A few forewords of history. Clusius, who wrote a short time after Tulips were known in Holland, divides them into three divisions, *Tulipa præcox*, *dubia* and *serotina*, according to their time of blooming. This division was followed by Gerarde (1597), Parkinson (1629) and Rea (1665), only *dubia* was changed into *media*. It is interesting to note that in the full lists of flowers which are given by the two last authors there are a great many under the heads of *præcox* and *media*, and very few under *serotina*. To-day the late-flowering section outnumbers the others; in fact, the division *media* has entirely fallen out of use, and early and late are the only divisions recognised. New seedlings have been raised in European gardens ever since the Tulip was introduced. It was soon noticed that the markings of the flowers varied very much. As time went on it was found that there were certain broad distinctions which constantly kept occurring, and so it became possible, as it was, of course, highly convenient, to group flowers of the same type together.

Again, as the cultivation of the Tulip spread over different countries, each one framed its own technicalities. France had its *agathes*, *paltots*, *morillons*, *marquetines* and *fantasques*; Holland its *bybløemens*, *verports* and *rigauts*; and England its *widows*, *edgers* and *paragons*. These all designated some particular form of marking or variation of size or shape; but it is impossible to determine the precise meaning which the old florists attached to them. Some have been obsolete for 150 years. There are few that are still used in modern gardening works and bulb lists; but these relics of the past that still remain have thus an added interest to their more obvious utilitarian one, in that they tell of a history which among flowers is in many ways unique. To come, however, to "practical politics" and leave what is only of academical interest, I propose to give a list of all the more common terms, such as *breeder*, *broken*, *roses* and *bizarres*, which are now in use, with a brief explanation of their meaning, adding as occasion requires an historical note.

JOSEPH JACOB.

## PRIZES FOR READERS. MAY.

### THE BEST FLOWERS AND SHRUBS FOR TOWN GARDENS.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above  
subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Saturday, May 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be

written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

May 12.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c. Lecture at 3 p.m. by Mr. Osgood H. Mackenzie on "Gardening in the West Highlands." Vincent Square, S.W.

**Notes from Baden-Baden.**—It seems to me that the Taurian variety of *Scilla bifolia* is scarcely cultivated in England, yet it is a very distinct early spring bulb. It differs from the type by its more compact and dwarfer growth and considerably greater number of individual flowers, which are of a brighter colour. It is excellent for edging, refusing to bear seed; it is slow to increase, and this may explain its scarcity. A clump of *Pulsatilla patens* var. *ochroleuca* made a show for itself, thirty-two of its lilac and sulphur yellow-coloured, downy-clothed flowers being all open at once. Among the many thousands of *Chionodoxa Lucilie* which came under my notice I have selected four varieties, prominent among which is *Leichtlin's* variety. Its flowers are double the size of the typical plant, and the colour is a peculiar blue, somewhat suffused with a reddish tone; this is certainly a plant for the future.—MAX LEICHTLIN, *Baden-Baden*.

**Studies of Kew Gardens at the Grafton Galleries.**—An exhibition of pictures by Mr. H. A. Olivier has recently been held in the Grafton Galleries, which, although primarily intended to show his portraits of Indian princes painted for the Waly College, Indore, before they are sent out, also included an interesting series of studies at the Royal Gardens, Kew, and some other gardens. The studies at Kew were originally started with a view to reproduction in a book to be brought out later, a colour book about Kew, by Mr. W. J. Bean, assistant curator. Some of the flower studies were particularly good. *Fritillaries* (No. 8), the flowers themselves were charmingly rendered, although rather spoilt by an uncomfortably blue-grey background, and in No. 13, "*Cypripedium*," the colour is very delicate. The study of "*George Nabonnand*" *Roses* at *Gravetye* (No. 16) is particularly fine, and hanging near it was a delightful view of "*The Lake*" at the same place. In Nos. 15 and 17, *Azaleas*, east and west side, particularly in the "*East Side*," the colouring of the flowers is gorgeous, although, perhaps, the blue-greenness of the background is rather unnecessarily insisted on. No. 14, "*The Lake, Kew Gardens, looking West*," the misty effect with the light breaking through, is very happy. To anyone really interested in flowers No. 47, "*The Iris Garden*," will appeal strongly, but the beds of *Iris*, although charming in themselves, hardly make a picturesque scene. One of the best things among the garden scenes is No. 106, "*Caroline Testout*," a large bed of the *Rose* brilliantly rendered against their background of the quaint formal garden, while hanging near was a sketch of *Persian Peach*, whose vivid rose against a bright blue sky forms another brilliant little study.

**Spring flowers at Dropmore, Maidenhead.**—The beautiful gardens at Dropmore are in their spring dress. We have seldom seen anything prettier than the masses of *Arabis* and *Aubrietia*, a perfect sea of blossom. Extensive alterations are being carried out and many improvements made under the superintendence of the head gardener, Mr. Page.

**The Blairgowrie fruit trade.**—An important scheme for the purpose of controlling

the prices of Raspberries was explained to a large gathering of Blairgowrie fruit growers the other evening by Mr. J. T. Connell. The meeting was presided over by Provost Smith. Mr. Connell gave a clear explanation of his plan, which is that of so regulating the supplies to the different markets that a glut would be avoided and the prices thus maintained. He has successfully worked it with the Strawberries of the Clyde, and was so confident of equal success with Raspberries that he was prepared to take the crop, subject to inspection, at a minimum guaranteed price. Several questions were asked, and the replies of Mr. Connell seemed to be satisfactory to those present, although the actual carrying out of the scheme was not absolutely decided upon.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### Yorkshire Gardeners' and the Royal Gardeners' Orphan Fund.

This fund, and the special appeal which is being made at the present time on its behalf in connexion with the coming-of-age festival on May 12, should, I think, be of especial interest to Yorkshire horticulturists, seeing that the inception of the fund was mainly due to a Yorkshire gardener, Mr. Clayton, late of Grimston Park; but probably many, like myself, have never hitherto given the matter very serious thought, or it may be that we are sometimes apt to think that such institutions having their headquarters so far away as London have not much claim upon us here in the North. A glance, however, through the annual report certainly shows that this is not the case. There are in Yorkshire five children in receipt of the benefits of the fund, viz., £13 per annum each, or £65 in all; but the whole of the subscriptions from Yorkshire are very much below this amount, and the proportion of it which comes from Yorkshire gardeners is very small indeed. One town in the Midlands (not a large one) sends half as much as the whole of Yorkshire. An appeal made during the past week to three small gatherings of gardeners in this locality had an immediate result of nearly 50s. being subscribed to the popular 1s. collection, and several volunteered to take collecting sheets for their respective districts, so that I hope this amount will be considerably increased before May 12. May I suggest to gardeners in other parts of the county that if the matter has not already been taken in hand, some such plan should be adopted? Those living in a district where no collection is being made, who would like to contribute and so swell the amount from Yorkshire, are asked to send their subscriptions to any of the following: Mr. Norman, The Elms, Weetwood, Leeds; Mr. Coates, Spring Bank, Headingley, Leeds; Mr. Wellwood, Wyther House, Kirkstall, Leeds; Mr. Waltham, Sandy Wood, Horsforth, near Leeds; or to our correspondent, Mr. George Carver, Chapel-Allerton, Leeds.—T.

**Peach buds dropping.**—Your correspondent "R. K." asks the reason for Peach buds dropping. Having had a long experience in growing in houses, with and without heat, in different parts of this country, I suggest to "R. K." that if he will keep the temperature of his houses 5° to 10° less than the temperature usually employed in this country when forcing them, until in flower, he may prevent failure, as they are very sensitive at this time of artificial heat. Dryness at the root is another cause, especially so if the soil is of a light and porous nature, as this will require considerably more water than a heavy soil. When watering let it be given until it stands on the surface of the soil. This I have always done in the resting season. This may not seem good practice; but at this period they are forming their buds. Again, when

he begins to force them, also when in flower and the early part of the stoning season, water should be freely given and the temperature should be rising. This should prevent failure if the soil and drainage is what it should be for Peach growing.—G. MACLEAN, *Chilwell, Notts.*

**Primula kewensis.**—To those in search of a really good thing for spring flowering let me call attention to the above plant. Happily it can now be obtained from seed. At one time it was doubtful whether or not it would seed freely, and at that time plants only could be bought. Now, however, a packet of seed will produce a large number of plants, which will quickly grow into flowering plants and make a fine display in the conservatory or cool greenhouse. It does exceedingly well in a cold frame, for it is nearly hardy, plants having survived from 10° to 12° of frost here. This is one of the most useful and floriferous plants of recent introduction. As a matter of fact, it will flower several times in one year, and by sowing at various times plants can easily be had in flower the whole year round. The colour is most pleasing, a really good yellow. The plants may also be increased by division; but I think much better plants can be raised from seed, which is produced freely if the flowers are fertilised by hand. This I find necessary. I know of few other plants which will give such a pleasing display of colour as the above *Primula* and *P. obconica*. The newer strains of the latter are most beautiful. What a pity it is that it proves such a nuisance to some people, which it certainly does. A few dozen plants raised from seed sown last March (1907) have been in flower since October, and look as if they intended going on till October next. I am enclosing herewith a few flowers for your inspection from these plants, and which I think you will say is a fine strain.—T., *Cirencester.*

#### **Cystopteris fragilis.**

In the enforced leisure of recovering from influenza I have been turning over back numbers of THE GARDEN, a most useful and fascinating occupation, and I noticed a remark by Sir W. T. Thiselton-Dyer on *Cystopteris fragilis* (February 10, 1906). Speaking of watering, he says: "That some measure of success was attained is shown by the fact that *Cystopteris fragilis* has become a positive weed." I should like to point out that this Fern flourishes exceedingly in broad hot sunshine as well as in moist shade. Some years ago in my walks between Wirksworth, Cromford and Middleton

I noticed on the distant mine-heaps in the bare fields a vegetation that struck me as peculiar. On going to examine it I found the rubbish-heaps thickly packed with *Cystopteris fragilis*. Anyone who knows the neighbourhood will be aware that the site, high, dry and sunny, was hardly the place to look for *Cystopteris*. Later experiment has confirmed the observation. I have grown many Ferns in baskets in the greenhouse exposed to the fullest sun, *Adiantum cuneatum* among the number, with marked success. Many Ferns which were ordinarily shy in sending up their lovely Prince of Wales's feathers of fertile fronds responded at once to this more sunny treatment. Amateurs could at least try it.—J. G. R. POWELL, *The Willows, Ledbury.*

## TREES AND SHRUBS.

### A NOTE ON BAMBOOS.

(*PHYLLOSTACHYS FASTUOSA*.)

**L**OVERS of hardy Bamboos ought not to neglect to obtain this handsome species, for it is one of the most conspicuous and easily grown of the many sorts available. Readily attaining a height of 18 feet or 20 feet, the canes are strong and upright, while the fact that the side branches are compact gives the whole plant a somewhat columnar appearance, which at once stamps it as distinct from any other *Phyllostachys*, or, in fact, any other hardy Bamboo.

worked, and, if poor, enriching material in the form of half-rotted leaves, well-decayed manure and good soil added. May is the best time to plant, as growth at that period commences at once. Should the weather prove dry, attention to watering must be given at least once a week. A mulch of well-decayed manure and leaves will be found beneficial, and, in fact, this attention annually will well repay the trouble. From the compact nature of the shoots as they spring from the stool it is a difficult Bamboo to propagate by division of the clumps; it is, however, in the habit of producing long rhizomes when planted in loose ground, and these may be severed, cut up into lengths, potted up and placed in a warm greenhouse for a few weeks when nice young plants are formed. Its noble appearance and distinct character among other Bamboos is noticeable in the accompanying illustration.

W. DALLMORE.

AN EASILY-GROWN HARDY BAMBOO (*PHYLLOSTACHYS FASTUOSA*) IN THE ROYAL GARDENS, KEW.

In general habit its nearest ally is found in *Arundinaria Simonii*, but the leaves are glossier than in that plant; the leaf sheaths are not retained to any great length of time, as is the case with *Arundinaria* and the foliage is not so easily damaged by cold winds. With regard to its hardness it may be stated that the leaves keep their colour in spring much longer than is the case with many sorts. Like other Bamboos, it has a penchant for throwing up strong shoots late in autumn, and these are injured by cold weather; however, those that are damaged to any serious extent can be easily spared at pruning time.

With all its associates it rejoices in rich soil and a good supply of water during summer. When first planted the ground should be well

### THE SHRUBBY SPIRÆAS.

THE genus *Spiræa* plays an important part in garden decoration, members of it being suitable for practically any position. By the water-side or on the rockery the herbaceous species and varieties give a welcome display of flowers during the summer and early autumn, while in the shrubbery and other parts the various woody members of the genus may be found more or less in bloom from March to October. The latter number some 130 species, varieties and hybrids, but many of them are only of botanical interest, while others are so much alike that it is only necessary to grow one of the type. The following notes are merely intended for the mention of the best of the shrubby *Spiræas*, and are not at all exhaustive, but those given should be included in every garden. They can be grown in almost any kind of soil, but a light and comparatively dry loam suits them best.

If they have too much moisture at the root, they are apt to make a gross growth with but few flowers, while a drier situation causes the shoots to be short and firm and the flowers larger and more freely produced. Full exposure to the sun is necessary, as, though they may live in the shade, yet they will neither grow nor flower at all well. Propagation is effected by means of cuttings, which can be either of half-ripened wood in August or of fully-ripened wood cut into 6-inch lengths and planted nearly their full length in the ground outdoors in October.

Botanically, the genus is divided into eight sections, which division is useful for the present purpose, as the members of each section possess the same character of growth, flower about the same time, and require the same pruning and general treatment. Among the plants mentioned below will be found some that are suitable for all sorts of gardens and positions.

#### SECTION I.—BOTRYOSPIRA.

*S. laevigata* is the only member of this section, and is a native of Siberia. It has a certain beauty of its own, but is of no great garden value. The foliage is pinnate and glaucous, and the flowers of a creamy white.

Bagshot, Surrey.

J. CLARK.

(To be continued.)

## THE ROSE GARDEN.

## THE ROSE ANALYSIS, 1900—1907.

(Continued from page 189.)

## TEAS AND NOISETTES.

**T**HIS refined and beautiful section is more conservative than that with which we have just been dealing; nevertheless, there is evidence of gradual but decided changes taking place in it, as will be seen from the particulars given below.

"White Maman Cochet deservedly heads the list, as it has done ever since it came into general cultivation in 1903, for there is no other Tea which possesses so many good qualities. At the last two exhibitions, however, Mrs. Edward Mawley has been rather more frequently staged. In fact, the last two years it was oftener to be seen in the prize stands than any other Rose in the show.

"Only one Tea was staged at the last exhibition exceptionally well, and that was Medea, which has only once before been as frequently shown. On the other hand, The Bride, Catherine Mermet, Mme. Hoste, Ernest Metz, Marie van Houtte, Caroline Kuster and Niphotos have never before been as poorly represented. Indeed, the only varieties which were set up in twenty or more prize stands were White Maman Cochet, Mrs. Edward Mawley, Maman Cochet, Mme. Jules Gravereaux, Comtesse de Nadaillac, Souvenir de Pierre Notting, Medea, Muriel Grahame and Souvenir de S. A. Prince. The foregoing particulars clearly show the declining positions of most of the smaller Teas, and the great popularity with exhibitors of those with large flowers like the first four varieties on the list.

"There are only three Roses in the table which are six or fewer years old, and which are therefore entitled to be regarded as among the 'newer' Roses. Mme. Jules Gravereaux (flesh, shaded peach), which was introduced in 1901, has risen since last year from No. 14 to No. 4. Souvenir de Pierre Notting (pale apricot yellow, shaded orange), a 1902 variety, has also much improved its position by rising from No. 14 to No. 7. There are no representatives for the years 1903 and 1904, but for 1905 we have Mme. Constant Soupert (yellow, shaded peach), which on its first appearance just manages to secure a place at the bottom of the list."

## TEAS AND NOISETTES.

Position in Present Analysis.	Average No. of Times Shown.	Times Shown in 1907 in Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	67.2	62	White Maman Cochet	1897	Cook	White, tinged lemon
2	59.7	68	Mrs. Edward Mawley	1899	A. Dickson and Sons	Pink, tinted carnine
3	50.1	54	Maman Cochet	1893	Cochet	Deep flesh, suffused light rose
4	34.5	47	Mme. Jules Gravereaux	1901	Soupert et Notting	Flesh, shaded peach
5	29.2	16	The Bride	1885	May	White, tinged lemon
6	28.7	32	Comtesse de Nadaillac	1871	Guillot	Peach, shaded apricot
7	28.5	35	Souvenir de Pierre Notting	1902	Soupert et Notting	Apricot yellow, shaded orange
8	27.7	33	Medea	1891	W. Paul and Son	Lemon yellow
9	27.2	14	Catherine Mermet	1869	Guillot	Light rosy flesh
10	25.0	20	Muriel Grahame	1896	A. Dickson and Sons	Pale cream, flushed rose
11	24.5	19	Bridesmaid	1893	May	Bright pink
12	24.2	26	Souvenir de S. A. Prince	1889	Prince	Pure white
13	23.6	18	Mme. Cusin	1881	Guillot	Violet rose
14	22.5	17	Innocente Pirola	1878	Mme. Ducher	Creamy white
15	22.2	15	Souvenir d'Elise Vardon	1854	Marest	Cream, tinted rose
16	20.6	10	Mme. Hoste	1887	Guillot	Pale lemon yellow
17	20.0	17	Souvenir d'un Ami	1846	Belot-Befougère	Pale rose
18	14.9	16	Cleopatra	1889	Bennett	Creamy flesh, shaded rose
19	14.6	17	Maréchal Niel (N.)	1864	Pradel	Deep bright golden yellow
20	13.2	9	Mme. de Watteville	1883	Guillot	Cream, bordered rose
21	12.1	14	Golden Gate	1892	Dingee and Conard	Creamy white, tinted rose
22	11.4	6	Ernest Metz	1888	Guillot	Salmon, tinted rose
23	8.7	3	Marie Van Houtte	1871	Ducher	Lemon yellow, edged rose
24	8.1	6	Princess of Wales	1882	Bennett	Rosy yellow
25	7.6	3	Anna Olivier	1872	Ducher	Pale buff, flushed
26	7.4	1	Caroline Kuster (N.)	1872	Pernet	Lemon yellow
27	7.0	4	Niphotos	1844	Bongere	White
28	6.9	1	Ethel Brownlow	1887	A. Dickson and Sons	Rosy flesh, shaded yellow
29	6.5	2	Honourable Edith Gifford	1882	Guillot	White, centre flesh
30	5.2	3	Rubens	1860	Robert	White, shaded creamy rose
31	5.0	5	Mme. Constant Soupert	1905	Soupert et Notting	Deep yellow, shaded peach

\* A new variety, whose position is dependent on its record for the 1907 show only.

Mr. Mawley states that this table will be found more conservative than the Hybrid Perpetuals and Hybrid Teas; the changes are less and not quite so startling. Mme. Jules Gravereaux, as befitting a Nickerson Rose, makes the greatest improvement, rising from the fourteenth to the fourth place, the only other alteration of any note being the advance of Souv. de Pierre Notting, which in the 1906 table tied with Mme. Jules Gravereaux at fourteenth, and now rises to seventh. Next year this will probably be found in the first half-dozen, displacing in all probability The Bride. How the Catherine Mermet family are descending the scale! It is not so very long ago since they were at the top, and if their positions were taken on this year's table only, none of them would figure in the first twelve.

Mme. Constant Soupert figures on the list for the first time at No. 31. Room will have to be found for this new-comer, and in the first half-dozen, too, as it was very promising last season and some very fine flowers were exhibited throughout the country. Mrs. Myles Kennedy is another Tea that will find its way into the next analysis, and will promptly proceed, like all Messrs. Alex. Dickson and Sons' productions, to take a higher place. I hear of nothing very startling in the way of new Teas from Continental sources; the great difficulty is to get the necessary size to bring them up to exhibition standard. Hugo Roller (William Paul and Sons), Harry Kirk (Alex. Dickson and Sons) and Mme. Edmond Sablayrolles (Bonnaire) are all beautiful Roses, but not, I think, likely to find a permanent place in this analysis, for this reason—they are very distinct in colour and will find a home in our gardens.

I have been asked to name the six best Teas for an ordinary exhibitor to cultivate. I do not think there is much doubt as to which they are in order of merit. I should place them as follows: White Maman Cochet, Mrs. Edward Mawley, Maman Cochet, Mme. Jules Gravereaux, Souvenir de Pierre Notting and Mme. Constant Soupert; and if the list was extended to twelve, would add Medea, Mrs. Myles Kennedy, Souv. de S. A. Prince, Mme. Cusin (for colour) Muriel Grahame and Comtesse de Nadaillac. The last two will be found the most difficult to grow; the others are fairly easy as Teas go.

These two tables form only a portion of Mr. Mawley's exhaustive analysis; for the remainder, dealing with decorative Roses as exhibited,

autumn-flowering Roses (both exhibition and decorative) and an audit of the new Hybrid Perpetuals, Hybrid Teas and Teas, I would refer your readers to the original article in the *Journal of Horticulture*. I believe also the whole analysis will be found in the National Rose Society's Rose Annual for 1908.

HERBERT E. MOLYNEUX.

## ROSE MRS. AARON WARD.

THIS grand Hybrid Tea novelty is a welcome addition to the yellow or apricot-shaded Roses. It is a fine-shaped bud and half-open flower, but expands into a rather wide blossom in the way of Mme. Charles de Luze. The great feature of the Rose is its colour. This is mainly the rich yellow or apricot which we obtain in Lady Roberts, but about one-third of the petals are of a flesh white tint. Perhaps with age of plant the yellow colour may become more pronounced; in any case it is a fine Rose, useful alike to the exhibitor and to those who grow for garden decoration. It seems to me to belong to that section of the Hybrid Teas represented by Joseph Hill, and certainly both Roses will prove to be among the finest M. Pernet Ducher has given us. Joseph Hill possesses such distinct qualities, both in foliage and wood, that it looks as though it was the commencement of quite a new departure in these beautiful Hybrid Teas.

## GUNNERSBURY HOUSE GARDENS IN SPRING.

**A**T any period of the year the above gardens are so interesting that a note on a few of the principal features at the present time will, I feel sure, be of interest to readers of THE GARDEN. The first thing to strike the visitor is the new work connected with the Peach wall. Here the old trees have been lifted, given a new border and replanted, the varieties being mostly midseason and late. Some new trees have also been introduced where necessary. Mr. Hudson thinks very highly of Late Devonian Peach, and has some splendid trees of this variety, also Sea Eagle, the Nectarine Peach and other late sorts. These are on a west wall, and opposite Apricots are given some parts of the wall, these having a glass coping. They are of recent introduction, and are at present on trial, as these trees are not a success in some gardens. Another idea, and one I think that will be found advantageous, is that Morello Cherries are being given more freedom, and rather less pruned than formerly. Last season I saw some splendid results from trees grown thus; the young wood is retained and the trees are only thinned out at the pruning.

Those who are interested in hardy fruit culture would do well to see the orchard here. The trees have been planted some ten years or so and are mostly bush, but they have been trained so exactly by depressing the branches, the main lower ones having been tied down to stakes, that every portion of the trees are exposed to the light and sun. Some of the strong growing sorts, such as Newton Wonder, are much more fruitful in a young state grown thus, and in addition the trees are very handsome.

The large amount of ground devoted to Strawberry culture is remarkable, and there is a great number of the Alpine varieties here, a feature that amateurs could well follow who like late fruits, as the culture is so simple. Mr. Hudson relies on one and two year old plants, and different treatment has been followed to what I have noted previously. The old plants that fruited last year have been hard trimmed or cut, and I think it may be a good plan in light soils, but in heavy land I should prefer to leave the runner. On the other hand, the plants can be kept cleaner, fed better, and will doubtless give the finer fruit.

The Large Red Alpine is much grown, but Mr. Hudson has some late Continental varieties on trial which promise well. The Gunnersbury Alpine is a splendid late fruit, the berries being long and of fine quality. For use from July to November the above fruits are invaluable, and for a supply at the ordinary season (June and July) Laxton's Fillbasket is a favourite, as, in addition to its fine cropping qualities, it is of excellent flavour.

The autumn Raspberries are also a feature in these gardens, and they are at this season quite bare, that is, the canes are cut down to the ground level. Then one comes across a hedge of cordon Gooseberries, a novel and most profitable mode of culture. Figs are grown in great quantities, and there are many pot trees, the earliest being St. John, the fruits of which are now being gathered. Trees to provide for a late summer supply are just given glass protection, the Brown Turkey, Nubian and Negro Largo being favourites for this purpose. Pot fruit trees are a splendid feature, and the earliest trees are now a mass of fruit, which requires severe thinning; this applies to Peaches, Nectarines and Plums. The trees seen have borne splendid crops for the past ten years. Later houses have just passed the flowering stage, and the Cherries in 9-inch and 10-inch pots are splendid examples of pot culture. The best early varieties are grown, and the Guigne de Annonay, a fine black fruit, is the earliest, this being followed by Rivers's Early Black, Belle de Orleans and such sorts as Governor Wood, Bigarreau Napoleon and de Schrecken for later use. A large number of pot trees of Peaches, Nectarines and Figs are in a cool house for late supplies, and I omitted to note that Peach Duchess of York is a favourite for early dishes, as are Cardinal and Rivers's Early Nectarines. Pot Vines are a great feature, and these are well furnished with bunches, the varieties being mostly Black Hamburg and Royal Muscadine.

Two houses are full of early Strawberries in pots, and the fruit in the early house is nearly full-sized, there being a splendid crop. Royal Sovereign is used in both houses, but the newer Laxton's Progress is being given a trial, and it promises grandly. A quantity of plants are in frames for a later supply. Space does not permit to dwell at length upon the many phases of fruit culture here; but I must add that the grand old Lord Napier Nectarine, that has borne such fine crops for thirty years, has this season lost a considerable part of its wood on one side of the tree, and this will naturally reduce the crop, otherwise there is a good set. Vines in various stages are looking well in the permanent houses, and in these structures are many other things of interest, such as large stocks of *Salvias*, *Heliotropes*, and other flowering plants that are being grown on.

The splendid trained trees of scented Geraniums are just beginning to grow freely, having been kept cool all the winter. Here, doubtless, are the finest examples of these plants in the kingdom. Mr. Hudson had a fine batch of *Amaryllis* (*Hippeastrums*) in bloom; these were unnamed seedlings, but they were excellent both in size, shape and colour. The Orchids were in splendid condition, some very nice *Dendrobiums* being in bloom. The late-flowering *Cattleyas* promise well, having fine growths. The Water Lilies under glass are just moving and are showing very strong growths; these in the summer are well worth a visit. G. WYTHES.

## THE GREENHOUSE.

### THE SUNDEWS (DROSERA).

OUR native Sundew (*Drosera rotundifolia*) must be familiar to many readers of THE GARDEN, forming as it does colonies of little dense rosettes of roundish leaves. It likes damp and boggy places where, nesting among the sphagnum which often covers large stretches of such ground, it is so pretty as to at once attract the notice of even the most casual observer. A notable feature is the stout hairs with which each leaf is studded, every hair being terminated by a tiny drop of glutinous substance, to which small flies and other little insects quickly adhere and ultimately perish. Considerable controversy has, at one time or other, been aroused on the question whether insectivorous plants, to which the *Droseras* belong, derive any nourishment from the insects

stalks, so that the entire plant reaches a height of 6 inches to 8 inches. It is also a native of Australia.

*D. capensis*.—One of the rosette-growing species with oblong-shaped leaves. As implied by the specific name, it is a native of South Africa.

*D. spathulata*.—An old and fairly well known species from Australia, bearing a considerable amount of resemblance to the one herewith figured. To the above must be added the nearly allied

*Drosophyllum lusitanicum*, a native of Spain and Portugal. This forms a somewhat woody stem, a few inches high, at the top of which the long slender leaves are disposed. It inhabits sandy shores and dryish rocks inland. I have made no mention of the flowers, but in most of the *Droseras* these are pretty and borne on slender stems.

#### CULTURE.

Except the limited number that occur in dry situations, the cultural requirements of the

ONE OF THE EXOTIC SUNDEWS (*DROSERA BURKEANA*).

they have caught. It is, I believe, still regarded as doubtful if such is the case.

When exposed to full sunshine, the leaves of the British Sundew become heavily tinged with red, under which conditions they are more attractive than those which grow in shaded spots. Sundews grow in various parts of the world, and a few exotic species are in cultivation, but outside botanic gardens they are rarely met with. The accompanying illustration of a species from Natal, *Drosera burkeana*, shows well the general appearance of many of the Sundews, including the glutinous hairs above referred to.

The Kew Hand List, besides this just-named species, contains the following:

*Drosera auriculata*, a curious climbing species from the dry districts of Australia. It forms a small tuber, and is thus able to pass safely through periods of drought, under the influence of which it would otherwise perish.

*D. binata*, known also by the name of *D. dichotoma*.—This has curiously forked cylindrical-shaped leaves; they are borne on rather long

Sundews may be best understood by observing our own British species growing in a state of nature. In passing it may be noted that *D. rotundifolia* is not the only species native of this country, there being really three, but this is by far the best known. As they are but shallow rooting subjects, the Sundews thrive best in pans rather than pots. A mixture of peat, sphagnum moss and a little sand suits them well, with the addition of a surfacing of live sphagnum. A portion of the greenhouse where they are not shaded from the sun is best for them. They all need a liberal supply of water, especially during the summer months.

Most of the species can be readily increased by cuttings of the stout fleshy roots, cut up into pieces about an inch long and laid in pans in a mixture of finely-chopped sphagnum and silver sand, placing them afterwards in a warm house. Three species, viz., *D. binata*, *D. rotundifolia* and *D. spathulata*, have been successfully grown by me in the sunny window of a dwelling-house. They were in a small Wardian

case on which plenty of air was given. The object of this amount of protection was to keep them from the dust, which in such a position would, from the glutinous character of the leaves, soon disfigure them. H. P.

### ROYAL OR FLOWERING FERNS.

THE Royal Fern (*Osmunda regalis*) is a true cosmopolite, for besides the British Isles it occurs in a state of nature over the greater part of Europe and Asia, extending eastward to China and Japan. It is also found in the Azores, Barbary and South Africa, while allied forms are plentiful throughout the Western Continent. The term Flowering Fern is often applied to this *Osmunda*, as the spore-bearing portions of the fronds, which occupy the upper part, usually towards the centre of the plant, are of a dense spike-like character, and at a little distance present the appearance of undeveloped flower spikes.

As might be supposed from a plant of such wide geographical distribution, the Royal Fern varies greatly in size and other particulars, for it has been recorded as reaching a height of 10 feet to 11 feet in different parts of these islands, but in a general way its fronds are from 2 feet to 4 feet long. In bleak, comparatively dry spots they are often a good deal less. The Royal Fern is essentially a water lover, an ideal situation for it being what is regarded in the popular mind as a Fern glen, that is to say, a somewhat low-lying position with a stream of water running through the lowermost part. Planted so that its crown is clear of the water, and yet sufficiently near that the roots have free access thereto, this *Osmunda* will grow luxuriantly, and form an object of great beauty. It is questionable whether it is the more beautiful in spring, just as the young delicate green fronds are first expanded, or later on when they are fully developed and the fructification on the upper part stands forth in such a decided manner. In many gardens there is a shaded pool or boggy spot, and in selecting plants for such a position the claims of the Royal Fern must on no account be overlooked. Under more artificial treatment, too, it succeeds well, as it may be grown very satisfactorily in pots, provided they are effectually drained and the roots given ample supplies of water. Stood partially submerged in a tank they form a striking summer feature, for, like most of our native Ferns, this *Osmunda* is deciduous.

The question of soil is by no means a very important matter, as the Royal Fern will grow in a loamy or peaty compost, while it luxuriates in the silt consisting principally of decayed vegetable matter and sand often brought down by running streams and deposited on their banks. Of the different forms in cultivation, the common Royal Fern (*Osmunda regalis*) is too well known to need any further description, and the most marked of its varieties are

*O. regalis cristata*.—Altogether of more dense growth, while the points of the fronds are more or less crested.

*O. r. gracilis*.—This variety is characterised by a looser and more slender habit of growth, the fronds being usually much less in number.

*O. r. japonica*.—A small growing form with spreading fronds, the barren and fertile ones being often quite distinct from each other.

This is more often treated as a greenhouse than a hardy Fern.

*O. r. j. corymbifera*.—Quite a dwarf-growing form and a delightful pot plant. The fronds are numerous and are only slightly ascending, while the weight of the crests cause the tips to droop over in a very graceful manner. This pretty Fern was sent home by Maries when travelling in Japan for Messrs. Veitch over twenty-five years ago, but even now it is far from common.

*O. r. palustris*.—As a pot plant this is far and away the most popular of all the *Osmundas*, being one of the Ferns grown in quantity by those who supply Covent Garden Market with decorative plants. It is of rather upright growth, with smooth red stems. On first unfolding the young fronds are of a bright crimson tint, but after a time they gradually change to the normal rather pale green tint. A very notable and interesting feature of this variety is the fact that, unlike all the others, the fronds of this variety are evergreen in character. It is a native of Brazil.

ONE OF THE EARLY TULIPS (TULIPA SAXATILIS).

Besides those above enumerated as varieties of *O. regalis* (though they are occasionally referred to as distinct species) there are two North American sorts, at least they are widely distributed on that Continent, but also occur elsewhere. The first (*O. cinnamomea*) is found in the West Indies, Brazil and Japan, as well as North America. This has the spike-like fertile fronds arranged quite separately in a dense tuft forming the centre of the specimen, and these impart to a fully-developed plant a very singular appearance. The second species (*O. claytoniana*) has, like the preceding, the fertile fronds gathered together in the centre, but in their case the spike-like portion is limited to the middle of the frond, the upper part widening out and bearing only barren leaflets. From this interrupted style of growth it is often known as *O. interrupta*. In addition to its being a native of North America this species is also found on the Himalayas. The cultural requirements of these two last are about the same as *O. regalis* and its varieties. H. P.

## THE FLOWER GARDEN.

### TULIPA SAXATILIS.

THIS beautiful Tulip, which is a native of Crete, has been in cultivation for nearly a hundred years, but is seldom met with in good condition or flowering freely. It is quite easily grown in a hot, sunny border, and one of its most essential needs is a thorough ripening of the bulbs after it has made its full growth. It is quite hardy in this country, but it should be planted rather deeply, and as it often comes into flower about the beginning of March it should be planted in a sheltered place, where it will not suffer from wind or rain. Its early-flowering qualities recommend it for use in the cold house, and a pan in full bloom, such as that shown in the illustration, is very attractive. The bulbs, which may be procured very cheaply, should be potted up in the autumn in a mixture of loam and sand. The pans should be plunged in ashes in a cold frame for the winter till they start growing, when they may be moved into the cold house. Its foliage of bright green shining leaves is distinct from all other species, while the flowers are of good size and bright mauve-purple in colour, with a yellow base. A coloured plate of this charming Tulip appeared in THE GARDEN for August 5, 1899. Although so early in flower it is closely followed by the lovely Turkistan Tulip (*T. kaufmanniana*), which makes a suitable companion for it, either in pans in the cold house or planted in some sheltered nook in the rock garden or sunny border. Other early-flowering Tulips include the rosy purple *T. pulchella* from Asia Minor and the mauve-coloured *T. Lownei* from Palestine. Both these are small-growing species well adapted for pot plants. The above-named Tulips are most charming subjects for a cool greenhouse in spring and should be cultivated far more extensively than they are at present. Given perfectly cool treatment they are but little trouble, and amateurs need have no hesitation in trying them. W. I.

### THE STRIPED SQUILL.

*PUSCHKINIA LIBANOTICA COMPACTA* is a charming subject for decorating the April garden, yet, although the bulbs are cheap, it is seldom seen. The little flowers (white, shaded and striped with blue) only rise to a height of about 6 inches, but when seen growing in a broad mass produce a beautiful effect. This Squill is quite easy to grow in a warm, well-drained situation. On sunny rockeries it flowers freely year after year. Many amateurs seem to think that all spring-flowering bulbs need is a moist, half-shaded position, but I have the bulbs under notice, together with *Chionodoxa gigantea*, doing exceedingly well on a bank which almost dries up during the summer months. E. TESCHEMACHER.

### SAXIFRAGA GRISEBACHII.

SINCE the introduction of this attractive species some few years ago it has rapidly grown in favour, as it is undoubtedly the most handsome of all the red-flowered Saxifragas. In cultivation

A DWARF ROYAL OR FLOWERING FERN (*OSMUNDA REGALIS PALUSTRIS*).

(See page 214.)

it has proved quite hardy when given a well-drained crevice or ledge in the rock garden, and will go on making fresh rosettes and increase in size. The plants delight in very gritty soil, with a plentiful admixture of limestone chippings, and enjoy a sunny situation. Here they will flower freely, often commencing in January in favourable seasons and lasting in good condition till well into April. In habit this Macedonian Saxifrage is distinct from all other members of this extensive genus, its nearest ally being the Pyrenean *S. media*, which has similar rosettes of leaves, but has racemes instead of spikes of flowers. Its singular appearance makes this plant most attractive, with its nodding spikes of closely-set flowers adorned with yellow stamens. The stout stems, as well as the bract-like leaves which clothe them, are of a bright rosy pink, the latter being tipped with green, while the flowers are blood red in colour. With age the colour of the stem fades and the bracts become more leaf-like, while the stem lengthens out, eventually reaching a height of 6 inches to 9 inches, or more in strong specimens.

Its adaptability for pot culture may be noted in the accompanying illustration, which shows a pan of plants three years old from seed. These have been grown on in cold frames, unprotected save in the winter months. Seeds germinate freely and are best sown in spring. As soon as they are large enough to handle the seedlings should be pricked off into small pots, two or three together, using a mixture of very gritty soil and limestone, with ample drainage in the pots. Care should be taken that the young seedlings are not choked with Liverwort in their young stage, and they should have the protection of a light against heavy rain. The imbricated silvery rosettes of leaves are very ornamental and vary a good deal in size. On account of its early-flowering habit this is a valuable plant for the cold house, where it is seen to much more advantage than when growing outside, although it stands the weather, and even frost, well when planted in a suitable situation.

W. I.

## KITCHEN GARDEN.

### BEET CARTER'S CRIMSON BALL.

**T**HE Beetroot is always welcome as early as possible, both for salads and for use as a separate dish, and those who can find room for a small quantity of the early section would do well to grow Carter's Crimson Ball, which is remarkable for its earliness and its excellent flavour. Round Beets are of great value at this season, as if sown at the end of April in the South, or the early part of May in the North, the roots can be lifted early in the summer when there is a great demand for salads, and the newly-grown or fresh, highly-coloured slices are much liked. These new types of Beetroot are much superior in every way to the old

flat roots, which were pale, stringy and flavourless; indeed, I do not think them worth growing. Crimson Ball is quite the reverse; it has a splendid colour and texture, and grows so rapidly that the roots are far superior to other forms for first supplies. I have, to secure early roots,

sown in boxes in frames and planted out on a warm border between rows of other early vegetables, such as Peas or Dwarf Beans, but even when sown in the ordinary way the growth is rapid, and the seedlings, in good land on a warm border, soon turn in fit for use.

### VEGETABLE MARROW TENDER AND TRUE.

**AMATEURS** frequently grow the Vegetable Marrow to advantage, and if a large space is to be covered the trailing varieties, such as the Long White or Green, are very good. But others have to make the most of their space, and here the above-named variety will be found most valuable. It belongs to the bush class, and has great merit, both as regards the solid depth of flesh and its delicate flavour. The fruits are roundish, with a pretty mottled green skin. It has early fruiting and free setting properties. The bush Marrows are not grown nearly as much as they deserve; they thrive well in ordinary garden soil if given a little food when in full bearing, and the plant, after a hot summer's day, delights in copious overhead waterings. The fruits of this variety are best when cut quite young, not larger than a cricket ball, and cooked whole. Treated in this way they are delicious.

### A VALUABLE EARLY FRENCH BEAN.

**I AM** aware we have no lack of good varieties of the French Bean, but there are none that crop in such a short time as Sutton's Forcing. It is far away the best winter Bean that I have grown, and it is so dwarf that unless the rows, when grown in beds, are quite close together, space is lost. The pods are borne quite close to the soil, and in the winter months the plants do not show any signs of running, but make a remarkably close growth. For pot work in the early part of the year it is most valuable; seed sown in December gave a good crop six weeks later, and this at a season of the year when these plants are not always a success. At that date, or for winter and early spring supplies, I advise 5-inch or 6-inch pots.

