianum*, *Vanda saoderiana*, *Sophran-Cattleya Gratrixe* and *Laelio-Cattleya Aleone* were a few that we noticed as being especially good. Silver Flora medal.

From H. S. Goodson, Esq., Putney (gardener, Mr. G. E. Day), came a nice collection of well-grown plants, including *Cypripediums*, *Cattleyas* and *Odontoglossums* in great variety. *C. fairieanum*, *Miltonia Leopoldii* and the curious little *Angraecum distichum* were three of the most interesting. Silver Flora medal.

The handsome group staged by Messrs. Cypher and Sons, Cheltenham, contained many very fine specimens that manifested the good culture meted out to them. *Miltonia spectabilis* moreliana, *Phaio-Cymbidium Chardwarensis*, *Cattleya thayeriana*, *Cypripedium concolor*, *C. Mandie*, *C. fairieanum*, *Masdevallia stupenda*, *Zygopetalum rostratum* and *Oncidium papilio majus* were only a few among the many interesting subjects to be seen. Silver Banksian medal.

Messrs. Stanley and Co., Southgate, London, N., exhibited an interesting group of *Cattleyas* and *Cypripediums*, among which were some choice and interesting plants. *Cattleya Harrisonii* alba Stanley's variety was one of the most beautiful, the flowers being pure white with the exception of a pale yellow blotch on the lip. *Cypripedium A. de Lairese* was in first-class condition. Silver Banksian medal.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. Joseph Cheal (chairman), Messrs. W. Bates, J. Willard, Alex. Dean, George Kell, W. Fyfe, H. Parr, A. R. Allan, J. Davis, W. Barnes, W. H. Dwyers, G. Reynolds, J. Jaques, Charles Foster, J. McIndoe, Owen Thomas and W. Ponpart.

Messrs. J. Veitch and Sons, Limited, Chelsea, staged a remarkably fine group of high-class vegetables, these including such subjects as Cabbages, Savoy Early Elm and De Vertus, Brussels Sprouts, Carrots, Parsnips, Potatoes, Beetroots, Onions, Turnips, huge heads of Celery and Lettuces of various sorts, the centre of the group being occupied with a collection of ornamental Gourds. The arrangement here was exceedingly good and showed the high-class produce off to the best advantage. Carrot Veitch's Matchless, a long, large, beautiful clean variety, attracted much attention. A very interesting and instructive exhibit. Silver-gilt Knightian medal.

From Messrs. Carter Page and Co., London Wall, came a very interesting and comprehensive collection of Tomatoes, all shapes, sizes and colours being represented. The yellow varieties were especially good. Silver Banksian medal.

Mrs. Trotter, Wyrham Park Gardens, Barnet, Herts (gardener, Mr. J. H. Juniper), exhibited three bunches of a white Grape, a sport from Black Hamburgh. The habit is stated to be vigorous, and the fruits free setting and of good keeping qualities.

A beautiful collection of Melons came from Lady Northcliffe, Sutton Place Gardens, Guildford (gardener, Mr. Joseph Gootley). These were a very well-finished lot, and the skins of all were well netted, thus adding much to their attractiveness. Hero of Lockinge, Sutton's A 1 and The Pear were the varieties shown. Silver Knightian medal.

A promising new Melon of good flavour named Barnett Hill Favourite was shown by F. H. Cook, Esq., Barnett Hill, Womersh, Guildford (gardener, Mr. A. Michelson). Apple Red Victoria, a beautiful large cooking variety, was exhibited by Mr. G. W. Miller, Clarkson Nurseries, Wisbech, and received an award of merit.

Mr. W. H. B. Fletcher, Aldwick Manor, Bognor, Sussex, exhibited a spray of *Vitis Cointetiae* bearing several clusters of ripe fruits, these being very rarely seen.

A collection of Apple Grenadier from Mr. Charles Luffen, West Dulwich, received cultural commendation.

#### FLORAL COMMITTEE.

Present: Mr. W. Marshall (chairman), Messrs. H. B. May, W. A. Binney, C. T. Drury, James Walker, C. R. Fielder, J. Jennings, C. Blick, W. T. Ware, Charles Dixon, A. Turner, H. J. Jones, E. H. Jenkins, James Hindson, J. T. Bennett-Poe, James Douglas and W. J. James.

Mr. Amos Perry, Hardy Plant Farm, Winchmore Hill, displayed in excellent fashion a particularly good lot of hardy things, notably Lilies, Larkspurs and Poppies. The former group was represented by such species as *tigrinum*, *auratum* and *speciosum* in variety, the Larkspurs in their many beautiful shades creating a fine display. *Artemisia lactiflora* (with creamy inflorescences) and *Endbeckia Herbolta* (a rich yellow and possibly an improved form of *R. nitida*) were noted for their pleasing effects. Silver Flora medal.

Messrs. William Cutbush and Sons, Highgate, had a capital group of Carnations, displaying the blooms in large vases in a most effective way. Some of the best were Helen Gould, Mrs. H. Burnett, White Perfection (very fine), Robert Craig, Victory and Britannia, the three last named representing the finest types of scarlet-flowered Carnations at present in cultivation. Messrs. Cutbush also set up a group of the showy *Coleus Cordelia*, the leaves of which are of a scarlet and bronze tone. Silver Flora medal.

Messrs. G. and A. Clark, Limited, Dover, had a small yet attractive group of hardy plants in which *Gladiolus princeps*, *Himmennannia fumarifolia* (a yellow Poppywort), *Gilia coronopifolia* (rich scarlet in tall spikes), *Kniphofia* in many showy varieties, *Helianthus mollis*, *Helienium*

*Bolanderi* Golden Gem (a showy plant with blackish disc), *Delphinium The King* (a fine deep blue with white eye) and others. Bronze Flora medal.

Messrs. H. B. May and Sons, Edmonton, filled a long table with well-grown examples of scarlet *Salvia*, the blue and white-flowered varieties of *Plumbago capensis*, *Bonvardias* in scarlet and white, a fine bed of well-flowered *Heliotrope*, and a brilliant lot of single, double and Cactus-flowered *Pelargoniums*. Silver Flora medal.

Mr. A. L. Gwillim, New Eltham, Kent, displayed superb blossoms on boards in colours of yellow, scarlet, orange, crimson, salmon and other shades of *Tuberous Begonias* representative of an excellent strain. Silver Banksian medal.

The *Gladioli* from Messrs. J. Burrell and Co., Cambridge, were a superb lot. The compactness of the well-formed spikes, the brilliant and decisive shades of colour and the handsome flowers all told of excellent culture. In not a few instances, as many as a dozen or thirteen flowers were seen on a spike. The fact that the great majority of those exhibited were seedlings as yet unnamed precludes us from giving a list of names. Silver-gilt Flora medal.

The Misses Hopkies, Mere Gardens, Shepperton-on-Thames, had a small rockery exhibit arranged with hardy plants.

Messrs. T. S. Ware, Limited, Feltham, put up an imposing group of hardy plants in the cut state, displaying in the most effective manner a large collection of seasonable subjects. The new double-flowered *Aster Beauty of Colwall* was shown in excellent form and there were numerous plants of interest or merit. Bronze Flora medal.

Messrs. William Bull and Sons, Chelsea, had a small group of stove plants with *Orchids*.

Mr. J. T. West, Tower Hill, Brentwood, had a capital lot of Cactus and Pompon Dahlias in many good varieties, the whole being admirably staged. Among the too rarely seen *Pompoms* Star, yellow; Darkest of All, maroon; Adelaide, lilac; Daisy, fawn; Douglas, maroon; and Donovan, lilac and mauve, were all good. Silver Flora medal.

Messrs. Eggett and Son, Thames Ditton, had a small group of hardy Ferns in variety.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, displayed an interesting lot of shrubs, deciduous and evergreen, in which we noticed *Rhus typhina* laciniata, *Buxus sinensis* (a very distinct species), *Spirea Aitchisonii*, *Ailanthus glandulosa* villosioriana, *Berberis purpurea* (Paul's variety), *Enonymus latifolius* in fruit, and many others. *Hibiscus* in variety and *Rosa sericea ptericantha* were also notable. Silver Flora medal.

Messrs. Carter Page and Co., London Wall, again set up a sumptuous lot of Cactus and other Dahlias, finely arranged in groups. Tufted *Pansies* also came from this firm. Silver-gilt Banksian medal.

The single and Cactus Dahlias from Messrs. J. Cheal and Sons, Crawley, were very good and effectively arranged. *Glencoe*, *Peggy*, *Columbine*, *Darkness*, *Snowdrop*, *Hector* and *Mrs. Bates* are all good single-flowered sorts. Silver Banksian medal.

Mr. W. Peters, Leatherhead, had a group of *Aster Lena* Peters.

Some very fine *Begonias* came from Messrs. Cannell and Sons, Swanley. *Rosebud*, a lovely salmon pink; *Washington*, scarlet; and *Polar Star*, a very fine white, were in every way excellent. Silver Banksian medal.

Mr. Frank Brazier, Caterham, had a large display of *Phloxes* and *Michaelmas Daisies*.

Messrs. Hugh Low and Co., Enfield, had a lovely lot of Carnations, in which *Britannia* and *Victory* were especially good. *Chironia ixifera* with pink flowers was also superb, while a variegated *Dracena* named *Prince Albert* of the *D. australis* section is a distinctly good and pleasing variety. Silver Banksian medal.

Messrs. James Veitch and Sons, Limited, Chelsea, had a glorious lot of *Nerine Fothergillii* major with scores of the attractive scarlet heads of flowers. Three species of *Æschynanthus*, viz., *pulcher*, with scarlet flowers; *grandiflora*, with vermilion-orange flowers; and *lobbianus*, with crimson-scarlet flowers and dark foliage. The same firm also staged a very large collection of shrubs, among which the *Heaths* and *Pernettyas* were very interesting. Silver-gilt Banksian medal.

Messrs. Barr and Sons, Covent Garden, filled a table with seasonable hardy plants, *Snagdragons*, *Sternbergias*, *Zephyranthus candida*, *Plantago maxima*, *Nertera depressa*, *Parnassia caroliniana*, *Kniphofia*, *Actea spicata* alba, *Phloxes*, *Primula capitata* and others. A fine display was made with *Sedum spectabile atrosanguineum*. Bronze Flora medal.

Messrs. Dobbie and Co., Rothesay, filled the end table of the hall with a remarkable lot of Cactus, Pompon and single Dahlias, the flowers being in splendid condition and most artistically arranged. The variety was well high endless, and in their many and gorgeous shades made a very effective whole, enhanced to a considerable degree by the introduction of the coloured sprays of *Kochia*. We have no hesitation in regarding this as the most representative and complete group of Dahlias we have ever seen, the *Peony*-flowered, show and other types, in addition to those already named, being fully represented. Silver-gilt Flora medal.

From Messrs. W. Wells and Co., Merstham, Surrey, came a representative gathering of early-flowering *Chrysanthemums*, *Pentstemons*, *Michaelmas Daisies* and *Phloxes*, the numerous varieties being displayed to advantage. Silver Banksian medal.

The Hardy Plant Nursery, Guildford, had many good seasonable hardy plants, such as herbaceous *Lolias*, *Gladioli* and *Michaelmas Daisies*.

Messrs. Pennell and Son, Lincoln, exhibited in fine condition their new Ivy (*Hedera dentata variegata*), perhaps the best of all silver-leaved Ivies.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## PHOTOGRAPHIC COMPETITION FOR OUR READERS.

WE frequently receive photographs from our readers of some pretty spot or corner in their gardens, and it has occurred to us that it would be interesting if prizes were offered for the best examples sent in. We therefore offer a first prize of two guineas for the best photograph of a reader's garden, and a second prize of one guinea. Each photograph must be accompanied by a written description of the garden. Photographs must be sent addressed to "The Editor, 20, Tavistock Street, Covent Garden, London, W.C.," on or before October 31, and the envelope or wrapper must be marked on the outside "Photographic Competition," and accompanied by a coupon, which appears in the advertisement pages. Each photograph must have the sender's name and address plainly written on the back. Rejected photographs will be returned if stamps are enclosed for postage. The Editor reserves the right to use any photograph and description that does not win a prize, and his decision must be regarded as final.

## NEW SEEDLING ROSES AT THE AUTUMN SHOW.

I THINK a description of the new Roses staged at the National Rose Society's autumn show, held in the Royal Horticultural Hall, Vincent Square, on Thursday in last week, would not be without interest to such of your readers as were not present. The class, taken as a whole, was memorable in more ways than one—in that the judges thought that no less than four out of the ten varieties staged were worthy of a gold medal, three others received a card of commendation, one they desired to see again, and of the two that were passed over one at least had already received the lesser award and the other variety put up was, unfortunately, not eligible, having already passed into commerce prior to November, 1907.

Perhaps there is no more vexed question troubling the Rose world at the moment than the judging of these new seedling Roses. Undoubtedly the seedling Rose class is the most difficult of any in the whole schedule to judge; and although the methods adopted have been improved of recent years, they are, I think, still capable of improvement, and no doubt the matter will receive the further consideration of the committee of the National Rose Society. At the same time, I am still of opinion that it will never be satisfactorily solved until the Roses are judged first of all as seen growing, secondly as staged, and that only those who have seen the

Roses growing in fair quantity and know them can really form a fair opinion of their relative merit.

I will take the flowers in the order in which they were staged:

*Lady Alice Stanley*.—A Hybrid Tea raised by Messrs. S. McGredy and Son of Portadown, Ireland; a large flower with a round petal of good shape, not quite the usual petal of the exhibition Rose, but none the less pleasing on that account, coming well to a point in the younger flowers. The scheme of colour is after the style of that old garden Rose Grand Duc A. de Luxembourg or the more modern Mrs. E. G. Hill, namely, having the deeper shade on the outside of the petal and the lighter shade inside, the reverse of the usual colour scheme, the colour outside being a deep coral rose, inside pale flesh, suffused pink. Fragrant, a good grower and free autumnal. Exhibited by the raisers in good form on more than one occasion this year. Awarded a gold medal.

*His Majesty*.—A Hybrid Tea also raised by Messrs. S. McGredy and Son. A fine dark crimson flower of great size and good substance; of the usual exhibition type with high pointed centre. The plant exhibited showed strong growth, with flowers produced at the end of each shoot; a very promising variety, fragrant. Gold medal.

*Lady Gwendoline Little*.—A Tea raised by Messrs. J. Jefferies and Sons of Cirencester. A pretty decorative variety, free habit and flowering profusely; flowers small but of good colour. Mme. Abel Chatenay colouring on a golden yellow ground would perhaps best describe this flower; fragrant. Awarded a card of commendation.

*Iceberg*.—A very interesting cross between wichuraiana and a Tea (I believe Niphetos), with the foliage of the wichuraiana and habit of growth of a good bedding Tea, the first of a new race that has great possibilities: raised by Messrs. Paul and Son of Cheshunt. The flower is a pure white, small, but perfectly formed; perpetual in character. One felt that some award other than a card of commendation was merited. Might it not be possible to have three grades of medals for these seedling Roses—a gold, a silver-gilt and a silver medal? As I have remarked, here was a new break, very interesting, a perfect Rose in its way that a card of commendation hardly did justice to. Messrs. Paul and Son are to be congratulated on striking another fresh line. Rose growers will always remember with gratitude that to them we owe the first Hybrid Tea. What is to be the name of the class of this fresh break I wonder? Awarded a card of commendation.

*A. Hill Gray*.—A Tea raised by Messrs. Alexander Dickson and Sons of Newtownards,

Ireland. A beautiful Rose of excellent shape, well staged in a tall stand. Delightful pale yellow colouring, fragrant and a good grower; undoubtedly the finest Rose staged in the class. The award of a gold medal was practically unanimous. Good Teas are scarce and are very welcome, especially when up to exhibition standard.

*Dr. O'Donel Browne.*—A Hybrid Tea approaching closely to the Hybrid Perpetuals, raised by Messrs. Alexander Dickson and Sons of Newtownards and sent out by them this year. A fine-shaped flower, resembling Dupuy Jamain in colour and shape but coming much better than that old favourite, being particularly good in autumn. A good vigorous grower with very strong perfume, and, moreover, free flowering; colour rosy carmine. Awarded a gold medal.

*Mrs. David Jardine.*—A Hybrid Tea also raised by Messrs. Alexander Dickson and Sons: as shown here not quite in character. A great number of flowers were staged, but some were deficient in size. This Rose has already made a great reputation in America under glass, and I believe it to be a thoroughly good Rose. At its best it reminds me of a pink-pointed Mrs. Theodore Roosevelt. Very free flowering, almost Tea-like in character; a good grower.

*Grace Molyneux.*—A Hybrid Tea raised by Messrs. Alexander Dickson and Sons, but not staged in its true form. Having grown this Rose for the last three years I can thoroughly recommend it. It has a strong Tea perfume, distinct foliage, its flowers produced on long stalks and very vigorous. Excellent for decorative purposes and sometimes coming good enough for exhibition. It has already received the National Rose Society's card of commendation, but as staged was not up to gold medal form.

*Mrs. William Cooper.*—Hybrid Tea raised by Messrs. Hugh Dickson of Belfast. A beautiful Rose, not shown at its best; pale flesh pink of Viscountess Folkestone colouring. Not perhaps quite distinct enough, but the judges asked to see it again.

A sport from Dorothy Perkins, the name of which I missed.—Staged by Messrs. Cocker and Son of Springhill Nurseries, Aberdeen. A very pretty shade of pink, said to be freer in autumn than Dorothy Perkins. A card of commendation was awarded.

*Teresa Devan.*—Staged but not eligible for the gold medal, as it had, unfortunately, been put in commerce prior to November, 1907. A Tea raised by Messrs. Garaway of Clifton, Bristol, of very beautiful colouring, quite distinct; old gold, flushed vivid pink. It is of great merit as a garden Rose, apparently free flowering, and the plant shown had good growth and foliage. Altogether a very interesting class, and, having regard to the time of year, showing great progress.

*Purley.*

HERBERT E. MOLYNEUX.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

September 29.—Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster, 1–6 p.m.

October 7 and 8.—National Chrysanthemum Society's Early Autumn Exhibition, Crystal Palace.

October 15 and 16.—Royal Horticultural Society's Exhibition of British-grown Fruit, Vincent Square, Westminster, S.W.

**Exhibit of English-grown Grapes.**—It will be known to most of your readers that the Royal Horticultural Society have, at their Wisley garden, the most complete collection of Vines to be found in this or any other country, and they propose to exhibit at the fortnightly exhibition of flowers and fruits to be

held on the 29th inst., at the Royal Horticultural Hall, Vincent Square, Westminster, about thirty varieties of dessert Grapes grown upon these Vines, so affording a unique and perhaps hitherto unparalleled opportunity for the comparison of so large and representative a collection of fruits. Such an exhibit is intended to be chiefly educational, and especially to draw attention to some of the smaller-berried varieties which so vastly surpass in flavour the larger and more showy varieties. Officers of the society will be in attendance with the exhibit on the 29th inst., to give information to, and to answer the enquiries of, visitors.—W. WILKS.

### United Horticultural Benefit and Provident Society.

—The monthly meeting of this society was held at the Horticultural Hall, Vincent Square, Westminster, S.W., on the 14th inst., Mr. Charles H. Curtis in the chair. Four new members were elected, making a total of fifty-two this year to date. The amount of sick pay since the last meeting was £39 13s. Mr. A. Hemsley resigned his office on the committee through pressure of business and inability to attend the meetings, which was accepted with regret, and a vote of thanks was accorded him for his valuable services for several years past. The annual dinner will be held this year at the Waldorf Hotel, Aldwych, W.C., on Thursday, October 15, at 6.30 p.m. Dr. R. Boxall of Abinger has kindly consented to preside on this occasion.

### Resignation of Mr. Charles Ross.

—Many of our readers will learn with regret that this veteran gardener, now in his eighty-fourth year, will be leaving Welford Park, Newbury, with which place he has been so long identified, at Michaelmas next. We learn also that Mr. W. Pope, formerly of Highclere Castle Gardens, has taken over the kitchen and fruit garden at Welford Park on his own account. During Mr. Ross's residence at Welford he has raised many fine Apples, and not long since was awarded the Royal Horticultural Society's Hogg medal as an Apple raiser.

## CORRESPONDENCE.

### Prizes for cottage gardens.

—The report in THE GARDEN for August 29 on the Countess of Selkirk's cottage gardens prizes is happily only one of many such instances where gardening is encouraged in the rural districts by the offering of prizes—in some cases of a substantial nature—by ladies and gentlemen of the neighbourhood. Fortunately, there appears to be a natural love for cottage gardening, especially of late years, and the rapid growth of horticultural shows has doubtless added great stimulus to this fascinating and profitable pastime; further, the offering of prizes, such as those mentioned above, acts as an incentive to each one to strive his utmost to beat his neighbour. The cottagers of Duffryn and St. Nicholas, near Cardiff, are particularly favoured in having valuable prizes to compete for, those for the "best vegetable garden" given by John Cory, Esq., and for the "best flower garden" by Reginald Cory, Esq. The gardens were judged in July, but though the entries were not so numerous as those mentioned in your report, the competition was very keen, and many excellent examples of well kept and cropped gardens were seen. I notice that Mr. Service, in his report of the Countess of Selkirk's garden prizes, advises the use of more hardy border flowers instead of so many usual bedding subjects. This is good advice; and the idea seems to have been grasped at Duffryn, where as many as thirty to forty distinct varieties of perennials were noted in some gardens. In the vegetable gardens instances were noticed of the keenness for gaining points by having a large

variety, but this idea in a cottage garden when carried to extremes is not advisable. In many gardens one saw perhaps half-a-dozen plants of Celery, Leeks or Tomatoes, and often of very poor quality. The better plan would be for exhibitors in cottage garden competitions to have a schedule of points drawn up for them, and such subjects that are known as the most useful to a cottager encouraged by giving more points. A good plot of Potatoes, or bed of Onions, for instance, should score more points than half-a-dozen small batches of less profitable subjects.—ARTHUR COBB, *Duffryn Gardens, Cardiff.*

**Autumn Roses.**—Some varieties of Roses are doing exceptionally well this autumn, and should the weather continue to be fine there will be plenty of beautiful flowers for some time to come. Caroline Testout is especially good, and although the flowers are not so large as they were early in the season they are splendid in form and colour. Mrs. J. Laing, too, is doing well, and is one of the best and most useful Roses we have. It is especially good for table decoration. Kaiserin Augusta Victoria is probably better now than it was in the early season. It is a mass of flowers of beautiful form and colour. This is a valuable variety for cutting during the autumn. Frau Karl Druschki has been flowering all the season, and the colour is just as pure now as earlier in the season. George Nabannand is a splendid autumn variety, and is worth growing for that purpose alone. Mme. Ravary is a splendid variety, and has been flowering all the season. The beautiful Mme. Abel Chateau, too, is a very continuous bloomer. Lady Battersea, Papa Gontier, Gustave Grunerwald, Maman Cochet and Richmond have all done well this autumn.—H., *Frogmore.*

**Caterpillars on fruit bushes.**—As your correspondent "A. P. I. S." is having trouble with caterpillars, I advise him to try the following next year as a preventive: Just as the Gooseberries and Currants are in flower, or about half set, dust the leaves all over with a mixture of 1lb. of Hellebore powder and 2lb. of flowers of sulphur thoroughly mixed together, dusting it on through a fine flour-dredger when the foliage is damp with dew or after rain, choosing a calm day. The powder will be washed off before the fruit is fit for use, but the effect will last the summer, and he will not be troubled with many caterpillars. A very good thing to kill them is to dissolve 2oz. of Matchless Cleanser soap in one gallon of water and syringe the bushes with it in the evening; but by using the powder he will have a preventive and will not want a cure, as I have proved.—R. H. MANN.

**Bulbs in good condition.**—In a recent call at Messrs. James Veitch and Sons, Chelsea, I learned that the Dutch bulbs have come over in remarkably fine condition; in fact, the supply is one of the best for many years. Hyacinths are large, firm and thoroughly well ripened; Tulips are very plump and richly coloured. This is good news and opens up a pleasing prospect for bulb-lovers.—W. P. W.

**Charming Cactus Dahlias.**—Whatever we may think of the Cactus Dahlias as garden plants, there is no gainsaying that they are very beautiful as flowers on the show-board. Among several pretty sorts at the National Dahlia Society's exhibition I noted the following: Daisy Staples, pink with white centre; Antelope, yellow with bronze outer florets; Faunus, fawn; Lusitania, orange scarlet with crimson edge, a splendid flower; Ibis, glowing orange; Harold Peerman, canary; Cecilia, pink, lemon centre; and Marjorie Cairnes, yellow with rose outer florets.—W. P. W.

**Classification of the Daffodil.**—There seems to be a very remarkable muddle in Class VII. of the new Narcissus classification of Daffodils. The committee "have been compelled to fall back on purely arbitrary divisions, determined chiefly by measurement," which they say "are now put forth by the authority of the

Royal Horticultural Society." It appears something new that any voluntary association should take to themselves the alteration of a classification which has been in the process of evolution by scientific botanists for a period of over 200 years. In this class are brought together the following species, together with some about which there is a doubt: *Triandrus* in all its varieties, and *calathinus*, which may or may not be a variety; *Jonquilla*; *juncifolius* with its allies *gracilis*, *serotinus* and *viridiflorus*; *biflorus*, which is said to be a hybrid; *odorus Campnelli*, *rugulosus* and *heminalis*, which are said to be hybrids; and *Tazettas*. As far as one can learn the *Tazetta* is common to the temperate zone of Asia, and has probably found its way to Europe in past ages through the Byzantium. It is a favourite flower in Persia, China and Japan. Its general growth and coarse habit do not seem to fit it to be shown in the same class as the delicate and graceful flowers of *triandrus juncifolius* and *Jonquilla*. And no one would ever think that the new classification was meant for any more than a guidance to show committees in drawing up their schedules. Yet how would these species look if shown in the same class? Some unlucky person who thought that the greater number of species he could show in the class would be a help to a foremost position, would find his exhibit utterly neglected for the great coarse *Tazetta*, with its strong smell, and the many coarser hybrids with incomparabilis flowers crammed six to twelve on one stalk. Fashion may demand size, but those who follow fashion oftentimes lose all sense of artistic feeling and become mere slaves in the following of Goliath. It would seem the wisest to allow the *Tazettas* and their hybrids a class to themselves and not have them bunched up with others to whom they have no affinity. In collections of *Daffodils*, species should have their proper place, and it would be a good thing if in many schedules a number of varieties to be exhibited should be fixed, not to be exceeded, in each class, section or division which is allowed to be shown in that collection. Only too often we find in a fifty class nothing but florists' flowers, with a preponderance of poetical and red-tipped cups, when in the schedule it is open to all species and varieties. It is to be hoped that committees of shows may keep species distinct from garden hybrids and not mix up the inter-breeding of species with the produce of hybrids.—A DAFFODIL LOVER.

**Rose Prince de Bulgarie with yellow flowers.**—I notice in THE GARDEN of September 14, 1907, that a correspondent describes Prince de Bulgarie as yellow. This has also been my experience this season. Not only Prince de Bulgarie, but also Joseph Hill has come a beautiful apricot colour, without any suspicion of pink. The autumn flowers, however, have reverted to the ordinary colours described in the catalogues. I may state that they were grown as standards and were not shaded. The soil is a heavy loam on sand. Is this a temporary reversion to the colouring of one of the parents or can it be explained in some other way?—C. O. JONES, *Norlands, Mount Road, New Brighton.*

**Grape Prince of Wales.**—In your note on page 430 I note what you say respecting this Grape. I am convinced it has a large future before it with those persons who cannot successfully cultivate Mrs. Pince; and there are numbers who fail with the latter, either in the size of the berry, or, what is more important, the colour is deficient. With Prince of Wales the colouring is so much easier and no difficulty is experienced. The berries are much larger, the bunch equally shapely, and, what is highly important, the flavour is all that can be desired. To many I have recommended Prince of Wales and none have regretted adopting the hint.—E. M.

**Scarcity of wasps.**—I do not remember a season when so few wasps have been in evidence. Last year about forty nests were

destroyed in or near these gardens, but at present (September 2) only two nests have been discovered and very few wasps are seen. This is a consolation to fruit growers, especially those who have large quantities of standard fruit trees, which it is almost impossible to cover with wasp-proof material. The reason for this scarcity is stated to be owing to the late, cold spring, a large number of wasps dying during hibernation. Workers are reported to be fairly numerous in some districts. Birds are the worst enemies this season, attacking Tomatoes, in addition to fruit. In our case it cannot be moisture they are seeking, as the garden is parallel with the river.—C. RUSE, *Munden Gardens, Watford.*

## THE GIANT PUFF-BALL.

The subject of our illustration is a large cloven example of the Giant Puff-ball (*Lycoperdon giganteum*, now usually referred to as *L. Bovista*). The name *Lycoperdon* is derived from the Greek *lukos*, a wolf, and *perdon*, dung, from the old belief that Puff-balls grew from the dung of the wolf. *Bovista* comes from the German *bohist*, a fairy ball. A modern popular name is

A GIANT PUFF-BALL.

Devil's-box, or, when the fungus is over-ripe, Devil's Snuff-box; the modern apt Greek name is *Kranion*—like a skull. We have in the illustration before us a cloven skull as represented by a cleft Puff-ball. Giant Puff-balls usually grow in gardens, orchards and rich pastures. Sometimes they grow in huge fairy rings from 30 feet to 50 feet in diameter, truly elfish productions. Individual examples often attain a very large size, a common diameter is 12 inches to 18 inches, with a weight up to 20lb. An example is on record of a diameter of 5 feet 4 inches one way and 4 feet 6 inches the other, with a height of 9½ inches. The Giant Puff-ball belongs to the edible class, and fungus enthusiasts eat and approve it. If tried for the table it must be when the flesh is perfectly white, then cut in slices less than half an inch thick, dip in beaten-up eggs, sprinkle with bread-crumbs, add pepper and salt if approved and fry till the surfaces are browned. The illustration is from a photograph kindly sent by Mr. R. W. Woosnam, Warley Mount, Brentwood, Essex. The Puff-ball shown, our correspondent mentions, was found in Southchurch Churchyard (near Southend-on-Sea); "it weighed 4lb. all but an ounce, and when cut through was found to be solid throughout."

## THE ROTATION OF CROPS.

THIS is one of the oldest phases of good kitchen gardening, yet it is safe to say that none is less perfectly understood by the majority of cultivators. The reasons for this failure on behalf of cultivators to grasp the elements of the rotation of crops need not be sought for in vain, the chief one being that hard-and-fast rules cannot be laid down concerning what particular crop shall succeed an existing one, and also that in many cases the grower has only a partial control over circumstances, and consequently is obliged to do the best he can with the soil at his command.

At the outset it may be as well to briefly consider the principles which underlie the rotation of crops. The chief object with most cultivators in changing crops is to get the best possible results from the soil, the idea being that different classes of plants require different kinds of food for their upbuilding; and there is, no doubt, a lot of wisdom in such a course. Another point, however, which is frequently overlooked, but which is equally or even more important, is the fact that certain diseases and pests attack certain plants only, and therefore by keeping these plants off the ground for two or three years a disease may be eradicated. Club-root of the Cabbage family is a disease which may be mentioned as an example.

As previously stated, a cultivator frequently has to do the best he can under existing circumstances, and often these are such as to render it imperative to overlap crops which would be much better if given entirely fresh ground. There are, however, many gardens wherein it is possible to give the various plots a change of crop each season, and wherever such a course is possible every effort should be made to adopt it.

As the question is naturally a very complicated one, only general indications and hints as to carrying out the work can be given; but these, coupled with intelligent application, will, I hope, prove of some use to amateurs and others who have only given the matter a passing thought. Taking the Cabbage family first, it has been proved that all the members thereof require practically the same kinds of food, and in addition, as previously stated, all are subject to attacks of club-root and other diseases and pests which do not attack some other classes of plants; hence it would be unwise to let a crop of Cauliflowers, for example, be followed by spring Cabbages, as the former will, to a great extent, have exhausted the soil of those particular foods needed by the Cabbages, and any disease which might have been present on the first crop would almost certainly make a host of the second. In practice it is found to be a good plan to let deep-rooting crops, such as Parsnips, Carrots or Beet-roots, follow any of the Cabbage family.

Potatoes, again, are another crop which ought not to occupy the same ground two years running, as they are veritable gluttons so far as potassic manures are concerned, and in practice it has been proved that much better results can be obtained by only cropping a certain plot with Potatoes once in three years. Any of the Cabbage family, Peas, Beans or Onions may, with advantage and safety, follow Potatoes, Carrots, Parsnips, Beet-roots or Celery. Generally speaking, Beans should not follow Peas nor *vice versa*, and this applies to any kinds which are closely related or belong to the same family, hence Tomatoes should not follow Potatoes. The same general remarks apply to flowers, and any Sweet Pea enthusiast, for instance, will avoid growing his favourites on the same soil two years running if he possibly can.

In gardens where such rotation is impossible of course the food difficulty is overcome to a great extent by judicious manuring, but the question of disease or insect attack can be only thoroughly dealt with by keeping a particular plot free from a crop that is likely to be attacked for several years. H.

## MESSRS. WATKINS AND SIMPSON'S TRIAL SEED GROUNDS.

TOWARDS the end of July we had the pleasure of visiting the very extensive trial seed grounds of the wholesale firm of Messrs. Watkins and Simpson at Twickenham and Feltham, and we noticed many fine varieties of flowers, some of which should find a place in every garden. We were specially interested in the vigorous manner in which selection is carried out. With everything an ideal is selected, and all that do not conform to this are pulled out and discarded, no matter what the cost may be. The result of this continuous selection is the evolution of strains of old and new plants that are far superior in every way to those with which growers of a few years ago were familiar.

Sweet Peas naturally occupied a prominent position in the trials, practically all the varieties on the market, and some that are not, being included. In many cases the firm's own stock was growing side by side with that secured from other sources, and the result was in nearly every instance favourable to Messrs. Watkins' strain. It is not necessary for us to here go into details of the varieties, but it may be interesting to record that a comparison made with Countess Spencer, Enchantress and Paradise, as grown here, revealed no appreciable difference in either.

Other hardy annuals were being tested in great variety and extensive tracts. Candytuft Giant Hyacinth-flowered is a strain that will, we think, soon oust the older white variety from all good gardens. As its name implies, the flower-spikes resemble in shape those of bedding Hyacinths, and, as the flowers are of the purest white, a bed of it would prove most effective; it is also excellent for cutting. Clarkia Tom Thumb double white is another annual that is already a great favourite. The plants possess a very compact habit, each being thickly studded with pure white flowers which resemble miniature Roses. In Dianthus superbissimus we have a remarkable strain of Indian Pink, the flowers being of enormous size, rich glowing colours, and possessing very heavily-crested petals, this latter feature giving them a unique appearance.

The annual Sweet William is at present almost a novelty. The strain seen was a very good one, and plants raised from seed sown last March were flowering freely. The annual Wallflower is a good companion to the foregoing and may be sown at the same season. It is obtainable in brown and lighter colours. Double flowers are not always an improvement on the single type, but the double Californian Poppy (*Eschscholtzia californica flore-pleno*) raised by Messrs. Watkins and Simpson certainly is. The strain gives a very large percentage of doubles from seed, and the large flowers are held erect on good stout stems. A strain of Zinnias with twisted petals has long been on the market, but the plants have never proved very satisfactory. A strain that we saw in these trials had, in addition to the twisted petals, a sort of crest on each, the flowers resembling miniature Cactus Dahlias. The plants appeared to be thriving well, and should do much in restoring the Zinnia to popular favour.

The Snapdragons or *Antirrhinums* were remarkable for the bright colours and freedom of flowering. The beautiful art shades seen in many of them were most attractive, and we hope to include some among our own flowers another season. Salmon Pink, Coral Pink and Vesuvius, a rich self orange variety, particularly appealed to us.

### A BLUE NEMESIA.

Nemesias are steadily advancing in favour as bedding plants, and the new hybrid dwarf compact Triumph strain seen possessed some quite new and lovely colours. The plants are of splendid habit and remarkably floriferous. A

blue *Nemesia* is indeed a novelty, yet we saw a good batch of one named Blue Gem. The plants are very compact and are thickly studded with flowers of a pretty Forget-me-not blue colour. This is one of the most charming annuals we have seen for a long time, and we can, with confidence, predict a most brilliant future for it. *Cosmos Early Rose* is another novelty that will prove most welcome. It is very early flowering and of a dwarf habit, the flowers being a pale rose colour.

Numerous other good annuals were seen, but a description of them would occupy too much space. We must, however, mention the wonderful strains of Cockscombs and Petunias. The former certainly were the most regular and beautiful lot of plants we have ever seen, the prize dwarf crimson being exceptionally good. Nor have we ever seen larger Petunia flowers than those of the firm's Excelsior strain. In addition to the enormous blooms we have rich colours, graceful outlines and vigorous plants, and we can confidently recommend this selection to lovers of this flower.

## THE FLOWER GARDEN.

### DAFFODIL NOTES.

#### PLANTING IN GRASS AND WOODS.

ALTHOUGH the planting of Daffodils in grass has become fairly general, there may, nevertheless, be some who would be glad of a few hints as to what and how to plant. Any variety of Daffodil will do well in grass provided its foliage is allowed to die down, or at least become quite ripened and yellow before the grass is cut. This point is vital. The reason is that the food for next year's growth is manufactured by the leaves, and there is no machinery which can enable them to put six days' work into four.

In the actual work of planting an immense amount of labour is saved by choosing a favourable time for the operation. I would never plant while the ground is hard and dry after its summer baking, but always wait for the advent of the autumn rains to moisten and soften it. Moreover, the bulbs will not root in hot, dry ground, so no time is gained by what may be termed premature planting. I have buried a considerable number myself one year with another, and have tried a variety of ways. Sometimes I have taken up odd single sods, at others I have flayed large patches at once, but I have come to the conclusion that the work can best be done by using such an instrument as Barr's Bulb Planter. "At every operation it lifts a clean, circular little sod of grass, which is released from the cup when the second hole is made and lies ready at hand to fill in the holes when the bulbs have been put in." In actual practice what I always do is this: I prepare an adequate quantity of fine light soil in which I put a fair quantity of bone-meal (about 7lb. to a bushel). On the day of planting I have two assistants, one with a box of this soil and a box of bulbs, whose work is to drop soil into the bottom of the hole which I have made with the Planter and then put the bulb on top of it; while the other with another box of soil puts a little more on the bulb and then replaces the little sod, breaking off some of the bottom to enable the ground to be made level. It is surprising how many can be planted in a day if three like this are at the job. As planting in grass is permanent this little extra trouble should not be grudged. It is labour that will be well repaid in the good seed off it gives the bulbs.

The most pleasing results from a spectacular point of view are obtained by making large, irregular colonies of one variety. The more uneven in outline they are the better, and there should be a few stragglers here and there in three or four places. In the mass itself there

should be about 5 inches or 6 inches clear between the holes, but here again a certain number of irregularities in the distances are useful in giving a sort of natural look. Over and above these larger clumps I would advise every now and again small ones of only a dozen or so bulbs, these to be planted just anyhow and with an occasional solitary bulb.

In planting in woods the same unevenness should be studied, and what is essential and should be carefully noticed is that comparatively open parts must be selected where the sun can get to the leaves to ripen them. I know a case where some bulbs were planted in total shade under some Elders, with the result that in the third year there was not a single bloom. As any kind—even the difficult white trumpets—will do well the choice is very large, and individuals can safely gratify their own particular taste without considering if what they propose will do well or not. There are two things, however, that are worth thinking about. First, that on the whole flowers that are borne well above the foliage, like *Leonie* and *Lobularis*, give a particularly good effect; and, secondly, that as propagation by offsets is very slow in grass, it would be well to select some free seeders which will naturally spread themselves by seed. In this last category I would mention *Abcissus*, *Obvallaris*, *Spurius*, *Golden Spur*, *English Lent Lily*, *Princeps*, *Albicans*, *Pallidus Præcox*, some incomparabilis and all the varieties of *Poeticus*. JOSEPH JACOB.

### NOTES ON IRISES.

#### DWARF, GRASSY OR BEARDLESS IRISES.

The few dwarf Irises of this group are among the gems of the genus. They are mainly moisture-loving, but plants that will thrive on dry rockeries and in moist peat beds are to be found among them. Their flowers, although small, are profusely borne, and what they lack in size is fully compensated for in wealth of flower, chaste colouring and that quiet charm that is inseparable from *Iris verna*, *I. cristata*, *I. flavissima* and *I. gracilipes*. All flower in May and June.

*I. agrostifolia*.—A very rare and somewhat tender species; flowers in February. Its blossoms are akin to those of *I. arenaria*, but are coloured cerulean blue.

*I. arenaria*.—The Hungarian Iris grows 4 inches to 6 inches high, and produces small but very pretty yellow flowers nearly 2 inches across, the falls of which are scoop-shaped and tinted a darker yellow. The leaves are finally 6 inches long, and arranged in close grass-like tufts often many feet in diameter. The rhizomes are small and pliant. Prefers a sandy soil and a dry position.

*I. cristata*.—A low-growing, curiously-rooted plant from the Southern United States of America; proves difficult to grow in any but damp peaty soils. It prefers to grow on the banks of waterways just above the water-level, so that the rhizomes may be normally dry but the roots in the moister soil below. The best plants of *I. cristata* the writer has seen were growing between large flagstones resting on a marsh, and the plants, though often covered with running water, flowered profusely. The rhizomes are often 6 inches long, very slender and bristle with small side growths that soon form goodly tufts in the right position. The flowers are lavender-coloured, fringed at the margins and furnished with a striking signal patch of rich orange. It resembles the flower of the wonderful *I. japonica* in colouring and shape, but rarely exceeds 6 inches in height. One of the daintiest Irises of this group, and worth every care.

*I. flavissima* is a charming little plant hailing from Siberia and countries southward. It makes slender grassy growths, forming a clump of slender leaves 6 inches long. The flowers are borne in pairs and are coloured lemon yellow, the falls of which are bearded orange yellow, and the long and very broad horizontally-poised blades are coloured orange also. The basal half

of each segment is chequered purple, and the fragrance resembles that of vanilla. It prefers a light sandy soil and full sunshine, but it much resents drought.

*I. Blondowii* is the Altaian form of stronger growth, reaching a height of 12 inches, and is about twice the size of typical *flavissima*. The colour scheme is similar.

*I. gracilipes*.—A fascinating Japanese Iris that everyone admires. It has long slender rhizomes which bear distinct leaf growths and flowers. The leaves do not exceed 1 foot in length, but the flowers are borne on stems a little longer, and they are coloured lilac with fringed margins, orange signal spots, and many flowers are produced on each stem. A miniature of *I. tectorum* in many respects, rare at present, as only one small colony has been discovered, and that is carefully guarded from the unscrupulous collector. It is quite hardy in the neighbourhood of London, but may require protection from a Yorkshire or Scotch winter. It increases fast and seeds freely under cultivation.

*I. ixoides* is a tender species requiring frame protection. It has slender leaves in flattened tufts, and bears numerous white flowers with rich blue blotches as in the Peacock Iris. Requires a warm position on rockwork and quite sandy soil.

*I. lacustris*.—A dainty, almost ever-blooming, American Iris, that may be described as a slender *I. cristata*, with short and narrow grassy leaves in broad tufts and slender stems bearing myriads of small lilac flowers with white signal blotches. A charming Iris for a damp site on the rockery, thriving well in sandy peat.

*I. prismatica*.—Another miniature, has slender growths like a meadow grass, wiry Rush-like stems, and generally two flowers in each sheath coloured a pale tint of violet. The standards and falls are equally  $1\frac{1}{2}$  inches long, but the latter are keeled greenish yellow, and are furnished with a white signal patch closely veined with violet. A very pretty species, seemingly rare, but of quite easy cultivation and is rapidly increased. The plants of *I. prismatica* to be seen in most gardens and nurseries are but forms of *I. versicolor*.

*I. ruthenica* is the Russian Flag, and forms singular fan-like growths bearing sedge-like leaves and slender-stemmed pale violet flowers that are exquisitely fragrant. It rarely exceeds 1 foot in height, and delights to grow in moist sandy soil at the foot of a rockery between boulders where the soil is cool.

*I. verna*.—A charming dwarf Iris from the United States, with stout blue-green leafage more or less rigid, and short-stemmed rich violet flowers 4 inches high, the standards of which are paler in tint, and the exquisite violet of the falls is relieved by an orange signal patch. Established plants give a perfect sheet of blossom, and the Primrose-like fragrance reveals their presence yards away. It likes a damp soil and a warm situation, and shows a marked partiality to leaf-soil, but it must not be allowed to dry out. Never disturb a thriving clump; it will resent it. M.

## ANTIRRHINUMS AND PENTSTEMONS IN WINTER.

THESE lovely flowers are quite hardy in the Southern Counties, and will withstand the weather of an ordinary winter without any protection. In the Midland and Northern Counties, however, it is advisable to give the seedlings, or rooted cuttings, the protection of a cool frame. Seeds may be sown in the autumn, and the resultant seedlings kept throughout the winter in boxes in a cold frame. Early in spring the young plants should be put out in a nursery border 4 inches apart, and carefully treated until May, when they should be transferred to their flowering quarters. Young seedlings, which are about 1 inch high, may be transplanted at once in a nice compost of sandy loam and leaf-soil in

a box. These young plants will grow and make sturdy specimens by next May, but they must be kept in a cool frame, as frost would penetrate the soil in the boxes if the latter were left in the open. Rooted cuttings must also be cared for in like manner. There is quite a difference between coddling the plants and giving them judicious protection. They are not weakened by the latter, but greatly strengthened, as more roots are produced before the time comes to put the plants in the flower borders. AVON.

## THE DALMATIAN BELLFLOWER.

(*CAMPANULA PORTENSCHLAGIANA*.)

THIS charming little Dalmatian Campanula is burdened with a cumbrous name, but it certainly is one of the most useful of the smaller-growing members of a family that plays a prominent part in furnishing our rock gardens; indeed, a rockery planted entirely with Campanulas would make an effective display for the late spring and summer months and last well into the autumn. Of free-spreading habit in half-shady or sunny

A COLONY OF THE DALMATIAN BELLFLOWER

situations, this Bellflower will soon cover a good space with its stoloniferous stems, which love to ramble among moisture-holding rocks or stones. In such positions it will produce masses of rich violet flowers from June onwards through the summer months. It is also known under the more acceptable name of *C. muralis*, and varies a good deal in the size of its bells. The Bavarian form bears the largest flowers, and is also very vigorous in habit; therefore it has been named *C. portenschlagiana major*.

This plant has often been confounded with the Italian *C. garganica*, quite a distinct species with wide-open flowers of a blue-lilac colour and more tufted habit, not stoloniferous. *C. portenschlagiana* is one of the easiest Campanulas to grow and delights in a somewhat half-shady situation, although it will grow in full sun providing that the roots can obtain moisture. When planting it should be provided with a gritty compost of loamy soil, to which may be added some broken limestone. This plant does not appear to ripen seeds in this country; at least, I have never seen any yet. However, it may be propagated readily by means of division in spring or cuttings in July. W. IRVING.

## THE ROSE GARDEN.

### ROSE MARECHAL NIEL AND CANKER.

Y OUR esteemed correspondent Mr. J. T. Strange, in *THE GARDEN* for August 22 on page 406, invites me to try and give him some further information in reference to the above subject. So far as memory goes, with reference to parentage of Maréchal Niel in the mid-sixties of last century I was frequently brought in contact with Messrs. Hollingsworth of Turkey Mills, Maidstone, who were great enthusiasts in Roses, especially Teas and Noisettes. On Mr. John, as we called him, coming home from one of the great London shows, where Maréchal Niel had been well shown, some discussion arose as to its parentage, and suggestions were made in respect to it, but in order to clear up the matter, if possible, Mr. John wrote to some eminent authority in France, and when I met him some time after he told me it was Solfaterre and Isabella Gray.

Some year or so after a bloom of Maréchal Niel was sent to me with a leaf-bud attached, and taking advantage of it I worked the bud on Isabella, the only available stock at the time. It took, made good growth and continued to grow at the end of an old greenhouse and flowered well without a sign of canker, Isabella being cut away to make room for its stronger rival. On visiting Maidstone some years after the old tree was still in existence, much neglected, but canker was not visible. I understand the place has changed hands and the old tree and greenhouse, like most old things, done away with to make room for a lawn tennis ground.

I am now experimenting with Maréchal Niel. One is grafted on Jaune Desprez, an old climbing variety, and the other on Ophir, another old and sweet-scented variety of the buff and salmon type. The two plants, although only 1 foot high, have two buds each and are doing well. If all goes well I intend to graft Maréchal Niel on that old free-blooming and growing variety Blairii No. 2 to try the effect, as at present I am unable to get Isabella. Messrs. B. R. Cant and Sons of Colchester write me to say they fail to trace it in foreign or English catalogues (I should be thankful

to any reader who could locate it); Messrs. Cant say my description of it, which I wrote for them, is correct. I cannot agree with Mr. Strange in his statement that it splits or has a green centre, but I must confess to not having seen a flower fully open. The following is the best description I can give of it: Foliage very like Aimée Vibert, very shiny, rather more spines on the under side of the leaves, which in nearly all cases carry seven leaflets; wood wiry and slightly tinged with pink, the partly-opened bud much resembling a light-coloured Souvenir de Pierre Notting, the calyx, like that of Soliaterre and Maréchal Niel, short, full and rounded, with a rather weak footstalk. I might mention that I obtained Isabella Gray from a very old Rose grower, Mr. Alex. Constable of Sandy Lane, Boxley, and I believe Messrs. Hollingsworth's came from the same source.

6, Avenue Road, Clapton, N.E.

## TREES & SHRUBS.

### EVERGREENS FOR AUTUMN PLANTING.

**W**HEN evergreens are to be planted at this time of year, it is always desirable to do the work as early as possible after the beginning of September, for at that period roots are active and the ground warm, while the autumn rains and heavy dews exercise a beneficial effect by keeping leaves and branches damp and so preventing undue transpiration. In most instances the ground will have been prepared previously, but in those cases where it has still to be dug the work should be done at once, and each position should be ready before the plants arrive. It is a very bad plan to obtain plants and then have to select places for them and prepare the ground. The plants have to be laid in and then disturbed again, while valuable time is lost, as every day is of great importance at this time of year, and the delay of a few days in planting may make all the difference between success and failure.

Although all evergreens are better planted either very early in autumn or late in spring, it is not absolutely necessary that all should be, for some, especially when planted in a small state, may be dealt with at any period, except during frosty weather, between August and June. Those subjects which lift with good, compact balls of soil, for instance, such as Rhododendrons, may be planted almost any time, but the majority of those which are lifted without soil, or with a comparatively small ball of soil only, should be planted before mid-October and as much earlier as possible. Some difficult subjects are Hollies, Evergreen Oaks, Portugal Laurels and Laurustinus.

When selecting material for planting it is always advisable to choose those with short, sturdy growths, rather than those with rank, strong-growing shoots. The latter look much the best plants, and inexperienced buyers would select them in preference to those of shorter growth and sturdier habit. The experienced man, however, knows that the strong growth of

young evergreens often denotes a few long roots and very little transplanting, while short growth suggests regular transplanting and plenty of fibrous roots. It is also better to select comparatively small and young plants rather than large and older ones, for they establish quicker, and often are quite as large at the end of five years as those which were considerably bigger at planting time. Of course, this does not apply in the case of large plants that can be removed with good big balls of soil.

In the event of root injury, or in cases where the heads appear to be out of proportion to the roots, it is a good plan to reduce the leafage at the time of planting. This can usually be done without disfiguring the plants by judicious

red. The illustration is from a photograph taken in County Donegal, where, in the peat soil, Rhododendrons, both hybrid and Himalayan species, flourish, and their blooms make a brilliant display for many months each year. S. M. W.

### WHAW-WHI (PLAGIANTHUS LYALLI).

Now is the best time to increase this lovely subject. It is, to my mind, one of the best of summer-flowering shrubs. The beautiful clusters of pure white flowers, which are produced in July, are separately borne upon a stalk about 1½ inches in length. Not only is it free flowering, but another of its merits is its lasting power.

The shrub itself has rather a spreading habit. The cuttings should be of this year's wood, about 3 inches to 4 inches long. Prepare a pot (about 5 inches) with sandy loam, making it very firm. Make sure that the drainage is perfect. Prepare cuttings in the usual way, and dibble them in with a pointed stick, being very careful to make the soil firm round the base of each. Water the cuttings in and plunge them in a frame of Coconut fibre with a little bottom-heat. A. J. J.

A GROUP OF RHODODENDRON SAPPHO IN A GARDEN IN IRELAND.

pruning and thinning out of the branches. Plants which are usually most satisfactory when planted in a comparatively small state without balls of soil are Pines in variety, Berberis Darwinii, B. stenophylla, B. japonica, B. nepalensis, Garrya elliptica, Portugal Laurels, Hollies, Evergreen Oaks of all descriptions, Tree Ivies, Arbutuses, Ceanothuses and Cotoneasters. Most of these establish readily when small, but are very difficult when large. K.

### A GOOD RHODODENDRON.

RHODODENDRON SAPPHO is a very showy subject, the blossoms of a clear, almost blue-white, the eye so dark as to appear black, except on the closest inspection, when it shows a deep prune

## COLOURED PLATE.

PLATE 1357.

### A NEW FRUIT—THE LOWBERRY.

**H**YBRIDISTS are often producing new flowers, fresh variation in foliage and improved habits of plants, but their labours in connexion with fruits are not rewarded so bounteously, and the process usually takes longer to obtain results. A cross between the Loganberry and Blackberry is the subject of the coloured plate issued with this week's number.

The Lowberry in appearance might at first be described as a gigantic Blackberry, measuring usually 1½ inches long, jet black in colour when ripe, and the fruit is very juicy. Although the Raspberry is one of the parents of this new fruit, the habit of the plant is more akin to the Blackberry, for the long canes run from 12 feet to 18 feet in one season.

The Lowberry should be planted with plenty of room to allow for this abundant growth, and may be trained on trellises in the same way as the Raspberry, and it also makes an excellent plant for training over arches, the bunches of luscious-looking fruits being most attractive.

Messrs. Hugh Low and Co. of Bush Hill Park, Enfield, exhibited this fruit at the Royal Horticultural Society's Holland House Show in July, and the interest then displayed by visitors proved that new fruits are as popular as new flowers. Messrs. Low recommend the planting of the Lowberry in well-manured soil and firmly securing the long canes. After fruiting the old canes may be cut away as in the Raspberry.

When exhibited, and at the time our plate was prepared, this fruit was called Low Junior, but the name has now been changed to Lowberry.

## THE FRUIT GARDEN.

### CURRENTS AND THEIR CULTURE.

**N**EXT to the Gooseberry there is no fruit better suited for the amateur than the Currants, as bushes are easily and cheaply procured, easily propagated, and require comparatively little cultural attention if a good start is made. The fruits, too, are useful for a variety of purposes, and for growing on a north wall the red and white forms are eminently satisfactory.

As stated above, a good start in their culture is essential, as the bushes will occupy the ground for some years, and, consequently, there will not be an opportunity of working it much during that time. All Currants delight in a good loamy soil, but the red and white varieties will do well in almost any, except pure sand, providing they have plenty of food and moisture supplied to them during the growing and fruiting season. Black Currants need a cool root-run, and they will thrive on soil of a damp but not water-logged character. The present is an excellent time for preparing the soil, and this work should be done without delay. Trenching is advisable, and unless the ground is already well enriched a good dressing of thoroughly decayed manure should be incorporated with the bottom spit. Ground thus prepared must be allowed to settle for a few weeks before planting, which can be done with much success when the soil is in good working order in November.

Red and white varieties are usually grown in cup-shaped bushes, and if two or three year old plants are purchased the foundation will already have been laid. The object of the cultivator will be to secure a number of main upright rods emanating from the top of a short leg or stem, all laterals being spurred back annually, the same as is done with Vines. A good plan is to shorten these laterals to within four leaves of their bases at the end of July or early in August, then at the winter pruning cut them again so as to leave only two buds on each. By doing this a number of well-ripened spurs are produced, and it is these which will bear fruit the following season. Trees grown on walls are usually trained fan-shaped, and sometimes as espaliers or cordons, pruning being precisely the same as that advised for bush specimens, *i.e.*, the spurring back of lateral growths. Black Currants are best grown as bushes, and the pruning of these is quite different to the system adopted for red and white varieties. Black Currants fruit almost exclusively on wood of the previous year's growth, hence pruning will consist of the entire removal of old worn-out growths during the late autumn or winter months.

As stated above, propagation of all the types is easily effected by means of cuttings taken during the autumn or winter pruning. These must be made from shoots of the previous summer's growth, those the same thickness as a lead pencil being the best. They must be firm and well ripened, and when the cuttings are made each should be about 12 inches or 14 inches long. It is best to cut close beneath a joint at the base, and the soft top of the shoot must be removed close to a bud. In the case of red and white varieties, all the buds, with the exception of four or five at the top, should be removed, as this

ensures a clean stem for the future bush. Black Currants are best when growths are pushed up from the base, consequently all the buds are left intact on the cuttings of these. Cuttings of all types should be planted as soon as made in well drained rather light soil, in rows 18 inches apart and the cuttings 9 inches asunder in the rows. The following winter the best of the resultant plants may be placed in their permanent quarters, or, better still, all can be planted more thinly in nursery quarters until they are two or even three years old.

During the growing season Currants of all sorts greatly appreciate soakings with clear water and weak liquid manure, and a mulching of short decayed manure over the roots during hot weather is of the greatest benefit. It frequently happens that red and white varieties set their fruits so freely that thinning in the early stages is necessary if good sized berries are desired, and this is a point that ought not to be overlooked. Plants grown on north walls are very valuable for late supplies, but where such a position is not available the supply may be considerably lengthened by tying up a few of the latest bushes rather tightly with brown paper, making sure that leaves and fruits are perfectly dry before doing this.

Aphides are the worst pests of Red and White Currants, but these are comparatively easily got rid of by any of the usual methods. Black Currants, of course, are considerably damaged by the big bud mite, a pest which it seems well nigh impossible to eradicate, the lime and sulphur treatment in the spring being, perhaps, the most effective. This sometimes, however, will scorch the young foliage rather badly, and must therefore be used cautiously. Some good varieties are: Red—La Versailles (Fay's Prolific and Comet) and Champagne Red. Messrs. Laxton Brothers have a new red one, which promises to be extra good. White—White Transparent and White Dutch. Black—Boskoop Giant (very fine), Lee's Prolific, Black Naples and Baldwin's Black.

### THE LOGANBERRY.

WITH the advent of other new hybrid berries of the Bramble section, the merits of the Loganberry are apt to be overlooked, yet it is a most useful fruit and should find a place in every garden where a fair amount of room exists. Reputedly it is the result of cross between a Blackberry and a Raspberry, but some are inclined to think that it is a true natural species. However that may be, it is one of the few useful fruits for which we have to thank our American cousins.

It is an exceedingly vigorous subject, frequently making growths 12 feet or more long in one season, hence it must be given plenty of headroom. A favourite situation for it is over an arch, where it forms a beautiful and at the same time useful plant. It delights in a deeply-worked, rich and rather heavy loam, which will afford it a cool root-run during the hot days of summer. After the fruits are gathered, the growths which have borne them are cut right out at the base, the best of the young ones being tied in to take their place and for bearing fruit the following year.

As will be seen by the illustration, the fruits are freely produced in large clusters, and they much resemble large Raspberries in shape and size, being red in colour when ripe. Owing to a rather acid flavour, they are valued more for preserves than for dessert, although when thoroughly ripened they very nice.

Propagation is easily effected by pegging down the tips of the young, non-fruiting canes and covering them with soil. Treated thus they quickly form roots, when they may be severed from the old plants in the autumn, and either grown for one season in a nursery bed or transferred direct to their permanent positions. As planting time will soon be here, those who have room and suitable soil for a plant should make a point of securing one. Naturally, such a fruit has quickly been made good use of by hybridists, the Lowberry and the Laxtonberry being two good fruits obtained by using it as a parent.

THE LOGANBERRY: ONE OF THE PARENTS OF THE LOWBERRY.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE HARDY FLOWER GARDEN.**—Dutch bulbs in great variety may be planted in their flowering quarters as opportunity offers. Hyacinths should be planted 4 inches deep and 7 inches to 8 inches apart; Tulips, 4 inches deep and 5 inches apart; Narcissus, 4 inches to 5 inches deep and from 8 inches to 10 inches apart, according to the size of the bulbs. Scillas should be planted 3 inches deep and about 2½ inches apart. Chionodoxas: Plant similarly to the Scillas. Muscaris require to be planted in the same manner; and Snowdrops and Leuciums when planted 3 inches deep and 3 inches apart answer very well. English and Spanish Irises also succeed very well when planted rather more than 4 inches deep and 6 inches apart. The pretty Winter Aconites if planted 1½ inches deep and 2 inches apart make a nice effect. Liliun candidum (the Madonna Lily) succeeds when planted 3 inches deep and 12 inches to 18 inches apart.

**The Vegetable Garden.**—For early supplies next year I am planting Cabbages in drills. Should the weather be very dry, I water them in with a copious application. Coleworts for quick results may be planted at the present time. I am lifting maincrop Potatoes now, and find they are not altogether free from disease. It is imperative that the diseased tubers be separated from the perfect ones, as they soon contaminate the latter. Celery has progressed remarkably well of late, especially where early planting was done. Plants are easily bleached by tying 6-inch strips of brown paper round them. In most cases two such strips are sufficient, following with the second lot when the plants have grown sufficiently. I am about to make a sowing of Hammersmith Cabbage Lettuce just now, and in conjunction with a sowing of Bath Cos future supplies are practically assured. Sow the seed in prepared quarters that have a sunny aspect.

**The Window Garden.**—Window-boxes may have the bedraggled summer-flowering subjects removed and be replanted with small shrubs. Those who do not care for shrubs may very well plant early-flowering Chrysanthemums, as these will make a gay display for some time to come. Wallflowers are always attractive, and if yellow varieties are planted together with Forget-me-nots, the effect should be beautiful indeed. Dutch bulbs in variety may be utilised

for the same purpose, and they are easily managed. For the window indoors bulbs should be potted up and plunged in ashes or Cocoanut fibre refuse until well rooted; they may then be placed in the window. Sponge foliage plants frequently to remove accumulations of dust.

**The Greenhouse and Conservatory.**—I am already housing the earliest of my large-flowered Chrysanthemums. The housing should be a gradual process. Ventilate freely the greenhouse in which the plants are placed. Glass houses in which more tender subjects are growing must be heated at night, otherwise some of the plants are sure to deteriorate. Lilies that have ceased flowering and the foliage of which has turned yellow should be cut down and the pots arranged on their sides; water should be withheld. I am now dealing with plants of *Plumbago capensis* that have been beautiful during the past summer. Shoots of this year's growth should be cut back to within

1.—POTATOES TO GIVE NEW ONES AT CHRISTMAS.

2.—POTATOES WITH SHOOTS FORMING; THE LATTER MUST BE PROMPTLY REMOVED.

1 inch or so of their base. Subsequently they will break into fresh growth. D. B. C.

### HOW TO HAVE NEW POTATOES AT CHRISTMAS.

It is scarcely necessary to say that a good dish of home-grown new Potatoes would be a most welcome adjunct to the roast beef, turkey, or other joint at the Christmas dinner, and as such are not by any means difficult to procure the cultivation of them is a subject which the beginner in gardening may safely undertake. It has long been known that tubers which had been kept over for a whole year without planting were capable of producing young ones without making any top growth; but it is only during comparatively recent years that this knowledge has been made use of in a comprehensive and practical manner.

Perhaps it may be as well at the outset to briefly explain what happens to the tubers to cause them to behave thus, as this will make matters much plainer to those not well versed in Potatoes. A Potato tuber if well ripened contains an abundance of food, chiefly starch, which, in the ordinary course of events, is used for the production and maintenance of shoots until they have made roots and leaves and are thus capable of forming their own food. When, however, new Potatoes are required during the winter

months the tubers are kept in the dark one whole summer, and any shoots that are formed are promptly and persistently rubbed off, consequently very little of the food that is stored in the tuber is used. Towards the end of the summer the Potatoes thus treated appear to tire of making, or attempting to make, growths, and consequently start the formation of new tubers and thus get rid of their stored-up food which represents energy. Of course, the conditions must be favourable for the Potatoes to behave thus, and as tubers must be selected at lifting time for the purpose the present is a good period to make a start. As will have been ascertained from the above remarks, tubers selected now will, if treated as described below, be in a condition suitable for producing a crop of new ones this time next year, and by treating them in batches new Potatoes will be obtainable all through the winter of 1909-10.

When lifting the crop select a number of the biggest tubers and make sure that they are quite free from disease. Fig. 1 shows a number of suitable Potatoes for the purpose. These must be stored in a dark, cool place for the winter, taking care, of course, that frost does not reach them. Early next spring sprouts will begin to form, as shown in Fig. 2, and these and any that are pushed subsequently must be promptly removed during the whole of next summer. In addition to the removal of sprouts next year, care must be taken to keep the tubers as cool and dark as possible, and they must not be kept too dry, else they will shrivel considerably, as shown in Fig. 3. The above remark must not be construed to mean that they need keeping wet; an earth or brick floor would be a suitable place for storing during the summer months.

By September of next year the Potatoes thus treated will be ready for the production of new ones, and to induce them to do this they may be treated in several ways. One large grower lays them out thinly on the floor or on shelves in dark caves, and covers them thinly with fine soil. For the amateur, however, such a course would be impossible, and where room is limited good use may be made of boxes, those about 12 inches in depth being most economical, as they will take two layers of tubers. A layer of fine light soil, about 2 inches thick, is first placed in the bottom of the box, then the Potatoes are placed on this several inches apart each way. On the top of these another 2 inches of soil is placed and then comes another layer of Potatoes, these in turn being covered with soil. Of course, where there is plenty of room, boxes to carry one layer of sets only will be the most convenient. A section of a box prepared with two layers is shown in Fig. 4. The soil should be nicely moist, not

3.—A MUCH-SHRIVELLED TUBER, THE RESULT OF KEEPING TOO DRY.

wet, when used, and, providing a proper situation is afforded the boxes, no water will be required. A suitable position is the floor of a greenhouse, where the temperature will range from 50° to 60°, and in such a place new Potatoes should be ready for gathering in about six or eight weeks. It is essential that the tubers be kept quite dark.

Fig. 5 gives a good idea of how the new Potatoes are formed on the old ones. As they become large enough for cooking they are removed and others will be formed, until all the stored or reserve food in the old Potato is exhausted. Of course, the flavour of Potatoes thus produced is not equal to that of tubers grown in the ordinary way; but if good flavoured varieties, such as Factor, Windsor Castle, or the better strains of Up-to-Date, are used, a dish of such new Potatoes will be by no means despised during the winter months. To ensure a crop on Christmas Day a batch of old tubers should be started about eight weeks previously and another

4.—SECTION OF A BOX OF TUBERS.

two weeks later, that is, providing the temperature given is as advised above. A lower temperature will do, say, 45° to 50°, but the formation of new Potatoes will then take longer.

#### POTTING UP OLD BEDDING PLANTS.

WITH the advent of the first slight frost the beauty of the majority of the plants which have occupied the beds during the summer months will pass away, and the owner must, if he desires to save them, lift the plants and take them under cover for the winter. The Geranium or Zonal Pelargonium is still a great favourite with many for bedding purposes, and although it is best to take cuttings in August or early September, and thus secure young plants for another season, it frequently happens that the supply runs short and the cultivator is glad to fall back on the best of the old plants in the spring. These old plants have at least one point in their favour, viz., that they commence to flower earlier and are usually more prolific than young ones.

In lifting the plants from the beds only the best and most shapely specimens should be retained, and these should have all soft growths and nearly all the leaves removed, and also the long, fibreless roots shortened. They may then either be potted up singly into 5-inch pots or else be placed fairly close together in boxes and some soil well shaken and made firm about the roots. It is necessary to drain the pots or boxes well, and soil of a more sandy or light character than usual should be employed. They must be kept in a frost-proof but cool and dry structure for the winter, the greatest enemy being a damp, cold atmosphere; hence great care must be exercised in applying water, as they will stand soil that is almost dry during the dull days of winter. Those that are potted up singly now will, of course, remain in the pots until bedded out next summer, but those stored in boxes will need potting off next February or March.

Fuchsias and Heliotropes may be treated in a similar manner, but the first named may be

stored in a shed, room or under the stage in the greenhouse so long as frost does not reach them and they are not subjected to wet conditions. Cannas may also be potted up singly or stored collectively in boxes of soil. Where a warm greenhouse is available a few plants properly potted in soil composed of good loam two parts, decayed flaky manure one part and a dash of sand may be placed therein, and fresh foliage will soon be formed and the plants rendered suitable for garnishing.

Tuberous Begonias should be lifted with their tops entire and placed thickly together in boxes of light soil or even leaf-soil for a few weeks until the tops naturally die off, when the corms may be taken out, cleaned of superfluous roots and soil and plunged in single layers in shallow boxes of clean sand or Cocoanut fibre refuse, the boxes then being stored in a frost-proof shed or room. The great point to bear in mind in the storing of bedding plants of all sorts during the winter is that damp is far more injurious to them than a low temperature; hence an endeavour should be made to keep the atmosphere in the structure wherein they are stored as dry and buoyant as possible.

#### SOLANUMS AND THEIR CULTURE.

SOLANUM CAPSICASTRUM, *S. Hendersonii* and Williams's hybrids all produce very fine berries. Probably the first of the three above named is the favourite variety with amateurs, and it is certainly a most useful plant for the embellishment of the greenhouse or conservatory, or even the dwelling-room window in autumn and winter. The plants are easily grown from seeds sown in a light sandy soil in March, or from cuttings inserted early in April. Some growers plant out the young specimens in June and lift and repot them early in September. Others grow them in pots throughout the season, and I do not hesitate to recommend the latter mode of culture as the best for amateurs to adopt if they will attend to the watering and feeding of the plants during the warm days of summer.

The right treatment of the plants at the present time is very important. Those that are to be lifted require very great care. Pots large enough to hold the roots and some soil must be obtained and a nice light, rich compost prepared. The plants should be carefully lifted with as much soil as possible adhering to the roots. Having drained the pots, place the roots and bail of soil in the pot, and then fill up any vacancy with the new compost. Press down the latter with the fingers and place the newly-potted plants in a cool frame. Supply them with water directly they are potted, but afterwards be careful not to give too much. A good syringing with clean water occasionally will be quite sufficient. It is also advisable to lightly shade the plants for a time from the sun's rays, but when they are established in the pots air and light should be freely admitted and weak doses of liquid manure given. Plants grown in pots during the summer should be taken to the shelter of a frame before frosts occur. Continuous feeding with soot water and liquid manure may be the rule in their case, then the foliage will be a deep green and the berries large and well coloured.

#### HOW TO GROW GIANT ONIONS.

THE inexperienced amateur generally waits until the spring before commencing the preparation of the ground for the Onion crop, but this is a mistake. Probably a plot of ground is available which is well open to the light and sunshine throughout the day and of a rather heavy nature, that is, inclined to be clayey; if so, it is an ideal rooting medium for Onions if it is properly prepared. In the first place it will be necessary at once to deeply trench the ground. Go down quite 3 feet, but do not bring up the cold subsoil; leave it below after thoroughly breaking it up.

Both the middle and the top portions should be left in the original positions, but the middle portion should also be partially pulverised. The top layer, however, must be thrown up in large lumps and be left so throughout the winter months. Do not mix any manure with the soil, but put in about 3lb. of lime (unslaked) to each square yard of ground, mixing it evenly with the top portion. The rains, frosts, snow and weather generally during the winter will have a beneficial effect upon these lumps of clayey soil. They will be pulverised and sweetened, and when, early in March next, the cultivator is able to commence the turning over of the top 18 inches of soil, it will crumble to powder. If the soil is always worked while it is in a comparatively dry condition it will form an ideal Onion bed by the middle of April, and towards the end of that month the young plants must be put out. Instructions on the raising and planting of the young Onions will be given in due course.

#### THE FLOWERING PERIOD OF VARIOUS BULBS.

ALL amateurs like to have a good idea as to the time when the different kinds of bulbs which they are growing will come into flower. The dates given below are approximate. If the weather proves to be very mild, the blooms will develop early; but if cold the flowering will be retarded.

Name.	Date of Planting.	Period of Flowering.
Hyacinths	..Middle of October.	..April to May 20
Tulips, early..	..	..April 20 to May 10
..late ..	..	..April 30 to May 25
Daffodils ..	..	..April 10 to May 10
Snowdrops ..	..	..February 1 to March
Crocuses..	..	..March 20 to April 20
Scillas ..	..	..February 15 to March 20
Anemones ..	..	..April 20 to June 1
Ranunculus ..	..	..June 1 to July 1

Dark-coloured soils of a light nature are warmer than light soils of a clayey nature. The dark

5.—HOW THE NEW POTATOES ARE PRODUCED ON THE OLD ONE.

ground attracts the sun's rays, and so becomes warm quickly in spring. Moreover, the water does not lodge in dark, light soils as much as in heavier loam; and all these conditions have an effect upon the growth of the bulbs in the ground. A quantity of road grit, sand and well-decayed leaf-soil should be added to tenacious loam. Drainage is also an important factor in the warming of clayey ground. Frost does more harm to bulbs growing in the latter kind of soil, on account of the excessive moisture in it, than to those in soil of a sandy nature, so it is advisable to put on a layer of Cocoanut fibre on the surface 1½ inches deep.

Bulbs should always be planted with a trowel or handfork and not with a dibber, especially where the soil is of a tenacious character. If the latter implement is used, a hollow space is frequently left beneath the base of the bulb, much to the detriment of the latter, as decay will often result. AVON.

## THE TOWN GARDEN.

**BULBS IN THE GARDEN.**—There are many scores of beautiful plants which can be successfully cultivated in town gardens, but of them all the most generally satisfactory are those usually known as Dutch bulbs. There is not a single garden in which they cannot be persuaded to grow with more or less ease, and in those places where reasonable attention is accorded they bring unbounded satisfaction. When once the bulbs are in they do not call for any cultural aid, for during the dull days of winter they are steadily making root growth and providing themselves with the power to supply food to the handsome spikes or blooms in the following spring. Hyacinths, Narcissi, Tulips, Crocuses and several others may be requisitioned with a certainty that the results will be gratifying to the owner and his friends.

**PREPARING THE SOIL.**—It is an excellent rule to avoid the use of natural manures entirely in the soil in which bulbs are to be planted, but it is erroneous to suppose that they will succeed perfectly in poverty-stricken ground. If the beds and borders were generously manured for the summer occupants it is improbable that it will be necessary to add any manure for the bulbs; but if the soil is poor, some sweet, thoroughly-rotted material should be incorporated with the second spit in such a position that it is impossible for the bulbs to come into actual contact with it. In any case it is imperative that the mechanical working shall be excellent, as bulbs are like practically all other plants in their appreciation of a friable medium in which to grow. This preparatory work should be carried out at least two weeks prior to the planting. Thus, immediately after the summer occupants of the beds have passed their best, they should be removed and the soil dug and manured, if necessary, for the bulbs.

**DEPTH OF PLANTING.**—This will, of course, depend upon the size of the bulbs, and the best rule to adopt is to cover all kinds with at least twice their own depth of soil. In light lands, however, it is permissible and often desirable to place them deeper than this, and Daffodils can always be put well down with advantage, as they grow more strongly and bloom magnificently. In small gardens it will add to the smartness of the garden to cover the beds after the planting is finished with a thin layer of Coconut fibre refuse. This will not, as many people suppose, convey any food to the plants, but simply make the beds neater for winter.

**TIME AND MANNER OF PLANTING.**—As has been said, the planting should be completed by the end of the first week in November, but it may be successfully carried out until the middle of December, while it can be done by the middle of October I think that the grower will gain; however, this is essentially a matter for each cultivator to decide for himself. He must, too, settle the precise system of planting. Personally I am in favour of clumps for borders and one variety only for a bed, but others will like lines in the borders to produce a ribbon effect, while many admire mixtures in the beds. If two colours are desired in a bed, charming associations may be made with an *Incomparabilis* Narcissus or a large trumpet Daffodil and a Hyacinth, or a Daffodil and a Tulip. Care must, however, be taken that the two utilised shall flower as nearly as possible at the same time, or the attractiveness of the combination may be destroyed entirely. For use among shrubs and beneath trees the bulbs should be distributed as naturally as possible and never planted in lines or clumps of any set shape. For this particular purpose the bulbs which are flowered in pots should always be saved, as they bloom well the first season, and if the position and soil suit them they will improve season by season if allowed to remain undisturbed.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**SOIL FOR HYACINTHS.**—I am fully convinced that many persons who buy bulbs very often blame the bulbs rather than their treatment, and it is largely due to not having proper soil. For growing the best quality flowers the soil is an important factor, and it ought to be prepared some weeks before it is wanted for use. A good compost would be one-third of fibrous loam, one-third of really first-class manure, about one-sixth of good leaf-soil and one-sixth of sharp sand. Take care that the manure is very old; new manure would practically ruin the bulbs. The whole lot should be thoroughly mixed up and in wet weather have some boards or sheet-iron placed over it.

All plants that have been cultivated outside for blooming in the winter should now be taken up, potted and housed, as we cannot depend upon the weather. Late Chrysanthemums, however, may yet be left out if the weather is genial. Permanent shading may now be dispensed with on greenhouses.

**Pots and Frames.**—These should have a good clean before receiving the occupants for the winter. Cinerarias, Primulas, Freesias and Calceolarias must be kept on stages near the glass so that they do not become drawn. In fair weather draw the lights right off cool subjects every day, and do not coddle anything.

#### HARDY FRUIT GARDEN.

Continue to gather such fruits as are ripe. Late varieties of Apples and Pears will go on growing for a considerable time yet. Do not store any bruised or speckled fruits, as these only court disappointment and trouble, and small fruit should not be stored with good samples. The proper way to test when fruits are fit to gather is to lift each in the palm of the hand in an upward direction, and if it is ready it will part readily from the spur.

**Lifting and Root-pruning Fruit Trees.**—These operations may be commenced as opportunities occur, remembering that the earlier they are done the sooner will the trees establish themselves, as while the soil is warm it is surprising how soon the fibrous roots are made.

#### KITCHEN GARDEN.

**The Cabbage Plot.**—If the ground has been prepared as advised and the plants are ready, lose no time in getting them established in their winter quarters. Brussels Sprouts are supposed to be fit for use with the advent of partridges, but they are not so good yet as later in the season. However, keep all decaying foliage picked off, as this allows the buttons more room.

**Tomatoes.**—Cut all the fruits now, and those not ripe, if cut with a long piece of stem and hung up in a house or frame, will ripen, and with care may be kept for a very long period. Small green fruits may be picked. These are used in chutney with much success.

**Cucumbers under Glass** if not already planted should be seen to at once, and in soil as recommended in the calendar for the 12th inst. Stop the shoots at one joint above the fruit and tie regularly. Do not overcrop the plants.

#### FRUITS UNDER GLASS.

**Vineries.**—Keep a little heat on all houses containing fruit, and ripen all late varieties as soon as possible. Keep the bunches looked over so that no damaged berries are left, as these soon injure others.

**Figs.**—Give these all air possible so as to ripen up the wood for next season.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

In the stove it will be necessary to reduce the water supply of such plants as the Allamanda and other summer-flowering climbers that have done their work for the year; but the reduction must be gradual, so that the wood ripens naturally.

**Eucharis amazonica** flowers naturally at this time of the year; but their season may be governed to some extent by withholding water for a week or two and then resuming its use in the form of liquid manure, combined with an increase of bottom-heat, which will cause the spikes to push up quickly.

**Cypripediums.**—Many of the cool house Cypripediums are now showing flower-buds, and it will add to their appearance when in bloom if the plants and stages are nicely cleansed from the sediment which sometimes adheres to them. This should be done while the buds are in the growths, and then there is no fear of injuring them. Most of the flowers will need supporting, and some neat stakes should be in readiness for the purpose.

#### THE FRUIT GARDEN.

**Strawberry Beds.**—Hoe and clean the surface of the ground, remove all runners, and should the weather continue dry give a liberal application of water, repeating it if required, especially with recently-planted specimens. A mulching of decayed manure applied immediately after taking off the runners, as well as feeding the plants, is of great assistance in dry weather.

**Gathering Apples and Pears.**—This must now have special attention. Gather each variety when it is ripe, always bearing in mind not to be too soon. Fruit gathered too early never attains the proper colour and flavour. Exercise every care so as not to bruise the fruit. The work of gathering Apples and Pears must be done only when the fruit is dry. Keep the fruit-room for the present well ventilated to carry off the moisture that always appears to collect about newly-gathered fruit.

#### KITCHEN GARDEN.

During fine weather keep the Dutch hoe at work among growing crops, as this will assist the plants in their growth and destroy countless small weeds, which make their appearance more freely now than at any other season of the year.

**Tomatoes.**—Reduce leaves upon plants in the open ground so that the sun may reach the fruit. These plants are easily injured by frost, and should have a light covering thrown over them whenever danger from this source is apparent. Plants in pots for winter fruiting will now have set several bunches of fruit, and must not be allowed to remain outside any longer or the cold nights will have an injurious effect on their constitutions later in the season.

#### THE ROSE GARDEN.

Preparations should now be made for obtaining a quantity of own-root Roses. The advantages of own-root Roses over those that are budded or grafted consist of immunity from destruction by frost, absence of suckers, continuity of flowering, greater longevity and economy. The most suitable wood for cuttings is that which flowered first this season. To ensure success I have always found it absolutely necessary to put the cuttings in early.

#### FLOWER GARDEN.

**Carnations.**—If well rooted, the earlier these are lifted and replanted the better, and the more likely are they to winter well. On the other hand, it is safer to leave them till the first or second week in October, unless they lift with a nice ball of roots and soil. The beds or borders should be well prepared, neither rich nor poor, and where the land is deficient in lime a good sprinkling of this in a fresh, slaked condition should be given.

T. B. FIELD.

(Gardener to Baroness Berners.)  
Ashwellthorpe, Norwich.

## NEW PLANTS.

**CATTLEYA HARRISONÆ** ALEA STANLEY'S VARIETY. This is a very pretty and pure flower of really exquisite form. The sepals and petals are of medium size, very firm texture, and of the purest and glossiest white imaginable. The labellum is comparatively large, moderately open, with beautifully crimped edges. This also is pure white, with the exception of a pale lemon-coloured band, about one-eighth of an inch wide, running across it about half an inch from the base. Shown by Messrs. Stanley and Co., Southgate, London, N. First-class certificate.

**Cattleya Maronii aurea.**—This is a very handsome flower of rather refined appearance and of unusual colouring. The rather narrow lanceolate sepals and the broader frilled petals are of a uniform golden yellow. The labellum is large and very spreading, with beautifully frilled edges. The throat is the richest possible orange yellow with carmine markings, the lip proper being bright carmine, suffused pale yellow. Shown by Sir Trevor Lawrence, Bart., Burford, Dorking. Award of merit.

**Populus alba lasiocarpa.**—A valuable and striking novelty from China which has endured the past three winters in the open at Coombe Wood with impunity. Only small, sturdy plants about 2 feet high were exhibited, and these, furnished with broadly-ovate cordate leaves 1 foot in length and about 9 inches in breadth, presented a handsome appearance. The plant is said to reach some 15 feet or 20 feet in height. The footstalks, which are some 4 inches in length, and the more prominent veins are coloured a reddish scarlet, the texture of the leaves being exceptionally strong and firm. Shown by Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

**Dahlia Betty.**—A single-flowered variety of rosy lilac hue with maroon-shaded centre. From Messrs. J. Cheal and Sons, Crawley.

**Dahlia Brigadier** (Cactus).—A showy variety whose well-formed flowers are reddish crimson.

**Dahlia Monarch** (Cactus).—A flower of reddish salmon tone with conspicuous yellow centre. Both the above were shown by Mr. J. Burrell, Cambridge.

**Dahlia Snowdon** (Cactus).—A snow white variety, very beautiful and pure.

**Dahlia Teutonic** (Cactus).—A striking shade of amaranth crimson, and one of the most effective we have seen, the much-incurred florets rendering it conspicuous.

**Dahlia Satisfaction** (Cactus).—Rosy carmine with white centre, the tips of the florets incurving in a very beautiful manner. These three were shown by Messrs. J. Stredwick and Sons, St. Leonards.

**Dahlia Flora** (Cactus).—A distinct and showy variety coloured yellow and fawn, the florets being white tipped.

**Dahlia Nellie Riding** (Cactus).—This variety is coloured a deep maroon crimson, a lighter shade pervading the extending florets, which are pointed with white. This handsome pair came from Mr. J. T. West, Brentwood, Essex.

**Dahlia Adela** (Pompon).—The blooms are of model size and form, and are of pure white colour. From Mr. Charles Turner, Royal Nurseries, Slough.

Each of the above Dahlias received an award of merit, and all the plants named and the under-mentioned new fruit were shown before the Royal Horticultural Society on the 15th inst., when the awards were made.

## NEW FRUIT.

**Apple Red Victoria.**—This is a new kitchen variety of very beautiful appearance, the exposed side being of a very brilliant glossy scarlet, with subdued yellow on the shaded portion. It somewhat resembles Gascoyne's Scarlet in shape, but is more brilliantly coloured and quite distinct. Shown by Mr. G. W. Miller, Clarkson Nurseries, Wisbech. Award of merit.

## LEGAL POINTS.

**Greenhouse (Tenant).**—An ordinary greenhouse built in a garden by a residential tenant and constructed of wooden frames fixed with mortar or cement to foundations of brick-work cannot be removed as a tenant's fixture. If it is a mere case resting on the land or even on a foundation it is an ordinary movable.

**Gardener's references (E. R.).**—A reference given to a servant becomes his property, and if handed to a subsequent employer or agent he can compel its return. If it has been lost or destroyed the servant generally has a claim to damages, but it is hard to estimate what the damages ought to be, and the servant must have acted reasonably and done everything possible to mitigate the loss, i.e., attempted to get fresh testimonials.

**Allotments (Garden).**—The holder of an allotment on the determination of his holding is, by the Allotments and Cottage Gardens Compensation for Crops Act, 1887, entitled to compensation for crops, including fruit, growing upon the holding in the ordinary course of cultivation, and for labour expended and manure applied in anticipation of a future crop. For fruit trees and bushes growing thereon planted by the tenant there is no compensation unless they were planted with the landlord's written consent, but where he is not entitled to compensation the tenant of an allotment may, before the expiration of his tenancy, remove by virtue of Section 7 (6) of the Allotments Act, 1887, a statute which was somewhat later than the one before mentioned.

BARRISTER.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Herbaceous plants (H. P. B.).**—If the border is much overhung by trees we do not think that Roses could be grown with very much success. If, on the other hand, the trees but slightly shade the border this might prove helpful, though we are bound to say we favour quite an open if sheltered spot for Rose growing in general. There are, however, many good and showy herbaceous plants that would prove a success, as, for example, single and double Pyrethrums, Phloxes, Kniphofias, Montbretias, Oriental Poppies and such like. Of the Pyrethrums, Hamlet, Monarch, James Kelway, J. N. Twerdy, Mrs. Bateman Brown, Pericles, Captain Nares, Melton, coccinea, Merry Hampton and Sherlock are all good and showy; while of Phloxes, such as Etna, Boule de Feu, Anguste Riviera, Flambeau, Regulus, Le Siecle, Lothair and William Robinson are all showy and distinct. The Flag Irises, single red and pink-flowered Hollyhocks, Gaillardias, Sweet William Salmon Queen and pink-flowered Antirrhinums would all be serviceable. The seeds of the Verbascums, Enothera biennis and Foxgloves could be sown thinly in the wood, but the Bracken will be best if roots are planted. The Bracken is not an

easy thing to transplant, and seedlings take a long time to grow. Where strong this Fern would outgrow the Nettles, otherwise the only way to get rid of them is to dig them out or cut them down frequently. It is highly probable, we think, that the leaves of your Violets have been eaten by caterpillars, but we could not say definitely without seeing them.

**Lilium giganteum (A. W. G.).**—The better plan will be to allow the growth to fully mature and then lift and replant the offsets. The length of time the plant is in position prior to flowering is responsible for the almost complete exhaustion of the soil in its vicinity, and to permit the offsets to remain, in the circumstances, would be to afford them a very poor chance indeed. In anticipation of their ripening off you might prepare a new position in readiness, arranging the young bulbs in a group with ample room for future development.

**Mecconopsis seedlings (Poppy).**—The seedlings should have been potted off when large enough to handle in a mixture of peat, loam and sand in about equal parts. It is best to get the seedlings along as quickly as possible in the early stages, but without in any way forcing or coddling them. You had better even now pot them off, and when established provide them with a cold airy frame for the winter months. What these things suffer from most in all stages is a damp or close atmosphere. Frost and cold are much less harmful than damp, and this must be guarded against at all times. Afford very little water during winter.

**Fungus-infested plants (Enfield).**—The portions of Rose, Snapdragon, Phlox, Sweet Pea, Statice, Stock and Ivy-leaved Geraniums sent were all so badly infested with fungus that we speedily consigned them to the flames. The Geranium leaves were eaten up with a warty fungus like that which attacks the Hollyhock. The Phlox leaves were burnt brown; indeed, it presented the most remarkable evidence of fungoid destruction among flowers we have seen. Pull or cut and burn at once everything that is thus affected, sparing nothing. Then get from some of our advertisers of mildew or fungus destroyers prepared Bordeaux mixture, with which they will send you full instructions for use, and spray that twice or thrice at intervals of ten days over every flower or plant in your garden. How it became so infested with fungus we cannot tell. Only severe remedies can save plants in it from destruction.

**Construction of Water Lily pond (F. O. Dobell).**—The chief defect in the construction of the pond would be the so-called brick tubs, and if you arrange brick receptacles at all these should be freely pigeon-holed, so as to permit the roots to pass out into fresh soil placed around from time to time. A simpler plan would be to sink the Water Lilies into their positions, first securing them in wicker baskets with about two pecks of loamy soil and cow manure. It is the rich muddy bottom of a pond that Water Lilies delight in mostly, and this you should try to imitate so far as you can. The amount of the overflow will be ample. You will be able to get from Messrs. James Veitch and Sons, Limited, Chelsea; Messrs. Barr and Sons, Covent Garden; Messrs. T. S. Ware, Limited, Feltham, and other dealers in hardy plants any of the colours you require; but you should remember that the blue-flowered forms belong to the *Nymphaea stellata* set and are not hardy. For the side pockets *N. odorata* varieties would be best. A matter of much importance is the foundation or bottom of the pond, and this should be made sufficiently strong to preclude the idea of shifting or settling down. A strong concrete bed of somewhat greater width than the full size of the pond should be first made, unless you have abundance of easily-tempered clay near which could be puddled into shape. In any case, some care will be required to make the pond quite watertight, as there is nothing more vexatious than a Lily pond whose water level cannot be relied upon.

### ROSE GARDEN.

#### Mildew on Crimson Ramblers

(T. E. Baines).—We should say your plants have been too dry at the roots. This condition of things will engender mildew as much as anything. It is just possible your plants contain a lot of old wood that should have been removed in March. Very often this old wood becomes so decrepit that it is incapable of yielding healthy new growth, the consequence being mildewed shoots. Now is a good time to cut out the old wood—that which is of a dark brown colour—and then tie up the new growths in their place. Afford good soakings of water and liquid manure alternately once a week during May and June and again soon after flowering. If you syringe with Lifebuoy soap water as soon as mildew is seen, you will check it if not entirely cure it. Use half a bar of the soap to three gallons of soft water and repeat this spraying every three or four days. To ensure the water and liquid manure finding its way to the lower roots it is sometimes advisable to make some holes around the plants with a crowbar. You do not say

whether your Ramblers are on a wall or not, but we have found this to be the very worst position to plant the Crimson Rambler.

**Rose Bessie Brown with drooping blossoms** (*W. G. R.*).—This is a common complaint about this beautiful Rose, and one that prevents us recommending it for garden cultivation. Under glass, where its blossoms can be tied up to sticks, and the rain and moisture of the air kept from them, it is an ideal variety; but unless tied up and its flowers shaded, it is a hopeless Rose to grow outdoors. We should say that Queen of Spain and Mrs. Myles Kennedy will replace this variety for garden culture, although it will be a long time before the exhibitor obtains a more perfect Rose than Bessie Brown.

**Philadelphia Rambler with malformed buds** (*Rebecca*).—It is the one great failing of this Rose to sometimes produce buds such as you send. Some seasons this does not occur to such an extent as this year. Possibly the cold nights we experienced not long ago are responsible for the trouble. It is certainly climatic, because under glass we have none of this difficulty with the Rose. The only fault there is that it does not yield its trusses quite so freely as one could wish. There are now so many beautiful ramblers that it does not pay to retain those with peculiarities such as this Rose has. Plant instead either Wedding Bells, Rubin or Mrs. F. W. Flight if you do not already possess them.

**Applying liquid manure to Roses** (*E. L. P.*). In watering Roses in the open ground it must be remembered that there is a great difference in their case to those grown in pots. In the latter instance one must be careful not to overload the soil with too much liquid manure; but with regard to plants in the open ground one may give them a good helping and they will not suffer from it. Considerable harm might follow if the liquid were too strong, but if given well diluted the plants can take a good paillful each. We have given vigorous plants a paillful of pure liquid as drained from a large heap of cow manure, and have seen no harm arise; on the contrary, the lusty vigour of wood and foliage clearly showed that the plants appreciated this excellent diet.

**Liquid manure for Roses** (*Ignoramus*).—The amount that should be given to each bush and rambler depends somewhat on their strength. Vigorous plants could utilise half a gallon of the liquids named by our correspondent "J. D." in our issue of July 4, whereas weakly plants should receive but very little, if any. We do not care to give these latter any chemical manures. In their case soot-water or liquid made from cow manure is much the safest, but to vigorous plants the chemicals named would give excellent results. You have misunderstood "J. D." when he advises the application of a certain manure on Monday and another mixture on Tuesday. He does not mean that you should continue watering with liquid manure. If applied once a week or once in ten days it would be ample, and we should advise you to vary the liquid manure, giving the plants some diluted cow manure and soot every other week. If the soil is dry water one day and apply the liquid manure the next. It does not follow if the surface soil be dry that the soil beneath is dry also.

**Cutting back a hedge of Penzance Briars and pruning other Roses** (*Perplexed*). If you prune the old hedge very severely, you will not obtain much bloom next year. We advise you to cut away at once one or two of the very oldest growths of each plant right down to the ground. You may have to sacrifice some new shoots in doing this; but it will have a beneficial effect by inducing new wood to grow from the base. This treatment should be adopted every June as soon as the plants are off bloom. Mme. Alfred Carrière, so grand upon a wall, is equally free-flowering when grown as a large free bush or pillar. The let-alone principle is advisable in this case, as with Grüss an Teplitz. Instead of pruning back the long growths, it would be well to tie or bend them over somewhat. This induces a freer blooming. Such varieties need a large space where they can develop. Grüss an Teplitz, when grown against a wall, should be very sparingly pruned. All that is necessary is to remove some of the old wood occasionally, and all young ripened wood should be laid in the entire length. We have had plants of Grüss an Teplitz in the open that have never been pruned, and they have flowered most profusely; but we recommend an annual removal of some of the oldest shoots. Réve d'Or is a somewhat shy bloomer and needs little, if any, pruning for some years. One of the finest plants of it we ever saw was one that had its straggling shoots clipped back with a pair of shears each spring. You should try and open out the plant in a fan shape as much as possible, so that light and air may penetrate, and do not object to a few growths drooping outward.

## FRUIT GARDEN.

**Growth on Apple trees** (*U. C.*).—The growth in the woolly aphids, more commonly called American blight. It is a terrible pest and difficult to eradicate, as it sometimes attacks the roots as well as the branches of trees. Experiments have for some time been carried out on the Duke of Bedford's experimental fruit farm at Woburn, in spraying fruit trees with different insecticides for the eradication of such pests. Here it has been proved that by spraying (gently

with a syringe) with White Rose paraffin all insects were killed with which it came in contact, leaving the foliage and branches of the trees unburned. In the past we have always urged caution to be exercised in the use of paraffin on fruit trees, either in summer or winter, for the eradication of insect pests, and even now, in the face of this strong evidence, we would advise you to try the experiment on one branch of a tree only at first, and if after the lapse of a week no ill effect on the foliage were perceived, you may confidently proceed with the spraying, with deadly effect as far as the aphids is concerned.

**Apple trees mildewed** (*W. H. E.*).—Your Apple trees are suffering from a bad attack of mildew. It is very seldom this disease attacks an Apple tree which is in a healthy and vigorous state. On the other hand, when at all feeble and out of health Apples are an easy prey to it; therefore the best way of preventing a similar attack in future is by trying to infuse greater vigour and strength to your trees, either by replanting or top-dressing with rich soil. If not too old for replanting, this should take place early in November, cultivating the land deeply and well enriching it with decayed manure before planting. If the trees are too old for replanting, take off the surface soil down to a good body of roots and top-dress with good loam and well-decayed farmyard manure in equal proportions. The trees will root freely into this new material next year, and consequently regain their vigour. When all the leaves have fallen, take away 2 inches of the surface soil round the trees and burn it, as it is sure to contain more or less of the mycelium of the mildew. There is no better insecticide for killing mildew than Bordeaux mixture. Spray your trees with this next winter.

## KITCHEN GARDEN.

**Onion Ailsa Craig** (*R. Hilton*).—Give the ground a dusting of guano round the roots, forking it in very lightly. Then give a good watering, which will wash the guano down to the roots of the Onions. One handful of guano will be enough for six or seven Onions. Do not let the manure touch the Onions. In another ten days give them a soaking of manure water from the stable or cowyard, and if they should be still growing and the weather is fine give them another similar watering at the end of another ten days. They will by then have about finished their growth.

**Finochio, or the Italian Fennel** (*T. M. D.*). Whether due to indifference for it as a vegetable or to difficulty in inducing it to make good or satisfactory growth, Finochio is very little grown in this country. It has stout, fleshy stems like a series of scales, and when the plants are half grown they need to be partially earthed up. Then about ten days later the plants may be cut for cooking. It is, properly boiled, fit for eating. The flavour somewhat resembles that of Celery, but is more refined. Seed to produce a summer crop may be sown in April in rows from 18 inches to 20 inches apart, then thinning out the plants to 9 inches apart, so as to allow for full expansion and partial earthing. In warm countries a sowing is made in late summer to stand the winter. Probably our climate is too cold to enable the plants to make full growth and thus become edible.

**Cabbage caterpillars** (*North Lancs.*).—The caterpillars which prey on your Cabbages are the product of the Cabbage moth (*Mamestra brassicae*). These moths deposit their eggs on the Cabbages, and the caterpillars soon hatch out. These feed on the leafage until they have performed their functions, then descend into the soil, where they hibernates as chrysalids, and come forth as moths again the following year. So long as the moths abound, so long will they infest gardens. It is needful to destroy the chrysalids in the soil during the winter, and burying them deep down helps to that end. Allowing poultry to scratch and feed on the soil also causes many to be destroyed. If the Cabbages were heavily dusted with lime or soot, this would help to keep the moth at bay, but would render the Cabbages inedible. Covering the Cabbages with fine muslin would protect them; otherwise the only remedies are to hand-pick the caterpillars or to dust the hearts with fine salt overnight, washing it off with clear water next morning.

**Insect-infested Globe Artichoke** (*G. W.*).—Ants use aphides very much as we do cows, but the smaller insects breed so fast that they need no larger insects to carry them. Evidently your Globe Artichokes are either too old or have to grow in very poor soil. It would, no doubt, be best were you to cut off suckers having good roots attached from your present plants next November and plant them out into deeply-trenched and well-manured soil in rows 4 feet apart. In the 1st of Wight the plants should need no winter protection, but more north they do. In the meantime fork up the soil about your present plants, give them liberal soakings of liquid manure and add a mulch of manure. Good growers do not allow plants to remain on the ground longer than three years. Pick off caterpillars as fast as seen, first

damping the parts infested with aphids, then dust freely with Tobacco powder. Tie cotton wool dipped in paraffin round the stems of the heads just below them to check the ascent of ants.

## MISCELLANEOUS.

**Worms on Strawberry and other plants** (*R. E. McDonnell*).—Are you quite sure that the worms you sent, which are one of the many kinds of earthworms, are the culprits, or are there some other creatures in the soil that have caused the injuries to your plants which you have overlooked? I rather think that you will find that there are. I have never known earthworms to injure plants in the way you say these have. Earthworms may be killed by soaking the soil thoroughly with lime-water. If you can find any other creatures at the roots of the plants, please send some and I will say if they are likely to be the offenders or not.—G. S. S.

**Insects under felt** (*L. E. E.*).—The insects which you found in the felt that was under your carpet were the grubs of the bacon or larder beetle, which feed on various animal substances—skins, leather, wool, bacon which has been kept hanging for some time, &c. The two smaller insects which looked like spiders were small beetles which I do not think have any English name, but are known to entomologists as *Niptus hololeucus*. They feed on a great variety of different substances, but are never found in such numbers as to be the cause of real injury. You should take up the felt and have it well beaten in the open air; this, however, you have probably done already.—G. S. S.

**School shows** (*L. S. H.*).—Bulbs, soil and pots usually have to be supplied to the children, and it will be necessary to arrange with a local gardener to give one or more demonstrations in the preparation of the pots and the subsequent potting of the bulbs. This we consider preferable to moss-fibre culture for children, as success depends in this case almost wholly upon watering, and, unfortunately, this cannot be taught. School gardens are arranged either for the scholars to work on individual plots about three-quarters of a rod in area or as a class on one large plot, the former being, in our opinion, preferable. We have no doubt that Mr. J. C. Newsham, Farm School, Basing, Basingstoke, would give you particulars of the system adopted in your own county.

**Names of weeds** (*Kingscote*).—The two most troublesome weeds you send are, unfortunately, too well known to us in England. No. 1, with the creeping, fleshy roots and creepig top growth, with pretty reddish flowers, is *Convolvulus arvensis*, or common Bindweed. Once it gets hold of the ground it is most difficult to eradicate. Beyond getting out all the roots possible by deeply forking the ground, almost the only other course is to keep it constantly cut down with the hoe, not waiting until it has made several inches of growth, but cutting it off the moment a tiny shoot is seen. Once it gets among the roots of Gooseberry bushes, Raspberries, Strawberries or other plants, the only course is to clear out the whole lot and work the soil deeply, picking out every piece of root seen and burning, then planting the ground with some crop that will enable the hoe to be freely used about it. Weed No. 2 is one commonly found in low-lying, wet soil which is very sour. It is known as Horsetail, but its proper name is *Equisetum*. This is a very deep-rooting weed, and its presence shows that the ground is waterlogged and needs draining, also that a dressing of ground lime, half a bushel to the rod, worked into it will do good in helping with the draining to sweeten the soil. All the same, all roots possible should be forked out, and, as with the other weed, the hoe kept in constant use to cut off all growths as fast as they appear. When that is done, these deep fleshy roots will die in time.

**Names of fruit.**—*Burntwood*.—1, Irish Peach; 2, Warner's King. —*Kite's Nest*.—1, Hereford Beaufin; 2, New Hawthornden; 3, Red Bietzheimer; 4, King of the Pippins; 5, Scarlet Pearmain; 6, Worcester Pearmain. —*Vinery*.—Your Grape is West St. Peter. —*A Constant Reader, Bedford*.—1, Ecklinville Seedling; 2, Ribston Pippin; 3, Cellini Pippin; 4, Worcester Pearmain; 5, Lord Sulfield; 6, Lord Grosvenor.

**Names of plants.**—*D. S.*—Rose Hon. Edith Gifford; —*H. H.*—1, Jeannie Dickson; 2, Jules Margottin; 3, Tom Wood; 4, Comte Raimbaud; 5, Reine M. Henriette; 6, Hugh Dickson; 7, Heinrich Schultheis; 8, Cheshnut Hybrid; 9, Louis van Houtte; 10, Hon. Edith Gifford; 11, Mrs. Bosanquet; 12, John Hopper. —*Begoni*.—A seedling variety of the tuberous-rooted Begonia, of which the forms are very numerous. —*Mrs. E. B. B.*—A seedling of *Phlox Drummondii*. —*W. E. G.*—*Tanacetum vulgare*.—*F. L. Italy*.—1, Probably *Calamintha* species; 2, *Mentha rotundifolia* variegata; 3, *Veronica spicata*. —*Glos.*—1, *Spinra japonica*; 2, *Macrotomia echioides*; 3, possibly *Fabiana imbricata*. —*C. O.*—*Rubus odoratus*. It bears red flat fruits. —*A. H. Pom.*—*Stanhopea Wardii*. —*C. H.*—*Patching*.—1, *Nicandra physaloides*; 2, *Silene Armeria*; 3, *Panicum capillare*. —*Anxious*.—*Rhus Cotinus*. —*W. G. H.*—1, *Tradescantia* species; 2, *Mimulus* species; 3, *Helenium autumnale cupreum*; 4, send when in flower. These specimens were so scrappy that it was impossible to name them all correctly. —*L. C. F.*—*Saltash*.—Cannot name them all only; send flowers. —*A. B.*—1, *Daucus Carota*; 2, *Polemonium caeruleum*; 3, *Potentilla argrophylla* variegata; 4, *Campanula latifolia*; 5, *Helianthemum vulgare* variegata; 6, *Gillenia stipulacea*; 7, *Verbascum phonicum*; 8, *Euphorbia Cyparissias*; 9, *Dicentra formosa*; 10, *Sedum roseum*; 11, *Hedera Helix aurea*; 12, *Eupatorium purpureum*; 13, *Anagallis arvensis*; 14, *Sidalcea malviflora*; 15, *S. candida*; 16 and 17, *Geraanium* species, cannot name without flowers.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## PHOTOGRAPHIC COMPETITION FOR OUR READERS.

WE frequently receive photographs from our readers of some pretty spot or corner in their gardens, and it has occurred to us that it would be interesting if prizes were offered for the best examples sent in. We therefore offer a first prize of two guineas for the best photograph of a reader's garden, and a second prize of one guinea. Each photograph must be accompanied by a written description of the garden. Photographs must be sent addressed to "The Editor, 20, Tavistock Street, Covent Garden, London, W.C.," on or before October 31, and the envelope or wrapper must be marked on the outside "Photographic Competition," and accompanied by a coupon, which appears in the advertisement pages. Each photograph must have the sender's name and address plainly written on the back. Rejected photographs will be returned if stamps are enclosed for postage. The Editor reserves the right to use any photograph and description that does not win a prize, and his decision must be regarded as final.

## THE ROCK GARDEN.

### HOW AND WHERE TO MAKE IT.

THERE is probably no phase of open-air gardening so little understood, so much abused and about which such erroneous ideas exist, even at the present time, as the formation of a rock garden, be it on a large or a small scale. Too frequently the amateur is precluded from making any attempt to form such a garden by false notions of expense. Others, again, in their desire to see all the Alps from the back door, rear up the most ungainly and unsuitable masses of rock, burrs or clinkered bricks, cemented together in such a way that plant-life is impossible even from the outset. Yet others, and the villa or suburban gardener more particularly, will endeavour, by the help of a few barrow-loads of clinkers, to set up a rockery of a kind in which there has been no foundation, no thought and, worst of all, no knowledge of the requirements of the beautiful flowers that it is intended should be grown. And then some will carefully cement every bit of clinker together, forming miniature water-tight compartments, in which there may be the merest scrap of soil. The roots are then imprisoned for life. These are among the many failings, errors and shortcomings which make up the grand sum total of failures and create not a little disgust in the minds of those most concerned.

### WHAT TO AVOID.

Clinkers, burrs and the cemented rubbish too frequently seen should be avoided, while tree

stumps, roots, the thicker branches of trees—seen in more than one instance horizontally disposed—are just as objectionable and out of place. Vertical masses of rock, or those piled-up wall-like structures with occasional projecting ledges, and into which the merest seam of soil is placed, are as bad.

### POSITION.

This should be quite in the open, away from the far-reaching evils of hungry tree-roots, such as Limes, Elms and Poplars. In gardens where the surface is undulating, or where bold mounds or prominences exist, the cost of making a rock garden will be greatly modified, and such positions deserve the greatest care and consideration. Avoid near associations, where possible, with the dwelling-house, and particularly the formal parts of the garden, where these exist.

### MATERIALS TO USE.

In so far as this concerns the right kind of stone for rock garden work, a great variety may be suggested, the most suitable being the varying forms of sandstone or millstone grit for first choice, while others, such as limestone, Kentish rag and the like, are very serviceable. Soft stones, such as the oolitic and magnesium limestone of the Cotswolds and other ranges, is not suitable, while the fossil-bearing strata of the same chain of hills are singularly effective when rightly placed. Stone that is either very hard or very soft should not be used.

### ARRANGING THE STONES.

One of the common errors in rock garden making is that of using stratified rock in an obviously unnatural manner. This and the up-ending of pieces of rock, giving the latter the appearance of a badly-used milestone, will at once render the rock garden unsightly. Three-foot-high pinnacles of rock, dotted over a mound of earth in a more or less regular way at frequent intervals, are just as much out of place as are those flat slabs of soft limestone sometimes seen with so many square feet of surface exposed the wrong way up, unclothed and unadorned by vegetation from year to year. Neither of these ways is geologically correct, nor are they suited to plant cultivation. By far the best class of rock is that roughly hewn and of rugged exterior, while thin slabs of rock should be given their proper place, i.e., broken up for mixing with the main body of the soil or for forming walls or fences.

Having discovered the natural lay of the rock, any portion of the same should be inserted in the soil bank or mound, with the top surface of the stone slightly inclining to the bank of earth, the front base-line being just buried from sight. In this way the soil of the bank gathers to the upper surface of the stone, and, forming a slope,

affords the best possible position and opportunity for the successful cultivation of many alpine. At a totally different angle, pressing more deeply to the main body of soil, another piece of rock should occur, or it may be two, one above the other, the upper one always receding sufficiently to receive plants in the nearly horizontal fissures, and not projecting or precipitous, where no plant could exist. The reader who can take in the position of these two pieces of rock as above suggested may be said to possess the key to proceed, and by providing a surface as diverse as circumstances permit, avoiding the walled-up pattern, bring the thing to a successful issue.

Very thin slabs of rock, arranged 3 inches apart and buried nearly their full depth in the soil, to be filled with soil, broken stone and the like, not merely afford variety but are valuable for the smaller tufted alpine and where the rocky fissure forms the most desirable spot. Above all things remember that your rock garden is intended to be a home for the plants, and with some knowledge of the conditions of growth and the requirements of the subjects the operator should not go far astray. As a word of warning, the unassisted amateur should not be too ambitious, contenting himself for a while with a 3-foot-high mound, or even a rocky bed or prominence.

E. H. JENKINS.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 7 and 8.—National Chrysanthemum Society's Early Autumn Exhibition, Crystal Palace.

### Flower show for our readers.

The announcement in our issue for the 19th ult., that the publishers intend to hold another flower show for readers of THE GARDEN next summer, has already created a considerable amount of interest, judging by the letters received. We hope to be able to definitely announce the date in an early issue, and the schedule will be carefully prepared to meet the wishes of readers as far as possible. Some useful suggestions have already been received and we hope other readers will furnish us with their ideas, all of which will receive careful consideration.

**United Horticultural Benefit and Provident Society.**—The twenty-second anniversary dinner of this society will be held at the Waldorf Hotel, Aldwych, W.C., on Thursday, the 15th inst., at 6.30 p.m. Dr. Robert Boxall of Abinger, Dorking, has kindly consented to preside on this occasion. It is earnestly hoped that all who possibly can do so will attend the dinner, and so make the function a successful and interesting one. The musical arrangements will be under the direction of Mr. Thomas Winter. Tickets (5s. each) to be obtained of the secretary, Mr. W. Collins, 9, Martindale Road, Balham, S.W.

**The new species of Poplar.**—Messrs. James Veitch and Sons, Limited, write: "We beg to thank you for the notice of our new Poplar in your issue of the 26th ult., on page 475. We would take the opportunity of pointing out that, through an error on the part of our printers, the name was given as *Populus alba lasiocarpa*, whereas it should have been *Populus lasiocarpa*, a true species and not a variety. Our plant has nothing to do with *Populus alba*, and is quite a distinct species. It was correctly labelled before the floral committee, and received a first-class certificate as *Populus lasiocarpa*."

**Resignation of Mr. H. Hemsley.** Mr. H. Hemsley of Crawley, Sussex, informs us that he has resigned his position with Messrs. Cheal and Sons, and that he has started business on his own account. Mr. Hemsley is an expert on herbaceous plants, and particularly rock and alpine gardening, and his book on the latter subject is, of course, a well-known work.

**Southampton Royal Horticultural Society.**—We are requested by the secretary of the Southampton Royal Horticultural Society to state that, owing to unexpected circumstances, the council are compelled to alter the date of the Chrysanthemum show from November 2 and 3 to October 28, 29 and 30.

**Sutherlandia frutescens.**—I was sorry to see, in visiting some of our London gardens this summer, that the *Sutherlandia* had not grown and bloomed so well as last year, when it was grown to such perfection in Finsbury Park. This plant has succeeded much better with me this year than last: I have timber in my stems three-quarters of an inch thick, and some plants have spread and shot out from the sides 2½ feet, producing a brilliant display of foliage and scarlet flowers. I attribute my success to saving my old seedling plants last year and taking cuttings in autumn and early spring from them, and not sowing seed. Another good wrinkle is to see that you pinch the plants moderately hard at the end of March and April; they then grow away into fine strong specimens. I have a bed mixed with *Abutilon vexillarium variegatum*, Mrs. Pollock *Geranium*, *Solanum Pyracantha*, *Anthericum variegata*, *Alyssum wulfenianum* with edging of *Alternanthera versicolor grandis*. The effect has been really beautiful and such a charming contrast to the usual bedding-out.—H. J. SELBORNE BOOME, *Holwell Hyde, Hatfield, Herts.*

**Memorial to Mr. George Nicholson.**—A committee is being formed with a view to inaugurating a fitting memorial to the late Mr. George Nicholson, F.L.S., V.M.H., ex-curator of the Royal Gardens, Kew, and editor of the well-known "Dictionary of Gardening." Anyone who is interested in the proposition may obtain further particulars from Mr. Wilfred Mark Webb, the hon. secretary of the Selborne Society, at 20, Hanover Square, London, W.

## PRIZES FOR READERS. OCTOBER.

### THE WINTER PRUNING OF HARDY FRUIT TREES AND BUSHES.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The object of this competition is to draw special attention to the important winter work of pruning in the hardy fruit garden. Special attention should be given to the reasons for pruning and the benefits to be derived therefrom, as well as to the actual work. Various types of trees and bushes should be dealt with, and root-pruning may or may not be included at the discretion of the essayist.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Wednesday, September 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Essays on fruit bottling.**—I see in THE GARDEN for the 19th ult. one of your correspondents writes to say that she wonders that in the last competition on fruit bottling no one mentioned Fowler and Lee's patent process. I wrote a description of their method of preserving fruit; but, seeing in their book that no one was allowed to describe it or have it printed, I wrote to ask their permission. They said that they did not wish anyone to describe their method, as it was a patent process only used by them, so, of course, I did not send in the paper for the competition.

—ETHEL KEEPE.

Will Mrs. Arnold kindly inform me where to obtain the clamp bottles she recommends in her essay on fruit bottling, and the price of same? It would also be interesting to know the price of the bottles recommended by D. Hill, and whether either of them could be obtained in or near London. The only bottles obtainable in Richmond appear to be those with screw stoppers, which seem to answer very well, the fruit being treated as Mrs. Arnold recommends. Although rather late for this year, it would be useful to know where to obtain the best bottles in future. I think if an advertisement of such bottles had been in your valuable paper the same week as the prize essay it would have amply repaid the advertiser, the chief difficulty with myself and friends being suitable bottles.—J. H., *Richmond*.

Kindly permit me to reply to your correspondents in THE GARDEN for September 19, page 455. I have no doubt whatever that the methods there advocated will answer; in fact, I know of an expert who considers 150° sufficient; but the conditions under which my article was written required the experience of the writer, and not manufacturers' instructions or expressed opinions of other people. In the opinion of your correspondents the fruit is boiled; this is not so, as it is impossible to do this in the time in a vessel heated by water and not actually covered by it. Anyone may test this by scalding milk in a double vessel. Pouring boiling water over the cold fruit sets the colour, and no after-process can spoil it. I have never found fruit to ferment by the use of sugar; in fact, it is used to counteract the effect of acidity set by the heating process. I have never had a burst bottle. Tomato purée is simply a culinary preparation and cannot be termed "bottled Tomatoes."—EMILY ARNOLD.

**Tulips in demand.**—I am told that nurserymen have a large number of orders for Darwin and May-flowering Tulips. Of the former, the following are in great demand: Clara Butt, rosy salmon; Edmée, salmon rose; Farncombe Sanders, dark salmon rose, tinged scarlet; Velvet King, purple; Pride of Haarlem, dark rose, shaded scarlet; Rev. H. Ewbank, heliotrope; King Harold, dark maroon; and Salmon King, salmon scarlet. Among the May bloomers, Picotee Yellow, yellow with faint crimson edging; Inglescombe Pink; Inglescombe Scarlet; Inglescombe Yellow; elegans alba, white with carmine edge; The Fawn, fawn, egg-shaped; and Bouton d'Or, a golden yellow, are being asked for on all sides. But early Tulips are also being sought after, especially varieties like Unique, white with soft yellow base; Sir Thos. Lipton, scarlet; La Remarquable, plum colour with lighter border; Rouge Luisante, deep rosy pink; King of the Yellows; and Pink Beauty. King of the Yellows is about the best early bedding Tulip of its colour.—W. P. W.

**Use of Rowan berries.**—I saw a question in THE GARDEN of the 5th ult. respecting Rowan tree berries. They can be utilised for jelly if picked from the stalks, put

into a saucepan and covered with cold water. Boil them down to a pulp, let the juice run through a jelly bag and weigh it, adding the same weight of castor sugar. Boil again and make it into jelly.—BARONIN GITA RANSONNET, Austria.

## THE KITCHEN GARDEN.

### SOME GOOD CABBAGES FOR SPRING.

**T**HE Cabbage crop in the early spring is an important one, as when this is early the land that has provided the green vegetable crop is available for other crops, and a small, compact, sweet spring Cabbage is a delightful vegetable, so that the amateur's attention should be drawn to this point and the importance of autumn planting and of the best varieties. There are now some excellent early spring Cabbages, and the amateur who does not sow should obtain the plants from a good source.

One of the earliest is Sutton's April, and this is a model Cabbage of very compact growth and quite free from bolting. It is remarkably early, and is rightly named, for I have had it the first week in April after a severe winter. Another very reliable early Cabbage is Sutton's Flower of Spring. This is a little larger than April, but equally valuable where quantities are required. It forms a compact head of a most beautiful shape and is exceedingly delicate in flavour. A very fine spring Cabbage is Sutton's Favourite, a compact dwarf variety with remarkable short stem or leg and an ideal amateur's variety. Sown in August, I have cut this variety in the middle of April. I have not noted Ellam's Early Dwarf, as I consider any of the three named above far superior and more reliable as regards bolting. Veitch's Earliest of All is a splendid early dwarf variety which I have had in five months from date of sowing. Veitch's new Incomparable is a very fine type of early Cabbage and will become a standard variety. It is medium sized, does not bolt and is of fine quality. Carter's Early Spring is a very beautifully-flavoured early head and never fails, it being remarkable for its hardiness, and it is well worth a trial for its compact growth and freedom from bolting. Carter's Early Garden has the same good qualities; it has a very distinct conical shape, is remarkably early and of a delicate flavour.

*Autumn Planting.*—It will be seen that there is no lack of good varieties to select from, and the amateur should be careful to get the plants from a good source, as he will then get a much better return. Of course, a great deal depends upon the planting; it is useless to plant in November or December and expect good heads in three months. I advise planting as early in the autumn as possible; for many years I planted my earliest on the land that had grown the spring-sown Onions, this being in good condition. It was not manured for the Cabbages, but deep drills were drawn in September and the plants put out when quite small in rows 2 feet apart and the compact sorts named 15 inches to 18 inches apart in the rows. In amateurs' gardens, if space is at all limited, these distances may be reduced a few inches, say 18 inches between the rows and 12 inches to 15 inches between the plants for the sorts named. Planting early in October will give excellent results, and the plants do well in good cultivated soil, but this must not be loose, as I find a firm root-run promotes a compact growth.

The plants are best when food is given early in the year when growth is active. It is an easy matter to give food in the way of guano, nitrates or liquid manure in the early spring, and the plants will then form hearts rapidly and the quality will be excellent. In poor land food should be given in the shape of manure dug deeply in the soil previous to planting.

G. WYTHES.

## THE ROSE GARDEN.

### STANDARD WICHURAIANAS.

**V**ERY tall standards of this section are most pleasing in the Rose garden. We shall soon have to be on the quest for tall Briars from the hedgerows if they are to succeed. Early planting is a great point. Nor do these stocks do so well when the roots are cut too hard. They need more bottom to supply sufficient sap during winter and early spring, and we can well afford more care in pruning away the suckers during summer. When we can procure stems 6 feet to 9 feet long and induce them to break from near the top we have the groundwork of the finest form of growing some of the strongest drooping Roses. Plant the Briar stock nearly a foot deep and stake it at once. This is very important, as any sagging will destroy callus and young roots as they form. Frequent sprinkling overhead during a drying wind is also a great help. We must not lose sight of the fact that stems of this length have a great deal to support before new roots are formed, and many fatalities occur through the plant withering up. Lady Gay, Farquhar, Dorothy Perkins, White Dorothy, wichuraiana, Elise Robichon, Evangeline, Hiawatha, Minnehaha, Evergreen Gem, Pink Roamer and Gardenia are a dozen grand varieties for this purpose. It is an improvement when the young shoots are carefully trained out wider from the stem during the first year. RIDGEWOOD.

### AN EXCELLENT CHECK FOR MILDEW ON ROSES.

**L**AST year, after a slight attack of mildew, I dressed the whole of my Rose garden with soot in December and again in March. This season the mildew appeared early in July rather badly. After the July and early August blooming was over, I thoroughly sprayed first with Mo-Effic, and two days later with a solution made with Jeyes' Cyllin Soft Soap. This process was repeated twice over every second day, and the effect was magical, the mildew being completely checked. Mo-Effic alone is good, but the Cyllin in Jeyes' soap after the Mo-Effic has really a marvellous effect. When rain came I gave a slight dressing of freshly-slaked lime and lightly hoed it in. It is beneficial in many ways, and thoroughly cleanses the surface of the soil. The Roses, rejoicing in their freedom, have thrown up plenty of new wood, the delightful coppery red and green shades of early spring. I have the promise of a splendid harvest of autumn blooms practically free from mildew, the rosarian's greatest enemy. Next season I shall apply this remedy soon after pruning, to prevent, if possible, the mildew appearing at all. E. E. F.

### A FINE LONG-STEMMED ROSE.

**F**LORISTS and all who grow Roses under glass for cutting purposes know well the value of an erect-growing variety, one that will produce its blossom at the end of a 2-feet to 3-feet growth. Such an one is Souvenir de Maria de Zayas, the beautiful Rose raised by Messrs. Souper et Notting and distributed by them in 1906. It is of a rather unique colour, a vivid carmine crise, with deeper shading, and perfect Camellia-like flowers of great beauty and most beautiful buds. I can confidently recommend the Rose under notice for the purpose named, and such a variety cannot fail to become useful in the garden, and, if I mistake not, in the exhibition box also. The great value of the Hybrid Teas as pot plants is this tendency to grow erectly, thus proving far ahead of the Tea-scented group, so much so that they must eventually displace them, seeing we are obtaining nearly all the colours found in the true Teas. Pharisaer is another grand sort for long stems, and no one can but admire its deep, shapely buds and huge petalled blossoms. Other excellent

varieties for a like purpose are Antoine Rivoire, Kaiserin Augusta Victoria, Clara Watson, Liberty, Richmond, Dean Hole, Lady Battersea, Mme. Abel Chatenay and possibly some of the more recent novelties. To obtain these extra long stems it is necessary to prune hard back to two or three eyes, and it pays to do this even if it means having a few more plants. P.

## BACKHOUSE'S NURSERIES AT YORK.

**D**URING the past summer we had the pleasure of visiting the very extensive and comprehensive nurseries of Messrs. James Backhouse and Sons, Limited, at York, a visit that brought home to us very vividly the up-to-dateness of this old-established horticultural firm. No matter what phase of gardening a visitor may be interested in, he will find his pet subject dealt with here, no less than 100 acres being devoted to horticulture at the York nurseries, in addition to 70 acres elsewhere.

A prominent feature of the York nurseries is a broad, straight walk over a quarter of a mile long, this being flanked on either side by well-stocked herbaceous borders, which the firm regard as a sort of natural shop window, because herein are displayed the plants which are actually for sale. We noticed an abundance of choice and beautiful subjects, among them being some remarkably fine Eremuri hybrids, large quantities of extra good Delphiniums, Hemerocallis and a huge plant of Geranium ibericum.

Messrs. Backhouse have long been famous for landscape gardening in all its branches, rock gardening in particular, and the beautiful rock garden in these nurseries is worth travelling a long distance to see. Any description, however vivid, cannot do this magnificent garden justice. It has been made now some fifty years, and some extent of the size of the garden may be gained if we mention that nearly 5,000 tons of rock were employed in its formation. It takes the form of a sunk garden, rock-besprinkled banks forming nooks and crannies springing up on every side, while in the centre and forming islands of various forms huge masses of skillfully-prepared rockwork tower upwards, the whole garden presenting a most natural and enchanting spectacle. In this delectable spot the choicest of rock and water plants find a most congenial home, and it is under such ideal conditions as these that one is made fully aware of the many beauties of these most valuable plants. *Ramondia pyrenaica* abounded everywhere, and it appeared to be equally as comfortable on the top of rocky mounds as in the fissures in the face of cliffs. A combination of choice hardy *Ferns* and Iceland Poppies draping a huge mass of rock, their graceful outlines and delicate colours being reflected in the water beneath, formed a picture that will long live in our memory.

Glass houses, naturally, are a prominent feature at such extensive and comprehensive nurseries as these, and as an illustration of how prompt the firm is to adapt itself to any new branch of horticulture we may mention that a large area is now devoted to the now popular winter-flowering Carnations. In addition to a most healthy and extensive stock of all the best standard varieties, we noticed some very promising seedlings, a lovely deep yellow variety called Queen of Spain particularly appealing to us. It is a true perpetual-flowering variety, the flowers are of good size and excellent depth and the calyx and stem are all that can be desired. Such a Carnation is sure to be much sought after as soon as plants are obtainable. *Malmaisons*, too, are extensively cultivated, and the stock is a most healthy and vigorous one. Roses in pots abounded everywhere, huge tracts being devoted to these, as also to Roses grown in the open beds, all the plants being in the best of health.

The show and regal Pelargoniums are not, perhaps, grown so extensively now as they were a decade or two ago, but Messrs. Backhouse evidently have a large demand for them judging by the quantity grown. We noticed some very beautiful varieties among them, and probably in the selection of the best only for propagation, as is done here, lies the secret of maintaining these plants in popular favour.

In the houses devoted to Palms may be seen every kind of plant which can be included under this category. Choice and popular kinds are all grown, and specimens from a few inches to many feet high can be supplied, the houses presenting quite a tropical appearance.

The indoor fernery is a beautiful and almost unique feature here. Huge Tree Ferns stand like sentinels at intervals as though guarding their smaller *confères* beneath, while draping the boulders on all sides are choice filmy Ferns in the pink of condition. The collection of these filmy Ferns is one of the best and most extensive we have ever seen, and there is very little in this direction that the firm cannot supply. The underground fernery is reached by a series of roughly-hewn steps, which lead one under an arch of rockwork draped with Ferns and Selaginellas of all sorts. Inside this arch the visitor finds himself in a sort of fairy grotto. Huge rocks forming all sorts of mysterious yet beautiful nooks and caves are piled on every side, while here and there water trickles through chinks, to lose itself in a clear reflecting pool beneath. Draping these rocks on all sides are Filmy Ferns, Selaginellas

and many other subjects suited for such a position. One magnificent specimen of *Todea superba* which crowned a jutting rock possessed fronds measuring over 4 feet in length, and all the plants were on the same luxurious and magnificent scale.

Coming once more to the open we found conifers of all descriptions, fruit trees, bulbous plants, annuals, forest trees and, indeed, every branch of gardening being catered for, and we might, if space permitted, easily fill a whole issue of *THE GARDEN* with the many good things noted. It must suffice, however, for the present if we repeat that there is no branch of gardening overlooked by this firm, and that gardens of all descriptions have been laid out by them in all parts of the United Kingdom.

## THE GREENHOUSE.

### WINTER IN THE GREENHOUSE.

**W**ITH a little care and attention to details the greenhouse may be made as interesting during winter as it is in the summer. Perhaps it will not contain the unlimited supplies of flowers which summer enables it to produce, but those which it does yield will, by reason of having no outdoor competition to contend with, appear doubly beautiful.

*Cleanliness.*—This is the first point to be rigidly enforced—in fact, it may almost be said to be the golden rule of greenhouse winter management—as plants are then grown under entirely unnatural conditions, and need all the assistance possible to enable them to make a creditable struggle against these.

Before the inmates are brought into the house, that house should be fittingly prepared for their reception by having its walls, woodwork and glass well washed and scrubbed with warm soapy water, forcibly syringing this into every nook and cranny. The walls should also have a good coating of hot lime-wash with a handful of size or cement added to each pailful to make it adhere; be careful that none of this wash gets on the painted woodwork, as it is injurious to paint. In cleaning the glass of the roof or sides, an old zinc label, flattened wire or something similar should be used to remove the accumulations of dirt and slime from between the laps. Do not forget to thoroughly clean beneath the stages of the house and sprinkle soot and lime upon all

ground surfaces where pot plants may ultimately rest.

After bestowing so much labour upon the house it would, of course, be folly in the extreme to bring into it dirty pots or plants; therefore scrub all the former and well syringe the latter before housing them. This will give the cultivator a clean bill of health to start with, and, if a short time is allowed each week afterwards to clean up a little the plants and house, both will be a credit to the owner. This weekly clean up cannot be too strongly insisted on, as much good results from it. Saturday is generally set apart for it in good gardening establishments; there the "young men in the houses" pick off all dead leaves and flowers, sweep down all staging and generally rearrange the plants so that the houses present a fresh appearance, which is good for the plants and for the employers. After the young men have finished, the boys are turned on with tubs of water, syringes, brushes and brooms, and all glass doors are washed and scrubbed, door-handles polished, and the floors of the houses thoroughly scrubbed. The result is a very smart appearance of the houses on Sunday.

*Disposition of the Plants.*—This is naturally a harder problem for the person who possesses but one house to solve than for he who has several of varying temperatures. Much, however, can be done by a little management in the way of accommodating plants according to their requirement. A few easily-affixed hanging shelves will be found of great assistance where the number of plants to be housed is in excess of the normal house-room. They may be used for wintering boxes of Geraniums, Mesembryanthemums, Lobelias and similar plants which will not need much attention in the way of watering, or for Cacti and succulents generally. Where hanging shelves are not available, all the plants mentioned, with others such as Crinum, Hippeastrums, Vallotas, Fuchsias, Heliotropes, Plumbagoes, Allamandas, Abutilons and many more which will suggest themselves, should be placed on the top shelf of the stage or in any position where watering is difficult.

Achimenes, Begonias, Crinum, Fuchsias, Caladiums, Cannas, Gloxinias, Hippeastrums, Vallotas, Gesneras, and even Maidenhair Ferns and Streptocarpuses (these two should be stood upright) may all be stored beneath the stages for the winter. Care should be taken that the pots are not placed too near the hot-water pipes, and that none of them are subject to a constant drip from the occupants of the stage above them. The pots may be arranged in tiers to any desired height, and a monthly examination will be all they require until growth commences in the spring.

The warmer end of the house, *i.e.*, the one farthest from the door and nearest to the stove-hole, should be given over, as far as possible, to the more tender plants, of which there are frequently a number, such as Coleuses, Eucharises, Dracaenas, winter-flowering Begonias, Saint-paulias, Cyclamen, double Primulas, Bouvardias, winter-blooming Zonal Geraniums and India-rubber Plants.

The end near the door may be used for accommodating the bulk of Arums, Deutzias, Salvias, Eupatoriums, Solanums, mollis Azaleas, forcing bulbs and Spireas, which may be transferred to the warm end as they are required to furnish flowers or decorative plants. In the intermediate portion of the house the general sorts of greenhouse plants may be placed, such as Primulas, Cinerarias, Pelargoniums, Clivias, Calceolarias, Hydrangeas, Campanulas, Genistas, Indian Azaleas, Rhododendrons, Camellias, Anthericums and so forth, which, while liking plenty of fresh air, will not tolerate cold draughts. If a number of the plants are stood upon inverted flower-pots a free circulation of air will be ensured and flatness avoided.

IN THE ROCK GARDEN IN MESSRS. BACKHOUSE'S YORK NURSERIES.

## TREES AND SHRUBS.

## BERBERIS (MAHONIA) ARGUTA.

**T**O the somewhat numerous Berberis family this new species makes a distinct and welcome addition, being named from a plant flowering at Glasnevin Botanic Gardens. This plant has been in the gardens for a number of years, but the source from which it was obtained has been lost, though it is thought to be a South African species. It is growing in a pot and is a straggling specimen about 5 feet high. As there is only one specimen, its hardiness has not been tested, but through the summer it is plunged outside, and it is wintered in a practically cold house.

Though the habit of this specimen is rather ungainly, yet when in flower during June and July the shoots are most graceful. The flowers are a pleasing shade of light yellow, and are borne on pendulous racemes 1 foot and sometimes more in length, and in some cases the pedicels bear two or three flowers. The main stem is very slender but of a wiry nature, and bears about thirty bracteate flowers, each measuring three-quarters of an inch in diameter. The seed is not produced very freely, even when the flowers are artificially pollinised.

The internodes of the stem are short, so that the leaves seem crowded at the top of the stems. The pinnate leaves have a yellow main rib bearing five to six pairs of leaflets. These leaflets are very stiff in texture, light green in colour, lanceolate in shape, ending in a sharp point. They also have a distinct cartilaginous margin, a few bearing spines but usually without, while the reticulate venation is strongly marked and prominent. The photograph shows a terminal shoot of this specimen and the free manner in which the flowers are produced. C. F. BALL.

## HARDY HEATHS IN FLOWER.

THE Heath family does not consist of a very great number of species, yet it is remarkable for the length of time over which its flowering season extends, for, to begin with the new year, we have that delightful hybrid *Erica mediterranea hybrida*, which often blooms throughout December and continues bright and effective till the end of March or nearly so. Following closely comes the dwarf-habited *Erica carnea* or herbacea and its white variety. The next to expand their blossoms are the large-growing *Erica lusitanica* or *codonodes* and the still larger *Erica arborea*, with that valuable hybrid between the two, viz., *Erica Veitchii*. By March, too, the several forms of *Erica mediterranea* put in an appearance and last for a long time. This staying power of the Heath family is remarkable, for most of them remain in good condition for three months or thereabouts from the opening of their earliest blossoms. The middle of September by no means sees the finish of the different hardy Heaths, for in looking over an extensive collection at that date the following were all bright and attractive: St. Daboc's Heath (*Daboecia polifolia*), represented by the typical plant with rosy purple blossoms, as well as the white and parti-coloured varieties; from spring till autumn this Heath continues to flower. The Gray Heath (*Erica cinerea*), whose varieties are numerous, had been in flower since midsummer, yet it, and particularly the rich-coloured forms, made a goodly show. Much the same, too, might be said of *Erica Tetralix* and *E. ciliaris*, with its variety *maweanae*.

Of those commonly regarded as autumn-flowering sorts, the first place must be assigned to the common Ling or Heather, whose varieties are very numerous. A popular idea is that the white Heather is extremely rare, but as a matter of fact it is not so; indeed, there are several distinct forms with white blossoms. In addition to these, many other varieties are remarkable for

the colour of their flowers, and some for their habit, while the yellow-foliaged sorts are, when in good condition, very striking. The Cornish Heath (*Erica vagans*) is a vigorous plant, and forms a dense mass of shoots thickly clothed with foliage. These shoots are now terminated by dense racemes of pinkish purple blossoms. It is less bright than some of the others, but for all this it is one of the best. A near ally of this last is *Erica multiflora*; but it is altogether a smaller subject than *Erica vagans*. The flowers, too, are decidedly paler. From this it may be gathered that the display furnished by the various hardy Heaths, even in the middle of September, is by no means a meagre one, and I may perhaps be pardoned for again advising the free use of these plants for filling large beds, forming clumps in front of the shrub border or for edgings to beds filled with taller shrubs, as in such positions the plants are seen at their best, and are capable of affording considerable pleasure to their owners. H. P.

## THE FLOWER GARDEN.

## GOOD AUTUMN FLOWERS.

**F**ORTUNATELY there are a host of beautiful plants which keep the garden gay during the autumn months, and these are continually being added to by the introduction of new things, or the reintroduction of old ones. At the time of writing, however, I question if there are many things which can surpass the plants mentioned below.

First, there is *Tritoma Uvaria* (aloides) and its numerous varieties, the best of which, I think, is *T. nobilis*. This is a fine, bold, free-flowering plant, much superior to the type. The flower-head is much longer and stouter and of finer colour. A most noble plant, worthy of a select place in the garden. Then there is *T. lachesis*, a beautiful yellow or orange yellow type, with long, well-formed flowers. Perhaps this is not quite so hardy as the above-mentioned forms, but is worthy of any little trouble in the way of protection during the winter. *T. Pfitzeri* is another bold variety of splendid colour and free-flowering propensities. *T. Macowani* is a delightful plant; a pigmy alongside the others, but of a beautiful orange scarlet colour, the spikes being produced in the greatest profusion. These four are really splendid autumn plants for the garden.

THE NEW BERBERIS, B. ARGUTA, IN THE GLASNEVIN BOTANIC GARDENS.

Just now *Montbretia crocosmaeflora* is a most beautiful as well as a most useful plant, and associates most pleasantly with the above plants. If this is divided every second year and the bulbs graded, the soil thoroughly prepared by deep cultivation, and some well-decayed manure and wood ashes incorporated with the soil as the digging proceeds, good results may be confidently looked for. If the work is done during the winter, care should be taken to place some covering on the surface as a protection against frost, but I have had quite the best results when the planting has been deferred until March, the soil having been prepared during the winter. A mistake frequently observed is leaving the plants in one place too long, when they become crowded and the soil exhausted, thus causing the plants to become too weak to flower satisfactorily. George Davison is a splendid yellow variety, just now in full flower, and makes a fine companion to *Tritoma Macowani*.

*Amaryllis Belladonna* is a plant which should be grown wherever there is a suitable place, viz., at the foot of a south wall. I do not suppose it would succeed as an ordinary border plant, at least, in the Midlands, not on account of its doubtful hardiness, but because the bulbs require a thorough baking after they have finished their growth. If there is a plant in cultivation which requires deep and good cultivation superior to another, this is the one. The soil should be from 2 feet to 3 feet in depth and of the best. Good sound turfy loam, a little good peat, a liberal amount of dried cow manure and coarse sand is what this splendid plant likes, and it will well repay the trouble of making a good border, and liberal waterings when in active

growth, which is spring and early summer. Sometimes this plant will cast its flower-buds prematurely, a sign, I think, of poverty, which is sometimes brought about through the bulbs being overcrowded. The only remedy is, of course, lifting, grading and replanting. There are several forms of this plant, the Kew variety being, I think, the best. We have two forms growing here, one vastly superior to the other and somewhat earlier.

THOMAS ARNOLD.

*The Gardens, Cirencester House.*

### THE ITALIAN WINDFLOWER.

(ANEMONE APENNINA.)

THIS is the wild Anemone of Italy, taking the same place in that country as our own Wood Anemone in our copses and brakes. It is a pretty little plant with downy leaves divided somewhat like those of *A. nemorosa*, and of a tender green tint. The flowers are sky blue in colour on the inside and paler on the outside,

It is, however, only when naturalised in the grass that its charms are displayed to the best advantage. The sight of a colony of these flowers clothing a grassy knoll at the foot of a giant Oak or Elm with a veil of blue is a delightful picture on a morning in early spring, the colour-effect being enhanced if Lent Lilies in quantity are associated with them, the pale yellow of the Narcissi forming, with the azure of the Anemones, the varied greens of the grass and of their respective foliage, a colour-harmony exquisite in its gradation of tints. Such glimpses as these, obtainable in almost every garden at a trifling cost, are far more satisfying to the eye than are the infinitely more expensive and less natural breadths of gaudy bedding plants to which, later in the season, the greater part of many a garden will be devoted.

*A. apennina* has been naturalised in numbers of English woods, so much so that by some it is considered to be a native plant. Where it is happy and the soil is to its liking, it spreads

the surfaces shimmering, and they are remarkable for their great size. The group has proved a puzzling one to the cultivator, and there is yet much to learn and something to unlearn before we can treat them properly. Various methods of culture have been tried and found deficient of the one essential element that assures free, vigorous growth that will flower freely. After considerable experience it was considered that lime was the one thing needful; but, so far as my experience goes, they grow infinitely worse in soils dressed with materials containing lime than they did in the natural loam. That lime may prove beneficial for soils mainly of vegetable composition is undoubted; but I think the natural loams provide sufficient lime for any garden plant, and that the *Oncocyclus* Irises find the lack of heat and, to them, the fitful climate of the British Isles far too much for their well-being.

We must consider the great difference between the climate of Syria, partially surrounded by a rainless desert and with a mean annual temperature of 65° to 70° Fahr., whose winds are hot and dry and whose plants are accustomed to prolonged periods of drought, and the climate of England, with a mean temperature approximating 50° Fahr., and so variable that the occurrence of ten consecutive fine days is heralded as phenomenal, while our summers are normally dry and our winters wet, the reverse prevailing in most dry regions. The one principal point in the cultivation of dry-region plants is that of drainage, choosing for them a wind-swept slope or the base of south walls. Soils for such plants should be pure loam with sand and coarse rubble added, and if they have permanent roots they invariably penetrate deeply. To help these roots the soil should be deeply dug and rough stony rubble or small boulders buried to form well-drained surfaces, upon which the roots can run as deeply as they will. Plants so treated rest quietly, and, the feeding extremities of their roots being low down, they are not likely to respond to every slight rainfall and thus produce young growths before winter, while a further provision against excess of moisture would be the free use of small conifers on rockery slopes, whose roots would absorb superfluous moisture and the soil around which would form excellent sites for the planting of these Irises; furthermore, the sinking of holes with a crowbar around plantations of valuable Irises of this group

will do much to help drain them dry and induce them to rest. Indeed, we should be able to grow many beautiful dry-region plants if we borrowed a leaf from Nature's note-book and used one type of plant to produce the conditions necessary for the well-being of another, making it a kind of protective host plant. It is much to be regretted that so many fine plants have been lost because we have not known how to treat them, and the stocks of such beautiful plants as *I. Gatesii* and *I. Lortetii* are not only very low in cultivation, but they are now becoming scarce in their native habitats. All the Irises of this group require protection from rainfall from July onwards.

*I. atrofusca* is a singular-looking plant from Palestine, with rounded, glossy, black-brown standards and black hairy falls, each 2 inches across; the whole flower spans 4 inches. Its growth is but moderately vigorous and it requires to be thoroughly dried off after flowering.

M.

(To be continued.)

THE ITALIAN WINDFLOWER, ANEMONE APENNINA, GROWING ON A BANK.

with from ten to twelve star-like divisions, which are narrowly elongated and surround a cluster of whitish stamens. It flowers in April and flourishes in open woods and shrubberies. It succeeds best in a porous soil rich in humus. There is a white variety and one with dark violet flowers, as well as a double form, but none are as beautiful as the clear blue type.

It is now to be obtained very cheaply in quantity, so that there is no reason why it should not be planted extensively in autumn. To dot it about in small clumps in the beds is a poor way of growing it, but by planting it in the grass we see it under conditions similar to those it luxuriates in on the Italian sward, and it creates a delightful effect. There are spots in most gardens where this Anemone could be planted and left to take care of itself, when, after a few years, lovely pictures, growing in beauty season by season, would result. In thin plantations, where the sun can reach it, charming pictures may be obtained.

rapidly, both by seed and by underground stolons, and soon occupies a large expanse of ground. In the rock garden it seems as much at home as when nestling at the foot of some monarch of the glade, and, blooming among the curtains of the white Arabis, it is one of the prettiest features of the spring. In the accompanying illustration it is shown growing at the foot of a steep bank at the end of a wood, where a few corms were planted many years ago. These have increased to such an extent that they now occupy the whole ground space at their disposal, and are a pretty sight when in flower in the spring.

S. W. FITZHERBERT.

### NOTES ON IRISES.

ONCOCYCLUS IRISES.

THIS is a race of remarkable Irises, mainly from the Holy Land and countries round about, whose flowers are wonderfully coloured, either sombre-tinted or in blends of grey, rose, white and blue,

## SWEET PEA NOTES.

## SWEET PEAS IN TUBS AND POTS.

**A**LTHOUGH these lovely flowers are grown so extensively in clumps and rows in the garden, in flower-beds and borders, we do not hear of them being grown as decorative plants in pots or tubs so much as they deserve. There are many advantages in growing them in this way. They can be got to flower earlier, as they can be placed, when in tubs or pots, in a warm, sunny, sheltered position until they begin to show their buds, when they can be moved to other places where it would not be convenient to have them planted in the open ground.

We grew plants in about twenty tubs in this way this year, the seed being sown last October, five seeds in a 6-inch pot, and the latter placed on a bed of ashes in a quite cool frame. The seedlings were allowed all the air possible after germination, the lights being kept tilted at one end unless the weather was very severe, and twiggy sticks were used for support when the plants were about 6 inches high. They do not require much water through the winter months, being best kept just on the dry side.

In early March we stand them outside on a bed of ashes in a sheltered place, putting up a temporary framework of a few strips of wood over them, on which are placed sheets of corrugated iron during heavy rains or sharp frosts; they are left in this place until April, when they are planted in the tubs. Suitable tubs for this purpose can be procured from any fruiterer for a few pence each. The ones we use are those in which the Canadian Apples are sent over, these being cut down to 18 inches or 20 inches and painted outside a nice shade of green.

A suitable soil for filling them is a good stiff loam, a little well-rotted cow manure, leaf-soil, mortar rubble and a sprinkling of bone-meal and superphosphate of lime, the tubs being filled to within 3 inches of the top, placing about 3 inches of well-rotted manure in the bottom first. This filling should be done a fortnight before planting, and the soil left during that time to sweeten and settle down. Our Peas treated in this way were showing buds on May 14.

For support nothing beats ordinary Hazel Pea-sticks about 5 feet or 6 feet high, selecting the thinnest for this purpose to avoid their being unsightly. When the buds begin to show colour liquid manure can be given freely, using it rather weak at first and increasing its strength gradually. Cow manure and soot water are splendid for them. If artificial manures are used, care should be taken not to use too much those containing nitrates, as this, of course, causes a rank, sappy growth at the expense of good blooms. Clay's Fertilizer and Canary Guano are good, also the special Sweet Pea manures.

Some of the best varieties for this form of culture are: Helen Lewis, Etta Dyke, Lady Grisel Hamilton, Mrs. Hardecastle Sykes, King Edward VII., Sybil Eckford, Mrs. Collier, Evelyn Hemus, George Herbert, Audrey Crier, Dainty, Princess Victoria, Miss Willmott,

Sutton's Queen, Dorothy Eckford, Mrs. Alfred Watkins and Lord Nelson.

EDWIN G. JACKMAN.  
*Aberdare, South Wales.*

## CROSS-FERTILISATION OF SWEET PEAS.

I WOULD like to say a few more words on this subject, even at the risk of being thought obstinate. After the very able letter from "D," published in THE GARDEN for August 22, one might think that I would give up all idea of outside fertilisation; but there are several things which do not seem clear to me still. I

as W. Booth seems to suggest. In "Mendel and His Principles of Heredity," by R. C. Punnett, is this significant passage concerning Sweet Peas: "In a row of normal plants we come across some healthy ones bearing very few or no seeds. The anthers in the blooms of these are sterile, with a very little poor pollen. Any seeds which do form owe their origin to insects, for the stigma or female part is quite normal and readily sets when crossed. These seeds give normal flowers, and in the next generation flowers with sterile anthers reappear in the proportion of 1—3. This case of sterile Sweet

Pea is interesting from its bearing on the problem of sex; we have here a unisexual flower—a female—suddenly arisen from the normal hermaphrodite form by functional suppression of the male organs. It suggests that in cases of flowers where the sexes are separate this condition may suddenly have arisen from the hermaphrodite form."

From such an authority we must admit there is considerable food for thought in this. I believe that if we knew the life-history of every plant we would find that they were all hermaphrodite in their early stage before they were to a certain degree developed; and who knows but that that degree is developing in the Sweet Pea even now? Of those people who pooch-pooch the idea of fertilisation by insects I would respectfully

ask: Why is the Sweet Pea strongly scented and highly coloured? It is generally accepted by botanists that the principal objects in the life of a plant are self-preservation and the reproduction and multiplication of its kind; that Nature will only tolerate self-fertilisation for a time; and that, where there is a choice between the two ways, cross-fertilisation is generally preferred. Now, if the scent and colour are not to attract insects for the purpose of crossing, of what use are they? They are certainly not there for the use of the insects without

getting something for it. Even before Darwin's time Andrew Knight, a noted botanist of his day, after experimenting on the edible Pea, which, be it noted, has neither the scent nor the colour of its relative, gave it as his opinion that self-fertilisation could not go on permanently. In conclusion, let me endorse all that "D." says about the desirability of some independent authority taking the

matter up and experimenting or testing in the way he suggests, which I think a very good one indeed.

*Leeds.*

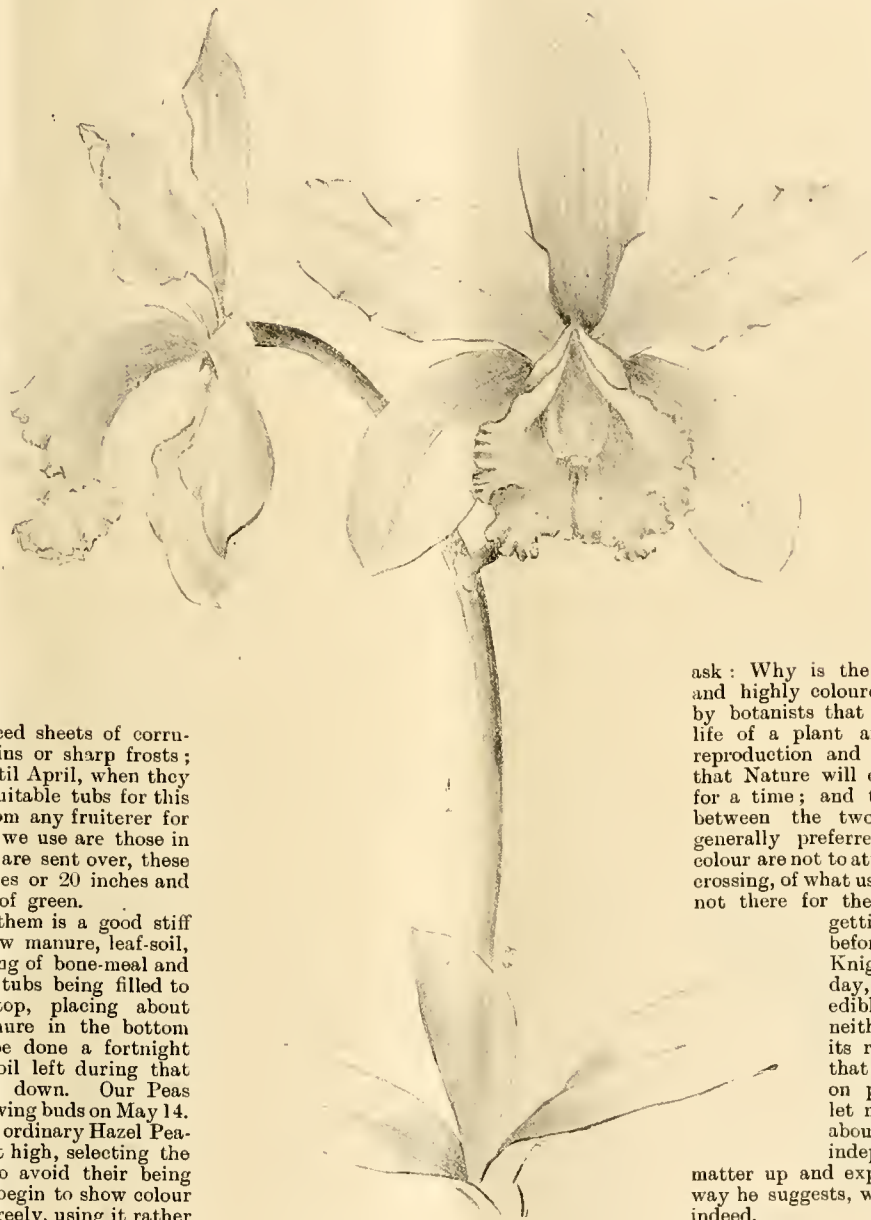

J. F. BARWISE.

CATTLEYA HARRISONÆ ALBA STANLEY'S VARIETY.  
(Reduced about one-sixth.)

cannot see why the introduction of the waved type should make such a wonderful change in the trueness or otherwise of their progeny if my suggestion is not the correct one. We have heard a lot lately of Mendel and his principles of heredity, and one might almost think that it was something newly discovered; but we may be sure that the late Henry Eckford was familiar with these principles before most of us were born, and I cannot admit that it clinches the argument,

## CATTLEYA HARRISONÆ ALBA STANLEY'S VARIETY.

THIS beautiful Cattleya was fully described on page 475 of THE GARDEN for the 26th ult. The flowers are pure white, with the exception of a pale lemon-coloured zone on the lip. It was shown by Messrs. Stanley and Co., Southgate, London, N., before the Royal Horticultural Society on the 15th ult., when it received a first-class certificate. It is the best of its class that we have seen.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**THE FLOWER GARDEN.**—Roses may be propagated by cuttings at the present time with the greatest success. I select fairly strong, well-ripened growths of the present season some 8 inches in length, and insert these in carefully-prepared sandy soil in a shady border in rows about 9 inches apart and a few inches asunder in the rows. Trim off the lower leaves of the cuttings with a sharp knife, cutting through the stem immediately below a joint, and insert them about 3 inches to 4 inches deep, pressing the soil firmly to the base of each one. Bulbs of the showy Tigridias should now be lifted. I tie them in bundles of a dozen or more bulbs in each, subsequently hanging them in a cool room or shed to dry off and ripen. The Montbretias succeed better when planted in the autumn, and for this reason should be dealt with forthwith. In heavy soils it is better to make up a bed of lighter soil. A mixture of light loam and leaf-mould, together with some well-rotted manure, makes an ideal compost. I take out soil at intervals in the border, filling in with the prepared material. The corms should be planted 3 inches deep and 3 inches apart, and if placed in fairly large colonies the effect in July and later is very pretty and attractive.

**The Greenhouse and Conservatory.**—From this time forth the cool greenhouse will benefit by a little artificial heat from the hot-water pipes. In potting up bulbs and other subjects be particularly careful always to use clean pots and crocks. Old pots should be soaked and washed quite clean, and new ones placed in a vessel of clean water to absorb moisture by these means. After a time they should be taken out and allowed to drain dry. Tender flowering and foliage plants that have been used for beds and borders outdoors should be removed to the

greenhouse or conservatory without delay. We may have a sharp frost at any time in the near future. That full advantage may be obtained from light and sun during the late autumn and winter months I am removing all permanent shadings from the glass.

**The Vegetable Garden.**—I am gathering the last of my outdoor Tomatoes, as frost may be expected at any time now. Small weeds are giving trouble in beds that were recently sown with Onions, Turnips and other things. These are being hoed over on fine days, in this way keeping the weeds under control. My best lot of Celery is just having its final bleaching operation carried out. I am continuing to plant hardy Lettuce on well-drained soil in sunny aspects. These plants will stand the winter well. Beetroot should be lifted as soon as convenient and stored in sand in a cool, dry cellar or other quarters. The roots have finished growth by this time, and if they are lifted with care and not bruised they should maintain supplies for a long time.

**The Cold Frames.**—Violets should have been planted in frames some time since; but if this has not yet been done no time should be lost in dealing with them. Old Cucumber or Melon beds in frames should be cleared and made sweet and clean, subsequently levelling down the soil preparatory to planting. Should there be the slightest suspicion of red spider, a burning of sulphur in the frames will speedily eradicate the pest. Do not plant thickly; 1 foot between the plants usually answers very well. Ventilate freely when the weather is favourable, and protect from frost when this is indicated by the atmospheric conditions at the time. Such plants as the fragrant Liliums that have ceased flowering may be stood in the cold frame forthwith.

**Hardy Fruit.**—The work of the beginner at the present period is to mark out quarters it is intended to plant with fruit trees during the next month or two. A good conception of what is required is an important factor when the actual planting has to be done. My Raspberries are now receiving attention. Old canes are being cut out and the new ones reduced to about four of the strongest. It is a mistake to retain more than four canes to each stool. Subsequent to this operation give the quarters a heavy mulching with some good lasting manure. Suckers from Plum trees are frequently left undisturbed too long. I make a rule to remove them in good time before they attain much size. Beginners are often puzzled to know why vigorous-growing fruit trees bear no fruit. The real reason is they need to be root-pruned, and this should be done forthwith. When gathering fruit see that it is perfectly dry and the baskets in which it is placed are lined with some soft material. No definite time can be given for gathering and storing fruit, this being entirely dependent on seasonable influences. D. B. C.

## HOW TO RETAIN OR SECURE BUDS OF CHRYSANTHEMUMS.

This is a matter that has given much concern to novices in the cultivation of the Chrysanthemum. Loose terms are often used when speaking of retaining or securing buds of the "Autumn Queen," and many growers have done what is quite wrong in consequence. The individual who coined the oft-repeated phrase, "taking the bud," has much to answer for, the misleading character of the term having induced beginners to do just the opposite to what was intended. There are many who have literally

2.—A "CROWN" BUD PROGRESSING SATISFACTORILY FIVE OR SIX WEEKS AFTER BEING RETAINED.

"taken" the buds from their plants by removing every one, in consequence of which no further buds have evolved and no flowers have developed on them. To "take" the buds is really to retain them, i.e., they are left on the plants. This is simple enough, but to appreciate the true significance of the term it is necessary to call attention to the different kinds of buds that each Chrysanthemum develops in the course of a season's growth. The natural functions of a Chrysanthemum plant in regard to bud production are several and interesting, and may be described as follows: Each plant produces what is more generally known as a "break" bud. The "break" bud is usually developed in late spring or early summer, and has the effect of causing the plant to break into or evolve a number of fresh shoots, in this way ensuring a more bushy plant. To the uninitiated this "break" bud would hardly be noticed.

In due course, especially in the case of plants for exhibition purposes, another bud is developed on each plant. This is known as a first "crown" bud. It is the "crown" buds that invariably worry the beginner, as he is usually at a loss to understand what is meant by the term and the character of the buds as they are evolved. As a matter of fact, the character of a "crown" bud is very similar to the "break" bud already described. By its development a "crown" bud causes the plant to break into fresh young, non-flowering growths immediately around it, and unless the "crown" bud be secured or retained (this latter is the better term to use), the bud soon becomes worthless for producing large and handsome blooms. Fig. 1 serves the purpose of explaining the character and development of the "crown" bud. It is not easy to photograph or illustrate in its early history, as this kind of bud is usually hidden among the young shoots that are evolved at the same time. In the illustration alluded to the first "crown" bud can be seen at the apex of the growth, with a narrow attenuated leaf or

1.—THE DEVELOPMENT OF A FIRST "CROWN" BUD. NOTE THE BUD ENFOLDED IN A LEAF AND THE YOUNG SHOOTS IN THE AXILS OF THE LEAVES.

bract enfolding it. Fresh young shoots will be observed around it, each one developed in the axil of a leaf. What the beginner must do in such circumstances is determined by what his requirements two or three months hence may be. As a rule first "crown" buds are developed in May and June, and sometimes earlier. First "crown" buds, as a rule, produce the largest flowers, although the latter are sometime devoid of the best and richest colours. Frequently these early buds, if retained, would produce their flowers too early for the grower's purposes, so that there are two or three considerations to be observed when determining whether or not to retain the first "crown" buds when they are evolved. This question of suitability of time of flowering is a matter that each grower has to determine for himself, so that we cannot advise him. Assuming he wishes to retain the first "crown" bud, the grower must proceed to remove the small shoots that surround it. In their earliest stages the fresh young growths are very brittle and break out from the axils of the leaves with the greatest ease. When the last growth is removed the bud is then retained, and stands at the apex of the older shoot quite alone. In consequence of this treatment the whole of the sap of this branch is diverted to the bud, and this latter begins to swell and expand, thus giving promise of producing a large flower in the flowering season. In Fig. 2 a first "crown" bud, which we here remark differs very considerably in the numerous varieties in cultivation, is shown progressing very satisfactorily; in fact, within a week or two it will be necessary to place such plants under glass as a protection against frost.

The beginner may now ask, What is a second "crown" bud? Second "crown" buds are almost identical with first "crown" buds, the only difference being their naturally later period

3.—A SPRAY OR CLUSTER OF "TERMINAL" BUDS.

six weeks—evolve their second "crown" buds, and these should be treated in exactly the same fashion as was recommended for first "crown" buds when they were retained.

Now, for decorative uses many growers prefer what are known to the initiated as "terminal" buds. These "terminal" buds are always evolved, sooner or later, on plants that have been grown on unhindered. They mark the termination of the plant's growth, and hence are described as "terminal" buds. "Terminal" buds are developed in clusters, and if all the buds are allowed to develop very beautiful sprays of blossoms are ultimately evolved. It is inconvenient in some instances to permit this, however. Sometimes the clusters of "terminal" buds are too densely crowded, so that it is impossible for the flowers to do themselves justice. Fig. 3 is a fair illustration of a spray or cluster of "terminal" buds. This is less crowded than many, but, were all these buds allowed to develop the beautiful flowers might unduly crowd one another. Readers should note that there are no young shoots surrounding these buds, as were observed in Fig. 1. More interesting and prettier sprays of blossoms may be brought into effect by reducing the number of "terminal" buds in each cluster. Fig. 4 shows how this may be done. The number of buds has been reduced to three, and these are left as nearly equi-distant as possible. By these means each individual bloom will have room to develop without overlapping its neighbour, and a charming spray of blossoms be developed in consequence.

There are readers, doubtless, who prefer to have one large bloom on each shoot that produces the "terminal" buds. Should this be so, all the smaller buds must be removed and the largest and best-shaped one in the cluster retained for this purpose. Fig. 5 shows a "terminal" bud treated in this fashion.

#### PROTECTING DAHLIAS.

It is a pity that these plants do not withstand frost, as herbaceous plants are at this season becoming weaker in the production of flowers; indeed, the majority of them have quite ceased to blossom, and border Chrysanthemums with Michaelmas Daisies are the only kinds that can compete with the Dahlia, but, unlike the latter, they are not spoiled by early frosts. The single-

flowered, Pompon and Cactus Dahlias are very useful for cutting for the decoration of the dwelling-house as well as for other purposes, and when the plants are destroyed a serious shortage of flowers occurs in many gardens, so that extra precautions should be taken to prolong the supply. Early frosts are usually not so searching as those that prevail later, so that a top covering will do much towards the preservation of the blooms. Where the plants are grown close together in blocks or in rows in the borders, it is a very easy matter to protect them by driving in a few posts strong enough to bear some cross-laths and mats or scrim. The latter need only be put on at night, and can be removed every morning about nine o'clock. Where the plants are grown singly a few of the best should be selected for protection. Three stakes and a single mat will be sufficient for each plant. Earwigs are very troublesome and soon mar the beauty of the flowers. They may be trapped in flower-pots partially filled with moss or hay, between two pieces of dry boards and in Broad Bean stalks. If Vaporite or Alphonol are used according to the directions supplied with them, earwigs will be beaten.

AVON.

#### A CATCH CABBAGE CROP.

THE amateur's garden is often without green vegetables early in the spring, and the deficiency is felt for a considerable period after; much of the garden may, in consequence, be unproductive. This to a great extent may be avoided by having a good supply of plants for later cropping. Young, small, sweet Cabbages are at least nine months out of the twelve profitable and palatable. By the term young, small, sweet Cabbages I mean those free from coarseness and having compact hearts. These are the sorts I advise the amateur to sow during September and early October, as if sown thinly on a well-drained exposed border the plants will winter well and give a succession of planting material from February to May. Thin sowing is, however, a most essential detail, because plants which are crowded in the seed-bed winter badly and are weak and unprofitable. Veitch's Earliest, Sutton's Favourite and Carter's Early Spring are all good varieties for this sowing.

G. W. B.

4.—HOW TO ENSURE A GRACEFUL SPRAY OF BLOSSOMS. NOTE THAT SUPERFLUOUS BUDS HAVE BEEN REMOVED.

of development and the beauty of their form as the flowers are developed. How are second "crown" buds developed? may be asked. When second "crown" buds are to be retained it is necessary to remove the first "crown" bud as soon as it is evolved and grow on one or more of the fresh young shoots that surround it. These will in due course—generally from a month to

5.—THE LARGEST AND BEST SHAPED BUD OF THE "TERMINAL" CLUSTER RETAINED TO FORM A LARGE FLOWER.

## THE TOWN GARDEN.

**BULBS IN GRASS.**—It is unfortunate that comparatively few town gardens afford much scope for the cultivation of bulbs in grass such as one sees in our public parks and gardens, for there is no system that is equal to it in charm. Wherever it is possible to have even a few Crocuses, that will be better than nothing at all, but it is only when accommodation can be provided for Daffodils, Tulips, Snowdrops, Dog's-tooth Violets and others that the full delight of the culture is ensured.

It is imperative that the utmost care shall be taken in the manner of planting, for if the bulbs are put in formal rows the effect will be the reverse of natural and attractive. The easiest method of placing the bulbs for planting is to take up a stand in some convenient spot and thence throw handfuls of bulbs in all directions, and wherever these stop after their travels let them be planted. There can then be no suspicion of systematic setting, and the picture when the plants are in bloom will be far more delightful as a consequence. If the bulbs all fall singly, planting should be done with the aid of one of Barr's excellent planters, as these readily cut through the turf, lift out this with the soil beneath and permit the bulb to be placed at any desired depth; as soon as it is in position the soil and turf are replaced and made as firm as the surrounding grass. It is, however, highly probable that some of the bulbs will run together in clusters, in which case a piece of turf of sufficient area should be lifted, the soil beneath taken out, the subsoil loosened and enriched with a little manure if necessary, some of the good top soil put back, the bulbs set in position and then the soil and turf replaced again, taking care to see that it is made quite firm.

One of the principal disadvantages of the cultivation of bulbs in grass is that one cannot cut the grass until the foliage of the bulbs is dead, for the simple reason that if this is done the bulbs will steadily get weaker and weaker and in the end fail to develop flowers at all. One would not, therefore, put bulbs in the more conspicuous portions of the lawn, but choose corners where the little inevitable untidiness would not prove too much of an eyesore to the ultra-fastidious visitor.

**BULBS IN WINDOW-BOXES.**—To finish a house the amateur gardener must have window-boxes, and, having them, must furnish them so that they will be attractive at practically all seasons of the year. It is, of course, obvious that he cannot have them a blaze of floral beauty during the winter months, but he can then have one or two small conifers, which will relieve the flatness and monotony, and in the meantime the bulbs that have been put in for the spring display will be coming along splendidly. An excellent system on which to work, if only one box is at command, is to fill it with really good soil in the spring for the summer plants, and when these are over to remove them and place the conifers and the bulbs in the same soil, or merely add a little fresh in which to place the roots. For the majority of boxes I think that nothing equals a light blue Hyacinth, such, for example, as Grand Maitre, with Sir Watkin Narcissi; but it is easy for anyone to choose selections of one, two or more kinds or varieties to his own taste. The bulbs should be set as low down as the depth of the box will permit, and it is advantageous to surface over with a thin layer of Cocoanut fibre refuse. It is much better, where it can be made convenient, to have two sets of boxes for each window, as one can then be brought on in the garden while the other is in beauty, and fresh soil suitable for the plants grown can be put in when required. The winter course is then to fill the summer box with handsome little shrubs, place the bulbs in the reserve box, and put it into position when the plants are well advanced for flowering.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**A** LITTLE more fire-heat must now be supplied when the weather is dull and the nights cold, or plants may suffer from damping. This can be avoided by judicious watering, airing and firing—three great points in successful plant-growing in winter. All plants of a tender character should now be brought under cover.

*Cyclamen* should now be placed in pits that are heated and carefully watered. Allow plenty of room between the pots so that there is a free circulation of air. Primulas may be placed in dryer quarters; these do very well on shelves in greenhouses or in low pits, and fancy Pelargoniums should be stood in a similar position. Zonals which are to give flowers all the winter should be brought inside and placed in a light structure near the glass and where the heat can be when necessary kept up to 55°.

*Chrysanthemums*.—Continue to house these, but be careful not to overcrowd or mildew will put in an appearance, and watering should be done early in the day to avoid water standing about at night.

#### FRUIT HOUSES.

*Melons*.—Ripen off these as soon as possible, as they will not be much in request now the weather is cooler.

*Peaches and Nectarines*.—Keep these trees well supplied with water and syringe daily till the foliage begins to drop. In the early house, where the leaves are ripe they may be brushed off and the house used to store more plants. Heat, however, must not be used.

#### THE HARDY FRUIT GARDEN.

Many varieties of Apples and Pears will now be ripe and should be most carefully gathered. The choicer varieties grown on walls and bushes should be gone over several times, as in most cases they will not all be ready at the same time. Pears require very careful handling, or they become bruised quickly. They should be lifted gently in a horizontal position, and, if ripe, they will part readily from the spur, when they should be placed on some soft wood wool and conveyed to the fruit-room; the above remarks apply with equal force to Apples. Later varieties ought to be left on the trees for some time yet. Early-fruited varieties may now be lifted or root-pruned, as may be necessary.

#### KITCHEN GARDEN.

*Cucumbers*.—These should be top-dressed little and often and be kept in a growing medium of about 70°. Do not let the plants bear too heavily at the start, as it is useless to grow more fruits than are wanted, and the plants will bear longer if gently cropped. The second batch of plants should now be ready to fill the places of the old ones, as it is from these plants we expect the winter supply.

*Potatoes*, if not all lifted, should be taken up at once and stored as recommended in a former calendar. If any disease is prevalent, burn all the affected haulm.

*Cauliflower*s sown last month must now be pricked out, some being put into cool frames and others on a warm border under a wall. Cauliflowers are much hardier than many people suppose, and if brought up hardy are much more useful and produce better results.

*Mushroom Beds*.—Collect material for making up these beds. Good fresh droppings from corn-fed horses are the best for the purpose.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*Cœlogyne cristata*.—This is one of the most useful and easily-managed Orchids we have, and with very little experience any lover of Orchids may with ordinary care succeed with it. As this beautiful species naturally flowers early in the year, it is advisable to have the means of maintaining a genial temperature of 55° to 60° at that period, in order to enable the blossoms to expand freely; but during the greater part of the year it thrives under perfectly cool treatment, and an ordinary greenhouse suits it well.

*Cyclamen*.—Full exposure at night, with the accompanying dew, is now making these grow apace, and every means should be taken to still further encourage their growth. A light top-dressing should now be given. Clay's Fertilizer and Thompson's Manure applied in equal proportions and mixed with sifted soil suits them well. Very little shading, if any, will be required from this time onwards, but abundance of air will at all times be needed.