G. W.

GRISEBACH'S ROCKFOIL (*SAXIFRAGA GRISEBACHII*).

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**FLOWER GARDEN.**—Pansies and Violas should be planted without delay for flowering in the near future; these plants prefer good soil and an open position where the plants can be sheltered from the midday sun. Sweet Peas that were raised in pots and boxes under glass, and subsequently hardened off in

1.—TUBEROUS BEGONIAS IN A DORMANT STATE. THAT ON THE LEFT IS PLACED THE RIGHT WAY UP, AND THE OTHER THE WRONG WAY.

the cold frame, may be planted now. Should the seedling plants not be hardened off sufficiently, let them remain in the frame a few days longer. Complete the sowing of hardy annuals without delay: I always sow the seeds thinly and evenly in well-prepared friable soil, the resulting seedlings invariably flowering in late July in ordinary circumstances. Within the next week or ten days sow the half-hardy annuals outdoors. I make a sowing where the plants are to flower, and find this answers very well indeed.

**The Vegetable Garden.**—I am staking some of my earlier Peas. Insert the stakes before the Peas get too tall. Scarlet Runners should be sown at this period if the resulting crop is wanted by the end of July or early August. Sow the seeds 6 inches to 8 inches apart in the row and cover them with about 2 inches of soil. Salads, in the form of Mustard and Cress and Radishes, if sown now will very soon provide supplies of these subjects; the two former should be ready in about two weeks, and the latter in from five to six weeks. Spinach is an indispensable vegetable, and for this reason I make a sowing every week or two. Sow the seeds 1 inch deep in rows, the latter being about 1 foot asunder. Spinach takes about eleven weeks to develop from the time of sowing. Beds of the earliest Onions should be dusted with soot to keep off the Onion fly. Beet may be safely sown at this time. Good deep soil that has not been recently manured is best for this crop. Sow the seeds 2 inches deep in drills 1 foot to 15 inches asunder.

**Orchids.**—To promote the well-being of my Orchids, I make a rule to damp down the house freely from this time forth through the summer when the weather is seasonable. Complete the repotting of Odontoglossums. These Orchids do better in small pots. A suitable compost for repotting is made up of two-thirds peat, one-third of charcoal, sphagnum moss and sand. Half fill the pots with crocks.

**The Greenhouse.**—Greater care in ventilating the greenhouse and conservatory is now very necessary, the temperature rising so rapidly when the sun is not obscured. Open the ventilators so that cold draughts may be avoided. Camellias and Azaleas that have gone out of flower I am now repotting. The former subject does well in a mixture of peat and sand, but

better in a compost of light turfy loam and a fifth part each of decayed leaf-mould and coarse silver sand. Any of my Azaleas (*A. indica*) that need repotting are given a compost of five parts peat and one part silver sand. I have tried using good fibrous loam and peat in equal proportions, adding thereto a fifth part of silver sand, and find this also answers well.

**Hardy Fruit.**—Peaches on walls should be disbudded, doing this in somewhat experimental fashion, especially in cold situations. A dusting of Tobacco powder among the leaves will prevent green-fly or black-fly effecting a settlement. Continue to afford these trees shelter in cold weather, especially at night. In preparation for early Strawberry supplies I am cleaning the ground between the plants and placing clean straw or litter thereon. By these means the ground is kept moist and cool and clean fruit ensured later on. Keep a sharp look-out for the Gooseberry caterpillar. Should this pest be in evidence, hand-picking may be adopted by those who have the time; the bushes should also have a dusting of lime.

**Chrysanthemums.**—Early-flowering Chrysanthemums may be planted outdoors in warm, sheltered situations at the present time. Where the flowering quarters are open and exposed, it would be better to wait another fortnight. In the meantime fork over the quarters and have the ground ready for planting. Pot on the later sorts that are to bloom in large pots. My best plants are now in 6-inch pots. Pretty decorative plants are doing well in 5-inch pots. D. B. C.

## THE TUBEROUS-ROOTED BEGONIA AND ITS CULTURE.

To the inexperienced grower the tuberous-rooted Begonia appears to be a somewhat difficult subject to deal with, but this is quite a mistaken notion. Given proper soil and suitable conditions in which to grow this plant, it is quite easy to manage. As a plant for greenhouse or conservatory embellishment the tuberous Begonia is one of the best, and apart from their use as plants for culture under glass, they have acquired a greater value of late years for beds and borders outdoors. Beds exclusively devoted to the tuberous-rooted Begonias make a most glorious display, and if sheltered quarters can be provided where also they may be shielded from the sun during the hottest period of the day in summer, they fully repay the grower for giving them this consideration.

**Raising Begonias from Seed.**—Seed from a reliable source should be sown in the earliest

3.—A TUBEROUS BEGONIA POTTED UP INTO A 5-INCH POT.

days of spring; in fact, January or February is not too early. The whole process of raising these plants from seeds was described on page 27 of the issue for January 18, so that it is unnecessary to go into details here. The small plant on the right, in Fig. 2, represents a seedling after the first pricking out. These seedlings should be transplanted in other boxes about 2 inches apart, and after getting established should be placed in rather cooler quarters.

**Starting the Tubers.**—Tubers as represented in Fig. 1 are just as they are received from the nurseryman. The first tuber reveals the concave formation when placed in its proper position for starting into growth. The tubers should be arranged in this manner, close to each other, in shallow boxes and in Cocoanut fibre or any light sandy soil. If placed in a gentle bottom-heat and kept just moist the tubers will very soon give evidence of new life by fresh growths in the concave portion of the tuber. Roots will be freely emitted from the tubers too. Observe the position of the second tuber in Fig. 1. The concave position is reversed and the convex is shown instead. Do not arrange the tubers in this fashion.

**Potting Up Tubers after Growth has Developed.** As soon as the tubers are making free growth and give evidence of vigorous root formation, pot

2.—THE PLANT ON THE LEFT IS A TUBEROUS BEGONIA THAT IS READY FOR POTTING UP; THAT ON THE RIGHT IS A SEEDLING AT THE RIGHT STAGE FOR INSERTION IN A BOX.

them up without delay. The illustration on the left of Fig. 2 shows a tuber well rooted and making free growth. This may be transferred either into a pot 3 inches in diameter or one measuring 5 inches across. The soil for this repotting should comprise loam two parts, well-decayed manure one part and leaf-mould and sand one part. Mix thoroughly and pot moderately firm. Give enough water to keep the soil just moist for the first week or so. The plants must now have plenty of light, and for this reason should be arranged on shelves near to the glass, taking care, however, to shade them from bright sunshine. As they become established the glass structure must be ventilated, as the plants, especially those intended for bedding purposes, must be gradually inured to harder conditions. Fig. 3 represents a more vigorous plant placed in a 5-inch pot, where it will soon become established and form a fine, sturdy specimen.

**Subsequent Treatment of Pot Plants.**—Plants intended for pot culture may be finally moved into pots either 6 inches or 8 inches in diameter, employing soil similar to that prescribed above.

1.—OLD CLUMP OF MINT LIFTED READY FOR DIVISION.

No heat is required after the end of May or mid-June in a normal season.

#### LIFTING AND PROPAGATING MINT.

MINT is one of the most popular herbs of the garden, and has been in use since before the Christian era. There are two types that are usually grown, one, the Peppermint, used for making the well-known cordial Peppermint, and the Spearmint, that is used in a green state—forced or otherwise—for culinary purposes. It is with the latter that we are especially interested in this note. The Mint delights in soil that is rich and moist; hungry, dry and poor soil should, therefore, either be enriched with a heavy dressing of good lasting manure or such quarters be avoided altogether. If given good quarters the Spearmint (*Mentha viridis*) will succeed in almost any aspect, although when planted in a sunny position the best results are invariably obtained.

*Propagation of Mint.*—The propagation of Mint is generally done either by cuttings or by division of the old roots. It is easily accomplished if done in the spring. Either March or April is a good time, as the growths are young and tender and root very readily. Cuttings will root quite freely if dibbled into moist sandy soil and a hand-light placed over them. By keeping them close for a few days and shading the cuttings during the same period the process of root formation will be speedily accomplished. The easier method of increasing the Mint, however, is by division of the roots during the period above named. Fig. 1 shows a clump lifted from an old bed of Mint. Here it will be noticed that the growths have numerous vigorous-looking roots, and in several instances fresh young shoots have recently evolved. The fresh green shoots may be detached and made into cuttings some 3 inches in length, and if these same cuttings can be removed close to the stem of the underground shoots when they are of the desired length so much the better. The old clump should then be broken up into numerous pieces of various length. Any piece of the old plant, so long as it has roots adhering, will very soon root into the soil of the fresh quarters. Fig. 2 is a good representation of a few growths broken out from the clump in Fig. 1. Observe how vigorous these underground growths are in appearance, and also note the young shoots that are already developing along the stems. The rooted cuttings above referred to should be planted out 3 inches apart in rows, and the rows should be 1 foot asunder. The divided portions of the old plant should be planted in trenches

some 2 inches to 3 inches deep, arranging the pieces about 9 inches asunder. The rows should be made 1 foot apart. Mint may be lifted at any time between October and April, and if placed in a cold frame or cool greenhouse will provide ample supplies before the beds outdoors develop their growth. Lift the plants at intervals.

#### A GOOD HOT WEATHER SPINACH.

No doubt many beginners in gardening have been much annoyed with the ordinary summer Spinach which has such a tendency to run to seed before the leaves are barely large enough to cook, and to all such the plant known as New Zealand Spinach can be thoroughly recommended. It is an annual that grows wild in New Zealand and Australia, its botanic name being *Tetragonia expansa*. It is an easy subject to grow, and although the flavour is not so good as that of Spinach proper it makes an excellent substitute. Rich, well-dug ground should be provided for it, raking the surface down well before sowing.

The seeds may be safely sown in the open ground early in May in rows at least 3 feet apart, thinning the seedlings when they appear to 1½ feet from plant to plant. Keep all weeds down, and as the summer advances the plants will grow and touch each other, thus almost entirely covering the ground. Water well during very dry weather. As soon as the plants are large enough, picking may commence, taking the tender young tops off for cooking. This induces the plants to branch afresh, and a crop is thus ensured until frost kills the plants. It is a most vigorous growing subject, hence it must be given plenty of room in which to develop.

#### WORK AMONG THE STRAWBERRIES.

THE trusses of flowers are now showing in the centres of these plants, and this is a sure indication that some amount of attention is required if the fruits are to be ripened in the best possible condition. The soil between the rows should be lightly stirred with a Dutch hoe, so as to uproot any weeds that may be present, and if they are at all large they should be entirely removed. Any old, partly dead leaves ought also to be removed, as they are of no use to the plant, are unsightly, and provide excellent harbourage for animal pests of various kinds. Then give the soil, especially close round the plants, a good dusting with lime and soot, taking care to keep it out of the centres of the plants, and finish off with a good mulching of some strawy material.

At this season long stable manure is excellent, as the plants will derive some nourishment from it, and by the time the fruits are ripening it will have been washed quite clean by rains and thus provide a good protection against splashing by heavy rains. Many amateurs make the mistake of using lawn cuttings as a carpet for the swelling and ripening fruits to rest upon, with the result that many decay, especially if the season is a wet one. Hay or dried grass in any form is almost as bad and should be avoided. Failing the long strawy manure advised, the next best thing is good, clean, sweet straw. Tan from a tanyard also answers very well, but it should be well sweetened before being used.

Nets should be overhauled and any holes that are present repaired, so that when the fruit is swelling they will be ready for placing in position. Netting is quite useless if any holes are left as birds are sure to find them.

2.—SPECIMEN UNDERGROUND PORTIONS OF MINT: NOTE THE ROOTS AND VIGOROUS YOUNG SHOOTS.

## THE TOWN GARDEN.

**THE UBIQUITOUS SLUG.**—The town gardener who poses as a philosopher makes pretence of deriving pleasure from the presence of slugs in his garden, not because they ruin scores of his choicest plants, but because he can have the supreme joy of killing them. Some cynic or another has said that every Englishman wakes up daily thirsting for blood, and if he be a gardener and cannot find anything bigger upon which to exercise his prowess, he can always find a slug or two in a town garden, and in dealing out sudden death he glories. Most of us would, however, be just as happy without the slugs, and an excellent way to get rid of them is to use Vaporite, but it will be essential to follow this up by scrupulously clean gardening, for although slugs are not particular, they certainly prefer the untidy to the tidy garden. Do not have any rubbish about, keep the plants trim and smart, use Vaporite, go out each evening with a lamp bent on slaughter, and the enemy will have to give way before such a determined onslaught.

**MULCHING AND FEEDING CLIMBERS.**—It is a regrettable fact that the majority of climbers seen in town gardens do not look as healthy and flourishing as they ought to do, and I do not think that the reason of this is usually far to seek. People who cannot resist damping the surface soil of their flower beds and borders every evening appear to think that when once a climber has been planted against a wall or an arch it does not demand any more attention, and it is left to its own resources. This is all wrong, more particularly in the case of those plants that are trained against walls.

It must be borne in mind that the position of the roots is such that they never get as much benefit from the rain that falls as the plants in the open garden, and, further, that the bricks of the wall suck vast quantities of moisture out of the ground. I would urge those who have climbers—and they are indispensable to the complete charm of the garden—to remove about 3 inches of the surface soil from over the roots and put in its place some rich compost, well firmed down; this done, soak the ground thoroughly with water, giving 5 gallons or 6 gallons to the square yard. To finish off the work in the best possible manner procure some good manure and spread it lightly on to a depth of 3 inches; this will convey food to the roots at the same time as it conserves the moisture in the soil. Should the owner of the garden have fastidious objections to the appearance of manure on the soil, he can easily cover it up with a thin sprinkling of fine soil, but it is just as well if it is left exposed.

**THE GREENHOUSE.**—This is a delightful adjunct to the town garden, and whenever space can possibly be found for one it should be erected as a permanent structure or a tenant's fixture, according to circumstances. During the summer it is apt to be somewhat neglected for the brighter pleasures of the garden, but its occupants must not be entirely forgotten, for they have probably already done us good service, and with reasonable attention will do so again. Time must at least be found for keeping the whole of the interior surfaces—pots, plants, benches, glass and floor—perfectly clean, and provision should be made for protecting the plants from the fiercest rays of the sun. For this latter purpose roller blinds, which can be raised or lowered at will, are indisputably the best, but where they are not at command a permanent shading, such as Summer Cloud or other similar compound can be painted on to the glass. The grower should also be especially careful that those plants which require water never suffer from the lack of it, but are examined daily so that their wants may be supplied. When plants are neglected and become debilitated they fall an easy prey to insect and fungoid attacks.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FLOWER GARDEN AND LAWNS.

**L**AWS should be frequently rolled and mown in order to keep them smart. Keep the beds and borders containing flowers neat and clean and the verges of grass well clipped. Bedding Calceolarias may be put into their summer quarters where they will get established before the hot weather comes on, and, therefore, give much better results. Beds containing bulbs of Hyacinths, Tulips and similar plants must be kept smart now.

#### PITS AND FRAMES.

These will now demand a lot of attention as they contain many subjects that are being hardened off, such as Verbenas, Fuchsias, Dahlias, Pentstemons and Petunias. These should be kept well watered and free from green fly. Gradually draw the lights entirely off them in fine and warm weather.

*Primulas* and *Cinerarias* may now be sown, the former in heat and the latter raised as cool and hardy as possible.

#### PLANTS UNDER GLASS.

Keep the paths in the stove frequently damped during sunny weather. Early potted plants that make rapid growth will now require shifting again. Take care that no plant becomes dusty or it may spread spider and thrips. If a plant does become so dry that the soil throws off water without being saturated, it should be immersed in a pail or tank for ten minutes.

*Gardenias* that have finished flowering may be cut back into the hard wood. Take care of the young batch recently propagated and pot on as the pots become full of roots. (Greenhouse plants should have more air now, and potting and tying should be the order of the day.)

#### KITCHEN GARDEN.

*Celery Plants.*—Continue to prick out these into a frame containing about 2 inches or 3 inches of good soil and manure. If treated thus they can be cut out in squares when ready and taken to the trenches with a good ball of roots.

*Brussels Sprouts.*—The first sowing will now require hardening off, and when sturdy enough may be planted out in good soil 2 feet 6 inches apart each way. A good plan is to put them out 3 feet 6 inches between the rows and crop with a short-haulmed early Potato, the latter coming off early and thus giving the sprouts ample room for development.

*Maize or Sweet Corn.*—The earliest batch should be hardened and planted out as soon as the weather becomes favourable for so doing. Sow late Peas, such as British Queen, Carter's Michaelmas and Ne Plus Ultra, about three times during this month.

#### HARDY FRUIT GARDEN.

*Autumn-fruiting Raspberries* of the Belle de Fontenay type, if not already done, should be cut down to within 3 inches of the stool. Take away the protecting material from Peaches, Apricots, Cherries and Plums as soon as the weather admits of so doing. Examine the trees daily for pests, and take strong measures if any aphides are seen. Spray with Extract of Quassia on a fine day about 3 p.m. or else early in the morning; this will prevent an immediate attack. I have found with Peaches, Nectarines and Cherries that the best way of dealing with a bad attack of aphides is to syringe with warm water, to 4 gallons of which a quarter of a pint of petroleum emulsion has been added, repeating this for a day or two.

#### FRUITS UNDER GLASS.

*Late Vines* coming into flower should have a night temperature of not less than 60°. Close

the house moderately early and shut up with a good sun temperature ranging from 75° to 90°. The latest Vines of such varieties as Lady Downe's Seedling should have the points pinched two leaves beyond the bunch, and let the laterals be brought down to the wires carefully, as they snap very easily.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**STEPHANOTIS FLORIBUNDA** should now be induced to grow freely by being placed in a brisk and moist atmosphere for a few weeks until the growths have attained a length of 10 inches or 12 inches, after which the plants may be gradually inured to a lower temperature. The ordinary plant stove is sometimes too warm and too moist for *Stephanotis*, and the result is that the plants under these conditions do not flower. Avoid training the shoots too closely together, as this only tends to provide one of the best harbours for mealy bug that can possibly be had.

**Orchids.**—*Dendrobium dalhousianum* is a large, handsome plant when well grown. The roots are strong and persistent, liking a very rough, open compost and large, roomy pots. Peat and sphagnum in equal proportions, with abundance of rough lumps of charcoal and crocks, suit it well. The pots must be more than half filled with drainage, protecting this with a layer of rough moss before putting the plants in position. Pot firmly, and keep the leads back as far as possible, so that they do not reach the rims for a couple of seasons at least, and finish the compost with a slight rise to the centre.

#### FRUIT UNDER GLASS.

**Melons.**—Where there is a constant demand for these it will be necessary to make sowings about every three weeks, a few seeds only being sown at a time. Melons succeed very well through the summer in frames on hot-beds where a bottom-heat of about 80° can be maintained, but both watering and syringing must be done with care and judgment if satisfactory results are to be obtained.

#### KITCHEN GARDEN.

**Runner Beans.**—These may now be sown outdoors with every prospect of success. The Scarlet Runner adapts itself to many methods of treatment, and a judicious use of the plant may serve to hide many a rough corner in the garden or to form a pretty and effective dividing line between the kitchen and flower department where these two sections of the garden adjoin. In whatever position it may be put well-manured soil is an absolute necessity if the same plants are to keep on bearing throughout the season.

#### HARDY FRUIT.

**Strawberries in the Open.**—The plants look well at present; the flowers are showing strongly and the young foliage is vigorous and healthy. Mulching should now be pushed forward as speedily as possible. Before attending to the mulching do not under any circumstance omit to apply a liberal dressing of lime or of lime and soot.

#### FLOWER GARDEN.

**Wallflowers.**—If for no other reason but its sweetness, the Wallflower should find a place, particularly in mixed borders. The single varieties are as easily raised from seed as a bed of Cabbage. They may be sown either in rows or in beds on light garden soil. For summer and autumn flowering the best time to sow is the beginning of May. When about 2 inches high prick them out into nursery beds in rows about 6 inches apart, where they may remain till the borders are dug in spring, when they should be lifted with balls and planted where they are to bloom.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Growing water plants in tubs** (*Cynthia*).—If you mix half a peck of charcoal with the soil used for each tub this will tend to keep the water fresh. Of course evaporation will be fairly rapid and so fresh supplies of water will be needed at comparatively frequent intervals. If you use the charcoal as advised you will not have much trouble with the water.

**Perennials for cut flowers** (*B. W. Atkinson*).—You are somewhat late to be planting with a view to getting a good flowering of many plants this year, but you may get some flowers if you plant good-sized examples of the best things. For instance, it is late or unseasonable now to be thinking of planting Spanish Irises, Flag Irises, single and double Pyrethrums, Trollius and many more, yet these are among the most beautiful and desirable of hardy plants in the cut state. You may, however, plant *Aster amellus* in many forms, *A. acris*, *A. lævigata*, *Helenium*, *Achillea*, perennial Peas, *Coreopsis grandiflora*, *Gaillardia*, any of the perennial Sunflowers, *Heliopsis lavis*, *Campanulas* of sorts, *Gypsophila paniculata*, *Phloxes*, *Leucanthemums*, *Erigeron speciosus*, *Anchusa italica*, *Galegas* and many more. By planting the Flag Irises, single and double Pyrethrums and Delphiniums now good plants and a more representative flowering would result another year. To the foregoing many bulbous-rooted plants should be added, but these could not be planted before the autumn ensuing.

**Alternantheras going off** (*W. S. C.*).—You say nothing as to the conditions of the treatment given to your *Alternantheras*, but after carefully examining those sent we can discover no special reason for their going off in the way they have done. There is little doubt in our mind that the trouble has arisen from what the gardener terms damping off, set up by overcrowding or by too close an atmosphere. Remember that all fungoid troubles of this class are best combated with a free circulation of air. Out-of-character specimens are somewhat difficult to name definitely, but apparently yours are *nana aurea*, yellow; *versicolor*, pink; and *paronychioides*, crimson.

**Narcissus coming a bad colour** (*Ignoramus*). It is just possible that the season of 1907 was largely responsible for the deficient colouring of the blooms to which you refer. The germ of the flowering, as you probably are aware, is laid nearly a year in advance, and any material check at the moment of the forming of the embryo bud during the summer of 1907 would only be revealed by the flowering in the spring of this year. The fact that the other sorts mentioned are of normal colour only strengthens the view that some local influence at the period of maturing last year is the principal cause of the failing. We are assuming that the bulbs have been well grown and are in other respects quite up to their usual standard.

**Tulips not flowering** (*A. D., Perranwell*).—The two bulbs sent are quite sound and healthy, with good roots, and to all appearance should have flowered well. The foliage on the one bulb has obviously been badly eaten by slugs, and as these pests seem to have a great partiality for Tulip bulbs and leaves, they are probably the cause of the trouble. The "small worms," which are a kind of millipede, are not present in sufficient numbers to do much harm, and we do not think the non-flowering can be attributed to them. They certainly would not be in the bulbs when they were bought, but would much more likely be caused by the manure used, as they live on decayed vegetable matter. Try to give a good dressing of lime in the summer or autumn when the bulbs are lifted;

it will tend to keep them down, and do not use the same sort of manure again. We should say that if some of the bulbs were very small when planted, naturally they would not flower much; or it may be, looking to the past summer, that the unfavourable climatic influences affected their ripening. Either of these causes would affect the bloom, but there is nothing about the bulbs sent to suggest them in this case.

### THE GREENHOUSE.

**Hyacinth bulbs gone wrong** (*Oropesa*).—Complaints as to the unsatisfactory behaviour of Hyacinths and other bulbs are very common this year, the general opinion being that it is to a great extent owing to the cold wet weather we experienced last summer, when the bulbs should have been ripening for another season. At the same time, of the bulbs sent by you the two in fibre had not a healthy root, and consequently failure was certain. They appear to have been kept in fibre sufficiently moist to cause the roots to start, and it then apparently got so dry that they perished. When bulbs are potted in good potting soil it is far easier to keep the roots in a regular state of moisture than when they are in Cocoanut refuse, which dries very quickly and is difficult to keep in an even state of moisture. You did right in separating the offsets, as they have, of course, a tendency to weaken the bulb. The general treatment as detailed by you leaves nothing to be desired; but, of course, if the bulb does not contain a good spike of blooms in embryo, no treatment will develop one. Still, if you use potting soil instead of fibre, you may reasonably expect better results.

**Plant to cover damp wall of greenhouse** (*I. R.*).—You cannot do better than plant *Ficus radicans*, a self-climbing green-leaved plant that will grow rapidly in a temperature ranging from 50° to 60°. A variegated form of it is also obtainable.

**Bottom temperature for Carnation cuttings** (*Novice*).—The bottom temperature mentioned in the article to which you refer is obtained from hot-water pipes. The beds of sand are formed on benches fixed over the pipes 1 foot or 18 inches away, so that the temperature of the soil is easily maintained 5° higher than that of the atmosphere. Please do not apologise for writing for information; we are always most pleased to assist our readers.

**Keeping Tree Carnations** (*M. A. M.*).—Tree Carnations may be kept year after year if they are carefully attended to. If they are treated for winter blooming they should, after the flowering period is over, be shortened back in order to obtain good free growth, and if the roots are in a healthy state they need not be repotted. In this case a liberal top-dressing is very helpful. It is certainly not necessary to throw the old plants away every two years, particularly when a supply of cut flowers is a consideration.

### KITCHEN GARDEN.

**Winter and spring Broccoli unsatisfactory** (*A. B. C.*).—The Cauliflowers would, undoubtedly, do well in deeply-trenched ground in the summer time. There is plenty of heat, of course, to mature the plants; but the loose, trenched soil is quite unsuitable for Broccoli, especially when the plants are grown in such an exposed position. They would succeed much better if grown in quite firm ground. For instance, if a plot of ground were cleared of Pea haulm at the end of the summer, it would be wrong treatment to deeply trench such ground and then plant Broccoli. The plants would grow luxuriantly, but they would suffer during a severe winter. The stems immediately below the leaves are not solidified, and when exposed to frosts they are injured and often killed. The proper treatment would be to simply level the ridges where the Peas grew and to put out strong plants in the firm, undug soil. The plants may not attain to a very large size, but they would bear fine, compact heads or flowers.

**Asparagus Kale** (*Sandy Soil*).—A medium rich loam suits this Kale best, but it can be successfully grown in a sandy soil; in fact, all the Kales will thrive in light and rather poor ground if it is well manured and the plants carefully grown while they are quite small. If once the seedlings become stunted through being left too long in their seed-beds they will never be satisfactory. Deeply trench the soil and put in plenty of rotted manure quite a month before the plants are put there. The seeds

of Asparagus Kale should be sown early in April and the resultant seedlings transplanted 4 inches apart in a nursery bed prior to being planted in their summer quarters.

**Melons and Cucumbers failing** (*E. T.*).—I have carefully examined your Melon plant and cannot find any trace of eelworms in it, though I have examined sections of the entire stem under the microscope, nor can I detect any insect pests in the soil, so that I am sorry that I cannot give you any clue to the reason of the failure of your plants.—G. S. S.

**Edibility of Gourds** (*W. J. W.*).—Of the twelve named varieties of Gourds in your list we can commend two only as truly edible, those being the Yellow Mammoth or Pumpkin and the Egg-shaped Ohio Squash, assuming yours are to be the same as we grew twenty years ago. This latter variety, with its marrowy yellow flesh, always seemed to us the best of all the Gourds or Marrows. All the rest belong to the ornamental section, and are grown for such purpose only. We saw one of the white egg-shaped varieties fruiting remarkably at Long Ditton last summer, and realised that if edible it would make a valuable garden variety. When cooked, however, it proved horribly bitter, and that seems to be the general character of the flesh of the ornamental varieties. Mr. J. W. Odell gave a very interesting lecture on Gourds to the Fellows of the Royal Horticultural Society in 1905, and he particularises many sorts by no means commonly grown for ornamentation, but his list of varieties suitable for eating is a very small one. Possibly many existing ones could be largely improved in productiveness were judicious cross-breeding undertaken.

### MISCELLANEOUS.

**Laying out a tennis court** (*T. R. W.*).—For a single tennis court the base or end lines should be 27 feet, and for a double court 36 feet. The side lines in each case are 78 feet long. The serving lines will be 18 feet from the base lines in each case, and the net is stretched exactly across the centre.

**Information about newly-planted Rambler Roses** (*E. J. Davis*).—As your Roses have evidently been pruned once there is not any need to cut the shoots back more, providing the wood is firm and the buds are good. If the wood appears soft at the top you must cut down to that which is plump and sound.

**First-class gardening dictionary** (*G. M. Widd*).—"Nicholson's Dictionary of Practical Gardening" is the most up-to-date and comprehensive gardening dictionary that we know. It is published by L. Upcott Gill, Strand, London, W.C., in four volumes, price £4 4s.

**Grubs from herbaceous border** (*H. H.*).—The grubs you forwarded are those of a fly belonging to the family Bibionidae, and probably to the genus Bibio. The flies no doubt lay their eggs at the roots of plants from which the grubs are hatched. I expect you would find that Vapourite, sown broadcast round the plant at the rate of 2oz. per square yard and worked in to a depth of about 6 inches, would kill the grubs. No liquid insecticide is of any use. The flies are those rather thin-bodied creatures which are black or reddish in colour, and which fly slowly from one plant to another, and are sometimes present in large numbers for a few days about the end of April or in May.—G. S. S.

**Using sulphate of ammonia** (*A Beginner*).—Sulphate of ammonia is a highly stimulating manure that acts very quickly and needs to be used very carefully. It is best applied as a top-dressing in quite small quantities, say, 2lb. per square rod, giving two dressings at intervals of three or four weeks, taking advantage of a wet day so that it is quickly washed into the ground. For pot plants a teaspoonful in from 2 gallons to 3 gallons of water will be enough, at least at first; but you may find it an advantage to increase the strength a little later on. It must not be used very frequently for flowering or fruiting plants; but for crops where leaves are desired, such as Cabbages, Lettuces, Ferns and Palms, it is most helpful.

**Preserving Ferns in a book** (*Calley*).—This is very simple and can be done by anyone. Cut the fronds at any time of the year, but do not cut them when they are wet. Then carefully spread them out between sheets of newspaper, place a board on top and weight this with bricks or anything that may be at hand. Place in a dry structure, such as a stove-hole or potting-shed. During the summer the fronds may remain between the papers until dry, but in the winter the papers should be changed twice the first week. When dry you can place the fronds in a book or paste them on sheets of stout paper. "Choice British Ferns," by Charles T. Drury, F.R.S., is a good book on hardy Ferns. It is published by L. Upcott Gill, 170, Strand, London, W.C.

**Colt's-foot and Bindweed** (*E. W.*).—There is nothing, we fear, short of digging out the roots that is likely to be of any practical use in the circumstances. We should not hesitate to dig it out, believing that the house would be secure enough on its own foundations to bear the effects of the soil disturbance necessary to do so. In applying salt, carbolic acid or aught else the ever-present difficulty is the depth to which the roots descend, and likewise their forked character. The roots of both plants are also very brittle, and even when forking it out you will need to exercise more than ordinary care. Pulling, as soon as a leaf is seen above the surface, is of some good at times, and you might for a time try this and the salting. Cutting down while the plants are in the greenish stage has a very weakening effect and is so simple as to be worth a trial.

## SOCIETIES.

### THE GREAT INTERNATIONAL EXHIBITION AT GHEENT.

THE following is an abridged report of the chief classes at the centenary exhibition of the Royal Agricultural and Botanical Society of Belgium, opened at Ghent on the 25th ult. The show was generally considered to be the most extensive and comprehensive ever seen in Belgium.

#### ORCHIDS.

Major Holford, C.I.V., C.V.O., Westonbirt, Tetbury, Gloucestershire, erected one of the prettiest and most comprehensive groups of Orchids in the show. The centre was occupied by a magnificent plant of *Cymbidium eburneo-lavium*, which carried about twenty large spikes of well-developed flowers. At the back and flanking this plant on either side were superb specimens of *Odontoglossums*, while in the front were smaller choice plants of such subjects as *Cattleyas*, *Brasso-Cattleyas*, *Cypripediums*, two very fine *Sophranites*, a large spike of *Cymbidium lowianum* Pitt's variety, *Miltonias*, an interesting specimen of *Bifrenaria Harrisoniae*, *Brasso-Cattleya* Mrs. J. Leeman, a fine plant of *Cattleya Mendelii* Westonbirt variety, with many other handsome sorts. The whole were splendidly grown, and the arrangement, with graceful *Palm*s, was such as to excite universal admiration. It was almost impossible to examine this fine display in detail owing to the numerous visitors that were constantly admiring it. The Orchid palace was the name generally applied to this masterpiece of British skill, and although it was not entered for competition the society awarded it an *œuvre d'art*.

The wonderful display of *Odontoglossum* hybrids that was staged by Mr. Ch. Vuylsteke, Loochristi, was probably the finest and most interesting ever seen at any exhibition. They were superb, and the immense range of variety was marvellous. Not only has this raiser advanced this popular race of Orchids in the markings, but the flowers shown also had distinct and unique ground colour, excellent form and were of splendid size and robust habit. What more can one desire? Perhaps the most remarkable of all were those in which yellow predominated. Of these the following were the most conspicuous: *O. loochristiense* Jusundum, white ground, mottled brownish crimson, with deep yellow edges; *O. wilckeanum* Clio; *O. wiganianum* Lucretia, deep yellow ground, spotted and mottled chocolate; *O. flavescens*; *O. lawrenceanum* Triumphale, deep yellow ground colour, which is almost obliterated, except at the tips, with rich dull crimson blotches; and *O. excellens* Apollo, bright canary yellow, with crimson markings. We might very well fill a column about the many good things to be seen in this exhibit, but lack of space forbids.

In a class for twelve *Odontoglossums*, Mr. Graise of Amiens staged some very choice forms in a glass case. *O. crispum* Orange Queen is a distinct plant with good-sized heavily spotted flowers and a decided orange tint in the mottling; the labellum has the characteristic yellow blotch in the centre. *O. ardentissimum* La Gloire, heavily mottled with magenta-purple; *O. a. President* Colliere, lilac tinted; *O. a. Empereur des Indes*, broad white margins to the petals with centres of purplish crimson; *O. Arlequin*, a twisted petalled variety with brownish crimson spots and blotches; and two plants of *Odontodia devoniana* (O. Edwardi X *Cochlodora uetzeliana*) were the finest of a very choice collection. One hundred franc médaille d'Or.

Mr. A. A. Peeters, Brussels, also had a very choice little collection of *Odontoglossums*, several very taking plants being among them. Continental raisers are evidently well to the front in taking advantage of the many possibilities to be derived from this genus.

The first prize for a specimen *Cymbidium* was won by M. J. de Hemptinne, with a grand plant of *C. lowianum*, which was carrying about twenty-five fully-developed spikes of good-sized flowers. The plant measured nearly 6 feet in diameter, and was a very good example of cultural skill.

#### GREENHOUSE FLOWERING PLANTS.

These were represented in moderate variety, although they do not seem to be quite so popular as they are at home. Messrs. Hugh Low and Co., Royal Nurseries, Enfield, Middlesex, staged a wonderful exhibit of winter or perpetual-flowering Carnations, which were arranged in magnificent style. The flowers were really grand examples of cultural skill, all being very large, of splendid substance and well-defined colours. *Lotus peltorhynchus* and moss formed a good groundwork. The flowers were arranged in vases of varying heights, two moss-covered pillars, adorned with white and red blooms respectively, occupying a central position. Several Orchids were placed at the end, a specially fine-flowered specimen of *Cattleya Mendelii* being noticed, the blooms of which were very large and of grand form and colouring. White Perfection, Britannia, Enchantress, Griffamme, Nell Gwynne, Winsor, Aristocrat, Mikado and a yellow seedling were some of the best Carnations. As this group was not staged for competition no award was made.

Mr. C. Engelmann, Saffron Walden, Essex, also exhibited a very fine group of these Carnations, the blooms being staged in vases so as to form a bank-like mass. The flowers were all of excellent quality and were most tastefully arranged with *Asparagus plumosus nanus*, thus providing a very pleasing foil of greenery. This group received an *œuvre d'art* and a 100 franc medal was awarded for Queen Carola, a magnificent new deep crimson variety not yet in commerce. It very much represents huge blooms of the Old Crimson Glove and has also the scent of that old favourite. It is a true perpetual-flowering variety and has splendid stout stems and non-splitting calyces. Other fine flowers in this group were

Rose Pink Enchantress, My Maryland, Beacon, White Enchantress, Lady Bountiful and Mrs. E. A. Patten.

Major Holford exhibited a very fine group of *Hippeastrums* in great variety, red, white and pink forms being represented in profusion. This group formed a semi-circular bank some 20 yards long, light *Palm*s being used as a neat and graceful background, with moss as a carpet. The flowers were magnificent, and it was pleasing to note that the anthers had been left on, thus allowing the flowers to be seen in a natural state.

Messrs. Ker and Sons of Liverpool were highly successful with a group of these plants entered in the class for the most beautiful group of seventy-five specimens. The first prize was awarded for the whole group, first for the best collection of forty plants, first for a collection of six novelties, first for a collection of six novelties (white-flowered varieties), and first for the best new variety or of recent introduction, this being Rose Perfection, a large, well-opened flower of a most charming rose colour. The varieties that won the first prize for the best six novelties were *Persephone*, white and red; *Fairy Queen*, white, lightly striped red; *Exquisite*, red, with white at the edges and tips; *Lord Kitchener*, deep crimson, no green in the throat; *Emperor of India*, glowing scarlet; and *Goliath*, red and white. The whole of the plants in this remarkable group were first-class, and we have never seen them better staged.

Messrs. Vilmorin-Andrieux and Co. of Paris in Class 13 had some very fine varieties of *Primula obconica*, *Anemulas* and quite a unique large-flowered hybrid *Cineraria*, the colour being dull scarlet. This was generally regarded as the best novelty among florists' flowers in the show. It was raised from seed in 1905, and will not be distributed until 1909. Certainly this variety stands quite alone so far as colour is concerned, and is possibly the forerunner of numerous varieties having red or scarlet in their colour composition. First prize.

Adjoining the above group was one by the same firm composed of other large-flowered *Cinerarias* in excellent colour shades, all the plants being very robust and floriferous. First prize.

A very interesting group was one staged by Messrs. B. Herreweghe and Sons, Brussels. This consisted of about fifty plants of *Chrysanthemum* Mme. Gustave Henry, these being only about 1 foot high, with a single stem, this being surmounted by a good-sized flower. Although interesting as showing what can be done, *Chrysanthemums* in April are not wanted by most people.

#### AZALEAS AND RHODODENDRONS.

The Azaleas at Ghent are the most conspicuous feature of the exhibition, the greater part of the large temporary building being occupied with splendid examples of these plants. In the centre of the building large beds of symmetrical and very floriferous plants were arranged, these being flanked on either side and at each end with other various-shaped groups, the whole presenting a most bizarre and gorgeous spectacle. The high state of perfection to which these plants are cultivated in Belgium is proverbial, and the world-wide fame was well upheld on this occasion. The following were some of the most notable groups in this section:

A large semi-circular group staged in the centre by Mr. A. D. D'Haene, Brussels, consisting of various-coloured forms of *A. indica*. These were magnificent plants, the colours ranging from pure white through whites and pinks, apricot, magenta, red, scarlet and crimson. This group was awarded a first prize.

The oblong group of *A. indica* variety staged by M. Anguste Haerens was exceedingly good. The plants were simply masses of grandly-coloured flowers, scarcely a leaf being visible. The arrangement was in the form of a bank, falling gently from a raised centre, thus showing the plants off to advantage.

A. D. D'Haene was awarded the first prize for a marvellous lot of *A. indica* forms grown in large tubs. These plants constituted the best exhibit of Azaleas we have ever seen. Many of them measured over 5 feet in diameter, and in shape resembled huge floral umbrellas. The colours were particularly well defined, and as examples of high-class culture these plants would be very hard to beat.

Mr. Ch. Vuylsteke's first prize group of twelve *A. indica* cultivated as pyramids was a most gorgeous one and created a great deal of interest. Every plant was trained in true pyramid fashion, and the flowers were produced in abundance on fine, healthy-looking plants.

In the class for twenty-five *A. indica*, cultivated as pyramids, the first prize was secured by Messrs. Sander and Son, St. Albans and Bruges, for a very fine lot indeed. All the plants were the picture of health, and for good shape and floriferousness would be very hard to beat. Le Printemps is a very fine glowing scarlet single; President Oswald de Kerehove, a double salmon pink with red markings at the bases of the petals; and John T. D. Llewellyn, double, flesh coloured, with red in the centre.

For twenty-five *A. indica* Julius Roehrs, a bright cerise-coloured double-flowered variety with waved or crimped petals, Messrs. Sander and Son were again the champions. This is a very handsome variety, the flowers being large and of good substance. For a collection of forty *A. indica* Messrs. Sander and Son secured second prize with a very beautiful lot of plants, these being mostly umbrella-shaped. We particularly noticed Baronne de Vrière, a large single white; Professor Wolters, single shell pink, with red in the centre and beautifully waved petals; and Charmer, a bright cerise single that is very floriferous.

Mr. Edward Pynaert-van-Geert, Ghent, secured the first prize for a sloping bank of seventy-five *Rhododendrons* in flower, not less than three varieties. All the plants here were good and flowering freely, but the colours of the blooms were not first-class. The same firm was also first for twenty-five specimen plants of *Rhododendrons*, which

were very tastefully arranged in a sloping bank. The colours here were much better, Lord John Broughton, a very deep pink variety, being particularly good.

Messrs. Endtz, van Nes and Co., Boskoop, Holland, staged a charming little group of *A. mollis sinensis* Mrs. A. E. Endtz, a deep yellow-flowered variety that is well known in this country. The blooms in this instance were a richer golden yellow than usual.

#### FOLIAGE AND FLOWERING STOVE PLANTS.

Judging by the exhibition these plants are much more in demand on the Continent than they are in this country, many magnificent specimens of various kinds being most beautifully arranged on the ground floor of the casino. Viewed from the landing at the top of the stairs the spectacle was very fine and provided a good example of the usefulness of this class of plants for certain purposes. Ferns, *Caladiums*, *Crotons*, *Palms*, *Dracenas*, *Marantas*, *Dieffenbachias* and similar plants were used in profusion, masses of scarlet being provided by enormous plants of the curious-flowered *Anthuriums*.

The exhibit of foliage plants staged by Messrs. Sander and Son in the class for a collection of twelve specimens of recent introduction and not yet in commerce was very fine indeed, and the jury awarded it the first prize. Some of the most interesting plants were two of *Pereskia godsefiana* trailed round wire balloons, *Cocos nucifera* aurea, a form of this well-known Palm with golden-coloured petioles; *Croton* Fred Sander, a very compact plant with hastate leaves, which are bright canary yellow at the base and dark green at the apex; *Caladium* Sander's Seedling, a beautiful bright rose-coloured large-leaved specimen; a very fine specimen of *Bromella* tricolor, a fine species with white, green and pink variegated foliage; *Philodendron Ilsemanii*, a *Caladium*-like plant with green and white variegated leaves; and *Pinanga* Micholitzii, a mottled green-foliaged Palm with a tinge of pink in the young leaves.

In this section the magnificent groups staged by Continental nurserymen were very fine, the large ground space allotted to each being tastefully filled with plants in the pink of condition. Messrs. L. Van Houtte, Ghent, received several prizes in various classes with superb plants of such things as *Caladiums*, *Crotons*, *Heliconias*, *Dieffenbachias* and *Dracenas*. M. Victor Hensel-de-Meester was another prize-winner in this section with splendid groups, consisting of *Caladiums*, *Nephtys picturata*, immense *Crotons* and *Maranta oppenheimiana*.

For a collection of twenty-five *Anthuriums* in flower the first prize went to Mr. Arthur De Smet, Lederberg. These plants were very bright and artistic, many colours being among them. One huge specimen of *A. scherzerianum* was carrying twenty-nine fully-developed and good-sized flowers, with an abundance of healthy foliage. In a class for a collection of twenty *A. scherzerianum* varieties the same exhibitor was once more first, the many beautiful plants making a very fine group.

For a very bright and beautiful group of *Crotons* the *œuvre d'art* was awarded to Mr. L. Delarue-Gardon, Lederberg. These plants were magnificent examples, the foliage being remarkably bright and clean.

A replica of the first exhibition held by the society a hundred years ago at "Frascati" was a most interesting feature of the show, and the small room of the inn was thronged with visitors all day long. The same kinds of plants as were shown then were on view, and included such old favourites as *Plumbago rosea*, *Justicia pulcherrima*, *Cineraria cruenta*, *Scilla maritima*, *Andromeda lucida*, *Erica herbacea* and the ever-popular *Heliotrope*.

#### FLORAL DECORATIONS.

For a natural effect of water and rock scenery the exhibit arranged in the temporary structure by Mr. De Smet would be very hard to beat. Painted scenery, representing rockwork and a pool of water, was fixed at the back, and in the front was a groundwork of moss with dried-up rivulets, rocks jutting out of these in a most natural manner, suitable dwarf-flowering shrubs being irregularly inserted so as to produce a unique effect.

The collection of various floral decorations from Lachaux, Paris, was a very fine example of floral art. The circular table was very pretty indeed, a tall vase filled with *Odontoglossums*, *Cologynas* and *Cattleyas*, with *Asparagus Sprengeri*, *A. plumosus* and *Smilax* for the greenery being used as a centrepiece. Under this long sprays of *Odontoglossum* and *Asparagus Sprengeri* were tastefully arranged on the cloth. Other vases and contrivances for holding flowers were filled with Orchids, Carnations, Roses, Lilies and other florists' flowers.

British horticulturists were well to the fore on the various sections of the jury, the following holding special posts: General secretary, Mr. R. W. Ker. Section 1, Mr. Harry J. Veitch, president; 2, Major Holford, president; 4, Mr. M. S. L. Low, secretary; 6, Mr. G. Gordon, president; 17, Mr. J. Weathers, president; 20, Mr. C. H. Curtis, secretary; 23, Mr. G. Paul, president.

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The quarterly meeting of this society was held at the Horticultural Hall, Vincent Square, Westminster, on Monday evening last, Mr. Charles H. Curtis in the chair. Five new members were elected, making a total of thirty for the quarter. Several cheques were passed, being payments to members over seventy years of age and others, including a payment of 2s. to a member who lapsed thirty years ago. Members over sixty years of age may now withdraw the interest on their deposit account, and several avail themselves of this privilege, as it enables them to pay their subscriptions more easily. The committee hope that many young gardeners will join the society during the year. Rules may be had from the secretary, Mr. W. Collins, 9, Martindale Road, Ballham, S.W.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden. W.C.

## THE MEANING OF TULIP TERMS.

THE following list of technical terms used in connexion with Tulips is arranged in alphabetical order, and contains those most frequently met with at the present day. I have tried to make the explanations as simple as possible and not too long.

*Base.*—The base of a flower is its bottom; it varies very much in its colouring. In a florist's Tulip it must be either pure white or yellow, whereas in *T. gesneriana* it is of a deep rich blue, and in *T. Didieri*, black with a yellow edge.

*Bizarre.*—This French word means strange or unconventional. It is now used to denote those flowers that have a yellow base, and which, when they break, have a yellow ground with markings of some shade of red or purple. In the early days of Tulip growing these yellow ground flowers were thought very little of.

*Breeder.*—When a Tulip is raised from seed it first blooms as a self, or it may be with a border of a lighter shade than the rest of the flower. In this state, before it breaks, it is called a breeder or mother Tulip. After a certain time the flower breaks, that is, it becomes striped.

*Broken.*—After starting life as a self-coloured flower, a time comes when the colouring matter appears no longer as a solid mass, but broken up in stripes and blotches. This may take place in two or three years, or it may be delayed for a very long time. It is a debateable question if this breaking is the result of maturity or disease.

*Byblæmen* is a term applied to broken flowers with white bases and white grounds. Originally it included both purple and red striped flowers, but its use is now confined to the former, whereas the latter are called *Roses*.

*Cottage or May-flowering.*—Many of the most beautiful of the late-flowering section of garden Tulips were found in old cottage gardens, e.g., Mrs. Moon, Caledonia and Fairy Queen. Hence the name has been adopted for the whole late-flowering section.

*Darwin.*—A new and vigorous race of self or edged Tulips, which are distinguished not only by their tall habit and strong stems, but also by their well-formed, cup-shaped flowers. They were introduced into commerce in 1889 by Messrs. E. H. Krelage and Son of Haarlem. There are no bizzarres in true Darwins. To class such a flower as Yellow Perfection as one is really a misnomer.

*Dragon.*—See "Parrot."

*Duc Van Thol.*—A small class of very early-flowering Tulips, which are descendants of *T. suaveolens*, a small red flower with a yellow edge. It now includes forms which are otherwise descended. The so-called scarlet Duc Van Thol is not really a Duc Van Thol at all.

*Dutch* is a term applied to the early-flowering section from their being raised and grown so largely in Holland.

*English.*—English Tulips are florist Tulips of especially good and correct marking. In late

years the best have been raised in England, hence the name.

*Feathered.*—When a Tulip breaks the markings vary a great deal. Two particular variations have been singled out by Tulip fanciers as "correct." One is when the colouring matter is confined to the edges of the petals, leaving the body pure; this is called feathered.

*Flamed.*—When in a broken Tulip the colouring matter runs up the middle of each petal and branches out towards the edges, the marking is said to be flamed. It is interesting to note that the same variety may exist at the same time as a breeder, and as either a flamed or feathered flower.

*Flemish.*—A robust race of broken Tulips, not so finely marked as the English.

*Florist.*—Broken Tulips which are distinguished by their pure base, fine form and even markings. It would take too much space to discuss these points fully.

*Italian or Florentine* is used in connexion with those Næo-Tulips which in the course of the last century have been discovered in Central and Northern Italy.

*Late.*—That section which usually flowers in May and early June. Speaking generally, they are much taller and finer than the early-flowering Tulips.

*May-flowering* is synonymous with Cottage or late flowering.

*Mother* is the same as "Breeder."

*Næo-Tulips.*—One of the points of greatest interest in connexion with Tulips is the finding of new species in Italy, and Savoy in France, within the last hundred years. It is a difficult matter to account for their appearance, seeing that they have always been found near inhabited places that have been frequently visited by botanists, e.g., Florence and Bologna in Italy and St. Jean de Maurienne in Savoy. These new Tulips are spoken of as Næo-Tulips. Three examples are *T. Didieri*, *T. mauriana* and *T. billietiana*.

*Parisienne.*—Hardy late Tulips grown in the neighbourhood of Paris and distinguished by their long, wiry stems and elegantly-shaped flowers.

*Parrot.*—Tulips with split and irregularly cut petals and curiously striped and blotched marking. They have been known since 1665, but until the inclusion of a purple and white coloured one by Messrs. Barr and Sons last autumn, called Sensation, all Parrot Tulips have been bizzarres. Sensation is a sport which was found in Holland in a bed of a variety called Reine d'Espagne.

*Rectified* is the same as "Broken."

*Rembrandt.*—A new race of broken Tulips derived from the Darwins.

*Roses.*—This is the name given to broken Tulips with white bases and white grounds with red, or some shade of red, markings.

*Savoy.*—Those species of Næo-Tulips which have been found in Savoy are called Savoy Tulips.

*Self.*—Tulips which are entirely of one colour, excluding the base, are called selfs, e.g., Inglescombe Scarlet is a self although it has a black base.

*Species.*—Varieties which are of natural or wild origin, e.g., *T. fosteriana* and *T. sylvestris*.

It is used in contradistinction to garden forms, e.g., Inglescombe Park or Prince of Austria. JOSEPH JACOB.

## PRIZES FOR READERS. MAY.

### THE BEST FLOWERS AND SHRUBS FOR TOWN GARDENS.

A First Prize of **FOUR GUINEAS**,  
A Second Prize of **TWO GUINEAS**,  
A Third Prize of **ONE GUINEA**,  
And a Fourth Prize of **HALF-A-GUINEA**  
are offered for the best essays on the above  
subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Saturday, May 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NEW ORCHIDS.

### ODONTOGLOSSUM CRISPUM QUEEN OF THE EARTH.

In this plant we have a handsome variety that is a long way removed from the type. The sepals and petals are rather broad, sharply pointed, and very much waved at the margins. The white ground is heavily and irregularly mottled with brownish crimson blotches of varying size. The labellum is rather large, somewhat pointed, and is of the same colour as the other segments, except for the usual yellow blotch on the centre. The plant shown was carrying one inflorescence composed of eight fully-opened flowers and one bud. Shown by de B. Crawshay, Esq., Rosefield, Sevenoaks. First-class certificate.

### CIRRHOPETALUM ROXBURGHII.

This little plant is of botanical interest only, the tiny inflorescences of cream and purplish flowers being very inconspicuous. The leaves are ovate and of a dull reddish green hue. Exhibited by Sir Trevor Lawrence, Bart. Botanical certificate.

### CIRRHOPETALUM WENDLANDIANUM.

The plant shown was a rather small one, and had a single inflorescence composed of six good-sized flowers. The colour of these is yellow at the base and dull red from thence up to the apex. The blooms are very long and taper off to a sharp bifurcating point. Shown by Sir Trevor Lawrence, Bart. Award of merit.

### ODONTOGLOSSUM PLATYCHEILUM SUPERBUM.

Here we have a very nice variety of a comparatively little-known *Odontoglossum*. The flowers are conspicuous chiefly on account of the labellum, which is very large, broad, and of a deep lilac colour, this being freely dotted with rather small magenta spots. The flowers are borne mostly in pairs from the sheaths of the bright green erect leaves. Shown by Sir Trevor Lawrence, Bart. Award of merit.

### ODONTOGLOSSUM NIVEUM.

This plant may well claim to be one of the, if not the, most graceful of all this family. The rather small flowers are freely produced in compound racemes, which are erectly borne on

medium-sized wiry stems. The flowers are rather small, segments narrow and pointed and twisted in a most pleasing manner. The white ground is freely besprinkled with clear, rich crimson spots, except at the apices, where the white remains pure. The plant shown was a very vigorous specimen, and had two large inflorescences. Exhibited by Messrs. Armstrong and Brown, Tunbridge Wells. Award of merit.

### HIPPEASTRUM (AMARYLLIS) PURITY.

This handsome variety with its large snow-white blossoms marks the greatest advance in the white-flowered forms we have yet seen, as it surpasses *Snowdon*, another variety from the same raiser, both in its purity and its fixed character from year to year. The seed of the new comer was sown in 1904, and having now flowered for three successive years its albino character is regarded as quite fixed. According to Mr. Fielder, it is not unusual for these white-flowered varieties to develop a shade of pink in the second year, and for this reason *Purity* has been given a longer trial and has remained true. The plant, like other white-flowered varieties, possesses great vigour, and already several offsets have been produced. Shown before the Royal Horticultural Society by Mrs. Burns, North Mymms Park, Hatfield (gardener, Mr. C. R. Fielder), on the 28th ult. First-class certificate.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

May 12.—Royal Horticultural Society. Exhibition of Flowers, Plants, &c. Lecture at 3 p.m. by Mr. Osgood H. Mackenzie on "Gardening in the West Highlands." Vincent Square, S.W.

**The recent weather.**—We are afraid the recent weather will have played sad havoc with many crops and garden plants, Roses in particular. One well-known amateur rosarian confided to me that he had lost over 200 plants, but we hope such disasters are not numerous. Those who had not sown their seeds will rejoice now. Little progress was made, and in many instances resowing must be done. If the mild weather at the time of writing continues, the fruit crop should be good.

**Royal Horticultural Society**—At the fortnightly general meeting of the Royal Horticultural Society, held on the 28th ult., a lecture was given by Mr. E. White on the "Profession of Landscape Gardening." Mr. Harry J. Veitch was in the chair. In the course of his remarks the lecturer said how difficult it is to define the mission of a landscape gardener, whose conceptions are not confined to garden or park enclosures, but are stimulated by an appreciation of landscape scenery, and are anxious to bestow its beauties upon districts where they are non-existent; in fact, to make all Nature a garden. The present rate of disappearance of natural landscape by the rush for country dwellings is great, and to the landscape gardener devolves the work of preservation and use of natural features of beauty. He referred to the Town Planning Bill now before Parliament, and the greater demand for landscape gardeners indicated thereby. Landscape gardening embodied a wide range of subjects and a University training where possible was indispensable. In Germany the subject is an important one in all public and horticultural schools, chiefly that of Potsdam. In France the central institution is the Ecole Nationale d'Horticulture in Versailles. The subject is also taught in Austria. The United States affords the model precedent, for here the landscape gardening is considered very serious, and the subject is found in the curriculum of most of the leading universities, especially that of Harvard, whose course includes the

principles of landscape gardening, elementary botany, experimental physics, physiography, elementary geology, principles of design in architecture, sculpture, &c. The lack of similar facilities in England is a matter for comment, and should demand the attention of educational authorities here. Thirty-seven new Fellows were elected at the meeting, including Lady Grey, Captain Cuthbert, D.S.O., Captain A. H. Thorburn and Mrs. F. L. Joicey.

**Cardiff and County Horticultural Society.**—The annual exhibition of the above society will be held on Wednesday and Thursday, July 22 and 23 next. The schedule is a most comprehensive one and some valuable prize are offered in many of the classes. Thus in Class 1, for a group of plants, the first prize is £15; and in Class 2, for amateurs, for a group of plants, £5. In other classes, for Roses, amateurs and open, and also for Sweet Peas, valuable prizes of plate are to be competed for. Copies of the schedule and full particulars can be obtained from the secretary, Mr. A. Maurice Bailey, 24, Duke Street, Cardiff.

**Journal of the Board of Agriculture.**—The number of this journal for April, which commences the fifteenth volume, contains several new features of interest. The size has been increased from sixty-four to eighty pages, and the additional space has been and will in future be filled with a monthly article dealing with the course of trade in agricultural produce during the previous month. An attempt will also be made to print from time to time reports on the condition of crops abroad, especially on the Continent, and on the trade in those articles of agricultural produce which compete with home-grown produce. Two other series of articles have been commenced, the first on weeds, fungi and agricultural pests, to be illustrated each month with a coloured plate, the other, on the agriculture of small holdings, showing what methods have been adopted by those who have been successful, with suggestions for those who are about to take up new holdings. As it is intended that these articles shall be of service to all classes of agriculturists, the price of the "Journal" (4d. monthly) will not be raised.

**Presentation to Mr. John Leslie, Pitculen, Perth.**—Mr. John Leslie, who is one of the best known of Scottish exhibitors, especially with Grapes, at the leading shows, having been appointed gardener at Oxley Grange, Bushey, Watford, Herts, and therefore leaving his present appointment at Pitculen, Perth, shortly, his many friends decided to present him with a testimonial. The proposal met with much response, and a handsome sum of money was contributed for the purpose, among the subscribers being Lord Provost Gibson, Edinburgh, and Mr. R. Wallace, K.C., late M.P. for Perth, both of whom wrote expressing their great esteem for Mr. Leslie. The presentation was made recently, the meeting being presided over by Dr. Thomson, rector of Perth Academy, who expressed great regret at their loss of Mr. Leslie, and spoke highly of his work for the Natural Science Society. Afterwards Mr. James E. Fenwick made the presentation, which consisted of a photograph of a number of gardening friends and a purse of sovereigns. Mr. Fenwick referred to the high esteem in which Mr. Leslie was held, the regret felt at his departure and the hope that he might have every success in his new sphere of labour. Mr. Leslie made a feeling reply. Mr. Leslie's career during the twenty-four years which have passed since he went to Perth has been marked by many successes as an exhibitor. He is universally recognised as one of the leading growers of Grapes in Scotland, and his prizes at the great shows in Edinburgh and elsewhere have been very numerous. Last year his Grapes won five out of seven firsts at Edinburgh. As a judge he has always been of service, and his reputation as such is of the most honourable kind.

**The Cyclamen-flowered Daffodil.**

The quaint little *Narcissus cyclamineus* is not too easy to establish, but when once it has made itself at home in a garden it thrives well and delights all with its singular flowers. To begin with, the flowers are large for the stature of the plant; then the outer segments are reflexed in such a way as practically to expose the whole trumpet, which is long and cylindrical, and quite as lengthy as that of many of the taller trumpet Daffodils. The flowers are of a bright yellow and are of great substance, lasting for about six weeks—a long time indeed for a Daffodil to keep in bloom in the open. It seems strange now that, although known to Parkinson, it was lost to this country and only reintroduced a few years ago. It is now happily established in a number of gardens, and I was much pleased to see it doing so well in the garden of General Stewart, Carruchan, on the Kirkcudbrightshire side of the Nith, where, the other day, there were fully fifty blooms in perfection in a clump at one time. The group was an attractive one, and, as *N. cyclamineus* seems to be increasing from self-sown seeds as well as from offsets, this note may be encouraging to some who wish to try this unique little flower of its class, but who fear to do so. At Carruchan the plants are in an ordinary border facing almost south-west, and in what was an ordinary soil inclined to heaviness and of a rather clayey texture, but which has been much improved by the addition of plenty of old decayed manure for several years since General Stewart entered upon possession of the place.—S. A.

**THE ROSE GARDEN.****PLANTING TEA ROSES FROM POTS.**

**D**URING the next three or four weeks plantations may be made of Tea and Hybrid Tea Roses that have been grown in pots. If the beds are well prepared and good hardy plants obtained, these specimens, though somewhat small, will make a splendid display during the early autumn. Beds that have contained early bulbs may be profitably planted with the beautiful decorative Roses that are now so plentiful; and what can be more lovely or more useful than these Roses? They are far more pleasing than many of the so-called bedding plants, and are quite as continuous in their blooming. Most growers now graft or bud the Tea and Hybrid Tea Roses on the seedling Briar, and it is found that such plants will grow most luxuriantly when the roots lay hold of the new soil.

Even if it be not possible to plant at once, I would recommend that the plants be obtained as early as possible, as then they could be sent without their pots if the ball of earth is carefully matted up.

In preparing the beds, remember that these Roses are very partial to good drainage and also to a somewhat gritty soil. Where leaf-soil abounds this should be liberally admixed with the loam, and if some bone-meal be added to the bottom soil and a little spent Mushroom-bed manure to the top the plants cannot fail to do well. In planting it is most essential that the ball of earth be wet throughout. If at all dry, let them be soaked for a few seconds in water. Plant very firmly and lightly mulch the surface with short decayed manure. Unless very dry weather follows, no further watering will be required. I prefer to raise the beds at least 6 inches above the ordinary level.

Varieties depend upon what one has already in the garden, but one cannot have too many of such beautiful Roses as Mme. Abel Chatenay, Lady Battersea, Mme. Ravary, Joseph Hill, Gustave Grunerwald, La Tosca, Pharisaeur, Anna Olivier, Mme. Leon Pain, Mme. A. Mari, and G. Nabonnand. P.

**THE GREENHOUSE.****HOW TO GROW FINE COCKSCOMBS AND CELOSIAS.**

**A**MATEURS who have plenty of heat may raise these plants in March, but where artificial heat is derived solely from hot-beds the end of April or early in May will be soon enough to sow the seeds. Both Cockscombs and Celosias are suitable plants for a cool greenhouse during the summer months. *Celosia cristata* is the florists' Cockscomb.

The amateur should adopt the following method of growing the plants. Make up a good

AN INTERESTING PLANT PARASITE: OROBANCHA ON A PELARGONIUM.

hot-bed composed of sweetened stable litter and tree leaves in equal quantities. Put a frame on the hot-bed and cover the latter with a layer of ashes or Cocoanut fibre to a depth of 6 inches, then fill a few seed-pans or boxes with some light, rich soil, and sow the seeds thinly, burying them a quarter of an inch deep with the same kind of soil. In the meantime fill more pans or boxes with sandy loam two parts, leaf-soil one part, and well-rotted manure one part. The latter should be passed through a half-inch mesh sieve, so that the particles will mix evenly with the other parts of the compost, and place the filled boxes on the hot-bed.

When the seedlings are about 1 inch high transplant them 3 inches apart in the prepared boxes,

still retaining them on the hot-bed. In due time pot each seedling separately in 3-inch pots filled with a similar compost. Allow the young plants to remain in these pots until the "combs" form, and pick out all specimens that show well-formed "combs," then repot the plants loosely in very rich soil and plunge the pots in the hot-bed.

From this time do not allow the plants to become potbound, but repot them, finally using 7-inch pots. When the latter are well filled with roots begin feeding with weak doses of clear soot water and then with diluted liquid manure and other artificials. When the "combs" are about three-parts developed the plants may be placed in the greenhouse. It may be of some interest to mention here that the Cockscomb is an instance where fasciation has become a more or less permanent feature. The plants to many people are more interesting than beautiful, but there is no gainsaying the fact that a few well-grown specimens give an air of distinction to a greenhouse during the late summer months, and for this reason, if for no other, a dozen or so should be grown.

*Celosia pyramidalis* should be grown in a similar soil, but the seedlings should be transplanted direct from the seed-pans to pot separately, and be kept growing freely all the time, frequent repotting before the plants get potbound being the best way to ensure the quick growth. The crimson-coloured varieties should be picked out, as these generally give the most satisfaction, though a variety of colours may be obtained from a single packet of seeds, mixed, and all may be grown where desired. These plants are often used for bedding and are very beautiful; but if the foliage be kept quite free from red spider they make charming greenhouse and conservatory plants and last in good condition for many weeks. A bed of damp shingles or ashes is better than a dry, wooden stage. Put some slates on the latter and cover them with shingle or ashes. AVON.

**AN INTERESTING PLANT PARASITE.**

MR. W. L. LAVENDER, gardener at Waltham Manor Gardens, Twyford, Berks., sends us a most interesting example of the Broom Rape or Orobancha growing on a Pelargonium, which we have had photographed and reproduced herewith. His letter reads as follows: "This curious parasite occurred on a plant of Zonal Pelargonium Albion. I first noticed the growth pushing up about the end of January last and at once thought that it resembled an Orobancha, so I told the man who watered the plant not to interfere with it. The Orobancha grew rather quickly and commenced to flower about the first week in March, continuing in flower for nearly a month, and probably would have flowered longer. The host plant was grown from a cutting struck in April last in sandy soil and potted finally into a 6-inch pot last July. The soil at each potting was a mixture of fibrous loam cut from the top spit of a meadow the previous winter and stacked. The leaf-soil was composed of Oak, Elm, Beech and a few Chestnut leaves, thoroughly rotted, and the manure was from the stables and had been previously used for a hot-bed. Some mortar rubble, soot and sand completed the compost. The cutting was struck in heat, grown on in a cold frame for the summer, and during August and part of September placed on ashes in the open, and then returned to a cold frame for a week or two. At the beginning of October the plant was taken to the position it flowered in, this being a shelf exposed to all the light, close to the roof glass in a house kept at about 55° and freely ventilated. It was watered with manure water made from cow manure, also with soot water, and was occasionally sprinkled with Clay's Fertilizer. The cutting was one I had given to me, so I do not know if any parasites had appeared where it came from."

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Free-flowering Daffodils.**—In THE GARDEN of the 4th ult. a correspondent writes that he has had seventeen blooms from twelve bulbs of Mme. de Graaff. I have a large number of Daffodils, Tulips, &c., in moss fibre every year, between eighty and ninety pots, and I have never known them so free flowering as this year, with only one or two exceptions. I had three bulbs of Mme. de Graaff which threw seven blooms between them. One of Messrs. Barr's "extra" Narcissus Emperor threw six blooms; six bulbs of that lovely Barrii Mrs. C. Bowley have thrown twenty-one blooms; two very pretty seedlings from Mr. R. Sydenham of Birmingham, named Leonie and Saturn, threw, in nearly every case, two blooms to every bulb; and so the list goes on, one of the few failures being Golden Spur, which was very poor. Barrii conspicuus has also flowered far more freely than I have hitherto known it to do. Perhaps these details may interest other readers.—HELEN PITCAIRN.

**Saxifraga longifolia and offsets.** It would be interesting to know how many have observed offsets on the true Saxifraga longifolia, as the instances in which these have been observed must be rare indeed. During a somewhat long experience I have never seen an offset on any plants of the true form, and its bearing no offsets has been frequently mentioned. One of the latest instances is in Mr. Reginald Farrer's book, "My Rock Garden," in which he says: "After this (i.e., after flowering) the plant dies without offsets, but matures seed so abundantly that one has no difficulty in raising as large a stock as heart can desire. The true Saxifraga longifolia may always be known by this inability to throw any secondary growths, which, I believe, is invariable." There is, of course, a plant called S. longifolia prolifera which produces plenty of offsets, but no one would compare it or any other with the true longifolia, which admits of no rivals of its class. The broad-leaved longifolias are either hybrids, which are very common, or are reversioners to some earlier form from which the real longifolia has evolved.—S. ARNOTT.

**Dwarf Peas.**—I note a writer refers to Gradus Pea as being dwarf. Is not that an incorrect description of it? as although commonly described in lists as of 3 feet in height, yet it usually reaches 4 feet, and grown under glass would naturally be higher. This excellent first early marrowfat so closely resembles Early Giant that many gardeners class them as identical. In any case the latter form rarely comes under 4 feet when well grown. Really these Peas, with many others, all remarkably fine croppers, belong to the medium growth section, perhaps the most reliable average section of Peas for general cultivation. Still, some gardeners, where they have ample room and deep retentive soils, stick to Duke of Albany, Alderman, Ne Plus Ultra and Quite Content, Peas which range from 6 feet to 7 feet in height. Really Dwarf Peas are found in Harbinger, William Hurst, English Wonder, Defiance, Chelsea Gem, Daisy, Omega and several others, none of which exceed 2 feet in height, and some are not more than 18 inches in height. These are universally classed as Dwarf Peas.—D.

**Leaf-curl on Peaches in New Zealand.**—I wrote you six or eight weeks ago re the dressing of Peach trees for leaf-curl with refuse of acetylene gas. I am pleased to say I have found what appears to be a complete cure for it. I was spraying some plants for green fly with Sunlight soap when I thought I would try it on the Peach trees. Its effect was marvellous; they were in a very bad state, with most of the foliage dying, and the fruit was about the size of Hazel Nuts. They commenced to send forth new shoots at once, and are now

maturing a splendid crop of fine fruit, with no sign of disease on the trees. Before saying anything further on the subject I would like to test the treatment a second time, and I cannot do that here for another season. It will be your spring when this appears, so readers in the United Kingdom can test it. I did not use a strong solution; four pennyworth of soap should make 6 gallons to 10 gallons of wash. I may state that a week or two before using the soap I washed the trees with a strong jet of fresh water, but I do not think that had much to do with the result.—J. G. PATERSON, *Fimarn, Canterbury, New Zealand.*

**The Gooseberry mildew.**—A serious case for the British taxpayer is raised when a deputation of Gooseberry and interested mycologists invites the British Government not only to at once order the destruction of any Gooseberry plantation, however large, in which any evidence of the mildew may be seen, but asks that with such order ample monetary compensation might be provided also. Are these Gooseberry growers willing to insure their plantations against attacks, or do they think the national purse is as deep as the ocean? They even object to the grower whose Gooseberry breadth may be affected from cutting out and burning the affected bushes, but insist on total destruction with consequent compensation. How many otherwise old and nearly exhausted plantations rapidly becoming worthless and perhaps also because of bad culture a ready prey to fungoid attacks it might not thus be profitable to destroy and get compensation. If compensation be paid for the Gooseberry mildew, why not for the Currant mite or for any of the many ills to which vegetable life is heir?—A. D.

**Elementary school gardening.**—That this form of gardening has become very popular as well as interesting to the public at large is evidenced by the special literature now devoted to it, and also, as shown in THE GARDEN, by the offer of prizes for the best essays on the subject. I would ask room to refer to a few of the points raised in Mr. Waldron's prize essay, recently published, because I think them open to criticism. It by no means follows that gardening is a subject specially fitted for village schools only. Children in villages are, by reason of their rural surroundings, brought naturally more in contact with Nature and with gardens than are children in towns, and as a result, when town children are afforded a chance to garden at school, they do so with an avidity and an enthusiasm that is delightful to see. If anything could, later in life, help to lead town men back to the land, it would be because of the earnest desire latent in them to put into practice that instruction at school which they have not forgotten and have warmly cherished. Mr. Waldron favours plots for two boys to work simultaneously. That is not by any means either good practice or common experience. Both teachers and boys prefer individual gardens. Not only does each boy take more pride in working his own plot, but he also seeks to emulate the best work done in any one plot. The pupil cannot shelter himself behind his fellow when he is responsible for the plot solely. It is advised that drills run north and south. That is based on the assumption that all school garden plots run east and west. Practically, they have to be fashioned in accordance with the shape of the land out of which created. It is a fallacy also to assume that it is best to have rows north and south. All the crops in the gardens are summer ones, and have to make their growth through hot, dry weather. When rows run north and south, the intermediate soil is fully exposed, the hottest rays of the sun scorching it. When rows run east and west, one crop shades the soil behind it, and thus it is less dried. Why do gardeners so prefer the shade of a north wall for summer crops but for that reason? Sowing two rows each on a plot of limited area of spring-sown Onions, Parsnips and Carrots, when one

row of each will suffice, thus shutting out Beet, Turnips and Dwarf Kidney Beans, is not good. Then Potatoes should have two rows, diverse varieties. Runner Beans may be in back corner clumps, leaving the space behind the row of Peas for Lettuce, Radish, Tomatoes or bush Marrows. Leeks, Celery, Brussels Sprouts, Broccoli, Cabbage, Kales and Cauliflowers, also, later, winter Onions, should all be sown in drills in a spare plot for transplanting when Potatoes, Peas and Kidney Beans have been removed. It is unwise to occupy the boys' plots with these things until later in the season. Mr. Waldron is not quite exact in classing Pentstemons, Snapdragons, Hollyhocks and Forget-me-nots as perennials; all have somewhat fugitive existence. I greatly prefer that at the first boys should be instructed in the proper measurements between the rows. But for some such instruction the first year the result would be distressing. In the second year they should have less restriction, but still have the most active oversight. Defects in these respects would be less attributed to the pupil than to the teacher. The proposal to give the boys prizes for good work in the shape of garden tools is altogether wrong. Seeing that in all schools proper tools are found, such prizes would have little value. Much better would be concise, clear, practical and well-illustrated books on gardening, as boys much appreciate these. Generally, in the county of Surrey, where local prizes are offered for boys, the judging is done by the county instructors on precisely the same basis as cottage gardens and allotments are judged. In some cases boys' garden produce is exhibited for prizes also. What would be far more satisfactory would be a county exhibition of school garden produce, each year each block of gardens competing, and not individual pupils. Without doubt, school teachers—where good gardeners, as many are—make the best teachers of gardening, as they have the art of teaching which the best of practical gardeners may not possess.—A. D.

**A good wall plant.**—I do not remember having seen Xanthoceras sorbifolia mentioned as a suitable plant for covering a wall, but for such purpose, however, it is highly satisfactory. As much cannot be said for it when planted out in exposed positions, for in such places it will grow often too fast to mature its growth sufficiently to produce flowers. There was a plant growing here for a great many years in such a place, but it never flowered. Some four years ago two plants were turned out of pots after being forced. One was planted against a wall with full south aspect, the other on a wall facing full west, and both have flowered very freely each year, with this difference only, that the one on the south wall is six or seven days earlier than the one on the west. Both plants grow very fast; the one on the west wall made growths 2 feet in length last year, and these were nailed to the wall and are now just opening their first flowers, nearly every growth being terminated by a truss of bloom. At the present season I do not think one could desire a finer flowering shrub for a warm wall, and when associated with Pyrus japonica must be most effective. I have no doubt that this fine plant would flower quite freely on a warmer soil than ours, and where a little protection was afforded by adjacent shrubs or trees. Evidently all that is required is thorough ripening of the wood. Coming into flower thus early it would be liable to injury by frost if exposed. One can also imagine a fine effect produced by this and various sorts of Magnolias. As to soil it is evident that it is not at all particular, any fairly good garden soil proving suitable, but thorough drainage is essential.—T. A., *Girencester.*

**Birds and buds.**—This neighbourhood seems to suit the bullfinch admirably, judging by the quantities that visit these gardens from the adjoining woods. They appear to commence their work of destruction about the first week in December or as soon as the leaves are off the

trees, and they have not done with the buds until the latest Apples are well in bloom. Commencing with the Forsythia, then on to Malus, Pyrus, Plums, Lilac, Weigela, Thorns, Almonds, Crabs, &c., and, of course, the Pears, Gooseberries, Currants (Red and White), Peaches, Nectarines, Apples, &c., the bullfinch would appear to be a most methodical bird. Sometimes it is argued (and rightly) that the bullfinch is not responsible for all the damage done; but they must have the major part of the blame, as I have not noticed any other bird at the buds, except when sharp frost and snow prevent their usual food from being got at. Coming to the various ways of preventing the buds being taken, it is entirely out of question to net every exposed fruit tree, &c., in the garden, and as the weather destroys the effects of soot, lime and such things very quickly, the best method we find is the gun with small shot. Having kept an accurate account for the past four winters I find the bag is 110, 116, 128 and up to the 12th ult., 158. I am quite at a loss to understand the *crescendo* in numbers, as we quite expected to record a *diminuendo*. However, perhaps in some neighbouring gardens it is thought to be hopeless to cope with these pests, judging from the amount of wire netting one sees about. Despite the frequent use of the gun here we boasted some half-a-dozen nests last summer.—J. G., *Battledene, Newbury.*

## NOTES FROM GLASNEVIN BOTANIC GARDENS.

A WONDERFUL PITCHER PLANT (NEPENTHES RAJAH).

THE collection of plants at the Glasnevin Botanic Gardens is known to include a great many rarities, and among them this *Nepenthes* holds a foremost place, Edinburgh being the only other collection in the British Isles which includes this plant. Borneo is its native country, where it was originally discovered by Sir Hugh Low, but the late Mr. F. W. Burbidge introduced it to cultivation in 1881, and it was then cultivated for a time by Messrs. Veitch and Sons. The Glasnevin plant is one of three seedlings from Messrs. Veitch's original importation; the other two seedlings died. Mr. F. W. Moore first gave these seedlings the usual hot and moist conditions required for *Nepenthes*, but seeing they did not grow satisfactorily, the last remaining plant was placed in a cool Orchid house, where it has remained ever since. Many species of *Masdevallias*, &c. are grown in this house, the temperature being kept at 50° to 55°, rising with sun-heat. After about twenty-six years' cultivation the three essentials laid down for its cultivation—namely, moisture, shade and an intermediate temperature—still hold good. The original plant grew rather tall, so the head was taken off and an effort made to strike it, but this failed in consequence of forcing. Fortunately, the old stem gave a break at the base and continued the life of the plant; in time this plant also got rather tall and leggy and the process of topping was repeated, and the break from the base is the plant now at Glasnevin. This time, before the head was severed, it was partly cut through some time previously and carefully mossed round, and now is making a small plant.

In its native habitat it is described as a terrestrial shrub about 4 feet high, rusty pubescent in all young plants, the leaves are thick, leathery and oblong, measuring 5 feet to 6 feet in length, including the tendril and pitcher, the pitchers having a capacity of two quarts. The plant in cultivation here is 2 feet in height, the leaves, exclusive of tendrils, are 14 inches long by 6 inches wide, while the largest pitcher holds about three-quarters of a pint. The rims or collars of the pitchers are showy, being very broad and of a rich reddish brown. The plant

has recently made four good leaves, which give promise of fine pitchers for this season.

### HIPPEASTRUM PROCERUM.

This *Hippeastrum* is a most distinct plant, differing greatly in colour and general habit from the majority of the other species of the genus. The bulb is large, in shape like an elongated flask, and covered with membranous scales. Arising from this sheath of scales are thick and sickle-shaped leaves, with a whitish, cartilaginous margin. The flower-scape bears several flowers, which have strong resemblance to those of the *Crinum*, but they are light bluish purple in colour; in diameter they measure 4 inches to 5 inches, with a length of 6 inches, the whole plant reaching about 2 feet 6 inches in height.

The bulbs will flower in a house from which frost is excluded, but as a rule it cannot be said to be a satisfactory plant under cultivation; it is found that strong imported bulbs give the best results. So far hybridists have not been successful in utilising its colour by crossing. Mr. Williams of Bahia was the first to introduce this plant from Brazil. In the year 1870 it was flowered by Dr. Rayner of Uxbridge, and is figured in the *Botanical Magazine* t. 5883 as *Amarylhis Rayneri*. C. F. B.

## INSECT PESTS.

### EARWIGS.

FEW insects are better known or less liable to be mistaken for another insect than earwigs; they are common everywhere, and are very troublesome and annoying in gardens, sometimes in dwelling-houses. That earwigs are not favourite insects there can be no doubt; but like many other creatures and things, they are not so black as they are painted, and in spite of the story that is so often repeated about their getting into persons' ears and brains which cause madness and death, they never do so. As a matter of fact they could not enter the brain, as the passage is blocked by the drum of the ear. It is curious, however, how universal this idea is, for in many European countries they are known by names which allude to this superstition. For instance, in France they are known by the name of *perce oreille* or ear piercer, in Germany as *ohrwurm* or earworm. Another superstition is that they do not fly. It is true that they are seldom indeed seen on the wing; but as they usually hide themselves during the day, only feeding and moving about at night, it is not to be wondered at that they are not seen in the act of flying. That they do fly is a well-proved fact, and their wings are such complex and wonderful pieces of mechanism that it is most unlikely that they would be provided with them if they were of no use.