#### HARDY FRUIT.

*Planting Raspberries*.—It is far better to plant in October, if this is possible, than to leave such important work until spring, for the plants will become rooted before the winter and start away vigorously in the spring. Rows of Raspberry canes should not be less than 6 feet apart, and the plants in the rows require a distance of 18 inches between them. The most satisfactory method of training the plants is to have two wires stretched between poles, the lower one about 18 inches or 2 feet and the upper one 3 feet or 4 feet away from the ground.

#### FRUIT UNDER GLASS.

*Late Vines*.—The most important work with late Vines will be preserving the fruit. To get bunches of the best quality all through the winter it will be necessary to give some warmth to raise the night temperature and dry up excessive moisture. A very little fire-heat will arrest decay. It often happens that vineries are used to shelter Chrysanthemums and other plants, and with continued supplies of moisture to the latter the Grapes are injured. In such cases I advise cutting the crop and bottling it.

#### KITCHEN GARDEN.

*Spinach for Late Spring*.—Where Spinach sown in the ordinary way—that is, in July or August—has proved a failure, I advise sowing now. Though there is no produce during the winter, there will be a grand supply in March and later, when vegetables are scarce. Spinach sown late does not get killed by frost. Sow thinly and do not thin till early spring, when the plants may be cut out for use as soon as large enough to handle.

*Endive and Lettuce*.—Plant out the last batch of Endive, also some more Lettuce. A good batch of Paris Market Lettuce planted out now in a cool house or roomy pit will afford some delicious and useful hearts about Christmas.

#### FLOWER GARDEN.

*Violets*.—These are often, through press of work, left out in the border later in the autumn than they should be, and consequently do not get established in their new quarters early enough. This makes all the difference to the flowers during the winter. As a rule, particularly in Midland and Northern districts, the end of September, or, at the latest, the first week in October, is late enough for placing the plants in frames.

*Outdoor Chrysanthemums*.—See that the plants are properly supported with neat stakes and ties, but avoid bundling them up too closely or tightly.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## THE LATE MR. GEORGE NICHOLSON.

**A**S briefly noted in *THE GARDEN* last week, the death of Mr. George Nicholson, ex-curator of the Royal Gardens, Kew, occurred on Sunday, the 20th ult. By his death horticulture and botany have lost an ardent disciple, while a large number of people in many walks of life have lost a devoted friend. In one position or another Mr. Nicholson was connected with Kew for a period of twenty-eight years, during which time he endeared himself to all with whom he came in contact. He was the son of a Yorkshire nurseryman, and commenced his horticultural career in his father's nursery at Ripon, subsequently moving to Messrs. Fisher and Holmes' at Sheffield, Messrs. Low and Co.'s, Clapton, and La Muette, Paris. He entered Kew in 1873, at the age of twenty-six, as clerk to the curator, the late Mr. John Smith, and succeeded to the curatorship in 1886, a position he was forced to relinquish in July, 1901, on account of serious heart trouble.

As a boy Mr. Nicholson is recorded as being "a brilliant student," and this trait in his character was more fully developed in after life. As a horticulturist and botanist he combined the two phases as few people can, and was excellent in both; nor were these the only subjects of which he was master, for he had an exceptionally wide knowledge on a great variety of subjects.

He had the reputation of being one of the leading British botanists in the country, and at one time he possessed a very complete collection of dried British plants. His knowledge of cultivated plants was also phenomenal. His special *forte* was hardy plants, and it was difficult to take him a specimen that he could not name at once or suggest its affinity, while in many instances he could quote references off-hand. The result of his great knowledge was presented to horticulturists at large in the encyclopedia of plants published in 1888, which has acquired world-wide fame under the title of "Nicholson's Dictionary of Gardening." This work he edited, and it is without doubt one of the most valuable books the student of horticulture can possess. In addition to this, he prepared numerous articles and monographs on trees and shrubs, two of the most important being monographs of the genera *Acer* and *Quercus*.

In 1893 Mr. Nicholson served as a judge for the horticultural section of the Chicago Exposition, and he spent several months visiting the leading gardens in the United States. Notes of his journey may be found in the *Kew Bulletin* for February, 1894. In recognition of his scientific work Mr. Nicholson was made an Associate of the Linnean Society in 1886, and he became a Fellow a few years later. In 1894 he was awarded a Veitchian medal, and he was one of the first to be awarded the Victoria Medal of Honour by the Royal Horticultural Society. In 1895 Vol. XLVIII. of *THE GARDEN* was dedicated to him, while in 1901 he was the distinguished Kewite selected to occupy the post of honour in the Journal of the Kew Guild. Although such an ardent worker Mr. Nicholson found time for recreation, and until the breakdown of his health he was an expert swimmer and mountaineer, while he was also a good tennis player.

After his retirement in 1901 he intended to revise "London's Encyclopedia of Trees and Shrubs" or prepare another work on similar lines, but was forced to abandon the idea through the extension of his malady. During the convalescent periods of his seven years' retirement he took in hand the compilation of a list of the flora and fauna of the Royal Gardens, Kew, his attention during the last two or three years being given almost entirely to butterflies and moths, and he was a familiar figure sauntering about with net and poison-bottle. For the last six months he had been a confirmed invalid,

and had been rarely free from pain. Until a fortnight before his death, however, he was able to be taken into the gardens in a bath-chair, where he keenly appreciated the sight of the trees and flowers he had known and loved so long.

A funeral service was held on Wednesday, the 23rd ult., at Christ Church, Richmond, after which the body was removed to the Woking Crematorium. The service was attended by the Director and most of his old colleagues at Kew, while numerous friends were present. As a tribute to his memory and work the Director and staff at Kew sent a wreath composed of coloured foliage of Oak and Maple, intermixed with sprays of Michaelmas Daisies.

The sympathy of all friends is with Mr. Nicholson's son and with his brother and sisters,

A RECENT PORTRAIT OF THE LATE MR. GEORGE NICHOLSON.

and especially with his sister who had been his devoted companion since the sad death of his wife, which occurred within a few years of their marriage.

## THE EDITOR'S TABLE.

### SWEET PEAS FROM WREXHAM.

Mr. G. Aitkens, Erddig Park, Wrexham, sent on the 14th ult. a very fine lot of Sweet Peas, many of them possessing stout stems 15 inches to 18 inches long. The blooms, too, were quite as large as those seen in July and the fragrance was most welcome. He writes: "I am sending for your table a few flowers of Sweet Peas gathered on September 14 off plants that were sown in January, and maybe you will gather from them how well these great favourites compensate us for the trouble bestowed upon them. I believe, should we get anything like good weather, with a few days of sunshine, there would be as fine flowers as any we have cut this year."

### AUTUMN FLOWERS FROM DUNS.

Dr. McWatt of Morelands, Duns, N.B., sends us a splendid collection of autumn flowers, which we specially welcome now that the gardens are beginning to look shabby. Among them we notice some very good hybrid Delphiniums,

which Dr. McWatt has raised from seed sown in February of this year. These include dark blue and white forms. *Perovskia atriplicifolia* is a Himalayan plant that we do not often see, and of which Dr. McWatt sends a fine spike, the blue flowers being particularly pleasing, and reminding one very much of a *Spiraea*. Among the Heaths sent we notice the white *St. Dabene's* (*Daboecia polifolia alba*) and the red, white and pink flowering forms of *Calluna vulgaris*, and also the golden-foliaged one, all of which are very handsome at this season. The other flowers included *Erigerons* of several species, such as *speciosus*, *glaucus* and *mucronatus*, and also the pretty little *Lobelia angulata*, which, with its small white tinged blue flowers, is a fine plant for carpet beds or for edges.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make *THE GARDEN* helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of *THE GARDEN*, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Information about bedding

**Fuchsias** (*Miss D.*).—It is now too late to strike cuttings of Fuchsias taken from the open ground, but with a little care the old plants may be kept safely through the winter, and these will flower more freely out of doors next season than the young ones would. The best time to lift them is towards the end of September. Any very long shoots may be shortened back for the convenience of handling, but they should not be pruned more than is necessary for this purpose. The lifting must be carefully done, and the plants be at once potted, using pots only sufficiently large to take the roots comfortably. After potting, the plants should be stood out of doors and given a thorough watering through a rosed water-pot, sufficient, in fact, to settle the soil in its place. Then, after being allowed to drain, they may be taken into the conservatory, where they should pass the winter safely. At that season an occasional watering, say, once a month, will be sufficient for them. As your conservatory is unheated, the better plan during severe weather will be to stand your Fuchsias on the floor, as far away from the glass as possible, and cover them with sheets of paper. This will keep out several degrees of frost. For the convenience of covering they may be stood closely together. On no account water them during frosty weather. This treatment is preferable to keeping them quite dry in a dark place. In spring, before growth recommences, the shoots may be shortened back sufficiently for the plants to form shapely specimens, but they should not be hard pruned.

#### Violet runners, Tulips and Wallflowers

(*E. M. L. B.*).—The runners you desire to plant in September would be no use whatever for flowering during the ensuing winter, but would make extra large plants for planting in open beds next April and for flowering during the winter following. It would be far better, if winter bloom is the aim, to plant the fine examples of Princess of Wales in the frame in the month named, and divest them at that time of all superfluous runners. Treat the latter as cuttings in a cold frame, and plant them in well-prepared soil in April, 1909. These unflowered runners may be put in boxes or pricked out under a hand-light. The best white-flowered plant we know for the Tulip-bed is the double white *Arabis*, which, flowering a little later than the single form, is

usually just in flower with September-planted Tulips, and, if the latter be of a scarlet or red tone, the effect will be excellent. The Arabis should be pricked out freely over the surface as soon as the Tulips are planted. The Alyssum, we fear, would not flower early enough even if autumn-sown. Provided the Wallflower seedlings have room for development, they will be all right till required for their permanent positions. If the plants are becoming drawn, remove the points of the shoots. Dwarfness, however, is more dependent upon the variety than any subsequent treatment, while thin sowing of the seeds or early transplanting of the seedlings will materially assist in keeping them true to their type in this respect.

## ROSE GARDEN.

**Tea Roses for autumn planting** (*Robert L.*)—You cannot do better than ask for the plants on the seedling or cutting Briar. Own-root plants would be best, but they are not easily obtained, and when they are they would be pot-grown and only fit to plant out in the late spring. As a rule, Tea Roses on the Briar give every satisfaction, especially if the soil is prepared for them. There should be at least 2 feet 6 inches depth of good soil, in which some well-decayed manure and half-inch bones are incorporated. If the soil is light, add cow manure liberally; if heavy, add some gritty material. The beds in both cases should be raised a few inches higher than the ground level. A few varieties of Tea Roses that would grow well in a northern garden are Mme. Lambard, Marie van Houtte, Anna Olivier, Marie d'Orleans, Souvenir de Wm. Robinson, Hon. Edith Gifford, Mme. Hoste, Souvenir de S. A. Prince, Francisca Kruger, Dr. Grill, G. Nabonnand, Lady Roberts, Mme. Antoine Mari, Mme. Jean Dupuy, Maman Cochet, Peace, Souvenir d'un Ami and White Maman Cochet. A few good crimson Hybrid Perpetuals are Hugh Dickson, Commandant Felix Faure, Charles Lefebvre, Ulrich Brunner, Ella Gordon, Dr. Andry, Mme. Victor Verdier, Eugene Firsi, Duke of Connaught and Earl of Pembroke.

**Roses budded in June** (*Amateur*).—As the budding was done so early it is quite natural for the buds to start into growth in such a season as we have had. We should allow them to grow, merely pinching off the flower-buds, but do not cut away any Briar growth. Such precocious buds are rarely any good the first season, and we always cut them back to one eye in February, when we remove the Briar growths. Seedling Briars are equally as easy to bud as Briar cuttings, the bud being inserted where the root-stem commences just beneath the branches. So long as the germ of the bud is intact the inside need not be perfectly level. If you cut the wood rather thinly it will come out easily without leaving any indentation near the bud.

**Roses for exhibition** (*E. W. C.*)—On the whole your list is a good one, but we think it would have been best if you had had fewer sorts and more plants of the very best. One hundred varieties constitute a very ambitious collection, unless you mean to go in for showing largely. Among the Hybrid Perpetuals, A. K. Williams, Horace Vernet and Xavier Olibo would need to be budded annually in order to obtain their blooms of exhibition standard; indeed, you would do well to plant some Briar cuttings and bud a few of several sorts, in order to prolong the season of flowering. Instead of Mlle. Eugenie Verdier we recommend Pride of Waltham, and instead of Jean Liabaud plant Victor Hugo, and Sultan of Zanzibar should be replaced by Commandant Felix Faure. You have got the Hybrid Teas and Teas very much mixed, and Boule de Neige belongs to neither class; this is a Hybrid Nuisette. Instead of Betty, Viscountess Folkestone, Boule de Neige, Francisca Kruger, Homere, President and Etoile de Lyon we recommend Melanie Soupert, Rene Wilmart Urban, Tennyson, Medea, Sylph, Celia and A. H. Gray.

**Rose Baby Dorothy as a pot plant** (*R. E. D.*)—This pretty little pot plant should be reported as soon as the blooms are over. As a rule, the growers produce them in very small pots compared to the size of the plants, and they would certainly need repotting now, so that the pots are well filled with new roots before the winter. As the plants are now in 5-inch and 6-inch pots, we advise repotting them in 7-inch and 8-inch pots. The best compost would be two parts fibrous loam and one part well-rotted manure—some that has been laid by for twelve months. A few quarter-inch bones (about a 6-inch potful to a barrowload of compost) would add much to the quality of the bloom, although in the case of Baby Dorothy it might be preferable to keep them as small as possible. After repotting stand the plants in a bed of ashes in full sun, watering them when required, which will not be very often. A spraying over in the evening would be beneficial. If you have a heated greenhouse, you could bring the plants in about November or December and prune them, and in about three months' time they would be in flower in a moderate

temperature of about 50° to 55°; but if you have only a cold greenhouse, do not start them into growth before February. Pot Roses should be started very steadily at first, affording them a temperature of about 45° by night and an increase of about 5° by day; but when growth is active, then the temperature may be considerably increased. Some other interesting Roses suitable for pot culture of the same class as Baby Dorothy are Mrs. W. H. Cutbush, Mme. M. Levavasseur and Rosel Dach.

## FRUIT GARDEN.

**Melon leaf spot** (*H. C. Wood*).—In the absence of specimens it is impossible to say definitely to what to attribute the spotting of the leaves, but from the symptoms described it seems probable that it is due to the fungus *Cercospora melonis*. This fungus has done a tremendous amount of damage, both to Melons and Cucumbers, in many parts of the country during recent years, and it appears to attack plants which have soft foliage much more readily than those that have been grown with more air and a slightly drier atmosphere. When once started the disease spreads rapidly and will cause the death of plants badly attacked in a very short time. The admission of as much air as is practicable during the day, and occasionally damping the paths with a solution of Calvert's No. 5 carbolic acid, one pint to five quarts of water, appear to be the best remedies, but great care must be exercised in the use of the carbolic acid, since if any fall on the foliage it will be killed, and too great a quantity in the air will do irreparable harm.

**Seedling Oranges** (*Orange Tree*).—As your seedling Orange plants grow so slowly, it would seem as if the soil they are in is rather poor. Being kept in a small room where probably there is none too much light and air does not induce strong growth. The plants need to be in a greenhouse or frame or under a hand light. Not that they will not do in a warm position out of doors for a time, but being under glass growth is assisted. Keep the plants quite clean from dust and insects. Very likely the adding to the soil in each pot, and just stirring it in, of half a teaspoonful of guano, to wash into the roots with the usual waterings, would materially help the plants. Do not overwater. Several years must elapse before they will produce fruit.

**Growing Melons in a pit** (*Salop*).—If you provide such bottom-heating power in your proposed Melon pit as would be furnished by two 4-inch hot-water pipes, how can you utilise that heat if you have filled the pit with manure? If that manure gave you some warmth at the first, it would be very temporary, and when once cold and covering up the hot-water pipes, how could the Melon roots benefit by the pipe warmth, which would be lost in the manure? Would it not be far wiser to have your bottom-heat pipes fixed 3 feet apart on a level in the pit, yet low enough down to enable stone wood-slabs to be laid across the pit 10 inches to 12 inches above the pipes? On those use pieces of turf turned upside down, and on the latter a few inches of good loam, but 6 inches deep in the centre. Too much soil, and especially rich soil, is bad for Melons, as it leads to too much leaf and canker. With your two 3-inch pipes for top-heat, the flow in front and the return at the back, you would have ample warmth to ripen Melons well.

## MISCELLANEOUS

**Situation in a garden** (*C. E.*)—Unless you have been a few years in a garden and thus obtained some practical knowledge of gardening, we fear, being at the age of eighteen, that your chances of being taken on in a garden or nursery as an improver are rather poor. If, on the other hand, you have had such practical experience and desire to get into Messrs. Veitch and Sons' nursery, your best way would be to write a letter of application to that firm for leave to enter their nursery as an improver, and to get some gardener who deals with the firm for seeds or plants to back your application. We know nothing as to the wages paid by the firm or the chances of getting employed by them. No doubt they have scores of similar applications.

**Various questions** (*G. Grahame, Italy*).—We do not know any *Sedum* called London Pride, and imagine you are thinking of *Saxifraga umbrosa*, the common name of which is London Pride. The *Salvias* are frequently referred to, and young plants may be obtained from Messrs. Cannell, Swanley, Kent, or Messrs. James Veitch and Sons, Limited, Chelsea. The *Wistaria* would be quite suitable for the pergola pole, but it does not ascend so quickly as some other species. The *Lithospermum* will succeed quite well if planted in peat and loam in equal parts and not given too dry a position. For the other portion of the Rose bed we think the beautiful and fragrant white-flowered Kaiserin Augusta Victoria would do. If, however, you desire to have a variety to balance the vigour of Caroline Testout, you will find the cherry red Ulrich Brunner a good bedder. The first-named is very charming, of good size and considerable freedom.

Mrs. W. J. Grant is a very good Rose, and the new scarlet Richmond is also very beautiful.

**Names of fruit.**—*D. Faulkner*—1, Worcester Pearmain; 2, Duchess Favourite.—*J. M. G., France*.—1, Colonel Vaughan; 2, Cox's Orange Pippin.—*J. D.*—Warner's King.—*W. Martineau*.—1, Peasegood's Nonesuch; 2, Warner's King; 3, Irish Peach.—*J. N. Bell*.—1, Wiltshire Defiance; 2, Old Hawthornden; 3, Sandringham; 4, Brandy Apple; 5, Yellow Ingestre; 6, Cellini. The Plum was smashed to pulp.—*J. T. L.*—1, Crimson Queen; 2, Cox's Pomonca; 3, Duchess of Oldenburg; 4, Worcester Pearmain; 5, Maak's Codlin; 6, Queen.—*C. Tibbles*.—1, Cox's Orange Pippin; 3, Northern Greening; 4, Queen Caroline; 5, Ribston Pippin.

**Names of plants.**—*A. B. C.*—The name of the flower enclosed is *Lobelia Firefly*. It should be quite hardy with you, so that you can leave the plants in the beds till the spring; then, if necessary, lift, divide and replant them. If your garden is much exposed a mulching of partially-decayed leaves will help to make them safe in the winter.—*E. A. P.*—1, Clematis, too shrivelled to recognise; 2, *Licaria vulgaris*; 3, *Malva moschata*; 4, *Achillea Ptarmica* (The Pearl); 5, *A. P. flore-pleno*; 6, *Eoconia cordata*; the *Spiraea* is *S. japonica* Anthony Waterer. All these were much bruised and could only be named with great difficulty.—*H. Rolson Hindmarsh*.—The shrub is the common Barberry (*Berberis vulgaris*); it is a native of this country.—*F. H. O. Pease*.—*Cypripedium barbatum*.—*Amateur*.—*Solidago lanceolata*.—*K. R. J.*—We believe the Rose to be one of the old *Noisettes* named grandiflora, but the blooms were much faded when they reached us and we are unable to name it with certainty.—*N. G. I.*—Roses: 1, Mme. Jules Gravenaux; 2, William Allen Richardson; 3, *Duchesse d'Anerstadt*; 4, *Bouquet d'Or*.—*N. Prunose*.—1, *Selaginella uncinata*; 2, *Blechnum* species; 3, *Chlorophytum elatum variegatum*; 4, *Hemantthus tigrinus*; 5, *Passiflora caerulea*.—*E. R.*—*Verbena Auletiata*.—*Chequer*.—1, *Pyrus torminalis* (Wild Service Tree); 2, *Crataegus punctata*.—*A. E. C. A.*—1, *Polygonum affine*; 2, *Ceratostigma plumbaginoides*; 3, *Coronilla Emerns*; 4, *Leycesteria formosa*.

## SOCIETIES.

### NATIONAL CHRYSANTHEMUM SOCIETY.

The first executive committee meeting of this society for the present season was held on Monday evening, the 14th ult., at Carr's Restaurant, Strand, when Mr. T. Bevan presided. Upon the application of the Royal Agricultural and Horticultural Society of Guernsey to be admitted in affiliation, the same was granted. It was reported that in answer to an enquiry of the authorities of the Franco-British Exhibition, no Chrysanthemum show was intended to be held there in connexion with the series of temporary flower shows. The committee appointed to consider the question of holding the National Chrysanthemum Society's shows in the Horticultural Hall, Vincent Square, reported that they could not advise any change for the present. The secretary reported also that the show of market varieties would not be continued this season, and a communication on the subject of the balance in hand was decided to be addressed to the chairman of the market show committee. The annual dinner will be held, if convenient to the president, on November 26 at the Holborn Restaurant, and a small committee was nominated to carry out details. For the purpose of judging the various miscellaneous exhibits at the October, November and December shows, the following judges were appointed, viz.: Messrs. D. B. Crane, C. H. Curtis, E. F. Hawes and D. Ingamells. The election of the judges for the October show then followed, with the result that Messrs. W. Howe, W. Wells, Cull, Eric Such, Emberson and Gower were elected. The meeting closed with the election of several new members.

### CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.

RECENTLY, at their rooms, Sunflower Temperance Hotel, a large attendance of members put in an appearance for the usual fortnightly meeting. The lecturer for the evening was Mr. M. E. Mills, Coombe House Gardens, who has on several occasions delivered some very useful and interesting discourses relative to plant culture. His subject was "Flowering Annuals," and to illustrate some of the varieties under notice he had the aid of lantern slides. In undertaking such a huge subject as this, he said, unfortunately, there appeared no real classification of these flowers, for oftentimes what one sees described as annuals are biennials or perennials, and, misleading as this description is, it makes it difficult to compile a list. The cultivation required is rich soil, deeply dug and pulverised by winter frosts. Soil of a light nature is best. For the hardy kinds seed may be sown in the open from March to the end of May, and what he particularly emphasised was the advisability of sowing thinly and gradually thinning out the seedlings. They are mostly branching, and if left too thickly together weedy plants will be the result. Seeds should be only slightly covered, especially the small ones. Being such a large field, it was impossible to go into the special culture of each one. However, he very kindly promised to continue his remarks on some future occasion. Owing to lack of time, the discussion following was rather limited, but a few remarks from several present added interest to the evening. A very hearty vote of thanks to Mr. Mills concluded an instructive evening.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## ROSE ENEMIES.

**R**ED RUST, or orange fungus, reminds us of the many enemies of the Rose, and in this number, which is largely devoted to the flower, a few notes on the subject will be helpful. We have received from correspondents in various parts of the country leaves badly infested with the winter form of the red rust, and it is from the black spores that the rust appears next season. Foliage thus affected should be collected and burned; and we have noticed that plants on hot and very dry soils have suffered more severely than those under opposite conditions. If the plants are carefully gone over and the leaves burned as suggested, the rust, we think, will be kept in check another year; but a good syringing, when the leaves are just appearing, with sulphide of potassium will probably prove an entire cure. It has been suggested that such plants should be transferred some time this month to another part of the garden. Fortunately, the general experience is that the rust inflicts no permanent injury, although the rosarian can do very well without it. The frequent use of the hoe will assist in keeping down fungoid pests, if a deep soil is provided in the first place; also prune the shoots hard back next spring.

*Grubs and Caterpillars.*—These and several other pests are dealt with by Mr. E. Mawley in "Roses for English Gardens." It is there mentioned that the Rose maggot and several other equally destructive leaf-rolling grubs and caterpillars are generally the first pests to attack the Rose in the spring. They will be found curled up in the young foliage, and must be sought for every few days and crushed between the finger and thumb, or much damage will be done. This is not a pleasant occupation, but, unfortunately, there is no other remedy, except it be to pick off the affected leaves and afterwards burn them or throw them into a strong solution of salt and water.

*The Frog-hopper, or Cuckoo-spit.*—The next enemy to appear will be the frog-hopper, or cuckoo-spit, a little pale green or pale yellow, frog-like insect, which will be found hidden in the centre of a small patch of froth deposited either in the axils of the leaves or on the leaves themselves. This, again, must be hunted out and destroyed by means of the thumb and finger, or removed with a small brush and deposited in the salt and water solution before mentioned.

*The Boring Grub.*—Holes will be often noticed in the tops of the stems of standard Roses; these are made by this pith-boring grub. As a preventive the ends of standard Roses should be painted with "knotting" at planting time, and the same precaution should be adopted with

the standard stocks. If the holes have been already made, a piece of copper wire thrust sharply down them will destroy the grubs; a little putty is used to close the holes afterwards. The same grubs also occasionally pierce the shoots of Roses, and seem especially fond of those made by standard Briar stocks. In this case, as soon as observed, the hollow ends of the shoots should be squeezed until firm wood is met with and then cut off. In this way the boring-grub will be crushed and the affected part of the shoot removed.

*The Rose Aphis, or Green Fly.*—In some seasons these tiny creatures are very numerous and troublesome, and if not frequently destroyed increase very rapidly. Most exhibitors keep green fly under entirely by the skilful use of the thumb and finger. This only shows how easily such pests may be kept in check if attacked directly they make their appearance and never afterwards allowed to congregate in any great numbers. Occasional sharp syringing with a garden engine with clean water will be found in most cases sufficient. Should this, however, prove ineffectual, the following well-known remedy may be used instead: Take 2oz. of Quassia chips and boil them in a gallon of water, adding a tablespoonful of soft soap before the mixture becomes cold; or one of the many insecticides on the market may be tried, keeping strictly to the directions supplied with the bottle.

*Thrips.*—These tiny creatures often injure Rose blooms in hot and dry weather, especially those of the Teas, by giving the petals a bruised and brown appearance. Spraying or syringing with clean water is the best remedy to employ, even at the risk of spoiling some of the existing blooms.

*Red Spider.*—This is another dry-weather enemy, and so small as not to be detected with the unaided eye. It generally attacks the lower sides of the leaves, and if not kept in check causes them to fall from the plant prematurely. The same remedy as for thrips is advisable.

*Mildew.*—Of all the insect and fungoid enemies of the Rose, this is, as a rule, the most troublesome to deal with. It appears as a white mould on the foliage, and if not promptly dealt with will quickly spread from one plant to another over the whole collection. It occurs at all seasons, but principally in autumn, when, if not checked, it will prevent the plants from flowering so freely as they otherwise would. Flowers of sulphur is a sure preventive, but each attack must be dealt with on its first appearance and the application repeated until a cure is effected. A very simple way of applying the sulphur is by shaking it lightly over the affected plants by means of a fine muslin bag on the first calm evening after the

mildew is detected. Although only the upper surfaces of the leaves are dusted over, it will be found in practice that the action of the sun will vaporise the sulphur and cause the surrounding atmosphere to be impregnated with it. Syringing or spraying with the following liquid will also prove effectual, more especially if the under sides of the leaves can be wetted with it. To make this mixture, half an ounce of sulphide of potassium should be placed in a gallon of hot water, well stirring it until the sulphide is dissolved. When cold the liquid will be ready for use. Warm days, followed by cold nights, are the most frequent cause of this pest, also a close, muggy atmosphere.

## PRIZES FOR READERS. OCTOBER.

### THE WINTER PRUNING OF HARDY FRUIT TREES AND BUSHES.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The object of this competition is to draw special attention to the important winter work of pruning in the hardy fruit garden. Special attention should be given to the reasons for pruning and the benefits to be derived therefrom, as well as to the actual work. Various types of trees and bushes should be dealt with, and root-pruning may or may not be included at the discretion of the essayist.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Saturday, October 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 13. — Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1—6 p.m. Lecture at three o'clock by Mr. Cecil H. Hooper, F.S.I., on the "Influence of Geology on Horticulture." Admission 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

October 15 and 16. — Royal Horticultural Society's Exhibition of British-grown Fruit, Vincent Square, Westminster, S.W.

### A rare and excellent early Apple.

Mr. George Frankum sends us from Woolhampton, Berks, one of the most delicious Apples we have tasted. It is called Miller's Seedling, and a variety we cannot find mentioned in the fruit-books of to-day. It reminds one of Irish Peach; but it is larger, clear yellow, striped and flushed with a peculiarly pretty shade of rosy red, and the flesh is firm without being unpleasantly hard; the flavour is delicious, possessing the sweetness of Irish Peach with something like that of Cox's

Orange Pippin. It is strange such an Apple as this is not better known. Mr. Frankum writes: "It is a local-raised Apple by an old-established nurseryman at Speenhamland, close to Newbury; the raiser's grandson now has the nursery. It is not generally known, but it is highly appreciated in the neighbourhood and always realises a good price. Mr. Tom Clarke, a large grower for market at Blenheim in the north of Berks, goes so far as to say that only three sorts of Apples should be grown, namely, Blenheim Orange, Cox's Orange Pippin and Miller's Seedling."

**Interesting gathering at Messrs. Cheal's.**—Messrs. J. Cheal and Sons, Lowfield Nurseries, Crawley, entertained their employees, with their wives and families, recently, on the occasion of the marriage of Mr. and Mrs. J. Cheal's daughter (Miss H. M. Cheal) to Mr. E. Wright. About 250 persons were present, and all enjoyed themselves very much.

**Royal Horticultural Society's examinations in horticulture.**—On the invitation of the Government of the United Provinces of India, the "general examination" of this society in the Principles of Horticulture is to be modified so as to fulfil the local requirements, and a first examination will be held in April, 1909, at Saharanpur. This suggests that possibly other countries and districts may feel it desirable to enter candidates for a similarly modified examination, in which case the council would doubtless be prepared to organise it. The examiners are leading horticulturists in England, and for examinations abroad will be assisted by suitable experts acquainted with the special horticultural conditions of the various countries desiring to adopt the society's tests. Other details arranged will be communicated on application being made to the secretary, Royal Horticultural Society, Vincent Square, Westminster, London.

### Wisley School of Horticulture.

The following is a copy of the report of H.M. Inspector on the Wisley School of Horticulture for the year 1907-8: "Provision is made for the training annually at this school of about thirty young men as scientific gardeners, and a diploma of the Royal Horticultural Society is awarded to the successful students at the end of the period of training. The course of instruction is designed to cover two years; but as yet only the first year course is in full operation. The course is extremely well planned, and is carried out by an efficient staff of instructors. The gardens of the Royal Horticultural Society are extensive and contain a very large variety of plants, both in the open and under glass. There is also a very well-fitted laboratory with good equipment for instruction in the sciences bearing on practical horticulture. The laboratory is under the charge of a well-qualified and skilled instructor, and the students receive a very thorough training in the scientific side of their craft. This instruction has, at present, to be made very fundamental and, in some respects, very elementary, as few of those admitted to the course of instruction have received a satisfactory training previously in the rudiments of science. When the second year course is in full operation it will be possible to do some fairly advanced work. Originality and thought on the part of the students are encouraged by weekly discussions in the evening, when selected students read papers which are criticised by the other students, and additional experience is gained by the students in acting on small committees in connexion with the arrangements for the society's shows in London. On the practical side, students appear to have a unique opportunity of acquiring a knowledge of the cultivation of all the plants that they are likely to meet with in the course of their employment, and those who qualify for the diploma should have no difficulty in securing remunerative posts. The Royal Horticultural Society is to be congratulated on the step it has taken to encourage the educational side of the craft."

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Sweet-scented Roses.**—I wonder if our Editor could find space for an "election" of sweet Roses? It would, I think, be helpful to many GARDEN rosarians now the planting season is upon us. I know several people who intend planting beds of sweet-scented Roses this autumn, and a list of the most fragrant flowers in the Hybrid Perpetuals, Hybrid Teas, Bourbon and others would be welcome.—J. T. STRANGE, *Firlands, Sulhamstead, Berks.* [We thank our correspondent very much for his interesting note. Perhaps our Rose-loving readers will send in the names of the varieties which they consider possess one of the sweetest attributes of the flower—fragrance.—Ed.]

**Tea Rose Isabella Gray.**—Mr. Edward F. Kemp will find the Tea Rose Isabella Gray catalogued by Messrs. Kelway and Son, Langport.—M. E. B.

**Galanthus Olgae.**—Bulbs received under the above name, potted on September 12 and kept outside under a north wall, were in full bloom on September 22 and were exhibited at a local show on that date, where they created a good deal of interest. There is no foliage as yet; but I cannot see that the flowers differ at all from *G. nivalis*. I have a suspicion that these bulbs must have been retarded; but perhaps one of your readers may know something about this plant, which is described as a "new autumn-flowering species from Greece."—F. HERBERT CHAPMAN.

**Tomato Frogmore Selected.**—Perhaps it may be of interest to other readers of THE GARDEN if I state what I have proved to be one of the best Tomatoes for outside and pot culture. It is Frogmore Selected. I think it can be well described as the best for early forcing and outdoor cultivation. The fruits develop to a medium size, very uniform and almost round in shape, solid and unusually firm. They are of a bright red colour with flesh of exceptionally good depth; and I find it also only contains a very small seed space. This Tomato has done exceedingly well with me, and I think it should be much more widely grown. I can confidently recommend it as one of the best.—G. A. LUDGATE, *The Gardens, Heath Lodge, Maidenhead.*

**Late Peas.**—Carter's Michaelmas is quite the best late Pea we have this season, and it is rightly named, as on Michaelmas Day we could pick quantities of fine pods, and if frost holds off we shall continue to gather much longer. It is a Pea of vigorous constitution and does not develop mildew like a good many varieties. A good plan to adopt against an attack by this pest is to put a double handful of flowers of sulphur into a pail or pot of milk and syringe the plants with it early in the season, spraying it well under the foliage. No Plus Ultra, good Pea that it is, grown by its side collapsed some weeks before, though in some gardens it is difficult to surpass, and should always be grown where Peas are wanted as long as possible, as its flavour is of the best.—W. A. COOK, *Leonardslee Gardens, Horsham.*

**Blue Hydrangeas.**—The blue Hydrangea question is a difficult one to solve; for instance, I have had six plants for seven years, which have always been rose colour until this year, when they have been a deep blue. Now here is where the difficulty of ascertaining cause comes in. I obtained from a neighbouring gardener a few cuttings of a true blue under any cultivation, he having obtained it direct from a large nurseryman in London. The character of growth was very

thin and dark blue in colour, altogether different to the ordinary type of Hydrangea. I saw it in flower and was satisfied I had got a real blue one. Now the ones I had and those that were given me were potted up at the same time and in the same kind of soil. My old rose-coloured plants came blue, and the true blue as I obtained it came red. I should like to hear from any of your readers who are interested in the question the cause of it.—R. KIDD, *The Gardens, Heaton Grove, Bury, Lancashire.*

**Layering Carnations.**—Reading recent notes on layering Carnations in THE GARDEN, I will give our experience. We layer about 2,000 annually with good results. I find an inch tongue very satisfactory, half under the joint and half above, taking care the knife is well in the centre of the stalk when finishing the upright cut. We find defective tongues more liable to break off when moving than long tongues. I may mention I visited a well-known nursery recently and my attention was called to a man layering Carnations. After making the tongue he cut the lower piece off close to the joint in the tongue. I asked him the reason for this, and his reply was that they root better.—H. HUGHES, *Leicester.*

## WHERE THE BRAMLEY'S SEEDLING APPLE COMES FROM.

MESSRS. MERRYWEATHER AND SONS' NURSERY, SOUTHWELL.

**S**OUTHWELL is famous for its glorious cathedral, old churches, quaint streets and the nurseries of Messrs. Merryweather and Sons, one of the oldest and most respected firms in the British Isles, and who first introduced the Bramley's Seedling Apple to the British public—one of the most toothsome varieties that ever tempted the palate of the fruit epicure. The writer paid his first visit to Messrs. Merryweather's last July, when Roses, hardy flowers and the acres of fruit trees were in summer beauty. There are several nurseries, and from one hilltop, if we remember rightly, where the magnificent orchard of Bramley's Seedling rivets one's attention, a beautiful view is seen of the cathedral. It was a misty day, but a picture of colour and beauty, with the walks of hardy flowers and acres of Roses as a fragrant foreground. We hope shortly to illustrate the Bramley's Seedling orchard to show the remarkable vigour of the trees, which are of historic interest to the horticulturist.

As these notes appear in our Rose Number we will confine them to this flower, and leave further remarks on the trees and shrubs and other features of the nursery for another occasion—before the autumn has quite flown. The collection of Roses is practically complete, and it is a pleasure to see the groups of the most beautiful varieties in the full tide of their summer beauty. A Rose identified with Messrs. Merryweather is the Baby Rambler, which was raised by this firm. We saw it in various phases—in the open garden, in pots and as standards—and in each form it fascinated one with the beauty of its flower colouring. It is well described by the raisers as a charming novelty, "growing outside to a height of about 2 feet; very bushy, branching habit; produces long feathery panicles of flowers in constant succession from June until the autumn frosts. The colour is a pretty bright carmine-pink, shading lighter to the centre; in fact, the colour of Lady Gay. An ideal Rose for bedding and massing. No other Rose is equal to it for decorative use in pots." This sums up the merits of one of the most interesting and useful Roses raised of recent years.

Another Rose that should be much seen in the future is Climbing Liberty. It is a sport from

that well-known Hybrid Tea, possessing the same warm crimson colour with, of course, an additional strength in the growth. We have never seen Hiawatha more sumptuous out of doors. This multiflora variety is increasing in favour every year. We well remember the glorious specimens in pots at the Temple Show, but in the open garden it retains its wonderful brilliancy of colour—crimson, with lighter centre, thrown into strong relief by the dark-coloured foliage. Another charming multiflora Rose is White Pet, and the drifts of spotless white flowers appeared as if a fall of snow had settled on the branches. Helene belongs to the same class, a vigorous climber with carmine buds, which, when expanded, are of a distinct lilac shade.

The rambling Roses are one of the features of this nursery. Fences are covered with them to set forth their usefulness for such purposes, and there are hedges of Roses, too, that delight the eye and drench the air with the perfume of their flowers. A few of the more noticeable of the rambling or climbing Roses were Ards Rambler, Goldfinch, the White Dorothy Perkins, one of the Roses of the future; Stella, Tausendschön, the Penzance Briars, of which Meg Merrilies is one of the most dainty; the wichuraiana hybrids, the richly-coloured rubra in particular; Aglaia, Blush Rambler, Euphrosyne, Lady Gay, Leuchstern, Mrs. F. W. Flight, one of the more recent and beautiful of rambling Roses; Philadelphia Rambler, Psyche, Tea Rambler, The Lion, Trier, Wallflower, a remarkable purple colour; and such sweet old favourites as Alice Gray, Bennett's Seedling, Dundee Rambler and The Garland.

I was delighted to see the favourites of old grown in quantities, which show that they are regaining to some extent their previous position. The writer has them on a pergola, except The Garland, which rambles over an Oak fence, covering it in flower-time with a multitude of white starry blooms with the faintest tinge of pink.

Brilliant and varied colouring came from the many forms of the China or Monthly Rose, the scarlet China veing with a Jacoby Geranium for dazzling beauty; for there is distinct beauty in such crimson splendour. Of recent years, thanks to the raisers of such exquisite hybrids as Mme. Laurette Messimy and Mme. Eugène Resal, this group is in all Rose gardens worthy of the name. The writer has before him a border of grey-leaved shrubs—Lavender, Rosemary, Jerusalem Sage (*Phlomis fruticosa*) and Lavender Cotton—among which are dispersed the China or Monthly Rose, as fresh in colour as a maiden's cheek, and the two hybrids named. One can see them through the latticed window, asking, so it seems, to look inside and fill the house with their delicious colour and subtle fragrance. The clear pink Hermosa, a group of which we remember in the Royal Gardens at Frogmore; Aurore, a mingling of fawn and orange; Cramoisie Supérieure, Ducher, Queen Mab; and Fellenberg we noticed especially, a Rose for the shrubbery which should be more sought after. It is of strong growth, the leaves of a dark colour, and from the first summer days until the winter months there are flowers, not scattered over the

shoots, but almost hiding them in their rich profusion.

The Teas, Hybrid Teas and Hybrid Perpetuals develop their true characters on these sunny slopes. A delightful Hybrid Tea is Marquis de Sinety, the colouring unusual and distinct, and this we hope shortly to illustrate as a coloured plate from flowers drawn in this nursery. Of this section we also, for their wonderful beauty, made note of Antoine Rivoire, Betty—a winsome beauty in spite of some unpleasant things that have been written of this variety—David Harum, Dean Hole, Ecarlate, Countess Annesley, Fran Lilla Rautenstranch, George Laing Paul, Irish Beauty, Irish Elegance, Kaiserin Augusta Victoria, Killarney, La Tosca, a noble Rose for grouping; Le Progrès, as rich as a cut Apricot in the colouring of its flowers; Mme. Abel Chatenay—Queen of Roses; Mme. Jules Grolez, Mme. Maurice de Luze, Mme. Ravary, a flower one never tires of; Mrs. E. G. Hill, Mrs. W. J.

THE NEW HYBRID TEA ROSE LADY ALICE STANLEY. (Much reduced.)

Grant, Pharisaer, Prince de Bulgarie, Triumph and Warrior. If these are not in the Rose garden they should be purchased this autumn; they belong to the list of the more recent acquisitions.

Among the Tea-scented varieties, very beautiful were Beauté Inconstante, Billiard et Barré, a Rose for a fence, its flowers of an intense orange colour; Corallina, a warm crimson, strong-growing bedding Rose; Corinna, Dr. Grill, G. Nabonnand, the loveliest Rose in existence in our estimation; Golden Gate, Mme. A. Mari, Mme. Jules Gravereaux, Morning Glow, Mrs. Myles Kennedy, Nellie Johnstone, Papa Gontier, Papillon and Sulphurea.

These lists are not representative; they merely include the Roses that at the time of our visit were unusually beautiful. Want of space prevents, at present, further reference to the horticultural treasures of this nursery. We left Southwell with regret.

## THE FLOWER GARDEN.

## NOTES ON IRISES.

(Continued from page 482.)

**I**RIS ATROPURPUREA closely resembles *I. atrofusca*. The standards are brown, shaded rosy purple, the falls darker, with a black signal. Culture of *atrofusca*. Asia Minor.

*I. Barnumei*, a new species, has purple-red flowers, self-coloured and of a satiny lustre throughout, veined a darker purple and furnished with a rich golden yellow conspicuous beard. A pretty plant and not so difficult to grow as many of its brethren. Asia Minor. The leaves are short and sturdy and the flowers resemble small *I. susiana*.

*I. Eggeri* is a small-flowered plant 3 inches to 4 inches in diameter, coloured rich violet, with purplish shading and as glossy as a raven's wing; a black signal patch adorns the fall.

*I. evbankiana* is a tall, slender-growing species with glossy leaves and medium-sized flowers, the standards of which clasp each other; they are coloured grey, regularly lined and minutely spotted purple. Falls horizontally poised, marked with a marbled signal patch of chocolate. It is a remarkable Iris, very singular in its angular outline, and inhabits the mountain ranges dividing Persia from Transcaucasia.

*I. Gatesii*.—Perhaps the most singularly beautiful Iris known to cultivation. The flowers measure 6 inches to 8 inches across, the standards of which are silvery grey, covered with a delicately traced netting of rich rosy purple. The large falls, shaped like elephant's ears, are partially covered with yellowish grey hairs. The surfaces of the petals shimmer under various changes of light, and one could study the flower for hours. The plant is distinctly lime-loving, and grows well in a harsh loam. Manure or a covering of any kind, save a glass light, seems fatal to it. Armenia.

*I. Helena*.—An Egyptian species of slender growth, the leaves of which are sickle-shaped and very short. The flowers are lilac, purple on the falls, shading to an orange marginal colouring. The signal patch is a black disc of velvet "pile." The root-stocks are slender, and the plants require less ripening than the others.

*I. iberica* is an old-time species from the Caucasus, the growths of which resemble the last-named plant. The standards are pearly white, of medium size, and the falls purplish brown, very rich in their varying shades; a black velvety signal patch occupies the centre of each. Not difficult to grow if rested well, and it may be grown well in a cool house if exposed to full sunlight.

*I. Lortetii* is a species from Palestine and a great beauty, agreeing in size and shape with *I. Gatesii*. The standards are pure white with violet tracery, the falls cream tinted, veined and minutely dotted carmine, giving an appearance of silvery pink. The signal blotch is coloured rich crimson purple, varying in degree with different specimens. A coloured plate of Iris *Gatesii*, *I. Lortetii* and *I. lupina* was issued with THE GARDEN of February 18, 1893.

*I. lupina*, the well-known Wolf's-ear Iris, has sickle-shaped leaves in close distichous tufts and greyish yellow flowers, the falls of which are "shot" with green and furnished with a large signal patch of greenish black. As a garden plant it proves easy to grow on light soils of calcareous formation and in warm situations, but it is hopeless to attempt its cultivation in wet districts. It can be grown well in a cold frame with a full exposure to the sun, but it is always best to lift and store the roots to prevent them starting into growth before winter.

*I. lupina robusta* is a magnificent Iris of stronger growth, agreeing with the type plant in general colouring, but the standards are "shot" with a bronzy tint, revealing remarkable shades of colour under varying degrees of light. The

STANDARD DOROTHY PERKINS IN THE REV. PAGE-ROBERTS'S GARDEN.

margins of all the petals are delightfully crimped and tinted old gold. Forms of *I. lupina* are widely spread throughout Asia Minor, and those hailing from Southern Turkey in Asia have naturally better constitutions than those from Armenia. *Robusta* can be easily grown with ordinary care.

*I. nazarensis*, considered by many to be a form of *I. Sari*, has sky-blue standards, veined with purple, and sombre-looking falls coloured slate-grey, veined with black-purple. The signal is coal black. Native of Palestine. Culture of *I. iberica*.

*I. nigricans* is a miniature of *I. susiana*, with deep black-purple flowers of varying shades; the glistening surfaces relieve the sombre colouring. Culture of *I. iberica*. M.

(To be continued.)

## THE GREENHOUSE.

## WINTER IN THE GREENHOUSE.

(Continued from page 480.)

**T**EMPERATURE.—The majority of greenhouse plants are happy with a minimum temperature of 40° and a maximum in ordinary weather of 50°. Slight variations will suggest themselves to growers of various classes of plants whose requirements, perhaps, call for slightly warmer conditions or are supplied by a rather lower temperature. Of course, sun-heat will readily run the maximum up far beyond 50°, but no harm will result from this if the cultivator takes advantage of it to admit an abundance of air. Then, again, dwellers near large towns, where the fog demon enswathes things horticultural and otherwise in his deleterious mantle, will do well to allow the temperature of their houses to rise 5° during these visitations, at the same time keeping all doors and ventilators tightly closed. Should a sunny day follow a foggy one, advantage should be taken of it to syringe the plants, as this will do much to rid them of any deposit left behind by the murky visitant. In contradistinction to these rises in the normal temperature it may be mentioned that although 40° is the best general minimum to aim at, yet 35° during spells of severe weather will be better than 40° maintained by excessive firing and overheated pipes. Even 30° on occasion will not harm many greenhouse inmates. Mind, I am not advocating 30° as a safe temperature, but I do know I have frequently found *Primulas*, *Cinerarias*, *Calceolarias*, *Deutzias*, *Spiraeas*, *Azaleas* and many other plants with their pots frozen to the stage without any harm resulting. Should a frost set in suddenly and catch hold of any of the plants—this they will show very plainly by drooping—run the blinds down as soon as this state of things is noticed and syringe all the plants with cold water not exceeding 35°. Keep the blinds down till all danger of sun reaching the plants is past, when they will be found to be none the worse for their brief encounter with the frost.

**Ventilating.**—The exercise of care in this particular is necessary, as it is safe to say that more plants are killed by damp in winter than by frost; therefore get rid of superfluous moisture by ventilating on all favourable or not too unfavourable occasions. There are few days in winter when it is not possible to give a little air by one of the top ventilators if these are properly arranged. What are known as hit-and-miss ventilators—made by the replacing of bricks on opposite sides of the houses near the hot-water pipes by sliding boards—are very useful for winter ventilation. The air being admitted by these is warmed before coming in contact with the plants above, and if a slight crack is opened at the top of the house at the same time, any vapour will be carried off, when the ventilators may be again closed. If the weather conditions have been so adverse for several days as to make ventilation a risky proceeding, the pipes may be heated rather above the ordinary degree for a few hours, say, once a week, and

air admitted to sweeten and renew the atmosphere. Ventilation should always be given as far as possible on the side of the house opposite to where the wind is blowing.

**Watering.**—This must be very carefully performed during the winter months, making sure that a plant is really in need of it before applying water, and above all things taking care not to fill the pots so as to overflow them. Every pot should be tried by tapping it with the knuckles, a stick, pocket-knife or something similar before water is given; and if any doubt is left in the mind of the waterer as to whether the plant needs liquid refreshment, give it the benefit of the doubt by withholding supplies until the next tour of inspection is made. If the water given to a plant does not drain away in a few minutes after the application, the drainage of the pot should be examined and put in order, for that is where the cause of the mischief will be found. On the other hand, should the water drain away as quickly as it is given, press the ball of soil firmly down into the pot, for it will doubtless have parted company with its earthenware associate through a previous sustained period of enforced drought. Watering should be performed in the morning, and half an hour after it is finished all superfluous moisture should be removed by broom or mop from the floor of the house. Pots that are filled with roots, such as those containing Genistas, Spiræas, Cinerarias, Eupatoriums, Salvias and bulbs generally, will need water every other day as a rule, while once a week will suit freshly-potted Primulas, Calceolarias, Cyclamen, Pelargoniums, fibrous-rooted Begonias and Bouvardias until their roots are working freely in the new soil. J. K. E.

(To be continued.)

## THE NEW ROSES LADY ALICE STANLEY AND A. HILL GRAY.

THESE two new Roses, of which illustrations are given, were fully described on page 465 of our issue of the 26th ult. The former is a Hybrid Tea raised by Messrs. S. McGredy and Son of Portadown, Ireland; and the latter is a Tea raised by Messrs. Alex. Dickson and Sons of Newtownards. Both were shown at the autumn exhibition of the National Rose Society, and our illustrations are of flowers exhibited there. Each variety secured a gold medal.

## ROSE DOROTHY PERKINS AS A STANDARD.

THE illustration from a photograph of Dorothy Perkins gives a fair picture of this good Weeping Rose. I tried to get one of Paul Transon, one of the very best, if not the best, of Weepers. It blooms early and late, and looks well at all times. As far as my experience goes with these striking plants, I would recommend, in addition to the above: Starlight, single-flowered, white, suffused with violet; White Dorothy, a sport from Dorothy Perkins; Evangeline, white, tinged with lavender; Joseph Lamy, flowers semi-double, porcelain white, with light pink edge; Kathleen, large bunches of single carmine rose with white eye; Tausendschön, large bunches of fine soft pink or rose flowers; Trier, semi-double, creamy white, good in autumn; Tea Rambler, coppery pink; Rubin, soft crimson; Ruby Queen, soft carmine rose; Aimée Vibert, white perpetual; Leontine Gervais, coppery red, shaded carmine; Félicité Perpétue, white. I find it is not advisable to use wood stakes; iron are the best. Wood or even Bamboo stakes soon decay, and one tall 8-foot tree is blown down before you are aware of it. If the trees are planted on the lawn, give a large circle not less than 3 feet in diameter for each tree. Grass should never be allowed to grow near the stem. F. PAGE-ROBERTS.

## SOME NEW ROSES OF 1908.

WITH the autumn exhibition of the National Rose Society the Rose season of 1908, so far as it is relative to the introduction of new Roses, has been brought to a conclusion. We are now in a position to review the Roses which have been fortunate in receiving recognition by the National Rose Society either by the award of a gold medal or card of commendation. The new varieties to which were given a gold medal are as follows:

*George C. Wand*, raised by Messrs. Alex. Dickson and Sons. A Hybrid Tea of good form, medium size, full, remarkable for its shade of colour—somewhat difficult to describe—bright light crimson suffused with orange; upright growth.

*Mrs. J. Campbell Hall*, a Tea raised by Dr. J. C. Campbell Hall. Cream pink, sweet scented, full and apparently of good constitution.

*Simplicity*, a Hybrid Tea raised by Messrs. Hugh Dickson. Very large, stout petals, single or almost single, colour pure white. In habit resembling Kaiserin A. Victoria.

*White Dorothy*, sent out by Messrs. Benjamin R. Cant and Sons. A pure white Dorothy Perkins. If anything it is stronger in habit and with slightly larger blooms than Dorothy Perkins, from which it is a sport.

*Dr. O'Donel Browne*, a Hybrid Tea raised by Messrs. Alex. Dickson and Sons. An exhibition variety, strong and erect in growth, with very large, full, well-shaped flowers; colour carmine rose, resembling Star of Waltham.

*Meta Weldon*, raised by Messrs. Alex. Dickson and Sons. A cream-coloured, globular, deep-petalled Hybrid Tea. Not yet in commerce.

Like *Meta Weldon*, there are other Roses not yet distributed which have obtained a gold medal. To refer to them would be going beyond the scope of these notes; but an exception, however, must be made in favour of a yellow Tea named *A. Hill Gray*. This Rose promises to be a favourite for the garden and suitable for exhibition. The growth is branching but somewhat slender, free-flowering habit, blooms fairly full, colour yellow, shaded white.

Cards of commendation were awarded among others to the following:

*W. R. Smith*, introduced by Messrs. Hugh Dickson. A robust Tea, colour creamy white, suffused pink, the edge of the petals being outlined with deeper pink, after the manner of *Mme. de Watteville*. It has all the characteristics of *White Maman Cochet*, both in habit and form of flower.

*Grace Molyneux*, a Hybrid Tea raised by Messrs. Alex. Dickson and Sons. Suitable for decorative purposes, owing to its freedom of flowering, but too thin as an exhibition variety. Colour white, shaded cream.

*Earl of Gosford*, a Hybrid Tea raised by Messrs. S. McGredy and Son. Attractive from its colouring, bright rose red, but apparently lacking in substance.

It should be recognised that the committee appointed by the National Rose Society to adjudicate on new seedlings or sports approach their task under somewhat difficult conditions. To the majority of the committee the Rose under consideration is unknown; they are ignorant of its classification, its parentage, its character as suitable for garden or exhibition. No information is afforded, not even the name of the variety. Thus they are not in possession of the full merits of the Rose before being called upon to make the award. One expresses no opinion on the decisions arrived at in 1908, but it having been the writer's privilege to see almost all the above-mentioned varieties growing in their respective Rose gardens, he is led to believe that on further acquaintance the best Roses of the year will prove to be—placed in order of merit—*W. R. Smith*, Tea; *Molly Sharman Crawford*, Tea; *Dr. O'Donel Browne*, Hybrid Tea; *White Dorothy* and *Miss Cynthia Forde*, Hybrid Teas. The first-named, if one is not mistaken, will be almost as popular as *White Maman Cochet*. *Molly*, the second on the list, is a creamy white Tea, with high centre, full and beautifully formed, fragrant and suitable for the exhibition stand and garden.

THE NEW TEA ROSE A. HILL GRAY.

(Illustration from the photograph taken of the exhibit at the Autumn Rose Show. Much reduced.)

cultivation. The last on the list is strong in growth, giving fine exhibition flowers of the colour of *Gustave Grunerwald*. It is said to be mildew-proof. JOSEPH H. PEMBERTON.

## JAPANESE ROSES.

(ROSA RUGOSA.)

AMONG the very varied tribes of the Rose no race can claim more hardiness or frost-proof qualities than the *rugosa* or Japanese section, and one is rather puzzled as to why it has not made a greater advance. All who have watched the group from its introduction are convinced that its possibilities in cross-fertilisation are immense, as witness that splendid variety *Conrad Ferdinand Meyer*, obtained by a compound cross between a Hybrid Perpetual, a Tea Rose and a *rugosa*. The beautiful and showy fruits of *Rosa rugosa* and *R. r. alba* are just now making our gardens very brilliant. What huge bushes these Roses will develop into if left unpruned, although if the plants are cut down to

the ground each year the seed-pods are much larger, and in this way the bushes do not occupy an undue amount of space. Of course, when employed as a shrub among other deciduous subjects the larger they develop the better. Even in the heart of large cities these Roses will be found luxuriating as no other Rose will do, and they make charming hedges if planted about 2 feet apart in well-trenched soil. It is not advisable to prune the first year, as some recommend; but the second year one or more of the growths may be cut down to the ground, as this will tend to keep the base well furnished. A

free-flowering variety. A very pretty hybrid between *R. rugosa* and *R. multiflora* is named Ywara. It has curious fringed single pure white flowers and is a variety worthy of introducing into any collection of these lovely garden Roses. Mme. George Bruant is tolerably well known, and, although somewhat eclipsed by Blanc Double de Coubert, it is a valuable sort. It is reputedly a cross between the old Tea Rose Sombreuil (a charming old Rose everyone should grow) and *R. rugosa*. The fragrance is delightful and its growth erect. A bed of five or six plants placed a yard apart each way will make

crossing with the Hybrid Perpetuals. We have in Mrs. Anthony Waterer a good crimson, this colour being imparted by the old favourite General Jacqueminot, which has also given to the flower a delicious fragrance for which rosarians are grateful. Mrs. A. Waterer is unrivalled as an early-blooming crimson, and I advocate some bold masses of it in the wild garden or clumps in the pleasure grounds, especially among other bold masses of such early-flowering Roses as Electra, Una, the Dawson Rose and similar types. Another variety, somewhat a rival to Mrs. A. Waterer, is one produced by that zealous rosarian M. Jules Graveraux. It bears the cumbersome name of Rose à parfum de l'Hay. Truly the fragrance is delicious, and for this quality alone it should be grown. The colour is a brilliant red and it is a free and continuous bloomer. With these sorts we are merging the rugosas largely into the Hybrid Perpetuals; in fact, they possess a greater likeness to the latter group than the former, and, of course, we do not obtain the fine showy fruit that gives to the type and its white form their originality. I am inclined to think our aim should rather be to extend the range of colours in the single forms, directing our efforts to bold flowers and distinct colours and retaining the seed-producing habit, which lends to the tribe not the least of its many attractions. In conclusion, I would commend a trial of these rugosa Roses upon standards. They make grand spreading heads of growth that become objects of much beauty when suitably located. P.

THE LITTLE-KNOWN ROSA RUGOSA SCHNEELICHT.

mixture of varieties is sometimes recommended, but personally I prefer one variety, or, at least, one colour. Hedges of these Roses are thick and as impenetrable as anything one can plant, and surely they would be more serviceable and certainly more beautiful than many of the hedge plants now employed.

There seems to be a tendency in this race to produce climbing varieties. The beautiful Schneelicht, of which an illustration is given, is a delightful variety with a climbing habit and producing fine clusters of snow white flowers. What can be more delightful than a clambering mass of such a Rose, with its deep green leathery foliage so immune from mildew? Then we have another very delightful sort in *R. repens alba*, which produces wonderful pendulous growths covered with thousands of snowy stellate flowers, that are charmingly displayed in the form of a weeping tree or falling over a high rockery or rootery. This Rose has the creeping habit of *R. wichuraiana*, and is possibly a cross with the same. The two groups apparently blend most effectually, and there are at Kew some most interesting crosses, one especially I noted having the glistening foliage of *R. wichuraiana* and its creeping habit, but of quite the leathery texture of *R. rugosa*.

*R. microphylla* × *R. rugosa* has delightful Azalea-like flowers, these being white, edged with pink. *R. humilis* × *R. rugosa* is valuable for its autumnal blooming. The buds are long and extremely pretty, of a crimson colour, opening to large single flowers. It is a most

a splendid bold effect in summer and again in the autumn. Blanc Double de Coubert is, perhaps, the sort most in request. In snowy purity it is equal to Frau Karl Druschki, and it is so free; the bushes rarely are minus a bloom from May to October. A variety recently appeared, named Souvenir de Philemon Cochet, that possesses flowers containing more petals than the last-named Rose, but I should not call it an improved variety. Certainly it has not such snowy white blooms.

I have already alluded to Conrad F. Meyer. It is a Rose almost as indispensable as Caroline Testout or Frau Karl Druschki. Its growths are very lusty and beautifully arrayed in red prickles and bold foliage. The blooms, of a clear and delicate shade of pink, are of immense size, almost rivalling the Hybrid Perpetuals in grandeur. The growth is so very vigorous that it deserves a place to itself, preferably as a free bush isolated upon the lawn, where it may develop into a huge bush, after the fashion of a Lilac or Syringa. Whether the white sport of this Rose, named Nova Zembla, will sustain its parent's reputation remains to be proved. It is said to be a Rose of beautiful form, very sweet and, of course, vigorous. The darkest flower of the group yet produced is Atropurpurea. The blooms are a blackish crimson in the bud, passing to maroon as they expand. Being produced in large clusters, the colour-effect is splendid.

Rich colours are still needed in this group. We want a good scarlet, and there can be no reason why we should not expect this from the

culture upon its own roots. Weak growers need some stimulating strength from a stronger source, and hence we use the Briar in one or other of three forms, also the Manetti, De la Grifferaie and sometimes a stock of such strong-habited Roses as Polyantha simplex. Many amateurs have an objection to the use of stocks because of the tendency to produce suckers at the expense of the Rose that has been worked upon them. This should not cause trouble. A little care in making up the cuttings for stocks, and careful trimming of the latter before planting out previous to budding, will avoid suckers. Only a very few varieties of Roses will thrive satisfactorily without the help of some stock, and these are almost confined to the Chinas and dwarf Polyanthas. I much prefer Dorothy Perkins, Crimson Rambler, Lady Gay and a few more of the wichuraiana section upon their own roots, but most of our best Hybrid Teas and Hybrid Perpetuals are very disappointing in that form.

In making up cuttings of Briar, Manetti or others for stocks we need wood that is firm and fairly ripe cut into 1 foot or so lengths, according to the distance the eyes or buds will admit. It is very necessary to cut out the eyes, except the top two or three. By cutting these out now we effectually stop any more from forming, and secure roots alone upon which to work the Rose buds later on. Of course, in the case of rooting Dorothy Perkins and others to grow on into plants one would not remove any of the eyes from the cutting. In fact, the suckers in this case are

## ROSE STOCKS.

LATE September and early in October are generally the best times to strike stocks for working upon the following year. The period is also suitable for rooting such

Roses as will thrive without foster stocks. As a rule the stronger the grower the better it will be suited for

most valuable and form a fair-sized plant the first season. Cut off close below an eye and insert the cuttings a little more than three-fourths of their depth, making them very firm. Frost will sometimes lift the cutting sufficiently to raise the base an inch or two from the soil it was resting upon. In such a case press down the cutting again as soon as the ground will permit and tread firmly along each side of the row. Frequent use of the hoe early in spring is a great help.

The following season the stocks can be lifted, trimmed over once more and planted out where it is intended to bud them. This time do not plant so deeply, 2 inches or 3 inches above the bottom roots being quite deep enough. At present the cuttings can be put in 4 inches apart, but the stocks should be allowed much more room, according to the growth of the variety it is proposed to work.

RIDGEWOOD.

## NOTES ON ROSES

GROWN IN A SMALL SOUTH BUCKS GARDEN IN 1908.

**T**AKEN as a whole the past season has been the best I have known for Roses in my little garden. Never before have they been so abundant throughout the summer, and for the first time in my experience green fly has failed to put in an appearance—no syringing whatever has been necessary. Caterpillars were innumerable, but these are a minor pest, because anyone with perseverance can overcome them. On our light soil in dry seasons thrips are much more difficult to conquer, and it seems impossible to get rid of them without spoiling the flowers. Of mildew, as is ever the case, there was more than enough, and in spite of many infallible remedies I think there always will be in gardens so confined by forest trees as mine is. Of all Roses I love best the dark Hybrid Perpetuals, but I can say little about them, as, notwithstanding repeated efforts, I fail to get any really good flowers. In spite of my many failures I am still an eager learner, and if anyone will teach me how to produce good dark red Roses from a light soil I shall be very grateful. In some cases the growth of Hybrid Perpetuals is quite good; for instance, I have had Ulster 6 feet high from a dwarf plant, and yet the flowers are poor from the exhibitor's point of view. Hybrid Teas do not do so well as I wish, but Duchess of Portland has been the most trustworthy as an exhibition flower during the past season. Unfortunately, though very beautiful, it is not a Rose for the garden, and there have been times when I have felt inclined to do away with it altogether.

In my opinion Florence Pemberton and Dean Hole are two of the best all-round Roses. Both have done well; the latter especially has been wonderful in colour. I think it requires much better living than the former. Le Progrès has made fine growth and flowered very freely as a standard. The form might be improved, but the colour is grand, and makes it worth a place in even a small collection. Mrs. Theodore Roosevelt, again, is a Rose for all, very good in form, and capable of producing magnificent flowers. Konigin Carola has been disappointing. Good in growth, beautiful in form and colour, the larger flowers are nearly always split. Of the newer Hybrid Teas grown here I like best Laurent

Carle and Mrs. Aaron Ward. Both are good in growth and colour, and the former promises to be useful for exhibition. I do not yet possess William Shean, but have no doubt it is a grand Rose. It has been one of the best flowers in a neighbouring garden where Roses are well grown. Writing away from home and without the help of my note-book, I had almost forgotten three lovely Hybrid Teas which have had a good season—M. Joseph Hill, Mme. Melanie Soupert and M. Paul Lédé. They all come from the same raiser, and, though perfectly distinct, they are somewhat alike in the beauty of their colour. The last named, in spite of being the oldest, is perhaps the least generally known, and in my opinion it is the best of the three for the garden. The June flowers were exquisite, but, like all Roses with the special Pernet-Ducher colouring, they must be shielded from the sun to be seen at their best.

Of Tea Roses, Mrs. E. Mawley is my favourite. Though making splendid growth as a maiden, it is not of the strongest constitution, and is apt to die young. In the matter of attention it is rather exacting, but in return for it it gives me better results than any other Tea, not excepting White Maman Cochet. In my experience there are not many Roses that give exhibition blooms without careful culture. To those who want fine flowers at the cost of little trouble, I strongly recommend Mme. Jules Gravereaux; treat it how you will it seems to thrive. The perfect Rose has yet to come; but the only weak point I have found in the above is its liability to mildew. Mme. Constant Soupert is a great acquisition, good as a standard or bush, grand in colour, of very strong growth, and likely to

pretty variegated foliage and flowers of a warm blush colour and delicious scent. Another most distinct Rose not often seen, though sent out years ago, is Roger Lambelin; the flower is shaped like a double Petunia, dark red edged with white, vigorous in growth, but with little or no scent. Unhappily, I have room for only a few climbers, and of those not universally known Trier is the most useful, blooming very freely throughout the season.

J. B. SHACKLE.

## ROSE MILDEW IN SMALL GARDENS.

**I**N an ordinary Rose season mildew makes its appearance only in the early autumn, or, at all events, not until then are the attacks sufficiently marked to seriously affect the appearance of the plants. Consequently, many growers of a small number of Roses pay no attention whatever to the ravages of this pest; indeed, they seem altogether ignorant of the reason why their Roses at that season become so unhealthy-looking. In the present year, however, mildew appeared unusually early, and, owing to the sudden changes in temperature and other atmospheric causes, has been ever since so general and persistent that even those growing a very limited number of Roses are now beginning to ask: What is this disease which disfigures our Rose trees and their flowers; and how can it be kept in check? The great secret—I call it a secret, because it is known to comparatively few rosarians—is to attack the enemy before it

THE GOLD MEDAL GROUP OF ROSES STAGED BY MESSRS. GEORGE PAUL AND SON OF CHESHUNT AT THE AUTUMN EXHIBITION OF THE NATIONAL ROSE SOCIETY.

do well in all soils except those that are too highly fed.

Of Roses grown here for the first time, Mrs. Myles Kennedy is easily the best, and will, I feel sure, soon take a high position in Mr. Mawley's most valuable Analysis. I would like to say a good word for two Roses not very often seen—Baronne Henriette Snoy and Auguste Comte; both grow well, and the latter is exceptionally beautiful in colour. To those who like curiosities I recommend Rosa Verschuren. It is a Hybrid Perpetual of fairly good growth, with

becomes visible to the naked eye, for the spores of mildew may have taken root as it were on the leaves a week, or even weeks, before they are suspected of being there at all.

For twenty years or more I have always managed to keep my own collection of over 2,000 plants practically free from mildew throughout the whole flowering season, but this has only been accomplished by repeated applications of the remedies employed. On the appearance, however, of the National Rose Society's little handbook, entitled the "Enemies of the Rose,"

I learned for the first time that I had invariably begun my defensive operations too late, for it was only when the first patches of mildew were visible on the leaves that I had thought of attacking them; whereas, had I acted wisely, I ought to have commenced sulphuring or spraying the plants directly after they had been pruned in the spring, and when very little young foliage had made its appearance.

I have said the great secret is to forestall the enemy; but there is another consideration equally important, and that is to allow the enemy afterwards no rest. That is to say, on noticing any slight curl in the foliage and the white mould accompanying it, the plan is to at once take means for destroying this insidious pest—the greatest and most common of all ills the Rose is heir to—on the plants so affected. Should the mildew afterwards show signs of spreading over the collection, the same measures should be adopted with the whole of the plants, whether affected or not. This may appear rather a large order; but in practice it will be found that, if the Roses are to be kept clean and in a growing and flowering condition throughout the season, there will be in the end a greater saving of time and trouble than if only half-measures had been adopted in the early stages of the attack.

As regards preventives of mildew and their application, for years I used nothing but flowers of sulphur, which was dusted lightly over the plants by means of a small muslin bag. Later on I came across some sulphur-bellows, which did the same work more quickly and satisfactorily. Last year I, for the first time, tried a liquid preparation. The one used was Mo-Effic (meaning most efficacious), which, at all events, proved less damaging to the flowers and more efficient than the sulphur, for, when sprayed, the lower as well as the upper sides of the leaves were reached by it. This year I have used a local preparation styled "V. 2 K.," which has proved quite as good as Mo-Effic, although the attacks of mildew have been this season more difficult to deal with. The small grower may make choice with advantage of any of

the remedies named. Flowers of sulphur dusted lightly over the foliage on the first calm morning or evening, while the dew is still upon it, will be found very helpful, and need not be washed off afterwards. Mo-Effic, which may be obtained of Messrs. E. Wright and Co., Brook Street, Bradford, or "V. 2 K." of Messrs. W. Cooper and Nephews, Berkhamsted, are both excellent remedies, and should be applied with a syringe with a fine spray like the Abol syringe, which is sold by Messrs. E. A. White, Limited, Paddock Wood, Kent. There are, no doubt, other preparations equally good to be obtained; but I only mention those which I have myself tried and found successful, and I give the addresses of the makers because I find so many small amateur rosarians are often deterred from using any remedies at all through want of such information. In using either of the above washes it is important that they should be applied only of the strength recommended on the directions accompanying them.

EDWARD MAWLEY, V.M.H.

### A FRAGRANT NEW ROSE.

WHATEVER may be the ultimate judgment upon the novelty Mrs. David Jardine, the fact remains that it is one of the most fragrant Roses we possess. It has that powerful perfume which has made La France so popular, and this novelty must be very welcome to many who have been disappointed at the absence of fragrance in so many of our Hybrid Teas. Mrs. David Jardine is so very distinct in habit, the growths being almost smooth with the stiff erect habit of the Hybrid Perpetual, but the delicate clear colouring of the Tea Rose. It is a pink Rose, and the marvel is that as so many new varieties are pink in colour, that there is a distinctness about them. I know of no Rose that has such an even, beautiful form, and I can quite believe it will supersede the Catherine Mermet race for general forcing purposes, because it looks to be a Rose that could be grown equally as well in a cool house as in one with greater heat, such as Catherine

Mermet requires. Our American friends are loud in its praises, and they are very keen judges of a forcing flower. Growers wishing to be up to date, and who are thinking of planting a house next season would do well to secure Mrs. David Jardine. P.

## COLOURED PLATE.

PLATE 1858.

### ROSE JOSEPH LOWE.

**T**HIS beautiful Rose originated as a sport from Mrs. W. J. Grant, and is being sent out by Messrs. Lowe and Shawyer of Uxbridge, Mr. George Mount of Canterbury, and Messrs. Hugh Low and Co. of Enfield, who kindly supplied the flowers from which the accompanying plate was prepared. Seldom if ever has a new Rose been so well or so frequently exhibited as this, and, when it is remembered that every flower was grown under glass, it is the more remarkable, and, at any rate, has proved beyond dispute its suitability for forcing, both early and late. There is in the flower a very distant resemblance to Mme. Abel Chatenay, but nothing like, to my way of thinking, so marked as some would have us believe. As seen out of doors in my own garden, the colour of Joseph Lowe much more closely resembles La France, and almost entirely lacks the salmon tint that is so characteristic of Mme. Abel Chatenay. Cut when young under glass there may be some resemblance; in the fully-developed flower they are wide apart. I have before me a bloom of each as I write.

I am afraid investigation through the lines of the respective parents of the two Roses will not help us much, as I believe there is considerable doubt as to the correct parentage of Mme. Abel Chatenay. Dr. Grill and Lady Mary Fitzwilliam are generally given as the parents of this Rose, but in the raiser's description Victor Verdier was named as the pollen-bearing parent at the time of its introduction. Be that as it may, I have long come to the conclusion that an argument based on the parentage or pedigree of any particular Rose is on very thin ice, and should and will carry little or no weight; so I will not pursue the subject, although it is interesting enough.

It is a coincidence that just as Mrs. W. J. Grant is known by two names (Belle Siebrecht being the other), so this sport Joseph Lowe seems likely to bear another name. Of the actual facts of the case I am not cognisant, but there is, I think, little doubt that Joseph Lowe is synonymous with Lady Faire, which was sent out by Messrs. Bentley of Leicester in 1906 and exhibited at the Saltaire show at the provincial exhibition of the National Rose Society the following year in the class for new seedling Roses, where it nearly got the gold medal, if my recollection is not at fault, but was certainly awarded a card of commendation.

I do not think there is any question that the two sports are identical; but under which name it will finally be known I should not like to say. Officially, I presume, the National Rose Society will call it Lady Faire; the trade and the public at the moment favour Joseph Lowe, because they have seen and know the flower as such.

It is too early to say very much about its growth and habit. With me small pot plants put out late in the spring have flowered well and

THE GOLD MEDAL EXHIBIT STAGED BY MR. GEORGE PRINCE OF OXFORD AT THE NATIONAL ROSE SOCIETY'S AUTUMN SHOW.

grown satisfactorily. They could not be expected to make very vigorous growth; all I can say is that they have behaved much better than the majority of plants so treated generally do. Undoubtedly the subject of these notes is a very beautiful variety that can be strongly recommended, and one that is destined to take a high place in popular favour.

Purley. H. E. MOLYNEUX.

## THE DAMASK ROSE.

**N**EAR the Provence, or Old Cabbage Rose, in sentiment as well as in a sort of natural classification, comes the Damask, an illustration of which is given showing the Rose associated with the Madonna Lily, and a beautiful association it proved to be—red and the purest white, as fair to look upon as the same Lily with the rich blue, graceful, feathery-leaved Larkspur (*Delphinium consolida*). The Damask Rose is charming, also, with its delicious though fainter scent and its wide-open, crimson flowers. The Damask Rose, with some of the older Gallicas, may be considered the ancestors of many of our modern Roses, and though there is no record of the earlier pedigrees, those who are old enough to remember some of the first Hybrid Perpetuals will retain the recollection of some Roses, such as Lee's Perpetual, in which such parentage, probably passing through a Portland Rose, of which group there are a few named kinds, is fairly traceable. The parti-coloured form is a charming bush Rose that should be much more used; it is known by the names Rosa Mundi, Cottage Maid and York and Lancaster.

The newly-found but really old garden Rose now called Hebe's Lip, otherwise Reine Blanche, seems to belong to the Provence group (gallica). There were formerly in old gardens some very dark-coloured Damask Roses called Velvet Roses, that are either lost or have become rare, as they are now seldom seen. When we were in Mr. Charles Turner's interesting nursery at Slough—and Turner's Crimson Rambler is famous the world over—we noticed a form of the Damask raised there, the crimson Damask, a single flower 5 inches across, and of a dazzling crimson colour—a pure and most effective shade. We have seen nothing quite so brilliant, and the bush was smothered, suggesting that for the fringe of woodland or in places which require lighting up, so to say, with colour, this is exactly the Rose for early summer. In these days when the Tea and Hybrid Tea sections seem to engross almost the entire interests of rosarians, a thought must be given to such old-world Roses as the Damask, and we are pleased that Mr. Turner has given a crimson Damask of such startling beauty.

## ROSES AND THEIR SCENT.

**T**HE Rose has formed the subject perhaps of more literature than any other flower; its history and cultivation have been so fully dealt with that it seems difficult to say anything fresh about it. But one, and that possibly the greatest of its charms, the scent, has of late been treated as a secondary quality to its colour, shape, habit of growth, &c.

A BEAUTIFUL COMBINATION OF RED DAMASK ROSES AND WHITE LILIES.

George Herbert asked "What is fairer than a Rose; what is sweeter?" and some of our critics will have it that we latter-day rosarians pay most attention to the first question and neglect the second. This may be true in a way, but I rejoice to see indications that the perfume, the "soul of the Rose" as someone calls it, is getting more consideration. I notice in Mr. Molyneux's notes on the latest gold-medal Roses that they are fragrant. Moreover, in one of the earliest catalogues to reach me this season, I find the fact of a variety being fragrant is dwelt upon as though the fact was really a big item to its credit.

For many years I have taken considerable interest in the scents of Roses, and, indeed, from their perfume have tried to speculate upon their parentage, and if this has not been a very profitable pursuit it has given an added pleasure to my walks in the Rose garden, which to those who, like myself, have grown Roses more years than we care to count is worth consideration.

There is no doubt that the scent associated with the Rose is the Old Cabbage or Provence perfume, found also in several old sorts of Roses, and no doubt this forms in a great degree the basis of the scent of our modern Roses. Most of our older red Roses possessed this scent in a greater or less degree, and I will mention a few of the sweetest old flowers that I can remember. Paul Ricant (Hybrid Bourbon), Baronne Prevost, Senateur Vaise, Alfred Colomb (Hybrid Perpetuals), and, later, Ulrich Brunner and Hugh Dickson. I name these haphazard, and readers will, no doubt, think of many more perhaps sweeter.

But with the multiplication of sorts, whether chance seedlings or so-called pedigree Roses, the old scent became blended in a number of ways, and one could almost form groups of Roses which from their scent, as well as other characteristics of growth, seemed to have common origin. To take the Victor Verdier race as an example. All these, such as Comtesse d'Oxford, John Hopper and others, including S. M. Rodocanachi, have the same odour, reminding one of a hock or choice white wine; in that giant Paul Neyron, a

sweeter perfume of the same character was to be found.

The Bourbon family seem to have a great range of scent, varying from the Malmaison type, in which I suspect the Musk, to Baronne Gonella, a very sweet Rose; Mme. I. Pereire and Zephyrin Drouhin, which, I think, is a Bourbon, perhaps one of the sweetest and latest flowers we have. There is a bunch on the table as I write (September 28).

Among the Teas we have several groups: The Dijon family, with their delicate, refreshing perfume; scarcely so sweet are the Mermets, which I should call pure Teas; then the Souvenir d'un Ami and its white sport. Mrs. Mawley has also a delicious odour.

To my mind the Watteville class, Mme. Cusin and Golden Gate, are almost the sweetest, and Comtesse de Nadaillac has a delightful perfume of its own. Is it possible that some of the sweetest Bourbon blood is intermixed with this class?

The Maréchal has been discussed lately in THE GARDEN, and Mr. Kemp, on page 469, says that its reputed parents were Isabella Gray and Solfa-terre. From my recollection of the latter I should say it was probable, if the evidence of scent has anything to do with it.

I am afraid to tackle the Hybrid Teas, both from consideration to the reader and from the bewildering varieties of scent we meet in this charming class, ranging from La France to the delicate perfume of Bessie Brown. Here, with Captain Christy, we get another hint of the Verdier type, and, alas! some of the scentless Roses. A very interesting group are the newer yellow Hybrid Teas. Mme. Ravary is very fragrant and Mme. H. Leuilliot has a strong apricot flavour, perhaps derived from the blend of Persian Yellow, which to some people is rather unpleasant in the original flower.

I must conclude this rambling paper, and will tell a true story rather *à propos* to my subject. Many years ago I was looking at a fine collection of Camellias; when the owner, an old lady, observed, "I think that really the betth of Camelliath ith, that they don't *thmell*." Long may it be before our Roses lose their scent!

J. T. STRANGE.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**THE FLOWER GARDEN.**—Owing to less satisfactory weather the flower garden is beginning to look untidy. Its appearance may be improved by a frequent gathering up of leaves and seared foliage. From this time forth hardy perennials should be planted, choosing dry days for this work. Readers who are beginners

1.—A COARSE, ELONGATED, HOLLOW-STEMMED SHOOT OF A PANSY WHICH IS USELESS FOR MAKING INTO A CUTTING.

should always remember to give each plant ample space for development. I make a rule to group the different subjects in colonies of three to six plants in each group. I am just lifting and dividing plants of London Pride. Dahlias should be lifted and stored away in a dry, cool shed or cellar as soon as the frost has cut them down. Other tender subjects, such as Begonias, Tigridias and Gladioli, should also be lifted and stored in like manner to the Dahlias.

**Roses.**—Our chief concern just now is to have the quarters that it is desired to plant in the near future ready for the

reception of our new Roses. If this subject is to do well, the quarters should be deeply dug and a heavy dressing of good manure incorporated at the time. I am thinning out the weaker growths of dwarf Roses, and in the case of the very strong growths that are retained I am removing about a third of each one.

**Hardy Fruit.**—What the winds have failed to remove I am now gathering as opportunity offers. Apples and Pears as they ripen or are ready for gathering are being carefully harvested. Take especial pains to avoid bruising the fruits. Strawberries that have been growing in pots for forcing I am now plunging under some rough protection. What is really needed is to place old frame-lights over the plants to ward off frosts and protect them from heavy rains.

**The Vegetable Garden.**—Make the most of all kinds of vegetable refuse by collecting and burning it. The soil of the garden may be enriched by dealing with the subsequent ashes as soon as they can be acquired. The last of our Potatoes have been lifted and stored, as no useful purpose can be served by leaving them in the ground longer. I make a practice of lifting and storing Beet and Carrots. They may be covered with a deep layer of sand, or stored in a cool cellar where ventilation can be afforded when required. A pit may be made outdoors in which to store these subjects if more convenient.

**The Cold Frame.**—These useful structures are now in frequent demand. Protection to the less hardy plants may be afforded by the cold frame at this season. I usually place the choicer bulbs that were recently potted up in cold frames,

covering these with cinder-ashes until they have made 1 inch or so of growth. Brompton and East Lothian Stocks when wintered in the cold frame give a much better display in the spring.

**Chrysanthemums.**—Complete the housing of all plants as early as possible. It is unsafe to leave any plants in pots outdoors longer, as severe frosts may seriously injure the buds and growths. Those who have a warm, sheltered quarter in their garden may group their plants in such a position, and in the event of a frost being threatened may protect the growths with a covering of light tiffany or scrim canvas.

**The Window Garden.**—No time should be lost in planting the window-boxes with bulbs; the earlier this is done the better. For indoor decorations I am placing bulbs in glasses and also planting others in bowls in fibre for the same purpose. This latter is a fascinating occupation, and the results are very satisfactory.

**The Greenhouse and Conservatory.**—Care in ventilating these structures is of the utmost importance at this season. When the temperature reaches about 55° the ventilators should be opened, closing them again in the late afternoon. The showy Hippeastrums should have water gradually withheld forthwith. Fuchsias, as they go out of flower, should be stored away under the greenhouse staging; very little water henceforth will be required to keep them in a satisfactory condition. Primulas and Cyclamen need a light, airy position at this season to promote their well-being. D. B. C.

## TOMATOES FOR FRUITING IN EARLY SPRING.

THE earliest fruits are obtained from plants raised from seed sown in September, or from cuttings of older plants propagated in October. Although many amateurs know how to raise plants from seeds, few, indeed, know how to do so from cuttings. Sometimes it is recommended that the tops of older plants should be taken off and put in as cuttings, but there are objections to this course. The tops are less vigorous than the side shoots; they are, furthermore, liable to fall victims to the dreaded disease sooner than the side shoots. There is also one more reason why the latter are the best to insert, namely, their tendency to make steady growth during the winter months and to commence flowering and fruit-bearing at a time when there is every likelihood of the crop being a most satisfactory one, viz., in early spring.

**How to Prepare and Insert the Cuttings.**—Select strong side shoots which are well exposed to the light on the old plants; these shoots should be about 6 inches long. Remove the bottom leaf and sever the stem immediately below it with a sharp knife; moisten the end and at once insert it, while wet, in a heap of dust-dry sand. The cuttings are thus made ready for inserting in the pots, which should be 3½ inches in diameter and filled with a nice light, sandy compost, free from old, exhausted soil which has been used for other purposes. One cutting will be sufficient for each pot, and it must be very firmly fixed in the centre.

**The Winter Treatment.**—Of course, a fair amount of artificial heat is absolutely necessary to successfully grow young Tomato plants in the winter-time, and, furthermore, bottom-heat is essential for the propagation of the cuttings so that they may quickly form roots. Plunge the

cutting-pots to their rims in a gentle hot-bed in a small frame. Give water directly the cuttings are inserted, but afterwards be very careful in this matter and only give water when it is absolutely necessary. When the cuttings possess roots take them from the hot-bed and grow them in a warm position and in as light a part of the house as possible consistent with plenty of heat. The young plants should be repotted before they become too much pot-bound, and be fruited in 9-inch pots. Use good fibrous loam, but not any manure. When the lowest trusses of flowers have set, the plants can easily be fed with artificial manures, and some superphosphate, at the rate of two teaspoonfuls to a pot, given twice in ten days and watered in will prove a capital stimulant and deepen the colour of the fruits. AVON.

## INCREASING THE PANSIES BY CUTTINGS.

THROUGHOUT September and October the Pansies, both the fancy and tufted types, may be propagated quite easily by means of cuttings. This is the generally recognised period when the work should be done, and there is usually an abundant supply of growths on the old plants from which desirable cuttings may be obtained.

The first consideration is making up the cutting-bed. At this period of the year it should be made up in a rather warmer aspect than would be the case were the cuttings taken a month or two earlier. Choose a position facing either south or south-west, if possible. Here the cuttings should root readily and be delightful plants for transferring to their flowering quarters in March or April next.

An ideal soil for the cutting-bed should comprise leaf-mould, sand and loam, or the ordinary garden soil in place of the last-mentioned, in equal quantities, passing these through a sieve with a half-inch mesh and well mixing the heap afterwards. This should then be levelled and made firm by pressing boards thereon or by the aid of a spade, so that the soil becomes fairly consolidated.

Those who have a cold frame should make up their cutting-bed therein; but four boards nailed together in the form of a square make a rough frame, and will answer equally well provided a rough frame-light or window-sash be used as a protection in moist or frosty weather.

The kind of material to acquire for making into cuttings needs some discrimination. In Fig. 1 an undesirable growth of the fancy Pansy is shown. This is a long, coarse shoot with a hollow stem, quite unfit for the purpose under notice, and for this reason readers should take care to avoid dealing with material of this kind. It is possible, of course, to root such pieces, but the chances are that a large proportion of them would fail entirely, and those that do survive would never possess much vigour.

2.—AN IDEAL SHOOT FOR MAKING INTO A CUTTING

3.—THE SAME SHOOT PREPARED  
READY FOR INSERTION.

In Fig. 2 we have a good illustration of the kind of growth that is required. Here, it will be noticed, the shoot is of recent development and not over-stout, but distinctly supple, from which ideal cuttings may be made. These are always to be found in a mass at the base of the plant, and at this season it is possible from a few old plants to obtain some

hundreds of cuttings before the propagating period is over.

Fig. 3 is the same cutting as represented in Fig. 2, properly trimmed and ready for insertion. The cuttings should never be more than about 3 inches in length; in fact, we prefer them rather less. The bracts, or leaflets, are cut off, as these often cause the cuttings to damp off, and the lower leaves are also removed close to the stem of the cutting itself. To complete the operation the stem is cut through immediately below a joint.

Fig. 4 is a sucker-like growth with several roots of recent development at its base. If the old plants are mulched with some light, gritty material and this worked well into the crown of the plant itself, in a week or two such little pieces may be broken out from the crown of the plant. In a little while these rooted, sucker-like pieces will develop into useful plants, so that their treatment is all the more simple in consequence and success assured. The cuttings and the rooted suckers should be inserted in rows in the prepared cutting-bed already described, observing a distance between each cutting of about 2 inches, more or less, and a similar distance, or rather more, between the rows themselves. In this way it is possible to insert some hundreds of cuttings in a comparatively small area. Should the weather be dry and sunny, cuttings must be sheltered from the sun during the daytime. Maintain a moist condition of the soil always—not necessarily a saturated condition—as this keeps at bay insect troubles, which invariably arise when the soil is dry and the conditions of the atmosphere are dry also.

#### ROSE PLANTING.

ALTHOUGH Roses may be planted safely any time between the end of October and February, providing due care be taken and we avoid moving them during severe frost, there is no gainsaying the fact that late October and during November are the ideal months. Having got the soil well turned over and manured, it is wise to plant as soon as possible, so that the whole may settle around the roots steadily before winter sets in. Failing to catch this chance, I would wait until February rather than plant when the ground is wet, cold, and likely to settle down harsh. It sometimes happens that the soil is very dry at the early digging up and the plants suffer a little from wood shrivelling. In such a case, water well around the roots as soon as a little of the soil has been placed upon them. Do not wait until the final treading up; the watering will not be so beneficial, and will have a tendency to cake the surface soil around the plant.

Manure should never be placed direct upon the roots; rather a little of the plain soil first and then the stronger on top of that. The roots thrive better if they have to grow 1 inch or so before they find it. Plant firmly, but do not ram the soil around the roots, and be careful

that they are spread out as much as possible. Bunching and crowding them is a great and common error.

The depth of planting needs a little consideration; 3 inches above where the bud was inserted upon the stock is a good depth for dwarfs, while standards are better planted about the same depth they were before lifting from the nursery garden. A little attention will show where this was, the portion of stem being plainly marked at the ground line.

How close to plant is too wide a question for this note; it depends entirely upon the class of plant and the object you wish them for. Nor can we give any sure guide as regards the different sections or classes, now that these vary so much even among themselves. Any time spent in trimming away suckers, even in their youngest stages, is well done now that they can be handled better; also cut back a few of the coarsest roots. If a drying time, especially from wind, sets in, afford a good syringing overhead twice a day so long as the wood appears distressed.

#### ROSES.

JUST a line about strong & weak (?) plants. Too many go into a nursery to choose the strongest plants without reference to the fact that they may be coarse and pithy in growth. A medium strong plant will transplant with greater safety and afford much better results. The wood is always better matured, and we generally get a sounder base. I have seldom known the Roses to ripen their wood in a more promising way than during this autumn. What most amateurs regard as a strong plant has frequently been grown in very rich soil, in order to get a large and showy plant, or to secure a few extra-sized blooms for exhibition. Such do not move well and thrive like one of medium strength transferred from loam to a well-prepared place in the garden.

A. P.

#### A BEAUTIFUL LILY.

THE name of a most beautiful Lily for the autumn, both for cutting and outside decoration, is *Lilium tigrinum* Fortunei. It grows upwards of 8 feet high, with a great profusion of flowers, and does well in the herbaceous borders or among hard-wooded plants, such as Azaleas, Rhododendrons and Kalmias. To be seen at its best half-a-dozen bulbs should be planted together in a batch and about 1 foot apart; the effect then is gorgeous. The long spikes should be tied up neatly to green Bamboo or other stakes, as, being so large, the wind will easily spoil them.

W. A. COOK.

#### PLANTING DAFFODILS.

WHEN these are grown in quantity it is necessary to lift a portion each year, especially when they are near large trees, and this lifting process should be in full swing now. Take up the bulbs with a fork; then trench the ground and add cow manure or bone-meal to make the soil rich. These manures will last several years. Then pick out all the best flowering bulbs and plant again thickly together. Take the smaller ones and plant in a rich border by themselves. The choicer varieties, such as King Alfred, Mme. de Graaff, White Queen and Lucifer, should have, in addition to bone-meal, some good sand placed under the bulb. This will keep the roots from decaying, especially in damp positions. Those grown in grass should be of the commoner type, as if not lifted they soon deteriorate, and are uninteresting except as a floral show. For individual beauty the bulbs must be taken up occasionally and the soil made rich by manuring. Narcissi will grow in nearly any soil for a season, but the best is a good rich loam. Emperor and Empress, pallidus precox, maximus, Sir Watkin, Stella superba, Telamonius plenus, Golden Spur, Horsfieldii and the Poeticus section are excellent

for massing for distant effect, and when planted in thousands have a charming effect. W. A.

#### HOW TO INCREASE BEDDING PLANTS.

DURING recent years hardy plants have become very popular, and for many reasons, chiefly, perhaps, owing to the beautiful and varied selection the planter has to choose from, and also from the fact that many of them may be grown entirely without greenhouses or frames. However, there are various sites in many gardens where the "bedders" still hold their own, and it would be difficult to produce a better (if as good) effect by the use of any other class of plants for furnishing the individual beds. It is often stated that as soon as the beds are at their best many of the plants are cut down and the effect is spoiled for the season. This, however, need not occur, for although a number of cuttings must be taken for propagation, this may be done without spoiling the plants. Certainly, if one cuts off the most prominent shoots from such plants as Geraniums, gaps would occur in the beds; but by carefully taking the cuttings from the most crowded parts of the beds a sufficient number may generally be taken without being missed. Before beginning to propagate, be quite certain, if possible, how many plants will be required for furnishing the beds next season; it is disappointing, when planting out begins, to find that the required number of plants is not at hand, while without careful calculation one may easily have too many of one variety and an insufficient number of others.

In the first place, prepare the soil, which should be light and contain a good proportion of silver sand. Pans, pots or boxes may be used. Generally it is best to use boxes or pans for the stronger-growing plants, and pots for such things as Ageratums, Iresines, &c. Drainage is essential, and must be provided both in pots and boxes, as wet, sour soil is most detrimental to the well-being of the cuttings. Make the soil firm and insert the cuttings with the aid of a small dibble, taking care not to place them too thickly, or they will probably damp off during the winter. Geraniums may be placed outdoors on a firm bed of ashes, damping them overhead occasionally and removing the dead foliage and any trusses of flower as soon as these are seen. Many of the other bedding plants may be readily increased by cuttings at this season, only they require the protection of a frame or bell-glasses, viz., Marguerites, Heliotrope, Tropæolum, Fuchsias, Abutilons, Coleus, &c.

During the winter keep the young plants near the glass, and admit all the air possible during fine, open weather. Do not keep the soil too wet; it is better to err on the other side, but, as with all plants, the happy medium is best. Good sturdy flowers will be produced if this attention is given them; but bedding plants are often looked upon as being too insignificant to require much care, and the result is that at bedding-out time very poor plants are at hand with which to furnish the beds. Good plants will give the best results, and will repay all the care bestowed upon them.

4.—A ROOTED SUCKER-LIKE  
SHOOT DETACHED FROM AN  
OLD PLANT. SUCH PIECES  
QUICKLY MAKE GOOD  
PLANTS.

## THE TOWN GARDEN.

**FRUIT IN TOWN GARDENS.**—Is it desirable that fruit shall be included among the crops grown in town gardens? Opinions differ widely upon the subject, and they are always in strict accordance with the modicum of success or failure which has attended the efforts made in this direction. Personally, I cannot acknowledge to much sympathy with it, for there are many disadvantages and comparatively few compensations. At the same time, I am bound to admit that friends of mine have grown some really good small fruits, and that in a few instances Apples and Pears are moderately satisfactory. The fact remains that fruits are grown by several townsmen, and it will, therefore, be appropriate to devote a little attention to the subject in this column.

**AUTUMN SOIL MANAGEMENT.**—One of the troubles of town gardeners, whether they be cultivators of flowers, fruits or vegetables, lies in the excessive drainage of the soil, the food both contained and put in it by intelligent manuring being washed away before the roots have had time to secure more than a tithe of it. This difficulty can never be properly overcome; but it is possible to do a very great deal by the consolidation of the surface and applications of manure in the autumn and the spring. On light soils, treading when they are fairly dry does an immense amount of good, but care must be taken in doing this on stronglands; they are preferably dealt with exclusively by manuring. The best method of conveying food to the roots is in the form of top-dressings of a mixture of manure and compost. To carry this out properly, the top 2 inches of old soil should be removed, the surface bared, carefully loosened and then the space filled in with the best material at command. Or, and simpler, the manure may be spread on the surface in the form of mulchings, taking care that it is sweet and in such a condition that it will not settle down into a close, pasty mass which will be impervious to air. If the appearance of this mulching is objected to, the owner has merely to dust on the top a little fine mould and all will be well. If the trees are not making satisfactory progress it may be necessary to apply strong liquid manure five or six times during the winter months; but judgment must be exercised in this matter, or coarse, unfruitful growth will assuredly result.

**PRUNING.**—It is not desirable to do a considerable amount of cutting each autumn, for the tree that is allowed to assume somewhat of its natural habit will invariably produce heavier crops of fruit. Of course, it is impossible to carry out this dictum in the case of trained trees, but with others it should always be kept in view. Whatever cutting is done should be limited, as far as possible, to the removal of misplaced branches and to thinning out in those places where there is the slightest suspicion of crowding, as it is imperative that full light shall have access to every bud upon the tree if the ripening is to be perfect. In all pruning it is essential that the habit of cropping of each tree shall be taken into consideration, as the indiscriminate use of the knife does more harm than good.

**PLANTING.**—In the probable event of fresh planting being necessary, the grower must observe one or two very simple rules, or he will not reap as rich a reward as he should do from his trees. In the first place, it is unwise to incorporate any manure with the soil in which roots are to be placed unless the land is absolutely impoverished, in which case only refuse material ought to be used. Rather than apply manure—the mechanical working of the soil must be as thorough as possible—sound loam should be worked beneath the roots and in between the layers, and necessary feeding can be done in the form of annual top-dressings of good manure. The soil must be well firmed about the roots, which ought to be spread out to their full extent in an outward and slightly downward direction. **HORACE J. WRIGHT.**

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### HARDY FRUIT GARDEN.

**APPLES FOR PLANTING.**—If the ground is being got ready as advised, the planting of fruit trees may be proceeded with as soon as the trees can be procured. It is a good plan to visit the nursery and select for one's self, and then no disappointment will follow, though I may say if the order is sent to a good reliable firm, they invariably send the finest trees and true to name. The following are twelve good varieties of Apples for cooking purposes: Lord Suffield (for August and September), Golden Noble, Peasgood's Nonsuch, Loddington Pippin, Warner's King, Lane's Prince Albert, Newton Wonder, Dumelow's Seedling, Blenheim Orange, Northern Greening, Norfolk Beaufin and King Edward VII.

A selection of Apples for dessert are: Irish Peach, Beauty of Bath, Quarrenden, St. Edmund's Pippin, Margil, Allington Pippin, Blenheim Pippin (small), Cox's Orange Pippin, Brownlee's Russet, Sturmer Pippin, Winter Reinette and Cockle Pippin. These are all well tried old favourites. Small trees for quick bearing should be on the Paradise stock, but for orchard planting I advise the free stock.

#### PLANTS UNDER GLASS.

*Allamandas*, *Caladiums*, *Ixoras*, *Clerodendrons*, *Gloriosa* and the like will now require a season of rest, and therefore water should be sparingly used and the temperature gradually lowered.

*Begonias* of the winter-flowering section, on the other hand, require a little more heat and close attention to watering, staking and tying. *Poinsettias* should now have a little more heat, and if the pots are well filled with roots a little manure will be beneficial. It is better to manure now than later. Continue to pot up bulbs for winter flowering.

#### FRAMES, PITS AND COOL HOUSES.

*Chrysanthemums* must now all be housed and any tender subjects put under cover of frames; but the lights should be drawn off on all fine days from early morning till as late as possible at night and, if frost is not expected, the lights should be tilted up during the night; in fact, do not coddle any plants at this season but give all the air and light possible.

*Border Carnations*, in places where they will not stand the winter, must be potted up and placed in a position where they can be afforded protection at any moment, and finally arranged in cool frames on a bed of ashes.

#### FLOWER GARDEN.

*Herbaceous Borders* must be kept clean and the plants staked, as the *Asters* or *Michaelmas Daisies* will keep the scene bright for some time to come. All the bedding plants of a tender nature may be now displaced by the winter section. The beds should be dug up and manured before *Wallflowers*, *Pansies*, *Polyanthuses* and bulbs are put in.

#### ROCK AND ALPINE GARDEN.

*Primulas* may now be divided and replanted, especially *P. viscosa*, *P. rosea*, *P. minima*, *P. denticulata*, *P. pulverulenta* and such varieties as *Primrose Miss Massey*, *Goldilocks* and *Sparkler*. Replant anything in the way of *Saxifrages* that may require it and use plenty of grit in the fresh soil. *Androsace* should be kept from the wet as much as possible—especially such varieties as *A. sarmentosa*, *A. villosa* and *A. Chumbyi*—and a little stock of these should always be retained in the reserve frame to provide against accidents.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*BEGONIA GLOIRE DE LORRAINE.*—This useful flower will now be growing apace, and the necessary tying and staking must be attended to. Light feeding may also now be given. Liquid farmyard manure, or, failing this, a slight dusting of Clay's Fertilizer, on the surface of the pots should be used. The same remarks regarding feeding will apply to the other varieties of *Begonias* now being grown for flowering purposes.

*Solanum jasminoides.*—The flowers of this charming creeper are freely produced, and are very useful at this time of year. Usually it is grown as a greenhouse creeper, which gives a pretty effect if trained across the principal rafters of span-roofed houses and the flowers allowed to hang down in a natural way. There are also a number of conservatories with high and bare back walls; these this plant would cover rapidly. Wherever such positions as those noted exist, I strongly advise the planting of this *Solanum*. It delights in moisture both in the atmosphere and at the roots, and the more freely it is allowed to ramble, the better will be the effect when in flower.

#### THE HARDY FERNERY.

Now is the best time of the year for planting Ferns out of doors, as, their season's growth having been made, they will bear removal better than when in a growing condition. There is little risk of injury provided reasonable care is exercised. When replanted in October the plants have an opportunity to make roots and become established by the spring. All Ferns should be removed and replanted with as many roots as possible. At this season also division of the crowns and rhizomes may be safely accomplished.

#### FLOWER GARDEN.

*Housing Tender Plants.*—It is quite time that all plants be housed which one is anxious to keep, such things, for instance, as *Palms* in variety, *Grevilleas* and any specimen plants more than ordinarily tender, such as *Heliotropes*. Where this work is in progress, it will be advisable to lift any inmates of the flower garden required for potting up. A batch of the *Paris Daisies* will come in very serviceable and furnish a good supply of flowers when the frost has made an end of nearly everything outdoors. If lifted carefully, well soaked and placed in a late Peach house in partial shade, they will feel little of the effect of their removal.

#### HARDY FRUITS.

*Figs.*—The crop on open walls has this season been very good, and now the fruit is cleared there should be no delay in preparing the trees for the winter, as I attach more importance to thorough ripening of the wood than to coddling or covering to preserve that which is only half matured. It is the embryo fruits at the points of the shoots which require light and air. All useless fruits should now be removed, also shoots and lateral growths which cannot be attached to the wall.

*Black Currants.*—Where it is contemplated making new plantations of these the work should now be taken in hand. To obtain fine *Black Currants* it is necessary for the bushes to make free growth, for, as the fruit is produced on the young wood, the more robust this is the larger the bunches and finer the berries. Where young bushes have been prepared they may now be carefully lifted with balls of earth and transplanted, when they will not fail to give a crop the next season. I think more attention should be paid to bush fruits; they are profitable, wholesome and give less trouble than the fruits of the orchard.

T. B. FIELD.

(Gardener to Baroness Berners.)  
*Ashwellthorpe, Norwich.*

## NEW PLANTS.

**ODONTIODA CHARLESWORTHII** GOODSON'S VARIETY.—This is an improved form of the beautiful *Odontioda Charlesworthii* which created so much interest at the last Temple Show. The flowers of this variety are larger than the type, and the crimson colour is also deeper, the rich yellow blotch on the lip being very pronounced. Shown by Mr. H. S. Goodson, Putney. First-class certificate.

**Cypripedium Bianca superba**.—A reputed cross between *C. Prospero* and *C. insigne* Sanderae, this handsome Lady's Slipper partakes largely of the last-named parent. The flower is of medium size, the ovate lanceolate petals being rather narrow and waved at the margins. The pouch, or lip, is rather drooping and very evenly formed, both petals and lip being of a uniform clear canary yellow. The dorsal sepal is large, somewhat hooded and of the purest white except at the base, where the colour is green. Shown by Lieutenant-Colonel G. L. Holford, C.I.E., C.V.O., Tetbury, Gloucestershire. First-class certificate.

**Cattleya Rutilant**.—This is a very beautiful addition to this large family. The flowers are large, the sepals being rather narrow and lanceolate, with reflexed apices. The petals are nearly twice as broad and beautifully crimped at the margins, the colour of sepals and petals being scarlet crimson. The labellum is large and spreading and of the richest velvety crimson hue, with faint yellow striation in the throat. The flowers are very fragrant. Shown by Messrs. Maron and Sons, France. First-class certificate.

**Cattleya Venus**.—The result of a cross between *C. Iris* and *C. aurea*, this plant partakes of both parents, but more largely of the first-named. The lanceolate sepals and broader petals are of a deep orange golden hue, and the broad reflexing labellum is rich crimson striated with gold, the canary yellow column being very prominent. Shown by Mr. H. S. Goodson, Putney. First-class certificate.

**Laelio-Cattleya Golden Oriole** Goodson's variety. This is a charming improvement on the original variety. The dull crimson ground colour of the sepals and petals is marbled over with orange, the lip being a deeper crimson colour and comparatively broad, deep yellow venations running well into the throat. Shown by Mr. H. S. Goodson. Award of merit.

**Oncidium incurvum**.—A large plant carrying sixteen tall racemes was shown. The flowers are small, the colour being a mixture of purple and white. They are borne rather loosely in compound racemes, which have the habit of incurving towards the centre of the plant. Shown by Baron Schröder, The Dell, Egham. Award of merit.

**Sophro-Cattleya Sara Westonbirt variety**.—The plant exhibited was a very small one carrying a single flower. The sepals are lanceolate and pointed, and stand out stiffly from the centre. The ovate petals are very broad with plain margins, the colour of both sepals and petals being dull purple. The labellum is small, of rich crimson purple, with a beautiful deep golden throat. Shown by Lieutenant-Colonel G. L. Holford. Award of merit.

**Nepenthes Dr. John Macfarlane**.—This handsome hybrid is the result of crossing *N. sanguinea* and *N. Curtisii superba*, from both of which it is quite distinct. The foliage is distinctly broad and leathery to the touch, the depending pitchers, which are among the largest of their kind, being of a blood red externally. The broad, deeply-lobed recurving rim is of yellow and crimson, and in strong contrast to the mottled character of the visible interior of the pitchers. From Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

**Pennisetum japonicum**.—A distinct, elegant and ornamental Grass, quite hardy and of perennial character. In some respects the established

clumps may be likened to the graceful *Eulalias*, and the brownish-white-tipped inflorescences of columnar outline render the species exceedingly attractive and beautiful. From Mr. Amos Perry, Hardy Plant Farm, Enfield. Award of merit.

**Selaginella emilliana aurea**.—A pleasing variety with leafage of a golden tint. The variety is of sub-erect habit, the fronds not more than 6 inches in length and of extreme beauty, by reason of the delicate tracery which characterises the plant. From Messrs. J. Hill and Son, Edmonton. Award of merit.

**Carnation Winona**.—An American variety of a clear rose pink shade, the flowers emitting a pleasing if delicate fragrance. From Messrs. R. H. Bath, Limited, Wisbech. Award of merit.

**Viola cornuta purpurea**.—We can only describe this charming variety as an ideal bedding plant, one well suited for massing in beds or borders, free in growth and profuse in flowering. It is not more than 6 inches high, of the true tufted type and rarely, if ever, producing seeds. The plant is content to flower for months together, in this way creating a picture of clear violet-purple that is not rightly conveyed by the varietal name given above. From Messrs. Gunn and Sons, Olton, Warwickshire. Award of merit.

## NEW DAHLIAS

The following new Dahlias came before a joint committee of the National Dahlia Society and the Royal Horticultural Society, and are thus entitled to the first-class certificate of the former and the award of merit of the latter body in each instance:

**Elsie Turner** (Cactus).—A yellow buff with pale fawn shading.

**El Vino** (Show).—The well-formed flower is of rosy lilac hue and very distinct.

From Mr. S. Mortimer, Farnham, Surrey.

**Monarch** (Cactus).—The flower is of a uniform pale orange with gold centre. From Mr. J. Burrell, Cambridge.

**Nellie Riding** (Cactus).—A very showy variety of crimson red tone, lightly touched white at the tips. From Mr. J. T. West, Brentwood.

**Norah Reynolds** (Pompon).—Small, well-formed flower of reddish hue.

**Lady Bountiful** (Single).—Rosy lilac, the base of the petals crimson. From Mr. M. V. Seale, Sevenoaks.

**Wellington** (Cactus).—Self crimson, save for the white-tipped florets.

**Satisfaction** (Cactus).—A clear and beautiful rose pink shade, approaching to white at the centre.

**Saxonia** (Cactus).—The flower is of ruby or wine colour, with purplish tips. This set of three were exhibited by Messrs. James Stredwick and Sons, St. Leonards.

## NEW FRUITS.

**Grape Prince of Wales**.—This is a high-class sport from the well-known variety *Mrs. Pince*, and can scarcely be regarded as a new variety, as it was shown last year and received an award of merit. The berries are large, black and slightly oval, and finish remarkably well, the bunches being long and tapering. The flavour is brisk and slightly Muscat. Exhibited by the

Royal Horticultural Society and granted a first-class certificate by the fruit and vegetable committee.

**Apple Renown**.—This is the result of a cross between Peasgood's Nonsuch and Cox's Orange Pippin. In appearance it partakes of the first-named most, but it has a considerable amount of the fine flavour of Cox's. The flesh is pale yellow and very firm, and it should prove a good Apple, both for dessert or culinary purposes, although it may be regarded as too large for the first-named purpose. Shown by Colonel Archer Houlton, Welford Park, Newbury (gardener, Mr. Charles Ross). Award of merit.

## MISCELLANEOUS.

## THE LEAF-CUTTER BEE AT WORK.

If you allow it to go about its business undisturbed it is as likely as not to commence operations in the window-casing inside the room, and then you can watch it daily bringing its clean-cut sections of Rose leaves wherewith to line its tunnel.

THE WORK OF THE LEAF-CUTTER BEE.

For that is what it cuts the Rose leaves for; and there are few more marvellous things in Nature than the ingenuity with which it cuts the sections of different shapes, using an oval one to line the bottom of the hole, so that when rolled it will make a sort of cap to line the extreme end. Next to that, and until the tunnel is lined throughout the length, semi-circular pieces are used, which roll neatly into mere tubes, without any surplus to make an end cap; and finally, it seals the top with a circular piece which fits as neatly as if it had been stamped out with a die. Of these it often uses four or five, in layers one upon the other, till the lodge is tiled to its satisfaction. One tunnel may contain five or six of these cells, each capped, lined and sealed with the same care, and each full of pollen-and-honey food for the young bee larva which will emerge from the egg which is laid in every cell. Finally the mouth of the tunnel is stopped up with earth.—*Country Life*.

## BLACKBERRY PRESERVE AND ROWAN BERRY JELLY.

At this season of the year, when Blackberries are plentiful, the following recipe can be highly recommended for an excellent preserve made from this wild native fruit. Take any quantity of ripe Blackberries and simmer them in a preserving pan over the fire until quite tender and juicy. Remove them from the fire and rub them through a hair sieve or coarse cloth, so as to get

all the pulp and juice through but extract the seeds. To every pound of pulp and juice add half a pound of crushed lump sugar, and boil quickly for half-an-hour. The preserve is much improved by adding a few Sloes to the Blackberries, which must be simmered with them, and also rubbed through the sieve, just to give a zest to the flavour; but not more in proportion than half a pound of Sloes to five pounds of Blackberries. The jelly made from the berries of the Rowan tree is a favourite delicacy in the North of England, but is very much condemned in Switzerland, where it is said that any concoction from the juice of these berries will "take away the memory." A myth, of course, as it is freely used in Scotland, and Scotch memories are not usually considered short. This jelly can be made in the same way as in the old recipe for American Crab jelly, and is used for dessert with biscuits, or as a substitute for Red Currant jelly with roast mutton. In the "North Country" it is usually taken in preference when handed at the same time. It does not seem to make its way South, as it is never seen in London.

MARTLET, in *Country Life*.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Herbaceous borders** (E. A. Vandets, Zeist, Holland).—In England the herbaceous border is most usually reserved for perennial herbaceous plants; that is, plants which live for several years and produce flowering stems each year. In such a border the annuals and other plants raised each year from seeds rarely find a place, but are grown with a very great variety of other plants, as annuals, biennials and those tender subjects like the Dahlia, in what we recognise as the "mixed border." In the "mixed border" all kinds of plants may be used very effectively, from the annual of 1 inch or 2 inches in height to the tallest-growing perennials, such as Hollyhocks. In this border, too, a display of the Rambler Roses is quite permissible, and these in early summer make a capital show. Please write again if you think we can further assist you by giving a list of suitable plants in either case.

**Stocks falling** (W. McGain).—The Stocks have been attacked by a fungus growth about the stem at ground level and slightly below, and the fungus encompassing the stem and permeating the tissues causes the collapse of the plant. The fungus growth is hastened by damp about the surface and deep planting. Keeping the plants moderately dry and giving an occasional dusting of air-slaked lime on the ground surface may prove helpful in the future. For the open garden, if you cannot plant in a fresh position, another year give a good winter dressing of lime and avoid manure.

**Dahlias in pots** (A. G. Gordon).—Pots 10 inches in diameter across their tops usually suffice for pot Dahlias. The soil should be three parts good turfy loam, the rest being old hot-bed manure and sharp white sand, well mixed and made fairly firm in the pots. Any Pompon varieties will do well, and a few good Cactus forms are Amos Perry, Mary Service, J. B. Ridling, Mont Blanc, Mrs. Carter Page and J. W. Wilkinson. But you would perhaps find the Pompon Cactus section better suited for pot culture; any of these should do well in pots. To have Dahlias in flower by the middle of July, you should get

plants in during April and pot up under glass during May. Your *Nigella* seed-capsules when ripe should give seed that will reproduce the variety true next year.

**Bedding Pelargoniums diseased** (W. J. C.). Your bedding Pelargoniums are attacked by what is known as the Pelargonium stem-rot, a fungus which bears the name of *Fusarium pelargonii*. It makes its home in the tissues of the plant, so that a good deal of the mischief is done before there is any external sign of the disease. It is of comparatively recent date, for it was first described by Dr. Cooke twelve years ago, since when it has gradually become more destructive. Whether the spores remain in the soil is at least an open question, but all diseased plants must be at once burned, and it would be decidedly risky to propagate from those that have been associated with them, as some, at least, may contain the germs of the disease. At first this pest was principally found on highly-fed plants, and it is probable that the softened condition of the tissues set up by stimulants will predispose those so treated to the attacks of this fungus. Deep planting, too, encourages the disease. Spraying the plants with Bordeaux mixture has been recommended with variable results.

### TREES AND SHRUBS.

**Cultivation of *Metrosideros floribunda*** (Colonel W. E. G.).—This is a native of Australia, and in common with plants from that Continent it needs the protection of a greenhouse in this country. The treatment given to the general run of hard-wooded plants will suit it well; that is to say, it needs during the winter a structure in which the thermometer ranges from 45° to 55°. The roots are of a rather delicate nature, so that even during the winter the soil must not be allowed to get too dry; at the same time an excess of moisture must be avoided. With regard to water it should be treated much the same as an Indian Azalea. Then it usually flowers during the spring and early summer months, and if any shortening back of straggling shoots is necessary this should be done directly the flowers are past. As soon as the cut-back portions begin to break into new growth is the time to repot, that is, if repotting is necessary; but the *Metrosideros* may be kept in good condition for years without being repotted. In that case the roots should be occasionally given a gentle stimulant, such as weak liquid manure and root-water mixed, during the summer months. If repotting is to be done, a mixture of two parts of peat to one part of loam and nearly half a part of sand will form a suitable compost. After potting, the plants must be kept in the greenhouse till the roots take possession of the new soil, after which they may during the summer be stood out of doors, taking care that they are well supplied with water. It may be mentioned that though the name of *Metrosideros floribunda* is to be found in gardening books, it is not now used by botanists, who give it the name of *Callistemon salignus*.

**Soil for Azaleas** (Rema).—The Azaleas concerning which you enquire will thrive equally well in peat alone, or a mixture of peat and leaf-mould. A mixture of sandy loam with the peat will be also equally suitable for them.

**Rhododendron flowers for inspection** (J. A.).—We can find no trace whatever of fungus on the *Rhododendron* leaves, but on the upper surface they are studded with minute particles of a wax-like secretion, which is by no means unknown among *Rhododendrons* and will do no harm.

**Specimen** (Malvern).—Four good deciduous trees for specimens, in addition to those you have, are *Crataegus Crus galli* prunifolia, *Robinia decussata*, *Æsculus carnea* Briotti and *Ginkgo biloba* (the Maidenhair Tree). The first three are flowering trees, while the first-named fruits well in autumn and the leaves take on brilliant tints previous to falling. The Maidenhair Tree is a very interesting and ornamental subject, but of rather slow growth when young. If you think it too slow for you, *Pyrus spectabilis* fl.-pl. is an excellent flowering tree, while *P. baccata* flowers and fruits well. You omitted to enclose your name and address.

**Information about Wistarias** (P. S. M.).—All the Wistarias named will grow well if trained to a high east wall, but we are afraid that they would not flower in a satisfactory manner. Presumably the plants will get the early morning sun, and in the event of sharp spring frosts the flower-buds are sometimes injured by the bright sun shining on them when frozen. This applies particularly to *W. sinensis*, for *W. multiflora*, being later in blooming, is not so liable to injury. We should be inclined to try a plant of *W. multiflora*, while other climbing and wall plants likely to flower well under the conditions named are: *Forsythia suspensa*, *Hydrangea petiolaris*

(*volubilis*), *Pyrus* (*Cydonia*) *japonica* in variety, *Jasminum nudiflorum*, *Crataegus Pyracantha* and *Viburnum plicatum*, which, given the protection of a wall, will soon mount upward.

### ROSE GARDEN.

**Rose plants dying** (Dorothy W.).—The larger of the two plants sent was, in our opinion, dead, or nearly so, when planted. Its roots are quite black. Probably the plants had been injured by frost before you received them, and they would not show this in the wood all at once. The small plant, presumably of Liberty, had healthy-looking roots, and we can only believe its condition was owing to its very small size and weakly growth. It would have been best if the plants had been hard pruned the first year, cutting them down to within 1 inch or 2 inches from the ground. Roses of this description always turn out best when this is done. They may have suffered after planting. It is always best to go over the beds about a week after planting and make the soil firm against their roots by pressing it with the heel; and if planted in spring some water should be afforded. We also noticed that the roots had not been trimmed. In the large plant these should have been shortened considerably. The best plan would be, as several plants are dying, to replant the bed in October or November, and then make sure that the roots when cut are white and healthy-looking.

**Rose blooms per post** (E. T. Barrett). As everyone knows, the Rose is not a good flower to last when cut, but it can be considerably aided if some simple rules are adhered to, and this is especially necessary when one has to send Roses a long journey per post. The flowers should be cut in the early morning, say, before seven o'clock, and immediately placed in a large vessel of water with their stems well in the water. Place them in a cellar or other cool place in the dark and allow the flowers to remain there until the evening. In packing them for post flat boxes should be used, those about 3 inches deep being the best. Some long grass is placed in the bottom of the box and the sides lined with thin paper. A little mound of grass is laid at one end and the flowers placed one at a time thereon, and when the row is finished start another, and so on until the box is full. A slight sprinkling with water will suffice, and then the paper is folded over the blooms and a thin piece of stick placed across close on to the stalks of the last row. This stick should fit tight into the sides of the box, and if so it prevents the blooms from moving. The box may be enclosed in brown paper if preferred. The great secret of success is to have the flowers about half open, and also to see that they are well charged with water before packing, and only place one layer in a box.

**Pot Roses and their treatment** (J. T. Cross). The best success is obtained from pot Rose culture when a greenhouse can be utilised entirely for them, but when they have to be grown with other subjects the matter is rather more difficult. We do not know what convenience you have for growing pot Roses, but as you ask for twelve names only we presume you will grow them in a mixed greenhouse. The best time to procure plants would be in October or November. These should be what are known as extra sized in 8-inch pots. Such plants are practically ready for forcing. All you would have to do would be to remove about an inch or two of the surface soil and replace this with some loam and well-decayed manure in equal parts. Having done this, keep the plants in a cold pit until ready for starting them into growth. We recommend pruning them in February, but they may be pruned earlier if you desire them to bloom early. It usually takes about twelve weeks from the pruning to the blooming. We advise chiefly Hybrid Teas with a few Hybrid Perpetuals. The Hybrid Teas should be pruned to about 12 inches from the top of pot, the Hybrid Perpetuals to about 6 inches. Where possible, prune to an eye pointing in an outward direction. At first very little water is needed, but plants should be syringed on bright mornings. When new growths are about 1 inch long give the plants a good soaking with water, and after this keep them evenly moist, but not too much so. Watering pot Roses is a most important detail. It is best to tap the pots with a stick, and if they give out a bell-like sound water should be afforded. It is in the early stages of growth that most care is needed. When the buds begin to form and foliage is ample, they can utilise much more water, and would

suffer if it be withheld. Liquid manure may be given when the bloom buds are about as large as Peas, and continued once a week until colour is seen. Good liquid manure can be made from cow manure and soot. Put a bushel of the former and a peck of the latter into separate bags and drop them in a tank or cask holding about 50 gallons of water. When soaked two or three days the liquid can be mixed with twice the quantity of water. As growths develop, tie them to small sticks, so that a uniform disposal of the shoots is maintained. When green fly or aphids is seen fumigate with Tobacco. This may be safely done by using Tobacco sheets or fumers, one of which is sufficient for 1,000 cubic feet. Repeat the fumigation whenever required. Do not allow green fly to gain much hold, as it makes the plants in a very dirty state unless checked. Mildew in very troublesome in pot Rose culture, but this may be checked by syringing the foliage with carbolic soap, half a bar of Lifebuoy soap to 3 gallons of soft water, applying it with a fine sprayer such as an Abol syringe. Be careful with the temperature. Start with about 45° at night, rising to 50° to 55° by day. As the growths advance, 50° to 55° by night would be about right, and 55° to 60° by day. If sun comes out brightly the glass will rise higher than this, but it will do no harm if the plants have been syringed and a nice moist atmosphere maintained. A dry, parched atmosphere is what pot Roses object to, and this is a sure encouragement to red spider. When this pest appears the Roses soon lose all their foliage and are considerably injured. We hope to have articles dealing with pot Rose culture before the time arrives. Twelve good varieties to start with would be: Hybrid Teas—Mme. Abel Chatenay, Richmond, Antoine Riviere, Jean Holé, Caroline Testout, Lady Battersea, Joseph Hill, Le Progrès and Florence Pemberton. Hybrid Perpetuals—Frau Karl Druschki, Ulrich Brunner and Mrs. John Laing.

**Red rust on foliage (Kames).**—This is a very common fungoid pest which visits most Rose gardens in late summer, and is especially troublesome upon the red-flowered and thorny-wooded Hybrid Perpetuals. It is very common also on the wild Briar in the hedgerows. To prevent this disease appearing another season it is necessary that all leaves bearing the winter spores should be collected and burned. If every leaf from the bushes and also those decayed on the ground were collected and destroyed, there would be little or no trouble next season. It is well in the spring, just as the foliage is expanding, to spray them with potassium sulphide, but there is little use in attempting any remedial measures now beyond destroying the foliage as it drops. If the Roses are not too old, it would be a good plan to transplant them in October to a new position, or replant them in the old position after well trenching the soil.

**Rambler for successional flowering (Yoshig).**—We have pleasure in giving the names of some of the best ramblers for your arches, and have grouped them in three sections, viz., early, medium and late. Some of these in the late section would flower both early and late. Early: Carmine Pillar, Ruby Queen, Electra, Euphrosyne and Waltham Pride. Medium: Gardenia, Rubin, Alberic Barbier and René André. Late: Hiawatha, Dorothy Perkins, Lady Gay, Blush Rambler, Longworth Rambler, Mme. Alfred Carrière and Griss and Teplitz. Dark red Roses for bedding.—This is a colour of which our collections are at present very meagrely supplied, but the following are the best: Liberty, Richmond, Princesse de Sagan, \*Louis van Houtte, \*Victor Hugo, \*Duke of Wellington, \*Alfred K. Williams, \*Hugh Dickson, \*Ella Gordon, \*Charles Lefebvre, Charlotte Klemm and Cramoisis Supérieure. Those marked with an asterisk are Hybrid Perpetuals and would not be so free-flowering in the autumn; but, unfortunately, there are no good dark bedding Hybrid Teas beyond those we have named. Griss and Teplitz would be a grand sort, only its growths are very strong. It could be pegged down or transplanted each year and replanted in the spring. This has a tendency to keep it dwarf, and when this can be done it is one of the best dark bedding Roses. Some of the Hybrid Teas and Chinas named are not dark red, but they are the nearest we can name.

## FRUIT GARDEN.

**Black Alicante Grapes splitting (Chas. W.).**—The split berries, we notice, are smaller than the normal healthy ones. We think the former must have been affected in their younger stage by a touch of mildew, which interfered with their growth and hardened the outer skin, preventing it distending as growth developed, hence the splitting, especially after heavy watering. The disease on the berries is also, we think, the result of an attack of some species of mildew. We advise you to cut out all the split berries and the worst of the diseased ones, and then dust the bunches carefully with flowers of sulphur when dry and blow it off again with a pair of bellows at the end of the third day; it will not hurt the Grapes if done with care. This application of sulphur will arrest any further progress of the disease, thus also preventing its spreading to the other Vines. The Vine leaves sent

have the appearance of having been burnt some hot, sunny morning before adequate air had been given to the vinery. Ventilate freely in warm weather now the Grapes are colouring and putting on their last swelling. Leave a notch of air on the ventilators top and bottom all night, and provide slight heat in the pipes to cause buoyancy and help the circulation of air.

**Manure for fruit trees (Yoshig).**—A good dressing in the autumn with basic slag would be an economical and efficient fertiliser for your fruit trees, and this could be followed in February by a liberal application of bone-meal. Fruits require good phosphatic manures, and the above would supply this. As the soil is light, some cow manure placed on the surface in autumn and dug in in spring would assist it to retain moisture.

**Caterpillars on Gooseberry and Currant trees (Tibston).**—Your Gooseberry and Currant trees are apparently attacked by the saw-fly caterpillar. To prevent an attack the best way of destroying them is by the removal in autumn or winter of 3 inches of the surface soil from under the trees, where most of the larvae are concealed, burning the same or burying it deeply. Burn all cuttings and decayed leaves as well, afterwards adding a top-dressing of new soil and manure in equal proportions to make up for that taken away.

**Melons to fruit in latter half of September (Ernest Moon).**—Melons take from twelve to fourteen weeks from the time the seed is sown until the fruit is ripe; therefore, to have them ripe at the latter part of September, the seed should be sown about June 12. Early in September it can be ascertained whether the fruit is a trifle forward or late for the time it is wanted by its size and appearance, and if too late it is an easy matter at that time of the year to apply a higher temperature to hasten it on, or, on the other hand, to retain its growth a little by the withholding of heat. Varieties: Hero of Lockinge, white flesh; Blenheim Orange, scarlet; Windsor Castle, scarlet.

**Young Grapes decaying (H. S. O. B.).**—Your Grapes are suffering from a bad attack of a disease which is termed "scalding." It is called by this name because the berries of the Grapes suffering from its effects have the appearance of having been parboiled or scalded. It is caused through late or imperfect ventilation on some bright and sunny morning while the internal atmosphere and even the berries are saturated with moisture. To check its ravages now and to prevent its recurrence next year, recourse must be had to freer ventilation, especially at the stage of growth (stoning) your Grapes are now at. A little chink of air should also be left on all night (both top and bottom ventilators), and it is a great advantage to have a little heat in the pipes at night. This keeps the air constantly moving and prevents the deposit of moisture on the berries.

**Peach and Nectarine trees in a cold house not setting their fruit (M. E. Dobbs).**—The primary cause of your young Peach and Nectarine trees not setting their fruit freely is their making so rampant and strong a growth, which it is difficult and almost impossible to ripen properly. As a consequence the fruit-buds are not properly developed and matured, the result being that the flowers are weak and generally devoid of abundance of healthy, strong pollen. This is also the cause of split stones. We advise you to lift and replant your trees towards the end of October, or as soon as they have cast their leaves, adding some maiden turf loam and a good sprinkling of lime to the soil, but no manure. The largest roots should be shortened by one-third their length and the others slightly shortened. The replanting should be carried out in dry weather, and care must be taken to place the soil carefully and firmly round the roots with the hands as the work proceeds, finishing by giving the trees a good soaking of water. The result will be that you will have as good a crop next year as you would had the trees not been lifted, and in addition you will have laid a foundation for the subsequent constant fertility of your trees. During fine weather from now onwards the trees must be exposed to ample and free circulation of air day and night, and as soon as the fruit is gathered open the ventilators wide and let them remain so night and day, unless the weather should be very rough. It would be better for the trees if all the roof-sashes could be taken off and remain off during the winter, and so expose the trees to the beneficial action of the weather. Where the drainage is good, Peaches like plenty of water at the roots while they are growing freely. As a rule a thorough soaking of the soil once every ten days will suffice. It is a serious mistake to let water run on the border through a hose for an indefinite time, as it not only chills the soil, but it impoverishes it as well by washing away many fertilising ingredients. During the summer it is a good plan to place a mulch of rotten manure over the surface of the soil as far as the roots extend. This not only conserves the moisture in the soil, but also nourishes the trees and helps considerably to lessen the volume of water required by them. The time of flowering and setting is the most precarious and anxious time in the whole year in the cultivation of the Peach. The best thing to do is to try and imitate Nature. The Peach when grown out of doors is never known to drop its buds or seldom to have split stones; therefore expose your trees to all weathers during winter, excepting, of course, when it may be very stormy and over-wet. Continue this treatment until the trees come into bloom, and even then keep the houses cool with a little air on top and bottom day and night. If danger is feared from hard frost let the roof and

sides be covered with mats or some other material, but do not quite close the ventilators. The temperature must be kept low while the trees are in bloom, and each bloom should be fertilised by the pollen of another being placed against the stigma of the flower operated on. As soon as the fruit is properly set the house may be kept warmer and less freely ventilated. All your Nectarines are good varieties. You might substitute Barrington Peach (a fine late variety) for Elruge Nectarine, also Violette Hative Peach for Early Grosse Mignonne.

**Stone splitting in Peaches (H. P. B.).**—This is a common complaint and, from observations we have made, seems more prevalent than usual this year. The cause is imperfect fertilisation while the trees were in bloom. The most effectual remedy to adopt is to take a hive of bees into the Peach house at the time the trees are in flower, or, failing this, have a rabbit's tail tied to a stick and draw it gently over the flowers. This will help to secure the pollen coming in contact with the stigmas of the flowers, without which fertilisation is impossible. Heavy rains are the cause of the Plums cracking.

**Nectarines and Tomatoes (Alpha).**—The cause of split stones in Nectarines is defective fertilisation of the flowers. You should carefully inoculate every flower by removing some pollen from the anthers and placing it in contact with the stigma, or if you keep bees place a hive in the house at the time the trees are in flower. Possibly, also, your soil may be deficient in lime. You would be safe in applying some to the soil this winter, as it is indispensable to the successful growth of all stone fruits. The weather must be more or less responsible for the Tomatoes splitting, alternating so frequently between wet and fine and cold and warm, and possibly too much moisture at the roots. The contracting and hardening of the skins of the Tomatoes and their turning a dirty brown or yellow colour are no doubt the result of an attack of Tomato fungus. This is brought about generally by planting in the same soil several times over, so that the soil becomes Tomato sick and often inoculated with the spawn of the fungus. Be sure and plant in new soil next year, adding a liberal sprinkling of lime, and do not plant too thickly in the ground.

**Plum trees not bearing and how to prune them (Plum Trees).**—Plum trees growing on walls are made of many main branches. It will simplify matters if we endeavour to show you how to prune one of the main branches, because each branch has to be treated in the same way. Start at the bottom of each of the main branches and cut back all the side shoots which grow from them to within five leaves of the main branch from which they start. When you come to the end or leading shoot, which may be anything from 1 foot to 2 feet long, cut a quarter of its length back. This is called summer pruning, and should have been done at the end of July, and it is all that is necessary to do at the present time. Winter pruning consists chiefly in cutting back the same side shoots which have been cut at summer pruning, this time to within two buds of their base. This will result in fruit buds forming at the base of these cut side shoots during the following summer, and which will or should bear fruit the year after. The shoot at the end of the main branch may still be further shortened to half its original length. Your trees may be growing too strong or making gross growth which cannot be ripened. In that case root pruning in autumn must be resorted to.

## KITCHEN GARDEN.

**Transplanting old Asparagus (F. T.).**—Very poor success is likely to attend the transplanting of old stools of Asparagus. The roots of the old plants have gone deep and wide, and, however carefully lifted, will get much broken. Generally very old plants are lifted and blocked close together in soil in a warm, dark place during the winter, where they will easily force shoots for cutting. When done the roots are thrown away. By far your best course is to have a piece of ground trenched 2 feet deep in the winter, have added to it one deep and one surface dressing of manure, and also add to each square yard 1oz. of fine bone-dust. Then in March get from a nursery strong three year old roots and plant them in trenches 6 inches wide and 4 inches deep, the rows 2 feet apart and the roots 20 inches apart in the rows. In this way you will get a bed to last for years.

**Onions diseased (T. E., Llandilo).**—Onions and their allies, the Leeks, Chives, &c., are liable to be much injured by the growth on them of several kinds of parasitic fungi. All the fungi bore into and through the tissues of the host plant, hence no external applications are of much use. The only thing you can do with any prospect of success will be to cut off the worst of the leaves and burn them, and then apply a dusting of a mixture of quicklime and sulphur in equal quantities to the plant, allowing it to remain on for three days, then syringing it off,

and when dry hoe and rake into the ground; it will help to destroy any spawn which may be there. The common name of the fungus is Onion mildew (*Peronospora schleideniana*). The disease, no doubt, is brought about in your case by some local cause of which we can have no cognisance. It may be that its mycelium has been laying dormant in your ground for some time, only waiting for favourable atmospheric conditions for its development. The best thing to do to prevent its recurrence in future is, we think, to trench the land deeply in order to aerate and sweeten it before planting Onions again, manuring the bottom spit with farmyard manure and the top spit with a liberal application of lime and using the hoe freely in summer while the plants are growing.

**Clubbing in the Cabbage family** (*H. Waters*).—The club-root of the Cabbage is due to one of the slime fungi called Plasmodiophora Brassicæ. The spores of this organism are in the soil, and under suitable conditions germinate and make their way into the root of some plant belonging to the Cabbage family. Practically all plants belonging to this family are attacked, both among vegetables and flowers, the Wallflower and the Stock suffering as much as the Turnip and the Radish, as well as weeds such as Charlock and Shepherd's Purse. When the parasite has entered the root it sets up irritation, causing a flow of sap towards the infected spot and a multiplication of the cells in that part, so that a large "club" is produced. The cells of this part become filled with the rapidly-multiplying organism, which derives its nourishment from the host, and eventually the root decays, setting the spores (into which form the pest has now gone) free in the soil ready to infect another cruciferous plant. The spores are able to live for at least four years in the soil. The method of treatment is to endeavour to kill the spores, and for this probably the best thing is quicklime applied in the autumn. Vaporite is also recommended. As far as possible avoid growing cruciferous crops on ground known to be infected for at least four years. Destroy by fire all plants clubbed. Do not throw them on the rubbish heap, give them to pigs or allow them to decay in the ground, and keep the ground free of cruciferous weeds. It is said that the most usual time for infection to occur is during the first six weeks of the life of the plant, and therefore very particular attention should be paid to seeing that the seed-bed is free of the fungus spores. Plants which are affected should not, of course, be planted.

**Lettuces all the year round** (*J. M. E.*).—The chances of securing a long supply of Lettuces will depend very much on the climatic conditions of the East Coast of Ireland and something as to the quality of the soil, which you say is poor. A fairly moist climate if not cold should be much help to the growth of Lettuces over a long season outdoors; but fairly good soil well manured is also needful to create quick growth, as if the growth is slow plants either bolt early to seed or the leafage is hard. To begin the season sow seed in shallow pans or boxes in a warm frame in January, February and March of Paris White Cos and any good Cabbage Lettuce, such as All the Year Round or Tom Thumb. Make similar small sowings monthly outdoors during the spring and summer, and in September sow Hick's Hardy Green and Black-seeded Bath Cos Lettuces in a sheltered position, also some Cabbage Lettuces, and while planting some when strong enough in a warm position outdoors on sloping borders plant others in frames a few inches apart in rich soil, keeping them fairly close till well rooted. If you had heated frames, either by pipes or manure hotbeds, small Cabbage Lettuces might be had from March onward, but without heat it is very doubtful whether even a mild climate would allow Lettuces to heart during midwinter.

### MISCELLANEOUS.

**Vaporite** (*R. W. A.*).—Vaporite is a proprietary compound, the composition of which is not revealed by the manufacturers, and, so far as we know, there is no analysis of it published. You might, if you liked, apply at the College laboratory in your town, but we do not know if the authorities would supply you with an analysis; probably not without a fee, at any rate.

**Fungus** (*F. H. N.*).—The fungus is the immature state of *Phialus impudicus*, a plant remarkable for its disgusting odour. It often, as in your case, grows near

decaying wood and habitations; sometimes it appears inside dwelling-houses. The only way to exterminate it is to remove it when seen in the young state, and to take away any decaying wood from the immediate neighbourhood of the house.

**Books on laying out gardens** (*Tyro*).—You may find what you want in a book entitled "The Book of Garden Designs," by Charles Thonger, price 2s. 9d., which can be obtained from the Publisher, 41, Wellington Street, Strand, London. You can also obtain from the same place "Garden Making," by Professor Bailey, price 4s. 4d.; this is by an American author. If you specially desire a quick-growing hedge plant, you will find the large-leaved Privet, which grows to a height of 6 feet and is very dense in two or three years, suitable. This needs clipping in summer and autumn; it is also very hardy. Plant in October or November. Take care to have the ground deeply dug 30 inches wide, and the soil finely broken; the plants should be 1 foot apart. It will be wise to cut back the new plants one-half the length of their shoots in the early spring; this will make the hedge dense at the bottom. You should start the relaying of your croquet and tennis lawn during October or November, as the soil becomes solid if well levelled and the turf well rooted by the following spring. When the turf is relaid, have a thin coating of fine soil well brushed in with a Birch broom after the relaying is complete, as this will do the grass good. When your turf is lifted, have the soil forked over several inches deep and finely broken. Have it evenly trodden over, but not rolled. See that it is perfectly levelled with the aid of a coarse iron rake. Use for that purpose, if you can get one, a bricklayer's level, or a spirit level stood on a long strip of perfectly straight wood. Before relaying the turves, lay each one out on a table and have all coarse weeds pulled out with a steel table-fork, as it is the best opportunity to have these weeds removed.

**Names of plants.**—*C. E. B.*,—1, *Pelargonium altum*; 2, *Polygonum polystachyum*; 3, *Maurandya caribæensis*.—*Miss M. E. Thomson*.—*Physgelus capensis*.—*A. L. Ford*.—*Lobelia cardinalis* and *Helenium autumnale cupreum*.—*M. Thonless*.—*Phytolacca acinosa*. Birds eat the fruits, so we do not think they are poisonous.—*E. N. Orsett*.—*Cuphea micropetala*.—*O. S.*—*Artemisia absinthium* (common Wormwood).

**Names of fruit.**—*R. N. R.*,—1, Plum Lawson's Gage; 2, Aston Town; 3, Duchess of Oldenburg; 4, Nelson's Codlin; 5 and 6, Wellington; 7, Flanders Pippin; 8, Calville Rouge; 9, Lamb Abbey Pearmain; 10, Tower of Glamis.—*W. J. B.*,—1, Gloria Mundi; 2, very close to Lord Derby, and not an improvement on it.—*D. C.*,—1, The Queen; 2, Warner's King; 3, Beauty of Bath; 4, Potts' Seedling; 5, Wellington; 6, Cellini Pippin; 7, Cox's Orange Pippin; 8, Monarch Plum.—*E. Quinton*.—1, Peasgood's Nonsuch; 2, Cox's Orange Pippin; 3, Colonel Vaughan.—*W. T.*,—1, Queen; 2, James Grieve; 3, King of the Pippins; 4, Sandringham; 5 and 6, Waltham Abbey Seedling.—*M. Millard*.—1, Cox's Orange Pippin; 2, King of the Pippins; 3, Bess Pool.—*J. R. D.*—John Apple.—*E. N. Orsett*.—Pears: 1, Conference; 2, Pitmaston Duchess. Apples: 1 and 2, Gloria Mundi. Emperor Alexander and Gascoyne's Scarlet should be exhibited as cooking Apples only.—*E. C. Shoosmith*.—The Pear was rotten when it reached us.—*G. W. S.*—Beurré Capiaumont.

## LEGAL POINTS.

### Compensation, fixtures, &c.

(*Barrow*).—As far as we can gather, you are merely living at home with your father, so that whatever rights there may be for compensation against the ground landlord must be asserted by your father under the Agricultural Holdings Acts; similarly as regards the removal of fixtures. It is quite possible, however, that the greenhouse referred to may be an ordinary movable vested in you; it depends on the degree of annexation. Also the answer to "*B. T. F.*" will throw some light on the situation.

### Market gardener's compensation

(*B. T. F.*).—There is such an Act as the Market Gardener's Compensation Act, 1895, a copy of which can be obtained from Messrs. Eyre and Spottiswoode, East Harding Street, E.C. The following are the chief points: It must have been agreed in writing that the holding shall be treated or let as a market garden, and if so agreed the tenant is entitled to compensation on quitting his holding, although such improvements may afterwards have been made without the landlord's special consent. The improvements comprise: (1) Planting of standard and other fruit trees and bushes permanently set out; (2) planting of Strawberry plants, Asparagus and other vegetable crops, and the erection or enlargement of buildings for the purpose of the business of a market gardener. He is further entitled to remove fixtures on

giving the landlord a month's notice (who can elect to take them at a valuation) and to compensation under the Agricultural Holdings Act, except so far as modified in the tenant's favour as above.

## BOOKS.

**The Insect Book.**\*—This little book, which is one of the series of "Country Handbooks" published by Mr. John Lane, is apparently a small and very much condensed edition of the larger work by the same author, "The Story of Insect Life." It is, of course, not written for the experienced entomologist; but as the author says, and his expectations should be justified, "it is believed that it will appeal to the merest tyro in entomology and those willing to learn something of the ways of the insect creation, and, as such, some useful mission will be served." It is, indeed, strange, considering how constantly we are brought into contact with insects, that the ordinary individual knows so little about them. They are not all as bad as the man in *Punch* who kept a turnpike gate. He was sorely puzzled, when a menagerie passed through his gate, to know under what heading of his scale of tolls he was to charge for the various animals. Having, at last, settled all to his satisfaction except the camel, he eventually came to the conclusion that he could not make any charge for it, "as it was a hinsect." Still, there are many persons at the present day whose knowledge of natural history is not much more accurate than that of the gate-keeper. No attempt is made to describe the various insects under their natural classification, but they are mentioned under the name of the locality in which they are most often found. The book is divided into six chapters—the first is an introduction; the second deals with the insects which are most commonly found in our gardens; the third, fourth and fifth with those of the water-side, woodland, meadows, heaths and lanes; and the sixth with our household insects. This method of arrangement has some advantages; it is easier to write about the insects in a chatty sort of way; but many of them—the common gnat, for instance—one would find difficult to localise in this manner. The author treats of it under "Garden Insects," yet it is a water insect for the greater part of its life. There are a large number of illustrations, many of which are life-size, others larger or smaller; but there is no indication as to whether a figure is natural size or not, which may be very misleading to the student. The figures, as a rule, are not first-rate. That of the burying beetle (Fig. 28) does not in any way show that the insect is ornamented with orange bands and spots; to all appearances it is simply a black insect. The common cockchafer, on the same page, is depicted much too large and clumsy, though the description says "our illustration is a remarkably good representation of the cockchafer," and no indication is given of its being larger than life-size. The caterpillar of the large white garden butterfly (Fig. 12) and that of the oak eggar moth (Fig. 25) do not show up well; they should not have had a dark leaf as a background. The representation of the house cricket (Fig. 36) is very quaint, but the legs are shown in a very unnatural position. The froghopper (Fig. 16) is drawn with its wings extended, a position in which it can be very seldom seen. When on a plant the insect always closes them tightly over its back, and if disturbed hops away so rapidly that it is impossible to see if it opens its wings or not. This little book is written in a very pleasant if discursive manner, and will no doubt have the effect, as the author hopes, of directing the attention of the reader to a deeper study of these interesting creatures.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

## SPRING BEDDING.

(First Prize Essay.)

IT is indeed strange, considering the wealth of suitable material available, that we do not find the practice of spring bedding more generally adopted and more varied in character, it being the exception rather than the rule to find gardens where anything beyond the ordinary is ever attempted. Thus we often find even large gardens where no pretence is made at making novel displays with spring-flowering plants—simply the same old varieties planted each year in the same style, and, in many cases, occupying the same beds as for years past. Small wonder the owners often vote spring bedding monotonous. Fortunately, my lot has always been cast in places where every encouragement was given to make the beds as attractive as possible at this season, and below I give combinations which have always found favour here and in previous situations I have held. Such well-known bulbous flowers as Scillas, Snowdrops and Crocuses are too well known and too frequently planted to need special mention here, one common mistake often noted being that of planting too thinly. Any of these to be really effective should be planted by the thousand, and the low prices at which they are now obtainable renders this possible even to those who have but slender incomes.

Dealing with the plants in alphabetical order, the first I would mention is the

### ARABIS.

The value of the Rock Cresses should on no account be overlooked by the gardener who aims at having a good display in the early spring. The common variety, albida, is well known and makes a good carpet for Hyacinths, Tulips or Narcissi of all shades of colour, while the variegated variety may be used with telling effect for either of the dark shades found in Tulips or Hyacinths. Beautiful as the old single varieties are, they are now for most purposes eclipsed by the double white variety of recent introduction. This is produced from cuttings, and grows equally as freely as the old alpina. The foliage is a trifle broader, the flowers somewhat resembling a small Stock or Lily of the Valley, for which it makes an excellent substitute, lasting well in a cut state.

Its use, either planted in large breadths or used as a carpet for bulbs, can scarcely be overestimated. Various combinations will suggest themselves to an intelligent reader. The various colours now obtainable in

### AUBRIETIAS

allows the spring gardener more scope than was possible a few years ago. A good collection of named varieties should find a place in every garden having any pretence at being up-to-date. Round beds of Tulip La Candeur with Aubrietia Dr. Mules found many admirers here

last spring, as also did Tulip Couleur Ponceau, having a groundwork of the lovely flesh-coloured variety Moerheimii.

It should be remembered in using any of the Rock Cresses that care must be taken to plant very thickly, in order that a good carpet may be assured at flowering time; blanks here and there often spoil what would otherwise have been very beautiful effects. Aubrietias come fairly true from seed, but personally I prefer division of roots.

### DAISIES.

These are not used so frequently as formerly, but their claims for spring bedding cannot be easily passed by. Used either in mixture or massed in separate colours they form at once an attractive bed, but, excepting for very small beds, I should hesitate to use them too freely, being too stiff, excepting when used as a carpet for other bulbs.

### MYOSOTIS.

These favourite flowers are quite indispensable where spring bedding is carried out, the colours harmonising or contrasting very favourably with most bulbs. The best yet under my notice is Star of Love, which grows only 3 inches or 4 inches high, and produces a mass of very pretty azure blue flowers. It makes an admirable setting for Tulips, the dwarf habit allowing the foliage and stems of these to be seen to advantage. Tulip La Candeur, Murillo or Rex rubrum, planted 1 foot apart, carpeted with this makes a splendid bed. Myosotis also does well associated with Narcissi when these are not planted too thickly, preference being given to the white or cream single varieties, the doubles not being so suitable for bedding. In addition to Star of Love, other good varieties are Victoria, Perfection and dissitiflora, each growing from 6 inches to 1 foot, the latter being very early-flowering, while for damp places, where little else will grow, the variety palustris will flourish like a weed. Having suffered considerably from rogues, or got hold of an indifferent stock at times, I have now given up raising Star of Love from seed, relying entirely on division of roots in June.

### PRIMROSES AND POLYANTHUSES.

In many gardens there has been quite a boom in the use of these of late years, and rightly so, for few or our spring-flowering plants offer so wide a range of colour, together with fragrance of bloom, as may be found in a good strain of these.

I find the best results are obtained by using them in beds of distinct colours, as by so doing we are able to arrange the colours so that they do not clash with other beds.

Beds of yellow and orange shades look well with Tulip Yellow Prince, which, in addition to its sweetly-scented flowers, has variegated foliage, which makes the bed attractive long before coming into flower. Beds of white and cream look well with red or scarlet Tulips, while for a bed of mixed varieties nothing excels Keizer's Kroon dotted 1½ feet apart.

### PANSIES AND VIOLAS.

These are especially well suited for spring bedding, coming into bloom early and remaining

in full beauty until it is safe to put the very tenderest summer bedding plants out.

The Cliveden varieties, white, blue and yellow, although producing rather small flowers, are very floriferous and well adapted for bedding purposes, being excellent for using with Tulips, choosing colours of suitable shades.

The show and fancies, although not quite so free-flowering, when obtained from a good source may always be relied on to produce extraordinary large flowers in the most fascinating shades and markings. A pretty bed is produced by planting the variety Beaconsfield with a border of *Santolina incana*, dotted with May-flowering Tulips.

#### SILENES.

For producing a mass of flowers in late spring few excel these, of which both double and single forms in white or pink are obtainable. They all flower later than most spring flowers, and for this reason their use should be confined only to those beds not required for filling with summer occupants until June is well in. We use the variety *pendula compacta rosea*, and find it useful for carpeting beds of Parrot or May-flowering Tulips, thereby making that portion of the garden gay when others are either past their best or not sufficiently forward to be attractive.

#### WALLFLOWERS.

There is no need to dilate on the use of these; their value for supplying colour and fragrance in early spring is generally recognised. I am no advocate for an indiscriminate mixture of colours, preferring beds either of one variety or a careful arrangement of colours to harmonise with other surroundings. The pale creamy flowers of *Primrose Dame*, planted alternately with *Ruby Gem* and edged with *Myosotis*, make a nice bed, providing it be sufficiently large to give effect to all colours.

Another bed may be planted with *Belvoir Castle* as a centre; next this three rows of the dark crimson variety *Vulcan*, which when obtained true is certainly the best of its shade; finishing with a double row of *Pyrethrum aureum* planted thick enough to make a bold edging. A few white Tulips among the dark Wallflowers, and Keizer's Kroon among the yellows adds to the appearance of the bed. Eastern Queen with Tulip *La Reine*, Harbinger with Tulip *Chrysolora*, or the Dwarf Blood Red with Tulip *Cottage Maid* are each very pleasing. For narrow borders, where more than one colour is desired, a back row of *Vulcan*, with Canary Bird next and a front row of *Primrose King*, edged with *Myosotis*, is very pretty, a few Parrot Tulips intermixed taking away any suspicion of stiffness.

#### NARCISSI.

I do not favour these in beds, preferring to see them naturalised under trees or in clumps in the banks, although I admit many pleasing combinations may be made by associating the single cream or white varieties with the dwarf-growing *Myosotis*, care being taken not to unduly crowd the bulbs in the beds.

#### ANEMONES.

The brilliant colours of these, produced in early spring at the time when flowers are scarce, make them specially welcome. They may safely be planted any time from October to February, either in separate beds or used as a carpet to other bulbous flowers. In addition to the foregoing, good use may also be made of small plants of *Prunus pissardii*, Golden Privet, *Euonymus*, &c., all of which may be used as dot plants over such dwarf-growing flowers as *Arabis*, *Alyssum* and *Forget-me-nots*. Many such arrangements as this will suggest themselves to the intelligent gardener who, having a progressive mind, is anxious to depart from the beaten track of former generations and produce beds which are at once novel, original and pleasing.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 27. — Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1—6 p.m. Lecture at 3 p.m., by the Rev. Professor G. Henslow, V.M.H., on the "Modification of Leaves and Stipules for Special Purposes." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster. Croydon Chrysanthemum Society's Show (two days).

**The Gardeners' Royal Benevolent Institution.**—The Rev. W. Wilks, M.A., Secretary of the Royal Horticultural Society, has forwarded a cheque for £10 to the funds of this institution, being the proceeds of harvest thanksgiving offertories at Shirley Church, of which he is the vicar.

**A new Water Lily tank at Kew.**—A new tank for the reception of hardy aquatics is now in course of construction in the Royal Gardens, Kew. The site selected is the sunk garden in front of No. 2 Museum, and this tank, when finished, will supersede the ugly, raised one which has existed for many years at the north end of the herbaceous ground.

**An interesting exhibition of Onions.**—As noted in our columns in the spring, Messrs. Rogers and Co. of Leamington Spa offered £100 as a first prize for the best Onion grown from seed supplied by them of their variety *Leamington Giant*. All Onions for this competition must reach Messrs. Rogers not later than the morning of the 21st inst. The judge will be Mr. E. Beckett, V.M.H., of Aldenham House Gardens, and an exhibition of the bulbs sent for competition will be held in Monsell's Repository, Windsor Street, Leamington, on Saturday, the 24th inst.

**Potatoes and Beets at Wisley Gardens.**—A meeting of a sub-committee of the fruit and vegetable committee of the Royal Horticultural Society was held on Tuesday, the 22nd ult. The midseason and late Potatoes and the Beet being grown for trial were examined, and it was resolved to recommend an award of merit to Potatoes 64, *Devanha Seedling*, from Messrs. W. Smith, Aberdeen, and 84, *British Champion*, from Mr. G. Carter, Cottenham, Cambs; to Beetroots 36, *Willow-leaved* (for ornamental purposes), from Messrs. Dobbie, Rothesay; 37, *Sutton's Blood Red*, from Messrs. Sutton, Reading; and 40, *Sutton's Pine Apple*, from Messrs. Sutton, Reading. A report to the above effect was laid before the full committee at Vincent Square on the 29th ult., together with samples of the produce. After due consideration and examination of the produce the committee adopted the report and sent it up to the council, who confirmed it on the same date.

**Black scab or wart disease in Potatoes.**—The Board of Agriculture and Fisheries desire to notify that 244 cases of wart disease or black scab in this year's Potato crop had been reported to them up to October 3. These cases have occurred in the following counties: Shropshire, 60; Staffordshire, 57; Lancashire, 50; Warwickshire, 25; Cheshire, 30; Worcestershire and Leicestershire, 4 each; Derbyshire, 3; Merioneth, 2; and 1 each in Perthshire, Stirlingshire, Dumfriesshire, Cumberland, Nottingham, Berkshire, Flintshire, Breconshire and Glamorgan. A few cases among field crops have been found in the counties in which the disease is most common; but in the great majority of cases the disease has occurred on allotments or in gardens in which Potatoes are constantly grown. Enquiries made by the Board lead them to think that wart disease is very common in gardens in five at least of the above-named counties. The disease has been known in certain districts for ten to fifteen years, and as growers have taken no steps to check its progress it is now causing serious loss. As wart disease may be carried from place to place in infected tubers, it is important to secure

seed Potatoes free from this disease. At the same time, the greater number of cases reported would appear to be due to the cultivation of Potatoes in soil previously infected, or to the use of manure containing refuse from a diseased crop, and in many instances the seed has been viewed with quite unjustifiable suspicion. It should be remembered that even in counties in which wart disease is common, it has not yet seriously affected field crops, and the percentage of diseased Potatoes offered for seed must be inconsiderable. All cases of wart disease must be notified to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. Persons notifying the disease will receive directions as to its treatment. It is believed that under careful treatment this disease can be eradicated, but if neglected it may render the soil unfit for Potato growing. In the case of farmers who sell seed Potatoes, notification of the disease is of especial importance, and failure to notify must be regarded as a serious offence. The Board desire to draw the attention of all seed-growers to the provisions of an Order issued under the Destructive Insects and Pests Acts, 1877—1907, which render persons concealing wart disease liable to prosecution and to a penalty of £10. In addition to the names already mentioned, wart disease is locally known as Cauliflower disease, "fungus" and canker.

## PRIZES FOR READERS.

### SEPTEMBER COMPETITION. — AWARDS.

In this competition prizes were offered for the best essays on "Spring Flower Beds," and a large number were sent in. Many essayists did not pay nearly enough attention to the combinations of spring-flowering fibrous-rooted plants with bulbous subjects, and where such combinations were given they were in many instances quite unsuitable, thus leading us to think that this phase of gardening is not generally well understood. The prizes are awarded as follow:

First prize of four guineas to Mr. F. R. Castle, Brumcombe Gardens, Foxcombe Hill, Oxford.

Second prize of two guineas to Mr. W. P. Wood, The Gardens, Oaklands Court, Kent.

Third prize of one guinea to Mr. George Cooper, The Gardens, Beauvoir, St. Saviour's, Jersey.

Fourth prize of half-a-guinea to the Hon. Mrs. Guy Baring, St. Cross Mill, Winchester.

The essays from the following are highly commended: D. B. Allwork, J. C. Wadd, F. Tansdell, James Pounsett, S. Bicknell, A. E. Groombridge, C. Blair, W. N. Morton, A. J. Cobb, E. K. Franklin, the Hon. Mildred C. Dany, Miss Hopkinson, F. Hay, C. W. Caulfield, Mrs. Wickham and Mrs. R. Chamberlain.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Rose Prince de Bulgarie with yellow flowers.**—As I wrote the paragraph about *Rose Prince de Bulgarie* having yellow flowers in THE GARDEN for September 14, 1907, mentioned by Mr. Jones on page 467, 1908, it may interest him to know that our flowers have been a normal colour this season. The plants were shifted last autumn and planted in rather heavier ground; also, I think this season they have had more moisture. Is it possible the alteration in the colour was due to the soil being rather drier in the first instance? Our plants are dwarf, and 1907 was their first season. I think, however, they were prettier with the yellow colouring. What good Roses General McArthur and Warrior are! I certainly think, from a garden point of view, they are to be preferred to Richmond.—WILLIAM P. WOOD.

**Curling Marechal Niel Rose of canker by budding on Isabella Gray.**—In "The Rose Amateur's Guide," by Thomas Rivers of The Nurseries, Sawbridge-worth, sixth edition (London: Longmans), 1857, page 135, article "Noisette Roses," I find the following: "Very recently some charming acquisitions have been made to this group; one of the most so is Isabella Gray, raised from seed of the Cloth of Gold Rose by Mr. Gray, a florist of Charleston, South Carolina. This is of the most beautiful bright yellow, quite as bright as the interior of the flowers of the Cloth of Gold; its flowers are not so large, but it is really a charming variety; it will probably bloom more freely than its parent, but as it was three years in this country before it gave flowers it will probably not be a free bloomer. It should be planted against a wall with a warm aspect." So far, Mr. Rivers; and he further remarks that "The Cloth of Gold flourishes remarkably well in Jersey." Have the present firm of Rivers any knowledge of the missing Isabel? It would be as well to enquire, as perhaps in some odd corner a plant might survive; if not, there may yet be a few plants in South Carolina's sultry clime, for if it requires a warm corner it would certainly bloom out there. In the meantime, I notice a footnote by Rivers on flowering the Cloth of Gold: "Plant a Banksian Rose against a wall (fortuniana is the best variety), and after it has made sufficient growth bud the Cloth of Gold on it. This stock (the Banksian) also suits well the other yellow Noisettes." I commend this method to your readers for experiment. First catch your Banksian, then bud it with Marechal Niel or the Cloth of Gold, and then—well! wait and see.—SYDNEY MARTIN, *The Lodge, Clarewood, Bickley, Kent.*

Fully twenty-five years since I planted a broad span-roofed greenhouse with Roses worked on standard Briar stocks, the roots being outside and the heads inside. Of these one was Marechal Niel, and that very quickly showed canker at the union. Other varieties were Gloire de Dijon, Mme. Berard, Reine Marie Henriette and Noisette Lamarque. Gradually, as I found these strong growers unsuitable for my purpose, I cut them hard back and budded Marechal Niel on the young growths. In every case the result was perfect health and not the least canker, although I had these Roses under my care for ten years afterwards. The house was soon filled with Marechal Niel growths, and the market value of the wealth of flowers thus obtained was considerable. Practically, to avoid canker it is only needful to work any strong-growing climber on the stock, allow it to make good growth to distend the stock, then work Marechal Niel, and the result will be splendid, healthy growth and fine blooms for many years.—A. D.

**A comparison of garden features.**—It seems to me at this time of year that it would be useful if readers of THE GARDEN could exchange notes as to what was most effective and successful in their gardens during the summer; and if you cared to print these notes it might lead others to give their experiences and we should all get some fresh ideas. Two short borders in my garden, each about 10 feet wide, were greatly admired by all visitors this year. One is composed entirely of scarlet and white flowers with dark red and grey foliage. At the back are Cactus Dahlias in varying tones of red, from the vermilion of Amos Perry to the velvety crimson of Matchless, H. J. Jones and white Peony-flowered Dahlias; these latter are most decorative, as they hold their large white single and semi-double flowers well above the foliage and grow to a great height. Here are also clumps of red-leaved Mountain Orach, 5 feet high, grouped with the scarlet-flowered, dark-leaved Cannas. Next come informal groups of Pompon Dahlias—White Queen and two very pretty scarlets, Mars and Bacchus—and a wide planting of the silvery-leaved Cineraria maritima.

Towards the front are bays of scarlet single Begonias, and at intervals large clumps of Lobelia fulgens Queen Victoria. None of the planting is at all formal; here and there Begonias run far back, and sometimes the Dahlias come forward. The Cineraria has rather encroached on the Lobelia fulgens, but the effect of the brilliant flowers growing through the grey foliage is most happy. Another border is a harmony of violet and pale yellow. There is a 6-feet-high trellis screen at the back covered with purple Clematis Jackmanii and Rose Alister Stella Gray. The mauve Dahlias are Countess of Pembroke and a charming Pompon called Pure Love. Then there is a mass of Anthemis tinctoria, the sulphur-coloured variety, rising out of a carpet of Verbena venosa. Violet Aster sinensis is grouped with a small pale yellow Zinnia, and at the turn of the path, where there is slight shade, is a large mass of Phloxes, with a wide border beneath them of single yellow Begonias. The Phloxes are now (September 28) past their best, but some fine clumps of a fine Michaelmas Daisy—Ryecroft Purple, I think—are coming into bloom behind them. There was here earlier also a group of Yucca filamentosa inter-planted with Lilium testaceum, which was a very pretty combination.—F. B., *Suffolk.*

#### **A useful early Plum.**

The accompanying photograph I took of a small branch of my Myrobolan Plum tree, and have much pleasure in recommending it to anyone wanting a very useful early Plum, for it is a nice size for tarts and ready to gather the first week in August. When the fruits are just turning colour they make a delicious preserve.—E. R. FULLER, *Kelvedon.*

#### **Iris Vartanii.**

This opened its first flower with me on the 26th ult., and others are in bud. This is much earlier than I have ever had it in flower before, and the flowers are not so welcome as in the dull, cheerless days of November and December. It would be interesting to have an explanation of this unusually precocious blooming.—F. HERBERT CHAPMAN.

**The Japanese Wineberry.**—A bush of this fruit in the kitchen garden here has done remarkably well this season, having been profusely laden with its bright red berries, which were in perfection for a month or more, and coming in just after the Raspberries had finished fruiting made a valuable addition to the supply of hardy fruits. The bush under notice is trained on stakes, completely covering a space of about 10 feet by 8 feet.—R. W. DEAN, *Audleys Wood Gardens, Basingstoke.*

## MESSRS. J. CHEAL & SONS' LOWFIELD NURSERY, CRAWLEY, SUSSEX.

**M**Y recent visit to this fine nursery—which is, after all, chiefly situated in Surrey—was coincident with the holding at the nursery of an extensive show of vegetable produce, the firm having by way of experiment, and one evidently highly appreciated by their many customers, originated a competition in various classes, the response being so great that the result quite took the firm aback, and ampler space had to be provided to satisfy requirements. Generally the exhibits were very fine, and I

A GOOD SPRAY OF THE MYROBOLAN PLUM.

could have selected from the whole a collection of nine dishes that would have made many professional growers "go under" in a competition. The exhibits represented the firm's seed stocks in every instance, and Messrs. Cheal may regard their stocks with the fullest satisfaction. As ample hospitality was also dispensed, the day was one of exceeding enjoyment to all concerned.

The Lowfield Nurseries have certain distinguishing features or elements. First, there is a huge collection of ornamental trees and shrubs, apparently of every conceivable description. Gold and silver, as well as purple, tints are very rich here. The firm, through Mr. Joseph Cheal, undertakes very large landscape gardening operations, and this description of work calls for

a large stock of those ornamental subjects which ladies and gentlemen now wish to have liberally planted. The old days for heavy, gloomy masses of trees and shrubs have for ever gone. Not only in connexion with these garden or park-making operations have the firm a staff of skilled draughtsmen constantly employed, but their rolling-stock is so considerable that it resembles that of a railway contractor.

Fruit is a second and very important feature of the nursery. Here on the marl of the district not only do trees thrive well, but they seem absolutely free from any description of insect or fungoid trouble. The alarmist will find at Crawley nothing to moan over. The fact which astonishes the visitor in walking over this great nursery and inspecting its fruit quarters is the immense number of trees in all stages of growth, and in all forms of training, there seen. Of flat-trained Peaches, Nectarines, Apricots, Plums, Pears and Apples, as also of cordons or in other forms, there seem to be enough to stock the nation; yet they all go out later. When the winter lifting season begins, then is the firm busy indeed. As my guide, the fruit foreman, said, one great, good result of the establishment of a nursery in a district is, not only that a great amount of labour is employed all the year round, but, just when other businesses become slack in the winter, the nursery trade is the most busy. Many employes have been with them for very long periods, a fact which speaks volumes for the employers. Specially heavy and fine this year is the Apple crop. The samples on the trees were superb. Quoted as wonderful croppers and carrying fine samples were Crawley Reinette (a splendid fruit, yet little known), Royal Jubilee, Newton Wonder, Lane's Prince Albert, Bismarck, Niton House, Bramley's Seedling, Norfolk Beauty, Lord Derby, The Queen, Gascayne's Scarlet, Winter Quarrenden (so well named), Duchess' Favourite, Peasgood's Nonsuch, Cox's Orange Pippin, Schoolmaster and many others, and especially Mr. C. Ross's varieties, Rival, Houblon, Paroquet, Charles Ross and others, all of fine quality and appearance. The firm specially prepare single cordon Pear trees, and these, 6 feet in height, furnished throughout with spurs, soon cover a wall.

A third speciality of the firm's work is found in Roses. These, again, are seen in immense numbers and of all descriptions. Specially strong are they in climbers, both in pots and planted out. A huge breadth of thousands of these latter showed growths 9 feet in height and some seven or eight to a plant, thus providing covering matter as soon as planted.

A long span house shows a bower of climbing Roses in pots, and one adjoining equally well filled with pot Vines, the canes hard and fully ripened.

The fourth speciality of the nursery is found in Dahlias. For these the firm has established a world-wide reputation, not only as growers and exhibitors, but also as raisers. While there may be seen a large collection of the show and fancy varieties, the flowers of astounding size and form, the labours of the firm have been most generally devoted to singles, of which they have the most beautiful varieties in the world. They also raise new Pompon forms and grow all the best-named ones. Of the wonderfully beautiful

THE NEW CACTUS DAHLIA SATISFACTION SHOWN BY  
MESSRS. J. STREDWICK AND SONS.

(Much reduced.)

Cactus varieties myriads of seedlings are also annually raised. Taking advantage of the opportunity to see so many Dahlias of all sections in full bloom, a chance such as a limited trial at Wisley fails to afford, I made a selection of twelve of each of the Cactus, Pompon and single sections most effectual as garden flowers, and of these I hope to furnish a list later on. I think for such a purpose the singles furnish most beauty. Some are singularly effective, and it is especially the aim of the firm, realising that for one exhibitor of Dahlias there are a hundred who grow them for garden beauty and cutting, to seek to create high-class garden decorative varieties.

## THE FRUIT GARDEN.

### A SMALL HOLDER ON HIS FRUIT.

THE following instructive notes appeared recently in *Country Life*: "Sir,—My fruit plantation consists of two acres of Apples, Plums and Damsons as top fruit, and Strawberries, Gooseberries, Raspberries and Red and Black Currants as bottom fruit.

*Green Gooseberries* were the first crop to pick and market. My young bushes of *Whinham's Industry* and *Crown Bob*, the earliest and finest varieties of this fruit, yielded abundantly—three bushels in all. I sent the first bushel to Covent Garden as an experiment. The price that week on the market was 7s. 6d. per half-bushel. I, however, was credited with 9s. only, less 2s. 3d. commission and carriage; that is to say, I got 6s. 9d. for my bushel, instead of 15s. from my nearest greengrocer. After this I sent the *Gooseberries* in to the nearest country town, and sold them to greengrocers at prices varying from 5s. to 3s. 6d. per half-bushel, according to the state of the market. It takes a man or woman an hour to pick a peck of green *Gooseberries* in the earliest part of the season. When the price drops to less than 3s. the half-bushel, *Gooseberries* become, for me, an unprofitable crop. The thinning-out process of picking them green leaves room for those that are left to ripen and swell into large fruit, so that one can fill a half-bushel basket more rapidly with ripe *Gooseberries* than when they are green. Half-a-crown for ripe *Gooseberries* may be as profitable to pick as 5s. for unripe ones. It must be remembered, too, that picking the fruit green helps the growth of young bushes immensely. I have sold my ripe *Gooseberries* for 3s. 6d. and 4s. per half-bushel, picking altogether from ten to twelve bushels. It is no use growing a small berry nowadays; the large reds are the favourites in the market.