Earwigs are a certain benefit, as they kill thrips and aphides. They are very cleanly insects in themselves, and always look bright. They have, moreover, a strong maternal instinct, which is not the case with most insects, who, having laid their eggs after the manner of their kind, appear to take no more thought about them, and leave them to take their chance in this inhospitable world. Not so with the earwig, who after depositing its eggs in a suitable place, sits on them as a bird would, and even broods over the young ones. Earwigs are very voracious, and chiefly feed on the flowers and leaves of various plants, the petals of Dahlias, Chrysanthemums and Carnations being their special favourites. They often attack fruit, especially Apricots, Peaches, Nectarines, Apples and Pears, and spoil Cauliflowers by creeping into them and rendering them dirty and unfit for use. They seem to have no objection to animal food, and, as already mentioned, sometimes feed on smaller insects. They have been known, when

other sustenance fails, to feed on one another. These insects hide during the day in all manner of different places; in fact, wherever there is a crack or crevice into which they can creep. They often hide in or among the petals of flowers, and have many natural enemies. Various birds, toads and some of the larger predaceous beetles are very fond of them, and many fall a prey to parasites. In the open air I cannot recommend any better method of destroying them than the old-fashioned one of trapping them, which may be done in various ways. Small garden pots filled with dry moss or crumpled paper placed inverted on the top of the stake or stick by which the plant is supported, pieces of Reed, Bamboos, the hollow stems of Sunflowers or Broad Beans, or, indeed, the stems of any plants which are hollow, cut into lengths of about 9 inches, placed among the stems or branches of the plants are very useful traps.

Pieces of crumpled-up paper or canvas laid among the shoots are also useful, and lengths of canvas or sacking folded loosely several times and laid on the ground near plants which are attacked by these insects may be used for the same purpose. Smearing the inside of any of these traps with a mixture of beer and treacle will render them more attractive. They should be examined every morning and the insects that they contain blown or shaken into a vessel of water into which sufficient paraffin oil has been poured to form a thickish film on the surface. This will soon kill them. Earwigs are able to move so rapidly that it is useless to try and spray them with any insecticide. Of course, by this means their food may be poisoned, but flowers and fruit cannot be treated in this manner. Though they often infest dwelling-houses, they do no harm as a rule, but they have been known to destroy insects which entomologists have inadvertently left within their reach on setting-boards; and a correspondent wrote recently saying that "they have invaded a country house to the destruction of all things therein." One can only imagine that this statement was intended to be taken with the proverbial "grain of salt," and that there were certain exceptions; but what articles were really destroyed unfortunately the "deponent sayeth not." It is difficult to suggest any method for destroying this insect in rooms, except by fumigation with hydrocyanic gas, which would be a very dangerous operation, as it would be so difficult in most rooms to open the windows from outside without inhaling some of the gas.

Earwigs are so well known that it is needless to give any description of them; but I may point out that the males may be known from the females by the shape of their pincers. Those of the male are curved, meeting only at their tips, while those of the female are nearly straight, only just the tips being curved. They are made great use of when the insect wishes to fold up its wings, which, as I have before mentioned, are very delicate and complex organs. The front pair are like those of the rove beetles (or *Brachelytra*), form short wing-cases for the other, which are many times larger, and, in order that they may be protected by these cases, they are folded in the most elaborate manner; they are kept expanded by a series of nervures, which radiate from a point like the framework of a fan. When the wing closes it does so just like a fan; the end half can then be folded back upon the other half, and with another fold, which it is impossible to explain in a few words and without a figure, the entire wing, with the exception of the hardened tip of the now tightly-folded organ, is covered by the wing-case. The young earwigs much resemble their parents in form, but they have no wings and are quite white. There are eight different kinds of earwigs native to this country; only two, however, are common. Besides our well-known species (*Forficula auricularia*) there is a much smaller species (*Labia minor*), which may often be seen flying about in the evening, but it is not recognised as a pest in any way. G. S. SAUNDERS.

## THE FLOWER GARDEN.

### ANEMONE BLANDA.

THE accompanying illustration shows one end of a broad edging of this Anemone in an exposed portion of one of my beds for herbaceous plants. The clump shown is a very early pale blue form, which generally shares with the Winter Aconite the honour of being one of the first dicotyledons to show flower in the new year. The outsides of its sepals have a decidedly rosy tint, but when expanded in the sunshine they are a clear Nemophila blue, with a white eye to the flower. Adjoining it in this bed are patches of other forms of *A. blanda*. This pale blue one is always the first in flower, closely followed by the pure white. Then comes the deeper blue form known as Ingram's variety, and, latest of all, the beautiful *v. scythnica*, with deep blue outer but brilliantly white inner surface, which is perhaps most lovely when the blossoms are only half expanded and showing both the blue and white sides. I find these forms seed very freely, and a large number of the seedlings are of the *scythnica* coloration. I have a very deep blue form, quite purple in the bud, which only thrives here on the shady and northern slopes of the rock garden, and never makes a good tuft as do the forms above mentioned, a few flower-stems appearing each year 2 inches or 3 inches apart. A beautiful rose-pink form a generous friend gave me lately promises to be

one of the most charming of early spring flowers, that particular colour being rare in the two first months. The finest form of all, however, is the beautiful double one, of so deep a blue that it becomes purple in the centre of the flower. This is only to be seen in one garden—in the West of England—where it suddenly appeared one spring, a spontaneous tribute from the grateful garden to reward the many years of loving care bestowed on it by its learned master. Long may they both flourish there!

Waltham Cross.

E. A. BOWLES.

### A QUICK-FLOWERING ANNUAL.

(*EUCHARIDIUM GRANDIFLORUM ALBUM*.)

THERE is little in the appearance of this plant or its flowers to suggest the Fuchsia of either our gardens or greenhouses, but this fact serves to show that it is unwise to trust to appearances, for the *Eucharidium* is certainly a member of the Fuchsia family, a family which, by the way, also includes the Evening Primroses. To some of the latter the *Eucharidium* bears a very fair likeness. It is a native of California, and may be treated as a hardy annual in this country. There is one point about *Eucharidiums* which is well worth remembering, and that is the short period that elapses between seed sowing and flowering in the warmer parts of the year. Sowing may be commenced as soon after the middle of March as the state of the soil and weather will permit, and successional sowings may be made until the end of May. It is these

later sowings which will be found so valuable in most gardens, as often only six weeks elapse between the date of sowing and the opening of the first flowers; eight weeks should see the plants in full bloom. This means that any blanks left in the borders by the departure of the early Tulips and Narcissi can be made good almost before they have time to assert their presence. And, moreover, the *Eucharidium* lasts long when it does begin to flower, in this respect being different from many of our most appreciated annuals. Of course, a sowing made at the end of May must not be expected to possess the longevity of one made in March, and neither of them compare with an autumn sowing for lasting effect. They should be kept in a mass to ensure the best display, and are best adapted for filling blanks in the borders, being scarcely suitable for sharing in the bedding display proper. There are now several species and varieties of the *Eucharidium* in cultivation, *E. Breweri* being the most showy, and that

illustrated the most chaste; the two look well in combination. The earliest sowings should be made on a sunny reserve border towards the end of March; the later ones are better made where the plants are to bloom, as establishing transplanted seedlings give trouble in a hot season.

### PROPAGATING SWEET PEAS BY CUTTINGS.

AN American correspondent asks for information about propagating Sweet Peas by means of cuttings, adding that he "knows of several new things, some of my own, and find propagating by seed too slow!" Considering the freedom with which most varieties seed in ordinary seasons there should be little need to resort to propagation by means of cuttings, a system of propagation which, if carried out to any extent, will soon ruin the constitution of the plants with which it is practised. It is quite possible, and even probable, that some of the bad features, such as shy seeding, weak constitution and, consequently, liability to attacks by fungoid diseases that have recently shown themselves among Sweet Peas, have been brought about by propagation by this means, hence its adoption is not advisable.

However, cuttings will root with comparative freedom if the tops of young plants, or even the side shoots, are taken off, made into cuttings about 3 inches long, the lower leaves removed, and then inserted into pots of rather sandy soil, these being plunged to their rims in Cocoanut fibre refuse in a rather close greenhouse with a temperature of about 60° Fahr. Plants raised under glass are the best for taking the cuttings from, as the growths are softer and thus root more readily.

### NEW PLANTS.

*CYRTOMIUM FALCATUM* MAYI.

THIS is a crested form of a well-known and useful Fern whose decorative value is considerable. The creasing in the new comer is confined chiefly to the ends of the fronds, which are divided and subdivided and slightly broader than in the typical plant. Shown by Messrs. H. B. May and Sons, Edmonton. Award of merit.

*NARCISSUS BUTTERCUP*.

A sturdy and richly-coloured variety, the parents of which we believe to be *N. odoratus* variety and *N. Emperor*. The new comer is of self-yellow tone, hardly so rich in colour as the first-named parent, and lacking that shining or glistening yellow tone which marks its namesake the Buttercup. At the same time it is a beautiful and distinct novelty, and apart from its sturdy and well-balanced character there is richness of colouring and that fragrance which betells the influence of the Jonquil Daffodil. For these reasons we welcome the new comer, and it is possible that other novelties in the near future may have this quality of fragrance imparted to them. Exhibited by Mr. Charles Dawson, Gulval, Penzance, before the Royal Horticultural Society on the 14th ult. Award of merit.

*TUNICA SAXIFRAGA* FL.-PL.

We have received the following letter in reference to this plant from Mr. A. M. C. Van der Elst, the managing director of the Royal Tottenham Nurseries, Limited, Dedemsvaart, near Zwolle, Netherlands: "This plant has been introduced by us this year, and in general appearance may be described as a *Saxifraga* of the mossy section with double *Gypsophila*-like flowers. The flowers appear about May and there is a succession until October. Few plants can be used for so many purposes; it grows quite as well in the shade as in the hottest sun, and it is not particular with regard to soil. It is a gem for planting on graves, because it is compact in growth, evergreen and flowers in the shade. It is a flower to cut, and excellent in pots and the border. I consider it is even more valuable than the double *Gypsophila*."

ONE OF THE BEST ANNUAL FLOWERS: *EUCHARIDIUM GRANDIFLORUM ALBUM*.

## THE KITCHEN GARDEN.

### ONIONS FOR EXHIBITION.

**O**WING to the record prizes offered this year by Messrs. Rogers and Co. of Leamington, the Onion should receive a great stimulus, and providing we experience a favourable season, there is every prospect that a very large and keen competition will be the result next October.

Fortunately, Onion culture is not confined to any particular class of men, as anyone possessing a moderately-sized garden may produce bulbs equal to the professional with acres of land at his command. But to be successful it will, of course, have been necessary to have raised the plants under glass and the ground prepared during the past winter and made ready for receiving the plants from boxes or pots during the present month. These should have been well hardened off, and when this has been properly done no weather will injure them after this date. The Onion revels in a deeply-trenched and well-enriched soil, but is not at all particular as to kind providing plenty of food is given it.

The surface should be neatly raked down and made thoroughly firm, and the plants put out at a distance of from 15 inches to 18 inches apart all ways. If in boxes bit with a small hand fork or garden trowel with as good a ball as possible. Care should be taken to arrange the roots so that these are not doubled up. Make them very firm, and if the weather be dry give a thorough watering in, at the same time applying a good application of fresh soot. Everything should be done to encourage the young plants to begin active growth at once. Unless the weather be showery damp over the tops two or three times daily, and Dutch hoe the surface twice weekly. After the plants have once become established, providing the ground is properly drained, hardly too much water can be given to the roots, both clear and liquid manure properly diluted. Soot should be applied once a week, being both a good stimulant as well as proving a check to the Onion fly, although this seldom seriously affects these early-raised plants. The surface should be kept stirred with the hoe, but not sufficiently deep to injure the roots. Mildew must be constantly watched for, and on the first appearance means must be taken to check it. Any affected plants should be taken away and burnt, and dust over the growth with sulphur and fresh chalk lime. Patent vegetable manure should be given according to the directions during showery weathery. I have found Clay's Fertilizer both safe and beneficial. The Onion is a gross feeder, but even this can be overdone, and growers frequently when their plants are doing as well as possible are not satisfied, and often overdose them, the result being ill-finished and badly-shaped bulbs in consequence. Mere size has little to recommend it. Well-ripened, firm and finished specimens should be one's aim, and when this is accomplished there is no reason why these should not keep thoroughly sound and good till the following April.

I cannot too strongly impress on those who have charge of them that too much care can hardly be exercised when handling the bulbs, as the slightest bruise will impair their keeping. Early planting and harvesting should always be practised. The crop should never be left on the ground a day longer after the growth is practically completed, but taken up and finished off under glass if possible.

*Elstree.*

E. BECKETT.

### CULTIVATION OF THE BEETROOT.

Now is the time to sow this, one of the most valuable and useful root crops of the garden. It is valuable because it is one of those roots which is available for use all the year round, and also because it gives a splendid return in value

and weight of crop for the labour expended in its growth. It is useful because of the many ways and forms in which it may be prepared for the table. Most of those ways are so well known that it may appear superfluous to mention them. Boiled and steeped in vinegar it becomes one of the most appetising and acceptable adjuncts it is possible to have to cold meat. As an ingredient in a good salad we know it is indispensable. Prepared as fritters it is excellent, and as a pickle it is liked by most people. There is no great skill required to grow the Beetroot successfully. Even a novice trying his hand at gardening for the first time may take the Beetroot in hand, feeling confident of success, provided he will follow certain lines of culture which I will endeavour to lay down and make clear.

#### SOIL.

A rich, light deep loam which has been deeply dug and generously manured the previous year for a crop of Peas or Cauliflowers is an ideal one in which to grow this root; but it will grow well in any ordinary soil which has been deeply cultivated and manured the previous year for any crop other than a root crop. It is not

young seedlings are apt to be injured by frost, and there is a danger also of the plants bolting into flower rather than to form good roots. The drills for the Turnip-rooted sorts should be 15 inches apart and the seeds should be buried 1½ inches deep. In the case of the long-rooted sorts the drills should be 2 feet apart and the seeds planted thinly 2 inches deep. In the case of the Turnip-rooted varieties, thin out the young plants as soon as they are large enough to handle to 6 inches apart, and in the others to 9 inches. Summer culture consists of the frequent hoeing of the ground between the plants in order to keep down weeds and to aerate the soil. The Beetroot is seldom or ever attacked by insect enemies or fungoid disease. As mentioned before, it is liable to injury from frost, consequently the roots should be dug up not later than the first week in November. In digging special care must be taken not to bruise or injure the roots, or the consequence will be that they will bleed when boiled and prove practically useless. In washing also before boiling equal care must be exercised not to break the skin. In lifting a four-tined fork only should be used, pressing it deeply into the soil some distance

A DRIFT OF ANEMONE BLANDA.

advisable to manure the land immediately before sowing Beetroots, as doing so has a tendency to cause the roots to fork out into different growths, which considerably reduces their value. It may happen with many that land in the condition above stated may not be available, in such a case, rather than plant in very poor soil, I would advise that a light dressing of well-decayed short manure be added to the soil at the time of digging.

#### VARIETIES.

For the first early crop I recommend the Globe or Turnip-rooted. It comes to maturity three weeks before the long ones, and this is an important consideration, as the flavour of a fresh Beetroot is infinitely better than that of an old one. This form of Beetroot is also valuable for growing on very light or stony land, where the deep-rooted ones do not succeed so well. Sutton's Globe and Carter's Crimson Ball are excellent varieties. Of the long varieties there are many good ones to choose from. The following three are among the best: Sutton's Blood Red, Carter's Perfection and Veitch's Dell's Crimson.

#### SOWING THE SEED.

The last week in April or the first week in May is the best time to sow. If sown earlier the

from the roots, and then prising the root up gently with the left hand and pulling it up with the right. In cutting off the leaves care must be taken not to cut them too close to the crown of the root or it will bleed; 1½ inches to 2 inches should be left. It is a good plan to place the Beet in small heaps together on the land for a week after they are taken up before storing, covering the heaps over with the tops cut off.

#### STORING.

There are many ways of storing Beetroot for winter, spring and early summer use. The best way I have found is to place them thickly in layers in fine soil in a cool storehouse or cellar, where they are safe from frost and at the same time perfectly cool. Another way is to clamp them out of doors, covering with straw and earth as is done with Mangold Wurtzel and Swede Turnips.

As a vegetable the silver-leaved Beetroot is valued by many. It should be grown in rich soil in drills 2 feet apart, and the young plants when large enough thinned out to 12 inches apart. It is the mid-rib of the leaf only which is used, which should be boiled and served like Asparagus, and the leaves pulled off as in Rhubarb not cut.

OWEN THOMAS,

## TREES AND SHRUBS.

## A BEAUTIFUL RHODODENDRON.

HERE is no more beautiful Rhododendron in the world than Pink Pearl, which, we think, may be considered quite hardy. It will be interesting, however, to see the effect the sharp frosts have had upon this and other of the more tender wild Rhododendrons and hybrids derived from them. The illustration shows a plant in Mr. H. M. Arderne's interesting

requiring the shoots to be well thinned out immediately after the blooms are past. By doing this air and light are admitted to the young growths, and finer and better flowers are produced.

*S. arguta* (*S. multiflora* × *S. Thunbergi*).—This is a hybrid of garden origin, and forms a dense bush 4 feet or so in height, with gracefully arching shoots laden from end to end in April with tiny clusters of pure white flowers. These last a long time in flower, and are very useful for cutting.

*S. chamædrifolia* is a widely-distributed species throughout Europe and part of Siberia, and is

in quite a young state. It is a native of Europe and one of the best of the genus for forcing.

*S. prunifolia* is a native of China and Japan and is of no garden value, but its double variety (*S. p. var. flore-pleno*) forms a plant 6 feet or so in height, with slender gracefully-arching shoots clothed from end to end with tiny double white flowers in April. Each individual bloom is perfect in shape, resembling a pure white rosette. The foliage turns to a brilliant crimson in autumn.

*S. Thunbergi*.—If only one *Spiræa* can be grown, this is the species to plant, as it is one of the most beautiful and useful of hardy shrubs.

It forms a plant 3 feet high and as much or more in diameter, with thin twiggy shoots covered in March and early April with tiny white flowers. Cold winds and frosts sometimes affect the flowers that are open, but the unopened buds expand fully and freely with more genial weather. The foliage turns to a lovely bronze crimson hue in autumn. Plants of this potted up in October can be forced into bloom early in the following spring and are valuable for house decoration or for cutting.

*S. Van Houttei* (*S. car-toniensis* × *S. trilobata*). This is a hybrid of garden origin, bearing white flowers opening in late April and May. The plant grows to a height of about 6 feet, with comparatively stout upright growths, which require to be kept well thinned to flower well. *S. Van Houttei* forces well, but requires to be brought on gently, too much heat causing the flowers to come "blind."

## SECTION III.—NOTHOSPIRÆA.

*S. bracteata* is a native of Japan and bears white flowers in May and early June. It is a strong upright grower, attaining a height of 6 feet and upwards and requires plenty of room to develop. The other member of this section (*S. nudiflora* ×) is of little or no garden value.

## SECTION IV.—SPIRÆRIA.

The members of this section mostly bloom during the summer months and the flowers are borne in corymbs, either terminal or clustered towards the ends of the branches. With the exception of *S. canescens*, which requires to be kept well thinned, the majority of this section are benefited by being cut back in early spring, as they bloom on the current season's growth. It is not absolutely necessary to cut them back, but the flowers are finer and better when a judicious amount of pruning is carried out.

*S. betulifolia* is a dwarf bushy species, rarely more than 2 feet high, with comparatively stout branches bearing terminal corymbs of pretty rosy pink flowers about the end of June. It is found irregularly throughout the Northern Hemisphere, and will thrive under almost any conditions of soil and climate.

Bagshot, Surrey.

J. CLARK,

(To be continued.)

RHODODENDRON PINK PEARL IN SOUTH AFRICA.

garden, The Hill, Claremont, near Cape Town. No finer specimen in the world is said to exist. It is 9 feet high, 8 feet through, and at the time the photograph was taken had 105 perfect clusters of flowers open. These clusters are very large, also the individual flower, and the colour is a delightful pink, as tender as the pink on the petal of a China Rose. The plant is growing near a Lily pond in black fibrous peat enriched with Oak leaf-mould and partially shaded. Mr. Arderne obtained the plant, then small, of course, in 1896, and it has succeeded wonderfully by the Lily pond.

## THE SHRUBBY SPIRÆAS.

(Continued from page 211.)

## SECTION II.—CHAMÆDRYON.

This is one of the most important sections, the members of it being mostly spring-flowering and

naturally a variable plant, some seven or eight varieties of it being known. The white flowers are produced in small clusters in early spring, but are not so showy as some of the other early-blooming *Spiræas*. It is a plant for odd corners, as it will grow and flower as well in partial shade or under rough conditions as it does when well treated.

*S. hypericifolia*.—This species is irregularly distributed throughout the northern hemisphere and forms a plant 4 feet to 6 feet high, with slender arching shoots clothed from end to end with small clusters of tiny white flowers in May. It is a handsome and graceful plant, but one which is not often seen.

*S. media* is more often met with under its old name of *S. confusa*, and forms a dense bush 6 feet or more high, with clusters of white flowers opening in late April and May. It is a handsome species and grows well and blooms freely

## COLOURED PLATE.

PLATE 1347.

## SOME BEAUTIFUL FUCHSIAS.

**M**OST amateurs are familiar with the ordinary Fuchsias and find little difficulty in growing them satisfactorily, for they succeed well under various conditions. After the introduction of the tuberous Begonias the Fuchsias were somewhat neglected, and though they are now coming into favour again they do not receive the attention that they deserve, especially in regard to hybridising and the raising of new varieties. I find we are indebted to the Continental raisers for most of the recent novelties, and in addition to the ordinary types some very distinct hybrids have been introduced from Germany. The coloured plate will give some idea of the beauty of these new varieties. They were introduced by Mr. H. J. Jones of Lewisham, who supplied the flowers from which the plate was prepared. Coralle, the variety shown in the centre, has soft green foliage somewhat after the fulgens type, with drooping terminal racemes of bright coral-like flowers with a shade of salmon. Andenken an H. Henkel, shown on the left, is a variety of freer growth, with leaves of a bronzy red tint; the flowers which are produced from the axils of the leaves and finish with a terminal cluster are of a peculiar shade of rosy pink shaded with orange. Gartenmeister Boustedt, on the right, is a very distinct hybrid with rather large foliage; the young tips have a bronzy tint and change to green. The flowers are produced in loose terminal panicles and are of a rosy red with a salmon shading.

In addition to the above there are several other distinct varieties. Of these Clio, dark bronzy red foliage and terminal clusters of salmon pink flowers, is very pretty; Trudchen Bondstedt has soft pale green foliage and clusters of pale salmon flowers; Thalia has rather large leaves of a deep bronzy red shade and terminal clusters of red shaded flowers. There are also several other distinct varieties. Many a fine variety from triphylla has a good compact habit, with terminal clusters of rather small deep crimson flowers.

All these hybrids have longer tubes, and the lobes, which are short, do not spread out, as in the ordinary Fuchsias, and most of them appear to be intermediate between *F. fulgens* and *F. corymbiflora*.

They are of easy culture, growing freely in an ordinary cool greenhouse. Pot the plants in a rich loamy compost and give more root room, that is, larger pots

than for the ordinary sorts; light and air are essential, but avoid draughts. Very little shade is needed. If watering is carefully attended to the plants may be fully exposed to the sun, except during hot summer days. Young plants should be propagated annually; the cuttings will root freely if taken from the young shoots early in the spring and treated the same as the ordinary sorts.

Few classes of plants afford greater scope for the amateur hybridist than the Fuchsias: the plants used for hybridising should have all the flowers removed, except those that are to be fertilised, and as soon as these flowers open take away the stamens. The pollen may be taken from other varieties by using a small camel's-hair brush. This should be applied as soon as the

pistil is moist at the point. The great mistake that many hybridists make is that they go too far, or rather save too much seed, and then

having a larger number of seedlings than they can accommodate some of the best may be lost. Take care that every seedling is grown on until it flowers. Seeds which ripen in the autumn should be kept until the spring before they are sown. It requires some care to extract them from the fleshy pulp. This can best be done by breaking the fruit open when they are quite ripe, and work the seeds out with the point of a knife or a small stick and carefully dry them. Being so small they perish if over dried. They should be kept in a tin box in a cool, dry place.

## FUCHSIAS FOR BEDDING.

Formerly the ordinary garden varieties of Fuchsias were considered too tender to be grown anywhere except in a greenhouse where they could be kept close and shaded from the sun. I think it was through nursing them up that they lost favour with so many. During the last few years they have been extensively used in flower gardens, and last season they did remarkably well. The large specimens seen in the parks and the beds of smaller plants all flowered well.

In private gardens I saw early spring-struck plants which had made fine specimens by August. Standard plants are also extensively grown in some gardens. These standing above, in beds of dwarf-flowering plants, make a fine effect. They may not be suited for exposed positions, but where they are sheltered from strong winds they flower through the season. They do best in rather heavy loam. For vases and window-boxes there are few plants which flower so continuously. For this purpose those of rather slender drooping growth are the most suitable. For ordinary bedding I

find that all the best double varieties will do well. Last season I noted, among others, Ballet Girl, Royal Purple and the Phenomenals, of which there are three varieties, these having white, pink and purple corollas, while all have crimson tubes and calyces, and the flowers are very large. Though the doubles do well I find that the singles, or those more after the type of Mme. Cornelson, which is one of the oldest white corolla varieties we have, is still grown extensively. In Regent's Park last year it was very fine. Lady Heytesbury, Display, Charming, Arabella and other free-flowering sorts succeed well.

I may add that while young plants will do well in the garden, the older ones are the more effective, and if taken up in the autumn they may be stored in a dry shed where the frost does not penetrate. When taken out and started in the spring they soon make good plants. If started from the first where they are fully exposed to the sun there will be little danger of the foliage getting burned, provided watering is properly attended to. Where very large vases have to be filled a good sized plant of any compact variety makes an excellent subject for the centre, the erect habit and drooping flowers showing off to perfection in such a position. For tubs to be placed on terraces no better plant can be found, as if given good treatment flowers will be produced throughout the summer and autumn. Plants grown thus need liberal feeding and plenty of water during hot weather. A. H.

NARCISSUS BUTTERCUP.

the Royal Horticultural Society  
and given an award of merit.

(For description, see page 226.)

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**W**INDOW GARDENING.—Sponge the foliage plants about once a fortnight, using tepid milk and water. By these means dust and insects are removed. The last of the spring bulbs are finishing their display in the window-boxes. I therefore propose to immediately replace these with *P. largoniums*, *Lobelias*,

I.—TUBERS OF THE GLOXINIA BEFORE STARTING INTO GROWTH. THE ONE ON THE LEFT IS THE WRONG WAY UP, AND THE OTHER IS CORRECT.

*Marguerites*, *Calceolarias* and similar subjects, being guided in these operations by the climatic conditions prevailing at the time. Only window-boxes in warm aspects should be planted as above advised. The flowering plants inside the window should now be making a gay display. In this connexion I have *Genistas*, *Pelargoniums*, *Hydrangeas*, *Heaths* and *Spiræas*.

*Roses*.—At this period I am giving considerable attention to my *Roses*, carefully looking into the growths and foliage for maggots and caterpillars that invariably infest them at this season. Recently-planted *Roses* I am now mulching with well-decayed manure, placing a good layer on the surface soil round about the base of the plants.

*The Flower Garden*.—Early spring-flowering plants in the beds and hardy border, if they have ceased flowering, may be lifted and transferred to other quarters to make room for the summer things. *Primroses*, *Polyanthuses*, *Daisies*, *Arabis* and similar plants may be dealt with. *Lilies* in the hardy border will derive considerable benefit from a mulching with well-rotted manure. I am now proceeding to place a good layer of this manure round about the surface soil. Vacant beds and borders should be forked over in preparation for planting in the immediate future. See that these quarters are levelled and raked over, and everything prepared in readiness for planting. Although the more tender subjects, such as *Geraniums*, *Calceolarias*, *Petunias*, *Lobelias*, &c., are often planted thus early, I am not disposed to plant so soon as usual this season. I think it will be better to wait a little longer. In the meantime, by the help of the cold frame I am thoroughly hardening off the more tender subjects. I would rather wait another fortnight than run unnecessary risk.

*The Greenhouse*.—Those who have the opportunity may now make a sowing of *Primulas* and *Cinerarias*. The former succeed when sown in a compost of one part fibrous loam, two parts leaf-mould and half a part of silver sand, all passed

through a fine sieve and well mixed. Sow the seeds thinly and lightly, and cover them with the finer soil. *Cinerarias* should be treated similarly in finely-sifted soil made up of two parts yellow loam and one part leaf-mould and coarse silver sand. The seed-pans or boxes must be well drained. The resulting plants should make a beautiful display in the early spring of the succeeding year. To assist germination, cover the pans with a sheet of glass and shade from the sun. For most greenhouses the temperature at this season should not exceed 55°. When the thermometer denotes this figure I open the ventilators so that it shall not be exceeded, closing them again in the late afternoon, by which time the sun has lost much of its power. At this season *Fuchsias* are growing freely; their well-being may be promoted by a light spraying overhead with water in the early morning and late afternoon. Continue to pot on recently-rooted *Geraniums*, *Petunias*, *Heliotropes*, *Fuchsias*, tuberous-rooted *Begonias* and similar flowers as they fill the smaller pots with roots.

*The Vegetable Garden*.—For late autumn and winter use make a sowing of *Cabbage*, *Savoy*, *Broccoli*, *Borecole* and *Brussels Sprouts*. The *Onion fly* is invariably troublesome in May, and, in order to anticipate its attacks, give the *Onion* bed a good sprinkling with soot over the surface soil; this is an excellent preventive. I am now making a sowing of *French* and *Runner Beans*, feeling quite safe in doing so. This should provide supplies at the end of July. D. B. C.

### GLOXINIAS AND THEIR CULTIVATION.

MANY people labour under a misapprehension with regard to the cultivation of the *Gloxinias*. They imagine this subject is a plant of difficult culture; but given suitable soil and proper conditions there is no reason whatever why a "beginner" in gardening should not grow these plants satisfactorily. For many years *Gloxinias* were regarded as stove plants, but time has proved that they may be grown successfully in a warm greenhouse.

*Raising Gloxinias from Seeds*.—During March and April, and even in early May, the seeds of *Gloxinias* may be sown, although we prefer the earlier period. From an early spring sowing the resulting plants should come into flower within five or six months, providing they are grown on carefully and their progress made continuous. A suitable soil for seedling raising should comprise leaf-mould, peat and fibrous loam, each ingredient passed through a fine sieve, and, with the addition of a small quantity of silver sand or fine grit, should be well mixed. Use shallow boxes or seed-pans, taking care to crock these receptacles so that good drainage is ensured. This done, fill in the prepared compost to within 1 inch of the rim, following subsequently with a thin layer of sand, on which the seed should be sown thinly. Moisten the soil previous to seed-sowing by holding the receptacle in a vessel of tepid water so that this can percolate through the soil. Take care not to permit the water to overrun the rim of the seed-pan, or disaster may follow. Do not cover the seeds with soil, but lightly

press them into the loose surface soil with the bottom of a flower-pot or anything similar. Place the seed-pans in a propagating frame or over the hot-water pipes where the temperature can be maintained at from 65° to 75° until the seeds have germinated. When the seedlings are large enough to denote progress stand the pans on shelves in a warm corner of the greenhouse, shading from bright sunshine. When large enough to be lifted with the aid of a small notched stick transplant them to pans or boxes, observing a distance between each seedling of 1 inch or less. Transplant in rows. Then keep the seedlings rather close for a short time, subsequently transferring them to 3-inch pots and ultimately into those 5 inches in diameter. Equal parts of loam, leaf-mould and peat, with a small quantity of thoroughly decayed cow manure, charcoal and sand, will make an excellent compost for the final potting.

*Starting the Tubers*.—The tubers vary in size and character. The two represented in Fig. 1 show one arranged in proper fashion with the slightly hollowed out cavity uppermost, and the other with the concave side downwards and improperly arranged. Many growers place their tubers straight in their flowering pots, but this is a course that is not advised. Far better is it to place the tubers in shallow boxes filled with either *Cocoanut fibre* or leaf-mould. Fig. 2 is a good illustration of tubers started into growth. To promote growth on the tubers the boxes containing the latter should be placed in a temperature of about 65°. The crowns should be just covered with soil and this damped over with the aid of a fine-rosed can each morning. In a comparatively short time they will commence to break into growth and develop roots quite freely, and the tubers are then ready for potting up.

*Potting up the Started Tubers*.—Opinions differ regarding this operation. Some growers prefer to first pot up the plants into 3½-inch pots and finally to shift them into larger pots, say, those 6 inches in diameter and known to gardeners generally as "thirty-twos." Other very successful growers prefer to pot up the started tubers straight away into either 5-inch or 6-inch pots. Either method may be successfully employed, and the latter method entails less labour. Fig. 3 represents a started tuber taken from the box of tubers seen in the illustration of Fig. 2. Take care not to damage the hair-like roots and do not attempt to free the tubers of the leaf-mould or *Cocoanut fibre* that adheres to the roots. For this potting use a soil made up of the following

2.—GLOXINIAS AT THE STAGE FOR POTTING UP.

ingredients: Really good fibrous loam one part, nice flaky leaf-mould two parts—use peat if the latter cannot be obtained, and half a part of coarse silver sand. This compost need not be sifted, but the heap should have a thoroughly good mixing before using. Crock carefully, covering the crocks with small quantity of the

feed and bring the crop to maturity. Not only should the rooting space be limited, but the soil must be made firm.

Twenty years ago many growers advocated starving the plants while they were young up to the stage when the first few trusses of flowers appeared; but it was a mistaken idea and quite the wrong mode to adopt. It is not wise to cause a check to growth at any time, and certainly it is not desirable to check the growth early in the season. Our summers are not too warm for the Tomato plant, and we are always anxious to get the plants forward early in the spring so that they will benefit to the full by the summer heat. A week gained in the early part of the summer is worth more than a fortnight at the end of it. So we must aim at growing healthy plants in a firm soil where the roots will be strictly under control. In this way the amateur will be able to stock his small house with profitable plants.

Use 10-inch pots for the plants to fruit in, but do not fill these pots at the time the plants are put in them. Leave ample space for a good top-dressing of soil later on, and so keep the plants progressing. When feeding is advisable, apply a teaspoonful of nitrate of potash or the same quantity of sulphate of ammonia to each pot. Nitrate of soda may also be used. Vary the food. Always water with clear water first, and occasionally give clear water only for the greater part of a week. Air and light are most essential. AVON.

#### WALLFLOWERS AND HOW TO GROW THEM.

THE Wallflower is such a common and popular subject that directions how to grow the many beautiful varieties may seem almost out of place, even to the beginner in gardening, yet the poor attenuated specimens that one frequently encounters each spring indicate that their culture, simple though it is, is not properly understood. Wallflowers are splendid subjects for spring flowering, and they have the advantage over Tulips and most Narcissi of being delightfully scented. Another point in their favour is that they are in leaf all the winter while the ordinary bedding bulbs remain out of sight.

Although strictly perennials, Wallflowers are best treated as biennials, that is, the seed is sown one year, the plants flower the next, and are then thrown away. Where very early flowers are required, a few old plants should be retained, as they produce their blooms earlier in the spring than the younger specimens. There is some diversity of opinion as to the best time to sow the seeds; some growers declare that good results cannot be obtained unless the seeds are put in during the first or second week in May, and others prefer a month later. Excellent results have been and may be obtained from sowings made during the last two weeks in May and the first week in June, and for all ordinary purposes this is early enough.

The best soil in which to sow the seeds is a well-worked one that is not too rich; ground that has been cropped since the last manuring is excellent, and if some old mortar can be incorporated this will be much appreciated. It is advisable to make flat-bottomed drills 1 foot apart and 1½ inches deep, and should the weather be dry, water them well before sowing the seeds. Scatter these thinly in the rows, cover with soil, rake level and make moderately firm. If dry weather prevails after sowing it may be necessary to water the seed-bed thoroughly through a fine-roset can at intervals as circumstances demand, the object being to effect germination as quickly as possible. When the young plants appear hoe between the rows so as to destroy seedling weeds. When the seedlings are from 2 inches to 3 inches high they must be transplanted, and as the weather is frequently very hot and dry at this season some care is needed. If possible select a dull, showery day for the purpose. Failing this,

give the young plants a thorough soaking with water one evening and transplant them the next.

The soil in which they are transplanted should be the same as advised for seed sowing, but it must be made firm so as to ensure a sturdy, hardy growth being formed. If planted in loose, rich soil thick, healthy-looking shoots and green foliage will be produced in abundance, but this will not stand the frosts and wet, cold winds of winter so well as the hard, sturdy shoots produced on comparatively poor ground. The best plan is to transplant the seedlings into rows 1 foot or 15 inches apart, allowing at least 6 inches from plant to plant. Give each one a good watering after the whole are planted and it may be found necessary, if the weather is very hot and bright, to afford some slight shade for a few days by placing leafy boughs among the plants. As soon as they are established any shading material must be removed and subsequent work will consist in frequently hoeing between the rows to keep down weeds.

By the end of the summer good bushy plants, each bearing several sturdy shoots, will be available, and after the summer bedding subjects have been removed the beds or open border spaces should be dug, incorporating some old mortar if possible, and the soil then trodden firmly for the reception of the plants. The distance to plant will vary somewhat according to circumstances. If it is intended to fill a bed or space with Wallflowers alone the plants may almost touch each other, but if Tulips are to be incorporated the plants must be set more thinly. Where the Tulips and Wallflowers are used together always plant the latter first, then the bulbs can be set in the open spaces between them. A day or two before lifting the Wallflowers for planting tread the soil firmly on each side of the row; this will enable them to be lifted with good balls of soil, a most important factor, as the plants then suffer but little by removal, and consequently stand the winter much better. October is the best month in which to do the planting, and if for any reason it cannot be done then, it is best left until the end of March. In the latter case it is even more important to lift with good balls of soil and disturb the roots as little as possible. If the above simple directions are consistently carried out, fine bushy plants laden with large racemes of fragrant flowers can be obtained by any amateur.

3.—ONE OF THE YOUNG PLANTS LIFTED FROM THE BOX READY FOR POTTING UP.

rougher portions of the compost. The tuber should be so arranged that the crown is just below the surface soil. When potting take care not to make the soil too firm. The plant represented in Fig. 4 has been potted up into a 5-inch pot, is now established and growing away freely and promises at an early date to come into flower.

*Subsequent Treatment.*—After potting the plants will not need much water for a time but when they begin to develop their large leaves and are making abundant growth the plants appreciate copious applications pretty frequently. The porous character of the soil ensures a somewhat free drainage, and on this account readers will understand the necessity for abundant supplies of water. Once or twice a week stimulants or liquid manures may be given with advantage. Let the doses err on the side of weakness, and, if possible, vary the character of the manure or stimulant that is applied from time to time. Never apply liquid manure, &c. when the roots are dry. First water dry plants with clean water, following later on with the manure water. After the plants go out of flower, gradually withhold water till the foliage dies down, then keep dry until starting the tubers again in the succeeding spring.

#### TOMATOES IN SMALL GREENHOUSES.

How to grow Tomatoes successfully in small glass structures is a problem that thousands of amateurs every year try to solve. The Tomato plant grows very luxuriantly indeed if it is planted in a border of loose soil. As a rule, there is not much difficulty in securing a good and healthy growth of stems, side shoots and leaves; but the difficulty is to obtain the coveted fruits in sufficient numbers to satisfy the ambition of the grower. The more luxuriantly the plants grow, the more space will be required in order to secure a full crop. Overcrowding is an evil; and this is sure to occur in a small house when the roots have unlimited run in a loose border soil. The remedy is to confine the roots of the plants in pots or boxes. The plants will not make long-jointed stems and big leaves, but short-jointed stems and medium-sized leaves. These conditions are favourable to a good crop of Tomatoes being produced. The fruits set freely in such circumstances, and when the grower has secured a good set he can easily

4.—A GLOXINIA POTTED INTO A 5-INCH POT AND WELL ESTABLISHED.

The following are all excellent varieties, and can be thoroughly recommended: Harbinger, early, brown; Belvoir Castle, bright yellow; Blood Red, reddish brown; Eastern Queen, chamois; Ruby Gem, ruby violet; and Vulcan, deep velvety reddish brown, very large spikes and one of the best for cutting.

## THE TOWN GARDEN.

**WORMS IN THE LAWN.**—When worms become very numerous in a lawn or grass plot they are a constant source of worry to the owner because they create such an untidy appearance by the numbers of their casts; but they must not be at once written down as enemies of the gardener. Where their numbers are considerable it may be fairly safe to assume that the drainage of the ground is defective, and in this event the worms do a certain amount of good by opening up the soil and admitting fresh air. Then, again, one can get a little benefit from them by the distribution of the casts, which have a certain amount of fertilising value; this should be done with a besom or birch broom, the operator taking long, swinging strokes. As soon as this has been done the lawn should be thoroughly rolled. If, however, the worms become too numerous, it will be necessary to take steps to reduce them, and for this purpose there is nothing to equal clear lime water, with which the ground should be thoroughly soaked; no harm will be done to the grass, on the contrary, it will be improved by the sweetening of the soil.

**HOW TO MAKE LIME WATER.**—As lime water is very commonly recommended in gardening articles, it may be well to give brief directions as to its preparation. Take a lump of fresh lime and place it in a bucket with a little water and then fill up the receptacle; stir vigorously, allow the liquid to settle and await events. If it is seen that there is a distinct sediment on the bottom of the bucket it may be safely concluded that the water is fully charged with lime; it should be strained off for use. If, however, there is no sediment, more lime should be added, stirring must again be done, and this should be continued until the sediment is seen, as in its absence there will be a deficiency of lime. Amateurs need not fear that they will make the liquor too strong; this is impossible, as the water will only hold a certain quantity of lime in suspension. The application will bring the worms to the surface and they can be swept up.

**PREPARING FOR BEDDING.**—The time will soon be upon us when we shall have to put out the plants which are to adorn the garden during the summer months, and it is most desirable that all preparatory work be pushed on so as to leave the way clear for immediate planting when the correct moment arrives. All bulbs should be lifted as the foliage turns yellow, or if this is not proceeding quickly enough they may be lifted and laid in by the heels in some convenient position where they can be occasionally watered. This is far better practice than laying them out to dry on a path while the leafage is still green, as when they are treated in this manner they never produce such good blooms in the following season. The plants in frames intended for the beds and borders should be watered as necessary, and have as much fresh air as possible, so as to finish off the hardening against the time that they will be wanted.

**DANGERS OF LOOSE, RICH SOIL.**—As soon as the ground is clear the digging and manuring for the succeeding plants will be put in hand, and I would warn growers of the dangers and disadvantages of over-looseness and over-richness. These conditions encourage the production of large and numerous leaves, but they do not favour floriferousness, and it is for the latter that we cultivate the majority of our summer bedding plants. In many instances the bulbs will leave quite sufficient food in the soil for the succeeding plants, and where this is not the case, I prefer to use 2oz. or 3oz. of superphosphate of lime to the square yard rather than add dressings of fresh natural manure. If this is worked in in very small spits it will yield its food to the plants and not encourage grossness in the slightest degree. If manure is used it should be well down in the bed, and the soil should be thoroughly firmed before the planting is done. **HORACE J. WRIGHT.**

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUIT HOUSES.

**THINNING GRAPES.**—Continue to thin Grapes in the second Muscat house. The latter Grape should be carefully thinned, so that each berry has sufficient space to develop, yet it must not have too much or the bunch will be loose. Tie up the best shoulder of the bunch and be careful not to prick the berries with the point of the scissors; Gros Maroc requires much care in thinning to have it in perfection, for the large berries lose half their charm if pressing each other out of shape. In thinning all late-keeping Grapes it is well to clear out nearly all the berries in the inside of the bunch. Keep the laterals pinched, going over them as often as necessary. It is a mistake to allow too much growth so that at a period wholesale stopping has to be done. Keep the floors damped down several times and last thing at night (10 p.m.), but be careful not to pour water on the pipes to cause steam. This is one of the primary causes of adventitious roots.

#### PLANTS UNDER GLASS.

*Primulas* may now be sown in quantity where these flowers are in request. Propagate by cuttings *Poinsettias* and *Euphorbias* and generally prepare for next winter. Pot off *Solanums*, *Cockscombs*, *Celosias* and *Caladiums*. *Caladium argyrites* is still a great favourite for decoration. Attend to the tying and training of *Clerodendrons*, *Allamandas* and *Stephanotis*, and see that the latter is free from mealy bug. A good plan is to syringe each week with Richards's NL All insecticide.

*Begonias.*—Pot on small *Begonias* of the Lorraine type and propagate for succession. These require a brisk heat to start them.

*Chrysanthemums* should be potted into the pots in which they are to flower. Do not allow them to become starved before this is done or the lower leaves will fall. To every barrowful of soil give a 6-inch potful of Bentley's Manure and thoroughly mix. Some growers put half-inch bones over the crook at the bottom of the pot, but I have never seen any material benefit from this. Overpotting is a mistake. Pot weakly-growing varieties firmly, as this is conducive to solid growth. Bush varieties should be stopped early so that they do not become leggy. These plants are general favourites for cut flowers, so also are the singles, which during the last few years have become great favourites.

#### FLOWER GARDEN.

*Early Chrysanthemums.*—Plant out on a well-dug border early *Chrysanthemums*. Prick out *Polyanthus* for autumn planting. Give plenty of room between the rows, so that the hoe can be freely used to keep down weeds. Pick off the seed-pods from early-flowering *Rhododendrons*. Plant out winter-flowering *Carnations* that are getting over. They will continue to flower all the summer and make good growths for propagating in August. Stir the soil among border *Carnations* and give a dressing of Wood's Carnation Manure. I have found this excellent for improving the colour of the blooms.

*Roses* on walls should be syringed with Quassia to keep down aphids, and should mildew put in an appearance dust at once with flowers of sulphur.

#### KITCHEN GARDEN.

*Betroot.*—Sow main crops, choosing light, rich soil. Sow more Vegetable Marrows, Salsafy and Scorzoneria. Prick out Lettuce, Cauliflower and Celery, and all crops that have been raised in boxes should the weather continue cold.

Sow more Runner Beans in boxes for planting out as soon as the weather proves favourable.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ALLAMANDAS.**—Young plants struck this season should be potted on as fast as they fill their pots with roots, and should be pinched two or three times during the season's growth. This applies to plants intended for ordinary culture; those for pillar or roof work must be run on to a single stem until the required height is reached. Plants intended to flower in August should now have the points of the young growths pinched out, and when the shoots have again broken into growth, manure water, weak at first, but increasing in strength as growth advances, may be given with advantage. I find nothing is better for producing healthy dark foliage than cow manure and soot water given in a clear state.

*Orchids.*—The month of May is a very trying one to those in charge of Orchid houses, the weather being usually capricious and necessitating frequent attention to the ventilators. Many of the plants are pushing into growth, and any check caused by cold draughts is very harmful. A little air at the top of the warm house suffices, even on the brightest days as yet, because usually there is a cold nip in the air though the sun is bright. The older foliage will stand a fair amount of sunlight, but where young shoots are forming they are very tender, and must be shaded early.

*Cucumbers.*—Where it is necessary to keep the early-raised plants through the season a considerable amount of care is required to maintain them in a fruitful condition. Not only must top growth be well looked after, but the roots must also have frequent attention in the way of top-dressing. If the cropping is regulated so that the plants are not distressed, they will go on bearing for a long time. The top-dressing should be rich, and applied often and in small quantities. Stimulants, of which ample supplies are required, should also be of a varied character, and be changed frequently, substituting artificial for liquid manure and *vice versa*.

#### HARDY FRUIT.

*Disbudding.*—Persevere with the disbudding of Peach and Nectarine trees, and keep a sharp look out for insects, dusting the same with Tobacco powder should any be found. As the weather is yet too cold to use insecticides, the use of Tobacco powder will in the meantime hold insects in check. Continue to protect trees at night, as this in a measure tends to avert blistering of the leaves, and do not hurry to uncover them on frosty mornings. Should any blistered leaves be found, the only remedy is to pick them off and burn them. Examine the borders, and if found to be in a thoroughly moist condition, apply a mulch of long manure.

#### FLOWER GARDEN.

*Polyanthuses.*—If not already done, seed of *Polyanthus* should be sown at once, and although a little shade is often advisable until the plants are above ground, I do not recommend a naturally shaded spot for sowing, as, given a dull, rainy time, growth is, under such conditions, not so sturdy and compact as one likes to see it. If the stock of *Polyanthuses* in flower is good, and there is no need to grow indifferent stuff in these days, an occasional inspection should be made to mark anything specially attractive, with the idea alike of saving seed and increasing the same by division if this be deemed advisable. Also it may be remembered that the habit of the plants is a subject for selection. A dwarf or tall strain, or a variety combining quality of

flower with distinct foliage, may be worth saving.

*Hyacinthus and Tulips after Flowering.*—These are often regarded as worthless if cleared off in time to make room for summer-bedding plants, but all they need to make them serve again is careful lifting and replanting. Put them somewhere in the open and water occasionally, so that the leaves may ripen off naturally. I find that bulbs so treated ripen up strongly and well and flower the next year.

#### KITCHEN GARDEN.

*Beetroot.*—A good sowing should now be made on a deeply-dug border that was well manured for a previous crop. Fresh manure has a tendency to cause the roots to fork and to make them coarse. For the main crop I find no variety superior to the Cheltenham Green Top; Dwarf Red and Blood Red are splendid varieties, being medium growers. For shallow land the Turnip-rooted Beets are valuable.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

### THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### TROPEOLUM DARMSTADT.

Mr. Gumbleton sends from Belgrove, Queens-town, County Cork, flowers of a most interesting *Tropeolum* called Darmstadt. It is quite double, and of an intense yellow, with scarlet feathering at the base of the petals. A more brilliantly coloured flower does not exist, even among such a family as the *Tropeolums*. Mr. Gumbleton says it was raised by Herr Henkel of Darmstadt, and in his note describes it as most free blooming and suitable for covering a trellis out of doors in summer.

#### WHITE CYCLAMEN FROM EPSOM.

Mr. George Boyd, The Gardens, Danehurst, Epsom, sends us magnificent flowers of a white Cyclamen. We have rarely seen flowers better than these and congratulate our correspondent on his success. He writes: "I enclose you a few of our white Cyclamen for your table. I am told by my gardening friends that they are very good. What do you think of them? The strain is Sutton's Giant White, from which I have saved the finest bloom for seed for several years. I sow seed the last week in September each year, and grow the plants on in gentle heat through the winter till about May, when I put them in a cold greenhouse for the summer, shading them from strong sun. They make fine plants by the autumn in 4½-inch pots, and this is the size I flower them in. I have had as many as fifty blooms out at once on a single plant. I give them no manure or feeding at all after the final potting, and apply water very carefully through the winter. I sow the seed in a pan of sandy soil, prick out the seedlings into a seed-box, from these into 2½-inch pots, using loam, leaf-mould and sand only, then into 3-inch pots with a little light manure added to the soil, and finally into 4½-inch pots, using equal parts of yellow loam, well-decayed cow manure, leaf-mould, a pinch of soot and silver sand. The blooms I send are from last year's plants."

## BOOKS.

### THREE ROSE BOOKS.

It is not often that by one post three books upon Roses arrive, and perhaps many readers will declare that such occurrences are a mixed blessing. The three books, however, are of the greatest interest and importance to the earnest Rose grower. Two of them are publications issued by the National Rose Society, and the third is the ninth revised edition of "Roses in Pots," by the well-known rosarian, the late Mr. William Paul of Waltham Cross. The society's publications are of the simplest and most practical kind, and contain short, pithy articles from leading rosarians; one is the annual for the present year, containing a fund of information in a small space, and the other is "The Enemies of the Rose," which has been in preparation for some time past and appears at an opportune moment. This year the pests which inflict the Rose promise to be more troublesome than ever. At the time of writing a bitter north-east wind is blowing across the garden, and this means an onslaught from the green fly and other hosts, which must be destroyed if one is to enjoy the feast of Roses that is one's reward for months of labour and, in the case of the exhibitor, anxiety. The book is illustrated with coloured drawings and written by the well-known authorities Mr. George Massee of the Kew Herbarium and Mr. Theobald, M.A., vice-principal of the Agricultural College, Wye, Kent.

We are much interested in Mr. Massee's description of the greatest plague the Rose grower has to contend with, the Rose mildew, which is well described as the most destructive and prevalent of all the Rose diseases. "Like most other parasitic fungi, it is sporadic in its appearance; during certain seasons it assumes the proportions of an epidemic, whereas on other occasions it does but little injury, but it is never entirely absent." And Rose growers take note: "The waves of serious disease are mainly due to neglect in not fighting the pest when present in the smallest quantity, which means that it is struggling against difficulties and could much more easily be overcome."

Rosarians, we think, do not appreciate sufficiently watching for the "spring wave of disease," which "is usually of a mild character and apt to be overlooked, or, at all events, neglected. This neglect may lead to serious results, for the scattered patches of mildew furnish the spores that affect flower-buds, and at a later stage set up the second wave of disease, which is mostly confined to the new growth." So beware of the spring attack. Many other excellent hints are given in this, we think, the most useful of the handbooks published by the society.

Every book written by the late Mr. William Paul is full of practical and useful thoughts, and "Roses in Pots" will appeal to all who wish to grow the flower under glass. It is freely illustrated and the cultivation most clearly explained; the lists of varieties for various purposes are invaluable. The following information on climbers will show the character of the book (page 34): "What we have hitherto been accustomed to regard as climbers are from the classes Boursault, Sempervirens, Ayrshires, &c. Magnificent as such must be regarded when growing in the open ground, often to the height of 20 feet and covered with immense trusses of bloom, their semi-double and transient flowers render the greater part not altogether suitable for growing in pots. A growth not too vigorous and finely-shaped flowers should be the criteria with regard to Roses grown in pots as climbers. As a great height is not in this instance desirable, the various Hybrids, the Noisettes and Bourbons may be chosen and trained upwards to about 5 feet, which will probably be found as high as convenient or manageable; not that we

would, however, altogether exclude the Ayrshire and Sempervirens, for among them a few admirable Roses may be found.

"Now one great point to be held in view in regard to this system of culture is, to induce the plants to flower from the summit to the ground; for if a few flowers only are to be produced at the top of the plant, then the dwarfier it can be grown the better. This complete flowering, judicious pruning and training will accomplish."

#### Cassell's A B C of Gardening.\*

When Mr. Walter P. Wright puts his pen to paper for the purpose of writing a book on gardening, he usually creates something that is, above everything else, thoroughly practical, and the volume now under review is most decidedly of that order. In reality it is a pocket illustrated encyclopedia of horticulture, written in plain, everyday English that the average man can easily understand, with illustrations that are included solely for teaching purposes, each one showing how some rather intricate gardening operation should be done. Condensation, or rather abbreviation, has been adopted throughout, yet all the genera that are of interest to gardeners are included, together with the principal species, whether they are hardy, half-hardy or tender, shrub, bulbous or herbaceous plant, colour of the flowers, method of propagation and the soil required to grow them in. Perhaps we cannot do better than quote one instance of the style adopted, as this will give readers a better idea of the book than any description can convey: "Antirrhinum (Snapdragon). Order Scrophulariaceæ. Hardy perennial plants of considerable beauty, especially in the case of the garden forms that have been introduced during recent years. They are invaluable for the border and in distinct colours for beds. Propagation, by seeds out of doors in August, or by cuttings of growing shoots in October in a cold frame. Antirrhinums can also be grown as half-hardy annuals, sowing seeds in warm frames in spring, and planting out at the end of May; they bloom within six months of seed-sowing. Soil, any ordinary garden soil. The principal species is majus, 2 feet, pink; but for general use the garden forms are of far greater importance." It will be seen that the above information covers the chief points that a practical man would need to know about Antirrhinums. At the end of the volume, in the form of an appendix, lists of the best varieties of florists' flowers, with their colours, are given, such as "The Best Types of Aster," "Twenty-four Sweet Peas for Exhibition," "Eighteen Sweet Peas for Garden Decoration," "Twenty-four Exhibition Violas" and "Twenty-four Bedding Violas," so that one may see at a glance the best varieties to grow for various purposes. This volume should be a constant companion of the gardener, whether he be amateur or professional, its size allowing it to be carried in the coat pocket. As a cheap, reliable and thoroughly practical encyclopedia of horticulture, this book will meet a long-standing demand, and we venture to predict that it will be one of the most popular gardening works that Mr. Wright has ever produced.—H.

#### The London Catalogue of British Plants.†

—To students of British botany the news that a new edition of this useful catalogue has been issued, in which the names have been brought quite up to date, will be welcome. As we advance in knowledge changes naturally have to be made, and although these may be somewhat disconcerting at first it is better to put up with a temporary inconvenience than to perpetuate what has been proved incorrect. The genus *Menchia* has been retained, and *Clinopodium*

\* "Cassell's A B C of Gardening," An Illustrated Encyclopedia of Practical Horticulture. By Walter P. Wright. 3s. 6d. net. London: Cassell and Co., Limited.

† "The London Catalogue of British Plants." Tenth edition. Edited by Frederick J. Hanbury. Price 9d. Messrs. George Bell and Sons, 6, Portugal Street, London, W.C.

for *Calamintha vulgare*, L., has been restored, but *Calamintha* is retained for the other species. Alien plants have been reduced somewhat by expunging those hitherto included that are of very rare or doubtful occurrence. The present edition has been mainly prepared by Mr. W. A. Clarke and the Rev. E. S. Marshall.

### MESSRS. E. WEBB AND SONS' PRIMULAS.

MESSRS. E. WEBB AND SONS, the well-known seedsmen of Wordsley, Stourbridge, make a great speciality of fine strains of the Chinese Primula, large quantities of plants being grown for seed

## ANSWERS TO CORRESPONDENTS.

### FLOWER GARDEN.

**Hints for bedding** (*Anxious*).—We could give you many additions to your list and not a few suggestions, but in view of what you say in your letter the exceptional situation would appear to require local knowledge. The four crescent-shaped beds would look well with *Heliotrope* and *Ageratum* alternately, the plants to be pegged down in each case. The centre

colours of things, whereas the edging to one bed is often seen to be in conflict with that of its neighbour.

**Plants for old wall** (*Mural*).—You do not say what exposure your wall has or its state as regards its condition of pointing, but on the presumption that an old one such as yours has the mortar loose and inclined to crumble, it would be easy to establish many flowers upon it. This is not, however, a good time to begin, and early autumn is better, employing seeds in preference to young plants, although with a good season many young plants might succeed. About the end of August or early in September insert three or four seeds in many of the little crannies

of the wall, putting a little soil in with them and covering with a thin piece of wall moss. If dry weather continues, try to keep the wall moist to induce germination; but if you cannot do so, those seeds which remain dormant will probably come in spring. Use fresh seeds if procurable. There are too many plants suitable to name in the limits of a reply, but any of the *Alyssums*, *Antirrhinums*, *Arabises*, *Arenarias*, *Aubrietias*, the smaller *Campanulas*, such as *garganica*, *portenschlagiana* and *pusilla*; *Centranthus ruber*, *Corydalis lutea*, *Dianthus cæsius* and other *Pinks*, *Erinus alpinus*, *Sedums*, *Sempervivums* and *Tunica saxifraga* are excellent for the purpose.

CHINESE PRIMULA WEBB'S NEW SNOW QUEEN AS GROWN IN MESSRS. WEBB'S NURSERIES AT WORDSLEY.

purposes annually in their nurseries at Wordsley. Our illustration is of a new one named Webb's New Snow Queen. It is a magnificent giant white of sturdy growth, the large flowers being produced very freely indeed. They are pure white, and of excellent substance, and are held well above a carpet of rich green foliage. This charming novelty is worth including in the best of collections. We had the pleasure some time ago of visiting Messrs. Webb's seed warehouses and nurseries, and were much impressed with the care taken to ensure the best seeds only being supplied to customers. Every precaution possible is taken that the plants for seed purposes shall be kept absolutely true to name.

star might be planted with single scarlet *Begonias*, having a groundwork of white Tufted *Pansies*, and both are continuous and free in flowering. The circular beds would be effective if planted wholly with pink-flowered *Ivy Pelargonium* pegged down at first and then allowed freedom, while the four pointed beds could be treated with mauve and yellow Tufted *Pansies* (*Violas*) in pairs respectively. The above arrangement will be a break away entirely from the system of lines and edgings of last year, and will be far more effective generally. The beds, which we imagine to be on the lawn and not marked out by gravel paths, are too small to admit of good treatment other than with massed

**Border for a bed** (*Thrifless*).—Yes, a border of *Thrift* would do quite well instead of the grass, and the brightest and best for your purpose would be *Armeria maritima lauchiana*, sometimes sold simply as *A. lancheana*, which has bright red flowers. A lower border of rock-work would be more attractive and varied in interest. This you could plant with a varied selection of alpine, such as Mossy and Encrusted *Saxifrages*, with some of the London Pride section, such as *S. Geum*, *S. Andrewsii*, or *S. primuloides*, together with *Silene Schafta*, *Tunica Saxifraga*, *Gypsophila prostrata*, spring *Phloxes* of the *setacea* or *subulata* type, *Sedums spurium*, *coccineum*, *oppositifolium*, *kamtschaticum* and

others of similar habit; and also with plants of the Thrift. If you wish something cheaper and more quickly grown, one of the *Cerastiums* would be excellent, and *Biebersteini* and *grandiflora* grow more quickly than *tomentosa*, the common one. These could be raised from seeds, but you would need to buy plants of most of the others. An alternative for this season would be a border of the annual *Saponaria ocyroides*, planting the perennials in late autumn for next year.

**Diseased Tulip leaves** (*A. Mackenzie*).—The leaves are attacked by a disease known in Holland as "The Fire." It is the result of damp cold nights, cold fog, or hail on the leaves—that is to say, these conditions are those which favour the growth of the fungus. The bulbs sent were quite healthy. If possible cut away the diseased parts of the leaves, but if they are too far gone nothing can be done. Our experience is that although the bulbs are weakened when the leaves thus prematurely decay, they are not permanently injured, and that if they are taken up and dried in the ordinary way they will grow the following year and produce fair results.

**Plants for large jars** (*Mabel G. D.*).—The following plants will be likely to succeed in your jars: Small-leaved Ivy, *Vinca minor*, common white *Arabis*, *Iberis sempervirens* and any *Andrietta*. All except the Ivy are good flowering plants, and all are, of course, evergreen. You might form an effective display throughout the summer by filling them with Ivy-leaved *Ceraniums*; some of the branches could be staked to give height, and the remainder could be allowed to hang naturally round the sides of the jars. You would, of course, have to select varieties whose flowers would not clash with the colour of the jars. By allowing *Arabis*, *Andrietta*, *Vinca* or *Iberis* to grow freely they will soon drape the jars effectively.

## TREES AND SHRUBS.

**Arundinaria Falconeri flowering** (*A. E. S.*).—It is more than likely that all the plants of *Arundinaria Falconeri* now flowering will die. Some people state that the life of a plant can be saved by cutting it down as soon as it shows signs of blooming, and others declare that after a lapse of time old stools that have flowered will again produce normal leafy shoots. So far as our experience goes, neither of these ideas are to be relied on, and, if an odd example now and then does start again, it is too pitiable an object for two or three years during the transitory state to warrant its inclusion in the garden. It is a much better plan to collect seeds from flowering specimens and start again with young plants. The seeds germinate quickly, and after the young plants have attained the age of one year growth is rapid. Anyone commencing with seedlings may depend on them being safe from flowering for at least thirty years. Some nurserymen in the South of England have already raised a stock of plants, which have attained a saleable size, from seeds produced from plants which bloomed two or three years ago.

**Making a Rhododendron bed** (*W. H. T.*).—Your bed should be treched to a depth of 1½ feet, the bottom of each trench being broken up as you go along. If your soil does not contain lime in any serious quantity, you may use from 1 foot to 15 inches of the upper portion or top spit to fill your bed with; on this spread about 6 inches of peat and fork it into the soil. You will find this much better than filling the bed entirely with peat. If your soil contains lime, remove the top 18 inches and import sandy loam from which lime is absent. The work may be done during April, but should not be delayed later. Any *R. catawbiense* varieties will be suitable; but you cannot go far wrong by selecting varieties which bloom during late May and June. The appended list is made up of good and vigorous sorts; but it would be as well to consult some local specialist about them, as some sorts do not thrive in every district: *Alexander Daneer*, rose; *Amphion*, pink; *Charles Bagley*, red; *everestianum*, rosy lilac; *Hermit*, scarlet; *James Nasmyth*, rosy lilac; *Lady Grey Egerton*, bluish; *Lord Palmerston*, rosy crimson; *The Queen*, white; *Mme. Carvalho*, white; *John Waterer*, crimson; *Michael Waterer*, crimson; *Sappho*, white, spotted red; and *fastuosum fl.-pl.*, lilac.

## ROSE GARDEN.

**Rose Fortune's Yellow with spotty foliage** (*Ignoramus*).—This Rose is very apt to fail in the way you state, and often it is owing to trouble at the roots. It is a variety that should have ample drainage and be severely pruned after it has blossomed, so that with heat and moisture during the summer a healthy new

growth takes place. There can be no doubt but that this beautiful Rose succeeds best when upon its own roots, as sometimes the falling foliage is owing to the faulty union when the plant is a budded or grafted one. At the same time, it is possible that you have given it an overdose of the manure. It is a powerful manure and should only be given to vigorous, healthy plants. As you say it is the plant's first year we think you would have been better advised if you had not given the artificial manure. If stimulants were needed a little soot water would have been most helpful, supplemented with liquid cow manure. The *Dielytras* having blossomed should be placed in a cold pit or in a sheltered spot and planted out in the garden in May, or, if preferred, they can be plunged in ashes in their pots in a sunny spot later on, and so kept until next season, when they may be brought again into the greenhouse.

**Tea Roses losing the foliage** (*A. B.*).—You do not say whether your plants are pot-grown, but we assume this to be so. It was natural for them to shed the old foliage in the autumn, and you should have pruned the plants about Christmas or a little later, cutting back the shoots pretty hard. The new growths would then have been stronger, coming as they should do from the best eyes. As it is we expect they appear near the ends of the small, thin wood, and such shoots can never be any good and are very prone to drop their foliage. You have probably kept the plants too moist. They do not require much water until new growth is active. You should always tap the pots, and only give water when they sound clear and bell-like. The variety *Niphetos* requires more heat than you can give with an oil stove, but *Marie van Houtte* should have succeeded. Try the plan of less watering and more heat if you can give it. The next growth may be better; if not, do not waste any more time on sickly plants, but procure new ones and make another start.

## THE GREENHOUSE.

**Ivy-leaved Pelargoniums diseased** (*Hampshire*).—Judging by the leaves sent, the Ivy-leaved *Pelargonium* appears to have been kept too warm and the plant too highly fed, or it has been given an excess of water at the roots. These causes combined would render the young leaves exceedingly soft in texture, and with the return of spring and increased heat in the sun the burnt-up appearance may be thus accounted for. This theory would explain the lower leaves being untouched, as naturally they are firmer in texture and better able to resist the brilliant sunshine. If the plant is not in good condition at the roots it should be at once repotted, taking away most of the old soil. Should this, however, not be necessary, the better way to combat this trouble will be to give the plant plenty of fresh air and discontinue the use of stimulants for a time, that is, if any have been used.

**Propagating Calanthes** (*E. C.*).—To propagate *Calanthes* take the top of the pseudo-bulb as a cutting. It should be taken off just below the natural joint, and the end portions must be dusted with charcoal dust and allowed to lie on the stage for two or three days before potting. This is a good time of the year to carry out this operation. The top of the pseudo-bulb that has been taken off must be potted the same as the bulb itself. Full directions for doing this were given in THE GARDEN for April 18.

## MISCELLANEOUS.

**Book on Vines** (*H. Gardner*).—Barron's "Book of the Vine" will suit you. It may be obtained from any publisher, price 5s.

**Peach foliage injured** (*C. J. E.*).—Your tree is suffering from a very bad attack of Peach blight. If the tree is so badly affected all over as is the branch sent, we certainly recommend you to pull the tree up and burn it, especially as it was affected in this way last year. This disease has always a tendency to return, and it may affect the other trees in the same house. Clear out the soil in which it has been growing, and plant a healthy tree in new soil in early autumn. Dress your trees next winter with the new mixture "Medila," sent out by Messrs. George Bunyard and Co. They claim for it that it is an effective preventive of this disease.

**Moss litter manure for hot-bed** (*Peter*).—The absence of straw in moss litter manure not only militates against its fitness for a hot-bed, but straw is also needed to assist in the proper building up of a hot-bed. It is questionable whether the manure for the purpose

named would not be improved if short straw were thoroughly wetted, then mixed with the manure. The moss litter seems to lack capacity to generate heat through fermentation as straw does. If you do not add straw, then have the moss litter manure thrown into a heap, damping it in the turning if at all dry, and, so soon as it has generated warmth, turn it and again moisten it, letting it so lie for a week before building it up as a hot-bed. It may be needful to fix stakes in the ground from 18 inches to 24 inches in height, to enable the sides of the bed to remain firm and upright. Before putting seeds or plants into the bed, allow any strong steam generated to escape for two or three days at the back of the frame.

**Name of fruit.**—*Rev. J. J. B.*—The Apple you send is Newton Wonder.

**Names of plants.**—*Ben Rhys*.—*Primula rosea*.—*J. Ferguson*.—*Eupatorium Purpureum*.—*W. A. B.*.—*Gasteria verrucosa*.—*W. H. Cox*.—*I. Seneio Kempteri*; 2. *Hemerocallis* species, cannot name without flower.—*R. O.K.*.—The Rose is Anna Olivier, one of the best Tea Roses.

## SOCIETIES.

### NORFOLK AND NORWICH SPRING FLOWER SHOW.

This exhibition was held in St. Andrew's Hall, Norwich, on the 25th ult. amid such weather as one would have expected at Christmas, snow and sharp frost being the chief topic of conversation. This naturally had a good deal to do with a falling off in the exhibits of *Narcissi* and hardy flowers. The indoor-grown subjects, however, were ably represented in all sections. Four circular groups of flowering and foliage plants were set up, and gave the centre of the hall a graceful appearance. The list of classes, with the first prize-winners in each case, were as follow: Circular group, Mr. W. Palmer, gardener to I. B. Coaks, Esq.; *Anemones*, R. Fellowes, Esq.; *Carnations*, Mr. W. Allan, Gunton Park Gardens; twelve bunches exotic flowers, Mr. W. Chettleburgh, gardener to Colonel Rous, Worstead; six bunches, Mr. H. Rider Haggard; twelve bunches hardy flowers, Mr. Louis Smith, gardener to R. Fellowes, Esq.; *Shotesham Hall*; six bunches, Mr. O. Corder; *Narcissi*, thirty-six varieties, three blooms of each, Mr. George Davison, gardener to Major Petre, Westwick Hall Gardens; twenty-four varieties, Mr. J. C. Blofeld; twelve varieties, all trumpets, Mr. G. Davison; twelve varieties, trumpets excluded, Mr. T. Chaplin; six trumpets, Mrs. Stedman; vase of *Narcissi*, Mr. G. Davison; *Pansies*, Mrs. M. R. Stedman; *Polyanthus*, Mr. T. Nottley, gardener to the Mayor of Norwich; six bunches of flowering shrubs, Mr. G. Davison; *Tulips*, Mr. L. Smith, *Shotesham*, and also for exceptionally good *Violets* in six varieties; *Amaryllis*, Mr. T. Nottley; *Anuriclas*, Mr. G. Davison; *Calceolarias*, Dr. Osburne. For *Cinerarias* in both sections, Mr. F. Williams, gardener to Louis Tillet, Esq., M.P., Catton, was first, staging the best plants ever seen at a Norwich show. In three classes for *Orchids* Mr. Rider Haggard was first, and was closely followed by Mr. L. Smith, *Shotesham Hall Gardens*. *Cyclamens*, Dr. Osburne; flowering table plants, Mr. W. Palmer; foliage table plants, Mr. W. Burtenshaw, gardener to H. Skelton, Esq.; *Lily of the Valley*, Mr. F. Williams; *Zonal Pelargoniums*, Dr. Osburne; *Primulas*, Mr. T. Nottley; *Roses* in pots, Mr. F. Williams; *Azaleas*, Dr. Osburne; *Strawberries* in pots, Mr. F. Williams; *Asparagus*, Mr. T. Chaplin; *French Beans*, Mrs. Thomson; *Broccoli*, Mr. W. Chettleburgh; *Cucumbers*, Mr. W. Laws, gardener to E. G. White, Esq., Eaton; *Mushrooms*, Mr. T. Nottley; *Potatoes*, Mr. W. Chettleburgh; *Peas*, Mrs. Lubbock; *Rhubarb*, Mr. A. Woodhouse, gardener to Sir H. H. Cozens Hardy; *Tomatoes*, Mr. W. Joice; collection of vegetables, Mrs. Lubbock; *Seakale*, Mr. N. Wright.

The trade contributed a pleasant display, which gave added interest to the exhibition. Deserving of special mention under this heading were Messrs. Daniels Brothers, Limited, Norwich, for a bold display of choice miscellaneous flowering and foliage plants, which bore evidence of grand cultural treatment. Hobbies, Limited, Dereham, most effectively staged various types of cluster *Roses*, also *Lilacs*, *Magnolias*, *Azaleas* and *Rhododendrons*. Mr. R. C. Nottent of Woodbridge and Ipswich displayed some choice examples of forced flowering shrubs, using the varieties of *Genista* with telling effect. Mr. T. E. Dawes, Syderstone, made a fine display of his new Challenge *Rhubarb*, for which he was awarded a bronze medal and also a certificate of merit. The attendance was much below last year, and as a consequence the gate money was £10 less.

### BIRMINGHAM DAFFODIL DISCUSSIONS.

By the above title I mean the interesting Daffodil conversation that always follows the ending of the toast list after Mr. R. Sydenham's dinner at Birmingham. A large number of prominent growers, hybridists, trad rs, exhibitors and enthusiasts are always present, and what they say and talk about cannot fail to interest a wide circle of friends in all parts. Mr. Davis of Christchurch, New Zealand, had undertaken the long journey at this particular time in order to be present, and so had Mr. van Waveren from Holland. The former told us there were a good many Daffodil shows at the Antipodes, e.g., at Christchurch, Dunedin and Melbourne, and that as a result of a big syndicate's purchase from Mr. Engleheart, they had flowers there that could rival ours. To make good his assertion he told us he proposed to send some over in ice for next year's show. I hope he will remember his promise, for such an exhibit would be most interesting. "Show Flowers: Their Cultivation and Development" was the nominal title of the discussion. It included such

questions as the frequency of lifting bulbs, protection from cold and wind, when to cut for show, and what to do with the flowers or buds when cut. This last seems a simple matter, and the man in the street would think it almost a joke that it should be mentioned at all. Nevertheless, Mr. E. M. Crossfield, who is one of our very best show men, told us that he had five temperatures in which to put the different flowers after they were cut. Another fact of interest was stated by Mr. Chapman of Rye, viz., that big buds should always be selected, and that it was advisable to make the cut in a slanting direction, so as to expose a larger absorbing surface. Everyone seemed agreed that a change of soil was, as a rule, good; but that the factor, which is more important than all others, is that of climate.

When the discussion seemed to be coming to an end the writer made a few remarks about the show classification difficulty. It does not seem to be much use to go on raising beautiful "doubtful" flowers if we do not know where to put them when we have them. A flower of Messrs. Cartwright and Goodwin's had been the subject of much difference of opinion up to the show, and to meet such cases it was suggested that something ought to be done officially by the Royal Horticultural Society. It would be a boon to every judge and every show committee to have some generally recognised standard to go by. What that standard is does not so much matter as that there should be one. Mr. P. R. Barr, Mr. W. Barr, Mr. James Walker, Mr. Sydenham and several others gave their views on the question, and so a most interesting talk delayed the hour of breaking up much later than usual. JOSEPH JACOB.

#### ROYAL HORTICULTURAL SOCIETY.

At the fortnightly meeting held at Vincent Square, Westminster, on the 28th ult., the exhibition was a very extensive and interesting one, despite the miserable weather that prevailed. Flowers were displayed in abundance, Narcissi, Roses and forced flowering shrubs predominating. The display was augmented by the exhibition of Auriculas and Primulas held under the auspices of the National Auricula and Primula Society. A few fruits were shown, just a few vegetables, and a most interesting little collection of salads came from Messrs. James Veitch and Sons, Limited, Chelsea. When will our leading growers give us some good groups of vegetables? They would much increase the interest of the exhibitions and also prove of educational value.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, W. J. Jefferies, W. Bates, H. Markham, Alex. Dean, E. Beckett, R. Lye, H. Parr, A. R. Allan, J. Millard, J. Lyne, Charles Foster, G. Reynolds, J. Jaques, J. McIndoe, Owen Thomas, George Wythes, W. Poupard, A. H. Pearson, J. Davis and J. Vert.

Messrs. James Veitch and Sons, Limited, Chelsea, staged a very fine group of Apples and Pears, including fifty-eight different varieties and all in an excellent state of preservation. Gloria Mundi, Bramley's Seedling, Harvey's Wiltshire Defiance, Lane's Prince Albert, Lord Hindlip, Melon Apple, Rhymor, Chelmsford Wonder, Claygate Pearmain, Annie Elizabeth, Belle Pontoise, Dumelow's Seedling, Blue Pearmain, Newton Wonder, Bismarck, Cox's Orange Pippin and Lord Derby were the best among the Apples. Silver Knightian medal. This firm also had a very interesting exhibit of Lettuces and Radishes grown under cloches in the French style. These were very fine and created much interest among visitors. The Passion Cabbage Lettuce is a bright green compact-growing variety with solid white heart; Early Frame Cabbage is a green tinged with brown sort and somewhat loose in texture; and Early Market Cos is a white variety of self-closing habit and large size. Silver Banksian medal.

Sir Edmund Loder, Bart. (gardener, Mr. W. A. Cook), exhibited a very fine dish of Seakale grown in the open from thongs planted in April last year. The heads were very large and firm and were perfectly blanched, the exhibit constituting the best we have seen of this vegetable for a long time. Cultural commendation. Some nice heads of Broccoli Sutton's Eastside, from seeds sown on May 2, 1907, also came from the same source.

The Right Hon. Lord Hillingdon, Hillingdon Court, Uxbridge (gardener, Mr. A. R. Allan), exhibited three boxes of very fine fruits of Strawberry Royal Sovereign. They were large, regular, well finished and of grand colour. A plant in fruit was also exhibited, this carrying seven large and well-ripened fruits. Silver Knightian medal.

#### ORCHID COMMITTEE.

Present: Mr. J. Gurney Fowler (chairman), Messrs. James D. Vinn, Harry J. Veitch, H. Little, W. Boxall, G. F. Moore, Richard Thwaites, John J. Cypher, J. Forster Alcock, Walter Cobb, W. P. Bound, Arthur Dye, W. H. White, H. A. Tracy, Gurney Wilson, J. Wilson Potter, C. J. Lucas and W. Bolton.

Mr. H. Little, The Barons, East Twickenham, staged a nice bank of well-grown Orchids, including many Cattleyas, Cypripediums, Lælio-Cattleyas and a few Odontoglossums. Cattleya Mossie, C. lawrenceana, C. schilleriana, Lælio-Cattleya hyemalis splendens, L.-C. highburyensis, Cypripedium Curtisii and C. villosum aurea were some of the best specimens. Silver Flora medal.

Messrs. Armstrong and Brown, Tunbridge Wells, staged a very pretty group of Orchids, the arrangement here being of a novel and pleasing character. Choice plants were thinly arranged at varying heights in a loose, irregular bank of Adiantums and fresh moss, thus affording visitors an opportunity of seeing them at their best. Odontoglossum crispum varieties, Cypripedium bellatulum, C. lawrenceanum variety, Lælio-Cattleya Mercia, L.-C. Isabella purpurata, a very curious little Bulbophyllum, Lælia

majalis and Masdevallia courtauldiana were the most conspicuous in a very interesting group. Silver Banksian medal.

Messrs. James Cypher and Sons, Cheltenham, had a very choice little group of grandly grown Orchids in the annex. Leptotes bicolor (very pretty specimen), Odontoglossum nevium, Lælio-Cattleya dominicum magnificum (very large and rich), L.-C. diglyana Mossie, Miltonia vexillaria, M. blueana and Ada aurantiaca were the most noticeable in a lovely group. Silver Banksian medal.