*Strawberries*.—The open *Strawberry* bed of twenty rods and the rows between the fruit trees and bushes cover about a quarter of an acre of ground. These are of the *Royal Sovereign* and *Paxton* varieties. The fruit has had to be closely netted against the attacks of birds, for my land is surrounded by preserves. Anyone investing in fish-netting should see that he gets somewhere near the width ordered. It is a trick of the trade to say that the 'measurements are not guaranteed.' I have bought netting purporting to be 21 feet wide, which, when laid out, covered only three

rows of Strawberries. We had three weeks of unclouded Strawberry weather of golden sunshine; but we could have wished sometimes for cloudy weather, when we bent our backs under the burning sun from three o'clock to half-past five, the berries turning crimson as we picked. The entire crop of Strawberries was sold to a greengrocer five miles away. He preferred to have the fruit in the evening, so that he could go round with it to the houses before breakfast the next morning, his trade being with 'the gentry,' who know the best time of the day to eat Strawberries. Strawberries, if picked dry in the afternoon, keep better than those picked with the morning dew on them. The total sales amounted to £8 5s., averaging 3½d. per pound during the three weeks of continuous picking. I arranged to take the Strawberries to the greengrocer four days out of the six; he called for them the other two days. Half a ton of straw to keep the fruit clean was used to a quarter of an acre of Strawberries, and from 30lb. to 50lb. were picked every day. Strawberries are not as convenient a crop for me, personally, to grow as other fruit on my little farm, because the bulk of the picking always takes place while we are busy haymaking; but in the face of the fact that I was able to realise 3s. 6d. per 12lb. peck in a year of a glutted Strawberry market, I have been tempted to layer runners for the making of many fresh rows. The runners should be taken from the best fruiting year-old plants, and not from the worn-out beds. It is a capital plan to plant three in a triangle instead of a single plant in the row; the resulting heavier crop pays for netting.

**Currants.**—Red Currants, as far as my experience goes, are the least profitable of all fruit to market. I find that when Red Currants have to be sold for 3s. the 12lb. peck—which is about their market price this year—they are not a profitable crop to grow, and it is better to 'jam' or bottle the entire lot than to sell them. The birds here are very troublesome. When the fruit is ripening I have to go round and tie up every bush in old muslin meat mufflers. These mufflers are hard to obtain nowadays, as there is an increasing demand for them by motor makers and repairers. Think, too, of the time it takes to pick even a gallon of Red Currants after you have secured your crop of beautiful crimson berries. Black Currants have been fetching about double the price of Red Currants; but I prefer to 'jam' these rather than to sell them at 4s. per half-bushel. At 6s., as lately, it pays to market them; but, taking into account the depredation of birds, the spread of the black mite disease and the cost of picking, I would rather cultivate any other fruit than Currants.

**Raspberries.**—Raspberries are a good paying crop in the punnet stage—that is to say, when one can make 5d. or 6d. a pound on them—but when most of the crop has to be bulked for the jam-makers on a glutted market, as has happened this year, it is better to jam or bottle the fruit yourself and make your own delicious preserves rather than to purchase an inferior compound known as 'Raspberry jam.'—R. E. GREEN.

[The black mite disease referred to by Mr. Green is not, strictly speaking, a disease, but is caused by an insect known as *Phytoptus ribis*.—Ed.]

## THE FLOWER GARDEN.

### VERBASCUMS AT GLASNEVIN BOTANIC GARDENS.

THE Mullein family includes numerous species, many of which are tall and stately and suitable for a place in the wild garden, and some of the more showy ones look well for the back of the herbaceous border. Several have been used with great effect in the Glasnevin border, and have been continuously in flower for about five or six weeks. *Verbascum leianthum*, of which an illustration is given, has been the most prominent species, and the best plant has sent up a huge stem 14 feet in height, half of this being a branching inflorescence covered with yellow flowers. The lower part of the stem is clothed to the ground with silvery foliage, some of the basal leaves measuring 4 feet by 2 feet. The plants were raised from seed obtained from Asia Minor and also from Mr. T. Smith of Newry. *V. phlomoides* and *V. longifolium* are two European species bearing a profusion of yellow flowers. They reach from 8 feet to 10 feet in height. *V. olympicum*, from Bithynia, also bears yellow flowers, with handsome silvery foliage; it grows about 6 feet to 9 feet high. If planted in a mass about 4 feet apart, it forms a most telling and effective group. Unfortunately, these three species are biennial, so to obtain a succession seeds should be sown each year.

The Nettle-leaved Mullein (*V. Chaixii*) is a native of South-west Europe. It is a true

perennial and a good showy border plant, with branching spikes of yellow flowers reaching 6 feet to 10 feet in a good deep soil. There is a white form named *V. Chaixii album*, which is also a useful plant. Probably the best perennial Mullein of moderate growth is one which has long been cultivated at Glasnevin as *V. densiflorum*, but is supposed to be a hybrid of *V. nigrum*. For continuity and profusion of bloom it has no equal. Starting to flower in June, it continues through the summer and often until autumn approaches. It commences to flower when about 2 feet high and makes a small bush of flowering shoots, which continue to grow and flower until they reach 4 feet or 5 feet. The foliage is evergreen and frilled towards the margin. The flowers measure 1 inch in diameter, in colour a tawny orange, deepening towards the centre, the filaments being covered with purple hairs. The plant seems to be quite barren here, but it may be propagated in autumn and spring by means of root cuttings.

*V. phoeniceum* is an attractive dwarf perennial, producing graceful spikes of flowers about 2 feet high. For the front part of the herbaceous border it proves a useful plant. From a packet of seeds quite a variety of colours are usually obtained, such as white, rose, lilac and purple. If the seeds are sown in boxes in heat during February, the plants will flower the same summer. *V. weidmannianum* comes from Asia Minor, and is one of Messrs. Haage and Schmidt's introductions. It has a rather slender habit, but reaches 4 feet to 5 feet in height. The flowers are 1 inch to 1½ inches in diameter and of an indigo blue, changing to deep purple. Though a true perennial, in some places it sows itself quite freely.

Several good hybrids have been raised by Mr. T. Smith of Newry from *V. phoeniceum* and *V. cupreum*. *V. hybridum* Daisy Hill is an interesting plant about 1 foot to 2 feet high, bearing continuous spikes of bright coppery orange-coloured flowers, each measuring 1 inch to 1½ inches in diameter. *V. newryensis* is a hybrid between *V. Chaixii* and *V. phlomoides*, with erect spikes of large yellow flowers with dark centres.

The following is the raiser's description of *V. hybridum* Lewanika: "One of the most remarkable plants ever raised here. It grows about 2 feet high, and produces its flower-spikes in such a continuous manner from June until October that it is never during that period out of bloom. The flowers are almost indescribable, being a curious shade of bronzy purple." These three hybrids are well worth a trial, and are true perennials. The Verbascums are not fastidious plants as regards soil, but deep loam, into which the roots can bore deeply, will give the best results. C. F. BALL.

### CACTUS DAHLIA SATISFACTION.

AMONG the many new Cactus Dahlias exhibited this autumn the variety Satisfaction is one of the best and most attractive. The colour is rosy carmine, with white at the bases of the petals, thus forming a sort of white centre. As will be seen by the illustration, the narrow petals are very much twisted. It was shown by Messrs. J. Stredwick and Sons, St. Leonards-on-Sea, before the Royal

A RARE MULLEIN (*VERBASCUM LEIANTHUM*) IN THE BOTANIC GARDENS, GLASNEVIN.

Horticultural Society on the 15th ult., when it received an award of merit.

### A MIXED BORDER IN SUSSEX.

THE herbaceous border and summer-house illustrated were made eighteen months ago upon a meadow site. The garden lies 800 feet above sea-level, and, in view of the rough winds that sweep Ashdown Forest, the rate of development is quite satisfactory. The summer-house is Oak-timbered and Heather-thatched. It faces due north. A sunk rock garden lies on the east side of it. The soil is very heavy, in spite of the sandstone formation. To drain the borders the central grass path was sunk 2 feet deep, the sides being upheld by a dry wall. The latter contains a large collection of Saxifrages, Sedums and Sempervivums, which are thriving well. The border contains the usual favourite perennial plants and annuals flowers are also made great use of. In the foreground of the illustration there is an effective combination of Mignonette, Nigella, Eryngiums and white summer Chrysanthemums. In the centre of the border a mass of *Lavatera rosea*, Hollyhocks,

## THE GREENHOUSE.

### WINTER IN THE GREENHOUSE.

(Continued from page 493.)

**I**NSECTS.—These generally increase abundantly during the winter months unless means are adopted for their suppression. Fortnightly fumigations with XL All will by prevention of insect-breeding render recourse to any drastic measures unnecessary. Though this will kill immature thrips, red spider and green fly in all stages, the older insects and the dreaded mealy bug and scale will not be destroyed thereby, unless doses strong enough to injure the plants are given. These tough-skinned gentry must be got rid of, therefore, by sponging the plants with warm, soft soapy water or a weak solution of Gishurst Compound, Fir Tree Oil, &c. As the under-surface of the leaves are the parts most favoured by the pests, these should have special attention. After fumigating it is always advisable to give the plants a good syringing, and admit air as soon as possible to reinvigorate the greenhouse

water in the boiler is heated by the back part of the fire, therefore never neglect this essential though decidedly unpleasant part of the stoker's duty. Two or three times a day should this thorough clearing be done, and the ash-box beneath the bars emptied daily. On examining the fire in the morning the bottom of the furnace will generally be found more or less covered by a clinker. Unless there is a good body of red fire—which there very seldom is if the furnace has done its duty—it is not advisable to attempt to remove this clinker; merely turn it on edge or slightly break it up, open the damper to its full extent and put a little fuel on the fire. Anthracite coal is useful for quickly invigorating a dull fire in the morning; when the fire has burnt up well and the temperature of the house is rising, the removal of the clinker may be completed. Never keep a large body of fire, that is to say, never keep the furnace full of firing. A fire-box filled to half its capacity will be found the most economical; the fire will be easily managed and the maximum amount of heat be generated. On a sudden burst of sunshine appearing a small fire can be readily smothered sufficiently to keep down the temperature, while a big one is, of course, beyond hope in this respect. This applies more particularly to the management of the fire in the daytime, when someone is generally at hand to replenish it as needed. At the final firing up at night the furnace may be well filled to its utmost capacity, almost all the draught taken off, and if any doubts exist as to the lasting qualities of the fire, a few shovelfuls of ashes may be thrown over the front portion near the door. A golden rule in regard to fires and stoking is worth remembering, viz., that when a furnace is found half full of fire in the morning the temperature of the houses will be low; when a fire is found to have almost burnt itself out the temperature will be correspondingly high. In other words: high fire, low temperature; low fire, high temperature. J. K. E.

## THE ROSE GARDEN.

### THE NEWER ROSES

(Continued from page 457.)

**C**OLONEL R. S. WILLIAMSON (Hybrid Tea, Messrs. Alexander Dickson and Sons, Limited, 1907).—As this was sent out only last year, I have hardly tested it sufficiently to speak definitely about its value for exhibition, but it is, undoubtedly, a fine Rose of great size with round petals of good substance, which in a cooler season would no doubt come with a good high centre; colour white with blush centre. I saw it at Newtownards recently, and it promised well.

*Dr. O'Donel Browne*.—This is sent out as a Hybrid Tea, but at first sight one would feel inclined to call this Rose a Hybrid Perpetual. I have known it for some time, but have not grown it. On each occasion that I have seen it, both growing and on the exhibition table, it has impressed me as a real good Rose which will be very useful to the exhibitor, its special feature being the number of excellent-shaped flowers it produces, split or quartered flowers being in the minority. Nothing more need be said to prove its utility. Messrs. Alexander Dickson and Sons have staged it frequently this year. Since the above was written this Rose has been awarded the gold medal of the National Rose Society.

*George C. Ward* (Hybrid Tea, Messrs. Alexander Dickson and Sons, Limited, 1908).—I noted this Rose as very distinct under its old name of Sir Henry Irving on more than one occasion, notably, at Saltaire in 1907, when exhibited by the raisers, its striking feature being its glorious colour. I only know one other Rose that possesses it, and that is Grüss an Sangerhausen, but here the orange vermilion is even more pronounced. It created a sensation when staged at

MIXED BORDERS IN MR. E. A. WHITE'S GARDEN AT CROWBOROUGH.

Rose Campion, Phlox and pink Snapdragons combine well with *Achillea* (The Pearl) and *Gypsophila paniculata*. Other good effects are obtained by the conjunction of scarlet *Gladioli* and *Eulalia elegantissima*, also blue *Convolvulus* minor mingling with the delicate green of *Kochia trichophylla*. Round the summer-house are grouped plants which gradually merge into the rock garden—*Dimorphanthus mandschuricus*, *Aralias*, &c., also *Veronica Traversii*, which at the time the photograph was taken were scarcely recognisable by reason of their being practically covered by the brilliant bloom of the Highland Flame-flower.

### TREATMENT OF LOBELIAS.

WHERE these are growing in situations rendering their removal necessary, they should now be boxed up, using the ordinary border soil that is fairly moist. Pack them thickly together, and do not give them a drop of water until they are pulled to pieces and restored in spring ready for a start. We often hear of losses through the winter months; these can invariably be traced to too much moisture.

inmates after the weary hours they have spent in a poisoned atmosphere. It is not often necessary to lower the blinds after fumigating in or during winter, but this should be invariably done when the hot, sunny days of spring and summer return. It is a wise plan, especially on a windy night, to let the blinds down while fumigating, as this will help to keep the smoke or fumes in the house.

*Stoking*.—Much in the successful management of the greenhouse in winter depends upon stoking, and it is safe to say that some stokers can keep up a given temperature by the use of half the fuel which others find necessary. In the first place, all flues and chimneys should be kept thoroughly clear. This will create a good draught, which will generate an intense and rapidly attained heat and raise temperatures to an extent and with a facility utterly unattainable with blocked flues and chimneys. Never be afraid to use the stripping or clinking iron freely along the bottom of the fire; clear fire-bars go an extremely long way towards successful stoking. See to it, too, that the iron goes well to the back of the fire; many furnaces are so constructed that the greatest portion of the

Manchester this year, and was unanimously awarded the gold medal. As seen growing it is vigorous and free-flowering, with a pronounced Tea perfume; with all these good points it is safe, I think, to predict a future for this Rose, both on the show-bench and in the garden.

*Grace Molyneux* (Hybrid Tea, Messrs. Alexander Dickson and Sons, Limited, 1908).—I have already referred to this Rose; here I will add that only occasionally, after severe disbudding and all the aids the exhibitor can give it, will it produce an exhibition flower, but can be strongly recommended as a garden Rose.

*George Laing Paul* (Hybrid Tea, Soupert et Notting, 1904).—This Rose continues to improve with age, and has frequently been exhibited this year. It is decidedly useful, as it comes well, of a good shape and form; not, of course, often a back-row flower, but deserves to be more grown.

*Grossherzogin Alexandra* (Hybrid Tea, Jacobs Welter, 1906).—I have seen no reason this season to retract the opinion I previously formed of this Rose, namely, that it is one of the best of the Kaiserin Augusta Victoria type. With me it has, I think, improved on its last year's form.

*J. B. Clark* (Hybrid Tea, Hugh Dickson, 1905).—I mention this Rose here because I owe it an apology. Until this year it certainly had done nothing with me to warrant its reputation, and I have said so on more than one occasion; but this year I have had many quite good flowers that have been very useful, and I think generally it has been shown in better form throughout the season. At its best it is very fine, as there is no larger dark red unless the new

*His Majesty* (Hybrid Tea, Messrs. S. McGredy and Son) may be found so. As seen growing this is similar in habit, but the petal and shape of the flower are quite distinct. This Rose has been called the Red Druschki, but I think His Majesty is a better name for it. I referred fully to it in THE GARDEN for September 26. Awarded a gold medal at the autumn show of the National Rose Society.

*Joseph Hill* (Pernet-Ducher, 1904).—This is generally called Monsieur Joseph Hill, but I am inclined to think that the "Monsieur" should be dropped, especially as Joseph Hill is a citizen of the great American Republic. If I was asked to name the best Rose that we have received from the Continent in the last four years, I think Joseph Hill would be my selection. As a cut-back it is splendid, but I am told that it does not take well on a standard. All my plants are dwarf and have done well; the finest Rose I have grown this year was one of this variety. It is free-flowering, the flowers coming very large if disbudded; shaded, the colour is wonderful. This Rose is a good grower, but apt to send up one strong shoot only, which if left alone will produce half-a-dozen good flowers. Remarkable as the flowers are, I know of no more beautiful foliage; the strong, bronzy green leaves act as a splendid foil to the flowers. One cannot give it higher praise than to say that it is one of the best Roses the raisers have sent us. Should be in every garden.

*Purley.*

HERBERT E. MOLYNEUX.

## SEASONABLE WORK AMONG THE ROSES.

No time should be lost in carrying out autumn pruning. This practice is a great aid to the exhibitor and also to all who delight in quality of bloom from their Roses. It is more applicable to the Hybrid Perpetual group; but there are some of the Teas and Hybrid Teas which are apparently ripening off, and to which a moderate amount of autumn pruning would be helpful. Old wood should be freely removed right down to the base of the plants, if possible. This is not always practicable, and can only be carried out where an annual system of autumn pruning has been in

has been delayed, it may still be done with profit, and it largely facilitates work in the spring. Standard Briars which have been budded should have the ties removed, and it a good plan to retie them again, but not tightly. Where insect pests are troublesome the ties are best removed altogether. Cuttings of Briars for dwarf stock should now be made, selecting good sound shoots with the least amount of pith possible. Make them into lengths of about 8 inches, and plant in well-worked soil with a gritty base for the cuttings to stand upon. The cuttings should be inserted in the soil almost their entire length. Cuttings of hardy Roses, such as Frau Karl Druschki, will root freely, and a goodly number should be inserted now. All of these hard-wooded cuttings should be inserted in an open part of the garden where they may obtain a fair amount of sunlight.

Repotting such plants as need it must not be delayed, but I would strongly advise amateurs to see that their pot plants are full of roots before they disturb them. Many plants are ruined by too much disturbance of the roots. When the roots are seen well around the ball of earth, then a shift into a size larger pot is desirable, and it should be done at once. Roses required for early forcing ought to be repotted in June. If this has not been done, simply top-dress them now with a little soil in which a good sprinkling of bone-meal has been admixed. An excellent compost for pot Roses is three parts fibrous loam, one part well-decayed one year old manure, and about 4lb. of bone-meal to a barrowful of compost. See that the pots and crocks are clean and dry, and be careful to pot firmly. After potting, stand outdoors on a bed of ashes and water about two days afterwards, if no rain falls in the meantime. Rambler Roses grown in pots should not be given too large a size; they flower better if the roots are somewhat confined. Ripen growths of forcing Roses by standing them in full sunlight. Those repotted in June should be laid on their sides for two or three weeks to dry them off preparatory for early forcing.

P.

FABIANA IMBRICATA GROWING IN THE OPEN IN CAMBRIDGE BOTANIC GARDENS.

## FABIANA IMBRICATA.

THE accompanying illustration is from a photograph of a plant growing in an exposed position in the Cambridge Botanic Gardens, where it has grown into a bush 3 feet high in a few years and has not suffered from frost, the only protection it has had being a little

rough litter about its base during severe weather. There is also a good specimen trained against a greenhouse wall which has attained a height of about 12 feet. Both these specimens are remarkably fine during June with their fresh, green, Erica-like foliage and white tubular flowers. The plant belongs to the Solanum family and not the Heath family, which it so much resembles in outward appearance. It is also a good subject for pot culture. Cuttings root readily in ordinary soil, and, if grown with the Heaths and other hard-wooded subjects, the plants are useful for the greenhouse in spring. There are about eleven species, all natives of South America, imbricata being a native of Chili. It has been in cultivation since 1838.

Rambler Roses have now, in most gardens, been looked over and all the old wood removed as far as practicable. Where, however, the work

E. J. ALLARD.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**C**OLD FRAMES.—Complete as soon as possible the propagation of the shrubby *Calceolarias*, as it is well to get the cuttings inserted before the hard weather sets in. The beautiful *Campanulas* which are in pots and are well rooted should be transferred to those of larger size. Six-inch pots should meet the needs of most plants. The earliest batch of bulbous subjects may be removed from the plunging material and the pots stood in the cold frame for a time. Carnation layers that are well rooted should be potted up without delay. To produce the better flowers it is necessary to cultivate the plants in pots.

**Hardy Flower Garden.**—In anticipation of frosts in the near future, I make a rule of lifting and replanting at this period plants in the hardy border as opportunity offers. It is a good plan to get as much of this work done as possible before the hard weather sets in. Hyacinths and other bulbs, if not yet planted, should be taken in hand at once. The *Anemones*, *Ranunculuses*, *Pansies*, *Sweet Williams* and numerous biennials may be planted at the present time.

**Greenhouse and Conservatory.**—For spring flowering I am just potting up a batch of *Gladioli* and other spring-flowering bulbous subjects. When finished, these pots are placed in some plunging material, where they may be kept cool and from whence they may be removed, when they have made an inch or so of growth above the soil, later on. The beautiful *Freesias*, if not already potted up, should be dealt with forthwith. *Chrysanthemums* that were housed in the earlier days of the month are fast opening their blossoms, and, that their

interests may be promoted, see that the glass structure is freely ventilated and water supplied in sufficient quantity to keep the soil moist in the pots. Should there be evidence of green fly on the *Chrysanthemums*, the glass structure should be fumigated for at least half-an-hour, and this repeated at intervals of a fortnight to keep this pest at bay. *Primula obconica* should be removed from the cold frame at this period, placing the pots on a shelf near the glass, where they are safe from frosts.

**The Vegetable Garden.**—Weeds are giving growers of vegetables much concern just now, the moister weather having encouraged their growth at a remarkable pace. For this reason make good use of the hoe on dry days, as by this means they may be kept in check and the prospects of the vegetable crops brightened thereby. Vacant plots of ground should be properly dug, turning in the weeds carefully. Crops that have not yet been gathered and placed under cover or some protection, such as Beetroot, Onions, Carrots and similar subjects, should be dealt with at once.

**The Hardy Fruit Garden.**—As the planting season will soon be upon us, preparation should be made for planting the different subjects. The thorough trenching of the soil is important. Order trees from nurserymen of good repute. Stone fruits, such as Plums, Cherries, Peaches, Nectarines and Apricots, benefit to a considerable degree when lime refuse is added to the soil. Freshly-slaked lime answers equally well when this is incorporated in moderate quantities. I always plant new trees when the weather is dry, and the soil in a fairly friable condition as a consequence, treading the soil firmly when the trees are put in.

**Lawns.**—The naturalising of bulbs, especially the *Daffodils*, may be dealt with at the present time. Groups, small colonies, or breadths of larger dimensions may be planted in the lawn with conspicuous success. My rule is to lift the turf with care by using a spade, taking out the soil and forking over the subsoil. The bulbs are then arranged equi-distant on this, generally a few inches apart, the soil being subsequently replaced and the turf rearranged in position. A beating down of the turf with the back of the spade completes the operation. To distribute worm-casts, I occasionally sweep the surface of the lawn, completing the work by giving the latter a good rolling. Grass that is growing unsatisfactorily may be generally attributed to its impoverished condition. To promote a better state of affairs it is a good plan to apply basic slag or bone-meal. About 4oz. of either manure to the square yard should be applied. D. B. C.

## HOW TO EARTH-UP CELERY.

This is an important point in connexion with Celery culture, and, as there are many beginners who may be in ignorance of how this work should be accomplished, we give in the present instance illustrations depicting the methods which may be followed.

Before the Celery can be treated in this manner, it is, of course, necessary that there should be a robust growth, and the plants must be growing away freely before it is possible to take them in hand. It is useless to begin earthing-up the Celery until there is 1 foot or more clear stem available to commence the bleaching process, so that unless the beginner's plants are in such a condition they must be left alone for a little while longer.

Earthing-up should be done on a fine day when the soil is in a fairly friable condition, so that it can be handled more easily. Should the soil in the garden be heavy and retentive in character, it is a good plan to work in some light and sandy material to make the soil more friable. The older method of earthing-up Celery was simply to place soil round about the "sticks," doing this with the greatest care so that no

2.—A SECOND STRIP OF PAPER PUT ON WHEN THE GROWTH WAS SUFFICIENTLY ADVANCED.

particles of earth reached the heart. We prefer to adopt the more satisfactory and simple method of tying round the plants thin cardboard collars about 6 inches in width. Should it not be possible to obtain cardboard, we use with great success strips of brown paper of similar dimensions. If the plants are tied round at intervals of each 6 inches of growth, bleaching operations may be carried out with considerable success and perfectly blanched specimens be brought into effect.

The illustration Fig. 1 depicts how this method of bleaching should be carried out. The beginner should take note of the method of tying as revealed in the illustration above alluded to. The tie should be in the centre of the brown paper, or, if time and material are of little import, two ties may be made round the same piece of brown paper, one at the bottom and the other at the top. If left in this condition for a week or two, the plants, assuming they are watered freely and liquid manure applied in order to promote rapid and satisfactory growth, will be ready for the second tie as depicted in the illustration Fig. 2. If a comparison be made between Fig. 1 and Fig. 2, the extra length of bleaching carried out in the second instance will be better appreciated. It is well to point out, however, that the plants should not be tied too tightly, but sufficient space left for the growth to expand. In the course of time

1.—METHOD OF BLEACHING CELERY BY TYING A 6-INCH-WIDE STRIP OF PAPER ROUND THE LEAF-STALKS.

3.—THE FIRST EARTHING-UP AFTER THE PRELIMINARY BLEACHING WITH PAPER.

it may be necessary to make a third tie, and even a fourth in the case of some of the more vigorous specimens that have grown away freely from the commencement.

For early work this method of bleaching has many advantages, because where this rule is followed it is unnecessary to place earth round about the plants in order to attain our ends. There comes a time, however, when, owing to climatic conditions, some protection against the inclement and frosty weather makes it necessary to earth up the Celery, and this should be carried out in the fashion described in Fig. 3. Here, it will be observed, the ties and paper are just visible above the surface soil, and this should be the rule until the next tie is made. Subsequently, in the course of a week or two, a further earthing-up of the plants will be necessary, and this should be done as in the former instance, taking good care that the growths do not get unduly pressed or damaged, or the soil get down into the hearts of the plants.

Fig. 4 serves the purpose of illustrating the second earthing-up, from which it is possible to see the even character presented by the rows when this work is completed.

The third or final tying and the subsequent finishing of the earthing-up is well portrayed in the illustration Fig. 5. A careful observation reveals the fact that the ridge is now of considerable dimensions, and this should be made quite even and firm to carry off superfluous water, and also in order to protect the hearts of the plants against severe frosts, which will, no doubt, ensue in the winter season.

Some growers make a rule of inserting small land drain-pipes between each stick of Celery, the former being used for the purpose of conveying manure water to the roots of the plants without causing damage to the paper or cardboard that embraces the latter. When water or manure water is applied without some protection being made, the paper may rot unduly early, and this may have the effect of causing the sticks of Celery to rot also. In any case, we prefer earthing-up the Celery by these means to the older and less satisfactory method.

Those who do not wish to take this trouble of binding strips of 6 inches of brown paper, &c., round the sticks of Celery, as advocated above, may carry out their earthing-up process in the simple and more primitive fashion that our forefathers adopted in the days gone by. What is of the utmost importance, however, is to prevent the soil working down into the heart of the plant, and to effect this end we first make a loose tie round the plants

with raffia, controlling all the growths and thus preventing the soil working down, as it is very likely to do unless such means of preventing the same be adopted. The soil is then worked round the sticks of Celery with the hands, and as soon as the earthing-up is done, which should be to a depth of 6 inches, more or less, the tie should be unfastened so that the growth of the plant may proceed apace.

#### PRETTY TABLE DECORATIONS IN THE AUTUMN.

VERY often, immediately after the first frost has come, there is a dearth of flowers suitable for the decoration of the dinner-table. In other instances variety or change is desirable, and the available stock of flowers does not admit of a decided change in the character of the decorations being made.

#### AUTUMN-TINTED FOLIAGE AND BERRIES.

In these we have ample material for carrying out various designs on the dinner-table. The

in various stages of ripening may also be found and mixed with the foliage. Vine leaves and those of the Ampelopsis and Ivy are sufficient in themselves to make a most effective display on the table. If ordinary care be taken of the branches and leaves gathered, they may be used on the table several times, as they are at this season in a matured state.

#### HOW TO ARRANGE FOLIAGE AND BERRIES.

On no account should these be arranged so densely as to block the view across the table. A light arrangement is absolutely essential. Sprays of a light nature should be laid on the cloth itself, and others arranged in tall vases so as to depend gracefully from them. Leaves also may be laid on the cloth. A formal design one night and an informal one the following night would be welcome. The berries should be associated with the foliage in as natural a manner as possible, and all leaves should be dry. Overcrowding must be strictly avoided, as nothing looks worse than a table so packed with decoration that no room is left for the plates, glasses and other ware. I have used the different kinds of leaves and berries extensively in the decoration of both very large and small dinner-tables, and so can personally testify to the charming effects secured. Visitors who are suddenly and unexpectedly confronted with decorations of this kind are delighted, and very rarely fail to express their astonishment and pleasure at the display. AVON.

#### DRAINAGE FOR POTS.

THERE is not a plant in existence that will thrive in a pot without drainage—and by this is meant a pot without some broken pieces of pot, called crocks, in the bottom. The object of this layer or layers of crocks is to allow the water to pass away quickly and to prevent the soil from filtering down and stopping up the bottom hole. Unless the soil is maintained in a very sweet condition, the roots get sickly, and eventually decay. The amateur must remember this most essential condition. The depth of this drainage will depend upon the nature of the plants and the size of the pots. Half-an-inch will suffice in very small pots, and in the case of Geraniums which are to be grown simply for bedding-out, one large crock will suffice. The pot most frequently used is called the 5-inch. Place the

larger crocks with the hollow or concave side downwards. On these place smaller pieces, and then a few still smaller. Next will come some rough portions of soil; if fine soil were placed immediately over the crocks it would quickly get washed among them, and so block the hole in the bottom.

4.—THE SECOND EARTHING-UP, SHOWING THE WORK IN A MORE ADVANCED STAGE.

beautiful tints and markings in the leaves and on the ripe berries of various wild plants, even those of the Ivy, show to great advantage in artificial light. One has only to walk to the kitchen garden to find some lovely leaves of Carrot, which, for richness of colours, beat the Maidenhair Fern and other foliage culled from plants in the greenhouse. Then we can combine the leaves of the Coleus from the stove with those of the Beetroot from the kitchen garden. Parsley, too, late in the autumn may be depended upon for the supply of variegated leaves somewhat similar to those of the Carrot. Bracken and other kinds of Fern fronds gathered from roadside and woodland paths are also available; sprays and leaves of the common Bramble look charming on the white table-cloth. If we closely study the Bramble leaves in the autumn, we find most beautiful shades of yellow, bronze and crimson on the dull green background of each leaf. Clusters of Blackberries, too,

5.—THE THIRD AND FINAL EARTHING-UP OF A VIGOROUS ROW.

## THE TOWN GARDEN

**HERBACEOUS BORDERS.**—Although the number of hardy herbaceous plants which will flourish in town gardens is more limited than in country places, there still remain an abundance with which to make a glorious display during the spring, summer and autumn months. Now, however, the plants are assuming the sere and yellow, and were it not for the Chrysanthemums and Michaelmas Daisies the garden would be almost dreary; these are still producing their share of flowers, and the freedom of growth and profuseness of blooming admirably adapt them for the small and smoky garden. No efforts should, of course, be spared to keep them beautiful as long as possible by the persistent trimming up of all the plants and the complete removal of dead and dying stems and flowers.

**MAINTAINING THE BORDERS.**—In order to maintain the borders in satisfactory condition over a considerable number of years, it is necessary to pay particular attention to the work of renovation, and something of this must be done each season. As a matter of fact, the plants are shorter-lived in towns than they are in the country, and it has been proved that it repays over and over again to remake the borders every two years, instead of every third or fourth year as answers so well in the rural garden. This operation is somewhat laborious; but if it is commenced in good time and a small portion only dealt with at once, it can be successfully accomplished without undue fatigue or the neglect of other garden work. It is an excellent rule to divide the border to be renewed into sections of 3 feet or 4 feet, according to its width, and to complete each one before another is touched. It is then most improbable that unfavourable weather will catch us when we have many plants out of the ground, and the operation proceeds comfortably and well. The first thing to be done is to lift all the clumps from the section. If the weather is pleasantly moist and cool, they may remain on the surface of the second division; but if it is hot and sunny, they must be covered with a mat, or they will unduly dry out. Then the soil should be taken in hand and thoroughly dug to a depth of at least two spits, and preferably three (this will mean that the roots of the plants will have from 20 inches to 30 inches in which to work), and into the second spit should be worked some of the best procurable sweet natural manure; in the possible event of only fresh manure being available, it will be wise to work it into the third spit; then make the top spit moderately firm and all will be ready for replanting. I am not of the opinion that it is ever good practice to replant the entire clumps, since young stock gives more and finer flowers; therefore, split up the clumps and plant small portions from the outsides, throwing or giving away the remainder to friends who require such material. It is essential in planting that the soil be made very firm about the roots.

**MULCHING BORDERS.**—In the year when complete remaking is not being done, the surface should be mulched with the best natural manure. The operator must trim up all the plants according to necessity and loosen the surface of the soil before the manure is spread on the top; of course, he will at the same time remove any weeds that may be present. When the mulching is on it may be necessary to spread over it a thin layer of fine soil, as its appearance may be objected to by some people. Care should be taken in this work that lumps of hot manure are not placed directly on the top of the crowns of the plants, but it must be worked well up to them on all sides.

**TIME OF WORKING.**—This work can be done at any time during the winter when the conditions of the soil and the weather render working on the ground possible; but the sooner it is commenced after the middle of the present month the better.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**T**HE work here will now consist of storing crops and cleaning ground and making it tidy till it can be dealt with for succeeding crops. Late Celery should be earthed-up in fine weather. Prepare Endive by blanching; take up Seakale and Chicory if wanted for early forcing, and let it lie for a few days exposed to all weathers, when it will receive a check, and after a week or two may be introduced to the forcing house.

Make up a Mushroom bed, and collect more manure for subsequent beds. Thoroughly turn the manure about for a week or two, and let it become fairly dry before it is made up, or the heat will not be maintained long.

#### HARDY FRUIT GARDEN.

**Pears for Planting.**—These are always in demand, and there is always a great glut just about the middle of October. The following are a few of the best varieties for planting to come in from August onwards: Beurré Giffard (about the best early Pear), Jargonelle, Williams' Bon Chrétien, Souvenir du Congrès, Triomphe de Vienne, Louise Bonne de Jersey, Marie Louise, Durondeau, Emile d'Heyst, Doyenné du Comice, Winter Nelis, Glou Morceau, Ne Plus Meuris, Beurré A. Lucas, Beurré Bachelier, Thompson's and, if a big Pear is required, Pitmaston Duchess. Catillac is about the best for stewing purposes, and is usable for several months. Any of the Pears noted above can be grown on the cordon system and in small collections. This method has much to recommend it, as it allows of a greater variety of sorts on a given space.

**Peach and Nectarine Trees.**—As soon as all the fruit has been gathered from late varieties, cut out any fruiting wood of the current year that is not required, and run a Birch broom lightly over the foliage to dislodge any loose and ripe leaves, so that the sun's rays can shine on every portion of the wood. Apply water if the soil is at all dry.

#### FLOWER GARDEN.

Roses may be lifted and replanted now, and this should be done if the plants show signs of being worn-out. Roses, like most other plants, delight in a change of soil. Do not leave the plants exposed while the operation of renewing the soil is going on, or the little roots may suffer considerably. Do this work, if possible, in fine weather, so that the soil can be worked down among the roots.

#### PLANTS UNDER GLASS.

**Tree Carnations** that are showing flower should now be assisted with weekly waterings of manure. Wood's or Bentley's preparations are quite safe and good. Keep the temperature about 55°, which is a nice growing medium, and syringe between the pots on all bright days to keep down insects.

**Malmaison Carnations.**—Flowering plants should have about the same temperature as the above, but plants, large and small, for next season's work should be kept cool and dry and close to the glass. The earliest plants may now be placed in 4½-inch pots for single flowers. Carnations suffer more from damp than any other cause, and plants in cool houses do not require much water at this season.

**Chrysanthemums.**—Now that the bulk of these are housed, they will require constant attention to the watering, and, if a plant or two are allowed to get dry, aphides will soon make an appearance.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**PRIMULA SINENSIS.**—Plants should now be removed from cold frames and given a well-ventilated structure. In arranging, it is well to give the same space as the individual plants are likely to occupy when in flower, as the foliage, being brittle, is apt to get damaged when handled. Before housing, a light top-dressing of Clay's Fertilizer, well mixed with finely-sifted soil, will supply all the stimulant necessary for them.

**Bulbs for Forcing.**—The chief thing to remember is to pot up the bulbs early, or as soon as they can be bought, which is generally early in October. If potted at once and plunged in a bed of ashes, Tulips and Hyacinths quickly root and are ready for removal to a pit or greenhouse during November and December.

#### FLOWER GARDEN.

**Herbaceous Borders.**—Any contemplated alterations in these may be carried out at once. Such borders ought to be cleared, manured and trenched every three or four years, and the earlier in the autumn this is done the better. Care should be taken in lifting and assorting the various plants, and the work should be carried out as promptly as possible. Care also must be taken to regulate the sizes and harmonise the colours as much as possible. All the more common and robust kinds should be sparingly used or excluded entirely; some suitable spot can generally be found for these in the shrub-beries or elsewhere.

**The Wild Garden.**—Now is the time to plant Foxgloves, Primroses and any other plants raised for this purpose, so that they may get established before winter. Where wild gardening is indulged in, the present should be a busy time in preparing pictures for the spring months. Natural informal stretches of Snowdrops, Crocuses, Narcissi and Tulips to succeed one another, with here and there groups of blue Apennine Anemones, Chionodoxas, Fritillarias and Camassias, cannot fail to appeal to and render one enthusiastic.

**Crocus speciosus.**—I must call attention to this beautiful plant. It has been blooming abundantly for three or four weeks past. It is seen at its best when carefully planted, say, a dozen corms in a patch, in good garden soil and then left undisturbed.

#### FRUITS UNDER GLASS.

**Orchard House.**—As the various orchard house fruits are gathered the trees should be put outside in a nice open position where they will not be subjected to drip from trees or overhanging buildings. Any that appear to require repotting should be attended to. Others may require attention in the way of drainage, for, in spite of the best care when potting, the drainage material is liable to get out of place or clogged occasionally, and this does much harm. The little pruning that is necessary for pot trees will probably have been done before now; if not, there should be no further delay in dealing with all kinds of stone fruits, especially Cherries, which are so susceptible to injury from the use of the knife.

#### KITCHEN GARDEN.

**Cabbages in Frames.**—Small plants from August sowings of Spring Cabbage should now be pricked out into frames, with a view to protecting them through the winter. The smaller the plants the better, provided they have healthy roots. Cos Lettuce should also be sown in the same way, as the weather we have had lately has induced a free and sappy growth, which would be easily injured by frost. Stir a little soot into the soil in the frames, as slugs are generally troublesome.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Carnations dying off** (H. K. Sy).—Judging by the roots and branches of the dead plant sent, your Carnation plants must have been very finely developed before they were attacked with wireworm. How to effectually get rid of these pests has been a difficulty with gardeners for all time. Nothing save catching and killing seems ever effective; but there has recently been placed on the market a soil fumigant named Kilogrub, for which the maker claims that it will kill these pests without doing the slightest injury to plant-life or to the soil. Your case seems a desperate one. You might experiment with it on a small scale with a sample tin, price 9d., to be had of Messrs. John Peak and Co., Bridgewater Chemical Works, Wigan, Lancashire. The best way we know of beyond this is by burying just under the surface of the soil sliced pieces of Carrots, Turnips, Potatoes or Lettuce stems. These will attract them in large numbers, and if daily examined and persevered with they may be greatly reduced.

**Variation in a Nicotiana** (J. G. R.).—It is highly probable that the variation to which you refer does not belong to *N. affinis*, but to *N. glauca*, in which group the colour range is considerable. Had you sent a spray of blossoms we could have given you the help you require. It is difficult to express an opinion as to the merit of a flower we have not seen.

### THE GREENHOUSE.

**Taking Hydrangea cuttings** (N. Ellis).—Hydrangea cuttings taken during September and inserted into pots of sandy soil will, if kept close in a cold frame, strike root by the spring, when they will commence to grow. The strongest of the shoots that have not flowered form the best cuttings. These should be taken off at a length of 4 inches to 6 inches, cut with a sharp knife immediately below a joint, the bottom leaves removed, and then inserted firmly into the sandy compost. Immediately they are put in a thorough watering through a fine-rosed can should be given, after which they will not need much water during the winter months; but still, the soil must not be allowed to become dry. In the spring, cuttings of the young growing shoots, taken as soon as they have passed their most succulent stage and put into a warm house, will, if they are kept close, root in two or three weeks.

**Coleus leaves dropping** (A Subscriber, Cork).—Coleus leaves, especially at this season of the year, drop with very little provocation, and in a dwelling-house where gas is burned nothing can be done to keep them in good condition. Throughout the winter the plants need a warm house in which a fairly dry atmosphere is maintained. A minimum temperature of 50° is necessary to their well-doing. It is not of great importance, but for convenience sake the cuttings are better put singly into small pots. "Gardening in Town and Suburb," price 2s. 6d. net, published by Longmans, Green and Co., 39, Paternoster Row, London, E.C., will give you the information you require. You omitted to send your name and address, hence the delay in replying.

### MISCELLANEOUS.

**Canker in Melons** (R. W. A.).—Presumably you allude to rotting off at the collar. In the first place, abstain from watering close to the stem; and in the

second, rub a mixture of powdered lime and charcoal into the affected part at the first sign of trouble.

**Yellow climbing Rose for greenhouse** (Cornwall).—Maréchal Niel is rather a difficult Rose to grow in an ordinary greenhouse. We think you would do better with Bouquet d'Or, Mme. Hector Leuilliot or William Allen Richardson. To induce it to flower a little later than the climbing Niphetos, you should prune it a week or two later. K. A. Victoria, Liberty, Caroline Testout and Mme. Abel Chateau may be grown as half-climbers; that is to say they would cover a space of some 5 feet or 6 feet fairly quickly; or you could obtain the climbing form of each sort, excepting the last-named, if you desire them for the roof. You omitted to enclose your name and address, and this causes delay in replying.

**Ice house** (M. F. W.).—The best position is below ground, with thick brick walls finally covered with soil, or inserted in a bank with north aspect, the chamber to take the form of a deeply-set cave. In such a position a small house need not be of greater internal diameter than 12 feet; the floor, as also the sides to several feet high, to be of stone or concrete. Set in a bank as you suggest, an opening large enough to admit of the Pine logs being closely arranged should be made. These Pine logs should be thatched with straw or Bracken and finally covered with moistened clay to assist in maintaining the requisite degree of coolness. By forming the house in the bank, you might, if the nature of the soil will permit, drive a deep chamber of oblong shape far into the bank; then, by erecting side walls 4 feet high, form a ridge roof of the Pine logs, to be first covered with sheets of corrugated iron and finally the soil. In this way you would doubtless secure the requisite conditions.

**Names of plants.**—Cobham.—*Cassinia fulvida* (synonymous with *Diplopappus chrysophyllus*).—F. C. Adams.—The Rose is *Hippolyte Barrean*, a Hybrid Tea. Rosebud.—Echamstress.—M. L. L.—*Helix* *Solerioli*. F. B.—*Spiranthes autumnalis*.—Miss Wakefield.—Clematis Jackmanii variety and Dahlia seedling (cannot match).—Weekly Reader.—*Colletia cruciata*.—Beginner A.—1, *Sedum sarmentosum variegatum*; 2, *Alyssum maritimum*; 3, *Mesembryanthemum cordifolium*; 4, *Begonia weltonensis*; 5, *B. acuminata*; 6, *B. metallica*; 7, *B. seedling* (cannot match); 8 and 10, *B. semperflorens* vars.; 9, *B. metallica* var.—A. Letch.—1, If this plant has fruits with hooks it is *Cupressus nootkatensis*, otherwise it is *Cupressus lawsoniaefolia*; it is not possible to identify without fruits; 2, *Acaphasis margaritacea*; 3, *Helichrysum petiolatum*.—H. Hatcher.—1, *H. Schultzei*; 2, *Catherine Soupert*; 3, *Souvenir de Dr. Jamain*; 4, *Irene Watts*; 5, *Violet Bouyer*; 6 and 7, flowers had fallen; 8, *Mme. G. Luizet*; 9, *Gloire des Polyanthes*; 10, *Margaret Dickson*; 11, *Anaë Alexieff*; 12, *Jules Margottin*.—L. E. Wither.—*Sedum telephium* and *Aster Amellus*.—C. E.—1, *Sedum roseum*; 2, *Eucynurus europæus*; 3, *Caragana arborea*; 4, please send when in flower.

Mrs. C., *Subscriber Weekly*.—*Ceanothus Gloire de Versailles*.—M. Somerset.—*Fuchsia procumbens*.—Blue Rock.—*Sedum spectabile* and *Salvia Horminum*.—R. B.—1, *Veronica salicifolia*; 2, *Ligustrum ovalifolium*; 3, *Veronica Traversii*; 4, *Escallonia punctata*. The discoloured piece of wood is probably Ash. The coloured portion is caused by a fungus named *Peziza ruginosa*. The Oak spangle galls (*Neuroterus lenticularis*) are caused by the larvae of the above-mentioned insects. The insects emerge from the galls in spring, lay eggs on the Oak leaves and then disappear. The galls appear again in autumn. The presence of the galls does not materially weaken the tree.

**Names of fruit.**—F. Dixon.—Worcester Pearmain.—R. E. D.—1, *Compte Flanders*; 2, *Uvedale's St. Germain*, very poor specimen; 3, *Pitmaston Duchess*; 4, *Catillac*; 5, *Marie Benoist*; 6, *Beurré Superfin*; 7, not recognised.—A. Preston.—*Doyenné d'Alençon*.—H. P. E.—1, *King of the Pippins*; 2, unable to recognise, possibly a local variety; 3, *Wellington* (Dumelow's Seedling); 4, *Gravenstein*; 5, *Scarlet Nonpareil*; 6, *Hawthornden*; 7, *Chelmsford Wonder*.—G. W. Euston.—1, *Beurré Clairgeau*; 2, *Emile d'Heyst*; 3, *Lane's Prince Albert*; 4, *Stone's Apple*; 5, *Lady Henniker*; 6, *Blenheim Orange*.—S. Smith.—1, *Eckville Seedling*; 2, *May Queen*; 3, *Cockle Pippin*; 4, *Bergamotte Espéree*; 5, very poor sample of *Compte Flanders*.—H. Nixon.—1, *Kewick Codlin*; 2, *Lord Derby*; 3, *May Queen*.—W. H. Fraser.—1, *American Mother*; 2, *Royal Nonsuch*.—E. S. Martin.—1, *Beurré Diel*; 2, *Marie Guise*; 3, *Hornead's Pearmain*; 4, *Beurré d'Amanlis*; 5, *Blenheim Orange*; 6, a form of No. 5; 7, *Mère du Ménage*; 8, *James Grieve*; 9 and 10, *Broomer Park*; 11, *Cox's Orange Pippin*; 12, *Improved Kewick Codlin*.—Jackson.—1, *Marie Louise*; 2, *King of the Pippins* (dessert); 3, *Fibbett's Pearmain* (cooking); 4, *Fearn's Pippin* (dessert); 5, *Sandringham* (cooking).—Woodbrook.—*Irish Peach*.—B. C. F.—The Queen.—X. X. A.—1, *Cellini Pippin*; 2, *Bess Pool*; 3, *Beurré Clairgeau*; 4, *Marie Louise*; 5, *Pear Maréchal de la Cour*; 6, *Yorkshire Beauty*; 7, *Old Hawthornden*.—C. G. O. B.—*Annie Elizabeth*.—H. M. B.—*Claygate Pearmain*.—Constant Reader.—1, *Cat's-head*; 2, *Golden Spire*; 3, *Lord Grosvenor*; 4, *Norfolk Beauty*; 5, *Prince Arthur*; 6, *Blenheim Orange*; 7, *Cellini Pippin*; 8, *Queen Caroline*; 9, *Northern Greening*; 10, *Boston Russet*.—C. A. W.—1, *Potts' Seedling*; 2, *Sandringham*.—Kite's Nest.—1, *Oslin*; 2, *Annie Elizabeth*; 3, *Rosemary Russet*; 4, *Boston Russet*; 5, *Fearn's Pippin*; 6, *Newton Wonder*; 7, *Reinette Grise*; 8, *Tom Putt*; 9, *Pearson's Plate*; 10, *Norfolk Beauty*; 11, *Tower of Glamis*; 12, *Cox's Orange Pippin*; 13, *Belle Dubois*; 14, *Flanders Pippin*; 15, *Belle Pootoise*; 17, *Peoniington's Seedling*; 18, *Duchess of Oldenburg*; 19, *Hoary Morning*; 20, *Golden Spire*.—G. White.—Apples: 1, *Nelson's Codlin*; 2, *King of the Pippins*; 3, *Golden Spire*. Pears: 1, *Doyne de Boussoch*; 2, *Marie Guise*; 3, *Forelle*.—H. J. D. Tennant.—Emperor Alexander.—W. H. R.—1, *Yorkshire Beauty*; 2, *Hambleton deux Ans*; 3, *Beurré Goubault*; 4, *Cox's Pomona*.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY.

THERE was a splendid display of flowers and fruits at the fortnightly meeting held on the 13th inst., and as the weather was fine visitors were also numerous. The splendid collection of Michaelmas Daisies from the Hon. Vicary Gibbs, and the collection of Apples from Lieutenant-Colonel Barton were the two outstanding features of the show, and deservedly came in for considerable attention.

#### ORCHID COMMITTEE.

Present: Mr. J. Gurney Fowler (chairman), Messrs. James O'Brien, de B. Crawshaw, Harry J. Veitch, Jeremiah Colman, H. Little, W. Boxall, R. Thwaites, F. J. Haubury, Stuart H. Low, A. N. A. McBean, C. H. Curtis, J. Forster Alcock, J. Cypher, J. Charlesworth, H. G. Alexander, Arthur Dye, W. H. White, H. A. Tracy, H. Ballantiae, Gurney Wilson, W. Bolton and A. J. Forster.

From H. Little, Esq., Baronshalt, East Twickenham, came a well-grown group, chiefly composed of *Cattleyas*, with a few other interesting subjects. *Laelio-Cattleya Luminosa*, a large specimen of *Cattleya Maottii inversa*, with some *C. Portia* varieties, were the most noticeable. A few small plants of *Cypripedium fairieanum* with *Oncidium* all added to the interest of this exhibit. Silver Flora medal.

Messrs. Hugh Low and Co. of Bush Hill Park, Enfield, put up a small but attractive group of very healthy plants, and all in a very floriferous condition. *Cymbidium erythrostylis*, *Laelio-Cattleya Firefly*, *Cypripedium Thalia gigantea*, *C. Milo Westonbirt* variety, *C. Maudie*, *Laelia Perrinii nivea* (with pure white sepals and petals and dainty cream and lilac lip), and *Bulbophyllum careyanum* were some of particular interest. Silver Banksian medal. The beautiful group from Messrs. Sauder and Son, St. Albans, was specially attractive on account of the magnificent plants of *Vanda cerulea* which were included. The flowers of these were intense sky blue, and the huge racemes made a grand display. Other plants noted were *Laelio-Cattleya Antigone*, *Cypripedium Olivia*, *C. Trafalgar* and *Laelio-Cattleya La France*. Silver Flora medal.

Messrs. Moore, Limited, of Rawdon, Leeds, had a small but good collection, among which we noticed *Cypripedium fairieanum*, *C. Mrs. F. L. Ames*, *C. menon-inversum*, *C. Melba*, the beautiful *Cattleya Armstrongiae* and the curious *Cynorchis peruviana*, with its pendulous racemes of dull cream flowers freely dotted with brown spots. Silver Banksian medal.

H. S. Goodson, Esq., Putney, S.W. (gardener, Mr. G. E. Day), put up a very fine group, which contained a large number of the choicer *Cypripediums* in addition to *Cattleyas*, *Miltonias* and *Odontoglossums*. The forms of *Cypripedium* insigne *Sanderæ* were particularly good. Silver Flora medal.

Messrs. Cypher and Sons' group from Cheltenham contained a large batch of *Cypripedium fairieanum*, many good *Cattleyas* and *Dendrobiums*. A few specimens that called for special mention were *Cypripedium Milo Westonbirt* variety, *C. bingleyense*, *C. triumphans*, *C. Olivia*, *Cattleya aurea*, *C. massiana*, *Odontoglossum grande* and *Masdevallia macrura*. All the plants shown were in the best possible health and evidently the result of high-class culture. Silver Flora medal.

Messrs. Heath and Son of Cheltenham staged a small group, in which *Odontoglossums* predominated. *O. grande*, *O. giganteum* and *O. Phalenopsis* were the most prominent sorts.

Messrs. J. and A. McBean of Cooksbridge, Sussex, had a small group of well-grown *Cypripediums* and *Odontoglossums*, *C. insigne* *Harefield*, *Hall*, *C. Maudie*, *C. Rossettii* and *C. albertianum* being a few of the best. Silver Banksian medal. Messrs. McBean also showed a magnificent specimen of *Cattleya bowringiana*, which carried ten large racemes of good-sized and splendidly coloured flowers. A beautiful plant of *Cattleya fulvescens* came from the same firm, and for each plant they received a cultural commendation.

From Messrs. Stanley and Co., Southgate, N., came a small group of good *Cattleyas* with a few others of botanical interest. Some seedlings of *Cattleya Minuca* showed considerable variation, although all from the same seed-pod. Silver Banksian medal.

Messrs. Charlesworth and Co., Hayward's Heath, Sussex (late of Heaton, Bradford), put up a wonderful lot of flowers of considerable interest, among which we noted *Phumina nobilis alba*, *Zygo-Colax wiganiensis*, *Cynorchis egertonianum*, *Laelio-Cattleya Luminosa* and *Oncidium Forbesii* with some beautiful hybrids. Silver Flora medal.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, Owen Thomas, P. W. Tuckett, John Harrison, Joseph Davies, G. Reynolds, J. Basham, P. C. M. Veitch, Alex. Dean, J. Willard, George Wythes, A. H. Pearson and Edwin Beckett.

Messrs. Hugh Low and Co. of Bush Hill Park, Enfield, exhibited a very good collection of Apples, which were splendidly finished and of good size. King of the Pippins, Cox's Orange Pippin, Kerry Pippin, Yellow Ingestre, Allington Pippin, Blenheim Orange and Cox's Pomona were a few of the best among dessert varieties, and New Hawthornden, Schoolmaster, Alfriston, Lord Derby, Beauty of Kent, Newton Wonder and Bramley's Seedling stood out well in the culinary section. Silver Banksian medal.

The magnificent collection of Apples from Lieutenant-Colonel Barton, Cheveney, Hunton (gardener, Mr. James Whittle), created quite a sensation, and rightly so. Rarely have we seen Apples exhibited in such excellent condition, and the fruit reflected the greatest possible credit on those

responsible for its culture. All were splendidly finished, and the huge specimens of Mère du Ménage, Emperor Alexander and Belle Dubois, which occupied the centre, were really wonderful. About eighty dishes were shown, and these included all the best dessert and culinary varieties in existence. Silver-gilt Hogg medal.

#### FLORAL COMMITTEE.

Present: Mr. H. B. May (chairman), Messrs. C. T. Drury, J. Walker, A. E. Bowles, J. Hudson, J. Green, Charles E. Pearson, A. W. Turner, G. Reuthe, W. Howe, J. F. McLeod, J. Jennings, R. Hooper Pearson, Charles Dixon, A. Turner, H. J. Jones, H. J. Cutbush, W. P. Thomson, E. H. Jenkins, W. J. James, Edward Mawley, George Paul, J. T. Bennett-Poë, W. T. Ware and George Gordon.

Messrs. James Veitch and Sons, Limited, Chelsea, brought a very fine group of new, rare and distinct conifers, not a few of them quite unique in character. The collection was a very large and complete one, and contained, among others, fine examples of *Pinus Armandii*, collected in China at an elevation of 5,000 feet, and which has proved, not only most distinct, but perfectly hardy in Messrs. Veitch's nursery at Coombe Wood. Other notable things included *Sciadopitys verticillata* (the Umbrella Pine), *Abies pungenis glauca pendula*, *A. p. glauca*, *Pinus pinea*, *P. ponderosa*, *P. laricio pycnantha*, *Torreya myristica*, *Abies excelsa fiedoniensis*, *A. Veitchii* Japan (very dark green and glaucous on the under-surface of the leaves), *A. subalpina lasiocarpa*, *Pinus pinaster maritima*, *Retinospora obtusa aurea* Crippsi, *Juniperus virginiana glauca*, *Abies hookeriana*, *A. nobilis*, *A. Omorika*, *Cupressus macrocarpa*, *Abies magnifica*, *Retelearia Fortunei*, *Cedrus atlantica glauca*, *C. a. aurea* and many more. A remarkable collection of beautiful, interesting and rare shrubs. There were about 100 distinct varieties exhibited. Messrs. Veitch also had a showy group of *Begonia elatior*, one of the winter-flowering class, the firm also having a fine lot of *Citrus japonica* in fruit. Silver-gilt Banksian medal.

The Misses Hopkins, Shepperton, had a small exhibit of alpine and rock plants in variety.

Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colchester, staged a lovely group of Roses, which, for mid-October, were of the highest excellence. Many notable varieties were included, such as Queen Mab, La Tosca, Gustave Regis, White Maman Cochet, Irish Elegance, Mme. Antoine Marie, Mrs. Edward Mawley, Corallina and others. Silver Banksian medal.

Mr. G. Reuthe, Keston, Kent, had a few hardy plants, such as *Crocus* and the pretty autumn-flowering *Snow-drop Galanthus Olge*, which, minus its leafage, is not unlike *G. nivalis*. *Oxalis lobata*, *Parochetus communis*, *Saxifraga Fortunei* and *Tropaeolum tuberosum* were also noted. Messrs. Eggett and Son, Thames Ditton, had a small rocky exhibit with hardy Ferns.

From Highgate Messrs. Cutbush and Son brought a splendid lot of Carnations, such as Winsor, Countess of Portland, Britannia, White Perfection, Robert Craig, Enchantress, Mrs. Burnett and Victory being among the best. Messrs. Cutbush also displayed a very fine lot of Orange trees in fruit, and the white and red-berried forms of *Pernettya mucronata*. *Dracena Brantii variegata* is a new variety striped longitudinally with yellow and green; a very fine plant for decoration. Silver Flora medal.

Messrs. H. B. May and Sons, Edmonton, filled a large table with hardy Ferns, comprising a delightful gathering of choice and interesting forms. The *Scolopendrium* were particularly well represented. A collection of shrubby *Veronicas* also came from Messrs. May and Sons. Silver Flora medal.

Messrs. George Bunyard and Co., Maidstone, had a large group of hardy plants, such as *Michaelmas Daisies*, *Lilies*, *Poppies*, *Anemones*, *Physalis Bunyardii*, *Aster trinellus*, *Desmodium penduliflorum*, *Kniphofias* and the like.

Messrs. W. Wells and Co., Limited, exhibited a very extensive group of *Chrysanthemums* and *Pentstemons*, the former in large or exhibition blooms, also single, decorative and early-flowering sorts. *Diana*, bronze; *Ethel Blades*, crimson; and Mrs. A. Thomson, rich yellow, among the latter were particularly fine. Silver-gilt Banksian medal.

Messrs. Paul and Son, Old Nurseries, Cheshunt, had a large collection of cut and other shrubs, such as *Cornuses*, *Weigelas*, *Berberis*, *Quercus*, *Acers*, *Pyrus sorbus edulis*, *Calycanthus occidentalis*, *Enonymus europæus*, *Encalyptus pulvinulenta* and *Paulownia imperialis*.

Messrs. Dobbie and Co., Rothsay, contributed a beautiful assortment of *Cactus Dahlias* in many choice colours. The flowers were excellent for so late a date.

Seasonable hardy flowers from Messrs. Barr and Sons included *Kniphofias*, *Michaelmas Daisies*, *Phloxes*, autumn *Crocuses* and other things.

The Hon. Vicary Gibbs, Elstree (gardener, Mr. E. Beckett), had a lovely table of *Michaelmas Daisies*, the many beautiful varieties being displayed to perfection. Apart from the many varieties of *A. Anellus*, some excellent seedlings were seen. *Maidenhair* (a small-flowered sort), *Chapmanii*, *Triumph* (a good cordifolius seedling), *White Diana*, Mrs. J. T. Raynor, Star Shower and *Climax* (a very handsome *Novi-Belgi* form, with lax pyramids of flowers) were some of the best. The arrangement was very effective. Silver-gilt Flora medal.

Messrs. G. and A. Clark, Dover, had a large display of hardy flowers, in which *Cimicifuga simplex* Clark's variety was prominent.

Mr. Seale, Sevenoaks, staged a capital exhibit of *Dahlias* and other flowers artistically arranged. Silver Banksian medal.

Messrs. T. S. Ware and Co., Limited, Feltham, had a varied display of hardy flowers, alpine and other things, *Viola primulifolia* being an interesting plant.

The Roses from Messrs. K. Harkness and Co., Hitchin, were very charming, such as Frau Karl Druschki, G.

Nabouhand, White Maman Cochet, Corallina and others eliciting admiration. Silver-gilt Banksian medal.

Messrs. J. Cheal and Sons, Crawley, exhibited single and *Cactus Dahlias*; and Messrs. Hugh Low and Co. staged *Carnations*, Orange trees in fruit and miscellaneous plants in flower.

Messrs. John Jeffries and Co., Cirencester, had a seasonable exhibit of hardy evergreen shrubs and conifers, such things as *Cedrus atlantica glauca*, *Abies pungenis glauca kosteriana*, *Cupressus lawsoniana elegans*, *Abies Veitchii*, *Picea lasiocarpa* and *Cupressus macrocarpa aurea* being among the best. Silver Flora medal.

Mr. H. J. Jones, Lewisham, S.E., had a very fine assortment of *Michaelmas Daisies* in all the leading sorts. *Diana*, *Albulus*, *William Marshall*, *Elaine*, *Calliope* (fine blue), *Ryecroft Pink*, *Melpomene* (dark violet) and Mrs. J. F. Rayner being among the best. A capital lot of *Chrysanthemum Moneymaker* (a good white-flowered sort) was also noted. Silver Banksian medal.

Messrs. H. Lane, Berkhamstead, had *Roses* and *Carnations*; and Mr. Frank Baxter, Caterham, had a large group of *Michaelmas Daisies* and early-flowering *Chrysanthemums*.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

THE early autumn exhibition in connexion with the above society was held at the Crystal Palace, on Wednesday and Thursday, the 7th and 8th inst., and proved a great success, many beautiful exhibits being staged. Many collections in the bunch classes were disqualified, owing to the bunches being over the specified size. We would suggest to the committee that the exhibits be arranged in future a little more in rotation, as this would add greatly to the convenience of visitors without detracting in the least from the artistic side of the show. As arranged on this occasion it was well-nigh impossible to track all the entries; otherwise the arrangements were all that could be desired.

#### DIVISION I.—OPEN CLASSES.

For a floral display of *Chrysanthemums* (plants or cut flowers or both), and suitable foliated plants, to be arranged on the floor, first honours went to Mr. F. Brazier, Caterham, Surrey, for a very effective group composed of large-flowered and decorative varieties, all well grown and in numerous warm colour shades. Messrs. J. Peed and Son, West Norwood, were a good second, the flowers in this case being intermixed with a few well-grown *Caladiums*.

In the class for twenty-four Japanese blooms, eight varieties, Mr. H. Parr, gardener to F. A. Bevan, Esq., Trent Park, New Barnet, was the only exhibitor, but the judges considered his collection worthy of first prize. His flowers were of medium quality, Mrs. A. T. Miller and Sapho being the best.

For twelve blooms of Japanese varieties, distinct, there were three entries, the premier award being secured by Mr. Martin Silsbury, Shanklin, Isle of Wight. His flowers were a very good lot, Algernon Davis, Glory (a new yellow seedling), Mrs. A. T. Miller and Shanklin (a new ivory white variety) being the best. Second prize went to Mr. G. Halsey, gardener to Mrs. J. Lyon, Caterham Valley, whose flowers were of medium quality, Bessie Godfrey being the best. The third prize collection was shown by Mr. H. Parr, New Barnet.

In a similar class for six varieties four competitors tried conclusions, Mr. C. A. Horton, gardener to T. L. Boyd, Esq., North Frith, Tonbridge, being first with really good flowers, Mrs. A. T. Miller and Mrs. W. Knox being specially noteworthy. Second prize went to Mr. F. Blackith, Ravenscroft Park, W., for a much inferior lot, Godfrey's Pride and Mrs. A. T. Miller being the two best. Mr. T. J. Broom, Holyport, was third.

Apparently there was only one entry in Class 6 for twelve bunches of early-flowering *Pompons*, this coming from Mr. John Smellie, Bushby, near Glasgow, and securing first prize. The flowers were a very good lot and had stood the long journey well. *Flora*, bright yellow; *Scarlet Gem*, crimson-scarlet; and *Mignon*, small, deep yellow, were the most conspicuous.

For two vases of nine Japanese varieties with foliage there were two entries, the first prize being appropriated by Mr. G. Halsey for very good flowers, well arranged. The second prize went to Mr. F. Blackith.

In Class 8, for twelve bunches, distinct varieties, grown in the open and not disbudded, the competition was good. A fine lot staged by Mr. J. Smellie, Bushby, near Glasgow, was disqualified, owing to the bunches exceeding the size limit, and the same reason disqualified those shown by Mr. G. Bowness. First prize went to Mr. A. Hawkins, Gordon Road, Ealing, for a good collection of very clean flowers, among which we noticed *Horace Martin*, *Jimmie*, *Polly* and *Roi des Blancs* as being extra fine. Mr. H. Parr, New Barnet, was a very close second.

In a similar class for twelve bunches, disbudded, Mr. A. Hawkins was again first for moderately good flowers, with the exception of the *White Le Cyne*, which were very dirty. *Goacher's Crimson* and *Marie Massé* were very fine.

#### DECORATIVE EXHIBITS.

For a table of bouquets, wreaths, &c., the first prize was withheld by the judges. The second prize went to Mrs. H. L. Sell of Luton, and the third to Mrs. A. H. Cole, Camberwell New Road, S.E.

In Class 11, for a table decoration of *Chrysanthemums* with suitable foliage, the competition was very keen indeed, the first prize being well won by Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Dornington, Laurie Park, Sydenham, with a beautiful display of yellow and bronze flowers, intermixed with *Asparagus Sprengeri*, *Koelia tricolorphylla* and *Grasses*. Mrs. H. L. Sell of Luton was a good second with flowers of similar colours, and Mr. R. Edwards, gardener to C. A. Morris Field, Esq., Beechy Lees, Sevenoaks, was third.

Class 12, for three *epergnes*, was well contested, Mr. A. W. Trossell, The Parade, Beckenham, winning the premier prize with a beautiful arrangement of yellow, bronze and white flowers and *Asparagus* and *Maidenhair Fern* fronds. Miss C. B. Cole, The Vineyard, Feltham, and Mrs. G. Knights, Border Crescent, Sydenham, were second and third respectively.

#### AMATEURS' CLASSES.

For a dinner-table decoration the entries were numerous, Mr. A. W. Trossell being placed first for a beautiful arrangement of yellow and white flowers, with *Maidenhair Fern*, *Asparagus* and *Amelopsis*. Mr. J. W. Harrison, Laurie Park Gardens, Sydenham; and Miss E. H. Ekins, Rushden, St. Albans, followed in the order named.

Two competitors only entered Class 15, for six bunches of early-flowering Japanese varieties grown in the open and disbudded. The first prize went to Mr. W. H. Chalk, Slough, for a remarkably good lot of flowers. Miss B. Miller, deep yellow; and *La Pactole*, bronze and old gold, were the two best. Mr. R. Sutherland, Auld Aisle, Kirkintilloch, N.E., was the other exhibitor, and he was awarded the second prize.

For twelve bunches of early-flowering Japanese grown in the open and not disbudded, the competition was better, there being six entries; but each was disqualified by the judges owing to the bunches exceeding the specified size.

For twelve bunches of early-flowering *Pompons*, Mr. A. Haggan, Bushby, near Glasgow, was the only exhibitor, and the judges awarded him first prize.

#### DIVISION II.—OPEN CLASSES.

For six bunches of early-flowering *Pompons* there were three entries, the first prize going to Mr. J. Smellie, Bushby, near Glasgow, for splendid blooms. The second and third prizes were won respectively by Mr. J. Emberson, Walthamstow, and Mr. W. J. Cornell, West Norwood.

For six bunches of early-flowering Japanese or decorative varieties, grown in the open and disbudded, the first prize was well won by Mr. J. Emberson, Walthamstow. His *Perle Châtillonaise* and *Goacher's Crimson* were particularly good. Mr. G. Bowness, Bushby, near Glasgow, was a close second, and Mr. J. Smellie was third.

The baskets of *Chrysanthemums* and autumn foliage and berries in this section were very pretty, Miss C. B. Cole of Feltham being the principal winner.

#### NON-COMPETITIVE EXHIBITS.

These formed, as usual, a very fine feature, and added greatly to the attractiveness of the exhibition.

Hobbies, Limited, of Dereham, Norfolk, put up a truly marvellous bank of *Dahlias* and *Roses*, the latter being remarkably good for so late in the year, and demonstrating to the full the value of the *Rose* for autumn decoration. Lady Ashton, G. Nabouhand, Mme. Jules Grolez, Betty and Mme. Abel Chateau were a few that called for special mention. Gold medal.

Messrs. W. Wells and Co., Limited, Mersham, Surrey, staged a beautiful semi-circular group, in which large and decorative *Chrysanthemums*, with choice *Michaelmas Daisies*, predominated. All the flowers used here were of the best possible quality, and the group fully merited the gold medal awarded.

Mr. Frank Brazier, Caterham, Surrey, arranged a large circular group on the floor, composed chiefly of the better class *Michaelmas Daisies*, with plumes of *Pampas Grass* and edged with cut trusses of herbaceous *Phloxes*. This was a very lightly-arranged group, but would have been better without the *Pampas Grass*. Large silver medal.

Mr. G. W. Riley of Herne Hill was showing his green-houses and rustic summer-houses and arches, which attracted considerable attention. Large silver medal.

Mr. J. Williams, 4A, Oxford Road, Ealing, exhibited "Rural Table Decoration," which appeared to be very useful as aids for arranging flowers. Small silver medal.

Messrs. T. S. Ware, Limited, of Feltham exhibited a very good bank of early-flowering *Chrysanthemums* and *Dahlias*, the latter including numerous *Cactus* and *Pæony*-flowered varieties in excellent condition. Gold medal.

The collection of fruit staged by Messrs. S. Spooner and Sons of Hounslow was very good indeed, the Apples especially being remarkably well coloured. The Pears too, were excellent and comprised many of the best varieties in season. Silver-gilt medal.

Mr. H. J. Jones, Ryecroft Nursery, Hither Green, S.E., staged a very good bank of *Michaelmas Daisies*, large and small-flowered varieties being freely represented in good condition. In addition, some excellent seedling Japanese *Chrysanthemums* were shown, the variety *Master James*, light crimson, with old gold reverse, being particularly good. Silver-gilt medal.

From Messrs. J. Laing and Sons, Limited, Forest Hill, came a good collection of *Crotons*, *Dracenas* and other stove foliage plants in great variety, together with *Cactus Dahlias*. Large silver medal.

Messrs. J. Cheal and Sons of Crawley, Sussex, were showing their beautiful single and *Cactus*-flowered *Dahlias* in great variety, the quality of the flowers being really first-class and reflecting great credit on the firm. A few early-flowering *Chrysanthemums* were also included. Silver-gilt medal.

Messrs. J. Peed and Son of West Norwood had an attractive display of their well-known seedling tuberous *Begonias* gathered from the open. These were arranged in masses of their respective colours and were most effective. Small silver medal.

Mr. Norman Davis, Framfield, Sussex, arranged a superb group on the floor, this being composed chiefly of well-grown *Michaelmas Daisies* with a few early-flowering *Chrysanthemums* intermixed. The arrangement and quality of this group were both of the highest order, and fully deserved the gold medal awarded.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

## NOTES FROM PARKS UNDER THE LONDON COUNTY COUNCIL.

BEING much interested in sub tropical bedding, my interest has been greatly increased this year by visiting some of our London County Council parks. The many different designs and ways of planting the beds really show considerable artistic ability, and give visitors many pleasurable and thoughtful occasions for a halt and for study. Should there be any of your readers intending to pay these wonderful gardens a visit this or next year, I would suggest their seeing the following parks in something like this order: Battersea, Finsbury, Peckham Rye, Springfield, Dulwich and Victoria. The above, to my mind, form a great study to those interested in the great gardening art of the day, and are well worth a visit from devotees with a few idle hours to spend. How many people know that such beautiful flower-beds are to be seen in London? I found out when visiting these parks that, in certain localities, the poorer the neighbourhood the higher the culture of the flowers, which, to my mind, are a real God-send to London humanity. I have learnt much this year on going round these different parks, and no doubt some of your readers who go round will do so also.

It may interest some to know which park struck my eye most. For skill in culture, planting, arranging and getting together such a collection of novelties in flower-blooms and foliage plants, Finsbury Park is first. Here are many striking beds producing great effect. There is one particularly beautiful round bed arranged with standard Gnaphalium macrophila, pink Lantana and a groundwork of the golden Fuchsia gracilis, Anthericum variegatum, orange Lantana, Mesembryanthemum cordifolium variegatum, Celosia pyramidalis, with a Geranium edging round the bed of Little Dandy. This highly uncommon contrast was extremely graceful. There were also two beds of standards, and dwarf plants under the standards of a good salmon-coloured Fuchsia Mrs. Rundle. I do not remember to have seen a more beautiful picture. The silvery foliage of Artemisia arborescens is very prominent among the flower-beds in this park.

The next and most beautiful park under the London County Council is Battersea (199½ acres) for both flowers and landscape. When I saw this park I thought, Why do people spend so much money going away from London? Every twist and turn in this extensive oasis is full of the most interesting peeps, and when in the sub-tropical garden one could well imagine, say, Brazil. The most striking feature was the valuable succulent bed which contained a most interesting plant, Portulaca afra, the bark of which resembles the elephant's hide and to the touch moves and

feels like a piece of indiarubber. There are also some beautiful specimens of the Phoenix Tree and a large, magnificent bed of the yellow Lantana named Drap d'Or, the best I have ever seen growing out in the open. In this spot precious and difficult-growing flowers abound in great perfection. It is really a wonderful sight of picturesque and clever planting. After leaving the gardens I took a trip on the lake in the motor-launch, just at dusk, and could well imagine myself far away from London.

By the way, the students' garden is well worth a visit, and it is a pity this is not made into a lovely Old English garden with a beautiful wall all round. Whatever you do, do not miss this park.

In Peckham Rye Park there are some very striking pyramid tower-shaped plants 6 feet high of Iresine brilliantissima, trained most perfectly in shape. It struck me what a beautiful effect Kochia scoparia trichophila would have against this grand plant. There was a particularly good carpet bed of standard and dwarf Coleus, not a single leaf being above another. There was also a fine bed of Paul Crampel Geranium. Also at Peckham is a new English flower garden, very beautiful and picturesque, and only opened this year. I noticed that the Kochia was named Kochia trichophila, but I believe the correct botanical name is Kochia scoparia trichophila, there being only one variety. This garden is full of beautiful arbours.

Springfield Park is especially good this year for the graceful and well-grown pyramid specimens of Fuchsias, Iresines, Indiarubbers, Plumbagoes, Heliotropes, Ivy Geraniums, and the Eucalyptus Gum Tree plants, planted in very large pots sunk in the turf and very artistically arranged, without cutting out the usual flower-beds; the arrangement, indeed, is quite a novel way of bedding out.

A walk through Dulwich Park at once leads one to admire the beautiful landscape. The Rose and American gardens are beautifully laid out. There is a fine carpet bed representing the arms of Dulwich College, also a good bed of standard Veronica Andersonii with Cannas for groundwork and the golden Fuchsia gracilis for edging. Another bed was the yellow Lantana Drap D'Or and the dark Celosia Thomsonii, and the succulent bed was very fine also; while another, just inside one of the principal entrances, was a bold effect of sub-tropical plants sunk in large pots in the grass, such as standard Veronicas, Plumbagoes, and some fine Fuchsias called Mrs. Rundle, Charming and Scarcity. All these beautiful beds gave a wonderful effect.

Victoria Park has a very fine bed formed and planted to represent the Prince of Wales's Feathers. This scheme has thousands of the Geranium called Flower of Spring and Iresine Herbstii plants, with a bold wide edging of blue Lobelia, while a mixture of various plants form the centre. I understand this bed took several weeks to plant, and can well imagine it from the size. The Kochias here were the largest and finest I have ever seen.

I have also visited Waterlow Park, Avery Hill, Brockwell Park and Golders' Hill this year; the feature of the latter is that not a single Geranium of any kind is used. The Old English garden was

full of beautiful rambling Roses blooming in great profusion—truly a pretty sight. I noticed many artists sketching in the cosy corners. This old garden contains all the herbs mentioned in Shakespeare's Works. A beautiful old sun-dial (minus a motto) graced well-grown clumps of Phlox, Zinnias and Kochias. The cultivated Thistle gave quite a tropical appearance.

Brockwell Park's Old English garden contains not only all the herbs, but the plants mentioned in Shakespeare's Works. There was a beautiful bed of Cockscombs and Celosias and some fine specimens of standard Heliotropes and Fuchsias. There was a lovely old wall sun-dial in the corner (again no motto). The laid-out flower-beds of the park I did not admire so much—the beds were in great need of rain.

Waterlow Park, from the Archway Road entrance, has a beautiful bank of mixed flowers. The Old English garden contains, besides the herbs, all the garden plants mentioned in Shakespeare's Works.

Avery Hill has a splendid winter garden and some beautiful flowers in the side terrace. The flower-beds in front, however, left much to be desired.

I was much struck with the happiness of everybody around me. All appeared to be greatly enjoying the different kinds of amusements provided by the London County Council, from a skipping-rope for the little children to the bowling-green for the older men. The only game which appears not to be played at present is golf. I was much interested in some of the side remarks overheard while admiring the flower-beds, such as "What a sin to spend such a lot of money!" What a lot of money "they" spend over these parks laying out these beautiful beds, which form a real lesson to anyone who is fond of gardening. If anyone thinks our money is wasted on our parks it is a very grave mistake, for I particularly watched with intense interest the great number who really did enjoy the lovely flower-beds in the London County Council parks, and I am quite sure the money is well spent and gives endless pleasure to many of the people of London. I hope the London County Council will spend more and more money every year in showing that London can, with all its smoke, fogs and disadvantages, produce flowers of the highest standard, second to none in the world. V.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

October 27.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1—6 p.m. Lecture at 3 p.m., by the Rev. Professor G. Henslow, V.M.H., on the "Modification of Leaves and Stipules for Special Purposes." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster. Croydon Chrysanthemum Society's Show (two days).

**Resignation of Sir Daniel Morris.**—Those connected with the West Indies will learn with regret that Sir Daniel Morris, K.C.M.G., has resigned the post of Imperial Commissioner of Agriculture for the West Indies. From 1886 till 1896 he was assistant-director of the Royal Gardens, Kew, and in the last-named year he was appointed to the West Indies post. His influence in these islands will long be felt, as it has been mainly through his energy that the cultivation of cotton has been developed. Sir Daniel was also for some time treasurer of the Royal Horticultural Society. His services to tropical agriculture will be greatly missed.

**Conference of fruit growers at the Wye Agricultural College.**—A conference of fruit growers will be held at the South-Eastern Agricultural College, Wye, Kent, on November 27, under the chairmanship of Mr.

C. W. Radcliffe Cooke, President of the National Association of English Cider-makers. "Insecticides" will be discussed by Mr. Spencer Pickering, F.R.S.; "Spraying and Spraying Machinery," by Mr. E. S. Salmon; and "Grading and Packing," by a representative from British Columbia.

**Horticultural societies of Ontario.**—The second annual report of the above societies, published by the Ontario Department of Agriculture, contains some most useful and interesting information to horticulturists. At the second annual meeting held in the City Hall, Toronto, fifty-eight delegates were present, and numerous addresses on horticulture, all of which are embodied in the report, were delivered. In the Province there are sixty-three societies with a membership of nearly 7,000. Under the new Act six other societies found it necessary to become merged with agricultural societies; their membership was 540. The total grants to societies in 1906 was \$5,956; the grants in 1907 amounted to \$8,000.

**Dundee Horticultural Association.**—The annual report of this flourishing horticultural association, which is doing so much excellent work in the district it covers, has just been issued to the members. It reports a small increase of membership and continued usefulness during the past session. The treasurer's statement is also of a generally favourable nature, there being a small balance in hand. The Social Fund shows a credit balance also, and the council record their thanks to those who gave the members the privilege of visiting their gardens, and also to the committee of the Technical Institute for the use of rooms. An admirable syllabus of papers for the coming session has also been prepared and is issued along with the report and list of office-bearers.

**National Rose Society.**—The next metropolitan exhibition in connexion with the above society will be held in the Royal Botanic Gardens, Regent's Park, N.W., on Friday, July 2, 1909. The date of the provincial show, to be held at Luton, is not yet fixed. The autumn show will again be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, the date fixed for this being September 16.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**"The Garden" Flower Show.**—As a reader of THE GARDEN for many years and an admirer of the valuable services it has rendered amateurs, I am much pleased to see the announcement on page 455 that its readers are promised another flower show in 1909. I am sure it will be most welcome, as they will have more time to prepare and obtain a much better knowledge of the work required, as, though the last show was splendid both as regards quality and effect, I feel sure the one promised will be a horticultural triumph. With regard to next year's show, I would ask the Editor to continue, as far as possible, the small classes to encourage amateurs with gardens somewhat limited in size—indeed, if possible, to favour this class—as these exhibitors are a large class and require more encouragement than larger exhibitors who show frequently. But by this I do not depreciate the latter, as the exhibits staged on the last occasion were equal to any at the leading summer shows. I would also suggest that a limit be placed in some of the vegetable classes. In a few cases I noticed there was quantity in excess of quality—I mean, too many varieties, whereas fewer would have been much better, as it would save carriage, space and time in many ways. To get a dozen good dishes requires considerable care.—AMATEUR. [We thank our correspondent very much for his kindly remarks, which shall have our fullest consideration. We welcome any suggestions

our readers care to make before issuing the schedule.—ED.]

**Lilac flowering in the open.**—I send a piece of Lilac cut to-day (October 14); several trees are full of buds. I have not previously seen Lilac bloom out of doors at this time of year.—A. H., *Storrington, Sussex.*

**Hedychium gardnerianum.**—This beautiful flower, a native of the Himalayas and commonly known as the Garland Flower, is not met with in gardens as often as it deserves. The handsome flower-spikes, with their delicious perfume, make it a most suitable plant for the conservatory, especially where such structures adjoin the mansion. A plant now in flower here, with three fully-developed spikes, each carrying fifty or more flowers, is an object of great admiration.—G. JOHNSON, *The Gardens, Durdley Lodge, Bishops Waltham.*

**Galanthus Olgae.**—Mr. F. Herbert Chapman is quite correct in saying that he cannot see that the flowers of this species differ at all from *G. nivalis*, as, like several other autumnal-flowering Snowdrops, it appears to be simply a form of our common Snowdrop. It is a Snowdrop I had for a few years, but lost in some way or other. In common with other Snowdrops of autumnal habit, it blooms before the leaves come, and should therefore be carpeted with some low-growing plant or planted in grass. It comes from Mount Taygetus, in Greece, and is there said to flower in October. After the first year it was usually a little later than that with me.—S. ARNOTT.

**Late Peas.**—In THE GARDEN for the 10th inst., page 490, one of your readers mentioned Carter's Michaelmas Pea as a good late variety. I have to-day (October 13) picked a fine dish of Ne Plus Ultra, and the growth is as green as one could wish to have; also I have Sutton's Satisfaction and Sutton's Latest of All in full bearing and looking the picture of health, and if frost does not set in I shall have Peas for at least three weeks. I used a lot of Vaporite in the soil before opening the trenches for the Peas, and I believe that has a lot to do with the plants being so green and vigorous.—JOHN TAYLOR, *Altyferin, Nantgarwedig.*

**Precocious Elms at Worthing.**—It may interest your readers to know that here in Worthing is an avenue of young Elms bright with the green of leaves that have anticipated normal events by some six months, and I have noticed, in one garden, an Almond, a Deutzia and a Spiraea in the same confiding condition. In Paris the same phenomenon is not unusual in the case of the Horse Chestnut, but I venture to think that very rarely in this country has the Elm borne two crops of leaves in the same year. Perhaps some of your readers will contribute their knowledge on the subject.—REGINALD RANKIN.

**Genista mantica.**—This pleasing Broom is again in bloom, after having flowered well for a long time in early and late summer, and its clusters of good yellow flowers are especially welcome in October. An Italian species, it is yet quite hardy in my garden, where it is now forming good bushes of deep green leaves, plentifully supplemented by the clusters of flowers already mentioned. It apparently delights in a sunny position and rather dry soil. Although quite hardy, it appears to like a little shelter from cutting winds, as a plant I have which is partially protected from cold winds by other shrubs is much more thriving than one which is quite exposed and in a place which receives the full blast of the coldest air we have here. The latter is rather badly cut at times, but invariably recovers as the summer comes on. This Broom is sometimes to be procured as *Carniola mantica*.—S. ARNOTT, *Sunnymead, Dumfries.*

**Sweet-scented Roses.**—In answer to your correspondent who asks for the names of Roses remarkable for fragrance, I have found in my garden that Dupuy Jamain, La France de '89

and General Jacqueminot are very sweet. Le Progrès, too, and Laurette Messimy have a very delicate scent, but these are more elusive than the three first named in their perfume.—MABEL A. G. DILL, *Dorset*.

—I beg to send my list of Roses which I consider most fragrant, but we have to remember that soil and situation greatly modify scent as well as colour. Here the soil is practically worthless, and the whole of my beds are made up to a depth of 2½ feet to 3 feet with artificial soil, a mixture of meadow loam, yellow loam, leaf-mould, manure and green marl, mostly carted from various distances; subsoil, sand. I have about 1,000 Rose trees. I may mention that no hand-picking of caterpillars or cures for aphides are needed here; an army of tits—great, blue, marsh and cole—do all the work, with willow wrens and even wasps when feeding their grubs; I feed birds all the year round. The most fragrant Roses, in open ground only: Common Provence (Cabbage) and common Moss, Mme. Isaac Pereire, Bourbon, and, what I consider an identical Rose, Marchioness of Lorne, the former excellent as a standard; Charles Lefebvre, Alfred Colomb, Heinrich Schultheis, Lady Helen Stewart, Mme. Victor Verdier, Duke of Teck, Mrs. John Laing, La France when well fed; Gloire de Dijon, strong Tea scent I do not care for; Mme. Berard, when it will open well, too full; Maréchal Niel, on warm wall; Mme. Engène Verdier, rather delicate, lovely; Pink Rover, Mme. Abel Chatenay, all the Gallica Roses, especially Village Maid; Conrad F. Meyer, rugosa; Rose à parfum de l'Hay, rugosa; Jersey Beauty, wichuraiana, half-open buds, a wild Rose scent; and for sweet foliage the Penzance Briars, especially Lady Penzance.—G. ROBINSON, *Ringwood, Hants*.

**Rosa Verschuren.**—In reference to the articles in THE GARDEN for the 10th inst., on Roses grown in a South Bucks garden, I should esteem it a favour if the writer, the Rev. J. B. Shackle, would say through your columns where Rosa Verschuren may be procured, as I cannot find it in any of my catalogues.—A. SAUNDERS

**A good crop of Melons.**—The illustration shows a crop of Sutton's Best of All Melon grown on the stage in a span-roofed house at Paddockhurst Gardens, Sussex. The house is 26 feet long and 14 feet wide. The plants are grown in wooden boxes the length of the house, and 14 inches deep and the same wide. The Melons are planted 1 foot 9 inches apart, and each carries from four to five fruits of good size and excellent flavour. These, perhaps, take more water by being planted in shallow boxes, but canker and stem-rotting are done away with. For early and late supplies bottom-heat is essential, and too much manure under them is often the cause of failure.—A. B. WADDS.

**Rose Isabella Gray.**—In reply to Mr. Kemp (page 469), I would suggest that he write to M. Jules Gravereaux, Roseraie de l'Hay (Seine), for the above-named Rose. I notice the variety occurs in the catalogue which this gentleman issues for private circulation. If he could not supply plants it is possible that buds or grafts could be obtained. Someone should take up the hobby of reviving some of these old golden Roses. I fancy they would surprise many present-day rosarians. It is true they were difficult to grow; but then the ardent rosarian would surmount these difficulties. In the "Rose Garden," by the late Mr. William Paul, Isabella Gray or Miss Gray is described as "flowers deep yellow, large and full, form globular, growth vigorous. A good climbing Rose under glass." The subject of budding Maréchal Niel upon other Roses is one full of interest. My father was one of the first to bud Maréchal Niel on to another Rose. He used the yellow Banksian as his stock, and he informs me that the buds produced marvellous blooms the first year, and created quite a furore when exhibited at the Crystal Palace. This was about the second year after Maréchal Niel was introduced. In THE GARDEN,

May 7, 1881, there is an account by Mr. C. M. Hovey, Boston, Mass., U.S.A., of a Maréchal Niel budded on to a plant of Solfaterre, this latter being on its own root, and one gathers from this article that he had a great success with the Maréchal in this way; but the experiment was carried out under glass. I wonder if anyone has tried the R. indica stock for Maréchal Niel. Mr. William Robinson informed me recently that he had seen a marvellous plant of that superbly-coloured Rose Georges Schwartz budded on this stock; but this, I believe, was in France. Here, in England, we should need to plant the R. indica under glass and then bud the Maréchal upon it, as the stock is not hardy. If the R. indica answers so well as a stock, why should not the common China also be employed? This could be grown outdoors against a south or west wall. If we can once obtain the right stock, so as to ensure the immunity of the Maréchal from canker, we shall accomplish much.—P.

**Roses with malformed centres.**—I have been much struck of recent years by what I believe is a growing tendency for our Roses to come what we locally call "quartered," or, in

## MESSRS. WM. PAUL AND SON'S WALTHAM CROSS NURSERIES.

**W**E recently spent a most pleasant afternoon in the extensive nurseries of Messrs. William Paul and Son at Waltham Cross for the purpose of inspecting the stocks of Roses, hardy ornamental trees and shrubs, and the fruit trees and bushes which will be sent to customers during the present planting season. The nurseries are situated about twelve miles from London on the Great Eastern Railway, trains running thither in about half-an-hour.

The Roses, of course, attracted us first, and the extent to which these are grown needs seeing to be realised. Of pot Roses there are many thousands, and we were particularly interested in some healthy-looking batches which have been specially prepared for the purpose of giving flowers from now onwards until well into the

A GOOD CROP OF MELONS AT PADDOCKHURST GARDENS, SUSSEX.

other words, with a split or confused centre. In carefully examining the blooms in even a first-prize box at any of our leading shows, this defect appears to me to be increasingly apparent, and not considered the serious blemish it was at one time looked upon to be. Some varieties seem much more prone to this malformation than others, and one of the greatest sinners in this respect with me is J. B. Clark. What is the real cause of this distortion of the bloom? At one time I thought the solution lay in injudicious disbudding; but, if so, why does Frau Karl Druschki, disbudded in exactly the same manner as J. B. Clark, always come with a perfect centre? Then, again, I have wondered if hard pruning has something to do with it; but I find that some plants I purposely pruned lightly were quite as addicted to the bad habit. Perhaps a too rich soil may be a contributory cause, and, lastly, possibly extreme fluctuations of temperature, retarding and accelerating the flow of sap alternately, may lie at the root of the evil. I should be glad to hear the opinions of other readers on this somewhat important subject.—B. W. PRICE.

new year with only the temperature of a warm greenhouse. These plants need no pruning or repotting, a little judicious feeding with the temperature named above being practically all they require. Richmond, Mrs. Aaron Ward (a very delightful Rose, with the colour of William Allen Richardson), Catherine Mermet, Hugo Roller and Marie van Houtte were a few that we noticed doing particularly well.

Of Roses in pots for forcing early next spring we inspected a very extensive collection of exceedingly healthy plants, among them being several houses filled with Ramblers in pots for providing the magnificent pillars of blooms such as are shown by Messrs. Paul at the Temple Show. Judging by the firm, well-ripened rods, many of which were over 20 feet in length, these plants will provide a rare optical feast next spring. We noticed a very fine lot of plants of the White Dorothy Perkins, which is an excellent companion for its pink prototype.

The Roses in the open were still giving some fine late autumn blooms, which for colour and perfume would compare favourably with the summer flowers. It would take too much space

to mention them individually, hence it must suffice if we say that all the best varieties belonging to each section are very extensively grown, and all were in the best possible health. A portion of the nursery devoted to all the old Roses—favourites of several generations past—was of considerable interest to us, those which were flowering being remarkable for their fragrance, a feature which is, alas! too often absent in our beautifully-shaped newer Roses, and which may be likened to marble statues. Many good varieties have been raised at the Waltham Cross Nurseries, among them being the well-known Medea and the newer sorts Hugo Roller, Warrior, Refulgence (a scarlet-flowered Hybrid Sweet Briar) and Elaine (a beautiful lemon white Hybrid Tea). A large quarter containing some thousands of plants of Dorothy Perkins was most interesting.

Camellias are still favourites with many people, and Messrs. Paul have one of the largest stocks in the country. The collection consists of nearly 3,000 plants in about 250 varieties, the size of the specimens ranging from over 15 feet high to less than 1 foot, the larger ones in particular being of a most symmetrical character. All were full of plump buds, which promise a good display of flowers later on, and the whole were remarkably free from insects.

Fruit trees of all sorts were largely in evidence, both in pots and the open ground, and many of them were carrying excellent crops. Pot Vines are specially dealt with, and we saw hundreds of well-ripened one year old plants ready for sending to customers. These are either suitable for fruiting in pots or for planting in permanent borders, and the plump buds and solid canes looked capable of producing a good crop of fruit if grown on in pots. Plums, Pears, Apples, Peaches and Nectarines, Apricots, Figs and Cherries are all grown extensively as orchard house trees, the plants being well formed and the wood thoroughly ripened. In the open the fruit trees were the picture of health. Long, yet sturdy, growths were the rule, the soil being especially suitable for these plants. Trained trees of all sorts are specially dealt with, and we noticed many beautiful cordon, fan-shaped and espalier specimens.

Another branch of horticulture dealt with here in a most thorough and comprehensive manner is the culture of hardy ornamental trees and shrubs, both flowering and rich-foliaged types being taken in hand. The methods of propagating these at Waltham Cross are different to those usually adopted, everything that it is possible to treat thus being raised on its own roots. This may, to the uninitiated, seem a trivial matter, but it is nevertheless a very important one. Many of us have bought, say, choice varieties of Lilacs to find, in the course of a few years, that the common stock on which they have been worked has superseded the good variety, eventually killing it outright. With a plant on its own roots such a catastrophe is, of course, impossible. Another point in favour of plants raised by layerings or cuttings is that they are absolutely true and regular in habit. Where seedling trees, for example, are used for the formation of an avenue, the chances are very great that some will grow faster than others and differ to some extent in other ways, but trees from layers, as stated above, will be quite true and regular. Maples, Philadelphuses, Lilacs, Poplars, Willows, Acacias, Lavenders, Buddleias, Beeches, ornamental Thorns, Crab Apples and, indeed, all kinds of hardy trees and shrubs are fully stocked, and it would be very difficult to give the firm an order which it could not execute. The business is under the personal supervision of Mr. Arthur W. Paul, who is one of the keenest horticulturists of the present day, and whose untiring energy maintains the firm in the high position it has so long occupied. The catalogues published by the firm and dealing with the various branches mentioned above are well worth perusal.

## THE FRUIT GARDEN.

### THE CULTIVATION OF THE GOOSEBERRY.

**F**OR a working-man and his family possessing a fair-sized garden, I question if we have a more useful or valuable fruit than the Gooseberry. It will grow equally as well in the coldest and most northern part of Britain as it does in the Midlands or the South, or even better. It is, I consider, the most certain cropper and the most prolific of any fruit we have, and the accompanying illustration goes to prove this. It is the earliest available fruit of the year for cooking purposes when picked green, and when planted in different aspects it will supply a delicious and health-giving food for many months in the year. As a preserve it may be enjoyed all the year round, either alone or mixed with other fruits, when it is invaluable to the poor for puddings or to spread on bread when butter is dear and often out of the question. No wonder our Government has hastened to enact a law for its protection from the much-dreaded American Gooseberry mildew.

The larger varieties are invaluable for growing for market when picked in a green state or when ripe, as they give a greater bulk and weight per acre than the smaller varieties, and consequently yield a better cash return.

The Gooseberry may be grown as a bush, standard, cordon or espalier. There are many rubbishy corners in cottage and other gardens lying idle, besides being a nuisance and an eyesore, where the Gooseberry bush if planted would thrive exceedingly well. It likes a deep, rather heavy soil and a cool position, and does not object to a little shade; but it will grow in any fairly good garden soil except that which is very thin and hot. It is also, perhaps, the easiest of all fruit trees to propagate. It is readily propagated by means of cuttings, and the best time to put them in is the last week in October. Choose well-ripened shoots of last year's growth of the variety it is desired to increase, taking them off the tree at their junction with the older wood. Decade the lower part of the shoot of all the buds to the extent of 8 inches, and cut off the top of the shoot to within four buds of the denuded part, leaving the buds on this part, as in due time these will form the bush. The cuttings will then measure about 12 inches in length. They should be inserted in fairly good soil 6 inches deep and 4 inches apart and firmly trodden in, and the position in which they are fixed should be shaded from midday sun. By the following October they will be sturdy, well-rooted little bushes, and should be replanted in an open quarter where they can have more room. The following year they will be ready to plant in their permanent quarters at distances apart for the larger varieties of 6 feet and the smaller 4 feet.

In small gardens a very good way of growing the Gooseberry is to train the bushes as espaliers in rows across the garden or by the side of walks, where they serve a useful purpose in hiding the vegetable crops at a time when they are decaying—not always a pleasant sight to see. The fruit grown in this way is more exposed to light and air, and consequently, in my opinion, much improved in quality and flavour.

I give below a selection of twelve large varieties suitable for market work, and twelve smaller for dessert:

#### LARGE VARIETIES.

*Red*.—Beauty, very large and a great bearer; Crown Bob, one of the largest and the earliest ready for picking green; Lancashire Lad, a great favourite for market; and Whinham's Industry, considered by many the best of all for market purposes.

*White*.—Of all these no doubt the best is Lancer; Lady Leicester, a fine variety with golden tinge when ripe, flavour excellent; Whitesmith, indispensable in any collection.

*Green*.—British Queen is among the best of the large greens, Telegraph being also very good.

*Yellow*.—Keepsake: This is one of the earliest ready to pick green for market; it is a handsome and popular Gooseberry. Leveller, an enormous bearer and early; and Langley Beauty, rich golden yellow, flavour rich and delicious.

#### SMALL VARIETIES FOR DESSERT.

*Red*.—Ironmonger, rich flavour, fine for bottling; Red Champagne, Dobson's Seedling and Warrington. The latter is fine for preserving and for late dessert.

*Green*.—Greengage, Langley Gage (one of the best in every respect), and Green Gascoigne.

*Yellow*.—Golden Drop, one of the earliest; Golden Lion, a late and valuable variety; and Yellow Ball, very small but delicious.

*White*.—Bright Venus and Whitesmith. The latter is rather large, but on account of its splendid flavour must not be omitted from a list of dessert varieties. OWEN THOMAS.

## SWEET PEA NOTES.

### ALDERSEY—ITS OWNER, ITS GARDENS AND ITS SWEET PEAS.

**I**T is impossible to write about the Aldersey Sweet Peas without a big introduction all about their originator and the lovely gardens where they have their home. Mr. Hugh Aldersey has all his life been a gardener, and so it was not surprising that when he came to live at the Hall after his father's death that he should set to work to improve, or probably it would be nearer the mark to say to recreate, the old gardens. Not far from the house there is a large square high-walled kitchen garden, which serves as a sort of centre for everything, for round about it on three sides are bright borders and green lawns and old spreading trees and a delightful rock garden full of good things, and all so deftly arranged and its wide paths so cunningly devised. Alas! it is necessary that these should be so, for otherwise their owner would never be able to visit his treasures. He is, sad to say, an invalid and is obliged to do all his gardening from a Bath-chair. Had I not known I would never have imagined that it was so, and as I stood looking on the beautiful arrangement of plants and shrubs there came involuntarily into my mind the old chestnut of the temperance reformer, who, boasting of a friend who had died at a good old age because, as he said, of his teetotal principles, was somewhat nonplussed when a voice from the audience shouted out "Aye, man, just think how long he would have lived if he had taken something."

It was on one of the few sunny days at the end of August that I was there, and the rockery was quite bright and gay. There were small sheets of the rose-flowered *Silene Schafta*, colonies of both the rose and white *Cyclamen neapolitanum* and the little crimson irid *Anemone cruenta*, trailing tresses of the Shamrock Pea, *Parochetus communis*, bushes of Sun Roses (*Helianthemum*), which had been cut back as soon as the first bloom was over, various *Veronicas*, notably *V. Bidwillii* and *V. canescens*, several *Campanulas*, *Lippia nodiflora*, *Tricyrtis hirta* (the quaint pinkish Toad Lily), *Polygonum capitatum* with its curious V-shaped markings on the leaves and pink flowers, *Scabiosa Pteroccephala*, *Cotula reptans* and many more too numerous to mention.

Flowering shrubs are a distinct feature, and there is a large collection of some of the best. *Erythraea Crista-galli* is only put out for the summer, but all the others are growing outside without any protection. *Jasminum primulinum* and *Solanum jasminoides* are seemingly at home

in a sheltered corner. *Garrya elliptica*, *Rhodotypos kerrioides*, *Romneya Coulteri* in large bushes, *Spiraea bracteata*, *S. Van Houttei*, *Veronica hulkeana*, *Olearia stellulata*, *Buddleias Colvillei*, *lindleyana* and *variabilis veitchiana*, *Carpenteria californica*, *Ceanothus* in about half-a-dozen varieties, *Cistus* in variety and *Coronilla Emerua* are enough to mention to show how many they are and how wide their range. Mr. Aldersey takes a great interest in Daffodils, and the long border, which, by the way, is about 5 yards wide, on the outside of the west wall of the garden is wholly given up to them. He has a fine collection, including some of his own raising. He is a great hybridiser and raiser of seedlings, and Carnations, Gladioli and herbaceous Phloxes have in turn attracted him. At present he has a grand lot of these latter, all of them of some shade of pink. Evelyn, a lovely dwarf salmony pink, was exhibited this year at Shrewsbury and gained an award of merit. Personally, I thought a taller one called Eleanor even more attractive for a garden. It has a conspicuous white eye with which to brighten up the whole truss. The pink, too, is of a very pleasing shade. Three glorious plants of *Clematis*, which were a mass of bloom on the south wall, must be noted before we pass the portal of what was obviously once the kitchen garden, but which is now only one in name. Here are all kinds of herbaceous plants in nursery beds and here are endless clumps and patches of the now famous Aldersey Sweet Peas. Unfortunately for me, they were past their best, but I was able to imagine the feast that Mr. Burpee and Mr. Sydenham had when they saw them earlier in the season.

It is a long time from 1893, when Mr. Aldersey grew his first Sweet Peas—twelve of Eckford's best varieties—to 1907, when the untiring efforts of twelve seasons' hybridising first met with public recognition, and were crowned with two awards of merit at the great Shrewsbury show. Poor health and such a disaster as overtook him in the wet season of 1901, when his seed harvest entirely failed and left him after all his years of labour with only one of his own raising—Mother o' Pearl, an old type, lavender grey in colour, hooded in shape, but very sweet—would have damped the energy of many a man, but, Phoenix-like, Hugh Aldersey arose from the ashes of the past, and with the practical experience that comes from failure (he had made, he told me, too many crosses and planted far too thickly), and the allurements of Silas Cole's beautiful new type of flower (Spencer), he again set to work to raise more new ones, and the net result to-day is a batch of eighteen very charming varieties.

Many of them were shown at Shrewsbury last month in Messrs. R. Sydenham's stand, but I wish they had not been put in their rustic table decorations, for I nearly missed them.

The best and most distinct of these eighteen will in due course be put on the market by Messrs. Sydenham, but from some correspondence which I have had with the head of the firm it will not be just yet. The stocks are not fixed, and very properly and very wisely Mr. Sydenham will not flood the market with what I call nothing

but "named mixtures" if he can avoid it. There are too many of these already. They make an old grower like myself long for the days of old Henry Eckford to come over again. I think I had almost every variety he sent out, and I hardly ever found a rogue.

The following is a list of the Aldersey Peas with the raiser's own description. I ought to say that, with the exception of Mother o' Pearl, they are all of the Spencer type: Amethyst, lilac, flushed rose; Coral, rose self; Cowrie, pale pink on cream ground; Flamingo, two shades of curmine red, the standard being the darker; Helen Grosvenor (award of merit, Shrewsbury, 1907), orange rose flushed with gold on a cream ground, an improved Helen Lewis;

A SPRAY OF GOOSEBERRY KEEPSAKE.

Jarjoon, lilac self; Mother o' Pearl, lavender grey, old type, hooded; Moonstone, light lavender, a flush of pink in the standard; Opal, light lavender self, a waved Nina Balfour; Pearl, silvery white; Red Admiral, cerise; Romani Rani (English, Gipsy Lady), cream, heavily flushed with salmon pink; Ruby, not unlike St. George, without the magenta shade in the wings, and produces flowers instead of tendrils; Scotch Pearl, lavender, both wings and standards flushed with rose; Seashell, bright rose on cream ground; Sylvia Lee (award of merit, Shrewsbury, 1907), bright salmon rose standard and wings; Topaz, primrose; Tortoiseshell, prawn colour. JOSEPH JACOB,

## THE KITCHEN GARDEN.

### AUTUMN AND WINTER VEGETABLES.

THERE is a wealth of good green vegetables obtainable all through the winter months if those kinds are grown which are reliable. Of course, at this season I can only briefly note cultural details, but mention of some vegetables that are not grown as much as they deserve should prove of interest to amateurs. A great many growers are not able to force such plants as Seakale, Asparagus and other kinds of vegetables, so that I shall not touch upon these, but those kinds that are easily grown and give a long supply.

The useful Celeriac is a vegetable that the amateur can grow to perfection and at a small cost; indeed, it is less troublesome, if I may use the term, than Celery, as there is far less labour and food required, and the plant is hardier and gives a crop from November to April. The seed is sown early in the spring somewhat like Celery, and the plants grown on and planted out in deeply-dug, well-manured land in rows or drills (not trenches) 2 feet apart. Unlike Celery, to which it is closely allied, it makes a bulbous growth like a large knob, and this is the edible portion. It has a distinct Celery flavour. When fully grown the roots are trimmed and stored in soil or sand in a cool place, much the same as Beetroot or other roots, but I have in the southern part of the country drawn some soil up to the plants and thus wintered them in the open, just covering them with litter in severe weather. I have found Erfurt, Prague and the Large Knob the best. Celeriac is also valuable as a salad. Boiled and sliced like Beetroot it is delicious, and it may be used in other ways as a salad. As a vegetable the common mode of cooking is to boil and serve with white sauce, but it is delicious boiled for a time in clear water, then finished with rich stock and served hot, or partially boiled and then cut in slices or large pieces and finished in butter.

Endive, such as the Large Round-leaved Batavian, is a splendid winter vegetable. I do not advise its culture in the same way as Celeriac for winter supplies, but in the autumn it is far better to make use of it than allow it to spoil, and when boiled it is excellent.

The value of the Cucumber when served as a vegetable is usually overlooked. It is delicious; and at this season there is often a full supply, and they may be used in a variety of ways as a vegetable. Couve Tronchuda is a vegetable not much used in this country, yet it is excellent in the autumn. It is more commonly known as Seakale Cabbage, the midrib or stalk of the plant being used like Seakale, and in the autumn the heads are cut and boiled. Like Seakale, it grows freely in any soil; but to get fine fleshy leaves it is well to sow in the spring and plant out in good land in May or June for an autumn supply. Plant 2 feet apart between the rows and half that distance in the row,

Salsify and Scorzonera are two distinct vegetables much overlooked by amateurs, yet their culture is as simple as that of Celeriac. The seed, if sown in May or June, will give fine roots for the winter. If sown too soon, both these plants, and especially the last-named, have a tendency to bolt or run to seed, so that the dates given are sufficiently early. The Salsify has the larger root, and should be given quite 2 feet space between the rows; and this distance is also suitable for the Scorzonera. The Mammoth is the best Salsify. The roots are lifted and stored like Beetroot. It is a great favourite on the Continent, and may be cooked in a variety of ways. The same remarks apply to the Scorzonera, a black, long root with a very peculiar flavour, quite distinct from other vegetables, and often much liked on this account. The Large Russian is the best type of Scorzonera.

Though a simple vegetable, I would call attention to the value of the yellow Turnips. These are quite distinct from the ordinary white roots, and they remain sound all through the winter. Golden Ball is very good, also Dobbie's Golden; the latter is a splendid keeper.

I have not dwelt upon green vegetables, such as Borecoles, Savoys and others of the Brassica

## THE FLOWER GARDEN.

### PAMPAS GRASS.

**F**EW hardy plants are more imposing and handsome in the autumn than *Cortaderia argentea*, popularly called the Pampas Grass. Our illustration of a bed in the Royal Gardens, Kew, will give a good idea of its value and beauty as a lawn plant when boldly grouped; for planting at the edge of woodland or shrubbery, where its waving silvery plumes stand out strikingly against the dark background, it is hardly surpassed. For some years subsequent to its introduction in 1848 this was botanically known and still is often met with in gardens as *Gynerium argenteum*, but it is correctly *Cortaderia argentea*. Differences of opinion may exist as to the necessity for changing the name after it has once become thoroughly fixed, but its great beauty at this season of the year affords no food for controversy, for it is in its way unapproachable. A good healthy tuft, with its long, arching, gracefully-disposed leaves, is at all seasons decidedly ornamental, but in early

A FINE CLUMP OF PAMPAS GRASS AT KEW.

type. The Kales are so well known that I need not describe them; we now have fine forms of the Scotch, such as Sutton's Arctic and others, but I would point out the value of the true winter Cabbages. These are quite distinct from the ordinary spring Cabbages and the Colewort varieties. The latter are not hardy enough to go through our severe winters, as when full grown they split badly, and this spoils the heads.

The most hardy variety is the Christmas Drumhead, a medium-sized flat head with very short stalk. This at Christmas is almost equal to a good spring Cabbage, and it is very hardy and remains solid and good for a considerable time. It should be sown in May or June for early supplies. St. John's Day is a true winter Cabbage and a very good-flavoured variety. There is also a new winter Cabbage called Veitch's Drumhead Colewort, which is very useful for its small, compact growth and excellent flavour. Much more might be said about vegetables for autumn and winter supplies, but the above notes will, I hope, arouse interest in this important phase of kitchen gardening. G. WYTHES.

autumn, when overtopped with its silvery plumes, there is then nothing to compare with it. Besides the ordinary form there is a variety with variegated leaves, and another in which the flower panicles are pinkish. This variety, known as Rendatleri, is not so beautiful as the type, but from its distinct appearance it is well worth a place in most gardens. In the South of England the Pampas Grass is hardy, but in more northern districts it cannot be thoroughly depended upon unless protected. The New Zealand *Arundo conspicua* (now *Cortaderia conspicua*), though less imposing, is harder than the Pampas Grass, and may therefore be planted in colder localities. Even this is, however, in many places benefited by a certain amount of protection. Both the above-named prefer a good deep soil with ample supplies of water during the growing season, but stagnant moisture in winter is injurious.

### UNCOMMON GARDEN BULBS.

THERE are a great many beautiful bulbous plants that are not often cultivated in our gardens, yet which would considerably add to their interest

and attractiveness. As a rule, ordinary culture would suffice for them; a fairly loamy soil is, however, all the better for being enriched with a little very old hot-bed manure and mingled with a large quantity of coarse river sand or roadside grit. Then, in planting bulbs, sand should always be used, a handful beneath each of the smaller kinds and more under giant bulbs, such as the Crown Imperial.

The white Grape Hyacinth is an extremely dainty little flower, seen at its best, perhaps, when filling a small bed as a carpet around groups of scarlet Tulips or bright rose Hyacinths. A fanciful name for this plant is Pearls of Spain; it is catalogued as *Muscari botryoides album*, and is not costly. Again, the white Tassel Hyacinth is much fairer than the old bluish violet kind, and is so hardy that it will thrive almost anywhere. For originality's sake, the Caucasian Starch Hyacinth (*Muscari paradoxum*) is to be recommended, for its colour is an indigo so deep as to be nearly black.

The popularity of Solomon's Seal, especially for shady parts of the garden, make the fact that some species are scarcely ever met with a surprising one. The prettiest is, undoubtedly, *Polygonatum Thunbergii*, for the flowers come in fine drooping clusters and are individually large, white, tipped with green, while the immense foliage is unusually bright in tint. This is about the same height as the ordinary variety, *Polygonatum multiflorum*; but there is a giant sort, 2½ feet tall, that would have a handsome effect in many parts of the garden, under trees, upon banks, or springing out of rockeries, as well as forming huge groups in borders or for bed centres; this is *Polygonatum verticillatum*. Although the blossom is cream instead of pure white, it is very showy and the foliage is remarkably free. None of these bulbs, or roots, cost more than a few pence each, and are cheaper by the dozen.

Edgings and carpets ought certainly to be made of the Lebanon Squill, a flower that becomes very dear to all who once grow it; there is such a refreshing clearness about the stripes of porcelain blue that run down its white petals, and the colour-effect from a slight distance is almost lavender. It does not usually exceed 6 inches in height, but flourishes in most borders, giving a welcome show each April.

It is said that wherever *Liliums* thrive, so, too, will *Sanguinaria canadensis* (the Blood-root), which is a lovely pure white, gold-centred little flower; the leaves are quite handsome, and the best way to use this bulbous subject is as a carpet for a stretch of damp, semi-shaded soil. The blossoms, about the size of Primroses, appear in profusion. There is no absolute need to add peat to the soil; as said before, the ground that does for *Liliums* will suit these bulbs well enough.

*Schizostylis coccinea* ought to have found its way into all gardens, yet it has not done so. It is one of the very few flowers of the bulbous class that do not begin blooming until October, and continues often during November; for this reason alone it is entitled to our attention, and the flowers themselves are very beautiful, set in elegant spikes and of the richest scarlet-crimson. It thrives in ordinary borders, and does well massed between shrubs or the larger herbaceous plants; grouped with late white Michaelmas Daisies or *Chrysanthemums* it can give one of the most striking features of that season. Bulbs cost only 5s. for fifty, so lavish planting can be indulged in. Another lovely way to use it is in groups with a carpet of dwarf white *Violas*, those that are of excellent bedding habit, either in beds or borders. When given liquid manure during its bud-forming time *Schizostylis coccinea* grows to a magnificent size. Its height is from 1½ feet to 2 feet.

A gem, indeed, is the Painted Wood Lily (*Trillium erythrocarpum*), and one that can be enjoyed by the owner of a shaded damp garden. The plant grows about 1 foot high and has snow white flowers blotched on each petal with bright

crimson. *Trillium grandiflorum* is a delightful all white large bloomer for a similar position. *Tulipa vitellina* is one of the prettiest of the hundreds of hardy or herbaceous Tulips that can be left undisturbed where once planted. Like most of the others it blooms during May, sending up self lemon blooms on stems 20 inches or more in length. Its value for cutting or as a garden adornment can be at once realised. A late Tulip of the same class is *Tulipa Sprengeri*, but this bears orange vermilion blossoms and is only 18 inches high. A smaller but remarkable flower, too, is *Tulipa orphanidea*, for the petals are orange and show a black centre.

Wherever the lesser hardy bulbous plants are loved, the familiar *Chionodoxas*, *Scillas*, *Crocuses*, *Snowdrops*, &c., should be accompanied by *Milla* (or *Triteleia*) *uniflora violacea*, for the sake of the china blue shade of the flowers, the petals of which are regularly striped with violet. It succeeds on the level as well as in rockery nooks, has a sweet perfume and is lasting in water. Probably there are few such inexpensive ways of permanently improving a garden as by planting quantities of the less familiar bulbs in it each autumn. E. D.

### LILIUM SULPHUREUM.

As you have accepted my photograph of *Lilium sulphureum* (syn. *wallichianum*), you will probably like to hear how I grow it so well. I find it does not thrive in my heavy loam, but requires peat, and I have succeeded with it for some years. This season it is 7 feet 2 inches in height, with fifteen blooms on the best stem. It usually has from five to seven. I stand beside it to show the comparative difference in my height—5 feet 9 inches. As I daresay you know, it has bulblets in the axils of the leaves, which take three years to become blooming bulbs.

Newton Abbott. G. S. PATEY.

## COLOURED PLATE.

PLATE 1859.

### FRILLED PERSIAN CYCLAMEN.

FOR some years past Messrs. Sutton and Sons of Reading have devoted a considerable amount of time and attention to the evolution of a strain of fringed or frilled Persian Cyclamen, and their labour has been rewarded by a strain which will now come true from seeds. As will be seen by the coloured plate (which has been prepared from flowers kindly supplied by Messrs. Sutton), these frilled varieties possess all the colour gradations of their prototype, and they will, we feel sure, soon become great favourites for the decoration of greenhouses during the dull winter and early spring months. Beautiful as the plain petalled forms undoubtedly are with their varied colours, there is still room for these more ornamental frilled flowers, and doubtless before many years have passed we shall find the same colours in these as in the ordinary forms.

## THE GREENHOUSE.

### HOW TO GROW CYCLAMEN.

SEEDS of Cyclamen may be sown at any time of the year; but as a rule the best results are obtained from autumn sowing, and, if a succession of flowering plants is required, sow again in January or February. Thoroughly clean the seed-pots or pans and provide them with good drainage. Fill them to within half-an-inch of the tops with a prepared soil consisting of good loam, leaf-mould and sand. The soil should be passed through a quarter-inch mesh sieve and

Seed sown in the early months of the year should be placed in heat at once.

The Cyclamen does not need a strong heat, but an even temperature must be ensured, as extremes are fatal. A light position and a temperature of 55°, rising to 60° during the winter, are suitable. During the summer a light shading may be necessary during a spell of bright weather, but a warm, humid atmosphere is necessary to ensure the development of the corms.

The seed germinates very slowly and very irregularly, some plants being ready for removal before many of the others have started. The plants may be carefully taken from the seed-pots as they become ready and transferred into others 2 inches in diameter, using a compost as

advised for the seed-pots. As the plants grow pot them into 3-inch pots, and at this shift use rather less sand with the soil. In potting always take care to leave the crown of the corm clear. A shelf near the glass is a good place for the young plants at this period of their growth. Do not allow Cyclamen to become dry at any time, or they will quickly fall a prey to aphids; should this appear it must be checked by fumigation. As the spring advances give air to the plants to encourage a sturdy growth, but in doing this be careful to avoid draughts. The plants should be ready for their final shift by the beginning of July. They will flower freely in 5-inch pots if carefully potted. A little dried cow manure finely broken up and mixed with the soil is beneficial.

During August and September the plants grow very freely, and when the roots have taken possession of the soil weak manure water may be given twice weekly. This is a material aid in the production of fine flowers. Some growers advocate growing the plants in cold frames during these months, and they are successful in their management; but as the days become colder they must be removed into a structure having a more congenial atmosphere, or the flowers will be poor and deformed. Well-grown plants of Cyclamen are very beautiful, especially some of the new shades of colour produced from seed of select strains which are now procurable, and the flowers are useful for a variety of decorative purposes. The important points in the cultivation are: An even temperature, a moist atmosphere, plenty of water at the roots (avoiding stagnation), free circulation of air without draught, light position and freedom from insect pests. C. RUSE.

Munden Gardens, Watford.

LILIUM SULPHUREUM GROWING IN THE GARDEN OF MR. G. S. PATEY, ALLER VIEW, NEWTON ABBOTT.

pressed firmly into the pots. The seeds of Cyclamen are much larger than those of many greenhouse plants, and therefore the soil prepared for their reception may with advantage be used in a coarser condition. Place the seeds about 1 inch apart, and cover with a quarter-inch layer of soil. Place a thin layer of Coconut fibre on the surface as an aid in checking rapid evaporation and also in keeping down the growth of moss. Seed sown in the autumn should be placed in a temperature of about 45° for fourteen days, after which transfer the pots to a warm house where a moist atmosphere is maintained.

### A PRETTY FLOWERING GREEN- HOUSE BULB.

(ACIDANTHERA BICOLOR.)

THIS is a decidedly uncommon bulbous plant, yet as seen in the cool portion of the T range at Kew it is well worth extended cultivation. A native of Abyssinia, this *Acidantha* has been known for over half a century, but a dozen years ago, when it was given a first-class certificate by the Royal Horticultural Society, it was recognised by very few. It belongs to the Iris family, and has certain affinities to the *Gladiolus*. H. P.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**H**ARDY FRUIT GARDEN. — The present is the best period for planting Plums, Apples, Pears, Cherries and kindred subjects. See that the ground is deeply dug previous to planting. As soon as the Currants drop their leaves I make it a rule to prune the bushes; the leading shoots should be shortened back to within 4 inches or 6 inches of their base. Lateral growths should be cut back to within an inch or so of their base to form fruiting spur.

*Greenhouse and Conservatory.* — I am now devoting some attention to Camellias which are to provide a welcome display of blooms next spring. I am sponging the leaves of the plants with a solution of soft-soap water, thus effectually removing lurking insect pests and at the same time thoroughly cleansing them. Chrysanthemums in glass structures need carefully overlooking at frequent intervals. Should warm and sunny weather prevail, the blooms must be shaded from the direct rays of the sun. The glass structure must also be freely ventilated, otherwise damping may set in. It is wise, even in the absence of frost, to have the hot-water pipes slightly warm, as this dispels dampness and assists the large blooms to unfold their florets. The temperature during the day in the greenhouse should be about 55°, and at night from 45° to 50°. Excessive moisture in the glass structure should be guarded against at this period, and for this reason wipe up water from the floor after watering is done.

*The Flower Garden.* — The hardy border may be replanted at this period. It is optional whether the work be done now or in the early spring, but many plants are better when treated at this period. Old plants should be lifted and divided into smaller pieces, giving preference for replanting the portions broken off from the outer edge of the old stools. New beds and borders ought to be trenched or deeply dug, and be given a heavy dressing of manure at the same time. Leaves should be collected and stored for future use. There are so many uses to which they may be put that they should be conserved as much as possible for use during the winter season. Straggling shoots of Virginian Creeper may be trimmed off, thus making them present a better appearance and contributing to the well-being of the plants. Lift Dahlias as soon as possible; that is to say, immediately after a frost has blackened the shoots. They are then an eyesore, and no useful purpose can be served by allowing them to remain longer in the ground.

2. — HYACINTH AT STAGE FOR BRINGING INTO THE LIGHT.

*Cold Frame.* — Plants that are growing away freely should receive abun-

1. — HYACINTHS PLACED IN GLASSES TO START GROWING.

dant ventilation in order to maintain the growths in a sturdy and firm condition. Auriculas at this time should be watered with rather more than ordinary care; otherwise there is a chance of the soil becoming too wet. What should be aimed at is to keep the soil just moist, erring on the side of dryness. All tender plants in the cold frame should be removed to a glass house where protection can be provided in case of frosts. It would be fatal to leave them longer in the cold frame, as we may safely anticipate the experience of frosts in the near future.

*The Vegetable Garden.* — In anticipation of frosts I make it a rule at this season to protect Cauliflowers that are maturing. It is a very simple matter, and may be done by bending one of the leaves to cover the head. This also preserves the colour. Carrots and Beet should be lifted without delay if this has not already been done. They may be stored in a cool cellar or placed in a sheltered quarter of the garden, where they may be covered with a thick layer of light soil as a protection against severe frosts. Roots may be taken from this mound from time to time as required. If left in the ground any longer the roots deteriorate. D. B. C.

## GROWING HYACINTHS IN WATER.

With the advent of the system of growing bulbs in moss fibre many predicted the extinction of the older method of growing, or, more strictly speaking, flowering of Hyacinths in water, yet the latter plan still has many adherents, judging by the numerous enquiries made about the subject. At the outset it will be well if the beginner fully understands the principles underlying this method of culture; then fatal mistakes which are frequently made will be avoided. It must ever be borne in mind that the flower-spike which is to appear later is already present in detail in the dormant bulb, and also that practically all the food that the plant will get to enable it to develop its leaves and flowers is stored within its tissues; therefore, the more solid and heavy the bulb the better will be the ultimate result. Most bulb merchants stock what are known as first-size bulbs, i.e., those which have been specially selected for their large size and firmness, and it is these only which are worth the trouble of

growing in water. Roman or Italian Hyacinths, too, are not suitable for the purpose on account of their straggling habits, good bedding Hyacinths being the sorts to employ. With these few points thoroughly grasped the amateur is well on the road to success.

Having secured the bulbs, the glasses must next be considered. Many fancy designs have from time to time been put on the market, but the ordinary type shown in the accompanying illustrations have yet to be beaten. Other things needed will be some charcoal, water, a dark cupboard and, subsequently, a light window or greenhouse.

Fig. 1 gives a good idea of the glasses as they appear when the bulbs are first placed in position. It should be carefully noted that the base of each bulb nearly, but not quite, touches the surface of the water. Two or three pieces of charcoal should be placed in the water in each glass, as this will keep it fresh, and the water must not be changed, especially after roots have been made. If any has to be added to make up that lost by evaporation, the work must be done as carefully as possible without disturbing the bulb. The glasses must next be stood in a cool dark cupboard for a few weeks until the bulbs have reached the stage shown in Fig. 2. It will be noticed that a number of rather thick, long roots have been formed, but top growth has not advanced much. This is just the reason why the glasses were stood in the dark cupboard; had they been placed in a light position the leaves would have been developed in advance of the roots, to the detriment of the flower-spike. Although a cool cupboard is advocated it must be frost-proof, otherwise the glasses will be burst by the expansion of the water when it is frozen.

Having, then, got our bulbs in the condition shown in Fig. 2, they may be gradually inured to the light, and by the time the stage shown in Fig. 3 is reached they may be given full light in a warm window or greenhouse. It will be noticed in this illustration that the leaves are opening. Fig. 4 shows a bulb of Roi des Belges, a good dark blue variety, at a much more advanced stage, with a plump flower-spike pushing up between the leaves, and Fig. 5 depicts the same bulb at its best. It will be seen in Fig. 4 that the water is traversed by a mass of roots reaching to the bottom of the glass, without which a good flower-spike is impossible. Bulbs flowered in this way are too weakened to be of further use, and their retention is not worth while.

## SPONGING PLANTS.

An experienced person can sponge the most tender leaf without doing it an injury, but the novice cannot do the work as well. A few hints on the subject will prove helpful, and practice will soon make the operator perfect in his work. There must be right

3. — HYACINTH WITH LEAVES OPENING.

4.—HYACINTH MAKING GOOD PROGRESS AND SHOWING A FLOWER-SPIKE.

principles to work upon, and these principles should be followed methodically. The sponging of the leaves of a few plants seems to be a very simple matter, so does the washing of a kitchen or a tiled floor in the conservatory, yet, if certain operations be left undone, the tiles will present a very smeared appearance, and the same applies to the leaves of plants.

*Why Sponging is Done.*—Sponging is done for two reasons, both equally important. First, to cleanse the foliage from all dust and encrusted dirt, chiefly that of soot, dust and the excrement of insects combined;

secondly, to rid the plants of injurious insects. The encrusted substance clogs the pores of the leaves, thus seriously impairing the general health of the plant; and the insects suck the very life out of their host.

*When Sponging may be Done.*—At any season of the year this work may be done, but in the autumn, and throughout the winter, it should be followed up closely. The syringing in summer cleanses the leaves very much. In winter less syringing is necessary; and as the majority of the leaves of the plants are, at this season, more matured and harder, the sponging may be done without the risk of injuring the foliage.

*How to Sponge the Plants.*—From the time that the leaves are moistened with clear water, or an insecticide, till they are dry again the plants should be shaded from bright sunshine. Sponging should be done with tepid water only. If dust or encrusted dirt only be present, the leaves must be syringed first. This will soften the hard substance on the leaves, and it can subsequently be removed with the aid of the sponge more readily; but if insects are present, attack them direct with the insecticide. Do not, as it were, erect any partition between them and the solution to be applied. In all cases where insecticides are used it is advisable to syringe the plants again with clean, tepid water before exposing the leaves to the sun. Use a soft sponge, and, supporting each leaf with one hand, gently draw the moistened sponge upwards from the stalk end towards the point. To effectively remove hardened soil from the leaves draw up the sponge several times lightly rather than use undue pressure. Smooth-leaved plants, such as Crotons and Dracenas, are more easily managed than those having leaves with a rougher surface. Sponge the stalks and stems of the plants also, and work the sponge well into the axil of leaf and stem where there are insects; but be quite sure you do not injure any young shoots growing there.

#### HOW TO TREAT MARGUERITES IN WINTER.

YOUNG, flowerless shoots root readily enough if inserted in sandy soil in shallow boxes, the same as Zonal Geraniums are treated. Of course, they do equally well in flower-pots. It is rather late in the season to take cuttings now, though they would soon form roots if the shoots have not been subjected to any frost.

It is, however, about the wintering of the rooted cuttings that I wish to speak. The bedding Calceolaria is often kept too warm and close throughout the winter months, and so also is the young Marguerite plant. Generally one sees the latter growing on a dry shelf in a warm greenhouse, infested badly with the leaf-mining maggot, with the result that nearly all the leaves are shrivelled and brown in colour, instead of being dark green and fresh.

With the aid of plenty of covering material Marguerites can be kept during the winter in a cool frame with far more success than in a warm greenhouse. The ideal place for them is a frame or low pit where a little heat can be turned on in frosty weather. The atmosphere should be neither too dry nor too moist, but the temperature should be cool according to the state of the weather. It is through subjecting the young plants to a high temperature, caused by heating apparatus, that the plants are often very unsatisfactory. A small quantity of rotted manure in the bottom of a shallow box and some sandy soil are all that is necessary for the cuttings to root in.

AVON.

#### PRIMULAS AND THEIR CULTURE.

FOR winter and early spring flowering Primulas are very popular, and, considering the excellent strains that may be procured, this is not surprising. At the present time plants in various stages of growth require frequent attention respecting potting, watering and rearranging in the pits or frames in which they are growing. Plenty of air is necessary to promote a strong, healthy growth, and the plants must also be arranged in a light position, although shade must be provided during bright sunshine. Many successful growers place the frames under the shade of a wall or building, and this is an ideal place for the plants providing the position is not damp.

Slugs are very fond of the tender foliage of the young plants, and if not destroyed often do a large amount of damage. They may be checked by sprinkling soot around the plants, and trapped by placing slices of raw Potato in the frames; they feed on the Potato, and, if these are frequently examined, large numbers may be caught and despatched.

Plants still in 3-inch pots will soon be ready for potting on into 4½-inch pots, which will be large enough for this late batch; they do not require large pots. Provide good drainage and use a sweet, light, sandy soil. Pot fairly firm, but do not ram the soil; the leaf-stalks are very brittle, and care must be taken that these are not broken. After potting, if the weather is dry, sprinkle overhead and provide shade for a few days until the plants begin to root into the fresh soil. They may remain in the frames until frost threatens, if desired, or they may be placed in a light, cool greenhouse. When the pots are filled with roots, well-diluted manure water will assist the plants, and fine trusses of flowers will be produced.

C. RUSE.

#### POTTING SOILS FOR PLANTS.

AMATEURS should lose no time in getting in a good stock of the different ingredients necessary for the making up of plant composts. When there is not a sufficient supply at hand the novice is tempted to make use of ordinary garden soil and other fibreless material which is quite unsuitable.

*Loam.*—This should be of a fibrous nature; if any fine soil is needed it can always be obtained from a heap of fibrous turves. The turves should be cut about 3 inches thick and stacked in an open position with a north aspect. Before putting down any turves scatter some dry, unslaked lime on the ground; this will kill any insects lurking there. Place all the turves with their grass sides downwards and finish the stack by forming a pointed roof; then the rain will not enter and make the turf in a sodden

condition. All turves should be cut from open ground, not near hedges, old banks, nor from under trees.

*Leaf-soil.*—This is a very important ingredient, because its presence causes the formation of innumerable small fibrous roots of plants, and, in the case of seedlings, it is most essential and for many kinds of bulbs almost indispensable. Form several heaps in some out-of-the-way place where the material can be left undisturbed for several years. First there should be the heap of leaves well rotted, then the one of half-decayed leaves and, finally, the heap of new leaves, so that there will be different grades suitable for use mixed with fine loam, or with coarse mixtures for placing in the bottom of boxes and pots.

*Peat.*—This soon perishes—that is, loses its toughness of fibre—if it is exposed to the weather during the winter time, but if kept dry it remains good for a considerable period; therefore store it in sheds or in any cool place where it can be kept dry.

*Manure.*—Here, again, we require littery and short manure. The latter is manure practically free from straw. Now, in all cases the manure-heap should be under cover and in a northern position. The direct rays of the sun cause evaporation; exposure to rain means that all the best portion of the manure will be washed away.

*Sand.*—Even road-grit, if carefully washed and dried, will make a valuable ingredient for mixing with potting soil, as it will keep the whole mass porous; but coarse silver sand is the best, especially where cuttings, seedlings and fine-rooted specimens are concerned. Store sand in boxes and keep dry.

AVON.

#### PLANTING MIXED BEDS FOR SPRING.

DOUBTLESS many amateurs will now be planting beds of mixed subjects for spring effects, and

5.—A FULLY-DEVELOPED FLOWER-SPIKE OF HYACINTH ROI DES BELGES.

there are a few details which should be fully observed if a good display is desired. Where bulbs and other plants, such as Arabises, Aubrietias, Wallflowers and Polyanthus are used in conjunction, these leafy plants should be inserted first, carefully laying them out at regular distances over the bed. When these are planted, go over the bed with the bulbs, laying out the whole before planting is commenced. Unless this is done it is almost impossible to get a regular bed of bulbs, and if the latter were planted first it is probable that in inserting other subjects many bulbs would be disturbed.

## THE TOWN GARDEN.

**HARDY PLANTS FOR TOWN GARDENS.**—It is thought by some people that the number of hardy herbaceous plants which can be successfully cultivated in town gardens is exceedingly limited, but this is not actually the case. If the grower studies his soil and improves it as may be necessary, there are scores of beautiful plants that may be grown to the utmost advantage. At the same time, there is no gainsaying the fact that certain kinds thrive far better than others; and as some amateurs are unable or unwilling to devote special attention to a plant that requires coaxing, it may be well to enumerate some of the most generally satisfactory.

At the outset I desire to impress upon my readers that I do not guarantee success with a single one of them, but am prepared to support my selections by asserting that they will always succeed provided that the care to which all plants are entitled is accorded to them. To merely stick a plant in and expect that it will go on growing in a satisfactory manner for an unlimited number of years is unreasonable. If it is such a one as will stand cultural neglect there is little doubt that at the end of two or three years it will have overrun the garden and become a pest instead of a pleasure (*Harpalum rigidum* may fairly be mentioned as an example of this); while if it is one that demands attention, then failure to provide it will simply mean that in the course of about two years it will die out. In planting, which will be done in November or in the spring (in many situations the latter is preferable), consideration will be given to the likes or dislikes of each kind in the matter of sun.

In all cases the soil must be deeply dug, and it is almost always imperative that some well-rotted manure shall be incorporated with the second spit. It should be allowed to lie fallow for two or three weeks between the time of working and the actual putting in of the plants, and even then, although the settlement will be good, it is necessary to plant firmly, and, if in the autumn, that the grower shall go over the border after every sharp frost and see that none of the plants has been lifted out of the soil. Should one be found in this condition, it must be at once pressed firmly down again or it will perish.

It may be well to state that this list will only embody hardy plants; those of an annual nature or which are of tender constitution, even though of perennial habit, are omitted. Practically all the annuals flourish satisfactorily, as also do many of the tender plants in favourable circumstances, but in other instances their success is so essentially speculative that I think it wise to exclude them. Some that will be named are strictly biennials, but they thrive so well and are such general favourites that one cannot possibly leave them out.

For spring we have Arabis, Armerias, Aubrietias, Auriculas, Double Daisies, Iberises, Irises, Polyanthus, Primroses, Saxifragas, Violas and Wallflowers (the latter are uncertain in many gardens, as it is difficult to winter them satisfactorily, but they are so fragrant and beautiful that they must always be tried). Pansies also do grandly where the soil is fairly strong and of good depth. For the summer choice may be made from Antirrhinums, Canterbury Bells, Carnations, Chrysanthemums, Helianthus, Irises, Lychnieas, (Enocheras, Paeonies (a deep, rich soil is imperative for these), Pentstemons, Phloxes, Poppies, Pyrethrums, Rudbeckias and Veronicas. For autumn there are Japanese Anemones, Chrysanthemums, Sunflowers, Achilleas, Inulas, Pyrethrums, Solidago, Sedum spectabile and Michaelmas Daisies. Needless to say, among the more tender plants which bloom superbly in town gardens in late summer and autumn are the Dahlias.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**C**AULIFLOWERS. — Prick out the last batch of these on a border where they can be afforded protection in bad weather.

*Celery*. — Continue to earth up, and have a stock of dry material in readiness for protecting from frost.

*Mushroom Beds*. — Continue to prepare horse manure for successional beds. Do not keep the temperature too high in the Mushroom house, and damp the floors and walls twice daily in dry weather. The temperature should rarely be allowed to go below 55° to 60°.

*Chicory* may now be taken up and placed in pots or boxes for forcing.

*Mustard and Cress*. — Sow this twice weekly if a good supply has to be maintained. Use shallow boxes and fine soil, and sow the seed on the surface. Do not cover it with soil, or the crop will be gritty. The boxes should be placed in a warm position.

#### PLANTS UNDER GLASS.

*Crotons* should be kept in the warmest part of the house and allowed all the sunshine they can get, in order to preserve their colour. Dracenas and foliage plants generally must be kept well syringed and sponged occasionally. Gardenias should be frequently syringed with XL liquid to keep down insect pests.

Houses containing Azaleas, Camellias, Rhododendrons, Callas, Boronias and the like should be kept as cool as possible and full ventilation given on fine days. Pot up retarded Lilies of the Valley and place them in cool frames or houses, covering the pots over with moss. About eight to ten crowns should be placed in a 4½-inch pot for house decoration, but those for cutting may be placed in shallow boxes.

#### FRUIT HOUSES.

*Peach and Nectarine Houses* must be kept cool and any lifting or root-pruning required attended to at once. The soil should be removed all round the ball of roots, also underneath, as it is there that the mischief is often caused. The tree should be made to rock from one side to the other, as it will then be certain that no tap roots remain.

*Vinerias*. — The early house may be pruned at any time now, but take care that no heat is turned on in cases where plants are housed. Houses containing late Grapes must be kept cool and dry, with just a little heat on damp nights. Where there are only a few bunches remaining in one house, they should be cut and placed in bottles of water and be accommodated in the Grape room or on shelves in another house which contains Grapes. By doing this the empty house may be used for a time for housing plants. The borders may be examined if the Vines have not been satisfactory, taking care to cover and protect all roots during the process.

#### HARDY FRUIT.

Continue to gather and store all fruits as they become ripe. Most Apples and Pears will be ready this month, but if they will not part from the spur readily, do not force them; they will keep all the better for thoroughly maturing.

Collect and get ready soil for borders that require renewing and for fresh planting. Old trees that have been in position a long time have drawn all the goodness out of the ground, and in such cases a good deal of new soil should be imported. Keep plenty of air on the fruit room.

W. A. COOK.

Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*CROTONS* can be strongly recommended for autumn propagation. With bottom-heat and a close frame there is never any need for partially striking the cuttings on the plants with moss, as this, which is more of a coddling process, is only advisable when the convenience is not what it should be for rapid propagation. The best-coloured shoots which are growing erect, or nearly so, make the best cuttings. The shoots can be cut off of a fairly good length, according to the variety, from 4 inches to 9 inches or 10 inches being very reasonable limits. The cuttings should have all but the two lower leaves left on; the others the young plants will retain for twelve months, and sometimes longer when a successful strike has been made. After they have lain for two or three hours in the water-tank, insert them singly in 2½-inch or 3-inch pots, according to their size, and see that the soil does not at any time become at all dry.

*Calanthe Veitchii*. — Those who are in the habit of feeding this Orchid as the spikes rise must now be careful not to do too much to it, for the roots are already beginning to lose their hold on the compost, and it is only reasonable to suppose that the plant has by now stored most of the nutriment it requires in its pseudo-bulbs.

#### HARDY FRUIT.

*The Loganberry*. — When the Strawberry and Raspberry crop is under the average, the Loganberry comes in very useful. It is less sweet than the Raspberry or Strawberry, which is an advantage. The fruits are borne in clusters, darker in colour than the Raspberry, and somewhat acid when nearly ripe; but if allowed to hang and become black they are sweet and useful for dessert. I find the Loganberry fruits well when grown on an east or north wall and treated much like the Raspberry.

#### FLOWER GARDEN.

*Spring Flowers*. — Beds cleared of summer bedding plants that are to be utilised for a similar purpose another year may be planted with spring flowers which are waiting removal from nursery beds. Wallflowers are certainly the most useful of spring flowers, and the variations of colours have undergone considerable improvements in the last few years. Polyanthus may be used largely if plenty of time is available in late spring in which to clear them away and prepare the beds for summer plants. A great point in the planting of these temporary things is to regulate the work in such a way that beds required early another year may be filled with plants that are quickly over, or the sacrifice of which while in flower is not much regretted.

#### KITCHEN GARDEN.

*Forcing Rhubarb*. — If this is desired earlier than usual any variety may be forced, but the early red-stalked forms are the quickest to give produce this side of Christmas. If clumps are lifted and placed direct in a rather strong heat they may fail to start satisfactorily. They would do better if first subjected to a frost or frosts.

*Broccoli and Cauliflowers*. — It is somewhat early to lift and store fully-grown plants in cold pits and frames with a view to having a good supply after those in the open have succumbed to frost, but we sometimes experience wintry weather in October and the early part of November, and this ought to be prepared for.

#### ROSE GARDEN.

Late October and throughout November is the best season for planting Roses. The ground should be trenched if the soil is sufficiently deep to admit of this, but, if not, double digging is the most satisfactory way of dealing with it, and into the bottom spit should be dug a considerable quantity of good manure which has had time to become fairly decayed. T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## NEW PLANTS.

**LÆLIO-CATTLEYA CÆRULEA WESTONBIRT VARIETY.**—This is a very pretty flower of large size, graceful outline and delicate colouring. The sepals are lanceolate and rather long and pointed, the petals being broadly obovate, with crinkled margins, the colour of both sepals and petals being the usual deep lilac hue. The labellum is rather long, spreading at the base, the margins of the expanded portion being very much crimped. The colour is rich carmine with a narrow pale lilac edge, with rich yellow extending well into the throat. Shown by Lieutenant-Colonel G. L. Holford, Tetbury, Gloucestershire. Award of merit.

**Cypripedium Charlesworthii bromilowianum.**—This is rather a small flower of unique colouring. The large dorsal sepal is pure white with the exception of a little green striation at the base, the comparatively small sepals and pouch being pale green. Shown by Mr. H. J. Bromilow, Raun Lea, Rainhill, Lancashire. First-class certificate.

**Lælio-Cattleya Mr. Gothard.**—A very large-flowered specimen possessing a beautiful colour combination and graceful form. The sepals and petals are of the usual deep lilac hue, but the huge, spreading labellum is of the richest possible crimson, the throat being dull purple with a faint yellow tinge inside. The edge is heavily frilled, thus adding to its beauty. Shown by Mr. H. S. Goodson, West Hill, Putney. First-class certificate.

**Cypripedium Lord Ossulston Sander's variety.** This is a beautiful addition to the large-flowered Lady's Slippers. The huge dorsal sepal is white, heavily tinted purple, with green striation at the base. The ovate-lanceolate petals are narrow and of a dull green colour with faint purple veinings, the large glossy green pouch standing out well from the back of the flower. Shown by Messrs. Sander and Son, St. Albans. Award of merit.

**Odontoglossum Pescatorei Sander.**—In this we have a very daintily marked flower of medium size and beautiful form. The sepals and petals are equally ovate with rather acute apices, the cream ground colour being freely and regularly blotched and dotted with pale brownish crimson. The labellum is comparatively large and open, the colour being dull cream, with rich yellow and brown markings near the column. Shown by Messrs. Sander and Son, St. Albans. Award of merit.

**Rose Mr. Alfred Tate.**—A beautiful and fragrant Hybrid Tea with exceptionally long buds, the colour of the expanded blooms displaying a delightful blending of salmon apricot and pale pink.

**Rose Mrs. Edward J. Holland.**—A lovely Hybrid Tea of deep rose colour that is most attractive. Very slightly fragrant.

**Rose Mrs. Wakefield Christie Miller.**—Also a Hybrid Tea of deep rose colour with blush shading. A showy variety in which we could detect no fragrance. Each of the above received an award of merit, the set being exhibited by Messrs. Samuel McGredy and Son, Portadown, Ireland.

**Aster Climax.**—A Michaelmas Daisy of presumably the *Novi-Belgii* type, and the largest and most handsome of the blue-flowered varieties yet seen. The flower-heads are produced in a not too dense pyramidal panicle, the solitary flowers appearing lower on the spike and well extended at an angle of 45° or more, and thus assisting the fine effect produced. Award of merit.

**Aster Maidenhood.**—One of the smaller white-flowered set, the blossoms produced in elegant sprays. Award of merit. Both were exhibited by the Hon. Vicary Gibbs, Elstree (gardener, Mr. E. Beckett).

**Nerine Countess of Altamont.**—A very pretty variety with undulated petals, coloured a deep

salmon rose. Exhibited by Mr. F. D. Goodman, Horsham. Award of merit.

All the preceding were shown before the Royal Horticultural Society on the 13th inst., when the awards were made.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

## ROSES FROM CHEPSTOW.

Mr. E. A. Price, Wallhope Cottage, Boughspring, near Chepstow, sends a few good autumn Roses, which are very fragrant. He writes: "I herewith forward you a few Roses for your table. I hope they will arrive in good condition. I should like your opinion on the Dorothy Perkins Rose. Is it not unusual for it to be in flower now? I have about twelve plants, which I have been propagating for sale purposes; nearly all of them have been in bloom since June, and they look (by the buds on them) as if they intend keeping on till the frost stops them. I may say I have propagated them by cuttings from one plant which I had three years ago. Do you think they have developed the perpetual habit by sporting, or is it owing to last season's weather?"

[There is certainly a perpetual-flowering tendency in Dorothy Perkins, but we do not think your cuttings possess any distinct trait from the ordinary variety, for we have had a similar experience. Some plants last summer produced flowers from July to October. These were raised from cuttings. We believe the tendency of own-root plants is to keep up a continuous new growth, and trusses of bloom are formed on the lateral growths which are so freely produced.]

## SWEET PEAS FROM ALDERSEY HALL.

Mr. Hugh Aldersey of Aldersey Hall, Chester, sends us some remarkably fine flowers of new Sweet Peas, which, on a foggy day in October, were most welcome. Tortoiseshell may be described as a rich-coloured Henry Eckford, but with larger and much-waved flowers; Flamingo is a beautiful cherry red waved variety; Ruby has a large, rich orange, waved standard with carmine wings; and Scotch Pearl is a pleasing advance on Frank Dolby. Romani Rani is a beautiful waved variety with a cream ground colour, suffused rich pink, and closely resembles Mrs. Henry Bell. Mr. Aldersey writes: "I enclose a few flowers of some of my new Sweet Peas, also a few sprays of St. George from a plant which is over 8 feet high and growing strongly, and from which I have not gathered a dozen spikes of bloom all the season. It seems to be a peculiarity of this variety to produce masses of tendrils at the expense of flowers."

## AN INTERESTING CONTRIBUTION FROM DUNS.

Dr. McWatt of Morelands, Duns, N.B., sent, on the 8th inst., a most interesting collection of flowering subjects. He writes: "I am sending you a branch of *Parrotia persica* (Iron Tree) showing the beautiful colour of the leaves in autumn. This tree is rare in cultivation, but it should not be so, as it is quite hardy and will

thrive in an open and exposed position, although it is stated in Robinson's 'English Flower Garden' that 'in the North it would probably require a wall.' It grows about 12 feet high. *Corylopsis spicata* is another very ornamental shrub resembling the Witch Hazel. It only grows a few feet high, flowering in early spring. *Cercis Siliquastrum* (Judas Tree) grows some 15 feet or 20 feet in height, with rather a crooked habit. It also flowers before the leaves appear. The three trees or shrubs mentioned are all very fine and should be more used for ornamental planting. *Bridgesia spicata* is a very good climbing plant for a wall. The leaves are a fine deep green. Here I have it covering a wall about 12 feet high facing south. I also send you some other things at present in bloom in my garden. Look at the three seedling Delphiniums; they are flowering in the open. I am certain you will agree with me that one of them will be difficult to beat. I think it is the best and most beautifully-coloured Delphinium I ever saw. I have not yet named any of my Delphiniums, but hope to do so next year. *Dianthus Atkinsonii* is a beautiful blood red, perhaps the best of the class, and so easily grown. How is it that it is in so few catalogues? *Arnebia echioides* (Prophet's Flower) seems always to be giving us blooms."

[The Delphiniums sent were of a beautiful sky blue colour. Among other things not mentioned were several varieties of Japanese Anemones, Gaillardias, outdoor-grown Polyanthus and Primroses, *Schizostylis coccinea*, the pretty little *Campanula trachelium*, and *Pernettya mucronata* with its pink berries.]

## SWEET PEAS FROM WINCHESTER.

Mr. D. Grant, Compton End, near Winchester, sends an interesting and beautiful contribution of Sweet Peas. Although the flowers had been considerably bruised in transit, enough remained sound to enable us to ascertain that they had received good cultural treatment. Among others we recognised Helen Lewis, John Ingman, Frank Dolby, Nora Unwin and Countess Spencer. He writes: "I send some bunches of Sweet Peas for your Editor's Table; the seeds were sown in January last, and we have had a very successful year."

## SWEET PEAS FROM COLDSTREAM.

Mr. James Logan, Castle Lane Gardens, Coldstream, sends an excellent contribution of Sweet Peas, which, in the middle of October, were most welcome. The flowers were large and possessed long, stout stems, such as we see in the summer, and were evidently the result of first-class cultivation.

## NOTES AT KEW.

At present there is much of beauty and interest to be observed in the Royal Gardens, Kew. The fine massed row of *Amaryllis Belladonna* along the front of house No. 1 and near the main entrance is at its best, the hundreds of large, delicate pink flowers contrasting well with the green foliage of *Zephyranthes candida* (the Peruvian Swamp Lily), which is used as an edging.

In house No. 4 a plant of considerable interest and beauty is *Salvia azurea*, which, with its azure blue flowers, makes a welcome splash of a colour too seldom seen in the autumn months. The specimens are of rather straggling growth, but this is not noticed when they are flanked with other kinds of more robust habit.

Those who love the spring Crocuses will also be interested in the autumn-flowering species, of which there is an excellent collection at Kew near the Iris garden, many of the species and varieties now being at their best. The following are some that specially called for mention in the middle of October: *Crocus pulchellus*, pale lilac.

with long, dull yellow tube; *C. lævigatus*, pale lilac with darker venations and a very short tube; *C. hadriaticus*, pure white petals with yellow base and bright orange scarlet stigmas; *C. longiflorus*, rosy mauve, yellow base and vivid orange scarlet stigmas; *C. medius*, large purple flowers with feathery, orange-coloured stigmas and long tube; *C. Salzmannii*, pale rosy mauve, star-shaped, rather short tube; *C. asturicus*, pale violet; *C. nudiflorus*, pale blue, cup-shaped flowers; *C. iridiflorus*, very distinct Iris-like blooms, possessing three large, boat-shaped segments of purplish blue colour, branching magenta-coloured stigmas and long tube; and *C. sativus*, a beautiful pure white with yellow base and bright orange scarlet stigmas. These autumn Crocuses are easily grown and seed freely, hence they should find a place in many gardens where bulbous plants are favoured.

## LEGAL POINT.

**Gardener's compensation** (*Pen A. R.*).—It is not surprising that employes do not consider the compensation afforded by the Workmen's Compensation Act altogether satisfactory. If a workman can hardly live on full wages, it seems rather absurd to ask him to live on half; still, for ordinary accidents the statute only provides for a weekly payment of 50 per cent. of his average weekly earnings, unless the servant is under twenty-one, in which case he gets full wages up to 10s. a week. The weekly payment only lasts during incapacity, and there is no reimbursement of doctor's expenses or solatium for pain, &c. On resumption of work at full wages, the claim to half-pay ceases, of course, although the workman may not necessarily have waived further claim; for instance, he may immediately discover that he is still incapacitated. The curious point in this case is that, on the facts as stated, the master appears to have made a profit out of the servant's mishap. This result, however, does not concern the servant; but the insurance company, if it finds it out, would be able to recover the balance from the master.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Border for perennials** (*S. Prosser*).—The western end will be the better position. In the first place you should endeavour to improve the soil by the addition of road sweepings, grit, light manure or burnt earth; anything, in fact, that will tend to make the heavy clay soil more porous, and therefore more congenial to the plants you wish to grow. A large number of the best perennials prefer a good holding soil, but in a heavy clay they are sometimes slow to become established. If the border is not yet made, and we presume it is not, we think your best plan will be to prepare it by trenching during the coming weeks, and endeavour to improve it

during the winter in the way we have suggested, planting it in the spring of 1909.

**Cutting down the Madonna Lily** (*Mrs. B. Spring Rice*).—The stems of the above may be cut down now with impunity; indeed, after the beginning of August in each year the stems are of not much benefit to the bulb, and may be earlier removed if previously wrecked by the disease. In the latter case, however, all the dead stems should be collected and burned.

**Sweet Peas** (*R. W. A.*).—You display considerable acuteness in your association of certain Sweet Peas. Sutton's Queen and Mrs. Henry Bell, Marbled Blue and Hester, Phenomenal and Mrs. Townsend, John Ingman and Mrs. W. King, Lord Althorp and Helen Lewis are very close to each other. We think you are not far wrong as to Ruby either; but we want to see more of this and Ida Townsend before speaking definitely. As regards Mrs. Collier and James Grieve, there are perhaps more hooded flowers in the latter and it is a shade larger, but they are very close. Is not Miss Davis nearer to Helen Lewis than to Countess Spencer? Enchantress, again, is Countess Spencer rather than Audrey Crier.

**Plants in an aquatic tank** (*J. E. R.*).—It is difficult to understand the rain-water becoming so dirty, and the only safe thing to try would be charcoal sunk in rather open mesh sacks. We are not aware that the fish would eat the water-snails. The most likely cause of the bud-dropping of the Liliiums is root dryness, or this and soil poverty combined. The earlier-flowering Fritillary may do quite well under similar conditions of soil, but the Lilies flowering or making growth while the tree was in full leaf would be robbed of all nourishment and moisture. We advise you to examine the Lilies at once and get them replanted in deeper and richer soils. We do not recognise the name of the plant you refer to in your third query, but if you send a specimen we may be able to identify it and give you the information required. The Rose was quite shrivelled up.

**Growing Christmas Roses** (*M. Kenney*).—There is no reason whatever why you should not succeed with these plants in the open ground, and success is more likely by this method of cultivation than by planting in tubs. The end of August and onward to the middle of October would suit quite well for planting. The chief items are soil preparation and good plants. By "good plants" we mean healthy examples with three or four leaves and not more than twice that number of crowns. This size of plant should be obtained in any case—the diminutive and leafless plant with weakened crowns will only make an effort to live, and will always disappoint. The Christmas Rose requires partial shade and not less than 2 feet depth of light, rich, loamy soil. Big clumps should never be planted intact. Suitable tubs should be not less than 18 inches in diameter, and preferably of the same depth. Such as these would accommodate three or four ordinary-sized plants. A good drainage must be secured. It is very doubtful whether from these autumn plantings you will get any flowers for next winter, as the Christmas Rose must be first established. A chief drawback to the latter mode of culture is that the plants often suffer neglect during the summer time, but when properly planted in the garden this is less likely to ensue. A good time for grafting the Apple would be March or April, and, if you desire to do this, you should plant a few Apple stocks during the autumn. As you are contemplating grafting it, no pruning or other work is necessary. If you write again in January next, we will give you full instructions as to grafting.

### THE GREENHOUSE.

**Stove for greenhouse** (*H. A. S.*).—As both oil and gas stoves consume oxygen, which is needful for plant-life, this mode of heating is, of course, less desirable than hot-water pipes. As this is probably out of the question, your better way will be to get a good-class oil stove and keep it properly trimmed and scrupulously clean. In this way the fumes will give but little trouble.

**Information about a Cactus** (*N. H.*).—A difficult matter to advise upon, as there are so many kinds of Cacti and the same treatment is not suitable for all. Again, we very much question if it needs a larger pot, as one 11 inches in diameter is very large for a Cactus. By far the better way will be to obtain the opinion of a practical man in your neighbourhood, who, by seeing the plant, will have a great advantage over us. Even in the case of it needing repotting, the season is now too late for it to be done. The better plan will be to wait till next April before the roots are interfered with. Meanwhile care must be taken not to keep the soil too wet; indeed, throughout the winter only enough water should be given to retain the soil in a slightly moist condition. A suitable compost for many Cacti may be made up of three parts good yellow loam, one part of peat or leaf-mould

and half a part each of sand and broken brick rubble.

**Culture of Malmaison Carnations** (*Rebecca*). You will find ample instructions for growing Malmaison Carnations in THE GARDEN for July 11, page 337. As a rule the layers made in July are sufficiently advanced to be potted into pots 4 inches in diameter, and to be established therein before summer has left us. As soon as these pots are well furnished with roots—that is, generally speaking, in September—the plants should be shifted into their flowering pots, usually 6 inches in diameter. If you desire large plants they may be potted on directly the flowers are over, but when in pots sufficiently large annual repotting is not necessary, though a top dressing and an occasional stimulant, as detailed in the article in question, will be beneficial.

**Keeping Geraniums through the winter** (*M. A. Gibbs*).—As you surmise, it is now too late to take cuttings of the Geraniums, and it is quite useless to try and winter them in a cold frame. This leaves the long shelf in the cookery school as the only place available for wintering your plants, though, with its varying temperature, it is by no means an ideal position for them. They might, however, succeed there if the plants do not at any time get frozen. A fine day should, if possible, be chosen for lifting the Geraniums, which may have the long succulent shoots shortened back and the strongest leaves cut off. Do not strip the leaves from the stems, but cut them off in such a manner that an inch or so of the leaf-stalk remains attached to the stem. This will quickly die and drop off, whereas if the leaves are stripped from the stem it often causes a wound, which may prove a seat of decay. The very long string-like roots, too, must be shortened back. Then take some clean pots, from 4½ inches to 5 inches in diameter, drain them by means of an oyster-shell or broken crocks and pot the plants, taking care that the soil is pressed down regularly and made moderately firm. After this give a good watering in order to settle the soil in its place, and after being allowed time to drain the plants may be stood on the shelf; if in a good light position, so much the better. They should be occasionally watered during the winter, but no more than is necessary; indeed, throughout that period the soil must be kept almost dry.

### ROSE GARDEN.

**Roses for shaded trellis** (*Rosa*).—Claire Jacquier is one of the worst you could have planted on a shaded trellis. It is rather a shy bloomer at first and needs a lofty, sunny wall or arch where it may extend its vigorous growths, and then it is a lovely picture after three or four years. Félicité Perpétue will do well. It is not a specially beautiful Rose individually; but when a plant is covered with thousands of flowers, as it will be in a year or two, it makes a fine show. Elise Robichon would do very well in the position, and it produces a lovely little bud. If you want large blooms, plant Conrad F. Meyer and Mme. Isaac Pereire. Although not so rampant in growth as the Rambler Roses, they would soon cover an ordinary trellis, providing you prepare some good deep holes for their roots. These holes should be opened about 3 feet deep and 2 feet wide and filled with the same soil if good, with manure liberally admixed. Tausendschön would grow very well; but it is only a one-season Rose, whereas the two last-named would bloom in summer and autumn.

**Rose Prince Camille de Rohan failing to open** (*G. H. Wheeler*).—From the specimen sent we believe the Rose to be Jean Liabaud and not Prince Camille de Rohan. This latter, although addicted to mildew, rarely fails to expand, whereas the other variety is notorious for this bad quality. It would help the flower to expand better if you removed the buds that surround the central one. By syringing as soon as mildew is seen with a solution of Lifebuoy soap, we think you will overcome the fungus. Take half a bar of the soap to three gallons of soft water, and spray with a fine sprayer every two or three days until checked.

**Preserving Rose blooms at exhibitions** (*Osprey*).—We are not aware that exhibitors put anything in the water to keep their flowers fresh. The reason the nurseryman's flowers were quite fresh compared with yours was doubtless because he had cut them either early in the morning or late in the evening and put them into water immediately they were cut, or he had culled them from young maiden plants. These have a greater staying power than Roses from cut-back or old bushes. On very hot days it is well to place the flowers into a vessel holding an abundance of cool water and keep the blooms as cool as possible for some hours before travelling with them. For this reason we prefer a travelling-box with tubes much larger than those usually employed in show boxes. The flowers can be transferred to the latter at the last half-hour. When at the show find out a cool place and keep your blooms there until a short time before the judging commences, and do not forget to tie the blooms, as this assists them to remain fresh a much longer time.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## TULIPS FOR CUTTING.

THE great desideratum in all Tulips which are to be used as cut flowers is length of stem. In certain exceptional cases stumpy flowers may be appropriate, but for ordinary room and table decoration, where gracefulness is all-important, good long stems are a necessity, and all the varieties mentioned in my present article will be found to possess such stems.

### FORCED VARIETIES.

For our earliest flowers in February we must rely on some of the early-flowering section. The ones that I would especially recommend to be grown are Thomas Moore, a lovely warm rosy apricot; Duchess of Parma, a long, pointed flower of a rich orange red, which shades into old gold at the edges of the petals; Prince of Austria, a good-shaped, sweet-scented orange brick red; Prince de Ligny, a deep yellow, peculiarly graceful flower; and White Swan, a snowy white, large globular bloom, borne on rather weak stems, which allow the flowers to assume a naturally drooping position. Before passing on I must not forget to say that I very much doubt if there is a more beautiful Tulip in existence for artificial light than a forced Duchess of Parma. On a well-appointed dinner-table set up in deeply-cut white glass vases, or in plain silver, it is without a rival.

A very useful section for growing under glass is the Darwin. Year by year we are becoming more familiar with their value in this respect. From the end of March onwards there is no difficulty in having good flowers in quantity, and I venture to think that a good many varieties lose nothing by this treatment, becoming more delicate and refined in their colouring, almost, in fact, illustrating the impossible as examples of gilding refined gold. Those who visited the early spring shows this year at Vincent Square will have seen them exhibited by Messrs. Wallace and Messrs. Barr more than once. Among the most satisfactory are: Lavender, Rev. Ewbank; reds, Europe and William Pitt; dark crimson, Donders; pink, Clara Butt; white and blush, White Queen and Margaret; dark shades, Zanzibar, Leonardo-da-Vinci (edged flowers) and Loveliness.

The Parrot or Dragon Tulips, with their curious lacinated petals, always command high prices in the cut-flower market. They are not suitable for real forcing, but if opened under glass they come a little earlier than those outside. Their stems are never strong enough to carry the flowers and always bend over. For this reason they are only suitable for positions where they can hang down, such as the top of a tall writing-desk, chimney-

pieces, &c. Cramoisie Brilliant, crimson; Lutea Major, yellow; and Perfecta, yellow and red, are three distinct and good sorts.

Very few Cottage or May-flowering Tulips can be recommended for growing under glass for cutting. They so soon lose all their shape. There are, however, two or three exceptions, viz., Isabella, which comes a delightful shade of buff, with an edge of old rose, and quite tall enough to be used in low vases; Didieri alba, a small, dainty, pure white, pointed flower, borne on a long rather weak stem, which gracefully bends when arranged in water; and such varieties as Jaune d'Enf, Plutagus, Sensation and Queen Alexandra, all of them of those quaint brown, old gold and yellow shades which are in some lists erroneously claimed as Darwins. These are very fascinating to those who like such quaint colouring.

### NATURALLY-GROWN VARIETIES.

There is no doubt whatever that the Darwins are an "easy first" in the adaptability of the different sections for cutting. Their tall stems and "florist"-shaped flowers, which never "quarter" with age, are what are wanted for vase decoration. There is really no need for any selection where every variety is equally suitable. Still, it may be of some interest if I mention the twelve that would be my choice, merely saying that I am very partial to the dark and lavender shades, and think medium-sized flowers better than very large ones. Blue Amiable, deep lavender; Rev. Ewbank, paler lavender; Clara Butt, pale salmon rose; Margaret, soft pale pink; Millet, dark crimson maroon; Barron Tonnage, rose edged with pink; Europe, carmine scarlet; Whistler, rich blood red; Velvet King, dark purple; Zulu, rich blue-black; Zanzibar, rich deep claret; Tara, deep ruby.

What I have already said about Parrot Tulips need not be repeated. I would always grow a few for cutting out of doors. Before mentioning any varieties in the May-flowering or Cottage section, may I say that I have a large collection, and give away a good many handfuls to friends in the course of the season. I mention it because the next time I see them I am so often greeted with the remark, "I did enjoy those Tulips; do you know they lasted a whole week, and some even longer." People are surprised at their lasting power in a cut state; but there is nothing remarkable about my Tulips: the only thing is that I always cut them as soon as the flower is open, and then the time of the year has come when there are no fires in the sitting-rooms. Here again, as in the Darwins, the choice is very large. Lack of space forbids my mentioning too many. The best thing I can do is to make three selections and label one dainty, another

handsome and a third beautiful, thereby, in some degree, suggesting their characteristics.

*Dainty.*—Characteristics: Their long stems; elegant, long and often small flowers; petals inclined to reflex. Retroflexa, soft yellow, exceptionally graceful; Didierii, red; Didierii alba, pure white; elegans alba, pure white, with narrow wire edge of rose; Marjolettii, deep cream, with red blotches at base of petals; sylvestris, yellow self.

*Handsome.*—Characteristics: Long stems; large, pointed or globular flowers; striking colours. Gesneriana, crimson-red; Lord Byron, cerise; Orange King, fiery orange; Inglescombe Pink, rose pink and salmon; Sensation, golden bronze; Hammer Hales, bronze yellow; Orange Beauty, orange red; gesneriana lutea, rich yellow; Admiral Kingsbergen, crimson and white striped; Louis XIX., immense bronze purple; Gold Mine, brown and orange striped; Emperor Alexander, purple and white striped.

*Beautiful.*—Characteristics: Long stems; variously-shaped flowers, with refined colouring. Vitellina, deep primrose; La Merveille, coral red; Picotee, white, edged with rose; Ellen Willmott, pale yellow; Kate Conner, soft rose; Beauty of Bath, rosy lavender and pale yellow; Leghorn Bonnet, chrome-yellow; Miss Jekyll, white; Flame, orange scarlet; Ada, white, with pale lavender interior; Zomerschoon, salmon and cream flaked.

JOSEPH JACOB.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 4.—National Chrysanthemum Society's Exhibition (three days), at the Crystal Palace.

November 5.—Bury and West Suffolk Horticultural Society's Show (two days). Bath Chrysanthemum Society's Show (two days).

November 10.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m.; Lecture at three o'clock on "British Wild Flowers in the Garden," by Mr. John W. Odell; admission, 2s. 6d.; Royal Horticultural Hall, Vincent Square, Westminster. West of England Chrysanthemum Society's Show. Leeds Baxton Chrysanthemum Society's Show. Horticultural Club, Mr. C. D. McKay on "The French Garden," Hotel Windsor, 6 p.m.

### Flower Show for our Readers.

We have much pleasure in announcing that the exhibition of flowers, fruits and vegetables for our readers will be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Wednesday, July 28, 1909. Some readers have suggested holding it on an earlier date in July; but this is impossible, as the hall is fully booked up for other shows. We hope readers will send in any suggestions relating to the schedule, and these shall have consideration.

**Trials at Wisley, 1909-10.**—The council of the Royal Horticultural Society have arranged for trials at the Wisley Gardens of the following fruits, flowers and vegetables during 1909. N.B.—Everything sent for trial must be named and the name and address of the sender attached. Fruit: Autumnal Raspberries, fifteen canes of each variety to be sent at once. Flowers: Tree Carnations, two plants of each variety; annuals, seed to be sent in January; garden Dahlias (show and Cactus excluded), two plants of each to be sent in April; early-flowering outdoor Chrysanthemums, two plants of each to be sent in April; Pentstemons, two plants of each variety to be sent in April. Vegetables: Potatoes, twenty tubers of each variety to be sent by February; also experiments with the same variety of Potato secured from as many varying sources as possible, under different soil and

climatic conditions. (Note.—Each variety must be labelled as being "early," "midseason" or "late.") Cauliflowers, quarter of an ounce of each variety; Lettuce, quarter of an ounce of each variety; Kidney Beans, half a pint of each variety. Growers, please note.—Autumn-fruited Raspberries: Fifteen canes of each variety of named autumn-fruited Raspberries, of which a trial is desired, should be sent at once to Wisley. All parcels should be addressed, if sent by post: The Superintendent, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey. If by rail: The Superintendent, Royal Horticultural Society's Gardens, Wisley, Horsley Station (London and South Western Railway), with advice by post to the superintendent. — W. WILKS, *Secretary, Royal Horticultural Society.*

**Sweet Peas in October.**—Mr. J. B. Price, Beechworth, Liverpool Road, Kingston Hill, writes: "This morning (October 16) I gathered a bunch of Sweet Peas. Having measured some stalks, I found them to be 10 inches in length; the blooms, although not quite so large as in August, were of good size and the colours vivid. This to me is certainly a record, proving the extraordinary mildness of the season."

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Lespedeza Sieboldii.**—The warm, sunny weather experienced during the early half of October has been very favourable for this shrub, and it has rarely been seen in better condition than during that period. Naturally a late September and early October flowering shrub, it frequently happens that the flowers fail to develop properly owing to insufficient sun or frosty nights. This year, however, it has been a perfect picture, the termination of every branch forming a large inflorescence of pretty reddish purple flowers. It is a native of Northern China and Japan, and has been known for a considerable period, though it is rarely met with outside scientific establishments. Its absence from gardens is doubtless due to its lateness of flowering and consequent unreliable character. In the neighbourhood of London it forms shoots up to 5½ feet in length, which produce ternate leaves and axillary and terminal inflorescences of reddish purple Pea-shaped flowers. The inflorescences are borne from every leaf-axil on the upper 2 feet or 2½ feet of each growth, the whole forming on each shoot a large, loose panicle of flowers. These shoots die to the ground-line annually, and are replaced by new branches from the rootstock the following spring. Like most other members of the order Leguminosæ, this plant thrives in light, loamy soil. It should be given a position exposed to full sun, for it fails to give really good results in a shady place.—W. D.

**The Wisley collection of Grapes.** While the exhibition at the Vincent Square hall, on the 29th ult., of a remarkable and most interesting collection of thirty-one varieties of house-grown Grapes in fifty-three bunches from the Royal Horticultural Gardens, Wisley, attracted great notice, yet the collection was in no sense presented as mere exhibition samples, but was displayed for essentially educational purposes. While Grapes are grown for exhibition in Great Britain with the highest possible skill, and with corresponding results, yet very largely in such cases the range of varieties is very limited; indeed, rarely exceeding some half-dozen. These are comparatively easy of culture, produce large bunches and fine berries, and when well finished are perfect examples of their respective varieties. The object of the Wisley collection, no less than forty varieties being grown in one large, broad, span-roofed house and almost entirely under similar conditions, was first to preserve

for comparison many old and little-cultivated Grapes, some comparatively new ones and those commonly grown for exhibition or market, such as most Vine growers are familiar with. The present year is the third from planting, and each Vine, with the exception of two recently planted, bore from five to six good bunches of fruit, thus enabling full comparison as to the respective merits of each variety to be made, as also thus enabling comparisons as to growth and leafage to be made at the same time. Then there were included in the collection several varieties that, while little grown, produce Grapes of very high flavour. These too seldom find a place in gardens where large showy Grapes are most favoured. Specially rich in flavour are Muscat Champion, berries large, round and reddish; Grizzly Frontignan, berries small and red; White Frontignan, berries white; Muscat of Hungary, berries almost green; Ascot Citronelle, berries amber, very rich flavour; and Muscat Hamburg, black in colour. Of comparatively small-berried black Grapes were West's St. Peters and Black Prince, and there was also the seedless Black Monnuka with its long, pointed berries. A little known greenish yellow Grape is Diamant Traube, excellent for a cold house. Of Vines generally carrying large bunches were Barbarossa, black; Syrian, white; White Nice, and Trebbiano, berries lemon yellow. Other good whites were Chasselas Napoleon, abrupt-shaped bunch, berries lemon colour; Foster's Seedling, Lady Hutt, Mrs. Pearson, Cannon Hall Muscat, Bowood Muscat, Muscat of Alexandria, Duchess of Buccleuch and Golden Queen, the latter having the richest golden hue of any variety. Of coloured varieties there were, of course, Alicante, Lady Downe's, Gros Maroc, Madresfield Court, Alnwick Seedling, Lady Hastings, Appley Towers, Black Hamburg, Directeur Tisserand, a variety of no special merit, and the new, and one of the finest of all the blacks, Prince of Wales. This Grape, which is a robust grower, carries rather long, tapering bunches, not unlike those of Madresfield Court, but the berries are round, very black and carry a dense bloom. It hangs well, berries have firm flesh and rich flavour, and it bids fair to become one of the most popular Grapes of the day. Since the introduction of Madresfield Court, over forty years ago, Grapes that have come into the front rank have been indeed few; Prince of Wales will be a valuable addition. When it is remembered that Black Alicante, Gros Colman, Lady Downe's, Black Hamburg, Madresfield Court, Muscat of Alexandria and Foster's Seedling seem to be the chief exhibition Grapes of the day, it is evident that a few others to increase the selection may well be acceptable. A few varieties at Wisley were over, and Gros Colman was not ready. Another year it may be possible in two sections to show bunches of all forty varieties.—A. D.

**Apple Clarke's Seedling.**—I have often wondered that one never reads any mention or commendation of Clarke's Seedling Apple. The only Apple catalogue I ever saw it in was Messrs. Merryweather's (of Southwell Nurseries, Notts), and to my surprise it has disappeared from even that one this autumn. In my opinion it is a first-rate variety—an abundant bearer, cooks beautifully and is, I am told by Apple fanciers about here, excellent to eat raw (I myself can say nothing about this last, as I am unable to eat raw Apples). But its chief merit, in my eyes, is its extreme hardiness. My garden is cold and damp. It is not a good Apple soil, and Clarke's Seedling is planted in about the worst part of it and, while most other varieties canker badly, it seems perfectly healthy. It takes on a lovely colour (deep orange with bright crimson side) and is an excellent late keeper; in fact, the only demerit it has, in my opinion, is that it makes but little wood, in consequence of its fertility. It shares this demerit with Lane's Prince Albert. I can confidently recommend it to anyone with a low-lying, cold, damp garden.—D. K., *County Cavan.*

**Rose Isabella Gray.**—I shall be very much obliged if "M. E. B." will communicate with me in respect of the paragraph in THE GARDEN of the 10th inst., page 490, respecting Rose Isabella Gray.—EDWARD F. KEMP, 6, Avenue Road, Clapton, London, N.E.

**Belladonna Lilies in Jersey.**—I enclose a small photograph of a clump of Belladonna Lilies taken during September in my garden here. These Lilies have bloomed better than usual this season, probably owing to the dry weather and abundance of sunshine at the time when the bulbs were ripening off. I have now seven clumps in full bloom, some of them having more than twenty spikes. I do not know whether they bloom as freely as this in England, but one of their characteristics in Jersey is that they flower almost equally well in any kind of soil. Those in the photograph were grown in a position facing nearly due south and in a poor rocky soil in which I find it hard to grow anything else. I therefore come to the conclusion that there must be something in the island air which they particularly like.—C. J. ROBIN, Steephill, Jersey.

**Apple Miller's Seedling.**—I noted the remarks regarding this Apple, and I am surprised that it is not better known. It gained an award of merit last season, and that was the first time I had seen it at any of the London shows, yet it is over forty years ago since I first knew it as one of the best early Apples in Sussex. It may not do so well in all districts, but, among some sorts planted for providing stock, a bush tree produced good crops for at least eight years successively. It is a pretty Apple with a transparent pale skin with red stripes on the sunny side, and I can say one of the best eating Apples grown, but not one which can be kept long. Nutmeg Pippin is another Apple which was not seen at the fruit conference held at Chiswick some years ago, and I have not seen it since I left Sussex; but there it was one of the best dessert Apples we had. It is of medium size and conical, and has yellow skin with dark blotches. Another Apple which was always to the front for flavour was Kerry Pippin. I have recently seen good samples of this, but it is not so well known as it deserves to be. For many years it always secured the first prize for the best-flavoured dessert Apple at the Brighton autumn show, which was held about the middle of September, but this Apple will keep much later. James Grieve has been so well shown this autumn that its value has been fully proved, yet I must say a word in its favour. I have only a small garden, and in it a small tree of this variety, from which I gathered about 100 good fruits this season, and, in addition to bearing the fruit, the tree when in flower was as pretty as any flowering shrub that could be planted. I am surprised that Apple trees are not more extensively planted in villa gardens, for they are ornamental as well as useful.—A. HENSLEY.

—This distinctly excellent early Apple has had recognition, as when exhibited two years since at a meeting of the Royal Horticultural Society by Mr. W. Fyfe, Lockinge Gardens, where the trees fruit abundantly, it received from the fruit committee an award of merit. Why the nursery trade do not secure stock and put it generally into commerce is, to me, a matter for surprise, as without doubt it is one of the handsomest, most crisp and best-flavoured of all early Apples. It is very largely grown in Berkshire, and only needs to be as widely known in the kingdom as in that county to be universally grown. All those who want a high-class September dessert Apple should grow Miller's Seedling. It is also a first-class market variety.—A. D.

## YORKSHIRE ROSES, HARDY PLANTS AND FRUIT TREES.

ON the first day of October, a day noted for its extreme warmth and bright sunshine, we had the pleasure of spending a few hours in the nurseries of Messrs. G. Gibson and Co. of Leeming Bar, Bedale, Yorkshire, and noting how Roses, hardy plants and fruit trees are dealt with there. The natural soil is almost pure virgin loam, such as would delight the heart of any good gardener, and of a character eminently suited for the production of healthy, well-rooted plants, and, when we have coupled with this a very exposed and open situation, there is little wonder that the Leeming Bar plants are so far-famed, and that they give quick returns in the way of flowers and fruits as the case may be. The business is under the personal control of Mr. G. Gibson, who is a business man to his fingers' ends and has done much to raise the firm to its present high position.

Roses are grown on a very extensive scale, some 50,000 dwarf bushes having been budded

being stocked in large quantities. A careful inspection of these revealed not the slightest trace of disease or insect pests, and such trees and bushes ought to give excellent returns.

Hardy plants of all descriptions are very extensively stocked by Messrs. Gibson, and many of our readers will remember the beautiful prize-winning groups staged by the firm at the leading shows during the past and other summers. Even at the beginning of October many of them were giving late flowers, thus enabling us to ascertain what they were like. Perhaps the best feature in the whole section was a large bed of Tritoma or Kniphofia nobilis hybrids two years old from seeds. Many beautiful varieties were noted among them, the brilliant yet refined-looking spikes making a grand display.

Wild gardening is now, of course, a very popular feature, and to keep well ahead of the times Messrs. Gibson have an extensive stock of such plants as Foxgloves, Aquilegias, Achilleas and Scabious, which are most suitable for such purpose. Of the rare Scabious alba a fine, healthy lot of plants was noticed, every care being taken to eradicate any which are not quite true, so that customers may rely on having white flowering plants when such are ordered. Of the Caucasian Scabious we saw some 15,000 plants, and among a large number of seedlings we noticed many that were carrying much diversified and beautiful flowers.

Herbaceous Phloxes and Delphiniums are naturally well to the front owing to their high value for garden decoration. Among the former Sheriff Ivory, clear pale salmon, crimson eye; the new Mrs. John Harkness, very large and of a pretty salmon shade; Mrs. E. Jenkins, pure white, large flowers; Roger Marc, large, deep salmon; Embracement, large, extra good salmon colour and dwarf; and Tour Eiffel, pale salmon, tall, were a few that we specially noted. Although the named Delphiniums were over, we noticed some very beautiful seedlings still flowering, and of which more will doubtless be heard.

Those who like the Mulleins, as the Verbascums are popularly called, should, if they have not already done so, make the acquaintance of V. Caledonia. This has a large spike composed of beautiful coppery bronze, shaded fawn-coloured flowers, and as the plant, when this main inflorescence

has finished and been cut down, pushes up a series of side shoots, it remain in flower for at least eight weeks, and is a true perennial. V. gloriosa has huge glaucous leaves and large yellow flower-spikes, and when well grown is truly a noble plant. The variety A. M. Burnie somewhat resembles Caledonia, but has lighter-coloured flowers.

The Aconitums are not grown so extensively as their merits demand, two that we saw at these nurseries being quite gems of their kind. These were A. Fisheri and A. japonicum. Both are of dwarf, compact habit, the helmet-shaped flowers being borne in a rather dense terminal raceme. The first-named has marbled blue flowers, and the latter has deep blue self blossoms. Among many other good things seen were Physalis Bunyardii (the Chinese Lantern or Winter Cherry, so useful for winter decoration), Michaelmas Daisies of all the best types, Achillea Ptarmica The Pearl (a beautiful white-flowered Yarrow for cutting), Oriental Poppies Lady Rosco, Princess Ena and Marie Studholme (the last-named being a beautiful dwarf-growing pale salmon sort raised at these nurseries), Montbretias of all sorts, Pæonies in large quantities, early-flowering Chrysanthemums in all the latest varieties, alpinas of various sorts, a beautiful lot of Gladioli seedlings and also magnificent flowers of the vivid scarlet G. princeps. The catalogues published by the firm are very interesting.

A CLUMP OF THE BELLADONNA LILY (AMARYLLIS BELLADONNA) IN A JERSEY GARDEN.

this summer, and standards, weeping standards, ramblers and other types are grown in similar proportions. Naturally, some varieties, such as Mme. Abel Chatenay, Caroline Testout, Grüss an Teplitz and Frau Karl Druschki, for which there is always a great demand, are grown more extensively than others, but all old and new varieties find a place in these nurseries. At the time of our visit many of the plants were still carrying superb autumn blooms, some of those on the varieties Hugh Dickson, Frau Karl Druschki and Fisher Holmes being quite up to exhibition standard, notwithstanding the late date. The feature that appeals to one most, however, is the vigorous, healthy growth that has been made during the past summer, growth which augurs well for the crop of blooms next year. Even the maiden or one year old bushes had, in the majority of cases, sent up three or four stout canes, which, owing to the open situation, had become well ripened.

Of the fruit trees a great deal more might be said than we have space for. The splendid natural soil, coupled with intelligent cultivation, have produced young trees and bushes of which any nurseryman might well be proud. Apples, Pears, Plums, Gooseberries, Currants, Raspberries, Blackberries, Loganberries and other kinds of hardy fruits are grown in all the best varieties, trained trees of all sorts, such as fan-shaped, cordons, pyramids, bush and standards,

## SWEET PEA NOTES.

VARIETIES TO GROW NEXT YEAR.—NOTES ON THE NEWER SORTS.

THE improvement which has been made in Sweet Peas during the last two or three years is so remarkable as to be almost without parallel in the history of any other garden flower. For over twenty years the patient labours of Henry Eckford led us slowly and steadily along the road of improvement; but with the advent of Countess Spencer a new energy and vitality seemed to infuse the whole Sweet Pea world. Experimenters sprang up all over the country,

Paradise Ivory is a splendid buff and quite reliable; the same cannot be said of most of the cream Spencers offered this year, a great many of which were neither cream nor Spencer. M. A. Linzee, a beautiful rose shade and of enormous size, is well worth growing. I have omitted Frank Dolby, as it is not a true Spencer and has many faults. I intend to try Zephyr next year in its place. A crimson Spencer is also offered for next year, and it will probably displace King Edward VII.

For those who wish to try something new I suggest Olive Ruffle (terra-cotta) and Nancy Perkins (orange); and, if they are somewhat lacking in fixity, we can overlook the fault in consideration of the great beauty of the blooms

never been able to discover insects near the blooms which are strong enough to force open the keel and come in contact with the stigma. My theory is this: that insects, knowing that they cannot force open the keel to feed on the pollen, have given it up altogether. If Mr. Barwise is such a strong believer in cross-fertilisation, why is it possible (as he wrote in THE GARDEN on August 8) that Mr. Bolton has Countess Spencer always true? I should be inclined to think that possibly an occasional flower would be cross-fertilised.

Students of botanical science do tell us that the bright colours and strong scents in flowers are to attract insects, which in many cases bring about cross-fertilisation, but in Sweet Peas this is not, to my mind, the reason in the present-day flower. If we knew the formation of the original Sweet Pea it might have been the case, but is it not possible during the process of time that the formation of the flower has altered, until now the wings and keel lie closely over the essential organ so as to prevent insects getting to them? During our time considerable alteration in the flower has taken place by the introduction of the waved standard, and who knows before the next decade has passed what is in store for us in the formation of the flower? If the flowers of Tree Ivy are examined about this time it will be found to have hundreds of insects upon it. Is it the sweet scent and bright colour which attracts them? I think not.

P. CLAPHAM.

AN OLD ESPALIER APPLE TREE DECAYED IN THE MAIN STEM.

many with more enthusiasm than judgment, and stocks were sent out so mixed that it was often difficult to know what they were intended to be. A reaction naturally followed, and now a number of reliable strains have emerged from the chaos and should be secured by all who wish to have the best.

First, we notice that the waved varieties have won all along the line; their splendid vitality, vigorous growth, freedom in throwing fours, enormous size, delicate colouring and beautiful shape more than counterbalance their one defect, want of fixity, a defect which is being steadily overcome. First and foremost comes the prototype of the new race, Countess Spencer, which may now be considered practically fixed. This is certainly the best pink variety. John Ingman, a rich carmine, and Helen Lewis, orange pink, are two of the earliest and best of the Spencer sports. Mrs. Hardecastle Sykes, bluish, and Nora Unwin, white, followed, and the year 1908 saw the debut of a number of splendid new varieties. Evelyn Hemus, cream, edged with pink, and Constance Oliver, a cream ground Spencer, are magnificent and quite fixed. Etta Dyke is the most reliable white Spencer and should certainly be grown. Elsie Herbert, resembling Evelyn Hemus, but with white ground, is not well fixed. The same may be said of Prince of Asturias, by far the largest and finest dark variety. The best way to deal with such unfixed strains is to plant them closer and cut out rogues as soon as they bloom,

that come true. Many other new varieties will be offered, but "I only speak of that which I do know." Still, if I might be allowed to prophesy, I would say that the cream ground Spencers of the type of Constance Oliver will be the greatest favourites for next year. A. E. WHITAKER.

Priesthorpe, Farsley, near Leeds.

## CROSS-FERTILISATION OF SWEET PEAS.

IN your issue for October 3, Mr. J. F. Barwise has an extract from "Mendel and His Principles of Heredity," by R. C. Punnett, concerning cross-fertilisation of Sweet Peas. I consider that extract is more evidence in favour of self-fertilisation than anything I could write. If the anthers are sterile, self-fertilisation is impossible, and I am not surprised that very few seeds were formed. But, as Mr. Barwise has said that cross-fertilisation is possible, why did not those plants with barren pollen become cross-fertilised by insects or wind and produce a good crop of seeds, as one would naturally expect? As I wrote in Nos. 1914 and 1919, cross-fertilisation is impossible. I, for one, pooh-pooh the idea of fertilisation by wind, insects or any other agency. Mr. Barwise may quote his authorities for what he writes (and he has a perfect right to do it); and I could do the same if I so wished, but I do not. I have always had a secret attraction for this fertilisation in Sweet Peas, and have studied it from various standpoints.

If cross-fertilisation does take place, what are the insects which bring it about? because I have

ALTHOUGH the fine *Scabiosa caucasica* was introduced as far back as 1803, it seems to have only been within the last thirty years that it became sufficiently well known to become a garden plant for the many. Unfortunately, some do not find it long-lived, while in other places, where it may be sufficiently hardy to stand the winter, it is frequently disfigured by the imperfect form of the flowers, these being never fully provided with the ray segments. Yet the delicate lilac or mauve colouring of the blooms atones for the defect it develops in some gardens, and the several lilac or mauve-coloured varieties, as well as the scarcer white form, are general favourites in the garden, for use as cut flowers, and also for exhibition purposes.

Now a rival has appeared in the shape of *Scabiosa japonica*, which, as the name would suggest, is a native of Japan, and has only become available for our gardens within the last year or two. It is undescribed in the principal gardening works of reference, and is not named in the latest edition of the Kew Hand List; but is mentioned in the great "Index Kewensis" as having been described by Miquel. It is now in bloom in my garden, and, although not quite so fine as *S. caucasica*, it will apparently prove a welcome addition to our hardy flowers of the border.

When at its full stature it is said to be about 2½ feet in height, but my plant, which is a young one from seed, commenced flowering when barely 2 feet high. It is a pretty, branching plant of quite erect habit, having a quantity of pinnatifid foliage, and yielding a number of mauve or rather lavender-blue flowers, about 2 inches across, on longish stems, which stand well above the foliage without the slightest tendency to droop. This is a valuable feature of this Scabious, which will commend it to those who desire cut blooms of this colour and character. I am not certain whether it will bloom earlier or not in subsequent years; but it flowered for the first time with me early in September, and promises to give blossoms until frost sets in.

S. ARNOTT.

## THE FRUIT GARDEN.

### PRUNING FRUIT TREES.

**W**HAT a common thing it is to see fruit trees, especially Apples and Pears, in robust health and making vigorous growth, but quite innocent of fruit! These trees, planted in rich garden soil, are top-pruned year after year, as often as not with the sole object of keeping them within bounds when they have been planted too close together, or because they would otherwise encroach upon ground required for growing vegetables. The result of all this is that in a very few years the balance of power between root and branch is completely upset; the roots have been allowed a free run and have taken the fullest advantage of it, and the tree throws out more and more vigorous young shoots every season in its vain endeavour to restore the balance and keep up with the growth below ground.

Where does one see the fruit on wild trees? Not on those clipped into the form of a hedge, but always on those which are allowed to grow naturally. Surely the lesson to learn from this is to allow trees to grow as naturally as possible, training and pruning them only when necessary to secure an evenly-balanced tree with room for each branch to develop. If the space they are to occupy must be limited, then reduce the roots in order to check top growth; but do not prune the tops for the sole purpose of getting the young growth out of the way.

#### ROOT-PRUNING

is an operation which should be carried out as soon as the leaves have fallen. If the tree is not large, lift it carefully, free the roots from soil, cut off the tap roots (those which grow downwards) and shorten any other long ones with a sharp knife. Preserve carefully the small or fibrous roots and replant in soil which has been trenched some time previously and allowed to settle. When replanting, place a slate in the bottom of the hole, make this firm and cover with 6 inches or so of prepared soil. On this plant the tree, spreading the roots out evenly all round, work more soil among them with the fingers, giving the tree a slight lift occasionally and then pressing it down again to settle the soil and roots together. Cover with more soil and tread firmly, taking care not to injure the roots.

When planted, the roots nearest the surface should be buried about 3 inches or 4 inches; give a mulch of long manure and secure against storms by using, in the case of a standard, three stakes fastened to the stem in a form of a tripod, each driven firmly into the ground, first wrapping some cloth or sacking round the tree to prevent injury to the bark where they are tied to the stem. This is a much better method than using a single stake. To secure a pyramid or bush tree, fasten three wires round the main stem just above a branch to keep them from slipping down, using sacking or cloth to prevent injury to the bark, and strain the wires tight to three stout pegs driven firmly into the ground at a sufficient distance from the tree.

If the soil is very heavy, old mortar rubbish, road scrapings, burnt garden refuse or other suitable material should be added to lighten it before planting; it is not necessary or desirable to use manure unless the soil is very poor or light, and then only that which is well rotted should be used; if there is any old turf or good loam available, use this.

When a tree that needs root-pruning is too large to lift, take a trench out half-way round about 3 feet or more away from the stem, cut off the large roots with a knife or an axe, work underneath, and cut away all roots growing downwards, then fill in again with fresh soil and make all firm, give a top-dressing of long

manure and secure from storms as advised. Root-pruning, if carefully done, will seldom fail to bring a too vigorous-growing tree into bearing, whereas branch-pruning alone will only have the opposite effect. It is often wise to prune only half the roots at a time if the tree is a large one, leaving an interval of two seasons before completing the work, so that the tree may not suffer from too severe a shock.

When a tree has been brought into proper condition, the crops which it will bear will help to check superfluous growth. The object of root-pruning is to encourage the formation of small fibrous roots, and it is especially necessary when the subsoil is composed of clay or other unsuitable substance, in order to prevent the roots striking down into this. If it is impracticable to prune the roots, the tops should not be pruned except to cut out any branches that cross, or to thin some out where they are too crowded. I have seen hard top-pruned trees, which have for many years been unfruitful, bear good crops after having been allowed to grow naturally for two or three seasons without touching the roots.

I think the photographs I send show rather clearly the effect of a check on the roots of an over-luxuriant tree. The first illustration shows the trunk of an espalier Apple which has lost at least two-thirds of its roots through decay in the main stem on the ground level. This tree has made little unnecessary growth since the decay set in, but, on the other hand, has produced heavy crops of Apples with the greatest regularity. The other illustration shows part of the same tree carrying as good a crop of Apples as anyone need wish to see.

W. A. WATTS.

### THE JAPANESE WINEBERRY.

THE illustration on page 534 depicts the Japanese Wineberry growing on a pergola in the gardens at Tynley Hall, Winchfield, Hants. The gardener there, Mr. J. Foster, writes as follows respecting it: "I must first inform you that we have six varieties of the *Rubus* (Bramble). We have *R. laciniatus*, Wilson Junior, Best of All, *R. phoenicolasius* (Japanese Wineberry), Kittating and the Loganberry. I find *R. laciniatus* is the best variety for cropping; Wilson Junior is a very good one, but does not bear so much fruit as the former. The Loganberry always bears well and is much earlier than the other varieties. The Japanese Wineberry has always given a good crop of fruit each year and is very sweet; the other two varieties are not such good

croppers with us. They have been planted four years; before we planted them I had the ground trenched two spits deep and put a good dressing of farmyard manure in the bottom trench. Ours is a heavy clay soil, which they seem to like, as they throw up young growths every year which reach over the pergola, which is 8 feet high. We treat them the same as Raspberries, *i.e.*, after they have done fruiting we cut out the old growths which have borne fruit this year and tie in about three strong young growths from each plant for fruiting next year. They are planted 6 feet apart, which seems a very suitable distance for plants growing on an arch or pergola."

### APPLE PINE GOLDEN PIPPIN.

IN the many notes that have at different times appeared in your paper as to the best dessert Apples, I cannot remember any notice of an Apple that deserves special notice, *viz.*, the Pine Golden Pippin. This is a somewhat small Apple ripening about the end of October, and, in my experience, at its best when eaten fresh from the tree. It was especially recommended to me some years ago by Messrs. Rivers's foreman, and I consider it far away the best early dessert Apple. The tree forms a handsome pyramid and is a good bearer, although I am not quite sure if it bears every year or alternate years. As it is a very heavy cropper, a failure to bear every year may be set down to excessive cropping.

Godmanchester.

G. H.

THE SAME TREE CARRYING A GOOD CROP OF FRUIT.

## TREES AND SHRUBS.

## FLOWERING SHRUBS IN JULY.

(Continued from page 444.)

**P**OTENTILLAS.—These form a very pleasing group of dwarf, free-flowering shrubs, but one seldom sees any other variety grown than *P. fruticosa*. All are worthy of inclusion, as they produce an abundance of flower for three or four months, require but very little attention and their neat appearance fits them well for the edge of the shrubbery. *P. fruticosa* has bright yellow flowers and grows from 3 feet to 4 feet high. It will succeed, as will all the others, in light or heavy soil. *P. Friedrichsenii* is a very pretty bush, quite as tall as the preceding, but with larger foliage and pale yellow

plant, and its silvery green leafage is very distinct. The large, flat heads of flower make it a conspicuous object.

The *Philadelphus* or *Mock Orange* family is admittedly among the most popular of deciduous flowering shrubs, but how often do we see *P. coronarius* the sole representative. Great improvements have been made during recent years, especially by the Continental nurserymen, and, though names are now legion, it is possible to make a selection suitable for the choicest shrubbery. All the stronger-growing sorts are benefited by having the flowering shoots removed as soon as the blooms are over, which enables them to send up robust flowering wood for the next season. These include *grandiflorus*, *Lewisii* and *Gordonianus*. The smaller-growing varieties are very beautiful, and unsurpassed for their delicious scent by any other shrub. Chiefly remarkable in this respect are *microphyllus* and

with blue, are both desirable, and some excellent varieties are: *Ceres*, rose; *George Simon*, rose; *Indigo*, blue; *Albert Pittet*, rosy lilac; and *Gloire de Versailles*. The last-named variety makes a magnificent wall plant, but can also be successfully grown in bush form. Few shrubs make more ornamental specimens than

*Eschulus parviflora* when sufficient space is allowed for its full development, and it is perhaps seen to the best advantage when planted on grass. The soil should be broken up well when planting and made good, so that a free growth results. This Chestnut will then make an immense bush 8 feet to 10 feet high and twice as much through, and during the summer makes a wonderful display with its quantities of racemes, which carry pure white flowers with conspicuous protruding stamens. I must not omit to mention that beautiful Chinese plant

*Clematis orientalis tangutica*, as it is so distinct and attractive with its solitary golden flowers, which are succeeded by a profusion of silky white filaments.

*Elstree.*

A. E. THATCHER.

## CLEMATIS MONTANA RUBENS.

ALTHOUGH normally a May-flowering plant, it is no uncommon thing to find specimens of this useful climber with a fair sprinkling of flowers during early autumn, and, as a rule, the blooms borne at this late period are richer in colour than those which are produced at the normal time. *C. montana rubens* is a Veitchian introduction, seeds having been sent to Messrs. Veitch by their collector, Mr. E. H. Wilson, when in China.

Although it has only been in general cultivation for a few years, it has already attained a fair amount of popularity. The rapid way in which it has crept into public favour is doubtless due to the ornamental character and good constitution of *C. montana*, for this is one of the most popular climbers we possess.

The variety grows quite as freely as the type, and, so far, flowers quite as well, while it thrives under similar conditions. It may be readily distinguished from the older plant by the red colour of the branches, leaf-stalks and flowers, this reddish hue also being discernible in the foliage. Cuttings root easily during summer, and the plant is suitable for placing against houses, arbours, pergolas or groups of rough Oak branches in the open ground. Good loamy soil suits it, while it also thrives in moderately rich but light ground. W. D.

## THE TUPELO TREE.

So rare a tree is this in Britain that it is not even listed by so eminent a firm as Messrs. Veitch and Sons, yet at Strathfieldsaye it is a very striking and beautiful deciduous tree, and is so rare, as well as handsome, that no less an authority than Mr. H. J. Elwes is reported to have said it was worth going 100 miles to see. The botanical name of the species in question is *Nyssa biflora*. It is a native of the Central States of North America, hence is quite hardy here. While this fine tree is tall, probably some 60 feet in height, yet its semi-drooping habit of growth keeps the branches from spreading widely. The foliage is moderately long and lanceolate, in colour a glossy pale green, in the autumn dying off to a deep rich hue. A. D.

THE JAPANESE WINEBERRY CLOTHING A PERGOLA IN THE GARDENS AT TYLNEY HALL, WINCHESTER.

(See page 533.)

flowers. *P. Salessowii* has white flowers and very distinct foliage, which is quite silvery underneath. Another white-flowered variety is *P. davurica*, which makes a neat and pretty bush. *P. micrandra* and *P. fruticosa humilis* are both of dwarf habit, with large bright yellow blooms, and are effective on the edge of the shrubbery or in the rockery. It is to be regretted that the

*Olearias* are not hardy enough for general planting, because they contribute some of the most beautiful evergreen shrubs. In warm and sheltered districts several may be planted, and *Olearia Haastii*, which makes a round bush 4 feet high and is clothed with white flowers, is the hardiest of all. *O. stellulata* is a very beautiful evergreen, with a mass of starry white flowers, and is deserving of every endeavour to preserve it through a sharp winter. It is easily propagated by cuttings. *O. macrodonta* succeeds with us in a warm corner and as a wall

purpureo-maculatus, a hybrid having a purple blotch at the base of each petal. This latter variety is quite hardy and extremely beautiful.

*Choisya ternata* is one of the most beautiful of evergreens and much hardier than many suppose. On a cold clay soil here in an exposed position it has never been harmed and always flowers very freely. As a wall plant the Mexican Orange is a great success.

The *Tamarisks* contribute to the shrubbery a pleasing variety, and their fine, graceful growths always associate well with stiffer surroundings. The most beautiful is *T. Pallasii rosea*, which produces large racemes of bright pink flowers in profusion. This is a somewhat new shrub of great merit.

*Ceanothuses*.—Although these are generally looked upon as wall shrubs, there are many which can be relied upon in the open, and few shrubs give a greater profusion of bloom. *C. americanus*, with white flowers, and *C. azureus*,

## THE ROSE GARDEN.

## THE NEWER ROSES

(Continued from page 511.)

**K**ONIGIN CAROLA (Turke, 1904).—Undoubtedly a seedling from Caroline Testout—satiny rose in colour, with silvery flesh on reverse of petal—all the characteristics of its parent, but coming rather more pointed, especially in the younger stages. I have had some quite good exhibition flowers this year. The plant is vigorous and very free-flowering.

*Lady Helen Vincent* (Messrs. Alexander Dickson and Sons, Limited, 1907).—This has been excellent on maidens, and I have seen many fine flowers, especially good under glass, of exquisite shape. The colour is a pale flesh pink with a deeper base. The Rose is very fragrant, and I think can be relied on. It is too early to speak definitely of its behaviour as a cut-back, but I must admit that the flowers from the laterals have been small and, therefore, disappointing. Very highly thought of by some of our leading exhibitors; undoubtedly worth trying.

*La Detroit* (Hoff, 1904).—A fine vigorous plant, the flower and habit showing the Testout strain; as growing with me hardly up to exhibition form; nice bright shade of pink.

*Laurent Carle* (Pernet-Ducher, 1907).—This Rose has hardly come up to expectations; it was supposed to be the best of this raiser's 1907 set. The colour is very fine, especially in the early summer, but it is hardly full enough. It should, however, be very useful in a cool season. Some fine flowers have been exhibited by the trade cut from maidens. Growth good, colour bright velvety carmine, not unlike a bright Marquis Lita.

*Lohengrin* (Schmidt, 1903).—If the colour would only stand, this would be a grand exhibition flower, as it has shape, form and size, but it loses colour very quickly when cut; perhaps in a cooler season it may last better. A fine pointed Rose, generally pale silvery pink that fades to a magenta tint, which is not pleasing; it comes much deeper in the autumn.

*Lyon Rose* (Pernet-Ducher, 1907).—This is undoubtedly a very valuable addition; its colour stands out as something distinct; reputed to be a seedling of Mme. Melanie Soupert. It has been frequently well exhibited, but I could not get enough petals into my flowers; at present, no doubt, suffering from over-propagation. Its colour will make it popular. Fragrant and a good grower, and a Rose that everyone who sees will want to grow; very good under glass. I

believe the other parent was a seedling of Soleil d'Or, so that we have not had to wait very long for something good out of *Rosa lutea*. A bloom of this Rose secured the silver medal at the National Rose Society's provincial show at Manchester this year for the best Hybrid Tea in Messrs. Hugh Dickson's box of twelve new Roses.

*Mme. Charles de Luze* (Pernet-Ducher, 1904).—This is a fine Rose, but I question if it is distinct

stage. A fine pointed Rose, very free-flowering and an excellent grower. I have not tried it on a standard, as all my plants are dwarf, but I am told it has come very fine this way. All these yellow-tinted Roses seem to be much finer in colour in the autumn, especially after rain.

*Mme. J. W. Budde* (Soupert et Notting, 1907). This just lacks size, otherwise a fine Rose; excellent shape, distinct carmine colour, free-flowering and a fair grower; what exhibitors call a front-row flower; will possibly improve with age.

*Mme. Maurice de Luze* (Pernet-Ducher, 1907).—A distinct Rose of a shape that is called cupped. It would be a pity if the pointed shape was to eliminate entirely all the others, as they have a distinct beauty of their own. The colour is deep pink, shaded carmine; a good broad petal. Good erect habit.

*Mme. Melanie Soupert* (Pernet-Ducher, 1906).—This Rose stands out by reason of its beautiful colour, and will become very popular. It has been frequently exhibited throughout the entire season, and is undoubtedly one of the best of the recently-introduced Roses. Like the majority, however, it is thinnish with regard to the number of its petals, but they are large and of good shape. Very fine under glass, and at its best in a cool season. Colour not easy to describe, as it is very variable—pale salmon yellow, suffused more or less carmine pink. An excellent garden Rose, as well as good for exhibition. Good erect habit and free-flowering; should be in every garden and will be much enquired after this season unless I am much mistaken.

*Mme. Philippe Rivoire* (Pernet-Ducher, 1906).—Another Rose sent out at the same time as Mme. Melanie Soupert that has been occasionally exhibited. I have only one plant, so can do little more than mention it. The colour is fine—apricot yellow with a lighter centre of nankeen; good bronze foliage. Very free with me, and, I think, worth trying.

*Purley.* H. E. MOLYNEUX.

NEW HYBRID TEA ROSE MRS. EDWARD J. HOLLAND. (Natural size.)

#### NEW HYBRID TEA ROSE MRS. EDWARD J. HOLLAND.

As will be seen in the accompanying illustration, this Rose possesses exquisite conical form with rather narrow, somewhat reflexed petals. The foliage is dark glossy green, which contrasts well with the deep salmon rose colour of the flowers. When exhibited, the flowers did not possess much fragrance, but possibly this may not be characteristic of the variety. It was shown before the floral committee of the Royal Horticultural Society by Messrs. S. McGredy and Son, Portadown, Ireland, on the 13th inst., when it received an award of merit.

enough to remain permanently with us. It is at its best in the autumn, when the colour at the base of the petals deepens into a good yellow. Not very full; colour, flesh white, deepening to nearly fawn.

*Mme. Jenny Gillemot* (Pernet-Ducher, 1905).—To my mind a better Rose than the last-named, but requires shading, as the colour bleaches very quickly in the sun; outside petals always go white with any age; saffron yellow in the bud

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE VEGETABLE GARDEN.**—No time should be lost in gathering ripe seed-pods of the Runner Beans. Spread out the pods under glass, if possible, for ripening off, so that the seeds may ultimately be removed in good condition. Seakale required for forcing should be taken up as soon as the leaves are ripe; to complete the ripening, it is a good plan to lay them in under a north wall or any cool border. After a period of resting in cool surroundings they will force more readily. Parsnips should be lifted as required, and not taken up and stored as is the invariable practice with Beet and Carrots. Well trench vacant ground as opportunity offers.

**The Hardy Flower Garden.**—Anticipating a bright display in the spring, I am planting well-known, popular hardy flowers. In this connexion may be mentioned Daisies, Forget-me-nots, Primroses, Polyanthus, Wallflowers and the pretty little *Silene compacta*. Groups here and there in the hardy border will make these quarters attractive, while in small beds by themselves, or as edgings to larger beds, some of the dwarfier subjects are charming. The present is an ideal period for planting Roses. If the order for new Roses has not yet been sent, there should be no further delay, as it is well to have the bushes. I prefer to have the Rose quarters prepared some time previous to the planting, as this allows the ground to settle down beforehand.

**The Cold Frame.**—Advantage should be taken of every fine day to give abundant ventilation to the plants in the cold frame. Plants in bad health should be lifted and healthy specimens planted in their stead. Decaying and dead foliage should also be removed and the surface soil between the plants occasionally stirred to aerate the same and to promote healthy root action. I am busy putting in another batch of shrubby *Calceolaria* cuttings, as there is always

a demand for these plants in the early summer. Many plants of the earliest batches of bulbs for forcing are growing apace, and for this reason I am removing the more forward specimens to the cool greenhouse.

**Trees and Shrubs.**—I am busy planting several of the better deciduous trees and shrubs at the present time, among which may be mentioned the deciduous *Berberis Thunbergii* and *B. vulgaris*; also the double and single Scarlet Thorns (*Crataegus*), Brooms (*Cytisus*), *Daphne Mezereum*, *Dentzia*, *Forsythia* (Golden Bell), *Genista* (Rock Broom), *Hibiscus*, *Hydrangea*, *Hypericum* (St. John's Wort), *Laburnum*, *Philadelphus* (Mock Orange), *Prunus* and *Pyrus* in variety, the Flowering Currant (*Ribes*), the shrubby Meadow-sweet (*Spiraea*), the Lilacs (*Syringa*) and the beautiful Snowball Tree (*Viburnum*). The foregoing and others may be planted with success during the present period. Do not attempt to prune evergreen trees and shrubs at this time; they are better when pruned in the spring.

**The Hardy Fruit Garden.**—The propagation of Gooseberries and Currants may be done at this season. Old trees provide an abundant supply of shoots from which to make cuttings, and these can be inserted in sandy soil outdoors, where the cuttings will root readily enough when the weather is fine and the garden soil workable. The prospects of stone fruits, such as Plums and Cherries, are improved when old mortar rubbish is forked in round about these trees at this period. Some growers use slaked lime when old mortar rubbish is not procurable.

**The Greenhouse and Conservatory.**—Cleanliness in the glass structures at this period is of the utmost importance if the plants are to be maintained in good health and the prospects of winter-flowering subjects made bright. See that the pots are made clean and the slimy surface soil in some pots scraped clean also. Give fire-heat to *Chrysanthemums* to assist the large blooms to open, and ventilate freely to carry off superfluous moisture. Water the plants in the morning. D. B. C.

### THINNING AND PLANTING RASPBERRIES.

If the thinning of Raspberry canes has not been done already, this work should receive immediate attention. It is a mistake to leave this work until later, although many growers wait until the early spring before taking it in hand. For the guidance of the inexperienced we have given in Fig. 1 an illustration of a Raspberry plant that has borne fruit during the past season. Here, it will be observed, there are quite a large number of stems, representing both new and old canes. As a matter of fact, owing to the want of a proper thinning of the canes last year, rather more stems than is good for the plant have been allowed to grow, in consequence of which the canes are somewhat weakly and unsatisfactory. All the canes that have borne fruit during the past season should first be dealt with. After cutting back each of these to within 2 inches or 3 inches of the ground, the growths of the present year must be taken in hand. The weaklings should be cut right out and only the strongest retained. Fig. 2 illustrates how this thinning should be carried out. It will be observed how drastic has been the cutting away of both old and worthless canes as well as those of a weaker kind. In this way we have been enabled to retain two of the best canes, and with

2.—THE SAME PLANT WITH THE OLD AND ALSO THE WEAK CANES REMOVED.

these we are more likely to do well than would be the case were a larger number retained. If the Raspberries are planted in rows, the canes must be thinned out to anything between 9 inches and 1 foot apart. These should be secured with twine to strained galvanised wires running the whole length of the rows. Where the Raspberries are growing in clumps, it is well to allow five to seven of the strongest canes that are near to the centre to remain, all others being cut out. Insert stout stakes for their support, securing the canes to the stakes at the time the pruning is done.

**Planting.**—Raspberries may be planted at any time during the autumn and winter, but the best times for making new beds undoubtedly are the months of October or November. Planting done at this period enables the plants to establish themselves more readily than they do later in the year.

**Soil.**—Although this subject will thrive in most soils, yet special measures should be adopted in the preparation of the quarters for their reception. Ground that is trenched or bastard trenched causes the plants to yield better than when less pains are taken in the preparation of the soil. Poor soil may be made fertile by the free incorporation of some good lasting manure at the time the quarters are trenched or dug over. A fairly moist condition of the soil appears to suit Raspberries, and a partially shaded position invariably causes the plants to develop berries of good quality and large size.

**Propagation.**—Raspberries are usually increased by suckers, an old bed producing an immense number when the plants are doing well. The greatest care, however, needs to be exercised in removing the suckers from the old plants. The illustration Fig. 3 is a fair representation of one of a large number of young canes that have been acquired from these sucker-like growths.

1.—A RASPBERRY PLANT NOT THINNED OUT. NOTE BOTH OLD AND NEW CANES.

Readers will note the vigorous character of the roots. Beginners may readily acquire such plants from their own old Raspberry beds, but, failing in this, any reputable fruit specialist will supply them. The more popular method is to plant in specially prepared beds in rows. The rows are usually about 5 feet apart. The canes should be planted about 2 feet apart in the rows and ultimately secured to stout wire as described above. The first row of wire should be about 18 inches above the ground, and the second row about 2 feet higher. There may be readers who prefer to plant their Raspberries individually or in groups of four, securing the canes in each instance to stakes. Insert the stakes, of which there should be three to each plant, in triangular fashion, observing a distance between each one of about 1 foot.

*Pruning.*—Fig. 4 shows the method of planting and how the pruning of these newly-planted canes should be done. As soon after planting as convenient we make a rule of cutting back the canes to within about 1 foot of the ground. Some growers prefer to cut back the canes more severely, but in practice we have found the above rule to answer very well. The reason for cutting back recently-planted canes is to induce the plants to break away strongly from the base in the succeeding spring or early summer, and this they invariably do when treated as we have described above.

*Subsequent Treatment.*—Before the hot weather of the succeeding summer is experienced, the quarters should receive a heavy mulching of good manure, and in periods of drought or very warm weather copious applications of water and liquid manure will be highly beneficial. Sucker-like growths should be removed during the first year, and weeds should be kept under from the beginning.

*Varieties.*—The following are good and reliable sorts: Superlative, Baumforth's Seedling, Carter's Prolific and Norwich Wonder. For dessert the White or Yellow Antwerp deserve a place in every garden.

### LIFTING CHRYSANTHEMUMS.

With the advent of frosty nights, the flowers of Chrysanthemums growing in the open garden will be considerably damaged unless some means are taken to protect them from the cold weather. Among the late-flowering varieties of the early Japanese decorative section will be found many beautiful sorts, capable of giving a display of flowers well into December providing the plants are given proper treatment. If a slightly warmed or even a cold greenhouse is available, matters will be much simplified; but, failing this, recourse can be had to the shelter provided by a spare room or even an outhouse.

I make it an annual practice at this season to lift the best of the plants which have buds showing colour and transfer them to large pots, small tubs, boxes and even old zinc pails with holes in their bottoms, and in this way secure an abundance of excellent flowers long after those left outside have been destroyed. The operation is really a very simple one. A few days before the plants are to be lifted the soil is firmly trodden round each; then a good watering is given and a spade thrust well in all round and about 6 inches away from the stem, thus cutting off any roots which may be outside the square or circle of roots and soil made. By doing this the check that must inevitably occur by the mutilation of the roots and lifting is spread over a period, and, consequently, is not so injurious to the plant. The pots, tubs, boxes or other receptacles used must

3.—A VIGOROUS SUCKER-LIKE GROWTH  
SUITABLE FOR REPLANTING.

have sufficient holes in their bottoms to allow water a free outlet, each hole being covered with a fairly large piece of broken pot. Over this is placed a thin layer of soil, and the plant is then lifted with a good ball of soil and roots and placed in the pot or tub, working the soil well down into all cavities and making the whole moderately firm. Providing the natural soil is of a comparatively open character, this will answer very well for the purpose; but if it is at all sticky it must be rendered more open and friable by the addition of sand, road sweepings or even Coconut fibre refuse or old mortar.

After the plant is properly transferred to its new position, the soil and roots must be saturated with water, but subsequent watering will only be needed at long intervals. All growths must be securely tied to stakes firmly inserted in the soil. H.

4.—THE METHOD OF PLANTING A NEW BED. NOTE THE CANES  
CUT BACK TO WITHIN A FOOT OF THE SOIL.

## THE TOWN GARDEN.

*STORING DAHLIAS.*—Many of these indispensable town garden plants will have been lifted before these notes appear in print; but, as a matter of fact, nothing is gained by hurrying the process along before the tops of the growths have been well blackened by frosts. However, my point at this moment is to allude to the storage of the stools after lifting. It is extremely common for amateurs to complain of serious losses during the winter months through the tubers rotting away. In those instances where the place of storage is itself damp, there is no trouble in finding the cause, and the remedy is equally obvious. But when the place is satisfactory we have to seek in other directions for the reason of the losses. I am of the opinion that the most frequent cause of failure is putting the stools away before they have been properly prepared. When the plants are cut down to within a foot or so of the surface prior to lifting, the basal parts of the stems contain a considerable quantity of moisture, and unless this is allowed to drain away, it is a prolific source of decay in the tubers beneath. The best course to pursue is to turn the clumps upside down on to the stumps of the shoots and allow them to remain in this position for a few days, when all the moisture will pass out of them, and storage is far more likely to be successfully accomplished. Any dark cellar or similar place that is free from drip will answer the purpose of a store, and if the time can be spared for an occasional examination of the stock, there will be few, if any, losses; in the event of one being found going wrong upon these inspections, it should be taken out and either destroyed at once, or have the bad portion cut clean away and the wound dressed with lime. It is not, of course, worth the trouble to store inferior varieties.

*CARNATIONS IN THE GARDEN.*—In those gardens where sparrows show a marked partiality for the growths of Carnations, it is an excellent practice to net them thoroughly with stout black thread, for the feathered visitors do not take at all kindly to plants that have been thus treated. The surface soil immediately round the plants should be carefully loosened, but the utmost care must be taken that the roots are not disturbed; after frosts, if it is found that the soil has cracked away from the collar, it must be firmly pressed down into position again, or the losses during the winter will be numerous. If a little short, sweet manure can be spared for mulching, it will do a substantial amount of good; but fresh stuff that will settle down into a close, impenetrable mass should be avoided as a plague.

*WINDOW-BOXES.*—If these have not been filled with bulbs for next season's display, there should not be any further delay. If two sets of boxes are at command the spare one ought now to be filled with the small shrubs kept especially for the purpose, and after the removal of the summer boxes the fresh ones should be put into their places. This done, the summer boxes can be immediately emptied and preparations made for stocking with bulbs. If the soil were new for the summer occupants, it will answer admirably for the bulbs with the addition of a little loam mixed into the top 4 inches or 5 inches, but if the soil has already produced two crops, it is desirable that it shall be displaced. A mixture of three parts of sound loam and one part each of sweet leaf-mould and thoroughly decayed manure, with sufficient sharp sand to keep it quite open, will fulfil all the demands made upon it by the Hyacinths, Tulips, Daffodils or whatever may be used.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### HARDY FRUIT GARDEN.

**C**ONTINUE the planting and renovation of fruit trees, such as Apples, Pears, Gooseberries, Cherries and Currants. Gooseberries and Currants look exceedingly well and do well as trained cordons, which may be either double, triple, or even hexagon shaped. When these styles are chosen young Larch saplings of about 8 feet in length should be used. The same style of tree may also be put on wire strained to iron uprights; about four strands would be sufficient. Grown thus the trees or bushes can be attended to very much better, and also the fruit is more easily gathered, kept clean and netted. A list of good varieties of Gooseberries has been given quite recently on another page. Good varieties of Currants are: Black.—Black Naples, a fine cropper and large fruit, and Carter's Champion, a very fine variety. Red.—Red Dutch, Raby Castle, a very fine and late variety; and La Versailles, a heavy cropper. White.—White Dutch and White Versailles.

*Raspberries.*—Hornet, Norwich Wonder, Superlative and Baumforth's Seedling are all most excellent croppers, and if I were asked to name one only I should mention Norwich Wonder. The best autumn variety is, undoubtedly, Belle de Fontenay, from which we have been picking rare baskets of most delicious fruits. To grow Raspberries well they should have as little disturbance of the roots as possible and be heavily mulched with manure every season, and the stools renewed about every five years, though when the plants are well cultivated they will last quite double that time and bear profusely.

#### PLANTS UNDER GLASS.

*Carnations.*—Keep these tied as the growths demand it; the first batch should now be giving nice flowers. The blooms must be cut as soon as they are ready, in order that no undue strain is made upon the plants. Enchantress and Mrs. Burnett seem great favourites. Cuttings taken from old plants should be kept on shelves near the glass. These make much more robust plants than those taken in spring. Malmaisons must be kept on the dry side; more plants are lost from damp than from frost. Old plants flowering must have sufficient heat to keep them on the move, or the blooms will not develop.

*Roman Hyacinths* may be brought along in a little heat now, if they are required. The sweet scent of these and Lilies of the Valley are always appreciated.

*Laroe-flowered Chrysanthemums* will need air and fire-heat, or the flowers will soon damp. Late bush and single varieties should be kept as cool and dry as possible, taking care that the plants receive a thorough soaking when they require it.

#### KITCHEN GARDEN.

*Hot-beds.*—Prepare these for forcing Asparagus. Collect leaves (tree) and make the beds up with half long stable manure and half leaves, shaking it well up and thoroughly mixing it. If very dry add plenty of water to make it heat. When found to be at the right temperature, mark out the spot for the bed and make the foundation 2 feet wider than the frame, so that there is room to walk around and attend to the frames. For forcing, three year old crowns or stools at least should be used; but four year old plants are the most remunerative and produce stronger growths.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*Pot Roses.*—It seems a pity to lose any of the numerous buds showing on the latest batch of pot Roses, more especially as we are getting so short of these and other flowers. Even if we were to allow these plants to remain out in the open, with the object of ripening them more thoroughly, I do not think this would be accomplished in a more satisfactory manner than by giving slight protection during the roughest weather. I find it a good plan to have the plants placed in a deep pit, and from these I can invariably find some clean and very acceptable blooms during rough weather. The lights are only put over them on clear nights when frost threatens and during heavy wind or rain.

#### FLOWER GARDEN.

*Herbaceous Borders.*—The arrival of frost and the necessity for making a clean sweep of all dead and decaying flowers will enable the planter to get to work on herbaceous borders as soon as possible, with a view to getting most of the work finished before severe frosts prevail. All things that do better for annual lifting and replanting should receive attention, and all stragglers be taken away. Borders of this kind should be planted as naturally as possible, but, at the same time, one does not want absurd mixtures, and to allow one species to encroach unduly on another will be greatly detrimental to the weaker plants. When replanting the front of a border, for instance, with such things as Hepaticas, Heucheras or the stay-at-home Campanulas, a wide berth must be given to the straggling Violet or the trailing Bellflower.

#### HARDY FRUITS.

*The Planting Season.*—It is a decided gain to get young trees properly planted before the winter fairly sets in. Before the late heavy rains, the ground, both in the open and particularly against walls, was much too dry for transplanting operations to be carried out without risk of failure; and I very much doubt if the borders sheltered by walls are yet well moistened. Before, therefore, trees are moved the borders should be examined and water given freely. If the soil is found to be at all dry or the soil that surrounds the roots after planting is done is also dry, or even on the dry side, a good soaking ought to be given before the surface is levelled over and mulched with strawy litter.

*Gathering Apples.*—The work of gathering the latest varieties of Apples and Pears should now be completed. It has been good for the fruit to leave some late varieties until now on the trees, but after the end of this month the weather cannot be relied upon to assist them.

#### KITCHEN GARDEN.

*Tomatoes.*—These have been good and plentiful this season; but the glut will now be over, and the cultivator who can keep the late-sown plants healthy as long as possible will have good fruits well into December, or even longer, if late setting was encouraged. Keep the foliage rather thin, and remove all fruits as they show colour to a dry, warm house and place them on shelves.

*Window Gardening.*—Where boxss are used, no time should be lost in getting any bulbs intended for spring display planted. Use good, fresh, loamy soil, and plant such things as Hyacinths and the finer Narcissi at the back, and Snowdrops, Crocuses, Scillas and the pretty Chionodoxas in front. When filled, place the boxes in some sheltered spot and cover them with about 6 inches of fresh coal ashes or Cocoonut fibre. Here the bulbs will form roots freely, and in the course of a few weeks will commence to start into growth, when the boxes may be taken out and placed in their proper positions.

T. B. FIELD.

(Gardener to Baroness Berners.)  
Ashwellthorpe, Norwich

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### AN INTERESTING FLORAL CONTRIBUTION FROM MOBBERLEY.

Miss W. Lloyd, Mobberley Hall, Mobberley, near Knutsford, sends a most interesting and attractive collection of flowers with the following note: "I am sending a box of flowers, chiefly off my small rock garden, which has not been made very long. With this spell of warm weather everything seems to be blooming freely again; in fact, most of the things I send have been flowering since the early summer, especially *Scabiosa caucasica* and *Gypsophila repens monstrosa*, which, I think, is the best of the *Gypsophilas*. The *Dianthus* is *Atkinsonii*, a beautiful colour. Of course, the *Cyclamen neapolitanum* has just started blooming. My Sweet Peas are very beautiful, and Countess Spencer is still giving four blooms on a stem. This weather is highly beneficial for the Roses, which will have their wood so well ripened for next year. The blue of the *Plumbago Larpentæ* shows up quite a long way off with its attractive red foliage."

#### ANOTHER CONTRIBUTION FROM SCOTLAND.

Dr. McVatt of Morelands, Duns, N.B., sends another interesting collection of hardy flowers, among which we notice several varieties of *Calluna vulgaris*, fine forms of *Gypsophila*, *Sedum Telephium*, *Michaelmas Daisies*, *Pyrethrums*, *Roses*, *Tritomas*, seedling *Delphiniums*, *Geums* and *Malvas*, all making a bright display in the autumn.

#### RASPBERRIES FROM NORTH FINCHLEY.

A correspondent signing himself "S. C. M." sends us good fruits of the Raspberry with the following note: "Enclosed are some Raspberries I picked at North Finchley on the 19th inst. Are they not very late, with exceptionally fine berries? Several more canes are promising for a still later crop should the weather remain mild."

#### PENTSTEMONS FROM SCOTLAND.

We have received from Mr. John Forbes of Hawick, Scotland, a most delightful box of Pentstemons, which are one of the chief autumn flowers in Scotland. Among the most noteworthy are John Deacon, which is a crimson shade; John Jennings, mauve-purple; Professor Pozzi, crimson; Sandringham, a very beautiful flower indeed, of a pretty self scarlet, one of the finest Pentstemons we have seen of recent years; Pink Beauty, self pink; Sir Dighton Probyn, deep crimson, with remarkably large flowers; Mrs. Callender, rich pink; Peach, white, just touched with pink; Mrs. Michie, bright crimson, with white throat; and Miss Stewart Peter, deep intense purple. All the varieties are distinguished by their remarkable strength of stem.

#### GUERNSEY LILIES FROM THE OPEN.

I am sending two spikes of Guernsey Lilies from the open ground. The scarlet one is *Nerine Fothergilli* major and the pink one is

new *N. Bowdenii*. In the majority of cases Guernsey Lilies are grown under glass, but in Devon and Cornwall they succeed admirably out of doors. With me they are growing in a narrow, raised border in front of a south wall and flower well every year. I have two patches of *Nerine Fothergilli* major, each with about a dozen bulbs. One colony flowers about a month earlier than the other, and the early one was a glorious sight in September, having twelve flower-heads with very fine trusses about 8 inches across, much larger than the one sent to-day. The individual flowers were about 2 inches across. When the flower-spikes are thrown up the plants have been leafless for about a month. Curiously enough, this is not the case with *Nerine Bowdenii*, whose leaves remained green right through September. Seeing this, I concluded that no flowers would be borne this year, as I felt certain that by the time the leaves had faded it would be too late for the spikes to be thrown up. I was extremely surprised to find, one day, two strong flower-spikes pushing up among the green leaves. The foliage is only now fading when the blossoms have reached perfection. *Nerine Bowdenii* is, as you will see, a very fine species, especially remarkable for the size of the flowers, which are rather over 4 inches across. The colour is also very pleasing, being a delicate rose-pink. It is a decided acquisition and evidently does as well in the open as *N. Fothergilli* major. This is a delightful thing, and a dozen great, fully-expanded flower-trusses, such as were to be seen here a month ago, are an extremely brilliant sight. The colour is the most intense and glowing scarlet, and when the sun is shining on the flowers the petals appear as if sprinkled with gold dust. Other plants in the border are *Cypella Herbertii*, which blooms through the whole summer and autumn, three species of *Zephyranthes*, the white, sweet-scented *Cyrtanthus McKenii* and the orange *C. Flambeau*, both of which flower well, the blue Chilean *Crocus*, *Tecophilea cyanocrocus*, the *Jacoea Lily*, *Sprekelia* or *Amaryllis formosissima*, *Ismene calathina* and *Pancratium illyricum*.—S. W. FITZHERBERT, *South Devon*.

[A delightful contribution to our table.]

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Information about Phloxes** (*H. Tyler*).—The following are among the best of the herbaceous Phloxes now in commerce: *Adonis*, salmon pink; *Aureo*, orange scarlet; *Coquelicot*, vermilion-scarlet; *Flambeau*, quite near the last, with crimson eye; *Etna*, bright scarlet; *Sylphide*, Mrs. E. H. Jenkins and *Mathilde Seroa*, all grand whites; *Iris*, violet blue; *Le Mahdi*, metallic violet; *La Siècle*, rose pink; *Sesostris*, purple; *Eugène Danzavilliers*, soft lilac, white centre; *Le Vengeur*, carmine, scarlet eye; and *Leonardo da Vinci*, white, maroon centre. "The English Flower Garden" should prove of much value to you, if not too expensive.

It may be had of any bookseller, or direct from John Murray, Albemarle Street, London. The price is 15s.

**Violet plants gone wrong** (*H. P. B.*).—At this time of the year Violets are very subject to attacks of fungoid diseases and red spider, which often cripple and weaken them beyond recovery, but we cannot find traces of either on the leaves sent by you. The leaves are very attenuated and without vigour or body in them, giving one the impression that they are growing in rather a too shady position and in poor soil, and probably suffering from want of water during the recent hot period. Clear away all the runners that may surround the plants on the ground, and give a mulching of rotten manure on the surface over the roots.

**Garden border and soil** (*Hopeful*).—You have, unfortunately, to contend against a very heavy and uncoagulated clay soil, which will require a very considerable amount of working before it can be made to grow many things. Were we in your position we should take up the whole of the plots, heel them in for the winter and then set about improving the soil. By deep trenching, the addition of light stable manure, grit, sand or the ashes from garden rubbish fires, much might be done. First trench the border deep and throw up the soil as roughly as possible for the frost to act upon it during winter; then get all the burnt ash possible to add to the surface. If you could collect rubbish and burn it and add the ashes to the border, you would be doing much to render it open and workable. In the spring add all the sand you can obtain and work it into the top soil. Avoid treading on it when wet. You need have no fear about the plants if you can, by the above means, render the soil more generally porous. If you could lightly burn half of it and mix the whole together, you would probably get soil of an ideal character.

### TREES AND SHRUBS.

**Maidenhair Tree in a bad state** (*Moor Hen*).—Your *Salisburia* or *Ginkgo* is evidently in a very bad state of health, which is probably due to bad planting. It is quite likely that it has been planted too deep. You had better take it up carefully at once, taking care to cause as little root injury as possible, and plant it in some good, well-worked ground, such as a kitchen garden, and nurse it up for a year or two before replacing it in a permanent position. When placed out again, prepare a hole 8 feet in diameter and 2 feet deep, so as to thoroughly work the ground; then fill it up to within 9 inches of the top and ram it well, mixing sand with the soil if the latter is heavy. Plant the tree so as cover the top roots with about half an inch of soil; then over the surface place a mulch of decayed leaves.

**Climber for north wall** (*W. H. T.*).—You cannot do better than plant *Ampelopsis Veitchii* against your wall. It is more likely to succeed in the position you describe than any other plant.

**Grafting Rose Acacia** (*John G. Kirsten*).—The Rose Acacia is frequently propagated by root-cuttings, but is sometimes grafted on stocks of the common *Robinia*. Dormant wood is used in spring, and the work is done indoors in a warm house. It is a rather difficult subject to graft, and, unless you have special facilities for grafting, it is doubtful whether you will be successful. You can, however, obtain plants at fairly cheap rates. If your plant is on its own roots, you can try root-cuttings in spring.

### ROSE GARDEN.

**Marechal Niel in cold greenhouse** (*P. F. P.*).—You should have retained the growths almost intact, but as you have pruned the plant you can only await its development. Do not attempt to force it into new growth, but allow it to come on quite naturally by giving air night and day for a time. When the new shoots are 2 inches or 3 inches long you can take off the side air, but still afford air from the roof during the day. By bringing up the plant in this hardy condition it will be able to stand any severe weather we may have during winter. It is always best to avoid exciting such Roses as this before Christmas, and it would have been better, seeing that your house is unheated, if you had not planted it until that time.

**Basic slag as an autumn dressing for Roses** (*Mrs. M. C.*).—Yes, you could not do better than give your Rose beds and perennial borders a dressing of this valuable phosphatic manure. It is best applied now and during the next few weeks. A good application would be about 4oz. to the square yard of surface. The usual dressing of farmyard manure could follow later in

November. It would be advisable to dig or hoe the basic slag into the ground as soon as applied.

**Roses distinct** (*R. R. R.*).—The varieties you name are absolutely distinct, and if you correctly named them the judges acted wrongly in marking your exhibit "not distinct," unless any specified group were named. Usually the schedule is worded, "Hybrid Perpetual and Hybrid Teas, distinct," or "Tea-scented Roses, distinct"; but if this were not done then your exhibit complied with the schedule.

**Roses for new bed** (*W. J. R.*).—The following selection would give you a splendid assortment. For the six standards, plant as follows: *Fran Karl Druschki*, *Hugh Dickson*, *Mme. Abel Chatenay*, *Griess an Teplitz*, *Phariseer* and *Mme. Ravary*; for the five half standards, *Caroline Testout*, *Lady Roberts*, *Commandant Felix Faure*, *Earl of Warwick* and *Antoine Rivoire*; for the two bushes, *Prince de Bulgarie*, *Mme. Leon Pain*, *Florence Pemberton*, *Liberty*, *Mme. Hoste*, *Vicomtesse Folkestone*, *Gustave Grunerwald*, *Paul Ledé*, *Victor Hugo* and *Mme. Antoinette Mari*. Plant in the order as named.

**Mildew on wall Roses** (*M. A. R. C.*).—The hot position which a nearly south wall involves is very trying for Roses if they do not possess a good deep root run, and there are few varieties that would not become mildewed when the weather changes so drastically as it has done this year. We do not think there will be any need to artificially drain the border, but advise you to have the ground treed to a depth of 2½ feet to 3 feet. This depth is much better than a wide border where the depth is not so great, as the roots can strike downwards and thus be away from the parching effect of bright sun. We think if you commenced to water the plants early in May, giving them good soakings once a week with diluted liquid manure, you would prevent mildew appearing to a great extent. If it should appear, syringe immediately with *Lifebuoy* soap-water, half a bar of soap to 3 gallons of soft water, and continue this every three or four days. A few good yellow or yellow shaded sorts that are rarely troubled with mildew are: *Mme. Boursin*, *Billiard et Barre*, *Claire Jacquier*, *Duchesse d'Auerstedt*, *Réve d'Or*, *Belle Lyonnaise*, *Bonquet d'Or*, *Le Soleil*, *Mme. Hector Leuilliot*, *Tea Rambler*, *Elise Robichon*, *Gardenia*, *Ernst Grandpierre* and *François Foucard*. We recommend you to give the border a mulching of well-decayed manure, that from an old heap being best. This should be done before you commence to water. For planting under the Holly hedge we think you could not do better than plant own-root bushes of some of the *wichuraiana* Roses, such as *Hiawatha*, *Jersey Beauty*, *Sweetheart*, &c. They always look cheerful even when their blooms are over. The type *R. wichuraiana* would also do well. We could not recommend the hardy *Cypripedium*.

### FRUIT GARDEN.

**Pears cracked** (*G. T.*).—The cracking of the Pears about which you ask is probably due to the Pear scab (*Fusicladium pirinum*). This fungus is capable of living through the winter in the fallen cracked fruit, and such should be collected and burned. It is also a good plan to collect and burn all the leaves as they fall. During the winter, and before the buds begin to swell in the spring, spray the trees with a solution of copper sulphate, 1oz. of the copper sulphate to 12½ pints of soft water. This must not be used after the buds begin to swell in the least. When the flower-buds begin to open next summer, spray the trees at weekly intervals for at least three weeks with a solution of sulphide of potassium or liver of sulphur, 1oz. of the sulphur to 6½ gallons of soft water.

**Persimmon plants from seed** (*A. E. S.*).—Fruits of all kinds when raised from seed take a much longer time to reach the flowering and fruiting stage than those propagated by grafting. In addition to this there is always a tendency in the case of seedlings (even when the seed is taken from one of the finest varieties) to revert to the original wild form, so that it is very probable, even in the event of yours fruiting, that it would be greatly inferior to the fruit purchased by you. There is no doubt that yours is the Japanese *Diospyros Kaki*. We have seen this bear fruits when not more than 6 feet high, but these were grafted plants, and even then a warm position is very necessary for it. As your plants are in such a thriving state it seems a pity to do away with them, and in two or three years more they may fruit. These remarks also apply to the seedling *Custard Apple*.

**Failure of Raspberry canes** (*A. M. T.*).—The unhealthy condition of the Raspberry canes is owing to the dry position and poverty of soil. This moisture-loving fruit is never successfully grown beneath trees. They do best when well out in the open garden and where their roots can be mulched with manure during May and June. The Raspberry requires generous culture, both in the shape of well-worked soil, liquid manure and mulching, if you would obtain a good crop of fruit. The young canes should also be thinned out to three or four when they show signs of overcrowding. By so doing, the energies of the plant are confined to these three or four canes, and, of course, to the fruit-bearing canes. You would do well to make a new plantation this autumn, taking care to start with well-rooted plants, and cutting them down to the ground the first season.

**Grapes decaying** (*B. E. C.*).—Your Grapes appear to us to be over-ripe, and this, we think, is the chief cause of the stalks of the berries decaying and the Grapes dropping. A too heavy application of water at the roots when Grapes are ripe will sometimes cause this, and especially if the vine is not well ventilated day and night. The best thing you can do now is to ventilate freely in warm weather during the day, leaving a small chink of air on both top and bottom ventilators all night, and providing at the same time a little heat in the hot-water pipes.

**Black Hamburgh Grapes not colouring** (*B. A. J.*).—Seeing that the foliage of your Vines is healthy, free from disease and from insect pests; it is difficult to suggest a reason for their refusing to colour this year when they have hitherto coloured so well. It may be that the Vines are carrying too heavy a crop. A Vine will only colour a certain weight of fruit; once this boundary is overstepped then Nature rebels. This is the most frequent cause of Hamburgs failing to colour of any we know; or it may be (as you suggest) caused by the exhaustion of some necessary constituents of the soil which is vital to the well-being of the Vine, such as potash, which forms one of its chief constituents. In any case, you will be safe in applying the following artificial manure to the Vines while they are in a state of growth: Dissolved bones, 1cwt.; nitrate of potash, 56lb.; sulphate of lime, 56lb. Less or more in the same proportion as may be required. Apply 2lb. to the square yard, watering it in, giving a similar dressing in three weeks' time. Serve the Alicantes the same.

**Spot on Peach leaves** (*F. R.*).—The foliage sent is suffering from an attack of a small species of fungus named *Cercospora persicae*. It is most difficult to destroy, because it is situated between the two surfaces of the leaves, where no direct application of a fungicide can reach it. The only thing you can do is to destroy every leaf by burning as it falls, and even to pick off the worst affected ones and serve them the same way. The little brown spots on the leaves will in time burst, and the fungus be thus liberated. An occasional application of sulphur to the tree will help to prevent it spreading where it comes in contact with. The leaves are very thin and poor, indicating a want of tone and strength in the trees, and in consequence inviting the attacks of fungoid diseases. Perhaps the soil in which your planted-out trees and those in pots are growing is poor. If so, replant and repot this autumn in the best Peach soil you can procure. We have come across Fig leaves affected in the same way as yours, and have no doubt that it is some species of fungus that has done the mischief. The cause of such an attack, we believe, must be looked for in conditions of growth inimical to the health of the trees—either too much heat and moisture being given or the branches and leaves being allowed to become too crowded together. The leaves are thin and without weight or substance, and therefore an easy prey for such attacks. Bury the diseased leaves as they fall, and try what a fresh admission of air and a judicious thinning out of the weaker branches will effect.

## KITCHEN GARDEN.

**Carrots cracking** (*A. A.*).—The cause of Carrots cracking or splitting is usually a heavy rain after a period of drought. During dry weather growth is checked and the tissues of the Carrots become hardened; then when rain comes the roots swell very rapidly and the tissues, being hardened, cannot expand fast enough, and the cracking is the result.

**Cleaning Tomato boxes** (*T. W.*).—The best method of thoroughly cleansing the boxes to be used a second time for growing Tomatoes will be to wash them out, if this be practicable, with a solution of Lysol dissolved at the rate of five parts by weight to the thousand of water (1oz. to 6 gallons), or they may be well dipped in this solution and allowed to drain after being cleansed of soil. If the dipping is resorted to, a solution of formalin may be used, diluting the commercial formalin with 500 to 800 times its bulk of water. Failing this, the boxes may be stood in a building that is as nearly airtight as possible and exposed to the fumes of sulphur burned in an iron vessel for a considerable time, and, if it be possible to have some steam about at the same time, the treatment will be the more effective.

**Celery leaves diseased** (*K. R. Image*).—You cannot do better than pick off and burn all the infested leaves. The eggs are probably all hatched by this time, and if they are not they are placed under the skin of the leaves and cannot be reached by any insecticide.—*G. S. S.*

**Tomato leaves shrivelling** (*E. B. M.*).—We think the sudden collapse of the leaves of your Tomato plant must be attributed to a too strong application of guano, which would have the effect of injuring the roots of the plants even if it did not touch the stems. Guano, of course, is an excellent stimulant when carefully applied. We prefer to mix it in water and apply it in liquid

form rather than spreading it on the soil and then watering it in. A handful of guano to 3 gallons of water is the proper and safe quantity to use at one time, and this may be given once a fortnight to heavily-cropped plants while in active growth. Yes, by all means transplant the young Wallflowers as soon as you can; they will make far sturdier and better plants than if left in the seed-beds till wanted for planting out. A cool aspect should be selected for them, east or west, and they should be planted 8 inches apart.

**Celery leaves browned** (*Constant Reader*).—The spotting and shrivelling of the leaves of the Celery is due to the attack upon it of a fungus, *Septoria petroselinii* Apli. If all the leaves are attacked it is not possible to do anything for the plants; but if there is only one plant here and another there that has the disease, it would be best to remove that entirely and spray the leaves of the rest with potassium sulphide, dissolved at the rate of 1oz. to 3 gallons a water. Care should be taken to burn the whole of the refuse leaves from the plants when they are lifted, and not to dig them in or leave them lying about, nor put them on the rubbish-heap. The bed next year should be made as far as possible from that this year, and seed from another stock should be obtained. You omitted to enclose name and address and this creates delay.

## MISCELLANEOUS.

**Caterpillars to name** (*E. Ballard*).—The caterpillars you enclosed are those of the "buff-tip moth" (*Phalera bucephala*), a very common insect. The caterpillars feed on the leaves of most trees. The moth is a large one, measuring 2½ inches across the upper wings, which are of a purplish grey colour with buff-coloured tips. The insect is seldom seen on the wing in the day-time, and when at rest with its wings tightly closed so resembles a piece of dead leaf that it is very difficult to detect it.—*G. S. S.*

**Dead bees under a Lime tree** (*Mrs. R. J. F.*).—Dead bumble-bees in a similar condition to those which you sent are frequently found under Lime trees. The bees are generally males, which gorge themselves with the honey, having little else to do, until they are quite drowsy and fall a prey to the tits and, perhaps, to other birds, who, having eaten the honey that they contain, drop the empty bodies. How these bees became mutilated was a mystery for some time, till a careful observer happened to be sitting under a Lime tree one day, when he noticed these dead bees falling from time to time, and on investigating the matter he found a great-tit emptying the humble-bees as fast as it could.—*G. S. S.*

**Gardeners' mutual improvement societies** (*H. W.*).—These are most excellent institutions and are productive of an immense amount of good throughout the country. Your own members will prepare and read papers upon which there would be a subsequent discussion, and occasionally you could get the services of a prominent lecturer. If your county council has a paid lecturer, you should make application to the secretary of the education committee for his services. The rules should be as simple as possible. If you write to Mr. R. B. Leech, The Cottage, Wood Hall, Dulwich, S.E., sending a stamped addressed envelope, we are sure that he will send you a copy of the rules of the excellent society of which he is the capable secretary.

**Cooking vegetables for eating** (*W. P. S.*).—Yours is a question in domestic economy rather than in gardening. Gardeners, however, have very intimate concern with vegetable cookery, as much of what they grow so well too often comes to table spoiled in the cooking. Still, in relation to the question whether certain vegetables are better steamed than boiled, this depends for reply so very much on habitual practice and on ordinary methods. So few care to practise methods they have had no experience in. Many vegetables, however, are better steamed than boiled, but their proper cooking depends very much on the force or heat of the steam generated, also in cooking quickly. Potatoes, Parsnips, Onions, Carrots, Broad Beans and Seakale are all better steamed. Still, the range may be wider. Why not try all vegetables that you cook both ways and see which you like best.

**Names of plants.**—*George Clark*.—1, *Crataegus Crus-galli* (Cockspur Thorn); 2, *Pyrus torminalis*.—*T. A. D.*.—1, *Aster dumosus*; 2, *A. Amellus*; 3, *A. Novi-Belgii densus*; 4, *A. turbinellus*; 5, *A. acris*; 6, *A. Novi-Belgii mala*; 7, *A. levis* variety; 8, *A. Nove-Anglie roseus*; 9, *Helianthus autumnale striatum*; 10, *Aster puniceus pulcherrimus*; 11, *A. levis* Robert Parker; 12, *A. Nove-Anglie pulchellus*.—*Grain*.—1, *Juniperus chinensis*; 2, *Calycanthus occidentalis*; 3, *Cupressus lawsoniana* variety; 4, *Ceratostigma plumbaginoides*; 5, *Cupressus lawsoniana aurea*; 6, *C. lawsoniana*; 7, *Populus deltoides*.—*J. M. B.*.—*Alnus glutinosa* *imperialis*.—*B. G.*.—*Medicago maculata* (Spotted Medick). A native plant!—*Mrs. Renshaw*.—*Sedum Sieboldii*.—*J. E. M. F.*.—1, *Verbascum thapsoides*; 2, *V. Blattaria*.—*F. C.*.—1, *Cupressus lawsoniana erecta viridis*; 2, *C. nootkatensis* variety; 3 and 4, *C. lawsoniana*; 5, *Thuya occidentalis*; 6, *T. orientalis*.—*N. Clarke*.—1 and 2, *Thuya plicata*; 3, *Cupressus lawsoniana*; 4, *C. pisifera*; 5, *C. nootkatensis*; 6, *Juniperus chinensis*.—*R. Dicknell*.—1, *Sedum spectabile*; 2, *Potentilla recta* var. *macrantha*; 3, *Linaria repens*; 4, *Aster Linosyris*; 5, *Hypericum morianum*.

**Names of fruit.**—*A. M. M.*.—1 and 6, Cox's Orange Pippin; 2, Schoolmaster; 3, Cobham; 4, The Queen; 5, Blenheim Orange; 7, Allen's Everlasting;

8, Yellow Ingestre; 9, Margil; 10, Red Streak; 11, King of the Pippins. —*J. A. Waller*.—1, Blenheim Orange; 2, Jefferson; 3, Chatley's Kernel; 4, Sops o' Wine; 5, Fearn's Pippin. —*Rutland*.—1, Mistle; 2, Queen Caroline; 3, Rosemary Russet; 4, Hollandbury; 5, not recognised; 6, Stafford. —*Wm. Ingall*.—A, Pickering's Seedling; B, Waltham Abbey Seedling. —*W. Martineau*.—1, King Harry; 2, Ross's Nonpareil; 3, Christmas Pearmain. —*Frank G. B.*.—1, Peasgood's Nonsuch; 2, Cornish Gillyflower; 3, Striped Beaufin; 4, King of the Pippins; 5, Cox's Orange; 6, Rosemary Russet; 8, Bismarck; 9, King of the Pippins; 10, Fearn's Pippin; 11, Pickering's Seedling; 12, Round Winter Nonsuch; 13, Royal Nonsuch. Pear: Josephine de Malines. —*F. F.*.—1, Scarlet Nonpareil; 2, Yellow Ingestre; 3, Tower of Glamis; 4, Duchess Favourite; 5, Cox's Orange Pippin; 7, Brandy Apple; 8, a local seedling; 9, Newton Wonder. —*John Dixon*.—Mère du Ménage. —*W. R. Roberts*.—Apple Peasgood's Nonsuch; Pear Pitmaston Duchess.

## SOCIETIES.

### THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE twenty-second anniversary dinner of this society was held at the Waldorf Hotel, London, W.C., on Thursday, the 15th inst. There was not quite such a large gathering as we have previously seen, but a very pleasant evening was spent. Dr. Robert Boxall, who is an enthusiastic horticulturist, presided, and was supported by the Hon. W. Fawcett, P. Ladds, G. B. Mason, J. Ingram, J. McKechar, W. H. Divers, J. N. Cox (representing Messrs. Hurst and Sons), A. J. Brown, J. T. Anderson, and Messrs. Veitch and Sons were represented by several of the leading men of various departments. Messrs. Osman, Pollett and other firms were also represented, and among the members of the society were Mr. J. George and Mr. George Wheeler, two of its first members, and Mr. Mortimer, who has attended every anniversary for twenty-two years.

After the usual loyal toasts, the chairman (Dr. Boxall) proposed "Success to the Society," and in doing so referred to the excellent work of its officers, the splendid financial condition of the society and the advantages derived from the benevolent fund, from which those who are over seventy years of age receive more than is offered by any other self-supporting society; also to the convalescent fund, which was started by N. N. Sherwood, Esq., V.M.H., and supported by Messrs. Veitch and others. After referring to the small cost for management and other details of the advantages of the society, he strongly recommended that all young gardeners should join as early as possible. The number given of members now on the books was 1,246, but there has been some added since. The value of the assistance of the Press was referred to.

Mr. C. H. Curtis (chairman of committee), in responding, announced that £1,100 had already been invested this year, new members were being added at every committee meeting, and suggested that the even and pleasant manner in which all the workings of the society were carried out made members rather inclined to leave smooth waters still.

The toast of "The Life and Honorary Members" was proposed by Mr. A. J. Brown of Chertsey, and in doing so he referred to the great advantages derived from the subscriptions from this source and the many advantages which young gardeners would derive from joining the society, and suggested that the older members should be more energetic in advocating the advantages of joining the society. Mr. Cox (of Messrs. Hurst and Sons), in responding, regretted the absence, through unavoidable causes, of many who in the past had done much good service in various ways, and expressed a hope that on future occasions more might be present. Mr. J. Harrison Dick proposed the toast of "The Visitors," and remarked that he, being the baby member of the committee, could not say much except to express the thanks of the committee for their presence. In response, Mr. Bowles (of the Royal Horticultural Society) made a humorous speech, strongly supporting the advantages of all gardeners joining the society.

The musical programme, under the direction of Mr. T. Winter, was well carried out, and a pleasant evening closed by the singing of "An'd Lang Syne."

### EAST ANGLIAN HORTICULTURAL CLUB.

At the October meeting of this club, the members present, numbering nearly 100 professional and amateur gardeners, were treated to a "pot-pourri" of subjects. At the invitation of Mr. E. Peake, the leader of the botanical section, five of its members contributed short essays as follows: Mr. H. Perry upon "How Plants Feed," touching mainly on root action; Mr. H. Goude upon "Leaves," in which he detailed their important work; Mr. L. Smith upon the "Leaf Insect and its Life," as watched by himself; Mr. T. Nottley upon "Our Native Poisonous Plants," which he had well supplemented by bringing specimens collected; and Mr. C. Burtenshaw upon "Summer Bedding" he had noticed on his holiday. These brought out a very good discussion, which was most instructive to those present. The exhibition was a keen one and splendid specimens of fruits (especially Apples), flowers and vegetables were staged. Messrs. Daniels Brothers, Limited, Norwich, sent some fine examples of their new sterling Potatoes, Prince Edward and Royal Norfolk, staged for their special prizes. Hobbies, Limited, made a display of Roses from their local Rose fields at Dereham, and included in it the new sulphur China Rose Chin-Chin China.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## SPRING FLOWERS.

### AUTUMN PREPARATIONS.

(Second Prize Essay).

HOW eagerly we all of us look forward each day in the new year to finding the first spring blooms—Iris reticulata, Aconites, Snowdrops or Hepaticas—and what a bounteous harvest of bloom appears if we are prepared to make due preparation the previous autumn! Yet, how many neglect their opportunities at this season, under the mistaken idea it will interfere with their precious summer bedding. This is a great mistake, for not only can the beds be cleared in ample time, but there is no time hardly in the whole year when flowers are more looked forward to, and when they are more welcome. When we consider how easily the necessary plants can be raised and how cheaply the best bulbs can be purchased, there is no reason why every garden worthy of the name should not be a perfect feast of bloom and the slight trouble and expense repaid a hundred-fold. In these few suggestions of beds for effect during the early part of the year, I have in most cases associated bulbs with some perennial or biennial plant. This plan has several advantages, not the least being that the latter clothe the ground when the bulbs are dormant, in flower they associate together, the colours of each tending to show the other off; also the foliage of the one prevents the rain splashing the soil on to the flowers, thus helping to preserve them and saving that bedraggled appearance rain-washed flowers possess. Again, most of the combinations used are of two only; a simply laid out bed is generally the most effective. They are arranged under the months; some plants are mentioned twice, as these have a longer season of flowering.

*February.*—Erica carnea (pink, 6 inches to 1 foot) with Snowdrops freely intermingled; Hamamelis or Witch Hazel (shrub, yellow flowers), with a thick carpeting of Chionodoxa Lucilæ (3 inches, blue) 4 inches apart. The above two are permanent beds. Wallflower Early Parisian (1 foot, brown), with edging of Chionodoxa Lucilæ. This Wallflower will often flower right through the winter. Aconites (3 inches, yellow), with Iris reticulata (4 inches, blue and gold); plant in clumps all over bed 3 inches apart.

*March.*—Polyanthus (1 foot, cream shades), planted 1 foot apart, with a carpeting between of Scilla sibirica (4 inches, blue), plant 4 inches apart; Polyanthus (brown shades) arranged similarly with Snowdrops; Alyssum saxatile (1 foot, yellow), 1 foot apart, carpeted with Scilla sibirica; Wallflower Harbinger (1 foot 6 inches,

brown), with edging of yellow Crocus, 3 inches apart; Leucojum (Snowflake) vernum (6 inches, white and green), 6 inches apart, with Scilla sibirica between. The Leucojum should be planted by August, to enable it to get established. It will often do where the Snowdrop gradually dwindles away. Anemone Hepatica (blue, 6 inches), 1 foot apart, with yellow Crocus intermingled; Anemone Hepatica rubra (red), with Scillas between; Anemone fulgens (9 inches, scarlet), 1 foot apart, with Chionodoxa between; Saxifraga cordifolia (Megasea) (1 foot 6 inches, rose), planted 2 feet apart, with Scillas between. The last five should be regarded as permanent. Doronicum austriacum (1 foot 6 inches, yellow), 18 inches apart, with a groundwork of Silene pendula compacta (6 inches, pink). The above Doronicum is to be preferred to the stronger Harpur-Crewe—a fine perennial—for this purpose, but the latter can with great effect be used for bedding, say, with an edging of any dwarf early blue flowering bulb or as a background to the bed of red Wallflowers.

*April* brings a regular blaze of colour. In addition to most of the foregoing during the early part of the month we have the following: Wallflower Eastern Queen (1 foot 6 inches, pink and apricot), with a broad edging of Myosotis (Forget-me-not) dissitiflora (1 foot); Wallflower Vulcan (1 foot 6 inches, crimson), with edging of Arabis alpina fl.-pl. (1 foot, white); Wallflower Golden King, with edging of double red Daisies (4 inches); Anbrieta Leichtlini (4 inches, rose), with dot plants, 18 inches apart, of Alyssum saxatile compactum; Iberis sempervirens, perennial Candytuft (9 inches, white), intermingled with Phlox Newry Seedling (6 inches, pale blue); Polyanthus, cream shades, 1 foot apart, with Muscari conicum Heavenly Blue (9 inches), intermingled, 4 inches apart; Iberis sempervirens, planted just clear of each other with Tulip Duc van Thol (8 inches, scarlet), between, 4 inches apart; Arabis alpina fl.-pl., 9 inches apart, with Tulip Keizer Kroon (1 foot 4 inches, scarlet, edged yellow) planted between, 5 inches apart; the same Arabis arranged with Tulips Prince of Austria (1 foot, orange scarlet) and Yellow Prince (9 inches) at 6 inch intervals alternately; Saxifraga cordifolia, 18 inches apart, with Narcissus Emperor (1 foot 9 inches), at 9 inch intervals between; Myosotis dissitiflora, 9 inches apart, with Narcissus Duchess of Westminster (1 foot 9 inches), at 6 inch intervals between. Waterwitch would be lovely here, if only cheaper. Silene pendula compacta, 9 inches apart, with Narcissus Sir Watkin (1 foot 6 inches), at 6 inch intervals between; Iberis sempervirens, 9 inches apart, with Jonquil Campenelle (1 foot 4 inches), at 4 inch intervals between; Daisy Bellis (double white), 6 inches

apart, Muscari conicum Heavenly Blue between; and Daisy (double pink) 6 inches apart, with Narcissus Empress (1 foot 9 inches) between. Hyacinths, which begin flowering this month, are best arranged in colours together; they do not associate well with other plants.

*May.*—Myosotis (blue) 6 inches apart, with Scilla nutans (Bluebell) rosea major (1 foot 4 inches, pale rose) planted between 4 inches apart. This Scilla should be planted quite 8 inches deep; it will thrive well in the shade, should be treated liberally, and left as a permanency. Dactylis glomerata variegata, a variegated grass, 6 inches high; plant 9 inches apart, with Darwin Tulip Clara Butt at 6 inch intervals between. This Tulip grows 1 foot 6 inches and is a lovely rose shade. Any of the Darwin Tulips could be used in this manner, while almost any carpeting plant could be used. It is advisable to clear the carpeting off after the Tulips have flowered, so as to well ripen the Tulip bulbs in the sun. Myosotis (blue) 6 inches apart, with May-flowering Tulip Bouton d'Or (1 foot 6 inches, deep yellow); Ixiolirion tataricum (1 foot 6 inches, blue) 6 inches apart, with Narcissus Poeticus plenus (1 foot 4 inches, double white) 6 inches apart. In addition to these most of the April beds will still be in full glory.

*June.*—Saxifraga Stansfieldii or S. hypnoides, perhaps the last (9 inches, white), small pieces 6 inches apart, with mixed Spanish Iris, blue shades (1 foot 6 inches). The same Saxifrage could be used for the English Iris, which is later than the Spanish, but larger—there are no yellow shades in the former, but they are, if possible, more beautiful—or the beautiful Iris juncea, which is a deep yellow, could be used; this flowers just after the Spanish and is a gem. Ranunculus, French or Persian (various colours, 1 foot) could be planted 9 inches apart, with either the above Irises between them. Plant the Irises during the autumn and Ranunculuses in the spring (March). Dactylis glomerata variegata, 9 inches apart, with Calochortus (1 foot, various colours) between at 4 inch intervals. The Calochortus should be covered during the winter with some litter. Take this off before the plants have made too much growth. They are beautiful flowers and too little grown.

WILLIAM P. WOOD.

(Head-gardener to A. W. W. Gordon, Esq.)  
The Gardens, Oaklands Court, St. Peter's, Kent.

## PRIZES FOR READERS. NOVEMBER.

### FLOWERS FOR A SMALL GREEN- HOUSE IN WINTER.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Monday, November 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 5, 6 and 7.—Forest Gate and Stratford Amateur Chrysanthemum Society, Town Hall, Stratford.

November 10.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m.; Lecture at three o'clock on "British Wild Flowers in the Garden," by Mr. John W. Odell; admission, 2s. 6d.; Royal Horticultural Hall, Vincent Square, Westminster. West of England Chrysanthemum Society's Show. Leeds Baxton Chrysanthemum Society's Show. Horticultural Club, Mr. C. D. McKay on "The French Garden," Hotel Windsor, 6 p.m.

**A famous Beech hedge.**—This year the cutting of the famous Beech hedge at Meikleour, the estate of the Marquess of Lansdowne, in Perthshire, has again been taken in hand. The task is by no means a light one, seeing that the hedge is about 100 feet high and a third of a mile long. Telescopic apparatus is brought from London for the purpose, and with this the greater portion of the height of the hedge can be reached. Above it the foresters have to climb the tree-trunks and fasten themselves with straps to the limbs, so that they can have their hands free for working. The platform of the telescopic structure sways greatly with the wind, and the necessary operation of cutting has often to be steadied by guy ropes. The hedge is cut every few years, and was last cut in 1900. It may be mentioned that this famous hedge was planted in 1715.

**In Aster time.**—Mrs. Danske Dandridge, who lives in West Virginia, writes: "One of our poets thus describes the upland Asters." [At this season we think of the beautiful autumn flowers, and the Aster is the sweetest.]

#### WILD ASTERS.

We dwell in arid places,  
We lift our starry faces  
From the bleak cliff.  
Poising so fairly,  
Tossing so airily  
To the wind's whiff.

Fragile but brave are we,  
Nestling at autumn's knee,  
While her leaves fall.  
We, with the Golden-rod  
Along the highways nod  
Welcome to all.

When falls the killing frost,  
Count not our lives as lost,  
We, for a while,  
Dream o'er the happy past;  
Look on the skies our last;  
Die with a smile.

### Dr. J. H. Wilson's new Potatoes.

At the seed and root show of the Fife Agricultural Society at Cupar, on the 20th ult., Dr. John H. Wilson of St. Andrews exhibited seventeen sorts of his new Potatoes, obtained from crossing nine varieties. They were exceedingly interesting, and, being accompanied by details of their parentage, afforded an opportunity to growers of observing the effects of the different crosses. The parent most frequently employed was Rector, one of Dr. Wilson's own, ten of the seventeen having this variety as one of its parents. One of the most promising appeared to be a variety derived from Rector and Bejant, another of Dr. Wilson's raising. The whole exhibit was valuable and created much notice.

**South-Eastern Agricultural College.**—A meeting of the governors of the South-Eastern Agricultural College, Wye, Kent, was held at Caxton House, Westminster, on Monday, the 26th ult., under the chairmanship of the Right Hon. Lord Ascombe. The

principal, Mr. M. J. R. Dunstan, reported an entry of 129 students for the session, of whom 124 were in residence, this being the largest number on record. A resolution was passed agreeing with the conclusions of the report of the committee on Agricultural Education and Research. A special horticultural course has been instituted under the superintendence of a practical fruit-grower, and will commence next January. A fruit-growers' conference will be held at the college on November 27, when insecticides, spraying, the packing and grading of fruit, &c., will be discussed.

### National Sweet Pea Society.

This society will hold its London show in 1909 at the Royal Horticultural Hall, Westminster, on July 23, and the provincial show will be held at Saltaire, in conjunction with the Saltaire Horticultural and Rose Society, on July 13. The annual meeting of the society for 1908 will be held at the Hotel Windsor, on December 11 at three o'clock. Arrangements have been made for holding trials of Sweet Peas in the gardens of the University College, Reading, in 1909, and it is proposed to make a charge of 2s. 6d. per variety sent for trial, and to receive varieties only from the raisers or original distributors. Any information respecting the forthcoming trials, &c., will be given by the hon. secretary, Mr. Charles H. Curtis, Adelaide Road, Brentford.

**Forcing Snowdrops.**—Speaking in a general way, this is almost impossible, although I know they may be brought into bloom slightly in advance of those outdoors. At this season many are now thinking of a supply of flowers from Christmas onward, and not a few are inclined to try forcing Snowdrops. If they are wished for very early, then the best way is to pot or box them early in the autumn, putting them in a cold position and covering with ashes. When growth is advanced, remove them into a cold pit. About Christmas they may be brought into a moist structure where the night temperature does not exceed 45°, giving them a light position with plenty of air, and if the temperature is not above 40° they will be more robust. Last year I tried forcing Snowdrops in a stove for an experiment by placing in six pots of well-rooted bulbs in the middle of December; they were put in a moist and cold corner. Out of the lot we never had a dozen blooms, all going blind. I have seen excellent Snowdrops grown with Seillas and Tulips in pots and boxes for the house, when brought on slowly in frames kept close and free from frost. Another way to obtain them early is by taking them up in clumps from the open ground when just showing flower. These may be forced well.—J.

### The Leamington Onion Show.

When it was first announced by Messrs. Rogers of Leamington that they would award £100 for the best specimen of their Leamington Giant Onion, it was expected that a large competition would ensue, and on Saturday, the 24th ult., no fewer than 1,700 bulbs were staged. The fortunate possessor of the first prize bulb was Mr. A. R. Searle, Castle Ashby Gardens, Northampton, who had a perfect specimen of over 3lb. in weight and well finished. The second prize fell to that well-known grower, Mr. S. J. Baker, Weir House Gardens, Hereford, who also had an extremely fine Onion; third, Mr. W. Turnham, Culham Court Gardens, Henley-on-Thames; and fourth, Mr. A. G. Gentle, Little Gaddesden, Berkhamsted. In addition to the substantial first prize, sixty others were awarded, and the majority of the Onions were large, well grown and sound. Prizes were also offered for a collection of vegetables grown from Messrs. Rogers's seeds, and the first, £5 and a gold medal was won by Mr. W. Folkes, Dunstable Street, Amptill, Bedfordshire, with very high-class produce. So pleased were the promoters of the show with the large competition that they propose offering some very substantial prizes again next year.

**Paris Chrysanthemum Show.**—

The annual show of Chrysanthemums, fruit and vegetables, to be held by the National Horticultural Society of France in the greenhouses on the Cours la Reine, will take place on November 6 to 15. As this will be the last show held there and the twenty-fifth Chrysanthemum exhibition held by the society, it is expected that a very fine display will be made. The city authorities have decided to demolish these greenhouses, which were erected during the time of the great 1900 International Universal Exposition. A large and varied schedule is provided, and there will be an interesting special exhibition of books, pamphlets, prints, pictures and engravings relating to the popular autumn flower.

**United Horticultural Benefit and Provident Society.**—

The monthly meeting of this society was held in the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, the 12th ult., Mr. C. H. Curtis presiding. Eleven new members were elected, making a total of sixty-three this year so far. Sick pay was much lighter during the last month, the amount being £25 10s. against £39 13s. the previous month. Mr. A. C. Hill of West Kensington was co-opted on the committee to fill the vacancy caused by the resignation of Mr. A. Hemsley. The usual quarterly payments were passed for old members on the Benevolent Fund.

**A curious Carrot.**—Curious growths frequently occur among vegetables. In pulling Carrots a few days ago, Mr. S. Hunt, gardener to Mrs. Willis, Ipswich Road, Norwich, drew out one which had evidently, in its young state, gone through the neck portion of a broken meat-extract bottle which was in the soil. At this point it naturally had to contract itself, but it had developed on either side to its usual proportions.—P.

**Daphne Dauphnil.**—This shrub is flowering very freely at the present time (October 19), rather earlier than usual, owing, most likely, to the recent warm weather. Here in the South it continues to produce flowers in mild weather until spring. Its neat habit, bright evergreen leaves, rosy purple buds and lilac flowers make it a most welcome addition to a collection of shrubs. Like many other Daphnes, it is very sweet-scented, and for that reason may be planted near the house in a sheltered nook not too much exposed to bright sun. We have it planted near a west wall, where it seems quite hardy. It makes, in a young state, an annual growth of about 9 inches, and, judging from this example, becomes a low, spreading shrub of about 3 feet in height.—J. COMBER, *Nymans Gardens, Handcross, Sussex.*

**Edinburgh Public Parks Committee.**—

Baillie Maxton, who has occupied so usefully the post of convener of the Edinburgh Public Parks Committee, retires at the present time from that office. During Baillie Maxton's term of office much good work has been done, and consideration of matters affected by the Saughton Park being occupied by the National Exhibition has necessitated a good deal of attention being paid to many involved questions, so that the convener has rendered much valuable work. It is to be hoped that the new convener will give the same hearty support to Mr. M'Hattie, the able superintendent of parks.

**National Chrysanthemum Society.**—

On Monday evening, the 26th ult., a meeting of the executive committee of this society was held at Carr's Restaurant, Strand, when Mr. Thomas Bevan occupied the chair. A good deal of time was taken up in the appointment of the various judges for the coming show and other details in connexion therewith. The Hendon and District Chrysanthemum Society applied for admission in affiliation, which was granted. The annual dinner to be held at the Holborn Restaurant was definitely arranged for November 26th, when Sir Albert Rollit, the

president of the society, will preside. The Dean Memorial medal will be allotted at the coming show to exhibits in the decorative classes, and awarded by the floral committee on the recommendation of the judges. The classes included are 25 to 30, 34 and 38 to 41 inclusive. Twenty-nine new Fellows and members were elected.

**A British Fern Society.**—Although the British Pteridological Society established at Kendal has done good service as a centre of the British Fern cult for many years, there is no doubt that its purely local character militates against its wider usefulness, and that, now our beautiful and, in many cases, unique British Ferns are becoming popular, a society on a more extended basis is desirable. The object of such a society should embrace a periodical publication describing and illustrating new "finds" and fresh developments in cultural selection, and also providing such general data as may assist the amateur in growing and propagating and acquiring a knowledge of what is being done generally in this particular direction. In the

Other papers please copy.—CHAS. T. DRURY, V.M.H., F.L.S., 11, Shaa Road, Acton, London, W.

**THE EDITOR'S TABLE.****ASTERS FROM SCOTLAND.**

Dr. McWatt sends a most interesting collection of well-grown Asters from Morelands, Duns, N.B., which show the great beauty these flowers give to the garden at this time of the year. The varieties are very fine in colour and size.

**MORE FLOWERS FROM DUNS.**

Dr. McWatt of Morelands, Duns, N.B., from whose garden we have received many interesting contributions, sends us another fragrant and beautiful collection, the Roses being particularly sweet. He writes: "I send you some spikes of nice white flowers cut from *Escallonia philippiana*. It is a very hardy, handsome evergreen, and makes a good bush and flowers freely. *Escallonia*

A BOWL OF ROSES GATHERED IN LATE OCTOBER.

United States there are several societies devoted to indigenous Ferns and their varietal forms, and periodical publications are issued with contributions from inside and outside sources which are very interesting. In Great Britain the only periodical issued is the brief annual report of the above-named society, although the amount of material in the British Isles is, from the varietal point of view, inexhaustible, the comparatively few species having yielded several thousand distinct varieties, which are constantly being added to by fresh discoveries of wild sports or new developments under culture. Under these circumstances, the writer, who for fully thirty years has been practically the champion of British Ferns in the British horticultural Press and in his two standard works, "Choice British Ferns" (Upcott Gill), now out of print, and "The Book of British Ferns" (Newnes), would be glad to hear from their admirers by a simple post-card, in order to judge whether such a society is practicable on the basis of a moderate subscription sufficient to cover printing and other expenses incidental to the programme indicated.

pterocladon also flowers freely and is quite hardy. It has a peculiar form of growth. The branch laden with scarlet berries is from *Cotoneaster frigida*. This forms a small tree and is sub-evergreen. The flowers are white. *Hydrangea paniculata grandiflora* is with me a free-flowering, hardy, deciduous plant. Among the Roses are Stanwell Perpetual (Scotch), the best of all Scotch Roses; Dorothy Perkins and Dwarf Dorothy. *Coronilla Emerus* with its Pea-shaped flowers and *Ceanothus de Plantières* with its blue flowers like *Gloire de Versailles*, but hardier, are also included."

**LILIUM NEPALENSE FROM NEWTON ABBOTT.**

Mr. G. L. Patey of Aller View, Decoy Road, Newton Abbott, sends us flowers of the beautiful Nepal Lily, *L. nepalense*, which is one of the most handsome Lilies we have, the rich golden petals with their maroon bases giving the flower quite a unique appearance. When fully opened the petals reflex, thus showing the maroon markings to advantage.

## NEW PLANTS.

**CHRYSANTHEMUM HILDA LAWRENCE.**—This is a single or semi-double flowered variety of much merit. The lilac-pink blossoms are of large size and well formed, and, naturally grown, the plants furnish sprays of the flowers on long and stiff stems. The variety is an exceedingly useful and attractive one, and should be of much value for conservatory decoration or in the cut state. Exhibited by Mrs. R. Gregory, Shoreham (gardener, Mr. Lawrence). Award of merit.

**Chrysanthemum Mrs. R. H. B. Marsham.**—A very fine exhibition variety of large size, pure white in colour. It is said to be a seedling from the well-known yellow F. S. Vallis, and, judged by the dozen fine blooms staged, is full of promise. Exhibited by Mr. Marsham, Bifrons, Canterbury. Award of merit.

**Chrysanthemum H. W. Thorp.**—A pure white incurved variety of excellent size and finish, and stated to be a seedling from Buttercup. From Mr. H. W. Thorp, Tunnington, Worthing. Award of merit.

**Chrysanthemum Sir Frank Crisp.**—A distinct Japanese variety of a reddish chestnut hue, and of exhibition size. The centre of the flower is of golden hue, the reverse of the petals being of the same tone. Award of merit.

**Chrysanthemum Master David.**—A splendid Japanese variety, with the broad strap-shaped florets that go to make a very handsome bloom. The colour tone, a shade of glowing crimson-scarlet, is one that is much admired, and doubtless the variety will become very popular. Award of merit. These two excellent varieties came from the raiser, Mr. Henry Perkins, gardener to the Hon. F. D. Smith, Henley-on-Thames.

**Chrysanthemum Felton's Favourite.**—A capital market variety of the reflexed type of Japanese. The colour is ivory white, a shade which is seen to great advantage under artificial light. The florets possess a firmness and crispness that denote good lasting properties, while the flowers are borne on long and stiff stems. From Mr. Phillip Ladds, Swanley. Award of merit. All the above were shown before the Royal Horticultural Society on the 27th ult., when the awards were made.

**Vanda cœrulea Charlesworthii.**—This is an albino form of the well-known blue-flowered *Vanda cœrulea*. The flowers on the plant shown were of good size and substance and of the purest snow white. Shown by Messrs. Charlesworth and Co., Hayward's Heath, Sussex. First-class certificate.

**Lalio-Cattleya Lustre gigantea.**—This is a very large-flowered variety, with a remarkably rich-coloured labellum. The sepals are long and comparatively narrow, the petals being very much broader and crimped at the margins and slightly reflexed. The labellum is large and reflexed at each side, the margins being beautifully frilled. The colour of the sepals and petals is the usual rosy mauve, and the labellum is rich carmine. Award of merit.

**Brasso-Cattleya Mme. Hye superba.**—As its name implies, this is a superb or improved form of the well-known Mme. Hye, and forms a beautiful addition to this bi-generic family. The labellum is particularly well fringed, and the colour zones of deep lemon, cream and mauve are most refined. Award of merit.

**Lalio-Cattleya Ostrude superba.**—A unique coloured flower of much attraction. The lanceolate sepals are purple, suffused cream, the broader petals being pale purple, with heavy flakings of dull carmine. The large, beautifully-shaped labellum is of the richest possible carmine hue, and contrasts well with the remainder of the flower. Award of merit. Each of the three named above were shown by Lieutenant-Colonel Holford, C.I.E., C.V.O., Westonbirt, Tetbury, Gloucestershire.

**Brasso-Cattleya Queen Alexandra Glenthorne variety.**—This is a very beautiful form of a well-known and lovely Orchid. The variety in question is larger, yet more refined than the type, the fringing of the large labellum being very delicate. The lemon tint in the throat is also much richer, and the whole flower is a good improvement. Shown by Gurney Wilson, Esq., Hayward's Heath. Award of merit.

At the meeting of the floral committee of the National Chrysanthemum Society, on the 25th ult., the following new Chrysanthemums received awards:

**Lady E. Letchworth.**—This is a very handsome English-raised seedling of ideal Japanese incurved form, the petals being very long, loosely incurving in very regular fashion, and building up a large, deep flower of exquisite form. The colour in this instance is lemon yellow with a paler reverse. First-class certificate to Mr. G. Mileham, Emlyn House Gardens, Leatherhead.

**W. J. Davis.**—A very handsome and striking Japanese reflexed flower, having broad petals of good length that build up a very deep flower of exhibition standard. The colour is a beautiful shade of rosy chestnut with a golden reverse to petals of good substance. Height about 5 feet 6 inches. First-class certificate to Mr. Mileham.

**J. Lock.**—Another very handsome Japanese reflexed flower of abnormal proportions, and one of the largest we have seen for many years. The petals reflex pleasingly, curling at the ends, and build up a monster flower, devoid of coarseness. The colour may be best described as yellow streaked red. Height about 6 feet. First-class certificate to Mr. Mileham.

**Exquisite.**—Another monster bloom of the most beautiful description, being a very much glorified E. Molyneux. The petals are very long and broad, and are pleasingly disposed in building up a flower of high quality. The colour is a bright shade of chestnut with a rich golden reverse. First-class certificate to Mr. Mileham.

**Lady Crisp.**—One of the monster Japanese blooms, quite devoid of coarseness, and possessing all that goes to make a valuable exhibition flower. The petals are long, broad, somewhat flat and slightly pointed at the ends, building up a massive flower of a golden yellow colour with pale reverse. Height 5 feet. First-class certificate to Mr. Perkins.

**Rose Pockett.**—This is evidently a variety of Antipodean origin, having very long florets of good width that make a large, spreading flower, though of somewhat shallow build. The colour in this instance is a shade of buff-yellow. First-class certificate to Messrs. W. Wells and Co., Limited, Merstham, Surrey.

In addition to the awards given by the Royal Horticultural Society, the varieties *Hilda Lawrence*, Mrs. R. H. B. Marsham, Sir Frank Crisp, Master David and H. W. Thorpe, described before, each received a first-class certificate from the National Chrysanthemum Society.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Rosa Verschuren.**—In reply to Mr. A. Saunders, this Rose can be obtained from L. Naylor, St. Hilda's Nursery, Harrow.—J. B. SHACKLE.

**Bottles for fruit.**—In consequence of changing my address, I had not been kept up-to-date with my copy of THE GARDEN. "J. H." (Richmond) will kindly excuse delay in answering the query on page 478. The clamp bottles used by me are manufactured by Abbott Brothers, bee experts and makers of all appliances for bee culture, Southall, near London (Great Western Railway). My bottles (No. 214) are 4s. 6d. per

dozen. Though they may be had in a larger size (this could be ascertained on application), I prefer the smaller ones, as they hold just the right quantity for use at one time.—E. ARNOLD, The Gardens, Carron Hall, Carron, Stirlingshire.

**Carnation Hon. R. H. Eden.**—As I am receiving letters enquiring about the new rosy apricot Carnation Hon. R. H. Eden, I shall be much obliged if you will kindly insert a little note in the next issue of THE GARDEN saying it may be obtained from the West of England Rose Farm, Henlade, Taunton. It seems likely to be as popular as you predicted when I first sent you some blooms for your table a year or more ago.—E. J. LLOYD EDWARDS, Bryn Oerog, near Llangollen.

**The National Rose Society.**—Please allow me a small space in your columns to express my views on the great advance in the competitions of the above society since the revision took place in its schedule. It goes to show the deep interest taken among the smaller class of growers. The keen competition and increase in the number of competitors really seem amazing. I think the committee has done wisely in introducing more classes; it gives greater encouragement for young members to join the society. When they see there is a chance of obtaining a prize, it stimulates them to greater exertions, they will increase their stock, and so go on climbing up into the higher classes, thus giving a better chance to those who are left behind. Great credit is due to the committee for introducing these additional classes; but there are a few points which I think still require attention. For instance, in the amateurs' classes there is a large gap between the growers of 1,000 and 2,000 plants. Suppose a man has 1,100 plants. He is not eligible to compete in the class for 1,000 plants, but must do so in the 2,000; consequently, he is heavily handicapped and the competition is unfair. I think the committee would act wisely if it introduced another class between the two, say, 1,500. Again, in the class for Teas and Noisettes a new class is required between the growers of 200 and 500 plants. I think if that were done the competition would be more even and give greater satisfaction to all concerned.—AMATEUR.

**London County Council Parks.**—I was much interested in reading "V.'s" impressions of the various parks under the London County Council, and it is gratifying to know that they have not, as was predicted by many, suffered under the new régime at Spring Gardens. I can quite enter into "V.'s" feelings, and small wonder that he is enthusiastic over the exceedingly beautiful floral display on every hand, or write lovingly of the sub-tropical garden in Battersea Park. Never in the history of this noble breathing-space has it presented a more beautiful appearance in every respect than during the past few years of Mr. Rogers's tenure of office. He may be termed an enthusiast, and I am sure it must prove quite contagious to amateurs and professionals alike who may be brought into contact with him. I have noted with much pleasure the improvements that have been effected from time to time. Shrubberies that were in existence under or in close proximity to very large trees, and, consequently, anything but satisfactory, have been entirely altered in character, and have given way to plants that present a beautiful appearance under these conditions. A big space that for a long time was a rubbish-heap has been transformed into a thing of beauty, and is altogether one of the most interesting parts of the park, while beautiful views have been opened up. I should like to express my admiration of the infinite pains that have been taken to maintain the high standard of excellence Battersea Park has always had for sub-tropical gardening, and those who have seen the arrangement this season will agree with me.—WALTER H. AGGETT, 70, St. James's Road, S.E.

**Earthing-up Celery.**—Regarding the article on earthing Celery in a recent issue of THE GARDEN, I find the better way (when not using paper) is to earth up just above the raffia ties; these then rot off before injuring the plant. I find by untying them, especially when the soil is dry, there is a danger of disturbing the leaf-stalks and some soil getting into the heart of the plant.—THOMAS DAVIES.

**Rose Prince de Bulgarie.**—Your correspondent C. O. Jones (page 467) has undoubtedly got this Rose true enough. It is really astonishing how much it changes in colour. At the time of writing (late September) it is very bright here; but my earlier flowers had no more of the deep saffron and orange yellow than one finds in an extra bright Clara Watson. It is constantly changing its colour, but is always pleasing.—A. P.

**Perfume in flowers and insects.** Mr. Barwise seems to infer that perfume in flowers is there specially to attract insects. That is a questionable assumption. No flowers are richer in perfume than double Pinks and Clove Carnations, yet insects do nothing to help fertilise them; indeed, as a rule, they do not seed. In how many plants does not rich perfume lie in the foliage? In what way can that perfume attract insects? It is so easy to reason from imperfect conclusions.—D.

**Calceolaria alba.**—What an interesting, as well as a useful, plant is this evergreen species of Slipperwort, flowering as it does so freely during the whole of the summer and autumn. As a groundwork in a large bed of Plumbago capensis it would have a pleasing effect, or more striking still would a mass of it be associated with Commelina cœlestis. The deep blue of this annual would be emphasised by the pureness of the white of the Calceolaria. As it was introduced from Chili in 1884, it is, of course, not a new plant, but it is a comparatively rare one, as it is seldom met with in gardens. Treated in the same way as C. amplexicaulis as to propagation and growth it will do well.

**Fabiana imbricata.**—The photograph displaying this plant so faithfully as reproduced on page 511 should incite gardeners of all sorts to grow this handsome subject much more than is now the case. Where the soil is heavy and retentive of moisture, and, consequently, cold in spring, the plant is not hardy in the open without any protection, even here in South Hants. At the base of a wall in almost any aspect, but preferably a southern one, is the site this plant loves, especially if the soil is of a light character. In such a site, with the addition of copious supplies of water at its roots during the growing season—July and August—growths 1 foot or more long are made, terminating in a full crop of blossoms next year.—E. M.

**A comparison of garden features.**—I think the idea mentioned by "F. B." (page 507) in connexion with this matter is excellent, and may be a real help to some of the readers of THE GARDEN. When looking over the gardens of friends, one often meets with a striking feature which seems so attractive and effective that one wishes that all their garden acquaintances might witness it and pass their opinion on the subject. It is not always large things that attract the visitor; indeed, sometimes the simple planting affords the most pleasure. As an instance of this, the writer well remembers under his charge a batch of the pretty little Cyclamen europæum. These were planted under the shade of a variety of the Cratægus, and each season the flowering of these humble little plants was looked forward to with pleasure, and they always gave a wealth of their pretty, bright red flowers during the months of August and September. They were planted in the turf, and the soil, being loamy, suited them to perfection. A much larger and more striking feature may be

produced by planting a large bed in the pleasure grounds with Pampas Grass, Michaelmas Daisies and, round the margin (but not too thickly), plants of Cotoneaster horizontalis. During the autumn this is very striking, and, when backed up by trees, shrubs, &c., the combination is decidedly good and attractive. There are many other features one might name, some fitted for large gardens, some for small; but I am afraid of taking up too much valuable space. A bed planted with Phlox Coquelicot, intermixed with Monarda didyma Cambridge Scarlet, in a partially-shady position has been much admired by visitors.—C. RUSE, Watford.

**Apple Worcester Pearmain.**—I think Mr. W. Baylor-Hartland is by no means the first grower who has a poor opinion of the above Apple, and refers to a less-known variety, Thorle Pippin, as an excellent early variety. At the same time, he says that Worcester Pearmain has nothing to recommend it but its colour and constant fruiting. These, however, are two strong points. I have not seen the Apple referred to; but I feel sure that growers who market their fruits will not lose sight of the older sort, on account of its free cropping, as good fruits always command a ready sale. Its earliness is a great gain to growers, and by many it is a great favourite on that account. Another point I would touch upon—and this is one, I am sure, Mr. Baylor-Hartland will not agree with me—and that is, I do not think the Worcester Pearmain eaten from the tree deserves the aweeping assertion that it is poor; indeed, I think, gathered fresh (not stored), it is by no means so inferior as described. Tastea, of course, vary; but in the South I have had some really good fruits of Worcester Pearmain late in August. Dr. Hogg says, in the "Fruit Manual," this Apple "is crisp, juicy and sweet, with a pleasant flavour."—GROWER.

**Layering Carnations.**—As I have read in THE GARDEN about various methods and opinions, I send you mine. I like to start layering the third week in July when possible. This year I saw advertised a layering knife, and procured one from Bees, Limited, and I have not used a finer or more useful tool for the work. In place of the old, but still good, upward cut, with this knife it is downward. Place the point of the blade between two joints and bring it out just below the bottom joint; the operation is then complete. I should think it a great waste of time making two cuts in a layer when one would suffice. I put down close upon 1,000 layers in two days. One great mistake in layering is to put the tongue too deep; a handful of road scrapings is enough for six or eight layers, and, if a piece of slate or broken pot be placed on the tongue, it will root within three weeks. All the shoots on a plant not layered should be cut off. When rooted the layers should be detached from the parent plant, and, if left for a few weeks, this other tongue will be rooted also. Do not coddle or pot them. If they cannot be planted where they are to flower by the end of October, leave them where they are and you will not have shoots 1 inch between the joints; I expect three or four in the same space.—W. WALLACE, Trinity House, Edinburgh.

—Reading recent notes in your valuable paper on the above subject, I give my experience for the benefit of your correspondents. I always layer a good batch, and successfully. When making the upward cut use a sharp knife, cutting into the stem immediately below the joint, running the knife straight up the centre to the next joint. Stop when the knife is through the joint, for if one stops in the middle of it the tongue is apt to break. Insert the tongue in the soil firmly and peg down into some nice light compost, such as old loam, leaf-mould and sand. Plenty must be put round the layer, which should be pressed in firmly, as birds sometimes are troublesome.—JAMES HOGARTH (gardener to Captain Tancred), Wexm, Hawick.

## THE FLOWER GARDEN.

### PROPAGATION OF THE DOUBLE SCOTCH ROCKET.

(HESPERIS MATRONALIS PLENUM.)

AS is well known, this beautiful border plant has been lost in many gardens simply because annual propagation was neglected. I do not go to the length of saying that it is only by taking cuttings every season that it can be saved, as I have myself quite a number of plants from two to four years old, and they still remain quite healthy and vigorous. At the same time, this plant very often dies off suddenly and unexpectedly, causing a great amount of annoyance, so that to ensure an abundance of fine healthy stock a number of cuttings should be inserted each autumn in pots or boxes, which can be wintered in a cold frame or in a cold greenhouse. It is difficult, usually, to secure good cuttings in August; but I have successfully rooted this plant as late as the end of October. The cuttings should be taken with a heel, and, although they are often very short, that matters little if care be taken to see that they are kept firm in the soil. Any good sandy compost suits them as a rooting medium, and the frame should be kept close and shaded for a fortnight or more, afterwards giving abundance of air on all favourable occasions, as this plant resents coddling. Where the shoots are too short to make cuttings, the plants should be lifted and carefully divided with a knife. Each piece with a crown and a few roots attached can then be potted into 3-inch or 4-inch pots, and also kept in a frame all the winter. If these little points are attended to each autumn with a section of the plants, there need never be any fear of losing this Rocket. The true variety is greatly superior to the tall French form, and both white and purple are equally desirable. I find the purple the more difficult from which to obtain good cuttings, and so have usually to resort to the division of the old stools. C. BLAIR.

### AUTUMN FLOWERS IN LINLITHGOWSHIRE.

AFTER having a very fine, dry summer, September set in both cold and wet, and at one time it looked as if even the hardy Asters would be entirely ruined by the long spell of dull weather. During September we recorded 4.71 inches of rain, which brings the total for the nine months up to 22.03 inches, which is fully 1.25 inches more than for the corresponding period of last year, which was considered an extra wet season. September slightly redeemed itself at the very end by giving us a few remarkably fine days, and as October is, up till the time of writing, quite summer-like (the glass registered over 75° in the shade for three consecutive days), the autumn flowers have come out very fine.

Of Roses, Caroline Testout, Grüss an Teplitz, Viscountess Folkestone, Killarney and Grace Darling have done best, and early in October were giving some really fine clean blooms. Asters are better in colour and cleaner than in most seasons, and are blooming freely. Rudbeckia Newmanii is much larger and brighter than ever before, and the same can be said of Helianthus Miss Melliish. Montbretias flowered well, but were rather spoiled by the wet, foggy weather. Some Delphiniums have thrown up a second crop of bloom, which is very rare for this locality. Pentstemons are extra good, as are also late Phloxes.

The dwarf Nemesises were sadly spoiled by rain, but with the warm weather have again opened quite a number of fine-coloured flowers. Dahlias are not now grown to any extent in the district, having been almost entirely superseded

by the Chrysanthemum, which seems to be specially suited to this locality. They are certainly extra fine this season, the best being Polly, Rosie, Nina Blick, Rabbie Burns, Carrie, Harrie, Market White, Lady Mary Hope, Wells White, Lillie, Blush Beauty, Claret, Roi des Blancs, Horace Martin, Crimson Massé, Maggie, Chimp d'Or, Craigmillar Park, Emily, Jenny and Orange. All these, and many others, make a wonderful display in the garden, besides being so valuable as cut flowers. Taken all round, the autumn flowers here are as fine as ever they have been at this season.

Preston House, Linlithgow.

C. BLAIR.

### DRY WALLS FOR ROCK PLANTS.

WHATEVER degree of knowledge we acquire about certain plants, either through practical work or study, the more deeply must the conviction be forced upon us that we can never exhaust their capacity for garden adornment, so much less are we likely to estimate correctly their powers to endure extremes of drought and moisture.

Many instances of a practical nature have brought this forcibly before me with regard to what are known as rock plants, and particularly in those instances where we employ them in dry walls, for in some districts this system of growing rock plants, *i.e.*, walls built of stone or brick with soil instead of mortar, is a comparatively simple operation, especially so where stone is available in good-sized pieces of moderate thickness, as, in these circumstances, fairly large courses of soil can be laid without endangering the stability of the wall, and the pockets may be correspondingly larger. Here, however, brick forms our staple building material, and such stone as I have managed to obtain lately has been uniform in shape and measurement, so that it is anything but ideal material for constructing walls for plants. However, as the event proved, success has been obtained by indifferent material, and it is quite evident that, where favoured with larger and rougher stones, dry walls have no limitation as suitable homes for beautiful and interesting plants. Of course, where retaining walls are built on dry-wall principles there is less likelihood of the plants suffering from drought, as the soil which backs the wall will always hold moisture, but it is quite otherwise when sun and air have free access to every surface of the wall structure; then it is that dry walls present the double problem of how best to supply and conserve moisture, and, in a lesser degree, it demonstrates what plants are best suited for this work.

This latter aspect I thought of the greatest importance a few years ago, but recently I have learned that the diversity of plants succeeding under these artificial conditions is much greater than I had supposed, and that the final test of

growing plants in dry walls is a practical one, namely, how and when to apply moisture.

Fig. 1 shows a small pillar in course of construction. In this instance I adopted the system of mortar bedding in the courses, but maintained a free exit for water in the joints. In these the plants were inserted, and both joints and the centre cavity were firmly packed with soil as building proceeded. The stone is of a regular thickness of  $4\frac{1}{2}$  inches, bedded level, and I think the illustration is sufficiently clear to show the method of cross-jointing, bedding and also the system of introducing soil.

Fig. 2 shows the same pillar completed and three months later; the Snapdragons form the most conspicuous feature the first season, the other plants will be more effective in future years. In both types of pillar water can be supplied at will from the top; in the moulded cap some holes are cut, 3 inches in diameter, for this purpose, while in the needle pillar the top is in the form of an open receptacle.

Fig. 3 illustrates a needle-like structure of stone some 7 feet 6 inches in height and built 18 inches square throughout; the stone varies but little in thickness, 2 inches to 3 inches forming the average. Each course is bedded in sifted soil, and, these being necessarily narrow, the stones were laid so that they dip slightly inwards to the centre of the pillar, thereby forming a cavity, which, except for an occasional stone bonding the sides together, was firmly packed with soil as building proceeded. Planting took place concurrently with building, only tiny scraps of rooted cuttings and seedlings being employed, and to this method I attribute much of the subsequent success of the work; further, this practice has much to commend it, as the roots are never broken and the plants have no difficulty in becoming established, so that steady progress is made from the start, which is, of course, impossible when plants are forced into a wall after completion.

The plants suitable for growing in pillars and dry walls are innumerable, and there appears no reason why Cerastium, Aubrietia and Snapdragon should monopolise to the exclusion of many equally beautiful and effective subjects. Among suitable dwarf shrubs we have all the forms of Cistus and Helianthemum, which latter, besides the forms of vulgare, includes a few erect evergreen species of singular beauty, such as *H. formosum* and *halimifolium*, many Genistas,

as *horrida*, *prostrata*, *pilosa*, *radiata*, and, where room can be found, *præcox* and *kewensis* are excellent. *Cotoneaster congesta* is a beautiful evergreen, and the newer adpressa promises to have merits for this work. *Olearia stellulata* is a mass of white in July. *Hypericums* are all good, and Rosemary, Rue, Lavender and Santolina are invaluable for the quiet tone of their grey leaves. I have recently planted a colony of *Artemisia brachyphylla splendens* in the wall, and the silver grey leaves are most effective when developed in full sun.

I think the dry wall is a great boon in gardens where the soil is heavy, and, consequently, many plants perish under ordinary conditions in winter; *Antirrhinum glutinosum* is an instance, though

1.—A SMALL PILLAR IN THE COURSE OF CONSTRUCTION.

Silene, Onosma, Dianthus and similar kinds all contain examples which are most reliable in a dry wall, and under these conditions their vigor is maintained from year to year and the plants give us their blossoms very freely.

THOMAS SMITH.

Walmsgate Gardens, Louth, Lincs.

### AN AUSTRALIAN DAFFODIL.

The illustration of the seedling Daffodil on page 548 is from a photograph recently sent to Mr. Hartland of Cork from Australia, and shows the success that hybridists there have attained in raising new varieties. It is a cross between *maximus* and Henry Irving, the former being the pollen parent, and was raised by Mr. L. Buckland of Camperdown, Victoria, who is an enthusiastic reader of THE GARDEN. Its well-balanced, deep yellow flowers are refined in texture and of great substance, and are borne on tall, stiff stems, which in Mr. Buckland's garden reach the height of 22 inches. It has strong, broad, blue-green foliage, which one can only hope is the outward sign of a vigorous constitution. It is a first-early, flowering with *maximus* and about two weeks before King Alfred. It is of great historical interest, as being the first Colonial-raised variety to obtain the highest award from the Royal Horticultural Society of Victoria, *viz.*, a first-class certificate, which augurs well for its future career. Unfortunately I am not able to give its name, but I will endeavour to obtain it, and if I am successful I will at once place my information at the disposal of readers of THE GARDEN, as it is just as well to keep in touch with any good variety raised in our Colonies.

JOSEPH JACOB.

### NEMESIAS IN SCOTLAND.

WHY are these lovely annuals so much neglected? They succeed well in any kind of season, and yet I fail to notice them in any but a very few gardens which I visit. This year they have been grand, both the large and small-flowered types. There can be no doubt that the latter is being wonderfully improved year by year, and this season the range of colour has been very much extended and brightened. I have had some grand deep crimsons, bronzes, oranges and pinks, besides the violets, lilacs and pale yellows that so much predominated a few years ago. In the large-flowered section I noted this year a beautiful lemon and an almost pure white. These were new to me. I have heard it said that the *Nemesias* remained for only a short time in flower, which, if true, would certainly be a drawback. Here they start to flower early in July and go right on until frost cuts them down. This applies to the small-flowered type; the other does not last quite so long. I grow Sutton's strains and find them suit my garden admirably, cold and late though it is.

Preston House, Linlithgow.

C. BLAIR.

2.—THE SAME PILLAR THREE MONTHS LATER.

# THE ROSE GARDEN.

## THE NEWER ROSES.

(Continued from page 535.)

**M**ARICHU ZAYAS (Hybrid Tea, Soupert et Notting, 1907).—This has been quite good with me. The raisers' description of the colour can hardly be improved on—soft clear strawberry cream, shaded brilliant rose. It is not a deep strawberry, but what is generally called crushed. It has a deliciously sweet perfume, and the flowers are of good size, full and imbricated rather than pointed. Altogether a good Rose that can be recommended. Vigorous growth and free-blooming.

*Marthe Bernardin* (Hybrid Tea, Guillot, 1907).—Not too good a grower and not too good a shape; a white rose with golden yellow centre, cupped shape that opens flat.

*Marquise de Sinety* (Hybrid Tea, Pernet-Ducher, 1906).—If this Rose was only a better grower, what a fine variety it would be! It is, I think, the deepest in colour of all the yellow Roses, but, I am afraid, rather tender. Deep golden yellow, outside petals tinged carmine. It requires shading if colour is to be kept. Hardly large enough for exhibition. If its constitution improves, it is better than *Le Progrès* or *Instituteur Sirdey*; but I should hesitate to say it was a better bedder than *Mme. Ravary*, and Harry Kirk will be found generally more useful.

*Marquise Jeanne de la Chataigneraye* (Hybrid Tea, Soupert et Notting, 1902). A good Rose handicapped by its name, and, like *Mme. Wagram*, particularly useful in autumn. A fine, large flower, requiring warm weather to open properly. It is very good with me as I write; white, with a good point, and a very vigorous grower.

*Mrs. A. M. Kirker* (Hybrid Perpetual, Messrs. Hugh Dickson, 1906).—I am surprised this Rose has not been more often exhibited. It is large enough, a good bright carmine in colour and grows freely.

*Mrs. Aaron Ward* (Hybrid Tea, Pernet-Ducher, 1907).—As seen under glass this was very fine, but outdoors the flowers have been very small with me, and have, therefore, been rather disappointing. It is variable in colour, but a good flower is very distinct; white outer petals, deep chrome or Indian yellow centre. Very pretty buttonhole flower, but so far not large enough for exhibition.

*Mrs. Conway Jones* (Messrs. Alex. Dickson and Sons, Limited, 1904).—This is a pretty Rose. A deeper-coloured *Bessie Brown*, but not, of course, quite so large as that variety and not so impatient of wet; it is freer flowering, especially in the autumn. I do not think the qualities of this Rose have been sufficiently appreciated.

*Mrs. David Jardine* (Messrs. Alex. Dickson and Sons, Limited, 1908).—I have already referred to this Rose in your columns, and can recommend exhibitors to try it. As seen growing it is one of the best of Messrs. Dickson's 1908 set, being a good grower, very free-flowering and with a delightful perfume.

*Mrs. E. G. Hill* (Hybrid Tea, Soupert et Notting, 1906).—This Rose is similar in colouring to *Grand Duc Adolph de Luxembourg*, but holds its head erect. A good bedder, but not often up to exhibition form.

*Mrs. Harold Brocklebank* (Messrs. Alex. Dickson and Sons, Limited, 1907).—This is a very beautiful Rose that I think highly of; delicious scent, and a fine decorative variety all the time, with an occasional flower good enough for the exhibition table. Exhibited by the raisers at Manchester and the Autumn Show. A

good grower. Colour creamy white, deepening in autumn to a soft yellow.

*Mrs. John Bateman* (Messrs. Alex. Dickson and Sons, Limited, 1905).—This Rose should be in every exhibitor's garden, as its form is so fine, seldom coming split, it is a Rose that will last when cut. The colour seems to have been much better with me this year, and I have been able to exhibit it on several occasions.

*Mrs. Stewart Clark* (Messrs. Hugh Dickson, 1907).—A Rose of similar colour, not quite so good in shape perhaps, but larger than *Mrs. John Bateman*. With me it is a tremendous grower, after the style of *J. B. Clark*; almost too vigorous, and probably would do best on a pillar. Good pointed centre and sweetly accented (above the average in this respect). Has been well shown in fine form by the raisers.

*Mrs. Theodore Roosevelt* (Messrs. E. G. Hill and Co., 1903).—Only mentioned here in case

3.—A STONE PYRAMID CLOTHED WITH BEAUTY.

there is any exhibitor among your readers who does not grow it. It has become indispensable, and will take a very high place in Mr. Mawley's Analysis.

HERBERT E. MOLYNEUX.

## ROSE BARONIN ARMGARD VON BIEL.

THIS is a grand Rose and one that has apparently escaped the notice of exhibitors. It is a seedling from Kaiserin Augusta Victoria, and is equal in form to that superb Rose, but with a colour and tinting very near *La France*. I believe it will eventually become as popular as *Mrs. Theodore Roosevelt*, a variety it resembles in all respects except colour. It is a splendid full, weighty bloom, and likely to last well on a hot day. Its fragrance, too, is very sweet. There is no doubt that Kaiserin Augusta Victoria is a fine Rose to breed from, and it is strange it yields so many pink seedlings.

# THE GREENHOUSE.

## EARLY TULIPS FOR POTS

**V**ERY much that I said about Daffodils for borders holds good with regard to single Tulips for pots. Any of them may be selected from a catalogue according to the fancy of the buyer and grown with an almost certainty of success if—and this is an important "if," for the beginner especially—they are not required to flower too early. It is difficult to get satisfactory results in January, but it is comparatively easy to do so in February, and easier still in March. Of course, some varieties, considered as effective decorative flowers, are better than others, and hence a list may be of service to those who are not very familiar with all the different sorts. Again, some are more suitable than others to bring on as first earlies, and these will be marked "early" in my descriptions.

With regard to double Tulips, many are exceedingly effective, and make a desirable change from the singles; and, with the same proviso about early flowering emphasised, they are just as easy to manage. I wonder sometimes why more of them are not grown, and can only surmise as the reason that the charm of their disordered petals and the length of time that they last in flower are not known.

These are not cultural notes, but I would, all the same, like to add a little advice to what I have already said. First, that an important point is to allow adequate pot room. Three bulbs in a 6-inch pot and five in an 8-inch is what I recommend. And secondly, that as the long, fine roots are produced in great abundance, they want plenty of water when they are in active growth; but care must be taken to have good drainage, as if waterlogged the buds turn yellow and eventually wither.

The small *Duc Van Thols*, of which the all-scarlet is the best and most popular, are a distinct type, and these may easily be flowered early in the year if they are well rooted before being brought into heat. I have divided my list into two parts, viz., veterans and new recruits. There are a certain number of early single varieties which seem to have crystallised from the general mass to form an inner circle from which pot varieties are almost invariably chosen. These are the veterans. They are all good, and my selection must not be taken as exhaustive. The new recruits contain the names of some of the lesser-known older sorts, a few of the newer ones and a proportion of striped and edged flowers, as I consider many of these types very beautiful and worthy of much more extended cultivation.

## VETERANS.

*Singles* *Alba regalis*, strong grower with beautiful frosted-looking leaves and creamy white flowers, splashed and speckled with fascinating bits of orange and carmine; scented. *Cottage Maid*, rather dwarf, pretty pink flowers edged with white. *Duchess of Parma*, a most reliable Tulip with long orange red flowers borne on tall stems. *Keizerskroon* (early), a large red with a broad margin of yellow round each petal; a robust grower. *Le Matelas* (early), a beautiful Tulip; a sort of deeper-coloured *Cottage Maid*. *Prince de Ligny*, a long, elegant-waisted, deep yellow flower; an uncommon shape in the early-flowering section. *Prince of Austria*, an exquisite shade of orange brick red; the flowers are borne on long wiry stems and are deliciously scented. A "Tulip of Tulips," President

Lincoln (syn. Queen of the Violets), a pleasing shade of pale violet; rather late. Proserpine (early), large globular flowers of a lovely rose-carmine, and a popular favourite. Vermilion Brilliant (early), a real bright scarlet; unsurpassed for pots. White Pottebakker (early), a fine reliable pure white. Yellow Prince, dwarf pale yellow, very sweetly scented; a good contrast to Prince de Ligny and all other yellows.

*Doubles*: Couronne d'Or, yellow flushed and tipped old gold. Imperator Rubrorum, fine large crimson self; the flowers are carried on good stiff stems. Murillo, a very popular and reliable Tulip; bluish white, which deepens to a pleasing rose with age. Premier Gladstone (syn. Gladstone), a beautiful rose self; full flower. Princess Beatrice, delicate rosy pink flushed with white. Tournesol, red, edged yellow, very bright and gay-looking; the earliest double to flower.

#### NEW RECRUITS.

*Singles*: Admiral Reinier, red and white striped; one of the best of this combination. Brunhilde (syn. Unique), pure white with a flame of gold on each petal; a very taking flower and a robust grower. Cerise Gris-de-lin, cerise, with a broad edge of ochre yellow; it is the unbroken form of Spendonck; but little known, or it would be much more popular. Couleur Cardinal, a late-flowering variety, which, although probably best outside, lends itself very well for late pot work; it has a fine erect habit with deep rich crimson flowers and a plum coloured shading on the outside of the petals. Globe de Rigint, a tall showy purple-violet with white feathering; may be called an early-flowering hyblemen; good for late pot work. Golden Bride of Haarlem, a particularly bright little flower of a brilliant crimson-red, striped and flaked gold. Grace Darling is a large crinkled globular flower of a rich orange scarlet, with a sort of bronzy flush on the exterior of the petals; a robust grower. Golden Lion of Hillegom, a glorious combination of sunset shades of orange, scarlet and gold; long pointed flowers; its weakness lies in its stem, which lacks strength to hold the bloom. Jenny, my favourite Tulip for pots; it has a stiff, sturdy habit and the flowers always keep their shape, even in old age; its colour is a beautiful cherry rose with a creamy base and creamy flames on the exterior of the petals; most deliciously scented; lasts a long time in good condition. La Remarquable, rich plum with a broad, pale primrose margin to the petals. A most distinct flower of the very oldest type of colouring, such as we get in the "Laes," Le Rêve (syn. American Lac or Hobbema), an art-shaded Tulip, salmon rose, blended with orange in imperceptible gradations; enormous flower; strong sturdy grower; it is historically interesting on account of the sudden rise in its price about 1901, when in a single season it quadrupled its value. Queen of the Netherlands, a queenly Tulip indeed, tall and stately and yet of the most refined and delicate blush white colouring; a shapely flower. Spendonck, rosy red markings on a buff ground, with a salmon flush over the whole bloom; a dwarf, sturdy grower and very distinct.

*Doubles*: I must mention just two, viz., White Murillo, a grand pure white, not too full, and with the centre petals rather tending to form a distinct middle, round which the others are irregularly arranged (no Paeony could be more charming); and Safrano, a lovely Tulip of the colour of a deep Maréchal Niel Rose; exquisite for ladies' dresses; with age it becomes flushed with rose.

JOSEPH JACOB.

#### LANTANA SALVÆFOLIA.

THIS Lantana readily lends itself to various methods of treatment, and though the blossoms are not so brilliantly coloured as in the case of some of the garden varieties, it is certainly by far

have experienced. A mass of this Lantana in full flower suggests at a little distance, at least in colour, one of the darker-tinted Heliotropes. H. P.

## COLOURED PLATE.

PLATE 1360.

#### THE LYON ROSE.

THIS beautiful novelty is a triumph of the hybridist's art, and it practically commences a new race or group, which the raiser has termed *pernetiana*. All who have studied Roses and their cross-fertilisation have been impressed with the possibilities awaiting development by the employing of species and varieties of very opposite affinities.

It is generally known that M. Pernet-Ducher produced his Soleil d'Or by crossing the Hybrid Perpetual Antoine Ducher with a variety of *Rosa lutea*, known as Persian Yellow. Soleil d'Or is a splendid Rose of an orange gold colour with a reddish centre. By using the pollen of this Rose the raiser has produced a number of remarkable coloured seedlings, and it is from the pollen of one of these seedlings that the raiser fertilised the Hybrid Tea Melanie Soupert. The result is seen in the superb Rose represented in the coloured plate.

The Lyon Rose will undoubtedly become a popular favourite, for it combines in itself all the attributes that go to the making of a good Rose, namely, colour, form, vigour, free flowering and fragrance. To describe its colour one needs the aid of the colour chart of the Royal Horticultural Society. The raiser calls it shrimp pink, with coral red centre and shaded with chrome-yellow. It is a wonderful tint, one that catches the eye immediately; but it will need careful location so that other Roses do not "kill it."

I have seen the Lyon Rose so badly grouped this season that its grand colour was not accentuated as it should have been. Unless a bed of it can be planted, I would suggest that either white or deep crimson Roses be placed on each side. The buds are not specially beautiful, but they open into large, full and somewhat globular blooms of very symmetrical form. The Hybrid Tea characteristics of free flowering have been imparted, although the flowers are not produced in large clusters such as this tribe is noted for. No one can mistake the relationship of the variety to the Briar family. The growths with their greyish colour and reddish prickles proclaim this fact. As a standard it will be splendid, making a fine spreading head such as one admires on a standard Rose.

For forcing purposes, especially in a cool house, the Lyon Rose will be a welcome addition, and it has remarkable staying powers, which will make it valuable for culture under glass. It is being sent out this season by Messrs. H. Merryweather and Sons, Limited, Southwell, Notts (who kindly supplied the flowers from which the accompanying coloured plate was prepared), and by Messrs. Hugh Low and Co. of Enfield, Middlesex. P.

A NEW DAFFODIL FROM AUSTRALIA.

the most popular of all the Lantanas in cultivation. Under the name of Lantana delicatissima it is to be met with in nearly all parks and gardens where summer bedding is carried out, being largely employed in the beds of mixed subjects now so much in vogue. For this purpose it is occasionally grown as standards, but more generally in the shape of loose pyramids, for, being of a semi-pendulous habit, it is very pleasing when grown in this way. Under these conditions the slender branches, partially drooping towards the tips, are thickly studded with compact, rounded clusters of deep lilac-coloured flowers, their tint varying in intensity according to the amount of exposure and sunshine they

## TREES AND SHRUBS. THE FRUIT GARDEN.

## ELÆAGNUS MACROPHYLLA.

**T**HIS large-leaved species belongs to the evergreen section of the genus, and is quite distinct in every way from others. It forms a large, dense bush, with ovate leaves 2 inches to 3 inches long, silvery on both surfaces when young. The upper surface of the young leaves is covered with coarse, greyish hairs, which disappear to a great extent with age. The branches in a young state are bright brown in colour, and the under-sides of the leaves and their margins are plentifully sprinkled with small dots of the same hue. The flowers, which are generally borne singly from the leaf-axils, are small, white and very fragrant, their presence being noticeable from a considerable distance during late autumn, which is the blossoming period. Like the other species, this Japanese plant thrives in light loamy soil, grows well and quickly forms an ornamental specimen. It may be increased from seeds or cuttings, but is frequently grafted on to stocks of commoner sorts. For beds, isolated specimens or groups in the shrubbery it is equally desirable; for either purpose, however, it should be planted in permanent quarters while young, as it does not transplant well after it has attained a considerable size. W. D.

## HINTS ON PRUNING CLEMATISES.

PERHAPS no phase in the culture of these beautiful climbing plants is less understood by amateurs than the pruning of the many varieties that now exist, yet the operation is comparatively simple when we know to what section a variety belongs. Clematises are grouped into six main divisions or types, viz., *montana*, *patens*, *florida*, *lanuginosa*, *Viticella* and *Jackmanii*. Plants belonging to the first three sections flower on the old wood in late spring or early summer, and very little pruning will be needed for these, all that is necessary being to thin out old, worn-out wood and leaving the vigorous young shoots their full length. The best time to prune these is November.

The *lanuginosa* section is one of the most beautiful of all, the flowers being produced on short shoots that emanate chiefly from vigorous shoots of the previous year. Pruning of this section is best done in February, shortening last year's shoots back one-third or one-half of their entire length. The *Viticella* and *Jackmanii* varieties flower in autumn on wood that is produced during the summer, and these are best pruned to within a few inches of the ground in early spring, so as to encourage the formation of vigorous growths from the base.

The training of these plants is frequently much neglected, the shoots being in very many instances allowed to look after themselves and twine their leaf-stalks around each other at will, the result at the end of the summer being a tangled mass that is exceedingly difficult to deal with. Attention should be given to the work of training during the growing period, thinning out all weak growths and thus giving the vigorous shoots the full benefit of the sun and a free circulation of air. I have been asked so often questions as to the pruning of Clematises that I thought the above information would be most welcome. The family is split up in many groups, and all are beautiful. D.

## APPLE CULTURE IN DEVONSHIRE.

**S**OME attention has recently been drawn in the public Press to the general neglect of Apple culture in this country and to the extension and improvement of which, with proper care, it is capable. There is no denying the fact that the fruit produce of this country ought to be considerably larger than it is, and especially so with regard to the Apple. In all parts of England, more or less, the orchards do not receive the attention in pruning and cleaning they ought to do, the result being not only diminished crops, but an untidy and uncared-for appearance.

In this county, noted as it is for its cider and, consequently, for its Apple produce, the orchards are, as a rule, the most neglected part of farm lands. The Apple trees, generally, are left to look after themselves, except at the time of fruit-gathering. They are

covers one side of the house, to push its way through the window frame into one of the rooms, where it is now growing on one of the internal walls, and, apparently, will grow on unmolested.

But to return to the Devonshire Apple trees, it is satisfactory to learn that the agricultural committee of the Devon Education Authority has recently had an offer of some 300 trees of different varieties of Apple from the National Fruit and Cider Institute, and it is proposed to plant 200 of these on a farm at Howton, near Newton Abbot, and the remainder at different centres in South and North Devon. The secretary of the Education Authority explained that the numbers and varieties of the trees were arranged by the director of the National Fruit and Cider Institute, and in order to get a proper blend for cider-making he had taken eight trees each of a sweet, bitter-sweet and sour variety, making twenty-four in all, to each experimental ground.

It is to be hoped that this will bring renewed interest to the Apple culture, and promote the growth of the Devonshire cider industry.

*Lympstone, Devon.*

JOHN R. JACKSON.

THE OLD ORCHARD OF BRAMLEY'S SEEDLING APPLE IN MESSRS. MERRYWEATHER'S NURSERY AT SOUTHWELL.

of all kinds of shapes, and the trunks and branches usually bear a thick coating of grey lichen. It seems never to enter the minds of owner or tenant to prune and clean, any more than it does to stop the growth of Ivy from completely enveloping the trunks and branches of timber trees either on roadsides or in hedges or fields.

Whether this state of things is due to absolute neglect or to an inherent dislike to pruning or removing any clinging plants, however beautiful, it is difficult to say. Many years ago I knew a lady living at Fulham in a house surrounded by large grounds in which were some fine trees. Close to the dining-room windows grew some large spreading Cedars which shut out almost every gleam of daylight, and, moreover, in high winds the branches lashed against the glass, which was being continually broken; but she preferred to keep the glazier employed, and to endure the darkness and want of fresh air, rather than to remove or shorten the offending branches. Another lady in the neighbourhood has allowed the Ivy, which

## HISTORY OF BRAMLEY'S SEEDLING APPLE.

THE splendid variety we illustrate from a photograph taken in Messrs. Merryweather and Sons' Nurseries at Southwell was a chance seedling there. Two Apple pips were put in a small pot: both grew, but one of them eventually died. The other one developed into a large tree and became the parent tree of the now wonderful variety.

The sowing of the seed and the planting of the tree were done by a Miss Brailsford, originally of Easthorpe, Southwell. This lady died, or left the town, and sold the garden, including this Apple tree, to a certain Mr. Matthew Bramley, a butcher in Southwell. The tree by this time was developing into full bearing, and eventually Mr. Merryweather's attention was drawn to it. Mr. Merryweather soon recognised its great merits, began to develop a stock of it and eventually sent it out. It got "highly commended" in 1876 and a first-class certificate in 1883.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**CHRYSANTHEMUMS.** — To maintain the plants in good health avoid a too close condition of the atmosphere in the glass structure. Ventilate without creating a draught on every favourable occasion. On damp, foggy days less air should be given and the lower ventilators opened, so that the air is

1.—A TYPICAL SIDE SHOOT OF THE YELLOW BEDDING CALCEOLARIA SUITABLE FOR MAKING A CUTTING.

warmed as it passes the hot-water pipes. Water very carefully. Brooms that give evidence of damping should have the decaying florets removed by the aid of forceps or tweezers, pulling out each floret at its base.

**Trees and Shrubs.** — The present is an excellent period in which to deal with evergreen trees and shrubs. Any that require to be lifted and replanted should be taken in hand at once. I prefer autumn planting for these subjects, and usually begin in the latter half of October, completing the operations by the middle of November, or thereabouts. Unless the replanting can be done during the above-mentioned period, I find it better to leave this work until the succeeding April. Should warm or dry weather succeed the planting, it is a good plan to syringe the plants frequently. Deciduous trees and shrubs may also be moved now with perfect safety.

**The Hardy Flower Garden.** — The planting of bulbs should be completed within the next ten days or so. In most gardens there is a surplus of Daffodils and other bulbs. I make good use of the former by planting them in the orchard, where, under Apple and other trees, they make a beautiful display in the spring. Crocuses and Snowdrops may be used in similar fashion with considerable success. Make good use of every dry day to get the hardy flower border into good condition. Many of the plants will be better if they are lifted and divided, and by these means it should be possible to plant in groups the

different kinds that were formerly represented by just one or two plants.

**Orchids.** — Blinds that have been so useful during the past summer and early autumn to screen the plants from the direct rays of the sun, may now be removed and stored away until another season. They may be required, however, during spells of severe frosts for covering the glass at night.

**The Greenhouse and Conservatory.** — When these structures are not being used for the purpose of flowering the Chrysanthemums, I make it a rule to go through the whole of the occupants, making everything clean and tidy before the wintry weather sets in. Not seldom the different subjects are unduly crowded together, so that the appearance of these structures is far from pleasing. Dirty pots, walls and benches should be made thoroughly clean and the plants be disposed tastefully throughout. Fuchsias, particularly large plants, must now be kept almost dry at the roots. Weak wood and dead and decaying leaves should be cut out of roof climbers. For early winter displays I am potting up imported roots of Lily of the Valley. I use selected single crowns and clumps, potting up these in either 5-inch or 6-inch pots. This subject flowers satisfactorily when grown in leaf-mould and loam, with just a dash of coarse silver sand to assist the drainage of these soils. Afford ample drainage for each pot.

D. B. C.

## HOW TO PROPAGATE THE BEDDING CALCEOLARIAS

YEARS ago the bedding or shrubby Calceolarias were more popular and were grown more extensively than they are to-day. They are free-flowering and easily-managed plants, and they are increased and perpetuated with comparatively little trouble. The shrubby Calceolarias are varieties of *Calceolaria rugosa*, a species of Chilean origin. These bedding types are somewhat tender, and need the protection of a cold frame during the winter. They are raised quite easily from cuttings in the autumn months, also by the aid of a hot-bed in the spring season. To increase and preserve the plants, the use of a cold frame is imperative. The work should have been done in October, but it is not too late now if it is carried out at once. The preparation of the soil in the cold frame is a matter of some importance, and therefore should be done well. Light, sandy soil is what this subject will root in very readily, and this can be prepared by sifting good heaps of loam, leaf-mould and sand in equal quantities, subsequently mixing these thoroughly to ensure an equal distribution of each. We pass our soils through a sieve with a half-inch mesh, this being quite fine enough. The prepared soil should be at least 6 inches in depth all over the bottom of the frame, and this should be spread evenly all over, levelled, and made quite firm by using the back of a spade or by the aid of boards and these trodden over. To complete the cutting-bed a layer of coarse sand should be evenly distributed over the surface soil. A few hours before it is proposed to insert the cuttings, the soil in the frame should be well watered, using a fine-rosed can for the purpose.

Our next concern is to know what kind of growths to procure from which our cuttings are to be made. As the yellow and dark varieties differ in their character, we have thought it better to illustrate both. Fig. 1 is a good example of the kind of shoot to procure for the purpose of making a cutting. This is the yellow

variety, which is certainly the less tender of the two, being really more "shrubby" in its character than its dark-coloured companion. Note the sturdy, vigorous character of the shoot, which has just been detached from the old stock plant. Fig. 2 represents a typical growth of the dark-coloured bedding Calceolaria. These growths are really the side shoots of the old plants.

The next consideration is, how are cuttings prepared in readiness for propagation? This is a simple enough matter. A good, sharp knife is essential, and assuming this is available, shorten back the growths to about 3 inches to 4 inches. The lower leaves should be trimmed off close to the stem of the cutting, and the latter cut through immediately below a joint. This treatment of the shoots completes the preparation of a cutting. Fig. 3 portrays a prepared cutting of the yellow variety. This is about 3 inches long and is trimmed of its lower leaves and cut through below a joint as advised above. Fig. 4 reveals the growth of the dark-coloured variety made into a cutting. These last-mentioned cuttings, as a rule, are rather larger than those of the yellow variety, and are more often made 4 inches long.

The preparation of the cuttings of this stronger-growing variety is very similar to that of the other shrubby sort. Insert the cuttings in rows in the cutting-bed, observing a distance between the cuttings of the yellow sort of from 2 inches to 3 inches, and in the case of the other variety fully 3 inches or rather more. The rows should be quite 3 inches apart, and, if there is

2.—A SIDE SHOOT OF THE STRONGER-GROWING BROWN-FLOWERED BEDDING CALCEOLARIA.

ample accommodation, allow more space between the cuttings in the rows. We have to remember the lifting period in the succeeding spring, and sufficient space must be left to do this comfortably.

When inserting the cuttings, first make the hole with a blunt dibber, then insert the cutting, allowing the base to rest on the bottom of the hole, and by the aid of the dibber

3.—A CUTTING OF THE YELLOW BEDDING CALCEOLARIA PREPARED READY FOR INSERTION.

press the soil firmly to the base of the cutting. Assuming this has been done in proper fashion, the cutting should be secured firmly in position, and this must be done in every individual instance. Give the bed of cuttings a good watering-in by the use of a fine-rosed can and then cover the frame with the light. Keep the frame close for a week or more, shading the same for an equal length of time. Subsequently, when the cuttings assume a fresh condition, shade during bright sunshine and admit air daily. Protect the occupants of the frame when frosts prevail by covering with mats, &c., and by placing littery matter round the sides of the frame as an extra protection.

#### A FEW HINTS ON FORCING BULBS AND PLANTS.

Good bulbs and plants may soon be spoiled through mismanagement while they are being forced. Inexperienced persons very often fail to water the bulbs directly they are potted, and so plunge them in the comparatively dry soil, under a bed of ashes. Bulbs so treated are slow in beginning to grow, and when the roots are formed they lift the bulbs partially out of the soil, because the latter is not set firm enough around them, owing to the neglect to water them at the time of potting. So you must give a thorough watering immediately the bulbs are potted, then the new growth will be free and even.

*Removing Bulbs from the Ashes.*—The new growths should be about 2 inches long at the time the pots are taken from the ashes. It is a mistake to remove them earlier, as also to leave them for a longer period. If empty, inverted flower-pots be placed over the newly-potted bulbs, the covering material will not come into contact with the new growths.

*Exposing the Bulbs and After Treatment.*—When taken from the ashes or sand, the bulbs should be placed in a frame. For three days leave the empty pots on them and, in addition, put a mat on the glass; then remove the empty pots, and three days afterwards take off the mat. The bulbs will now be ready for placing in the forcing-house. During the first week keep the temperature at about 58° by day and 50° at night. When the spikes show signs of growing freely give 10° more heat.

*Feeding.*—Weak doses of soot-water, liquid manure or artificials should be given to assist the growth of the flower-spikes. Cease applying stimulants when the flowers are about three parts developed.

*Roses*—If the plants are lifted and potted this autumn, they should not be placed in a forcing

temperature before next spring, in order to get the very best returns from the plants. Established plants in pots will withstand forcing best, and these should be the ones to force first. Keep the plants outside, but have the roots well protected from frost by packing dry litter or leaves around them. Teas and Hybrid Teas should have the protection of a cool frame if one be available.

*Azaleas.*—It is very important that the ball of soil be kept moist. These plants, too, should be kept in cool frames, from which they should be taken to the forcing-house. Do not give the plants any manure water before the flower-buds commence to open, else the buds will drop off.

*Lilacs.*—These plants may be forced soon after they are potted. They should be placed under a stage or in a Mushroom-house, kept in darkness, and syringed daily until the flowers are developed. A rather high temperature and moist atmosphere are necessary until the flowers open. Then the plants should be gradually exposed to the full light; but it is advisable to shade them from the sun's rays. Only clear water is needed. Do not expose the plants to cold draughts.

AVON.

#### SNOWDROPS IN GRASS.

THE amateur who possesses a healthy grass plot can produce a beautiful effect thereon in early spring, and at very little expense, by planting now bulbs of the common Snowdrop, which is such a universal favourite with all. Even where the grass has to be mown at a comparatively early date these bulbs may be planted, because their growth is usually finished before mowing need be done in the spring. The one thing to avoid above all others is a formal design; plant in irregular clumps with a stray bulb or two, forming a sort of connecting link between each cluster of bulbs. Where beds of standard Roses or other shrubs are present in lawns, Snowdrops may be planted under them to great advantage. When planting these bulbs in grass it is far the best to lift a good square of turf, then well loosen the soil beneath, and if it is lacking in plant food incorporate with each square yard a good handful of finely-ground bone-meal. After the bulbs are inserted the turf can be replaced, and the whole made snug and tidy for the winter. The pretty little Winter Aconite (*Eranthis hyemalis*) is also a splendid subject for planting in grass at this period.

4.—A CUTTING OF THE BROWN BEDDING CALCEOLARIA READY FOR PLANTING.

## THE TOWN GARDEN.

*LAYING TURVES.*—One of the easiest and best methods of renovating lawns which have become patchy through constant wear is to cut out the bad sections and lay down new turves. There is, of course, one obvious disadvantage in this, and that is the trouble experienced in procuring turves which are free from weeds; but if this can be ensured, then the work should be put in hand at once. It may be done at any time during the winter, but if they can be got in position now it is far more likely that they will have grown together perfectly satisfactorily by the time the lawn is required for regular use again next year. The first thing is to procure the necessary turves, and the second is to cut out the patches; this must be done with care, and if the soil beneath is poor it is excellent practice to dig it fairly deeply, incorporate some good decayed manure with it, and make the soil as firm as the surrounding area before the turves are put in place. These must join closely up to the grass on all sides, and some fine soil should be worked in round the edges; this completed, beat the whole down firmly and the operation is finished. If the turves were cut about 1½ inches thick and well beaten down on to good soil, the plants will soon make a fresh start, and it will scarcely be possible to see where the patches have been put in the spring.

*BASIC SLAG FOR LAWNS.*—Although the principal feeding of grasses on lawns is put in hand in the spring when growth is recommencing, it is possible to do much good by starting the operation now. Amateurs who fully appreciate the fact that grasses demand food just as the plants in the borders do are the people who achieve the most satisfactory results, and one of the simplest ends to this is to dress the entire surface of the grass during the present month with basic slag. It is extremely slow in yielding up its food virtues; hence the necessity for autumn application if full value is to be derived. The precise amount of the dressing must obviously depend upon the condition of the grass and the feeding that it is proposed shall be done in the spring, but one may safely use 6oz. to the square yard, while in many cases 8oz. will not be too much. In all points of this nature it is essential that each grower shall use his own judgment, bearing in mind that over-feeding is as bad as the reverse.

*HARDY PLANTS.*—The planting of these should be pushed forward with all speed, as the end of the month may bring weather which will render it impossible for anything to be done of this nature for many weeks, or even months. As has been previously advised, the soil must be deeply and thoroughly cultivated, and some good manure should be put into the second spit, the planting being done firmly in all cases, and only when the soil is in a suitable condition for working. Practically all kinds may be dealt with this month.

*ROSES.*—There is no need to reiterate the fact that these are by no means the most satisfactory plants for the town garden, in which there is commonly a deficiency of light and air and where the drainage is almost invariably excessive. Notwithstanding this fact, it is certain that amateurs will continue to endeavour to grow them, and they will find their reward in occasional gratifying successes. This month of November is the best that can be chosen for planting the Hybrid Perpetuals and the Hybrid Teas, but I would recommend the Teas being held over until the spring, as the percentage of losses in the first winter after autumn planting is often considerable. The soil must be deep and in good heart, and if it is possible to mix in a large proportion of strong, new loam the chances of success will be immeasurably increased. Lay the roots out to their full extent and work new soil firmly between them.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### HARDY FRUIT GARDEN.

**THE BLACK CURRANT MITE.**—This, commonly called big bud, is causing much anxiety, and therefore steps should be taken, wherever it is present, to combat it, either by rooting up the trees and burning them or, if they are not very bad, by picking off now all affected buds and burning them. These buds contain quantities of whitish mites, which feed upon the embryo leaves and flowers. After the buds have been picked off, throw a quantity of lime under the bushes and spray thoroughly at intervals in the spring with alkali wash. New plantations should be made as soon as possible of all Currants and Gooseberries, and pruning of these bush fruits may be started.

**Apples and Pears.**—Finish planting these as soon as possible, and get them tied or nailed in position to protect them from damage by wind.

**Peaches and Nectarines.**—These may be transplanted now, taking care to secure a nice ball of earth, and well ram the soil when the trees have been replanted.

#### FRUITS UNDER GLASS.

**The Early Vinery.**—The Vines may be pruned now if all the leaves have fallen. Cut the spurs hard back to two eyes. Clean the house thoroughly by washing the glass and woodwork with warm water and paraffin soap. Afterwards the Vines may be painted with XL Insecticide, and, if dirty, this operation may be performed several times before the Vines are started into growth. If mealy bug is present, more drastic remedies must be employed—the Vines should be scrubbed and all the loose bark taken off, and on bright days the rods be carefully looked over, using a small brush and petroleum or methylated spirit, as these pests can be seen crawling about on sunny days.

**Peaches and Nectarines** in the early house may be similarly dealt with, and, when the house is clean, finish off by whitewashing the walls with hot lime into which a handful of sulphur has been placed. This gives off fumes very distasteful to red spider in the spring. Prepare soil for top-dressing both vineries and Peach houses.

#### FLOWER GARDEN AND SHRUBS.

**Rhododendrons** may be planted now, choosing nice snug positions for early varieties. There are some Rhododendrons that flower in the beginning of the year when frost is not severe. *R. nobleanum* is often in flower in January, and *R. præcox* and *R. ciliatum* are most charming early varieties and look well in beds or borders.

**Roses** may be now planted. Do not allow any to remain out of the ground longer than is necessary; cover over the roots at once, and if any come in from the nursery it will be well to dip the roots in water and syringe the bushes as soon as planted. Existing Roses that are not satisfactory may now be taken up, the beds retrenched and some good loam added.

#### KITCHEN GARDEN.

If the hot-bed have been made as recommended, some Asparagus may now be planted in frames. Put about 3 inches of soil over the hot-bed, then place the crowns as thick as possible, put over about 3 inches of fine soil and give a good watering to settle it. Put the lights on and tilt them up at the back to let off vapour. Rhubarb and Seakale can now be put into a dark room or Mushroom-house, either in pots, boxes or in a border. W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)

Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CARNATIONS.**—The early batch of winter-flowering varieties will now be commencing to flower. Before the buds open, those which show any sign of splitting at the calyx should each have a small indiarubber ring slipped over it ready to be drawn up slightly over the base of the calyx when the flower commences to open. Winter Carnations are amenable to a little forcing, but are best when kept rather cool, a night temperature of 55° being sufficient to keep them going. A gentle circulation of air should be given to prevent too sappy or flabby growth. Watering must be done with care.

Where the roof of the greenhouse or conservatory is at all thickly covered with climbers of any kind, the growth of these ought to be reduced as far as possible at once. It is impossible to grow flowering plants of any kind successfully during the winter season where the roof is darkened to any extent by climbing plants.

#### FLOWER GARDEN.

**Planting Irises.**—In gardens where cut flowers are needed during May and June, the English and Spanish Irises are regarded as indispensable. I like to get my bulbs in during the early part of November, as by keeping them light and the blooms are in consequence smaller. I plant on both a west and north aspect, and thus prolong the season. Many of the mixed varieties of Spanish Irises, as well as the named self-coloured sorts, are exceedingly beautiful, rivaling the choicest Orchids. The English Irises flower about a fortnight later than the Spanish section, a great advantage where a succession of flowers is wanted. The present is a capital time to plant that beautiful little gem, *Iris reticulata*. This is exceedingly hardy, blooming in the keenest spring weather and possessing a fine aroma not unlike Violets. It is most useful for forcing in gentle warmth, and then comes in for mixing with small Ferns in baskets for the drawing-room or dinner-table.

**Summer-flowering Chrysanthemums.**—I have never known these to be so satisfactory as they have been this year. For brightening up our shrubberies and borders at this season nothing can surpass them; cuttings of these ought now to be taken off and rooted—five or six in 3-inch pots—using good sandy compost. These will strike readily in a cold frame, in which they may be wintered.

#### KITCHEN GARDEN.

**Autumn-sown Onions.**—The first time the ground becomes fairly dry, go over the autumn-sown beds and firm them well, as if much frost catches them when in a loose condition it injures the young bulbs, especially on heavy soils. Before firming these, run the Dutch hoe between the rows and remove all weeds, drawing a narrow rake through them after firming is completed. Apply soot and wood ashes in equal parts, as, although the grub does not usually attack the bulbs at this season, by incorporating this mixture with the surface soil there is less liability of attack during March and April.

#### HARDY FRUIT.

**Wall Trees.**—Usually at this time of the year the days are fairly warm; therefore any work that can be done with comfort should be pressed forward as much as possible. We often find the work of pruning and nailing left till frost sets in, but no greater mistake can be made. Where Pear trees are affected with scale the branches should be scrubbed with an old brush, using Gishurst Compound or some other well-known insecticide. T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the 'Answers to Correspondents' column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Lilium candidum not seeding** (*Lilium*).—The Lily in question in this country seeds but sparsely and only occasionally, and out of thousands of plants not a seed-pod has been seen for years. There is, as you say, abundance of pollen produced, but the plenitude of the pollen is of far less importance in such cases than is its fecundity. The pollen grains of most Lily species are of a coarse nature as a rule, and artificial pollination might be better achieved by your collecting the pollen in a small box or phial, the former preferred, and exposing it in a warm room for a day before applying it. In this way and by repeated attempts, assuming always that the stigma is in the receptive stage, you may presently attain your desires. If you merely wish to obtain seeds of the species referred to, you have not much to gain, as the plant is easily increased from scales; but if you are experimenting at cross-breeding the case is different. *L. testaceum* is said to be a cross between the above species and *L. chalcedonicum*.

### Androsace sarmentosa in winter and treatment of Banksian Rose

(*C. E. B.*).—You will be able to winter *Androsace sarmentosa* quite well in the open if you cover it with a sheet of glass, elevated about 5 inches or 6 inches above the plant, so as to throw off rain but to allow plenty of air. If you prefer, however, you can lift and winter it in a frame or greenhouse, but it must have plenty of air. *A. lanuginosa* would have wintered with the same treatment. You can divide the tufts, but this should be done now, when the plants may also be lifted. It is best to put the tufts at the ends of the runners in small pots separately. The Banksian Roses are not everywhere good bloomers, and the method of pruning which is found most satisfactory is merely to thin out the dead wood and to shorten slightly the long, strong shoots, the flowers coming from the laterals or side growths. Even with this treatment it is a shy bloomer with many.

**Sweet Peas for inspection from Hampstead** (*E. G.*).—The flowers sent were very small, although, of course, most welcome at so late a date. There is nothing unusual in being able to gather flowers from these plants for four months; but considering your locality, we think yours have done very well indeed. Try and do them even better next year; then perhaps you will get more threes or even some fours.

**Plants for tree trunks** (*Ge.*).—We have no Fern in mind that would be likely to succeed in the position you name, and would rather suggest planting *Yucca recurva* for the purpose. Other useful subjects would include *Megasea cordifolia purpurea*, *Cotoneaster microphylla* and *C. horizontalis*, while the common Sabine (*Juniperus Sabina*) would also prove a most effective plant. All those named are perfectly hardy and far more likely to succeed in the position indicated than any member of the Fern family.

**Chrysanthemum leaves failing** (*E. J. W.*).—It is somewhat difficult to say definitely the cause of the leaves of your Chrysanthemums failing. We think that the trouble is to be attributed to overwatering. It is quite a common failing with growers who appear to possess a desire to treat their plants in too generous a

fashion, in consequence of which they naturally resent a surflet of good things, and their leaves are of no further service to them. Water your plants more cautiously in future, and never apply water in any form unless the soil is dry.

**Dividing *Yucca filamentosa* (*Alpines*).**—The best time to divide a clump of *Yucca filamentosa* is in late spring. The whole plant should be taken up carefully without breaking off the somewhat long roots, then the different stems should be separated with a sharp knife and not merely torn apart. After planting again they must be shaded for a time and syringed occasionally to keep them from flagging. With reference to *Ethionema grandiflorum*, it would be wiser to keep the young plants as they are in the cold frame during the winter, and plant them out in March or April, choosing a hot, sunny ledge, and using a compost of gritty loam with a good depth of soil and perfect drainage.

***Iris Kempferi* for pots (*L. S.*).**—The members of this group are not usually grown in pots, but if so grown should be treated exceedingly well. For the winter, and while the plants are at rest, the pots should be removed from the water and either plunged in the open garden or placed in a frame or pit. Drying off, as this term is usually understood, would be most harmful, and the removal of the plants from the water will afford them rest enough. Early in April next, or in March, give the plants a shift into pots two sizes larger than the present ones, removing a good deal of the old soil and giving a fresh supply of rich material in its place. Weak liquid manure may be applied to plants in full growth; but if you repot the plant as suggested, it will not, if the pot is immersed in water, require any stimulant of this kind following the repotting. You do not say what the size of the plant is or whether it has flowered.

## TREES AND SHRUBS.

**Fungus on Beech tree (*W. Caird*).**—The fungus upon the Beech tree is *Polyporus squamosus*, one of the commonest of the "bracket" fungi. The bracket-like outgrowths which are so conspicuous in this case are formed annually, and are the fruit of the fungus, the vegetative part, or mycelium, of which lives inside the tree, feeding upon the wood and causing it to rot. If the fungus has been growing for long on the tree the mycelium has probably spread for a considerable distance in the wood, and will be very difficult, if not impossible, to destroy. The only thing that can be done is to cut out the affected part to the depth of 1 inch around the healthy wood and paint the wound with Stockholm tar. It is very important that old wood should be removed from trees and that all wounds, however caused, be painted, for it is through unprotected wounds that fungi such as this first gain an entrance. All the fruits of the fungus should be destroyed by fire. If the trouble is old-standing it is probably too late to do much to save the tree, since the cutting would have to go too far, but the destruction of the fruits will help to prevent other trees from being infected.

**Information about a *Jasmine* (*Grace Gardner*).**—Your shrub is a form of *Jasminum humile*, sometimes called *J. revolutum*. You can prune it any time between now and March. Thin it out well and reduces it in height; there is no special pruning necessary. You may use ordinary dubbin or cart-grease for greasing fruit trees. You must, however, place grease-proof paper between it and the bark. It is not of use for Cherry trees; Apples and Pears are the principal trees for which grease-bands are required.

**Pomegranates not flowering (*R. Heyworth*).**It is difficult to account for the behaviour of Pomegranates, for in the same garden, under apparently the same conditions, some plants will flower well and others rarely bear a blossom. All you can do is to give them as sunny a position as possible, in order to get the wood well ripened. Any necessary pruning should be done in early spring. Should growth be very vigorous, a little root-pruning will probably do good. You might obtain information from your friend who possesses a flowering specimen as to the method of culture adopted.

**Shrubs for exposed position in Ireland (*J. Smyth*).**—The following shrubs are suitable for the position near the sea you describe in Ireland: *Olearia Haastii*, *Veronica speciosa* and all varieties, *V. Traversii* and other shrubby New Zealand species, *Tamarix pentandra* (*hispidula aestivalis*), *T. gallica*, *T. tetrandra*, *Escalonia macrantha*, *Euonymus japonicus* and varieties, *Laurustinus*, *Forsythia suspensa*, *Berberis stenophylla*, *Pyrus floribunda* and *Spiraea* in variety. With a good shelter belt of these things you may grow many other shrubs in the more sheltered parts of your garden. For your low-lying ground near your pond you can plant *Alnus glutinosa* and var. *imperialis*, *A. incana*, *Salix babylonica*, *S. alba*, *S. fragilis*, *S. vitellina*, yellow and red-barked varieties (these should be cut down annually); Golden Elder, *Weigela*, *Cornus alba*, Bamboos in variety

and *Arundinaria nitida*, *A. Simoni*, *A. anceps*, *Phyllostachys fastuosa*, *P. viridiglaucescens* and *Arundinaria japonica* for preference. Good Water Lilies are *William Falconer* and *James Bryden*, red; *Mariacea carnea*, flesh; *gladstoniana*, white; and *tuberosa flavescens*, yellow.

**Planting flowering shrubs (*A. H. W. D.*).**—You cannot do better than trench your ground, keeping the surface soil to the top each time. Trench 1½ feet to 2 feet deep and break up the bottom of each trench. In the bottom place a good layer of cow manure, then through the remainder mix in a good quantity of leaf-mould. The other manures had better be left out at present, but in twelve months' time, after your plants have become established, you may give a light dressing of bone-meal with advantage. A surface dressing of cow manure and leaves mixed may be applied after the planting operations are completed.

**Increasing white Heather (*J. B.*).**—This may be increased either by cuttings or layers. Cuttings 1 inch or so long are inserted in pots of peaty soil and placed in a moderately warm propagating case, or under hand-lights in a shady border out of doors. July to September is the best time for taking cuttings. Layers are put down any time during spring or summer. The branches are usually weighted down with stones and are left for two years before being disturbed. When young, it is a good plan to cut the plants back each year after flowering to keep them sturdy. It is not, however, any use cutting branches back into old wood.