Messrs. Hugh Low and Co., Royal Nurseries, Enfield, Middlesex, were represented by a nice collection containing some very fine plants of Dendrobium barbatulum. These were very floriferous and made quite a striking display. Cattleya Mendelii General Botha and C. intermedia alba were other fine plants in this exhibit. Silver Banksian medal.

From Messrs. Heath and Son, Cheltenham, came a nicely-arranged group of various subjects. These included Odontoglossums, Cattleyas, Cymbidiums, Cypripediums and similar kinds in great variety. Silver Banksian medal.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gardener, Mr. Davis), exhibited a very fine group of Oncidium marshallianum. One plant was exceptionally good, the huge pseudo-bulbs being surmounted by five magnificent inflorescences. The individual flowers, too, were very fine, the colour and substance being first-class. This plant received a cultural commendation, and a silver Flora medal was awarded for the group.

#### FLORAL COMMITTEE.

Present: Mr. William Marshall (chairman), Messrs. Charles E. Shea, C. R. Fielder, James Douglas, W. A. Binney, J. Green, T. W. Turner, G. Reuthe, J. Jennings, J. W. Barr, W. F. Ware, Charles Dixon, Arthur Turner, Charles E. Pearson, William Cuthbertson, J. T. Bennett-Poe, H. J. Cuthbush, W. P. Thomson, E. H. Jenkins, W. J. James, C. T. Drury, E. C. Nofcutt and James Hudson.

Messrs. James Veitch and Sons, Limited, Chelsea, staged a fine assortment of Daffodils in many choice varieties, also a delightful lot of pot-grown plants of Schizanthus in many colours, and which are known as Veitch's grandiflorus hybrids. They are certainly a very fine strain with larger flowers than the type, of deeper colour and with a more compact habit of growth. Among many interesting things from this firm we noted batches of Primula cockburniana, Hydrangea Hortensia rosea (blue), Veronica diosmifolia, Rhododendron Lady Alice Fitzwilliam, together with a choice lot of Cinerarias of an excellent strain. Silver Flora medal.

Messrs. G. and A. Clark, Limited, Dover, exhibited alpine and early hardy flowers in variety, including Aubrietias, Primroses, Daffodils, Starch Hyacinths and other flowers.

Mr. Alex. M. Wilson, East Keal Manor, Spilsby, had a pleasing lot of new Narcissi, many being seedlings bearing numbers only. Of the named sorts King's Norton, self yellow ajax; Grayling, white, with lemon cup; and Cuckoo, a lovely white flower, with lemon orange crown, were among the best in the group. Some capital bunches of Polyanthus represented an excellent strain of these flowers.

Stove plants of table utility came from Messrs. William Bull and Sons, Chelsea, the firm also displaying a collection of Daffodils.

Messrs. Cannell and Sons, Swanley, had a large, imposing lot of their Zonal Pelargoniums, handsome bunches of these invaluable flowers being set up in superb fashion. There were some three dozen vases of these showy flowers staged in the leading sorts. Silver Banksian medal.

Messrs. T. S. Ware, Limited, Feltham, had a large display of Aubrietias, such as Græca, Mr. Mules, Bridesmaid (pink), Prichard's A1 (a very dark variety), Crimson King and others. Primula Sieboldi was also largely displayed.

The Misses Hopkins, Shepperton-on-Thames, had a very charming exhibit of early hardy flowers most tastefully arranged on a rockery bank in moss and rocks. Single and double Primroses, Aubrietias in variety, Primula frondosa, Auricula Queen Alexandra (a fine yellow-flowered sort of robust growth), Fritillarias, Gerberas, Cambric Poppies and many more were included, the whole being nicely displayed. Silver Banksian medal.

Messrs. Barr and Sons, Covent Garden, staged a delightful lot of choice Narcissi, representative of several sections of the flower. Buttercup is a lovely flower of the richest golden yellow, very firm in texture and of splendid stature; Furnace, with fiery orange cup, is a gem in its way; while Staysail, Faction, Radiant (a glorious Poet), Peter Barr, Cygnet, Pedestal, Lucifer, Mrs. Betteridge, Chancellor, Cosmos and Pixie (a glorious Engleheartii) were among the best of a wonderful lot.

Messrs. William Cuthbush and Sons, Highgate, had a very fine group of Heaths, Spiræas and Carnations in fine flower. Rhododendron Smithii aurea in many fine bushes was exceptionally well grown, the pale yellow trusses of bloom being most effective. Colons Cordelia is very showy and good, and the new Spiræa Peach Blossom is very fine. The Carnations were superbly shown, Robert Craig making a grand display. Lady Hermione was also fine, and Victory is one of the best of the scarlet sorts. Silver-gilt Banksian medal.

Mr. H. J. Elwes, Colebourne, Gloucestershire, showed a few interesting plants, such as Cantua dependens, Alpina nifans, Amaryllis and Bonariæas.

Messrs. Hugh Low and Co., Enfield, had a very fine display of Metrosideros floribunda, a score of specimens, each 2 feet or more across, making a most effective display with the scarlet bottle-brush-like inflorescence. The plant is known as the Bottle-brush Tree, and is one of the most showy of Australian plants. Silver Banksian medal.

Messrs. Dobbie and Co., Rothesay, set up a beautiful lot of bedding Violas and Pansies in great variety, the many

self-coloured flowers attracting a good deal of notice. Snowflake, Royal Sovereign, A. J. Rowberry, Blue Cloud, Admiral of the Blue and Maggie Mott were a few of the most distinct. A fine strain of Polyanthus came from this firm, and among these were a few of the gold-laced varieties. Silver Banksian medal.

Mrs. Burns, North Mylms Park, Hatfield (gardener, Mr. C. R. Fielder), showed fine white Amaryllis seedlings, of which Purity is, perhaps, the best of all.

A very fine specimen of Echium callithyrsum, with only two of the fine blue inflorescences on a 6-feet high plant, came from Mrs. Bridget Talbot, Berkhamstead (gardener, Mr. E. Pinnock). It is a very handsome plant of quite woody growth.

The Carnations and trumpet Lilies from Mr. W. H. Page, Hampton, were superb. Enchantress, Mrs. Lawson, White Enchantress, Britannia (very fine scarlet), White Mr. Lawson, Winsor, My Maryland and Governor Roosevelt were all grandly displayed over a bed of Maidenhair Ferns. Silver Flora medal.

Mr. George Mount, Canterbury, again showed Roses in superb fashion. Bold groups of Ulrich Brunner, Frau Karl Druschki and Mme. Abel Chateaufort at the ends and centre were very fine, and these, with fine groups of Mrs. Sharman Crawford, Catherine Mermet, Captain Hayward, Richmond, Liberty, Joseph Lowe and John Laing, made a really grand display. Silver-gilt Banksian medal.

Mr. G. Reuthe, Keston, Kent, had a most interesting lot of hardy things, many species of Primulas, Fritillarias, Aconitum nemorosum atropurpureum (very fine), Androsace carnea, with a number of Saxifragas and other plants. Paracarya angustifolia is a fine blue-flowered plant of merit, growing 1 foot high or more. Some pretty Daffodils and flowering shrubs were included in the group. Silver Banksian medal.

A group of Rhododendrons, such as Aucklandii, Dalhousii, victoriana Aucklandii hybrida, with handsome bunches of Cantua dependens and Posqueria longiflora, came from Mrs. F. G. Godman, Horsham (gardener, Mr. Moody), and formed a sumptuous feast of the flowers named.

Mr. J. R. Box, West Wickham, showed a very pretty lot of alpine plants, pans, &c.

Messrs. Cartwright and Goodwin, Kidderminster, had a lovely lot of the newer Narcissi, in which Chloe, Evangeline, Weardale Perfection, Homespun, Rising Sun (a fine yellow self), Mme. de Graaf and Astrophel were among the finest.

Messrs. Pope and Son, King's Norton, Birmingham, had a pretty group of Narcissi, in which Glory of Leiden, Lucifer, Gloria Mundi, Weardale Perfection and others were seen. Among the seedlings many were very fine, and gave one pleasure to view.

An interesting group of plants, such as Rhododendrons, came from Messrs. Paul and Son, The Old Nurseries, Cheshunt.

Messrs. Frank Cant and Co., Colchester, staged many pillar Roses in variety. Silver Banksian medal.

Lilacs, Berberis and other shrubs were freely shown by Messrs. J. Cheal and Sons, Crawley.

Messrs. Paul and Son, Waltham Cross, had a few lovely Roses, Lyon Rose (copper, with salmon merging to pink) being very pleasing. Albatross (a good white) and Kathleen (a deep carmine pillar variety) were also noted. Silver-gilt Banksian medal.

Messrs. Carter and Co., High Holborn, displayed Cinerarias in a large, well-formed bank. Silver Flora medal.

Mr. L. R. Russell, Richmond, had a delightful group of Azaleas, Lilacs, Prunuses and Clematis arranged in the most pleasing fashion. Silver-gilt Banksian medal.

Messrs. R. and G. Cuthbert, Southgate, had a lovely group of Azaleas, Lilacs, Prunuses, Wistaria and other plants associated with Palms, Acers and other plants. Silver Flora medal.

Alpine and rock plants were shown by the Misses E. and M. Kipping, Hutton, Essex, Primroses and Auriculas being prominent.

The Guildford Hardy Plant Nursery showed Primulas, Aubrietias, Thalictrum anemonoides and many other choice plants.

Messrs. Peed and Son, West Norwood, arranged a group of alpine plants in boxes, together with Gloxinias in good bloom. Silver Banksian medal.

Mr. M. Prichard, Christchurch, Hants, had a pleasing exhibit of Aubrietias, Cyclamen, Crown Imperials, Primula Sieboldi and other plants in a quite fresh condition. Silver Banksian medal.

Mr. James Douglas, Great Bookham, Surrey, showed three fine plants of Myosotidium nobile (the Chatham Island Forget-me-not) in fine condition.

Messrs. George Bunyard and Co., Maidstone, had many delightful hardy plants, such as Marsh Marigolds, Primulas, Aubrietias, Daffodils and Saxifragas. Silver Banksian medal.

Messrs. Wallace and Co., Colchester, had a delightful lot of Tulips and hardy flowers generally, Caltha polypetala being very fine.

Mr. C. E. Waters, Balcombe, Sussex, had a very pretty group of Carnations of the American section in many good varieties. Silver Banksian medal.

Messrs. H. B. May and Sons, Edmonton, staged a group of flowering and foliage plants, in which Ferns, Petunias, Clematises, Calceolarias and other plants were seen. Silver Flora medal.

Messrs. Carter Page and Co., London Wall, exhibited a charming lot of Tufted Pansies in many varieties; and Mr. Robert Sydenham displayed Narcissus and Lily of the Valley in fibre moss.

Tulips were freely displayed by Messrs. Cuthbert and Co., Southgate; and Messrs. George Jackman and Son, Woking, had Primula Sieboldi and other good hardy plants in plenty.

SOME NEW FUCHSIAS.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

## HOW TO MAKE A SMALL ROCK GARDEN.

(First Prize Essay.)

ONLY to those who have made or possessed a rock garden is known the intense fascination and perennial interest which attaches to the culture of the little alpine races.

Much more space than is here permitted would be required in which to thoroughly instruct the uninitiated in the art of making even a small rock garden which would be entirely suited to the needs of all its charming inhabitants. The likes and the antipathies of each one of these must be studied and learned by experience (a far better instructor than a library full of books), such as, for instance, that *Ramondia pyrenaica* droops in the sun, that lime in the soil will kill the beautiful ever-flowering *Lithospermum prostratum*, while our brilliant little native *Sedum aere*, though waxing fat, will refuse to bloom if given much or rich soil. By studying a few leading trade catalogues the beginner will find which plants require sun or shade, moist or dry positions and so forth. A general outline only, therefore, will be given to enable the rockery to be constructed, and a list of 100 suitable plants arranged as to colour and selected so that there may be bloom all the year round.

### SITUATION.

Select your ground in the open, if possible, but if it must be near a building, then on any but the north side. Large trees and shrubs overhanging or near the rockery are fatal to success. The general trend of the garden should be north and south, in order that practically all parts may be reached by the morning or afternoon sun, for the majority of alpine delight in sunshine.

### MATERIALS.

Large and small limestone and sandstone rocks of irregular shapes will be required, while tree stumps and anything in the nature of bricks, clinker or artificial stonework must be avoided. The soil should consist of gritty loam, made rich or poor here and there as required, and mixed with a quantity of sandstone chips in order that while it may be moist and cool in summer it will be porous and light in winter, for, at all costs, there must be thorough drainage. Stagnant moisture is among the worst enemies of rock garden plants.

### CONSTRUCTION.

The shape of the garden matters little so long as Nature is studied and, as far as possible, followed. Avoid straight lines by making the rockery in all its parts as irregular as the mountain homes of our alpine friends. Create a definite idea in your mind and keep to it ; then mark out on the ground the proposed outline, clearing away all grass and vegetation for a distance of at least 3 feet, as it merely acts as a harbourage for

slugs and other pests and detracts from the appearance of the garden. Having collected the materials, carry out your preconceived design, always bearing in mind that each rock should be two-thirds buried and one-third exposed, that the soil must fill up all spaces below, behind and between the rocks, leaving no empty hollows for roots to enter and perish in, and that the upper surfaces of the rocks should slope inwards and downwards in order that rain and moisture may find its way to the roots of the plants and not towards their crowns. It will be found of advantage to so construct the garden that any part of it may be reached without treading on other parts, containing, perhaps, deciduous treasures or germinating seeds. For this reason it will be best to make a winding pathway, at least 3 feet in width, through the garden, and paved with flat, irregular stones, placed at intervals and slightly raised above the general level of the path. Some alpine, though small in stature, have very long roots, which creep and find their way for many inches down below the rocks in their search for food and moisture, therefore throughout the garden there must be plenty of root room, that is to say, depth of soil, which in no case should be less than 1 foot.

Again, since such plants as *Saxifraga longifolia*, in their native haunts, grow in verticle crevices in the faces of cliffs, provision must be made to meet their wants by constructing miniature precipices as well as level spaces, care being taken, when building, that the rocks do not project beyond or overhang those below them, as in this case moisture cannot find its way in. These steep positions will also be required on the north or shady side of the garden, where we will find *Ramondia pyrenaica* and its more beautiful form *alba*.

In this way the garden will gradually be built up and take form, with gentle slopes and levels, and steep diminutive cliffs, down the faces of which trailing plants will fall with fine and natural effect ; then there will be well-drained peat-filled pockets for miniature *Rhododendrons* and *Daphnes* ; narrow chinks for *Androsaces*, *Sedums* and *Saxifrages*, with dry stony positions for *Sempervivums*. Thus we shall avoid creating one of those horrors so often seen, which look more like graveyards than rock gardens.

Having completed the building of the garden, it should be well watered and allowed to settle before being planted.

As much thought must be given to the planting as is necessary in the construction, for not only must the plants be placed where their colours may blend harmoniously with those of their neighbours, but also where they are in no danger of being overgrown and smothered by more vigorous kinds. It is useful to remember that bulbs, such as *Snowdrops*, *Chionodoxas* and *Muscari*, do well, and look well if planted where they may in time push up their leaves and flowers through some carpeter like *Saxifraga Whitlavi* compacta or *Arenaria balearica*. The following plants are given as most suitable for a small rock garden, needing little or no special care in their culture, and from which the necessary number may be selected according to the size of the rockery to be filled. The colours

refer, of course, to the flowers and fl.-pl. means double flowers:

*White*.—*Anemone alpina*, *Arabis albida* fl.-pl., *Arenaria balearica*, *A. montana*, *Cerastium tomentosum*, *Cistus florentinus*, *Crocus*, *Dryas octopetala*, *Galanthus nivalis*, *Hutchinsia alpina*, *Iberis sempervirens* Little Gem, *Leucojum autumnale*, *Primula pubescens* alba, *P. denticulata*, *Ramondia pyrenaica* alba, *Saxifraga aizoon*, *S. graulata* fl.-pl., *S. pyramidalis*, *S. longifolia*, *S. Wallacei*, *S. Whitlavi* compacta, and *S. valdensis*.

*Pink and red*.—*Androsace carnea*, *Aubrietia Moerheimi*, *A. Fire King*, *Armeria maritima*, *Anemone fulgens*, *Dianthus alpinus*, *D. caesius*, *D. neglectus*, *Daphne Cneorum*, *Geum rivale*, *Helianthemum Beauty*, *H. Double Red*, *Hepatica triloba* rubra, *Lychnis alpina*, *Phlox amena*, *P. subulata*, *Potentilla nitida*, *Primula rosea*, *P. viscosa*, *Rhododendron racemosum*, *Saponaria ocymoides* splendens, *Saxifraga muscoides*, *S. oppositifolia*, *S. Rhei*, *S. Guildford Seedling*, *S. umbrosa*, *Sedum Lydium*, *Sempervivum tectorum*, *S. Laggeri*, *Shortia galacifolia*, *Silene acaulis* and *S. Schafta*.

*Yellow*.—*Alyssum saxatile* fl.-pl., *Adonis vernalis*, *Cheiranthus alpinus*, *Crocus*, *Draba aizoides*, *Fritillaria armena*, *Helianthemum luteum*, *Hypericum Coris*, *Iris pumila* lutea, *Linum flavum*, *Morisia hypogaea*, *Primula auricula*, *Papaver nudicaule* (various colours), *P. alpinum* (various colours), *Saxifraga Sancta* and *Sedum acre*.

*Blue*.—*Anemone blanda*, *Aquilegia alpina*, *Campanula garganica*, *C. g. hirsuta*, *C. pusilla*, *C. muralis*, *Chionodoxa Luciliae*, *Gentiana acaulis*, *G. verna*, *Hepatica triloba*, *Muscari*, *Myosotis dissitiflora*, *Scilla sibirica*, *Veronica rupestris* and *Lithospermum prostratum*.

*Mauve, purple, &c.*—*Anemone Pulsatilla*, *Aster alpinus*, *Aubrietia purpurea*, *A. Dr. Mules*, *Erinus alpinus*, *Crocus*, *Colchicum autumnale*, *Iris pumila cerulea*, *Phlox Stellaria*, *P. divaricata*, *Primula denticulata*, *P. farinosa*, *P. marginata*, *Ramondia pyrenaica* and *Sempervivum arachnoideum*. CAPTAIN TREHERNE.

*Muirbarn, Strathaven, N.B.*

## PRIZES FOR READERS.

### APRIL COMPETITION—AWARDS.

In this competition essays on "How to Make a Small Rock Garden, with a List of Suitable Plants," were asked for. The prizes are awarded as follows:

The first prize of four guineas to Captain Treherne, Muirbarn, Strathaven, N.B.

The second prize of two guineas to D. B. Allwork. No address sent; please forward it.

The third prize of one guinea to H. Buckton, 53, Albion Place, Reading.

The fourth prize of half-a-guinea to the Rev. H. Kingsmill Moore, D.D., Cedar Mount, Dundrum, Dublin.

The number of essays sent in was very large, and the quality was correspondingly high. Evidently rock gardening is a most popular subject at the present time, and our readers seem to have a very good grasp of the principles underlying the proper construction of a rock garden. The lists of plants submitted were, generally speaking, good, although a few were weak. A curious feature about a number of essays was the fact that they were almost identical so far as general statements were concerned, although the phrasing was different. Those from the following were particularly good, and deserve high commendation: Gilbert Walshaw, E. J. Lloyd Edwards, D. Reynolds, C. W. Caulfield, James R. Taylor, Alfred B. Melles, George Cooper, Mrs. C. L. Sutherland, W. H. Scott, W. E. Wood, A. M. Darling, Miss Barclay, P. Reid, S. Johns, G. H. Webster, W. L. Lavender, W. H. Morton, C. W. Crosby, L. Bigg-Wither, Leah Daly, G. Satterley, F.

Corlette, James Glasheen, J. W. Forsyth, M. E. Dishburn, E. Anderson, R. Laycock Routh, H. J. Poate, Ralph E. Arnold, H. Lancelot Robson, A. L. Simpson, F. W. Lovell, A. M. Morton, J. H. Yarrow, B. J. Beckton, T. H. Barnard, Ruth B. Cannon, A. H. Thompson, M. R. Dunn, E. P. Martin J. Richards, Mrs. F. A. Bardswell, E. H. Howard and C. Blair. One competitor, whose essay was also commendable, and accompanied by a photograph, omitted to attach name and address.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

May 26, 27 and 28.—Royal Horticultural Society's Spring Flower Show, Inner Temple Gardens, Thames Embankment; 12 noon to 7 p.m. the first two days, 9 a.m. to 6 p.m. third day.

**Kew Guild Dinner.**—We are requested to remind our readers who are Old Kewites that the annual dinner will take place at the Holborn Restaurant on the 25th inst., at 7.30 p.m.; and that the secretary, Mr. W. N. Wino, would be glad to hear before the 18th inst. from all who intend to be present.

**Royal National Tulip Society.**—The annual exhibition in connexion with the above society is to be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on the 26th inst. A silver cup and numerous silver medals are offered for competition, and it is hoped that lovers of this old-fashioned yet beautiful flower will do all they can to make the exhibition a success. Copies of the schedule and full particulars can be obtained from the hon. secretary, Mr. W. Peters, Farcet House, Cambridge.

**A new source of Cajaput oil.**—In the genus *Melaleuca*, which comprises a number of species—all fine evergreen trees or shrubs, natives of Australia—several species are in cultivation as greenhouse plants in this country, among them being *M. Leucadendron* var. *minor*, and *M. squarrosa*, which are interesting plants outside their horticultural value. Most of the species are more or less aromatic, from the presence of a volatile oil in the leaves, the timbers are intensely hard and durable, and the barks are remarkable for their paper-like nature. It is for one or other of these properties that most of the species have some economic value, though the most important and best known in this connexion is *M. Leucadendron* var. *minor*, a tree growing from 15 feet to 20 feet high and a native of the Indian Archipelago, the Malay Islands, and Australia. From the leaves of this plant the well-known Cajaput oil of commerce is distilled. Rumphius describes the mode of collecting and distilling the oil as follows: "After gathering the leaves they are put in sacks where they become hot and damp; they are afterwards macerated in water and left to ferment for a night before distillation." Two sackfuls of the leaves are said to yield only three fluid drachms of oil. It is mostly distilled in Celebes, Bonro, and Amboyna, and comes to this country in ordinary black glass wine or beer bottles. It is used in this country internally as a stimulant and antispasmodic, and externally—either alone, or in the preparation of croton oil liniment—as a rubefacient. Good Cajaput oil should be of a deep green colour. Quite recently a new source for Cajaput oil has been reported from Australia, where one of the native species (*M. uncinata*) is said to yield an oil resembling the Malayan product in some respects; "but its stearoptene or solid alcohol is a new substance not hitherto described or investigated, nor does it agree with any known substance obtained from plants. It may be that this discovery will have profound importance. Eucalyptus oil has attained world wide repute, and it is likely that the Australian Cajaput will

soon be recognised as a useful agent by medical men and chemists." Maiden states in his "Useful Native Plants of Australia," that the leaves of *M. uncinata* "if chewed are very useful in alleviating and curing ordinary catarrh. This observation is well worth repeating, especially as this particular species is widely distributed, and there is no reason to suppose that this property is confined to this species." A similar oil, but in very small quantity, is furnished by *M. squarrosa*, the bark of which, on a full grown tree, is composed of innumerable layers of a thin, papery nature, which are easily separable, and are used for making shields and canoes, and for covering huts, as well as for tinder and for other applications.—JOHN R. JACKSON, Claremont, Lympstone, Devon.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Narcissus Buttercup.**—In the excellent account given in your issue of the 2nd inst. of the Midland Daffodil Society's show at Birmingham I notice that your correspondent refers to the complete stock of *Narcissus Buttercup* as having changed hands. As this may give a wrong impression I write to say that the stock of this variety, which is very limited, is in my possession, and I have practically only decided to this season break the stock, and have parted with a very few bulbs. —CHARLES DAWSON.

**The perpetual-flowering Carnation as a summer-flowering plant.** Last summer one or two of our best gardens had experimental beds of perpetual-flowering Carnations planted out for summer flowering in the open, and they gave perfect satisfaction in this somewhat new sphere. We, at Messrs. Hugh Low and Co.'s nurseries, carried out rather extensive experiments in this direction, and found that plants put out in early May produced an abundance of flowers during the summer and were much more satisfactory than the ordinary border Carnation. It is no small advantage in being able to plant Carnations out in May for summer flowering, because with the ordinary border Carnation autumn or very early spring planting has to be done to ensure summer bloom. The best class of plant for summer flowering is that from a 5-inch pot with from eight to ten growths, that which has produced an early winter crop of bloom or which has been wintered in a cold frame giving similar results. Early-rooted cuttings in 3-inch pots with four or five growths also give quite good results. Almost any variety of the perpetual-flowering Carnation does well when so grown, and Lady Bountiful, White Perfection, Robert Craig, Harlowarden and the Enchantress family give grand results. During the last winter we had quite a large collection of perpetual-flowering Carnations planted out in the open along with ordinary border varieties, and hardly a plant has succumbed to the severity of the season and are now making good growth for flowering again. In an absolutely cold frame we wintered several thousands of perpetual-flowering Carnations in 5-inch pots, and these withstood 15° of frost and scarcely a plant has died.—MONTAGU C. ALLWOOD.

**The Poeticus section of Narcissus.**—Amid the trials and troubles that beset Daffodil enthusiasts as to where one section ends and another begins, I had hoped that at any rate those who cultivate and study true Poeticus (as I do) had little to fear in their regard, but at the Birmingham show my faith was a little shaken. I was there shown several flowers spoken of as Poeticus, which were masqueraders. One was on Mr. P. D. Williams's stand and was pointed out to me as the deepest red-cupped Poeticus yet raised. I had a good look at it, but it certainly was not true Poeticus. Again, Sir J. Gore-Booth's representative showed

me a flower of the much-vaunted Acme, which he had not put up, as it was not quite in form. Now Acme is a very perfect flower in its way, but again I say, at the risk of raising a storm, it is not true Poeticus. If the raiser were to tell me he could vouch for the integrity of its parentage I should tell him there had been some wandering bee about. The crown of Acme has a very fine shade of red suffused evenly throughout the whole of it, but it is not Poeticus red. To my mind there is no red like Poeticus red, as there is no white just like Poeticus white, and I believe I could tell an interloper anywhere. The colouring of Poeticus is so lovely, pure and distinct that the very greatest care should be exercised to maintain the section in its integrity, and no flower showing a trace of "outside blood" should be permitted within its pale.—

POETASTER.

**Sweet Pea nomenclature.**—Seeing the letter *re* Sweet Pea Nomenclature in THE GARDEN, may I add my mite to the correspondence. I do not see any objection to the giving of personal names to the lovely flowers; in fact, I think they are far more distinctive than such words as Pearl, Lovely, Beauty, &c., and provided we steer clear of the bastard Latin, so dear to the lovers of the Orchid, and do not start weighing them down with such titles as Dorothei Eckfordiensis or Horaconii wrightiana I do not think we can seriously find fault.—

F. W. B.

**Crickets in a greenhouse.**—I saw in THE GARDEN for April 25 that some one had been writing to you for advice as to how to get rid of crickets in a greenhouse. About two years ago the potting-shed and greenhouses here were infested with them. One day I noticed two large ones in a condensed milk tin, clearing out a little milk that had been left in it. I put in a teaspoonful more milk and added a teaspoonful of weed-killer powder to it, and put the tin back in the same place again. I have not seen or heard a cricket here since.—J. RAWLINGS, *The Gardens, Ridgmount, Enfield.*

**Double Arabis.**—In a short time the spring bedding-plants will be cleared from beds, and a note on the above-named subject will not be out of place. They should be lifted with a spade and heeled in in good soil in a partially-shaded place and well watered. By next October they will be a mass of growths. If these are broken off about 5 inches long and put in 3 inches deep with a trowel, 98 per cent. will grow and flower the following spring. I have put in thousands of cuttings this way, always trying to get it done during October and the first week in November, and it has always been successful.—J. RAWLINGS.

**Finches and Polyanthus buds.**—It is most disheartening to learn from "Festina Lente" that finches, in addition to sparrows, had learned to pick off the buds of Auricula and Polyanthus flowers. Having suffered severely so far as Polyanthus were concerned in and near a town from sparrows picking out the flower-buds ere developed into flowers, I had thought it was due to the general absence so early in the spring of other forms of vegetable food in or near towns. In any case, these depredators have made the growing of these beautiful hardy spring flowers near to populous places most difficult, except the plants be protected by nets or black cotton, this latter, simple as it is, having shown itself to be, so far as the sparrow is concerned, an excellent protector. But when finches, the most destructive of all garden birds, prey on our spring flowers, reckless of such simple obstructions as cotton or thread, we find it difficult to be longer tolerant when birds become man's enemies rather than his friends; the protection now granted them must be withdrawn and, in spite of real or spurious sentiment, they must be destroyed. At our present rate of progress soon nothing will be safe from birds except where gardens are wired or netted all over.—A. D.

## AN ANGLO-FRENCH ENTERPRISE

IN GROWING FLOWERS AND VEGETABLES IN THIS COUNTRY.

**I**N the little market town of Thatcham, in Berkshire, an interesting Anglo-French vegetable and fruit industry is being developed. Thatcham is situated three miles to the east of Newbury and fourteen miles south-west of Reading, and is watered by the river Kennet, and bounded on the south by the river Auburn, which separates Berks from Hants. The soil is gravel and clay, with a sub-soil of gravel, clay and peat, which does not sound very promising. In spite of this, two ladies from Wales have settled there and have brought over from France a clever gardener. In the five acres of land they have commenced a very interesting and somewhat novel method of growing early vegetables and salad stuff for London and other markets. For the vegetables only one acre has been cultivated, as it is found to be sufficient; the rest of the ground has been planted with fruit trees. The area is enclosed by high corrugated iron fencing and the whole plot is one hot-bed. As you enter the place the rise in temperature is remarkable. The hot-bed is intersected with footways just wide enough to allow a man his passage through, all the soil, manure and things required for cultivation being carried on men's shoulders.

On these hot-beds a thin layer of well-sifted soil is placed, and crowded all over them are small frames of the simplest possible construction, and these are supplemented by hundreds of bell-glasses or cloches. Under each cloche are Lettuces, the Cos in the centre and the Cabbage round, every tiny space left being filled in with Carrots, Radishes and small salad; not a fraction of an inch is wasted, and as fast as one Lettuce is cut another is pricked out. A thousand Lettuces a day is the present output; the packing-cases for these even are made on the premises. The French gardener, who is the instructor as well as a most diligent worker, and has practised this method for many years in France, lives in a bungalow in the middle of the enclosure. Melons also are grown, and are supposed to be a paying crop if got in early enough. Some of the fruits are already set, and it is to be hoped that they will get sun enough to ripen them in our uncertain climate, for whose vagaries their guardian from a sunnier clime has no good word.

The demand already for Miss Jones's vegetables is very great. Besides this industry these energetic ladies have started a jam factory, so little Thatcham is well on the way to prosperity. About profits and expenditure it would be as well for those interested to go to the owners, who are most kind about answering questions and anxious to exploit their valuable ideas. I am assured that it is likely to be a most profitable concern, and I believe that it would answer to start other gardens on the same principles. As there are fourteen pupils of both sexes attending the work these would eventually be able to instruct others, but the simplicity of the method hardly requires much tuition.

There is no doubt that these home industries are what are wanted to help England and to keep her sons and daughters on the land. We have the finest agricultural country in the world, and in many parts of Berkshire alone a much finer soil than Thatcham. It would be perfectly easy with energy and a small capital to start just such another garden. The system is not costly, because it is such a rapid way of producing. The plants under the cloches grow much quicker than those in frames, owing to the light having perfect access. The soil is so carefully prepared that there is little danger of the ravages of the slugs and snails which so often destroy one-half of the seeds sown in ordinary conditions. The cloches are expensive and

are easily broken, and I should fancy the stable manure used must tot up to a considerable sum, but as a set-off against these two items the labour is not heavy. After some years residence in a small Berkshire village I can commend that. If agricultural England is to be saved it must be done by the educated classes taking the lead and showing the working man how to use his brains and his hands to his own advantage. They say that the power of work is lessened by the boys being kept so late at school. I am not going to argue whether this is true or not, but I am certain it is no use putting up notices in a village that holdings and allotments can be had on application until an incentive is given to the men to work. Here there has not been one single application. We have, however, now begun to instil into the minds of the villagers a desire to work for themselves by starting a small society, and several cottagers are growing Peas, Beans, Lettuces and Sweet Peas for a market we have found in London. We choose the sorts of Peas, &c., and when ready all the vegetables will be brought to us and each grower will receive market price without responsibility of carriage or packing. We have also started an egg industry, and we are sending to a well-known London restaurant about 1,000 eggs a week. These are brought to us every week in large or small quantities. The idea has been received with great enthusiasm, and it is impossible to buy more beautiful eggs, which are also highly approved of by the purchaser. The price given is ruled by the nearest market. This week we have added Water-cress, grown in pure, untainted streams, quite a boon to the town that accepts the dangerous stuff grown in the neighbourhood of London on its own sewage. We hope at no very distant period to see the allotments taken and the little society on its own feet. The working man's day ends at five o'clock, and the hours afterwards which he now spends in the public-house he could turn into gold. This better way we are trying to show him.

A. DE LACY LACY.

## THE EDITOR'S TABLE.

WILD DAFFODILS FROM THE LAKE DISTRICT.

Mr. Cuckney of Arnside, Carnforth, sends a most interesting box of wild Daffodils, with the following note: "I am sending you by post a few flowers of *N. pseudo-Narcissus* as they grow in countless thousands in the beautiful Lake District. The flowers are just as gathered from near Cartmell Fell Church (this is a most primitive building; no touch of the restorer here, it is God's acre all aglow with *Narcissus*), in a little narrow dingle, with its small, rushing stream tumbling over rocks. After the glow of Daffodils this dingle is just one mass of the loveliest Lady Ferns, many of them last year over 5 feet high. In open spaces also grows the Grass of Parnassus, fair as its name implies, having the waxen whiteness and delicate green veins of a Snowdrop."

DAFFODILS FROM MR. PETER BARR.

Mr. Peter Barr, V.M.H., sends us another interesting lot of Daffodils from his Scottish home. Considering the very rough weather we have experienced in the South we were much surprised to receive flowers in such good condition. Among many others the following were particularly good, both as regards colour, shape and size: *Maximus*, large, rich yellow trumpet self; *Gloria Mundi*, flowered under glass; *Glory of Leiden*, *Nelsonii* major, *Santa Maria*, resembling *maximus*, but with narrower perianth segments; *Captain Nelson*, *Queen Anne's* double Daffodil, *Minnie Hume*, a charming *Leedsii* form; *Leedsii amabilis*, *Engleheartii* Sequin, a chaste flower of this new and popular section; *Barri* conspicuus, a very fine bloom; *incomparabilis* J. C. Backhouse, *incomparabilis* Mabel

Cowan, poeticus Cassandra, grown under glass; Mrs. Langtry, Katherine Spurrell, a lovely Leedsii; P. R. Barr, Victoria, princeps, the white form of which Mr. Barr says is the true Margueretta; Horsfieldii, Princess Ida, Mme. Plomp, very large; odoros rugulosus, Mrs. Vincent, moschatus, King of Spain, very handsome; Millie Barr, Admiral Togo, and the pretty little triandrus calathinum.

#### PRIMULA OBCONICA FROM SURREY.

Mr. George Boyd, Danehurst, Epsom, Surrey, sends some excellent blooms of a purple-flowered strain of this valuable Primula. He writes as follows: "I enclose a few sprays of Primula obconica from a plant among a batch of seedlings raised from Messrs. Webb's seed. It is far better than any of the others, as it has long, stout, wiry stems, and I consider it quite worth growing on. Primula obconica is one of the very best plants to grow for table decoration, the blooms last for a long time, the plants are easy to grow, are continuous blooming, and their beautiful lilac colours leave nothing to be desired. I sow a packet of seed each year, the first week in March, scattering the seed on some finely-sifted soil, watering the soil first, and then place a pane of glass over the pan. When the seedlings are

## TREES AND SHRUBS.

### THE SHRUBBY SPIRÆAS.

(Continued from page 228.)

**SPIRÆA BELLA.**—This is a native of temperate Himalayas, and is a strong-growing species, attaining a height of upwards of 5 feet, and bearing clusters of deep pink flowers opening in June.

*S. canescens* is a tall-growing plant from the Himalayan region, and forms a large bush 6 feet to 8 feet in height, with slender, arching branches clothed with corymbs of snow-white flowers in June and July. It has a free and graceful habit, and makes a splendid small specimen when grown as an isolated plant.

*S. japonica* (*S. callosa*) is an old and well-known species, and is found from Northern India through a great part of China to Japan. When left unpruned it reaches a height of 6 feet or more, but when kept cut back every spring it only reaches half that height. The rosy red flowers are produced in late summer, and are borne in terminal flat corymbs 6 inches to 1 foot across on young, vigorous shoots. There are several varieties, of which alba, which grows

by underground growths, each slender shoot attaining a height of 4 feet or so, and terminated in July and August with a dense panicle of rosy red flowers. It is a plant for the wild garden or rough spots where it has room to spread about.

*S. salicifolia* is a widely distributed species, being found from Eastern Europe to Japan, while one variety of it hails from North America. The type somewhat resembles *S. Douglasi*, but has rather paler flowers and a less spreading mode of growth. The variety paniculata is a native of North America, and has broader foliage and larger panicles of flowers than the type. Varieties floribus albis, f. roseis and minor are described by their names.

#### SECTION VII.—BASELIMA.

In this section the foliage is pinnate, and the flowers are borne in large clustered panicles. They require little pruning as a rule, but are benefited by an occasional thinning.

*S. Aitchisoni*.—This is a native of the Himalayan region, and makes a plant 8 feet or more in height, with stout stems clothed with elegantly-cut pinnate leaves, and terminated in August and September with large panicles of snow-white flowers. It is a handsome plant during the summer, and the warm brown-red of the stems makes it a welcome addition to the garden in winter.

*S. lindleyana* is also a native of the Himalayas, and somewhat resembles the preceding, but the foliage is somewhat coarser and more rugose, and the stems are green. The large panicles of white flowers open in August.

#### SECTION VIII.—HOLODISCUS.

*S. discolor* (*S. arifolia*).—This is the only member of the section, and is a strong-growing species from North-west America, reaching a height of upwards of 12 feet. The stout, greyish stems are topped in July with feathery plume-like panicles of creamy-white flowers. It is a very easy plant to deal with, and when in bloom is one of the handsomest subjects in the garden.

Bagshot, Surrey.

J. CLARK.

### A NEW GUELDER ROSE.

(VIBURNUM CARLESII.)

This is a most valuable addition to hardy evergreen flowering shrubs and one that will be welcomed by all lovers of choice plants. Of Chinese origin and recently introduced, we are not sure if the plant has flowered previously in Britain. The plant possesses an additional value by flowering in the spring-time with Pyrus, Magnolia and other subjects then in beauty. It forms a bush of spreading habit with hoary or downy ovate, slightly serrate leaves, and the flowers are produced in terminal clusters somewhat freely. The blossoms, which are deliciously fragrant, are at first of a pinkish hue, but upon expansion are of the purest white and in form remind one of *Luculia gratissima* somewhat reduced. The exhibited example to which we now refer was grown by Sir Trevor Lawrence, Bart. (gardener, Mr. Bain), and had received the protection of a cold frame. The plant is believed to be quite hardy, and, indeed, has proved to be so in Yokohama and other places. A few more novelties in the way of fragrant flowering shrubs would be most welcome, especially those that flower in the spring. The advances that have been made in this direction during recent years lead us to hope that flowering shrubs will soon take the prominent place in the garden that they deserve. Shown before the Royal Horticultural Society on the 14th ult., when it received an award of merit.

A SHADE-LOVING PLANT: OMPHALODES VERNA. (See page 241.)

up I prick them out into a seed tray. When two or three leaves have formed they are potted up into 2½-inch pots, repotting as they advance into growth till they reach 6-inch pots. A mixture of two parts loam, one part leaf-mould and one part well-decayed manure, with a little sand, suits them admirably."