**Information about Azaleas (*E. H. Greenwell*).**—The most suitable Azaleas for your purposes will be calendulaceum varieties. If you order from a nurseryman and state the colours you desire he will supply you with them. The varieties you describe are termed (thence) Azaleas, from the fact that many of the earlier hybrids were raised in Ghent. It would be advisable to keep *Philadelphus Lemoinae* separate from the Azaleas, as it requires rather different treatment. Spring is a good time to plant. It will, however, be better for you to obtain some peat to dig into your ground rather than use the moss litter as you describe. Your Azalea mollis will probably grow more rapidly presently; growth is frequently slow for several years after plants have been grown in pots.

**Pruning shrubs (*Amateur*).**—The best time of year to prune your evergreen shrubs is in April. If you prune them hard now, you will make them look bad for the winter, and if you have to cut any of the branches back into the thick wood, they will probably die, as they will have to wait so long before they can begin to grow again. If you prune in April, new growths will quickly appear and the plants will furnish up again during summer. You will have to sacrifice the flowers of some of your shrubs for one season. If you plant strong pieces of *Seakale* now, you ought to obtain strong crowns for forcing next year. Cover the crowns up with pots, boxes or barrels, and make a hot-bed round and among them. Have the tops of boxes loose, so that by removing a little manure and loose boards you can see how the forcing is going on without disturbing the boxes.

## THE GREENHOUSE.

**Hints about Nerines (*F. F. Jones*).**—As soon as the Nerines show their flower-spikes, a little stimulant, such as weak liquid manure and soot-water mixed, will be helpful, but great care must be taken not to overdo it; indeed, some cultivators prefer not to give any stimulants at that time, but the majority are in favour of a few weak applications. Not only must liquid manure be applied with care, but water also. An excess of moisture at the roots is very injurious to Nerines in general. Another point with regard to the culture of these beautiful plants is that they should not be disturbed at the roots more than is absolutely necessary; but if repotting must be done, it should be carried out directly the flowers fade. A suitable compost is two parts of good yellow loam to one part of peat or leaf-mould and silver sand mixed. This will remain in good condition for years, an important consideration in the successful culture of Nerines. Those that are not repotted may, without disturbing the roots, be top-dressed with the same compost. This brings us to another matter of great importance, and that is, the Nerines make their growth during the winter and spring months, hence at that time they should have a good light position assigned them, and an occasional stimulant is then most helpful. As yours are now throwing up their spikes, we presume that you have mastered the necessity of keeping them absolutely dry when dormant. The old tunics had better be allowed to remain till they become quite detached from the bulbs.

**Heating a small greenhouse (*X. F. Z.*).**—We have seen particularly good results in such a greenhouse as you specify by the use of a hot-air paraffin stove by

Rippingille. The price is about 30s. Of course, the heater must be as far from the plants as possible and ventilation carefully attended to, while the trimming of the lamp is also of great importance. The quality of the oil is, in addition, a great consideration.

**Keeping Pelargoniums (*Geraniums*) in winter (*G. H. W.*).**—To keep *Geraniums* through the winter without artificial heat is not easy, especially if the winter season be a severe one. We believe you can succeed, however, by giving early attention to the plants it is intended to winter, getting the wood well ripened by exposure to the sun and by withholding water gradually from the roots. Have you a spare room or a window with a warm, sunny aspect? If so, you should winter them there very well. An oil-stove in a spare room should carry you through successfully, provided you keep the soil fairly dry at all times.

**Pelargonium for inspection (*A. W. Perry*).**—The petals had all dropped from the flowers sent, but we were enabled to see that the variety of *Pelargonium* is a very good one. It belongs to the *Regal* section, and is much in the way of *Prince Henry* and *M. Emmanuel Lias*. Whether it is distinct therefrom cannot be definitely stated without actual comparison, and we advise you to take a good representative truss, gum the flowers securely and forward to Messrs. H. Cannell and Sons, Swanley, Kent, asking their opinion thereon. Anxious as we are to oblige in all respects, florists' flowers are better left to florists themselves.

**Water Lily in heated greenhouse (*R. G.*).**Whether the hardy Water Lilies would do much good depends entirely upon the heat of the greenhouse; but if heated in the ordinary way, the forms of *Nymphaea odorata*, which may be had in several colours, would be most suitable. There are, of course, many sorts that prefer more tropical conditions, while the fine blue-flowered varieties of *N. stellata*, which send their handsome flowers fully 1 foot above the surface of the water, always make a telling display. The *stellata* varieties should be planted for starting in January, the others would be best done between October and March.

**Ivy-leaved Pelargonium for inspection (*C. Daines*).**—Your seedling Ivy-leaved *Pelargonium* is a very pretty one, but the season is too far advanced for a specialist to give an opinion thereon. It seems to us to be a good deal in the way of some others, but, of course, habit, freedom of blooming and other particulars have to be taken into consideration. We advise you to take some cuttings at once and next year grow on a few plants, and when these are in good condition send a specimen to some specialist, such as Messrs. H. Cannell and Sons, Swanley, Kent. In such a place a comprehensive collection is grown, and comparison with the best forms is therefore easy.

## ROSE GARDEN.

**Black spot on Rose foliage (*M. R.*).**Your plants seem to be badly affected with this fungus. The insecticide was not the cause of its appearance. It is very rife this year, especially in certain districts. You should have all diseased foliage burnt as it falls, and next spring, following the pruning, have the plants sprayed every week with Mo-Effic or some other good fungicide. If this were carefully carried out we think you would gain the upper hand of the fungus. We do not think the plants will suffer much from this fungus, although it must have a certain injurious effect upon their vitality.

**Protecting Niphetos grown as a standard (*T. W. M.*).**—It seems a pity to disturb your tree in order that you may protect it in the greenhouse. We have grown this grand old Rose in quite as cold a position as you describe. If you cannot obtain Fern or Furze, some dry straw-bands or some sheets of brown paper would make fine protective material if hard weather sets in. Tie the branches up to form a cone as nearly as possible previous to wrapping them up in the straw or paper. Should you be able to plant the Rose out into a good border in your greenhouse, you would, no doubt, be well repaid, as here it would develop into a huge tree, larger than one could expect outdoors, because the protection of the glass ensures a more thorough ripening of the wood. We do not, however, advise you to pot up the tree, as very rarely such plants are a success in a cold greenhouse.

**Rose cuttings in water (*C.*).**—We do not hold ourselves responsible for the statements of our correspondents. Doubtless some varieties of Roses would form roots when placed in a vessel of water; but it would be much more satisfactory to root them in silver sand, the latter being kept well moistened. If a bottom-heat be provided, and 2 inches or 3 inches of sand placed above, Rose cuttings taken from blooming shoots will root most easily. The foliage should be retained and

frequently sprinkled with water during the day for the first two or three weeks. The cuttings should be in a sunny position, but kept shaded from the sun by sheets of newspaper laid on the glass.

**Classes of various Roses (G. C. Oakley).**—All the varieties you name, save one, belong to the Hybrid Perpetuals. The exception is *Robusta*. This is a Bourbon Rose, or rather a hybrid of this group, but minus its late-flowering propensity. All five varieties are dark crimson.

**A Rose freak for inspection (M. F. Bullock).** The Fern-like formation of the calyx of the bloom sent is very peculiar and interesting. We believe the Rose to be one of the Mosses, possibly *Eugène Guinoisseau* or *James Veitch*, but could have been more certain if you had sent a piece of the growth. We have seen a similar freak upon the old Moss Rose *Salet*. You should try and propagate your Rose by budding from the shoot that produced the bloom or putting in a cutting at once.

**Rose Philadelphia Rambler (F. D. Wilmshurst).** We do not consider this a satisfactory Rose. It is rather a shy bloomer until it has made a lot of old wood, and its blooms often appear with deformed centres and much mildewed. A much more beautiful sort would be *Rubin*. This is a grand colour, although not so deep as *Philadelphia Rambler*. *Hiawatha* and *Delight* are two fine-coloured varieties that approximate more nearly to the *Dorothy Perkins* type in growth. If you desire an early summer-blooming sort, plant *Rubin*; if a late July and August bloomer, then *Hiawatha* would be best.

**Rose buds blighted (E. R. J.).**—The buds with growth attached are taken from the variety *Her Majesty*, probably the worst Rose grown to be attacked by mildew. It is rarely free from it at this season of the year, although the July blooms generally come clean. You should cut away the shoots which look as though they have been whitewashed and burn them. Probably you will have to cut away 2 feet of growth on each shoot, as we have had to do this year. We do not think you need be concerned about next year's attack, because if you spray the plants before you see the mildew you may be able to check the fungus. A solution of Lifebuoy carbolic soap is a good remedy for mildew if applied in the early stages and persevered with at intervals of a few days. Half a bar of the soap to three gallons of soft water is the proportion to employ. There is also a good preparation called *Mo-Efic*, which is very effectual.

**Roses for round bed (H. A.).**—We think of the two sorts named, *Killarney* and *Caroline Testout*, the latter would be the most satisfactory all-round sort for a pale pink, and as you desire a second variety you could not do better than plant *Marie Croibier* with it, as the latter is a deep pink sport of the former. They both possess the same habit of growth. If you desire half-standards and half-dwarfs, you should have *Caroline Testout* as the half-standards, because you might find a difficulty in obtaining half-standards of *Marie Croibier*. As an alternative, *Gustave Grunerwald* or *Lady Battersea* would associate well with *Caroline Testout*. *Mme. Jules Grolez* would be a splendid contrast in colour to *Caroline Testout*, but it is scarcely so strong in growth. *General Macarthur* would be a good red variety, but it has a little tendency to change to "bluish," which you have an objection to, although this could be overcome by frequent removal of the old blooms. It is a splendid fragrant sort that should be in every garden.

## KITCHEN GARDEN.

**Supplying a large family with vegetables (R. W. D.).**—We are absolutely certain that no gardener, however clever, can supply an average of twenty-five persons with vegetables, including Potatoes, for a three months' supply from an area of ground only three-quarters of an acre, especially as from such a garden has to be taken out paths and, doubtless, some trees and bushes. At the very least, a vegetable garden for twenty-five persons should be of not less than 2 acres, as to supply so many mouths entails, on any gardener, a big demand. No one having the slightest claim to practical knowledge would assert that from three-quarters of an acre such a supply as you need can be had; still further is such a result impossible when soil is of very moderate quality. To expect so much from so small an area of ground, and to blame the gardener for any lack of the supply, is most unreasonable.

**Tomatoes with curled leaves (T. R. F.).**—There is no sign of fungus or insect upon the leaves sent. If, in addition to the curling mentioned the whole plant wilts, it is no doubt affected with "sleepy disease." For this there is no cure, as the fungus, which is its cause, enters the plant from the soil and grows upwards so as to fill the vessels by which water is conveyed from the root to the foliage with its mycelium, and thus cuts off the supply of water. All such plants should be removed, as the spores of the fungus are produced upon their stems near the base. The soil should not be again used for Tomatoes, nor should they be grown in the house again until it has been

disinfected by washing with a 2 per cent. solution of Lysol or a similar disinfectant. If this wilting of the plant is not seen, send us further specimens to include the stem and some of the fruits which are going wrong.

**Cucumber stem for examination (T. L.).** There is no evidence upon the roots of the plant of attack by eelworm. When eelworms attack the roots of Cucumbers or Melons nodules are produced upon them. Your plant appears to have gone off at the collar with a sort of collar-rot, so far as can be seen from the specimen sent, which had, when it reached us, become rotten and infested with the grubs of some dipterous fly. Cucumbers sometimes go off at the collar through becoming too wet just at that part. A sprinkling of lime around the base of the stem tends to check this trouble.

**Peas decaying (Ignoramus).**—The fresh, undecayed manure would certainly not be conducive to the successful growth of the Peas, especially in a period of dry and hot weather such as we have had this summer. The spasmodic watering of Peas does more harm than good; but if given in moderate quantities once or twice a week while the Peas are in full pod in dry, hot weather, heavier and better quality crops will result. For the promotion and maintenance of healthy growth in Peas from the time they are sown until they are taken up there is nothing so effective as the frequent application of the hoe to the surface of the rows. It should be applied at least once a week in dry weather. We are inclined to think that it was the raw manure which sickened your Peas.

**Slugs infesting the Cabbage tribe (Restless Richard).**—There is a wash on the market, said to be non-poisonous, which the maker claims to be death to all aphids, caterpillars and other garden pests. It is named *Abol*. It may be had of all seedsmen and nurserymen or of the manufacturers, Messrs. C. A. White, Hop and Fruit Growers, Paddock Wood, Kent. You might give a shilling tin a trial and spray the Cabbage and Cauliflowers with it as per directions given with each tin. We deprecate the use of poisonous washes of any sort to vegetables which have afterwards to be eaten. Lime and soot mixed together is the old remedy, and is still effective in driving slugs away if carefully applied in dry weather. This nourishes the crop as well, and is easily washed clean afterwards.

**Potato tumour (Cheshire).**—The Potato tubers sent show an exceptionally bad attack of what is known as Potato tumour (*Edumyces leproides*), a disease first seen in this country in 1901. Happily, so far it has been very local, but it is one of the worst diseases of the Potato known. If all the tubers on your allotment resemble those sent, the crop is utterly ruined. Not a tuber or any portion of the eruptions on it, which are full of fungus, should be left. All should be collected and burned. The ground should then be at once dressed with gas-lime at the rate of a bushel per rod, evenly spread, and at once well forked in to mix with the soil. Do not plant Potatoes on that ground for a couple of years, but plant diverse crops sown in March. Where it is proposed to grow Potatoes next year, dress in midwinter with a bushel per rod of fresh kiln lime. Put it down in heaps of a bushel and cover with soil. It will soon slake; then spread about and at once fork in. If preferred, ground fresh lime not slaked may be applied and forked in.

**A new kitchen garden in Wales (H. P. P.).** Of the three alternative ways mentioned of building a garden wall in a district so exposed to high winds, we should decidedly choose the hollow brick wall. Wood, besides being perishable, is one of the worst possible mediums to plant fruit trees against. As an alternative plan, we should like to suggest that you build a composite wall instead, part stone and part brick, which, we think, you would find more satisfactory in every way; that is to say, build in the first instance walls of stone and mortar to the necessary height, facing the same with bricks cemented in. We suggest this as we presume that stones are plentiful and cheap in that part, and therefore the cost would be much less, and certainly the walls would be more substantial and warmer than a hollow one. Against such a wall buttresses would have to be built at intervals of 20 feet, in order to protect the trees from strong, sweeping currents of cold winds in spring. They would have the effect of breaking them up. They would also act as supports to the portable glass coping.

## FRUIT GARDEN.

**Pears diseased (H. Waters).**—The Pear is very badly affected by the fungus *Fusicladium pirinum*. The deep cracks are due to an early attack, which destroyed the skin and prevented further growth, while the smaller spots are due to a later attack. The fungus attacks not only the fruit, but the leaves as well, and probably the shoots. A similar fungus attacks the Apple and produces similar spots upon the fruits and leaves. The method of control is to drench the tree during the dormant period with iron sulphate solution, made in a wooden vessel by pouring 1 pint of strong sulphuric acid on 25 lb. of iron sulphate and adding by degrees 50 gallons of water. This must not be used in the spring or summer when the leaves are on the tree. Just as the buds begin to burst spray the tree with Bordeaux mixture of half the usual strength,

again when the petals have fallen, and twice more at intervals of about three weeks. All dead leaves should, as far as possible, be destroyed, and damaged fruits as well, while the tree should be kept free of dead wood. Persistence in this will doubtless reduce the disease to a minimum, but unless these points are attended to the disease is likely to spread and do damage to surrounding trees.

**Late Grapes mildewed (F. E. Chambers).**—The Grapes are badly infested with mildew, which should be destroyed as soon as possible or the crop will be ruined. The way to do this is by dredging sulphur thickly over the bunches, using a pepper or some other dredger for the purpose and holding a newspaper under the bunch to catch the falling sulphur. The sulphur may be blown off with a pair of bellows after it has been on for two whole days. It will then have destroyed the mildew. The Vine leaf appears to us as if it had been scalded by sun-heat consequent on defective ventilation, and possibly, as you suggest, from insufficiency of water at the roots. Give the Vine border a thorough good soaking of weak manure water. Ventilate freely by opening the front and back ventilators fairly wide on warm and sunny days, closing them entirely up at 4.30 p.m. after first having syringed the walls, border and all available surfaces (excepting the Vines themselves) copiously. By doing this the temperature of theinery will probably rise to 85° or 90° for a short time. This moist, warm atmosphere will force into the Vines a good and wholesome growth each day. Towards 7 p.m. admit a small chink of air again both on the front and back ventilators, applying at the same time slight heat to the hot-water pipes.

**Name and information about an Apple (Apple, Brockley).**—The name of the Apple is *Mr. Gladstone*, one of the best early Apples we have and ripe in July and August. It is of compact and moderate growth, and succeeds well as a standard in the orchard or as a bush in the garden. The tree should not be pruned too hard; but the weakest branches should be thinned out in winter to prevent any overcrowding.

**Muscat of Alexandria and Foster's Seedling Grapes decaying (P. H. R.).**—The Grapes appear to be dead ripe, and the cause of the decay in the berries must be attributed, we think, to the want of a little heat in the pipes to keep the air of theinery more buoyant and dry. Heavy watering at the roots when Grapes are ripe we have known to cause the same injury, especially to Muscats. The other varieties mentioned are not so sensitive to these conditions.

**Loganberries and Hollyhocks (Town Gardeners).**—The Loganberry could be planted in September or October, and plants may be obtained from anyone advertising fruit trees in our columns. The *Gladioli* must be lifted each year as soon as frost appears, the corms to be stored in a frost-proof shed till the end of March, 1909. The *Monothretrias* and *Lilies* will be safe in the open ground, as they are quite hardy. The best way to obtain a hedge of Hollyhocks is to plant strong seedlings in May in the required positions, when rather more than a year hence they will give you the desired reward. As you have not done this, your next best plan will be to plant strong plants in September, arranging them in double or treble lines. The best way to combat blight on fruit trees is to syringe them once a fortnight with Cannell's Fruit Tree Wash. Write to Messrs. Canuell and Sons, Swaleay, and obtain an *Abol* Syringe for applying the wash. Grease-bands will prevent the moth from ascending and laying its eggs, but this will not deter the blight. An emulsion of soft soap and paraffin is also excellent for general application.

## MISCELLANEOUS.

**A plague of slugs (G. W.).**—Your garden seems to be exceptionally troubled with slugs. We have found, by long experience, that it is possible to rid a garden of such pests in time, as their production does not go on for ever, by night hand-picking, by laying down Cabbage and Lettuce leaves in all directions as traps, under which they shelter during the day, by putting down small heaps of brewers' grains, into which they creep and may thus be destroyed, by watering close to walls or fences with brine or strong soot or lime water, also watering with strong lime water over plants infested by slugs at night and soon after dusting thickly with fresh slaked lime or fresh soot. The constant following up of the enemy in this way ultimately results in success. Ducks running in a garden devour many. The frequent forking up of the soil exposes eggs to birds to prey upon. All these are aids to slug destruction. Specially put down many leaves as traps, as these prove very effective.

**Caterpillars for inspection** (*R. Boodle*).—The caterpillars you forwarded are those of the peppered moth (*Amphidasis betularia*), a common insect. They feed on the foliage of the trees they infest, but do not do much harm as they are not found in abundance.—G. S. S.

**Ladies' horticultural colleges** (*A. G. W.*).—Other than the Swanley Horticultural College for Ladies, female students are included at the University College, Reading, a first-class institution. For admission application must be made to the Principal. You may also care to write to Miss May Crooke, a talented horticulturist who has, we believe, a ladies' college for garden instruction at Manor Farm, Bredons Norton, Tewkesbury. We cannot tell you as to fees. Information concerning these can be obtained from the respective Principals.

**Moss litter and spent Hops as manure** (*H.*).—To have these materials in good condition mix one cartload of spent Hops with two cartloads of peat moss litter manure, throw all into a heap, well damping it as put together and allow it to lie to partially heat. Thrust a pointed stick into the centre of the heap, and by drawing it out occasionally the heat of the heap can be tested. So soon as hot turn the heap again, and again damp it in the turning. Allow it to lie to heat again, then turn once more and allow it to slightly heat. It will then be in first-class condition for application to the soil. If, however, the manure is not required for some time, make the heap flatter or longer so that it heats less rapidly. When treated as above advised, the moss litter has parted with certain acid properties, and the whole more readily decomposes in the soil.

**Catching shallow-working moles** (*Puzzled*).—In common with yourself and, doubtless, many readers of THE GARDEN, we have in the past greatly suffered from the working of moles in light soils, in seed-beds, flower-beds and in various other directions. Two courses only were ever open to us, both needing very keen sight and attention. Many of the moles we have killed by standing with a narrow, long-tined steel fork watching their work, and the moment there was evidence of the creature lifting the soil near the surface, to thrust in the fork close by and lift the mole out, killing it at once. The other course was to stand with a loaded shot-gun or a large loaded pistol close, and the moment the creature was seen lifting soil to discharge shot into it. That either killed it or scared it away for good. Traps in these surface runs are useless, and there may be no evidence of the whereabouts of the deep main runs.

**Plants attacked by pests** (*Anxious*).—The Vine is attacked by mealy bug, a pest which calls for immediate and strenuous efforts towards its eradication. The Peach leaves seem to be swarming with red spider. This usually multiplies very rapidly when the house has been allowed to become too dry and hot. In the case of both the Vines and the Peaches, proper and thorough cleansing of the houses during the dormant period should not be neglected. The leaves of the stove plants are covered with a black fungus. This fungus is not attacking the leaves, but is growing upon the honeydew deposited upon the leaves by aphides (or fallen upon the leaves from aphides attacking other plants), and is harmful to the plants only indirectly. But the honeydew covers up the breathing pores of the leaves and the black fungus checks the access of light to them, thus preventing them from fulfilling their functions. The leaves, where possible, should be sponged and the house fumigated at intervals with one of the approved fumigants now on the market.

**Insect for identification** (*K. R. Image*).—The insect you send is a male specimen of one of the many species of hover flies belonging to the genus *Syrphus*. They are among the most useful insects in our gardens, as their grubs destroy large numbers of aphides. The females lay their eggs on the shoots of some plant infested with aphides, and the resulting grubs are blind and legless, about half-an-inch long, with a body which gradually tapers towards the head. The mouth is furnished with a double hook. A grub is able to retain its position on the shoot by means of some fleshy protuberances near the tail, and it is very interesting to watch one of them feeding, as it stretches out its body to its full length and feels about until it finds an unfortunate aphid, into which it immediately strikes its hooks, and, raising its head, holds the insect up in the air so that it cannot possibly escape, sucks it dry, turns its head on one side, drops the empty skin and then searches for another victim. I have seen one of these grubs suck out the contents of a full-grown aphid in the course of a minute and a-half, and they will continue for some time killing one after another as fast as they can catch them.—G. S. S.

**How to raise "bent" grass from seeds** (*T. M. B.*).—The seeds should be sown in spring in the open ground; but some difficulty would probably be experienced in getting a good crop of this grass established in the shifting sand dunes, unless more than ordinary trouble was taken to prepare the ground. This grass roots deeply as well as on the surface. From the nodes of the stems roots grow and enter any soil which they come into contact with, so that the habit of the plant is spreading. This being so, it would be advisable to sow the seeds in duly prepared patches of ground, the small plots being about 2 feet across and several feet apart; then the young plants forming the clumps would soon meet and so hold the surface soil in a firm grip. The plots should be prepared by adding a small quantity of heavier soil in which to sow the seeds. The latter part of March or early in April would be a good time for the sowing. Also, seeds should be sown generally all over the sand dunes. If the weather proves to be wet, the seeds will germinate freely. The variety *vulgaris* (*Agrostis vulgaris*) is the name of this

common bent grass. Seedsmen advertising in THE GARDEN would supply you with seeds.

**Fence across a garden** (*Sulphurland*).—The fence across the lawn would only partly protect the border at "A," which would still be exposed to the wind at each end and down the pathways. Moreover, it would render the lawn one-sided and out of proportion. A much better protection would be afforded by your erecting against the west wall and through its entire length a sort of wind-shield. By sinking Larch or other good posts that could be bolted to the wall and rise at least 5 feet above it, a cross-barred Larch or other trellis of wood could be affixed thereto quite easily. Then, by planting Irish Ivy in a well-dug and manured trench at the base of the wall, a good and permanent covering would quickly ensue and provide a wind-screen of the most effectual kind, and one also that could be kept in excellent order by being closely cut with shears each year.

**Marestall weed** (*M. E. W.*).—The weed you have under the above name is an *Equisetum*, and is known under various local designations. When you say that the weed is no sooner cut down than it comes up strong almost directly and chokes ordinary plants, it is but too evident the soil must be very full of the deep-running fleshy roots. Unless you can have the ground trenched or deeply worked, the roots so far as possible being picked out in the process, the chances of freeing the soil of the weed seem poor. Failing doing that, there is no other resource but to keep the hoe constantly in use, cutting the growths hard down to the soil so fast as they appear. When that is done, it is possible and probable that in time the roots, for lack of top growth, will die out. The presence of the weed indicates that the soil is sour and wet. Draining it and also giving it a heavy coat of lime should also help to kill the weed.

**Artificial manuring** (*W. D.*).—No doubt the peat moss litter manure applied to the garden soil you mention was ill-prepared, and had not parted with the acidity so common in that manure until it has been expelled by occasional part heatings and turnings. With respect to artificial manures, the most rapid in solution are steamed bone-flour, finely-crushed kainit and sulphate of ammonia. The two former, in equal proportions, should be dressed on land in January, and well forked in at the rate of 6lb. per rod area of 30 square yards, the sulphate of ammonia, at the rate of 3lb. per rod, being sprinkled between growing crops during April, May or June, all at once or in two diverse dressings, and at once well hoed in. Your soil would probably derive benefit from one or two dressings of coarse salt, at the rate of 2lb. per rod between crops and hoed in, applied in June and July. Soils become exhausted only from lack of proper manuring and when one form of crop is grown in constant succession.

**What to do with a small town garden** (*H. L. Cairns*).—We can quite imagine your soil has become exhausted, and we advise you to have the ground properly trenched and a heavy dressing of good, partially rotted horse manure incorporated at the time. By all means add bone-meal if you can procure the same. Ichthemie and other guanos should be used in liquid form and applied to the plants when they appear to need a stimulant or are coming into bud. You should be able to grow a *Pyrus japonica* satisfactorily on your wall with a south aspect. We should grow in the same aspect *Violas* and *Pansies*, *Delphiniums*, *Lupines*, *Pyrethrums*, *Heleniums*, *Veronicas*, *Phloxes*, *Erigerons*, *Galegas*, *Lilium candidum*, *Geums*, *Potentillas*, *Gypsophila paniculata*, *Lathyrus latifolius* albus, perennial *Snailflowers* and early-flowering *Chrysanthemums*. For shady borders plant *Solidago canadensis*, *Spiraea* in variety, *Foxgloves*, *Lythrum virgatum* Rose Queen, *Rudbeckia Newmanii*, *Michaelmas Daisies*, *Alyssum saxatile*, *Campanula macrantha*, *Arabis alba* fl.-pl., *Primroses* and *Polyanthuses*, *Salomon's Seal*, *Funkia Sieboldii*, *Heimerocallis flava*, *Hebeborus niger* and *Chrysanthemum uliginosum*. We hope that the above lists will meet your requirements.

**Diseased Gooseberry leafage** (*H. S.*).—There is no doubt evidence of the presence of fungus on your Gooseberry shoots sent, but not sufficient to indicate that it is an attack of Gooseberry mildew. It is noticeable that the worst evidences are found on the very weak shoots, while, with the exception of spotted leaves, the strong shoots seem free from fungus. Even the spotted leafage seems more due to that minute sucking insect, thrips, than to any other cause. Most certainly, in any case, at once spray the bushes twice at intervals of eight or ten days with a solution of sulphide of potassium or Bordeaux mixture, but the former is best for this special purpose. Half an ounce of potassium sulphide dissolved in a gallon of hot water is the proper proportion. After the bushes have dried, severely prune out all weak shoots, rake or sweep them up and burn, also every leaf that falls during the autumn. A heavy dressing of manure should do the bushes great good.

**Mealy bug on Vines** (*J. W. P.*).—Mealy bug is a most troublesome pest in a vine, and must be tackled at once. Hold a basin or some receptacle in one hand and scrape off into it all the insects you can find, scalding them later. Where you find any, at once touch the place with spirits of turpentine, using a small paint-brush for that purpose. It is just possible you have grown some infested plants in pots in your vine, and these had bug on them unseen by you. Paint over your Vine stems in every part with a mixture of soft soap 2lb., sulphur 2lb., and half a pint of turpentine. Make these into a stiff paste, then boil or scald 1lb. of Tobacco in a gallon of water, strain that and mix water with the paste, add more water and a little clay to make it thick, then well

coat over every part of hard wood. That should be very effective. Paint house or wood crevices also.

**Black Hamburg Grapes mildewed** (*W. M.*).—In the first place, the mildew should be killed, or it will be sure to appear year after year. The simplest way to destroy it is by dredging sulphur over the Vines while they are dry, leaving it on for three days and keeping the house close and shading densely. The sulphur may be blown off afterwards (still being dry) with a pair of bellows, and the Grapes will be none the worse and the mildew killed. Be careful the house is dry all the time. The overflow water mentioned, if it finds its way to the Vine border, is most likely accountable for the mildew. The best thing to do will be to make provision to divert it into some other channel. The name of the Plum is Orleans, the Prune Monsieur of the Continent. It is a second-rate dessert Plum, but excellent for preserving or for culinary purposes. It is hardy and prolific.

**Mushrooms in a malt house** (*P. G.*).—Mushrooms would succeed grandly in such a structure, summer and winter. Whether you can make it pay as a business depends greatly, in the first place, on whether you can command a good supply of fresh manure from corned horses delivered at your place at a moderate price of, say, 4s. per ton; and, in the second place (and this most important too), management comes in. If you do not understand the business, it is easy to learn, that is if you are in earnest in the matter and short of actual experience gained in working under a practical Mushroom grower. We know of no better way of learning the business than by investing 1s. 2d. in a little book on the subject written by Mr. J. F. Barter, Mushroom grower, Napier Street, Wembley, R.S.O., Middlesex, one of the most successful growers of the day. Now is a good time to begin to grow them.

**Charred bones as a fertiliser** (*Hopeful*).—If you can char the bones you refer to without burning them to ashes, but enabling them to be crushed fine, they will make excellent phosphatic manure, while the ash of burnt wood furnishes excellent potash. These manures may be mixed before applying it to the soil, but the proportions would have to be determined by the respective quantities you may have. Soot is always a good fertiliser if it comes from house chimneys or flues; but if from a furnace it is of little value. If you could apply the bone and wood ash at the rate of 10lb. per rod of ground and the soot a peck per rod great good should result. To have a fairly enduring nitrogenous element in your mixture, add to the previous-named quantities 5lb. of Rape dust per rod. This is cheap and can be had from any manure merchant. If your bones are not charred, but broken up fine, they will make better manure, but will be much slower in action. Soil returns crops in proportion to the way it is fed or manured.

**Inoculation of leguminous plants** (*E. W. C.*).—The literature on inoculation of legumes is very scattered, but an excellent review of the whole subject is given in Bulletin 71 of the United States of America Department of Agriculture, Bureau of Plant Industry, and a considerable mass of additional information is to be obtained in the bulletins of the various States experiment stations. A full report of the effect of inoculation of Peas in a garden soil will be found in the forthcoming volume of the Journal of the Royal Horticultural Society. An excellent account of the influence of different coloured rays of light upon plant growth is given in Pfeffer's "Plant Physiology" (English translation), where also there is a good bibliography of the subject.

**Grapes decayed** (*G. C.*).—The mouldy and decayed appearance of the berries is the result, we think, of an attack of *Erysiphe communis* (Berkeley) rather than *Oidium Balsamii*, and brought about by a too moist condition of the atmosphere and a too low temperature at night. When Grapes are dead ripe, as these are, cold and damp are fatal enemies and should be guarded against by the provision of slight heat in the pipes, with air at night. With this precaution Grapes will hang until they shrivel. Sulphur is the foundation for all effective fungicides. You cannot apply anything better for the destruction of mildew.

**Names of plants.**—*L. Barker*.—*Browallia speciosa* and *Nerine undulata*.—*Rev. A. B. Stenerson*.—*Semele androgyna*.—*E. Edge*.—The red Aster is *Novae-Anglie ruber*; the other *A. Novi-Belgii grandiflorus*.—*S. H. B.*.—*Senecio taugatus*.—*G. Ross*.—1, *Lady Mary Fitzwilliam*; 2, *Amazone*; 3, *Mrs. Sandford*; 4, *Bouquet d'Or*.—*M. S. W.*.—*Jacobinia magnifica*.—*T. C.*.—The flowering plant is *Clivia miniata* and the Fern is *Adiantum formosum*.

**Names of fruit.**—*Delamere*.—1, *Norfolk Beauty*; 2, *Rawthornden*.—*J. D. Winter*.—1, *Apple Lamb Abbey Pearmain*; 2, *Marchal de la Cour*; 3, *Brown Beurré*; 4, *Josephine de Malines*; 5, *Passe Crassane*.—*No Signature*.—1, *Apple Beauty of Hants*; 2, *Northern Greening*.—*G. C.*.—*Pear Beurré Diel*.—*A. P.*.—*Pear Beurré Superfin*. Apples: 1, *Mank's Codlin*; 2, *Blenheim Orange*; 3, *Peasgood's Nonsuch*.—*J. Ramsden*.—1, *Cox's Pomona*; 2, *Wealthy*; 3, *Nelson's Codlin*; 4, *King of the Pippins*; 5, *Wellington*; 6, *Annie Elizabeth*; 7, *Cellini Pippin*; 8, *Pickering's Seedling*.—*J. W. Gaunt, Leeds*.—1 and 4, *King of the Pippins*; 3, *Pickering's Seedling*; 5, *Kentish Filbasket*; 6, *Keswick Codlin Improved*; 7, *Northern Greening*; 8, *Keswick Codlin*; 9, *Wellington*.—*R. Mott*.—The Pear is *Glout Moreau*. With regard to Apples, I might be a small Mank's Codlin, but too small to name definitely; 2, *Duchess of Oldenburg*.—*J. England*.—1, *Yorkshire Beauty*; 2, *Christmas Pearmain*; 3, *Allington Pippin*; 4, *Rosemary Russet*; 5, *Beurré Superfin*; 6, *Belle Julie*; 7, *Thompson's*; 8, *Swan's Egg*.—*W. G. D.*.—1, *Emperor Alexander*; 2, *Golden Noble*; 3, *Gold Medal*; 4,

Rosemary Russet; 5, Mank's Codlin; 6, Worcester Pearmain; 7, Braddick's Nonpareil; 8, Yorkshire Beauty; 9, Pear Swan's Egg—*J. Seaman*.—1, Blenheim Orange; 2, Flanders Pippin; 3, Malster; 4, Duke of Devonshire; 5, Annie Elizabeth; 6, Waltham Abbey Seedling; 7, Sandringham; 8, Ecklinville Seedling; 9, Cellini Pippin; 10, Allen's Everlasting; 11, Wyken Pippin; 12, Adam's Pearmain; 14, American Mother; 15, Wellington; 16, Norfolk Beautin; 17, Winter Peach.

## BOOKS.

**French Gardening: Gold Producing Soil.\***—In his preface the author remarks that his object in writing this little book is to try to stimulate interest in the now much-talked-of French gardens and to put before the public in a cheap and popular form an outline of what the so-called new methods of cultivation are and to give sufficient details in regard to the apparatus used and its cost, that anyone reading it will be enabled to start the system on a small or large scale. We congratulate the author on the excellent way in which he has carried out the difficult task he set himself to do. This little book tells you all about a French garden and how to form the same in England, and the best time to begin, and gives approximate cost. It tells you also how to make the glass frames and how to use them, and the same of bell-glasses or cloches so largely employed in France. It tells you of manures and manuring and how to cultivate the soil under this system and also of the things to grow and how to grow them. It cannot be claimed for the system that it is anything new in this country, as vegetables in winter and early spring have been grown under glass in England in private gardens for decades past, and we should not be surprised to hear that the method was copied from us in the first instance. Be that as it may, it behoves British gardeners to wake up and see to it that, if land in the environs of Paris is made to yield £700 per acre per annum in English gold (more or less) that English soil by British skill, enterprise and labour is made to yield as much or a little bit more. We are told that the rent of these Parisian gardens runs to from £40 to £60 per annum per acre. The best land within a radius of twenty miles of London can be had at from £2 to £5 an acre. The carriage of produce from Paris to London amounts to 95s. per ton. The carriage from the radius mentioned to London cannot amount to more than 20s., and as regards manure, the most important item in connexion with the successful working of this system, it is probably cheaper and more plentiful in London than in Paris. Considering the matter from all points, we think there is no reason whatever why English gardeners, if they set themselves to work on the lines suggested in this book, should not be equally, if not more successful than their French neighbours in supplying the English market with an unlimited supply of what is now supplied almost exclusively by French gardeners to their immense gain and to our loss. Whether or not those who embark on the business make it a success depends almost entirely on the practical knowledge of the work by the gardener and on the enthusiasm and industry he puts into his work, associated, of course, with efficient and economical management. Let no one start lightly on the business before having previously had a few years' training under a competent man, and then only start in a small way to begin with, remembering that it takes at least £1,600 to equip and start a garden of only one acre in extent, and in the hands of an inexperienced or incapable person this sum would soon be sacrificed.

**School, Cottage and Allotment Gardening.†**—In the preparation of a book

devoted to these prosaic and simple aspects of horticulture any author finds about his theme little that is heroic, but much that calls for practical knowledge. It is, perhaps, because to a prolific writer like Mr. Weathers the range of matter thus offered was limited, that the book devoted to the above and wider subjects now before us has expanded into one dealing with gardening in a wider sense, and also has materially added to its size and cost. For such special objects as seem to have been in view, cheap manuals, more condensed and very elementary in description, find the readier sale. All the same, Mr. Weathers, who, as a County Council horticultural instructor enjoys exceptional opportunities, has done his work well, and if amid the many who are interested in school gardens, and in cottage and allotment gardens, a wide circle of readers can be found, then most certainly great good should result from careful perusal of the book. Briefly put, the divisions range over the "Formation of a Garden"; of elementary school gardens, including plans and methods of cropping; of cottage gardens, and general information as to their culture and cropping; also as to allotment gardens in similar sense. Just so much would have made a very useful small manual. But beyond those things come descriptions of soils, hot-beds, fruit gardens, hardy flower borders, trees and shrubs, the vegetable garden generally, garden calendars, and, by no means least, some 147 questions on subjects relating to gardening, which any candidate for examination in horticulture may well study and find replies to. These are questions that are well suited to school teachers or garden instructors, but such as ordinary workers would certainly find much beyond their powers. Illustrations form a strong feature of the book, and generally are very helpful. That is specially so with several garden plans, on some of which methods of cropping for rotation are shown. Very useful also are those which show methods of layering, grafting and pruning, also the general training of fruit trees. But we take grave exception to the fan-shaped tree on page 78, which shows a stout centre vertical stem, a young growth never found in true fan-shaped trees, the centre being invariably kept open for gradual filling with small inner shoots. The illustration of a garden brick edging on page 6 is not only upside down, but describes a method of making a garden edging that is costly and objectionable. A brick on edge laid in mortar with the joints closed with cement is far cheaper and better. In dealing with manures and plant foods the author seems to have gone much beyond the capacities of workers or generally illiterate readers, but the matter is of great value to school teachers and budding instructors. Clearly the book, excellent as it is, cannot well be used as a school reader, nor is it elementary enough in its later pages for the average cottager; indeed, it might be more fitly in the hands of the young professional gardener who wishes to become an intelligent expert in his profession. Our author is not in love with what is known as Nature study. In that belief we cordially join. It is so far mere playing with Nature, and teaches nothing practical. Whatever is done in the school should always have in view the fitting of the child to become in later life a useful worker and citizen. Whatever may be the deficiencies of Nature study, and no doubt it is a pretty study, at least school gardening does teach the child something that is to him very practical and unquestionably useful. It is in the portion of the book thus devoted to so important a subject we find most interest, and regret Mr. Weathers has not compiled a small manual devoted to that subject solely, and such an one as would be used as a class book in the schools in hours devoted to horticulture on wet or wintry days. In dealing with cottage gardens and allotments we note with pleasure that the strongest emphasis is laid on deep working of the soil. There is no feature in gardening that is more important or does so much to make it

successful as deep preparation of the soil. Then comes good feeding of it with well-prepared manures, and last comes cropping and cultivation. Cropping here includes proper thin sowing of seeds and equally proper thinning of seedlings. All this is most valuable instruction, which it seems will be needful to continue to give for all time. We cordially hope the book may have a wide sale and thus help to render to gardening very valuable service.—D.

**The Book of Nature Study.**—The Caxton Publishing Company announce an important work to be entitled "The Book of Nature Study." The aim of the volume is to give detailed and systematic guidance to parents and teachers in introducing children to the study and love of Nature. The common animals and flowers are dealt with by acknowledged experts, who are at the same time experienced teachers. Technical language will be, as far as possible, avoided. Such subjects as the soil, rocks, weather conditions and children's gardens are also among the subjects treated. The editor is Professor Farmer of the Royal College of Science, whose technical familiarity with, and deep interest in, the whole movement in favour of the scientific study of Nature is well known. Contributors include such names as Professor J. Arthur Thomson, Professor W. W. Watts, Mr. W. P. Pyecraft, F.Z.S., Dr. W. H. Lang, D.Sc., and others. The work will be elaborately illustrated and will also contain a series of folding models, showing internal structures, &c.

## SOCIETIES.

### READING GARDENERS' ASSOCIATION.

#### LECTURE ON "VEGETABLES FOR EXHIBITION."

THERE was a very large attendance at the Abbey Hall, Reading, on Monday, the 19th ult., on the occasion of the second fortnightly meeting this session of a most useful organisation. The subject of the evening was "Vegetables for Exhibition," with lantern-slide illustrations, by Mr. Pritchard of Aldenham House Gardens, and, as may be well imagined, proved a powerful attraction. The president, Mr. Alderman Parfitt, J.P., occupied the chair, and in calling on Mr. Pritchard to begin his lecture, happily referred to the summer excursion of the association to Aldenham House on July 15, dwelling on the courteous reception of the party by the Hon. Vicary Gibbs, Mr. Edwin Beckett, the head-gardener, and his staff. After some introductory remarks dealing with the necessity of the exhibitor having a thorough plan of campaign, which must be carefully thought out months before the showing season arrives, the further necessity of method in all things, combined with care and thoroughness in cultivation, the lecturer enumerated the particular vegetables which are considered the "sheet anchor" of the successful exhibitor. The first picture to be thrown upon the screen was a view of Aldenham House, which was received with loud cheers. The lecturer then proceeded to show slides of perfectly-grown Cauliflowers, Runner and Dwarf Beans, Peas, Onions, Leeks, Beets, Carrots, Parsnips, Celery, Potatoes, &c., giving cultural instructions for each subject as it appeared, with advice as to dealing with insect pests, proper manuring, lifting and other details connected with the successful growing of vegetables for exhibition.

During his remarks Mr. Pritchard placed upon the screen many fine pictures of splendid collections of vegetables that had taken highest honours in England, Scotland and Ireland, including the Temple and Holland House shows, Edinburgh, Belfast, Shrewsbury, Northampton and other great horticultural exhibitions. It being close upon nine o'clock when Mr. Pritchard, who was loudly applauded, sat down, only a short time remained for discussion; but in the brief period at liberty many questions were put and satisfactorily answered. Mr. Pritchard being also greatly complimented on the instructive and exhaustive character of his lecture. Among those taking part in the short debate were the President, Messrs. Foster, Powell, Durward, Wynn, E. J. Dore, &c.

Mr. Charles Foster, Assistant-Director in Horticulture at the Reading University College, kindly exhibited a very beautiful collection of Apples, the fruit being displayed in boxes with a view to illustrating the best method of marketing. Mr. Foster also exhibited some well-grown Carrots (Sutton's Favourite and Champion Horn) and a large specimen of Cardoon.

Mr. E. J. Powell brought a most interesting tray of new Potatoes from retarded tubers of the 197 crop, the old tubers having been placed in a cold frame on September 7 last.

Mr. J. Wynn showed a fine basket of Sutton's Ailsa Craig Onions, and Mr. Durrant again staged a lot of exceedingly beautiful Dahlias.

Six new members were elected, and votes of thanks to the lecturer and the president concluded the meeting.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE WINTER PRUNING OF HARDY FRUIT TREES AND BUSHES.

(First Prize Essay.)

PASSING over the well-nigh untenable dictums of hard pruning on one hand and that of non-pruning on the other, it may be confidently assumed that a middle course between the two extremes is justifiable. Taking in review order any one of the larger species of fruit, more particularly the Apple, on making a study of its varying modes of growth and bud production it becomes evident that wide differences exist, and that, while some varieties require considerable pruning to induce a shapely form and ultimate fruitfulness, others reach the same point with little or no assistance in this way. This arises principally from the fact that the majority of varieties produce fruit upon spur or lateral growths emitted from the main branches, while some others, such as Worcester Pearmain, Lady Sudeley and Gladstone do this more freely at the points of the branches, the mere thinning out of which at intervals is all that is necessary in the way of pruning.

### THE OBJECT OF PRUNING.

This at first is done to aid in carrying out the proper formation of the tree, whether this be bush, pyramid, standard or any of the various styles of training favoured for walls and fences. In this way a young plant requires superabundant shoots to be removed, to allow ample space for the full development of those retained and to afford opportunities for sun, light and air to gain access with the least possible restriction to all parts, so that wood, buds and fruit, each and all, arrive at thorough maturity after the season's growth. The main object, therefore, in pruning is to so regulate the branches in the first place, and afterwards the side or lateral growths, that this is accomplished.

Apples and Pears grafted upon the Crab and free stocks respectively are prone to excess of growth in their early stages or until fruit is produced. To yearly prune off this exuberance only augments the evil, as still stronger growths follow. The proper remedy for this is a judicious system of root-pruning, taking care, however, that in the case of a very vigorous plant the work is not carried to extremes at first. It is better spread over several seasons, doing a portion, according to the hold the roots have of the soil, in each. A standard tree having unlimited head room requires but little pruning either at the roots or the top; thinning the shoots in its earlier stages to the requisite number, and afterwards removing any entirely that take an unseemly direction and thus tend to unduly crowd the central part of the tree, are usually sufficient.

### BUSHES AND PYRAMIDS.

Where space is ample these may also be allowed to grow freely, consequent upon the

trees being kept in form and well furnished with fruiting wood in all parts. Any shoots having a propensity to outgrow others should be proportionately reduced in length, and in the case of the pyramidal form of tree, repression of the topmost growths must, in the early stages especially, be carried out to assist the flow and equalisation of sap to all parts. Trees growing against walls or other erections, whether trained in fan shape, cordon or horizontal forms, always grow most freely at their extremities, or, in the case of horizontals, along the highest branches. Summer pruning is the proper corrective with these, which, if properly carried out, leaves but little to be done in winter excepting the shortening of any shoots previously stopped and the thinning out of fruit-spurs where too thick, and occasionally the entire removal of those rendered effete and rough with age, to make room for others more promising.

*Plums.*—The Plum as an orchard tree, whether grown as a bush or standard, is very easily managed, and as most varieties bear fruit early, not much pruning is required; thinning out cross branches or those misshapen, and the timely stopping of any shoots showing an excess of vigour, is usually sufficient. As trained trees against walls or espalier rails the case is different; here with age the spurs are apt to get long and unsightly, more especially so if summer stopping of the young growths is not well attended to. Hard pruning of these should, if possible, be avoided: first, because if cut back to the hard wood they often fail to again break at the point of severance, and blank spaces are thereby made; while, secondly, the most common ailment of the Plum—gumming of the branches—often follows severe use of the knife. In other respects, repression of topmost growths and careful thinning of the branches and bud clusters will maintain the trees in health, vigour and fruitfulness. As an aid to the latter, a systematic course of root-pruning should be carried out, particularly so for a few years after planting, or until the fruit-bearing stage is reached.

*Cherries and Apricots.*—Dessert varieties of the former and Apricots are managed most successfully upon the spur principle, and very similar in all respects to that detailed for Plums. Summer management of both is of the greatest importance; timely pinching of the shoots from June onwards leaves but little by way of pruning to be done in winter. Fruit-buds are produced very freely on both, and an effort should be made to keep these near the wall by summer treatment if possible. Morellos fruit principally upon the previous year's shoots, for which room must be made by pruning out those that have fruited; foreright shoots, except the very shortest, are best cut clean away.

*Peaches and Nectarines.*—These also bear fruit upon the previous year's wood, but, owing to precocity of flowering, pruning is best deferred until February, when most of the older growth may be removed and the young used to replace it. In pruning, the unripened points of the shoots should be cut away, leaving, in every instance, a triple bud at the extremity to ensure a shoot again springing therefrom, which would not ensue were the terminal a flower-bud only.

*Figs* are best pruned in spring when all danger of severe frost is past. As many of the short, naturally-formed spurs as possible should be retained, while all damaged points or branches too thickly placed may be removed and others used to replace them.

#### BUSH FRUITS.

The *Gooseberry* is the principal and most highly valued of these. In pruning, the centre of the bush should be cleared of all intercrossing shoots, cutting these back close, after which all others may be thinned according to necessity, but without shortening, unless they are malformed or project much beyond reasonable limits and thus destroy the symmetry of the plant. Some of the shoots may be pruned to within 2 inches of their bases to form spurs, should bareness be prominent; but with young, well-furnished plants the extension principle is best and the evil of thickets of growth which usually result from spur-pruning is avoided.

*Red and White Currants* are both worked upon the spur system, and the plants are kept in order and well furnished with fruiting wood throughout without much trouble. Aged, broken, or worn-out branches must occasionally be replaced by others left the previous year to succeed them.

*Black Currants*.—With these it is important that sufficient shoots start from the ground level to eventually form a large spreading head of growth; afterwards an annual thinning out of any branches too thickly placed, thus giving light and air free access, is all that is required, as the naturally-formed spurs along the branches will be ample for crops without the necessity of pruning side shoots.

*Raspberries* of the summer-fruiting section require the fruiting canes of the current year to be cut away close to the soil as soon as the crop is gathered, and the young growths, which by this time have nearly completed their season's growth, be thinned in accordance with the style of training carried out; but whether the canes are secured to trellises in rows or drawn together around a central stake, the space between each should not be less than 8 inches. The points of the canes are best left intact until the winter is past, to obviate water obtaining a lodgment in the hollow end, and so causing mischief. The height at which pruning should then be done depends very much upon the method of training followed; but if the canes have been kept upright during growth, and are therefore nearly straight, 6 feet from the soil is a very convenient height, the fruit being easily gathered and protection from birds by means of netting made possible. Autumn-fruiting varieties are best cut over close to the ground in March and the resultant growths thinned in due course, as these produce fruit upon wood of the current year.

The *Blackberry Family*, including the Loganberry and hybrid varieties, should have the old bearing shoots cut away yearly, doing this for preference in the late autumn and those of the previous summer be secured in place thereof. Regulation of these depends upon the space available; where this is ample, a loose, almost unrestricted growth favours fruitfulness.

*Damsons* may be allowed to grow somewhat more thickly than most fruit trees, and a clearing away of small, almost useless branches from about the centre of the trees and upon the larger limbs is better than hard pruning.

*Filberts and Cob Nuts* are best grown in bush form, and require careful attention at the start to keep the shoots spread evenly in a circle upon a short stem. After-management consists in maintaining this form so that the centre of the bush or tree is always clear. Pruning is best done in February when in bloom, and as growth is apt to become too concentrated, much that is barren is then distinguishable and may be pruned away.

JAMES DAY.

Galloway House Gardens, Garlieston,  
Wigtownshire.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 14.—Mansfield and District Chrysanthemum Society's Show.

November 24.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m. Lecture at 3 p.m., by Mr. Joseph Cheal, on "Italian Gardens." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

**Photographic Competition for our Readers.**—Owing to the large number of photographs received for this competition, we are unable to announce the prize-winners this week, but the work of selecting the winning photographs is being pushed on as rapidly as possible, and we hope to be able to announce the results very shortly.

**Belgian honour for Mr. Harry J. Veitch.**—It is with the greatest pleasure that we learn that the King of the Belgians has conferred upon Mr. Harry J. Veitch, V.M.H., the insignia of a Chevalier of the Order of Leopold, and His Majesty King Edward VII. has been graciously pleased to issue a licence permitting Mr. Veitch to accept and wear the same. We offer our heartiest congratulations to Mr. Veitch on his being selected for such an honour, which he thoroughly deserves.

**Lecture at Redhill.**—On the 16th inst., at Penrhyn Hall, Redhill, at 7.30 p.m., Mr. W. S. Murray, of the firm of Messrs. James Murray and Sons, Deptford, London, S.E., will give an illustrated lecture on "Seed Inoculation with Nitrogen-fixing Bacteria."

**British Gardeners' Association.** The next meeting of the London branch will be held on Thursday, November 12, at 7.30 p.m., when Mr. J. Harrison Dick will give an illustrated lecture on "Famous Gardeners." All *bonâ-fide* gardeners are privileged to attend. The Secretary desires all those intending to become members to hand in their forms before the lecture. A public meeting of professional gardeners will be held at the New Hall of the Co-operative Society, Clay Hill, Haslemere, Surrey, on Saturday, the 14th inst., at 7.30 p.m. An address upon the "Aims and Objects of the British Gardeners' Association" will be given by Mr. J. Weathers, F.R.H.S. (secretary of the British Gardeners' Association), supported by Mr. E. F. Hawes. All professional gardeners in the district are invited to attend. Full discussion will be allowed.

**Scottish Horticultural Association.**—The usual monthly meeting of the Scottish Horticultural Association was held in the Gould Hall, St. Andrew Square, Edinburgh, on the evening of November 3. There was a large attendance and several exhibits were on the table. Among these were Chrysanthemums from Mr. W. Williamson, Logie Green; Roses from Messrs. Todd and Co.; *Salvia splendens* from Mr. Staward, Belford House Gardens; and various plants from the open garden from Mrs. Algie, Toghier House, County Mayo, Ireland. The paper of the evening was the appropriate one of "Chrysanthemums: The Growing and Showing of Large Blooms for Beginners." As was to be expected from a grower of the experience and skill of Mr. D. Nicoll, Rossie, Forgandenny, who was the essayist, the paper was one of the most practical and useful as yet given before the association on the Chrysanthemum, and it was treated in a way which rendered it most valuable. Mr. Nicoll began with the preparation and striking of the cuttings, and gave a thorough *résumé* of the operations and treatment needed to secure the finest blooms. The selection of varieties for the various purposes was also ably dealt with. Mr. Nicoll received a hearty vote of thanks for his lecture.

## PRIZES FOR READERS.

### OCTOBER COMPETITION.—AWARDS.

In this competition the prizes were offered for the best essays on "The Winter Pruning of Hardy Fruit Trees and Bushes." This proved a very popular competition, and a large number of good essays were sent in. The prizes are awarded as follows:

First prize of four guineas to Mr. James Day, Galloway House Gardens, Garlieston, Wigtownshire.

Second prize of two guineas to Mr. W. G. Wadge, Viceregal Gardens, Dublin.

Third prize of one guinea to Mr. Gilbert Walshaw, Cheswardine, Griffith's Road, Wimbledon.

Fourth prize of half-a-guinea to Mr. G. Cope, 100, Bournbrook Road, Selby Park, Birmingham.

The essays from the following are highly commended: Arthur Smith, Ontario, Canada; G. E. Greenhow, D. Lewis, Miss G. E. Pollard, T. W. Herbert, L. Johns, D. E. Elder, M. Dearden, W. H. Scott, A. E. Groombridge, G. H. Webster, "Hortus," E. Stenlake, F. G. Tuteher, J. W. Watkins, A. Payne, W. Hooke, S. J. Briscoe, F. Landsdell, A. R. Gould and Miss M. L. Smith.

Many essays appeared to have been derived principally from books, but in the majority the operation appeared to be fairly understood. Many ignored the fact that in well-cultivated trees summer pruning would have previously been done.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Apple Clarke's Seedling.**—It is really wonderful how experiences differ. Your correspondent "D. K." finds this a good cropper; we have grown it for twenty years at Chilwell and Lowdham, and during that time I have only seen one crop. Your correspondent describes the Apple and its habit perfectly, but I would add that although a profuse bloomer the flowers are so tender that it seldom carries fruit, and it is about the last variety which I would recommend for a low-lying damp garden. The above remarks will explain to amateurs why Messrs. Merryweather (who, I believe, sent this Apple out) have, in company with other nurserymen, dropped this variety from their catalogues. Old fads are hard to kill, but I thought the idea of putting slates, stones, or what not under fruit trees had expired. It seems from the issue of THE GARDEN for October 31 that such is not the case. It would be interesting to know what benefit the slate is supposed to give to the tree? Fruit trees on proper dwarfing stocks, which have been raised from cuttings or layers, not seed, bedded, lifted, transplanted and worked, are not prone to make tap roots, but when fine stocks are used I fancy it would need a good-sized slate to prevent their making tap roots if they were so disposed. It is true that the roots cannot grow through the slate, but they would not find much difficulty in growing round it; on the other hand, these slates or stones prevent capillary attraction, and a tree planted over a good-sized one would in a hot season be about as happy as live eels in a frying-pan over a brisk fire. Many people induce tap roots by placing manure under the roots of trees when planting; if they would apply it to the surface of the soil as a mulch the roots would be tempted upwards instead of downwards, and the slates may be relegated to that limbo in which we have placed the old practices of burying dead dogs or even horses in Vine borders, or plastering these same borders with a couch of wet manure every winter to the exclusion of the air and the consequent death of the Vine roots.—A. H. PEARSON, Lowdham, Notts.

**Garden Peas.**—Referring to the letters concerning Peas, I sowed Thomas Laxton on July 20, after early Potatoes, and gathered an excellent lot of well-filled pods on the 16th ult., and an equally good supply again on the 24th ult. Last year I sowed the same sort of Pea too early, on June 24; they came in about the end of August. The row now standing is entirely free from mildew. I use posts, nails and string; they are preferable to sticks.—S. JACKSON, *Clinton House, Kingsland, Shrewsbury.*

**Sweet Peas in flower.**—I noticed in THE GARDEN (page 530) a paragraph mentioning the gathering at Kingston Hill on October 16 of Sweet Peas with stalks 10 inches long. This morning (October 30) there were some in my garden that were picked with stalks equally long, and a bright pink. There are still plenty of buds and the plants are quite fresh and green, this being a fortnight later. Of course, I am much further north than your correspondent. I thought this information would interest you.—B. TINNE, *Delfield, Aigburth, Liverpool.*

**A well-grown Cypripedium.**—I am venturing to send you a photograph of a pot of Cypripedium insigne now in bloom with us. There are no less than thirty-five blooms in full beauty and two of the stems each bear two blooms, which I believe is somewhat unusual. The plant is growing in a 12-inch pot, and, being such a fine specimen, it occurred to me you might be interested to see the photograph.—WILFRID TILLET, *Old Catton, Norwich.*

**Autumn tints.**—The present display of colour in the trees, which we all look forward to with so much interest, is most disappointing; indeed, I cannot remember so poor a display in this part of the county of Gloucester. I first noticed that the Norway Maples were not giving us their usual blaze of bronze and gold. Instead of the leaves remaining on the midsummer growth till the last, they fell off about the last week in September, after turning crimson, which is rather unusual. I believe this can be explained by remembering that just as this growth had finished a spell of exceptionally hot weather set in, which caused most trees to flag. This dry weather lasted nearly a month, and the drought penetrated to a considerable depth, causing Beech trees to cast many of their leaves. Referring to my diary, I find that the hot spell of weather began on July 18 and ended on August 25, but for several days after this there was only an occasional storm. I think this rather long spell of exceptionally hot weather is wholly responsible for the poor colour in our deciduous trees and shrubs. The Beech is one of our finest trees at this season of the year; it does so well on the limestone which abounds on the Cotswolds. All the leaves were scorched by the long drought, and are now falling before turning the usual brilliant golden and bronze colours. None of the Maples are giving us a really good display for the same reason; in fact, many of the Japanese kinds lost their leaves while they were still green. They usually make the most gorgeous display. *Acer colchicum rubrum* lost its leaves (except a few which are still clinging to the bottom branches of the trees) three weeks ago. *Rhus cotinoides*, a beautiful shrub which brightens up the grounds at this season, has now lost nearly all its leaves without colouring very much. However, the abundance of fruit which many of our wild trees are carrying atones to a great extent for the loss of foliage. The Spindle Wood (*Euonymus europæus*) is very fine indeed, so are all the wild Thorns and Viburnums. I never saw the wild Ro-es bearing such an abundance of large, brightly-coloured fruit as at the present time. Some of the garden Roses are also giving a bright display, particularly the Penzance Sweet Briars, *Rosa rugosa* (Japanese Rose) and other single Roses. Many of our summer Roses are well worth growing, apart from their summer display.—T. ARNOLD, *The Gardens, Cirencester House, Cirencester.*

## THE KITCHEN GARDEN.

### MESSRS. SUTTON & SONS' TRIALS OF TOMATOES, RUNNER BEANS AND POTATOES.

TO the ordinary gardener, whether amateur or professional, few visits have wider interest than is found in one paid to a large trial ground, such as Messrs. Sutton and Sons have at Reading. It is in such places that one sees not only so many things which are not common in gardens, but also so many that are represented in numbers far beyond the capacity of any ordinary garden. Thus at Reading we saw this autumn a truly wonderful trial in the open ground of Tomatoes. It was not a trial on walls or fences, but right in the open farm land, and where every plant, although having plenty of light and air, had not the least shelter or special treatment. The plants were arranged in rows of ten; there were 250 such rows, each one staked and every plant treated alike, making in all 2,500, and thus forming, with some seventy or more varieties with several rows of each, an unrivalled trial. Generally, the fruit crop was an enormous one, and there

A WELL-GROWN PLANT OF CYPRIPEDIUM INSIGNE IN THE GARDENS OF MR. W. TILLET, OLD CATTON, NORWICH.

was no disease of any form. Winter Beauty, Prince of Wales, Magnum Bonum, Sutton's Satisfaction, Peachblow, Early Market, Red Dessert, Golden Nugget, Golden Queen, Sunbeam and many others were carrying truly marvellous crops. As a trial of Tomatoes in the open ground we have never seen one more extensive or better.

Runner Beans again presented a huge trial, scores of rows, well staked, growing side by side, showing the relative and always high-class merits of Prizewinner, Best of All, Al, Sutton's Scarlet (a great improvement on the old scarlet), Mammoth White (a greatly-improved Czar) and others.

Then we went to a trial of spring-sown early Cabbages, the best probably being Sutton's Earliest, dwarf, solid, small-hearted and a very perfect stock; Little Gem, a delightful little Cabbage for summer and autumn use; All Heart, very fine conical hearts and few outer leaves; Tender and True, Early Oxheart and Improved Nonpareil, all of the very best for spring sowing, though not for autumn sowing. There was, too, a large breadth of Earliest of All Savoy, having very solid hearts, such as should be equally valuable for private use and for market sale.

At the Southgate Gardens there was a large trial of seedling Potatoes, and in another somewhat distant garden we saw lifted a breadth of 100 plants of a seedling, 195, which evidences at once a superb late Potato, a heavy cropper, having no over-large or coarse tubers, and, for a wonder, no Up-to-Date blood, but absolutely distinct. This variety, not yet named, is from Abundance crossed with Langworthy. In this case every one of the 100 roots was lifted, not a tuber being disturbed, and as they were thus exposed they presented one of the most interesting Potato shows we have ever seen. A well-known Hampshire gardener who grew this fine seedling writes of it in terms of high admiration, especially for its crop, quality and distinctness. The firm have many other seedlings coming on of which more will be heard in due course. Among others, a special line is being produced for those who seek for high flavour in Potatoes, and it is hoped these will come into commerce during the coming winter.

In the deep cellars that are below the old massive Southgate mansion a trial of Mushroom spawn was seen. Here were beds made up on entirely the same lines and spawned at the same time, yet showing marked difference in production. The new Twentieth Century spawn, by which name it is known, produced under entirely diverse conditions from the old form, is seen to be fully a month earlier in production of Mushrooms, and also to give a much finer and more solid sample. Thus are things progressing.

### A VALUABLE EARLY RHUBARB.

(DAW'S CHAMPION.)

At this period of the year growers have to think of the winter and spring supply, and both for forcing and for first crops in the open the above is a really fine Rhubarb, and so distinct in every way that the fruit and vegetable committee of the Royal Horticultural Society gave it an award of merit on February 13 as a new forcing variety, and a first-class certificate on March 27 for its earliness in the open and for general excellence. Certainly it is only on very special occasions that a new fruit or vegetable is honoured in this way. By this it will be seen that the new Daw's Champion has exceptionally good points and is well worth a trial, and I would certainly recommend it for both forcing and open ground. It is less acid than older sorts, has a splendid colour, is very free and the long, thick stalks are of bright colour. B. M.

### PEA SUTTON'S PEERLESS.

As a midseason and late variety I consider Sutton's Marrowfat without an equal, and certainly it is the finest culinary Pea for a light soil that I have yet tried. It is strong and vigorous in growth, not quite 3 feet in height and grown on the above-mentioned class of soil the variety has proved a grand Pea in every way, and especially valuable to the amateur. As seen growing the handsome pods are a great attraction, and on the exhibition table would carry great weight. The yield, both of pods and corn, is in every way excellent, the climax being reached by its superb flavour and colour when cooked. The plant is practically proof against mildew, a high tribute perhaps in a very trying year. The first-class certificate gained by it in 1903 has obviously been well merited. E. JENKINS.

### CAULIFLOWER PLANTS.

WHERE these are in pots they should have all the air it is possible to give them. The lights may be removed in fine weather and replaced again on the approach of rain, and tilted up in such a way as to give the greatest possible quantity of air without subjecting the plants to excessive moisture. This will have the effect of causing succulent growth, rendering the plants unfit to stand a week or more of darkness when covered up in severe weather.

## TREES AND SHRUBS.

## THE FORSYTHIAS.

**D**URING the dull, foggy days from November to January it is pleasant to think of all the garden glories that are to come and conjure into the murky gloom a remembrance of past scenes. Of all the lovely promises I look forward to in the near future, one of the mental pictures I carry about with me on a thick, dark winter's day is almost the earliest, certainly the best of all—that glorious and wonderful sight of the Forsythias, those shrubs whose luxuriant showers of bright golden

growth or by dint of close clinging to a sheltered wall may withstand the inclemencies of the season, they cannot compare with the Forsythias, which are large, full-grown shrubs some 10 feet to 12 feet high and as much as 6 feet or 8 feet through, literally covered with the pendulous flowers nearly the whole length of stem.

I would not forego the sight of these for any other early garden picture, beautiful as they all are, and for however small a garden my first choice of a shrub would be these. They are quick growers, will thrive in any position and almost any soil, from one so poor as to be almost all gravel to a rich loam. They can be allowed their natural grace, in which case only slight pruning is necessary after the flowering is over,

or they can be kept to a required size and trimmer form for planting in beds, and to this end must at the height of 3 feet or 4 feet be cut down when the flowering period is over. The shoots will then grow to 5 feet or 6 feet, and the process must be repeated early each year if the same result be desired.

Propagation may easily be effected either by cuttings put in sandy soil and kept in the greenhouse or taken in October and put in a sheltered border. These will soon root, and

may be expected to flower the second or third year after. Another way is to allow the long stems on the trees to bend over till they touch the ground, when, often even unaided, they will strike and take root.

There are practically four sorts, notably *F. suspensa*, which is the finest of all, with which we may include the synonyms *F. Sieboldii* and *F. Fortunei*. This is the most graceful, and is suited to almost any purpose we may wish to put it. Then come *F. intermedia*, smaller and rather more upright in growth, and *F. viridissima*, still less free in its habit, but which has the bark on its stems a good bright green, and in autumn the foliage colours to a warm purple. The fourth variety, *F. europaea*, is as yet somewhat of a stranger, and not so happy in its surroundings as are the three former. This is of slower growth, has thicker leaves and shorter branches without the grace of *F. suspensa*, grows to the height of only about 3 feet to 5 feet, and is, in fact, distinct from the others in general habit. It is of recent introduction into this country, having been brought in 1899 from Albania, its native home, where it habitually bears fruit, in this respect differing from the other Forsythias, which have all been imported into Europe from Japan and China and have never yet been known to fruit in our Continent.

E. CURGWEN.

## HYDRANGEA PANICULATA GRANDIFLORA.

WHEN well grown this is one of the best of autumn-flowering shrubs, as it keeps in flower for a considerable time and is very showy. The type, *H. paniculata*, is a Japanese shrub that grows 6 feet or so high and several feet through, and it has been cultivated in British gardens for about

thirty years. The leaves are ovate, 4 inches to 6 inches long and serrated. The flowers are white or cream-coloured and borne in large terminal panicles, most of the blooms being small and fertile, the others large, showy and sterile. They appear in August and last through September. The variety *grandiflora* is very much like the type in habit, but the inflorescences are composed mainly of sterile flowers, and are much larger than those of the type. When they first open they are white or cream-coloured, but with age they become suffused with red. When young, healthy plants are grown in very rich soil, it is possible to obtain exceptionally fine heads of flowers often as much as 18 inches long and 1 foot through at the base. To obtain inflorescences of these dimensions it is necessary to restrict the plants to a few growths, cutting hard back each year. Grown to a full-sized bush, as the one shown in the illustration, which is from America, the flower-heads are more abundant, but are much smaller. Grown in pots and subjected to very slow forcing, *H. paniculata grandiflora* makes a very useful market plant; it is, however, a difficult shrub to force really well.

W. DALLIMORE.

## SWEET PEA NOTES.

## CROSS-FERTILISATION OF SWEET PEAS.

**Y**OUR correspondent Mr. P. Clapham (page 532) asks: "What are the insects which bring it about?" and says that "he has not discovered insects near the blooms which are strong enough to force open the keel and come in contact with the stigma." I do not propose to answer the main question directly or suggest the cause; but as to the insects, may I be permitted to state my observations and, incidentally, draw attention to a useful adjunct to the Sweet Pea grower. Some of my flowers are visited by what I take to be a small black beetle about one-tenth of an inch long. Several of them may be seen inside and through the semi-transparency of the keel of the flower. I have not observed how they get there, but there they are, and, as far as one can see, without any apparent damage to the flower. I have usually considered them harmless. Their object, however, must surely be to feed on the pollen. It is the same little beetle one finds so frequently buried in a Carnation bloom along with the much smaller thrips. Then, again, what about the earwig? This pest and marauder goes more directly to work, often taking a generous slice off the end or side of the keel or flower. They have a partiality for blooms half open, having the good sense, no doubt, to get the pollen at its best. Oh yes! Mr. Earwig undoubtedly likes the pollen. May I support this statement by the following lucky experience. These last two seasons I kept a hive of bees, not successfully—they dwindled. They gathered a moderate amount of pollen, which is mixed by them with a small quantity of honey and stored in the lower portion of the cells in the frames, and used eventually to feed the young grubs. It is mainly pollen with just sufficient medium to bind and keep it stored in position. Well, the bees swarmed, and I lost the small colony there was, being eventually left with the empty hive and a few frames of food as above stated. It was situated some 4 yards or 5 yards away from and opposite the centre of a row of Sweet Peas some 16 yards long. It remained there for a week or two neglected. Judge of my agreeable surprise, on opening the hive with the intention of clearing it away, to find the cells tenanted with numbers of earwigs, all buried head downwards in the cells on the frames feeding on the pollen food, and noticeably neglecting the smaller number of honey cells. In two operations, at about a week's interval, I slaughtered nearly 505 of these pests, and have at various intervals

A STANDARD HYDRANGEA PANICULATA GRANDIFLORA.

bells make such a welcome sunshine in the midst of frost.

I know a spot in the heart of a smoky city where the Forsythias have been planted with a loving hand, lavish but not unrestrained, so that a perfect wealth of yellow sunny bloom is to be seen in the cold, sharp days at the end of February, when the sun is up and days are bright, but still cold, bitterly cold. Yet in spite of it the Forsythias put out their lovely golden drops untouched by the icy chill, which proves too much as yet even for most of the early little bulbs. No sight more glad some than this in all the year. Even the Daffodils, Snowdrops and Scillas which later come to form so lovely a picture fail to give us the same keen pleasure as these lovely sunny shrubs at a time when almost all else in the garden is but green and brown.

Do not be afraid to overplant—have them in profusion; once you know their worth your cry will be for more and yet more. Give them room to grow and expand and shake out their long stems with the yellow blooms. Plant them generously, not just here and there, but many together in a clump in the shrubbery, by a border, or a few together on the green grass, or, again, by a wall, up a fence or over a bank or rockery, and you will never regret the space allotted to them. The display they make at the first greeting of the sun and spring will repay you well enough, and then later, when all the blossoms are done, the leafage, too, will give you pleasure, and the form and growth of the whole plant is graceful and attractive.

How grateful we must be to such hardy, precious things on which we rest our eyes and which usher in the spring. Not many plants can brave the cold as they do, and, although there may be some few which by reason of low

killed quantities since in decreasing numbers. Now, Mr. Editor, forgive my lengthy digression; but what a trap and ideal board and lodging, the natural shelter of a weather-proof wood hive, with the daintiest of food and a well-stocked larder! Truly a real "Come into my parlour"; wholesale only! As to the bees, although I have occasionally observed them making a close inspection of the flowers, they practically, I think, neglect them. The small beetle, however, I take it, creeps inside the keel and wanders about; but the earwig boldly hacks a way through and gets to business head first, I suppose (like the bee cell), and the rest is easily imagined. I think, therefore, Mr. Clapham's statement that insects do not come in contact with the stigma needs explaining, notwithstanding the rather confident tone he adopts. A. A. G.

I HAVE read with great interest the various letters and articles in your recent issues on the subject of "Cross-fertilisation of Sweet Peas." I am a small grower of these lovely flowers, and have had them under close supervision for the last few years; but I do scarcely any seeding. I have found many instances of the prolonged anthers extending beyond the keel (which seems to split so often in the Spencer type), and this must render these special flowers subject to cross-fertilisation by insects.

I find about the end of July that my Sweet Peas are infested with small beetles, which are inside the keel, and that they can make their exit at pleasure is proved by the fact that if a vase of Peas is put on a white cloth there are numbers of these little beetles to be seen on it very shortly. As they can fly, they doubtless pass from plant to plant. If other growers have visits from these same beetles, may they not be responsible for the cross-fertilisation to a certain extent? I do not remember being troubled with these beetles when I only grew the old type of flower, and cannot say if they make their exit from them as they do from the Spencer type; but they are often quite a nuisance on our dinner-table, as they drop from the flowers in large numbers. Next season I will take special notice if this is the case when using flowers of the old type only, or I will gladly send some specimens of the infested varieties (of both types) to any expert who cares to send me his address. MRS. G. LEIGH SPENCER.

*The Priory, Cliford, Herefordshire.*

## TWO BEAUTIFUL COLOURED-LEAVED PLANTS.

PLANTS that are evergreen and have coloured foliage are always welcome in the garden to cut from. *Shortia galacifolia* has this merit. Early in the spring, when at Coombe Wood Nursery, I was much impressed with this growing in pots. The plants were about 1 foot high, the foliage a reddish bronze or deep claret red. In one of the houses I noticed some of these had just begun to throw up their flowers, which are of a Snowdrop-like nature and thrown well out of the leafage, contrasting beautifully with the red foliage. At a Royal Horticultural Society's meeting last spring I observed this plant was shown well in flower in one of the hardy plant exhibits. It is a North American plant, and is said to require a cool, moist, shady position. *Galax aphylla* deserves to be more known. This has neat, rounded, toothed foliage, beautifully tinted, and is evergreen. It produces dense spikes of white flowers. Of late years this has been much sold in Covent Garden for its bright foliage, and is seen largely in bunches during the autumn. When these high-coloured foliage plants are well placed they brighten up the garden during the winter months and are most valuable to cut from, and when arranged with suitable flowers they are most attractive. These plants are within the reach of all who have gardens. J. C. F.

## THE FRUIT GARDEN.

### RENOVATING OLD VINES.

FEW gardening operations are so full of possibilities as the renovation of old or unfruitful Vines, and such are frequently to be met with where it is not always convenient or advisable to root them out and replace. If Vines are old and renovating measures are to be taken, while the leaves are still green and as soon as the fruit can be cleared is a good time to commence operations. Let me point out for the benefit of any amateur readers who are anxious to grow good Grapes, that no amount of attention to temperatures or shoot or bunch manipulation will produce fruit of superior excellence, or even keep Vines in a fruitful condition for any length of time, unless the necessary elements for building up good vigorous wood are applied to the roots. Let me also impress upon the cultivator the absolute necessity of guarding against stagnant moisture at the roots. If the border lies high, or has a subsoil or underlying bed of gravel or sand, no danger need be feared on that score. Where, however, the conditions are the reverse of this steps must be taken to afford ample drainage and raise the surface of the border to a higher level than its immediate surroundings. To this end take out a trench along the front of the border, afterwards a fork must be used to gradually work back the soil from the roots, which, when laid bare, should be kept well moistened by wrapping them in mats or sacking, which must be repeatedly damped. Meanwhile the house should be kept close and moist, the foliage well syringed, and during bright sunshine shading must be resorted to.

every cartload of loam about two barrow-loads of old mortar or lime rubbish and rather more than half a hundredweight of coarse crushed bones be added. The whole should be well incorporated, the turfy loam having previously been roughly chopped up with a sharp spade. This should be wheeled in to form the border, the roots being carefully spread out and covered with the hand as the work proceeds, pruning back with a sharp knife any long, straying roots which seem destitute of feeding fibres.

Some of the Vines of which I have charge are of great age, and previous to my taking them had been considered worn-out and useless. We, however, decided to give them another chance, with the result that for the past few seasons they have given us the best fruit of the varieties on the place. As our fruit range is at the highest part of the garden, and we have a subsoil of sand and gravel, the operation of border renovation was somewhat simplified. We cleared away the old soil till we came to roots, many of which were pruned hard back, as they were almost destitute of feeders, the border being afterwards filled in with soil like that already described.

To sustain fertility, every spring we fork in a fair dressing of the finest bone-meal procurable, and wood ashes (these are kept dry till required for use), afterwards putting on a light mulch of cow manure.

Naturally, after having taken so much trouble with his Vine border, the operator will soon be looking for improved results, and these are best brought about by allowing a considerable extension of growth. This will, of course, add vigour to the rooting system, so that the fullest advantage can be taken of the new soil by the Vines. With our Vines we decided to run up new rods from the old roots, cutting out the old rods as

THE TWO BUNCHES OF BLACK HAMBURGH, CUT FROM OLD VINES, WHICH WON FIRST PRIZE AT SHREWSBURY SHOW THIS YEAR.

This practice must be followed up until the roots appear to have taken hold of the new soil.

Prior to making up the border care must be taken to provide ample drainage, which should consist of half bricks and any material of a similar character through which water can readily pass. Over this squares of turf should be placed grass side downward. This will, of course, keep the finer soil from working down among the drainage.

Whenever possible, good turfy loam should form the basis of a Vine border. I prefer it inclining to heaviness rather than otherwise, only a greater proportion of mortar rubble is necessary to keep it somewhat porous. I am not very much in favour of too many ingredients being included in the composition of the border, and would suggest as a guide that to

soon as the new ones were fruiting two-thirds the length of the rafter (20 feet). To furnish these young rods a bud or break was selected, as near the bottom of the old rod as possible, stopping the shoot when it had reached a length of from 5 feet to 6 feet, and cutting back at pruning-time to 3 feet or 4 feet, according to the strength of the cane, repeating the process till the top of the house was reached.

From the renovated Vines referred to in my notes we have cut bunches of Black Hamburgh weighing over 6lb., and in August of last year the two Hamburgh bunches which won first prize among fifteen competitors at Shrewsbury great show in the open class, and also in the same class this year, were cut from the same vineyard. W. H. WILSON.

## THE ROSE GARDEN.

### GOOD ROSES FOR FORCING.

**T**HERE are certain varieties of Roses which are never seen more beautiful than they are when grown under glass. Such a one is Sunrise, the charming sport from Sunset. We are now obtaining a marvellous colour from pot-grown plants in a greenhouse with the least amount of artificial heat. It is a variety all should grow where slight forcing can be done. I do not recommend it for a cool greenhouse. There are numbers of lovely Roses that may be grown in cool houses, including some of the best of the Hybrid Teas, but this one needs artificial heat to develop its growth and bloom. The beautiful buds are quite the richest ochre red one could imagine on the outside of the flower, with a centre of orange gold. The lovely rich ruby red foliage is also a great attraction.

This is a good time to make a commencement in pot Rose culture, and plants should be secured before the best are all sold. Those in 8½-inch pots are the best value. If handled rightly they will give a number of blooms this coming winter and spring. The plants are usually prepared for forcing, and no repotting would be needed until next summer. It is sometimes advisable to give a top-dressing of compost, consisting of two parts fibrous loam, one part well-rotted manure, and a good sprinkling of bone-meal. Plants are often procurable that would go on flowering at once without any pruning. Just keep them in a temperature at night of about 55° with a little top air on, and they will give numbers of charming buds. These same plants could then be used for forcing after Christmas if rested for a time prior to pruning them.

A Rose house must sooner or later form a feature of every establishment. The blooms produced under good management are of exquisite beauty, so clean and refined and free from the blemishes that often mar the outside flowers. Where it is possible to provide a house with borders to plant the Roses into, this is the very best method of culture. Inexpensive structures are now obtainable, or they can be constructed by any handy man. In some places pit-lights 6 feet by 4 feet are used for the roof, and most useful they are, for being removed in summer the plants receive the rains and natural culture during that time. A house of a simple description erected upon a new piece of meadow land, the house running north to south, would be a capital start. Have the land well trenched, taking care to bury the top turf and work in manure and half-inch bones liberally; then plant

out some of the extra-sized plants alluded to, or plant bushes and standards from the open ground and grow them for one season with the lights off.

It is surprising what make-shift structures can be used for obtaining Roses earlier than those outdoors. Some of the grand cut flowers seen at the May exhibitions are grown in skeleton houses with a roof of glazed pit-lights and boarded or canvas sides to confine the air. Even artificial heating is sometimes dispensed with, although a row of 4-inch pipes would materially help the development of the blooms.

It may be asked what sorts should be grown. Here are a few I can recommend: Frau Karl Druschki, Richmond, Captain Hayward, Liberty, Mme. Abel Chatenay, Rhea Reid, Caroline Testout, Mme. Ravary, Mrs. John Laing, Mrs.

THE NEW SINGLE CHRYSANTHEMUM HILDA LAWRENCE, SHOWN BY MRS. R. GREGORY, SHOREHAM.  
(Much reduced.)

Aaron Ward, Joseph Lowe, Lady Battersea, Antoine Rivoire, Farbenkönigin, Joseph Hill, Mme. Segond-Weber, Lady Roberts, Lyon Rose, Prince de Bulgarie and Paul Ledé. P.

### ROSE A PARFUM DE L'HAY.

This is one of the rugosas that is seldom seen, yet it is one of the best of its class. In growth it resembles Mercedes, and like the rest of its class does not suffer from mildew or red rust. Perhaps its most valuable point is its late flowering. It is a brilliant and quite distinct red, never better than during late autumn, and is very sweet-scented. A. P.

## THE FLOWER GARDEN.

### NOTES ON IRISES.

(Continued from page 492.)

**I**RIS PARADOXA is a singularly beautiful plant from Persia. The leaves are tapering and sickle-shaped. Flowers 6 inches to 8 inches high, with massive clasping standards coloured pale reddish purple, veined with thin lines of blue and suffused with a silvery pink shade. The falls are short, horizontally poised, coloured dark purplish brown and entirely covered with close velvety "pile," resembling the back of a humble bee; the tips alone have arrow-head-like processes free from hairs.

*I. paradoxa choschab* is the best form and, according to good authority, the original *I. paradoxa*. The standards are silvery white and delicately veined blue. The falls resemble the type plant. These *I. paradoxa* require very careful treatment, and they are best grown in raised beds of poor soil, covering the plants with a light to ripen them for at least three months, commencing in July. Numerous hybrid seedlings retain in some degree the beautiful characters of this parent with the freedom of growth of the Bearded Irises.

*I. sofarana* is a vigorous-growing plant with tapering, inflated leaves and stout stems bearing one flower each, the standards of which are rounded, white or grey, thickly veined deep purple and spotted with a multitude of dark chocolate dots. The falls are similar to the standards, but dark purple, a few thin lines of white or grey showing here and there, and a large patch of velvety black adorns the centre, sparsely covered with black hairs.

*I. magnifica* is a finer plant and exceptionally vigorous for an Iris of its type. The petals are deep grey, dotted with silver grey; the signal patch is very hairy and coal black. A beautiful Iris of free growth, whose vigour should prove sufficient to

overcome any cultural disabilities it may have to undergo. Natives of Palestine and countries northward.

*I. susiana* is a vigorous plant from Asia Minor, 1 foot to 2 feet high, the leaves of which are tapering and inflated, the sheaths very large and the flowers exceptionally massive. They span 8 inches across and their petals are nearly 6 inches wide, coloured grey, with minute lines of dark chocolate on every surface. The general appearance is that of a dark greyish brown colouring and the signal is heavy patch of glistening black clothed below with a thicket of yellow-tinted black hairs. In some specimens the falls are "shot" with a yellowish tint and

the standards are often minutely dotted as well as veined. The plants can be grown well at the foot of a south wall, and their roots delight to run down the surfaces of the bricks to the wall's foundation. It is quite an easy plant to grow in such a position.

*I. urmiensis* is a dwarf species with sickle-shaped leaves 6 inches long and primrose yellow flowers, the standards of which are boldly erect and massive, shot with various shades of yellow. The falls are slightly darker but not so large. A charming little plant, but difficult to manage. Treatment of *paradoxa*, which the plant resembles in habit. Persia. M.

### NEW CHRYSANTHEMUM HILDA LAWRENCE.

THIS, as will be seen by the illustration, is a single-flowered variety, the colour being a pleasing lilac pink, the well-formed flowers being freely borne on good stout stems, thus rendering it a splendid variety for cutting and decoration in general. It has been shown this season by Mrs. R. Gregory, Shoreham (gardener, Mr. Lawrence), and has received an award of merit from the Royal Horticultural Society and a first-class certificate from the National Chrysanthemum Society.

### NEPETA MUSSINII.

THIS pretty little Cat-mint is a native of the Caucasus, and grows about 15 inches high, soon forming a good tuft. The numerous spreading stems are thickly covered with sage green leaves, hoary on the under-side; later they are almost hidden by a wealth of lavender blue flowers. It can be planted in the front of the herbaceous border, in dry positions on mounds in the rockery, or even between the stones on the face of the rock wall. Light, sandy soil suits it best, and it is easily propagated by division in early spring. J. COMBER.

*Handcross, Sussex.*

### EARLY-FLOWERING CHRYSANTHEMUMS.

#### SOME GOOD SINGLE-FLOWERED VARIETIES.

SINGLE-FLOWERED early Chrysanthemums suitable for border culture have improved in a remarkable manner in recent years, and both last year and during the present season there is good reason to be pleased with what raisers of these useful flowers have achieved. Varieties that were distributed three years ago completely altered the character of the garden during the autumn months, and now with recent acquisitions the future success of these flowers seems to be assured. The following are excellent sorts:

*Hilda's Favourite*.—A beautiful free-flowering plant that comes into flower in late August and continues to bloom throughout September and early October; colour, crimson terra-cotta; height, 2½ feet.

*Dr. Ingram*.—This is an ideal single variety for the border. The plants possess a good habit, bearing clusters of warm-coloured blooms in lovely sprays and of good form; colour, terra-cotta; September; height, 2 feet.

*Florence Gillham*.—A profuse-flowering plant with a beautiful bushy habit. The chaste white blooms with yellow disc are borne in graceful sprays; September; height, 2½ feet.

*Junio*.—Another free-flowering plant with a capital bushy habit of growth, and one of the best of this colour, which is yellow, slightly tinted

bronze; flowers in late August and September; height, 2 feet.

*Eric*.—This is a sturdy little plant bearing a free display of blooms of good form; the colour in this instance may be described as a pleasing shade of rosy bronze; September; height, 2 feet.

*Merstham Glory*.—In this instance the plants are large and bushy, and the display is very beautiful and striking in consequence; colour, bright purple-crimson; September; height, 2½ feet.

*Cecil*.—This is a distinct variety and rather less bushy than most others. The flowers are very pretty and of good form; colour, rose pink, with white zone round yellow disc; September and early October; height, 3½ feet.

*Jeanette*.—A charming blush pink flower of pleasing form. The plant is bushy, free-flowering, and the effect in the border is good. A white zone round the disc adds to the effectiveness of the bloom; September; height, 2 feet.

*Resolution*.—Free-flowering and bushy, bearing dainty blooms on a good length of footstalk;

growth; free-flowering; September; height, 2 feet.

*Spitfire*.—A most effective border plant. The flowers are not of very good form, but they last well in a cut state; free-flowering, bushy and robust; colour, fiery crimson base, paling to fiery red at the tips of the florets, which are gold with a gold reverse; erect habit; September and October; height, 3 feet.

*Clarice*.—This is a new sort, bearing lovely ruby crimson blooms with a greenish yellow centre. The plants are a mass of rather small blooms that retain their colour well; September; height, 2½ feet.

*Snowstorm*.—A free-flowering novelty, with rather broad florets, of even form and good size; September and early October; height, 2½ feet.

*Jessie Wallace*.—For its bushy, branching habit and its free-flowering propensity this new variety will be valued. The plant evolves large flowers of good form, the colour of which is old rose salmon on a lemon yellow ground; September and early October; height, 2½ feet.

THE CAUCASIAN CAT-MINT (NEPETA MUSSINII).

colour, rose pink with white zone round yellow disc; September; height, 2½ feet; sweet-scented.

*Pathfinder*.—This is a charming starry flower, beautiful for decoration. The flowers are rather small but of beautiful form; colour, lovely bronzy buff; September and early October; height, 2½ feet.

*Surrey*.—Quite distinct from all others in colour, which may be described as salmon cerise. The flowers are of even form and are beautiful under artificial light; September; height, 2 feet.

*Philadelphica*.—Another plant with a very good habit of growth; colour, rose pink with a white zone round yellow disc; September; height, 3 feet.

*Venerable*.—For border culture this is an excellent sort. The flowers are of medium size and of a deep reddish terra-cotta colour; September; height, 2 feet.

*Terpsichore*.—In this instance the dainty blooms are of a bright yellow colour, and they are borne in useful sprays on a bushy habit of

*Lady Mollie*.—This plant is [remarkable] for the warm, rich colour of the flowers in the autumn sun. The colour may be described as rich reddish bronze, paling with age; lovely sprays; capital bushy habit; September; height, 2 feet.

*Marie Corelli*.—A beautiful addition to the yellow varieties; charming as a plant and valuable for cut-flower use; September; height, about 18 inches.

*Kathleen*.—A charming free-flowering single of rather small size; the colour is most effective, being bronzy buff; dwarf habit; September.

*Formidable*.—For its lovely rose pink blooms this variety is much thought of; September is its period of flowering; nice bushy habit of growth; height, 3 feet.

*Canada*.—Another free-flowering plant with a desirable bushy habit of growth. The flowers are of good form and are borne in cluster sprays; colour, pretty rosy bronze; September; height, 2 feet. D. B. CRANE.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE VEGETABLE GARDEN.**—On every possible occasion when the weather is fine and the soil not too wet I make it a rule to dig vacant pieces of ground. This should be done in no slipshod fashion, but be trenched or hasted trenched and a heavy dressing of good manure incorporated at the time. Asparagus tops, in most gardens, should now be sufficiently well ripened to justify their being cut down. Let this be done carefully, cutting them back to within about 6 inches of the ground. The surface of the beds must be kept free from weeds, and although the process is tedious, I find it is safer and better to pull them up individually.

**Trees and Shrubs.**—Planting should be proceeded with apace, so that the work may be completed before the hard weather sets in. Ground to be planted should be trenched or dug to a depth of at least 2 feet, as this will give both trees and shrubs a free root-run. As the trees, &c., are received from the nursery they should be carefully inspected, so that when the planting is done they should be planted at the same depth as they have been in the ground previously. Hollies and Evergreen Oaks do well when planted at this season; the soil is still fairly warm and the roots still active. Make it a rule to stake all trees as they are planted; this is often neglected, to their detriment.

**The Hardy Fruit Garden.**—This should be a busy season where hardy fruit trees are considered. Almost every kind of hardy fruit tree may be planted during the present month. It is well to draw attention to the importance of keeping the roots as near the surface as possible, as the roots of deeply-set trees cannot possibly come within the sun's influence. Beginners so frequently fail with fruit trees because they plant them in soil of too porous a nature. They must have hard ground below and a surface dressing of 2 inches of friable soil to prevent evaporation. Shoots of Black Currants affected by the gall-mite should be cut off and burnt. The presence of this pest is generally indicated by a swelling of the buds, so this should be an easy matter to determine. A judicious system of root-pruning is an immense advantage in the case of trees of vigorous growth bearing small and unsatisfactory crops.

**The Hardy Flower Garden.**—Complete the planting of spring and early summer-flowering hardy plants as soon as possible. In this connexion Daisies, Primroses, Forget-me-nots and Wallflowers play an important part. I am busy with the hardy border just now, lifting and dividing old and unduly large plants and replanting these in specially-prepared quarters, grouping the divided pieces in three, six or a dozen in each group or colony. In this way I have a charming picture in the flowering season. Beds of Lily of the Valley are also being dealt with at the present time. Impoverished and overcrowded plants are being lifted and planted in mellow soil.

**Chrysanthemums.**—The large blooms have damped off badly

this season, more particularly those resulting from buds retained early in August last. Late crown as well as terminal buds are giving better results. Plants of the December-

1.—YOUNG, STRAIGHT ROOTS OF HORSERADISH SUITABLE FOR FORMING A NEW BED.

flowering varieties must be kept fairly cool, although less air should be given now than formerly. When the buds show colour, only just warm the hot-water pipes; this will give the necessary stimulus to the opening of the blossoms.

D. B. C.

2.—CROWNS ABOUT 3 INCHES LONG FROM WHICH GOOD RESULTS CAN ALSO BE OBTAINED.

### INCREASING AND CULTIVATING THE HORSERADISH.

This is a subject that is very rarely discussed in the pages of horticultural journals, yet it is a root that is welcome on the dinner-table on many occasions in the course of the year. It has come to be regarded as an indispensable article in the kitchen garden, and there is always considerable pleasure in being able to draw upon one's own supply rather than purchasing in the ordinary way from the greengrocer. It is a native plant, and in a wild state is usually found growing in moist situations; but under good culture it will thrive in almost any soil and in almost any situation. Because it so readily adapts itself to any position there is a tendency to allocate to it a position in any out-of-the-way corner of the garden, where it is customary to give it but little attention.

Straight sticks that are quickly grown should be the aim of the cultivator. I have seen remarkably fine crops grown on ground that has been dug two spits deep and the subsoil turned over with the fork. This should give from 2 feet to 3 feet of good soil in which the roots can penetrate.

As it is essential that the soil should be of a rich character, I would be disposed to plant in quarters that have previously been allocated to Celery, Onions or similar crops, where the soil is invariably of a rich nature and has also been well tilled.

At any time during November or December the trenching of the soil should be taken in hand. Work in a liberal dressing of well-rotted horse manure if the land be of a somewhat heavy character. If it is of a light and sandy nature, incorporate an equally heavy dressing of well-rotted cow manure. This should be buried somewhat deeply, so that the roots do not reach it too soon; otherwise it may have the effect of distorting them, which is a serious detriment.

Previous to the planting, the surface soil should be broken up and raked over and the bed made even. I find it better to plant in rows about 1 foot or rather more apart, observing a similar distance between each set or crown as it is planted. This gives ample space for each one to do itself justice, and subsequently, when lifting them, this may be accomplished without damage to the roots.

Suitable material with which to increase our supplies are clear, straight roots, each one having a crown, the roots varying in length from 6 inches to 1 foot and of the thickness of one's finger. Fig. 1 is a good illustration of the kind of material to use for this purpose. The two outer ones represent growths about 6 inches long, and the one in the centre a clean, straight growth about 1 foot in length.

It is the rule to bury the crowns 6 inches below the surface of the soil, and for this purpose deep holes should be made in which they may be dropped. These crowns will quickly develop into ideal sticks, and if inserted at the present time should make excellent roots by next autumn.

There are growers who prefer to plant crowns, 3 inches in length, of the kind represented in Fig. 2. The method of planting is aptly described in the illustration Fig. 3. Here it will be noticed that the promising

3.—THE METHOD OF PLANTING CROWNS IN PREPARED HOLES ABOUT 6 INCHES DEEP.

crown is inserted some 6 inches deep in the hole prepared for its reception, and if the holes are filled up both below and above the sets with fine ash or the surface soil raked over them, growth will be made very quickly.

In Fig. 4 is given an illustration of a stick of Horseradish of an undesirable kind. This is in consequence of want of proper preparation of the soil before the crown was planted. It will be observed that the growth began well, but when about 6 inches in length the root was caused to divert, this being due either to the want of proper preparation of the soil or to the addition of new manure too near the surface. Fig. 5 represents three excellent sticks of Horseradish, the result of soil being deeply dug and well broken up, and from crowns inserted as represented in Fig. 1 and Fig. 2. D. B. CRANE.

#### CLIMBERS FOR A GREENHOUSE.

CLIMBING plants trained under the roof, or to any pillars in the greenhouse, if kept in neat order, always give to the interior of the structure a more furnished appearance, even when there is a good collection of pot plants in it.

Of course, climbing plants may be very successfully grown in flower-pots, but it is advisable to plant them in borders where these are available. Climbers should be regarded as permanent occupants, hence care must be taken in the making of the border. The best compost should be used; the old or original soil must be removed and some good fibrous loam, leaf-soil, peat and sand put in for the plants to root in.

The strongest climbers, such as the Plumbago and Bougainvillea, should be planted in positions where there will be ample room for the branches, and those of more moderate growth, such as the Swainsonia, in places where the area to be covered is more restricted.

**How to Make the Borders.**—When we grow plants in pots we see that the drainage is perfect and the pot of suitable size. The same care must be exercised when growing plants in confined borders. There must be efficient

drainage and rootingspace for each kind of plant. Example: For a Plumbago the prepared border should be 2 feet wide, 3 feet long, and at least 1 foot deep, exclusive of drainage material, which should be about 6 inches deep.

Broken bricks, clinkers or cinders may be put in as drainage material. On this place newly-cut turves grass side downwards, and then fill up the space with the prepared compost, making it moderately firm. Put in the plants carefully and neatly, covering the roots about 1 inch deep with some of the finer portion of the compost. Give water at once to settle the soil around the roots; afterwards be careful not to give too much water. When new growth commences in the spring, water will be needed in greater bulk. At first tie up the branches loosely so as to allow the plants to settle down in the new bed. Planting may be done now.

**Suitable Climbers.**—The following are good kinds to plant: Plumbago capensis (light blue), P. c. alba (white), Clematis indivisa, C. lobata, Acacia riceana, Bignonia jasminoides, Clianthus

4.—THE RESULT OF PLANTING IN SOIL THAT HAS NOT BEEN DEEPLY CULTIVATED OR THE MANURE DEEPLY BURIED.

puniceus, Habrothamnus elegans, H. scaber, Kennedya rubicunda superba, Lapageria alba, L. rosea, Passiflora alata, P. caerulea, Rhyncospermum jasminoides, Swainsonia Osbornii, Tacsonia exoniensis, T. smythiana, T. van Volxemii, Bougainvillea glabra and climbing Roses. AVON.

#### THE TOWN GARDEN.

**CLIMBERS ON WALLS.**—These add immensely to the interest and beauty of the garden, and, whether they are grown for the sake of their flowers or foliage, should have proper attention if they are to produce the most satisfactory effect. Unfortunately, there are many people who appear to think that when once the plants have been placed in position they may be left to look after themselves, with the natural result that they become tangled masses of growths, many of which are

bare at the base, while practically the whole of them are more than half-starved. This must not be. If the plants have annual cultural attention it is certain that they will give a most generous response. At the present time the grower may cut out all portions for which there is not an abundance of space, and he should, further, see carefully to the requirements of the roots. The surface soil for 3 feet or more from the wall should be lightly pricked over with a fork, and if the soil is dry, as it commonly is at this season of the year, thorough soakings of water must be applied. When this has worked its way down, a mulching of short, sweet manure 1 inch or 2 inches in thickness ought to be spread on, and the food virtues contained in it will steadily find their way down into the soil, to be appropriated by the roots in the future. Or, and in many instances it is preferable, the cultivator should remove the top 2 inches or 3 inches of soil and put in its place some rich compost, such as old potting soil with its equal in bulk of sweet manure, or rather less of that and some leaf-mould; as soon as this is in place it should be covered with a thin layer of fine soil.

**BULB PLANTING.**—This work should be carried to completion as rapidly as possible, for practically all kinds of bulbs are showing clear signs of top growth, and when this time arrives they are far better in the soil, as they lose decidedly the longer they are left out. It is unnecessary to enter into full details of the cultural methods which bring about the most gratifying results, as these have already been given in this column. It may, however, be permissible to remind readers that if manure is used it should not be in such a position that it can come in actual contact with the roots; that the planting should be done at least twice the depth of the bulbs; and that if they are still deeper the probabilities are that the grower will be the gainer in the end, although the blooms may be a little later.

**THE GREENHOUSE.**—It is more than likely that this structure will now be given over almost entirely to the Chrysanthemums, which are just at their best, and for the benefit of these plants,

5.—HORSERADISH LIFTED FROM BEDS THAT WERE PROPERLY PREPARED.

as well as any other occupants, it is imperative that all parts of the house shall be kept scrupulously clean. At this season of the year the light in town gardens is none too abundant, and the gardener who keeps the glass clean, so that the rays of light shall not be obstructed in the smallest degree, is the one who has the best chances of success. At the same time the floors, shelves, stages, pots and walls should also be clean, but in effecting this it is essential that no water shall be spilled about the place, or, if it is, that it shall be at once mopped up, because it is desirable that the atmosphere shall be kept moderately dry for the sake of the Chrysanthemums, which are prone to damp off when the atmospheric moisture is excessive. Watering of all plants must be done with great care, a supply only being given in advance of dryness.

**ROOM PLANTS.**—The principal detail in connexion with the management of plants in rooms during the winter is that they shall be watered with the utmost intelligence, and that they shall be kept perfectly clean by frequent sponging with tepid water. At least once a week the leaves should be washed with warm, soft-soapy water, as the accumulations of dirt during the fogs of winter quickly stop up the pores and prevent the plants breathing properly. HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**Y**OUNG seedling Cyclamen should be kept near the glass, and see that they do not get an attack of thrips. These pests cripple the tiny leaves and they refuse to grow. If the soil and surroundings are kept moist thrips will not attack the plants.

**Gladioli.**—Pot up corms of these for gentle forcing in the spring. G. Colvillei albus (The Bride), Fairy Queen—rosy white to pale rose—Rosy Gem and Salmon Queen are very fine for cutting and most useful. Spanish Irises also are most useful, and can be grown and forced gently. These should be potted up at once; Canarybird, Chrysolora, La Nuit, Mont Blanc and Lady Blanche are all good for the purpose.

**Coleus thyrsoides** should have a light position in a warm house. This is very effective with Poinsettias in the conservatory or in the house. Gesneras should be kept at a temperature of 60°, and if the plants are strong and require stakes place these under the leaves so that they are not visible. No plants should have supports unless really necessary. Begonias of the Gloire de Sceaux and Lorraine section should be kept in a warm temperature; the two together make a fine and effective display.

**Carnations.**—Give these a nice growing temperature; pick off all the small buds. Do not keep the plants too wet, or rust may put in an appearance, and do not leave the flowers on the plants longer than is necessary. Enchantress, Lady Bountiful, white; and Britannia, scarlet, are now extra good. Yuletide is good at Christmas, and very often this old favourite has flowers when some of the newer varieties fail at that season.

#### FRUIT HOUSES.

**Pot Vines.**—When these are used for the first crop no time should be lost in procuring them, and a gentle hot-bed made of tree leaves and stable manure must be got ready. This should be extremely mild. When the Vines are plunged, the temperature must on no account exceed 70°; therefore, if these are to be started in December, the bed ought to be prepared at once. If ripe Grapes are desired at the end of April

or beginning of May, the house ought to be closed by December 1. Black Hamburg and Foster's Seedling are about the two best to grow for such work.

**Peaches and Nectarines.**—These must be pruned and tied as fast as opportunity permits, as when this is done it gives more opportunity to get on with other work.

**Orchard Houses.**—Where permanent trees are planted, such as Plums, Pears, Cherries and the like, root-pruning or lifting should be carried out as quickly as possible and the pruning done. In lifting these trees see that the soil is well rammed; this helps the trees to make short, firm wood.

#### KITCHEN GARDEN.

**Onions.**—Look over these in the store-room, taking out all unsound specimens; these soon injure sound bulbs. Winter Spinach should be kept free from weeds, and on a dry day move the ground with a hoe; this stimulates growth and prevents the soil from getting sour.

**Broccoli and Cauliflower.**—Take up all heads that are large enough and place them under cover away from frost.

W. A. COOK.

Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ORCHIDS.**—Growers of these in the neighbourhood of large towns will find that for the next few months they have a difficult task before them, the heavy atmosphere bringing with it all kinds of impurities. The first thing needful is, of course, to clean the glass outside, and this is best done by washing with clean water, which will be necessary as often as twice or even three times a week during foggy weather. The inside of the glass does not get coated over so quickly; but as often as time can be found to do so, this ought also to be cleaned.

**Early Roman Hyacinths.**—One of the chief mistakes that are made in connexion with the early forcing of these is that of putting the bulbs too early into strong heat before the plants have rooted sufficiently. The time of introduction into heat should be proportionate to the time the bulbs have been potted. If from any cause the bulbs are not received or even potted as early as usual, allowance must be made for this by keeping them longer in the open, so that the fullest possible amount of roots may be produced.

#### KITCHEN GARDEN.

**Forcing Seakale.**—A commencement may be made as soon as the crowns are ripe enough, and if they are taken up and allowed to remain in the open shed for a few days they will force all the better. Where only a limited quantity is required, the Mushroom house is a good place to grow it, either in pots or boxes; but pots are the most convenient, for protection can readily be given to the young shoots by turning a pot of the same size over the one in which the plants are placed. Complete darkness is necessary; there must be a covering thrown over the whole batch heavy enough to exclude light. A temperature of 60° will be quite sufficient to bring the crop along in three weeks from the time the roots are introduced to the house.

#### FLOWER GARDEN.

**Wall Climbers.**—Many of these will have been allowed to grow a little beyond their bounds during the autumn. They should now be overhauled and all superfluous growth cut away, to relieve the plants of a little of their weight and to prevent them from becoming blown away from their fastenings. In many cases it will be advisable to retain a considerable portion of the young wood which has been made, and to make room

for this some of the weak and useless sprays should be cut out.

#### FRUIT GARDEN.

**Strawberries for Forcing.**—The most suitable quarters to winter these in are cold pits or frames, where they can be plunged in ashes or leaves up to the rims of the pots and the lights only used over them in time of extreme weather. The next best place is outdoors in a position sheltered from cutting winds, standing them on a hard bottom, well plunged in leaves or ashes.

#### ROSES.

**Autumn Pruning.**—There can be no doubt that Roses in most instances are much overpruned, more especially when they are required for garden decoration as distinct from exhibition flowers. I know that far better results will follow autumn pruning of all such as the Teas and most others that are not cut back hard in spring. Such varieties as Aimée Vibert or William Allen Richardson are often cut back in spring, to their detriment, the shoots being cut either too hard back or left in a thick, tangled mass. If such trees had a little of the small spray cut out from the centre now and the weak, unripened points taken from the shoots, they would not start any the earlier in spring.

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

#### FLOWER GARDEN.

**Violet Princess of Wales (A. M. F.).** The runners should certainly be removed if you desire to centralise the energies of the plants into a few crowns to provide the best blooms for winter. If, on the other hand, you wish to form a group in a sheltered spot in the open, it is less important that the whole of the runners be removed. You may, in the latter case, allow a percentage of the stronger ones to remain to provide a succession of bloom. If you have not removed the runners prior to the date of your enquiry, we fear it is late to start, as the central crowns will have been rubbed, to some extent, by the existence of the runners. What exactly should be done depends not a little on the present condition of the plants.

**How to propagate early Chrysanthemums (Ajax).**—We do not advocate the division of the old roots (stools) in the autumn, as they are not then in a condition for this treatment. This division should take place in the spring when new growth has been made, and when the old plants may be lifted and each broken up into numerous pieces. We prefer to propagate by cuttings as the days begin to lengthen in January, and good shoots are then available; they invariably root quickly. January, February and March are excellent months to insert cuttings of the early-flowering sorts. To propagate cuttings in the cold frame it is imperative that frost be excluded. This may be achieved by placing plenty of leaves or litter round about the frame and covering the frame-light with mats in frosty weather.

**Anemone japonica alba (M. H. M.).**—The Anemone roots have been attacked by a fungus, which in the case of these plants is of a very destructive character, and frequently extends to the whole of the plants in the

same group or bed. Had you taken action a year ago the loss of so many plants might have been avoided. The wisest thing to do now is to lift and burn the whole of the plants—putting them on the rubbish-heap is a very dangerous practice—and, finally, dig out and discard the whole of the soil. The lime dressing you refer to was applied too late. On no account plant any other Anemone in the soil or the bed for a couple of years, as by that time the fungus may have exhausted itself. If you decide again to plant the Anemone, get your plants from a distance, and when replanting avoid the close proximity of the present fungus-stricken site.

**Gladioli and Chrysanthemums** (W. G. R.). The Gladioli appear to be suffering from some fungoid attack, and the spores of the fungus may have been present at the time of planting in the old skins. We can only advise you to divest the corns of all the old skins when lifting is done and burn the latter. Another year, in addition to a fresh site given at planting time, try powdered lime and sulphur placed about the base of the plant and against the stem. By applying this during the early stages of growth the disease may be held in check. The reddish brown colour of the leaves of the Chrysanthemums is due to root dryness and an impoverished soil, which frequent applications of liquid manure should rectify. "Rust" is really a species of fungus vegetating in the cuticle of the leaves. If your plants are attacked by the latter, cut the affected leaves off and burn them.

## TREES AND SHRUBS.

**Pruning Magnolias** (A. M. E.).—The best time to prune Magnolias is April. As a rule, the less pruning done to them the better, unless you prune the young branches only. Large branches should be removed with great care. Cut them well into the remaining wood and tar each wound over at once. In pruning young branches of *M. grandiflora*, cut them back into one, two or three year old wood, but not into older wood if you can avoid it. By doing the work in April, young shoots are soon formed and the wounds quickly begin to heal. When removing large branches be careful not to injure the bark on the remaining wood, or disease will probably result.

**Moving Buddleia globosa** (Emilei Boutein).—It is doubtful whether you will be able to transplant your specimen of *Buddleia globosa* successfully now that it has attained such a large size. If you do attempt the work you had better cut it back as you propose. A great deal will depend on the weather for a few weeks after transplanting. Its age is in its favour, for it has plenty of vigour. When digging round the plant start 5 feet from the stem and carefully fork out all roots without injuring them; then, in planting, lay each root out straight, and if any have been damaged, cut the broken portion away with a sharp knife.

## MISCELLANEOUS.

**Names of fruit.**—H. S. T., *Rye*.—The Apple is Golden Noble. Miss Symons.—1, Striped Pippin; 2, Fern's Pippin. W. P.—The Apple is a local seedling of handsome appearance, but of only second-rate quality. M. A. T.—Pears: 1, Pitmaston Duchess; 2, Winter Nelis. Apples: 2, Reinette du Canada; 3, Bess Pool; 4, Round Winter Nonsuch; 6, James Grieve. F. A. A.—Apple Reinette du Canada. R. Plomer.—Apple Emperor Alexander. E. J. Padbury.—The red Apple is New Bess Pool; the russet one, Rosemary Russet. Colonel B. Willey.—Apples: 1, Tower of Glamis; 2, Hawthornden. F. Dunn.—1, Mere du Ménage; 2, Hall Door; 3, Hambling's Seedling. W. J. W.—1, Golden Noble; 2, Old Hawthornden. G. R.—1, Beauty of Kent; 2, Duchess Favourite.

**Names of plants.**—H. Quick.—*Salvia azurea*.—S. W.—Cannot name without flowers. The name of the Fern is *Adiantum Capillus-veneris* variety imbricata; the other plant is *Crotalaria capensis*. W. D.—Your Orchid is an unnamed seedling. A. Leet.—*Asperula azurea*. A. Y. Z.—1, *Stephanotis floribunda*; 2, *Nerium Oleander*; 3, send when in flower; 4, *Humulus japonicus* variegatus; 5, *Senecio Cineraria*; 6, *Agasthea celestis*; 7, *Acacia* species, send when in flower. A. R.—1, *Azara microphylla*; 2, *Berberis Darwinii*; 3, *Veronica Traversii*; 4, no specimen; 5, *Daphne oleoides*; 6, *Vicia major* var. elegantissima; 7, *Thymus Serpyllum* variegatus; 8, *Coronilla Emerus*; 9, *Veronica cupressoides*; 10, *Spartium junceum*; 11, *Berberis vulgaris*; 12, *Sedum reflexum* var. cristatum. W. Judd.—1, *Aspidium falcatum* var. caryotideum; 2, *Gymnogramme japonica* var. variegata; 3, *Aspidium obtusatum*; 4, *Pteris cretica* var. albo-lineata; 5, *P. cretica*; 6, *P. serrulata*; 7, *Adiantum Capillus-veneris* var.; 8, *Pteris serrulata* cristata; 9, *Pellaea rotundifolia*; 10, *Davallia canariensis*; 11, *Adiantum cuneatum*; 12, *Arundinaria Fortunei*. A. F. C.—1, *Fuchsia cordifolia*; 2, *Cestrum elegans*; 3, *Eugenia myrtifolia*; 4, *Cestrum aurantiacum*; 5, *Acalypha Macafeana*; 6, *A. species* or garden variety. G. Lees.—The Maple is *Acer rubrum* and the other plant the Spindle Tree (*Eunonymus europaeus*). F. L., *Dorchester*.—*Eleagnus pungens*. E. W. C.—1, *Alonsoa Warscewiczii*; 2, *Cerastostigma*

*plumbaginoides*; 3, *Astrantia major*.—W. Mathews.—*Russelia juncea*.—Miss R.—Seeds of the Birch (*Betula alba*).

## SOCIETIES.

### BRIGHTON AND SUSSEX CHRYSANTHEMUM SHOW.

THE annual exhibition took place on the 3rd and 4th inst. in the Dome and Corn Exchange. The entries, though numbering over 300, were not all forthcoming, probably accounted for by the late unfavourable weather.

#### OPEN CLASSES.]

In Classes 1 and 2, for a group of Chrysanthemums only, with Ferns or other foliage plants respectively, Mr. Edward Jones, gardener to Harry Young, Esq., Withdean, received the premier award in both instances, he being the only exhibitor.

For a group in a space 11 feet 6 inches by 6 feet 6 inches, for quality and effect, Mr. George Bennett, gardener to P. H. Bayer, Esq., Hatch Beauchamp, Withdean, was first. Twelve bush plants, decorative varieties: Out of five competitors Mr. G. Lambert, 17, Bognor Road, Chichester, was an easy first, thus winning the handsome silver cup and society's silver medal offered for this class. Mr. George Bennett was second and Mr. C. Norman Marshall, Withdean Nurseries, Patcham, third.

For a collection of Orchids, arranged with Ferns or other foliage plants, Mr. W. Hill, gardener to G. W. Ryder, Esq., Broadhill, Keymer, was the champion, followed by Mr. E. Jones.

#### CUT BLOOMS.

For thirty-six Japanese, not less than twenty-four varieties (handsome silver bowl and society's silver medal), Mr. C. J. Dicker, Frant Court, Frant, was first, staging very good blooms of Mrs. F. S. Vallis, Walter Jinks, Mrs. W. Knox, Beatrice Gay, Bessie Godfrey, Mary Inglis, Lady H. Conyers, &c. Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashstead Park, Epsom, was second and Mr. J. Harris, gardener to Colonel C. P. Henty, Avisford, Arundel, third.

Twenty-five Japanese, as cut from the plant, not less than eighteen varieties: Messrs. James Stredwick and Son, Silverhill Park, St. Leonards-on-Sea, secured the premier place here; Mr. C. J. Dicker was placed second, with Mr. J. E. Hickson, gardener to the Rev. F. S. Slater, New Wick Park, Lewes, and Mr. Charles Earl, gardener to O. E. d'Avigdor Goldsmid, Somerhill, Tonbridge, third and fourth respectively.

For twelve incurved, large-flowered varieties, distinct, Mr. G. Hunt was first with good blooms of Buttercup, Duchess of Fife, Pantia Ralli, C. H. Curtis, William Biddle and Mrs. G. Denyer, followed by Mr. M. Tourle, gardener to Captain J. R. Smiley, Horsted Place, Uckfield.

Twelve Japanese, large-flowered, distinct: Here Mr. E. Jones was first with good blooms of E. J. Brooks, Swanley Giant, Algernon Davis, Mr. W. Knox, Jessie, M. Godfrey, &c. Six incurved, any one variety: Mr. G. Hunt was placed first with Buttercup; Mr. J. Harris second with Embleme Poitevene; and Mr. M. Tourle third for Mrs. F. Judson.

#### FRUIT.

Grapes, white, three bunches: First, Mr. Charles Earl, with Muscat of Alexandria; second, Mr. A. H. Geall; third, Mr. A. Kemp, gardener to C. R. Scrase Dickens, Esq., Coolhurst, Horsham.

In a similar class for black Grapes, Mr. Charles Earl was again first, followed by Mr. S. Woolgar and Mr. A. H. Geall in the order named.

Dessert Pears, four dishes, distinct: Mr. W. J. Finch, gardener to F. A. White, Esq., Oakleigh, East Grinstead, was a good first, his exhibit including a very fine dish of Pitmaston Duchess; Mr. J. E. Hickson was second and Mr. A. Morris Field third.

#### AMATEURS' DIVISION.

For twelve Japanese (amateur members' challenge trophy and society's silver medal) Mr. C. Fox, Tunbridge Wells, was first, Mr. E. Farrell and Mr. H. West being second and third respectively.

#### TRADE EXHIBITS.

Messrs. Balchin and Son were present with an artistically-erected framework, the inside of which consisted of bowls of Chrysanthemums and cut flowers of Orchids, surrounded by very fine examples of Crotons, the whole being embedded in Ferns, &c., while from the roof were hanging bowls and baskets of cut Chrysanthemums, the outside being adorned on two sides with Begonias Gloire de Lorraine, edged with Maidenhair Fern and ornamental Grass. The entire erection was draped with trails of Smilax, from which peeped out numerous electric lights. Gold medal.

Messrs. George Miles and Son had an artistically-arranged collection of miscellaneous flowering and foliage plants around a centre of fruit, surmounted by various floral designs on brass rods. Silver-gilt medal.

Messrs. Cheal and Son and J. E. Hickson made magnificent displays of fruit. Silver-gilt medal. Barnham Nurseries, Limited, also showed fruit. Silver medal. Miss Alice Smith for hardy perennials and rock plants was awarded a bronze medal.

Messrs. Sutton and Sons exhibited an excellent table of miscellaneous vegetables, including Ornamental Gourds, Melons, &c. Silver-gilt medal.

### NATIONAL CHRYSANTHEMUM SOCIETY.

THE great autumn exhibition arranged by the above society was held at the Crystal Palace on the 4th, 5th and

6th inst., when a good display of flowers was to be seen. Signs are not wanting that the single-flowered and decorative varieties generally are ousting the large, mop-like blooms from their hitherto supreme position. Although many of the classes arranged for these large blooms were well contested, we do not think the flowers, especially the incurved, taken on the whole were quite up to the usual standard.

#### DIVISION I.—OPEN CLASS.

For a floral display of cut Chrysanthemums, with the addition of any appropriate foliage, as plants in pots or otherwise, to be arranged on the floor in a space not exceeding 300 superficial feet, Mr. F. Brazier of Caterham won first prize with a beautifully-arranged lot of flowers in a circular group. Single and large-flowered varieties formed the centre, these being placed in Banihoostands of various heights, large-flowered Japanese sorts forming an edging.

*Trade excluded.*—A floral display of Chrysanthemums and suitable foliage plants in pots, with the addition of cut blooms and any appropriate cut foliage, to be arranged on the floor in a circular space of 200 superficial feet. Here Mr. W. Howl, gardener to Lady Tate, Park Hill, Streatham Common, was awarded first honours for a charming group. Plants of large-flowered sorts surmounted by a large Palm formed a sort of pyramid in the centre, decorative varieties of all sections, with a few large blooms, being tastefully placed with Maidenhair Ferns, Crotons and other foliage plants to form an edging.

#### OPEN CLASS.

For twelve vases of specimen blooms of Japanese Chrysanthemums, distinct, each containing three blooms of one variety, with not less than 6 inches of stem above the vase (Chrysanthemum foliage must be added, but upon separate stems), four competitors tried conclusions, Mr. G. Hall, Melchett Court Gardens, Romsey, Hants, winning first prize with a very good lot of flowers, notable sorts being W. E. Etherington, Edith Smith, Marquis of Northampton and Mme. P. Gadaelli. Second honours went to Mr. J. Dymock, The Gardens, Rush Court, Wallingford, for blooms but little inferior to those which won first prize; Maud Jefferies, F. S. Vallis and Mrs. Norman Davis were especially fine. The third prize was awarded to Mr. W. Iggulden, Frome, Somerset.

#### SPECIAL CLASS.—CUT BLOOMS.

In the national competition of affiliated Chrysanthemum and horticultural societies the Dulwich Chrysanthemum and Horticultural Society were placed first, the blooms staged being a very good lot, especially the large Japanese and incurved sorts. The Reigate and District Chrysanthemum Society were the only other exhibitors, these being awarded the second prize.

#### DIVISION II.—OPEN CLASSES.—CUT BLOOMS.

The society's Holmes Memorial challenge cups were offered, in addition to substantial cash awards, as first prizes in Classes 5 and 6 for thirty-six incurved blooms, distinct, and forty-eight Japanese blooms, distinct, respectively. In the first-named class there were three entries, Mr. W. Higgs, gardener to J. E. Hankey, Esq., Fetcham Park, Leatherhead, being placed first for a grand lot of flowers. Mrs. G. Denyer, Charles H. Curtis, G. F. Evans, Edwin Thorp and Mrs. F. Judson were almost perfect. The second prize was well won by Mr. G. J. Hunt, gardener to Pantia Ralli, Esq., Epsom, for a well-formed collection of rather small flowers. Amber Beauty, Buttercup, Romance and Mrs. F. Judson were sorts that called for special mention. Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, was third. In the Japanese class six exhibits were staged, the cup and first prize going to Mr. G. Hall, Melchett Court Gardens, Romsey, Hants. His blooms were a remarkably fine and even lot, and well deserved the award. F. S. Vallis, W. Gee, W. A. Etherington, Magnificent, A. Davis, Mrs. A. T. Miller and Mme. Rivoli were a few that specially appealed to us. Mr. W. Mease was a good second, Mr. W. Higgs and Mr. W. Iggulden being placed third and fourth respectively.

The special first prize of 5 guineas in Class 7, for twelve vases of incurved blooms in twelve distinct varieties, three blooms of each, is given by the vice-president, C. E. Shea, Esq. Three competitors entered here, the premier award being secured by Mr. W. Higgs of Leatherhead, whose flowers were rather small but of splendid shape. Frank Trestian, Mrs. Barnard Hankey and Buttercup were particularly noteworthy. Mr. G. J. Hunt of Epsom was second with good blooms of Clara Wells, Lady Isabel and Embleme Poitevene among others. Mr. H. Parr, gardener to F. A. Bevan, Esq., New Barnet, was third.

For twenty-four plants in pots, not less than six varieties, there were only two entries, Mr. F. Brazier, Addison Road, Caterham, securing first prize for a collection of large-flowered Japanese varieties. Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Laurie Park, Sydenham, was second with some beautiful specimens of single varieties.

For twenty-four Japanese blooms, distinct varieties, which have been distributed by the donors of the prizes during 1906-7-8, but six at least to be of the last two season's introduction, blooms to be shown on boards, trade growers excluded, the competition was good, Mr. G. Hall, Melchett Court Gardens, Hants, being the champion. His flowers were really superb and called for the highest praise, Mrs. N. Davis, William J. Neil, Mary Donnellan and Thomas Stevenson being extra good. The second prize went to Mr. A. Jefferies, Moor Hall Gardens, Harlow, Essex, who also staged a splendid collection, Annie Hamilton, George Mileham and W. Howe being especially noteworthy.

The first prize offered by Sir Albert Rollit, LL.D., D.C.L., for twenty-four blooms of Japanese, distinct, was won in very strong competition by Mr. J. Dymock, Rush Court Gardens, Wallingford, with a remarkable fine lot of flowers, among which we specially noticed Mrs. N. Davis, F. S. Vallis, Mme. Nagelmackers, Mrs. A. T. Miller and Walter Jinks. Mr. William Holden, Ewell House Gardens, Ewell, was second with an even lot of flowers. Mr. A. Chandler, Rugby; Mr. G. Hall, Romsey, Hants; and Mr. A. Jefferies, Harlow, followed in the order named.

The first prize offered by the Ichthemio Guano Company for twelve Japanese blooms, distinct, was well won by Mr. G. Hall, Romsey, Hants, in very good competition. Among his blooms we noticed particularly good one of F. S. Vallis, Magnificent and Lady Talbot. Mr. A. Chandler, The Gardens, Coton House, Rugby, was a good second, F. S. Vallis being extra large in his dozen. Third and fourth prizes were won respectively by Mr. W. Holden, Ewell, and Mr. G. Mileham, Leatherhead.

There were six entries in the class for one vase of five white Japanese blooms, one variety only, the first prize being allocated to Mr. J. Vert, gardener to Lord Howard de Walden, Andley End, Saffron Walden, for splendid examples of Mrs. A. T. Miller. Mr. G. Mileham, Leatherhead, was second with the same variety, third and fourth prizes going to Mr. F. Brazier, Caterham, and Mr. H. Ellis, Farnham, respectively.

In a similar class for yellow flowers there were seven competitors, Mr. W. Iggulden, Frome, Somerset, being the champion with superb blooms of F. S. Vallis. Mr. A. Jefferies, The Gardens, Moor Hall, Harlow, was second with the same variety. Mr. W. Higgs, Leatherhead, and Mr. G. Mileham following in the order named.

In a similar class for any colour, white and yellow excluded, the competition was not so good. Mr. A. Jefferies was first with good flowers of Walter Jinks. Mr. G. Halsey being second with the same variety. The third and fourth prizes were won respectively by Mr. H. J. Hedges, Sydenham, and Mr. H. Parr, New Barnet.

For twelve incurved blooms, distinct, seven competitors entered, Mr. J. Preece, Warley Place Gardens, Essex, coming out on top. Among his excellent blooms Emblem Poitevene, Daisy Sontham, W. Biddle and Clara Wells called for special mention. Second prize went to Mr. W. Higgs, Fetcham Park Gardens, Leatherhead. G. F. Evans and Lady Isabel were shown well here. Third and fourth prizes went respectively to Mr. W. Mease and Mr. G. J. Hunt.

For six incurved, one variety only, Mr. G. Mileham, gardener to A. W. Miller, Esq., Emylly House, Leatherhead, was the champion with excellent examples of Buttercup. Mr. A. Osmond, South Norwood, was second with C. H. Curtis, and the third prize went to Mr. H. Parr, New Barnet, for Buttercup.

There were only two entries in the class for six varieties of disbudded Chrysanthemums as grown for market. The first prize was well won by Mr. A. Robertson, gardener to F. J. Yarrow, Esq., St. John's Wood. His examples of Lady Hanham, Charles Davis and Vivian Morel were excellent. Mr. J. H. Humphries, Maisey Hampton, near Fairford, was second.

Three competitors entered in the class for twenty-four large Anemone blooms, Japanese included (eight varieties), the first prize being awarded to Mr. A. C. Horton, North Frith, Tonbridge. Mr. A. Henderson, Bromley, Kent, and Mr. J. H. Humphries, Maisey Hampton, near Fairford, followed in the order named.

In a similar class for twelve varieties, Japanese excluded, the competition was poor. Mr. A. C. Horton again winning the first prize with good specimens. Mr. A. Henderson was second and Mr. J. H. Humphries third.

For twelve large-flowered Japanese Anemone blooms Mr. A. C. Horton, Mr. A. Henderson and Mr. J. H. Humphries again won in the order named.

The class for six vases of Pompons, distinct, was a pretty one, but should have been better contested. Mr. F. Fitzwater, gardener to T. Braby, Esq., Bushey Lodge, Teddington, was first with beautiful flowers, Elsie Jordan and William Sabey being particularly attractive. Mr. J. H. Humphries was second and Mr. J. W. Harrison, Sydenham, third. In a similar class for Anemone Pompons Mr. F. Fitzwater and Mr. J. H. Humphries were the winners.

Five competitors entered the class for twelve vases of singles, distinct, the first prize going to Mr. H. Redden, gardener to G. W. Bird, Esq., Manor House, West Wickham. Edwin Nottell, Miss Tackey Bird, Frank Redden and Wickham Giant were superb here. The second prize was well won by Mr. C. J. Simpson, St. John's Nursery, Chelmsford. Among his flowers we particularly noticed Edith Pagram, Crown Jewel and Metta.

#### FLORAL DECORATIONS.—OPEN CLASSES.

In Class 25, for a floral decoration of Chrysanthemums for a dinner table, yellow and bronze blooms only, with any suitable foliage, out of the seven competitors Mrs. A. Robinson, Park Hill, Carshalton, was first with a very delightful design, Asparagus plumosus, Croton leaves and Ampelopsis trails being used for garnishing. Second honours went to Mr. T. W. Stevens, Laurie Park Gardens, Sydenham; and Mr. A. W. Frossell, Beckenham, was third.

In a similar class for any colour other than yellow or bronze, Mr. R. F. Felton of Hanover Square, W., was first with a remarkably fine and beautiful design. In addition to the first prize, Mr. Felton also took the Dean Memorial gold medal for the best decorative exhibit in the show and the Felton Cup offered in connexion with the above two classes. As this was offered by Mr. Felton, he generously presented it to the winner in Class 25.

For a basket of natural autumn foliage or herries the competition was very good, the first prize going to Miss C. B. Cole, Feltham, for a beautiful design. Mrs. F.

Brewster, Canterbury; Mrs. G. Knights, Sydenham; Miss E. H. Elkins, St. Albans; and Mrs. R. Edwards, Sevenoaks, followed in the order named.

#### AMATEURS' CLASSES.—SECTION A.—CUT BLOOMS.

For twelve Japanese, distinct, there were four entries, the first prize going to Mr. W. Rigby, 60, Wickham Road, Beckenham, for an excellent lot of flowers. F. S. Vallis and Henry Perkins were worthy of special notice. Mr. T. W. Stevens, The Gardens, Laurie Park, Sydenham, was second; and the third prize went to Mr. C. B. Gabriel, Horsell, Surrey.

For twelve incurved, distinct, Mr. A. Osmond was the only exhibitor, but his dozen were awarded first prize.

#### SECTION B.—CUT BLOOMS.

For nine vases of singles, not less than six varieties, Mr. C. M. Collingwood, St. David's Hill, Exeter, was the only exhibitor, but the judges awarded him first prize.

For twelve Japanese blooms, distinct, there were four entries, Mr. C. M. Collingwood being placed first. His flowers were an excellent lot, F. S. Vallis and A. Davis standing out well above the others. Mr. C. Fox, Tuobridge Wells, and Mr. A. Williamson, Haslemere, were second and third respectively.

For twelve incurved, not less than six varieties, there were only two competitors, Mr. J. King, Hendon, and Mr. C. M. Collingwood winning in the order named.

The smaller amateurs' classes were generally not well contested, although some good flowers were to be seen. Lack of space forbids detailed mention of these.

#### FRUIT.—OPEN CLASSES.

For three bunches of white Grapes there were two entries, the first prize going to Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, Caterham, for good bunches of Muscat of Alexandria. Mr. H. Parr, Trent Park Gardens, New Barnet, was second.

For three bunches of black Grapes (not Gros Colmar) the competition was good, first prize going to Mr. T. W. Hill, gardener to S. L. Wigg, Esq., Roekshaw, Merstham, for three excellent and well-finished bunches of Alicante. Mr. W. Lintott was second with the same variety, and Mr. Howe, gardener to Lady Tate, Streatham Common, was third, he also showing Black Alicante.

For three bunches of Gros Colmar Grapes the first prize went to Mr. A. C. Horton, gardener to J. L. Boyd, Esq., North Frith, Tonbridge, for very good and well-finished bunches. Mr. W. Howe and Mr. J. Clement, Commonwood House Gardens, near Chipperfield, followed in the order named.

For six dishes of dessert Apples, distinct, the competition was good. Mr. W. Stowers, 50, Harold Road, Sittingbourne; Mr. E. Montague, Grey Court Gardens, Ham, Richmond; and Mr. R. Edwards, Sevenoaks, winning the first, second and third prizes respectively.

In a similar class for culinary varieties Mr. W. Stowers was again first, Mr. H. Ellis, Farnham, and Mr. H. Parr, New Barnet, following in the order named.

For six dishes of dessert Pears, the first and second prizes were won respectively by Mr. A. C. Horton, Tonbridge, and Mr. R. Edwards, Sevenoaks.

#### VEGETABLES.

For a collection of eight kinds of vegetables, to be grown from their seeds, Messrs. E. Webb and Sons of Stourbridge offered valuable prizes. The first prize was won by Mr. E. Beckett of Aldenham House with a superb collection of produce, in which Tomato Viceroy, Leek Champion Prize, Onion Masterpiece and Cauliflower Late Guardian were seen in extra fine condition. Mr. W. Waterton, gardener to R. H. Comyns, Esq., Farm House, Watford, was a good second.

A number of prizes were, as usual, offered by R. Sydenham, Limited, Birmingham, the principal one being for a collection of eight stated kinds. Seven competitors entered for this, the premier award going to Mr. Silas Cole, gardener to Earl Spencer, Althorp Park, Northampton, for a very fine group. Parsnip Hollow Crown, Onion Ailsa Craig and Cauliflower Autumn Giant called for special mention. Second honours fell to Mr. W. Folkes, Amphill, Beds, and third to Mr. J. Kerr, Loudwater, Rickmansworth (gardener, Mr. T. Avery). Mr. Folkes, Mr. Basile and Mr. Cole were prominent first prize winners in the other vegetable classes.

#### MISCELLANEOUS EXHIBITS.

As usual, the trade exhibits were largely responsible for the success of this great show. They embraced many subjects, each of which provided a great amount of interest to visitors.

Messrs. H. J. Jones, Limited, Ryecroft Nursery, Lewisham, S.E., had a bold and handsome oblong group in front of the great orchestra. Large vases and Bamboo stands were filled with typical varieties and novelties, including Master David, Sir Frank Crisp, Lady Crisp and other certificated Japanese varieties. Large gold medal. This exhibit also won the gold medal for the best miscellaneous exhibit in the show.

Mr. Norman Davis, Framfield, Sussex, was also awarded a large gold medal for a table group of superb exhibition flowers and singles, &c. Mrs. N. Davis, white; Mrs. C. Penford, bronzy yellow; Algernon Davis, orange yellow; and Mlle. J. de la Crouce, pale salmon pink, were beautiful Japanese blooms, and there were many grand single-flowered sorts.

Messrs. W. Wells and Co., Limited, Merstham, Surrey, had a charming group of Chrysanthemums, mostly of a decorative character. The singles were very pretty, notably, Sylvia Slade (lake), Metta, Grace and Nellie Kiding. Good market Japanese sorts were R. F. Felton, rich golden yellow; Freda Bedford, rich bronze; and Clara Vermum, reddish crimson. Gold medal.

Market Chrysanthemums were displayed in excellent fashion by Mr. Phillips Ladds, Swanley Junction, Kent. Here were to be seen grand masses of such Japanese sorts as Heston White, W. Duckham, Winter Cheer, Framfield Pink, Esme Reed (the new white for pot culture), Market Red and others. Gold medal.

Messrs. H. Cannell and Sons, Swanley, also showed decorative Chrysanthemums finely. Singles were in the ascendant, although there were other good Japanese decorative sorts. Zonal Pelargoniums were very bright and pleasing, and the display of 125 varieties of Apples, &c., was very attractive. Gold medal.

Mr. W. J. Godfrey, Exmouth, Devon, had a splendid table group of large-flowered Japanese as well as single and other decorative Chrysanthemums. We noted lovely large-flowered singles Reginald, lemon yellow, and C. J. Ellis, richest terra-cotta, as good things, also exhibition Japanese J. W. Molyneux, Frank Molyneux and Helena Williams, the latter a lovely yellow sport from Mme. R. Oberthur. Silver-gilt medal.

Messrs. J. Peed and Son, West Norwood, S.E., had a large circular group of Chrysanthemums pleasingly finished with foliage plants, a lovely table of winter-flowering Carnations and an attractive collection of Apples, for which they were awarded a gold medal.

The comprehensive collection of over 200 dishes of Apples and Pears from Messrs. G. Bunnard and Co., Limited, Maidstone, were a fine feature of the show. The fruit was of a high order of merit and a source of great interest to many. Gold medal.

Decorative designs in Chrysanthemums and other flowers were shown by Messrs. Felton and Sons, Hanover Square, W. A harp in golden Chrysanthemums, chaplet, baskets and other subjects were all well done in different colours, Orchids, &c., being used here and there for a finish. Silver-gilt medal.

Messrs. Hobbies, Limited, Dereham, had a group of Roses, cut flowers and plants that was much admired, and, together with a group of single Chrysanthemums set up in vases, well merited the large silver medal awarded to them.

A beautiful lot of single-flowered Chrysanthemums were shown by Mr. C. J. Simpson, St. John's Nursery, Chelmsford. There were numerous vases of well-grown flowers, all the better sorts being exhibited. Large silver medal.

The Government of British Columbia displayed a fine lot of Apples, carefully graded and packed in original boxes. The flavour of the fruit was good and the colour excellent. Silver-gilt medal.

Rustic arches and other rustic work, including pergolas and an array of horticultural sundries, secured a large silver medal for Messrs. H. Scott and Son, Woodside, S.E. A similar award was made to Mr. G. W. Riley, Herne Hill, S.E., for greenhouses, frames, a pergola and other rustic work.

Small silver medals were awarded to the following firms: Mr. H. W. Thorp, Durrington, Worthing, for a table group of Chrysanthemums, including the new white incurved Mr. H. W. Thorp; Mr. F. Brazier, for Roses, herbaceous plants and Chrysanthemums; Messrs. J. Cheal and Sons, Crawley, for Apples in good form and condition; Messrs. J. Laing and Co., Limited, Forest Hill, S.E., for a table group of stove and greenhouse plants; Miss R. Davies, Upper Norwood, S.E., for decorative designs in variety; Mr. J. Williams, Ealing, W., for rustic table decorations and other designs; and to Messrs. W. Duncan Tucker and Sons, Tottenham, E., for greenhouses and garden frames. Other miscellaneous exhibits were: Ichthemio Guano, from Messrs. W. Colchester and Co., Ipswich; Cheap Greenhouse Company, Sydenham, S.E.; and Messrs. D. Dowel and Son, Hammersmith, horticultural sundries.

#### CHELMSFORD AND DISTRICT GARDENERS' ASSOCIATION.

On Friday, the 30th ult. (the president, E. H. Christy, Esq., F.R.H.S., taking the chair), Mr. Charles T. Drury, V.M.H., F.L.S., gave a lecture to a very full audience of the members of this association on "The Wonderland of Ferns," illustrated by a large number of most interesting lantern slides. The lecturer dealt first of all with the immense debt owed by mankind to the Ferns and their allies of the long-distant Coal Age, when they built up those wonderful stores of future fuel which practically formed the foundation of all our industries and comfort of the present day. He pointed out, too, that it was from the same source that all the flowering plants were evolved by slow gradation and modification of some of the members of the family, though, strange to say, the Ferns of that period which did not so diverge from the beaten track are only differentiated in a minor degree from those of the present day, so that an inconceivably long period of evolution must have antedated coal formation to permit of the evolution of such highly-developed types. The peculiarities of Fern reproduction, as distinct from that of flowering plants, were then described and illustrated, and their wonderful capacity for "sporting"—the lecturer's special study—was exemplified by a number of slides showing some of his own discoveries and a series of the finest forms extant. Selective culture as applied to these wild "finds" was then treated of, and examples of sudden and wonderfully-marked advances in type so obtained were thrown on the screen, the pedigree slides on which the several steps of advance were shown side by side being particularly interesting. In conclusion, the lecturer strongly advocated the cultivation of these far more beautiful and yet equally hardy varieties in gardens and conservatories in preference to the common or "weed" forms usually grown, and, as evidence of their value as decorative plants, a view of his former British fernery at Forest Gate was shown and acknowledged by a burst of applause as abundantly proving his case. A very hearty vote of thanks concluded the meeting.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

## THE ROYAL BOTANIC GARDENS, KEW.

FEW books relating to gardens or gardening published during the last four or five decades can claim to be of such general interest as the magnificent volume by Mr. W. J. Bean\* and published by Cassell and Co. We all know and love the beautiful gardens with their wealth of floral and sylvan treasures; hence their history from the earliest times right down to the present day is most welcome, and when it is set forth in such a pleasant literary style as that adopted by the author, even the most fastidious cannot, we think, fail to be completely fascinated by the book, which must be the result of many months' patient research and hard work.

The reader is introduced to the volume and his or her appetite whetted by a masterly introduction from the pen of the late director, Sir W. T. Thiselton-Dyer, and then follows the first part dealing with the history of the famous gardens. We learn that the first mention of the village occurs in a Court roll of the manor of Richmond in the reign of Henry VII., and early in the eighteenth century it became a Royal place of residence. We are next informed that the gardens, as they exist to-day, are composed of several properties, the two chief being the grounds of Kew House, a Royal residence demolished in 1803, and the grounds of the Royal residence at Richmond known as Richmond or Ormonde Lodge, both of which are described in the happiest way by the author. Passing over much interesting information, we come to the time of the first Aiton, who was recommended by Miller to superintend the Botanic Garden at Kew, a post held by him and subsequently his son until 1840. The year 1772 saw the appointment of Sir William Banks as scientific director, and in the same year it was decided to send out from Kew the first of the many plant collectors. In 1789 William Aiton's "Hortus Kewensis" was published.

In 1803 a collector named Ker was sent to China, and the well-known plant double Jews' Mallow (Kerria japonica flore-pleno) was then introduced by him, along with many other plants. One can readily imagine with what interest the flowering of plants received from abroad at this period was looked forward to, because, it must be remembered, vast tracts of land then existed about the flora of which very little was known. At this period Kew was at its zenith, but dark days were in store. Thus we learn that in 1820 the

younger Aiton had several places under his direction, and the gardens were, undoubtedly, at this time in a very bad way; and probably it was owing to the love of plants and the untiring energy of John Smith, who entered Kew in 1822 and was made curator in 1840, that they survived. In 1838 matters had become so bad that a committee was appointed to enquire into the management of the gardens, Dr. John Lindley, the famous botanist, being at the head. Their report, we learn, was far from favourable, but some valuable suggestions were made by Dr. Lindley, many of which were subsequently adopted.

In 1841 a happier period dawned for Kew, as it was in this year that Sir William Hooker was appointed director, and the same year witnessed the admission of the public to the gardens every week-day. In 1844 the erection of the Palm-house was commenced, and the following year the pleasure grounds were added to the botanic gardens. From this time matters were pushed on rapidly, and in 1848 the first museum, now known as No. 2, was opened to the public. A feature of the work at Kew at this period was the raising of trees and shrubs for planting in the various Crown and public lands, and we learn that Battersea Park owes most of its arboreal features to Kew. In 1860 the large Temperate House was commenced, and, although the large central block and the two octagons were finished two years later, the structure as it now exists was not completed till 1899.

The year 1865 saw the death of Sir William Hooker, a man who by his enthusiasm and energy had converted the gardens from chaos to the first and foremost botanical station in the world in a little over twenty years. He was succeeded by his son, Dr. Joseph Dalton Hooker, who did splendid service during his official career, and who, although long since retired, is still, we are pleased to say, in the land of the living.

In Part II. English landscape gardening at Kew is dealt with, and this is, we think, one of the finest features of the gardens. Go where we will, some pleasant bit of scenery is sure to comfort us, and very seldom is there a jarring note. Architectural features, of which there are some classic and curious examples in the gardens—the formal garden, avenues, vistas and lawns, wild gardens, water and woodland (a very beautiful feature at Kew), Rose gardens and pergola, Rhododendrons, Azaleas and Bamboos—are all included in this part. In Part III. the scientific aspect of Kew is pleasantly dealt with, and those who are not well acquainted with the work carried on at Kew will learn a great deal from this portion of the volume. Part IV. is devoted to the rare and extensive

\* "The Royal Botanic Gardens, Kew: Historical and Descriptive," by W. J. Bean, assistant-curator, with an introduction by Sir William Thiselton-Dyer; 20s. Cassell and Co., Limited, Ludgate Hill, London, E.C.

tropical and warm-temperate plant collections, and the final portion is devoted to the hardy plant collections, including, of course, the splendid arboretum and rock garden.

The preparation of such a volume could not have been entrusted to better hands than those of Mr. Bean, whose close connexion with the gardens, extending over a long period, enables him to deal with the subject with authority and affection. The numerous half-tone illustrations from photographs by Mr. E. J. Wallis and most of the reproductions in colours from Mr. H. A. Olivier's paintings are well executed. Such a book deserves to, and will, we think, live so long as the love of gardening exists among us, and we congratulate the author on its appearance.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

November 24.—Royal Horticultural Society. Exhibition of Flowers, Fruit, &c., 1 p.m. to 5 p.m. Lecture at 3 p.m., by Mr. Joseph Cheal, on "Italian Gardens." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

**Sir Daniel Morris, K.C.M.G., V.M.H.**—The president and council of the Royal Horticultural Society have unanimously appointed Sir Daniel Morris to be an honorary life Fellow of the society, in recognition of his valuable services to horticulture in various parts of the Empire.

**United Horticultural Benefit and Provident Society.**—The monthly meeting of the above society was held on Monday evening, November 9, at the Royal Horticultural Hall, Vincent Square, Westminster, Mr. Thomas Winter in the chair. Eight new members were elected, making a total of seventy-one this year to date. The deaths of two members were reported, and the amounts standing to the credit of the late members were paid to the widows, being £25 7s. 4d. and £16 5s. 5d. respectively. Sick pay for the month was £36 4s. The trustees were asked to invest £300 in Corporation Stock. The dinner on October 15 last, at the Waldorf Hotel, was very successful.

**The National Chrysanthemum Society's Show.**—At the Judges' Luncheon held at the Crystal Palace, November 4, on the first day of the show, Sir Albert Rollet, D.C.L., LL.D., president of the society, occupied the chair, and there was a large muster of judges, exhibitors, officers and other members of the society. Considerable enthusiasm was aroused by the receipt of a telegram from the president of the French Chrysanthemum Society at Tours sending cordial greetings to their English brethren, and a reply was sent later reciprocating the good wishes of the French Chrysanthemumists. The president proposed the joint toast "The Judges and Exhibitors," and in doing so called attention to the educational work which the society was undertaking by encouraging the culture of the Chrysanthemum. The work that was being done was really a "national" work. He knew the judges had had an arduous task, but he was quite certain they had acted throughout with the strictest impartiality. To the exhibitors they were indebted for one of the finest shows that had ever been staged in the Crystal Palace or elsewhere. The toast was coupled with the names of Messrs. W. Wells and J. W. Moorman (for the judges), and Messrs. H. J. Jones and R. Cannell (for the exhibitors). The toast of the Crystal Palace Company was proposed by Mr. E. F. Hawes and replied to, on behalf of the company, by Mr. G. O. Starr, the general manager. The chairman of the executive committee, Mr. T. Bevan, proposed the toast of "The President," which was enthusiastically received with musical honours.

### Hedges of Michaelmas Daisies.

This seems a somewhat novel description to apply to Michaelmas Daisies, yet it is a fact. In Lord Aldenham's garden at Elstree this year Mr. Beckett has a real hedge or screen of one variety—the Hon. Edith Gibbs—pale blue. The mass is about 14 yards long, 7 feet wide and about 6 feet high. As I saw this novel arrangement in the middle of October it was, indeed, a glorious mass of its delicately tinted blooms, so profuse and so elegantly formed were the plants; the semi-drooping side branches swept the ground. —E. MOLYNEUX.

**The war on rats.**—In connexion with the deputation which waited upon Lord Carrington, President of the Board of Agriculture and Fisheries, on October 29, it may be of interest to mention that the French Government voted the sum of £12,000 for the extermination of rats and mice in agricultural districts in France. Danysz Virus, prepared at the Pasteur Institute, Paris, was the means officially employed, and, thanks to the timely measures taken, the farmers obtained complete and speedy relief from the troublesome pests, by which their crops had been previously devastated. Danysz Virus, it may be added, was awarded a silver medal at the Franco-British Exhibition.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**The National Rose Society.**—I have read with very great interest the remarks and suggestions made by "Amateur" in THE GARDEN of November 7, page 544, under the above heading. I quite agree with him that there should not be too large a gap between the classes in the amateur section; but as the classes in the schedule are so very well set out and defined to suit all growers, the competition cannot be called unfair. The greatest and most grievous point in my mind is, how is the committee going to satisfy itself that the exhibitors do exhibit in their proper classes in accordance with the number of exhibition Roses they grow? I should hail with great delight some system by which every exhibitor would be compelled to make out a correct return of all the exhibition Roses he grows, duly checked and signed by two members of the National Rose Society who live in the exhibitor's immediate neighbourhood, and then sent in to the secretary every year in the month of May. He would then know how the members exhibited and in what classes, and, if necessary, submit it to a meeting of the committee prior to the show, to satisfy himself that the rules and regulations had been faithfully adhered to by the exhibitors. —PERPLEXED.

**Late autumn flowers.**—Having seen several lists in various papers of flowers still blooming this month, I think the enclosed list of flowers, which were all in bloom on November 7 in the garden, may be of interest to your readers: Begonias, Asters (various), Primroses, Polyanthus, Schizostylis coccinea, Montbretias, Cornflowers, Erigeron, Rudbeckias, Poppies, Lavender, Chrysanthemums, Campanulas, Veronicas, Potentilla, Lobelia cardinalis, Rock Roses, Cyananthus lobatus, Tunica Saxifraga, Linaria alpina, L. dalmatica, Omphalodes linifolia, Tradescantias, Aubrietias, Oxalis, Anchusa italica, A. capensis, Geum, Hypericum, Nigella Miss Jekyll, Arotis grandis, Plumbago Larpenae, Verbenas, Phlox armeniaca, Linums, Arenaria montana, Hellebores, Cheiranthus, Jasmines, Pentstemons, Silene alpina, Mignonette, Antirrhinum, Gypsophila flore-pleno, Sisyrinchium, Dicentra eximia, Alyssum, Bergamot, Paris Daisy, Sedums, Heaths, Gladiolus, Violets, Wallflowers, Periwinkles, Houstonia cœrulea, Physostegia, Anagallis, Borago laxifolia, Helenium pumilum, Anthemis tinctoria, Diascia Barberae, Carnations, Trollius, Nepeta, Myosotis, Anemone japonica, Gaultheria procumbens, Mertensia, Salvia patens, Cranesbill, Nicoti-

ana Sanderæ, Spiræa, Ceanothus, Solanum jasminoides, Escallonia, Roses, Perowskia and Stocks. This garden is situated rather high, and up to the time of writing nothing has been touched by frost, although the grass has been quite white several mornings. —THOMAS CRADOCK, *Fairy Hill, Shinrone, King's County.*

**Suckers on Gooseberries.**—In pruning Gooseberry bushes there is one class of shoots which must not be spared, but which are to be eradicated entirely, unless under exceptional circumstances for filling up a vacant space; these are the rank growths known as suckers. Most people have had experience of a tooth drawn by a dentist; this is the method to be used with suckers. They should be twisted out of the socket with the fingers and wrist so that no future growths will result. —WALTER SMYTH, *Holywood, County Down.*

**Apple Scarlet Pearmain.**—While in making up a list of a selection of dessert Apples it seems impossible to omit Worcester Pearmain, a very superior Apple for the table, the old Scarlet Pearmain is likely to be omitted; indeed, it is one of the old varieties now too little heard of. Yet the fruits are much of the form of those of Worcester Pearmain, are handsome and beautifully coloured, flesh firmer, more juicy, having greatly superior flavour, and have the merit of keeping longer, being quite good from the beginning of October till Christmas. Dr. Hogg terms it a first-rate dessert Apple, yet it is elbowed out of cultivation by newer varieties that quite lack its flavour, beauty and general excellence. The tree is a good medium grower and does well on the Paradise stock. The fruits are oval, very slightly ribbed, have close eyes, long stems and are easily recognised. Were it a new variety it would be well boomed. —A. D.

**Olearias.**—Flowering shrubs were dealt with in THE GARDEN of the 31st ult., page 534, and it is stated there that the beautiful Olearias are not hardy enough for general planting. That would seem vague to all southern and western counties and both in and around London. Your correspondent also omits the most beautiful of all, namely, *O. gunniana*. This is the best of the family, and grows more vigorously and flowers more freely than either of the others. *O. stellulata* is loose in growth altogether, and does not flower so freely as *O. gunniana*, which develops into a round bush-like plant. We have several plants fully 6 feet high, and more perhaps through them. These are remarkable when in flower. I enclose a shoot of *O. stellulata* and *O. gunniana*, and one can feel the difference without seeing them. *O. myrsinoides* is of a straggling habit, but is none the less beautiful. It has larger leaves of a darker green than either of those mentioned, and flowers with great freedom. We have plants of this 6 feet high. *O. macrodonta* has flowered exceptionally well, and as it shows very much later than either of the others it is very valuable. We grow this in several places in the open. *O. Haastii* is of course hardy, but the flowers are not nearly so good; they are of a dirty white. The finest batch of these I have seen are at Warnham Lodge, the seat of Sir Henry Harbin. *O. nummularifolia* is a curious species, and resembles a miniature Araucaria by the small, compact, leathery foliage. *O. oleagnifolia* is a fine foliage plant, and somewhat resembles *Senecio Greyii*; it has leaves 3 inches to 5 inches long and the under-side is covered with white "felt." This beautiful kind should have the protection of a wall. *O. nitida* has large, ovate leaves, and flowers very freely in August and September. With regard to hardiness, we registered 18° of frost on two successive nights last winter, and the Olearias were quite uninjured. Many are deterred from planting them because they are considered very tender. I should suggest that good strong plants be obtained before planting in final positions, and, if the soil is clay, mix up a suitable compost and plant them in it. —W. A. COOK, *Leonardlee Gardens, Horsham.*

**The Crimson Damask Rose.**—I do not wonder you were impressed with this Rose when seeing it in Mr. Turner's nursery at Slough. It is a glorious Rose, giving such a patch of colour that no other variety can. The flowers are so gorgeous, too, in their lustre and so large when fully developed that the time cannot be other than short when we shall hope to see it in nearly every garden where single Roses are not prohibited. Mr. Turner very kindly sent me a plant some three years since, which has pleased many with its glowing colour.—E. MOLYNEUX.

**The Tupelo Tree.**—I was very interested in the note written by "A. D." page 534, respecting the Tupelo Tree. There is a beautiful specimen of *Nyssa sylvatica* growing in the grounds at Munden. This tree has been planted nearly seventy years and the pendent branches have a spread of about 50 feet, height of the tree about 25 feet, girth 3 feet 6 inches. During the last few years the tree has grown very freely, and it has been necessary to erect substantial supports for the almost horizontal branches. In its younger state growth was not so rapid. It is growing in a rather low position, the soil being of a moist, loamy nature. A younger specimen planted a few years ago, and which I understood was procured through Messrs. Veitch and Sons, is growing very satisfactorily in the same grounds. It is about 9 feet in height, and so far the growth is perfectly erect and the branches show no signs of becoming pendent, as they are in the older specimen. The foliage on both trees is very beautiful during the autumn. The tree flowers in the spring, the blossoms being very small and produced in dense heads. The *Nyssa* is certainly a tree which should be more frequently planted in this country.—C. RUSE.

**The beauty of Nemesias.**—I can endorse all that Mr. Blair says of this subject, for to my mind it is one of the most beautiful and most useful of the annuals. Grown in small beds round my lawn between standard Roses, it has delighted everyone who has seen it, and I have been surprised to find how few enthusiasts realised its value until brought face to face with it. Here in this favoured spot my *Nemesias* were in bloom this year by the middle of June, and the beds were still presentable in mid-September. I refer to Sutton's strains of the large-flowered type. As Mr. Blair says, it does well in any season, but it is essentially a sun-loving subject, and its brilliant shades are seen at their best when fully opened by the sun. I cultivate my garden without professional assistance, and rely largely upon annuals for beds and mixed borders. There are so many beautiful things among the hardy and half-hardy sorts that one can produce the most delightful effects; but I have discovered nothing more striking and more easily grown than the *Nemesia*.—W. M. ELKINGTON, *Ladye's Hill, Kenilworth.*

## BOOKS.

**The Florist's Bibliography.**—The publication of "The Florist's Bibliography," by Mr. C. Harman Payne, is of more than ordinary importance to all who take an interest in the history of flowers. For very nearly a quarter of a century the author has been a worker in this field himself and a diligent collector of books. Beginning with the *Chrysanthemum*, of which flower he is indeed "a master in Israel," and before whose shrine in Paris on the 6th inst. he laid unique rarities in the way of books, pamphlets and pictures, he has gradually extended his sphere of interest, and to-day his own library contains about 2,000 different works on florist's flowers and the flower garden generally. As will be gleaned from the preface, "The Florist's Bibliography" had its origin in a wish to help some personal friends, who were "students of horticultural literature," by

publishing a little list of his own books. Fortunately for the literary worker in floriculture he did not stop here, but resolved to make it as complete as possible by including other works which he did not happen to possess himself. To this end various sources of information have been drawn upon, notably Pritzel, Johnson and the library catalogues of the Massachusetts Horticultural Society and of the National Horticultural Society of France, and the result is the wonderful *pioneer* effort in the volume under review. It is a splendid bit of work in a new field of bibliography, but, like every first attempt, it is not absolutely perfect. Some dates will want revision, other rare or very little-known books will have to be added, asterisk marks denoting several editions will want inserting, possibly a little rearrangement will be deemed beneficial, and, certainly, to keep it up to date, as the author, I am happy to say, intends to do, new volumes will have to be noted and classified. It is a book that is badly wanted. Gardeners and dealers (even specialists) are, as a whole, woefully ignorant of the literature of garden flowers. A small work, dealing with a

*Société Nationale d'Horticulture de France*, with its well-arranged catalogue and its 15,000 volumes on horticultural and allied subjects, all under the supervision of probably the greatest living authority on such books, M. Georges Gibault. Or take what is said to be the finest horticultural library in the world, that of the Massachusetts Horticultural Society, which began to be formed in 1830 and to-day contains 17,000 volumes, a number which is being added to very largely every year. The Lindley Library, which is the library of the Royal Horticultural Society of England, has 6,000. I must pass on and say one or two parting words about the principles which have guided the author in his selection of what he has included. Firstly, it is essentially a *Florist's Bibliography*. Florist to-day has two meanings. I asked a foreman the other day what he called a florist's flower; his reply was, anything that is sold at a florist's shop—a reply which reminded me of Bishop Wilberforce's definition of an archdeacon as a man who performs archidiaconal functions. The next day I asked that well-known authority, Mr. Alexander Dean, the same question, and his reply was some-

ARCTOTIS ASPERA ARBORESCENS IN A DEVONSHIRE GARDEN. (See page 572.)

certain florist's flower, and published in 1908, begins by stating "information available for its history is not as plentiful as we could wish"; possibly the author, if he consults "The Florist's Bibliography," will be surprised to find there are no less than fifty volumes that he might have gone to for what he wanted. Quite recently, too, one of our very best practical men told me he had been asked if there was a special book on the Fuchsia, and that he had replied there was none. Mr. Harman Payne mentions seven.

Taking another point of view: supposing anyone wanted to get a list of what has been published on some particular flower. If the aforesaid person were a member of the Royal Horticultural Society he would very likely have read in his Book of Arrangements (page 130) of the "magnificent horticultural library" at Vincent Square, and, in his innocence, he would think he would be sure to find what he wanted there. He would have a rude awakening. Quite recently I have asked for "Le Père d'Ardène" and Malo on the Tulip and d'Ombraïn on the Gladiolus, but they were not there. One cannot help feeling the difference between ourselves and the

thing to this effect: Florist's flowers are flowers which have been improved by cultivation, largely with the idea of competing at shows, and of which the points as to what constitutes excellence, and by which they must be judged, have been laid down by experienced cultivators. Mr. Harman Payne takes a sort of *via media*, and includes not only Tulips and Carnations, but also such things as Cannas and Lilies and "hardy flowers and perennials." Serial publications are entirely omitted, and so, too, are books such as Alfred Smee's "My Garden" and Ellwanger's "The Garden's Story," which certainly are about gardens but do not confine themselves to plant life. There are no books on the Rose included, since a full bibliography of this great flower has been published in Spain by Señor Vagara. Although exigencies of space have to weigh with the keenest of enthusiasts, I do regret that we have not at least a selection of some of the more important works; it would add so much to the completeness of the volume. Books on flower-lore and floral art have a place in the bibliography; so, too, have books on the flower garden and flowers generally, the object aimed at being to

give the student and book-lover a complete *vade mecum* of all that pertains to floriculture and florist's flowers. The book is an octavo volume of eighty pages, the product, as the highly interesting frontispiece suggests, of one who has made this subject his hobby, and it is published by that most obliging firm of gardening-book specialists, Messrs. William Wesley and Son of Essex Street, Strand, at 3s. 6d. I congratulate Mr. Harman Payne on his choice. It is no slight gain to both author and purchaser to have as principals of the publishing firm men who are like-minded with themselves. JOSEPH JACOB.

## THE GREENHOUSE.

### FUCHSIAS FOR AMATEURS.

THE Fuchsia family, represented by species and varieties innumerable, stands out almost alone in the varied purposes for which it may be employed in gardens, for in the humblest, as well as in the most pretentious, Fuchsias of some kind or other can be depended upon to contribute their share to the floral display.

There is no doubt that Fuchsias have made considerable headway in popular favour within the last few years, more particularly in large establishments, where, either in bush or standard form, they are bedded outside during the summer months. This is not at all surprising, as during the latter part of the summer and in early autumn, when so many bedding plants are past their best, the Fuchsias yield a magnificent display. It is, however, not my intention to treat of Fuchsias in this way, but rather to point out their great value to the amateur with but a single greenhouse or even without one at all. Their accommodating nature during the winter stands them in good stead, as Fuchsias can be safely kept during that period in a window or empty room, or, if the winter is not too severe, in a stable or shed of any kind, provided they are just safe from frost. They can also be wintered in a cellar, and if it is so situated that they can have a little light and air during mild weather so much the better. Throughout the winter very little water will be needed; indeed, old plants may be kept quite dry, though they are better if watered occasionally. Young plants, whose stems are in a more immature state, cannot stand extremes as well as the old ones, hence occasional watering is in their case more necessary. Being naturally of a deciduous character, the beginner need not be at all nervous when all the leaves drop.

With regard to the wintering of Fuchsias, those that have been grown in pots should be allowed to remain therein; but where planted out in the garden, the better way is to lift them carefully and pot them, taking care that the pots chosen are not too large. A fine day should be selected for the purpose, and, after being potted, a thorough watering must be given to settle the soil in its place before the plants are placed under cover. These remarks apply to Fuchsias in general, for there are a few which need no protection, and even if cut to the ground during the winter they push up new shoots from the base which will flower the same season.

Among the many purposes for which Fuchsias may be used are the following. They may be grown in pots and allowed to assume their natural bushy character. In this way they are valuable for windows, balconies or for the greenhouse. Next, when too large for this purpose, they can be either planted or plunged out of doors during the summer months, or, should there be no such convenience, if put in large pots or tubs (old butter-tubs are very suitable for the purpose), they may be stood in proximity to the house, in a courtyard or, in fact, almost anywhere.

A marked feature of most Fuchsias is the more or less drooping character of the shoots and blossoms. Owing to this they are seen to

great advantage when occupying an elevated position, and they are therefore well suited for growing in suspended baskets, for the edges of balconies, or for similar purposes. This drooping character also enables them to display their charms to the full when they are trained to the roof of a greenhouse, for which position the loose rather than the compact-growing varieties are preferable. A greenhouse roof clothed with a selection of Fuchsias and supporting myriads of flowers of different hues suggests a glimpse of fairyland. A feature greatly in favour of Fuchsias as roof plants is the fact that during the winter they are devoid of foliage, and consequently do not obstruct the light at that season of the year when it is so essential for the plants underneath.

A selection of varieties suitable for the several purposes is herewith appended. At the same time, it may be pointed out that so numerous are the varieties that a good deal depends upon individual taste. The following, however, are all distinct and well-proved sorts.

*For Placing Out of Doors During the Summer.*—Amy Lye, whitish tube and sepals and reddish salmon corolla; Ballet Girl, double white corolla; Brilliant, sepals coral red, semi-double corolla, reddish violet; Earl of Beaconsfield, yellowish salmon; Elegance, red sepals, purple corolla; Flocon de Neige, single white corolla; Mrs. Marshall, white tube and sepals, carmine corolla; Mme. Cornellison, single white corolla; Marinka, nearly a self crimson; Phenomenal, double purple corolla; Rose of Castile, whitish sepals, purple corolla; Scarcity, a fine dark flower; and White Phenomenal, double white corolla. To these must be added Alice Hoffmann; this flowers freely when but a few inches high, and makes a very handsome bed or edging to the larger varieties. The corolla is single and clear white in colour. Varieties remarkable for foliage distinctions, all of which do well out of doors, are gracilis variegata, Cloth of Gold, Meteor and Sunray.

*For Pot Culture in the Greenhouse.*—Avalanche, double violet; Ballet Girl, double white; Cadmus, single white corolla; Countess of Aberdeen, nearly a self white flower; Frau Emma Topper, double rose-coloured corolla; Guiding Star, white tube and sepals, rosy red corolla; Gertrude Pearson, coral red sepals, dark plum purple corolla; Lady Heytesbury, white sepals, purple corolla; Lord Byron, a very dark rich-coloured single flower; Mrs. Rundle, orange salmon; Phenomenal, double dark; Royal Purple, deep velvety single corolla; and Valiant, bright red self-coloured flower.

*For Training to Roof of Greenhouse.*—General Roberts, reddish tube and sepals, purple corolla; General Grenfell, coral red sepals, bluish corolla; Lustre Improved, white sepals, red corolla; Mme. Cornellison, single white corolla; Mrs. Rundle, orange salmon; Monarch, large bright red flowers, nearly self coloured; Marvellous, double violet corolla; and The Shah, bright red sepals, single violet corolla.

*For Baskets.*—Beauty of Exeter, mauve-coloured corolla; Charming, deep red; Delight, single white corolla; Elegance, crimson sepals, purple corolla; Jubilee Queen, white sepals, red corolla; Molesworth, double white corolla; Mrs. Rundle, orange salmon; Rhoderick Dhu, large single bluish corolla; and Scarcity, single plum-coloured corolla.

Beside all these there are some very beautiful hardy sorts, which, in the more favoured parts of these islands, attain the dimensions of large bushes. Even where they are liable to be injured during the winter they throw up strongly from the base. The hardiest of this class are corallina, or exoniensis, as it is often called, gracilis and Riccartonii. In addition, there are several others nearly, if not quite, hardy. Many of them are rather dwarf in growth and exceedingly floriferous. The hardiest variety with a white corolla is, as far as my experience goes, Mme. Cornellison, which is so much used for bedding-out in the parks during the summer months. H. P.

## THE FLOWER GARDEN.

### ARCTOTIS ASPERA ARBORESCENS.

ACCORDING to the 1900 supplement to Nicholson's "Dictionary of Gardening," *Arctotis aspera* was introduced into this country from South Africa in 1710. In the same work *A. arborescens* is stated to be synonymous with *A. aspera*, but a writer on the genus in THE GARDEN in 1892 held that *A. arborescens* was merely a variety of *A. aspera*, in which he was doubtless correct. There are about fifty species of these South African plants, but few except the annual types are to be met with in English gardens, since they are unsuitable for open-air culture except in the warmest spots in the British Isles.

In the Isles of Scilly *A. aspera arborescens* assumes huge dimensions and flowers through the whole summer. As may be seen from the illustration on page 571, of a specimen 4 feet in height and 6 feet in diameter, growing in a garden on the shore of Start Bay, the plant is very distinct in character, its deeply-cut, grey leaves being striking even when it is not in flower, while the white, Daisy-like blossoms, about 3 inches across, with a yellow rim surrounding the disc, are very attractive. The petals are pink on the reverse, and the buds, which are of the same colour, afford a pleasing contrast to the white expanded blooms.

It can be grown in the open in Devon and Cornwall, but in exceptionally severe winters, such as the two last, it is generally killed unless protected. In the winter of 1906 my plants of this *Arctotis*, and of the handsomer *A. aureola*, were cut to the ground. In the spring the latter broke again from the roots, but *A. aspera arborescens* never reappeared and had to be renewed.

For the culture of the *Arctotis* the warmest and driest spots obtainable should be chosen. A southern exposure at the edge of a retaining wall is one of the best positions possible, and a few inches of light soil overlying a good depth of broken bricks, crocks and sherds will suit them perfectly, since the drier the soil and the more rapid the drainage the better they succeed. Rich soil is totally unnecessary, as it merely tends to produce rank growth at the expense of the flowers. The plant is extremely rapid in growth, a rooted cutting planted out in the spring often attaining a diameter of 4 feet by the autumn, even in the poor rooting medium already described. The flowers, if cut when expanding, remain fresh in water for a long period.

*Arctotis aureola* is an even more handsome species. This has flowers of a deep orange tint, fully 4 inches across, and is of far more compact growth, spreading but little. It is also hardier than *A. aspera arborescens*, having sprouted from the roots the last two springs though cut to the ground by the severe winter frosts. The annual *A. grandis* was highly lauded at its first introduction, but its flowers are not borne in sufficient quantity to render it a plant of high decorative value, and its rampant growths are so brittle that each requires a separate stake, which detracts from its appearance in the border.

South Devon.

S. W. FITZHERBERT.

### SINGLE-FLOWERED CHRYSANTHEMUMS IN AUTUMN.

Now that we have such an array of beautiful early single-flowered Chrysanthemums, that make the borders bright during late August and September and the earliest days of October, we need to look round to see what is to take their place as they go out of flower. We are more than pleased with what has been achieved with these early-flowering outdoor varieties, but we must admit that we recognise in others that come into flower immediately subsequent thereto a value quite distinct from those that preceded them in their

period of flowering. There are growers who think very little of the early-flowering single *Chrysanthemums*; but they are of great value for indoor decorations in a cut state and last long. At the moment, we have in our vases indoors blooms that have been used for decorations for quite a fortnight, and many of the flowers look almost as fresh as when they were first gathered. We, however, welcome an addition to the single-flowered section of a comparatively new type of plant that flowers throughout the whole of October. In open weather they continue the display in the outdoor border, and the fine breadths of colour that these plants produce when grouped in masses of one kind is very striking.

We are more particularly interested at the moment, however, in propounding their claims for decorative uses indoors during their period of flowering. Recently we had sent to us an interesting number of beautiful varieties from Mr. W. J. Godfrey of Exmouth, Devon. This raiser has succeeded in enriching our collection with a series of large, medium-sized and small flowers of the single-flowered varieties. Dowdy colours appear to be absent; there are interesting yellow shades, some of which are particularly bright and pleasing. One of the most striking varieties is named

*Lady Coleridge*.—This is a very beautiful flower with two or three rows of petals, which are of medium breadth; they are borne in beautiful sturdy sprays, so that the individual flowers may be broken out of the spray and used separately, or the whole spray may be disposed in a vase by itself. The colour is a bright rich tone of yellow, and the richest we have seen in these flowers for a long time. The high, well-formed disc of a deeper shade of colour, tinted green, adds to the attractiveness of the flower.

*Lillie Godfrey*.—This is another charming large-flowered single sort. The flowers are in cluster sprays that need to be partially disbudded for them to be seen to advantage. The colour is its most pleasing feature, this being a distinct shade of delicate mauve pink. We have admired this flower for its colour, which has a beauty peculiarly its own.

*Devonshire Lass*.—This is a delightful variety, having beautiful large single flowers that are borne in elegant sprays on long footstalks without disbudding. It would be easy to mistake this variety for a large spray of the well-known yellow *Marguerite*; the flowers being larger, however, are more attractive. They have a single row of florets, which are well disposed, and the colour is primrose yellow with a greenish yellow disc. Individual sprays make a very pretty decoration.

*Mrs. Lestock Thornton*.—This is another pretty yellow single flower of small to medium size. The flowers are borne in cluster sprays. While they look pretty in an undisbudded form, the effect would be still better were they partially disbudded. The petals droop slightly and are neatly disposed round a large, well-formed disc.

*Godfrey's Gem*.—Some growers might regard this as too small and uninteresting; but all those who know the value of the small-flowered sorts would appreciate the variety under notice. It is a miniature-flowered single, having rather narrow, flat, blunt-ended petals that are disposed in a single row round the yellow disc. The flowers are borne in sprays on slender panicles, and the colour is a bright chestnut crimson with a yellow disc. This is a very dwarf plant, and on that account may appeal to some readers.

*Kathleen Davies*.—An interesting medium-sized single of a pleasing shade of pale fawn, tinted rose colour. The blooms are developed in pretty sprays that need not be disbudded.

*Countess Fortescue*.—This is a pretty rosy bronze flower that must be disbudded to be appreciated at all. In undisbudded form it is not of much use, but when well grown and disbudded it is welcome.

*Mrs. Kennaway*.—This is a white single flower of medium size and pleasing form, having

(*Lupinus polyphyllus*). It is a native of Columbia, and was introduced to this country as long ago as 1826. Although the type has blue flowers, there are now a number of varieties and hybrids with blossoms of varying shades from pink to pure white. The plants will thrive in any ordinary garden soil, and if the old flower-spikes are cut down level with the soil as soon as the blossoms are over, a second crop of flowers may often be obtained. The accompanying illustration shows the value of this *Lupine* for massing, a point that should not be overlooked where planting on an extensive scale is adopted.

## THE FRUIT GARDEN.

### APPLES AT ALDENHAM HOUSE.

ONE of the most promising orchards on grass that I know is at Aldenham. The trees are from twenty to thirty years old, have abundance of space, have been well attended to and, being standards and half-standards, they are most shapely, and give abundant crops of brightly-coloured fruit when there are Apples in the neighbourhood. The soil is mainly composed of clay, like the bulk of it at Aldenham; but with thorough preparation, *i.e.*, trenching deeply, the trees have been brought to as near perfection as possible. At one time the trees were almost at a standstill until Mr. Beckett had the whole of the soil deeply trenched, thus relieving it of stagnant moisture and admitting air to the roots also. The improvement has been marvellous, thoroughly surprising even the most sanguine.

Blenheim Orange is a great favourite here, and deservedly so, as the variety is of such excellence that no doubt it is a seedling form, and a good one, too. The fruit is large, shapely and so rich in colour as to render the tree quite a conspicuous object. Cox's Orange Pippin

growing as a half-standard is one of the finest trees of that variety I have seen. Annually it bears heavy crops of medium-sized, clean, highly-coloured fruit. Hoary Morning, high colour (though it naturally is anywhere), seems to be exceptionally so at Aldenham House. This is an Apple that should be more grown, especially when it is known how much the American fruit of high colour is preferred to the ordinary English produce. Tower of Glamis gives remarkable crops of large, clean, desirable fruit. Small's Admirable is one of the best of late-keeping Apples; here it is an almost certain cropper, and therefore finds appreciation. Mère du Ménage is represented by a desirable tree that gives immense-sized fruit, especially when we consider the crop it carries. The new Norfolk Beauty is receiving attention, Mr. Beckett having seen this Apple growing and cropping so freely in its home.

A full-sized tree of Scarlet Nonpareil, with its clusters of fruit, is a conspicuous object in the landscape. Wellington is a favourite at

A GROUP OF THE MANY-LEAVED LUPINE (*LUPINUS POLYPHYLLUS*) IN MR. WILLIAM HUDSON'S GARDEN AT SURBITON.

a greenish yellow centre. Either in sprays disbudded or undisbudded, this is a useful flower.

*Miss Violet Elgar*.—This is a free-flowering, medium-sized single variety, evolving dense cluster sprays of bloom with several rows of petals. The colour is a pleasing bluish white, which contrasts effectively with the large yellow disc.

*Cinderella*.—A very distinct and pretty little single-flowered sort. For decorative uses it is ideal. The dainty little blooms are some  $1\frac{1}{2}$  inches to 2 inches in width, and of a starry character; they are pleasingly disposed in sprays. It is profuse flowering, and we think this charming little plant will become very popular. It is pure white, with a greenish yellow centre.

I may mention that these single-flowered *Chrysanthemums* are fragrant. D. B. CRANE.

### THE MANY-LEAVED LUPINE.

Among our hardy perennials few are of greater general value than the many-leaved *Lupine*

Aldenharn. It annually supplies a full crop of desirable fruit. Lord Derby succeeds remarkably well, giving good exhibition fruit in quantity. Potts' Seedling is free from canker, giving full crops of clean, handsome fruit, and when that is the case this is a desirable Apple. The Queen at Aldenharn House seems to fill up its fruit better than in many places. As a rule the flat appearance of this Apple militates against its market value. King of the Pippins as an early September Apple is here in request; it crops freely and colours highly.

In the kitchen garden growing as bush trees I saw the finest fruits of Charles Ross I have yet seen, and remarkable in colour they were.

## COLOURED PLATE.

PLATE 1361.

### TWO GOOD PEARS.

(EMILE D'HEYST AND BEURRÉ ALEXANDER LUCAS.)

**E**MILE D'HEYST is the rich cinnamon russet fruit shown in the plate. Although this has been in commerce for some sixty years, it is only recently that it has become recognised. The tree is not a vigorous grower, but extremely productive and bears regularly; even in bad years it generally bears a fair crop of fruit. It ripens at the end of October and in November, and is of very refreshing flavour, the flesh melting. It is best as a cordon or small bush on Quince stock, but does well as a standard and is one of the best dozen grown. The fruit is large from small trees.

Beurré Alexander Lucas is a handsome fruit of

## THE KITCHEN GARDEN.

### THE ART OF TRENCHING AND MANURING.

**A**LTHOUGH some divergence of opinion is, without doubt, justifiable as to the comparative benefits of winter and spring trenching, yet in very many cases we believe the former should manifestly be the rule; while in dealing with those soils which it is really better to treat in spring, practical considerations often arise to make winter trenching a necessity. It usually happens that there are more vacant plots and borders in the garden, and more spare time on the out-of-door gardener's hands at this season than when spring, with all its demands upon time and labour, arrives.

*Good Cultivation.*—The necessity for deep digging as a condition of successful cropping has long been proved by all gardeners worthy of the name; but beyond a general notion of the benefit of working the soil and exposing it to the effects of "weathering," much uncertainty prevails among us as to the actual principles underlying the process. For principles there are, and these of a nature which makes their bearing a matter of first importance to the practical man. Following out the fundamental idea, with which

science has acquainted us, that the soil is alive and must be treated accordingly, it is here proposed to touch briefly on a few of these principles. It will be found that, without exception, they demonstrate the importance of frequent and thorough cultivation.

*The Living Soil.*—It must be borne in mind that soil is inhabited by multitudes of minute forms of vegetable life, known as bacteria or germs. These organisms act upon nitrogen, gradu-

ally converting the ammonia of nitrogenous matter into nitrate, and thus making it available as a plant food. This gradual change is known as nitrification. Nitrification is a process of oxidation, or burning, and as such can only take place where the oxygen of free air can combine chemically with ammonia in the soil. It is obvious, therefore, that to enable the bacteria to do their work soils must be properly aerated. A certain degree of warmth and of moisture is also absolutely necessary. Lastly, the presence of lime, phosphates and potash is needed to provide suitable nourishment for the soil organisms.

H. C.

(To be continued.)

THE PERSIMMON FRUIT GROWN OUT OF DOORS.

Worcester Pearmain, Gascoyne's Scarlet and Peasgood's Nonsuch were carrying excellent fruit of quite exhibition form.

Swanmore.

E. MOLYNEUX.

### PERSIMMON FRUITING IN THE OPEN.

THE enclosed Persimmon was grown by my neighbour, F. L. Carslake, Esq., Darracombe, Newton Abbot. I thought it might be of service to you for illustration. It is growing on a south wall out of doors, and ripened its fruit this season. This, I think, must be rather unusual for this country.

G. S. PATEY.

free growth, bearing regularly, and is less liable to spot than most Pears. It ripens in November, and has a brisk acidulous flavour, with the Williams's Bon Chrétien taste; it is a very welcome fruit in its season. On a wall it is often very large, and it succeeds on the Quince stock in all forms and as a wall tree. Both are excellent varieties and deserve to be far more extensively planted in gardens than they are at present, as good, well-finished fruits of either are always welcome. The specimens from which our coloured plate was prepared were kindly supplied by Messrs. George Bunyard and Co., The Royal Nurseries, Maidstone.

## THE ROSE GARDEN.

## DAMASK ROSES.

**M**AY I add a few more notes on this interesting race in addition to those in a recent number of THE GARDEN? There is much confusion in the mind of the general public regarding "Damask" Roses. In many instances when they are enquired for deep red Roses are meant, while in the dictionary we find the word "damask" interpreted "silk woven with flowers." But what Rose growers regard as Damask Roses are a race by themselves. Professor Crepin, in his "New Classification of Roses," given before the National Rose Conference in 1889, places *R. damascena* under the section of *gallica*, and he says, "Many authors have considered *R. damascena* (Miller, 1768) to be a distinct type, classing it in section *gallica*, but it is probable that this Rose is a hybrid produced from *R. gallica* crossed with a species of the section *canina*." We shall probably never know the origin of some of these older types of Roses; there is much conjecture but no solid basis, and I am afraid we must rest content with the scrappy information which we have. That *R. damascena* has played a great part in giving us our present-day Hybrid Perpetuals seems certain. Mr. W. Paul, in the "Rose Garden," says as much, and he informs us that M. Laffay raised some of the earliest Hybrid Perpetuals by crossing the Perpetual Damask with the Hybrid Chinese and Hybrid Bourbons. These Damask Perpetuals were grown many years ago, but they have now dwindled down to about one sort, *Rose du Roi*, a variety possessing in a marked degree the leathery leaves and rigid growths of *R. damascena*, with a perpetual habit of flowering. So late as the end of September this year flowers were found upon this variety. In France these Roses are known as *Rosiers Portland*, and I see M. Guillot catalogues six different varieties.

Whatever their origin, the group of *R. damascena* is of very ancient introduction. They are largely used in Bulgaria and other places for the production of rose water and attar of roses. Although, strictly speaking, the old Red Damask does not belong to *R. damascena*, its name will always be retained by lovers of garden Roses. I wonder if it was this Rose that Spenser had in mind when he wrote in the "Shepherd's Calendar":

Upon her head a crimson coronet,  
With Damask Roses and Daffodillies set.

This variety has semi-double flowers of a very bright crimson colour. It has produced the beautiful striped Rose named *Rosa Mundii*, which very frequently passes for *York and Lancaster*. It is one of the most picturesque of Roses, and should be in every collection.

Mr. Turner of Slough has raised a very beautiful variety of the group under notice, which he calls *Crimson Damask*. It has single flowers of the most brilliant crimson, 4 inches to 5 inches across, produced in great quantities early in June.

*Mme. Hardy* is one of the best of the group. The flowers are pure white, of cupped form and produced in large clusters. The habit is erect and growth vigorous.

*Leda* or *Painted Damask* is an extremely beautiful Rose with its quaint, lake-margined petals. The ground colour is blush, tinged with flesh.

*La Ville de Bruxelles* has flowers of a vivid light rose colour. The expanded flowers are most charming when seen in early summer before other Roses are out, and it has a striking grass green foliage.

*York and Lancaster*.—The true variety, but a Rose one need not be anxious to obtain. The flowers are a dull pink, white striped and not very pretty. Certainly *Rosa Mundii* is much the better Rose.

*Hebe's Lip* or *Reine Blanche* is one of the loveliest of the early Roses, its semi-double flowers being prettily tipped with carmine on a white ground.

*Mme. Soetmans*.—Flowers pale flesh, changing to white, form cupped; a very fine sort. P.

## ROSE ELECTRA.

ONE cannot praise this Rambler too much. It seems so decidedly superior to *Aglaia*, although there is room for both sorts; the latter appears in bloom about a week earlier than *Electra*. It

Given fine weather we get some very handsome individual blooms, and a few double sorts, such as *Maman Cochet* and *White Maman Cochet*, are often better in autumn than at any time.

What we want, however, in autumn are Roses that will compete in showiness with other denizens of the garden, such as the Dahlias, Starworts, Anemones, Rudbeckias and others. Now, have we such Roses? I say, yes. Can we not claim this distinction for *Caroline Testout* or its beautiful white sport, *Admiral Dewey*? Is not *G. Nabonnand* a perfect gem in the autumn, and its lovely sport, *Peace*, equally so? What a delightful and brilliant effect we may obtain from *Grüss an Teplitz*, especially when grown as a standard, or from a mass of *Corallina* with its lobster red blooms!

Of the newer Roses, really good autumnal sorts are to be found in *Richmond*, *General Macarthur*, *Königin Carola*, *Joseph Hill*, *Gustave Grunerwald*, *Countess Cairns*, *Earl of Warwick*, *Elizabeth Barnes*, *Countess of Gosford*, *Betty*, *Marquise de Sinety*, *Edu Meyer*, *Mrs. David McKee*,

THE RAMBLING ROSE ELECTRA GROWN IN A MASS.

matters not how we grow it—pillar, spreading bush, or standard—its lovely sprays are always attractive. This Rose, when fully out, is almost a pure white, and its flowers lift themselves quite erect, which adds much to its value as a decorative variety. A mingling of this and *Carmine Pillar* would be delightful, or with one of the bright-coloured *Penzance Briars*, such as *Anne of Geierstein* or *Meg Merrilies*.

## SOME GOOD DECORATIVE ROSES.

COMPARATIVELY speaking, how few of our Roses can be truthfully described as decorative. By that I mean decorative as garden plants. We know very well there are numbers of varieties that will produce blooms in the autumn months, but there are not many sorts that make a really good display. To obtain this we require varieties whose developed blooms remain in good condition a considerable time. So many sorts commence to decay rapidly and thus give to the cluster a very woe-begone appearance. The very double Roses are the worst to grow for autumnal beauty.

Bertha Kleman, Mrs. Aaron Ward, Ecarlate, Harry Kirk, Warrior, Lady Ashtown, Mrs. E. G. Hill, Lena, Mme. Paul Varin-Bernier, Mrs. Dudley Cross, Mrs. Isabelle Milner, Chateau de Clos Vougeot, Souvenir of Stella Gray, Mme. Segond-Weber, Mrs. David Jardine and many others. There are two special groups we must not overlook when making our plans for autumn display. These are the dwarf Polyanthas and the China or Monthly Roses. They are really indispensable, and full of charm with their exquisite clusters and artistic colours. No one can afford to overlook such as *Aschenbrödel*, Mrs. W. H. Cutbush, *Rosel Dach*, *Phyllis*, *Eugénie Lamesch*, *Perle d'Or* and *Canarienvogel* among the Polyanthas, and *Charlotte Klemm*, *Comtesse du Cayla*, *Arethusa*, *Baronne Piston de St. Cyr* and *Queen Mab* among the Chinas.

Just a word in conclusion, and that is, do not be afraid to plant closely if an effective display is desired. From 15 inches to 18 inches is ample space for two or three years. The distance apart can be increased when the plants are transplanted, as they should be periodically. P.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE WINDOW GARDEN.**—I am planting small shrubs in the window-boxes just now; there are several subjects that answer well for this purpose, notably the golden-leaved *Euonymus*. Bulbs that have not been planted yet should be dealt with without further delay. A few such bulbs yield a welcome

*The Hardy Flower Garden.*—While the weather remains open, there are many things to attend to in these quarters. Dutch and other hardy bulbs should be planted as soon as possible, as it is full late for this work already. Group the different subjects in bold masses of one variety in each group, as this is far more effective than planting them in lines. Observe the same rule when lifting and dividing hardy perennials and biennials. When grouping the different subjects, avoid crowding them in the colony; instead, allow ample space for each individual plant to do justice to itself. Those who wish to have a bright display in the garden in the spring should plant at once the Primroses and Polyanthus, the double and single-flowered *Arabis*, *Forget-me-nots*, double Daisies, as well as the beautiful *Aubrietias*.

*The Greenhouse and Conservatory.*—Observe the greatest care in watering from now until the winter season has passed. Water the plants only when the soil is dry, and be quite certain of the fact. The Primulas are already evolving promising trusses of blossom, and for this reason will derive considerable benefit by an occasional application of weak manure water. The same remarks apply equally to the Cinerarias. I am just potting up a batch of Tuberoses and a few other late bulbs, and the last batch of *Spiraea japonica* is receiving this attention also.

D. B. C.

### THREE GOOD BULBS FOR POTS.

ALTHOUGH the work of potting up bulbs for spring flowering should have been finished several weeks ago, it may still be performed where circumstances have prevented it being done earlier. Such good results cannot, of course, be expected from bulbs potted at this late date, but presentable flowers will be produced if reasonable care is taken over the work.

*Hyacinths.*—The many beautiful bedding varieties impart a brilliant colour to the greenhouse in early spring. The bulbs may be potted from September to November. The soil for Hyacinths should be rich, a suitable mixture being loam, leaf-mould, well-decayed manure and coarse sand. Place one bulb in a 5-inch pot, or three bulbs in 6-inch or 7-inch pots, according to the size. Make the soil firm in the pot, leaving the top of the bulb just protruding above the surface. Water each pot and plunge in a bed of ashes or Cocoanut fibre for six weeks. Here the bulbs will root freely, when the pots can be moved into a cool, airy greenhouse or frame. Very little fire-heat should be used in the house

where the Hyacinths are growing. A dozen good sorts for the greenhouse, all of which can be obtained at a reasonable price, are: White, *La Grandesse*, *Leviathan* (tinted blush) and *Mme. van der Hoop*: rose, *Cardinal Wiseman* and *Moreno*; red, *General Pelissier* and *Prince Albert Victor*; blue, *King of the Blues*; light blue, *Czar Peter* and *Queen of the Blues*; purple, *William the First*; mauve, *Lord Balfour*; and yellow, *Yellowhammer*. All the above are varieties with single flowers.

*Crocus.*—In the garden the Crocus is one of the earliest bulbs to open its flowers in spring. By growing a few in pots in the greenhouse or window, the delicate blooms will open several weeks in advance of those outside. Being so easily grown, and coming up year after year without being disturbed, the Crocus has for years been very popular in small gardens; in fact, before the bulbs of Daffodils and Tulips became so cheap the Crocus was the principal bulbous plant grown for flowering in spring. Pots 5 inches in diameter are a useful size to employ. Ordinary potting soil, such as that used for Geraniums and Fuchsias, is suitable for the Crocus. Having placed a few broken crocks and rough soil in the bottom of the pot for drainage, fill it up to within 1½ inches to 1¾ inches of the top with the potting compost, making the whole fairly firm. Next place the bulbs on the soil; ten bulbs is about the average number to place in each pot—seven round the sides and three in the centre. To complete the potting cover the bulbs with soil, leaving a quarter of an inch to half an inch space for watering. Subsequent treatment consists in plunging the pots outside for a time, and eventually removing them to the garden frame or cool greenhouse. Water whenever necessary, especially when the pots are full of roots. The number of varieties is numerous, a few of them being *Mont Blanc*, pure white; *King of the Blues*, dark purple; *Sir Walter Scott*, large white flowers, striped lilac; *Cloth of Gold*, rich yellow; *La Majestueuse*, white, striped purple; and *Royal Blue*, dark blue. In addition to the above sorts, several species of Crocus are admirably adapted for growing in pots, a strong point in their favour being that they flower several weeks in advance of

TWO GOOD POTS OF THE PRETTY CROCUS BIFLOROUS.

return in the way of fragrant blossoms in the spring. Foliage plants indoors will, from this time forth, need more care in regard to watering. Tepid water should be applied at all times during the winter season, and the plants must not be watered unless the soil is fairly dry.

*Trees and Shrubs.*—So few beginners appreciate the real value of the Ivies. Dwellers in and around the neighbourhood of large towns so often desire to cover up unsightly walls and fences, besides other all too apparent bare spaces in the garden. The Ivy in variety is an ideal subject for this purpose and may be planted at the present time. Other climbing plants may also be planted now, as well as evergreen and deciduous trees and shrubs in great variety.

*The Hardy Fruit Garden.*—Planting, lifting and root-pruning will occupy much time now, and the results amply justify this work being proceeded with before the hard weather sets in. I am now dealing with the Raspberries, cutting out all growths that bore fruit last summer, as well as weakly shoots of the past season's growth, retaining only the strongest shoots, which are securely tied to stakes or to trellis-work.

*The Vegetable Garden.*—As opportunity offers I am clearing all available ground of exhausted vegetable crops, burning or burying the same and trenching the quarters in drastic fashion. I am incorporating a very heavy dressing of partially-decayed manure. In gardens where the soil is light and sandy, cow manure should be applied in heavy dressings, as soil of this character is quite voracious. On the other hand, where the land is of a heavy and retentive kind, partially-decayed horse manure applied in liberal quantity will assist to lighten the same. A dressing of lime or ashes resulting from burning the rubbish of the garden will further assist in rendering heavy soils more congenial. Cover the tops of the ridges of Celery with boards or littery matter at the first approach of frosty weather.

THREE POTS OF THE PAPER WHITE NARCISSUS, ONE OF THE EASIEST TO GROW AND EARLIEST TO FLOWER.

A GOOD POTFUL OF BEDDING HYACINTHS.

the varieties. Four of the best are *C. biflorus*, white, striped black (the variety illustrated); *C. chrysanthus*, yellow; *C. Imperatii*, violet, fawn and black; and *C. Sieberii*, purple.

**Paper White Narcissus.**—Both for cutting in midwinter for room decoration and as a pot plant in the greenhouse, the fragrant pure white flowers of the Paper White Narcissus are highly prized. The bulbs are cheap, 9d. to 1s. per dozen being the average price for good bulbs. Many of these will send up two flower-spikes, a few three. Provided there is a little manure in the soil, that used for Fuchsias and Geraniums will do equally well for Narcissi. Place three bulbs in a pot 5 inches in diameter and four or five bulbs in pots 6 inches across. Cover about two-thirds of the bulbs with soil pressed only moderately firm. Those who only grow their bulbs to obtain flowers for cutting will find it much less trouble to cultivate them in boxes 3 inches or 4 inches in depth. Place the pots or boxes outside and cover to a depth of 4 inches with old ashes or Coconut fibre. Examine them in about a month, and, when the pots are nicely filled with roots, remove the bulbs to a frame or cool greenhouse, shading the yellow growths till they become green. They may then be brought into the warm greenhouse and gently forced, or if in a cool house the flowers will be rather longer in making their appearance. Paper White Narcissi require plenty of water throughout the growing season. As soon as the flower-spikes show, weak manure water will be very beneficial to them.

#### CHICORY OR WITLOOF.

This excellent and wholesome salad is not very extensively grown in this country, but on the Continent it is a great favourite. It is a splendid

subject for supplying salad material in midwinter when little else is available, and for this reason should be included in every good garden. On the Continent, too, the blanched leaves are frequently cooked and served as a vegetable. It is easily raised from seeds, which should be sown in rows 12 inches apart in the open at the end of May. Thin the seedlings early to 6 inches apart in the rows. Cultural requirements during the remainder of the summer will consist in hoeing between the rows to keep down any weeds that appear. The plants will grow in almost any well-worked soil, but prefer that of rather a heavy nature.

At the end of the autumn the roots will rather resemble Parsnips, and will then and onwards through the winter be ready for blanching. A very simple way of doing this is to procure a deep wooden box, such as a Tate sugar chest, place 2 inches of soil in the bottom, then stand the roots, after removing the old leaves, in an upright position and 3 inches apart each way on this soil. As the work proceeds fill in with light soil, Coconut fibre refuse, or leaf-soil to within 1 inch of the crowns of the roots. When the box is full give one watering through a fine-rosed can, cover the box over with mats to exclude all light, and place in a greenhouse where the temperature ranges from 45° to 55°. New leaves will soon be formed, and as they are produced in the dark will be beautifully blanched. Water will not be required during the time the roots are in the warm temperature. When about 4 inches to 6 inches long the leaves are cut and served in any manner desired. A second crop can be obtained from the same crowns, but the leaves will be small. After being thus forced the old roots are useless and may be thrown away.

#### THE CULTIVATION OF WATERCRESS.

ALTHOUGH this most popular salad can be successfully grown in a moist and shady corner of the garden, the resulting heads are strong and of poor flavour, and its culture thus is not advised. Those who are fortunate enough to possess a running stream of clear spring water may, however, easily secure an abundant supply of first-class material with but little trouble. Boards on edges should be inserted across the stream at distances of about 6 feet, so as to check the current and ensure a depth of 2 inches or 3 inches of water. In the bottom place a 1-inch-thick layer of clean road sand, and in this dibble the pieces of plant. Young shoots easily root, and if any trouble is experienced in procuring plants, bunches of Watercress purchased from the greengrocer will answer very well. Spring is the best time to plant. Weeds must be rooted out as they appear. Cut the heads just under the water, then others will quickly appear. Do not allow the plants to run to seed. It is a good plan each spring to thin out the growths, discarding old and straggling ones and retaining the compact and robust shoots. If the boards advised above are firmly fixed they are useful for placing stout planks upon, so that the Watercress can be gathered with comparative comfort.

## THE TOWN GARDEN.

**CHRYSANTHEMUMS AFTER FLOWERING.**—The utility of Chrysanthemums for culture in town greenhouses has been repeatedly proved to demonstration, and one has only to visit the homes of many amateur gardeners to find to what a remarkable degree of excellence the blooms may be brought in circumstances which are the very reverse of favourable. The plants provide their grower with occupation throughout the whole of the year, for before the blooms are past for one season cuttings must be prepared for insertion to produce plants for the following year. As soon as they have finished flowering the stems should be cut down to within 9 inches or 1 foot of the pot, and the soil must never be permitted to become dry; on the contrary, it must be watered with more than ordinary care, for the object now is to develop fine sucker growths from which cuttings will be made in due course. Small pots, each providing accommodation for one cutting, should be crocked and filled with soil consisting of three parts of sound loam, one part of sweet leaf-mould, and one-tenth part of sharp sand, and the base of the cutting must in all cases rest upon the bottom of the hole bored for it. The soil should be made pleasantly moist, and the pots can be placed in a case in the greenhouse or even in a cold frame; but, in the latter event, more than usual care must be exercised both in ventilating and watering in order to guard against damping.

**LILIUM AURATUM.**—The Golden-rayed Lily of Japan is the most beautiful of the superb family to which it belongs, and fortunately it is one of the most satisfactory for cultivation in our town homes. At the present time magnificent British-grown bulbs are procurable which, if correctly potted and managed, will produce splendid blooms in the spring. They are rather more expensive than the imported bulbs offered in the spring, but they seldom suffer from disease and invariably give superior flowers, so that they are really the cheaper in the long run. A compost of three parts of fibrous loam, two parts of thoroughly decayed leaf-mould and one part of rotted manure, with sufficient sand to keep the whole mass open, answers admirably. The crocking of the pot must be carefully done, but the depth of drainage material must not be great, as low potting, to afford ample space for subsequent top-dressings, is most desirable. A little moss should be put over the crocks, then a thin layer of soil, and finally a layer of sand for the bulb to rest upon. As soon as this is completed the bulb is set in position, coarse sand is scattered over and round it, and sufficient soil is used to just cover the top. A gentle watering to settle the soil finishes the operation. As growth advances, it is necessary to add top-dressings of rich compost, for if this is kept pleasantly moist it will encourage the formation of stem-roots, by the aid of which the plants will feed freely and bring far greater satisfaction to the grower. If the potting has been done so high that layers of compost cannot be added in the manner suggested, zinc collars should be fitted inside the rims and reach 3 inches or 4 inches above them, and the increased space available can then be filled with the compost for the stem-roots.

**PLANTING IVY.**—The smaller, ornamental-leaved Ivies are excellent plants for covering the walls and fences of town gardens, and the present is probably the best time in the whole year for planting. If possible, loam should be provided, so that the plants shall have every chance from the start; but if this is unavailable and the ordinary soil is poor, some sweet manure must be added. Firm planting is imperative and the soil should be heavily watered as soon as the work is finished. Subsequently frequent syringings of the stems will keep them plump and fresh, and the plants will make grand progress in the growing period of the following year.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLEASURE GROUNDS.

**P**ROCEED with the planting of shrubs and trees as the weather permits. In planting, it is very often necessary to trench the ground, even if plants are shallow rooted. Rhododendrons and Azaleas should be planted in quantity, and the soil need not be all peat if the ground is prepared by digging it three good spits deep, keeping the top spit on the surface and breaking it up as fine as possible. The material for planting in should consist of a small quantity of peat, a like quantity of leaf-soil (one year old), some sand or road grit and some well-rotted cow manure. When planting, place a good shovelful on the bottom of the shallow hole and fill in around the roots with three parts of the mixture to one of the soil. Plant as shallow as possible and ram the soil quite firm around the plant.

*Conifers and Shrubs* of all kinds that are being planted or lifted are much benefited by a little good material being used, and when planted it is a good thing to mulch with leaf-soil. This keeps the frost from the roots and gradually yields to the soil some plant food.

#### ALPINE GARDEN.

Watch for small bulbs making new growth, and set traps for slugs and put black cotton over pet plants that the birds attack. When plants have outgrown the space allotted to them, it is best to break them up and replant, at the same time using some fresh soil, which should be well rammed into the little crevices, as the tiny roots of rock plants always search for moisture.

Cover over to keep from wet *Androsace Chumbyii*, *A. sarmentosa* and *A. villosa*, or they will suddenly damp off. A few of these should always be kept in the alpine house or in dry frames; have some protecting material in readiness for any plants that may require it.

#### KITCHEN GARDEN.

*Seakale* that is intended for forcing should now be taken up and the ground trenched so that all the roots are cleared away, and in this process save all the long, straight roots to form cuttings. The roots must be from 6 inches to 8 inches long, and the top of the root be cut square and the bottom obliquely. These will callus over and make heads during the winter. Those crowns that are left for late use should have a shovelful of ashes (coal) placed over them; this will keep slugs away.

*Forcing*.—Force now Rhubarb, Chicory, Dandelion and Mustard and Cress. Some of each should be put into the forcing-house every week, or as often as may be necessary to maintain a constant supply.

#### FRUIT GARDEN.

Lose no opportunity in getting on with the lifting and planting of fruit trees, and also start pruning. See that no woolly aphid exists. If its presence be detected, go round with some methylated spirit and with a stiff brush paint the insects; this will kill them. Spray all the trees with Richards's XL All Wash. I have used this for some time and find nothing better, and the bark of the trees is well preserved. Every portion of the tree must be done.

*Fruit-room*.—If all the fruit be now gathered, look over all early varieties and eject those that are unsound; but the less the fruits are handled the better. Keep plenty of air on to dispose of moisture. Label all the varieties so that each sort can be found at a glance.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*CHOISYA TERNATA*.—Considering what a beautiful plant this is when it does well, it is surprising that it is not more grown. The flowers and foliage both have a rather pleasant scent and are welcome for cutting. The best place to flower it is in a cool greenhouse. It is one of the plants that so easily strike root that nurserymen can always supply it; but if required to be propagated at home, now is the time to take cuttings of the half-ripened shoots and place them singly in pots in a greenhouse or frame.

#### ORCHIDS.

*Winter Treatment of Catechins*.—Some growers complain of not being able to keep the bulbs of *Celogyne cristata* plump from autumn to spring. The chief reason, doubtless, is attempting to keep the plants in an almost root-dry condition, which invariably ends in shrivelling. It is a mistake to attempt anything like dryness at the roots, and a frequent supply of water should be given. Some who keep the roots dry give quite a cool-house treatment during winter, and, of course, in such quarters root moisture would soon work mischief. The best and safest temperature, in order to allow of the moisture recommended, is one of about 60° at night.

#### HARDY FRUITS.

The weather has been very open and mild, just what is required by those who have a considerable amount of planting to do, and all that is required in that way with home-grown stock is, or should be, now completed, but with bought-in stock the case is different, as one has to wait until the nurseryman is ready to send, and as there have been no frosts sufficiently severe to influence the fall of the leaf, the chances are that orders given will not have been dealt with so early as usual. The most one can do is to be as nearly as possible prepared to deal with the trees when they come to hand.

*Figs*.—To make certain of a crop of outdoor Figs, protection of the wood is necessary, and to this end the branches should now be unfastened from the wall, tied loosely into bunches and brought down as low as possible into a position where they can be conveniently covered with some dry material, such as Bracken, over which some old Russian mats may be lightly bound. The branches should then be fastened securely either to the wall or to stakes, but the nearer they can be brought to the wall the more shelter they will get from rain, and the protecting materials should always be kept as dry as possible.

#### KITCHEN GARDEN.

*Endive*.—It will not be safe to leave Endive out on wet, exposed borders after this date, especially in the case of the curled varieties. With repeated rains and frosts the centres soon get crippled and practically spoiled. Any surplus plants of the latter section still out of doors may be blanching where they stand by simply covering them with flower-pots or by placing broad slates flat on them when in a perfectly dry state. In lifting the ordinary broad-leaved plants, see that they are quite dry; then tie up each plant with a piece of matting in order to prevent any soil finding its way into the centres.

#### FLOWER GARDEN.

*Roscs*.—Hedge Briars for budding next summer should be planted without delay. Trim and plant as soon as possible after they are taken from the hedgerows. When trimming, leave on every bit of fibrous root; but the old, stumpy root may be reduced. Burnt earth and garden refuse should be freely used in the soil when planting Briars. T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

### NEW PLANTS.

*CYPRIPIEDUM DANTE MAGNIFICUM*.—This is one of the highly-coloured section, and forms a very beautiful addition. The large dorsal sepal is beautifully shaped, being narrow at the base and spreading rapidly towards the apex. The white ground is very heavily striped and blotched dull crimson, with some green at the base. The petals and lip are of the usual shape, the green ground colour being heavily overlaid with glossy brownish crimson. Shown by Lieutenant-Colonel Holford, C.I.E., C.V.O., Westonbirt, Tetbury, Gloucestershire. Award of merit.

*Cattleya Fabia Cooksonie*.—A very beautiful and refined-looking flower of medium size. The sepals and petals are pure white and of the usual shape, the labellum being large and beautifully coloured. The interior is bright carmine, with a narrow white margin, this extending well into the throat and there suffusing with the richest yellow. Outside, the pale carmine and yellow colours are delicately veined with white. Shown by Mr. N. C. Cookson, Oakwood, Wylam-on-Tyne. Award of merit.

*Cattleya Clarkie intensa*.—This is a highly-improved form of the well-known *C. Clarkie*, the colours of sepals, petals and labellum being much richer than in the type. Shown by Mr. L. de Rothschild, Acton. Award of merit.

*Sophro-Cattleya Doris*.—This is at once the largest and brightest member of this bi-generic family, and is fully worthy of the high honour conferred on it. The flowers are of the usual shape, but large and of good substance. The general colour is a vivid orange scarlet, this in the labellum being suffused with very rich golden yellow. The plant shown was carrying four fully-developed flowers and appeared to be of a vigorous character. Shown by Mr. J. Gurney Fowler, Woodford. First-class certificate.

*Nephrolepis amabilis*.—A very handsome new Fern with gracefully arching fronds some 2 feet in length. The compoundly forked or tasselled side pinnules are of the multicaps form and render the new-comer distinctly pleasing and beautiful. Shown by Messrs. J. Hill and Sons, Lower Edmonton. First-class certificate.

*Nephrolepis rufescens Marjii ornata*.—A very striking and distinct form of this well-known species, and a welcome addition to the Fern tribe. Shown by Messrs. H. B. May and Sons, Edmonton. Award of merit.

*Begonia Clibran's Pink*.—A very charming addition to the winter-flowering section of Begonias, and one likely to become immensely popular by reason of its delightful habit of growth and the profusion of large, pure salmon pink blossoms which adorn the plant. Little more than 15 inches high when shown, the plant develops a large head of blossoms above the handsome leafy growth, which constitutes so admirable a setting to the flowers. The variety possesses the merit of great charm, combined with an ever-popular shade of colour and absolute distinctness from all existing varieties. Shown by Messrs. Clibrans, Altrincham, Cheshire. Award of merit.

*Chrysanthemum Purity* (Japanese).—A pure white variety of large exhibition size and fulness, the drooping florets giving the bloom a very handsome appearance.

*Chrysanthemum Hou. Mrs. Lopes* (Japanese). A pure yellow variety, good in colour, florets of medium width and drooping, the flower-head almost a counterpart of the last named in form. A handsome variety of good finish. Both came from Mr. Martin Silsbury, Shanklin, and each obtained an award of merit.

*Chrysanthemum Sylvia Slade* (Single).—The flower is of large size, and the florets, which are coloured a reddish carmine, are encircled with pure white at the base, thus rendering the variety most distinct.

*Chrysanthemum R. F. Felton* (Decorative).—Colour intense golden, very rich and telling, and the flower-heads are borne on stout and stiff stems.

*Chrysanthemum Hetty Wells* (Decorative).—A pleasing and distinct variety, in which the predominating colour shades are pink and bronze. These were exhibited by Messrs. William Wells and Co., Limited, Merstham, and each obtained an award of merit.

All the above were shown before the Royal Horticultural Society on the 10th inst., when the awards were made.

## PRIZES FOR READERS. NOVEMBER.

### FLOWERS FOR A SMALL GREENHOUSE IN WINTER.

- A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Monday, November 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### THE GLASTONBURY THORN.

Mr. J. A. Bragge of SADBOROW, Chard, sends a flowering spray of the Glastonbury Thorn. He writes: "My Glastonbury Thorn has always blossomed hitherto on Old Christmas Day; but this year, by way of a change, it is now (the 7th inst.) in full bloom. I enclose a branch."

### FLOWERS FROM NORTH DEVON.

As evidence of the mild weather experienced on the beautiful coast of North Devon, Mr. R. Nethercott sends some flowers cut from the open garden. Among them are some lovely Sweet Peas of many shades of colour. Although lacking somewhat in the brilliancy of the earlier season, they are still very effective. Very pretty were the varieties of that useful annual Delphinium Consolida, with rose-pink and purple-blue flowers. The Potentilla, which was raised from seed collected in the Himalayas, is *P. nepalensis*, an old favourite in gardens with its deep crimson flowers. It is also known as *P. formosa*, and while most of the forms of it are of somewhat straggling growth, there is a

compact little variety in cultivation called *P. nepalensis* var. *nana* with somewhat lighter-coloured flowers. The typical plant is closely allied to that other garden favourite, *P. argyrophylla*, from the same region, and seedlings spring up spontaneously round old flowering plants. *Salvia farinacea* is an interesting, if not particularly showy, plant. It is a native of Texas, and has been in cultivation for over half a century. Growing to a height of about 3 feet, it is of branching habit, with smallish ovate leaves and long, interrupted inflorescences of violet-blue flowers. The noticeable feature of the plant is the densely white tomentose calyx, which is sometimes tinged with violet. It may be raised from seed sown indoors in March, and, after planting out, soon comes into flower, lasting till cut down by frost. Except in warmer localities, it seldom sets seed; but plants may be kept through the winter by means of cuttings struck in the autumn.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Protecting Tulip bulbs from mice** (*B. D. T.*).—Red-leading the bulbs should certainly prevent the mice from taking them. Moisten the bulbs, then roll them in the lead so as to thoroughly coat them with it. Red lead will not injure the bulbs.

**Bulbs in grass** (*West Sussex*).—We presume the bulbs are in woodland grass where the soil is deep or of a strong character, and therefore promotes excessive vigour in the coarser types of grasses. There is no reason why you should not mow the grass until the moment the growths of the plants appear, or in certain circumstances you may cut away the roots of the grasses—the more vigorous ones in particular—as late as January, by skimming the surface with a sharp turfing iron. This is, of course, a somewhat drastic measure on the face of it, but you would find plenty of living roots remained to supply a fresh sward in good time. In certain instances, where much coarse herbage obtained, you could fire it during the late autumn months; but we could not advise you to do this without knowing at what depth the bulbs were originally planted. Your difficulty is increased by the length of time over which your bulbs would flower.

**Violets with diseased leaves** (*M. E. R.*).—You should spray your Violets with a solution of paraffin emulsion or arsenate of lead, 3oz. to 10 gallons of water. Wet the under-sides of the leaves as well as the upper.—G. S. S.

**Lychnis chalconica** (*C. L.*).—The above species of *Lychnis* is not a difficult plant to grow by any means, but it has a decided preference for rather strong, moisture-holding soils. As yours appears to be of the opposite nature, this is probably the reason of the failure. If you raise seedlings of the plant quite freely, and arrange these about 8 inches asunder in a group of any size required, you may have better success. By deeply digging out the soil and introducing at 9 inches deep a heavy layer of cow manure, you should not have much difficulty in growing this plant, even in light soils. Old plants that have been divided are not usually a success; but seedlings have much vigour. Sow the seeds in the open thinly in

drills, and when the plants are a few inches high transplant them to their permanent places.

### THE GREENHOUSE.

**Sowing annuals and perennials in cold frame** (*Alan*).—Many annual and perennial subjects may be sown now and grown on in a cold frame, particularly such as *Antirrhinums*, *Caotbury Bells*, *Carnations*, *Digitalis*, *Eschscholtzias*, ornamental Grasses of sorts, *Linums*, *Lupines*, *Malvas*, *Pentstemons*, *Potentillas*, *Polyanthuses*, *Primroses* and *Stocks*. Sweet Peas sown in a frame may be planted out in the spring when frosts are over, and will flower sooner than those sown out of doors.

**Cacti culture** (*W. E. B.*).—The only book on Cacti we care to recommend you is "Cactus Culture for Amateurs," by W. Watson, curator of the Royal Botanic Gardens, Kew, price per post, 5s. 4d. The book is of a complete character and is profusely illustrated. As to Cacti growers, there are very few; these plants have a very limited sale. You will get well served by Messrs. H. Cannell and Sons, Swanley, Kent, as they have a very large collection of all varieties. The firm would, on application, no doubt send you a list of their collection. The book is published by Upcott Gill, Strand.

**Treatment of *Vallota purpurea*** (*M. N. B. D.*).—This plant should be encouraged to make its growth now, and for this reason it should be given a good light position in the greenhouse and be watered when necessary. If the pots are full of roots a little weak manure water occasionally will be of service. With this treatment the plants will grow freely and build up good bulbs for next year's display. Though the plants are to be watered when necessary, you will, of course, understand that even if growing freely they will not need the same amount of water as in the summer when moisture dries up so quickly. *Vallotas* are rather apt to lose a few of their leaves immediately after flowering, but their place is quickly taken by others, that is if the roots are in good condition. With regard to the *Hippeastrum*, you may gradually lessen the water supply, but as it was a seedling so recently it must not be dried off altogether. It should in the winter be kept in a structure maintained at a temperature of 50° to 60°, and be given just enough water to keep the soil slightly moist. By the month of February additional water may with advantage be given. Next year, as the bulb will be much larger, it may be safely kept dry during the months of December and January. As your plant is in a 6-inch pot, it is not likely to need repotting, but when required this may be carried out just as the plants are ready to start in the new year.

### ROSE GARDEN.

**Rose foliage diseased** (*Rev. G. R. B.*).—Your Roses have a bad attack of the orange rust. Rose growers do not pay much heed to this fungus, as it rarely appears until after the first blooming and is usually confined to the Hybrid Perpetual group. All the same, it is very unsightly and doubtless weakening to the plants for them to prematurely lose their foliage. You can only pick the leaves up and burn them, and next spring, as soon as new growths appear, spray with a solution of sulphide of potassium. If you observe any of the rust on the wood, paint the spots with methylated spirits and water in equal parts.

**Perpetual-flowering Crimson Rambler** (*Captain C. F. O.*).—The new variety Flower of Fairfield has been highly recommended, but we have not yet flowered it ourselves, therefore cannot pass any opinion upon it. If you desire something new in the way of rambles try *Goldfinch* and *Tausendschon*, or *Delight* and *White Dorothy*, or *Paradise* and *Joseph Billiard*. All of these are very lovely, and each pair would flower about the same time. If you desire Roses of continuous flowering propensities the following would be best: *Alister Stella Gray*, *Longworth Rambler*, *Grüss an Teplitz*, *Rosette de Legion d'Honneur*, *Mme. Alfred Carrière*, *Belle Vischysoise* and *Trier*.

**Climbing Roses for a greenhouse** (*W. H., Rhyt*).—If you desire strong-growing Roses for your purpose that will give you some

good button-hole blooms, the following would be very suitable: Climbing Kaiserin Augusta Victoria, Climbing Niphetos, Climbing Mrs. W. J. Grant and Climbing Liberty. If you have a rather small greenhouse and desire a continuous production of buds, a selection should be made from the less vigorous sorts, such as Lady Roberts, Bridesmaid, Mme. Abel Chatenay and Richmond. These could be grown in large pots and placed on the front stage and trained up the roof. In a year or two the roof will be partly covered with a rich growth. What are known as extra-sized plants grown in pots would give you the best results.

**Rose Gruss an Teplitz with extra dark blooms** (Cae. Lindfield).—We think this is the effect of very bright sunshine; in fact, some of the petals seemed almost burnt. We should say the colouring arises from either the above-named cause or your soil has a special influence upon the Rose. This frequently happens. Some varieties are scarcely recognisable when grown in different soils.

**Rose foliage turning brown** (D. B. Allwork). The foliage sent has been attacked with the Rose slugworm. It is the larva of one of the sawflies, and it devours the upper skin of the Rose leaf and makes the latter eventually turn brown and shrivel up. The slugworm can be killed by spraying the bushes with Hellebore Wash, and in winter you should have the surface soil beneath the plants burnt and fresh soil put in its place.

**Potting up standard Roses** (W. H. S.).—There is no difficulty whatever in the potting and repotting of standard Roses. Do not on any account put them into pots too large to save trouble in repotting. A pot Rose, be it standard or dwarf, should never be repotted until it needs it, and that is when its pot is full of roots. We should say you would require 9-inch pots the first season; these are known as 16's. The next year, if the plants need repotting, give them a size larger, and so on until you have them in 13-inch and 15-inch pots. You will probably not need to exceed this. The varieties you name will do very well in pots. Be careful to use some good compost, consisting of three parts fibrous loam and one part old manure well broken up. A 6-inch pot of bone-meal should be added to a barrow-load of compost. Some growers prefer to give the bone-meal after the trees have been established twelve months; then it is applied to the surface and just pricked into the soil. After the trees are potted in October, they should be kept outdoors until frost threatens. It is a good plan to grow them entirely outdoors the first year, but if you desire to bring them into the greenhouse they must only be given a very moderate temperature at first. When roots are active and new shoots are growing rapidly, more heat may then be given. When potting prune the heads back to about 9 inches to 12 inches from where budded, and they will not require much more pruning the first season.

### TREES AND SHRUBS.

**Increasing Crataegus Pyracantha** (H. Schone).—Crataegus Pyracantha may be increased either by means of cuttings or seeds. Seeds may be collected at once. They should be separated from the fruit and sown thinly in well-drained pans of soil, and be stood in a temperature of 50° to 60°. The compost may be made up of two parts of fibrous loam, one part of leaf-soil and one part of sand. The seeds may germinate next spring or they may lie in the soil for a couple of years. Cuttings may be made from young shoots 3 inches to 4 inches long in August or September, and be dibbled into a bed of soil in a cold frame similarly composed to that recommended for seeds. The bed must be made quite firm and the cuttings firm also when inserted. Protect from frost and keep quite close until roots are formed, which is usually about the following March or April.

**Scotch Heather from seeds** (E. M. M.).—The raising of Heaths from seeds is tedious, and in the case of Scotch Heather, which might be procured in quantity cheaply, it would be more advantageous to purchase plants, and either propagate from these by division, each portion with a few rootlets attached making a plant, or by cuttings of the small tips put into peaty soil surfaced with sand, watered down, and placed in a frame to root. If you still prefer raising the Heather from seeds, sow the latter as soon as ripe, if they can be obtained, on the surface of peaty soil with some sand intermixed with it. Give the merest surfacing with soil of the same kind. If the seeds are sown in the open, choose an exposed part of the reserve garden for the purpose. If in boxes, merely keep in frame

during the winter. When the seedlings appear weed carefully, and when they can be readily handled transplant into similar soil until ready to plant out. You will have some time to wait before you can secure plants of any size from seeds.

**Pruning Clematis Jackmanii** (G. May).—You may cut your plant of Clematis Jackmanii back to within 1 foot of the base of the wood that has been formed this year. The work may be done early in February. The only large-flowered white Clematis that can be grown with little or no pruning is *C. montana*. The flowers are about 2 inches across. You can, however, obtain several white-flowered forms of *C. Jackmanii*, of which Jackmanii alba and Snow Queen are good ones. These, of course, will require pruning.

**Destroying tree-stumps without blasting** (J. R.).—You can destroy tree-stumps by boring holes in them 1 inch in diameter to a point somewhat beyond the centre. The holes should be three parts filled with saltpetre and then filled up with water and tightly corked. After three months have passed remove the corks, fill the holes with paraffin and then set on fire. By this means they will gradually smoulder away. Pine needles are not of any value for manure, or not of so much value as leaves from deciduous trees; in fact, they are poisonous to many forms of vegetation.

**Climbers for east wall** (E. T. Cripps).—You will find the following climbers suitable for your east wall: *Jasminum nudiflorum*, *Prunus triloba*, *Hydrangea petiolaris*, *Crataegus Pyracantha*, *Ceanothus veitchianus* and *Escallonia macrantha*. The latter three are evergreen and all grow rapidly, except the *Hydrangea*, which is a little slow for the first year or two. If you desire a more rapid grower, *Cydonia japonica* or *Rosa bracteata* will be suitable. If you give them good material at planting time, they ought to thrive well in the border.

**Shrubs for Bournemouth** (F. M. S.).—A selection of shrubs for the position you mention about Bournemouth would be as follows: Evergreens—*Laurustinus*, *Euonymus japonicus*, Tree Ivies, *Escallonia macrantha*, *Olearia Haastii*, *Veronica Traversii*, *V. buxifolia*, *V. speciosa* and varieties, *V. Stuartii*, and, in fact, any shrubby *Veronica*, *Rhododendrons* in variety, *Berberis stenophylla*, *B. Darwinii*, *B. japonica* and *B. Aquifolium*. Good deciduous subjects are *Philadelphus coronarius*, *P. Lewisii*, *P. Lemoinei*, *Weigela* in variety, *Flowering Currants*, *Forsythias*, *Spiraea arguta*, *Brooms* in variety—especially *Cytisus scoparius andreanus*, *C. albus* and *C. praecox*—and *Genista virgata* and *G. tetensis*. When planting, dig large holes and give a little good soil to enable the shrubs to make a good start.

**Trees and shrubs for North Ireland** (F. M. S.).—It is not possible to give you accurate information on this subject without knowing something of the local conditions—whether the soil is light or heavy, wet or dry, and so on. For trees you cannot do better than plant similar ones to those which are found to thrive in that particular neighbourhood. For light ground Scotch Pines, Austrian Pines and Birches ought to succeed, while for heavy ground common Ash and Austrian Pines might be used. Shrubs similar to those recommended for Bournemouth would succeed, except that if the district is very cold you might leave out the *Veronicas*. *Vitis inconstans*, or *Ampelopsis Veitchii* as it is frequently called, will be suitable for your wall. The common Irish Ivy is the quickest-growing Ivy, while a good companion for it is *Clematis Jackmanii*.

### KITCHEN GARDEN.

**Exhibition vegetable points** (J. L. H.).—In the paragraph in THE GARDEN for August 15 last, to which you refer, while the principal kinds of vegetables exhibited at the Shrewsbury Show were specified, nothing was said as to the points awarded to each dish or kind. There the maximum number of points each dish can obtain, no matter what kind, is seven. In the Royal Horticultural Society's Code of Judging, maximum points range from seven to some kinds, six to others and five to others. But it is not easy to determine how far this latter scale is fair or generally adopted, as it is based more on table value of a vegetable than on difficulty of production. The most difficult kinds to grow well of those named on August 15 are Celery, Leeks, Cucumbers, Carrots, Peas and Onions. Then come Potatoes, Tomatoes, Cauliflowers, Parsnips, Beets and Marrows, as all being the more easily produced. We should

apportion to the first-named six kinds maximums of seven points and to the others six and five maximums. As to what number of points on this scale each dish would get in a competition would depend on quality.

**Celery diseased** (Seaside).—Your Celery is badly infested with a fungus (*Phyllosticta apii*) that is somewhat common this year. If all the plants are like those of the sample sent there is not much hope for the crop. To prevent the fungus spreading all the leaves should be cut off and burned.

**Potatoes diseased** (T. E.).—The Potatoes sent are suffering from two or three troubles. They appear to have "grown out" owing to wet weather following ripening, to have been attacked by one of the forms of Potato scab, but not that called the black scab, and to have served as a feeding-ground for millipedes and slugs. Can you send a few more for further investigation?

### FRUIT GARDEN.

**Apple diseased** (Mrs. E. J. B.).—The Apple has been attacked by the Apple scab fungus (*Fusicladium dendriticum*), which caused the formation of scabby spots upon the fruits, and these spots have served as aress through which other fungi have been able to gain an entrance and produce decay. The thing to aim at is to prevent the attack of the Apple scab fungus upon the fruit, and as this not only attacks the fruit, but the leaves and branches as well, it is a difficult thing to do. All dead wood, twigs as well as branches, should be removed and burned during the winter, and the tree should be drenched with a solution of iron sulphate made by dissolving 25lb. of iron sulphate in water to which sulphuric acid is added (1 pint). Pour the acid on the iron sulphate in a wooden vessel, then add the water gradually until 50 gallons have been added. In the spring spray the tree with Bordeaux mixture just when the leaves begin to develop, and again when the petals have fallen. The Bordeaux mixture must be used at half the strength of that used for spraying Potatoes. The variety is Cox's Orange Pippin.

**Pruning standard and half-standard fruit trees** (F. C.).—As regards standard trees of Apples and Pears, whether growing in the orchard or garden, provided there is plenty of head room for expansion, the system now generally practised and acknowledged as the best suited for this class of tree is that of thinning out and regulating the branches at winter pruning, with no summer pruning or stopping of the current year's shoots either in summer or winter. This system of pruning entails less labour, and results in the crop forming chiefly on the outside branches of the tree, with usually very little fruit in the middle. Half-standard trees may be treated in the same way with equal success, provided there is plenty of room for expansion. After saying this in favour of the thinning out process, or the extension system of pruning as it is termed, we must not be understood as condemning the closer pruning (understood as spur-pruning) of half-standard trees. No doubt the practice entails more work; at the same time the restriction of growth which follows the adoption of this system enables the grower to plant a larger number of trees per acre, with a heavier yield as a compensating factor. When trees are pruned on this principle, every main branch of a tree becomes as it were an independent cordon, and should be treated as regards pruning in the same way as if they were grown singly on their own roots. The result is that, unlike trees pruned on the extension system, which bear fruit chiefly on the outside branches, every main branch of a tree so pruned is capable of bearing fruit the whole way from the base to the summit.

**Fruit trees diseased** (L. T. Simpson).—The shoot is attacked by the fungus *Nectria ditissima*, causing the disease known as canker. Certain varieties of Apples are more subject to the disease than others, and it would be well if, in planting, these varieties were omitted as far as possible. The fungus is spread by means of spores which are produced upon the cankered spots, and these spores can attack the shoots only through wounds. In this case the infection was through a dead spur.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## HOW TO DEAL WITH FROZEN PLANTS.

NOW that winter is close upon us our thoughts will naturally turn to the protection of those plants from frost which cannot be regarded as hardy in this country. In a well-regulated garden there will not be much danger of frost reaching such plants, as proper precautions will have been taken, but there is always the possibility of accidents happening to the heating apparatus, so that it is well to know what to do with tender plants which frost has reached. It has for some time been recognised that it is not the actual freezing which does the mischief so much as the method of thawing, the point to aim at being a gradual and slow dispersal of the frost.

In a normal plant the cells are filled with liquid which, when frozen, naturally expands, rupture of the cell walls occurs and the whole organism of the plant becomes disorganised. Providing we can thaw such plants sufficiently slowly, it has been proved that the cells will once more assume their normal forms and the plants be not much the worse. Another point of importance is to keep all tender plants, which are in the least likely to be reached by frost, as dry as possible without fear of injury from drought. It has been conclusively proved that a plant whose cells are comparatively empty of liquid will stand some degrees more frost than one of the same kind whose cells are turgid; hence the advice given above.

If by any means frost has reached a plant or plants, our duty is to thaw it as slowly as possible, and there are several ways of doing this. Where the plants are in frames the utmost care must be taken to prevent a sudden rise of temperature, and to this end all mats or other covering must be left on the lights if there is any possibility of the sun shining thereon. Amateurs who possess cold greenhouses, or glass structures but imperfectly heated, may perhaps some morning find that practically the whole of the contents are frozen; and such a catastrophe has even happened in good establishments owing to a sudden defect in the heating apparatus. In such a case the first thing to do will be to turn off the valves of the hot-water pipes and so prevent any possibility of the heating apparatus righting itself. Next procure mats, straw or any other material that will form a dense shade, and cover the glass with these so as to prevent the sun's rays reaching the plants. Then thoroughly syringe the frozen plants with very cold water, and keep up this syringing until it is evident that the frost has been gradually eradicated from the tissues.

This may mean an hour or more of very disagreeable and cold work; but better this than the total loss of a houseful of plants.

The remarks as to gradual thawing apply with equal force to rather tender plants which with some protection will stand the winter outside. Much damage is frequently done to such plants by the premature removal of protective material; it should be left on until there is no doubt whatever that a gradual thaw has taken place. It should also be remembered that the best material for protective purposes is that of an open, coarse nature, which will always contain an abundance of air and will not absorb so much moisture as that of a close nature. If these rather tender plants growing in the open have been severely frozen before protective material was applied, much good may be done by shading them from sunshine and syringing them with cold water, as advised for plants indoors.

## A PRETTY WILD GARDEN IN GLOUCESTERSHIRE.

EARLY in September I received a kind invitation from Dr. Bowles to visit his beautiful garden, which is on a hill nearly 700 feet in height, with the vast Forest of Dean in the background and the Cotswolds in the distance. There, too, are seen the River Severn and the Wye, the whole forming a picture that can never be forgotten. The house and gardens are well sheltered on the north, and the wild garden, which is enclosed, occupies about two acres on the slopes and appears to the visitor to be much larger, as the approach is through a secluded wood with choice Ferns, large tufts of hardy plants and Fuchsias, and relieved here and there with peeps of the valley below and the reaches of the river. Dr. Bowles is an enthusiastic amateur and is very proud of his charming garden, and justly so, as he has done much to add to its charms, his chief regret, and one I fully share with him, being that the large, tender plants grow so freely that they entail more labour yearly to protect them, and each year a few are being left, as their size prevents their removal; it is hoped they may prove hardier than expected.

In the wild garden there are three stretches of water on different levels and arranged in a charming manner. The masses of Bamboos of various kinds are splendid, and there are stately trees of the Deodara and certainly one of the finest Araucarias I have ever seen. The tree, when it loses its lower branches, sends out large bushy growths, making it a telling feature in the landscape. Some of the conifers were planted sixty years ago. Immense masses on the water's edge threaten to thrust out others of a more delicate nature. I noticed fine bushes of *Arundinaria nitida*, and the previous owner of the beautiful garden, who planted so largely and with such good taste, evidently never expected such fine growths or the plants to occupy so much space. A very fine

group has flowered this year, and this will make a large gap, but Dr. Bowles and his interesting head-gardener, who had foreseen this, will give a trial to some of the smaller sorts of *Arundinaria* and *Phyllostachys*.

Here I saw some fine plants of *Hedychium* in flower. These are lifted and kept dry in the winter, and the *Brugmansias* are used with great taste dotted here and there, the variety mostly used being the large-flowered *Knightii*. To show how the tropical plants thrive here at this time of year, I would mention that noble plants of *Musa Ensete* have made magnificent leaves, which are not broken in any way, though each winter when the plants are housed these are removed for the sake of space. Seedling plants sown two years ago are from 5 feet to 6 feet in height, and there are others, *Musa sinensis* having more colour than *M. Ensete*.

The *Cannas* are important plants. Here they are very fine with a noble old *Pinus excelsa* in the background. There are some fine plants of *Ricinus* in variety and clumps of *Nicotiana* of the larger forms. Among the last-named are some clumps of *N. affinis*, grown for their perfume. The *Eucalyptus* has stood severe winters here and is over 20 feet high, and the *Aralias*, of which *A. papyrifera* does well, are very fine. Japanese Maples are quite a feature. In the spring and early summer the *Iris* plays an important part, and I think in future will do more so, as Dr. Bowles is gradually weeding out large masses of *Polygonums* that have had too much latitude. From these notes it will be noticed that the wild garden has a fair amount of tender plants which are somewhat prominent, and these I think in time will give way to hardier subjects, as they are equally beautiful and give less trouble. Still, I should regret the loss of the noble *Musas*; but of late years *Chamerops excelsa* and *C. humilis* have made excellent growth and are quite hardy. They have as companions the New Zealand Flax, *Yuccas* and *Agaves* in variety. On the higher banks are grand plants of *Hemerocallis* in variety and clumps of *Agapanthus*.

Considerable use is made of the *Fuokias*, which thrive well under the shade of the larger plants. The Grasses are well represented. *Eulalia japonica* thrives excellently, also *Arundo* conspicuous and others. The *Spiraeas* are also well represented, and there are fine examples of the shrubby section. Delightful nooks are filled with Ferns such as *Osmunda regalis*. On the outside of the wild garden, leading to the house, some of the best varieties of flowering shrubs are found. Dr. Bowles has recently added to the grounds, and an old wall is a feature with various interesting plants. Much more could be written of Priors Mesne, but my note concerns the beautiful wild garden and trees. G. WYTHES.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

\* \* The dates given below are those supplied by the respective Secretaries.

November 26.—Royal Horticultural Society. Exhibition of Colonial Fruits, Bottled Fruits, &c., 1 p.m. to 6 p.m. Lecture at 3 p.m., by Mr. Archibald Brooks, on the "Cultivation of Citrus Fruits." Admission 2s. 6d.

November 27.—Royal Horticultural Society. Exhibition of Colonial Fruits, Bottled Fruits, &c., 10 a.m. to 6 p.m. Admission 1s. Royal Horticultural Hall, Vincent Square.

December 8.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m. Lecture at 3 p.m., by Mr. D. B. Crane, on "Chrysanthemums." Admission 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

**National Sweet Pea Society.**—The annual general meeting of members of the

National Sweet Pea Society will be held in the North Room, Hotel Windsor, Victoria Street, Westminster, London, S.W., at 3 p.m., on Friday, December 11.

**French Chrysanthemum societies.**—At this season of the year we cannot do better than draw our readers' attention to the French National Chrysanthemum Society, founded fifteen years ago, and which has done so much to popularise the flower in France. It now numbers 800 members and publishes an interesting and useful monthly journal which is supplied free to members. A much more recently founded society is that called the Association des Amateurs et Jardiniers Chrysanthémistes, whose headquarters are at Paris. This society, too, publishes a monthly journal called *La revue Chrysanthémiste*, issued free to members. To any admirer of the popular autumn flower desirous of keeping *un courant* with what is going on in the Chrysanthemum world, these two publications are indispensable. In both cases anyone interested in Chrysanthemums, either in France or elsewhere, is eligible for membership.

**Renovating old Vines.**—Will Mr. W. H. Wilson, who wrote the article on the above subject in our issue for November 14, kindly forward us his address?

**Sweet Peas in bloom in November.**—You may be interested to know that here on the East Coast we still have Sweet Peas in bloom, *Roses*, *Mignonette*, *Gaillardias* and *Geraniums*. Last week we had two good dishes of green Peas, and expect more if the frost keeps off. We also have been gathering good Mushrooms in the fields between us and the sea.—KATHARIN S. HOARE, *Sidestrand Hall, Cromer*.

**Ernest Calvat.**—This eminent Chrysanthemum raiser still finds favour among his own countrymen and apparently among American growers from what we have recently read in the American horticultural papers. At the Paris Show Calvat's new seedlings were awarded the grand prix d'honneur offered by the Minister of Public Instruction. At Tours he was also awarded an objet d'art, one of the highest prizes at the disposal of the jury. Eighteen first-class certificates were awarded to his seedlings by the Paris floral committee.—C. H. P.

**Increasing popularity of the Sweet Pea.**—As indicative of the tremendous strides that the Sweet Pea is making in popular favour, we may mention that at a lecture on Sweet Peas given recently by Mr. Horace J. Wright at Carlisle, under the auspices of the Carlisle Horticultural Association, about 200 members were present, the lecture and discussion occupying nearly two hours. When a similar lecture was given by Mr. Wright at the little town of Hailsham in Sussex the audience comprised about 100 persons.

**Presentation to Mr. J. Andrews of Woodbridge.**—On the 4th inst., at the autumn Chrysanthemum show at Southend-on-Sea, the chairman, on behalf of the society, presented Mr. J. Andrews with a silver cigarette case, suitably engraved, at the same time thanking him for the valuable services he had rendered the society at their annual exhibitions on so many occasions, and for the time he had given the society for many years. Mr. Andrews has been for a long time the principal worker and also secretary of the Woodbridge Horticultural Society, an important show in the Eastern Counties.

**Chrysanthemums in Glasgow parks.**—In the various winter gardens in the Glasgow parks an excellent display of Chrysanthemums is made every year, and this season they have, as a whole, been extremely good. The number grown at the Botanic Gardens has been considerably reduced to make room for other plants, but many large-flowered and other

varieties have been very good and have made a fine show in the Kibble Palace. At Camphill the blooms have been splendid, and the space devoted to these flowers has been utilised with great taste, good colour groups having been arranged. The blooms are large and of high finish. Bush plants and singles have been increased in numbers and have been very fine. A single raised here and called Camphill is in increasing favour. It has good pale pink flowers. At Tollcross Park, Mr. Wilson, the foreman, has made an excellent display, making the most of his somewhat limited accommodation and showing large blooms and bush plants, both single and double. Miss Wilson is a good deep pink single raised in this park and much grown about Glasgow. At Springburn the show has been one of the best ever seen in this park. A house has been filled with plants grown for large blooms and others in bush form. The display has been very fine indeed, the only drawback being the comparatively small size of the house, which is an annexe to the spacious winter garden. At Glasgow Green, in the People's Palace, there has also been a show of fine flowers, so that the people of Glasgow have no reason to complain of the provision of good flowers made for them.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Iris histrioides flowering early.**—Following my recent note on the precocious flowering this season of *Iris Vartanii*, it may interest some of your readers to know that *I. histrioides* was flowering freely with me on November 13, although I do not think it has previously flowered here before until after the shortest day.—F. HERBERT CHAPMAN, *Rye*.

**Drying and bleaching Pampas Grass.**—I should esteem it a favour if any reader of THE GARDEN who has successfully dried and bleached the plumes of this Grass will give me details of their methods. I have always dried mine by shaking it over a warm stove, thereby making it very fluffy, but it never remains so for more than a week or two. Mine is the erect-growing form.—Mrs. P. O.

**Apples for the North of England.**—The following Apples are some of the best for the North of England. They give a succession and should be planted in large quantities instead of planting a great number of different sorts. Dessert—Beauty of Bath, Worcester Pearmain, James Grieve and King of the Pippins. Kitchen—Lord Grosvenor or Potts' Seedling and Lane's Prince Albert. Dwarf trees are best.—(Rev.) J. BERNARD HALL, *Corbridge-on-Tyne*.

**Colour of Chrysanthemums.**—Among the many notes about Chrysanthemums which I have read this year, there is one thing I have not seen mentioned, viz., the curious want of colour in some of them. Of course, this may not be the case elsewhere, but here many which ought to be crimson are merely yellow, and pink or deep yellow ones are proportionately pale. For instance, George Gordon is yellow, Margot and Source d'Or cream and lemon-coloured respectively, Miss Chrissy is pale terra-cotta and many others quite unlike their usual colours. The plants are good and flowering abundantly, but were it not for the labels we should not know them again. One glorious crimson, viz., G. C. Childe, seems to have become extinct. For two years I have sought it among leading nurserymen without avail, and am inclined to give it up in despair unless some kindly amateur will take compassion and restore to me once more this coveted variety.—C. B. MYERS, *Dunningwell, Millom, Cumberland*.

**Comparison of garden features.**

There was a singularly artistic bed in Greenwich Park during the month of October. It was about 20 feet by 5 feet, situated in a moist and sheltered hollow, and the soil was the usual made soil of parks. The background of the bed was composed of clumps of the feathery glossy-leaved *Phyllostachys* (Bamboo) in variety, and in the foreground, dotted plentifully between them, were the common Red-hot Pokers (*Tritoma Uvaria*). This combination formed a most beautiful picture, and may be as new to at least some of your readers as it was to me.—J. HEAP.

**A prolific Marrow plant.**—I do not know if I am justified in writing to you about a remarkable Marrow plant I have had this year. I have cut 115 Vegetable Marrows off one plant, hardly one under 8 inches long and a good size round. Being such a prolific plant I saved one fruit for seed, which I cut at the end of August, and it weighed 19½ lb. I was advised to save another, which I did, and out that the second week in October; this weighed 21 lb. We began cutting at the beginning of July and kept on till after the middle of October. Some of the runners were over 50 feet long. It was planted between the Potatoes, without any manure whatever in the ground, but I kept it fed with manure water. Off this plant at our annual show on Bank Holiday (August) I took second prize in the gardeners' and gentlemen's class with a pair, and also third prize in the amateurs' class with a pair.—H. CARLEN, Sen., *Petersfield*.

**Apple Worcester Pearmain.**—The correspondence in *THE GARDEN* relating to this Apple is very interesting, especially to those gardeners who require a September dessert Apple. We grow several trees of Worcester Pearmain in these gardens, and find it an excellent Apple to follow Irish Peach and Beauty of Bath, both of which are practically over by the first week in September. Unfortunately, the colour of this variety seems a great attraction to the blue tits, these rogues usually sampling the finest fruit; and when the trees are of any size it is difficult to protect them from these pests. In South Devon we find the flavour, when eaten from the tree or a fortnight after storing, to be sprightly and sweet, but after that time the fruit seems to lose much of its crispness. The handsome appearance, however, of Worcester Pearmain will always ensure it a prominent position as a market variety, and as a September dessert Apple it is here preferred to that other beautiful sort, Lady Sudeley.—T. H. BOLTON, *Powderham, Exeter*.

**Perpetual-flowering Carnations outdoors.**—Now that these flowers are again being very extensively exhibited at the various shows, it may be of general interest to record my experiences with a few plants. Last winter several plants in 6-inch pots were obtained from Messrs. Hugh Low and Co. of Enfield, and, as a greenhouse was not available, they were stood in the window of a spare room where a fire was seldom made. During the cold weather the plants were frequently frozen, but despite this they gave an occasional bloom of medium quality. The second week in May two plants, *Brittania* and *White Lawson*, were planted in the open garden in Essex, and by the end of the month were firmly established. From that date until the end of October not a week passed without at least five flowers being gathered from *Brittania*, but *White Lawson* did not give so many. All the flowers were of good size and colour, although the plants were growing in full sun. Certainly they would have continued to give flowers several weeks longer could they have remained undisturbed, but removal to a new house necessitated the transplanting of the Carnations. Unfortunately, a strict count was not kept of the flowers produced during the months named by *Brittania*, but they could not have been many less than 100. The transplanted specimens I intend to leave outdoors during the coming winter and thus test their hardiness.—H.

**MESSRS. CLIBRAN'S NURSERIES AT ALTRINCHAM.**

**T**HESE nurseries, situated at Altrincham, near Manchester, and close by Hale Station, rank among the most extensive and comprehensive in the country. We use the word comprehensive advisedly, as it would be difficult indeed to mention a branch of horticulture not dealt with by the firm. Both indoor and outdoor gardening is catered for, and every available inch of space appears to be put to the best possible use without in any way overcrowding the plants. To give readers some idea of the extent of the business, we may mention that no less than twelve distinct catalogues are published by the firm.

At the time of our visit the numerous large glass houses were full of interesting subjects, of which perhaps the new winter-flowering Begonias were the most beautiful of all. Readers will be comparatively familiar with the older members of the race, which are all stocked at Altrincham, in addition to several new ones, among the novelties being *Lucy Clibran*, a beautiful orange and salmon variety with double flowers; *Clibran's Triumph*, orange red double blooms and very robust and handsome foliage; and *Bowden Beauty*, large double pink flowers, which are produced in abundance and continuously from July to December inclusive. Of the well-known *Gloire de Lorraine* we noticed a magnificent stock. *Washington*, a lovely double-flowered scarlet tuberous variety, gives much promise of being an excellent subject for summer bedding.

Young Palms entirely filled one large house, and some idea of the extent to which these are raised at Altrincham will be gained from the fact that no less than 240,000 *Kentia* seeds were sown this year, in addition to many other kinds. The beautiful and rare *Phoenix humilis Roebelinii* finds a congenial home here, and we noticed quite a large stock of it, the beautiful drooping leaves rendering it very attractive.

Although possibly *Crotons* and *Dracenas* are not grown so extensively as they were a decade or two ago, Messrs. Clibran must still have a heavy demand for them, as thousands of brightly-coloured plants occupied several of the houses. Some of the named *Crotons* are exceedingly beautiful and splendidly adapted for table decoration. We specially noticed *Prima Donna*, with narrow leaves of bright yellow and green; *Belle Kyrie*, twisted foliage; and *Alfreda*, narrow leaves and very vividly coloured. Those who are familiar with the old yet beautiful *Acalypha Sanderi* (*hispida*) will be interested to know that at Altrincham they have a new one called *A. Clibranii*, which has beautiful variegated foliage that renders it exceedingly useful for decorative purposes.

Of *Bouvardias* we saw no less than 2,000 plants, and *Cyclamen* were being grown on the same extensive scale, some exceedingly good colours being noticed among them. The *Winter Cherry*, as *Solanum Capsicastrum* is popularly called, is a most useful subject for winter decoration, the bright orange red berries and green foliage being most welcome in the winter months. So large is the demand for this plant that the firm find it necessary to grow not less than 4,000 plants every year, the whole at the time of our visit being laden with green fruits, which by now have doubtless ripened and thus taken on their brilliant colour.

Now that the *Chrysanthemum* season is with us, it may be of interest to mention that about 2,000 decorative plants are grown at these nurseries for cut flowers, and exhibition plants are grown on the same extensive scale, all the best and newest varieties being included among them, and all were in the best possible health.

Retarded *Liliums*, *Lilies of the Valley* and other plants are also dealt with for providing their beautiful and fragrant flowers out of season.

Of the cone-flowered *Primrose* (*Primula obconica*) we noticed a particularly good strain, something like 4,000 plants being grown at one time. *Zonal Pelargoniums* are also largely cultivated, and we saw an interesting hybrid between a *Zonal* variety and one of the *Ivy-leaved* section.

Among outdoor plants were *Roses* innumerable, and several thousand climbers are grown in pots, so that they are suitable for planting out at almost any season. *Clematises*, *Passion Flowers* and, indeed, all kinds of climbers in pots seemed to prevail in several houses, a beautiful *Passion Flower* named *Clibranii* especially claiming our attention. This is a lovely shade of crimson, with white anthers, which give the flower a very refined and striking appearance. *Vines* and *Fig trees* in pots are a speciality of the firm, and we saw hundreds of healthy specimens ripening up their wood ready for the winter months.

Herbaceous plants, bulbs, hardy evergreen and deciduous ornamental trees and shrubs, fruit trees and bushes, forest trees, *Carnations* and other florists' flowers, such as *Dahlias*, bedding plants, landscape gardening and horticultural sundries are all dealt with in their respective departments. It may perhaps be thought that with such an extensive business it is impossible to give proper attention to every branch; but so far as we could see everything is divided up into departments, so that even the smallest order will receive prompt attention from the specialist to whose department it relates.

**THE FRUIT GARDEN.****THE OUTDOOR CULTURE OF GRAPES.**

**P**ROBABLY no fruit tree is capable of arousing so much interest, curiosity and enthusiasm in its growth as the *Vine*; but, unfortunately, in this country this enthusiasm and interest is almost wholly centred in its growth as an exotic under glass. I wish it were possible to arouse as much interest in its culture out of doors, on cottage and other warm walls; what a vista of delightful pleasure and keen enjoyment such a possibility opens out to not only those amateurs who find the greatest rest and recreation in the pursuit of some aspect of gardening, but also to those artisans and workers who, in ever-increasing numbers, find gardening in their spare time the best and greatest source of recreation and delight. Many are discouraged by the thought that great skill and considerable experience are required in its growth before success can be attained; but this is not so. It is as hardy as the *Virginian Creeper* and just as easy to grow, and the leaves of some of the varieties are equally as handsome in the autumn by reason of their rich, striking colours, to say nothing of the attractiveness and the value of the black or golden clusters of ripe Grapes. There are two simple but important conditions which must be provided before success can be attained. The first is a warm aspect. This is available in all the Home Counties round London, also in the South and West of England and in Wales. The best aspect no doubt is that facing full south; but the *Vine* will succeed very well when planted against a wall facing south-west or even west.

The *Vine* is a lover of warmth, both at its roots and its branches; therefore the soil in which it is planted should be of a warm nature. In fancy I can hear exclamations of disappointment at this statement, as the soil of many would-be growers is of a cold and heavy character, preventing, as it would seem to them, the possibility of their succeeding in the growth of the *Grape* out of doors; but it does nothing of the kind if the means I recommend are taken to improve the quality of the soil and to raise its temperature. This may be done in the first instance by

effective drainage, laying down pipes 3 feet deep for the carrying away of surplus moisture. One drain will be sufficient. The next thing to do will be to trench the ground 2½ feet deep over a 12-foot square where the Vine is to be planted. Before starting the trenching there should be prepared a good cartload of material ready to mix with the natural soil, composed of the following ingredients: To five barrow-loads of turfy soil add two barrow-loads of old bricks broken to the size of hen's eggs, one barrow-load of old plaster or mortar rubble, one barrow-load of well-decayed manure, half a barrow-load of quarter-inch bones and the same of fresh lime and of bone-dust. This must be thoroughly mixed with the natural soil in trenching, and a similar proportion of the worst and heaviest soil thrown out and wheeled away as trenching proceeds, to make room for the new soil. This treatment will raise the temperature of the ground by many degrees, and will form an ideal medium for the healthy growth of the Vine. In the case of lighter soil resting on a subsoil of gravel or some other porous material the drain may be omitted and also the broken bricks; but all the other constituents mentioned should be added at the time of trenching, and some of the poorer soil taken away to make room for the new. It sometimes happens that a path or some other obstruction is in the way, and in this case it must be broken up and relaid afterwards over the border; it will do no harm to the Vine, as the latter likes firm soil to root in.

**Planting.**—Any time in October or up to the end of November will do very well, or in spring from the end of February to the middle of April. A one year old Vine is the best, and by this I mean one propagated last spring—not a cut-back plant. With a fork prepare a hole, 15 inches square and 4 inches deep, in the border close to the wall where the Vine is to be placed, and have ready a small quantity of finer soil (the same as the border soil, only passed through an inch-mesh sieve) for placing among the roots of the young Vine in planting. Turn the Vine out of its pot

and shake away all the soil from its roots. Cut the ends of the strongest ones back by a few inches, disentangle them all as much as possible, lay them in the bottom of the hole, having pressed it firmly first, spread out the roots evenly, and with the hands place the prepared Vine soil carefully and firmly among and over the roots until the level of the surface of the border is reached.

Shorten the Vine rod to half its length and tie securely to a stake. Early in January it should be again cut to within 3 inches of its base. Early in November place a mulch of half-decayed strawy manure over the roots and round the stem. This will protect the roots against too much wet in winter, which is more detrimental than hard frost.

The Vine may be left without further notice until spring, when I hope to revert again to the subject, giving details of spring and summer culture. The Vine should have a good watering as soon as planted. The only varieties to be depended on for this purpose are the Black Hamburgh, the Sweetwater, Black Cluster, Royal Muscadine and Reine Olga, a new black variety of great promise.

OWEN THOMAS.

## WORKERS AMONG THE FRUIT.

MR. CHARLES ROSS.

As we intimated recently, this venerable and highly-esteemed gardener resigned his position

as head-gardener to Colonel Archer-Houblon, Welford Park, Newbury, Berkshire, at the close of last month, after a service of almost forty-nine years. This estimable gardener, now in his eighty-fourth year, is yet happily in full enjoyment of mental energy and experience. We trust that many years of such mental vigour and of much physical activity may be his. Mr. Ross has, it

may be said, more than any other raiser made his mark on the Apple. He has devoted fully forty years to the work of intercrossing varieties specially with the object of producing, if possible, a superior race of dessert Apples, and, as results have shown, not without material success. No doubt his greatest success was with the Peasgood's Nonsuch and Cox's Orange Pippin cross, two Apples of widely dissimilar character, but from which came the variety which bears the veteran's name, Charles Ross, also The Houblon and Rival, both very fine varieties. Charles Ross has, when it is grown large, very much of the quality of Peasgood's Nonsuch; but when grown small on older trees and not too liberally fed, the fruits have very fine flavour. There are few more striking figures in the world of fruit than this fine old gardener, who has been not only a distinguished raiser of fruits, but a faithful servant for many years.

It has fallen to Mr. Ross to obtain from the Royal Horticultural Society no less than three first-class certificates for Apples and ten awards of merit. Even now he has other fine seedlings to be presented, and some of these will doubtless add to the list of honours. Besides the three named, Welford Park Nonsuch (raised in 1892), Bella, Armored, Atalanta, Mrs. Phillimore, Rival, Paroquet, Hector Macdonald, Encore, Ruddy and Opal are of his raising and are in commerce.

THE APPLE ENCORE, RAISED BY MR. C. ROSS. (Much reduced.)

THE WELL-KNOWN DESSERT APPLE CHARLES ROSS. (Much reduced.)

A very fine late cooking variety is *Excelsior*; this has not yet been offered to public notice. A few years since the Royal Horticultural Society presented Mr. Ross with a Hogg Memorial medal as evidence of its appreciation of the work he had done in Apple-breeding. Mr. Ross is of Scotch extraction, his father having been head-gardener to a former Earl of Rosebery at Dalmeny, Midlothian.

As a youth he served several years in various good Scotch gardens, including Dalkeith, under the famous McIntosh; and later took the first position as head-gardener at Fairlawn, Kent. While there he planted a *Wellingtonia gigantea* as a memorial of the Celebration of Peace after the Crimean War in 1856. It was in 1860 he removed to Welford Park, and was head-gardener there for the long period named, securing the warm esteem of his employers, neighbours and friends. From their origin till this year he has not missed the Royal Horticultural Society's fruit shows as exhibitor or as judge.

## THE KITCHEN GARDEN.

### THE ART OF TRENCHING AND MANURING.

(Continued from page 574.)

**USES OF TRENCHING.**—As a means towards carrying out the above principles of (1) aëration, (2) regulation of temperature, (3) drainage and (4) soil nourishment the operation of trenching is of the greatest possible value, by reason of the opportunities it affords for pulverising and granulating the soil and for exposing it to atmospheric influences, thus improving both its mechanical texture and fertility and encouraging the healthy action of manures.

**How to do the Work.**—By trenching is, of course, understood digging the ground at least two spits in depth. In the kitchen garden, trenching three spits deep is desirable; the work should be carried out thoroughly once during each year. Herbaceous borders should be trenched two spits deep every third year at least, and this will give opportunity for the division and replanting of perennials. For the ordinary work of trenching two spits deep, commence by marking out a trench, 18 inches wide, across the surface of the plot or border, and remove the soil dug out to the place where it is desired to finish the work. The condition of the soil should be considered before deciding the question of complete or partial inversion; usually, however, it will be found that what is required is to deepen the tilth by allowing it slowly to assimilate with the barren subsoil, and thus also to improve the latter by the gradual exposure of a portion at a time. Having removed two spits' depth of soil from the first trench, loosen the bottom to a depth of 6 inches. Manuring, on which subject some notes will be found at the conclusion of this article, should begin here. Proceed to mark out the next trench and cut down to the depth of a spit. A sprinkling of Vaporite—against the ravages of the wireworm—may be given over the now equal surfaces of the two trenches. Dig out the remainder of the first spit of the second trench, placing the soil on the top of that already turned into the first trench. Here may be incorporated some other manure or fertiliser. Take out the second spit of the second trench and fill up the first with the soil dug out. These processes will be repeated until the entire plot has been worked, the last trench being filled with the soil removed from the first.

**The Use of Manuring.**—At the time of trenching, the nature and condition of the soil and the kind of crops to be grown must be carefully considered in deciding what materials are needed for enriching, lightening, &c. Here, again, it will

only be found possible to indicate a few guiding principles, which will, it is hoped, be supplemented by a deeper study of the subject. Lime or chalk is an essential to soil fertility, not only because, except in a few special cases, it provides a real plant food, but because it is necessary for the preparation, retention and distribution of plant foods already to be found in the soil and in manures. If doubt exists as to whether or no a soil requires liming, a mixed sample may be tested by placing it in a tumbler and pouring on it a wineglassful of muriatic acid. If the mixture does not fizz and bubble freely the soil is shown to be in need of lime, and a dressing of this should in some suitable form be carefully applied. The effect of chalk and humus, *i.e.*, the organic matter of soils, upon one another is very rapid. Together their work is of the greatest possible value, both in regard to soil warmth, drainage and nutriment. As the principal object of manuring lies in the maintenance in the soil of a sufficiency of humus, it will be found that dressings of farmyard and stable manure, leaf-mould and green garden crops may almost invariably be applied with safety. When the materials used are not well decayed they should be applied as a

MR. CHARLES ROSS.

bottom dressing only, so as to avoid the risk of injury to roots occasioned by contact with manures in a fresh state. Heavy soils are rendered lighter, more porous and more generally friable by the use of organic manure, while light soils are by the same means helped to retain moisture. The evolution of carbonic acid caused by manuring in this way assists in liberation of potash and corrosion of phosphates in the soil, while it also causes the retention and distribution, as required, of ammonia and of potash. Since nitrate, phosphate and potash are all necessary as plant foods—nitrate for promotion of growth, phosphate for increase in fruitfulness and potash for improvement in quality—the immense benefit of manuring as an indirect means towards plant nourishment will at once be clearly seen. If, in addition, the plant food directly supplied by organic manures, which is relatively small in amount, be carefully supplemented by applying suitable fertilisers of the artificial or inorganic description, a high state of soil fertility will in time be reached, a state which should be easy to maintain by continuing at regular intervals the operations here described, supplementing them by frequent surface cultivation with the fork and hoe. H. C.

## THE FLOWER GARDEN.

### ALSTREMERIAS AND THEIR CULTURE.

**T**HIS genus of pretty *Amaryllids* from South America is but poorly represented in gardens, for out of fifty species known to botanists but six are in cultivation, and of these only three are widely known. Judging from Mr. Baker's description of these plants in his "Handbook of *Amaryllidæ*," there are many that would prove of great interest and value as garden plants, while a few appear to be better than anything we have at present. Several of the strangers are doubtfully hardy, although it is likely they would do well where *A. pulchella* succeeds, and that a light soil and a warm position are all they would require. There is a general lack of absolute hardihood in most of the *Alstroemerias* grown to-day. They may thrive for years unprotected and yet succumb to a protracted frost of unusual severity, or they may fail to survive the frosts of the first mild winter unless the fasciated roots are deeply buried, the soil made firm about them and the growths protected with litter should they appear too early.

*A. aurantiaca* is the common Herb Lily, an invaluable border plant worth a lot more attention than it generally gets. It bears quantities of orange-coloured, green-tipped flowers, streaked rich bronzy red internally and arranged in umbels. The stems vary from 2 feet to 4 feet in length, according to cultivation. There are several garden forms, of which *aurea* (rich yellow and but faintly streaked) and *lutea* (a pale yellow unspotted form) are good.

*A. hermantha* is a very highly-coloured *Alstroemeria*, with all the good attributes of *A. aurantiaca*. It has deep blood red flowers of similar size and shape. The true plant is somewhat rare and apparently more tender than a spurious plant; really a highly-coloured *aurantiaca*. It is the more showy of the whole family, the petals being very broad, expanding fully, while the buds show the olive green tips in relief with the deep red of the petals. It hails from Chili, and was at one time more common in gardens than it is to-day. In cold, wet districts, where it fails to grow well, it should be afforded house-room. *Albida*, its white form, is not a refined plant; the white is a poor grey at its best, and the greenish tips change from green to a nondescript yellow.

*A. Ligtu*, more widely known under Dr. Phillipi's name, *A. chilensis*, is represented in gardens by a series of very beautiful forms varying from white through pink, lilac and red to crimson. The growths are quite deciduous, attaining a height of 3 feet to 4 feet, bearing large compound umbels of ten to forty flowers,  $1\frac{1}{2}$  inches to 2 inches across the petals of each, and often 18 inches across the entire inflorescence. Every flower is regularly striped a darker shade of the same colouring and flushed externally with purple. The finest of this series known to me is the beautiful variety *Mrs. Salter*. The variety *pulchra* is a refined variety of variable colouring, the flowers of which are as regular as a florist's *Amaryllis* and very shapely. These and many other forms of *A. Ligtu* grow well in any light, warm border, requiring the protection of light litter when newly planted and during very sharp, wintry weather, especially if the soil is very wet at the time of freezing. These forms of *Alstroemeria* are invaluable for their yield of cut flowers; sheaves after sheaves may be gathered from old-established cultivated clumps, and they never wear out and lose vigour if they can spread at will or are surface-mulched occasionally. The species is very widespread in Chili, and scores of forms have received distinct names.

*A. pelegriana* is a more tender species of tall growth, requiring greenhouse treatment and a

roomy pot for its well-being. It has slender, leafy stems 4 feet to 5 feet high bearing lilac rose flowers in umbels of ten to fifteen, each flower 3 inches across and 2½ inches long, tipped with a large patch of green externally and heavily spotted purple on the inside of the inner petals. It is a splendid garden plant, well worth the little attention it requires, and reminding one of the more elegant Lilies in its graceful contour and pretty colouring. The plant is an old inhabitant of gardens and several seedling variations are sometimes met with, but none of these equal the old pure white unspotted alba, a beautiful plant bearing large umbels of spreading flowers faintly tipped with green. The forms of pelegriana have very long claw-like cusps and the outer petals are distinctly three-lobed. It flowers in May and June.

*A. pulchella* is a Brazilian plant with curious flowers of a deep crimson hue distinct from any others in the shape of the blossoms. It has stout stems 2 feet to 3 feet high, bearing small umbels of reddish crimson, green tipped, loose tubular flowers, the petal tips of which are furnished with a long incurving claw. They do not expand fully, hence the rich claret colouring of the interior is not apparent unless closely examined; the inner petals, small and also hidden, are striped, feathered and spotted with brown. It is a singular-looking plant, but possessing a certain type of beauty and resembling *Brodiaea coccinea* in its colour scheme, and also, in some degree, in the shape of its flowers. It dislikes a clay soil, and requires protection in the first season from wintry frosts in early spring as the growths push through the soil. It makes compact tufts and is not so prone to ramble as the other species. I have raised many plants from seeds but have seen no variation whatever, a remarkable feature in an *Alstroemeria*, for all the others have long ago sported forms till it is now impossible to determine where one species ends and another begins. It appears likely that an amateur with the necessary spare time would find this genus an interesting one to study and improve. The species *intercrossa* readily, seed freely, grow freely and their roots would travel round the world if carefully packed, hence there would be no difficulty in securing new species known to exist for extended operations in hybridisation. All of them are interesting, and many of them are markedly beautiful already. Who is to be warden?

G. B. M.

### ODONTIODA CHARLES-WORTHII GOODSON'S VARIETY.

At the Royal Horticultural Society's Temple Show in May last a considerable amount of interest was evinced in the beautiful crimson-scarlet bi-generic hybrid Orchid named *Odontioda Charlesworthii*. The subject of our present illustration is a highly-improved form of that remarkable plant, the flowers being larger and the colour more vivid. It was shown before the Orchid committee of the Royal Horticultural Society by Mr. H. S. Goodson of Putney on September 29 last and received a first-class certificate.

## THE ROSE GARDEN.

### THE NEWER ROSES.

(Continued from page 547.)

**N**ADIA (Hybrid Tea).—I do not know the raisers of this Rose, nor have I grown it, but I have seen it in fine form at several nurseries, and it promises to be good enough for exhibition. Growth, moderate; colour, pearly white, with large petals of good substance; shape, globular and very full.

*La France* and the habit of *Caroline Testout*, and, if it combines the qualities of these two Roses, few of us will ask for anything better. It was strongly recommended to me by a German correspondent, so I pass on the recommendation; but I have not grown this Rose.

*Pharisaer* (Hybrid Tea, Hinner, 1903).—A beautiful Rose, but not often good enough for exhibition; full, long bud—not quite enough petals, perhaps, but very free-flowering. No doubt a cool season will suit it better than the one just past has done. Pale flesh, deeper centre; a fine grower with good foliage.

*Princess Marie Mertchersky* (Schwartz, 1903).—This is a great favourite of mine. The flowers are large with stout, long petals, and beautifully formed. When better known it is bound to become popular, as it has not a bad fault and at its best is very fine. A good grower and of delicate colour—pale flesh, pink centre. Makes a fine standard and can be recommended as a good all-round Rose.

*Queen of Spain* (Hybrid Tea, Bide, 1907).—This Rose I must admit has been a trifle disappointing with me. After seeing the raisers put up such fine exhibits one expected great things, but apparently it, too, prefers a cool season. I could not get any point to my flowers, the majority coming with a hole in the centre, where the point should have been, very much after the style of *Antoine Rivoire*, of which Rose, I believe, it is a seedling. It was awarded the gold medal of the National Rose Society.

*Reine Carola de Saxe* (Hybrid Tea, Gamon, 1903).—A beautiful Rose this, fine shape, colour flesh pink, good all round, being free-flowering and occasionally good enough for exhibition.

*Renée Wilmart-Urban* (Hybrid Tea, Pernet-Ducher, 1907).—The trade generally speak well of this Rose as likely to be very useful for exhibition. It is a great flower, pale flesh in colour, yet distinct, of excellent shape, and the plant grows well.

*Robert Baessler* (Hybrid Tea, Hinner, 1904).—Supposed to be an improved *Frau Karl Druschki*, but he who so described it must have had a vivid imagination. With me it has done nothing to justify such a description, and I cannot recommend it.

*Souvenir de Maria de Zayas* (Hybrid Tea, Soupert et Notting, 1906).—This Rose has done well with me, and I can strongly recommend it. The flowers all come a good shape, after the style of J. A. K. Williams, but bright pink in colour, tinted carmine; sweet scent, free-flowering and a good grower.

*W. E. Lippiatt* (Hybrid Tea, Messrs. Alexander Dickson and Sons, Limited, 1907).—A fine dark

crimson Rose that I can strongly recommend. The flowers are always of good shape and a good colour, but, of course, from its very nature an old flower turns maroon or purple. It has a fine point, plenty of substance, particularly free in the autumn and is strongly perfumed. I am inclined to think it the best dark Rose of recent introduction. I am not sure, but I believe this Rose was exhibited by the raisers on more than one occasion under the name of H. V. Machin.

ODONTIODA CHARLES-WORTHII GOODSON'S VARIETY. (Natural size.)

*Otto von Bismarck* (Hybrid Tea).—A Rose of this name has been expected for a long time; but I understood it was to be blood red in colour. Possibly the donors of the prize (a sum of £150), which was offered for the best Rose raised in Germany, to be called O. v. Bismarck, would not wait any longer. *Frau Karl Druschki* would have been awarded the prize if it had not been white; but the irony would have been too marked. This Rose is described as the colour of

*William Shean* (Hybrid Tea, Messrs. Alexander Dickson and Sons, Limited, 1906).—From the exhibitor's standpoint it is impossible to speak too highly of this Rose, undoubtedly the largest now in cultivation. It has been wonderfully well shown, not only by the trade, but by some of our leading amateurs, notably Mr. E. J. Holland of Sutton, in whose garden I saw the largest flower of this variety (and that means the largest Rose) I have met. I will not give the figures, as that might lead to controversy. This variety is bound to take a high place among exhibition Roses. Its only fault is that the colour is inclined to run, but perhaps the season has had something to do with it. Its size will make it one of the indispensable Roses.

*Yvonne Vacherot* (Hybrid Tea, Soupert et Notting, 1906).—A Rose of very different stamp, but of distinct merit. Its great feature is the very beautiful arrangement of the petals, large grand petals, finished off with a fine point, making a very refined flower. The early flowers are quite up to exhibition form, but those that come later lack size. A medium grower; colour, pale porcelain white with a suggestion or suffusion of pink. At its best a very beautiful Rose.

This is the last of the newer Roses that can be said to be exhibition varieties, treating them alphabetically, and I now pass on to the Teas for the same purpose. They, unfortunately, can be counted on the fingers of one's hands.

*Dr. Felix Guyon* (Tea, A. Mari, 1902).—This Rose has undoubtedly improved, both in size and vigour. On its behaviour with me this year I am inclined to say it is a better Rose than Mme. Vermorel. The colour is coppery yellow, the flower of good substance and the plant is a good grower. Should be more grown.

*Freiherr von Marschall* (Tea, P. Lambert, 1904).—One of those Roses on the border line. A garden Rose first that will sometimes produce an exhibition flower. Fine colour, almost red—dark carmine perhaps best describes it; a good grower and fairly free.

*Helen Good* (Tea, The Good and Reece Company, 1907).—An American sport of Maman Cochet, pink in colour, that should be worth trying. I have not grown it.

*Mme. Constant Soupert* (Tea, Soupert et Notting, 1906).—As I anticipated last year when writing of this Rose, directly we could get it propagated naturally, by which I meant outdoors and not grafted under glass, we should find it a strong grower. In habit and general appearance the plant bears a great resemblance to that fine Tea Souvenir de P. Notting, and I should not be at all surprised to learn that that Rose was one of the parents of Constant Soupert. It is good enough and large enough to join the select body of the larger exhibition Teas, which hardly number more than half-a-dozen at the present time. The only fault I can find with Constant Soupert is that the petals are somewhat "papery." Deep yellow, shaded peach; large, well-formed flowers, and a strong grower.

*Mrs. Myles Kennedy* (Tea, Messrs. Alexander Dickson and Sons, Limited, 1906).—The powers that be—the seedling Rose committee of the National Rose Society—have decided that this Rose is a Tea, so it would be treason to suggest that it is anything else. The colour is delicate

silvery white, with a picotee edge of pale pink. This is a very beautiful Rose; the early flowers come of good size and excellent shape. It was awarded the gold medal of the National Rose Society, and every exhibitor will have to grow it.

*Molly Sharman Crawford* (Tea, Messrs. Alexander Dickson and Sons, Limited, 1908).—I have known this Rose for some time and can strongly recommend it. It is very distinct, of a beautiful shade of white that has a slight green tint in the younger flowers. Good growth and free flowering. I have no hesitation in saying it is the best Tea of its year; nay, of recent years. It will not be long before it will be recognised as one of the best six Teas for exhibition. I do not think it has been shown for the gold medal.

*Paula* (Tea, Messrs. Paul and Son, 1908).—Hardly full enough to be often found in the

year. Among these nothing is more beautiful than the Roses. As can be readily seen by the illustration, it has been possible to cut blooms often equal to those of July, and in some cases, owing to the sun being less powerful, the rich tints of the blooms surpass those produced in summer.

The name Hybrid Perpetual suggests at once perpetual-flowering Roses, but few of this section bloom to any extent in autumn. The chief exception with us is that beautiful white Rose Frau Karl Druschki. It cannot, however, be considered a true Hybrid Perpetual, as one of the parents is a Hybrid Tea. No collection of Roses is complete without this variety. Other Hybrid Perpetuals we obtain a few good flowers from in autumn are Dupuy Jamain, bright cerise, and Victor Hugo, rich crimson.

#### HYBRID TEAS.

It is in this section that we find most of the beautiful autumn-flowering Roses. There are also plenty of buds and flowers on those of the Tea and China sections, but they do not open or stand the weather so well as the Hybrid Tea varieties. In addition to their value for the garden, they are unrivalled for cut-flower decoration, as can be readily seen by the enclosed photograph, which was taken on the 3rd inst., all the blooms being cut from the open air. The following are the most notable sorts at present in flower, given in approximately their order of merit: La Tosca, Richmond, Augustine Guinoisseau, Mme. Abel Chatenay, Caroline Testout, La France, Liberty, Grösse an Teplitz, Earl of Warwick, Mme. Ravary (the best yellow bedding Rose I am acquainted with; the buds are excellent for sprays and buttonholes, being a rival to William Allen Richardson, but not quite so deep in colour; this was introduced in 1899), Viscountess Folkestone, Mrs. W. J. Grant, Lady Ashtown (rose, overlaid with silvery pink, the base of the petals tinted with yellow; pointed buds, free and constant; one of the best of the newer Roses for bedding and of good growth) and Mme. Jules Grolez.

#### TEA ROSES.

At the present time the majority of these are clothed with buds and flowers, but being more tender than the Hybrid Teas they are susceptible to rain and damp nights experienced at this season of the year. When required for indoor decoration it is better to cut the buds and allow them to open in water. Several varieties are very good at present; the first two of the undermentioned

are classed as Teas, although from their growth I suspect there is some Hybrid Tea blood in them. General Schablikine, coppery red, free-flowering, vigorous growth for a Tea Rose, an excellent bedding variety. Curallina, deep rosy crimson, beautiful in the bud for cutting, the strongest-growing Tea Rose with which I am acquainted, free and constant bloomer till spoilt by frosts; introduced in 1900. Souvenir de Pierre Notting, golden yellow, shaded apricot, large full flower, very free, plants at present covered with blooms.

Other good Tea Roses at present in flower are Anna Olivier, G. Nabonnand, Mme. Lambard and Princesse de Sagan. Baby Dorothy: This delightful little Rose is usually described as a dwarf Dorothy Perkins; the flowers, however, are several shades deeper in colour.

*Purley, Surrey.* HERBERT E. MOLYNEUX.

#### ROSES IN NOVEMBER.

The weather is seldom so favourable for our hardy plants in late autumn as it has been this

ROSES GATHERED IN NOVEMBER

*Surrey.*

A. O.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**T**HE GREENHOUSE AND CONSERVATORY. — Anticipating next year's demands, I am just making a sowing of Cyclamen seeds in shallow boxes and pots and placing them in a temperature of about 55°. In such circumstances this subject will do well. I am also at the moment repotting Liliums in anticipation of requirements early next season. Winter-flowering Carnations will now be making a free

other. All full-grown plants must have a covering in winter, and there is nothing better than dry leaves. If these subjects are tied when dry and a good mulching of leaves or Fern litter placed round about them, it will keep them in good condition. Continue to dig and trench vacant ground as opportunity offers. In frosty weather it is a good plan to wheel on to such quarters an abundant supply of good manure, so that when the weather becomes more genial digging operations may be proceeded with apace.

*The Hardy Fruit Garden.* — Recently-planted fruit trees, if not already mulched with manure, should have this attention at once. Cuttings of Gooseberries and Currants may be inserted at the present time. This is an easy means of increasing these useful subjects, and the cuttings root readily enough.

*Window Gardening.* — Hyacinths that were placed in glasses some time since are now giving evidence of growth. The foremost of these should be removed from their dark quarters to light and airy positions, as from this time forth their growth should go on unhindered. Plants indoors need watering with increasing carefulness. Avoid the use of cold water, which will have the effect of chilling the plants. I invariably use tepid water when this has to be applied, and the results are then all that can be desired. Plants that are growing away freely, such as Dutch bulbs in pots, as soon as they are removed from the plunging material should be freely watered.

*The Hardy Flower Garden.* — Complete as soon as possible the lifting and replanting of subjects in the hardy flower border, taking care to mulch the plants as soon as the planting has taken place. Borders that were somewhat impoverished, which the grower has not cared to interfere with this season, will derive considerable benefit by a heavy mulching with some good lasting manure. This should be thoroughly decayed, in which case the effect will not be unsightly. The present is an excellent time to form a rock and alpine garden — these are becoming increasingly popular, and deservedly so — and any beginner who desires to make his garden more than ordinarily interesting will be well advised to have even a small portion of his garden allocated to this purpose. Take advantage of every favourable opportunity to sweep the lawn, using a good Birch broom. This will have the effect of distributing worm-casts, and if the lawn be well rolled subsequently the result should be in every way satisfactory.

D. B. C.

### HOW TO PROVIDE A WINTER SUPPLY OF PARSLEY.

In many gardens it is a comparatively easy matter to procure winter quarters for Parsley in a position sheltered from the cold and cutting winds of the north and east. During the late autumn and throughout the winter season the aim of the cultivator should be to keep the plants growing, and this may be assured by planting in well-worked soil of a light and rather dry nature. We make two or three sowings during the year, and for winter supplies find a

May sowing answers our purpose better than any other. We are quite aware that some growers make a sowing so late as July and succeed remarkably well with the crop; beginners, however, can hardly expect to do as well. The seeds are usually sown thinly in drills about 1 inch deep in rows 1 foot or rather more asunder. Parsley derives considerable benefit from frequent applications of soot in the growing period. Assuming the seed was sown during the summer months, the plants should now be useful pieces with which to deal and be quite equal to the specimen shown in Fig. 1. When lifting these plants take care to get down well underneath them, or the prospects of success may be jeopardised. We always use a fork for lifting Parsley and find that this answers the purpose very well.

We may safely anticipate long spells of hard frosty weather, and during such periods our outdoor hed, even though it may be in a warm aspect, will be likely to fail us. For this reason measures should be taken in anticipation for providing supplies of Parsley throughout the winter by other means. Many growers lift and replant their Parsley in rather deep boxes of good soil, and these are placed in a cool greenhouse or cold frame, from whence frost may be excluded in hard weather, especially by observing care in covering the latter structure. Other growers, again, make good use of large pots for this purpose, a few such pots providing a useful supply where the demands of the house are not excessive. Fig. 2 represents three plants potted up into a 9-inch pot. The latter should be crocked carefully and open soil of a rich kind be used for the repotting. Pot rather firmly and water in the plants immediately. Afterwards stand them in the cool greenhouse or frame, covering the latter in frosty weather with mats.

A system we much prefer, because of its simplicity and the ease with which the plants can be managed, is that of planting out Parsley in cold frames. In Fig. 3 we have a small frame in course of being planted with lifted plants of Parsley similar to those seen in Fig. 1. When planted in a cold frame it is so easy to give Parsley the advantage of ventilation in mild and open weather. We plant Parsley in frames for winter use about 8 inches apart. Fig. 4 represents a plant raised in heat in the early spring, grown on well during the summer and early autumn, and then lifted intact and placed in a 10-inch pot. This is a very simple means of providing a

1.—A YOUNG PLANT OF PARSLEY SUITABLE FOR LIFTING AND POTTING.

display, and if placed in a light position will continue to do so for some time. Herbaceous Calceolarias and Cinerarias, both of which are very susceptible to the attacks of injurious insect pests, need constant supervision and careful culture at this period. The best position for these is on shelves near the glass. Those who have inserted cuttings of Zonal Pelargoniums (Geraniums) are prone to keep the soil too moist at this season. They should only be watered when the soil becomes really dry, and then one copious application should suffice to keep them in a satisfactory condition for some time.

*The Cold Frames.* — In mild and open weather the frames should be well ventilated, especially in the case of those containing Calceolaria cuttings, as this assists to keep the atmosphere dry. Never hesitate to overlook plants repeatedly, removing decaying foliage and anything of a nature that is likely to promote decay. When watering has to be done — and this is very necessary in the case of many pot plants — this should be done in the morning, so that superfluous moisture may be carried off before late afternoon, at which time the frame-lights will need closing.

*The Vegetable Garden.* — Lettuces and Endives, which are so valued at this period of the year, should be sheltered from frost in some way or

2.—THREE PLANTS SIMILAR TO THAT SHOWN IN FIG. 1. POTTED UP INTO A POT 9 INCHES IN DIAMETER.

3.—A NUMBER OF PLANTS INSERTED 8 INCHES APART IN A COLD FRAME.

bountiful supply of their ever-welcome leaves and assures the grower a continuous supply for a long time to come. A few such plants should be ample for small households.

Growing crops outdoors may be protected by placing boards on either side of the rows, or by embracing the whole of the bed by the same means and covering the plants with mats during frosty weather.

#### HOW TO TREAT BEDDING PLANTS IN WINTER.

VERY often inexperienced persons lose many bedding plants during the winter months through wrong treatment. I have lately seen collections suffering greatly through neglect. Take Zonal Pelargoniums for instance; throughout the autumn there are scarcely any decayed leaves to be found on the rooting cuttings, only a few of the basal leaves; but when the fogs come and the dull, sunless days faded leaves are found in plenty. These leaves, if allowed to remain on the plants, become saturated with moisture which quickly affects the stems of the plants, ultimately causing the entire loss of the latter. Now, in the very best-managed structure some leaves will turn yellow and fade; but in every instance they should be removed forthwith before others near them are affected.

In indifferently-heated structures the difficulty of safely wintering the stock is the greatest; but much care should be taken in the matters of watering and ventilating. It is safer to keep the soil rather dry than too moist. When water is needed give sufficient to quite moisten the whole of the soil through, and then let the latter get moderately dry before applying more; also take care to do the watering in the early part of the day and avoid wetting the leaves. Keep the atmosphere as dry as possible and do not ventilate too freely in adverse weather.

Calceolarias in frames require more air than Zonals and damp is not as great an enemy to them; still, it is advisable to prevent it accumulating in excess in the frames, and to this end take off the whole of the glass lights for several hours during the early part of a sunny day when the air is not frosty.

Marguerites require almost similar treatment to Calceolarias, but frost must be excluded. If, however, either of these two kinds of plants get frozen, keep the lights closed and the glass well covered with mats day and night until the thaw has been complete. So treated the young plants will not suffer serious injury; but if exposed to the air and sunshine while in a frozen condition they will be badly damaged.

*Tender Plants.*—The more tender kinds of bedding-out plants, such as Coleuses, Iresines, Heliotropes, Mesembryanthemums, Verbenas, &c., are often kept on shelves near the roof-glass of a warm plant house; but during very

cold or frosty nights their position near the glass is a very cold one. The central part—on the stage—of the structure may register 60° of heat while the part immediately under the glass is at freezing-point. No wonder, then, the leaves become sickly and finally fall off. Even if it means the erection of a temporary stage, it would be better to do so and place the stock of tender plants near the centre of the house until the end of January. Some plants of a hardier nature may be put on the high shelves. Very little ventilation is necessary, and all water given should be of the same temperature as that of the house itself. Cold water will naturally lower the temperature of the soil, which cannot be good for the plants.

AVON.

#### DIGGING AND TRENCHING.

Every unoccupied plot of ground will be considerably improved if it is at once trenched or at least deeply dug, leaving the surface as rough as possible. By treating it thus many grubs and insect eggs are exposed to birds, and frost will pulverise the soil so that in the spring a light forking over is all that will be needed to ensure a beautiful fine tilth for seed sowing. In ordinary digging beginners frequently make the mistake of inserting the spade or fork in a sharply sloping manner, with the result that the soil is not turned up to the full depth of the tool employed; it is proper to thrust the tool in as straight as possible, and thus take advantage of its full length.

#### THE TOWN GARDEN.

*PROTECTING TEA ROSES.*—In those gardens where there is a good amount of fresh air, Tea Roses thrive very well and bring a considerable amount of pleasure and satisfaction to their growers; but the losses during the winter are apt to be rather severe unless methods of protection are resorted to. As a rule it suffices to carefully cover up the junction of the stock and the bud, for if the shoots above get killed back, new breaks will come away with the genial growing weather of the spring. In many gardens ashes are used for this purpose, but as far as one can

see they have no material advantage over the ordinary soil. Whichever is employed should be built well up to the stem to such a height as to cover the union at least 2 inches beneath the surface. It should be brought up with fairly sharp sides so as to throw off the rain, as when this runs down to the stems persistently in the winter, it is as likely to do serious injury to the plants as the frost itself.

*LIVE EDGINGS.*—There can be no doubt that these are far more attractive in gardens than such "dead" edgings as tiles, bricks or stones; but it is equally certain that they have substantial disadvantages. As a harbourage for slugs, snails, and other pests they serve a real if not a useful purpose, and it is well-nigh impossible to keep them clean. However, they are highly appreciated, and it is most unlikely that they will ever go entirely out of favour. Apart altogether from the disadvantage to which allusion has been made, there is one other point that is often overlooked in connexion with them, which is that they demand attention. Some people appear to think that when the plants are put into position they will not require any attention at all, but will continue to grow satisfactorily for an unlimited number of years. Such, as a matter of fact, is very far from being the case, for in almost all instances they demand remaking once every three years, and if this work is due for carrying out this winter, it should either be accomplished forthwith or left over until the spring. The first thing is to lift the plants, and as the weather is now somewhat uncertain, it is wise to do the border in sections so that only a comparatively few plants shall be out of the soil at one time. Directly they are up, thoroughly dig over the soil to a depth of at least 12 inches, and work into the lower part some sweet manure. This done, plant pieces from the outer sides of the old clumps, as the centres are almost sure to be brown, bare and weak. The soil must be thoroughly firmed about the roots and heavily watered when the plants are in position.

*THE VALUE OF LIME.*—Considering how valuable lime is as a corrector and sweetener of the soil, it is a matter for surprise to me that it is not more extensively used by town gardeners, who rely so largely upon natural manures to maintain the fertility of the garden. The constant use of these things leads to an excess of humic matter and the soil becomes greasy-looking. When this state of affairs prevails the plants will not grow satisfactorily, for although there may be an abundance of food in the ground it will not be available for the plants. Lime will put matters right again. It should be applied generously, covering the surface to a depth of half an inch or three-quarters of an inch; leave it on the

top for a few days and then work it in, taking very small spits so as to equalise the distribution. Not only will the lime act upon the humic matter and set free the stores of unavailable food, but it will also destroy the spores of any fungi with which it may come in contact and also the grubs of lurking insect pests. Where natural manures are used exclusively, liming should be had recourse to once in about every five years; but soils differ so much that each cultivator has to ascertain the precise period from his own practical experience. It is sometimes difficult to procure, but a friendly local builder will usually come to the rescue with a sufficient supply for a small garden.

HORACE J. WRIGHT.

4.—A PARSLEY PLANT RAISED FROM SEED SOWN IN FEBRUARY. SUCH PLANTS LIFTED AND POTTED NOW PROVIDE A GOOD SUPPLY OF PARSLEY THROUGH THE WINTER.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**PREPARING PLANTS FOR FORCING.**—This will now be necessary. Therefore place a few Roman Hyacinths in heat, some very early Daffodils, a few Azaleas Deutsche Perle and also some of the old Single White. This forces very quickly into flower and is a beautiful clear white. Also place Lilacs, Azalea mollis and Laburnum in a gentle heat, and a batch of Freesias. *F. refracta* alba is the earliest to flower. Retarded Spireas should now have a light position. These are more useful at Christmas than later in the spring. Put in more Lily of the Valley crowns to keep up a succession. The retarded roots should not be put into heat for at least ten days; a cool, moderately-dark position is the best until then. A frame covered with mats or under a cool-house stage are suitable places to start them.

*Plumbago rosea* or *coccinea* now showing flower should be kept in the intermediate house with a temperature of 60°. This is a fine showy flower for the cold, dark days.

#### FRUITS UNDER GLASS.

**Peaches.**—Prune, dress and tie the trees in the early house as soon as possible. Prune away as much of the big wood as possible, remembering it is on the wood of the current year where we expect fruit next year. Do not tie the branches too tightly, but as straight as possible from the base, and allow plenty of room between the shoots. Do not be afraid to prune too much. All thin and weakly wood should be taken out; if not done now it interferes with the growth later on and has to be cut away.

**Cherries** should be pruned and cleaned and the house got ready. As soon as it can be done, pot Strawberries. These must now be got into cold frames to protect them from heavy rains.

#### HARDY FRUIT GARDEN.

**Cherries** may still be planted. Well-drained soil with plenty of old mortar rubbish mixed will be found to be a good growing mixture. Cordon trained trees should be 2 feet apart; fan shape, 15 feet to 20 feet; bush and pyramids, 9 feet to 12 feet. I find Cherries do not like being pruned very much; therefore as much of the pruning as is possible should be done with thumb and finger in the growing season. May Duke, Black Tartarian, Elton Pine, Knight's Early Black, White Bigarreau, Waterloo, Bigarreau Napoleon, Florence, Early Rivers and Frogmore Bigarreau are all varieties that do well here, both as cordons, bush and dwarf trained.

**Apricot trees** should be cleaned and trained as soon as possible. The more work of this kind that can be done at this season the better, as often such weather comes that it cannot be got on with, and when there is a pressure of work it is sometimes done carelessly. See that no old ties remain; all should be cut and replaced with new.

#### PLEASURE GROUND.

**Autumn Tints** have this season been glorious; in fact, I have never seen them so fine. Acers of all kinds may now be planted, and also Berberis Aquifolium, B. Thunbergii and B. vulgaris. B. acuminata, B. diaphana and B. Thunbergii minor are newer varieties and are most beautiful. Among some of the best Acers are A. rubrum, A. dissectum, A. japonicum (Oaksakukii), A. polymorphum var. platanoides and A. pennsylvanicum (the wood of this variety is striped with white lines and is effective after the leaves have fallen).

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardlee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**POINSETTIAS.**—The most forward of these will now help to brighten up the dull days with their showy bracts. Feeding must be discontinued, but younger stock intended for Christmas decoration should be liberally fed, syringed and fully exposed to all available light. A nice brisk temperature should be afforded now the colder season is here.

**Cinerarias.**—Plants raised from the earliest sowing will soon be pushing up their flower-stems. The pots by this time should be quite full of roots, and will, consequently, require frequent applications of diluted liquid manure. When subjected to more than an ordinary greenhouse temperature, the flower-stems become drawn up so as to render the plants unsightly.

**The Christmas Roses or Hellebores.**—A cold frame or even hand-glasses will bring these plants into bloom by Christmas if put on now. Though the plants are very hardy, the glass covering keeps the flowers clean. There are some beautiful varieties, and the pure white sorts are the most valuable. *H. angustifolius* is one of the best; this has large flowers with a fair length of stalk, is a pure white and of free growth. *H. maximus*, the largest of all, is a beautiful flower, but not so pure a white, being slightly tinged with pink. The well-known major is also a beautiful winter flower, having pure white blooms when given glass protection. Good strong plants full of flower-buds may be purchased at a trifling cost from any nurseryman making a speciality of the Christmas Rose; and if potted up now and placed under glass will produce a wealth of blooms from Christmas onwards.

#### FLOWER GARDEN.

Besides the alteration of some borders and the planting of others, there is not much to chronicle in the way of flower garden work at present, except the gradual digging up of beds that remain empty through the winter, and mulching those herbaceous borders that are in a satisfactory condition and require no alteration.

**Pampas Grass.**—Now the winter season is fast approaching, I may draw the attention of those having young plants of this to the advisability of protecting them in some way. My method is to place some dry Bracken round the collars of the plants to the height of about 1 foot. In this way the plants get enough protection, and they grow away well the next season. I never protect the large clumps, and find that they invariably take care of themselves.

#### HARDY FRUIT.

**Peaches on Walls.**—In the northern parts of the kingdom there is often much difficulty in getting the wood of these well matured, particularly during a season like the present, when there has been so little sunshine during the autumn. To assist the ripening allow the trees to remain nailed to the wall, as what little warmth is generated thereby will be of great benefit in maturing the sappy growths.

#### KITCHEN GARDEN.

**Turnips.**—The Turnip crop will now have completed its growth, but the roots, like those of many other things, are best when left in the ground till wanted. I do not, however, advise that they should be completely exposed to all weathers, as this tends to rotting at the crowns and to a general falling-off in quality, but they may be kept in the best possible condition by having the soil drawn over the roots. To provide for a supply in case sharp frosts should set in, some portion of the crop may be covered with sufficient litter to keep the frost out of the ground. Late-sown batches may be left to take their chance, as they will continue growing through the winter whenever the weather permits.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Herbaceous border (Vicar's Wife).

Our chief objection to your arrangement of the plants is the repetition of long lines, and unless the border is situated at the extremity of a lawn, for example, and viewed chiefly from the front, it will savour of formality. We note, too, that you do not include any of the white perennial Marguerites or white Phloxes, and you would do well to embrace some of the white Michaelmas Daisies, such as *ericoides*, *vimineus* and *Purity*, and such blue-flowered ones as *Calliope*, *William Marshall* and *Novi-Belgii densus*. One of the most desirable of blue-flowered plants is *Delphinium Belladonna*, 2½ feet high and almost perpetual blooming. You do not say what *Veronicas* you possess, but the most valuable is *V. subsessilis*, 2½ feet high, of vigorous growth, and much the best for massing for effect.

#### Seedling Carnations (Miss E. M. Boghurst).

The better way to have treated the Carnations would have been to layer all the strongest shoots as soon as the flowering was completed, and in this way the rooted layers would have made good plants for setting out in September or in October for flowering again next year. Now, however, it is too late for layering, and the success of transplanting examples of large size will largely depend upon the way it is done. We do not quite understand why the plants "are so out of the ground." If you mean the basal growths and roots are out of the ground, a mulching of soil will suffice; but if the phrase refers to the top growth or stem-shoots, then it would appear that some at least of your plants are of the Tree variety, in which case the shoots on the upper branches or stems may be treated as cuttings. The better way with seedling Carnations is to sow seeds in January each year and plant out in May, the plants flowering a year later.

#### Tulip bulbs for inspection (E. Strang).

The Tulip bulbs are badly diseased and are not worth putting into the ground; it would be far better to burn them. It is quite probable that new bulbs put into the same soil would be attacked by the fungus which has destroyed these, unless the ground has a dressing of lime, which might check the growth of the fungus.

#### East border (A. H.).

You do not say whether you wish for flowers or fruit on the wall, and you give no idea of its height or even its length. In much the same way you give no information about the size of the border, and we may therefore give you a list of plants quite unsuitable to your purpose. Why not tell us whether the soil is light or heavy, and, in addition, the width and length of the border? With these particulars before us it might be possible to give you useful advice. In any case the border should be prepared by deep digging and manuring, and this done the planting could follow in due course.

#### St. John's Wort not flowering (E. R. B.).

It is impossible to give more than general information on this subject without knowing which particular variety of St. John's Wort you refer to, as there are a great many sorts. *Hypericum calycinum*, the common large-flowered one, may be cut over each year. *H. moserianum* may also be cut over fairly hard. *H. patulum* may be cut about half-way back; that is, half-way down the previous year's shoots. *H. Androsæmum* may be cut almost to the ground line. *H. elatum* should be treated like *H.*

patulum, and also *H. hircinum*. The small-flowered forms require no more than the removal of the old flower-heads. As a rule, *Hypericum*s blossom freely. If yours are inclined to form weak shoots, give a surfacing of manure next spring.

**Sutherlandia frutescens not flowering** (*B. R. O.*).—The non-flowering is merely a question of age, and if all is well and the plants given protection for the winter—they will not prove hardy in the open in your district—the strongest should flower in the early summer of next year. The plant, as indicated by its specific name, is of sub-shrubby habit, and youthful plants rarely flower in the first year from seeds, unless the seeds are very early sown and the young plants grown under the most favourable conditions. As a foliage plant in northern gardens it is not to be despised. The plants should be early potted up and wintered in a greenhouse at about 45°. If you bed the plants out next year, you had better plunge them in their pots, as this is calculated to promote an earlier flowering. You would, of course, have to water them during hot weather.

## TREES AND SHRUBS.

**Name and information about a plant** (*J. M. B., Monmouth*).—The specimen you send is *Phillyrea media*. It will be unwise to cut it down this autumn. The most favourable time for pruning such a shrub is April or early May, just as growth is commencing. *Phillyrea*s are, however, rather bad subjects to prune hard back, for although they sometimes break again well this is not always the case, and even if the plant grows it takes several years to make a respectable-looking specimen again. If you cut it down now, it will have to remain in a dormant state until next spring, which will have anything but a beneficial effect on the plant. If at the present time it is a shapely specimen, it would be advisable to leave it alone.

**Pruning Heaths** (*A. L.*).—It is not advisable to cut Heaths back into old wood, but it is advantageous to shorten them a little annually, not going lower than within a few inches of the base of the previous year's wood. By judicious pruning you can certainly obtain much more shapely plants than is possible without, and if you commence while the plants are young you do not need to resort to hard pruning. Frequently all that is necessary is to remove the old flower-heads within 1 inch or 2 inches of growth. *Daboecia polifolia alba* may be cut back any time during winter and spring, but with such things as *Erica carnea* and *E. mediterranea* you must wait until after the flowers have fallen in spring before you attempt to prune. All the autumn-flowering sorts may be pruned during winter or early spring, the spring-flowering sorts as soon as the flowers are over.

**Ericas growing too strongly** (*Daisy*).—We advise you to lift the plants at once and pull them to pieces, then replant the best of the tufts and thus afford the *Lilium* more space. You could, of course, cut them back, but we think the replanting would be best. The size of the bed, 6 feet by 4 feet, would be a very suitable one for the *Daboecias*, and they should succeed if you have the bed mulched in hot weather.

**Lilac leaves browned** (*Mrs. L. R. R.*).—From the appearance of your Lilac leaves we imagine that the plants have suffered from drought; this you may, perhaps, be able to ascertain now if you remove the soil from one side of the roots. Lilacs are improved by pruning, if the work is carefully done. The best time is as soon as the flowers are over. You may then remove suckers and all weak inside wood, so that the strength will be thrown into the permanent wood which is intended to produce flowers. In July the bushes may be looked over a second time and some of the weakest of the current year's shoots rubbed out. A good watering with manure water two or three times during spring and summer will be helpful, while a surfacing of rotten manure is also beneficial.

**Name and information about a shrub** (*C. H. Goodie*).—The shrub, of which you send a specimen, is *Leycesteria formosa*, a native of the Temperate Himalayas and a near relative of the *Diervillas*, or *Weigelas* as they are sometimes called. It thrives in any good garden soil, but it is not satisfactory in that of poor quality. It may be increased by means of seeds, which are borne freely, or cuttings of half-ripe shoots may be inserted in sandy soil indoors during summer. You can grow it as a specimen bush, or, if planted in rich soil, you can cut it down to the ground each year in March. By this method of culture you will obtain good strong shoots, which will flower well and be ornamental in winter after the leaves have fallen by reason of the bright green colour of the young bark.

## THE GREENHOUSE.

**Preserving Poinsettias** (*A. Reader*).—The best way to preserve Poinsettias is, immediately after they are cut, to immerse the ends for about 1 inch in boiling water for a couple of minutes. This does not prevent the absorption of water by the stems; consequently, the foliage as well as the coloured bracts are preserved fresh. Sealing the ends with a red-hot iron has been recommended, but while this prevents bleeding it checks the absorption of water; consequently, while the bracts are preserved in a fairly fresh state, the leaves droop quickly.

**Raising Nerine seedlings** (*Greyhound*).—The seeds of *Nerines* quickly deteriorate, for which reason they should be sown as soon as they are quite ripe. In a temperature rather above that needed for established plants, the seeds soon germinate and push up their grass-like leaves. Even young plants resent being disturbed at the roots more than is absolutely necessary; therefore a compost of a lasting nature should be chosen. The major portion may consist of good loam, lightened by some silver sand, and, if necessary, by some well-decayed leaf-mould. This last, however, will to a great extent depend upon the consistency of the loam. The first season the young plants should not be subjected to any drying-off process, as the bulbs are so small, but the second year they may be treated as established plants. In three years from seed many of them should flower.

**Cattleya Mossiae** (*A. B. C.*).—The flowering season of *Cattleya Mossiae* is in the summer months. As yours are in such a bad condition, the better way will be to turn them out of their pots, shake quite clear of the old compost, cut off any decayed roots and repot in a mixture of peat and sphagnum. The pots must be clean and half filled with broken crocks. Care should be taken that the pots used are not too large, for overpotting is likely to prove fatal to plants in poor condition.

**Treatment of Calceolaria Burbridgei to form tall plants** (*J. M. G.*).—*Calceolaria Burbridgei* is naturally of quick growth, so that it is a simple matter to obtain large plants from 3 feet to 6 feet in height, and even taller. All that is necessary is to shift the plants on as they require it into larger pots, using a fairly good holding compost, such as four parts curly loam to one part each of well-decayed cow manure and leaf-mould, with about half a part of sand. As illustrating their rate of progress, we may mention that some plants of ours, struck from cuttings in the spring of last year and wintered in 5-inch pots, were in the early spring of this year shifted into pots 10 inches in diameter, and are now about 5 feet high and full of bloom. Of course, they were wintered in the greenhouse, and after potting kept there till all danger from frosts was over, when they were plunged outside. Plants like this can be kept on for flowering year after year, as, if the pots are sufficiently large, they can be assisted by occasional doses of liquid manure or some of the stimulating plant foods now so much used.

## ROSE GARDEN.

**Protecting Rose William Allen Richardson** (*Beta*).—This Rose requires very little protecting; in fact, it will pass through an ordinary winter unharmed. As the position of your tree is somewhat draughty, it may be advisable to bind up its growths with a dry hay-band when a sharp frost threatens, and release them again at mild intervals. You could bind them in an upright position, securing them to a tall stake. At the end of September pinch out the points of the shoots. This will tend to harden them and thus prepare them to stand the weather better.

**Roses and mildew** (*Mrs. M. G.*).—The varieties you name are not specially subject to mildew, although we cannot say either of them are perfectly immune from the fungus. This pest has, as you say, been very troublesome this year, especially since the first blooming, but we think if you sprayed the plants immediately a few spots are seen with Lifebuoy soap solution you would keep the mildew in check. The various remedies, of which the above is a good one, should be persistently applied as new growths develop if they are to be effectual, and it certainly pays to do this. Half a bar of the

soap to three gallons of soft water is the strength recommended.

**Rose Helene Guillot with unripe growth** (*Beta*).—It frequently happens that some plants will send up from the base late in the season such a growth as you describe and such shoots are practically useless another year. The best plan is to pinch out the point at once; then at pruning time cut it down to one eye. Nearly always an early shoot starts from this one eye and proves very useful the same year, for it will carry a grand truss of bloom.

**Rose Conrad Ferdinand Meyer with blighted foliage** (*L. Dinall*).—The fungoid disease which has attacked the foliage is the Rose rust, known also as orange fungus. It is very often met with, and causes little harm excepting that it does not look nice to see the Roses prematurely denuded of their foliage. Next spring, just when the new leaves are expanding, spray them with a solution of sulphide of potassium. If the rust spots appear on the wood, the patches should be painted with a solution of equal parts of methylated spirits and water, rubbing it well in with a sponge.

**Rose Gruss an Teplitz failing to bloom** (*R. M. Stanley*).—You did wrong in cutting out the old wood at pruning time. This should only be done with the rambler race and exhibition Roses. Our plants of Gruss an Teplitz have had none of the old wood taken quite away, but, of course, it has been shortened. If you preserve the shoots that are made this year and cut them back to about 4 feet from their base and tie these over next spring, you will obtain plenty of bloom, although perhaps it will be rather late. Some growths springing up from the base of the old wood this autumn carried fully thirty buds and blooms in one cluster.

**Yellow companion to Dorothy Perkins** (*G. H. Rippling*).—We wish we could say there was a yellow Dorothy Perkins. There is now on the market a white variety of this popular Rose, but at present no yellow. One of the best Roses to plant to bloom at the same time as Dorothy Perkins is *Alister Stells Gray*. This has yellowish white flowers in clusters and is a perpetual bloomer. There is no double crimson Rose of the type of Dorothy Perkins. *Rubin* is a rosy red double flower and *Non Plus Ultra* is a good rich purplish crimson, but these bloom at the same time as *Crimson Rambler*, which is a little in advance of Dorothy Perkins. Gruss an Teplitz is a grand scarlet climber for autumnal floweriug.

**Roses with erect double blooms** (*R. Smalls*).—Of the varieties you name only Joseph Hill and Dean Holo can be said to have large double flowers produced upon erect stems. Some of the others are splendid garden Roses, such sorts as *Mrs. Peter Blair*, *Betty*, *Le Progrès*, *Harry Kirk* and *Mme. E. Boule*, producing their blooms upon erect stems, and although rather thin they make up for it in profusion. *Paul Ledé*, *Hugh Dickson* and *Caroline Testout* are large and handsome, but their blooms droop a little. It is becoming exceedingly difficult to satisfy all our varied desires, and it is far better to be content to take Roses as they are than trying to obtain what does not exist. The following are very fine Roses and might comply with your stipulations: *Florence Pemberton*, *Mrs. Theodore Roosevelt*, *Antoine Rivoire*, *Captain Christy*, *Corona*, *Dora*, *Hélène Guillot*, *Kaiserin Augusta Victoria*, *Lady Ashtown*, *Mme. Maurice de Luze*, *Lady Falmouth*, *Mme. Emée Metz*, *Mme. Jules Grolez*, *Marquise Litta*, *Duchess of Portland*, *Mildred Grant* and *Queen of Spain*. If you want extra large double Roses you will have to go to the Hybrid Perpetuals for them, but do not expect much autumn bloom.

## FRUIT GARDEN.

**Grapes diseased** (*W. E. Napier*).—Your Grapes are suffering from a disease termed shanking. No one so far has been able to discover the actual cause of it, but all experienced men are agreed that it results from some over-strain the Vines have been subjected to in the previous year or two. The following causes, or a combination of them, will bring it about: Allowing the Vines to carry too heavy a crop, destruction of the foliage by red spider the previous year, defective root-action, and keeping the border too wet or too dry. It is seldom or ever that this disease attacks a healthy, vigorous Vine.

**Apple trees on flower border** (*Enquirer*).—If the two Apple trees on your herbaceous border make strong growth, the shade they throw and consequent drip from the leafage in wet weather on the plants beneath would be almost as harmful as the exhaustion of the soil by the roots. If you wish to save the trees, would it not be better to turf down the portions of the border under the trees rather than have in these starved hardy plants? If you wish to keep the border intact, why not have the trees removed, replacing them with tripods of stout Larch poles, over which to train strong climbers or rambler Roses? If you open a trench all round the tree 3 feet from the stems,

cutting off close every root, possibly so drastic a course would kill the tree, and you could then shorten the heads and cover the stems with climbers. But with the trees removed, soil worked deep and manured, then the Larch poles fixed, climbers would do far better than in starved soil.

**Nectarines cracking** (*Nectar*).—We think it is decidedly a case of scalding the skin of the fruit at the time of stoning. The skin of the Nectarine being smooth and thinner than the Peach makes it more susceptible to this injury. The remedy would be to remove the trellis further away from the glass and to ventilate more freely for a short time at this stage while the sun is hot at midday. When the stoning is over the danger is past.

**Book on fruit culture** (*W. H. S.*).—"The Fruit Garden," a splendid work recently published, dealing exhaustively with the Apple as well as all other fruits, written by George Bunyard, V.M.H., and Owen Thomas, V.M.H., may be had from this office, carriage paid, for 13s. A useful book, devoted to the culture of the Apple alone, is "The Book of the Apple," by H. H. Thomas, which may be had from the Publisher, 41, Wellington Street, London, W.C., price 1s. 2d., post free.

**Walnut trees not fruiting** (*Fruitless*).—It is impossible to say why your Walnut trees do not produce fruit. From what you say of the conditions under which they are growing they ought to do well. From their size they are evidently old enough to fruit well, though it is a tree that fruits better as it advances in age. You might try the effect of root-pruning on one tree. This will check growth and possibly result in the production of fruit, though it will prevent the tree from forming such a fine specimen as it would otherwise do.

**Mulberry tree injured by an application of agricultural salt** (*Lady F. C.*).—The old tree, from the description given, has, we are afraid, suffered serious injury. The hopes of its recovery must rest on whether the roots are strong enough to reassert themselves when growth commences in spring. If they do, it will greatly help the recovery of the tree if a top-dressing of turfy loam (with half a gallon of bone-meal added to every barrow-load) is placed over the roots on the surface as far as the branches extend and about 4 inches deep. In the meantime the best thing to do will be to give the tree two or three good soakings of clean water as soon as possible. This will be sure to wash away some of the saline properties left about the roots.

**Nectarine tree unsatisfactory** (*J. Heap*).—Judging by the texture and appearance of the leaves, we conclude that your tree is in feeble health and not strong enough to properly nourish and mature so heavy a crop. This, we think, is the cause of the fruit being small and of imperfect flavour. The spots on the leaves are what are termed sun spots, and are caused by a sudden burst of hot sunshine striking on the leaves while they are damp and before adequate ventilation has taken place in the morning. Sometimes the same effect is produced by the over-application of an insecticide or a fumigating preparation. Your best remedy is to replant your tree this autumn in new turfy soil, so as to infuse new strength and vigour into it, and to avoid overcropping in future.

**Fruit growing on chalk** (*B. T. F.*).—Our knowledge of the Chiltern Hills is too limited to enable us to advise you as to a good position there for fruit growing. Apart from having a suitable site, it is also needful to be near a railway and a good market. These are important considerations. As to what fruit will grow well on chalk, we find in all directions almost every description of hard fruit, Apples, Plums, Cherries and bush fruits do well. Some of our great Kentish and Sussex fruit nurseries are on chalk, and yet they produce fine growth and superb fruit. Naturally, much depends on the shallowness or depth of the surface soil before the chalk base is reached, but even then the surface is full of carbonate of lime. Pears probably are the least satisfactory fruits if the chalk base is near the surface. Look well about your district and note how fruit trees thrive.

## MISCELLANEOUS.

**Peat moss and horse manure for Mushroom-growing** (*H. and S.*).—This has been frequently tried, and, as far as we know, always without success.

**Keeping gold-fish during the winter** (*Weybridge*).—The best plan to adopt with the gold-fish will be to remove them from the outdoor tank on the approach of frost and place them in a tub of water in a cool greenhouse or dwelling-house; then place them outside again when danger of frost has gone.

**Climbers for a garden screen** (*D. C.*).—The following climbers will be suitable for your screen: *Jasminum nudiflorum*, *Lonicera japonica*, *L. j. reticulata*, *Clematis montana*, *C. Viticella*, *C. Jackmanii*, *Rose Dorothy Perkins*, *R. Hiawatha* and *R. Tea Rambler*. You might use a mixture of these or select any one and use that alone.

**Painting the insides of plant-tubs** (*H. E.*).—It is not wise to paint tubs inside in which plants are to be grown, and probably Stockholm tar would be quite as detrimental. The best plan is to slightly char them. This is easily done by giving the wood a painting over with ordinary petroleum and then placing a handful of lighted shavings or paper inside. When this is blazing, roll the tub slowly along on the ground until the whole of the inner surface is charred and blackened; then turn

the tub upside down and thus extinguish the flames. Tubs treated thus and painted or tarred outside will last for a long time. Care must be taken not to burn the wood much during the charring process.

**Liming a garden** (*G. H. Rippling*).—As your garden has been some twenty years in course of formation, we should say a dressing of lime would be very beneficial. You can, however, ascertain whether lime is needed by a very simple chemical test. Take ten or twenty small samples of the soil from different parts of the garden and mix them together; then place a small sample in a tumbler and pour on it a wineglassful of muriatic acid. If the liquid fizzes and bubbles freely, the soil may be taken to contain a sufficiency of chalk. If it is necessary to give a dressing, this should be done in the winter months. Slaked lime should be used at the rate of 6oz to the square yard.

**Learning market gardening** (*B. W. N.*).—The conditions under which market gardening is conducted in this country differs greatly, because of diverse soil, climatic conditions and labour, from the conditions which prevail in British Columbia. To get needful information concerning those conditions in that colony your best course would be to write to the Agent-General's Office for British Columbia, Victoria Street, Westminster. If you resolve to start as a market gardener here, we should strongly deprecate your attempting to do so from mere book knowledge. It really needs practical training in a market garden for a few years and some practical experience in market selling to fit anyone to start in such a business. However, you may get from the Publisher, 17, Farnham Street, "London Market Gardens," price 1s. 2d. post free, and from the Publisher, 41, Wellington Street, Strand, "Fruit Farming for Profit" and the "Book of Market Gardening," 2s. 9d. each, post free.

**Laying out a garden** (*Landseape*).—We have numbered the more important spaces to which you refer and give you some suggestions, but it is by no means an easy task to advise in the case of a site of which we have no knowledge. Could we have seen the spot we should have been in a position to give you more definite advice. The position marked No. 1 would be best if grouped with flowering shrubs such as *Rhododendrons*. No. 2 space could be levelled up and made into a Rose garden, arranging and planting the beds with one variety only. At the house-side a pathway would appear necessary and possibly a narrow border for showy flowering plants. The No. 3 plot could be devoted to grass with choice conifers here and there and a variety of beds filled with choice herbaceous things and bulbous plants, the No. 4 position being devoted to a rock garden extending to the summer-house if need be. As you are willing to pay a fee, cannot you get advice on the spot?

**Removing "fairy rings" from a lawn** (*Salop*).—To remove "fairy rings" from lawns, water the rings, especially on the outside edge, with a solution of sulphate of iron. Dissolve 3lb. of sulphate of iron in 10 gallons of water and use it when the ground is damp. If the turf is hard, loosen it with a fork previous to use. It will probably be necessary to repeat the watering two or three times at intervals of a fortnight. Another way to clear the ground is to dig out a trench 1 foot deep where the turf is affected, fill up with new soil and return. Well-rotted farmyard manure forms as good a dressing as anything for lawns, while malt-dust, bone-dust, leaf soil or sea-sand are also good. If the ground is poor you cannot do better than use farmyard manure now and a mixture of malt-dust and sea-sand next April. The latter should be sown thinly during damp weather. Soot is also an excellent manure for lawns, and may be used two or three times during the year. It should be sown during wet weather. An index is always published at the end of each year to articles and notes which appear in THE GARDEN.

**Gold-fish dying** (*W. E. M.*).—The disease you mention as having attacked your gold-fish has been frequently noted. It is difficult to account for its appearance, but it may have been introduced with the fish and been practically dormant until the fish were removed to another tank where conditions may have been more favourable for its development. There is really no reason why the Water Lilies should not thrive in your tank, providing they were transplanted carefully. The death of the Apogoneton is probably due to transplanting. It is a good plan with both new and old tanks to change the water frequently, especially where it remains at all stagnant. Whenever possible, it is advisable to allow the water to run continually in and out of the tanks. It is quite probable that your Lilies will improve next year, especially if you give them a little new loam before they commence to grow next spring. The cement ought not to have had any injurious effect on the plants, though a lot of lime in the water might affect the fish. The Lilies ought to thrive in either rain or your well water, as they thrive alike in districts where water is comparatively free from lime and where lime is prevalent. We advise you to run the water out of the tank, clean it well and refill. Any fish that appear to be free from disease should be kept apart from infected ones. Next year it will be advisable to change the water at least once a fortnight if you cannot let it run in and out continually.

**Names of fruit.**—*W. Martineau*.—1, King Harry; 2, Reineette du Canada; 3, Cox's Orange Pippin; 4 and 6, Lamb Abbey Pearmain; 5, Emperor Alexander; 7, Blenheim Orange; 8, King of the Pippins.—*R. Eddy*.—Allen's Everlasting.—*M. Bavin*.—1, Wellington; 2, Winter Quarrenden; 3, Annie Elizabeth.—*Reader*.—1, Oslin; 2, Cornish Gilliflower; 3, King of the Pippins.—(*Miss*) *E. A. Perkins*.—1, Annie Elizabeth; 2, Belle Dubois; 3, Newton Wonder; 4, Pickering's Seedling; 5, Golden Noble; 6, Golden Spire.

**Names of plants.**—*Jim*.—1, *Salvia Grahamii*; 2, *S. coccinea*; 3, *Azalea caracasavica*; 4, *Erigeron mucronatus*.—*Mrs. May*.—*Sedum reflexum* var. *monostachyum*.—*J. T.*.—1, *Cupressus lawsoniana* aurea; 2, *Thuja orientalis* filifera; 3, *Picea excelsa* var. *dumosa*; 4, please send when the plant is in flower; 5, *Cupressus lawsoniana* erecta viridis; 6, *C. obtusa*; 7, *Thuja orientalis*; 8, *Cupressus lawsoniana*; 9, *C. (Retinospora)* pisifera squarrosa; 10, *Juniperus communis* var.; 11, *Cistus* species; 12, *Lycium chinense*; 13, *Wayfaring Tree* (*Viburnum Lantana*).—*J. E.*.—1, *Cotoneaster frigidus*; 2, *Taxus baccata fastigiata* aurea; 3, *Thuja occidentalis*; 4, *Abies nobilis glauca*; 5, *Thuja orientalis* aurea; 6, *Cupressus lawsoniana*; 7, *Taxus baccata* variety.—*Marland*.—*Artemisia lactiflora*.—*Frederick Parks*.—1, Cannot name without flowers, probably *Salvia* species; 2, *Berberis vulgaris*.—*Charles F. Webber*.—*Symphoricarpos orbiculatus*.

## SOCIETIES.

### COLCHESTER CHRYSANTHEMUM AND FRUIT SHOW.

THE annual exhibition in connexion with this society was held in the Corn Exchange and a portion of the Town Hall on the 14th inst. The principal feature of this show is the splendid array of hardy fruit and the great interest displayed by amateurs, and the society is most fortunate in having such an enthusiastic horticulturist as chairman in Mr. O. G. Orpen, the eminent amateur rosarian, and a good committee.

Groups were excellent and above the average as regards quality, the premier position being obtained by Mrs. de Larpent, Lexden (gardener, Mr. Richardson), this being beautifully arranged with a splendid lot of plants of incured blooms and singles at the back. Mr. W. Diaper, Colchester, was a good second. The last-named exhibitor had the best plants in bloom, Mr. H. H. Weatherall being second; Mr. Weatherall was first in the smaller class and Mr. Beard second.

**Cut Flowers.**—In the Japanese section Miss Willmott, V.M.H., Warley Place (gardener, Mr. Preece), was an easy first with grand blooms, the best being F. S. Vallis, Lady Talbot, Reginald Vallis, President Viger, Bessie Godfrey and Leigh Park Wonder. Miss Willmott also exhibited the best bloom in the show, taking the National Chrysanthemum Society's silver medal with F. S. Vallis; W. E. Eyre, Esq., Braintree (gardener, Mr. Doig), was an excellent second, having fresh flowers of good size and quality. In the incured section Miss Willmott was first with a beautiful stand, the best blooms being Duchess of Fife, Mildred Lynne, Daisy Sonham and Embleme Pottevene; W. E. Eyre, Esq., was a close second. For singles Mr. Fincham, Colchester, had splendid flowers, Mr. P. Wolle being second. In the smaller class for amateurs C. Portway, Esq. (gardener, Mr. Stock), was first and H. G. Tetley, Esq., Braintree, second. In the incured section Messrs. Portway and J. Arnold were the leading exhibitors.

**Dinner Tables, Vases and Baskets.**—There was a most spirited contest in these classes, and no less than eleven tables were shown, Miss C. F. Harwood, Colchester, being first with a delightful arrangement of Mme. A. Chateau Roses, Lilies of the Valley and autumn foliage; Mrs. H. Turner, Bures, was second, and Mrs. F. Chapman third. Mrs. F. H. Cooke, Birch, was first for baskets, Miss Harwood second, and Mrs. Butcher, Ipswich, third. Miss H. Seabrook, Tolleshunt d'Arcy, and Mrs. Butcher were equal in the vases, which were delightful. For a distinct floral design Mrs. O. G. Orpen, Hillside, West Bergholt, was first with a very choice arrangement of Tiger Lilies and Lilium Harrisii, with Croton foliage forming a cross on a floral base, which was much admired; Mrs. C. E. Rice of Colchester was second. R. G. Francis, Esq., was first with splendid Violets.

**Fruit.**—For Grapes the Hon. W. Lowther, Campsea Ash, Wickham Market (gardener, Mr. Andrews), was an easy first with fine bunches of Black Alicante, A. T. Osborne, Esq., being second. The last-named exhibitor had the best bunches of Muscat of Alexandria. For the best collection of Apples (cooking varieties) the Hon. W. Lowther was first, having very fine Bramley's Seedling, Lane's Prince Albert, The Queen and Emperor Alexander; this class contained the best dish in the show, viz., Peasgood's Nonsuch. The second award was secured by Miss K. M. Courtauld, Colne Engaine, who had very fine examples of Gascoyne's Scarlet, Warner's King and Peasgood's Nonsuch. In the smaller class J. L. Godlee, Esq., Wakes Colne, was first and E. F. Baggis Rolfe, Esq., Warmingford, second. The Hon. W. Lowther had the best lot of Peasgood's Nonsuch in a class for these, J. L. Godlee, Esq., being second. Mr. Bullock of Colchester had the best Blueheims, S. F. Hurnard, Esq., being second. The first prize in the class for a collection of late dessert varieties was secured by Miss K. M. Courtauld (gardener, Mr. Barthing), O. G. Orpen, Esq., Hillside, West Bergholt, being a close second. For a collection of Pears the Rev. R. W. Chilton, Warmingford Rectory, was first with grand fruits, and for the smaller collection the Hon. C. Hanbury was first and the Hon. W. Lowther second. Mrs. H. de Larpent, Lexden, had the best Doyenné du Comice, this also being the best dish in the Pear classes, the Rev. R. W. Chilton being second. The best lot of cooking Pears came from Mr. W. Strowgler, Colchester.

**Vegetables.**—The best collection in the large class came from the Right Hon. J. Round, Birch Hall, Colchester (gardener, Mr. H. Bishop), the Hon. W. Lowther being a close second and Mrs. S. Webb third. Messrs. Strowgler and Harwood were the leading exhibitors in the order named in the class for six varieties.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE WINTER TREATMENT OF OLD FRUIT TREES.

IN thousands of old orchards and gardens all over the country fruit trees may be found whose condition is most deplorable and which renders them veritable cumberers of the ground. Probably in many instances the best course to adopt with such specimens would be to dig them out and burn them; but this is not always desirable, nor is it altogether necessary, especially if the varieties include such good old favourites as Apples Blenheim Orange and Ribston Pippin or Pear Williams's Bon Chrétien, as it frequently happens that they may be induced to once more produce good crops of fruit of excellent quality by the expenditure of a little time and money.

There is no better time than the present for the overhauling of such trees, and as work is usually not very pressing in the garden at this period, the labour may be well expended in this direction. The branches will be the first portion of the tree to attend to, and usually with neglected specimens these will be found in very bad condition. The growths will be overcrowded; canker, American blight, moss and lichen will probably abound; and possibly some of the wood will be dead. Overcrowding can, of course, be comparatively easily remedied, yet it must be done with intelligence and care, else more harm than good may accrue. The first growths to be removed are any that are dead or badly infested with canker or American blight, following with those which have been allowed to cross and chafe each other. When all such have been got rid of, it is probable that the tree will need very little more thinning; but should it still remain too crowded, the oldest and most worn-out branches should be taken out next. In the removal of growths care must be taken to cut down quite flush with a main branch, and in the case of dead shoots the cut must be made well into live tissue, the wound in either case being pared over smoothly with a sharp knife and then coated over with coal tar, taking care to keep this off the surrounding bark.

Any canker wounds that remain must be carefully pared out with a sharp and strong knife, cutting well into live wood, and these must also be painted over with tar, preferably Stockholm. Bad patches of American blight may be dealt with in the same way. Where moss and lichen are present these must next be dealt with, and where they are at all dense they should be scraped off, together with any loose and dead bark, using a blunt knife or scraper for the purpose. After this scraping and cleaning give the tree a thorough syringing or spraying with the

well-known Caustic Winter Wash, after which it will have a clean and much-improved appearance. Previous to the spraying, all wood and rubbish removed from the tree should be taken away and burned, as thereby any insects, eggs or fungoid germs that may be present will be destroyed.

Having devoted so much attention to the branches, we must next turn to the roots, and it is in the treatment of these that the most good can be done. If possible, the soil or turf should be entirely removed to a depth of 4 inches from the trunk outwards, about as far as the spread of the branches (taking care not to injure the roots), replacing it with some well-chopped turfy loam. Where it is impossible to remove the old soil as advised, much good may be done by forking it up and placing a 6-inch-thick layer of the new soil on top for the same distance from the stem. After the new soil is placed in position, make up a mixture of the following manures: Superphosphate of lime, 10lb.; nitrate of potash, 5½lb.; nitrate of soda, 7lb.; and sulphate of lime, 7lb., and spread this evenly over the surface at the rate of a quarter of a pound to every square yard. This mixture may either be given now or early in the spring, and it is specially recommended for trees that are subject to canker.

Another point not very well known in the treatment of these old trees is the application of liquid manure to their roots during the winter months. This may seem contrary to general ideas, but it has been the means of putting new life and vigour into many an old and apparently worn-out tree. It may be applied strong without any fear of it doing harm.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

\* \* The dates given below are those supplied by the respective Secretaries.

December 8.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m. Lecture at 3 p.m., by Mr. D. B. Crane, on "Chrysanthemums." Admission 2s. 6d. Royal Horticultural Society's Hall, Vincent Square, Westminster.

December 9.—Perpetual-flowering Carnation Society's Show, 1 p.m. to 5 p.m. Admission 1s. Royal Horticultural Society's Hall, Vincent Square, Westminster.

South-Eastern Agricultural College.—At the recent examination held by the University of London, the following students of the South-Eastern Agricultural College, Wye, presented themselves, and all three were successful in obtaining the B.Sc. (Agriculture) Degree: C. J. Alexander (Kent), W. G. Burgess (Surrey), and R. V. O. Hart-Synnot (Ireland).

**Potatoes in Great Britain.**—The preliminary statement regarding the estimated produce and yield per acre of Potatoes and other root crops has now been published by the Board of Agriculture and Fisheries. The estimated total produce of Potatoes for the current year is 3,919,798 tons as compared with 2,977,485 tons in 1907. Of these England heads the list with 2,719,539, Scotland and Wales following in the order named with 1,048,559 and 151,700 tons respectively. In England this year 391,083 acres were devoted to Potatoes as against 381,891 in 1907, the figures for Scotland and Wales being 143,692 and 27,330 as compared, respectively, with 138,888 and 28,141 acres last year. The average estimated yield per acre for 1908 is: England 6.95 tons, Scotland 7.30 tons, and Wales 5.55 tons, the average of ten years being, respectively, 5.75, 6.03 and 4.99.

**Pear Dana's Hovey.**—This is a rather small, russety Pear, but of soft buttery flesh and very pleasant sweet flavour. It is by no means new, as it has been grown in various parts of England for some years. On stiff soils it is liable to come gritty, but on drier soils and worked on the Quince stock the fruits are sweet and very pleasant eating. It is a midwinter Pear, as the fruits often keep well till January. For some reason or other it has not previously been sent to the Royal Horticultural Society's fruit committee. It was so much liked that on the 24th ult. it received a practically unanimous award of merit. Shown by Messrs. James Veitch and Sons, Chelsea. The variety is said to have been raised by Mr. Francis Dana of Massachusetts, and by him named after Mr. C. M. Hovey of Boston.

**A home-made fruit preserve show.**—The showing of various American and home-made preserves before the Royal Horticultural Society's fruit committee from time to time led, at a recent meeting of that body, to the strong expression of a wish that a special exhibition, with classes and prizes to suit all sections of competitors, should be annually instituted for the purpose of affording to this description of home industry all possible encouragement. At present this form of industry is largely in the hands of traders who, as a rule, do their work remarkably well. But all the same, it is felt that to every form of preservation of fruit or vegetables as food by private persons, and especially by the working classes, the fullest aid should be given. The Colonies having had several shows specially devoted to their products, and no material benefit to them having resulted, it is worth while turning to home-workers and giving them every possible assistance. On the 24th ult. there was an interesting exhibit of vegetable chutney in bottles from Buckinghamshire, and a large one of fruit products from New York.—D.

**Colonial and home-grown bottled fruit show.**—A splendid exhibition of Colonial fruits and home-bottled British-grown fruits was opened by the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., in the Royal Horticultural Society's Hall, Vincent Square, Westminster on the 26th ult. The exhibition was held under the auspices of the Royal Horticultural Society, and proved a great success. British Columbia was represented by a huge and beautiful display of Apples. The Government of Ontario sent Apples, Pears, Grapes and a large consignment of vegetables, the latter comprising Celery, Potatoes, Parsnips, Beetroots, Cabbages, Cauliflowers, Carrots and others, the quality, however, after making due allowance for the long journey, being much inferior to exhibition vegetables staged in this country. A huge collection of Apples, some Pears and bottled Gooseberries, Currants, Cherries, Plums and Raspberries were well shown by the Government of Nova Scotia. The Botanic Section of the Imperial Department of Agriculture, Dominica, staged an excellent group of West Indian fruits such as Limes, Cocoanuts, Oranges, Shaddockes, bottled Guavas

and Bananas. The West Indian Produce Association, Fenchurch Street, London, E.C., also had a very attractive collection of West Indian produce. The New Zealand Government sent a consignment of Apples that had been preserved by cold storage. Among the home-bottled British-grown fruits some attractive displays were seen. Lady Algernon Gordon-Lennox sent a beautiful collection from Broughton Castle, where her ladyship established a small factory in the village last year for the purpose of encouraging the culture of fruit among the cottagers. Mr. W. Poupart, jun., and Miss Edith Bradley also staged good exhibits. Other prize-winners in this section were Miss C. Jones, Orpington; Mrs. W. H. Plowman, Westminster; and Mr. G. H. Jolly, Long Acre, W.C. For home-bottled vegetables (amateurs), Mrs. V. Banks, Park Street, W., and Mrs. W. Parlour, Croft, Darlington, were the prize-winners; and for a collection of fruit jellies and fruit cheese, Mrs. Banks and Miss M. G. Thompson, Potter's Bar, took the prizes. For a collection of jam Mrs. Banks and Miss Thompson were equal first, and Mrs. E. J. Beckett, Aldenham House Gardens, was second.

**Dundee allotment gardens.**—The plot-holders of the Kinnaird and Stirling Street allotment gardens are concerned at the intention of the Corporation to take the ground for the building of cottages in connexion with a housing scheme they are entertaining. A few days ago a committee of the Council visited the gardens and received the plot-holders, who pointed out the loss they would experience in the event of the gardens being taken over. They also expressed the opinion that other suitable sites could be secured for building. The committee has agreed to have a report on other sites for the houses, so that it is hoped the threatened evictions of the allotment gardeners may not now take place.

## PRIZES FOR READERS. DECEMBER.

THE BEST EVERGREEN SHRUBS  
FOR WINTER EFFECT AND HOW  
TO GROW THEM.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF A-GUINEA  
are offered for the best essays on the above  
subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Thursday, December 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE

(The Editor is not responsible for the opinions  
expressed by correspondents.)

**Flowers out of season.**—We had on the 25th ult. several Azaleas (mollis) in flower,

also Azalea sinensis, Rhododendron dahuricum, R. ponticum (also several plants of R. noble-anum, which, of course, is not out of season), Erica codonodes (lusitanica), Primroses (blue, yellow and white), many Roses and Fatsia (Aralia) japonica variegata, sprays of which were exhibited at the meeting of the Royal Horticultural Society on the 24th ult.—W. A. Cook, *The Gardens, Leonardslee, Horsham, Sussex.*

**Perpetual-flowering Carnations out of doors.**—Your correspondent refers on page 583 to a very interesting point on this plant, for although most of the varieties of the perpetual-flowering Carnations have been grown out of doors at Messrs. Hugh Low and Co.'s Bush Hill Park Nurseries during the last winter, thus proving them quite hardy, I think your correspondent is probably the first to grow them in a dwelling-house. It would be interesting to hear if other readers of THE GARDEN have succeeded in this way. Your correspondent's success was possible because he started with good plants in 6-inch pots. I would not recommend the experiment with small plants.—L. J. C.

## Placing slates under fruit trees.

May I be allowed to say a word in favour of the practice of placing slates or other material under fruit trees with a view to curtailing their roots? which practice your correspondent Mr. A. H. Pearson so thoroughly condemns in your issue of the 14th ult. I do not suppose for one moment that any advocate of the method would adopt it in growing Apple trees under the conditions of soil which prevail in Messrs. Pearson's nurseries, as doubtless those conditions are favourable to the cultivation of fruit trees; otherwise they would not be grown there. Mr. Pearson appears to have fallen into the practice of condemning customs or methods which are of no apparent benefit in their own circumstances, therefore must of necessity be useless everywhere else, quite regardless of the difference of soil and other conditions which exist in different places. I wonder if Mr. Pearson ever had to grow fruit trees on walls in strong clay loam, with clay to the depth of 4 feet to 5 feet, into which the roots could spread, causing annual shoot growths of anything up to 6 feet in length; or did he ever attempt to root-prune such trees. If he were ever to attempt such a task he would perhaps realise that the plan he so disagrees with can be of some utility. To thoroughly root-prune trees of ten years' growth or so is no light matter under such circumstances, as a trench of 2 feet to 3 feet in width must be dug out to allow an excavation sufficiently large to be made, to get at the roots under the tree, right back to the wall; whereas if the tree is resting on a base of some material impermeable to roots of 3 feet or so square, the labour involved in the operation is considerably diminished, as the necessity for completely undermining the tree is obviated, and directly the edge of the slate, or whatever else is used, is reached all round, one can rest assured there are no other roots that require to be cut through. We have in these gardens several young Plum trees on a wall 6 feet high, planted in a border about 3 feet wide, bounded by a hard garden path. These trees were root-pruned two years ago as well as possible under the existing conditions. One side of the path was taken up to give the necessary room to work. During the present year they have again made shoots of 5 feet in length, despite the dry season. Had the plan I am writing about been adopted when they were planted, the labour of keeping them efficiently root-pruned regularly, till they had acquired a fruiting habit, would have been very much reduced, as will be apparent to anyone who has ever done any root-pruning. Personally, I consider the practice to be of the greatest utility, especially in the case of Peaches and Nectarines where their cultivation has to be attempted in such soil as I have described, and provides a means by which failure may be turned into success, proper attention being given to other matters. Mr. Pearson's simile *re live eels*

in a frying-pan and the roots of fruit trees, taken in connexion with the kind of soil mentioned above, savours too much of the hypothetical.—R. W. DEAN, *Audleys Wood Gardens, Basingstoke.*

### What amateurs have done for the garden.

—The death of Mr. Martin Smith of Hayes, Kent, removes from horticulture one of its leading amateur florists. Although keeping a staff of gardeners, Mr. Smith was a devoted florist, and the work he did personally among Carnations will live long after him. It is to men such as Mr. Smith, the Rev. Mr. Horner, the late E. S. Dodwell, Samuel Barlow and others who, while having ample means, were or are devoted florists, that floriculture owes so much. These men all found in its pursuit a delight and an attraction that were to them of the strongest.

Happily we have some other good amateur gardeners and florists like them yet; but there is in such work ample room for many others to find enjoyment. Necessarily the amateur who embarks in the cultivation of any one or more kinds of flowers should first fully realise what each kind needs, and, having done so, then proceed to work for improvement and development in such directions as may seem most desirable. The great florists' flowers have been Auriculas, Polyanthuses, Tulips, Pansies, Roses, Carnations, Dahlias and Chrysanthemums; but the work of the old florists was largely limited to the four first-named and Carnations and Dahlias. Of course, any description of flower may be regarded as a florists' flower in the old or recognised sense, if it be specially made the subject of florists' labours, in its development, in the same way that others have gone through the mill. So far as Tulips, show Auriculas, Pansies, Roses, Carnations, Dahlias and Chrysanthemums are concerned, while new varieties having some slight difference from others may be raised, yet in form, outline or other florists' properties no advance is now being made. In such things as Pelargoniums, Fuchsias, Petunias, Verbenas, Begonias, Gloxinias, Cyclamen, Chinese Primroses, Cinerarias, Calceolarias and some others, all, to some extent, regarded as florists' flowers, there is little or no room for improvement in form or beauty. Hence, when so much that is florally perfect has been accomplished, it is but wasting time to work where the work is practically done. The old gold-laced Polyanthus

was once an excellent florists' flower, but in Cheshire Favourite and Exile were found practically perfection, and not a seedling so good as either has since been raised; but the border Polyanthus and the border Auricula offer to any enthusiastic florist a fair field for labour. Probably no plants more deserve such devotion; none would better repay it. Among the border perennials, the Phlox, in spite of all that has been done, offers a good field for further labours; and possibly also does the Sweet Pea, although its field of operations, because there are so many workers in it, is materially limited. If Chrysanthemum raisers could furnish a superior race of singlea they would render good service. Myriads so called and named are devoid of form and beauty, are really not singles, and have colours which are detestable.—A. D.

## MR. HARRY J. VEITCH'S GARDEN.

A BEAUTIFUL garden has developed during the past ten years at East Burnham Park, Slough, a fact which will surprise no one who is aware that the place belongs to Mr. Harry J. Veitch. To the satisfaction of everyone except himself, circumstances have forced Mr. Veitch back to the control of the great nursery at Chelsea; but, fortunately, the principal work in the garden of his charming Buckinghamshire home had been done before the crisis which brought about his return to Chelsea arrived. I cannot enter upon a full description of the garden, but I may

THE LATE MR. MARTIN E. SMITH AND HIS GARDENER, MR. CHARLES BLICK, ADJUDICATING ON SEEDLING CARNATIONS.

mention one or two features that must be of interest to your readers.

*The Rose Garden.*—Apart from the question of design, the leading principle is one variety in a bed. In the case of all beds (not those of Roses alone) Mr. Veitch is against mixtures. He holds that differences of height and habit are sufficient in themselves to condemn the mixing system. The pergola in the Rose garden is somewhat uncommon. The pillars are thick, square ones of burrs. Timber is only used at the top, and consists of the usual rustic material. The sides are quite open. The pergola is well covered, and is a very handsome feature.

*Bulbs in the Grass.*—Throughout all the principal parts of the flower garden the plan is adopted of planting up the grass with bulbs. Alongside most of the main paths there is a broad

belt of grass that is kept free, and is closely mown and trimmed in the orthodox manner, but beyond this the turf is all filled with bulbs. The consequence is that there are many series of charming colour expanses, especially in late winter and early spring. There were groups of Cyclamen in bloom in September.

*Portulacas in the Rockery Paths.*—As my visit was paid at mid-September the rock garden was naturally far from being in full beauty, but it had its interest all the same, and not least in the paths. These are laid with flattish pieces of Portland stone, those in the centre averaging about 18 inches square, and those at the sides half the size or less. A variety of plants find homes in the interstices, but much the most beautiful on this occasion were the Portulacas. They were really lovely, and I commend the use

of these beautiful and inexpensive annuals for the same purpose elsewhere. They were mainly sown near the edges, and the brilliant flowers of yellow, carmine, rose and other colours made a glittering border to the walks.

*The Flame Nasturtium.*—Near the front door there was a belt of *Tropaeolum speciosum* in full bloom, making a most glowing picture, and even suggesting (if I may be pardoned the parallel) something of the warmth and cordiality of the welcome which the visitor receives at these hospitable portals. The Flame Nasturtium in the Home Counties! "Why not?" asked the host, smiling. Many people who had tried the plant would only groan at the question. But there it is, full of vigour, quite at home and flowering gloriously. I do not know if it is doing better than usual this year as a result of the heavy summer rains. Perhaps so; certainly it is thriving as well as could be wished.

*The Sub-tropical Garden.*—Some readers will probably remember the sub-tropical gardening that used to be such a feature of Battersea Park twenty-five years ago. Mr. Veitch has revived its glories at East Burnham Park—nay, I think he has done better. So far as I can remember the work at Battersea Park (and my memory seems tolerably fresh) it savoured a little too much of design and was somewhat overcrowded. There is a breeziness about Mr. Veitch's plan which irresistibly reminds one of the manner of the man himself. It is broad, expansive, spacious; in fact, the mind is robbed of all sense of a set design in it. The garden is on the out-skirts of the park,

beyond the rock garden, of which it is, in a sense, a continuation. It is the end of the gardening and merges almost imperceptibly into the park. The beds are large and there are broad belts of turf around them all. The dominating one in September was a fiery mass of *Kniphofia aloides* Mrs. Charles Mason in front of bushes of Golden Elder and Purple-leaved Nut. The effect was superb. Another splendid bed was one of *Nicotiana sylvestris* (the white Tobacco), with a belt of the annual Prince's Feather (*Amaranthus hypochondriacus*) in front. Being in semi-shade the flowers of the Tobacco open early. Among foliage beds was one of the Grass named *Eulalia japonica gracillima* and another of the common Cardoon; both were very effective.

WALTER P. WRIGHT.

## THE FLOWER GARDEN.

### SUITABLE PLANTS FOR EDGINGS.

**N**OW that alterations are in full swing in our gardens, it may be useful to draw attention to those plants whose habits render them suitable for forming edgings to beds or borders. Too frequently one sees the useful Box monopolising all the edges, with the result that many other useful and interesting plants are excluded. It is only intended to deal here with those edgings which may be regarded as permanent; those formed for summer effect only can be better treated in the spring months.

Among those plants of a shrubby nature suitable for edgings, the pretty little *Euonymus radicans* must take a foremost place, and, as it will thrive well under trees, it has an extra claim to our consideration. The type has green leaves, but there is a lovely silver variegated form which makes an equally good edging. The growth of both is more rapid than that of Box, and, as they will stand clipping well, they may be regarded as splendid edging subjects.

Where the soil is comparatively light and free from lime, some of the Heaths make charming and uncommon edgings. Provided a fair amount of leaf-soil can be incorporated with the natural ground, peat will not be necessary. Of course, these plants will not stand clipping the same as Box or *Euonymus*, but they may be kept within bounds by annually removing the old flowers with a portion of the wood, this being done as soon as the flowers have faded. Among the best for this purpose are *Erica carnea*, *E. cinerea*, *E. mediterranea hybrida*, the common Ling (*Calluna vulgaris*) and St. Dabeoc's Heath (*Daboecia polifolia*).

For a hot position where the soil is sandy and dry the pretty little Rock Roses are splendid. The type is a native of this country and is known botanically as *Helianthemum vulgare*. It grows but a few inches high and gives its yellow flowers in abundance during the summer months. Varieties with scarlet, orange, crimson and white flowers may also be obtained, and some also have double blossoms. The growths should be shortened back after flowering is finished.