#### ROSE CATHERINE MERMET.

Mr. George Leadbetter, The Gardens, Elm Hurst, Wilmslow, near Manchester, sends flowers of this beautiful Rose, which, for glass-grown flowers, are very fine indeed. He encloses the following note: "For your table I am sending a few flowers of Catherine Mermet, in my humble opinion one of the best all-round Roses. It is a very pleasing colour, is a beautiful flower either in bud or fully open, and is not without perfume, so that I think it may fairly be called one of the best. For room decoration or for button-hole work it is very good indeed. The flowers sent have been cut from a tree planted out at the end of a greenhouse with south aspect, and it generally gives us three crops of flowers during the year. I fancy a poll on the most popular inside Rose might be interesting, and I think Catherine Mermet would give a good account of herself."

about 2 feet high and bears white flowers; Bumalda, also dwarf, and having pink flowers; glabrata, a pink-flowered form with broad, glabrous leaves; and superba, with deeper-coloured flowers than the type, are the best. The variety Anthony Waterer should not be omitted from any garden, as its deep red corymbs of flowers are produced from July to September, and its dwarf, bushy habit renders it a suitable subject for small beds or the fronts of borders.

#### SECTION V.—PACHYSTACHYA.

*S. brachybotrys* (*S. canescens* × *S. Douglasi*).—This is a hybrid of garden origin, and forms a large upright bush 6 feet to 8 feet high, with short terminal spikes of pale pink flowers opening about midsummer. The growths of this plant should be kept thinned to encourage young, strong shoots.

*S. nobleana* is a native of California, and makes a plant about 3 feet high, topped with short panicles of rosy red flowers in July. It is of no great garden value, nor are any of the other members of this section, which are all hybrids, so much resembling the above two that it is unnecessary to plant them.

#### SECTION VI.—EUSPIRARIA.

*S. Douglasi*.—This is a native of North America, and makes a spreading plant, increasing

## THE FLOWER GARDEN.

### HISTORY OF THE PRIMROSE, COWSLIP AND AURICULA.

**P** RIMROSE is not so old a name by centuries as Cowslip, the latter being Anglo-Saxon, while Primrose is derived from the French. The Cowslip, on account of its presumed medicinal qualities, is frequently referred to in old medical treatises, and there is no question that it is our fragrant wild flower the writers had in mind. It appears not as Cowslip only, but also as Plaggis, Pagle, Paigle, Peter, Herb St. Peter, Palsiewort, Maierole and Primerole. Not infrequently the Oxlip is confounded with the Cowslip; on the other hand, Primrose, with its variants in English, probably represented plants other than our Primrose. It was, indeed, not until the time of Edward VI. that we can be certain of the identity of the flower. We know, at least, that the Daisy and *Primula veris* were identical; hence, when Chaucer describes the carpenter's "fair yonge wyf" as a "Prymerole," it may be merely the fourteenth century way of saying she was a "Daisy!"

Lydgate, too, seems to have had the Daisy in his mind when he writes that "the fraisshe Prymerollys Ther levys splaye at Phebus up-rysing." But as *Pimpinella*, *Ligustrum* (Clover?) *Calendula* and *Solsequium* is each regarded as *Prymrose* or *Primerolle*, to say definitely that Daisy is intended would be somewhat fanciful.

Oxlip does not occur at so early a date as either of the above. In Turner's "Herbal" (1562), part 3, page 80, it is mentioned in the chapter "Of the Coweslippe," that the latter is of two kinds. "One is redder than the other and the paler; they differ also in smell, for one smelleth better than ye other. The one is called in the north contre, of some a Cowslip and the other an Oxislip, and they are both call(ed) in Cambridgeshire Pagles." In the same chapter is the note, "Our Primrose which I never saw grow in any place saving in England and East Freseland." The Auricula was first introduced to English gardens, according to Gerard, as "Beares Eares or Mountain Cowslips," and was cultivated in London gardens towards the end of the sixteenth century. The first writer who distinguished this plant as the Auricula was Evelyn in his "Kalendarium Hortense" (1664), but in the following year Rea mentions it in a way that shows the name to have been in common use long before that time.

The Polyanthus is a still later flower. It is first referred to by Parkinson in his "Paradisus," and is described by Ray and other botanists

later, but the name itself (sometimes *Polyanthos* and *Polyanthous*) does not occur until the beginning of the eighteenth century.

The Cowslip is first described as a garden plant by Turner in the chapter of "A New Herbal," already quoted. "There are," he remarks, "some grene Cowslippes and some dubbel, tripel, quadrupel that grow in gardines." Double, it may be remarked, is equivalent to two rows of petals, triple to three and quadruple to four rows. Cowslips are not mentioned in either "The Gardener's Labyrinth" or "The

the esteem in which they were held in the country as apart from London.

R. P. BROTHERSTON.  
(To be continued.)

### AURICULA PHYLLIS DOUGLAS.

THIS is a very showy and well-formed Alpine Auricula of large size, with cream centre and mauve and purplish shading. It was exhibited by Mr. James Douglas, Great Bookham, Surrey, before the Royal Horticultural Society on the 28th ult., when it was granted an award of merit.

A NEW ALPINE AURICULA: PHYLLIS DOUGLAS. (Natural size.)

### OMPHALODES VERNA.

ALTHOUGH an easy plant to succeed with and one which soon forms a large colony when suitably planted, *Omphalodes verna* is not nearly so extensively grown as its merits deserve. The date of its introduction is given by Nicholson as 1633, so we may reasonably regard it as a very old garden plant, and though tolerably familiar to the majority of growers of rock plants, there are many amateurs to whom it will come as a welcome addition among their spring flowers. A cursory glance at this *Omphalodes* naturally leads one to infer some close affinity with the Forget-me-nots (*Myosotis*), and the thought not infrequently finds expression, "What a beautiful Forget-me-not!" The flowers are intensely blue, having a conspicuous white eye in the centre, this colour combination being so striking that, coming unexpectedly upon it, one can scarcely credit such richness of colour as being real nor the capacity for such purity being possible so early in the year. It is true that a faint suspicion of purple lurks in the opening buds, but this taint readily becomes dissipated as the flowers fully expand, and throughout April and May the flowers are produced with unblemished purity, being borne upon 6-inch stems with great freedom.

*Omphalodes verna* spreads by means of Strawberry-like runners, which are freely produced by vigorous plants, and by these runners propagation is readily effected. It enjoys creeping about over and among tree stumps and stones, and will bear a considerable amount of shade with apparent indifference.

Nor is there any difficulty with soil, as plants growing either in or out of limestone succeed with equal luxuriance. The plant is a perennial, belongs to the Borage worts, and is generally considered a native of Southern Europe.

T. SMITH.

Walmsgate Gardens, Louth, Lincs.

### WILD PINKS.

ALIKE esteemed for their beauty, fragrance and the variety of conditions under which they succeed, the *Dianthus* family is more or less

Profitable Arte of Gardening," but a year or two later, in Lyte's "Herball" (1578), they occur as garden flowers. By Gerard we are re-introduced to the double Paigle "so commonly knowne that it needeth no description," and "Cowslips, two in a hose," appear for the first time. In 1618, Mr. Lawson, a Yorkshireman, in "The New Orchard," mentions "Purple Cowslips and Double Cowslips," as garden flowers of great beauty, and adds, in the 1623 edition, "double double Cowslips," which is interesting, as showing not only a break in the colour, but also

A NEW GUELDER ROSE: *VIBURNUM CARLESII*. (About two-thirds natural size.)

recognised in every garden. Some of them, like *D. Carthusianorum*, with its tall stems thickly set with clusters of red flowers, and *D. cruentus*, commonly known as the "Blood Pink," with black stems supporting vivid crimson flowers, are useful for the herbaceous border; of lesser stature, with deliciously-perfumed flowers and yielding a great range of beautiful colours, is *D. barbatus*, or the Sweet William, still held in high esteem as one of the best of old-fashioned garden flowers. Perhaps the brightest range of colours in the *Dianthus* family is found among the hybrid Chinese or Indian Pinks, *D. chinensis* and *D. chinensis Heddewigii*.

There is a large section of these wild Pinks which show to indifferent purpose when treated as border plants, their natural home being the rugged slope of the mountain, and they can therefore be employed to advantage in gardens when boldly placed upon the rock garden or draping the face of some old weather-worn wall, while one of their greatest charms is that they lend themselves to informal grouping by the side of steps, around sundials or beside some old stone seat. The wild Pink (*D. plumarius*) from which so many fine garden Pinks have originated, is pre-eminently suited for these positions; it is robust in growth and soon forms a large spreading mass of glaucous leafage; the flowers are generally rosy purple, but the shade varies a good deal from seed. *D. cæsius* (the Cheddar Pink) is similar in growth, but with shorter flower-stems, while there are several named forms of this Pink which are quite distinct.

*D. monspessulanus* has narrow grassy foliage, producing deeply-fringed flowers of a pleasing shade of mauve-pink. *D. deltoides* (the Maiden Pink) is quite one of the loveliest species; the plant is very dwarf, having deep rose-coloured flowers with a dark circle. Established plants flower during early summer, but treated as an annual it will flower well into October. *D. neglectus* is one of those brilliant species which no garden should be without; the foliage is very narrow and grass-like, forming close, dense tufts from which arise large solitary flowers of a lovely rose-carmine colour. It is generally recommended as a granatic species, but it succeeds when planted in the chalky soil of this district.

*D. alpinus* forms a close-set mass of herbage, producing big rose-coloured flowers freely spotted with crimson; it succeeds best in gritty soil, and I find it enjoys more than an ordinary degree of moisture in summer. *D. glacialis* is not a success in chalk soil, and has therefore to be planted in a prepared compost of sandstone, being one of the best mountain species.

Most of these wild Pinks grow freely in rather poor soil, or that which is just rich enough to promote vigorous growth without the least suspicion

of rankness, otherwise the shoots become sappy and the plants have a straggly appearance. On the other hand, poor soil accentuates the tufted habit and imparts a deeper hue to those having glaucous leaves, while the firm and well-ripened shoots always produce the richest and most abundant harvest of flowers.

#### AUBRIETIA LAVENDER.

THE varietal name is sufficiently descriptive of the colour of this variety for general purposes, apart from which it may be regarded as the best of its shade up to date. The flowers are large, and are borne with characteristic freedom on a perfect habit of growth. It was exhibited by Mr. M. Prichard, Christchurch, Hants, before the Royal Horticultural Society on the 28th ult., when it received an award of merit.

AUBRIETIA LAVENDER. (Natural size.)

## THE ROSE GARDEN.

### ROSE MEDEA.

THINK we do not sufficiently realise what a valuable Rose this is. I would rather possess it than that shy bloomer Cloth of Gold, a variety it resembles in certain points. The marvellous fulness and beauty of its blooms appeal alike to the exhibitor and those who love Roses for the garden decoration, and it is a sort that is not at all difficult to grow. Under glass in almost a cold house I have had its superb blooms almost as large as a goose's egg. Exhibitors have proved its value many a time, especially during a trying hot season, as it is one of the few Roses that will stand the ordeal of a hot show tent. The colour is of a beautiful lemon yellow, with canary yellow centre, and the blooms are globular, with high centre. It has a splendid habit, yielding marvellous foliage, and it would be a grand sort for a 5-foot wall with west or south aspect. Doubtless the most successful form to grow it is as a half-standard. P.

### SINGLE AND SEMI-DOUBLE ROSES AS STANDARDS.

WITH the advance of good taste in gardening and a departure from the old florists' stereotyped ideals there will be an opportunity of displaying some of the lovely single and semi-double Roses in a manner that a few years ago would have seemed ludicrous. I am persuaded that if such Roses as Bardou Job, Irish Elegance, Gloire des Rosomanes, Stanwell Perpetual, Old Crimson China, Sinica Anemone and such like were budded upon standards and allowed to develop into such glorious heads as they are capable of doing we should find they would quickly gain a notoriety that would make them in great demand. The more semi-rampant the growth the better. What a grand standard Zepherin Drouhin would make with its spreading head of most lovely rich rose-pink blossoms and delicious

fragrance. Such Roses as these are far and away superior for growing on stems than such stiff puny growers as Louis van Houtte or Victor Hugo. If Roses of this latter type are wanted on stems, then let them be short, so that their moderate heads may correspond to the dwarfness of stem.

I am certain the more picturesque we try to make our Rose gardens the more we shall have need to go to these outside sorts to lend us their aid, and we shall have to bnd our own if they are not procurable. The advent of the wichuraiana race, with its possibilities of elegant growth when on stems, has opened the way for still further advance. We find now all sorts being budded on standards, not only Rugosa and China Roses, but even the ramblers of all sections, and I for one welcome this innovation.

### AYRSHIRE ROSES.

THE true value of these fast-growing Roses is apt to be overlooked in these days when the wichuraiana group is so popular. hut these latter, except in a few instances, do not produce the splendid display of blossom that we obtain from sorts such as Bennett's Seedling or Virginian Rambler. What a delightful mass of snow-white blossoms a large plant of Bennett's Seedling will produce if allowed to grow absolutely as it likes without even so much as taking out the old wood.

Ruga is a very excellent sort, almost Tea Rose-like in its refinement, and of a delicate pink tint. It is a lovely sort to ramble up an old tree; in fact, most of the Ayrshires are splendid for this purpose.

Dundee Rambler is effective in a mass, but it has rather a wild Rose-like style about it, but in Virginian Rambler we have a really lovely gem, the large clusters of expansive white flowers being prettily edged and suffused with pink. Queen of the Belgians is a near approach to a Tea Rose in colour, for it is a creamy white and a large double flower. The growth of this variety is especially slender. These Ayrshire Roses make splendid weeping plants, and may very suitably be grouped with wichuraiana Roses for the same purpose. Their season of flowering is from the end of June to the third week in July. If only one variety can be grown I would recommend Bennett's Seedling.

This group should not be confounded with the Rosa Semper-virens tribe, generally known as evergreen Roses, a title few of them can justify in their behaviour.

### ROSE RENEE WILMART-URBAN.

THIS fine novelty was well exhibited by Messrs. William Paul and Son of Waltham Cross at a recent meeting of the Royal Horticultural Society. In its form and substance there is evidently in this variety a Rose that will gladden the heart of the exhibitor. It reminds one somewhat of Souvenir du President Carnot in the delicate flesh pink of the inner petals, and in form there is a resemblance to Queen of Spain, without the somewhat too close arrangement of the petals, which would seem to point to the latter Rose being a difficult opener in a wet season. I certainly think in the Rose under notice M. Pernet-Ducher has given us one of his best. Evidently it is going to be a splendid pot Rose, for in size, firmness of petal and erect stem it is all that one could desire.

P.

## THE KITCHEN GARDEN.

### ORNAMENTAL GOURDS FOR ARCHES AND FENCES.

WE do not make enough use of the above during the summer months, and in most amateurs' gardens there is a bare fence which could be utilised, or these plants are most effective when carried over arches or doorways. I have also seen them effectively used on a fence to hide a building or divide one portion of the garden from another when the screen was only required during the summer. To get the best results early seed-sowing is advisable, so that the plants can be put out about the middle of May. It often happens that amateurs are unable to purchase seedlings; and I am not quite sure but that this is a gain, as it is such an easy matter to pass off inferior varieties, or, at least,

following are worth culture and are of a trailing or running habit: Turk's Turban, rich orange coloured fruit, yellow flesh and of good flavour; Pineapple, a very peculiar shape, white skin and a good late variety; Orange Marrow is a very early distinct sort with delicate flavour, a good winter variety as it keeps well; Winter Crook-neck is much liked in the States, it is an ornamental variety and quite distinct; Fordhook is also excellent; Golden Bronze is a very dark green form, with golden flesh and very sweet; Marblehead is very productive, it has a grey skin and is a good keeper with very dry and sweet flesh; Delicata is orange yellow with green stripes, very small and prolific, and also one of the earliest to mature; Delicious is a green variety, orange flesh, sweet and one of the best for pies.

The plants when placed in their growing or fruiting quarters do well in a light soil, and if the ordinary soil is at all heavy it is well to lighten it with any rich light material. A spadeful of well-decayed manure for each plant mixed with the

WILD PINKS IN THE GARDEN.

the sorts not asked for, when one has to purchase from an unknown source. It is an easy matter to sow seed in small pots, and place these in a box and cover with a sheet of glass till quite strong enough to plant out. I have sown seeds late in April and early May; indeed, the latter date gives good plants by the end of the month. These plants, once they get a good start, grow so rapidly that they soon cover a large space, and, given liberal supplies of food in the shape of liquid manure, they fruit grandly; they also delight in being damped overhead in the evening after a hot day.

Varieties are numerous, and they assume all shapes and forms, which make them most interesting. On the Continent there are many forms, and in the United States they are mostly known as Squashes; some are very large, others small and highly coloured. In this country the distinct forms are not often catalogued, mixed ornamental Gourds being usually offered, but even then one gets some interesting objects. The

soil will give good results, and in a dry season it is a good plan to mulch the surface with short manure.

AMATEUR.

### RUNNER BEAN VEITCH'S HACK-WOOD PARK SUCCESS.

THIS new Runner Bean, recently raised by Mr. Bowerman, is well named, as it certainly is a decided success, not only on account of its size, but for its earliness and good eating qualities. It bears straight, handsome pods, averaging from 9 inches to 12 inches in length. The pods, in addition, are produced in clusters in great numbers, often as many as ten hanging on one stem. At the trials conducted by the Royal Horticultural Society this new Runner Bean received an award of merit. It is a fine Bean for the amateur who can only grow a limited number of plants, as grown on a fence or wall its handsome pods are much admired, and its early cropping makes it more valuable.

G. W. B.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**T**HE GREENHOUSE.—Young plants of the Heliotropes and Petunias that were struck some time since I have just pinched. The tip of each shoot is taken out, and this causes them to make bushy plants. Bouvardias may be propagated at this period for flowering next winter. These plants are increased by stem or

1.—ROOT OF COMMON THYME SUITABLE FOR LIFTING AND DIVIDING.

root cuttings, but the former is the method I invariably practice. Young growths some 2 inches to 3 inches in length should be selected for cuttings. Trim off the lower leaf and cut through the stem just below a joint. Insert the cuttings around the side of a 3-inch pot that is well drained with crocks and filled with light sandy soil, and plunge the pots in Coconut fibre refuse where a genial bottom-heat can be provided. For flowering next autumn I am just putting in a batch of Geranium cuttings. Five or six cuttings in a 5-inch pot, using a sandy compost, will serve the purpose of propagation very well. Observe care in watering, and never make the soil too moist.

*The Vegetable Garden.*—French and Runner Beans may be safely sown at this period to follow the earliest supplies. Turnips should be sown in quarters that have been carefully prepared. Sow in fine weather in rows about 1 foot to 15 inches apart, and, roughly, 1 inch or rather less deep. Sow for successional supplies once a month till August. Many autumn-planted Cabbages have "bolted." I gather the tops for kitchen use before they get too far advanced and then root up the plants. The quarters are then forked over and replanted with fresh young plants, which invariably go ahead at once. I am planting the first of my Vegetable Marrows, giving the plants a position in a frame placed over a hot-bed that is now almost spent. By these means I am able to procure the fruit in mid-July. The frame-light is removed immediately all fear of frost is past. Parsnips have made much progress of late. I am now thinning these, leaving the plants about 1 foot apart in the rows. A weekly hoeing between the rows is highly beneficial.

*The Flower Garden.*—Should the weather be more settled at this period I do not hesitate to

plant climbing Nasturtiums, tall Convolvuluses and Canary Creeper. For covering unsightly walls and fences and for garden arches and trellises they are useful subjects. Half-hardy annuals that have been raised in heat and thoroughly well hardened off in the cold frames may now be planted in their flowering quarters. Begin with the warm and sheltered situations in case we should get a late snap of frost. In the event of plants being purchased, they should be subjected to cold frame treatment for a time, as it is very probable they may be very tender. To make room for other subjects, Primroses and Polyanthuses may be lifted and divided, assuming they are large plants. The divided pieces should be replanted in a spare corner of the garden, to be again lifted and planted in their flowering quarters in the autumn. In this way provision is made for the succeeding spring display.

*The Fruit Garden.*—At the present time I make it a rule to apply liquid manure, made from cow or horse manure, to Gooseberries, Raspberries and Currants. Do not apply this too strong, however, but see that it is well diluted. A mulching of the surface soil about the Gooseberries is also highly beneficial at this season. Sunlight soap in solution is an excellent and cheap insecticide for spraying Apples. Should aphides infest Cherry, Plum and Peach trees, a spraying with Fir tree oil in weak solution in the early morning or evening will eradicate the pest.

*Cold Frames.*—Dahlias that have been potted up some time and are well established may now be placed in the cold frames. For a few days keep the lights on and shade from bright sunshine. Subsequently gradually inure the plants to hardier conditions. Bedding plants that were removed from the greenhouse a short time ago should also be given hardier treatment preparatory to planting outdoors. Take note of the weather, and close the lights should frost be anticipated. Chrysanthemums in pots that are now in the cold frame should be placed outdoors in a sheltered situation. The early-flowering varieties may be removed outdoors or lifted and planted in their permanent quarters. D. B. C.

### METHODS OF PROPAGATING THYME.

THE Thyme is one of the more popular herbs, but, unfortunately, it is not met with in our gardens nearly so frequently as was the case a few years ago. There are so many uses to which this herb can be put that it becomes a matter for surprise that the present generation fail to appreciate its real worth. The botanical names of the Thyme are *Thymus vulgaris* for the common Thyme and *Thymus Serpyllum vulgaris* is the Lemon Thyme. The common Thyme is a native of Spain and Italy and the Lemon Thyme of Britain.

*Soil.*—Although the Thyme prefers a rather light and sandy soil that has been well drained, it will succeed in many odd corners of the garden, provided the position be a sunny one. Heavy soils are not recommended, as the plant does not appear to thrive therein. Before planting the soil should be deeply dug and well manured, and if this preparatory work can be done some time beforehand so much the better. The plant may be increased by division, by cuttings or seed.

*Seeds.*—The spring is an excellent time to sow the seeds, and if we had the choice of time just now we should most certainly choose the month

of March. Success may attend our efforts, however, by making a sowing even at this protracted period. Procure a shallow box and fill this with any light sandy soil that has been passed through a sieve with a half-inch mesh, and sow the seeds thinly on the surface of this, lightly covering them with some of the finer soil. Those who have a hot-bed, from which a gentle bottom-heat can be obtained, may place the box on this and thus ensure speedy germination of the seeds. We would prefer, however, to make a sowing on a bed of light soil in a sunny aspect now, and are confident good results will accrue. When the seedlings are 1 inch or 2 inches in height transplant them 3 inches apart in rows, and when they have attained a useful size finally plant them in their permanent quarters.

*Division.*—At this season it is an easy matter to acquire an old plant from a nurseryman or from the garden of a friend, and with this we have sufficient material to make quite a large number of ideal pieces that will ultimately develop into capital plants. Fig. 1 represents a plant such as market growers send to market in large numbers. It is a simple matter to divide a plant of this description into either large or small pieces. In Fig. 2 there is represented one of the larger divided portions of the original plant. From a large plant it is possible to make quite a number of such pieces, and these are obtained by pressing both fingers and thumbs well into the centre of the plant. Assuming the demand for plants is small, these larger pieces will amply suffice for supplying the needs of

2.—ONE OF THE LARGER DIVIDED PORTIONS OF THE PLANT SHOWN IN FIG. 1.

most small gardens. However, there are undoubtedly cases where for seasoning and other uses the Thyme is more frequently in demand. Where this is so the larger divided pieces may be divided again, these sub-divisions of the old roots each making small plants that will quickly develop into useful specimens under proper conditions. The divided pieces of the old plant as represented in Fig. 3 give a very good indication of the character of the sub-divided portions.

3.—SUB-DIVIDED PIECES OF FIG. 1.

It is necessary, of course, when breaking up the pieces to endeavour to retain as many roots as possible, and this is all the more easily done by placing both fingers and thumbs well down among the roots, thus bringing the latter more under control. If there is a desire to grow the Thyme extensively, each individual growth may be utilised for this purpose. Fig. 4 portrays four different growths, each with roots or root-lets developed in varying degree. That on the extreme right reveals a number of roots already evolved and its nearest neighbour with a lesser number. The two shoots on the left have been detached with what is known as a "heel," and these pieces root quite readily.

By using the pieces with a "heel" attached it is possible to regard these as cuttings. They should be dibbled in a few inches asunder in sandy soil outdoors in specially prepared beds, and this work may be proceeded with from this time forth and throughout the summer months. Should the weather be unduly warm, it may be well to shade the cutting-bed from the direct rays of the sun until they are rooted. Always maintain the soil in a moist condition. Plant the larger divided portions 1 foot apart each way in prepared quarters in a sunny position outdoors, and except for an occasional hoeing between the plants to aerate the soil and to keep the weeds under, nothing further will be required. Lemon Thyme, referred to earlier in these notes, cannot be increased by seeds. We always increase our plants in the spring by division of the roots as advised for the common Thyme. The Gold and Silver Thyme, as the two prettier forms are more often spoken of, are capital for edgings if lifted, divided and replanted in the spring. The golden variety maintains a bright colour throughout the winter and spring months. To ensure a neat appearance during the summer an occasional clipping should be given.

#### OUTDOOR TOMATOES.

TOMATO plants which are intended for planting outdoors should be grown as sturdy and hardy as possible. The best position for the plants at the present time is a cold frame standing in a sheltered and sunny position. Air should be freely admitted to the plants at all times except during frosty nights, when the lights should be closed and protection afforded by means of mats or litter. During warm days the lights may be entirely removed. Water the plants when the soil shows that the roots are becoming dry; on bright days, when the pots are full of roots, water will be required twice daily. When watering, fill up the pots, do not apply water to any plants in dribblets, but give sufficient to nourish every tiny fibrous root that the pot contains. The plants should not be allowed to become too crowded, and as frame room is often none too plentiful at this season it may be advisable to remove some of the plants about the middle of

the month (May), standing these under the shelter of a wall or building. In this case it is advisable to erect a light framework of poles or Bamboo canes over which mats can be placed during the night to protect the plants from frost. Stakes must be provided, and all side shoots should be removed as soon as they are discernible.

It is safe to plant Tomatoes outdoors about the end of the first week in June. During bright, warm summers in the South Tomatoes have yielded a splendid return when planted in open fields and gardens. Owing, however, to the uncertainty of the weather it is always advisable to plant on the warmest and most sheltered site possible. The foot of warm walls or fences are good positions for the plants. Room for plants may often be found between fruit trees which are trained to warm walls. Failing any wall or fence select the warmest corner of the garden in which to plant. If the soil is in good condition, all that is needed at the time of planting is to prepare holes about 3½ feet apart each way, place a stout 5-foot stake in the centre of the hole, turn out the plants, the roots of which must be in a moist condition, place them at the foot of the stake, fill in the soil and tread firmly. Where there is plenty of room give the plants more space for the convenience of their after treatment. Tie the plants loosely to the stakes as growth advances, water when required and keep the soil around them frequently stirred with the Dutch hoe. A mulch of half-rotten farmyard manure is most beneficial during hot summers, as it provides food to the plants and retains the soil in a moist condition. After four bunches of fruit are set the top of the plants should be pinched out just above the succeeding leaf, as it is seldom that more than four bunches can be matured when grown outdoors. Some growers pinch the plants after the third bunch, but this is a question that must be decided on the spot. Two varieties which have proved excellent for outdoor culture are the happily-named Satisfaction and the new Carter's Sunrise.

*Munden Gardens, Watford.*

C. RUSE.

#### CANTERBURY BELLS AND HOW TO GROW THEM.

It would be difficult indeed to find a race of plants that will give a better return for a little trouble than the old-fashioned yet beautiful Canterbury Bells, as the several forms of Campanula Medium are popularly called. The seeds are cheap and easy to buy, the seedlings can be raised with a minimum amount of trouble, and the resulting plants are so easily accommodated that they form an ideal subject for the beginner to try his or her 'prentice hand on. The plants are true hardy biennials, although by sowing early in the spring under glass plants can be induced to flower the same season.

The early part of June is an excellent time to sow the seeds, as the resulting plants then have an opportunity of developing into fine sturdy specimens by the end of autumn. Well prepare a seed-bed in an open position by forking it up thoroughly and breaking any large lumps encountered. Then

tread the surface rather firmly and rake over, so as to get a good tilth of fine soil in which to sow the seeds. Draw out flat-bottomed drills 1½ inches deep and 1 foot apart, and scatter the seeds thinly therein. Should the soil be very dry, give the drills a good watering before sowing the seeds. As the latter are small and rather light, a still day should be chosen for the sowing. Cover the seeds with about an inch of fine soil and rake all down neat and tidy. If dry weather prevails after sowing, it may be necessary to give good waterings through the fine rose of a can at frequent intervals until the seedlings have developed their first true leaves.

When the young plants are sufficiently large to be handled with ease, they must be pricked out singly in a bed of well-worked moderately rich soil, placing them in rows 15 inches apart and 6 inches asunder in the rows. If possible choose a showery day for the pricking off, and failing this do the work one evening, giving each plant a good watering in when the work is finished.

Treatment for the remainder of the summer will consist in hoeing frequently between the rows and giving an occasional soaking with water and weak liquid manure. With the end of autumn comes the usual time for transferring the plants to their flowering quarters. This should be done carefully, moving a good ball of soil to each plant so that the roots are disturbed as little as possible. The distance apart to plant where beds are to be filled is, roughly, from 15 inches to 18 inches each way, and when in flower the plants will touch each other and thus form a floral mass. For the front of a border a good system is to insert three plants to form a triangle, each side of which is 18 inches. If it is not possible to plant in the autumn, excellent results can be obtained by leaving the plants in the nursery bed until March, and then place them where they are to flower. In this case a little extra care is needed in moving them. When coming into bloom each plant will need the support of a short, stout stake, and as soon as the flowers are fading they should be removed; by this means a second crop of flowers is frequently obtained.

Canterbury Bells make excellent pot plants for the cold greenhouse. During October carefully lift some of the strongest plants with a good amount of soil adhering to their roots and pot them into pots of a convenient size to take the plants. Usually 6-inch or 7-inch pots are suitable. Give a watering in and then plunge the pots to their rims in ashes in a cold frame for the winter, giving an abundance of air on all possible occasions. Early in the spring the plants may be removed to the greenhouse and there allowed to develop their flower-spikes. The one thing to remember is that Canterbury Bells are quite hardy, hence coddling in any form will end in disaster. Besides the ordinary type in white, pink and blue shades there is the Cup-and-Saucer form.

4.—SINGLE GROWTHS. THE TWO ON THE RIGHT HAVE ROOTS; THOSE ON THE LEFT HAVE BEEN DETACHED WITH A HEEL AND MADE GOOD CUTTINGS.

## THE TOWN GARDEN.

**THE CARE OF HEDGES.**—There is not the slightest doubt that the streets of our towns are immensely improved in appearance by the trimly-kept hedges with which the occupiers adorn their forecourts and in which they obviously take such a great pride. The prime favourite for this purpose is Privet, the green preponderating, though the Golden has come more into popularity during the past decade. Euonymus is used to some extent, but the fact that it is liable to serious infestations of the small ermine moth hinders its extensive planting. Laurels and Aucubas also enjoy a meed of favour, but they are too large-leaved for the majority of fronts. However, it matters little what the particular plant may be, provided that it is correctly attended to at all seasons of the year. As a rule clipping is done cleverly and regularly, but few growers seem to give a thought to the desirability of watering occasionally, and also to the application of weak liquid manure. The position of the roots of most hedges is such that it is impossible for them to get the benefit of the rain that falls, and this deficiency of moisture should be compensated for by heavy watering. The soil must first be loosened, and then the water given at the rate of at least four gallons to the square yard; a few hours later follow with a similar quantity of liquid manure, such as soot water or Clay's Fertilizer in solution. If this is done thrice in the summer the hedge will be vastly improved in thickness.

**ANNUALS.**—The present is an excellent time to sow the seeds of all hardy and half-hardy annuals in the garden. It is, of course, more than probable that seeds will have been got in some time back, but those sown now will provide later flowers, and the longer we can keep our gardens attractive the better. The wisdom of sowing half-hardy annuals out of doors earlier than this date is doubtful, as the youngsters are so tender that many will be lost. For sowing where the plants are to bloom I have had the most gratifying successes with Phlox Drummondii, Ten Week Stocks and dwarf Victoria Asters. With good soil and allowing the plants an abundance of space I have had Phloxes quite equal to those from frame-sown seeds, but they have been rather later. Stocks also are invariably very fine, but Asters vary with the weather of the season and the natural quality of the soil. In moderately strong ground and a cool season they are splendid, while in light soils and hot summers they become eaten up with fly, which it seems impossible to hold in perfect subjection. In the case of hardy annuals I find that all thrive satisfactorily, except the Chrysanthemums, with which I have never been really delighted, as they come weedy.

**WATERING.**—The importance of watering must never be overlooked by the town gardener. In many cases, as everyone is doubtless perfectly well aware, as much harm as good is done by the aid of the water-pot, but this is only in those instances where it is customary to give mere surface sprinklings each evening, sufficient water only being given to moisten the top half inch of soil, and thus make the ground steadily colder and colder. By watering is now meant thorough applications that will soak well down and rise steadily, bringing food to the plants. If this is made the rule the frequency of application will be much reduced, and one may be assured that each time water is given it will do material good. In one respect at least sprinkling is excellent, but this is not when directed towards the surface of the soil, but to the leaves of shrubs and creepers. Hosing after dry days then washes off the accumulations of dust and thus leaves the foliage in a condition to perform its functions, while at the same time many of the commoner insect pests will be subjected to a course of treatment to which they strenuously object.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**H**IGH pressure is generally placed on this department during this month, and any seeds that have failed through the late Arctic weather should at once be made good. Asparagus seedlings in seed-drills or beds should be thinned as soon as they can be handled, and whenever they come up in twos or threes they should be thinned to one.

*Cutting Asparagus* should be done with regularity and all the shoots gathered as fast as they become fit, sorting them out afterwards for the various purposes.

**Broccoli.**—The latest batch of these should now be sown, using those varieties which are expected to come in about this time next season, such as Latest of All, Late Queen, Model and Carter's Summer. Savoys, Kales and sprouting Broccoli should also be sown. The old Scotch Kale and the Asparagus Kale are very hardy and give a lot of wholesome dishes at a time when greenstuff is short.

#### FLOWER GARDEN.

*Material for beds and borders* should now be gradually hardened and made ready for planting out as soon as all fear of frost is over. Sow another batch of annuals for succession, and thin out those already sown. Sow more Sweet Peas for late flowering; give these good culture to produce the best results. Plant out early-flowering Chrysanthemums in the herbaceous border; a good supply of these is always acceptable in the reserve garden for cutting purposes. Plant in a position where they can be protected from October frosts.

**Polyanthuses.**—Prick these out in the nursery garden for planting out in the autumn; give plenty of room so that a hoe can be pushed between them to keep down weeds. Pick off all seed-vessels from Narcissus as soon as these have finished flowering. This process helps to ripen up the bulbs.

#### HARDY FRUIT.

*Cherries and Peaches* must be looked over carefully and kept clean from black fly. Peaches should be syringed with Extract of Quassia and at a strength that will kill the aphids. Pick off any distorted leaves which have been caused by the cold weather, and when warm weather arrives they will produce clean, healthy foliage. Start disbudding as soon as the growths can be conveniently handled. Cherries should be examined also for the slugworm (*Selandria Cerasi*). These attack the foliage.

**Apricots.**—These must be looked over frequently. There is a yellowish green insect (*Ditula angustiorana*) which does injury very quickly by feeding on the leaves, and forms a colony in the ends of the shoots, thus causing the leaves to curl up.

*Gooseberries* should be syringed with Quassia. This will sometimes ward off an attack of the dreaded caterpillar. All big buds must be picked from the Black Currant bushes, as it is now that the maggot will be shifting its quarters, and the best possible way to get rid of the pest is by this method. Burn all the buds gathered.

#### FRUIT HOUSES.

*Sow Melons* now and again in a fortnight for the latest crops. Melons ripening should have a chink of air left on the top ventilators at night. Continue to thin late Grapes as they become fit. Stop all lateral growths, and tie in the main growths. Water thoroughly and wash in some of Thomson's or Le Fruitier; this will help the Vines considerably.

W. A. COOK.

Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CINERARIAS.**—In most places these plants are not required in flower until after Chrysanthemums are over, and in most cases the middle of May is time enough to sow. Although Cinerarias are among the easiest of plants to grow if kept clean and well treated in other ways, it is surprising in how many gardens their culture ends in failure. The seeds germinate freely in a greenhouse temperature, and if sown thinly in pots the seedlings may remain there until they are in the rough leaf, when each one may be pricked into the centre of a small pot, using as compost good loam with a liberal addition of leaf-mould and decayed manure.

**Orchids.**—Many of the varieties of the Cattleya and Lælia species will now be advancing their flowers through the sheaths. It is advisable to place plants that are in a forward condition in a position where they may obtain the maximum amount of strong light, with due consideration for protection of the foliage from injury by the direct rays of the sun. This will be found not only to add substance to the flower, but considerably assist in the colour development.

#### FRUIT UNDER GLASS.

**Orchard House.**—Fruit trees in pots will need constant attention if they are to be kept in a healthy, flourishing condition. Some of the early varieties of Cherries will be approaching maturity, so the trees must not be allowed to suffer from want of moisture or they will be deficient both in size and flavour. Keep the trees clean by a frequent use of the syringe on fine days when the house is closed. The shoots of trees occupying walls should be kept tied in while they are plant, for if allowed to get hardened before doing so there will be more difficulty in getting them into their places.

#### FLOWER GARDEN.

**Summer Bedding Plants.**—The spell of cold weather experienced at the latter end of March and the early part of April was responsible for arresting the progress of spring-flowering plants. Wallflowers, Myosotis and things of a similar nature are consequently very late, and will be removed when just at their best if the early planting of summer-flowering stuff is practised, the alternative being to let them remain as long as they are furnishing a good display, and see that the plants that are to follow them are thoroughly well cared for, so that when they are planted out they will be in a condition to go well away without check.

#### ROSES.

Should we get cold east winds green fly will make an appearance, and unless this is checked the points of the young shoots will soon become so badly infested that growth will be stunted and few flowers of any quality be produced. Syringe the plants with some insecticide that is distasteful to the insect, such as a solution of soft soap and Quassia, or anything that will not injure the foliage.

#### KITCHEN GARDEN.

**Frame Cucumbers.**—With these plants every bit of warmth should be conserved, then there will be healthy plants and a good crop. It is not advisable to put out plants that have been some time in pots; far better plant those with four or five stout leaves 6 inches to 9 inches high with fresh roots that will soon take to their new quarters. Shade, warmth and moisture are the three principal factors; and, given these, fruit may be cut in four to six weeks from the time of planting. With shade little air is needed, and early closing is a necessity, allowing ample moisture in all parts of the frame, not only at the roots, but all over the surface of the soil.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**A selection of garden Cactus Dahlias (Tilson).**—The following constitute the chief varieties of the selection of garden Cactus Dahlias made by the National Dahlia Society. The selection is taken from trials in various places or made by growers generally. Amos Perry, deep crimson; Dainty, lemon yellow, shaded pink and gold tipped; Ena, pure white; Glow, yellow, suffused apricot; Mrs. J. S. Brunton, yellow, shaded salmon; Pearl, pink, tipped white; Star, bronze and yellow; Alexander, maroon-crimson; Lustre, vermilion-scarlet; Primrose, sulphur yellow; Florence Stredwick, pure white; and Mrs. H. L. Brousson, yellow, shaded salmon. Cactus Dahlias at the best are not good garden plants, as so few have stiff, erect flower-stems. They want a little help in the way of thinning and disbudding so as to enable the flowers to be well seen. Some day it is hoped a real garden or decorative strain will be created.