The common St. John's Wort (*Hypericum calycinum*) forms a most attractive edging during the greater part of the year, and, like *Euonymus radicans*, will thrive in moderate shade. This also needs its growth shortened back after flowering. The smaller Periwinkle (*Vinea minor*), is another excellent edging subject for a shady position, its dark green foliage and bright blue flowers rendering it most attractive. With the exception of the *Euonymus*, all the plants mentioned above are best when allowed to form an edging 9 inches to 1 foot wide, but the *Euonymus* may be kept as narrow as Box.

Among herbaceous subjects mention may be made of *Pinks*, *Armerias*, *Cerastium tomentosum* and *Saxifrages* of various sorts, all of which must be kept in bounds by an annual lifting and replanting. With so much material to select from there is little excuse for monotonous effects, and still less for the use of ugly dead edgings which have little beyond durability and cleanliness in their favour. F. W. H.

### MOISTURE AND ALPINE FLOWERS.

It is unfortunate that there are so many people under the belief that alpine flowers are necessarily denizens of dry and arid mountains, thriving best when in the crevices of bare rocks, deriving almost all they want from the air and basking all the summer days in the brightest of sunshine. These have not learned that the number of alpine flowers which flourish under such conditions is but small and that many require for their happiness and welfare plenty of moisture at all times. A *Sempervivum* or a *Sedum* may delight in almost unbroken daily

sunshine, and may flourish perfectly in a dry corner between two rocks; but this treatment will be fatal to the vast majority of alpine, which require a fair amount of moisture if they are to be long-lived and happy. One sees such things constantly disregarded, although, of course, the offenders are generally beginners. Yet "old hands" may at times be observed planting some moisture-loving subjects far up on the rockery, where they can only make a struggle to exist—a struggle which generally ends in defeat and the loss of the plant. To plant, say, *Primula rosea* far up on the rockery in a dry and sunny place is simply to court its destruction, while there are also many beautiful subjects, which, while they may live high up on dry soil, would simply revel were they treated to a considerable amount of moisture at all times.

One cannot well give a list of such subjects, for the fact is that no such list would be nearly complete. There are many experiments yet to be made, and there is also this circumstance to be taken into account—the plants require more moisture in one district than in another, this depending upon the amount of the rainfall. I am thus making this note more suggestive than exhaustive, and the grower will be wise to do some experimenting upon his own account.

Among the *Primula* species we find a good many examples, as may be expected when we see the behaviour of even our common wild Primrose when on a dry hedge-bank compared with one "by a river's brim," which is free and magnificent as compared with that which is starved and dry. But there are species which need even more moisture than this and which delight in such a place that their roots are constantly within reach of water. *Primula rosea* is a case in point, and it is never really happy except when its conditions are such that it can have water in abundance at all times. And, curiously enough, some of these plants are much harder in water than they are when under dry conditions. This is probably because they are thus more vigorous and better able to stand hardships. Thus, for example, *Primula Poissonii* is much harder in wet places than in dry, and even in boggy ground covered at times in winter with almost 2 feet of water, caused by the flooding of the adjacent stream, it is much harder and more flourishing than in a drier place. In dry soil it will only give a short flower-stem some 6 inches, 8 inches or 12 inches high. In moisture it will run up to 1½ feet to 2 feet and live for years.

*Acænas* are other plants which seem to like moisture, although they will thrive in a dry place also. The finest example of *A. microphylla* I ever saw was in a low boggy place in a garden, where it had covered a space some yards across with its bronzy leaves, all brightened up by the crimson spines on the flower-heads. Compared with a similar plant in dry soil it was as the sun to the moon in brilliancy.

To take another example, the Spring, as well as the Summer Snowflakes, are much finer in a moist place than in a dry, and these are followed in this preference by some of the *Chionodoxas*, *C. Tmolusii*, for example, which at home flowers amid the melting snow, thriving with a good deal of moisture about its roots and bulbs. *Chrysobactron Hookeri* is another good plant which delights in moisture, although it will grow in the border or the rock garden; while among the *Gentians* we find that *G. Andrewsii* to be long happy needs to be so planted that its long roots can touch the water or be at least within reach of the moisture percolating from it. One can grow the *Calthas* in the border also, but they are never so glorious in their colouring as when within touch of moisture. The lovely *Galax aphylla* is another example, and the exquisite *Linnea borealis*, which is but poor when in dry soil, will cover a good space with its tiny leaves and exquisite flowers in a bog or marshy piece of ground.

Few can grow *Nierembergia rivularis* well, but they would be more successful did they treat it

as a moisture lover. I have never seen this lovely White Cup so charming as in pots set in pails of water so that the drainage of the pots was covered with the liquid. One might go on almost *ad infinitum*; but, as I have already said, this note is merely suggestive, and is written with a view to showing that the cultivator should experiment until he discovers which of his plants require moisture with him and which do not. Of course, this must be done with discretion, as there are some things which do not require or which detest moisture. All plants of a succulent character should be relegated to the drier places, as well as most of those with silvery or woolly leaves, although this rule is not invariable.

In advising experimental work I am also hearing in mind that moisture at the roots is less required in a heavy soil than in a light one, in shade than in sun and in wet districts than in dry ones. S. ARNOTT.

## THE GREENHOUSE.

### LIFTING AND FLOWERING CHRISTMAS ROSES.

**I**T is really most surprising how amateurs with a cool or slightly-warmed greenhouse will worry themselves and also their gardening friends over the attempt to grow plants quite unsuitable for such a structure, and yet at the same time ignore many beautiful and suitable subjects because they happen to possess the good trait of being hardy. One of the best that can be included in the latter category is the Christmas Rose, as *Helleborus niger* and its varieties are popularly called.

There are numerous gardens where a good supply of these plants may be found, and to lift, pot and transfer some of them to the greenhouse is but a simple task. Where plants are not available they may be purchased; but it is well to buy them locally if needed for greenhouse work, as the roots should not be out of the soil for long. As these roots are naturally long, deep receptacles must be used, and unless extra deep pots are available it will be well to rely on small wooden tubs or even lard pails, the latter being obtained very cheaply from the grocer. Of course, a number of holes must be made in the bottom for drainage, and over each of these a good-sized crock must be placed, this usually sufficing for drainage with a little well-decayed manure placed over the bottom of the tub.

Each clump should be lifted with a bountiful supply of soil adhering to its roots, and care must be taken not to break the clump into several pieces. If the plant is a large one, it is highly probable that its mass of roots and the soil adhering to them will almost fill the receptacle; but this does not matter in the least, providing just sufficient room is left to enable the operator to work a little fine soil down the sides of the clump and thus make the whole snug and firm. Give a good soaking with water, and then stand the plant either in the cool greenhouse or in the coolest part of a warm one. Buds will soon begin to push from the crowns, and until they open a light syringing with clear tepid water each morning will greatly assist their development. As the blossoms naturally open outdoors in midwinter, hard forcing or anything approaching it must not be resorted to.

In addition to the old *Helleborus niger* the varieties *maximus* and *major* are excellent, the flowers of these being larger. If the flowers are needed for placing in water they should be cut, not pulled, and the stems slit up at the base for 1½ inch, otherwise they appear to be incapable of absorbing sufficient moisture and, consequently, quickly fade; but treated as advised the blooms will last fresh for several weeks.

## PHOTOGRAPHIC COMPETITION FOR OUR READERS

**W**E have much pleasure in announcing that the first prize in our Photographic Competition has been awarded to Mrs. T. H. Barnard, Kempston Hoo, Bedford, whose picture of a bordered garden path is reproduced in this number, together with a short description of the garden in which it was taken. The second prize is awarded to the picture of a Herefordshire garden that appears on this page, together with a description given by Miss K. D.

## A BORDER OF PICTURESQUE BEAUTY.

THIS photograph (page 599) shows a narrow path in my garden which for three or four weeks in the autumn is quite a picture. The path is about 50 feet long, and is bordered with Aster (*Callistephus*) *sinensis*—mauve is the colour—backed by a hedge of Michaelmas Daisies, chiefly *laevis*, *Novi-Belgii* and *Novi-Angliae* varieties. These are staked with twiggly branches, not bunched up to single posts as is so often the case. The result is extremely attractive, particularly on a sunny morning early in October when multitudes of bees and many butterflies throng the air and flit from flower to flower. At the

## SWEET PEA NOTES.

## CROSS-FERTILISATION OF SWEET PEAS.

**Y**OUR correspondents "A. A. G." and Mrs. G. Leigh Spencer on page 560 mention the presence of small black beetles in the keel of Sweet Peas, and suggest that it might be possible that cross-fertilisation is brought about by them in some way, seeing that they possess wings. Now, I have known about these small beetles for years, and have come to the conclusion that their presence in the keel is of small moment; in fact, I attach so little import-

A STRAIGHT PATH FLANKED WITH HERBACEOUS BORDERS AND YEW HEDGES. SECOND PRIZE PHOTOGRAPH IN OUR PHOTOGRAPHIC COMPETITION.

Pilkington of her garden. A very large number of photographs were submitted for this competition, and among them are several excellent garden pictures that we hope to reproduce later. A number of competitors, who clearly have beautiful gardens, have overlooked the fact that, as a rule, it is impossible to reproduce satisfactorily in a photograph a comprehensive view of a beautiful garden. Had greater attention been given to small pieces of the same gardens, far more satisfactory and pleasing pictures would have been obtained. The photographs from the following are highly commended, and will be reproduced in THE GARDEN in due course: Mrs. J. E. Ward, Mr. Thomas Taylor, Mrs. J. M. New, Mr. W. Virtue, and Miss D. Page-Roberts. We are very much gratified with the result, and hope to have another competition shortly.

end of the border, nearest the building, are two clumps of pink Chrysanthemums. In the transverse border, a glimpse of which is seen under the window, are pink Pompon Chrysanthemums and *Crocus speciosus*.

MRS. T. H. BARNARD.

*Kempston Hoo, Bedford.*

## A HEREFORDSHIRE GARDEN.

THIS is a garden in Herefordshire we rented for several years. The herbaceous border was a constant source of enjoyment, beginning with the bulbs in the spring. The old Yew hedges made a lovely background, though no doubt they drew a good deal of goodness out of the soil.

MISS KATHLEEN D. PILKINGTON.

*Sandside, Thurso, N.B.*

ance to them that I purposely avoided them in my notes when I said that neither insects, wind or any other agency (except human) could bring about cross-fertilisation. It was for this reason: These small beetles could not get into the keel before the flower was properly developed, therefore cross-fertilisation was not possible, seeing that pollination was effected and fertilisation had taken place before or just when the flower was half developed. This, to my mind, is the one main point in the fertilisation of this flower.

I will endeavour to explain in as few words as possible how I have come to the above conclusion. If the flower of a Sweet Pea is cut in two longitudinally just before it is half developed and the stamens and pistil are examined carefully, the stamens will be found to be united by their filaments to form a kind of tube, the anthers remaining free, the ovary running up

this tube formed by the united filaments. Now at this stage the pollen-sacs are just beginning to burst, and the stigma is situated just below the anthers. Examine another flower a few days older in the same manner, and this will be found with the stigma a little longer than the first and embedded in the midst of the escaped pollen and the stigma completely covered with it. At this stage pollination has taken place, and within a few more days the stigma will have extended quite clear of anthers, and fertilisation will have been effected and the pod begun to develop. All this has taken place *before* the flower became properly expanded, and also before the stigma has reached the apex of the keel. After this stage and while the petals are expanding to a fully-developed flower the pod is making rapid progress, and very soon the stigma appears outside the keel. After some days the apex of the pod makes its appearance and the flower gradually dies.

In those cases where the stigma has been seen to protrude outside the keel it is the fertilised ovary which is developing. If this ovary is examined as in the case of the flower longitudinally, the young ovules or seeds will be found to have made some growth.

I must thank the Editor for his kindness in allowing the pages of *THE GARDEN* to be open for this interesting discussion. It has brought to light the opinions of various growers, some for and others against cross-fertilisation, and to a few it still presents a problem of some complexity. To my mind it will not be properly settled until some recognised authority takes it in hand and extends over some years careful observations, with records as carefully made that not a doubt will be cast upon its authenticity.

P. CLAPHAM.

*The Gardens, Brookleigh, Calverley, near Leeds.*

HAVING read several letters in your paper on the fertilisation of Sweet Peas, I think the following extract from the "Life of Charles Darwin," by his son, the present Professor of Botany at Cambridge, may be of interest to your readers: "Papilionaceæ were the first flowers to attract Darwin's attention by their obvious adaptation to the visits of insects, and one of his sorest troubles. The common Pea and the Sweet Pea gave him most difficulty, because as they are as obviously fitted for insect visits as the rest of the order, yet their varieties keep true. The fact is that neither of these plants being indigenous, they are not perfectly adapted for fertilisation by British insects. He could not at that time know that the co-ordination between a flower and that particular insect which fertilises it may be as delicate as that between a lock and its key, so that this explanation was not likely to occur to him. The pollen or fertilising element is in each species adapted to produce a certain change in the egg-cell, just as a key is adapted to a lock. If a key open a lock for which it was never intended, it is an incidental result." A. E. S.

It may interest your readers to know that I also found the little black beetles emerging out of the folded flowers of the Sweet Peas, and concluded that there could be no doubt that they were main agents for the fertilisation of the flowers. On the 14th ult. I picked two bunches of Sweet Peas—Scarlet Gem, Nora Breadmore, Lady Grisell Hamilton and Frank Dolby—very sweet and with very fair stems. The plants have been in flower since June, and they were watered twice in June and July with Nitro-Bacterine, to which I attribute the vigour and long flowering season of the plants. They were sown in pots and planted in clumps of from five to six plants.

FRESHWATER.

I HAVE frequently seen bees and other insects gathering pollen from Sweet Peas, but as fertilisation is effected *before* the flower is properly opened, these cannot effect cross-fertilisation.

A. W. H.

## THE ROSE GARDEN.

### IN DEFENCE OF EXHIBITION ROSES.

AN AMERICAN'S VIEWS.

TO those who have attended any of the National Rose Society's metropolitan exhibitions, and have seen there the thousands of glorious blooms of exhibition Roses, the above title and these notes may seem, to say the least, superfluous. Nevertheless, I am convinced that many beginners and inexperienced amateurs, who do not look upon the Rose simply as an ornamental plant to be grown principally for colour effect and to beautify the garden, but who believe that "the value of the Rose is in the glory of its individual flowers"; in other words, who want the perfect Rose—perfect in form, size and colour—have been prevented from growing the so-called exhibition Rose principally for two reasons, which I will try and give in as few words as possible.

The first is, I take it, the fear of failure, caused by the idea that somehow the name "Exhibition Rose" was given to a class of Roses that were very difficult to grow and were only suitable for the skilled exhibitor. This is an error. The definition given in the National Rose Society's catalogue is as follows: "Exhibition.—That its blooms are sufficiently large, full and well-formed to allow of their being shown singly at Rose shows." That is all, and the growth of the plant has nothing at all to do with it.

As a matter of fact, there are, among the exhibition Roses, some few varieties that are very difficult to grow successfully, but they are generally so noted in the catalogues and may readily be avoided, while the great majority are as safe for the novice to grow as most of the so-called garden Roses, except, perhaps, some of the very strong growers, such as the *wichuraiana* and *Polyantha*.

This may sound like a rather strong statement, particularly as one is apt to see in the gardening periodicals at least two articles in praise of garden Roses to one of exhibition sorts, and I would not like to have anything here written construed to mean that the beginner may expect at the start to be able to grow exhibition blooms up to the standard set by the experienced exhibitor at the Rose shows—far from it; but I do assert most emphatically that, if he will give to his exhibition Roses, and particularly to the preparation and location of his Rose beds, the care that would be necessary to grow successfully the majority of so-called garden Roses, he will be rewarded with blooms that for form and colour will leave little to be desired, though they will probably be lacking in size until study and experience shall have taught him the art of pruning and disbudding more thoroughly. He must not, however, expect that all blooms will come well, but even those that are faulty in shape will, for the most part, compare favourably with the garden sorts for interior decoration. The other reason for the neglect of exhibition Roses (particularly the newer varieties) by those for whom these notes are written is that so much has been said lately of their lack of perfume. Well, if it be really so that any considerable number of the newer exhibition Roses are wanting in scent, perhaps the point is well taken (though we do not give up growing many other beautiful flowers because they have no perfume); but is it so? I must confess that on going carefully over the catalogues and Mr. Mawley's excellent "Rose Analysis," the cause of this general lament still remains a mystery to me.

If by perfume we mean only the attar, or otto, of Roses sent, then I will willingly acknowledge that many of the newer Roses are without it. But surely this is not the only perfume to be prized! If so, why is the Violet or Mignonette so highly esteemed? Is not the fragrance of the Tea Rose and

the perfume peculiar to many another Rose as much a Rose perfume as that of *Rosa centifolia*?

To me the delicate fragrance of such Roses as Bessie Brown, Dean Hole, Mrs. W. J. Grant, Killarney, Joseph Hill and the like is much more delicious than that of the attar of Roses; but of course that is only a matter of taste (and the reader will probably add "very poor taste" when I confess that the scent of Gloire de Dijon, Kaiserin Augusta Victoria, Florence Pemberton, Queen of Spain, &c., are actually disagreeable to me) and I quarrel with no one for having his own choice of perfume; but that is a very different thing from denying any fragrance to those Roses which do not have the so-called Rose scent.

Beyond question, there are some very beautiful Roses that are entirely lacking in scent, but the number is comparatively few; and as there are so many fragrant ones, it seems unfair that these few, beautiful and important as they are, should cause the whole class of newer exhibition Roses to bear the reproach of lacking fragrance.

In conclusion, I wish it understood that in no way have I meant to belittle the wealth of beautiful garden Roses that have recently come among us; there is no question as to their value. The object of these notes is simply to encourage those who, while admiring and loving the exhibition Rose, have felt that it was beyond their skill to grow it, or, having a limited space in which to grow Roses, felt they could not spare any for scentless varieties.

White Plains, New York. A. L. SQUIRE.

### HYBRID PERPETUAL ROSES AS CLIMBERS.

SELDOM do we see this type of Rose treated as climbers, yet they succeed well trained in that way. Some six years ago I planted a number at the back of a wide herbaceous border, training them up Larch poles; in fact, they were the tops of trees with 10 inches of the branches left on next the stem, which have a rustic appearance as well as being useful to train the Roses upon. The spring following the planting the Roses were cut hard back, but since then they have not been pruned at all, except in cutting the flowers, which are most profuse. It is surprising what a quantity of flowers can be had from the strong-growing Hybrid Perpetual Roses growing on the let-alone principle, especially if the roots receive annually a good dressing of farmyard manure carefully dug in without doing damage to the roots.

E. M.

### COLOURED PLATE. PLATE 1362.

#### WEeping STANDARD ROSES.

WITH the advent of the lovely *wichuraiana* Roses weeping trees have had a great development, and it will soon be as uncommon to find a garden without its weeping Roses as without its ramblers on arch, pergola or pillar. The superiority of the tribe named for this special purpose is owing to the great flexibility of their growths, and they are capable of forming a natural drooping tree, which we only find in their rivals the Ayrshire and Evergreen sections. The subject of our coloured plate, Dorothy Perkins, is recognised as one of the very best varieties to form a weeping standard. It will give us its wealth of blooms from July right on to October, and for this reason it is perhaps still the most popular of the group. Not only are the long, drooping growths covered with clusters, but we have enormous bunches of blooms arising right from the very crown of the tree.

In planting weeping Roses it is advisable to procure them as tall in the stem as possible, but it is rarely that they can be purchased with more than a 5-feet to 6-feet stem, although 10 feet to

12 feet would be none too tall. They should be planted as early in the autumn as practicable, and great care is needed to give them a good start. The position must be well prepared. If the soil is good, let it be trenched 3 feet deep and the same in length and width, incorporating some good, well-decayed farmyard manure. The stations for each tree should be prepared fully a month before planting. When planting keep the roots within about 9 inches or 10 inches of the surface, taking care to provide good substantial supports to protect the trees from the violence of gales. The first season after planting little or no pruning is necessary; but the growths may be adjusted by means of a wire hoop placed beneath, so that a uniform head is maintained from the commencement. After a year or two the trees will grow naturally without any artificial aid. As the heads develop in bushiness they should be relieved of some of the oldest growths quite early in the autumn; but the long, young growths should be retained, as they provide us with the grandest clusters of blooms.

There is a growing demand for *wichuraiana* Roses of ordinary standard height, and really useful they are to plant in certain conspicuous angles in the Rose garden where they are thoroughly isolated. These standards are also delightfully displayed in the centre of a bed of dwarf Polyantha Roses, which may either harmonise or form a suitable contrast. For instance, a drooping standard of *Hiawatha* could have as an undergrowth the charming *Eugénie Lamesch*, or use *Alberic Barbier* as a standard and *Perle des Rouges* beneath. In addition to the sorts already named, others that do well in weeping form are *Lady Gay*, *Elise Robichon*, *Edmond Proust*, *Réné André*, *wichuraiana rubra*, *Paul Transon*, *wichuraiana alba* (type), *Ferdinand Roussel*, *Jersey Beauty*, *Gardenia*, *Evergreen Gem*, *Pink Roamer*, *Débutante* and *Sweetheart*, and there are three recent novelties that must not be overlooked, namely, *Paradise*, *Joseph Billiard* and, last but not least, the *White Dorothy Perkins*.

Of the Ayrshire and Evergreen Roses the best are *Félicité Perpétue*, *Flora*, *Bennett's Seedling* and *Virginian Rambler*. The multiflora group, represented by such as *Crimson Rambler*, *Rubin* and *Aglaia*, can be trained to form weeping standards, although their natural habit of growth is more diffuse than drooping. By the aid of wire hoops for two or three years their growths may be trained downward, and well-developed heads make a gorgeous display.

Another most charming Rose for weeping is *Rosa sinica Anemone*, but it should be planted in a very sheltered position. Some of the strong-growing Teas, Hybrid Teas and Noisettes are capable of being formed into most beautiful objects as weeping standards. Perhaps some of the finest specimens of this class are to be found at *Sherfield Manor*, near *Basingstoke*, the seat of *J. B. Taylor, Esq.* Here we may see wonderful standards of *M. Desir*, *Souvenir de Mme. Joseph Metral* and such like, and their growths nearly reach the ground. All who know these Roses will readily

understand what effect they would make when in full bloom. The long, young growths are kept tied down to wire hoops and over the old wood, so that there is a prodigious display of bloom. Of course, the merit of employing these Tea Roses as weepers is the more continuous blooming we receive, although it should be remembered that they require a well-sheltered position so that the old growths escape injury from frost.

All weeping Roses should be liberally fed with liquid manure from the time their buds

are seen until they show colour, and a dressing of good farmyard manure should be given each spring. The value of weeping standards as pot specimens has not yet received full recognition; but all who have grown them are loud in their praise, especially when the stems are not too tall, for then they may be employed in a great variety of ways by the skilled decorator.

The specimen from which the accompanying coloured plate was prepared was kindly supplied by *Hobbies Limited*, *Dereham*, *Norfolk*. P.

A BORDER OF PICTURESQUE BEAUTY. FIRST PRIZE PHOTOGRAPH IN OUR PHOTOGRAPHIC COMPETITION. (See page 597)

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**C**HRYSANTHEMUMS.—Plants that are past their best I am now cutting down, as this will encourage the development of fresh shoots which will provide the necessary cuttings from which next year's supply of plants is to be obtained. After the plants are cut back, give them a light and airy position in

1.—AN EXAMPLE OF OVERGROWN BOX EDGING THAT NEEDS LIFTING AND REPLANTING.

the greenhouse or conservatory near to the glass; this will keep the new growths short and sturdy. Should green fly be seen on the shoots, dust the affected parts with Tobacco powder. Late-flowering varieties that are fast coming into flower should be given manure water until the blooms are two-thirds expanded. Ventilate with care and maintain a buoyant condition of the atmosphere.

*The Vegetable Garden.*—At this period Seakale roots may be lifted for the purpose of forcing. I prefer comparatively young roots to all others, leaving strong old clumps in the ground in their usual quarters. The latter should be covered with proper Seakale pots, boxes or tubs that are bottomless, which can be covered with lids and removed as required. Cover the pots, &c., with horse or other litter sufficient to create a brisk heat, and growth will not be long before it is apparent. When forcing the roots under glass I prefer to arrange the young ones close together in large, deep pots or boxes in good soil, leaving the crowns just visible above the surface and providing a genial bottom-heat. Progress may soon be reported.

*The Hardy Fruit Garden.*—Recently-planted fruit trees should have the surface soil round about their bases mulched with some long manure. Wall fruit trees are better dealt with at this period rather than deferring the work of pruning and nailing until the early spring. The first to receive attention are the Pears. Prune these with a strong, well-sharpened pruning-knife, observing the greatest care that the spurs shall not be torn away. The general idea in pruning is to see that all the main branches of the tree are well furnished with a number of short spurs in dense clusters. Continue to plant fruit trees when the weather is suitable, i.e., when frost is absent and the soil in a condition to deal with it satisfactorily.

*The Greenhouse and Conservatory.*—There is a tendency with plants that have been kept in too close and ill-ventilated glass-houses to become subject to the attacks of green fly, and any so affected should have speedy attention. It is imperative that the plants be fumigated, and, that the result may be satisfactory, I recommend the use of any of the well-known vaporising compounds for this purpose. Ventilation is a most important item in cultivation at this period. Give air on every favourable occasion. Currents of cold air are most injurious; for this reason, therefore, open only the top ventilators and do this cautiously, otherwise a serious check may be experienced by the plants. Greenhouse climbing plants that have hitherto been neglected should be pruned without further delay. Cleanliness must be specially observed in these dull and often sunless days. Foliage plants will derive considerable benefit from a periodical sponging, and in the case of very dirty plants it may be wise to use a solution of soft soap and water for the purpose.

*The Hardy Flower Garden.*—Although it is getting very late to plant spring-flowering plants, I am filling a few spare beds with these subjects. I am hurrying on with the hardy flower borders, hoping to complete the work of lifting the overgrown plants for the purpose of dividing them, and also busy in mulching other plants in the border before hard weather sets in. D. B. C.

## LIFTING AND REPLANTING BOX EDGING.

THE use of dwarf Dutch Box as an edging to beds and borders was quite common some years ago, but in more recent times the practice is less frequently followed than the excellence of this subject fully justifies. Opinions differ very considerably as to the material that is best as edging for our gardens. Many present-day gardeners are disposed to ignore the use of Box as an edging, arguing that this subject encourages and harbours slugs and snails, and also that it is not possible to use weed-killer to destroy weeds on the paths when a live edging such as Box is planted. From careful observation and in the writer's experience the above-mentioned arguments do not hold good. Slugs and snails do not give more than ordinary trouble when the hoe is brought into frequent use. The constant stirring of the soil is most distasteful to these pests, and by the frequent use of the hoe the surroundings become less tenable. It is possible to use weed-killer in the centre of the paths, &c., providing a good layer of soil be spread over a space within 12 inches or 18 inches of the Box edging; this will lessen the risk of damage to the roots, and weeds near to the edging must be hoed up or removed by the hands. If allowed to go unclipped too long and in other ways neglected, Box will, of course, become very unsatisfactory, but when planted with due care and clipped periodically the result is very pleasing. To grow Box edging well it should not be clipped too often nor too hard. Newly-planted Box edging should be clipped but once in two years, except in the case of plants that are doing exceptionally well. Subsequently, when thoroughly established, an annual clipping will be necessary to keep the edging in neat and trim order. Opinions differ as to when Box edging should be trimmed, some growers urging a spring operation, while others are equally strong in their opinion that a late June or early July clipping is better. At this latter period the growth is practically completed, but if, through lateness of the season, the plants are still growing away freely it would

be better to defer this work for a week or two longer.

In my experience Box edgings may be planted within a period beginning in October and ending in April if frost of a severe nature does not prevail. Box edgings must not be planted under trees, where the drip from this source is a serious deterrent. Neither should an absolutely shady position be chosen. Those who have no old plants or edgings to lift may purchase suitable material from a nurseryman at so much a lineal yard, and one such yard will make 3 yards when broken up and replanted. Fig. 1 is a good illustration of Box edging that has been neglected. To lift such plants, however, is not a very difficult matter. A good spade or fork inserted well down under the plants will lift them with comparative ease. Fig. 2 depicts a small portion of the old Box edging as portrayed in Fig. 1. With ordinary care useful material may be obtained from the old plants, as illustrated in Fig. 3. Here, it will be observed, are three of the shorter pieces, each with a few roots adhering, these latter largely ensuring a satisfactory result to the planting operation. I have often planted pieces that were quite devoid of roots, and these have come through the ordeal very well. More than ordinary care has, however, been taken in preparing soil of a fairly good and friable nature with which to fill in the small trench that is usually taken out. Previous to the replanting it is necessary to mark off the position with proper lines, and then to cut out

2.—A SMALL SECTION OF THE EDGING SHOWN IN FIG. 1.

a vertical trench some 6 inches or rather more in depth. It is important to keep the surface soil level and also to make this firm, as this facilitates the planting in no mean degree. Proceed then to one end of the trench, placing the sprays of the prepared pieces so that they just touch one another and form a continuous line throughout the whole length of the row. As the sprays are adjusted in position soil should be placed in the trench and this made

3.—DIVIDED PIECES OF THE PLANT SHOWN IN FIG. 2. NOTE THAT EACH PIECE HAS A FEW ROOTS.

firm to prevent them from falling out, subsequently banking up the soil to the Box edging and treading the former in quite firmly to complete the operation. The tops of the divided pieces of the old plants should be kept about 2 inches to 3 inches above the soil, so that the reader will see the prepared pieces should be some 8 inches to 9 inches in length. Fig. 4 aptly portrays the method of planting. The illustration shows a portion of a row already planted, and also reveals the open trench, indicating how this work is proceeded with.

D. B. C.

#### THE CARE OF GARDEN TOOLS.

It always pays to take care of garden tools. Sometimes the amateur notices work requiring attention, and if he could lay his hands on the tools required immediately, with the assurance of finding them in a good condition, a considerable amount of time and trouble would be saved. Frequently, however, after an exhaustive hunt, he finds the implements not far from the place where they were last used, and, of course, in anything but a satisfactory condition.

After using garden tools, always clean them and see that they are thoroughly dry before placing them in a dry shed or other store. Tools which are allowed to become clogged with soil and stowed away in this condition are very bad to work with, and the work done with such tools cannot be satisfactory. The same applies to tools which rust through being left out in the wet or which are not dried after use.

During the winter it is a good plan to rub a little oil over tools before hanging them up in the shed. This ensures freedom from rust, and all gardeners know well how beneficial it is to have clean, sharp tools to work with. These rules apply to all implements used in the garden—spades, forks, rakes, &c., as well as shears, scythes, and other sharp-edged tools. When one once gets into the way of cleaning his tools after using them, he will be amply repaid by the greater ease with which the various garden operations can be performed.

C. RUSE.

#### LILIES OF THE VALLEY IN WINTER.

MANY amateurs fail to force these flowers satisfactorily, and there are several reasons why they fail. For instance, the crowns and roots of the Lilies are kept too dry and the temperature is allowed to vary too much. We will presume that the crowns have to be purchased. When they are brought in see that they are kept in a moist condition until safely potted. They are best kept in a cool, dark place; but do not lose any time in getting them potted. Thoroughly drain each pot, put in the crowns at 1 inch

apart and make the soil firm around them. If the roots are very long shorten them somewhat, but not more than is absolutely necessary. When duly potted in a compost of light, fresh loam and leaf-soil in equal proportions, with a free admixture of coarse sand, give a good watering and then place the pots in a cool frame, or plunge them rim deep in fine ashes. Keep the crowns free from frost. When forcing keep the pots surrounded with moisture, and this is best done by plunging them in Cocoanut fibre in a box or frame fixed on hot-water pipes and then covering all with damp moss 3 inches in depth. If the plunging material be watered occasionally, the moss sprinkled with temperature of about 60° maintained in the house, with a few more degrees around the pots, the spikes of flowers will appear in about ten days. At this stage the moss must be gradually removed, the pots stood on the plunging material for two days and then removed to a warm position on the open stage. Shade the plants from bright sunshine, and if desired they may be placed in the greenhouse after the flowers and leaves have well developed in the warmer structure. At all times avoid exposing the plants to a draught. Always give tepid water.

#### OVERHAULING STAKES.

DURING the dull and cold days of December, when work outside is frequently at a standstill, the amateur cannot do better than overhaul the stakes which have been used for plant supports during the past summer. It will be found that many of these are partially decayed at that point which corresponds with the surface of the soil, and to use them in this condition next summer would be waste of time. They should be cut through at the point named and re-sharpened, and any that need it given a coat of paint. When this is dry the stakes may be sorted into their various lengths and tied into bundles of a dozen, twenty-five or fifty, according to their thickness. They will then be ready for use without delay next summer, when waste of time must be strictly avoided.

4.—METHOD OF PLANTING THE DIVIDED PIECES SHOWN IN FIG. 3.

## THE TOWN GARDEN.

**FALLEN LEAVES.**—In those town gardens where there are shrubberies it is practically certain that the surface of the soil will now be covered with fallen leaves. These cannot be allowed to remain, as they make the garden so untidy; but the general custom of raking them off and transferring them to the rubbish-heap is equally undesirable, for in rotting down they provide the natural food of the plants that produced them, and their removal means deprivation for which compensation is seldom made in the form of manure. The best course is to dig the border over carefully, going sufficiently deep to well bury the leaves and weeds, but not so far down as to seriously injure the roots of the plants. A disadvantage arises where bulbs have been planted, for these are almost certain to be disturbed. In these circumstances it is wiser to prick over the surface with a fork when the leaves have been removed and afterwards to apply a good mulching of natural manure, covering this in its turn with a layer of fine soil. The leaves taken off will rot down in the rubbish-heap and will eventually find their way back to some part of the garden, there to afford some sustenance to other crops; they should never be wasted, but, of course, the heap must be in an obscure corner.

**DIVIDING PINKS.**—Where these most beautiful and fragrant plants have been established for three or four years and are commencing to get bare in the middle, no time must be lost in lifting, dividing and replanting healthy, vigorous young pieces. As soon as the old plants are taken out, the soil must be deeply dug and generously manured in the second spit, while into the top spit some old mortar rubbish may be advantageously incorporated. Firm the ground well after moving it, or it will settle considerably and the plants may suffer seriously in severe frosts. In selecting portions for replanting, always take those from the outer sides of the lifted clumps, for they are cleaner, healthier and more vigorous, and, consequently, make finer plants in the ensuing season. For a time after the operation the border will look rather thin, but the excellent attention which was accorded to the soil will ensure rapid growth and the plants will soon fill out and produce a much more satisfactory display than they did in the previous season. Other live edging plants may be similarly treated if they require it.

**CHRISTMAS ROSES.**—These plants thrive splendidly in town gardens where the soil is deep and in thoroughly good heart, but it is futile to attempt their culture where the soil is thin and poor, at least, without having previously deeply worked and judiciously enriched it. The great trouble in those places where the plants do grow is not to get an abundance of flowers, but to have them spotless in colour; as a rule, unless some special measures are taken, they soon become dirty with smuts and are then practically useless. There are two courses open for adoption by the cultivator, and he must choose the more convenient. The simpler plan is to procure some hand-lights with which the plants may be covered where they are growing; the blooms will expand admirably and they will remain perfectly clean. The other method is to lift clumps of medium size well set with buds and put them into large pots; it is not essential that there shall be much fresh soil, but the roots must be worked well down and the soil made firm about them. If these are placed in the conservatory or greenhouse and carefully watered, the buds will develop into beautiful white flowers of considerable size.

**FUMIGATING.**—With the excellent materials that are now procurable at such reasonable prices and are so clean and effectual to use, there is less excuse than ever there was before for the presence of insect pests in conservatories and greenhouses.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**EARLY CHRYSANTHEMUMS.**—Propagate these and throw the old stools away to make room, or one or two of each may be kept in case of accident with the cuttings. Late varieties should be kept in a dry, airy house and afforded a little heat when the weather is damp. Another batch of bulbs should be taken from the frames to the house now, in order that a good supply may be ensured for the festive season. A number of early Azaleas, which have made a good growth and have prominent flower-buds should be put into a warm house and forced slowly, when they will quickly give flowers. See that the foliage is quite clean and free from thrips before they are taken into a clean house, and if any doubts exist mix up a preparation of NL All and soft soap in a large tub or tank and immerse the plant bottom upwards in this, taking care not to wet the soil. Have another tank handy full of clean water and in this rinse it thoroughly. A batch of well-ripened Lilacs and Laburnums can be introduced also. These will do well in a vinery just started if no other accommodation is available.

**Ferns.**—Keep these on the dry side, but maintain the stages and floor moist and thus keep down insects and the plants fresh. Lilies of the Valley, Roman Hyacinths, Cypripediums and Cymbidiums may be brought into the fernery for effect and for a slight hardening before being used in the house for decoration.

#### PITS AND FRAMES.

Take care that plenty of protecting material is kept close at hand, as sharp frosts may occur any night and the work of many months be destroyed.

**Cinerarias** must be watched for aphides and slugs; the latter soon spoil the foliage of good plants. Give plenty of air on all favourable occasions.

#### FRUIT UNDER GLASS.

**Early Vinery.**—If the rods have been cleaned and pruned, the border renovated and the house thoroughly cleaned and disinfected, the latter may be closed now, but no fire-heat applied.

**Peach Houses.**—Continue to clean these as fast as possible. Many gardeners have to house a considerable number of their Chrysanthemums in these, and, as the plants will be rapidly disappearing, lose no time in getting the houses cleaned and painted where necessary; also attend to any trees that require attention at the roots. Many plants can be again stored in the houses after this operation has been effected.

#### KITCHEN GARDEN.

**Cucumbers.**—Keep this house at 70° in the day and 65° at night. This temperature will grow and satisfy the wants of the plants. Cut the fruits as soon as they are full grown and syringe the foliage twice daily.

Give plenty of air to all frames in the kitchen garden, and in dry weather pull the lights off. See that young Cauliflowers and Lettuces are free from slugs, and dust the soil around the plants with Sluicide or lime and soot mixed. Keep decaying leaves from Endive and Parsley. Take up some Mint and Tarragon and place in pots or boxes, according to the demand, and stand these in frames. Keep a fire going to burn up all rubbish, and the ashes will be useful to go back again to the land. These are very good for placing in seed-drills and for putting over the top of the soil at pricking-out time.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**COOL ORCHIDS.**—The cool Orchid house at the back of a north wall is not so frequently met with as formerly. It is in the winter time that the advantage of a more open and light position is most beneficial. The majority of the section of *Odontoglossums*, to which *O. crispum* and its allies belong, will be growing freely, and the roots should be now working well in the new material supplied some time ago. The glass should now be kept quite clean outside by frequently washing it down and inside by syringing. The plants, too, in some instances are arranged too far from the glass, and may, by elevating on inverted pots, be brought much nearer to it.

***Rivina humilis.***—This pretty berried plant is often grown in far too much heat and heavy shade, the result being that the berries fall off with the least disturbance and the leaves fall early, leaving a half bare-looking plant. If brought on slowly in a cool greenhouse with barely any shade, pretty and useful plants will be the result, and the berries will be of good colour and so firm that a vigorous shake will be necessary to make them fall.

***Azaleas for Forcing.***—Where a large quantity of cut flowers is desired early, old plants are the best for this work. Such varieties as *Deutsche Perle* and *Fielder's White*, if the growth has been well ripened early, will come into flower at this season with very little forcing. Azaleas are very liable to the attack of thrips and red spider. Syringing the plants freely and on no account letting them become dry at the roots will keep these pests at bay.

#### FLOWER GARDEN.

The flower garden in winter, as a rule, presents anything but an attractive appearance. Much might be done, however, to brighten and adorn the beds from November to May by planting ornamental shrubs and conifers in small, shapely specimens. The following are some of the most useful plants for this kind of work: Gold and silver conifers, Tree Ives, variegated Box, *Cryptomeria elegans*, the various forms of *Euonymus*, golden Hollies in quite a small state and *Aucubas*.

#### KITCHEN GARDEN.

***Asparagus Beds.***—The sooner now all *Asparagus* beds are divested of their ripened growth the better, as the surface soil can be cleared of weeds which have grown since applications of salt became impracticable. Opinions differ as to the value of manuring *Asparagus* beds which are in good bearing condition. I think manuring at this season in many cases does more harm than good, as a mass of manure causes many roots to decay, and those which do survive are weak and only throw up poor Grass. I would much rather rely upon liberal supplies of food through the growing season than give manure now, as at that time the roots can more readily absorb the food given.

#### LEAF SWEEPINGS.

At this season the main task of the gardener consists in sweeping up fallen leaves from walks and lawns, and the ordinary workman enters upon an almost insensate struggle to restore neatness to Nature. Personally, I like a certain amount of disorder in our gardens in the autumn, for the colour of the leaves and their rustle in the wind teach us many moral lessons. Besides, in many cases the natural dead leaf covering is of the greatest use to plants, whose roots are protected by it against their winter trials. Most of the sweepings in shrubberies and the rougher parts of the pleasure grounds are not only waste of labour and money, but actually injurious.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## NEW PLANTS.

**CYPRIPEDIUM ARETHUSA.**—This is a very pretty member of the Lady's Slipper family, and is the result of a cross between *Milo* and *Sallieri aureum*, both of which it partakes. The large dorsal sepal is very pretty, a very broad white band surrounding a rather small zone of green, the latter and part of the white being heavily besprinkled with medium-sized dull carmine circular dots. The petals and labellum are of the usual size and shape but of a pale yellowish green hue, slightly tinted bronzes. The plant shown had two good flowers and an abundance of healthy foliage. Shown by Lieutenant-Colonel G. L. Holford, Tetbury, Gloucestershire. Award of merit.

***Odontoglossum Groganæ.***—This is one of the larger-growing hybrids, and the specimen shown possessed a large compound raceme some 5 feet long, the rather small dull carmine and crimson flowers being rather thinly placed thereon. The plant makes huge pseudo-bulbs and long, narrow leaves with acute apices. Shown by Mr. J. Hubert Grogan, Slaney Park, Baltingham, County Wicklow. Award of merit.

***Cypripedium etoniense.***—This is a large and beautiful flower, the result of crossing *acteus langleyensis* with *insigne* Harefield Hall variety, both parents of which it partakes and, consequently, must be good. The large dorsal sepal has a broad margin of white, the edge being daintily frilled, with a pale green well-defined patch at the base, this green colour and a little of the white being well dotted with large and small dull carmine spots. The petals are rather narrow and long, and the lip is large with a narrow pale yellow margin, the colour of lip and petals being glossy bronzes overlying pale yellow. The pale yellow column is very conspicuous. Shown by Messrs. J. Veitch and Sons, Limited, Chelsea. Award of merit.

***Vanda cœrulea R. Chollet.***—This is one of the finest and most beautiful *Vandas* we have ever seen, and is very decidedly a great advance on the type. The flowers are the same shape as the old and well-known *cœrulea*, but very much larger and the colour is a much deeper sky blue. The plant shown was carrying one huge raceme composed of fifteen perfect flowers, and formed a verystriking and beautiful subject, fully deserving the first-class certificate awarded.

***Cypripedium Dreadnought.***—This is the result of a cross between *Troilus* and *insigne* Harefield Hall variety, and a very beautiful flower it is. The dorsal sepal is enormous, with a slightly incurved margin of pure white about half an inch in width. Under this comes a large patch of very pale green, freely dotted over with irregular brownish crimson dots. The petals are comparatively narrow, with the edges much crimped, the colour of these and the rather long lip being bronzy crimson with a glossy sheen. First-class certificate. Both were shown by Messrs. Sander and Son, St. Albans.

***Polystichum aculeatum gracillimum Druryi.*** This absolutely unique novelty will make a splendid addition to hardy Ferns, and it is certainly one of the most elegant varieties we have seen. The plant, too, is remarkable by reason of the wide break it forms as compared with its immediate ancestor, a frond of which was also on view. The fronds are distinctly arching and of graceful character, their lace-like delicacy constituting quite a feature. From Mr. C. T. Drury, Acton. First-class certificate.

***Chrysanthemum Merstham Jewel.***—A very beautiful variety of the single-flowered section, the blossoms at a short distance being not unlike a *Gaillardia* in colour. As shown in the undisbudded sprays, the variety was distinctly pleasing and good and should become exceedingly popular. From Messrs. William Wells, Limited, Merstham. Award of merit.

***Primula Malacoides.***—A new species collected in Yunnan, China, at an altitude of 9,000 feet, and said to be quite hardy. In its flowering the

plant resembles a glorified *P. Forbesii*, but the blossoms are of much larger size, more starry and the general effect much more graceful. The predominant colour of the petals is lilac, succeeded by a white ring and yellowish eye. The obovate petals are deeply indented, the numerous blossoms being produced on short peduncles, the spike carrying several whorls of the flowers. The leaf character is intermediate or nearly so between *P. cortusoides* and *P. Veitchii*, the bluntly obtuse leaf-blades being 2 inches or 3 inches long, heavily notched at the margin, supported on petioles about 3 inches in length and obscurely tomentose on the under-surface. The flower-stems and blossoms are covered with farina. The exhibited plants were rather more than 1 foot in height, profusely flowered and had resulted from a sowing of seeds made in April last. An elegant novelty of very considerable merit. Exhibited by Bees, Limited, Mill Street, Liverpool. Award of merit.

*Chrysanthemum Calceolonia*.—The largest single-flowered variety we have seen, the flower-heads being about 6 inches across and flat or nearly so. The colour is pink, a ring of white appearing at the base of the florets. Exhibited by Messrs. George Williams and Sons, Manor House Nursery, Cardiff. Award of merit.

All the above were shown before the Royal Horticultural Society on the 24th ult., when the awards were made.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Turistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Tennis court border** (A. H.).—If you could widen the border and secure a width of 4 feet or even 5 feet you might get a very fine display for a considerable period. For example, at the margin you could plant a broad band of white, yellow, or blue Tufted Pansies, next to this scarlet or pink Pentstemons, behind which the fine white Phlox Mrs. E. H. Jenkins could be placed, and last of all a line of scarlet Tritoma Uvaria. These things are especially valuable for effective planting and would afford a display for some weeks. It would be necessary to obtain by early sowing strong seedlings of the Pentstemons, but the Pansies and other plants, all of which should be planted in lines, may be planted now or in March. As the border would require some preparation, we think your better plan will be to prepare it first by trenching and manuring. If the width we have suggested is too great, reduce it to 3 feet and leave out the back row of plants.

**Agapanthus not flowering** (K. R.).—It is very probable that the dull, cold weather experienced last summer has a good deal to do with the non-flowering of the Agapanthus, as it is very important that the growth is well ripened. For this reason they should, during the latter part of the summer and in autumn till it is necessary to take them indoors, be fully exposed to the sun.

**Planting Parma Violets** (C. B. B.).—The Violets may be planted now in a frame with every prospect of success, provided you have, or can obtain, good, strong, well-established plants for the purpose. The soil in which they are planted should consist of half good garden soil and half decayed leaf-mould. Press the soil firmly to the plants. When planted the top of each should be

within 6 inches of the glass. Give the plants a good watering after they are in, and plenty of air day and night while the weather is open. They should be protected from frost by placing mats over the glass at night.

**Anemone diseased** (R. R. Gibb).—The plant you send is a form of *Anemone japonica* (the Japanese Wind-flower), which has been attacked by a fungus at the root. Your only safe course is to dig up the diseased examples and burn them, and you will be well advised if you dig out the soil and discard this also. Unfortunately these fungoid diseases are on the increase, and there is a great probability of the germs remaining in the soil to affect new plants. We have no desire to unduly alarm you, but it is not unlikely that the disease may spread to the remaining plants in the bed. If you discard the soil and burn the stricken plants, you might, with fresh soil added to the bed, plant a centre of *Aster cordifolius*, which, in conjunction with the margin of Anemone, would be distinctly pleasing.

### THE GREENHOUSE.

**Keeping Daturas and Oleanders through the winter** (Clapham Common). Both the Datura and Oleander may be safely wintered in a greenhouse, provided the temperature during sharp frosts does not fall below 40°. You complain of the plants not flowering and state that they were put out of doors during spring and summer. This, we should think, is the cause of their non-success, as they cannot be safely put out of doors till the middle of June. Both plants are liberal feeders, and it is possible that they need either repotting or a stimulant of some kind; but you say nothing as to their size, the condition they are in, or, in fact, anything about them on which we can base our opinion. While very anxious to oblige our correspondents, we are frequently greatly handicapped by the entire absence of details in the query submitted.

**Roman Hyacinth bulbs for examination** (Miss E. C. H.).—The bulbs are much too small to flower in a satisfactory manner, and you could not possibly hope for even a fair display from them, however treated. It appears to us very probable that the bulbs were kept dry too long before being potted. Being so small they would naturally suffer more quickly than the larger bulbs. You speak of the others doing well, but the Roman Hyacinth ripens earlier in the season than the various Dutch bulbs, and if not potted till the latter are it will, of course, have been out of the ground for a longer period than any of the others. The tiny white worms were no doubt in the soil, possibly in the egg state, and as soon as they were hatched the decaying portion of the bulb furnished them with food. With regard to covering Roman Hyacinths with ashes when potted, we have, after several experiments, failed to find any advantage in this treatment. That it is at all events not necessary is proved by the fact that, on August 20, we potted a quantity of Roman Hyacinths and stood them in an ordinary greenhouse on a stage occupied by Pelargoniums, Fuchsias, &c. There they rooted freely, and have been for the last fortnight in full flower.

**Grubs eating Cyclamen** (J. S. Grubb).—The grubs which are attacking your Cyclamen and other plants are those of the black Vine weevil (*Otiorhynchus sulcatus*) or a very nearly-allied species, the clay-coloured weevil (*O. pifurcus*). These grubs are so alike that it is very difficult to say to which species they belong, and their habits are exactly the same. No liquid insecticide is of any use, but you might try Vaporite. Make four holes in the soil round the plant 2 inches or 3 inches deep and half an inch in diameter, put a little Vaporite into each (enough to fill 1 inch in depth of the hole) and fill up the rest with soil. If this does not kill the grubs, the only thing to do is to pick them out from among the roots. The parent weevils feed on the foliage of Vines, Feros and many other plants; they only feed at night, hiding themselves very carefully during the day. If you suspect that a plant is attacked by the weevils, lay it on its side on a white cloth, and about an hour after it has become dark throw a bright light on the plant and the beetles will probably fall on to the cloth; if they do not, give the plant a good shake. Small bundles of hay or dry moss, placed so that the beetles can creep into them to hide, make good traps.—G. S. S.

### ROSE GARDEN.

**Roses for a novice** (A. H. C.).—You will find Jubilee to be a very good dark Rose and Victor Hugo a good scarlet. As you have such good sorts as Captain Christy, Frau Karl Druschki, Mrs. John Laing, Ulrich Brunner and Xavier Olibo, we recommend the following: Hugh Dickson, Caroline Testout, Charles Lefebvre, Mme. Abel Chatenay, Mme. Ravary, Mme. Jules Grolez, Anna Ollivier, Mme. Hoste, Antoine Rivoire and Prince de Bulgarie. Three good ramblers different to Crimson Rambler, Dorothy Perkins and Aglaia would be Hiawatha, Blush Rambler and Félicité Perpétue.

**Rose foliage diseased** (The Young Gardener).—The injury to your Rose foliage has been caused by what is commonly termed the Rose blight. Its scientific name is *Sphaerotheca pannosa*. The only way to prevent a serious attack is to be on the look-out for it in its early stages, when it may easily be destroyed by the application of sulphur to the leaves and branches. The cause of one row of Peas coming deformed and the other not must be due to some local conditions about which we do not know.

**Roses for new beds** (M. A. S.).—We think the width of the parallel beds a very good one. You will be able to plant in these beds three rows each. For the centre row we suggest half-standards. They take off the formality that all bushes possess and tend to elevate the Rose garden from the stereotyped style. The quantity of plants required would be twelve half-standards with stems of about 2 feet 6 inches and thirty-two bushes or dwarfs. Be careful to choose free growers and free bloomers for the half-standards. For the diamond-shaped centre bed you could not do better than plant your standard weeping Dorothy Perkins, and around it we recommend four half-standards and sixteen bushes. Beds Nos. 3, 4, 6 and 7 would take thirty-six bushes each, and we suggest a pillar Rose in the centre of each of these beds. As to arrangement, we think it would be best if each bed were a distinct colour. You could, of course, have several sorts in each bed. The centre bed should be crimson, Nos. 3 and 7 yellows, Nos. 4 and 6 pinks, Nos. 2 and 8 crimson and reds, and Nos. 1 and 9 whites and creams. Arches would look well at the points where the paths approach nearest to the diamond bed, and these should be of contrasting colours to the beds near them.

### FRUIT GARDEN.

**Plum trees barren** (Sage).—Do not cut back the branches of your trees, but cut right out the weakest. Then dig a trench half-way round the tree, 3 feet deep and 1½ feet wide, 6 feet distant from the stem of the tree, wheeling the soil away and cutting all roots seen. Fork the soil away from the roots to within 3½ feet of the stem of the tree, shortening back all the strong roots seen, but taking care of the smaller ones for replacing in the new soil. This should consist of turfy soil (without the grass) cut about 5 inches deep from a pasture-field, mixing with it a peck and a-half of lime and a gallon of bone-dust to every barrow-load. Place the roots carefully in this new soil, making it firm about them until the whole trench is filled up, afterwards giving the whole a good watering. This root-pruning will check the vigour of the tree's growth and induce it to bear fruit. The other half of the tree may be served in the same way two years hence. Towards the end of October is a good time to carry out this work.

**Hardy Vine Reine Olga not fruiting** (Ber. G. R. E.).—Seeing that your young Vine has grown freely and is healthy it ought to have shown fruit before now. The trouble is, we think, that the growth it has made has not been properly ripened by the action of the sun, and free passage of air among the branches has been excluded by allowing the Vine to carry too many branches and too much foliage. Should this be so, the best thing for you to do at once will be to reduce the main branches or spurs radiating from the stem of the Vine to a distance of 10 inches apart, and shortening each of these spurs or branches to 15 inches in length. Out of these main branches or spurs sub-laterals (or what are commonly termed second and third growths of young shoots) will have possibly grown. These should be cut back to within four leaves of their base, and every subsequent growth they make should be cut or pinched off at the third young leaf, the object being to concentrate the force of the Vine in forming and maturing plump and fertile buds which will produce fruit the following year. The only winter pruning necessary will be to cut back these main spurs to within two buds of their base. If you will remind us we will recur to the subject next spring.

**Apples, Pears, Plums, Apricots and Cherries to plant in a light loam with sand and gravel subsoil** (A. L. Simpson).—If you have a good depth of light loam resting on sand and gravel subsoil, say, 2 feet to 2½ feet of loam, you may venture to plant the trees named with every prospect of success, provided the land is properly prepared for their reception; but if you have only from 9 inches to 1 foot of loam to deal with, your prospect of permanent success would be a poor one. The trees would probably go on all right for a few years, but as fruit-bearing time came on the trees would collapse, especially in hot summers, and prove a loss and disappointment. The way to prepare the land is to trench it 2½ feet deep, applying well-decayed manure at the rate of twenty tons to the acre, planting the trees towards the end of October. We should prefer to start with three years' old trees. These will be well formed by then, and have also abundance of good fibrous roots. They will not bear much the first year, but half-a-dozen fruits each will not hurt them. The second year more may be allowed, but they should not be allowed to carry a heavy crop until the fourth or fifth year. You do not say whether you require dessert or cooking varieties of Apples, so we give six of each from which to choose, all of

which are among the best in their season. Dessert Apples: Mr. Gladstone, July and August; Devonshire Quarrenden, July and August; Lady Sudeley, April; Cox's Orange Pippin, October and November; Allington Pippin, December and January; Allen's Everlasting, March and April. Cooking Apples: Potts' Seedling, August; Stirling Castle, October; Lord Derby, November and December; Blenheim Orange, November and December; Bramley's Seedling, January; Newton Wonder, February and March. Pears: Jargonelle, July; Williams's Bon Chrétien, August and September; Louise Bonne of Jersey, October; Beurré Hardy, October and November; Doyenné du Comice, November and December; Beurré de Jonghe, January and February. Apricots: You had better plant two Moor Park and one Powell's Late, against a wall, of course. Cherries: Frogmore Early Bigarreau, Governor Wood, White Heart and Waterloo.

**Nectarine Lord Napier shrivelling while young** (*Enquirer*).—After the good treatment you say your tree has had it is difficult for us to assign a cause or to suggest a remedy for the shrivelling of your fruit at this stage of their growth. What is termed "ringing," which means the slitting of upright shallow cuts in the bark of hide-bound trees, has been known to produce good results in the way of increasing their fertility by aiding the expansion of the bark in such congested parts, and, consequently, giving a freer vent to sap circulation. You might try this by cutting three slits (bark deep) one in the middle and one on each side, nearly the whole length of the stock. These cuts disfigure the bark more or less, but they do no harm. We suppose the tree was not syringed about this time with any insecticide? Or do you think that bad quality glass in the light over the tree has had anything to do with scorching the fruit? This happens sometimes. We are strong believers in the practice of lifting and replanting Peach trees whenever there is anything amiss with them. We have never known the practice fail in producing the desired result. We advise you to try this again this autumn, lifting your tree completely out of the soil and replanting in rather heavy turfy virgin loam, mixing with it a gallon of bone-meal and a peck of lime to each barrow-load of soil. If it does not improve after this we should throw it away and plant another.

### MISCELLANEOUS.

**Destroying lawn weeds** (*T. O.*).—The weed-killer you enquire for is known as Lawn Sand, and is a composition in powdered form that, strewn over lawns which contain broad-leaved weeds, burns them up and in that way destroys them. The result is, of course, to make the lawn look spotted and disfigured until the weeds die away and the grass grows over the vacant spaces. This Lawn Sand afterwards exercises certain manurial powers, causing the grass, which does not retain the sand, to grow all the stronger. You can purchase it from any horticultural sundriesman, and probably any seedsman; it is sold in tins or in casks. Particulars as to its use are usually given with the article. In any case you can purchase Lawn Sand from the Boundary Chemical Company, 27, Cranmer Street, Liverpool.

**Names of fruit.**—*A. E. W.*—1, Beurré Clairgeau; 2, Marie Louise d'Uccle.—*Anxious*—Cat's-head; 2, Golden Noble; 3, a small King Harry; 4, Hambling's Seedling.

**Names of plants.**—*T. B. P.*—*Cestrum elegans*.—*E. Kepp*.—*Ornithogalum lacteanum*.—*E. H. P.*—Cannot name from material sent.—*S. H. B.*—*Escallonia exoniensis*.—*J. Cozens*.—1, *Cycas revoluta*; 2, *Davallia elegans*; 3, *Pandanus utilis*; 4, leaf insufficient for name; 5, *Strelitzia Regine*; 6, *Sparmannia africana*; 7, *Albizia lophantha*; 8, *Empatorium wlemannianum*; 9, *Eucharis amazzonica*; 10, *Dracena Sandere*; 11, *Podium aureum*; 12, *Asplenium Nidus-Avis*.

### SOCIETIES.

#### DARLINGTON HORTICULTURAL SOCIETY.

The annual autumn exhibition in connexion with the above society was held in the Drill Hall, Darlington, on the 18th ult., when a grand display of flowers, fruits and vegetables was made. The show was opened by the Mayoress (Mrs. B. Biggs), who was accompanied by the Mayor, and during the day the Lord Mayor of York visited the hall.

For twenty-four Japanese Chrysanthemums, not less than eighteen varieties, the silver challenge trophy was won by Mr. J. E. Hathaway, gardener to Mr. J. Brennard, Baldersey Park, the second prize going to Mr. J. Lester, gardener to Sir J. E. Backhouse. In Mr. Lester's collection was found the best bloom in the open classes, this being a magnificent specimen of Duchess of Sutherland.

For twenty-four incurved varieties Mr. Hathaway was again first, Mr. M. Sargent, gardener to Lady Payne Gallway, being second; and for twelve Japanese Mr. J. Lester was placed first, Mr. W. G. Chandler securing the premier prize for twelve incurved blooms.

For specimen plants of Japanese varieties Alderman Bartlett was the champion, Mr. E. Hutchinson being a good second. Mr. Hutchinson was first for three pots of Begonias.

In the class for two bunches of black Grapes Mr. Hathaway secured the first prize with splendid bunches, Mr. J. R. Gardiner, gardener to Lady Cowell, being second. In a similar class for white varieties Mrs. T. Brown was placed first. For six dishes of culinary Apples Mr. W. C. Modrell was first, and in a similar class for dessert varieties Mr. Modrell was again first.

For a collection of vegetables the prizes were won respectively by Mr. T. Seymour, Mr. G. Danby and Mr. W. Knight.

In the amateurs' classes the first prize for a collection of Japanese Chrysanthemum blooms was won by Mr. G. Dalton, Mr. W. Chandler being first for a collection of incurved blooms. Mr. Stewart was first for a dish of Apples and Mr. T. Watson for a dish of Pears.

#### NORWICH CHRYSANTHEMUM SHOW.

The opening day of this three days' fixture was unfavourable with regard to the weather, and this, no doubt, kept away many visitors, causing a marked falling off in the attendance. St. Andrew's Hall and Blackfriars Hall, Norwich, were well filled with exhibits in spite of the fact that the entries numerically were behind those of several previous years. Three good circular groups of pot Chrysanthemums and foliage plants were staged; the first prize here went to Mr. W. Palmer, gardener to J. B. Coaks, Esq., Thorpe, who was closely followed by Mr. C. Burtenshaw, gardener to H. Skelton, Esq., St. Helen's House, Mr. W. Rush, gardener to F. P. Hinde, Esq., Thorpe, bringing up the rear. The large Japanese cut-bloom classes lacked that spirited competition one likes to see. The best stands of blooms in this section came from T. A. Rising, Esq., Ormesby; Mr. H. Goude, gardener to E. Reeve, Esq., Catton; Lord Rendsham's gardener; Mr. M. W. Brooke, Attleborough; and Mr. W. Laws, gardener to E. G. White, Esq.

Pompons, singles and naturally-grown flowers seem to become more popular each year; incurved varieties are fast falling away from public favour in this district and made a poor display.

Miscellaneous cut flowers and pot plants were classes that allowed of a wide range of choice subjects to be exhibited. In these were a grand collection of Orchids from Mr. H. Rider Haggard, Ditchingham. Some fine cut blooms of exotic flowers came from Mr. L. Smith, gardener to Robert Fellows, Esq., Shotesham Park; he also set up a fine batch of choice and rare specimens of Orchids from his valuable collection. Mr. H. Goude, gardener to E. Reeve, Esq., exhibited six exceptionally good Begonia Gloire de Lorraine in a class for these. The plants, growing in 5-inch pots, were perfect in every way and reflected great credit on the grower. The other classes for Primulas, Cyclamen, Pelargoniums, Salvias and the like all added beauty to the floral section. Mr. W. Allan, Gunton Park Gardens, won the silver challenge bowl for the best collection of twelve varieties of fruit. Lord de Ramsey (gardener, Mr. A. Coombe) sent some wonderful Alicante Grapes, which were far away winners in a strong class.

Apples were the most keenly contested section of the whole show, and some choice examples of both dessert and kitchen sorts were seen. Pears had for their champions such growers as Mr. G. Davison, Westwick; Mr. Hanson, gardener to Sir Savile Crossley; Mr. W. Allan, Gunton; and Mr. H. Goude.

Vegetables included all the seasonable sorts and were numerous. The trade growers made a good display, the more prominent of these being Messrs. Daniels Brothers, Limited, Norwich, with all the subjects in season from their Town Close Nurseries. Hobbies, Limited, Dereham, had a bank of single Chrysanthemums and outdoor Roses; these were good for so late in the season. Mr. R. C. Notcutt had flowers and fruit.

#### ABERDEEN HORTICULTURAL SOCIETY.

The annual meeting of this society was held in the Music Hall, Aberdeen, the other evening, when there was a good attendance. The chair was occupied by Bailie Milne. The directors' report was of a rather disappointing character, due mainly to the reduction in the drawings at the show, owing to the wet weather of the last day. There had also been a falling off in the membership. The income amounted to £416 13s. 8d. and the expenditure to £477 2s. 11d., a loss on the year of £60 9s. 3d. There is, however, a balance to the credit of the society of upwards of £30, and it is hoped that more favourable weather will recoup the loss on the year. The following office-bearers were appointed: Hon. president, Lord Provost Wilson; chairman, Mr. Burnett of Powis; auditors, Messrs. W. Reid and W. Wyllie; secretary and treasurer, Mr. J. B. Kennet.

#### DUNDEE CHRYSANTHEMUM SOCIETY.

The annual two days' show of this society was opened in the Kinnaird Hall, Dundee, on the 27th ult. by Mrs. Trunhart, wife of the Lord Provost of Dundee. The show, taking it as a whole, was much superior to that of last year, the entries showing a slight increase, while the quality was generally considered finer. Cut blooms were very good, although the absence of such well-known exhibitors as Mr. James Beisant and Mr. D. Nicoll was expected to militate against the character of the blooms in the leading class. From the display in other classes it is evident that the smaller decorative varieties and the singles are gaining ground in the district. Chrysanthemums in pots were splendid, and a notable feature was the competition for Begonia Gloire de Lorraine, where some very fine plants were shown. Decorative work was particularly well done. Little encouragement is given to exhibitors of fruit and vegetables, and in the latter section the display was of no special merit.

In the premier class for Chrysanthemums—that for twelve vases, for which the City of Dundee Corporation Vase was offered—Mr. J. F. Stewart, an exhibitor coming to the front with these flowers, took the leading position with twelve fine vases, among his best blooms being Lady Conyers, F. S. Vallis, Mme. Cadbury and Algernon Davis; Mr. James Rae, Ethie Castle, was second. For eight vases of Japanese, Mr. James Beis, Binrock, was first. For six vases, Mr.

W. Dickson, Adderley, led; and other first-prize takers with Japanese were Messrs. A. Stephens, J. E. Davis, A. Duncan, J. F. Stewart, D. K. Meston and G. Scott. Mr. D. K. Meston was first for singles. Mr. George Scott, Seathwood, was first for twelve pots, Japanese, and he occupied a similar position for six pots. Mr. R. Collic, Drumkilbo, was first for Grapes; Mr. W. Benzie, Errol, for kitchen Apples; Mr. R. M'Naughton for table Apples; and Mr. A. McIntosh for Pears. Mr. James Kinnear had the best collection of vegetables.

Trade exhibits were not numerous, but were very fine. Messrs. Storrie and Storrie, Glencarse, made a good display of fruit trees in pots, Apples and various pot plants. Messrs. W. P. Laird and Sinclair made a great exhibit of decorative designs and other specialties of the firm. Mr. D. C. Hutcheson exhibited American Carnations, and Mr. G. Reid, Inverlay, Broughty Ferry, made a capital show of Cyclamen.

#### ABERDEEN CHRYSANTHEMUM SOCIETY.

The annual show of this society was opened on the 27th ult. in the Music Hall, Aberdeen, by Mrs. Ogilvie Gordon. The exhibits were considerably fewer in number than last year, but showed no diminution in quality. Cut blooms were very fine, the premier award for twelve vases of Chrysanthemums falling to Mr. A. Morton, gardener to the Dowager Duchess of Seafield, Cullen House, Banff, with twelve splendid vases of Japanese. Mr. W. Patterson, Balmie, Aberdeen, was a good second. Mr. Morton was also first for twenty-four vases in twelve varieties. Mr. A. Oliphant was first for twelve in nine varieties. For incurved, Mr. J. Jenkins, jun., was first. Decorative and single Chrysanthemums were very finely shown, Mr. John Petrie, Crathes, being first for eighteen decorative Japanese in vases. Mr. R. Begg was first in the leading class for singles. An unusual feature is provided here, this being a class for twenty-four trusses of Christmas Roses. Mr. William Milne was first for these. Other cut flowers were also good, and baskets, bouquets and other florists' work were admirably exhibited. Leading winners were Mr. A. Douglas, Mr. J. Joss, Mr. J. Petrie and Mr. J. Strachan. An exhibitor from Dumfries, Mr. R. A. Grigor, Dalswinton, had it all his own way with the decorative display. Plants were good, the first for four Chrysanthemums going to Mr. J. Tough, and that for six in 6-inch pots to Mr. R. Begg. Fruit made a good display, Mr. R. Singer being first for a collection of baking Apples and Mr. A. Paterson for dessert varieties. For black Grapes Mr. A. McLeod was first, and for white Mr. A. Reid. The best collection of vegetables was shown by Mr. E. Joss.

### OBITUARY.

#### MR. DAVID STALKER, NAIRN.

WE regret to have to record the sudden death of Mr. David Stalker, head of the firm of Messrs. David Stalker and Son, nurserymen, Nairn. Mr. Stalker, who had been in delicate health for several years, was eighty-two years of age, having been born at Cornhill, Banffshire, in 1826. He began life as a farm servant, afterwards becoming an apprentice gardener. On the expiry of his apprenticeship he moved about for a considerable time to gain experience and improve his position in his calling. His last appointment as gardener was at Holme Island, Grange-over-Sands, whence he went to Wales to take up an appointment as factor. Thence he went to Hunterston Castle, Ayrshire, in a similar position, where he remained for several years. He then bought the Nairn Nurseries, where he carried on business for twenty-four years in company with his son. In 1901 Mr. and Mrs. Stalker celebrated their golden wedding. Mrs. Stalker and his son survive him.

**The Christmas Number of "Country Life"** for December 5, contains, among other articles: "Tredegar Park.—I." (illustrated); "West Highland Terriers" (illustrated); "Wild Country Life"; "The Common Tern" (illustrated), by W. Bickerton; "The Insurance of Livestock"; "Pictorial Photography of the Year" (illustrated), by Ward Muir; "Head-dress in Finistère" (illustrated), by Francis Keyzer; "Fouquier Tinville," by Rowland Strong; "In the Garden"; "To Christina and Katharine at Christmas," by Ford Madox Hueffer; "The Wild Reindeer in Scandinavia," by Rugde; "Snow on the Farm" (illustrated); "Mrs. Green.—III.: The Deceivings of an 'Ormed Cow,'" a Story, by Evelyn E. Rynd; "Horse and Hound in the Provinces" (illustrated).

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## TABLE DECORATIONS FOR CHRISTMAS.

EVERYTHING should be bright at this festive season, and those who have to superintend the decoration of the dinner-table will, no doubt, wish to have it as gay as possible and probably somewhat different from last year, and, naturally, an improvement upon previous efforts will be desired.

Flowers, except those that are forced, are rather scarce at the end of the year; but a little good management and forethought will help to tide over difficulties. It is wonderful what there is to be found in the hedgerow suitable for our purpose. I am referring now to those who are so placed that they cannot obtain delicate flowers, but are able to gather from the hedges. In many parts of the country the fluffy Clematis is to be found in abundance, and also the bronze and yellow fronds of Ferns. Coupled with these are Holly berries and also the black ones of the Ivy. These may be arranged to give a delightful effect. In the taller vases the bearded Clematis may be loosely placed with a few Fern fronds, and the smaller glasses may contain a few sprigs of Holly with berries, or the Ivy.

Then, again, think out some arrangement of the Fern alone. The light brown fronds judiciously mixed with the reddish bronze ones are sufficient for the vases, and if some of the flat fronds are laid on the cloth to form stars around candlesticks and dishes, and others which are narrow placed to form a tracery on the white cloth, a very charming result is obtained.

Red Holly berries arranged in bunches on the top of the Fern fronds would do for another table. Now we come to Ivy alone. Not a single flower need be used; the vases and the cloth would be tastefully furnished by using very slender branches of Ivy in the vases, so that the ends hang over the sides gracefully and nearly touch the cloth, and equally slight branches intermixed with thicker ones on the cloth. A spray laid here and another there are most effective. Plucked off, the Ivy leaves are very suitable for placing around the bases of various dishes and ornaments, for forming into stars, tracery and different designs on the cloth.

The leaves of Brambles, Beech, Oak and other trees are useful for the same purpose. Again, how very nice a few vases of grasses gathered from the roadside look. There is a simple beauty in all these which may be presented in a pretty form.

I will now give a few hints on the arrangement of the more tender flowers and greenery. Late-

flowering Chrysanthemums are a boon to the decorator. The blooms remain fresh for quite a week after they are cut, especially if half an inch of stem be cut off twice during that time; the sap-vessels are thus kept open and water admitted. Nearly all the very large blooms are at this season gone, so that very heavy arrangements are more easily avoided. Under artificial light scarlet, carmine, bronze, pink and white show to the best advantage; therefore, when selecting the blooms in the greenhouse or shop it is well to remember this.

In a natural state large and small flowers and partially-developed buds grow together on a plant. We follow Nature by associating them also on the dinner-table; lightness is more easily secured, especially if each bloom is free of its neighbour. Lilies of the Valley and white Roman Hyacinths look splendid with a few scarlet Zonal Pelargoniums and Maidenhair Fern fronds. The two first-named come from a high temperature, but they will, however, last a long time fresh if not subjected to cold draughts.

A very pretty table decoration for Christmas consists of spikes of Calanthes (C. Veitchii) and Fern fronds, and if some of them are placed on the shelf over the fireplace the general effect is enhanced; indeed, I think it is advisable to often have the same kind of flowers on the mantel-board as are placed on the table. A completeness is thus given to the whole arrangement. The lovely tints in Vine leaves, when the latter are used for the dessert dishes, have a fine effect on a white cloth.

Palms, Crotons, Dracenas, Cyperuses, Ferns and Aspidistras placed in recesses and on the table look charming. Primulas, Cyclamens, Azaleas, Poinsettias and Begonia Gloire de Lorraine are suitable for the table and also the room generally. Avon.

## PARROT TULIP SEEDLINGS.

A GENTLEMAN in New Zealand writes to say that seven years ago he was fortunate enough to save some seed from a Parrot Tulip, and that seven of the seedlings flowered last August. He describes them as being about 15 inches high and of ordinary Tulip shape. Two are crimson-pink with the lower part of the segments white, one is light yellow with a bright crimson edge, one is creamy white with a pink edge, and the others are creamy white with slight crimson markings on the divisions. This is an extremely interesting fact, for as far as I can learn it is the first authenticated case of seedlings raised from a Parrot parent. I fancy most of us would have thought some Platystigma would have appeared, but it is not so. The origin of Parrot Tulips is somewhat obscure. From my own observation and from what I can learn from others they are in all probability sports, and, moreover, any

variety may take on this peculiar form. Last April, at one of the Royal Horticultural Society's meetings, I saw a *Chrysolora* whose petals were well on the way to becoming Parrots; and at Mr. van Tubergen's grounds at Haarlem this spring I saw an *Eleanora* which had quite taken on a Parrot form. Mr. E. H. Krelage knows a lilac and yellow Parrot that originated some little time ago from a Bybloemen Tulip in a Haarlem nursery. The reason why they are not met with earlier in the history of the Tulip is probably that they were originally looked upon as undesirable and severely repressed. One of the first recorded is called *Le Monstre Jaune*, and in 1745 Weinmann, who pictures several, labels them "Monstrosities." As a parallel case I would refer to what has happened to the *Chrysanthemum*, the *Carnation* and the *Dahlia* in our own immediate days, when types are popular and much appreciated which a very short time ago were discarded as worthless. The experience of our New Zealand friend seems to bear out my theory. It will be of great service if, after the next flowering season, he will send a note about the behaviour of those which have yet to flower, and also what he finds the result to be of his equally interesting *Platystigma* offspring.

JOSEPH JACOB.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

\* \* The dates given below are those supplied by the respective Secretaries.

December 11.—National Sweet Pea Society's Annual General Meeting at the Hotel Windsor, Westminster, 3 p.m.

December 22.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

**November competition for our Readers.**—Owing to the large number of essays submitted for this competition, we have been unable to get them judged in time to give the results in this issue; but these, together with the first-prize essay, will appear next week.

**Hobbies, Limited's Exhibition.**—An interesting exhibition arranged by Hobbies, Limited, was held in the Memorial Hall, Farringdon Street, London, E.C., on the 1st, 2nd and 3rd inst., this being opened on the first day by Sir George White, M.P. In addition to many beautiful examples of fretwork, wood-carving, modelling, &c., the horticultural department was well represented, bulbs, Cacti, *Chrysanthemums*, Roman Hyacinths in flower, Roses, fruit trees, seeds and other horticultural goods being attractively displayed. Such an exhibition held in the heart of the City of London should do much towards fostering a love for healthy hobbies among our workers.

**Edinburgh parks and open spaces.**—Mr. J. W. McHattie, the city gardener of Edinburgh, has prepared an able and exhaustive report on the parks and open spaces of the city, and this was presented to the Town Council at their last meeting. Mr. McHattie's report was warmly commended at the meeting, giving, as was stated, information the council never had before respecting the numerous parks and open spaces of Edinburgh.

**Mildness of the season—flowers from Goodwood.**—We have received an interesting gathering of flowers from Mr. F. Brock, The Gardens, Goodwood, Chichester. The Roses were exquisite. The following notes accompanied this welcome contribution to our table: "*Acacia nerifolia* was planted out of doors two years ago in a sheltered border when it was about 3 feet high. It is now about 6 feet in height, and has been flowering continuously since the beginning of September. *Cytisus racemosus*: This was planted with the above

shrub and on the same date. It is growing very rapidly, and has been flowering profusely for the past five weeks. *Laburnum*: Flowering for the second time this year. *Parochetus communis*, *Cheiranthus Cheiri* and *Gypsophila prostrata rosea*: From an exposed rockery." Also sent were the fragrant winter-flowering *Honeysuckles* *Lonicera flexuosa*, *L. halleana* and *L. brachypoda*, and the *Arbutus* from an old tree in a fairly sheltered part of the garden. *Ceanothus azureus* was gathered from a shrub on a south wall, and the *Rosemary* from an old bush in the garden. The Roses were delightful, and comprised three of the most beautiful sorts in cultivation—*Hermosa* (a fresh pink shade), *Mme. Laurette Messimy* and *Mme. Eugène Resal*.

### Plants in flower at Chaddlewood, Plympton, South Devon.

Mrs. Soltan-Symons writes as follows: "Having noticed in THE GARDEN of November 28 a list of flowers in bloom at King's County at the beginning of that month, I send you a list of shrubs, herbaceous and alpine plants in bloom on December 1 in my garden. This list may interest your readers as showing the extraordinary mildness of the season. *Abelia rupestris*, *Abutilon vexillarium*, *A. Vitifolium*, *Andromeda cassinefolia*, *A. floribunda*, *Aralia Sieboldii*, *Berberis Darwinii*, *Calceolaria Burbidgei*, *Ceanothus Gloire de Versailles*, *Choisya ternata*, *Chrysanthemum frutescens*, *Clianthus puniceus alba*, *Cobaea scandens*, *Coronilla glauca*, *Correa ventricosa*, *Crinodendron Hookeri*, *Desfontainea spinosa*, *Erica codonodes*, *Escallonia macrantha*, *Eupatorium weinmannianum*, *Euryops Athanasiae*, *Fuchsias fulgens*, *pumila* and *Riceartonii*, *Grevillea alpina*, *G. rosmarinifolia*, *Helianthemum* (double red), *Hydrangea Hortensia*, *H. Otaska*, *H. Thomas Hogg*, *Jasminum nudiflorum*, *J. primulinum*, *Keria japonica fl. pl.*, *Lonicera Periclymenum japonica*, *Lupinus arboreus*, *Magnolia grandiflora*, *Nandina domestica*, *Osmanthus ilicifolius*, *Rhododendron arboreum*, *Salvia grahamiana*, *S. fulgens*, *Spiraea prunifolia fl. pl.*, *S. Thunbergii*, *Spartium junceum*, *Teucrium argenteum*, *Veronica* (var.), *Viburnum Tinus*, *Weigela hortensis nivea*, *Anemone coronilla*, *Borago laxa*, *Delphiniums*, *Calceolaria mexicana*, *Erigeron mucronatus*, *E. philadelphicus*, *Eryngium olivierianum*, *Geranium Endressii*, *Helleborus* (Christmas Rose) *maximus*, *Iris stylosa alba*, *Modiola geranioides*, *Narcissus Polyanthus*, *Pansies*, *Papaver cambrica*, *P. c. fl. pl.*, *Pentstemons*, *Polyanthus*, *Potentilla crimon*, *Primulas japonica*, *denticulata* and *obconica*, *Oriental Poppies*, *Violets La France*, *Baroness de Rothschild*, *Princess of Wales*, and *Amiral Avellan*, *Roses* in variety, *Arabis albida fl. pl.*, *A. saxatile*, *Aubrietias Dr. Mules* and *purpurea*, *Asteriscus maritimus*, *Campanula garganica hirsuta*, *Campanula portenschlagiana*, *Corydalis lutea*, *Erysimum pulchellum*, *Iberis sempervirens*, *Little Gem* and *coriacea*, *Lithospermum prostratum*, *Linum caribonense*, *Malvastrum lateritium*, *Millias*, *Oxalis floribunda*, *Polygonum vacinifolium*, *Polygala buxifolia*, *Parochetus communis*, *Phlox setacea*, *Vinca acutifolia* and *Veronica rupestris*."

The following were in flower on the 1st inst. in Sir John Thorneycroft's garden at Steyne, Bembridge, Isle of Wight. In an accompanying note it is mentioned that "this autumn seems to be an exceptionally mild one; even the sharp nip of frost a few weeks ago did not affect us here, as we have Dahlias growing and looking very bright with bloom, also *Heliotrope*. The list I enclose I do not think is a bad one. I may say our Rose garden looks as if it were July instead of December 1; the sorts of Roses mentioned are perfect gems for late autumn blooming. *Salvias splendens grandiflora*, *Petunias*, *Corydalis lutea*, *Cistus* in variety, *Ceanothus* in variety, alpine Strawberries in flower and fruit, *Clarkia*, *Silene pendula compacta*, *Laurustinus* (beautifully in flower), *Escallonia montevidensis*, *Romneya Coulteri*, *Fuchsia*, *Veronica*, *Matthiola bicornis*, *Lavender*, *Nasturtiums*, *Spanish Broom*, double and single *Gorae*, *Petasites fragrans*,

*Heliotrope*, *Armeria vulgaris* (common Thrift), *Helleborus niger maximus* (Christmas Rose), *Dahlias* (Cactus), *Aralia Sieboldii*, *Crane's-bill*, Ivy-leaved *Geraniums*, *Blackberries*, *Jasminum nudiflorum*, *Clematis cirrhosa*, *Solanum jasminoides*, *Arabis alpina*, *A. a. flore-pleno*, *Periwinkle*, *Hydrangea*, *Convolvulus minor*, *Yucca gloriosa* (a very large spike); a large quantity of *Roses* in variety—especially *Mme. Alfred Carrière*, *G. Nabonnand*, *Marie van Houtte*, *Champion of the World*, *Mme. Lambert*, *Cramoisi Supérieure*, *Corallina* and *General Schablikine*—are flowering very freely, *Stocks*, *Mignonette*, *Polyanthus*, *Primroses*, *Scabious*, *Limnanthes Douglasii*, *Iberis sempervirens*, *Chrysanthemums*, *Cosmeas*, *Erysimum Golden Gem*, *Wallflowers*, *Alyssum saxatile compactum*, *Nicotiana Sandera* and *affinis*, *Lithospermum prostratum*, *Valeriana officinalis*, *Sweet Violets*, *Dog Violets*, *Lupinus arborea*, *Berberis Darwinii*, *Choisya ternata*, *Begonias*, *Marguerite Carnations*, annual *Chrysanthemums*, *Coronilla glauca*, *Marguerites*, *Trollius*, *Aubrietias*, *Plumbago*, *Larpenae*, *Michaelmas Daisies*, *Gaillardias*, *Marigolds*, *Delphiniums*, *Tagetes*, *Leycesteria formosa*, *Sweet Briar* and *Koniga maritima*."

## PRIZES FOR READERS. DECEMBER.

THE BEST EVERGREEN SHRUBS  
FOR WINTER EFFECT AND HOW  
TO GROW THEM.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above  
subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Thursday, December 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**National Chrysanthemum Society's exhibitions.**—How much longer will the above society continue to hold its exhibitions at the Crystal Palace? It is really distressing that such lovely displays of flowers should be staged there with comparatively few visitors to see them. The winter exhibition this year, held as recently as the 2nd and 3rd inst., is a case in point. Here were beautiful flowers and fruits arranged in a most attractive manner, yet the visitors were very few indeed. Possibly the cold weather may have induced some to stay away, for the Palace was and usually is notoriously cold; but this was not the case with the October and November shows, yet the number of visitors then was far from satisfactory. Can it be that the *Chrysanthemum* is losing its hold on public favour, or are there other reasons connected with the Crystal Palace that tend to keep the public away?—A VISITOR.

**Bulbs in moss fibre.**—The accompanying illustration is from a photograph sent to us, and represents *Narcissus* Sir Watkin growing in Mr. Robert Sydenham's moss fibre from bulbs supplied by him. They were grown by Dr. McNeill of Bridlington, some twelve to fifteen bulbs being placed in the fibre in October, 1907, and the photograph was taken in March of this year. About twenty-seven flowers were produced, thus forming the charming mass shown in the illustration and demonstrating forcibly the value of this system of cultivating bulbs for decorative purposes.

## THE FRUIT GARDEN.

### FRUIT TREES IN POTS.

**D**URING recent years the cultivation of such fruit trees as Cherries, Apples, Plums and Pears in pots has been developed to a considerable extent, hence a few notes on the system may be of value at present. It must not be supposed that trees cultivated thus are intended for a general crop, because, owing to the time and trouble expended on them, such a crop would not be profitable. Where, however, very choice fruits are needed for exhibition or dessert the system is invaluable, and it is chiefly for these purposes that the fruits are thus grown.

Another point to remember at the outset is that these trees, generally speaking, will only need the protection of a glass house for a short period of the year, outdoor treatment being the best at other times. This, of course, does not apply to cases where Cherries or Plums are needed some time in advance of the crops that ripen outdoors. The chief advantage, then, in growing trees in pots is that they can be taken into a glass house just before the flowers open and kept there until the fruit has set well, when they can be once more placed in the open. When the fruit is ripening the trees may again be placed under glass and there allowed to finish their fruits, which they will do much better than those trees growing entirely out of doors. For the North of England and Scotland, where it is rather difficult to get well-finished Apples, Pears and Plums of choice varieties, the system is especially valuable.

One point that the amateur must always bear in mind is that no coddling will be tolerated; in large establishments special houses are erected for the purpose, these being light and so constructed that an abundance of air can be given the trees at all times. Where special houses are not possible, one where plenty of light and air is available should be chosen. The amateur should, if possible, buy trees that are already established in pots, as at least a season will be gained by this means. If this is impossible, select those that possess plenty of fruit-spurs and pot them up in the autumn, using pots measuring 10 inches in diameter. Three year old trees are the best to start with, and any long, straight roots must, of course, be removed to enable the ball to go into the pot.

The best soil is very fibrous loam, with a little thoroughly decayed manure, some old mortar and a dusting of bone-meal added. Place one good-sized crock over the drainage hole, then a few half-inch bones, and over these some of the rougher compost. The soil must be well worked among the roots and rammed moderately firm. The Apples selected should be grafted on the Paradise stock and Pears on the Quince, as these stocks naturally have a dwarfing effect on the growth of the trees. After potting is done plunge the pots to their rims in ashes or Coconut fibre in the open, where they may remain all the winter.

Trees lifted from the open should not be allowed to bear a crop the first summer.

During the summer months, when growth is active, frequent applications of water will be needed, and these may be supplemented occasionally by weak solutions of artificial manure that contains a good percentage of potash and phosphate. Keep the pots plunged and adopt summer pruning, this consisting chiefly in the cutting back of lateral growths early in July to within three buds of their bases. This will tend to produce spurs and also enable the buds that are left to become well ripened during the autumn.

When trees are established they are, as stated above, taken into an airy and light house just before the flowers open so as to avoid the possibility of injury by frost. Fertilisation will usually be effected by bees, but it is as well to brush the flowers each morning with a rabbit's tail fastened to a stick. When the fruits are swelling nicely the trees can be again plunged in the open, or, if room is available, allowed to remain where they are, giving careful attention in each case to watering and feeding. As ripening time approaches those trees outdoors are brought into the house and given all the air and sun possible, this applying only to Apples,

A GOOD BOWL OF NARCISSI AS GROWN IN MR. ROBERT SYDENHAM'S MOSS FIBRE.

Pears and Plums. Cherries will always finish well outdoors.

The question of repotting is a rather vexed one. Some good growers like to repot the trees each autumn, as they are then more under control; others repot only once in three years, relying on top-dressing during the meantime. Whichever system is adopted the end is practically the same, as the main object is not to give the trees larger pots, but to provide them with new soil to replace the old. Thus in repotting a good deal of the old soil is removed from the roots without unduly disturbing them, and the tree returned to a pot the same size as the one it was previously growing in. When top-dressing is resorted to, as much as possible of the old soil is removed from the surface and replaced with good new compost. Both repotting and top-dressing should be done early in the autumn, just before or as soon as the leaves have fallen. Soil as advised for potting up new trees is suitable for these purposes. Of course, when top-dressing is being done it will be necessary to examine the drainage and see that the hole in the bottom of the pot is not blocked; if it is, the tree should be turned out of its pot and the crocks rearranged so that superfluous water has a free outlet.

## THE KITCHEN GARDEN.

### AUTUMN TREATMENT OF ASPARAGUS BEDS.

**I**F the work has not already been done, no time must be lost in clearing off all the dead tops of the Asparagus and also any weeds and other rubbish that may be present on the surface of the soil. The old tops should be cut off close to the ground, and these, together with any other rubbish removed, must be promptly burned, so that any eggs, insects or fungoid diseases that may be present will be destroyed. This removal of weeds and rubbish will, of course, mean that a certain amount of soil will be taken away, and this should be replaced with some from the alleys or pathways.

Every autumn, as regular as the season comes round, the question of autumn *versus* spring manuring presents itself, and each system certainly has its adherents. While no hard-and-fast rules can be laid down concerning this important item in Asparagus culture, much may be gained from experience coupled with observation and a knowledge of the plant's growth. For example, where the soil is of a highly porous character, manuring in the autumn will not do any harm; but whether it will do any real good is another question. It must ever be remembered that normal Asparagus plants are now resting, and in such a condition they will remain until the end of February; consequently, any manure which is in the meantime rendered available for plant food cannot be made use of by the crop for which it is intended, and it is only reasonable to assume that by the time the plants are in a condition to use this food it will have been washed far beyond their reach.

In the case of soils of a more retentive character, in which some cultivators are obliged to grow Asparagus, of course the plants are in the same latent condition, but the plant food will not be so easily washed away. Another and more serious evil, however, presents itself. A layer of manure placed on the surface of a bed at this season quickly becomes saturated with moisture and remains so all the winter; consequently it acts as a sort of sodden blanket to the bed, maintaining the soil in a very wet and cold condition and at the same time excluding air, a condition that is certainly injurious to the plants. The above points granted, it will be seen that autumn manuring in the case of light or porous soil may not do any harm, yet can do but little good, and on heavy soils is certainly capable of much mischief.

In the early spring, however, the plants will commence to grow, and consequently any food washed down to them from the manure placed on the surface can be used at once to the plant's advantage, and, in the case of heavy soils, without any fear of injury being done; consequently, manuring in the spring, with good supplies of liquid manure during summer when growth is active and new crowns are being made ready for the next spring, is undoubtedly the best method to pursue, and this has more than once been proved in actual practice. Should circumstances arise that make it absolutely imperative for manuring to be done in autumn, long, partially-decayed manure should be chosen, as this will remain lighter on the bed, take longer to decompose and thus become available for the plants. H.

### THE CULTIVATION OF EDIBLE MAIZE.

ALTHOUGH varieties of the common Maize or Indian Corn have for many years been grown in this country for ornamental purposes, little attention has been given to them from a culinary standpoint; yet where warm glass structures are available during the early months of the year and plenty of space for the plants to develop in during the summer, a very welcome addition

to our vegetables may be obtained from this source. Possibly the cultivation of these plants for culinary purposes has been considerably retarded by the fact that, until quite recently, the varieties suitable for and obtainable in this country were of a very inferior quality, but this is not now the case, several excellent varieties being offered by our leading nurserymen.

The end of January is not too early to sow the seeds, these being placed singly in  $2\frac{1}{2}$ -inch pots filled with a good open soil, with which a little very much decayed manure has been incorporated. If these can be stood in a hot-bed frame germination will soon result, but failing such a position they must be placed in a house with an average temperature of  $55^{\circ}$ , as Maize are naturally warm-loving subjects. As soon as the plants appear, a little judicious ventilation may be given, taking care, however, to avoid cold draughts, which will, if they reach the plants, cause a severe and irreparable check to growth. When the seedlings are about 4 inches high they will have filled the small pots with roots, and they may then be moved into pots measuring 5 inches in diameter, using soil for this potting composed of two parts good fibrous loam, half a part sand and half a part thoroughly decayed manure, potting moderately firmly. After the plants are well established in these pots they may be given more air, and a light position near the glass is essential, the temperature at no time to fall below  $60^{\circ}$ , the point to aim at being free and unchecked growth of a robust character.

In a few weeks the plants will have filled the 5-inch pots with roots, and they should then be moved into others 7 inches in diameter, using the same kind of soil and making it rather more firm. In these pots the plants will remain until planting-out time, which will be the first or second week in June, abundance of air being afforded them for a few weeks previous to planting out so that their tissues have become well hardened.

In the meantime the preparation of the summer quarters must be undertaken, and this will consist of deep digging or, better still, trenching, incorporating with the soil a heavy dressing of thoroughly decayed manure, as the plants are decidedly gross feeders. The soil that suits them best is one rather inclined to be stiff and that does not dry up rapidly. The size of the plot will, of course, depend upon the number of plants to be grown. They will need a distance of at least 3 feet between the rows and a distance of 2 feet from plant to plant in the row, and for some of the stronger-growing sorts 4 feet is none too much between the rows.

When planting out make a hole large enough to sink the ball of soil and roots well into the soil and work some fine material round the ball, a good watering in completing the operation. If the position is exposed to strong winds, light stakes and ties may be necessary until the plants have become well established, but usually these are not required. During dry weather a mulching of short manure over the roots and copious supplies of water are highly beneficial.

In addition to the fact that until comparatively recently only inferior varieties were obtainable, the question of gathering and cooking the cobs has doubtless done much to give this vegetable a bad name, as, unless proper care is taken over these apparently simple points, the whole season's work may be of no use whatever. It is safe to say that the majority of growers allow the cobs to get too old before gathering them. They should never be used for culinary purposes after the Corn has begun to turn mealy inside; when a seed is opened it should be milky inside if the Corn is fit for cooking. The cobs are cooked in their jackets and care must be taken not to boil them too long, else the Corn will turn hard and mealy. A few experiments in this direction will soon enable anyone to ascertain the precise amount of boiling required. Sutton's Early Dwarf and Country Gentleman are varieties that may be relied upon.

## TREES AND SHRUBS.

### GOLDEN-LEAVED CONIFERS FOR WINTER DECORATION.

THE various golden-leaved conifers are useful subjects for decorative gardening and may be used for a variety of purposes. Unfortunately, some of the more delicate-constituted ones cannot be grown with success in the vicinity of large towns and cities where the atmosphere is rendered impure through smoke or chemical fumes, and even those which grow moderately well under these conditions are shorn of much of their beauty by the coating of dirt which collects on the leaves during winter. Under better conditions, however, in a purer atmosphere and away from smoke, where branches and leaves keep clean, they are most effective, and the colour keeps good for the greater part of the year.

Perhaps of the golden-leaved conifers the various Yews, varieties of *Taxus baccata*, are the most useful, for they thrive in most gardens even about towns. The leaves keep a good colour for many months and only become dull for a short period previous to new ones being formed. As a rule the brightest colour is found on the under-sides of the leaves, but, as they usually turn upwards the colour is brought prominently into notice. Some of the best are *aurea variegata*, *Barronii*, *adpressa aurea*, *elegantissima*, *Dovastonii*, *aureo-variegata*, *fastigiata aurea* and *f. Standishii*. The variety *Barronii* is specially worthy of notice on account of the rich coppery colour of the leaves, while *elegantissima* and *Dovastonii aurea* are remarkably graceful in appearance; *adpressa aurea* is of very neat habit with tiny leaves, while the *fastigiata* varieties are golden forms of the Irish Yew.

Next in importance to the Yews are the varieties of *Cupressus*. Of *C. lawsoniana* the variety *lutea* has golden foliage and is of similar habit to the type; *gracilis aurea* is remarkable for its graceful appearance, the secondary branches being pendulous. A golden variety is known of *C. nootkatensis*, while of *Cupressus* (or *Retinospora*) *obtusata* there are several varieties. *Crippsii*, a form of the last named, is a particularly rich-coloured variety of *aurea*, while *gracilis aurea* is of very dainty appearance. *C. pisifera* provides us with several good golden varieties, *plumosa aurea* and *filifera aurea* being the best. *C. macrocarpa lutea* is a vigorous-growing variety of the Monterey Cypress, remarkable for its rich colour during summer and autumn and its change to a greener tint during late winter and spring. It is an excellent subject, especially for gardens in the vicinity of the coast. The common American *Arbor-vitæ* (*Thuja occidentalis*) provides several golden varieties, that called *lutea* being the best. Of *Thuja plicata* there is a variety *aurea*, and another, *zebrina*; the latter has green and golden-marked shoots. The Chinese *Arbor vitæ* (*Thuja orientalis*) provides a golden variety named *aurea*, which is a neat-growing plant. *Juniperus chinensis aurea* is a pretty golden variety of the Chinese Juniper, while among Pines we get a golden variety of the common Scots Pine (*Pinus sylvestris*).

In addition to these there are numerous varieties with more or less variegated foliage, but they are inferior to those mentioned above for general work. Some of them have a diseased appearance and the golden patches die out. Those to which prominence has been given are, in almost all cases, strictly golden coloured, and the plants present a perfectly healthy appearance, being, except in colour, exact counterparts of their respective types, as easy to cultivate and growing at about the same rate. K.

### NEW TREES AND SHRUBS.

The different autumn catalogues are always awaited with interest by lovers of hardy trees

and shrubs, as some promising novelties are sure to be announced. This year one catalogue in particular contains many subjects likely to reach a high position in our gardens, viz., that of Messrs. James Veitch and Sons of Chelsea.

*Buddleia variabilis superba*.—Yet another form of this *Buddleia*, of which the variety *veitchiana* has already become a general favourite. The variety *superba* is described as having larger epikes and more deeply coloured flowers than any of the others, and being a fortnight later in blooming than *B. variabilis* itself.

*Clematis repens*.—This resembles *C. montana* in growth and floriferousness, but the individual flowers are much larger, being from 2 inches to 3 inches in diameter. They are pure white in colour and at their best in August.

*Cotoneaster applanata*.—An exceedingly graceful species of *Cotoneaster*, which was given an award of merit by the Royal Horticultural Society last autumn. The leaves are ovate, dark green above, and covered underneath with a greyish tomentum. The berries, which are borne in great profusion, are, when ripe, of a bright scarlet colour.

*Ilex Pernyii*.—A dense-growing and exceedingly pretty little Holly which was given a first-class certificate by the Royal Horticultural Society as recently as September 1 this year. It has been known for some years, but its introduction we owe to Messrs. Veitch. The berries are red, like those of the common Holly.

*Pinus Armandii*.—This Pine, which belongs to the *Cembra* section, has been long known through the French missionaries. This is, however, the first time it has been distributed.

*Rhododendron intricatum*.—In the spring of last year this little *Rhododendron*, then shown under the name of *R. nigro-punctatum*, gained many admirers and was awarded a first-class certificate by the Royal Horticultural Society. It is a dwarf species of rather upright habit, with a profusion of trusses of small lavender-coloured flowers.

*Rosa Moyesii*.—A vigorous-growing Rose with single deep red flowers. Apart from its own intrinsic merit this species may prove of considerable value to the hybridist.

*Vitis repens*.—Another of the many ornamental Vines that we have received from the same source. It is a strong grower of a self-clinging nature. H. P.

## THE GREENHOUSE.

### CLEANSING GLASS HOUSES.

THIS is a very necessary operation, not only because the general appearance of the house is improved and more light admitted through the cleaner glass, but because many insects hibernating in corners and crevices are thereby destroyed. The materials required are a good scrubbing-brush, a syringe, small paint-brush and bottle of paraffin, soft soap (1lb. is sufficient for a small greenhouse) and two pails, one for soapy, the other for clean water. For lime-washing a fibre brush will be needed (hair or bristle quickly curl in hot lime-wash) and one gallon of unslaked lime.

Remove all plants as far to one end as possible. Vines that have lost their leaves may be pruned. Creepers covering the roof should have their branches tied in bundles, or in the case of plant climbers, such as *Lapagerias* and *Tacsonias*, they may be rolled up in rings, beginning at the points and securing them occasionally with a tie. All corners and crevices may be treated to a dose of paraffin applied with the paint-brush. Next collect all old ties and other rubbish and destroy them by burning.

Wash from the top of the roof downwards. Commence by spraying a portion with hot soapy water (half an ounce of soft soap to one gallon of water). Scrub the woodwork and glass

systematically, the framework of the light first, afterwards the sash-bars, finishing with the glass; be careful to leave no part untouched. Syringe off all the loosened dirt, &c., with clear water, using considerable force. When this is finished, place the lime at the bottom of a pail with water to just cover it, and when the lime is crumbled or slaked stir in enough water to make it the consistency of cream. Scrape or scrub any green patches on the walls and apply the lime-wash, carefully working it into all holes and crevices, and finally clean off any splashes on woodwork or pipes with a moist rag. Wash the benches and renew the shingle or shell covering them. If the lights can be opened and the house freely ventilated, so much the better; it will then be ready for the return of the plants after they, too, have been cleaned.

When it is possible to entirely remove all plants and creepers, insect pests may be exterminated by burning (in a flower-pot over hot coals) about half a pound of sulphur to every 100 cubic feet of space. No other ordinary method of killing insects is so effectual.

J. COMBER.

### THREE GOOD GREEN-HOUSE PLANTS.

*LEONOTIS LEONURUS* (Lion's Tail). This is a beautiful subject for autumn and winter; the colour (bright orange scarlet) is such as is appreciated by most people. The flowers appear in whorls up the stem, and sometimes there are as many as eight to ten whorls on a well-developed growth, and as many as eight or ten growths ought to be secured in an 8-inch pot. The plants must be afforded sufficient heat to keep the blooms from damping, when they will last for four or five weeks in good condition. They are easily propagated in the early spring from cuttings, and after flowering they should be cut back similar to *Salvias* and the growths made from the base used as cuttings. A few old stools grown on and planted out in the herbaceous borders look well during August and September.

*Salvia leucantha* is another old plant that has come into favour again, and is just now making a bold show and is much admired. It has long spikes of bluish purple flowers, which are like plush, being soft and covered with a down-like substance. These require similar treatment to the *Leonotis* mentioned above, and the flowers also last a long time.

*Thysacanthus rutilans*.—This is also a plant of old acquaintance which has sprung into popular favour, and when grown well is exceedingly ornamental. Its long trails of scarlet blooms are very effective, hanging down 2 feet from the apex of the plant. These, however, require stove treatment and should be propagated annually from cuttings. W. A. Cook.

### SOPHRO-CATTLEYA DORIS.

BI-GENERIC hybrids are now comparatively numerous in the Orchid family, but none surpass in beauty and refinement the subject of this note. As will be seen by the illustration, the flowers are of good size and the substance is all that can be desired, while the vivid orange scarlet colour is most enhancing, and is much intensified by the exceedingly rich golden yellow which suffuses the labellum. It was shown before the Orchid committee of the Royal Horticultural Society, on the 10th ult., by J. Gurney Fowler, Esq., of Woodford, when it received a first-class certificate.

## THE ROSE GARDEN.

### PLANTING ROSES AGAINST TREES.

WHEN an amateur is told to plant a Rose to climb up a tree, he, as often as not, simply turns over the soil, sets out a Rose, and is afterwards surprised that it barely exists. As I have been successful in getting Roses to cover fruit and other trees, a few words on this interesting subject may be welcome.

THE NEW SOPHRO-CATTLEYA DORIS. (Natural size.)

We must remember that the soil at the base of a tree, especially if it is an old one, is sure to contain roots and to be exhausted. Therefore a hole, quite a yard in diameter and three spits deep, should be dug about a foot distant from the tree, choosing a spot that is not likely to contain any main roots. Some turf should then be placed grass downwards at the bottom of the hole, and on this some good loam mixed with manure, wood ashes and a little bone-meal. The ground must be made firm and the Rose can be planted at once.

Before filling up the hole it is a good plan to sink half a cask (with the bottom knocked out) in the ground. This will keep tree roots at bay for some years, giving the Rose time to grow strong. Try and plant away from the drip of the branches. Very often the outer branches of an old Cherry or Apple tree bend to within 5 feet or 6 feet of the ground; under these branches a Rose can be set, the growths being led up to the boughs by means of a post. Roses do well when planted in such a position, since they escape most of the roots of the trees.

When Roses are thus induced to ramble over the trunks and branches of old trees a most delightful effect is produced, and the method should be widely adopted where old trees exist and where the soil is at all suitable for Roses. Even where the natural ground is not suitable it may be rendered so by adding new as advised above.

All strong-growing Roses may be used for growing on trees, but those of a slender growth are

perhaps, the best, as rough winds will not break their subtle shoots. Thus the Ayrshire Roses (Bennett's Seedling, Dundee Rambler, Ruga, Virginian Rambler), evergreen types (Félicité Perpétue, Flora) and the wichuriana hybrids (Alberic Barbier, Dorothy Perkins, Hiawatha, Lady Gay, Rubra, &c.) are very suitable. Carmine Pillar, Mme. d'Arblay, The Garland, Blush Rambler, Crimson Rambler, Euphrosyne and Polyantha grandiflora (an enormous grower and, therefore, good for this purpose) will also succeed. E. TESCHEMACHER.

### ROSES IN THE WILD GARDEN.

MANY unprofitable plots of ground are capable of being rendered attractive by naturalising rambling Roses. The wild garden is the most fitting of all spots for numbers of the single and semi-double varieties that need plenty of room to attain their fullest dimensions. No one who has ever seen the beauty of these Roses when growing unrestrained and untouched by the knife will desire to tie them in closely and cut away more than half their growth with the pruning-knife, as is too often done. Roses planted near old trees soon send their shoots among the branches until the whole head is covered with Rose growth, which droops gracefully downward on all sides and creates a lovely picture when smothered in flower.

Where Brambles show luxuriant growth Roses will usually do well, but it always pays to give them a good start by providing them with a rich and deep bed, when they will at once commence to make vigorous shoots. So many Roses are suitable for the wild garden that it is difficult at

first to know which sorts to select. When a large space is at the disposal of the planter, almost all the rambling varieties may be utilised; but in a small garden only a few of the most attractive should be planted.

Many of these Roses cover an immense space when perfectly developed, and should, therefore, be fully 20 feet apart. All climbing Roses should be on their own roots, as in the wild garden constant supervision is impossible, and it is disappointing to find a plant smothered in a mass of Dog Rose or Manetti suckers which are choking and impoverishing it. The greater number of Roses suitable for the wild garden are summer-flowering varieties, but some there are that have the advantage of bearing autumnal blooms. Of the sempervirens race *Félicité Perpétue*, *Myrianthes Renoncule* and *Flora* are among the best; while of the Ayrshires the shell pink *Virginian Rambler*, the white *Dundee Rambler* and the blush pink *Ruga* are beautiful. The *Dawson Rose*, with its dense mass of fragrant pink flowers; *Carmine Pillar*, a remarkably strong grower with rich crimson single blooms; *Dorothy Perkins*, a charming Rose with shell pink blooms which are often produced well into the autumn; and *Lady Gay*, very similar, are all eminently adapted to the wild garden, as is *Crimson Rambler*, but its crude colouring renders it undesirable.

Most of these will become huge bushes in a short time. The *wichuraiana* Roses are specially useful for covering banks, which they clothe with a veil of glossy foliage spangled with blooms at flowering time. *Jersey Beauty* is probably the most rampant grower of all Roses and will spread rapidly in all directions. *Rosa multiflora simplex* is a lovely sight if trained to a post 12 feet or so in height, when its long shoots arch over gracefully and fall almost to the ground on all sides, the plant presenting a beautiful picture when it is transformed to a sheet of white in summer. The *Austrian Yellow* and *Austrian Copper*, with their wondrous colouring, must on no account be omitted, but the Roses named are but a tithe of those that might be employed to beautify the wild garden.

S. W. FITZHERBERT.

## THE FLOWER GARDEN.

### VIOLAS FOR EXHIBITION AND HOW TO GROW THEM.

THE ever-increasing popularity of the Viola or Tufted Pansy, either for bedding or exhibition purposes, is a source of gratification to those who have done much to improve these beautiful flowers; but it is to be regretted that too little attention is given to its cultivation by the gardening journals—at least, from an exhibitor's point of view—and it is from the standpoint of an exhibitor that these few notes are penned. Violas are pre-eminent for bedding purposes, blooming as they do from early spring until late autumn. With ordinary care and cultivation they are a mass of colour, while for table decoration they are equally as good as many better-known flowers. No garden can be complete without its bed or border of Violas, and, perhaps, to the amateur a few cultural hints may be of service.

It is often stated that the Viola thrives equally in a sunny position or in the shade; but my experience is that a cool spot shaded from the heat of the noonday sun and free from exposure to the wind is an ideal situation for the plants, exposure to the full heat of the sun having a detrimental effect upon them, the blooms rarely approaching the size obtainable from plants placed in the shade.

In the autumn or early winter ground should be well dug and left to the influence of the frost, and in January a good dressing of lime applied to the soil is advisable, for after a top-dressing of lime Violas have to me yielded better results in the following summer. In March manure is trenched into the soil 1 foot below the surface and well trodden down. In April the plants are removed to their permanent quarters, and here the gardener will find that a little extra trouble will repay him. A compost comprising loam and leaf-mould in equal parts, with the addition of half the quantity of sand, should be procured. A hole should be made with a trowel

and the plants deposited. Care must be taken to ensure deep planting. Afterwards the surface of the bed should be kept open by means of a hoe or fork.

The Viola is a gross feeder and may be well dosed with liquid manure after the usual watering; but the application of nitrates so often recommended should not be countenanced, inasmuch as these produce straggling plants, while the bloom soon loses its lustre, and when cut and placed in water is quickly dead. In July a top-dressing of leaf-mould or old and well-broken stable manure can be given, though liquid manure given once a week is preferable. From time to time the old growths may with advantage be removed, though it is not advisable to so deplete the plant as to leave only tender shoots, which take time to mature and bloom.

For those preparing blooms for exhibition it is the practice to remove practically every flower before it reaches maturity, and in the gardens of some exhibitors I have seen hundreds of plants and not a single bloom. The flowers are carefully removed until a short time prior to a show, and then the plants are allowed to bloom. This may be a good practice; but personally I have found better results to be obtained by ceasing to feed with liquid manure until a month before a show, and then to allow the blooms to develop. The recommendation to disbud up to ten or fourteen days from a given date has often resulted in few blooms to select from.

It is essential in preparing flowers for exhibition that they should be sheltered from exposure to wind and rain, and for this purpose sashes or garden lights should be placed at the height of 18 inches over the bed. If sashes are not procurable, strips of calico or muslin fastened to Bamboo rods will answer the purpose, though care must be taken not to allow the cover to fall inwards and so touch the blooms.

In September or October cuttings can be removed from the plants and inserted in sandy soil under the shelter of a hedge or wall, and in a sandy soil it will be found that there will be little difficulty in rearing as many plants as may be desired. Of course, the shelter given by a garden frame is a safeguard against the loss of cuttings, but the average English winter is not too severe for the Viola, and it must not be forgotten that the best plants are those that have withstood the frosts.

In the selection of suitable varieties to grow, the amateur should be careful to procure the best plants and to ignore the cheap rubbish dumped on the market, which, when seeded a second time, revert back to the wild variety. Plants in named varieties can now be procured so cheaply that it is not worth the candle to obtain inferior stocks. Care should also be taken not to procure the varieties which throw up thin papery blooms, but rather those with clean-cut petals and bold, distinct eyes. The following list of varieties may be of assistance:

*Whites*.—*Mrs. H. Pearce*, rayless, with yellow eye; *Bethea*, lightly rayed, huge size, and for all-round purposes easily the best white; and *Duchess of York*, similar to *Bethea*, but not the same vigorous habit.

*Yellows*.—*Isolde* is pre-eminent among the yellows, a strong grower and a perfect flower; *General Baden-Powell*, a deeper yellow of immense size, but liable to "wrinkle"; *William Lockwood*, another grand yellow, but needs careful cultivation to reach perfection; and *Rose Noble*, a deep orange

A BEAUTIFUL MASS OF ROSES IN A WILD GARDEN IN DEVONSHIRE.

yellow, but does not attain the size of the first-named yellow.

**Creams.**—Lady Knox, undoubtedly the finest self Viola ever raised, is perhaps the most refined flower extant, and the raiser's description is not overdrawn; Mrs. V. W. Bertram, another cream, rayed, a massive bloom; and Mary Burnie, a huge creamy white Viola, tipped with heliotrope.

**Purples.**—Sir James Knox, the best of its class; Malcolm Carmichael, a striking colour, though hardly a self, still a pretty bloom; Bailie Watt, deep colour, shading somewhat lighter towards the top petals; Hugh Reid, another grand flower and should be in every collection; and Crossie Robertson, for colour and form one of the finest Violas in cultivation.

**Crimsons.**—Crimson Beauty, a large flower of perfect habit and a constant bloomer; Mrs. S. Mitchell, rich colour, top and bottom petals streaked magenta; and Henry Almond, another fine flower, perhaps the largest of its class.

**White Grounds.**—Mrs. George Paterson, a magnificent flower of great beauty, makes a fine spray; Jeannie Peattie, a fine variety with dark border; Effie, a fancy, makes a delightful spray; and Neidpath Castle, heavily rayed, but otherwise a perfect flower.

There are numerous older varieties which have yet to be improved upon, viz., Duke of Argyll, the best all-round Viola in existence; Ethel, fawn, an improvement on the older J. C. Erskine; Lady Grant, slightly rayed white, edged bluish purple, has sported badly this season; Minnie J. Ollar, described correctly as one of the old champions and still is hard to beat; Mrs. C. M'Phail, rosy heliotrope, a constant bloomer but of straggling habit; Kate Houston, white ground, belted with mauve; Mrs. Chichester, white, flaked with purple; Mrs. J. H. Rowlands, rose, poor habit; Ada Jane, marbled lavender, comes in poor form in the spring but is indispensable for exhibition; Maggie Currie, another rose ground; James Pilling, white ground, edged lavender, a leading variety; Kate Cochrane, crimson purple; and Mrs. T. Allardyce, light mauve, a flower of great size and beauty.

From the above list the amateur should be able to procure a good selection; but as the best dozen varieties I would give Lady Knox, Duke of Argyll, Mrs. H. Pearce, Sir James Knox, Mrs. George Paterson, Jeannie Peattie, Isolde, Ethel, Effie, Minnie J. Ollar, Mrs. M'Phail and Malcolm Carmichael.

W. C.

## THE BEST FIFTY HERBACEOUS PLANTS.

As a lover of herbaceous plants, the writer has often wondered what he would grow if his border capacity would accommodate, say, only fifty varieties or patches, which must be the case in many small gardens. At this period of the year, when attention is turned to the making and renovating of herbaceous borders, it may be of interest and a help to those intending to devote space to this most delightful phase of gardening, and who have not the room for a large collection but are desirous of having the aristocrats of the hardy plant kingdom, to see the list that was, after much thought, decided on. In its

compilation the points that have been taken into consideration are beauty and duration of both bloom and foliage, diversity of habit and ease of cultivation. An effort has been made to avoid a predominance of any one colour, and at the same time to have the various shades fairly represented.

It will be noticed that in the case of *Lychnis coronaria* Walkeri, *Papaver nudicaule* and *Verbascum olympicum* three species are included which cannot truly be classed as perennials, but owing to their habit of freely reproducing themselves they may, for garden purposes, be so dubbed. If *Glaucium flavum tricolor* did the same, as is the case with its near relative of the same name less the tricolor, it would be included in my list, but beyond experiencing its remarkable beauty for practically a whole summer I have had no experience of it. With us

best fifty perennials, as with the quantity so limited many really fine things must perforce be left out; but the formation of a list might be a source of interest to devotees of hardy plants during the long winter evenings when the flowers are no longer with us.

The following are my selections: *Anchusa italica* Dropmore variety, *Alstroemeria chilensis*, *Aconitum Napellus* Spark's variety, *Achillea Ptarmica* The Pearl, *Anemone japonica* Queen Charlotte, *Anthemis tinctoria*, *Aquilegia* hybrids, *Astilbe Davidii*, *Bocconia cordata*, *Campanula celtidifolia elegans*, *C. turbinata* Isabel, *Centranthus coccineus*, *Chrysanthemum maximum* Robinsonii, *Coronilla varia*, *Cimicifuga americana*, *Delphinium* hybrids, *Echinops* Ritro, *Erigeron macranthus*, *Eryngium amethystinum*, *Gaillardia grandiflora*, *Galega Hartlandii*, *Geum coccineum* flore-pleno, *Gypsophila paniculata* flore-pleno, *Helenium pumilum* magnificum, *Helianthus* Miss Mellish, *Hemerocallis* Kwanso foliis variegatis, *Heuchera* bri-zoides gracillima, *Iris germanica* Purple King, *Kniphofia corallina*, *Lilium croceum*, *L. candidum*, *Linaria repens* alba, *Linum narbonense*, *Lupinus polyphyllus* bicolor, *Lychnis coronaria* Walkeri, *Lythrum Salicaria* roseum superbum, *Monarda didyma* Cambridge Scarlet, *Enothera missouriensis*, *Paeony* double white Chinese, *Papaver orientale*, *P. nudicaule*, *Phlox* Sylphide, *Pyrethrum* hybrids, *Salvia Sclarea*, *Scabiosa caucasica*, *Sedum spectabile* atrorubrum, *Senecio Clivorum*, *Spiraea ulmaria* aurea, *Statice latifolia* and *Verbascum olympicum*.

J. REYNOLDS HOLE.

Balderton, Newark.

## IRIS STYLOSA.

ALTHOUGH this plant is quite hardy its flowers are so delicate, and, blooming as it does in mid-winter, some means should be devised to throw off heavy rains and snow. The flowers are generally hidden in its large, grassy foliage, so much so as to escape the notice of those who are not familiar with its habits. Its flowers are a lovely sky blue and fragrant, equal to some of the stove Orchids. This Iris is happiest planted in a single row quite at the foot of a south wall. The low walls of vineries afford a capital position for it. The border should be slightly raised above the surrounding level, the soil light and well drained. Give no manure. Endeavour to encourage

a dwarf, well-ripened growth, conditions that tend to its profuse flowering. In such a position as described, a few short lights over the plants will afford the necessary protection, and good flowers may be picked at intervals for some weeks.

## LIMNANTHES DOUGLASHII AS AN EDGING PLANT.

If a bold edging is wanted to a long border, this showy annual should certainly be used. The plants in the accompanying illustration were set out quite 18 inches apart in the autumn, and during June made a fine display. *L. Douglasii* is, perhaps, the hardiest of all garden annuals. Frosts and wet never kill it, even when it is moved in midwinter. It reproduces itself freely from self-sown seed and will do well anywhere, being a good subject for slug-infested gardens, since these pests do not touch it.

E. TESCHEMACHER.

A BEAUTIFUL EDGING OF AN EASILY-GROWN HARDY ANNUAL (*LIMNANTHES DOUGLASHII*).

*Verbascum olympicum* is rather variable, the great flower-spikes being sometimes of a rather straggling nature, but a really well-shaped specimen is second to nothing. *Spiraea ulmaria* aurea does not appear to be at all generally grown, but a group of it on a border at Messrs. Backhouse's York nursery was a striking sight early in June, the foliage being of the most brilliant yellow. If the soil were too light and the position too hot for *Astilbe Davidii* to succeed, *Aster Amellus* Riverslea Beauty might be substituted for it; but before eliminating such a grand thing every effort should be made, and in Mr. Prichard's nurseries at Riverslea it succeeds admirably on the open border.

By dividing *Lythrum roseum superbum* into small pieces each autumn we get excellent results, the difference between plants so treated and others left for two years being quite marked. Probably no two gardeners would agree as to the

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE FRUIT GARDEN.**—Grape Vines under glass should be pruned now, beginning with the earliest. Cut back the lateral growths to a good plump eye near to their base. Shoots that have not borne well should be cut back to about 4 inches to 6 inches, securing these to the main stem by drawing them to the side of the latter. Brown scale or American blight is a source of trouble to many hardy fruit trees. An excellent remedy is to apply a strong solution of soft soap or Sunlight soap, using 3oz. of either substance in a gallon of water. Later on, when the buds begin to move, apply the same solution but at half the previous strength. A free dusting of slaked lime in the early morning is another remedy for the same pests.

**The Vegetable Garden.**—I am lifting for winter supplies healthy roots of Mint. These are being placed in rather shallow boxes and covered with soil. Subsequently they are placed on the greenhouse bench, where the more genial atmospheric conditions promote quick growth and ensure supplies from January onwards. Collect and put in heaps all vegetable refuse, such as weeds, haulm, leaves and similar accumulations. There is no better time than the present for doing this work. Add to this matter, to the extent of one-third of its bulk, quicklime, turning over the heap to ensure an even distribution of the constituents. Materials that will burn, such as old Pea-sticks, Cabbage-stalks, tree-prunings, &c., should be burnt and the ashes stored for future use.

**The Hardy Flower Garden.**—The beauty of Christmas Roses may be preserved by affording the plants some protection. There are several means of doing this. Old frame-lights, window-sashes, bell-glasses and sheets of glass held in position by any device that may suggest itself to the grower may be utilised for protecting the flowers from rain and smuts at this period. The last of the outdoor Chrysanthemums are long past their best, and should therefore be cut down forthwith. Give the roots a mulching with thoroughly well-rotted manure, as this protects the old stools through the winter.

**The Greenhouse and Conservatory.**—To assist in making a pleasing appearance in these struc-

tures, I am potting up successional batches of Lilies of the Valley. The stately Spiræas, too, should receive similar attention, as their early display is always much valued. The beautiful *Deutzia gracilis*, so easily grown, together with a few *Azalea mollis* will soon yield a welcome display of blooms if placed under glass where the temperature can be maintained at anything between 55° and 60°. Cyclamens are always a welcome feature in midwinter and rather later, but need careful culture just now. Rap the pot with the knuckles to ascertain whether the soil is dry or not; do not be deceived by appearances.

**The Window Garden.**—The use of tepid water for watering the plants at this period is essential to their well-being. Foliage plants should be periodically sponged to remove dust from the leaves and thus improve their health and appearance. Bulbs that have made a fair amount of growth may now be removed from the plunging material and stood in the window. For some years past I have used pretty little bush Ivies for the window-box; they are very hardy and always interesting.

**The Cold Frames.**—My concern for the moment is the careful overlooking of Carnations and Auriculas. When maintained in conditions that are somewhat close there is always a tendency for green fly to infest the plants. For this reason watering and free ventilation are items of culture that are carefully observed. On fine days, too, Violets will derive much benefit from an abundant air-giving. In anticipation of severe weather, I always have in readiness a supply of mats and long litter with up the frames.

### EASY METHODS OF FORCING SEAKALE.

This is one of the choicer vegetables that few beginners ever think of trying to deal with.

Many possibly regard it as a subject quite outside the region of their own skill, but such an idea should never be allowed to prevail. For this reason the notes in the present instance are written in the hope that wrong impressions may be removed, and, by a series of photographic illustrations, the culture of this excellent vegetable may be made quite clear.

In the present instance we propose to deal with Seakale for forcing, pure and simple. There are several methods in which this forcing may be done, and we will deal with those that are of the simplest and that with ordinary application and care a beginner may succeed with. In an earlier issue we gave instructions how to prepare Mushroom-beds outdoors, from which it will be gathered

temperature of the material is an all-important item. It is equally important with Seakale at this early period. To have Seakale at Christmas it will be necessary to give the roots rather more heat than Mushrooms during the forcing period. Those who have Seakale in their gardens may lift their own roots for forcing purposes. It is usual to lift one year old roots that have been specially grown for this purpose, placing these thickly in boxes or large pots, with the crowns just level with the surface soil, which should be just below the edges of the boxes or pots. Those who do not possess roots must perforce purchase what they require from their nurseryman. These supplies are always available, and special measures are taken to raise suitable roots for the purpose. The roots are not at all expensive, and a dozen strong and sturdy-looking specimens may be obtained for the sum of 2s. or thereabouts. We have reproduced in

2.—THREE ROOTS PLANTED IN A LARGE POT READY FOR FORCING.

1.—SEAKALE ROOTS WHICH HAVE BEEN LIFTED FROM BEDS IN THE OPEN AND HAD THEIR THONG-LIKE ROOTS REMOVED.

Fig. 1 three typical Seakale roots such as may be purchased for forcing. From their appearance it will be quite apparent that the long, thong-like roots peculiar to this subject have been removed. They have been detached with a sharp knife from the main root and retained for the purpose of making a new plantation outdoors. What is to be done with the large roots is a question that naturally arises from the beginner. We would suggest that care be observed in the first case, and that culture be of an experimental kind. Raise a few plants in large pots or deep boxes in the first instance and see how the plan succeeds. Pots 10 inches in diameter and others of lesser dimensions may be utilised. In these receptacles there may be placed three, four or five roots. For the purpose of illustration we have reproduced in Fig. 2 three roots adjusted in position in a large pot. Here it will be observed the crowns are just level with the surface soil and the latter just below the rim of the pot. When completed water in and cover with a pot of the same size, placed in an inverted position over the other. Those who have a greenhouse may place the pots under the staging, where a genial temperature can be maintained. Readers not possessing a glass structure may with almost equal success stand the pots in a warm cellar, where they must be kept perfectly dark.

Those who desire to raise a larger quantity of Seakale at this period may accomplish this very successfully by utilising deep boxes and planting thickly in these. The boxes must be deep, fully 9 inches to 10 inches being essential if the roots

3.—SEAKALE ROOTS PLANTED IN A LARGE, DEEP BOX READY FOR FORCING.

are to do well. Arrange the roots in a manner somewhat similar to that seen in Fig. 3. Here we have planted two rows to show the method of arrangement, which should be done so that the roots alternate in the rows. In this way the plants do better and ample space is allowed for the development of the growths. Another box of similar dimensions should be acquired, and after the one containing the roots has been placed near to or over the hot-water pipes running under the greenhouse staging this second box should be placed over the other as a covering. Seakale to be forced satisfactorily must be kept in the dark, and this should be seen to from the first. Water in the roots in the first instance, and inspect the boxes, &c., from time to time, always maintaining the soil in a moistened condition. In Fig. 4 we give an illustration of how to force Seakale in the open ground. Here there are three crowns growing in the open which may be forced with the greatest ease. The flower-pot in the photograph is used to cover the crowns, which it does adequately and well. This in turn is covered with manure litter and leaves, which will maintain a suitable temperature to force the roots into growth. As far as possible maintain an even temperature of from 55° to 60°. This is not difficult, as a fresh covering with manure litter invariably accomplishes this end. Special Seakale pots are made with movable tops for inspection purposes, but tubs, barrels, boxes and pots may be made to answer the same purpose.

#### WINTER WORK IN THE OUTDOOR GARDEN.

DURING the short, dull days of winter the amateur, and occasionally the gardener, are apt to let work in the outdoor department slide or even overlook it altogether, with the result that when the busy days of early spring rapidly approach, as they are wont to do, many tasks are found undone which might with advantage have been carried out during the slack winter period. In a well-regulated garden there will always be plenty to do in connexion with the outdoor department during the winter, and a reminder of a few tasks may be of assistance to readers. Where shrubberies have not been tidied these may be attended to during open weather. Any shrubs which have overgrown their bounds may have some of their longest and oldest branches entirely removed (except those which flower in the spring on wood of the previous year's growth, which should, of course, be pruned immediately after flowering), and in the case of commonplace subjects it may be found advisable to entirely remove them so as to make room for the choicer plants. All dead wood will also need removing. After this all leaves and annual weeds may be raked or hoed into the more open

spaces and there buried, throwing some of the clean soil taken from the trenches made for this purpose over the roots of the shrubs. Where a specimen has not made satisfactory growth during the past season, it may be as well to give the soil over its roots a 6-inch-thick coating of well-decayed manure.

In the kitchen garden digging and trenching operations will be in full swing, and both here and in the fruit garden advantage should be taken of frosty weather to wheel manure into the desired positions so that it will be ready for use immediately the weather breaks. When the soil is so wet that it is inadvisable to tread upon it, the work of renewing or revarnishing labels may well be attended to, and stakes also should be thoroughly overhauled and any old ones that need it, as well as new ones, given a good coat of green paint. Tools also may be given attention, such as hoes, shears and other simple cutting implements usually requiring grinding or sharpening in some other way.

Draining plots which are too wet is another eminently winter operation in the outdoor garden, and one which is easily capable of producing very good results if properly carried out. Undoubtedly pipe-drains are much the best, and these should be laid at least 18 inches, or, better still, 2 feet below the surface, so that there is no fear of their being disturbed by digging or trenching operations. Of course, a suitable outlet for the drain must be chosen before the work is commenced, and this should, if possible, be at the lowest portion of the plot which it is intended to drain.

Carriage drives and walks of all sorts may be formed or old ones renovated during the winter, but it is well to defer giving the final coating of fine gravel until March, as then it will last clean and bright all through the summer. Boundary hedges, too, will possibly need attention, and any trimming or stopping of gaps needed should be attended to without delay. Then Pea and Runner Bean stakes may well be trimmed and sharpened and tied into bundles of various lengths, so that when they are required they can be obtained at a moment's notice. Nothing is more annoying than having to stop and trim Pea-stakes when they are required, as work is always very pressing at that particular period in all gardens.

4.—FORCING SEAKALE OUTDOORS. THE POT IS PLACED OVER THE THREE CROWNS SHOWN AND THEN COVERED THICKLY WITH LEAVES OR MANURE.

## THE TOWN GARDEN.

**PLANTING HEDGES.**—Where, as is unfortunately the case in vast numbers of town streets, the houses have only small forecourts in front of them, it is obviously impossible to do anything in the way of forming and planting beds, and if it were possible, it is more than likely that the flowers and plants would be stolen. There is, however, usually sufficient space for the accommodation of a hedge, and such should always be planted, for it will improve the appearance of the house and the road to a very great extent. I am familiar with several London streets in which all the householders strive in friendly rivalry to have the best hedge, and it is surprising how excellent an impression is created in one's mind as one passes along.

Taking all things into consideration, ordinary Privet is the best plant to choose; the golden form is bright and attractive in summer, but it has a dull, dirty aspect in the winter which is never apparent in the green. *Euonymus* is sometimes utilised, and as long as the small Ermine moth caterpillar keeps away all is well; but when this pest descends in hordes upon the plants one may say farewell to brightness and beauty for some time, for the stems will be quite defoliated. Of course, the pest can be destroyed, but it is certainly much easier to eay it than to do it.

Whatever is chosen must be prepared for in the same thorough manner. In practically all instances planting will have to be done beneath the shelter of the front wall, and it is certain that the soil will be poor; therefore, let it be dug to a depth of at least 2 feet, and with the lower soil mix a heavy dressing of rotted manure, while with the top soil should be incorporated some refuse manure, such as that from a hot bed. In planting, the mould must be made very firm about the roots, and, as soon as they are in, water should be applied in large quantities and must be given again at frequent subsequent intervals, for the bricks will suck much of it from the ground, and the plants will not flourish as soon as it becomes quite dry. In the spring the applications of water may be supplemented with a little weak liquid manure, but this must be used with care, as it is not desirable to encourage too gross a habit of growth in the plants.

**HOEING BORDERS.**—The surface soil of all the borders in the garden should be kept hoed over frequently during the winter months, provided, of course, that the soil is not frozen hard. It is not that weeds grow in this season; even they have to take a rest sometimes, but the persistent loosening does a substantial amount of good by admitting unlimited supplies of fresh air, thus keeping the ground far sweeter than it otherwise would be.

**INDIAN AZALEAS.**—These are among the most delightful of all plants for the room, conservatory and greenhouse during the early months of the year, and they are neither difficult nor expensive to procure. It is true that the plants are not such as one would recommend the town gardener to grow on from the young state, as they demand pure air and a considerable amount of care in management; but thousands are annually imported from Holland and Belgium upon which the buds are already set, and it is these that the amateur should purchase. They are almost invariably grown on short legs and their compact heads will be set with hundreds of buds. As soon as they arrive they should be placed in pots only slightly larger than those previously occupied, and the ball must be surrounded with a compost of loam, peat and sharp sand; this must be made very firm, or the water given will run through it instead of passing through the inner ball and roots. The utmost care should be exercised in watering at all times, as either too much or too little will be followed by the casting of many of the buds. HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**N**OW that Chrysanthemums are on the wane, other flowers will be needed to keep up the gay aspect of the conservatory. If my notes have been followed, there will be a good show now of Begonias Gloire de Lorraine, Gloire de Sceaux, Mrs. Heal, &c., and Primulas in quantity. These should be kept in light positions and in fairly dry quarters, when they will continue to flower for a long time.

*Lily of the Valley*, *Spireas*, Roman Hyacinths and Narcissi will be making a good show now, and in warm houses the Poinsettia and Plumbago rosea are at their best. In addition to these there should be plenty of Calanthes, Cypripediums and Zonal Pelargoniums. Great care is needed to keep these free from aphides, and if a plant is allowed to become too dry it will soon develop some pests; therefore it is necessary to look over them very carefully every day and water those plants well that require it, leaving nothing to chance.

*Freesias*.—A good batch of these should be introduced into heat now if they have filled their pots with roots. They will respond to a temperature of 55° to 60°, and the flowers should be supported with neat stakes.

*Lilium Harrisii* may be put into heat as soon as the buds are showing, but it is not advisable to put them in too high a temperature, as the flowers do not develop so thoroughly.

#### KITCHEN GARDEN.

Some ground should be trenched and a fresh supply of Horseradish planted. This vegetable is in request in most establishments as a condiment for roast beef and ought to be grown more than it is; as a rule, it is grown in an out-of-the-way place where it struggles for existence. Choose a piece of ground in the open, trench it 2 feet 6 inches deep and put plenty of manure at the bottom; then select some thin, straight roots 8 inches to 1 foot long, and see that these have only a single crown. Plant them 9 inches apart in the rows and 15 inches between the rows. If this system is followed up, fine roots will result.

*Artichokes*.—These are also most useful vegetables. The whole crop of the Jerusalem type may be taken up and stored in sand or ashes outside, and the ground dug or trenched at the earliest opportunity. During this process take out every root and small tuber, or these will come up where they are not wanted. Globe Artichokes should now have another layer of ashes around the base as a protection from frost, and if hard frost prevails, some light litter may be placed over the foliage.

*Cauliflowers and Broccoli*.—Take up all the heads as they open and store them in deep frames or sheds. If they are dug up with the stems, they will last several weeks without any harm if placed on a damp bottom.

#### HARDY FRUIT GARDEN.

Continue to prune Apple and Pear trees as fast as possible. Where trees have been summer pruned there will not be so much to do. The experienced pruner will see at a glance what to cut away, as the buds are already plumping up for a fine show of bloom next season. The work of root-pruning may still be accomplished in open weather and ground got ready by trenching for further or improved plantations, but all planting should be done as soon as possible now. In wet weather see that a good supply of stakes is prepared, tools sharpened and cleaned.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ORCHIDS**.—The work is now chiefly of a routine character, and consists in keeping the temperatures regular, damping judiciously but not abundantly, and giving as much air as possible without unduly lowering the temperature. With regard to watering at the roots, everything depends upon the kind and the state of growth. Cattleyas of all sorts will need greatly diminished supplies, small plants, of course, requiring more attention than those of a larger size and having a greater body of compost about them.

*Deciduous Ferns*.—Among the stove and greenhouse Ferns few lose their fronds entirely at any period of the year, yet among those which do so there are some desirable species. It not infrequently happens that these get lost during the dormant period, sometimes through improper treatment. In the culture of all the deciduous Ferns it is desirable to give them such treatment as will induce them to go to rest in the autumn; they will then have more strength to start early in the year.

#### FLOWER GARDEN.

With the approach of winter and the possibility of the commencement at any time of a spell of protracted frost, any of the plants in the flower garden above ground or beneath the same in the shape of bulb, corm or tuber that may require protection should at once receive attention. Individual plants of *Yucca filamentosa* (which makes a charming bed in summer) should be staked and tied up, or frost and wet will rot the heart of the plant. The same remark applies to *Arundo conspicua*, not nearly so hardy as the true Pampas Grass.

#### KITCHEN GARDEN.

*The Protection of Celery*.—I find the best plan, if the weather should become unduly severe and there is no covering of snow, is to lay some dry litter or Bracken Fern along the sides of the rows and then to shake a little of the very lightest and driest loosely along the top. If a heavy covering be put on and snow were to follow directly afterwards, when a thaw set in it would become a wet and sodden mass, and the Celery would suffer accordingly.

#### CHRYSANTHEMUMS.

Care will now be necessary in supplying the old stools with water; too much is injurious, as it creates a paleness in the young leaves which is objectionable. When the leaves are rendered so pale in colour, a long period often elapses before they regain their wonted vigour. It is surprising how little water is needed to induce growth to be made from the base after the plants are cut down. Where the roots are bare on the surface they should be covered with a portion of sandy compost. In stubborn cases, where growth refuses to move at the base, it is necessary sometimes to rectify the drainage if this has got out of order, and even plunge the pots in a gentle bottom-heat and syringe the stems several times daily.

#### HARDY FRUIT.

*Gooseberries*.—The pruning of these bushes is often delayed as long as possible in consequence of the loss of buds by birds. The bullfinch and others will soon be on the alert and do much mischief. I do not advise delaying pruning, but take measures to keep these pests away. I am not an advocate of the severe pruning often practised. Of course, it is necessary to well spur back the plants trained on walls, but the close cropping over is not advisable. I advise the thinning of shoots, shortening loose or straggling branches, cutting back to a well-placed inner shoot and removing any sucker growths, shortening any branches that press down towards the soil. It is not necessary to thin severely.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## BOOKS.

**Holly, Yew and Box.**\*—At the present time, when everyone is thinking of Christmas decorations, the volume now under notice provides pleasant and, at the same time, most instructive reading. The author, who has charge of the splendid arboretum at Kew is, of course, thoroughly at home with his subject, and the information given is, as one would expect, thoroughly reliable and up-to-date. The descriptions of the varieties of the common Holly (*Ilex Aquifolium*) are those of Moore, which appeared many years ago in the *Gardeners' Chronicle*, as also are some of the excellent leaf illustrations. In addition to these descriptions cultural details and the uses of the plants are given, and many legends and superstitions connected with them are quoted. Besides Hollies, Yews and Boxes, chapters on other evergreens (conifers excluded) are added, hardy Heaths, Bamboos and their allies, Rhododendrons, Evergreen Oaks and Ives, Laurels, Daphnes, Elæagnuses and Escallonias coming under this heading, and these chapters certainly add considerably to the value of the book. The many illustrations in black and white are beautifully executed and serve the purpose of instruction in a decided manner, and both author and artist are to be congratulated on the excellence of their work. A slight error in the titles to the group of Yews facing page 191 will probably be rectified in the next edition. The initial letter "I" is there given to indicate Taxus, and this may possibly be confusing to the uninitiated.

**Le Chrysanthème dans l'ornementation des jardins et la décoration de la maison.**—M. Albert Maumené, a well-known French writer on the art of floral decoration, has recently issued in pamphlet form the text of the paper he read at the Toulouse Conference of the French National Chrysanthemum Society last year, and for which a silver-gilt medal was awarded him. It runs into sixteen pages octavo, and will interest those of our readers whose tastes are æsthetic in Chrysanthemum matters.—C. H. P.

**My Garden.**†—This slim volume is somewhat a new departure in the domain of garden literature, being written entirely in verse. There is no settled scheme or arrangement in the book; the author has simply jotted down verse on such congenial subjects as "The Borders," "Flowers," "The Rose Garden" and "The Sun-dial." The illustrations are very good, and we congratulate the author on being the possessor of such a delightful retreat; it is rather impossible to particularise any one more than another, as they are unnamed, but that facing the Prologue is one of the most charming.

**Studies in Gardening.**‡—This may be described as a splendid shilling's worth, even in these days of cheap garden books. Printed in excellent style and neatly bound, the book consists of a series of articles on the theory and practice of gardening, originally published in *The Times*. They are on a variety of popular and interesting subjects, and are well written by one who is indeed no 'prentice hand. There is a capital introduction, followed by articles, the names of only a few of which we can give, viz., "Campanulas," "Pinks," "The Improvement of Garden Flowers," "Common Sense in Gardening," "Lilies," "The Theory of Garden Design," "English Ideals of Gardening," "Gardeners," "The House and the Garden," "Raising Perennials from Seed," "Saxifrages," "The Fifty Best Hardy Perennials," "The Fifty Best Rock Plants," &c.

\* "Holly, Yew and Box, with chapters on other Evergreens," by W. Dallimore, 7s. 6d. Mr. John Lane, The Bodley Head, London.

† "My Garden," by J. T. Prior. Published by Elkin Mathews, Vigo Street, W.

‡ "Studies in Gardening." Price 1s. *The Times* Office, Printing House Square, London.

**The Flowers and Gardens of Japan.**—A delightful book, uniform with the "Italian Lakes," published by the same firm a short time ago and painted by the same artist. The book, which is very nicely got up, is illustrated with fifty of the most dainty little pictures of views in Japanese gardens. The Wistaria, Chrysanthemum, Plum blossom, Cherry blossom, Iris and numerous other favourite flowers of the Far East are most attractively presented, and the letterpress is none the less interesting. From an artistic, legendary and historical point of view the book will furnish many an opportunity for pleasant reading, and is certainly the most agreeable book on the subject we have seen for a long time. Briefly stated, the contents include chapters of descriptive matter on landscape, nursery and temple gardens; on the Plum, Cherry and Peach blossoms; on the Wistaria, the Pæony, the Azalea, the Lotus, the Chrysanthemum and many other floral favourites. No one can peruse these chapters without realising to a fuller extent than before how largely the love of flowers enters into the minds of the Japanese people, who have their special *fêtes* and shows on certain days for their greatest favourites. Some of the stories and legends are quaint and interesting, and the book is certainly a valuable addition to modern horticultural literature.

## LEGAL POINT.

**Prize cup (Orchid).**—"A gardener under a verbal promise from his employer that 'whatever he won he should have' enters for a prize competition and wins for a certain number of years. Finally, the cup becomes the property of the winner after various successive triumphs, according to the rules of the show, and the employer now claims it from his servant. Has he any right to it?" The answer depends partly on the elements of contract and the doctrine of possession. If the contract as between master and servant had been executory and the cup had passed into the master's possession on the award, it would be necessary for the servant, in addition to proving the express or implied request to enter the competition to give some evidence of "consideration," or else he might fail in an action to recover the cup or damages. It is possible also to imagine that some bother might arise as to whether the master did or did not intend to enter into legal liability and contractual relationship. In the case before us there appears to have been sufficient "consideration" to support even an executory promise, as the servant after accepting the promise put himself to certain expense in connexion with the show, which he paid out of his own pocket. But whatever doubts there might be if the contract was executory and the cup had after the award passed into the possession of the master, there can be none if the cup is in the possession of the servant under the circumstances above mentioned, and in my opinion the servant can keep it.—BARRISTER.

## OBITUARY.

### HENRY NEVARD.

THERE has recently passed away, at the age of seventy-seven, one of the most successful cultivators of the Rose of bygone days. I refer to Henry Nevard, who was for some forty-six years head Rose-grower to the well-known firm of Messrs. B. R. Cant and Sons of Colchester.

Mr. Nevard was a born rosarian, and few could stage a seventy-two more deftly than he. How

he loved the Rose, especially those superb sorts such as *Souvenir d'Elise Vardon*, *Niphetos*, &c., now so rarely seen! The present-day somewhat flimsy varieties would not have found an admirer in Mr. Nevard. I believe I am right in saying that Henry Nevard took part in the first exhibition of the National Rose Society, which was held in St. James's Rooms in or about the year 1857, and from that day to the time he retired to enjoy his well-earned rest he was a force to be reckoned with. Only this season Mr. Alexander Dickson said of him that when they saw Ben Cant and Nevard come along they knew there was going to be a hot contest.

Many a Rose-grower will recall the cheery face of our departed friend, and will miss him equally as much as they missed the stately presence of Dean Hole or the sweet countenance of the Rev. H. D'ombrain. It is to be hoped that Messrs. Dickson or some other raiser will perpetuate his memory by giving his name to a real good sterling

THE LATE HENRY NEVARD.

novelty, one that is likely to live for a long time. Mr. Nevard was buried in Myland Churchyard, Colchester, on October 23 last. P.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Annuals and perennials under trees (I. Heap).**—It will depend entirely upon the density and continuity of the shade as to what plants will grow, and possibly a few experiments will be best. You give us no idea of the extent of the intended area for planting. We therefore advise you to sow seeds of Poppies, Snapdragons, Evening Primrose, Foxgloves,

Primroses, Marigolds, Cornflowers and the like, and note results. For perennials you might plant a very liberal assortment of Day Lilies, many hardy Ferns, Lenten Roses, Megaseas, Primulas of sorts, Woodruff, Acanthus, Michaelmas Daisies, London Pride, Saxifraga peltata, Hepaticas and others, while of bulbous plants you might select Lilies, Daffodils, Scillas, Winter Aconites, Dog's-tooth Violets, Lily of the Valley, Muscaris and a host besides. You could only obtain a display of annuals in September and October by a special late sowing of seeds. The chief of the bulbous plants flowering at this period are Lilies, Colchicums and autumn Crocus. Of perennials the Sunflowers and Michaelmas Daisies are the chief things.

**Anchusa leaves dying (A. St. L.).**—The leaves of the Anchusa are not attacked by any fungus or insect pest, but are dying off for the autumn. The plant is quite deciduous, and the leaves always in dying turn the peculiar colour shown by the specimens sent.

**Polygonum for a summer-house (Aline C.).** The Polygonum you require for your summer-house is *P. baldschuanicum*. It is of rapid growth and flowers well in a young state. When well grown it forms one of the handsomest of all climbers. *Alyssum maritimum compactum* is a useful subject for carpeting Rose beds. It is very dwarf and does not interfere seriously with the Roses. When all is said, however, Roses without a carpet thrive most satisfactorily. Surface plants always rob the ground to some extent, while it is difficult to give the Roses stimulants with a carpet of other plants, and a little food material during summer is highly appreciated by Roses.

**Aquilegias and Hollyhocks (E. M. L. H.).**—If we understand your letter aright, you sowed seeds of the former group in July in the open. If this is so and the seedlings are not unduly crowded, let them remain till the end of February next and replant them in good soil. These plants are adverse to frequent removal, and you could at the time stated transfer the larger plants to permanent positions. The smaller plants should be ready to plant out by the middle of May. You might with advantage plant the strong seedling Hollyhocks into their permanent places without delay. To pot them and keep them in a cool greenhouse for the winter would probably do greater harm than the exposure in the open border. It is important that the seedlings be firmly planted in good and deep soil. We do not remember seeing a plant from you; please send again.

## THE GREENHOUSE.

**Dividing Agapanthus umbellatus (Electrical).**—When it is intended to divide the blue African Lily (*Agapanthus umbellatus*) it should be done early in the spring just before the plants start into growth. At the same time we wish to point out that the *Agapanthus* never flowers so freely as when thoroughly established in large pots or tubs, and thus forming large masses or clumps. Such being the case, if you divide your plants next spring you must make up your mind for a lessened amount of flower for a year or two. *Agapanthus* may be readily kept throughout the winter in an ordinary greenhouse, the main point being to see that they do not get frozen. They may be wintered in such places as stables, coach-houses, &c., provided they get a certain amount of light and are quite safe from frost. During the winter they may be kept quite dry at the roots, or watered two or three times during that period. This will depend upon the situation the plants occupy.

**Treatment of Amaryllis (J. Watts).**—As your *Amaryllis* are in 8½-inch pots we naturally conclude that the bulbs are large, and, if so, they may be kept quite dry without risk for a longer period than smaller ones. If they are lying on the ground underneath the stage and away from the hot-water pipes, they should not take any harm if kept dry till the new year. Then they may be stood on the stage and watered. Of course, this must not be done should the weather be very cold, as in this case it is far better to wait for a mild period. The month of February will be quite early enough to water them regularly, and even then only just enough should be given to keep the soil slightly moist till the leaves commence to push up. You will understand that throughout the winter a temperature of 50° to 55° is necessary for the *Amaryllis*, though the thermometer may sometimes fall to 45° without injury, providing the soil is quite dry. Any whose roots are in bad condition may be repotted in February, but annual repotting of the whole of the bulbs, which was formerly considered necessary, is not now regarded in that light. Established, well-rooted bulbs may, after the flowering season and when growth is taking place, be supplied with occasional doses of liquid manure instead of repotting.

\* "The Flowers and Gardens of Japan," painted by Ella du Cane, described by Florence du Cane, A. and C. Black, Soho Square, London.

## TREES AND SHRUBS.

**Planting a Laurel hedge (A. B. C.).**

You can certainly plant a Laurel hedge this autumn; indeed, October is about the best month for doing so. The best time to trim the hedge is in June, as the short growth made after that time quickly takes off the cropped appearance. Laurel hedges should be cut with a knife and not shears, as in using these last the large leaves are likely to be cut in two and thus spoil the appearance of the hedge. This last sentence will also apply to all large-leaved subjects used for hedges. The spring is the best time to trim Ivy, as the young leaves are then immediately pushed out and quickly hide the bare shoots.

**Information about Butcher's Broom (H. Jones).**—In some instances male and female flowers are borne on the same plant in the case of the Butcher's Broom, but more frequently male and female flowers are borne on different plants. In some places it appears to be a shy fruiter. If you examine your plants next year when in flower, you will be able to ascertain whether you have the two sexes or not. If you have, try hand pollination.

## FRUIT GARDEN.

**Pear tree unfruitful (N. G. T.).**

Undoubtedly the tree is making too much growth, and probably has a tap-root which has gone down into the subsoil. You cannot do better than root-prune the tree at once. Make a trench about 3 feet from the stem of the tree in a half-circle this year, and complete the circle next year. If you make a fairly deep trench you will soon find out if there are any tap-roots; if so, just sever them with an axe or spade. Give the tree a mulching next spring with well-rotted manure, mixed with an equal quantity of soil and a little bone-dust added. This will encourage surface roots, which is what the tree wants.

**Grape Vines diseased (C. E. Westgate).**—If you will send us some of the leaves or wood of the Vine affected we will do our best to tell you the nature of the disease and the best way of getting rid of it. Also please send your name and address.

**Standard Plum trees not bearing (R. R.).**—This seems to us a clear case for the application of the knife to the roots of the trees. Trees not bearing fruit are naturally more vigorous and free-growing than are those which bear fruit. Root-pruning was fully described in our issue for September 12, which please see.

**Peach, Plum and Cherry trees to plant within a netted enclosure (J. Romanes).**—Pears: Williams's Bon Chrétien Louise Bonne of Jersey, Emile d'Héty and Doyenné du Comice, all on Quince stocks. Plums: Rivers's Early Prolific, Green Gage, Dumelow's Superb Gage and Kirke's Cherries: Frogmore Early Bigarreau, White Heart, Governor Wood and The Noble.

**Sludge from cesspit for orchard fruit trees (A. W. M.).**—It depends on what the nature of the sludge is. If it is the drainage from a farm or stable-yard, then the application of the quantity you mention would do much good if applied in early winter and again at the end of January. But if the sludge only contains the ordinary drainage of roads, &c., its application to fruit trees would be worse than useless.

**The best six Peaches and three Nectarines to grow under glass to ripen in succession (Peach House).**—The earliest varieties to ripen are Alexander, Waterloo, Early Beatrice and Early Louise, but we do not advocate the planting of either of these in so limited a collection on account of the tendency most of them have to cast their buds in winter or spring, and also because of the comparatively small size they attain. In case you decide to include one on account of its earliness, Waterloo is the best, and is ripe about ten days earlier than the next we shall mention, namely, Amsden June. The next in succession are Dymond, Crimson Galande, Royal George, Noblesse or Violette Hâtive. Noblesse is, no doubt, the finest flavoured of all our Peaches and is large in size, but it is not a heavy cropper; on the other hand, Violette Hâtive is one of the best in all ways. Walburton Admirable and Princess of Wales.—The former is a fortnight later than the latter, but does not crop so heavy, neither is it so handsome as Princess of Wales. Of Nectarines, Cardinal is about ten days earlier than any other variety and good in every respect. Lord Napier and Spenser.—The latter is one of the latest, largest and best.

## MISCELLANEOUS.

**Canker in Parsnips (Kent).**—The root sent shows traces of gnawing by one or other of the ground animals that are so often omnivorous in their habits. Possibly the pest in this case is one of the surface caterpillars, the grub of the Cabbage moth or an ally, but there is nothing to show what the exact culprit is. These

caterpillars may be found just at the surface of the soil around the roots of the plants which they attack. Vaporite should be applied.

**Feeding gold-fish (Rita).**—Gold-fish can be kept in good condition for some years by feeding them on ants' eggs, with a few breadcrumbs at long intervals and a tiny sprig of Watercress occasionally during the summer months.

**Plants to cover north wall (H. E. G.).**—We presume that you do not wish to confine yourself entirely to plants of a true climbing habit, as that would deprive you of several subjects which would be of use, while it would narrow the selection considerably. Camellia japonica proves an excellent covering for a north wall; it certainly requires training, but is always beautiful and green. It will flower during May and June. Crataegus Pyracantha may also be planted. It flowers before July, but fruits profusely in autumn. Cotoneaster microphylla is another evergreen of neat appearance which fruits freely. Under favourable circumstances it attains a height of 20 feet. Jasminum nudiflorum grows freely and blooms well during winter, while Escallonia exoniensis bears white flowers freely during July, and Hydrangea attissima forms a very neat covering, which has the advantage of being self-clinging. When you first plant these things be careful to work the ground well, and if it is poor add good material. Good loam, with the addition of a little peat for the Camellia, will be found suitable.

**Names of fruit.**—J. W. Tandy.—Gascoyne's Scarlet. —A. Rogers.—1, Pickering's Seedling; 2, Gravenstein; 3, Lemon Pippin; 4, Northern Greening; 5, Dartmouth Crab. —Subscriber.—Grape Lady Downe's Seedling and Apple Sissy Apple, a variety found in Monmouthshire. —G. Johnson.—1, Cellini Pippin; 2, Hollandbury; 3, Allen's Everlasting; 4, Melon Apple; 5, Tower of Glamis; 6, Reineette du Canada; 7, Josephine de Malines; 8, Brown Beurré. —D. Mc.—1, Pear Beurré d'Anjou. Apples: 2, Bramley's Seedling; 3, Wyken Pippin; 4, Lamb Abby Pearmain; 5, Sugarloaf; 6, rotten; 7, Baumann's Red Winter Reineette; 8, Rosemary Russet. —F. S. P.—1, Hollandbury; 2, Golden Noble. —Ashham.—1, Ribston Pippin; 2, Stoke Edith Pippin; 3, Margil; 4, Tower of Glamis; 5, Hall Door; 6, Yorkshire Beauty; 7, Beurré Diel. —H. Young.—Adam's Pearmain.

## SOCIETIES.

## NATIONAL CHRYSANTHEMUM SOCIETY.

THE winter exhibition arranged under the auspices of the above society was held in the Crystal Palace on the 2nd and 3rd inst., when a good display of single, decorative and large-flowered Chrysanthemums was made. Unfortunately, visitors were very scarce, although the exhibition was well worth going a good distance to see. Mr. R. M. Witty and his committee had made excellent arrangements and deserve better support from the public.

## DIVISION I.—OPEN CLASSES, CUT BLOOMS.

There were six competitors in the class for eighteen Japanese, not less than twelve varieties, the first prize being won in good style by Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashstead Park, Epsom. His flowers were superb for so late a date, and comprised good examples of Mrs. J. C. Neill, Miss Miriam Hankey, Mme. R. Cadbury and John Peed. Mr. H. Humphrey, gardener to Lord Lindlow, Lamport, Northampton, was second, and the third prize went to Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead.

In a similar class for twelve blooms there were also six entries, the first-prize lot being again staged by Mr. Hunt. We specially noticed good blooms of John Peed and Mme. P. Radaelli in this exhibit. Second and third prizes were won respectively by Mr. W. Mease and Mr. J. Preece, gardener to Miss Willmott, Warley Place, Essex, both of whom staged good flowers.

For twelve incurved, not less than six varieties, four competitors tried conclusions, Mr. G. Hunt once again proving the champion. His flowers were a grand lot, especially Mlle. L. Faure and W. Wainwright. Mr. J. Preece and Mr. W. Mease followed in the order named.

In the class for nine vases of large Japanese blooms, not less than six varieties and not less than three blooms in a vase, there were only two competitors, Mr. G. Hunt again appropriating the first prize with a very beautiful collection, in which John Peed, Algernon Davis, Mrs. J. C. Neill and Mme. R. Cadbury figured conspicuously. The second-prize collection, staged by Mr. A. C. Horton, Tonbridge, was very inferior.

For twelve vases of single varieties, distinct, set up for effect with own foliage only on a table of stated dimensions, four exhibits were staged, the premier award going once again to Mr. G. Hunt for a beautifully-arranged table of good flowers. Annie Farrant, Doreen and Lady Winsor were specially attractive. Second and third prizes were well won by Mr. W. Newton, gardener to Mrs. Nathan, Little Heath Wood, Potter's Bar, and Mr. F. Brazier, Caterham, respectively.

For six vases of Japanese, distinct, three blooms of one variety in each vase, there were only two entries, Mr. W. Newton being first with good blooms, Algernon Davis and Mme. P. Radaelli being the best. Mr. M. Rayment, gardener to W. Beech, Esq., North Ockenden, Romford, was second.

In a similar class for spidery, thread-petalled or plumed Chrysanthemums two competitors entered, first honours being awarded to Mr. C. B. Gabriel, Eastdale, Horsell, Surrey; Sam Caswell was the best variety. Mr. J. A.

Humphries, Maisey Hampton, Gloucestershire, was awarded second prize.

For six vases of small Pompons, first and second prizes were won respectively by Mr. J. A. Humphries and Mr. C. B. Gabriel. In the class for a large vase of exhibition Japanese and incurved blooms, with any foliage, there were eight entries, the first prize being well won by Mr. R. B. Leech, gardener to J. C. Ern, Esq., Wood Hall, Dulwich, with a beautiful arrangement of golden blooms, green Fern-fronds and red-tinted sprays of Berberis Darwini. Mr. J. Simon, gardener to W. W. Mann, Esq., Bexley, Kent, was second with excellent golden and white blooms arranged with Asparagus Sprengeri, and the third prize went to Mr. W. Mease.

In a similar class for single, spidery, thread-petalled or plumed varieties, seven vases were staged, the first prize going to Miss C. B. Cole, The Vineyard, Feltham, for a very beautiful, artistically-arranged vase. Second honours fell to Mr. H. J. Hedges, Kirkdale Nursery, Sydenham, and Mr. R. B. Leech of Dulwich was placed third.

In a similar class for Pompons there were four entries, the first prize vase again coming from Miss Cole; Mr. J. W. Harrison, Sydenham, and Mr. W. Webb, Sydenham, following in the order named.

For a hand-basket of Chrysanthemums with any foliage the entries numbered five, the first prize being won in good style by Miss Cole, who pinned her faith on yellow flowers with just a few crimson interspersed, with Asparagus Sprengeri and A. plumosus for garnishing. Miss E. H. Elkins, Rushden, St. Albans, and Mr. F. Brazier, Caterham, followed in the order named.

Nine tables were arranged in the class for a table decoration of Chrysanthemums and suitable foliage, first prize going to Mr. T. W. Stevens, gardener to W. H. Stone, Esq., Donnington, Laurie Park Gardens, S.E., for a beautiful arrangement of yellow and crimson flowers with foliage of the same hue and also some green sprays. The second and third prizes went respectively to Mrs. A. Robinson, Carshalton, and Mr. A. W. Trossell, Beckenham.

## MISCELLANEOUS PLANTS.

For a group of Chrysanthemums and other plants arranged on the floor, the first prize went to Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham Common, for a beautiful group, in which single yellow and white Chrysanthemums were largely used, some Begonias Gloire de Lorraine and Poinsettias providing welcome colouring. Mr. T. W. Stevens, Sydenham, was second.

For a collection of flowering, berried and foliage plants arranged in a circle on the floor, Mr. Howe was again first, his group including well-grown Liliums, Poinsettias, Cypripediums, Begonias, Primula obconica and Lily of the Valley. Second honours went to Mr. H. J. Hedges for a group in which Begonia Gloire de Lorraine was the chief constituent.

## AMATEURS' CLASSES.

For twelve Japanese, not less than six varieties, five exhibits were staged, Mr. W. Walters, Burton-on-Trent, winning first prize with moderately good blooms. The second and third prizes were won respectively by Mr. W. G. Prudden-Clark, Hitchin, and Mr. T. W. Stevens, Sydenham.

There were six entries for six Japanese, not less than four varieties, the prizes being awarded respectively to Mr. W. Rigby, Beckenham; Mr. H. Baker, Sydenham; and Miss E. H. Elkins, St. Albans.

For six vases of any varieties, three blooms of one variety only in a vase, first and second prizes went respectively to Mr. W. G. Prudden-Clark, Hitchin, and Mr. G. Moorman, Hampton Court, these being the only exhibitors.

For one large vase of any Chrysanthemums with suitable foliage, the prizes were won in the order named by Mr. W. Webb, Laurie Park Road, Sydenham; Miss E. H. Elkins; Mr. W. Gooding, Edenbridge; and Mr. E. Houlton, Dulwich.

## MISCELLANEOUS GROUPS.

Mr. H. J. Jones, Ryecroft Nurseries, Lewisham, S.E., was showing in his usual high-class style, the arrangement of his large group being superb. A new single named Cloth of Gold looked very promising, its old gold colour being particularly attractive. True Gold, very rich yellow; Mrs. Wakefield, glowing crimson, yellow centre; Rose Queen, an old rose single; and Kathleen May, an Anemone decorative of beautiful rich crimson, were others that we specially noticed. Gold medal.

Messrs. H. Cannell and Sons, Swanley, Kent, were showing their famous Pelargoniums in their many glorious hues, together with a large number of single Chrysanthemums, among which we noticed Cannell's White, a very large pure white with lovely twisted petals, and undoubtedly an excellent late sort. Large silver medal.

Mr. Philip Ladds, Swanley Junction, Kent, arranged a beautiful circular group of market varieties on the floor, these being in splendid condition, interspersed with Ericas, Palms, Ferns, &c. Mr. Ladds also had a beautiful lot of cut blooms arranged on a large table edged with Ferns in small pots. Gold medal.

Mr. G. W. Riley, Herne Hill, exhibited his well-known rustic summer-houses, garden seats and tables, green-houses, frames and heating apparatus. Silver medal.

Messrs. John Peed and Son had a table filled with small Cacti, and also numerous rock and alpine plants.

Messrs. W. Wells and Co., Merstham, staged a grand lot of Chrysanthemums, among which were many singles of great merit, including the beautiful new Merstham Jewel. Large silver medal.

Mr. Norman Davis, Framfield, Sussex, staged a very beautiful and extensive exhibit of single Chrysanthemums, these being most tastefully arranged in vases and baskets of various heights on a dark green ground colour, and a few Maidenhair Ferns stood between. The effect was decidedly pleasing, and, as the flowers were all good, the judges properly awarded him a gold medal.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE NATIONAL ROSE SOCIETY.

### A MEMORABLE MEETING.

THURSDAY in last week must be regarded as a red-letter day in the history of the National Rose Society. The annual meeting, a report of which will be found on another page, was of intense interest, and testified to the vitality not only of the society, but of horticulture itself. The meeting was attended by the greatest Rose-growers in the world, amateurs and the trade mingling together to instil, if it were possible, into the hearts of all who love their gardens a greater interest in the Queen of Flowers.

The meeting was largely attended, and the chair was occupied by the outgoing president, Mr. E. B. Lindsell, whose successes in the great tournaments of Roses that take place during the summer months are proverbial. Gathered round him were such men, whose names we cherish, as Mr. Edward Mawley, the hon. secretary, Mr. E. Molyneux, the late hon. treasurer, and the former president, Mr. C. E. Shea.

We predicted not long ago that the list of members would be 5,000, but doubts were cast upon this prophecy. The following, however, from the annual report, will show the tremendous strides that have been made: "During the past year 785 new members have joined the society, or 200 more than in any previous year. Allowing for the losses by death and resignation, the total number of members is now 3,150. Taking the year as a whole, two new members a day have, on an average, been added to the list of membership."

Few societies offer such privileges to its members as the National Rose, and we point them out here with the object of still further swelling the roll. Members subscribing £1 1s. will be entitled to six 5s. tickets and subscribers of 10s. 6d. to three 5s. tickets of admission to the society's metropolitan exhibition; or, if preferred, any of those tickets may be used instead for the society's provincial show, which will be held next year at Luton. In addition to this, each member will receive, in proportion to his subscription, either four or two tickets for the society's autumn Rose show, to be held in the Royal Horticultural Hall, Vincent Square, Westminster. New members will, on joining the society, receive copies of the following publications: "The Enemies of the Rose," issued in April last, the "Official Catalogue of Roses," the "Hints on Planting Roses," and the "Report on the Constitution of Rose Soils." Also, in February next, the new and revised

edition of the "Handbook on Pruning Roses" and the "Rose Annual for 1909" will be sent to all the members.

The publications of the society are of great value, and have been compiled by a committee of experts. Such manuals as these have not only helped forward this excellent institution, but spread far and wide an increasing love of the Rose. Another pleasant feature of the report is the success of the autumn exhibition, and the fifth took place last September. Quoting from the report, it is mentioned "that this exhibition was not quite so large as that of the previous year, but the general quality of the blooms was surprisingly good, considering the trying character of the season. Now that this exhibition is becoming generally known it is attended by the members in largely-increasing numbers."

With regard to the society's financial position, nothing can be sounder, and it was with the greatest satisfaction that the meeting was enabled to grant an honorarium (the sum of £100) to Mr. Mawley for his splendid work—a work of love—for the society since its foundation.

It will interest those members who were not present at the meeting to know that, owing to the great increase in membership, it has been necessary not only to give the secretary and the treasurer greater assistance, but to engage the services of a paid chartered accountant, and this step is accentuated by the excellent motive of relieving the society's principal workers of a considerable burden.

And may we now pay a tribute to those who have worked so unselfishly, without any desire for financial reward, to bring the society to its present proud position? Mr. E. Molyneux, after four years' devoted service as the hon. treasurer, has felt compelled to relinquish his task; and we can well understand that such an organisation, with a membership of over 3,000, must entail a large amount of arduous work. Mr. G. W. Cook, whose portrait we give in the present issue, has undertaken to continue the great services that have been rendered by Mr. Molyneux in the past.

Mr. Lindaell, under the rules of the society, which do not permit a president occupying that office for more than two years, has retired, and the Rev. F. Page-Roberts, Rector of Strathfieldsaye, occupies this position, and a worthier choice could not have been made by the annual meeting.

The usual annual dinner followed, and the new president delivered a delightful speech. The whole proceedings suggested that this was no ordinary meeting, but a reunion of rosarians who love the Rose and are delighted to meet at their annual gathering those who are imbued with the same enthusiasm. Among those present as guests were Sir Daniel Morris and Sir George Watt.

## NATIONAL SWEET PEA SOCIETY.

THE annual general meeting of this flourishing floricultural society was held at the Hotel Windsor, Victoria Street, Westminster, on the 11th inst., Mr. W. Cuthbertson presiding and fifty-six members being present. Among the members attending were Messrs. A. Watkins, G. Unwin, Robert Sydenham, William Deal, A. J. Stark, G. S. Brunton, G. F. Drayson, G. A. Bunting, T. W. Turner, J. M. Bridgford, E. Teschemacher, H. J. Jones, C. Foster, Horace J. Wright, S. B. Dicks, A. Dean, T. W. Stevenson, C. W. Breadmore and E. W. King.

The annual report for 1908 and the balance sheet for the year ending November 30 were presented and unanimously adopted. In the report many items of an interesting and instructive character are to be found, and it is pleasing to note that growers and raisers have every confidence in the conduct of the society's trials at Reading under the supervision of Mr. Charles Foster, than whom we think a better and more independent supervisor could not be found.

In future the committee proposes to receive new varieties only from the raiser or introducer for the purpose of these trials, but it is arranged that a further set of trials will be held at Reading next year, under the committee's direction, for the sole purpose of testing the correctness and purity of stocks of Sweet Peas that may be sent by seedsmen. For the special trials of new Sweet Peas the committee proposes to make a charge of 2s. 6d. per variety, while for testing stocks of older varieties a charge of 5s. per stock will be made. In each case the sender will receive official notification of the merit of the variety or stock sent.

It is pleasing also to note an increased membership, the total number of members up to date being 786 and affiliated societies 51. The financial position of the society is thoroughly sound, and the balance sheet shows a balance in hand of £44 0s. 1d., less outstanding amounts totalling £11 11s. 2d. This is nearly double the amount in hand at the end of the financial year 1907, and the committee may, therefore, be congratulated on the prosperity of the society.

Mr. N. N. Sherwood was re-elected treasurer and Mr. Edward Sherwood as acting treasurer, many remarks appreciating the good work done by these gentlemen being made. The president for 1909 is Sir Randolph Baker, Bart., who is an enthusiastic lover of the Sweet Pea, and who will, we feel sure, prove an admirable president. Mr. Horace J. Wright was elected chairman for the coming year in the place of Mr. Edwards, who retires by rotation, and who has done much excellent work for the society during the past. In thanking the society for the honour conferred on him, Mr. Wright said he would be pleased to offer a silver cup, value 21 guineas, to be competed for by small growers.

Mr. C. H. Curtis was heartily thanked for his past services and unanimously re-elected hon. secretary, an honorarium of 25 guineas being also unanimously accorded him in appreciation of services rendered during the past year. The following new members were elected to the general committee: Messrs. H. G. Bartleet, W. J. Stevens, W. Lumley, E. H. Christy, R. F. Felton, William Deal, H. C. Till, H. D. Tigwell, H. Shane and Silas Cole.

Rule 3 was altered so as to read that subscriptions become due on January 1 each year, instead of February 1 as hitherto; but a motion to alter Rule 6 so as to make those members of the general committee who do not attend a committee meeting during the year ineligible for election the following year was withdrawn.

The London exhibition for 1909 is fixed for July 23, at the Royal Horticultural Hall, Vincent Square, Westminster, and the provincial show, on July 13, at Saltaire, Yorkshire, under the auspices of the Saltaire Rose and

Horticultural Society. All lovers of the Sweet Pea who are not already members should make a point of joining this society, which is doing so much to foster the culture of this beautiful and fragrant flower by all classes.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

December 22.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c., 1 p.m. to 5 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

**Plants in flower at Wimbledon.**—"J. R." writes from The Gardens, Alyn Bank, Wimbledon, S.W., as follows: "As a constant reader of THE GARDEN, I often see notes of interest on flowers sent from country gardens. Thinking it may be of some interest to other readers, I append a list of flowers gathered in the open garden here on December 5: *Arabis albidula flore pleno* (the double white *Arabis*), *Aster alpinus*, *Centaureas* in variety, *Calceolaria Burbridgei*, *Delphinium*, *Erigeron alpinus* Lowii, *Gazania grandiflora*, *Christmas Rose* (*Helleborus niger*), *Helleborus olympicus*, *Lithospermum prostratum*, *Linum narbonne* (blue) and the white form *L. n. alba*, *Pyrus japonicus* albus, *P. j. sanguinea*, *Pansies*, blue and yellow *Primroses*, *Polyanthuses*, *Hybrid Tea* and *Hybrid China* Roses, *Scabiosa caucasica*, *Schizostylis coccinea*, *Sweet Alyssum*, *Veronica spicata variegata*, *Verbenas*, *Wallflowers*, some of the *Ambretias*, *Campanula turbinata* and *C. muralis* major. The above-named flowers were gathered in good condition, and are evidence of the mildness of the season." Also sent were fruits of the alpine Strawberry.

**Holly berries.**—The nearness of the annual Christmas festival has led to the discovery—one of special concern to decorative florists—that berries are very scarce, and, indeed, in many localities where these fruits are commonly plentiful none is now to be seen. That circumstance may be due to two or three successive crops having exhausted the creative forces of the bushes or to some other cause not easily explained. Certainly, remembering what a good edible fruit crop we have had, it seems unlikely that the spring weather sufficed to kill the bloom, and it is much more probable that bloom was absent or was infertile. It will be learnt with profound regret by all that Holly berries are so scarce. It hardly seems as if the festive season of Christmas can be duly honoured without their abundant presence.—A.

**Apples and Pears at Christmas.** Planters should, when selecting trees, think of their supply for the Christmas festivities, for often at this period when the supplies are most appreciated they begin to fall short. Pears in season then are *Passe Colmar*, *Thompson's*, *Glou Morceau*, *Charles Ernest* and *Hacon's* *Incomparable*; and *Catillac* for stewing. Apples: *Adam's Pearmain*, *Cox's Orange Pippin*, *Blenheim Orange*, *Scarlet Nonpareil* and *Melon Apple*; and for cooking and baking, *Blenheim Orange*, *Sandringham*, *Lane's Prince Albert* and *Lady Henniker*. These are all most delicious. In addition, a good dish of *Medlars* is greatly appreciated, and at Christmas these are just ready. A good supply of *British Cobs* and *Walnuts* should be retained for this season.—W. A. Cook.

**Garden Dahlias.**—We learn that at the Royal Horticultural Gardens, Wisley, where trials of *Cactus Dahlias* have taken place during the past two years to determine the fitness of certain recently-raised varieties for garden decoration, *Cactus* varieties next year will be excluded from the trials. This will enable the merit of *Pompons* and *singles*, with some ordinary decorative forms, to be tested for such purposes. It is well known that many of the *singles*, if the decayed flowers be often gathered,

give very beautiful effects in the garden. At the first exhibition of the newly-formed National *Dahlia Society*, it is, we learn, proposed to have a class for three varieties of garden *Cactus Dahlias*, to be shown in vases of three bunches or trusses of each. The object of this class is to enable *Cactus Dahlias* grown for garden decoration to be shown without wires or disbudding and to display their floriferousness. At *Dahlia* shows, so far, disbudded flowers alone seem to have found favour.

## PRIZES FOR READERS.

### NOVEMBER COMPETITION AWARDS.

In this competition prizes were offered for the best essays on "Flowers for a Small Greenhouse in Winter," and proved to be a very popular competition, a large number of essays being sent in. The prizes were awarded as follows:

First prize of four guineas to Mr. Arthur J. Cobb, The Gardens, Duffryn, near Cardiff.

Second prize of two guineas to Miss S. Randolph, Chartham Rectory, Canterbury.

Third prize of one guinea to Mr. Alfred Eames, Heanton Satchville, Dolton, North Devon.

Fourth prize of half-a-guinea to Mr. John Botley, Scarlett's Park, Twyford, Berks.

The essays from the following are very highly commended: C. W. Caulfield, F. G. L. Moir, T. Whysall, M. C. Aldiss, A. F. Groombridge, C. Comfort, E. D. Smith, W. H. Morton, Mrs. Macalister, Mrs. C. W. Earle, D. Lewis, B. Duncan Thomson, James Rawlings, Mrs. J. Traherne and W. McDermott. Many otherwise good essays failed to reach the winning circle because plants were named which would require a stove temperature to grow them in, and many essayists omitted the winter or perpetual-flowering *Carnations*.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Spring bedding.**—I have read with interest two prize essays which have lately appeared in THE GARDEN on the subject of "Spring Flower-beds," the writers of which apparently have been in the way of carrying out their schemes of spring gardening without regard to expense. There is, as we know, no disputing about tastes, and therefore I feel free to say that if I possessed the millions of which I have such a plentiful lack I would not desire the spring gardens of mosaics recommended by your essayists, were they ever so cunningly executed. *Keizerkroon Tulips* dotted 1½ feet apart over a carpet of mixed *Polyanthus* may be the last word in "up-to-date" gardening; but we had been taught to think that THE GARDEN, rightly or wrongly, set its face against the easy and commonplace style of tricking out a garden in mosaic patterns. I think if you search among the back volumes you will find various eloquent protests against the employment of unlimited numbers of flowers of the same kind and colour to produce carpet designs in gardens. And what else but carpet bedding are your prize essayists advising? It is not easy to see why designs worked out in blue *Myosotis* and yellow or scarlet *Tulips* should be right, when designs in *Lobelias*, *Geraniums* and *Calceolarias* are wrong. And if this "up-to-date" gardening is desirable, surely a little more resource and inventiveness might be expected from the gardeners of large establishments. *Tulips*, *Hyacinths*, *Pansies*, *Narcissi* and *Anemones*, with a few low-growing things like *Arabis* and *Aubrietia*, pretty well exhaust the material used by these "up-to-date" gardeners. Not a word about the exquisite flowering shrubs—*Forsythias*, *Flowering Currants*, *Cydonias*, *Daphnes* and others—which alone or in combination give such a charm to spring

AN OLD POTATO TUBER PRODUCING NEW ONES.

flower-beds. If you were to offer a prize for an essay on "Attractive Features in Spring Gardening," excluding the use of Hyacinths, Tulips, Narcissi and garden Anemones, and rigorously barring the use of the words "carpet" and "dot plants," you might get something of another kind, but something still worth reading. At any rate, you would set spring gardeners thinking. Deprived of his bags of assorted colours from Holland, the spring-garden artist would no doubt at first feel himself aggrieved; but he would find abundance of material left if he only knew where to look for it.—A. W. [The question you raise is, as you yourself suggest, a matter of taste, and to deal with your letter fully would require several columns. There always will be two great schools of garden designers—the natural and the artificial—and we can only say that, as in almost every case, there must be to some extent a combination of the two, so we think we are doing a useful work in offering prizes for suggestions for dealing with the more or less formal beds that are to be found in most gardens. In an enclosed square, on a formal terrace, or on the edges of a wide expanse of lawn abutting on the grey walls of some old mansion such beds are most appropriate, and probably nothing would look half so well as the bright colouring which you despise. It is difficult to see how you would deal with such parts of the garden if you excluded Tulips, Hyacinths, Narcissi, Anemones, or, as you term them, "the bags of assorted colours from Holland." Of course, if you have no such positions to fill, then it is a different matter altogether, and there would be no need for any "dot plants" or "carpets"; but even then a spring garden without any spring-flowering bulbs would be very much the same to most people as the play of "Hamlet" without Hamlet. If you would send us a short essay on "Attractive Features in Spring Gardening, excluding the use of Hyacinths, Tulips, Narcissi and garden Anemones, rigorously barring the use of the words carpet and dot plants," we will gladly give it space.—ED.]

**A Potato tuber producing new ones.**—I enclose a photograph of a curiosity which you may think of sufficient interest to figure in your interesting paper. The Potato in question is one of last year's crop which had been stored in a dry cellar for several months and was about to be thrown out to make room for other things. In its efforts to produce after its kind in untoward circumstances, it seems to have developed from the slit on its upper side not only foliated shoots, as shown at the top, but also several tubers, as seen on another shoot issuing from the inside. On the heel also are a few tubercles with all the appearance of eyes as on a mature specimen. My difficulty is to

explain the source of nourishment that enabled it to make such a brave effort at self-propagation, as the skin remained as dry and perfect as any of the others which showed no such propensity. It is regarded by men acquainted with the habits of the Potato as a most unusual development, and I shall be very glad to have your opinion regarding the probable cause of its productiveness. — (Rev.) J. J. MARSHALL L. AIKEN, *Berwickshire Naturalists' Club*. [It is not unusual for old Potatoes to produce new ones in this way, and the fact that they will do so is frequently turned to practical use. If our correspondent will turn to pages 472-3 of our issue for September 26 last, he will find an illustrated article on the subject.—Eo.]

**Squirrels in London.**—It is not often that Londoners have an opportunity of watching the antics of these interesting little creatures; therefore I think some of your readers may be glad to know that there are a few to be seen occasionally in the vicinity of what I hope Mr. Gardiner will forgive me for dubbing the "Broomstick Avenue," the pathway running from the Tea-house in Kensington Gardens to the misplaced—because here so undesirable—statue of "Physical Energy." They are also not unknown in Regent's Park.—E. CURGWIN.

**Pampas Grass in Scotland.**—The accompanying illustration of Pampas Grass is from a photograph sent to us by Mr. John Kyle, Carthay, Forries, Elginshire, N.B., and represents a fine specimen of *Cortaderia argentea*. The specimen is now twenty-one years old, and has occupied its present position for eighteen years. No protection is given it in winter beyond that furnished by its own leaves except a mulch of decaying leaves, which is spread on the soil over its roots and forked in in the spring.

## RIVIERA NOTES.

**COSMOS SULPHUREUS.**—What a delightful addition to autumn flowers this little-known annual has proved to be! Although not absolutely new, it is, I think, but little known on account of its flowering so late that seed is scarce. This will not, however, be the case on this coast, and everyone should make a note of its charm. Its name, sulphureus, is misleading, as its colour is the richest possible shade of orange, which glows in the sunshine like burnished copper. Unlike the well-known lilac or white Cosmos, which are tall, slender and rather straggly in habit, this newer variety is of excellently neat habit, branching freely and flowering most abundantly at the axils of each leaf. Its fresh green foliage is much less finely divided than those we are so familiar with, and it makes a round, spreading bush of less than 2 feet high, covered with foliage and flower down to the ground. Its period of flowering promises to be very prolonged, and altogether it is an annual much to be recommended, even for English gardens if an early start is made and a few seedling plants kept in pots plunged in the soil so that they can be put into a greenhouse in case of autumn frosts. Its foliage and pretty growth alone would make it desirable.

*Impatiens Holstii* also has shown itself a very desirable plant for the autumn garden here, while *I. Oliveri* is rather disappointing, as it grows too big and flowers so sparingly—at least, as a young plant. If in another season it should prove more floriferous, it is a bold-growing shrub for a somewhat shaded border or shrubbery, and I note that there are a few seedlings of much brighter and deeper pink than the type, so that there may be some development in that way. With hybridisation it will be possible, I hope, to intensify its colouring and preserve its hardiness, which is considerably greater than that of other Balsams.

*Lavendula abrotanoides* is a little-known Lavender that is of some merit for its winter-blooming qualities. Its neat, finely-pinnate foliage is a good foundation for the bold, branching spikes of bright lavender flowers which make a cloud of misty blue in the distance above its foliage.

*Tritoma primulina*, or *longicollis*, has been flowering freely and its lemon-coloured spikes of flower are very attractive when well grown. It is rather difficult to manage here as it cannot stand the heat of the sun in summer, and only one little group has survived out of three that I made last winter. It would be interesting to know the conditions under which it grows in its own country, as it would be extremely attractive in a good bold mass.

*Nerine tardiflora*, on the other hand, is in robust health and vigour, throwing up many spikes of flower with its fresh young leaves and making offsets freely. It seems so near *N. Mansellii* that it must, I think, really be a hybrid; whether of garden origin or not I do not know. But its bright heads of rose carmine are very lasting and, as the heads of flower-buds are considerable, it is a very decorative bulb for a suitable corner or grouped with *Cypripedium insigne*, which flowers at the same time. It is always a regret that

*Dahlia imperialis* cannot show its beauty under glass or grown in a pot. This year it has been unusually magnificent, owing, I think, to the rains of last August and the very genial November sunshine. If only it were possible to induce it to flower at another season, I can imagine nothing more superb for a public park or any place where it can have enough room to show off its stature and grace of flower. It is curiously constant in its season of flowering. Almost to a day it opens on November 1 and does not do more than last in flower for the month, but for that time it is unapproachable, so long as no rough wind has ruffled its pendent bells. This season the

Winter-flowering *Roses* are not as promising as they were last year. The rains in August came too early and spoil their rest, and the late heats in October and early November have made the shoots too long and thin, so that the first flowers are by no means as good as they might have been. Rain is much needed before the ground chills down with the long nights or the snow on the mountains has cooled the air. As in other years, the neat habit and late-flowering qualities of

A FINE PLANT OF PAMPAS GRASS GROWING IN A SCOTTISH GARDEN.

*Chrysanthemum Seedlings* deserve notice. The trade in seed is as yet little developed, but the strain is improving yearly, so that I hope in a few years many gardeners will grow and enjoy a good batch of seedling *Chrysanthemums* for winter bloom. As pot plants they are wonderfully neat and compact compared to their growth another year. EDWARD H. WOODALL

## THE GREENHOUSE.

### FLOWERS FOR A SMALL GREENHOUSE IN WINTER.

(First Prize Essay.)

**S**UITABLE subjects for providing a supply of bloom throughout the winter for a small greenhouse are legion, and what to grow and what not to grow will depend largely on the possessor's taste. To an enthusiastic amateur the cultivation of many sorts would, perhaps, most appeal as being more interesting, but it is not certain that this process would give the best results as far as a supply of bloom is concerned. However, in whichever direction tastes or circumstances lie, the main point to be observed will be to grow only such as are suitable, for it must be remembered that the one temperature will have to suffice for all once they are placed in the greenhouse, and here it may be mentioned that a frame or two will be an absolute necessity. Further, as a high temperature would only tend to hasten the fading of the blooms, only such as require strictly greenhouse treatment must be attempted. General neatness, too, should be taken into consideration, and, as far as possible, plants grown which after flowering are not unsightly when left in the greenhouse; but many can either be placed elsewhere or thrown away.

A span-roofed structure will be found most convenient, fitted with centre and side stages and a neat shelf or two suspended from the roof. In such a house, with the plants judiciously arranged at will, according to their requirements, much success may be obtained. For the purposes of this article, the term "winter" may be taken as applying from October to the end of March, or practically from the time outdoor flowers are over until they commence again in spring. The subjects mentioned in the following notes are considered easy of culture, and may be relied upon to give a display of bloom commencing with those flowering in

*October.* This month presents no difficulty in maintaining a bright appearance in the greenhouse, for we can have the popular *Chrysanthemums*, *Salvia splendens grandiflora*, *Zonal Pelargoniums*, *Love-lies-bleeding* *Sutton's Giant* and *Begonias*. The latter, from bulbs started late in spring, will continue well into this month and can, after flowering, be laid on their sides under the stages. *Chrysanthemums* will form a principal feature from now until well into January if care is taken in the selection of suitable varieties for forming a succession. A mistake often made is to have a big blaze all at once, and by Christmas, or long before, *Chrysanthemums* are a thing of the past. Exactly what sorts to grow and the style in which they are to be grown will here again depend on individual taste, some preferring large blooms, others small and suitable for room decoration. Personally, and especially for a small greenhouse, I think the bush system, supplying a moderate number of medium-sized flowers, and a selection of the charming single varieties far preferable to the large blooms. A few varieties suitable for this purpose and to give a succession of blooms are as follows: Single-flowered.—*Stella*, Miss Mary Anderson and *Eureka*, white; *Ladyemith* and *Mary Richardson*, pink; *Kitty Bourne* and *Sir George Bullough*, yellow; *Merstham Jewel*,

bronzy red; and *Doris Stevens*, crimson scarlet. Japanese, for bush or decoration.—*Lady Selborne*, Mme. R. Oberthelm, *Alice Byron*, *Niveus*, *Princess Victoria* and *Ethel*, white; *Vivian Morel*, Mrs. Barkley and *Framfield Pink*, pink; *Source d'Or*, *Mabel Morgan*, *King of Plumes* and *Thompson*, bronze and shades of yellow. A good batch of the pretty *Pompon Sœur Melaine*, should also be included. *Salvia splendens grandiflora* is to be particularly recommended. Few things, if any, can surpass the dazzling effect produced by the long racemes of bright, fiery scarlet flowers; they are readily propagated from seeds or cuttings, and when growing strongly are greatly benefited by a few applications of manure water. *Zonal Pelargoniums* from spring-struck cuttings and grown outdoors through the summer, pinching out any flower-spikes as they appear until September, when they must be placed in the greenhouse, will flower freely this and next month and again early in spring. F. V. Raspail (double scarlet) is a good

MR. G. W. COOK, THE NEW HON. TREASURER OF THE NATIONAL ROSE SOCIETY.

(See page 617.)

variety and bright for winter decoration. A plant not generally known for pot culture, but which makes a good acquisition for the greenhouse, is *Love-lies-bleeding Sutton's Giant*, and is almost as effective as *Acalypha sanderiana*, which requires a stove temperature. Its usual position is in the sub-tropical garden or for the centre of large beds, where it makes a handsome plant. A few plants left over from this purpose were potted up, and the limited root-space has had the effect of inducing it to throw its long tails of flowers, with less foliage, and is now very effective and somewhat of a novelty in the greenhouse dotted among other plants. Most of the above-mentioned plants will continue to bloom through

*November*, and their list may be added to by the addition of *Carnations* (*Tree* and *Marguerite*), *Primulas*, double *Violets* and *Marguerites*. The first named are universal favourites, and amply repay the attention necessary for success. They can be grown from seeds or cuttings, the latter being the usual method of propagation and

imperative if named sorts and large blooms are desired; but seedlings, I think, give less trouble with more flowers, though, naturally, they are not so fine and, of course, a small percentage will be single, but these, too, are pretty. A good light position near the glass must be given them and they will continue to bloom throughout the winter. *Primulas* of the *stellata* and Chinese varieties are, when well grown, very beautiful with various coloured flowers of great richness. The seeds must be sown in April and May for flowering now. An ideal place for them in the greenhouse when brought from the cold frame in September will be on a shelf near the glass, removing to stages when in bloom. *Marguerites* can easily be had in bloom this month and continued so for a long time by striking cuttings in autumn or spring and growing them on as for bedding. About the end of June cut back and rest the plants for a time; when growth recommences shake out and repot. A few *Violets* are always appreciated, and can be taken up from the open ground and potted in September. With the advent of

*December* flowers are not usually so plentiful; a lot of the *Chrysanthemums* are over and the bright *Salvias* finished, but the *Arum Lily* will make a valuable asset, and can be assisted by *Mignonette*, *Sutton's Christmas Pink Stock* and *Cyclamen*. *Roman Hyacinths* and *Paper-white Narcissi* will also readily force for Christmas, and their delicious fragrance will be welcomed. *Cyclamens* to bloom in December will require fourteen months from the time of sowing seeds. *Mignonette* is sown thinly in 5-inch pots (in which it will flower) during August and the *Stock* in May. *Arums* to flower early are best rested during summer in their pots, and at the approach of new growth, usually the end of July, they should be shook out and repotted, or a top-dressing may be found sufficient. When making rapid growth and throwing up their spikes, assist them with manure water; they will repay it by continuing to bloom until May.

*January* often brings with it the severest weather of the year, and when the outside is in the grip of frost, flowers are more highly appreciated. We can have, in addition to many previously named, *Genista fragrans*, which, as its name implies, is scented, and another deliciously perfumed favourite is found in *Freesias*. To get the latter in flower now the bulbs must have been well ripened and potted early. From now onwards the days will gradually lengthen, with a corresponding increase of sunshine, and during

*February* and *March* many of the greenhouse occupants will flower freely, especially the *Geraniums*, *Carnations* and *Cyclamens*; these can also be supplemented by *Cinerarias* brought into the greenhouse from frames when the *Chrysanthemums* are over; needless to say they would have been kept secure from frost. Any of the early-flowering bulbs will be ready now, especially *Crocus*, *Muscari* and early *Tulips*, also the pretty little *Iris reticulata*. *Wallflowers*, too, are well worth a place if only for their perfume; some varieties, such as *Blood Red*, *Harbinger* and *Sutton's Earliest* of All come into bloom early.

In addition to all the subjects enumerated, there are the retarded bulbs and plants, which are quite easy of management, such as *Lily* of the Valley, *Spiraeas* in several varieties, *Liliums* and *Lilacs*, their time of flowering relying on when received; all can be had in flower before Christmas, but with only greenhouse temperature additional time to that usually credited to bring them to perfection will be necessary. If space can be found for a few climbers, nothing is better than *Roses*, *Maréchal Niel*, *Anna Olivier* and *Niphetos* being among the best, and *Ivy-leaved Pelargoniums* *Souvenir de Charles Turner* and *Mme. Crousse*. One final word of warning must be given with regard to watering. Do this in the mornings and only when really necessary, always avoiding undue moisture.

ARTHUR J. COBB.

The Gardens, Duffryn, near Cardiff.

## THE ROSE GARDEN.

## SOME NEW ROSES.

**T**HESE are a few of the most reliable of the new Roses meriting general cultivation, and are all strong and free flowering:

*Dorothy Page - Roberts* (Hybrid Tea).—A unique shade of coppery pink, perfect in shape; a thin Rose. In a hot summer the colour and shape make up for this, and in the autumn it is magnificent.

*Elizabeth Barnes* (Hybrid Tea).—One of the best Roses sent out by the famous Newtownards firm last autumn. It is in shape very like Mme. Abel Chatenay; the colouring is perfect, a delicate rose beautifully blended with fawn and yellow. The greatest connoisseur in the Rose world will be pleased with this.

*G. C. Waud* (Hybrid Tea) is of excellent habit and flowers freely; the blooms are of good shape and substance, and light vermillion in colour. It is charming in every way.

*General Macarthur* (Hybrid Tea).—A pretty shade of bright crimson, really good in the autumn, fair size and has a delicious perfume.

*Grace Molyneux* (Hybrid Tea). This is worthy of the fair lady whose name it bears. It is a Rose of great beauty, flowers freely and is of a creamy white shade, with faint pink and apricot shadings in the centre of the bloom.

*Harry Kirk* (Tea).—Of very robust growth, delightful yellow shade, good shape, flowering freely. We shall hear more of this in the future, as it is quite one of the best.

*Lady Helen Vincent* (Hybrid Tea).—A delicate shade of pink, excellent shape, with a high-pointed centre; a Rose everyone should possess.

*Lyon Rose* (pernetiana).—A very vigorous Rose with good-shaped blooms of a magnificent salmon blended with red and yellow. It is already making its way to the front.

*Mrs. Aaron Ward* (Hybrid Tea) is a colour we want, viz., apricot and peach. The blooms vary in colour, flowers of both shades being produced on the same plant; very good shape.

*Mme. Melanie Soupert* (Hybrid Tea).—Yellow with carmine shading, large, good - shaped blooms with huge, deep petals. It is becoming a favourite.

*Mme. Maurice de Luze* (Hybrid Tea) has already made its way. It is a large, high-centred bloom, excellent in every way and of a brilliant carmine pink. It is very vigorous.

*Mme. Second Weber* (Hybrid Tea).—This is a perfect Rose in every way, delicate pink with flesh and salmon shadings and very large petals. It has a delicious scent.

*Marquise de Sinety* (Hybrid Tea).—Yellow beautifully blended with peach, a glorious colour, large blooms but rather thin; owing to the size and substance of the petals it is exquisite.

*Rhea Reid* (Hybrid Tea).—A real crimson, vigorous and of excellent shape. It will be in great demand because of its lovely colour.

*René Wilmar Urban* (Hybrid Tea).—This is a delightful shade of salmon pink, of excellent shape and one of the best of the

newer Roses. It is vigorous and lasts well in a cut state.

*Senateur Saint Romme* (Hybrid Tea).—A lovely shade of rosy salmon blended with yellow, splendid shape and really good in every way.

*Souvenir de Maria de Zayas* (Hybrid Tea).—A very pleasing shade of bright carmine, exquisite shape, with a high centre and of fair size.

*Souvenir de Stella Gray* is a Tea most beautiful in shape, scent and colouring, red and cream delightfully blended and veined with apricot; a delightful Rose.

We all know those two famous Roses Dean Hole and William Shean. Others that are good are Countess of Annesley, Countess of Gosford,

still, it thrives and is seen in many gardens as vigorous as ever. It is worthy of note that in some trade lists this is classed as a Hybrid Perpetual, while in others as a Hybrid Tea. To many this classifying is confusing.

Those who have had to grow a collection of Roses on various soils know how they thrive beautifully in one place and refuse to grow in another. This is how I have found La France. When residing in the West of England, in a low situation and strong soil this refused to grow, and after trying it as standards and dwarfs and in various positions I gave it up as a failure. Previous to going West I was most successful with it on a light soil, and at that time I grew upwards of 100 sorts, and this was one of the most reliable.

In my present garden, which is greatly exposed, with a light sandy soil, this season on dwarfs on the seedling Briar stock it has been glorious, and at the end of August was giving a splendid second crop of flowers. When it thrives in this way it is certainly one of the most desirable Roses to grow. Many amateurs about here have found its reliability, judging from the number grown.

I am convinced many Roses thrive better in a somewhat light soil, and I have come to regard very heavy soils as being overpraised for many varieties.

Camberley.

J. C.

THE REV. F. PAGE-ROBERTS, RECTOR OF STRATHFIELDSAYE, THE NEW PRESIDENT OF THE NATIONAL ROSE SOCIETY. (See page 617.)

## ROSE LA FRANCE ON LIGHT SOIL.

Some old Roses are surpassed by new ones, while others outlive the majority of new introductions. The variety above named cannot be termed new;

made in wood or wire, and covered with variegated Holly bearing plenty of berries, serve well for special positions, and last a very considerable time. A square room may be made effective by using four long festoons, one from each corner, bringing them to the centre and fastening the four ends together with a bunch of Mistletoe, in the centre of which may be used the light Pampas Grass plumes and old decaying Fern fronds with good effect. A good bowl of Holly, with its scarlet berries, should be used on Christmas Day on the dinner-table, and this may be livened up with Lily of the Valley sprays. These decorations do much to suggest to the minds of all those concerned the idea of peace and goodwill to mankind.

W. A. Cook.

## CHRISTMAS DECORATIONS.

**B**RIGHTLY decorated rooms form an extra charm to parties, both large and small, and even in the humblest homes a little decoration is usually carried out for the festive season. When making wreaths, or festoons for throwing across a large room or to grace pillars, fasten a string to some support at each end, leaving enough to make the tie firm, then cut up pieces of common Laurel, Portugal Laurel, Retinospora, Holly, Box and Ivy from 7 inches to 10 inches long. Begin at one end of the string and mix the material thoroughly as the work proceeds, tying all firmly with green string. Festoons can thus be made thick or thin, according to the work that is to be done.

Coloured paper can be used with much effect. Flowers of all colours and large and small can be made quite nicely with it, and these dotted about among the evergreen are very showy. Designs

## THE FLOWER GARDEN.

## IRIS OCHROLEUCA.

**T**HIS Iris, tall and stately in its growth, with white flowers marked with yellow blotches, has been thought to be the origin of the heraldic device called the *fleur-de-lis*. While this is by no means certain, the idea is borne out by the following remarks in the "Encyclopædia Britannica" on the *fleur-de-lis*: "According to an old tradition it was first employed as an armorial bearing by Clovis I., and represents the Lily presented by an angel to that monarch at his baptism, the three *fleurs-de-lis* of his shield being the sign of the Trinity. Newton considers it to be the figure of a Reed or Flag in blossom, used instead of a sceptre at the proclamation of the Frankish kings." But there are other, quite different, theories as to the origin of this device, and as, among other places, it has been found in the design of the head-dresses of Egyptian sphinxes, its connexion with *I. ochroleuca* does not seem very definite. The photograph reproduced was taken from a plant just as it grew, no arrangement of the flowers being made. There is another variety of it called *gigantea*, which, as its name implies, is larger.

F. H. HUTTON.

*Vicar's Court, Lincoln.*

## NOTES ON MULE PINKS.

No low-growing hardy plant is more beautiful than the Pink named Napoleon III. Some people think it difficult to cultivate, but this is not so when good treatment is afforded. In my garden, on a dry sandy soil, this year it has bloomed for months, and good flowers were open the first week in October. In the spring I had six good plants, and from these I have raised five dozen nice young ones. I gave them liberal culture with plenty of moisture. So many fail with this Pink through starving it. If the plants are weak, they should not be allowed to flower till they have gained strength. Nothing roots more freely under hand-lights or in pots in a close frame; but they must be removed to the open as soon as they are rooted, or they will suffer in constitution.

Another beautiful Pink is *multiflora splendens*. This is an improvement on the normal type, having larger and more highly-coloured flowers. Both this and Napoleon III. have good robust habits. *Stratiflorus*, with its evenly-striped flowers, is charming and a change, besides being vigorous. Beautiful as these are, the white *Marie Pare* is more so. In many gardens this is prone to die off suddenly. I have had trouble in this way, and until this summer I was under the impression that it was not reliable. When visiting Crosby Hill, Camberley (where I found one of the best and choicest collections of hardy plants I have ever seen), I saw this and the other varieties named growing most freely, in large masses 2 feet to 4 feet across in separate colours, in a border in the full sun, and evidently they had been there many years. I was told that the white variety gave no trouble. I still

have a love for Anne Boleyn, Ascot, Lord Lyons, Hugh Clere and many of this class, remembering the fine masses of these in gardens thirty years ago. J. C. F. C.

## SOME BEDDING ARRANGEMENTS.

[In reply to several correspondents.]

DURING the past few weeks we have received communications from several of our readers asking for suggestions for summer bedding for the year 1909, and we believe we shall be serving the best interests of a large number if we at

excessive richness of the soil in which the plants are bedded out. In such a case the remedy is twofold, and strong-growing plants should either be bedded out in their pots—those of 5 inches diameter being most suitable—or the richer soil of the bed replaced by some of much poorer quality. Obviously the easier way would be to bed the plants out in their pots, and in the case of Pelargoniums, whether of the Zonal or Ivy-leaved section, this is frequently done, the result being a sturdier growth and larger quantity of flowers; indeed, the giant trusses of bloom which on these plants are the rule in most of the London

parks and gardens are produced in this way and with comparatively poor soil. On the other hand, the amateur whose one desire is to excel in such matters as summer bedding will not infrequently give his plants "something to grow in," to use a common phrase. And in this at least they do not fail; but the huge leaves and fat and gouty stems are not calculated to produce good flowers.

Another way of ensuring against leaf-growth is to provide either a poor soil or make the soil about the plants quite firm by treading or beating. While speaking of errors in the bedding-out system, we would point to the lack of original ideas in not a few gardens; and in some of the letters before us it is obvious that the summer bedding arrangements of certain gardens are still confined to Lobelia, Calceolaria and the so-called Geranium, the owners being unable to get away from the monotonous rings or circles of plants which, we are not surprised to hear, do not even satisfy those who were responsible for them. It is in these circumstances to be hoped that the suggestions appended below will be of service. Not a few of our readers are anxious to obtain masses of blue for beds, and some of the more serviceable subjects are blue *Viola*, *Agathæa cœlestis* (a charming subject rarely, if ever, used and a perpetual bloomer), the double blue *Lobelia*, *Salvia patens*, *Delphinium Belladonna* and *Anchusa italica* *Dropmore* variety. For large beds where blue-flowered plants are in request, we cannot too strongly recommend *Plumbago capensis* and *Verbena Lovely Blue*. We saw a large, circular bed of the latter a year ago with some 5,000 plants in it, and for colour or fragrance it surpasses anything we have seen.

In those instances where the large beds are oblong or square and on the turf, we would suggest an imposing central pyramid of *Campanula pyramidalis*, with smaller pyramids of *Plumbago capensis* at each corner; and in the oblong bed a further group on the long side, the groundwork to be filled with the *Verbena* above named. In such cases the *Plumbagos* should be set out, five in a group, the plants 2½ feet high and in pots. Lightly trained for a time and then allowed more freedom, these will give one of the most delightful beds conceivable, the plants flowering for many weeks in succession. In the same colour range, though a little distant from true blues, we have the richly-scented *Heliotrope*, and this treated in the first instance as tall pyramids, as in the former case, with a groundwork of *Verbena venosa*, provides

A BEAUTIFUL IRIS (*I. OCHROLEUCA*) IN A LINCOLNSHIRE GARDEN.

once comply with these requests and endeavour to furnish our readers with good, if not novel, ideas, such at least as are likely to give satisfaction if carried into effect. The general trend of the letters before us refer unmistakably to the unsatisfactory behaviour of certain plants during the present year, a condition of things largely, if not wholly, due to the weather; and such a condition of things may occur again.

Failures in greater or lesser degree we must expect in any year. Some of these are avoidable; others the reverse. For example, a by no means infrequent cause of partial failure is the

a permanent and fragrant summer bed. In the case of a large bed the Heliotrope plants may be five or seven in a group and not less than 5 feet high when planted. If need be, such a bed may have a groundwork of a similar colour tone, or even the same variety of plant. Where such an arrangement is decided upon, the principal plants should be more freely disposed over the entire surface of the bed, the groups alternating with each other. The purplish-flowered Lantanas and Verbena venosa also make a good self-coloured bed, the former either in pyramids or standards; indeed, diversity of form in such instances adds much to the beauty of the whole, while assisting to destroy any idea of sameness or monotony.

#### WHITE BEDS.

These may be had by using white Violas, white Alyssum, white Bouvardias, Campanula pyramidalis alba, Galtonia candicans and Plumbago capensis alba. In such a case white-leaved plants, such as Leucophytos Brownii, Centaurea candidissima or Gnaphalium microfolium could be planted with advantage. In the case of very large beds, where one colour alone is desired, a rather distinct effect may be secured from white or grey-leaved plants alone. For example, take Gnaphalium microfolium as dwarf and tall pyramids, solitary dot plants of either Centaurea candidissima or Dactylis glomerata aurea longissima—the variegated “Ribbon Grass” is not a bad substitute for this plant—the ground surface to be covered with Leucophyton Brownii, or even Cerastium if not allowed to flower. The whiter tone of the two last named will throw into greater relief the silver grey tones of the other plants named. Where very large beds of white-flowered plants are desired, Campanula pyramidalis alba would form an imposing centre, the white Plumbago capensis as pyramids taking the corners and sides at intervals of about 4 feet, the white Peach-leaved Bellflower Moerheimii freely grouped between, and the surface carpeted with white Viola Purity or any other good white-flowered sort. Should the size of the bed admit of its use, Galtonia candicans may appear, and where possible the white Bouvardia jasminoides or the larger-flowered B. Humboldtii corymbiflora could replace any failing plants. From our experience white-flowered beds require greater study and closer attention than the rest. In other instances the white Liliums, as candidum, longiflorum and Krætzleri, could be employed. White Antirrhinums should not be forgotten.

(To be continued.)

#### BOYD'S CASSABA SNOWDROP.

(GALANTHUS ELWESII CASSABA BOYDII.)

SINCE the death of the late Mr. James Allen, whose articles in THE GARDEN brought home to many a knowledge of the varieties which exist in the Snowdrop and the possibilities of improvement possessed by our “harbinger of spring,” little has been done in the way of selection and seedling-raising. Many of Mr. Allen's best flowers are, however, still in cultivation, and there are a few gardens in which a considerable variety of Snowdrops is to be found.

Mr. William B. Boyd of Faldonside, Melrose, still happily with us, has done more than any other in the United Kingdom to search out and preserve distinct varieties of this flower, and that figured in the accompanying illustration, from a photograph taken in my own garden, shows to some extent his keen discernment in selecting flowers of much beauty or distinctness. The variety of Elwes's Snowdrop called Cassaba has long been recognised as one of the finest forms of the species, and the one illustrated and selected by Mr. Boyd is the largest and finest of all, while it has a peculiarity, not constant, but frequently existent, in the presence of a green marking on the outer petals near the extremity. The tube of the flowers is also almost entirely

green, and the resulting contrast between the dark green and the pure white is as effective as anything of similar colouring in the floral world. In form Boyd's Cassaba Snowdrop is excellent, while its size, though great in comparison with most other Snowdrops, in no way becomes ungainly. I have had it in my garden for a few years, and it is prized as one of the finest of my collection.

## COLOURED PLATE.

PLATE 1363.

#### A BEAUTIFUL NEW CALCEOLARIA.

ONE of the most beautiful novelties raised of recent years is the Calceolaria Golden Glory represented in the coloured plate. We noticed it flowering superbly last summer in the garden of Mr. Leopold de Rothschild at Gunnersbury House, Acton, and

A RARE SNOWDROP (GALANTHUS ELWESII CASSABA BOYDII).

were astonished when Mr. Hudson told us it is quite hardy. This is a revolution in the flower world, and should lead to the plant enjoying in the near future a lasting popularity. Not only is this Calceolaria hardy, but the colour of the flowers is a peculiarly beautiful golden yellow. The plant is smothered with this “Golden Glory” for months. Its origin is interesting. C. plantaginea was crossed with a variety of the herbaceous Calceolarias, and Golden Glory is the result. We anticipate that it will be the forerunner of an interesting and beautiful race. Messrs. Robert Veitch and Son of Exeter are to be heartily congratulated on their success.

Their description is as follows: “As a greenhouse plant it will be invaluable, but as a hardy herbaceous plant it will take a high position for its glorious colouring and for the length of time it remains in bloom. Not only has it stood out-of-doors in Devonshire, but the plants which were grown in the Royal Horticultural Society's Gardens at Wisley withstood over 20° of frost.”

## SWEET PEA NOTES.

#### THE CROSSING OF SWEET PEAS FIFTY YEARS AGO.

I HAVE come across a seed list of my uncle's of fifty years since, which is most interesting, and in which the offering of seeds of Sweet Peas is headed thus: “Purple, purple; Painted Lady, various; Scarlet, scarlet; White, white; finest mixed, various.” The puzzle now to me is that, prior to what Mr. Eckford did for Sweet Peas, the bees or insects of the past must have been all drones and not proper workers, else why have not all the John Ingrams of the period interfered with and not allowed the modern workers of both bees and men such credit? How is it that, with all our advancement of science, the insects and bees are such a great help now in the crossing of Sweet Peas, and that in the days that are passed we never reached beyond three or four colours? I might say of five, because shortly after the period mentioned we

got Invincible Scarlet and, I think, Invincible Purple.

At the time of which I speak we had no seedmen's printers and purveyors of the modern day seed packets; so much so that, when I was a lad, it was in a packet such as I send, put up in “brown-paper” fashion. But Sweet Peas were a bother to put up, as, for instance, when you had them all ready to handle and put up, in would come a countryman saying he wanted a “stone of Clover, some Italian Rye Grass,” &c., to whom you would have to attend. Meantime the cat (whoever saw a seed warehouse without one?) would come and bring her kittens to play hockey with the seed, or probably the farmer would spread himself over the counter and upset them all. Yes, it was a great bother the putting up of garden seeds fifty years since.

In conclusion, may I repeat: Why did not the bees help us all fifty years since and give us at that time all this botheration over our John Ingrams and Spencers?

WILLIAM BAYLOR HARTLAND.

Ard-Cairn, Cork.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**G**REENHOUSE AND CONSERVATORY.—The most should now be made of Cyclamens, Primulas and Cinerarias. When well grown they last quite a long time, but to be maintained in this satisfactory condition they must be given a light and airy

1.—A TYPICAL CROWN OF LILY OF THE VALLEY AND SUITABLE FOR FORCING.

position. *Azalea mollis*, *Deutzia gracilis* and *Spiræa japonica*, if placed in a glass structure where the temperature is from 45° to 50°, will quickly commence to make growth. Later on, when the buds begin to show colour, the plants should be accorded a warmer temperature, say 55° to 60°. Seedling plants of the decorative *Asparagus* in its various types may be raised quite easily, and the present period may be chosen for this purpose. *A. plumosus* and *A. Sprengeri* are two most useful varieties.

**Hardy Fruit Garden.**—Even at this protracted period it is not too late to plant many of the more popular hardy fruit trees. The grower should, however, take the precaution of only planting these when the ground is free from frost. Overcrowded branches of old orchard trees should be subjected to a thinning-out at this period. Give special attention to overcrowded branches in the centre of the tree, so that light and air may get in among the branches, thus ensuring better growths in the future. Moss or lichen is a constant source of anxiety in most orchards, and trunks of trees that are suffering in this respect should be drastically treated at the present time. It is our practice to wash the affected parts with lime in solution, which is prepared by dissolving lime in water until it is of a creamy nature. Slaked lime may also be dusted on plants infested with these same troubles.

**Hardy Flower Garden.**—We are still planting creepers and climbing plants to cover unsightly corners of the garden and for many other uses,

making an exception, however, in the case of Clematises, which should be planted in February next. Those who have delayed the planting of the double *Arabis* may even now utilise side growths of this hardy plant for the purpose of making edgings round their beds and borders, and it may also be grouped in colonies in the border, where the effect in the spring season is exceedingly attractive. The golden *Privet*, which the public are beginning to appreciate better than the green kind, should be planted for the purpose of making a neat hedge or as a screen in the garden. This is a very easy subject to root; growths of recent development from which the lower leaves have been removed make excellent cuttings, and may be inserted in sandy soil with the sure prospect of their rooting. Take advantage of the present time to top-dress the lawn, using finely-sifted manure together with loam and good garden soil. Grass treated in this fashion invariably responds with vigorous growth later on. Those possessing lawns will have the satisfaction of seeing a more delightful appearance in the succeeding spring.

**Cold Frames.**—*Chrysanthemums* that have been cut back after flowering should be placed in the cold frames without delay. If allowed to remain here for some time, new shoots will evolve, from which cuttings may be procured for next season's supply of plants. Care should be taken, however, to mat up the frames in frosty weather. On fine, sunny days it is a good plan to remove the frame-lights for a time, taking care to cover them again at night in case of cold weather ensuing. *Picotees*, *Auriculas*, *Pansies* and *Carnations* will require careful attention at this period; but by giving an abundance of light and air as opportunity offers, damping of the foliage and the collars of the plants will be avoided.

**Orchids.**—Cool *Orchids* that are grown in glass houses with a minimum of heat will require much care and attention at this season. It is very easy to give the plants too much water in such circumstances, so that before supplying them with water first ascertain whether they really need it. Plants that are resting must have only very little water occasionally, just sufficient, in fact, to prevent them shrivelling.

**Trees and Shrubs.**—Trees and shrubs may be planted at the present time, provided the soil is not wet or frozen. Deciduous shrubs require attention at this period. Dead wood should be cut out of them so that live growths may have a better chance of doing well. D. B. C.

## FORCING LILY OF THE VALLEY.

For forcing purposes we should be able to procure the necessary crowns from our own bed of *Lily of the Valley*; but it may be that the reader of these notes has no such resources to draw upon. For this reason he must have recourse to the nurseryman for the necessary supplies. The best possible crowns should be procured. The system now so popular with nurserymen of retarding the crowns enables the would-be grower of *Lily of the Valley* to procure the necessary material for forcing at almost any period of the year. When the crowns are procured they should be dealt with at once.

It is our invariable practice when they look rather dry to soak them for an hour or two in slightly tepid water, as they become plump and better for this simple treatment, and their prospects are also brightened thereby. Fig. 1 is a fairly good illustration of a crown of *Lily of the Valley*, and unless the majority of those that we may have purchased are quite equal to this one in appearance we should hardly be content. For the information of those who do not know, we wish to point out that when crowns of this subject are planted outdoors it is usual to grade them into three sizes—large, medium and small—planting the different grades in rows or in quarters by themselves. The forcing of *Lily of the Valley* may be done in pots, boxes and other equally suitable receptacles. For small quantities pots measuring 5 inches or 6 inches in diameter answer the purpose splendidly. Some growers place as many as twelve to fifteen crowns in a 5-inch pot; but we fear it would be impossible to arrange that number in a pot of this size were crowns of the kind depicted in the illustration Fig. 1 potted up. We are satisfied with a lesser number. Ten good crowns potted up equidistant in a 6-inch pot will serve the best interests of this plant. Those who prefer to use 5-inch pots may, of course, do so. The vigorous roots are not easy to adjust in so small a compass, and to arrange each crown satisfactorily needs just a little care. Compost of a somewhat light character is best, that made up of leaf-mould and loam in equal quantities and sifted being suitable. If to the foregoing ingredients there be added a fair sprinkling of silver sand and the whole well mixed, we have an ideal compost. Shake it well down between the roots as they are adjusted in the pots, so that the crowns when the operation is completed are just visible above the soil. Fig. 2 serves to illustrate this point. In the picture the crowns are just a trifle too far out of the soil, but this was done for the purpose of illustration.

Those who have no pots available for this purpose, or whose demands are rather heavier

2.—TEN CROWNS POTTED IN A 6-INCH POT.

than most others, should utilise the services of boxes some 4 inches or 5 inches deep. By these means forcing may be readily accomplished, and quite a large number of crowns may be arranged in a box measuring 15 inches by 12 inches. Fig. 3 serves to show the method of arrangement of the crowns. When adjusted about 2 inches, more or less, apart the plants do well. The box in the present instance is only partially planted, in order to show how the work is proceeded with.

When the pots or boxes are all filled, they should either be arranged in a cold frame or else stood outdoors on a thick bed of ashes. First of all, however, the crowns should be well watered in, as this will avoid the necessity for a further watering for some time to come. Arrange the pots, &c., in regular order on the bed of ashes, covering them with a good layer of moss, taking the precaution at the time to overlook the latter for slugs and other insects, as these would quickly demolish the crowns. Those who have the convenience would find it an advantage to spread out the moss on the ground, watering this all over with hot or boiling water, in this way destroying lurking insect pests. When the pots are properly adjusted in position and covered as we have suggested with a layer of moss, they should present the appearance as represented in Fig. 4. The exposed sides of the pots would, of course, be covered up as seen at the end of the row. In about three weeks the first pots should be withdrawn and placed in a gentle heat for forcing. On no account give the pots of plants too much heat in their early stages, otherwise you will be courting failure. Bottom-heat is essential, but this should be of a fairly genial nature. Deep boxes (sufficient to embed the pots) should have holes cut in the bottoms of them and then be filled with Coconut fibre refuse, plunging the pots in this material. Place the boxes over the hot-water pipes or on a hot-bed and maintain them in a moistened condition at all times. A damping overhead is also highly beneficial. As soon as the buds begin to show white, but not earlier, remove the pots from the plunging material and gradually inure the plants to a lower temperature. Draughts must be avoided at all costs, otherwise failure will soon have to be recorded. Moist, genial conditions are what should be striven after, and ultimately the plants may be stood on shelves and side benches of the greenhouse and conservatory. At intervals of a fortnight bring in other batches, and in this way maintain the supply throughout the winter and early spring.

### THE WINTER TREATMENT OF CACTI AND SUCCULENTS.

AMATEURS usually experience some difficulty in wintering successfully some or all of the many plants which may be regarded as coming under the above heading, yet they are tolerably easy to manage providing a few well-defined points in their culture are properly attended to. Undoubtedly their worst enemy is dampness, and the cultivator must earnestly endeavour to maintain the atmosphere of the house or frame in which the plants are growing in a comparatively dry and buoyant condition. The greatest trouble is that the mischief resulting from over-watering or moist atmosphere is frequently unobservable until it is too late to adopt remedial measures, many a healthy-looking plant resting for weeks on a decayed base, and the centre also may be decayed without being noticed.

A brief study of the character of these plants will convince the veriest tyro that very little water will be required during the dull days of winter. All possess very thick skins and few stomata, as the breathing pores are called, and as it is through these pores that moisture escapes it is obvious that the plants cannot use much water.

But even where proper care is taken in the watering of succulent plants some will rot off level with the soil, owing to a little moisture collecting there, and to prevent this must be the aim of the grower. An excellent plan is to scoop out about 1 inch of the ordinary potting soil and replace it with coarse but clean sand, or even

3.—CROWNS PLACED IN A BOX READY FOR FORCING.

some sifted mortar rubble will do. This ensures the base of the plant, which is the most vulnerable part, being kept dry and safe over the winter. Should decay be noticed when it has just started, it may frequently be stopped by paring out the affected portion quite clean, then dusting the wound well over with finely-powdered charcoal and standing the plant in the warmest and driest place in the house. Where a plant has rotted right through at its base its life may possibly still be saved, but drastic cases need drastic measures. The best thing to do with such a specimen is to cut away all the decayed tissue and dust the wound with powdered charcoal as advised above, then lay the plant up on a dry shelf until the spring, when it may be potted up in some very porous soil mixture. That such dry treatment will not harm but rather benefit many of these tough-skinned inhabitants of our greenhouses the writer has proved over and over again, and he well remembers a section of an *Opuntia* which had accidentally been left hanging in the pocket of an old overcoat in the potting-shed for about three months; this when found had emitted several roots from its base. H.

### THE TOWN GARDEN.

FROST AND SOIL.—There is not at this period of the year a great amount of work which the amateur can do in the garden, and he, therefore, devotes the major portion of his time to the occupants of the greenhouse or conservatory

and the plants growing in the rooms. It is, however, possible to do really sound work whenever the weather is favourable, especially in relation to the soil. Any ground that is vacant or that lies between plants and can be dug should be well loosened to a depth of about 8 inches or 10 inches, and the top ought to be left rough. This condition will facilitate the admission of water and air, and if we get frosts later the water will be frozen and thus the soil will be mechanically considerably improved, for in the spring when we want to put out plants or sow seeds it will be extremely simple to secure the indispensable fine tilth by merely forking down. At the same time as this is proceeding the soil will be securing and holding stores of plant food, and when the roots of the plants reassume activity in the spring the nutrient matters at their disposal will be very quickly appropriated.

WEEDS.—As a general rule, we take it that all plant-life in the garden goes to rest during the winter, and even weeds do not then make material progress, but if they do show themselves they should be immediately destroyed. With a little mild weather seedling weeds are practically certain to push through, and the Dutch hoe run lightly through the surface will at once account for them. Or if it is considered better and the conditions of planting and weather are favourable, the soil can be turned over, burying the weeds some inches beneath the surface, where in rotting down they will yield a certain amount of food of which the legitimate crops will assuredly take advantage in due course.

SLUGS AND SNAILS.—In certain circumstances these may fairly be regarded as the friends of gardeners—for example, few amateurs can persuade themselves to thin out their seedlings sufficiently and the slimy visitors do it for them, and the effect is that the grower secures finer results. This, however, must not be taken as suggesting that they should be preserved; on the contrary, the good cultivator wages persistent warfare against them and does his level best to completely exterminate them from the garden. This is quite as it should be, for if they do a certain amount of good in the direction already indicated, it is perfectly sure that they do a vast amount of harm. At this, as at other seasons of the year, the gardener should destroy every enemy that he can find, and he should make as much time as possible to go out and seek for them. Slugs and snails alike can be picked up and put into a bucket or other vessel containing salt, being transferred thence when dead to the rubbish-heap. Or the slugs can have a coating of salt put upon them on the ground and subsequently be pricked into the soil, while the snails can have their shells broken and left for the weather to waste them into the soil. These are sure means of destruction and will bring their reward next season, in that fewer cherished plants will be lost by the depredations of these insidious enemies. In seeking for them do not forget heaps of rubbish, stone edgings or plants that afford shelter by the sides of paths.

BULBS FOR CHRISTMAS.—In just one week from now Christmas will be with us—may I take the opportunity of mentioning it to wish all my readers a most happy and festive season and a prosperous and happy New Year?—and it will then be necessary to have as many flowers as possible in perfection. At first glance it may seem useless to call attention to it now, but it is not actually so, for flowers that are in a fairly forward condition may be brought to perfection at the required moment by placing them in a closer, moister atmosphere, where the temperature is several degrees higher than that in which they have been previously growing. It is surprising what can be done in six days.

HORACE J. WRIGHT.

4.—METHOD OF ARRANGING POTS FILLED WITH LILY OF THE VALLEY CROWNS.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**P**LANS should now be made for the cropping next season, and this is easily done by marking out on a sheet of paper the quarters or divisions of the garden. This very much simplifies matters when the actual sowing and planting takes place. The plots can be manured and treated exactly as their requirements demand, and in the long winter evenings this is a good form of amusement to the man who is fond of his garden. A kitchen garden can be made both productive and smart, be it either small or large, by some thought and perseverance. It is not the man who has the best garden that always wins prizes, but the one who studies his crops from start to finish. There are plenty of good growers who could win prizes, but, on account of neatness and love of method, they do not like interfering with their crops, which they must do if they exhibit.

**Forcing House.**—Keep up a good supply of Chicory, Dandelion, Rhubarb and Seakale. Fresh lots should be placed in heat every week. See that the Mushroom-bed does not become dry, or it will quickly cease bearing. Prepare more manure for subsequent beds. Lilacs may be forced quite well.

**Asparagus Frame.**—In planting the second lot a pinch of early Radish seed may be sown on the soil; this will come in useful. Keep the frame covered in severe weather.

#### FRUITS UNDER GLASS.

**Vineries.**—The early house, which was closed at the beginning of the month, should now have a little fire-heat turned on to keep the temperature up to 50°. Syringe the rods twice daily in sunny weather.

**Peaches and Nectarines.**—The earliest house must now be closed and the trees sprayed or syringed daily. Plants in successional houses should be pruned and tied, and see that every old tie is cut, or in it may form the foundation of some pest, which will develop as soon as heat is applied.

#### PLANTS UNDER GLASS.

**Chrysanthemums.**—As these pass out of bloom they should be cut down and placed in cold frames, when cuttings can be taken as they become fit.

**Freesias.**—A good batch should now be got into warmer quarters. I find it best to keep these in cold frames till wanted, when they respond readily to a temperature of 50° to 55°.

**Lilium Harrisii.**—These may be top-dressed and have a neat stake put to them. Give them a temperature of 60°, and they will make fine decorative plants for the conservatory and mansion.

**Violets** should be grown as hardy as possible. Draw the lights off on mild days and tilt them at night when the weather admits of so doing. Keep all the decaying leaves picked off and dust between with soot and a little bone-meal; this will be found to help the plants very considerably.

#### FLOWER GARDEN AND PLEASURE GROUND.

Keep this department neat and tidy. Take care of the leaves that have been collected, as these are always useful, and a good heap of leaf-soil is a fine thing for any part of the garden, it being in constant request. Climbers on walls, pergolas and tripods may now be cleaned, pruned and tied, and any alterations that are necessary on lawns, borders and walks should be proceeded with at once. W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**SHOW PELARGONIUMS.**—These ought now to be well rooted in their first pots and ready for a shift into those in which they are to flower. Only a moderate shift should be given, as the plants do as well and are far more useful when the pots used are comparatively small in proportion to the size of the plant itself, provided that they are given good soil, and they are also more easily fed when the flowering time approaches. Previous to potting the plants should be carefully looked over and those that are on the dry side watered, so that the balls are in a fairly moist, but not wet, state when turned out. The new soil, too, should be in the same condition—moist enough to be rammed without becoming springy, and not wet enough to become pasty under the rammer.

#### FRUIT UNDER GLASS.

**Fig Trees** that are grown in cool houses and do not ripen their second crop of fruit are often weakened by the latter being allowed to remain on the trees until autumn. Some people have an idea that these late-formed fruits will ripen early next year if allowed to remain on; but this is not usually the case, for isolated fruits only mature occasionally, the majority falling off as soon as the sap commences to rise in the spring. Unless the trees are extra vigorous and need checking, all the Figs formed too late in the season for ripening should be removed as soon as they are large enough to handle.

#### HARDY FRUITS.

**Pruning Apricots.**—Many growers advise leaving the Apricots till early in the year before pruning, but I do not. In many cases there is little to prune if summer stopping has been attended to; the chief work is the extension of terminals, giving more room and equalising the space between the new wood. By allowing the trees to grow freely there is less canker and gumming. The Apricot being the first to open its flowers, it is well to attend to it first. Remove poor surface soil down to the fibrous roots and top-dress with good loam, decayed manure and bone-meal.

#### SHRUBBERIES.

These should now have attention. Where the occupants are thick and becoming overgrown, some of the commoner shrubs, such as Laurels, should be cut out and grubbed up to make room for the remainder. Overgrown masses of the common Rhododendron may be reduced to something like order by cutting out many of the tall, naked growths and pegging down others to cover the vacant spots. The old stools will then break away and form good growths with all the appearances of plants in their prime.

#### FLOWER GARDEN.

If notes were taken from time to time of any specially useful flowers, now is the time to plant; and even if no great amount of space is available, there are few gardens where room cannot be found for at least a few things that are in their respective seasons either of great interest in the open air or valuable for cut flowers. An instance of specialities may be cited in those white varieties of different species that are always in great request; those flowers that stand exceptionally well in water; and those, again, that can be produced easily in quantity and can, therefore, be recommended for special seasons of the year. In planting the work should be well done, and in the case of gross-feeding plants, as Pæonies, or those that once planted may be looked upon as fixtures in their respective situations, the ground should be thoroughly and deeply worked, and a liberal proportion of good manure added as the work progresses.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## NEW PLANTS.

**BRASSO-CATTLEYA CLIFTONII.**—This is a very beautiful addition to this charming bi-generic family, and shows a rare and delicate colour combination with exquisite form. The flower is of Cattleya shape and measures 7 inches in diameter. The sepals and petals are of a very delicate mauve hue, the large, moderately-fringed labellum being of a still paler mauve ground colour, with a carmine blotch at the apex and the base of the throat, the remainder of the throat being very rich yellow. Shown by Messrs. Charlesworth and Co., Hayward's Heath. First-class certificate.

**Dendrobium Celogyne striatum variety.**—This may be regarded more as a curiosity than beautiful; but it is of garden interest notwithstanding. The narrow petals and sepals are of a very pale primrose ground colour, heavily blotched with dull crimson, the large and curiously-shaped labellum being almost black and looking very much like a protruding tongue. Shown by Mr. H. A. Tracey, Twickenham. Award of merit.

**Cypripedium Armstrongii.**—A beautiful addition to the Lady's Slippers and one of a most pleasing character. As usual, the dorsal sepal is the most conspicuous feature, this being very large and somewhat hooded. Except at the base it is pure white, with a deep carmine stripe running down the centre. The petals are very narrow and much crimped at the edges, the greenish yellow ground colour being somewhat obscured with dull crimson. The lip is of medium size and glossy brown in colour. Shown by Messrs. Armstrong and Co. Award of merit.

**Cypripedium Troilus Lord Nelson.**—This is a large and bright-looking flower with very regular and pleasing markings. The huge dorsal sepal has a large zone of greenish yellow ground colour, heavily dotted with large, circular dots of dull brownish crimson, the edge being a broad band of pure white. The sepals and lip are of the usual shape, the latter being extra large and standing well out, the colour of both being a glossy brownish crimson. Shown by Messrs. Sander and Son, St. Albans. Award of merit.

**Chrysanthemum Ball of Gold.**—A moderately large Japanese incurved variety of a yellow shade of colour that approximates to the once popular yellow-flowered variety W. H. Lincoln Improved. As recently exhibited this late-flowering variety appeared to possess many of the attributes of a good market Chrysanthemum; that is to say, the build of the flower, the firm stem and stout, short peduncle were noticeable, quite apart from the texture of the petal and the compact form of the flower as a whole. Exhibited by Messrs. R. H. Bath, Limited, Wisbech. Award of merit.

All the above were shown before the Royal Horticultural Society on the 8th inst., when the awards were made.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### PRECOCIOUS LEUCOJUM ÆSTIVUM.

I have on two occasions previously forwarded you notes, which you have published, on a form of the Summer Snowflake which flowers with

me in midwinter. My first communication mentioned that they were in flower in the month of February, and the second, a year later, that they were in bloom in January. This year they are in flower even earlier, being expanded in the first week of December. I send you two flower-spikes that you may judge for yourself. There is no doubt that they are the Summer Snowflake and not the Spring Snowflake, as their stems are nearly 18 inches in length. These Snowflakes, when I grew them in my garden at Torquay, proved flowerless for several years. I had some correspondence with Mr. Arnott about them, and he kindly sent me some bulbs which flowered well. On leaving Torquay I sent some of each lot of bulbs to a neighbouring garden, and on visiting it in February, 1902, found that my hitherto flowerless Leucojums were in bloom. A year later I brought them down to Kingswear, where they have flowered annually in the depth of winter. Though these Snowflakes are in full bloom, there being over twenty flower-scapes, Mr. Arnott's bulbs, which are growing alongside them, have not as yet shown even a leaf-tip above the soil. It is curious that, after a period of flowerlessness that extended over some years, these Leucojums should have developed such a precocious habit, for December and January is certainly an abnormal time for the flowering of the Summer Snowflake.—S. W. FITZHERBERT.

#### CYPRIPEDIUM INSIGNE FROM NORWICH.

Mr. T. B. Field, Ashwellthorpe, Norwich, sends excellent flowers of the Lady's Slipper Orchid (*Cypripedium insigne*). He writes: "I am sending for your table flowers of *Cypripedium insigne*. It is doubtful if, for general usefulness, this old plant in its best forms is surpassed by many of the more recent novelties. The length of time the flowers remain fresh, either on or off the plants, is remarkable, while its easy culture readily commends it to all."

#### BANKSIAN ROSES IN DECEMBER.

Miss E. M. Boghurst, Ingeneuk, Copdock, sends us several flowering sprays of the yellow Banksian Rose, which, although rather small, are quite fresh and well opened. In an accompanying letter, Miss Boghurst mentions that the plant is growing on a south wall and that it is covered with buds.

#### ST. BRIGID ANEMONES.

We have received from Messrs. J. T. Gilbert and Son, Anemone Nurseries, Dyke, Bourne, Lincolnshire, flowers of the beautiful St. Brigid Anemones, which are so welcome at this season of the year. They were gathered from a bed of seedlings sown last March, and the plants have been in bloom since the end of August. If the present mild weather continues there will be blooms for Christmas, as there are hundreds of half-expanded buds.

## LEGAL POINTS.

**Mistress and servant** (*H. B. T.*).—A lady, when a servant was engaged, promised him half a pig in the autumn. Autumn, in the popular sense of the phrase, is passed and gone, but "no pig is forthcoming." The fact that the promise is in the lady's handwriting is of some importance from the evidential point of view, but it does not really affect legal liability because it was not under seal; in fact, we doubt the legal liability of this hountiful lady. If held out as part of the servant's forthcoming wages, it is a trifle vague as to the kind of pig, although it does not at first sight appear impossible for a reasonable county court judge or twelve reasonable men fairly acquainted with the pig and bacon trade to estimate what an average autumn pig is worth. Liability is more doubtful still if,

after stating the wages in cash, it was thrown out as a statement of mere future intention, similar to the case of the parent who states over his glass of wine that he would give £1,000 to the man who married his daughter, and his friend, taking a mental note of the remark, married her, but did not recover that £1,000. If the cheerful remark was made after the servant was already engaged the lady is certainly not liable, as there is no consideration for the promise. We are rather afraid that she has been too much for you. Morally she is liable; but then women, as a rule, are not affected by rules of this sort unless implicated with religious sanctions.

**Liability for injury** (*H. B. T.*).—A servant has the misfortune of straining his back while cleaning out a well and is laid up for seven-teen days. His mistress promises to make up his wages, but is again oblivious of her promise. As incapacity was not permanent, justifying instant dismissal at common law with wages up to date, the relationship of master and servant subsists and wages run on as usual till the expiration of the usual week's (or month's) notice of dismissal. The only magnanimity here (if any) was shown in not giving the usual notice. The promise to make up the wages was quite superfluous, as he was entitled to them by law already. It is easy to be liberal with promises, which cost but little. BARRISTER.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Water Lilies for pond (*E. M. L. B.*).

For the more important groups you cannot do better than secure some of the *Marliac* hybrid Water Lilies, and of these the finer things are *Nymphaea Marliacea albida*, *N. M. carnea* and *N. M. chromatella*. The *Laydekeri* group of these *Nymphaeas* also contains some brilliantly-coloured flowers, and of these *N. L. fulgens*, *N. L. lucida* and *N. Robinsonii* are among the richest coloured. In addition, you might include *N. tuberosa*, very hardy and free-flowering, and *N. alba candidissima*, a large pure white free-flowering variety of our native kind. These would be best irregularly disposed, arranging the three first-named so that they occupy the more central positions and the deepest water. If more are needed, you will not err in getting any of the good varieties of *N. odorata*. If your pond is a natural one, and, as is most usual in a depression, with grassy bank or slope dipping into the water, you might further beautify the surroundings by planting groups of *Bulrushes*, the *Water Flag*, *Iris Pseud-acorus*, *Ranunculus Lingua grandiflora* and the double or single-flowered *Arrowheads* (*Sagittaria*), all of which prefer shallow water. In planting and arranging, avoid over-grouping and make no attempt to hide the water's surface, an error which is far too common even to-day. If your pond has a natural or mud bottom, you could plant all the *Nymphaeas* in wicker baskets, with a bushel of rich and rather clayey loam and cow manure, fixing the rhizome

or root so that it would not float. If the pond is an artificial one, in which little or no mud deposit exists, you had better introduce some soil also, otherwise the growth and flowering will be minimised. The planting may be done at any time between now and the end of March.

**Carnations mildewed** (*J. Pike*).—You may dust your *Carnation* cuttings with sulphur the same as you treat the *Roses*. At the same time, too much atmospheric moisture may be the cause of the mildew increasing so rapidly, and if you have been keeping the frame quite close, it will probably help matters if you give a little air for an hour or two each morning.

**Information about *Anemone japonica*** (*M. M.*).—This plant is so easily established in ordinary garden soils, whether light or heavy in their nature, that we feel sure there must be some peculiarity either of the plants or the situation. It sometimes happens when the ground plants have been roughly handled that they do not so readily take to their fresh quarters, and very old plants often resent removal. Try planting in a light, well-drained soil, not shady or dry, and purchase strong ground roots. The *Mecouopsis*, as you probably are aware, is a biennial and would die after flowering. The second plant is much more likely to produce a better flowering. You might erect a large sheet of glass over it, or the top portion of a handlight, at a foot from the earth to throw off the winter rains, but do not encompass the lower portion, leaving this to admit a free passage of air.

### TREES AND SHRUBS.

**Pruning Austrian Pines** (*A. L.*).—The best time to remove living branches from *Austrian Pines* is in summer. It is almost impossible to stop bleeding, but there is less bleeding in summer than at other times. Cut the branches close in to the trunk and dress the wounds with tar as soon as the work is done. If you wish to remove dead wood only, that may be done now, as there will be little or no bleeding from the wounds made by the removal of dead wood. Wounds in this instance ought, however, to be also dressed with tar.

**Screen hedge near Scotch Pines** (*Susan*).—If you wish for an informal hedge and *Rhododendrons* thrive in your neighbourhood, *Rhododendron ponticum* will prove an excellent subject; if, however, *Rhododendrons* will not thrive, and you prefer a hedge that can be kept trim and narrow, plant a mixture of *Thorn* or *Quickset* and *Holly*, five plants of the former being used to one of the latter. Well work the ground previous to planting, and if poor, manure well, taking care to so place the manure that it will not come in contact with the roots at planting time. A little good soil placed about the roots will assist the plants to become established. When planting *Rhododendrons* do not use manure, but give a little peat or leaf-mould during the progress of the work.

**Information about *Abutilon vitifolium*** (*E. S. K.*).—*Abutilon vitifolium* is really a semi-tender plant, which thrives best in the warmer parts of the country. In Cornwall and other places with a similar climate it thrives in the open ground, where it forms a bush 8 feet or 9 feet high and as far through. In Berkshire you may succeed in growing it at the foot of a warm wall with a south aspect or planted out in a sunny greenhouse. It likes light loamy soil and plenty of sun. When young it grows rapidly and makes soft wood, which often winters badly; as it advances in age, however, growth is shorter and firmer. You may succeed with it by growing it in a large pot or tub placed indoors during winter and outdoors from May until frost comes. Plants two to three years old often flower well.

### ROSE GARDEN.

**Ulrich Brunner pegged down** (*E. S. H., Clapham*).—The growths that have been tied down and have flowered may now be cut away, and this will considerably aid the development of this year's growths ready for next season. As regards the bulbs of *Lilium lancifolium* (*speciosum*) *rubrum*, we advise you to lift them, put them into pots of dry soil and keep them in a frost-proof pit or shed where they escape moisture. They should be preserved in much the same way as *Dahlia* tubers. Boxes of dry sandy soil would do as well as the pots.

**Moving standard *Roses*** (*A. B. C.*).—If you mean that the standard *Roses* have been several years in their present position, there will, of course, be a risk in moving them. You can, however, move them now.

**Basic slag for *Rose* beds and borders** (*C. Martineau*).—This excellent fertiliser should be applied at once at the rate of 3oz. to 6oz. per square yard. It supplies not only lime but phosphoric acid, and is most useful in the stimulating of *Roses* and fruit trees, but being very slow in its action it is best to apply it in autumn or winter.

**Zinc labels for Roses** (*N. G. I.*).—Any seedsman would supply you with Yeats's zinc labels, and they answer fairly well, but they are not nearly so good as Yeats's Acme labels. These have raised letters in white with a black background, and are very durable and neat-looking.

**Yellow and orange-tinted Roses** (*Daisy*).—Your selection is a very good one with the exception of Betty and Countess of Gosford. These two are practically pink and salmon-tinted varieties. A very beautiful sort would be Mme. Paul Varin-Bernier and another is Perle des Jaunes.

**Conrad F. Meyer with diseased foliage** (*L. Johnston*).—The foliage sent is badly affected with red rust, the black sooty appearance on the under-side of the foliage being the winter stage of this fungus. We do not believe this disease to be the cause of the death of some of your plants, although it sadly disfigures the Roses it attacks and the foliage falls prematurely. You should collect and burn every diseased leaf, and remove a little of the surface soil and burn this also. In the spring spray the young shoots with a sulphide of potassium solution and persevere with the spraying during the summer, using a very fine sprayer.

**Grass on Teplitz with spotted foliage** (*Mrs. N.*).—Your plant is attacked by the black spot. Probably the position is rather a damp one or the roots are not healthy. As the plant is only three years old you could very well replant it, and if you decide to do this make the border suitable by taking out the old soil to a depth of 3 feet each way if possible and 3 feet deep. Put about 6 inches of broken bricks in the bottom, then return the soil after mixing with it about 5lb. or 6lb. of bone-meal and a little well-decayed manure. In the spring cut down to the ground one of the old growths, and those remaining train in a zig-zag fashion on the wall. This will induce them to send out new growths near the base.

**Rose-growing in Scotland** (*F. M. E.*).—You will find a very useful little book in "Roses and Rose Culture," by William Paul, which we think will supply such information as you need. If you watch our columns also, you will gather many cultural hints as the time for the various work comes round. We gave some useful pruning hints in our issues of March 7 and 14 last. To check the exuberant growth it may be well to transplant the Roses next month, replanting in the same positions. In the spring do not prune very much. Leave the strong growths from 2 feet to 3 feet in length, and the others in proportion. You might check the extra vigour of the Sweet Peas, &c., by planting them in pots and plunging them in the soil over their rims. The large plant of *Lilium auratum* could be transferred to a larger pot or small tub without disturbing the bulbs, of course giving some new soil to the bottom and around the roots. As a rule, Lilies pay for repotting after the second year. When the roots show on top, some pieces of dried cow manure should be laid on, upon which the roots may feed. For convenience of applying manure in this way, some gardeners place the bulbs half-way down the pot and fill up as growth advances with good compost.

**Roses in lean-to greenhouse** (*Frau Karl Druschki*).—It is very possible that the trouble you have had with mildew arises from the roots of the Roses growing outdoors being in uncongenial soil; but there are so many causes that would bring about mildew that we are unable to say definitely unless we saw the house and the plants. We have usually found a good spraying with a solution of Lifebuoy carbolic soap to keep the mildew down if it is applied before the fungus obtains a firm hold. The usual strength is half a bar to three gallons of soft water. There is another good preparation called Mo-Efic, which you should try. Some of the worst mildewed parts must be cut off the climbers at once and burnt. At pruning time cut in the lateral growths fairly hard, but any long roots made this year should only be moderately pruned. Perhaps you could renew the soil about the roots of the two climbers, giving them some good compost consisting of loam two parts, well-rotted manure one part, and about 3lb. of bone-meal to a barrowful of the compost. This could be done during November. As regards your straggling pot plants, possibly it may be best to plant these out in your garden and procure some fresh ones, as they seem to be somewhat worn-out. We have seen such plants make wonderful growth after being planted out. Procure some prepared plants in 8-inch pots. These will be ready for pruning and starting into growth at any time. Some good Roses for pot culture are Caroline Testout, Frau Karl Druschki, La France, Anna Ollivier, Lady Roberts, Niphetos, Liberty, Mme. Abel Chatenay, Lady Battersea, Antoine Rivoire, Joseph Hill, Mme. Hoste, Mrs. Aaron Ward, Richmond and Hugh Dickson. A few good Chrysanthemums are Bonnie Dundee, Carrie, Dorothy Seaward, E. P. Barlow, G. J. Warren, Horace Martiu, La Grande Dragon, Lord Cromer, Rayonnante, William Seaward and White Quintus.

## FRUIT GARDEN.

**Cooking and cider Apples** (*W. G. Watson*).—The following are among the largest and best cooking Apples: Lord Grosvenor, August and September; Grenadier and Golden Spire, September and October; Lord Derby and Tower of Glamis, October and November; Warner's King, November; Bismarck, November and December; Lane's Prince Albert, Blenheim Orange, Wellington, Newton Wonder, and

Bramley's Seedling. The last five are in season from December to March. Cider Apples: Bennett, Devonshire Red Streak, Forest Styre, Foxley, Golden Harvey, Golden Pippin, Herefordshire Red Streak, Downton Pippin, New Woodcock and Siberian Harvey.

**Fumigant for mealy bug on Vines** (*A. B. C.*). Fumigation by means of hydrocyanic acid gas has been recommended for the purpose, but it is of so deadly a nature that extreme care is needed. Full details as to its use may be found in the "Book of Garden Pests," by R. Hooper Pearson. You will find an instructive article on "Freeing Vines from Mealy Bug" in THE GARDEN for February 15 last (page 75).

**Grubs on a Quince tree** (*X. M. D.*).—The leaves of your Quince tree are attacked by the grubs of the Pear saw-fly (*Eriocarpa atra*). The grubs are generally known by the name of the Pear slug-worm. They become chrysalids in the soil under the trees, and if, during the winter, you removed the surface soil to the depth of 3 inches and burnt or buried it deeply you should be free from this pest next season; but, of course, your tree may be visited by the saw-flies from a neighbouring garden. Spraying the leaves with an arsenate of lead wash would kill the grubs by poisoning their food.—G. S. S.

**Nectarine tree unsatisfactory** (*J. Heap*).—Probably our correspondent is right in his diagnosis of the cause of damage to his Nectarine tree leaves, and also in suggesting that the same fungus (*Cercospora Persicae*) may be responsible for the damage to the fruit also. The best antidote to apply against the recurrence of another attack is the application of some well-known effective fungicide, such as Mo-Efic, which, when applied as directed by the makers, is most effective in the destruction of mildew. The "Fruiter" or any other powerfully stimulating artificial manures are excellent when used sparingly, but we have seen disastrous results following their too liberal application and manifesting itself very much in the same way as your tree is affected.

**Sowing seeds of Pears, Apples and Plums** (*J. W. Griffiths*).—You may sow seeds of Plums, Apples and Pears in beds out of doors in ordinary kitchen garden soil, covering them with about their own depth of soil. Do not add fresh manure to the ground previous to sowing, but select a patch that was manured last spring and from which a crop has been taken. It is advisable to sow the seeds as soon as ripe, and previous to sowing roll them in red lead, which will keep them safe from mice. By raising trees from seeds in this way you may be fortunate enough to obtain, occasionally, a good variety worth placing on the market. If you secure one really first-rate variety from 10,000 plants you will be fortunate. Should you only need plants for your own use, by all means obtain grafted plants of standard varieties. You will find these far more suitable than plants raised from seeds.

**Melon plants failing to set fruit** (*G. H. T. L.*). You seem to have treated your Melon plants very well with one important exception, viz., you have failed to supply warmth. During such a season as the past, when of late there has been little sunshine, with heavy rains, strong winds and a low temperature, no Melon plants would thrive and set or carry fruits unless aided by artificial heat. This for these plants should not fall below 60° at night and reach fully 75° in the day. In Melon houses the temperature is often higher. In such case moisture in the form of vapour is generally supplied. You might have induced Cucumbers to grow under the conditions furnished, but those would probably have been unshapely. It is quite possible also the soil was too much enriched with manure, and especially with liquid manure. Your other queries are essentially agricultural and require the attention of some practical farmer.

## KITCHEN GARDEN.

**Clubbing in Cabbages and Turnips** (*Desperate*).—To plant Cabbages or Turnips in soil that is infected with club-root is to court failure. The only thing that has been found really effective is to dress the soil with quicklime at the rate of seventy-five bushels to the acre. This dressing should be put on in the autumn, and if not quite successful in the first year a lighter dressing should be put on in the next. Cabbages should not be grown in the same soil two succeeding years, nor should weeds belonging to the same family be allowed to establish themselves. Diseased Cabbages or Turnips must be burned, not dug in or thrown upon the rubbish heap or given to pigs. It should be remembered that the dressing of quicklime for a gravelly soil is a very heavy one, and one that may have a bad effect on the other crops that are to follow, especially in the absence of abundant organic matter. Great attention should be paid to growing the seedlings in soil that is known to be free from the disease.

**Mushroom for naming** (*W. A. G.*).—The fungus was in a rather bad condition when it arrived, but it appears to be *Agaricus arvensis*. This species is somewhat similar to the common Mushroom, but has a nearly smooth cap

and the stem is less solid than in the ordinary Mushroom, the smell is strong instead of slight, and not pleasant as in the common Mushroom. The flesh stains yellow and the gills are at first almost white. It is often eaten and used in the preparation of catsup.

**Destroying old Horseradish bed** (*E. M.*).—Assuming that your object in destroying the Horseradish in your old bed is to use the ground for other purposes, there is no better course to take than to open a trench 2 feet wide and deep at one end of the bed, then have the entire bed trenched gradually in that way, getting out every portion of the roots. If you wanted to grow better Horseradish in a fresh bed, trench and well manure a plot of ground and replant the best and straightest of your roots, with or without crowns, at least 12 inches apart, and you will have fine roots for sale next year. If you do not care to trench the old bed as advised, then keep its surface constantly hoed or pared over with a spade, doing it every week during the summer. By thus destroying leaf-growth there will be no further root-growth, and the root will in time die away.

**Globe Artichokes a failure** (*W. G. B.*).—The ground on which the Artichoke is to be grown next year should be deeply trenched and heavily manured this autumn, leaving the surface of the soil rough for exposure to frost during winter. The best variety we know is Sutton's Selected Large Green. Young plants of this should be obtained and planted the first week in April 4 feet apart each way. They should be planted rather deeply and the soil pressed firmly against the roots. As soon as the plants have done flowering cut down all the old flower-stems, and as winter approaches protect the plants by placing a cone of ashes round the stem about 7 inches high and 12 inches in diameter at the base. This should be removed in spring and a top-dressing of rich farmyard manure placed 3 inches deep over the roots. You will find they will flower much earlier the second year, and continue to do so until the autumn.

## MISCELLANEOUS.

**Gardening books** (*A. B. M.*).—A list of gardening books suitable for a lending library would be a very long one, as books are very numerous and written on every conceivable aspect of gardening. You do not say whether your library is for lending purposes or for reference. If the former, some number of the books with special mention of the particular aspects of gardening and possible cost should be mentioned. If you want books for reference, then costly and substantial books should be purchased, as these usually include the experience of the most practical writers. If you would kindly further intimate what you desire it would enable us to answer your query all the more easily. Books that are fairly useful for young readers range from 1s. to 20s., and high standard books, well illustrated, cost as much as from 40s. to 60s. each, though some are in two, three or more volumes.

**Staging in a greenhouse** (*Auricula*).—For the staging it is preferable to use an open instead of a close stage. Battens 3 inches by 1 inch make a very desirable stage if they are given a coat of priming and two good coats of paint. In fixing them they should be so arranged that there is a space of three-quarters of an inch to 1 inch between each batten. We have had no experience of the boiler named by you, and can, therefore, say nothing as to its qualities. The Loughborough boiler, advertised weekly in THE GARDEN has, to our knowledge, given great satisfaction in many cases. Glass for the roof cut in the shape indicated cannot be readily obtained, as though once thought highly of, its use now is practically discontinued, as it did not prove generally effective. A groove in the sash-bars is a great preventive of drip. There is no particular advantage in using 26oz glass for the roof, as the 21oz. is stout enough for all reasonable purposes.

**Are Roses greenhouse plants?** (*Rex*).—A correspondent wants to know whether climbing Roses are greenhouse plants. It appears that at a country exhibition last summer a class was provided in the schedule for a collection of stove and greenhouse plants grouped together for effect, Orchids admissible. The first-prize group contained plants of Dorothy Perkins and other Roses in bloom, the point it is desired to clear up being whether the judges were justified in giving a prize at all to a group so constituted in the face of the wording of the class in the schedule. There is generally a great deal of what may be termed "artist's licence" allowed in the formation of these popular and beautiful groups at exhibitions; but, strictly speaking, we think that Roses were inadmissible in a class so worded, being a hardy plant. Greenhouse plants, in the strict term of the word, are only half or semi-hardy, hence requiring the protection of a greenhouse to grow in.

**Names of fruit.**—*Barn Rocks*.—Grapes all smashed to pulp. Apples: 1, Lady Henniker; 2, Peasgood's Non-such.—*R. Windsor Rickard*.—Apple Old Hawthornden and Pear Marie Guise.

**Names of plants.**—*A. L. Ford*.—*Cedrus atlantica glauca*.—*Miss J. M. N.*.—*Clematis cirrhosa*.—*T. H. O. Pease*.—1, *Salvia rutilans*; 2, *S. angustifolia*; 3, *Aceria sanguisorba*.—*Lancastrian*.—1, *Anthurium magnificum*; 2, *Peperomia Saundersii*; 3, no specimen; 4 and 5, *Begonia Rex* varieties; 6 and 7, *Codiaeum*, garden varieties; 8, *Cordylone terminalis*; 9, *C. species*; 10, *Dieffenbachia Corderi*; 11, *Oncidium incurvum*; 12, *Arundinaria Fortunei*; 13, *Pteris cretica*; 14, *P. c. variety*; 15, *Asparagus plumosus nanus*; 16, *Nephrodium Filix mas cristatus*; 17, *Aspidium angulare*; 18, specimen too poor to name; 19, *Thuya orientalis*.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## WEeping ROSES.

**W**EEPING Roses are so beautiful in the garden that a few general notes upon their cultivation may be serviceable to amateurs, particularly as the planting season is now in full swing. The name is comprehensive but applicable, though one might as fairly describe them as shower Roses, seeing that the long, pendulous shoots when flower-laden form, as it were, perfect cascades of bloom. The best stocks for forming weeping standards are those of the Polyantha or Dog Rose; the latter is the common Briar of our hedgerows. These should be fairly straight and strong, averaging 10 feet to 12 feet in height. November is a good month to obtain Briars, as when planted at that season they recover from the check of removal before spring. After gathering the roots are shortened back to 6 inches and all branches cut clean to the stem, leaving a long, straight shoot, and all dormant buds are removed, leaving four or five at the top of the stem. Plant the stocks in any good garden soil and stake firmly and well above the head; then shorten the stocks to 8 feet to 10 feet and tie securely. As the buds begin to swell in spring, remove all except those selected for forming the shoots to bud into, and any growths which show from the roots must be carefully pulled out, as cutting with the knife tends to increase suckers. When the Briar shoots begin to lengthen they must be supported by cross stakes securely fastened to the upright pole; this prevents any damage being done to the head by winds. July is the best month for inserting Rose buds into the stocks; generally from the middle to the end of the month will find the bark running freely, and while the shoots are in this condition success can almost be guaranteed. Select plump buds; those near the base of a shoot are preferable to those from the top, as the latter are too soft, but the former soon "take" and ultimately develop strong growths. A fortnight after budding the ligatures may be loosened to examine the buds, and if these are progressing favourably the budding cotton or raffia is replaced, not tied quite so tight, and in four or five weeks this can be dispensed with entirely. At this season the pole which supports the stock should be made perfectly rigid, as also the cross stakes, after which no further attention is necessary until spring. Some time in March or early April the plants are pruned, by cutting the Briar shoots back to the inserted buds, and when these have grown long enough they are tied to the cross supports, to prevent rupturing, until the union becomes thoroughly hardened.

Good examples of weeping Roses may be had in two years by this system, provided a good foundation is laid, first by selecting strong Briars, then securing a limited number of strong breaks from the stocks, and by employing good sound buds. After two seasons' growth they can be permanently placed in the garden, planting as early in November as is practicable. Use a good stout painted iron stake to support the stem, to which by four or six arms a light iron hoop is attached; this ensures perfect rigidity, while it materially assists in developing the drooping habit. The foregoing notes will be most serviceable to amateurs who can procure and bud their own stocks; others must, necessarily, buy their plants ready formed through the channel of trade growers. The positions in which weeping Roses become effective are well-nigh innumerable and vary in almost every garden. It is best to avoid positions where any depression marks the ground, but a slight eminence increases the weeping effect; angles of walks or those formed by shrubberies are suitable, while central positions or marked points within the Rose garden may gain both in variety and picturesqueness by introducing standards in weeping form.

Almost any well-enriched garden soil grows this type of Rose well. The ground should be dug two spades deep and manured—decayed farm manure and bone-meal—previous to planting. The soil under the Rose should be carpeted with Violas or similar plants until the Rose shoots touch the ground. In no instance would I recommend turfing up close to the stem. Subsequent manuring must be according to the vigour of the plant and at the discretion of the cultivator, increasing the stimulants either by liquid manures in summer or as solids worked into the ground during winter.

Pruning will be confined to shortening back a few of the shoots at planting, after which some of the old growths may safely be removed every year after flowering.

The best varieties are, unquestionably, those having wichuraiana blood. Not only does the natural disposition of these lend themselves to this form, but their extended season of flowering combined with the bright glossy semi-evergreen foliage gives them priority, as these are features so marked as to be almost essential in a plan where the plants must often be conspicuous for the greater part of the season. To this group belong such beautiful Roses as Alberic Barbier, Dorothy Perkins, François Foucard, Lady Gay, Hiawatha, Minnehaha, Jersey Beauty, Paul Transon, René André and White Dorothy.

Some of the climbing Roses can also be so grown; a few of the Ayrshire Roses are

excellent, but their flowering period is, unfortunately, brief. Among the best are Dundee Rambler, Félicité Perpétue, Longworth Rambler and The Wallflower.

Two Roses which have been grown successfully in this form here are Mrs. F. W. Flight and Perpetual Thalia, the former a new semi-double pink Rose, which lasts in full beauty over six weeks at midsummer.

THOMAS SMITH.

Walmsgate Gardens, Louth, Lincs.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

\* \* The dates given below are those supplied by the respective Secretaries.

January 12.—Royal Horticultural Society's Meeting and Exhibition of Flowers, Fruits and Vegetables, Vincent Square, Westminster, S.W., 1 p.m. to 5 p.m.

January 23.—French Gardening Society of London Annual Dinner at the Café Royal, Regent Street.

**British-grown fruit show.**—It will come as a surprise to many growers of fruit in this country to know that the Royal Horticultural Society has decided not to hold the great autumn show of British-grown fruit in 1909. The reasons given by the council are that this annual autumn show is every year practically a replica of the previous year's show, and that many British-grown fruits cannot possibly be shown, or, at least, shown in perfection, at any one show of fixed date, and also that vegetables are somewhat neglected. To make up for the absence of this popular show the council have substituted in its place a somewhat similar series of prizes for British-grown fruit and vegetables, but these are spread over the whole year, so that every fruit may be shown at its best. Prizes will therefore be offered at every fortnightly show held at Vincent Square during the year 1909, particulars of which are included in the society's "Notices to Fellows," which appear in the current issue of the journal.

**National Dahlia Society.**—It will, we think, be a matter of general satisfaction to Dahlia growers to learn, as reported on another page, that the National Dahlia Society and the London Dahlia Union have amalgamated. For some time past the advisability of such an amalgamation has been recognised, but unfortunately difficulties cropped up, hence it is pleasing to find that these have been removed. With the joining of the forces of the two societies we hope that a new era has dawned for the Dahlia, and that its many merits will be recognised more fully than they have been in the past. It is a pleasure to note that Messrs. J. Green, William Cuthbertson and E. F. Hawes, who have been such enthusiastic workers for the now defunct London Dahlia Union, have been elected to official positions in the amalgamated society, and we congratulate the members on securing their services.

**East Anglian Horticultural Club.**—This club still continues to prosper, as was shown by the report presented by the secretary, Mr. W. L. Wallis, at the annual meeting held on Wednesday, the 9th inst., at the Boar's Head Hotel, Norwich. The report congratulated the club on the useful work it had carried out in the matter of educating its members by means of essays, lectures and the monthly exhibitions. It stated that the membership now stood at 343 and had the substantial balance of £139 16s. 6½d. to its credit. The thanks of the club were accorded to F. W. Harmer, Esq., for his gift of books to the library. In the aggregation of points gained at the exhibitions, Mr. W. Shoesmith proved to be the champion of the year, and he also secured the sole possession of the Girling Challenge Cup, having won it on two former occasions.

The auditors, Messrs. J. F. Betts and H. Perry, presented their financial statement, which was most satisfactory. The election of officers next took place. Mr. J. Powley was elected president, Mr. T. B. Field acting vice-president. The vice-presidents were all re-elected as before. Mr. Charles Daniels was elected treasurer, and the indefatigable secretary, Mr. W. L. Wallis, 11, Royal Arcade, Norwich, was re-elected with acclamation. Six vacant places on the committee were filled by Messrs. H. Goude, W. Rush, C. Hines, H. J. Cowell, E. Goldspink and R. Abel. Mr. J. C. Abel was re-elected librarian, with thanks for his past services. Several alterations of rules and competitions were adopted. A syllabus of lectures and essays for the ensuing year was announced. Miss Dawson Paul, Eaton, Norwich, has generously presented a silver cup for competition to replace that won outright by Mr. Shoesmith. It was decided to hold a dinner the second Wednesday in January.

**French gardens.**—We learn that M. Aquatias, the well-known French gardener, has accepted an engagement to forthwith undertake the development of French gardens at Tiptree, Essex. Tiptree is a place noted for small holdings, there being no fewer than 250 small holders there operating areas varying in extent from one to fifty acres, and growing chiefly fruit, seeds and flowers. The laying-out of three French gardens has already been begun at Tiptree, and in a few days M. Aquatias will personally superintend the creation of a fourth. The introduction of this system into Tiptree by Mr. F. Mynott of Brook Hall has provided employment at what is usually a slack season of the year, more than fifty men having been engaged in laying water mains, building houses on small holdings, and preparing the soil for French gardens during the last three months.

**A new magazine.**—From all accounts the Garden City is fast becoming a centre of public spirit and enlightened citizenship. It is, therefore, natural enough that a new illustrated magazine called "The City," and mainly devoted to matters of civic growth and life, should be produced there. It is printed at the Arden Press and published by Messrs. J. M. Dent and Co., two houses which were among the first to remove their works to Letchworth. In the first number articles by Miss Hope Rea on the "Civic Spirit," and Mr. J. H. Wicksteed on the "Results of Five Years' Work," contrast vividly with a description of the solitudes of the Syrian Desert by Dr. Adrian Fortescue. The new monthly is edited by Mr. Henry Bryan Binns; the price is 6d. net.

**Lady Veronica Bruce and a gardeners' society.**—Lady Veronica Bruce, daughter of the Right Hon. the Earl of Elgin, like the other members of the family, takes a great interest in gardening, and showed her zeal to help the affairs of a local horticultural society—that of Charlestown, Limekilns and Pattismuir—by taking the chair at the annual meeting, which was held in the Queen's Hall, Charlestown, the other day. Lady Veronica Bruce made a graceful and competent chairman, and at the close of the proceedings was heartily thanked for her presence and services. The report of the committee was a highly satisfactory one, and much of this is due to the interest taken in the society by the Earl of Elgin and his family. Lord Bruce was also present at the meeting, and took part in the proceedings.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Spring bedding.**—Your correspondent "A. W.," on page 618, raises a much-debated question as to the uses of spring plants for bedding purposes; but there are one or two points which, although of the greatest importance from a

practical standpoint, he ignores altogether. In the first place, perhaps I may be permitted to point out that Tulips or Daffodils, carpeted with other dwarfier-growing plants, are not carpet beds as the term is generally understood, but rather are they combinations of one or more colours. The question, however, that most concerns practical men is, What would "A. W." do with his beds of Forsythias, Flowering Currants, Cydonias, Daphnes, &c., after the plants have finished flowering? Perhaps to his tastes these shrubs are beautiful when out of flower; but I fear few employers would care to see them in prominent places. A gardener, rightly or wrongly, is expected to keep certain beds bright and well furnished for as many months as possible in the year, and consequently has to arrange his spring combinations accordingly. I fully recognise the beauty of the shrubs in question, and if we could afford to dig them up and discard them after they have flowered, or, better still, induce them to flower almost continuously throughout the summer, they would be admirable for the beds. Now that the Editor has given him the opportunity, "A. W." should certainly give fellow-readers the benefit of his cultured tastes; but may I remind him to be, above everything else, practical?—E. M. D.

**Lilies of the Valley in the winter.** First buy as many roots as can be afforded, remembering always to order them with flowering crowns and continue to do so for four or five years, when the cultivator will be independent of salesmen. Force them as desired for these years, always giving sufficient water, otherwise miserable flowers and few leaves will be the result. As soon as they have flowered, harden them off and plant them out in a shaded border 1 foot apart, each year successively. In the fourth year begin with the first planted, taking them up with a turf spade 4 inches thick. They may be put into shallow boxes, or, better still, planted out in the inside vinery border just at the time that heat is applied to the Vines. Never attempt to force these plants before they have been submitted to cold nights or frost. Before winter begins, short horse manure may with advantage be spread over the beds outside. The Editor will no doubt recollect a lawsuit some years ago, when a customer sued a firm; a few blooms appeared among the lot ordered, simply because they were not flowering crowns to be sold at a cheap rate. It takes three years for flowering crowns to grow. They, when housed, would be syringed at the same time as the Vines, and these slabs of roots will be put under glass in succession once a fortnight, or otherwise, according as they have bloomed. The grower will be able at least twice a week to pull out, not cut, enormous bunches of flowers and perfectly-coloured leaves, which are just as beautiful. May I ask how to get rid of a certain kind of thrip which spoils the Christmas Roses out of doors, and how to make the plants throw up longer stems? *Tropaeolum speciosum* has given me much trouble for years, as they never seemed to thrive or grow to any length. These last two years, however, they have done perfectly, rising full of bloom up to about 14 feet, simply because they were planted out with a north aspect, only getting a little sun in the evenings. Use light moist soil with plenty of drainage and a little peat if any is available. They cannot stand sun at their roots, as the soil, if heavy, gets baked.—X.

**Muscat of Alexandria Grape and the Royal Horticultural Society's fruit committee.**—This Grape has attained to very high distinction, not only as the richest-flavoured variety in cultivation, but also as one of the handsomest and most prolific. It has many other characteristics, but its chief one, I think, lies in its difference of growth under varying conditions of soil, temperature, quality of wood, age of Vine, &c. So marked and often have these changes been, and still are, that no Grape has ever given rise to

greater doubt and controversy regarding its identity. Its eccentricity in this respect is, doubtless, responsible for the many other claimants to the title of distinct varieties of Muscats having come forward from time to time to contest its claim to be the only Muscat, such as Bowood, Archerfield Early Muscat, Charlesworth Tokay, Tottenham Park Muscat, Tynningham Muscat, &c. Most Grape-growers now agree that mistakes have been made in the past in giving distinctive names to these various forms of Muscat of Alexandria. The slight variations noted are solely due to the varying conditions under which the Vines (as noted above) have been grown. It is time that this question was set at rest and the claim of these so-called varieties be disallowed. The only other distinct Muscat is Cannon Hall. I am led to make these remarks about this Grape by an incident which happened at the fruit committee's meeting of the Royal Horticultural Society on the 24th ult. It appears that Mr. Vert of The Gardens, Audley End, had exhibited these Grapes in a class provided for the variety at a country show held recently. The first prize was withheld, the judges coming to the conclusion that it was not the Muscat of Alexandria. Mr. Vert, having some doubt in the matter and wishing to have it set at rest, took a bunch off the same Vine and placed it before the fruit committee on the above date, with the result that some members contended that the variety was the true Muscat of Alexandria, others expressing doubt on the subject. The matter ended in a proposition being made and carried inviting Mr. Vert to send another bunch to the next meeting, which took place on Tuesday, the 8th inst., other members of the committee bringing other samples of the true variety for comparison. The question was soon settled, the committee coming to the unanimous conclusion that the variety was the true Muscat of Alexandria; indeed, it proved to be the richest-flavoured Grape of the samples presented. Had Mr. Vert not taken this step, probably his Muscat Grapes would have been tabooed at this and other shows afterwards. Looking back, it seems now a pity that a similar course was not taken in respect to the incident of Muscat judging at the 1907 autumn fruit show of the Royal Horticultural Society, seeing that the fruit committee in the first instance were undecided respecting the identity of Mr. Vert's Grape. No judge, however well up he may be in fruit culture and knowledge, need reproach himself on his inability to fix the identity of this variety in all cases.—X. Y. Z.

**Mistletoe.**—As great quantities of this parasite are in great demand at this season, a word or two as to how to grow it will not be out of place. At this season and during the early months of spring the berries wanted for inoculation should be covered over with a small-meshed net in order to keep away birds, or if the weather be frosty the birds will devour them. In the month of April take a berry and make an incision in the bark of the tree in which it is wanted to grow, squeeze in a berry, which must contain a seed, tie a piece of gauze over it and the operation is complete. Mistletoe is well berried this season, but, strange to say, Hollies, which were so full of bloom, have now scarcely any berries on them. I think the tropical weather in the autumn started a second growth and so forced the berries from the branches.—W. A. COOK.

**Flower shows at the Crystal Palace.**—The complaint of a "Visitor" that the National Chrysanthemum Society held a beautiful flower show at the Crystal Palace early in the month and that visitors were very few indeed reads interesting in face of the fact that the National Dahlia Society has arranged to hold its early autumn show at the Palace next year. Certainly at the Palace the committees of these societies meet with very liberal treatment. In addition to a good pecuniary contribution,

their advertising is done for them, and every possible accommodation, with some medals to boot, is found. That is far more liberal treatment than is shown by the Royal Horticultural Society to similar societies. But of what use is all this liberality if visitors are not there to see the show and, especially, of what benefit is it to the trader to incur the heavy expense he does to exhibit? Is it the case that the many very fine and wonderfully cheap shows provided all the year round by the Royal Horticultural Society have killed attendance at other London shows? Certainly flower shows without visitors are indeed folly. How is public interest to be created?—D.

#### The best fifty herbaceous plants.

Although Mr. Reynolds Hole's article on page 611 is interesting and his list contains many precious and indispensable subjects, I think there are several serious omissions. Surely one would rather grow *Campanulas persicifolia* and *lactiflora* (a neglected but exquisite plant) in preference to *Coronilla Varia*, which, I take it, is only suitable for a rough, dry bank. Instead of *Anthemis tinctoria* (pale yellow) the bright yellow variety *Kelwayii* should be tried. No herbaceous border should lack the lovely *Kämpferi* Irises, for although they are recommended for pond banks, they succeed admirably in ordinary soil providing plenty of water is given them during the growing season. And can one imagine a collection of perennials which does not contain that showy plant *Doronicum plantagineum excelsum* (Harpur Crewe), the first perennial to bloom that is useful for cutting. Ought not *Centranthus coccineus* to be omitted, and where are the *Veronicas*?—E. TESCHENACHER.

### PERPETUAL-FLOWERING OR AMERICAN CARNATIONS.

A VISIT TO TANGLEY NURSERIES, HAMPTON.  
NOTES AND REFLECTIONS.

ACCORDING to a tale which used to be current in North Wales, two gentlemen were one day travelling on the Cambrian Railway. Presently one asked the other whose property they were passing through. "Mine," was the reply. The question was repeated several times and the same answer given. Soon the train stopped, and the questioner got out and went to the guard and told him he thought he had been travelling with a mild lunatic who thought all the country was his own. "Oh," said the guard, "don't you know who that is? Why that is Sir Watkin." Substitute *Lilium longifolium* for the country, Christmas flower-markets in England and Scotland for the train, the Brothers Page for Sir Watkin and myself for the disturbed questioner, and you get an idea of the quantities grown by the four brothers at Hampton and my own surprise at the vastness of their undertaking. I had journeyed down one lovely day at the end of November to see the American Carnations at Mr. W. H. Page's. For a long time I had noticed how good his blooms invariably were whenever they were shown in public, and I wanted to see them growing, as I have a little collection myself.

It is nearly twenty years since the first Page boy left the old home at Teddington and settled down at Hampton, to be joined in due course by three brothers, not as partners, but as friends, who buy and sell together as much as possible. *Lilium longifolium giganteum* by the hundred thousand and *Lilium speciosum* varieties by the ten thousand! This gives an idea of the immense trade they do between them in this one kind of flower alone. Roses come next; then *Narcissi*, mainly *Golden Spur*, *Emperor* and *ornatus*. The brother to whom my visit was paid grew last season 660,000 *ornatus* himself. To hold his flowers he has twenty large glass houses, ranging in size from 190 feet by 30 feet to

100 feet by 12 feet. At the time of my visit about half were full of the healthiest Carnations one could wish to see. The only sign of anything amiss was in a batch of that brilliant but rather difficult variety *Brittania*, and this was nothing serious. In the stress of work it had not been housed in time and the ends of the leaves looked withered. It has a very thin skin, which makes the plant susceptible to damp and change of temperature.

#### HISTORY.

Mr. Page used at one time to grow such varieties as the once celebrated *Miss Joliffe*, and later on the equally well-known *Uriah Pike*, but after an interregnum, in which practically no Carnations were grown, he started with the new American varieties, realising as he did their superiority over any existing types as market flowers for cutting and decoration, because of their long stems and perpetual-flowering properties. This new type had for its ancestors the "Remontant" Carnations of France. These were first imported to New York, in 1852, by a French florist named Charles Marc. Four years later the firm of Dailledouze, Zeller and Gard received some seed from a Lyons florist, and also some plants of *La Purité*, described as a lovely rose; *Mont Blanc*, white; and *Manteaux Royal*, variegated red and white. From these beginnings, favoured and, it may be, made possible by the brighter sunlight and drier air of the States, the new race has been built up, not by one but by many patient and painstaking workers in the New World, until at last in 1896 the famous sale of Mrs. Thomas W. Lawson for \$30,000 took place, and by its notoriety brought before the flower-loving public of England the fact that such a grand type was in existence, and that their own British "trees" must look to their laurels.

#### NAME.

At present there is a good deal of undecidedness as to the name by which this vigorous and distinct race should be known. A front page of a weekly gardening paper is before me as I write, and it contains two advertisements, in one of which they are called "American" and in the other "Perpetual-flowering." There is a decided tendency to the same uncertainty in the schedule of the Perpetual-flowering Carnation Society, and, if I may venture an opinion, the name I incline to myself is that adopted in its pages by the chairman of the floral committee (my friend Mr. S. Mortimer), who heads his advertisement "American Perpetual Carnations." The latter word denotes their peculiar characteristic, for it is a mistake to suppose that they only bloom in winter, and I feel sorry when the term "winter-flowering" is applied to them in lists and advertisements, as it is misleading. The true type with proper management will give us flowers all the year round. I hope the Perpetual-flowering Carnation Society will be most rigid in requiring this essential in their distribution of awards. "American" denotes the country of their origin. Mr. Smith has given us the *Brittania* and Mr. H. Burnett the delicious *Mrs. H. Burnett*; but let us not forget that our inspiration came from the far side of the "herring-pond." Moreover, the fringed and their somewhat crowded-looking arrangement of the petals (and, would that I could add, their invariable strong Clove scent and non-splitting calyx), mark them off as distinct and leave room for another type of perpetual flowers, of which I think I see the small beginnings, when the outline of the petals and their arrangement will more nearly resemble the old English type that has delighted our florists from the days of Maddocks and Thomas Hogg down to those of Dodwell and Douglas, a type which might then be called "British." I have dwelt upon this point because there is something in a name, and if it can be suggestive, so much the better.

JOSEPH JACOB.

(To be continued, when culture and suitable varieties will be dealt with.)

## THE FRUIT GARDEN.

### SOME AUTUMN FRUITS WORTH GROWING.

**F**IRST on the list come the autumn Strawberries, and the past autumn has been one of the most favourable on record for these, as the rainfall in August and early September caused the fruits to swell freely, and the warmth later ripened the fruits. It does not occur to many amateurs that the ordinary fruiting summer Raspberry, if the canes of last year are cut down to within 6 inches of the soil in February or March, will fruit freely in the early autumn, especially such varieties as Superlative, Hornet and Semper Fidelis. The Strawberry also, if planted late in the spring and the first blossom removed, will make a fresh growth and fruit later, and forced plants put out in the open crop grandly in September; but my note more concerns the true autumn fruits, such as the alpine Strawberries, autumn Raspberries, cultivated Blackberries and, in the northern parts of the country, the hybrid or Loganberries are valuable for autumn fruiting, and of late some excellent sorts have been added to the last named.

Strawberries of the perpetual or alpine type, that fruit freely through the autumn, are well worth amateurs' attention, as though the fruits, as regards size, do not compare with the large summer varieties, they are, as regards crop and flavour (the season considered), well worth room in all gardens where fruit is appreciated. The culture is most simple, the plants being easily raised from seed or propagated from runners like the summer varieties. The runners are planted out in deeply-dug, well-enriched soil on an open, sunny border early in the spring, in rows 18 inches apart and 12 inches between the plants. For late fruits the flower-trusses must be removed till July.

The best autumn Strawberry is St. Antoine de Padoue. It is one of the largest, is a free grower, and from beds made in the early spring a crop, as stated above, may be gathered till November if the weather is open. A new variety that promises to make its mark as an autumn fruiter is Laxton's Perpetual; this is a large fruit, and was obtained by crossing Monarch, a summer variety of great excellence, with St. Joseph, a perpetual of French origin, and the result is a very late fruit of the perpetual race. There are others, such as the older St. Joseph referred to and Louis Gautier, a white variety shading to pink, and La Constante d'Automne. These are all French varieties. The alpine are smaller but delicious autumn fruiters and well worth growing. There are several, the best being Belle de Meaux Bergeri and the Gunnersbury Alpine; they require the same culture as the perpetuals.

The distinct types of autumn Raspberries are not numerous; but recently we have had a splendid addition to these fruits in the new Veitch's November Abundance, recently awarded a first-class certificate by the Royal Horticultural Society. It is a very fine autumn fruit and a great bearer. Of older varieties there are Belle de Fontenay, a large fruit and very prolific; October Red and October Yellow. These do well if trained to fences or hurdles in an open position, providing the canes are cut down to the ground in February and the growths that are made later trimmed, only leaving a few of the strongest at each stool.

The Blackberries cultivated are worth room when space is available, and one of the best, viz., the laciniatus or Parsley-leaved Blackberry, is very good, but it requires plenty of room. It is a grand subject for a fence and should be planted 10 feet apart. It is often called an American Blackberry, but it is of British origin and far superior to the American type, at least, in our climate, as it fruits much more freely. In a warm soil and with a good summer Wilson

Junior and Best of All are the best of the American varieties.

The Wineberry is a plant that everyone can grow, and though an earlier fruit than the Blackberry, it is really first-rate. It is a novelty from Japan, but it has been grown sufficiently long in this country for one to know its value, its correct name being *Rubus phoenicolasius*. The berries are Mulberry-shaped, grow in clusters, are very sweet and juicy and much liked by birds. It makes an excellent preserve, and grown no a fence or post fruits freely.

Another berry less known is a new introduction from North China by Messrs. J. Veitch named *Rubus innominatus*. It bears long panicles of orange red fruits in great profusion in September and has very handsome foliage. The fruits somewhat resemble a Blackberry in flavour, but are larger. It does well on a wall or warm fence.

G. WITHERS.

### APPLES FOR ORNAMENT.

IN small gardens the custom of planting varieties of Apples that are of high and conspicuous colour for ornament is on the increase. In addition to their flowering value in spring, the richness of the fruit colouring in the autumn, especially upon the late sorts, gives a pleasing tint to the landscape that is much appreciated, especially, too, when the trees are planted as standards in the ornamental portion of the garden. I would ask, What could be more ornamental on the lawn than a perfect standard tree of Worcester Pearmain, for example? Not only does this form of planting give beauty to the surroundings, but it is quite of an utilitarian character also. I append a list of desirable Apples as well as being of a high colour. As a guide to those who do not know the varieties, I attach the time of season as well as place them in their proper classes—kitchen or dessert. Dessert: Lady Sudeley, August; Worcester Pearmain, September; Ben's Red, October; Duchess of Gloucester, October; James Grieve, October; Viscount Castlereagh, October; and Baumann's Red Winter Reinette, January. Kitchen: Barnack Beauty, November; Gascoyne's Scarlet, December; Paroquet, December; Wagener, March; Wealthy, October; and Mère du Ménage, January.

E. MOLYNEUX.

## TREES AND SHRUBS.

### RARE AND GOOD SHRUBS FOR PLANTING.

**A** FEW hints to intending planters regarding some of the more choice and select shrubs may be of interest. There are now many beautiful shrubs that will grow as freely as Laurel, and which should be made use of instead in the gardens of small suburban residences.

*Desfontainea spinosa*.—This is a Chilean plant and a most charming evergreen, with prickly, Holly-like foliage. The flowers are of great substance and very beautiful, being scarlet tipped with orange. They are pendulous and tubular, and 2 inches to 3 inches in length. The plant looks well when grown on a wall or planted in the open. It requires good rich soil and not too wet a position, and should be sheltered from the north and east winds. The flowers appear after midsummer, and a plant in good condition will continue to flower till the end of October. The best time to plant is from the beginning of March till April.

*Escallonia macrantha* is a beautiful species with dark, glossy, shining leaves and flowers of a crimson-red colour, which are produced all the summer. It is a valuable plant for covering a wall. It requires good open soil and thorough drainage to grow it well, and is easily propagated

by cuttings planted in the open in some very light sandy soil. It may well be planted in November or February.

*E. exoniensis* is a hybrid of great merit and of upright habit, with handsome foliage retained through the winter. It has large spikes of white flowers, which are produced in the autumn, and it stands the winter well. *E. rubra* is also a fine variety.

*E. langleyensis* is a most desirable plant for a wall, the branches being furnished their whole length with bunches of rosy carmine flowers.

*Berberis Darwinii*.—A common but beautiful ornamental shrub, well worthy of a place in the garden, and when planted several dozen together the sight from a distance is very entrancing. It is easily propagated from seeds or layers. The plants should be pruned hard to keep them in bounds.

*B. Thunbergii*.—This is a most lovely plant in spring, with myriads of golden pendulous flowers, and more charming still in the autumn, as few, if any, shrubs excel this for colour. A few plants in elevated positions show to much advantage. It is an easy plant to grow and is not particular as to soil.

*Andromeda floribunda*.—A compact and rather dwarf shrub. It has small evergreen foliage, and the flowers are white, Lily of the Valley-like blooms, these appearing early, sometimes by the end of February should the weather prove mild. It is easy to cultivate and not at all particular as to soil, but prefers one that has been trenched and enriched with leaf-soil and cow manure. It can be layered or struck from cuttings. It is an easy plant to move, as it usually carries a good ball of earth.

*A. japonica* is very hardy and ought to be well known, as it is one of the very best for effect. It has evergreen leaves, and the flowers, which are creamy white, hang in long racemes. The best time to transplant this is October or November, as it then has a fair chance to settle down and root before it flowers.

*Choisya ternata*.—A good evergreen plant with masses of lovely white flowers resembling Orange blossom. It is very free-blooming and growing if planted in rather light soil, but is apt to get cut back by frost if exposed too much. It blooms in May and often again in September and October, the flowers being very sweetly scented. It is rather impatient of removal, as it does not make fibrous roots and nearly all the soil falls away, especially from large plants.

*Olearia Gunnii*.—This is a charming small-leaved evergreen shrub, compact and neat in habit, and in spring is covered with a mass of white Daisy-like flowers. It is quite hardy and a most desirable plant for any portion of the garden. It can be struck from cuttings, which should be put under a hand-glass. A very good plan to increase the stock is to split up a plant, as it quickly makes good specimens treated thus. October is the best month for replanting.

*Clerodendron trichotomum* is a Japanese deciduous shrub, but quite hardy and flowers in September and October, the blossoms being white with red discs. It grows freely and soon makes a good-sized shrub 8 feet to 10 feet and more in height.

*C. fortitum* is a species that should be planted in a sheltered position. It has large foliage and flowers on the terminal shoots, the blossoms being pretty rosy pink and beautifully scented. The foliage, however, has a pronounced disagreeable odour.

*Chimonanthus fragrans grandiflora*.—This is one of the most beautiful and remarkable shrubs from Japan, as it flowers in midwinter and the blossoms are delightfully fragrant. It succeeds best planted against a wall in a south position and should be pruned immediately after blooming, as it flowers on shoots of the current year's growth.

*Desmodium penduliflorum* is a lovely plant when in flower. It flowers late, when blooms on shrubby plants are scarce, the blossoms being

produced in long, pendulous racemes of a reddish purple hue, the individual flowers of which are Pea-shaped. It sometimes needs a little litter or ashes over its roots in winter. February is a good time for removing or transplanting.

*Eucryphia pinnatifida* from Chili is a most beautiful deciduous flowering shrub, growing 8 feet to 10 feet high and bearing white flowers with yellow anthers, and in August is certainly the most welcome of all shrubs. It requires fairly rich soil, and will not bear removal very well. It may be raised from seed or layers, but takes two years or more to root from the latter. Nice little plants can be got from seed in two years. The largest plant here seeds very freely.

*Fremontia californica*.—This plant is only semi-deciduous, although it is often called a deciduous plant. It is a good climber and bears large bright yellow flowers 2 inches to 3 inches across in the spring. It should be somewhat protected in severe weather.

*Philesia buxifolia* from Chili is an evergreen of great beauty when in flower, and it likes a peaty soil. It bears Lapageria-like flowers during the summer and grows about 2 feet high.

*Solanum crispum*.—This has proved hardy and is an interesting shrub of strong growth, as it often grows 8 feet or 10 feet in a year. It bears pretty blue flowers with yellow centres in the spring and is good for a wall or the open.

*S. jasminoides* is a white-flowered plant and very handsome on a wall. This flowers in July, August, September and October, and should be allowed to ramble at pleasure, when it is a perfect climber. W. A. Cook.

Leonardslee Gardens.

#### RHODODENDRON HERCULES.

This is one of the largest-flowered, and certainly one of the richest-coloured, of the hybrid set known as Javanico-jasminiflorum, and in addition to producing a very handsome truss of shapely campanulate flowers is, by reason of its colour, one of the most distinct of the race to which it belongs. The predominant shade of colour is golden orange with apricot, mingling with which is a suspicion of rose that lends additional warmth and beauty to the flower generally. Other charming varieties of this group—and for which gardeners are indebted to Messrs. James Veitch and Sons, Limited, Chelsea—are Ne Plus Ultra, crimson-scarlet; Aphrodite, blush pink; Cloth of Gold; King Edward VII., bright yellow; President, clear buff yellow, tinted with rose; and Baroness Henry Schröder, delicate rose and the best of this shade. A special value attaches to these hybrids by reason of their flowering throughout the winter months, the blooms continuing a long time in perfection.

## THE ROSE GARDEN.

### A LOVELY TEA ROSE.

**D**URING the autumn months the beauty of many Roses is brought prominently into notice, for then they show themselves to be real acquisitions for their late-flowering propensity. Such a one is General Gallieni. It is a Rose one would not find in many catalogues, yet it is one of the best varieties sent out by M. Nabonnand, a raiser who has given us such precious gems as G. Nabonnand, Comtesse Festetics Hamilton, Comtesse Panisse, Papa Gontier, Marie d'Orleans and General Schablikine, a variety that charmed the late Dean Hole so much. All of these the amateur would do well

shy flowering, and should be given a dry, open position to obtain the best results. In such positions it would be best on a wall or pergola. A friend with a small garden in the north of London planted it some years ago, giving it a good larder to start in, which induced a most vigorous growth. In the spring he pruned it back, and as a result had but few flowers. This autumn, when chatting with him about it, he said that this last spring he resolved to allow the shoots to remain 6 feet or 8 feet long, and he had a glorious show of flowers for months. These long shoots all produced trusses of bloom the entire length, and sent up strong shoots from the base for another year. I am convinced that many good Roses suffer from the too free use of the knife. Sorts that are prone to make long, strong shoots should be allowed to have their head if blooms are wanted. J. Crook.

Camberley.

### ROSE THERESA BEVAN.

AMONG the Roses seen at the National Rose Society's exhibition on September 17 few were more striking than Theresa Bevan. It is of very free growth, and certainly one of the best late-flowering sorts in the Teas or Hybrid Teas. I should hesitate to say which class it belonged to without seeing more of it, but it is evidently a grand novelty. A flower brought from the exhibition lasted quite a long time and was very attractive. In the bud stage this Rose is a good coat flower, opening to a large decorative bloom. The colour is difficult to describe—coppery red, intermingled with salmon. We sometimes find this shade in the brightest blooms of Beauté Inconstante and Souvenir de William Robinson. The Rose is quite distinct, and as a decorative variety would most probably have gained a medal of the National Rose Society, only Messrs. Garraway of Bristol distributed it a little too long ago to enter for this distinction. It is still quite new, being, I believe, sent out two or three years ago. Anyhow, it is a most striking colour, and the habit of the plant is all that can be desired. A. P.

### ROSES KONIGIN CAROLA AND CAROLINE TESTOUT.

THERE is a similarity in the flowers of these two grand Roses, but yet sufficient difference to stamp them both as first-rate. I should call Konigin Carola a more refined flower, both in colour and in petal. The pink shade is wonderfully clear and beautiful, and the insides of the petals, also the reflexed edges, are a clear, silvery white. One does not find the jagged edge of the petals that somewhat mars Caroline Testout, and the

THE BEAUTIFUL WINTER-FLOWERING RHODODENDRON HERCULES, SHOWN BEFORE THE ROYAL HORTICULTURAL SOCIETY RECENTLY BY MESSRS. J. VEITCH AND SONS. (Reduced one-third.)

to add to his collection, for they are very vigorous. General Gallieni has a sort of old gold centre with the outer petals crimson and blood red. The flower varies in its colouring, but it is always charming. P.

### ROSE GRUSS AN TEPLITZ.

Few Roses have been more widely planted than this, and rightly so, its bright crimson flowers attracting all Rose lovers. Another recommendation is its free growth. In our light soil it blooms abundantly. Roses that are of a vigorous habit are most suitable for these soils. In those of a cold, heavy nature, this Rose is prone to be

centre is inclined to be pointed. If anything, the flowers are larger, with a superb spread of the petal that makes the bloom appear even larger than it is. In the matter of growth Caroline Testout is superior, and if it were a question of vigour I should certainly recommend the older Rose. It would be a good plan to plant both sorts, using Caroline Testout for the centre and Konigin Carola for the outside of the bed. If standards of Caroline Testout were used, then the groundwork could be made with bushes of Konigin Carola. Although some individuals profess to being able to detect fragrance in Caroline Testout, I must say I cannot do so, and unfortunately the newer Rose has little, if any. This is rather surprising seeing that that sweet Rose Viscountess Folkestone was one of its parents. P.

### ROSE ISABELLA SPRUNT.

I do not think we see nearly enough of this Tea-scented Rose. It is one of the most free-flowering, a vigorous grower, not liable to mildew, but really a hardy desirable Rose. The orange yellow buds are most useful in a cut

## THE FLOWER GARDEN.

### PINK AND WHITE GLORIES OF THE SNOW.

HERE are yet some of us who remember with pleasure the interest taken in the introduction of Chionodoxa Lucilæ, Lucilia's Glory of the Snow, through the bulb merchants (although it had been in a few botanic gardens before that) and the rapidity with which it leaped into favour. It was a welcome flower with its lovely blue white-centred blossoms, and I question if any one of the other Chionodoxas which have since found their way to our shores has ever attained an equal favour or has given such delight to its grower. But, although the typical Chionodoxa Lucilæ has blue and white flowers, like such allied plants as the Scillas, it is of a sportive character and breaks away from its normal hues into shades of white and pink. Some of these are exceedingly beautiful, and the bulbs of pink or white varieties which have been imported have been readily purchased by

to 6 inches, or even 8 inches deep. It may be added that there are also pink and white varieties of the other Glories of the Snow.

Dumfries.

S. ARNOTT.

### THE SCILLAS.

THE Scillas are an important race of spring and summer flowering bulbs with bright and interesting flowers. Two types are generally grown—the starry-flowered type, of which *S. bifolia* is a familiar example, and the bell-flowered type, well represented by our native Bluebell. A third group is neither so popular nor so useful. This is *S. peruviana*, which has broad leaves and a spreading inflorescence in summer. There are many Scillas, quite unknown to gardeners, that one could recommend as useful plants; and there are others, which were introduced long ago, that we ought to contrive to do without now that so many beautiful bulbs are available, particularly *S. autumnalis* and *S. italica*, both of which are of poor colouring and weedy. The native Bluebell enjoys, as we know, the half shade of the open copse rather than full sunshine, and probably many kindred species would appear to better advantage in open shrubberies, planted in Nature's own lavish way, than they do as tufts in the plant border. Most of the cheaper Scillas produce seeds so freely that one often regrets the need for destroying seedlings in cultivated soil, which would speedily clothe many an unsightly patch of worn turf beneath trees and help to make bright and cheery spots in spring if they could have their own way. Rarities, of course, would have places selected for them on rockeries or elsewhere; but the majority of Scillas should be grown rather in colonies than separately. Even in border planting it is better to have a broad sowing of bulbs that would be satisfying in their rich coloured display than a thin line or a series of little tufts.

*S. amena*.—This, the Star Hyacinth, is too often confounded with the Siberian Squill, and there are many who regard the two names as synonymous. There is a resemblance between the two plants and a great colour distinction. The flowers of *S. amena* are royal purple or plum coloured and they appear late in spring. It is effective on rockeries when well massed.

*S. autumnalis* is a slender plant with thin spikes of rosy lilac, starry flowers, but it is not an effective garden plant. Its white form, *albus*, is choicer and a neat plant to group on rockery slopes. Any soil suits it.

*S. bifolia* is a well-known little plant and very charming in the mass; it grows well in any soil that is not very heavy and wet. The flowers are deep ultramarine in colour, starry in outline, but wonderfully pretty when produced from short turf. *Alba*, its white form, is a refined little plant that everyone would appreciate when growing on a rockery slope. It does not increase fast, but is comparatively long-lived. It does not promise to be useful as a grass bulb, and it cannot well be naturalised, as seedlings revert to the type. *Carnea* is a poor little plant—a pallid, weakly rosea of little garden worth; the colouring is a dull flesh tone. *Rosea* is a better plant, not wholly rose coloured, but with a lilac tint. It is effective when planted in a setting of *Herniaria* or similar mossy plant. *Taurica* is a rich violet-coloured form, inexpensive, free of growth, and will prove more useful than the type; the colouring is better and more decided. These little Squills are among the first flowers of spring, and they are excellent rock plants that one would not care to be without.

*S. chimensis* (*Barnardia scilloides*) is a pretty but quite neglected autumn-flowering Scilla, producing spikes of rosy pink flowers, small individually, but closely arranged in a dense spike 9 inches high and lasting well till quite late in the year. One could recommend it for rockeries and raised borders. It prefers a damp soil and a warm position.

PINK AND WHITE GLORIES OF THE SNOW IN A SCOTTISH GARDEN.

state, especially for bouquets. As the flowers fully develop the colour is a pleasing canary yellow.

A plant growing on the west side of the Post Office here is a remarkable sight every June; the 15 feet height of space and 12 feet wide is one mass of pale yellow, which lasts a long time in flower. The same plant gives a heavy successional crop again in September and an occasional bloom during the autumn.

Swanmore.

E. MOLYNEUX.

### ROSE MISS GLEGG.

Does anyone know the history of this Rose? I had it from Messrs. Rogers and Son, Red Lodge Nurseries, Southampton, but I cannot see it noted elsewhere. I call it a free-flowering, very fragrant, cluster Rose, which opens its flowers early in July. In colour the buds are bluish white, changing to pure white with age. It gives clusters of twenty to thirty blooms on each shoot. I do not call it a climbing variety, as the growths made annually are not more than 4 feet long. The foliage is deep green and not evergreen. I grow and recommend it as a standard on the common Briar. E. M.

lovers of the flower. Some of the shades of pink are not altogether what one would desire, but raisers have been at work to select the prettiest and to secure seedlings from these.

The group of which the accompanying photograph shows a part is composed of a number of bulbs sent me some three years ago by that benefactor to flower-lovers, Herr Max Leichtlin of Baden-Baden, and all are seedlings raised by him. All are beautiful, the whites being, as a rule, of the utmost purity and the pinks ranging from almost blush to a warm pink.

The group is cultivated among the plants of a small collection of hardy Ferns, which I grow on the east side of a hedge, and before the Ferns have assumed their foliage the Glories of the Snow deck the rough border with their beautiful flowers. Here one may, in passing, point out the value of early bulbs among hardy Ferns. Although the Chionodoxa generally likes a fairly moist soil, it is not particular in this respect, and that in which this group is growing is partly robbed of its moisture in summer by the roots of the hedge. With deep planting, such as the Glory of the Snow likes, however, the flowers are excellent and the plants thrive well. In planting the Chionodoxas may be put from 4 inches

*S. hispanica* (the Spanish Scilla), better known perhaps as *S. campanulata*, embraces in its forms some of the best May-flowering bulbs of its class. They are better adapted for border planting, for shrubberies and for naturalising in the same way as the Bluebell, but in open, sunny places where the latter would not appear so effective. The type plant is light blue in colour, very floriferous and vigorous, often throwing spikes 18 inches high in good cultivated soil. Alba is pretty, excellent in colonies in the plant border, but there is a larger form with very large bells which I have distinguished as *grandiflora*. It is the white counterpart of *Excelsior*, and the spikes curve gracefully as in *S. patula*. *Atrocerulea* is a dark blue selection, differing only in its richer colouring from *S. hispanica*. *Excelsior* is a giant, and quite the best Squill for border planting; the colouring is not very distinct, but the large size of the bells and the enormous spikes are excellent features. This plant, treated like the common Hyacinth in pots, is worthy of extended use in conservatory decoration. It requires good culture to maintain its vigour. *Rubra* resembles the type except in colour, which is a clear pale red; but the best of the reddish forms is *Rose Queen*, a delightful variety, still somewhat rare; the colouring is a pale rose, soft in shade and very clear, becoming silvery as the flower ages. It is none too vigorous and its increase in a heavy soil is slow, but under more favourable conditions it would doubtless thrive better. It is an excellent plant of refined colouring, quite distinct from the many nondescript roses and reds that one finds in this family and which are so much overrated.

*S. italica* is a starry-flowered Scilla, blooming in late spring. Its flowers vary somewhat from lilac purple to slate blue, the latter predominating. As now available the species is hardly worth garden room, but there are several shades in chance seedlings that one could welcome, notably a pretty lavender-coloured form and a turquoise blue, which, when available in quantity so that they can be massed, will re-establish the popularity of this species. The better types hail from Cilicia. Alba, a rare white form, is one of the gems of the spring flora. The flowers are quite colourless and very dainty. These Squills require a warm slope and a thorough ripening in autumn, otherwise the bulbs decay at the disc.

(To be continued.)

### IRIS WARLEYENSIS.

AMONG the hardy bulbous Irises there are many flowers of rare beauty, and there are few which cannot be recommended to admirers of these fascinating flowers. Among the different classes, those of the character of *Iris orchioidea* will commend themselves to all. Within recent years we have had some additions to their ranks, and that called *warleyensis*, after the famous garden of Miss Willmott's, has acquired much favour since its introduction, especially as its cost is quite a moderate one, and places it well within the reach of those of slender means.

It is a charming flower, with blooms of a pleasing purplish blue, adorned with a yellow

blotch and having their beauty heightened by a white crest, with various little markings, such as are possessed by the prettiest of the Irises, and which add so considerably to their beauties. Its merit may be gauged by its being awarded a first-class certificate by the Royal Horticultural Society.

*Iris warleyensis* grows with me to nearly 1 foot high and is quite hardy, although its early flowering makes it desirable that its flowers should have some little glass protection in spring in case of severe frost occurring while they are open. This can be easily given by means of a bell-glass or hand-light.

I cultivate it on a low rockery facing almost due south, and in what is practically sandy loam. Planted in early autumn about 3 inches

should be stated clearly, however, that these pot-plunged plants require a little more attention in dry seasons.

### SCARLET BEDS.

Here we have a greater range of subjects probably than in any other shade of colour, and standard or pyramid Fuchsias and Pelargoniums occur at once as the principal plants for grouping as in the last-named colour. Then in dwarf Pelargoniums, double Begonias, Verbenas, scarlet *Salvia Gloire de Zurich*, *Celosias*, the rich-leaved *Begonia Triomphe de Lorraine*, *Cannas* either of leaf or flower to match, *Antirrhinums* and the like we have a variety difficult to surpass. *Iresine* and *Coleus*, if available, may be also of good effect.

### PINK BEDS.

The chief plants in this shade of colour will be pink Fuchsias and pink Ivy-leaved Pelargoniums, than which we have nothing more beautiful when arranged informally as tall pyramids, several in a group. A very large oblong bed could be filled with such at intervals of 4 feet over its entire area. If bold pillars of the Rambler Rose *Lady Gay* occupied the central part at like intervals or rather more, a bright picture would result. The groundwork of such a bed should be Begonias, Verbenas, or the same Ivy-leaved Pelargoniums pegged down. There are many other plants which are most effective when used as a judicious mixture. For example, a large bed may be ideally beautiful if simply planted with the blue and white *Plumbago capensis*, while another effective combination would be Ivy-leaved Pelargonium *Charles Turner* and *Calceolaria Burbidgei*. The hardy Fuchsia *gracilis*, 2½ feet high, with pink, cream and crimson Begonias covering the soil, is most striking. A good early bed, say, for June, July and August, would be *Rose Liberty* and a white *Viola*; again, scarlet Fuchsias, variegated *Cock's-foot Grass* and white *Alyssum* as groundwork. Scarlet *Salvia Gloire de Zurich*, with *Dactylis elegantissima* as groundwork throws out the intensity of the scarlet. *Plumbago capensis alba*, *Lobelia Queen Victoria* and white *Alyssum* form a most effective combination, and equally good a rich dark-flowered single Fuchsia as pyramids, variegated Ribbon Grass on the ground and edged with white

*Alyssum*. A striking bed may be had by first arranging variegated *Dactylis*, and subsequently grouping and interspersing crimson *Celosias* and the dwarf crimson *Begonia Lafayette*. The *Celosias* in this case should appear in small circles, the variegated Grass occurring between these and the Begonias.

Instances such as these could be multiplied indefinitely; but still deserving of mention for great freedom of flowering are the orange-flowered *Streptosolen Jamesonii* and the blue *Ageratum*. In many gardens the Summer Cypress (*Kochia scoparia*) finds favour, but the formal columnar outline of the plants will not be appreciated by those who are in search of informal subjects for bedding. The above combinations are given more as suggestions than anything else, because we fully realise that tastes differ considerably. Readers can, however, modify these suggestions to suit their own requirements.

IRIS WARLEYENSIS GROWING IN A SCOTTISH GARDEN.

deep, it will flower in spring and be certain to give pleasure to its owner and his friends.

Dumfries.

S. ARNOTT.

### SOME BEDDING ARRANGEMENTS.

(Continued from page 622.)

#### YELLOW BEDS.

HERE as the principal plants, precisely on similar lines as before, *Calceolaria Burbidgei* or *C. amplexicaulis*, yellow Tufted Pansies, yellow *Antirrhinums* and *Celosias* may be used. We do not know of any plants to equal the first-named for profuse flowering and general effect. Tall plants 3 feet high, set out in their pots and arranged five or more in a group, will during the season form an informal pyramid 4 feet high at least, and by reason of its restricted root-space the leaf-growth is but moderate. It

## GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**T**HE WINDOW GARDEN.—Small evergreen shrubs may be planted in empty window-boxes at the present time. The watering of indoor plants requires care. Succulents and Cacti should not be watered until the end of January. Pots of bulbous plants should be placed in the windows of the warmest room, maintaining the soil in a moist condition, using slightly tepid water. Sponge the foliage of ornamental-leaved plants occasionally, using tepid water mixed with soft soap. Other flowering plants will benefit by receiving similar treatment.

*The Vegetable Garden.*—In frosty weather, when the ground is hard, see that the wheeling on of manure is proceeded with apace. These opportunities should be watched for and immediate advantage taken of them as they arise. On the other hand, keep off the ground when it is wet. On no account spread the manure until the soil has thawed and has also become fairly dry; then proceed with the digging without delay. Potatoes intended for seed should be examined; those with long, attenuated sprouts should have the latter removed and care taken to spread out the tubers less thickly. Sturdy, short sprouts are desirable. Seakale, Rhubarb and Asparagus that it is desired to force should be lifted forthwith, placed in boxes and removed to the greenhouse at once. The roots may be planted quite close to one another, as space must be economised at this period. Endive pays for care in the blanching process, and this may be effected by placing a large flower-pot in an inverted position over each plant. The hole in the bottom must be covered to exclude light, otherwise the blanching will not be successfully accomplished.

*The Greenhouse and Conservatory.*—Chinese Primulas and Cyclamens are now looking quite gay. To maintain them in a healthy condition care must be taken not to water the plants too much. Watering is the all-important item in successful culture at this season. Less will be required by the plants now than at any other period of the year. Roses under glass must have attention. Those planted out or in pots in the cool greenhouse should be pruned now. Shorten back this year's shoots of the Hybrid Perpetuals

to 2 inches, 3 inches or 4 inches, according to their strength and size. Cut the less vigorous Tea-scented Roses back to 3 inches, 6 inches or 9 inches, according to the vigour of the current year's growth. I usually remove 1 inch or so of the surface soil of Roses in pots, and give a top-dressing of some good, rich lasting soil in which is incorporated a small quantity of concentrated manure of some sort. Bulbs growing freely may be moved to a light position on shelves in the greenhouse. As growth becomes more pronounced, plenty of water will be required. The warmth of a cool greenhouse or conservatory may be kept in in very cold weather by covering the ends and sides and the lower portions of the roof with mats, &c., until the cold snaps have passed. For forcing, I am potting up a number of Lily of the Valley crowns, and boxes are also being used for the same object. In the warmer glass structures look out for the attacks of aphides; the points of shoots of *Lilium Harrissii* are very susceptible to the attacks of this pest. Fumigate the greenhouse with vapourising compound or dust the affected parts with Tobacco powder. Climbing Roses should be pruned at this period. Shorten the growths about one-fourth of their length.

*Trees and Shrubs.*—When the ground is free from frost, plant all kinds of trees and shrubs.

2.—TYPICAL JAPANESE ANEMONE CHRYSANTEMUMS.

Hedges in variety should also be planted now. In this connexion Yews, Laurels, Holly, Hawthorn, Thuja, Cupressus and Privet should be dealt with. Continue to plant climbers and creeping plants. Should the roots of trees and shrubs be dry, give them a good soaking with water if frost is absent. On no account plant these subjects when the roots are very dry. Heel in the trees should the weather be frosty, and wait until the next favourable opportunity to plant them. In shrubberies and borders where a plant has perished, remove the same at once, and replace it with a good specimen of some other or a similar subject.

*Hardy Fruit Garden.*—Raspberries must be pruned without further delay. I have just cut out old and weakly canes, also removed the tops of those retained, leaving a good plump bud at the top. These canes are secured to wires strained to uprights, and others are having the support of stout stakes. Recently-planted fruit trees are being treated to a mulching of good, partially-decayed manure. I am completing the pruning and nailing of Pears and Plums on walls. That the latter may be done quite satisfactorily, the young shoots laid in have ample

3.—A DECORATIVE JAPANESE CHRYSANTEMUM.

room to swell by adjusting the shreds with more than ordinary care. Neglected trees in the orchard should have immediate attention. Thin out crowded growths in the centre, and also side branches that cross and interfere with one another. D. B. CRANE.

## TYPES OF CHRYSANTEMUMS.

*Hairy Chrysanthemums.*—Varieties that may be placed within this category are few in number, and new sorts are seldom raised. Chrysanthemums of the description under notice chiefly belong to the Japanese or Japanese incurved sections, and their chief peculiarity consists in a covering of short, glandular hairs on the reverse of the petals. These hirsute appendages are more pronounced in some varieties than in others. The plants are not difficult to grow if second crown buds are retained; these are the third series of buds that appear on the plants in the course of a season's growth, and they invariably produce blooms of good colour with the glandular hairs well developed. Few sorts can be recommended, the better ones being: *Hairy Wonder*, large, colour deep fawn; *Louis Boehmer*, soft rose-pink, dwarf; *Mrs. C. B. Freeman*, deep golden yellow sport from the last named; *Mrs. Dr. Ward*, bronze, large full flower; *King of Hirsutes*, pale lemon yellow; and *Princess Henry*, beautiful silvery pink.

*Reflexed Chrysanthemums.*—This type is seldom seen now at the shows, although sometimes in market or cottage gardens. The flowers are of medium size, more or less spherical in form and notable for their bright colours; the petals reflex, building a bloom of reflexed or recurving form. Good typical varieties are: *Cullingfordii*, brilliant crimson, with golden reverse to the petals, rather late flowering; *King of Crimson*, rich crimson, large full flower; *Elsie*, pale canary yellow; *Golden Elsie*, rich yellow (the two last-mentioned sorts are free flowering and of easy culture); *White Christine*, white; and *Pink Christine*, light pink. A good outdoor sort is *Cottage Pink*, the true name of which was originally Emperor of China.

*Pompon Chrysanthemums.*—This is a much-neglected type and embraces what are known as early-flowering Pompons, Pompons and miniature-flowered Pompons. They are all very pretty, developing their flowers on plants of bushy growth and in the greatest profusion. Their diminutive character adds to their charms, both as cut flowers and as plants. The blooms are either somewhat flat or nearly globular, averaging

1.—A LARGE-FLOWERED ANEMONE CHRYSANTEMUM.

1½ inches in diameter, neat and compact in form, and formed of short, flat, fluted or quilled petals; very pretty when gathered in free-flowering sprays that have had some of the buds thinned out. Early-flowering varieties are: Orange Pet, golden orange, tinted bronze; Mme. Ed. Lefort, reddish bronze; Yellow Mme. Ed. Lefort, a bright yellow sport from the last named, dwarf; Mr. Selly, pretty rosy lilac, dwarf; Veuve Clicquot, beautiful bronzy fawn; and Lyon, rosy purple. Pompons that flower in November are the following: William Westlake, golden yellow, slightly suffused red; Mlle. Elise Dordan, soft lilac pink, pretty globular flower; Prince of Orange, light orange amber; Rosinante, blush rose, should be disbudded; Osiris, pretty shade of soft rosy purple, tipped gold; and William Kennedy, a beautiful crimson amaranth.

*Miniature-flowered Pompons* are miniature representatives of the type. Some of the flowers are not more than three-quarters of an inch in diameter, and others, generally speaking, seldom exceed 1 inch in diameter. They are dainty in form and make excellent decorative material when cut in free-flowering sprays. Representative sorts are: Snowdrop, pure white, height 3 feet; Primrose League, pale yellow sport from the last-named, flowering in November; Katie Mannings, rosy bronze, of beautiful form; Victorine, rosette-like flowers of a maroon crimson colour; Little Pet, deep bronze, very free flowering; and Lilac Gem, pale rosy lilac. Two good early sorts are: Anastasio, soft purple violet, very free and branching; and Little Bob, a very effective crimson brown sort. Both are useful for border culture.

*Anemone-flowered Chrysanthemums.*—These flowers are very quaint, and as plants for decorative uses should be more largely in request. They are divided into three sections, viz., large Anemones, Japanese Anemones and Pompon Anemones.

*Large Anemones* have two distinct sets of florets, one quilled and forming the centre or disc, and the other flat and more or less horizontally arranged, forming the border or ray (Fig. 1). Good sorts are Descartes, bright crimson-red, very fine disc, early; Cincinnati, blush guard florets with paler disc; Mrs. Judge Benedict, rose-tinted guard florets and sulphur-yellow disc; Gluck, golden yellow guard florets and disc, high in the centre; Mme. Robert Owen, pure white self, free flowering; and M. Charles Lebocqz, buff and suffused yellow ray florets and bright yellow disc, rather tall.

*Japanese Anemones* are noted for their large size and fantastic form. The disc is more or less regular in outline, the ray or guard florets varying considerably in length and character. In some cases the florets are narrow and prettily twisted, and in others they are broad and curled. In some instances the ray florets droop and form a beautiful fringe or tasselling to the flowers (Fig. 2). The best sorts are: John Bunyan, light yellow guard florets, deeper yellow centre; Mme. Lawton, rosy white guard florets, yellow centre; Sir Walter Raleigh, pale blush guard florets, deeper coloured centre, very large; Queen Elizabeth, fluted guard florets of a lemon yellow colour, disc rich yellow; W. W. Astor, blush guard florets, yellow disc; and Duchess of Westminster, silvery blush guard florets and lilac disc.

*Pompon Anemones.*—These are miniature forms of the large-flowered sorts, and for decorative uses are very beautiful. They are of easy culture and dwarf growth, and have small leaves. A good selection should comprise Marie Stuart, pale lilac guard florets, sulphur yellow disc or centre; Emily Rowbottom, creamy white sport from the last named and ideal for decorative uses; very free flowering; Antonius, a beautiful golden yellow self, dwarf; Regulus, cinnamon guard florets, brownish disc, dwarf; Eric, a charming orange buff, dwarf; Calliope, ruby red guard florets and red disc, dwarf; Gem of Earlwood, rosy blush guard florets and citron disc, lovely in sprays, late flowering; and Magenta King, a

pretty flower with magenta guard florets and yellow disc. Many of the plants are not more than 3 feet in height and are charming for greenhouse or conservatory.

*Spidery Chrysanthemums.*—These are flowers with horned, forked, notched, wire-like or thread-like petals, and embrace some of the most delightful of all the decorative Chrysanthemums. With few exceptions the flowers are small and are borne on plants varying between 3 feet and 4 feet in height. Another of their characteristics is that the plants are late flowering. Throughout December they are much sought after. The better varieties are: Mrs. Filkins, bright yellow, horned variety; Mrs. James Carter, pale yellow, thread-like petals; Chevenix d'Or, rich golden yellow, very fine; Mrs. W. Butters, white fluffy variety; Sam Caswell, pink, pretty and distinct; Bertie Bindon, pure white, thread-like petals; Jessie M. Cole, soft canary yellow, a pretty variety for cutting; Lovely, pure white of spiral formation; and Crimson Tangle, crimson and gold, with silk-like florets. Two large-flowered sorts are King of

pressed back again it will assuredly fail. As a matter of fact, it is wise to examine all recent planting after frosts in case of trouble, as it does not demand much time and often spells the difference between success and failure, and is therefore thoroughly repaid.

*LAWNS.*—It is not now the season for devoting much time to the cherished grass plot, as the weather is never so genial that we can sit about and enjoy the greenness of the sward. We may, however, if we feel so disposed, do much now to favour a fine lawn later on. As we cannot walk or stand about on the grass, the opportunity may be taken to apply a top-dressing to it, which will, for the time being, completely spoil its appearance, but will eventually do it a vast amount of good. There is almost always some old potting soil at disposal, and from this all crotches should be riddled out; then mix it with about its equal bulk of refuse manure, such as that which has done service in a Cucumber or Melon pit or a Mushroom bed, and spread the whole evenly over the entire surface of the grass. The rains will steadily wash the food virtues of the material

4.—A NATURAL SPRAY OF MEDIUM-SIZED SINGLE CHRYSANTHEMUMS.

Plumes, a deep yellow flower with notched and curled petals, and What Ho, a large flower with few, long, stout, tubular petals almost 5 inches long, colour pale buff yellow.

## THE TOWN GARDEN.

*PLANTING SHRUBS.*—It is comparatively common for a spell of pleasant, open weather to come during the first and second weeks of January, and when this does occur those who have two or three shrubs waiting to be planted should get them in forthwith. To commence a large operation of planting would be unwise, but for odd plants it is excellent practice to take advantage of all the opportunities that present themselves. The soil must neither be sodden nor frozen, and it must be sufficiently friable to permit of working well in between each set of roots; firmness in finishing off the task is imperative to success. If any planting is done now it will demand incessant watching during frosts coming shortly afterwards, for these will penetrate deeply into the freshly-moved ground and possibly lift the plant out of it; unless this is at once firmly

into the soil and just as surely wash away all traces of the application, so that when we want the use of the grass again we can have it without the smallest fear that any objectionable particles will be apparent. In the event of this course of procedure being inconvenient, one of the finest things for the grass is to dress it with basic slag at the rate of 6oz. to the square yard, and the sooner this is put on the better, as it is slow in yielding up its food virtues, which will therefore be ready when the roots of the grasses are actively searching for food in spring.

*STAKES.*—After they have done service for a few seasons there are not many stakes which do not show signs of giving out, and this should be accepted as indicative of the necessity for renewal. It is not a difficult operation, and it is essentially one that can be put in hand at this quiet season. Unless it is imperative no attempt should be made to bore new holes, as it will answer the purpose just as well and will be much easier if the new supports are pressed well down into the old holes. The new stakes must be of at least the same thickness, and preferably rather larger than those removed.

*WALKS.*—Those which are made of gravel demand a considerable amount of attention

during the winter, for it is at that season that they are worked thoroughly and firmly down so as to remain in perfect condition in the summer. It is, of course, necessary that considerable judgment shall be exercised in rolling and other operations, but if things are put in hand when the weather is right nothing other than good can accrue. If the walk is dull and it is impossible to sprinkle on a little fine gravel, the surface should be lightly pricked over with a pick and then rolled heavily down again; it is wonderful how much this will brighten it up. For rolling successfully it is necessary to have the gravel wet, but it must not be in such a state that it will pick up beneath the feet or on to the roller, or far more harm than good will inevitably be done.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**F**ORCING DEPARTMENT.—This will now be a busy time, as in most places flowers and vegetables are in great demand in the early months of the year. Such subjects as Seakale, Chicory, Dandelion, Endive, and Mustard and Cress must be placed in pots or boxes now every week, in order that the demand may be met. An Asparagus bed should be made up about every month on the same lines as recommended for the first. Some stools of Rhubarb may be taken up if Apples are likely to become short, securing good big roots from which the small side crowns should be taken off and planted subsequently to fill the spaces.

Continue to introduce to the forcing house Lilacs Mme. Lemoine and M. Louis Spathe, Spiræas, Azaleas mollis and indica, Tulips, Hyacinths, Narcissi and Roses. Do not attempt hard forcing at the outset or it may prove fatal.

The latest batch of Poinsettias should be removed to a cooler structure when the bracts have thoroughly developed. The warm conservatory or nice airy rooms where there is continual heat suit these to a nicety, and I know of no plant that looks better in rooms at night, as it can be arranged with almost anything. A good combination is with a foreground of Lily of the Valley, Roman Hyacinths, yellow or white Chrysanthemums, Ferns and Bouvardia. Euphorbia jacinthiflora is now useful and can be used similarly to Poinsettias.

**Carnations.**—Keep a little air on the house and maintain a temperature of 50° to 55°. Young stock coming on should be pinched as soon as the plants have grown enough, so that they will break low and secure a good foundation for fine plants. Cuttings may be taken off soon where they have not been propagated and for later plants. Malmaisons should be kept as dry and cool as possible, giving heat only during frosty weather. Plants in flower or showing buds should be kept at the same temperature as recommended for Tree or winter bloomers, viz., 50° to 55°.

#### LAWNS AND PLEASURE GROUND.

Keep the lawns swept and rolled weekly, so that the turf shall be maintained in good and pleasing condition. Keep the beds containing spring-flowering plants and bulbs in respectable order. Mulch Roses, and, if the weather is severe, shake a little Bracken over the heads of Tea and other tender varieties. Bulbs and plants peeping through the ground should be protected from the ravages of insects by using soot, which, however, must not be smeared over the foliage,

and black cotton forms a barrier against sparrows if put on soon enough.

#### HERBACEOUS BORDERS.

In dry weather these borders may now be rearranged and trenched; if they are too large to be done in one season, do a section each year. These borders require to be trenched about once in every five or seven years, and if done well there is no necessity to disturb them more often. Take a plan of the border and improvements required, so that the plants can be reinstated as the work proceeds; if the border exceeds 20 feet wide, tall plants are necessary for a fine effect. Bulbs should be put back as soon as possible, or they may feel the effects of shifting. Thin out very much Montbretias and heavily manure, as the plants respond to high feeding more than many imagine.

#### HARDY FRUIT GARDEN.

Continue to prune and train all trees in the open and Apples, Pears, Plums and Cherries on walls. Thoroughly spray all trees. Do not puddle the ground in wet weather by trampling, but use some planks to get on it where necessary. Finish planting if there is still some to do and if the weather is open. In severe or wet weather prepare stakes, labels and everything which may be required; look over netting and repair, and put on one side for rough work. When a large net becomes unfit for its purpose, it is most useful for cutting up to be put over isolated trees or seed-beds. Examine the stores in the fruit-room and eject all unsound fruits.

#### KITCHEN GARDEN.

Continue to trench in fair weather. Examine stocks in the store-room, reject all unsound specimens and look out seed Potatoes. Prepare sets of Horseradish and Seakale, and write labels. Turn out store and shed and thoroughly clean them, as there is a time for discarding and making a fire, and gardeners should learn when this is necessary.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardlee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CYPRIPEDIUM INSIGNE.**—At this period of the year very few Orchids are of greater value than this well-known kind. Its general hardiness, vigour, freedom of flowering and simple requirements fit it for those who have but little time at their disposal. A cool greenhouse suits it admirably, and during the summer months a partially-shaded frame or pit is better still. With this treatment it is possible to retard the flowering very considerably and secure a fine display of blooms in the winter season. The advantages on the side of cool treatment are considerable, not the least being a good display of flowers at Christmas. Hardily grown throughout, the plants do not suffer in the same proportions when subjected to the uncongenial conditions of the sitting-room as do those grown in warmer structures.

#### KITCHEN GARDEN.

**Forcing Rhubarb.**—Now is a good time to cover up roots in their permanent quarters, and I am quite in favour of this mode of culture, as the produce is of better flavour than that from lifted roots forced in a warm house. Any material at hand will suffice for covering the roots, but Rhubarb pots are best if expense is not studied. Old cement casks answer well, and in cases where hard forcing is not intended only a slight covering is given to hasten growth. In covering it is advisable to use material that retains warmth and in sufficient quantities. Roots not intended for forcing early are none the worse for a covering of light litter. These will give earlier growths than those left fully exposed.

#### FRUITS UNDER GLASS.

**Vines.**—The greater portion of the pruning should take place by Christmas, even though the Vines are not to be started for some months, as there is no need for further delay when the crop is off and the leaves have fallen. Early pruning relieves all anxiety as to bleeding, and there is then no need for using styptic afterwards.

#### HARDY FRUITS.

**Mulching Raspberries.**—This work should be attended to now. Many wait till spring, when the soil between the rows on stiff land is wet and cold from the winter rains. They then dig in a quantity of cold spit manure, mangling all the best surface roots, which every practical fruit-grower well knows are the best. True, fair crops of fruit are produced under these conditions, but the fruit is small and flavourless compared with that produced from canes rooting near the surface. I get the best results from thinning out all the old fruiting canes early in autumn, raking off the stale unused mulching, giving a good broadcast sprinkling of burnt garden refuse and re-mulching with spent refuse from old hot-beds.

#### FLOWER GARDEN.

**Spring Bedding Plants.**—Now is a good time to take stock of the various kinds of bedding plants required for the flower garden next spring, as there will be ample time to increase the stock of many of the soft-wooded plants, such as Fuchsias, Pelargoniums, Lobelias, &c. Zonal Pelargoniums will strike most readily at this season, providing a temperature of about 60° can be given them. These should be inserted singly in 3-inch pots, choosing ripe, hard wood, in a light sandy compost. Old plants which have been growing in pots for autumn flowering will supply good cuttings for this season, and the old plants will break away and make good material for filling vases in the spring.

Complete the planting of bulbs. Hyacinths, Tulips and Narcissi planted now will flower well in April next. There must, however, be no delay, or the season will be lost. Cut down hardy Fuchsias. I spread a thin coat of dry flaky manure over beds of choice Pansies, Pentstemons and Phloxes, both to protect from frost and afford nourishment by the solvent action of snow on the manure.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## SWEET PEA NOTES.

#### THE TELEMLY SWEET PEAS.

**T**HESE Sweet Peas still seem but little known. As they flower about three months from the time of sowing, plants raised under glass in September may be had in bloom by Christmas, if carefully managed in a house which receives as much light as possible. The time is, therefore, not far distant when we shall be able to cut these precious flowers all the year round, for there is no reason why the large-flowered varieties grown in pots during the summer (and cut back once or twice) should not bloom throughout the autumn if housed on the appearance of rough weather. The Telemly Sweet Peas produce very pretty, though small, flowers in many delightful shades of colour, some sorts being particularly brilliant. Sown under glass or in a cold frame about the middle of January, and planted out early in April, they will bloom quite a month ahead of the popular summer-flowering sorts, autumn sowings, wintered in a frame, opening their blossoms even earlier. I should certainly advise amateurs to try this new and interesting race of annuals, for although much remains to be done in the way of selecting and improving them, they are even now well worth extended cultivation.

E. TESCHEMACHER.

## BOOKS.

**The Book of Garden Pests.\***

There is yet another book on insect pests. This volume, however, includes, which many do not, a certain number of fungus pests, which is very useful as far as it goes, but it is quite impossible in a book of this size to describe all the fungi which fairly come under the designation of pests, and the same may be said of the insect pests. This work is divided into eleven chapters. The first is headed "Friends and Foes," the next "Insecticides," then "Fungicides," "Pests Common to Many Species of Plants," "Tuberous and Bulbous Plants," and so on, closing with one on "Concluding Generalities." The author says in an introductory note: "More space has been allotted to preventive and remedial measures, which are of practical value to cultivators, than to details concerning the life history of each pest or disease." This is as it should be, for many details in the life history of insects or fungi are only of interest to entomologists or mycologists. As so many insects attack a large number of different kinds of plants, it is by no means the most convenient arrangement to describe the insect under the name of a certain plant. For instance, the bulb mite, which, however, is not an insect, does not confine its attention to bulbous plants, and many caterpillars are very omnivorous. The chapter on "Friends and Foes" is a very good one, particularly the paragraph on "Cultivation and Hygiene." Directions are given for compounding certain insecticides. It will, however, generally be found that buying the mixtures ready made will save much trouble and in the end be more satisfactory, unless they are required in large quantities, when the question of expense comes in. Care should be taken to obtain such compounds from reliable firms or their agents. In the recipe for making "Eau celeste" on page 27, the word sulphate is omitted after the word copper; the direction should read, by dissolving 2lb. of copper sulphate. It is mentioned on page 84 that "Eau celeste is a proprietary remedy," but this can hardly be the case, as the directions for making it have just been alluded to, and in most books giving recipes for fungicides one will be found for this compound. An interesting photograph is given facing page 105 of an Apple infected with mussel scale. This insect, no doubt, sometimes attacks the fruit, but more usually confines itself to the branches and young wood. In alluding to the Black Currant mite, it is stated that "it is uncertain whether a very similar mite which infests the Hazel is the same species. Experiments, however, have been made which prove that they are not the same species, and that they will not attack the Black Currant. No mention is made of the Currant aphid (*Aphis ribis*), which at times is the cause of much injury to the leaves of that plant by causing them to curl, thus preventing the pests from being sprayed. As soon as any of this insect is detected on the bushes, the under-sides of the leaves should be at once sprayed with some insecticide containing soft soap if the leaves are not already too much curled; if they are, the best thing is to gather and burn them. Under the heading of Vine weevils it is recommended as a means of catching these beetles that freshly-tarred paper should be spread under Vines to catch them when they fall on being disturbed. A simpler plan, which is quite as effective, is to lay a white cloth under the Vine or other plant which is being attacked; the weevils, when they fall, lie quite motionless for a minute or so, feigning to be dead, with their legs closely drawn to their bodies, giving the operator plenty of time to pick them up. In the account given of mealy bugs, we read of "the white cottony material that grows on the dead bodies of

the bugs"—this surely is a mistake, for the material is a secretion of the insect and not a fungus; the former could not be produced after the insect's death. The bugs are of a dark pinkish colour, covered with a white mealy secretion, except just where the joints of the body join, where the colour of the insect may be seen. The eggs are laid in a kind of bag known as an ovisac, composed of loose white fibres secreted by the mother; often a number of these ovisacs are found massed together with the parents on the plants. In the account given of wireworms on page 168 no mention of their size is made; nor is any indication given on the plate containing figures of this insect that they are very much enlarged. This is very misleading. The warty disease of Potatoes is spoken of as (*Edomyces leproides*). This fungus was at one time thought to be the same as the Beetroot tumour fungus (*O. leproides*), but it has since been found to be a quite distinct organism, the name of which is *Chrysophyctis endobiotica*. Among the pests mentioned as surface caterpillars, those of the great yellow underwing moth, which are very common and destructive, are omitted. The description of the Asparagus beetle (*Crioceris asparagi*) is very inadequate; it is said to be a "greenish coloured insect," whereas it is one of our most beautiful beetles. The head and antennae are bluish black, the thorax or fore-body is of a deep red colour, and the wing-cases and legs are steel blue; on each of the former there appear to be three yellow spots, but the outer edges of the wing-cases are yellow, to which the supposed spots are joined. The Bean weevil (*Bruchus germanus*, or rather *B. rufimanus*), is said to be a very small beetle, but as beetles go it is not, for it is two tenths of an inch in length and bulky for its length. The author uses the word chrysalids, but the plural of chrysalis is chrysalides. There is a mistake on page 190, for we read "the beetle known as leather jacket"; this should read, the grub known as leather jacket. The last chapter on "Concluding Generalities" is a very interesting one, and should be read by every one who has the opportunity of doing so. The author excuses himself for not giving a glossary of the botanical and chemical terms used by him; but as far as we have noticed the book is unusually free from technical terms and has a good index. We can strongly recommend this book, as it is one of the most practical which has come under our notice. It is of a handy size, well printed and illustrated. There is a great omission in many of the figures, namely, that the natural size of the insect is not shown. Unless this is done no proper idea of what the insect looks like can be formed.—G. S. S.

**British Mosses.**†—The reissue of this admirable little book on a much-neglected subject is very welcome. Though hardly coming into the category of a handbook, it is a masterly sketch of the structure, reproductive methods and family history of the Mosses. The author sets out by quoting Lord Bacon and Ruskin on the Moss plant, the former as having expressed the opinion that a Moss "is a rudiment between putrefaction and a herb," the latter, in sublime ignorance, seeing no reason why the Pineapple should not be included in the Moss family. Sir Edward pursues his subject with much method and with almost Huxleyan lucidity; so that he who reads and ponders can hardly fail to grasp the leading facts in the life-history of this humble but interesting plant. Not the least important feature in the book is the breadth of survey in so little compass; thus we find not only classification and morphological details, but an interesting sketch of all that is anomalous in the Moss family. We learn that reproduction may be normally, by means of spores, by gemmæ, by budding from the protonema, and by offshoots from the plant itself, as in the sphagnum. The author emphasises the "vast gulf" that

exists between the Mosses and Ferns, "the widest in the whole vegetable kingdom," and describes it from the evolutionary standpoint, but refrains from suggesting any bridge with which to cross the chasm. He gives us much suggestive matter on the part played in Nature by the Moss, particularly in connexion with the growth of peat and its action as a devastator of forest land. Many illustrations, diagrams and tables elucidate the text, and the work concludes with a bibliography of the subject. Just the book to whet the appetite for more knowledge on a fascinating subject, but why entitle it "British" Mosses?

**Gardens, Past and Present.**‡—Mrs. Davidson is a well-known authority on the subject, and this book should prove a most useful addition to the library. It is most pleasantly written, interesting to a gardener, while to an amateur with a wish to know more on the subject it should be of great value. In the words of the author, her object is not to be technical but suggestive. The book is divided into three parts. Part I. gives a most interesting history of the various kinds of gardens from the time when England, under Agricola, was the granary of the then known world, showing the debt we owe to the Romans for the grains, and vines, and trees they introduced, to the last chapter in this section, describing the Wisley Gardens, now the home, through the generosity of the late Sir Thomas Hanbury, of the Royal Horticultural Society. The chapter on the Physic Garden is full of charm and interest. In ancient times our doctors went to Italy to study medicine—many of them to Padua—where, in 1545, was established the first physic garden. Nearly 100 years later our first physic garden was founded at Oxford, and the stories of the visits there of Tradescant, John Evelyn, and the famous meeting between Dillenius and Linnaeus form pleasant reading. What we owe to the Flemish and Huguenot refugees who flocked to England is well told in the chapter "Rural England in the Past." They not only brought their textile industries with them, but established all kinds of gardens, notably vegetable ones. Mrs. Davidson tells us that in the reign of Henry VIII. the Queen's table had to be supplied with vegetables and "sallets" from the Low Countries, six Cabbages and a few Carrots costing £1 of our current money, so that these old foreigners paid for the hospitality we accorded them when they taught us the art of cultivating vegetables. The chapter devoted to the history of the introduction of trees into England is attractive reading. The authoress speaks of Gerard, who "sows his seeds, attending God's leisure, for flowers and fruit." Part II. is devoted to various kinds of gardens—formal, wild, Rose, bog and water gardens and bulb and herb gardens—each and all having their own special chapter, and in every case suitable plants, with their names and habits, are given by this charming writer. Possibly in this section "The Garden of Herbs" is most interesting, because it is not so frequently treated. Part III. is devoted to the seasons of the year and the arrangement of a succession of plants, not in their separate gardens, but as a harmonious whole. It treats of borders, names of plants, the grouping of colours and foliage, and is altogether a good finish to a most delightful book. We wish Mrs. Davidson would contribute even more to the apparent overflow of books upon gardening, many of which are not worth a moment's perusal. The authoress of "Gardens, Past and Present" is never dull. There is a sweet charm in her work, though, we believe, this is the first publication under her name. We have known and advised her contributions to the Press for many years. Here we have a book that is instructive which should bring a sense of comfort to the fireside in the long winter evenings. If the rain beats against

the window, or the garden is shrouded in snow, we can still think of the flowers that give beauty to the garden in spring, summer and autumn.—E. T.

## LEGAL POINT.

**Gardeners' partnership** (B. T. F.).—A great deal of what is seen in an ordinary partnership deed or agreement is merely the law of partnership put into the form of ordinary covenants or promises. In any other kind of deed this would be considered bad conveyancing, but it is defended on the ground that it informs the partners of their rights and duties without always running to a lawyer, although it is difficult to see why this object could not be attained equally well by purchasing a copy of the Partnership Act for a few pence. Notwithstanding, it is not wise to dispense with the services of a solicitor, and, of course, I cannot draw such a deed in this column. If, however, you attempt to draw up an agreement, after fixing the term the partnership is to last, by far the most important point is to provide that on the death of one of the partners during the term his share shall be valued and paid out by certain instalments, and that on giving a proper bond to secure the amount the business and assets shall become the property of the survivor. Unless some arrangement of this kind is made, the business will have to be wound up and the goodwill sold, and, although the survivor has the best chance of purchasing it, surprises sometimes occur.—BARRISTER.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Violas diseased** (H. Ridout).—The Violas are attacked just at the collar by the fungus *Sclerotinia*. The source of infection by this parasite is the soil, and it is usually worst in soils in which there is an insufficiency of lime. When once a plant is attacked there is no probability of a cure. The plants are best burned and the place from which they are taken treated with quicklime. The fungus forms resting bodies on parts of the plant, and in the soil when there is much organic matter present, where it passes the winter.

**Growing Dahlias** (Hazel Grove).—It is common practice with the best growers of Dahlias to pinch or cut out the leading shoot of a plant when it is 12 inches or so in height, and to carry up later three stout main branches, setting stakes to each branch to draw them out from the centre, thus leaving to each one ample space to side-branch freely, which they do. Later, while each main branch is secured, but not too tightly, to its stake, side shoots are thinned out if found to be too dense. But when the plants are grown in garden borders to flower as profusely as they like, very little thinning out of branches is done. If good flowers are wanted, not only

should side shoots be thinned, but flower-buds also. When so treated a mulch of manure is placed round each plant, and in dry weather liberal overhead waterings are given; then Dahlias as a rule do well. Dahlia plants from cuttings should be got into 5-inch pots, well rooted and hardened ready to plant out the first week in June.

**Nelumbium out of doors** (J. W. Matthews).—It is quite improbable that you will be able to get the various forms of *Nelumbium* speciosum to thrive out of doors, even under the most favourable conditions in the British Isles. You may, however, obtain pink, red, yellow and white Water Lilies which would thrive out of doors in most parts of the country, and these would probably answer your purpose. It is impossible to say what the bulbous plant you mention is. Cannot you send us a specimen?

**Herbaceous plants** (M. A. Dawkins).—The Michaelmas Daisies are very free growing, and make a great mass of needless shoots each year where opportunity for so doing is afforded. In dealing with such plants, therefore, only the more vigorous outer-placed shoots should be utilised in the replanting, and by taking single bits of such as these and arranging them a few inches asunder over a large area of ground, a rare picture results at flowering time. A large number of subjects may be similarly treated.

**Violas with leaves curling** (A. D. Z.).—We cannot say what is the cause of the curling, unless the plants are attacked by mildew; the shoot was too withered when received. The old stems may be cut off without further delay, pruning back the plants so that only the young shoots forming a central tuft remain. The cause of the falling of the Clematis is sometimes regarded as innate weakness; at others it is probably due to fungus or injury. We think Lady Lonsborough would be a better variety, and pot plants may be planted at once. The Rose Fortune's Yellow will not prove a success with you, but you should retain Mme. Berard, which should do itself credit another year. Spray the plants with sulphide of potassium, 2oz. to three gallons of water. The Wistaria would be too vigorous, we think, for the wall, and such flowering plants as *Jasminum nudiflorum*, *Pyrus japonica*, *Ceanothus azureus* and *Crataegus Lelandii* would be better suited. Rose Almée Vibert, an old yet valuable sort, is free and hardy.

### TREES AND SHRUBS.

**Planting Rhododendrons** (Ashdown).—If your soil is moderately light and Rhododendrons thrive well in it, you need only trench the ground 1½ feet deep before planting them. You may prepare the ground now and plant in the spring. It is hardly advisable to plant in the depth of winter. The following will thrive well and can be procured cheaply. None are scarce and all will thrive in a wood. *R. ponticum*, *catawbiense*, *fastuosum flore-pleno*, *Sappho*, Lord Palmerston and the Queen. When you plant, be careful to keep the roots near the surface of the soil and give each bed a top-dressing of decayed leaves as soon as the planting is done.

**Self-clinging climbers** (W. Roland Peck).—Your choice of self-clinging climbers is very limited and consists of *Ampelopsis Veitchii*, *Ampelopsis Engelmanni*, *Ivies* in variety and *Hydrangea petiolaris* or *H. scandens* as it is sometimes called. If you have your walls wired or covered with trellis-work, you can have a much wider choice. The following is a suitable selection:—*Clematis montana*, *Ceanothus veitchianus*, *Crataegus Pyracantha*, *Myrtus communis*, *Jasminum nudiflorum*, *Escallonia macrantha*, *E. langleyensis*, *Camellia japonica*, and Roses such as *Gloire de Dijon* and W. Allen Richardson. It is quite probable that the evergreen, red-flowered shrub you allude to is *Escallonia macrantha* or *E. rubra*; both form excellent wall plants, and in the south-west counties they form large bushes in the open ground. If you can send a small piece in flower the correct name can be given.

**How to prune Buddleia variabilis** (M. J.). You may go over your *Buddleia* now and prune it sufficiently to make it look tidy for the winter, but do not cut the growths more than half-way back. Then in March cut the shoots back to within 6 inches of the base of the wood which has been made this year. By cutting the plant hard back each spring you will obtain strong young shoots which will produce much larger panicles of bloom than would be produced if the plant was left unpruned or only pruned slightly. As the plant is a rank

feeder, you had better give it a surface dressing of well-rotted farmyard manure at pruning time, or not later than the end of April. An application of liquid manure occasionally during summer will do good.

**Treatment of the Bilberry** (Mrs. E. P. Keep). It is not absolutely necessary that *Vaccinium Myrtillus*, the Bilberry or Whortleberry, should be grown in peat to get it to fruit. Although it thrives most satisfactorily in peaty soil, it also succeeds in loam, providing lime is not present in any serious quantity. When you first plant it, make the soil firm about the roots and put the plants in fairly close together. The great thing is, with this class of shrubs, to get them to grow dense enough to shade their own roots, for, although the branches like sun, the roots require to be well shaded without being buried deeply in the soil.

### FRUIT GARDEN.

**Spots on Muscat Grapes** (O. H.). The stalks of the berries of the Grapes sent are dead and the berries are over-ripe. The cause of the spot is natural decay, consequent on decay being accelerated, we think, by the air of the vinery being too damp and the atmosphere too low. We do not think that the painting of the pipes or whitewashing the walls has had anything to do with bringing about the spots. If it is necessary for you to keep Muscat Grapes for any considerable time after they are ripe, a little heat in the hot-water pipes must be used to keep the air fairly dry and warm, with ventilation. The berries are a good average size.

**Filling up holes in old fruit trees** (Atomizer).—You cannot use anything better than cement for this purpose. The cavities must be thoroughly cleaned out, scraping and paring all decayed wood right down to the living tissue, then fill in with cement mixed stiff and bring it out flush with the trunk of the tree. The caustic winter wash referred to is made by dissolving 1lb. of commercial caustic soda (95 to 98 per cent.) in water, then 1lb. of crude potash or pearlash in some more water. When both have been dissolved mix them well together and add three-quarters of a pound of treacle or soft soap, stir well, and add enough water to make the whole mixture up to ten gallons. This wash has a burning effect on the hands, and it is wise to wear old clothes and rubber or at least leather gloves when using it. If care is taken to get as much to windward as possible the operation is without danger.

**Peach trees in greenhouse** (Susan).—The border of soil for the Peach trees will require to be at least 2½ feet deep and 8 feet wide. If your Peach-growing venture is to turn out a success, you must make everything else subservient to the Peach. For instance, when growth is dormant during winter the trees must be kept perfectly cool with plenty of air circulating among them, and also when in bloom air must be admitted on all favourable occasions, no matter what other things may suffer. Bearing these points in mind, no doubt the house can be made to yield useful service in the way you wish, as well as in bearing good crops of Peaches.

### ROSE GARDEN.

**Rose Rosel Klemm** (A. F. R.).—This is undoubtedly the name of the Rose you saw. It is a Hybrid Tea and was raised by Herr Huiner. You could possibly obtain it from Herr Peter Lambert, Rose-grower, Trier, Germany. The selection for your new Rose-bed is on the whole a good one. We should, however, omit Grüss an Teplitz, as it is too strong in growth; and Mme. Hector Leuilliot and Mme. Jules Gravereaux would need to be supported by sticks and planted in the centre of the bed, as they are of climbing habit, although they will bloom well if pruned back to about 3 feet from the ground each year. Marquise de Salisbury does not yield very beautiful buds. We would suggest Liberty or Richmond instead, and in place of Grüss an Teplitz we would recommend Joseph Hill or Paul Ledé. For the three climbers on your fence you could not do better than plant Mme. Hector Leuilliot, Mme. Jules Gravereaux and Grüss an Teplitz, replacing the two former in your bed with Lady Ashtown, Earl of Warwick, Mme. Ravary or Killarney.