**Exhibiting and staging Narcissus (C. D.).** If you desire to succeed in exhibiting the above in open competition you must be prepared to give yourself a little trouble, and to carefully observe a few simple rules. A primary consideration is that the blooms are quite clean and free from smut and dirt. This is best secured by gathering the blooms when they begin to expand, the drooping stage of the fully grown bud or at the first signs of opening being the best time. At this stage of the proceedings the question of "timing" the blooms for the show arises, and nothing but experience and judgment can help you in this. We can, however, tell you that a bloom gathered in the early opening stage may, in the warmth and moisture of a greenhouse at this season of the year, develop fairly well in twenty-four hours, though it may not be clear or quite in character, and that the same bloom may, by placing it in a cool cellar, be kept in good condition for a week or even ten days or more. Blooms that have been quickly opened in artificial heat, especially those varieties belonging to the poeticus and incomparabilis groups and their cross-bred forms, do not last very long, the perianth segments incline to reflex on the tube, and in other ways display their sensitiveness at a method of treatment which, to say the least, is quite foreign to these plants. To what extent this may ensue will depend largely upon the way the work has been done. Another important item is stature, i.e., length of stem, and blooms gathered early in the opening stage have grown but little more than half their length. In these circumstances an inch or more may often be gained by pulling the blooms instead of cutting them as usually recommended. When gathered, the flowers should at once be placed in water, employing cylindrical vases for the purpose, so that the blooms may be kept erect. If the flowers are placed in any shallow receptacle where the stems can possibly assume an horizontal position, you will find that in a few hours the stems will have curled upwards, and being then fully charged with water, will break at very little pressure. It is important, therefore, that erect vessels only be employed or that ample precautions are taken to keep the stems as erect as possible. The curled stem is about the most awkward thing an exhibiting amateur has to contend with, and the beginner might easily make so simple an error. Where bunches of so many blooms each are required, the bunches should be made up fully twenty-four hours before the show, and by giving absolute freedom to each flower in the bunch, secure not only the best arrangement possible but a well-faced bunch withal. Equally necessary is it when opening the blooms to give each ample room for its expanse of wing. Threes or sixes are easily arranged by placing a plug of paper or moss in the tube to keep them erect. The most effective way of staging the blooms is by arranging them on a step stage, painted a dark green if possible. A little of their own foliage should be added to each vase. In those instances where a background is necessary, one of dark green baize will be found to be the

best, or a good result may be secured by arranging the flowers in a bank of good green moss. Grey-green canvas is not so good, and the more so when many white or pale sulphur-coloured blooms are employed. Always adopt the natural pose of the variety when staging, that is to say, a variety of the drooping type, as in some ceruus forms, should not be made to look at you in any rigid or staring fashion, which would at once destroy its character. You cannot exhibit two varieties of Aubrietia; or indeed two forms of any one plant or group as "one variety," and "twelve varieties" must be taken to mean that the "collection" is to contain twelve varieties only. If you have given us a copy of the wording in the class to which you refer, it would appear that a "Collection of hardy spring flowers" is asked for "in twelve varieties." If, on the other hand, the class reads thus: "Best collection of hardy spring flowers, not less than twelve varieties," you are certainly at liberty to show duplicates. You should have sent us a copy of the schedule, which is always most welcome in these cases, as so much turns on a very small word or phrase. Possibly you could send us the schedule as it is.

**Tree Peonies (Jap.).**—If your Peonies were only planted last autumn you will be fortunate if you have flowers this year, as they generally require to be established for about three years before they bloom. Your soil is not very suitable, and you will require to manure freely and to water liberally in dry weather. The guano is best applied in the form of weak manure water, which can be given at intervals during the growing season, but it would be much better to top-dress round about the plants with good old rich cow manure. In any case mulching should be practised in your light soil with gravel underneath. Failing good manure, some straw might be put about the plants and plenty of water given as suggested.

**Daffodils in grass (Cam.).**—In many gardens Daffodils are not flowering so well as last year, and we have visited a number of places where the blooms are very scarce, probably due to last year's dull and sunless summer. Did you leave the foliage on until it became yellow, as should be done? Neglect of this is a frequent cause of failure. Another is want of sun, although in some gardens many Daffodils do with less sun than in others. The following are the later bloomers which do best with shade: Fred Moore, odoros heminalis, o. pleus and Campenellea. This is a very limited list, and you may add Countess of Annesley, Golden Spur, Henry Irving, obvallaris, spurius, English Lent Lily, princeps and the Poeticus varieties. A few of these are a little early for you.

**Garden position and borders (A. Saunders).** It is not possible for us to tell you the position of your garden from the oblong sketch you submit, and if you desire to be accurate a compass will afford you the best guide on the spot. For general purposes the position of the sun at noon will possibly meet your requirements. So far as flower gardening is concerned, the surroundings have far more to do with success or failure than the actual position in such a case, and walls and high buildings are at times somewhat troublesome. If you will give us these particulars and whether you require permanent subjects or merely summer-beding things, we will assist you as much as possible. If the garden is not overshadowed by trees or buildings, you may grow many plants; but the above particulars and the extent of the garden will be helpful in dealing with a subject of which we have no information.

**Hardy Primulas (Mrs. B. M. L.).**—We are glad that the articles on hardy Primulas have interested you, and are pleased to see the photograph of your flowers, which do you credit. Seeds of all those named are not offered by the trade, but Thompson and Morgan, 5, Carr Street, Ipswich, can supply seeds of *Primula frondosa*, *P. pedemontana* and *P. rosea*, with many more. An article on raising hardy Primulas from seeds will appear in THE GARDEN shortly. *P. marginata* and *P. nivalis* you will have to buy as plants. *P. rosea* could be grown quite well by plunging the plants in pots outside in summer, and bringing them in when showing signs of bloom. The pots, if well drained, could be set in flats or saucers of water when in the house. All the hardy species would be better outside during summer, as you suggest, but will be better plunged in the ashes or in sand than simply set on the top. You will find these flowers delightful as pot plants, but they must be kept absolutely free from green fly.

**Violet culture for ladies (E. R.).**—Whether you may successfully grow Violets for market and make a living profit thereof depends on many things, such as the nature of the soil, situation, culture, marketing and prevalent prices. Because so easy of transit, Violets come to us in immense quantities from the Continent, where, favoured with warmth and other conditions, these flowers are easily grown. With us it is not possible to obtain early Violets except from frames, and to have a big supply of flowers such as could be sent to market day by day a big range of frames would be needful. It is only in that way early flowers of the De Parme and Neapolitan doubles, and Princess of Wales, Admiral Avellan and other singles can be got early outdoors; but there are other things to be considered. If you live in the London fog area, and Woodford is hardly out of that area, then Violets find in fogs formidable troubles, as these kill leafage wholesale. Violets, again, are subject to the attacks of a fungus, which often eat up the leaves; but if you have a good deep natural soil and the position is sheltered from north-east and east winds, and will plant out your Violets on beds made to slope slightly to the south, the beds being 6 feet wide and of any length, the plants in rows 12 inches apart,

you may have, in spite of the troubles we have indicated, material success. You should get plants in at once, and plant out as advised. The ground, besides being deeply worked, should have in it a fair dressing of half-decayed manure and a good dressing of soot. If you could have a number of common wooden frames having lights to cover them fixed in a very sheltered position, and filled to within 6 inches of the glass with good soil, then in the autumn lift strong plants from the open and plant them into the frames, nearly close together, giving a good watering, and putting the lights over, but giving some air behind, flowers should come a month earlier than outdoors; while the stock remains healthy, they can be propagated readily each autumn. Isaac House and Son, Coombe Nursery, Bristol, grow Violets largely, and may give you an opportunity to obtain practical instruction.

### THE GREENHOUSE.

**Tuberous Begonia stems rotting (R. W.).**—Such trouble with Begonias is by no means unknown, and it is considered to be caused by the plants receiving more nourishment than they can assimilate, and in this way decay is set up by the rupture of some of the tissues. This is borne out by the fact that plants less liberally treated are seldom or never troubled in this way. As far as we can see, there is nothing whatever the matter with your treatment, but would advise you to lessen the manure water during the coming season. A favourite plant may be increased by division or by cuttings. If three or four shoots are thrown up from a tuber it can be divided into as many pieces as there are shoots. The best time to do this is when the shoots are about an inch long; they must then be at once potted. If the tuber has only one shoot it may, when long enough, be taken as a cutting, after which more shoots will be pushed up. Lastly, the flowers may be fertilised with pollen from the same plant; but although most of the seedlings will probably be the same, there is no certainty that any of them will be identical with their parent.

**Dendrobium for name and valuation (S. C., Bexley Heath).**—As far as can be judged by a single flower, and that in a partially shrivelled state, the *Dendrobium* is a cross between *D. Ainsworthii*, itself a hybrid, and *D. nobile*. Its value will, of course, depend upon the size and condition of the plant, but if healthy it may be worth from 10s. 6d. to a guinea. On this point, however, nothing definite can be said.

**Iris for cold greenhouse (W. S. C.).**—All the early bulbous Irises are suitable for the above-named purpose, and so far as their cultural requirements are concerned, may be grown in pots or pans of sandy loam with every hope of success. The size of the pot to employ would depend entirely upon whether you desire to cultivate solitary examples of each or to group several in one pot. We may say here that nearly all the species and their varieties are quite cheap by the dozen, and a dozen bulbs of many sorts could be readily accommodated in a pot 7 inches across. Single bulbs may be grown in pots of 3 inches or 4 inches across. The bulbs should be planted in September. The following are the best of the winter and early spring-flowering sorts: *I. alata*, December; *I. stylosa* or unguicularis, winter-flowering, not bulbous, may be planted at once and grown on for flowering; *I. persica* in variety; *I. Tauri*, *I. Heldreichii*, *I. Danfordiae*, *I. reticulata* and its varieties, *I. Histris*, *I. hanfroidii*, *I. Krelagei* major purpurea, &c. *I. sindjarensis* and *I. orchidoides* are of larger growth and require more room. The above, with the exception of *I. orchidoides*, all flower during the first three months of the year, and the majority in February.

**Geranium buds poor (E. M. K.).**—Judging by the poor attenuated condition of the buds sent, we have little doubt that the roots of your Geraniums are in a very bad state, and therefore quite unable to take advantage of the liquid manure so liberally supplied to them. A dose of manure once a fortnight would be quite sufficient for even healthy plants at this season of the year. The only thing you can do to renovate your Geranium seedlings is to turn them out of their pots and shake almost, if not quite, clear of the old soil, as, being so impregnated with manure, healthy roots will not start in it. Then repot into comparatively small pots in a mixture of loam, leaf-mould and a liberal sprinkling of silver sand. If well incorporated together these ingredients will form a good sweet compost. The pots for the reception of the plants must be effectually drained, and after the potting is done the plants must be stood in a good light position in the greenhouse, but where they are shaded from the direct rays of the sun. They must be kept watered, but at the same time care must be taken not to get the soil too wet, as the main object is to further the development of good healthy roots. When the pots are well furnished with roots the plants may, as required, be shifted into larger pots. It is a very common mistake to give plants in ill health liquid manure, for, as with human beings, the illness must be overcome before rich nourishment can be taken. We cannot understand your question re *Daphne Cuscutum*, for you speak of it as a tree, whereas in reality

it is a low-growing shrub about 1 foot in height. It naturally forms a tuft composed of many shoots, and propagation is readily effected by pulling it to pieces after the manner of a herbaceous subject. No pruning is needed. *Daphne Cneorum* thrives best in a fairly moist soil containing a certain amount of peat or leaf-mould.

### ROSE GARDEN.

**Roses pegged down** (*Mrs. L. G.*).—The object of bending over the long growths of Roses is to induce the eyes all along the shoot to start into new growth and to produce blooms. If the long growths are not so bent, the sap flows to the extreme ends, and only those buds at the ends will move. If you observe a wild Rose in the hedgerows you will usually find some long growths have arched over naturally and they are studded with shoots and blooms. It is not at all necessary to peg the ends into the soil. The best plan is to drive a few stout pegs into the ground, then attach tarred twine to them by making a notch so that the string cannot come off. The end of the growth is then secured to the string and bent at any angle preferred. The ends may touch the ground or be a foot or so away; it is immaterial. We like to peg one or two growths and allow the others to grow naturally on such plants as are suitable to treat in this way. If such as W. A. Richardson are pegged, all the growths may be bent, and towards autumn a number of new shoots will spring up from the base, and after attaining a height of about 3 feet will flower at their extreme ends, and most lovely sprays they will produce. Any Rose at all shy in blooming should have its growths trained horizontally or arched over. This will induce it to bloom quicker than anything, only the growths must be hard and well ripened. We cannot expect much bloom from pithy wood. We have seen standards of such shy bloomers as *Réve d'Or* with their growths tied out horizontally to a framework of Bamboo, and in a year or two they bloomed marvellously. Some of the old growths are removed after flowering, and new growths take their place another year.

**Roses for growing near Manchester** (*N. A. C. W.*).—It is most difficult to grow good Roses in the neighbourhood of large cities such as Manchester, but even there a deal depends upon the soil. If you could obtain a barrowful of really good soil for each plant, you might be rewarded with fair success, especially if you took the precaution during the growing season to thoroughly cleanse the foliage every evening. Good white varieties would be *Frau Karl Druschki*, *Gloire Lyonnaise*, *Baronne de Maynard* and *Violette Bouyer* as bushes, and if you have space to grow a climber plant, *Mme. Alfred Carrière* or *Félicité Perpétua*. Yellow Roses are difficult to grow, even under favourable conditions. We believe one of the best would be *Bouquet d'Or*. This is a half climber, but may be grown as a bush if afforded plenty of space and sparsely pruned. Other good sorts are *Josephine Bernacchi*, *Marie van Houtte*, *Mme. Hector Leulliot*, *Gustave Regis* and *Soleil d'Or*. If you can utilise a very fast-growing sort suitable to grow over an arbour or similar building, or against a dead tree, plant the wickiana *Gardenia*, a real gem, yielding most lovely canary yellow buds. Should you be able to find room for a good pink, plant *Caroline Testout*; or if a strong, bold grower were needed, plant *Conrad F. Meyer*. This fine Rose may be grown into a large shrub as you would a *Lilac* bush.

**Roses to flower during winter and spring in France** (*C. C.*).—It is not at all difficult to have Roses in bloom during the winter and early spring in such a locality as the Riviera, especially if the easy opening sorts, such as *Safrano*, *Papa Nahonnand*, *Papa Gontier*, &c., are grown. The best plan to adopt is to keep the flower-buds removed during autumn, then go over the plants and thin out shoots where crowded and allow the others to bloom. A few portable glass lights made to lean against each other so as to span over the bushes would be a great help if your district is at all a cold one. Climbing Roses on walls would pay to have a glass structure built in front of them, and about 3 feet or 4 feet or more distant from the wall. Such a structure should have air admitted from the base, and the ends would have no doors, so that a free circulation of air could be maintained at all times. It is difficult to advise you as you do not explain whether you are sheltered or otherwise, but as a rule these winter Roses, even in sunny France, pay for some slight protection from the weather without diminishing the supply of air. *Acacias* would be all the better if one or two growths were cut back to the base. This would encourage a more bushy growth nearer the ground. Your soil would benefit by applications of liquid manure during the growing season. We should say it is the want of such manure that causes the foliage to turn yellow. You will find "Century

Book of Gardening" a great help to you, also "Trees and Shrubs" by E. T. Cook. To enable the *Bougainvilleas* to blossom early in the year, they should be grown in pots in a greenhouse where a temperature of about 55° at night can be maintained. During the summer such plants require a good ripening of the growths by full exposure to the sun.

**Roses with unhealthy growths** (*Mrs. A. M. B.*). All the growths sent were of such a soft, pithy character that we are not surprised they are in an unhealthy condition. We believe frost is mainly the cause, and you should have such growths cut away at pruning time, for they cannot give you good results. It seems to us that your Roses are growing too rank, that is to say, the soil is too rich. What is wanted in order to obtain good blooms is ripened, medium wood. You must not overdo them with manure. If this variety of which you send shoots is *Climbing Devonensis*, we are not surprised to see them, for it is much given to produce very rank growth, especially after such a wet summer. Try pruning hard back any plants that are showing these injured growths, even cutting them down to the ground, but retain the hard, ripened wood. We should have been able to give you more information had you afforded us more details.

### FRUIT GARDEN.

**Diseased bark of Apple tree** (*W. F. S. H.*).—The tissues of the bark are permeated by the mycelium of a fungus, which is the probable cause of the flaking off of the bark. The hyphae of the fungus in all probability secrete a ferment which has the power of attacking a portion of the cell walls of the tissues of the host and so liberating one cell from another. The fungus is very likely a species of *Polyporus* or a near ally. Several species of that and allied genera attack fruit and timber trees and produce symptoms similar to those seen here, but usually the wood is also attacked. You do not say whether that is the case here or not. In the absence of the fruit of the fungus it is not possible to say what species it belongs to, but most of them are wound parasites. If the tree is of little value it would be just as well to remove it and burn it, because when the fungus produces fruit the tree will be a menace to others in the garden.

**New greenhouse for fruit** (*B. K. G.*).—It is better to have the wire trellis running from front to back under the rather than crossways. If placed crossways you will find that it will render the work of cleaning the roof and washing the glass most tedious and difficult. The wires should be at least 2 feet below the glass in order to prevent the sun from burning the foliage in hot weather. A Peach tree would not succeed on the back wall. The shade would be too dense and the temperature too high; on the other hand, a Fig would succeed fairly well in such a position, and so would Figs grown in pots if placed in the lightest position in the house. The best varieties to grow are *St. John's*, *Brown Turkey* and *White Marseilles*.

**Spot on young Fig fruits** (*C. W. G.*).—The cause of the brown spot at the end of the Fig is a too close and moist atmosphere. Give more air and a little extra fire-heat in order to keep the air more buoyant and dry for a time, and you will find the injury arrested. The *Carnation* foliage sent is suffering from an attack of a virulent fungus, commonly called the *Carnation rust*. Once it gets a thorough hold of the plants it is fatal to their future success. It has destroyed scores if not hundreds of fine collections in England. If only a few of your plants are affected, we advise you to throw them away or certainly to keep them well isolated from the healthy plants. A too close and damp atmosphere favours the growth of the fungus, therefore let a free circulation of air play among your plants. You might try spraying with methylated spirits and water, one part of the former to 100 parts of water.

**Almond trees gumming** (*D. S.*).—The cause of gumming in Almond trees (and it is a common one) is the action of hard frost in winter injuring the abnormally strong and soft growths made in summer. The Almond, especially if planted in rich soil, is very apt to produce those strong soft branches, with the inevitable result of damage by frost, and as a consequence gumming is sure to follow. To prevent this the tree should be planted in moderately poor soil only. As regards the tree under notice, we should cut out the dry rot part, afterwards washing the wound clean with soap and water, and as soon as dry paint over the wound with *Stockholm tar*. The gumming part (not the whole branch, only the part injured) should be cut out also, and afterwards served in the same way. In the autumn examine the roots, when, we think, it will be found that two or three strong fibrous tap-roots have been formed, which have struck deep down into the subsoil. These are usually the cause of the growth of these strong branches. When found they should be cut clean through, 1 foot below the surface of the soil, taking all possible care not to injure the smaller surface roots of the tree while carrying out the work. This treatment should restore your tree to perfect health if carried out with care.

### KITCHEN GARDEN.

**Tomato plants diseased** (*F. J. H.*). There is no doubt that your Tomato plants are suffering from an attack of the Potato disease fungus (*Peronospora infestans*). The conditions which favour the growth of this fungus are dull skies like we have had lately, too much moisture at the roots and about the stems of the plants, and the crowding of them too closely together. We do not know if these conditions are responsible for the mischief in your case; if so, we would at once give the plants more room, so that air may circulate freely among them, and thus render the land on which they stand less wet and sodden. Better still would it be to remove the plants to fresh ground on which Tomatoes had not been placed before, as it is a well-known fact that the mycelium of this fungus, once it has secured a footing in any soil, will reappear year after year if the conditions for its growth are favourable. A keen look-out should be kept for affected plants, which should be destroyed, as there is no known cure for the disease.

**Cucumbers in a cold frame** (*Tantallon*).—We take it for granted that by the term "cold" frame you mean one without hot-bed or any other form of artificial heating. In such a frame, which is entirely dependent on sun warmth for the requisite heat for Cucumbers, it is useless to look for such heat until the end of May at least. Your course just prior to that should be to place your frame firmly on the ground in the sunniest position in your garden, to well fork up and pulverise the soil in it, then to put in the centre a bushel at least, and more if you have it, of a compost composed of three-fourths well-decayed turfy loam and the other part of decayed old stable manure well mixed. Leave that as a mound, give the entire soil a good soaking of water, then shut it up close to allow the sun to warm the soil, covering up the frame closely at night to box the sun-heat in. After three or four days put out your plants into the centre of the mound. If the soil be fairly moist when planting is done no water is needed. If dry, then give the plants some tepid water. Shut up the frame close all day, giving the plants a little shade if the sun shines out hotly, and covering over the lights with mats at night to box in the warmth generated. If the frame be a single light one of the normal size, 6 feet by 4 feet, two plants which may have been in one pot will suffice. If a smaller frame, one plant will be ample. When tiny white roots are seen coming out from the sides of the mound, a thin coating of fresh soil should be added, and just a very tiny sprinkling of some guano. As the plants grow strong give a little air at the back of the frame, and a liberal sprinkling with sun-exposed water just as the sun goes off the frame each evening before shutting close down. If the plants grow dense, thin out fruitless shoots. Plants should be purchased from a florist to plant.

### MISCELLANEOUS.

**Cocoanut fibre refuse as manure** (*Beginner*).—Were yours a stiff, holding soil, working into it a dressing of Cocoanut fibre refuse that has been during the winter employed to cover bulbs in pots would be very helpful in rendering the soil more porous; but as your soil is light the effect would be to render it too porous, and thus dry quickly. You could, however, use the refuse to mulch or top-dress flowers or crops where the soil does dry too quickly, especially were it laid on an inch thick directly after the soil had received a good soaking of rain or a watering. It is a slow decomposing fibre, but dug into any soil would gradually decay and thus become plant food. Were it used as advised, then dug into the soil in the autumn, especially with some manure, it would no doubt become decomposed materially through the winter. If you prefer to store the refuse in a shed or heap outdoors for covering bulbs next autumn it will be safe to do so.

**Fungus affected lawn** (*Laxtonian*).—The sample of soil from your lawn sent shows it to be as full of fungoid mycelium or root matter as is Mushroom spawn. No doubt it is the same as the fungus which creates "fairy rings" in pastures. That impoverishes the grass while active, but as the mycelium spreads into new ground its old mycelium dies and thus for the moment becomes manure for the grass, thus causing the green rings or clumps seen in pastures. But each year as the rings spread wider, the inner soil becomes exhausted or poorer and the grass starved and weak. Presuming, however, that your grass is not influenced thus, it is to be assumed that, while the fungus in the soil runs deep and kills or impoverishes the deep-rooting grasses, the surface soil is less affected; hence with wet weather shallow-rooting grasses do well. Dressings of sulphate of ammonia are recommended as correctives of the trouble, but while it is worth your while to test such dressings by applying at once and again a month later 2lb. per rod area of very finely-crushed sulphate it is possible that such may not be effectual, and that only breaking up the lawn in the autumn, dressing it with 40lb. per rod of well-broken gas-lime, letting it lie on the surface for a month, then well forking it in, will prove a complete remedy.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE WILD GARDEN.

AMONG the more interesting phases of modern gardening, the wild garden or the naturalisation of hardy plants in or near the woodland, the shrubbery, copse, or similar places deserves more than a passing thought. The wild garden must not be confounded with grass gardening, or the planting—too often in meaningless fashion—of thousands of bulbous plants in meadow or park or pasture, but rather that thinner planting or grouping of varied plants, bulbous and otherwise, that help to provide in unkept garden scenery those touches of Nature all too rare even at the present time.

Just what the wild garden should be cannot be arranged by any fixed plan. Any formality of this kind will be the undoing of the whole. It must, therefore, be regarded rather in a local sense, and from the standpoint of soil and surroundings in particular; but those who know the country and have seen the sheets of the white Wood Anemone, the taller effects of the Bluebell, or the pale sulphur tones of the Primrose now fringing the copse, or presently spreading in greater profusion into the woodland itself, will require little guidance when it is desired to adapt this most beautiful of Nature's ways of flower gardening to the garden itself.

The wild garden is just that particular spot in the garden, be it the shrubbery, the outer fringe of the lawn, the shady or half-shady dell, or copse or glade or woodland, where the plants, once placed, not merely take care of themselves, but in an unmistakable way thrive much better and are seen to far greater advantage than in garden beds or borders in the trimmer parts. In these latter the bare soil—dark, sombre, uninteresting—too frequently catches the eye, and in winter time the "kept" flower border is bereft of the life and interest that even dead stems afford. In the wild garden it is not so, and here, while the Bracken in its maturer tones still provides a picture in the landscape, we have also those natural beauties of Oak, Birch or Dogwood, in grey, silver or scarlet respectively, waiting the rare gleams of sunlight to reveal their charms. At the same time, the Hazel in the copse may be studded with its ruby-like blossoms, and a little later the yellowing of its catkins catches the eye, and just then the Winter Aconite, Snowdrop or Grecian Windflower carpeting the ground beneath leafless trees may be seen, or later, the Glory of the Snow (Chionodoxa) and the Apennine Windflower, staining with blue the sides of woodland walks and drives and the rugged tufts of verdure from which these spring.

Presently, in cool and shady woods and like places, the Primrose spreads its leafy tufts, or the Wood Anemone and the Bluebell are seen, sometimes alone, sometimes carpeting the earth in sweet companionship. In the wild garden no bare places should be seen, and much may be done by free plantings of the Megaseas, Christmas and Lenten Roses, with Helleborus viridis and other species to secure this end. Just what a wild garden may be depends not a little upon its immediate surroundings, but the more densely shaded parts, banks or slopes may be permanently clothed with such Ferns as Scolopendriums, Polystichums, &c., and be carpeted with London Pride or other suitable plants. In the Royal Gardens, Kew, near the Cumberland Gate, may be seen in February a pretty effect of this type of planting, and where Snowdrop, Christmas Rose, Hepatica, hardy Cyclamen and Fern go hand in hand to render the spot more beautiful. Not least in point of beauty or effectiveness is a small grouping of the remains of the Honesty (Lunaria biennis), the remnants of whose silvered inflorescence are seen at some distance. At the outskirts of the lawn, and where by a steep bank or slope some higher ground is reached, the Solomon's Seal should be seen, and in cool, moist places certain Bamboos, the Acanthus or Saxifraga peltata would be seen to advantage. In shrubbery borders the Evening Primrose and the Foxglove should meet the eye, while in the background the taller stems of Helianthus decapetalus or H. orgyalis would be an advantage.

In the woodland itself or the approaches and in places where the Rhododendron and other shrubs grow quite freely the taller-stemmed Lilies should be seen. Of these none are better than the forms of L. auratum, together with Henryi, tigrinum in variety and others. Near to a shrubbery belt of Laurels the white Madonna Lily should be seen, and in more thickly-covered spots colonies of the giant species of the Himalayas would be a great gain. In quite moist or wet spots Liliun pardalinum and L. canadense should be freely grouped, and so, too, the larger growing of the Spireas, or those giants of Ferns the Royal Ferns (Osmundas).

Of Tulips, Daffodils and the like there is no end, and many of these are seen at their best in quite wet places, such as near the margin of a lake or pond. In those districts where Heather and Bracken abound much should be made of them, and where difficulty is experienced with the latter the raising of seedlings is suggested. In the smaller gardens the opportunities for this planting or effective grouping are not great, but any unkept corners may be utilised by the London Pride, Ferns, the great wealth of Daffodils, Crocuses or Snowdrops, Dog's-tooth

Violets, &c. The Daffodils alone are quite a host and appear to thrive better than in the more richly-fed soils. Where a belt of evergreens afford the requisite shelter the giant Asphodels or Eremuri should be planted with care, and few things are so noble or so good in flowering as these.

Hampton Hill.

E. H. JENKINS.

## NEW ORCHIDS.

BRASSO CATTLEYA HEATONENSIS WESTONBIRT VARIETY.

THIS very handsome Orchid is one of the very highly-fimbriated forms of this bi-generic family, and in addition to this fimbriation we have a unique colour scheme and flowers of enormous size. The sepals are long, lanceolate and recurved, with bluntish tips, the colour being a mixture of cream and faint purple. The labellum naturally is the most conspicuous portion of the flower, this being very broad; canary yellow in the centre, this being surrounded by a broad band of pale old rose colour. Shown by Major Holford, Westonbirt, Tetbury, Gloucester. First-class certificate.

CATTLEYA MOSSIE GOOSENSIANA.

This is a very pretty variety of an Orchid that has been largely used for hybridising purposes in the past. The sepals are narrow and of medium length, the colour being white very faintly tinged with purple. The petals are very broad, pointing off rather shapely at the apex, and the colour is very pale lilac. The labellum is very conspicuous, this being rather spreading, much waved at the edge and of a bright purple ground colour, surrounded by a narrow white band. At the base of the labellum and extending down the throat the colour is rich yellow. Shown by Sir Trevor Lawrence, Bart. First-class certificate.

ODONTOGLOSSUM WILCKEANUM SCHRODERIANUM.

This, as one would expect, has a good amount of yellow in its colour composition, and the specimen exhibited was a very beautiful one indeed. The flowers are large and very freely produced on a stout, robust stem. The bright yellow ground colour of the sepals, petals and labellum is heavily blotched with large masses of rich brownish crimson, the yellow at the tips being left unspotted. The markings are very distinct and regular. The plant shown had ten fully-developed, large flowers and a number of healthy leaves and pseudo-bulbs. Exhibited by Baron Schröder, Egham. First-class certificate.

ODONTOGLOSSUM APTERUM MOSSIE.

A very small plant of this carrying only two flowers was shown. The flowers are of medium size, much wooded, and of a creamy white colour, except the labellum, which is spotted with dull yellow dots. Exhibited by Mr. J. Moss, Wintershill Hall, Bishop's Waltham. Award of merit.

ODONTOGLOSSUM ILLUSTRE THEODORA.

This is one of the few rosy lilac-covered Odontoglossums, the older flowers being of this hue, and each segment edged by a very narrow white band. The blooms open an almost dull orange colour, apparently changing to the lilac hue with age. The blooms are of medium size only, and are loosely placed on a rather thin stem. Shown by Mr. de B Crawshaw, Rosefield, Sevenoaks. Award of merit.

ANGRECEM GERMINYANUM.

A very curious little Orchid with white and dull greenish yellow flowers, the segments of which are attenuated and form almost spiral threads. The leaves are small, opposite, and very much like those of the Crassulas in general appearance. Shown by Sir Trevor Lawrence, Bart. Award of merit.

ODONTOGLOSSUM OSSULSTONII GLEBELANDS VARIETY.

This is a beautiful variety, the long pendulous raceme on the plant shown being composed of twenty-one flowers. The white ground of these is very densely mottled with dull magenta, the characteristic yellow blotch appearing on the labellum. The flowers are loosely placed on the stem, and the raceme is slightly compound. Shown by Mr. J. Gurney Fowler, Glebelands, South Woodford. Award of merit. All the above were exhibited before the Orchid committee of the Royal Horticultural Society on May 12, when the awards were made.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

May 26, 27 and 28.—Royal Horticultural Society's Spring Flower Show, Inner Temple Gardens, Thames Embankment; 12 noon to 7 p.m. the first two days, 9 a.m. to 6 p.m. third day.

**The Kew Bulletin.**—This publication for May contains a mass of information that should be of special interest to those interested in economic botany and in the work being done by Kew men at the botanical stations abroad. The contents comprise particulars of the South African locust fungus, new rubber-containing plants, Cacao pests of Trinidad, mud-binding Grasses, raffia fibre from Madagascar, with reports on the botanic stations of the West Indies.

**Bath and West and Southern Counties' Show.**—The fire protection arrangements for the above show, which opens at Dorchester on the 27th inst., have received most careful attention and have again been entrusted to the capable hands of Messrs. Merryweather and Sons. A detachment of their private fire brigade will be in attendance, men being on duty day and night. The fire station in the show yard will be well equipped with motor and horse fire engines, there will be a system of fire-mains and hydrants laid down, while hand pumps and buckets will be placed at various points about the yard. Efficient means of fire protection at agricultural shows is an absolute necessity, and the precautionary measures taken in this respect cannot be too elaborate.

**Next year's Hyacinth show.**—The president and council of the Royal Horticultural Society have accepted the offer of the Dutch Bulb Growers' Society at Haarlem of prizes for forced Hyacinths, to be competed for at the society's exhibition to be held on March 9, 1909. The prizes are as follows: Division I., for amateurs and gentlemen's gardeners: Class 3 (eighteen Hyacinths), first prize, £6 6s.; second prize, £5 5s.; third prize, £4 4s.; fourth prize, £3 3s.; fifth prize, £2 2s.; sixth prize, £1 1s. Class 4 (twelve Hyacinths), first prize, £5 5s.; second prize, £4 4s.; third prize, £3 3s.; fourth prize, £2 2s.; fifth prize, £1 1s. Class 5 (four pans containing Hyacinths, ten roots in one pan), the blooms of each pan to be of distinctly different colour, first prize, £4 4s.; second prize, £3 3s.; third prize, £2 2s.; fourth prize, £1 1s. Division II., for nurserymen: Class 6 (for the finest collection of Hyacinths, either in pots or pans or in glasses), prize, the gold medal of the Dutch Bulb Growers' Society at Haarlem, valued at 50fr. Regulations: For class 3 and 4 each bulb must be in a separate pot (size optional). Classes 3, 4 and 5 must be all single flowers; no flowers may be tied together. An exhibit must not contain more than one specimen of any one variety. Exhibitors may show in not more than one class, except in the following: Competitors may enter in Classes 3 and 5, or Classes 4 and 5, or singly in either one. In Classes 3, 4, 5 and 6 all bulbs shown must have been forced entirely in Great Britain or Ireland.—W. WILKS, Secretary.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Tulip Ophir d'Or with bulblets in the leaves.**—I wish to record what I suppose is a remarkable development in three specimens of Tulip Ophir d'Or. They have each produced good-sized bulblets in the axils of the lowest leaf and well out of the ground, each plant being in full flower. Also another plant of the same variety has produced two fully-developed blooms on one stem at the same time. Any remarks thereon will be greatly appreciated, as I have never seen anything of the kind before, although I have grown hundreds of the same variety, which I consider quite one of the best of its kind.—A. E. SPER.

[Several varieties of Tulips almost always, under favourable conditions, develop bulblets in the axils of their leaves. The well-known Mrs. Moon usually has a bulbil in the axils of its lowest leaf. It is more unusual among the early varieties as far as our experience goes. It frequently happens that Tulips have two flowers on one stem, but as a rule one is much finer than the other. Last year we heard of a lot of Artus that had many double-flowered stems among them. The reason usually assigned is that they have done very well the previous year and accumulated some extra energy, which they get rid of in this way. It is extremely interesting to hear of your experience with Ophir d'Or.—Ed.]

**Polyanthuses at Camberley.**—Mr. John Crook, whose beautiful strain of border Polyanthus secured wide popularity while he was resident at Forde Abbey, having now come to reside at Camberley, Surrey, has there in his garden at Fingest several thousands of these charming spring flowers in bloom, and when seen by me just recently they exhibited in a very remarkable degree their recuperative capacity, having but just previously been buried in snow, which laid all the flowers flat to the ground. But on the 7th inst. all traces of that visitation had disappeared and the blooms in every case stood up stiff and erect, and as seen in such numbers and in blocks of colours presented a delightful show florally, such as no similar spring flower could furnish. Great blocks running into several hundreds of plants, white, yellow, red, crimson, mauve and purple, with others of mixed hues, gave beauty which served to delight and over which any lover of flowers might well rejoice. Not a single plant out of so many represented any other form of propagation than raising by seed, and that one fact also assists so greatly to popularise the Polyanthus, because of which everybody can grow it, and it seems to do well alike in all soils. It costs but a small sum to secure seed sufficient to raise hundreds of plants, hence they are everybody's flower literally. Many of the reds, crimsons, mauves and purples were surpassingly fine in form, as in size, and rich in colouring. Oddly enough ladies seem to prefer browns, buffs, terra-cotta, or similar quaint hues such as do not usually appeal to the sterner sex. These prefer the more fixed and richer colours, named with pure whites and glowing yellows. In any case, whether seed be purchased in colours or in mixed forms, quaint colours will certainly crop up, while the original ones will be chiefly reproduced.—A. D.

**Erica codonodes.**—I have read the article in THE GARDEN of the 25th ult. on Heaths with much interest, but am surprised it does not include Erica codonodes, the beautiful Australian Heath. It does not appear to be described under any other name, as its long spikes of white blooms, tipped with pink, which begin to appear in January and last until April in Devonshire, are unlike any of the varieties mentioned. It is quite hardy, and flowers best if

clipped over after the time of blooming.—F. SANDERS. [*Erica codonodes* is a synonym of *E. lusitanica*, a plant which has also been called *E. polytrichifolia*. In the article in THE GARDEN the plant is mentioned as *E. lusitanica*. As you say, it grows well in Devonshire; it is also largely grown in Cornwall, where it is highly thought of. It is an excellent shrub, and well worth growing on an extended scale in the warmer parts of the country. You are wrong in considering it an Australian plant, as it is a native of Spain and Portugal.—ED.]

**Narcissus Buttercup.**—As several erroneous accounts have appeared in the Horticultural Press of *Narcissus Buttercup*, described and illustrated in THE GARDEN, page 229, will you kindly allow me to state that it was raised by myself from N. Emperor by pollen of N. jonquilla.—G. H. ENGLEHART.

**Cactus Dahlias.**—It would be interesting to know which is really the best way of storing Dahlia tubers. Last season, after the frost had cut down the plants, I lifted all my tubers with the exception of one, which was of the Cactus variety, and, strange to say, when taking these from the shed in which they had been stored I found they had all rotted away. The plant which I left outside, however, has withstood all the frosts and is now making good shoots. It would be useful to hear the experience of other readers of your valuable paper.—E. G.

**An interesting plant parasite.**—Your illustration of the parasite *Orobanch* reminds me that some years ago I had one that grew up through a *Pelargonium* planted in the border here, and, wondering what it came from, I carefully removed the soil and found it attached to the roots of the *Pelargonium* in the same way as shown in your illustration. At that time I thought it a very exceptional occurrence, but evidently the *Pelargonium* is a congenial host. It would be interesting to know if it is subject to any such parasite in its native home in South Africa.—R. J. G. READ, *Ealing*.

**Rabbits and wire netting.**—I am sure all those who are tormented by rabbits eating their garden produce should be most grateful to those of your correspondents who have been kind enough to write, giving suggestions for the prevention of such a state of affairs. I have been at my wits' end for the past twelve months. Bulbs, which I paid 3s. 6d. each for, were uprooted and nibbled, and either left on the ground in the frost or else were carried bodily away (this latter presumably by rats, which abound in great numbers all round my premises). Rose trees and bushes were eaten through, more especially Noisette bushes, as the rabbits seem to prefer tender green wood. Tough standard Roses were merely eaten through the bark and left to die; but the Noisettes were eaten down to the earth. All told, I think I am not exaggerating when I say I have lost over £10 worth of Lily bulbs and Roses during my first winter here. It is especially remarkable that the cheaper bulbs (which I would not have minded so much losing) were never attacked, such as the common Madonna and Tiger Lilies, but I had some white Turk's Caps, some Henryii and several beds of *Auratum rubrum vittatum* Lilies, all of which were utterly annihilated. Just as things had reached such a climax I had become positively murderous, I saw Mr. Fred Street's letter in THE GARDEN and tried the buried wire netting, with a piece turned up all along the lower edge. Although I was positive my enemies would find some way of getting in it has been erected three weeks and up to the present has been a complete success. This is all the more wonderful, because this place is a sandy, rocky soil, ideal for wild rabbits, and they exist in shoals for miles around. Through the columns of THE GARDEN I tender my sincere thanks to all who have given such helpful suggestions concerning the rabbit nuisance.—J. HUTH, *Bures, Essex*.

## HISTORY OF THE PRIM-ROSE, COWSLIP AND AURICULA.

(Continued from page 241.)

IN the "Paradisus" nine kinds of Cowslip are described, of which the Primrose Cowslip is not improbably a *Polyanthus*. Those worth mention are respectively "Cur'd Cowslip" or "Gallegaskins," in which the calyx was crumpled and frilled like the garment of that name then worn, "Hose-in-hose, the Franticke or Foolish Cowslip, or Jack-an-apes on horsebacke," which had the calyx developed into leaf-like forms (the Jack-an-apes of Gerard is noted in his "Herbal" as an Oxlip), also "the greene Rose Cowslip or double greene feathered Cowslip." From the description the "flower" of this was simply a calyx of an abnormal size and shape, divided into many narrow leaves. Rea notes a great variety in the colours of the Cowslip, of which one was a Hose-in-hose.

By the beginning of the eighteenth century Cowslips, as garden flowers, appear to have gone out of fashion, or rather, perhaps, they were superseded by the *Polyanthus*, Miller, in 1733, remarking of the double yellow that it was very rare. The Primrose is in several respects a better garden plant than the Cowslip, and the early gardeners, as well as the ladies who in mediæval England effected as much for the progress of gardening as the ladies of to-day are doing, seem to have taken kindly to the garden forms of the Primrose. The earliest date, however, it is possible to assign to the Primrose in the garden is 1578, when Lyte mentions it as "fayre and dubbel." A special paragraph is devoted also to the green Primrose. Tusser catalogues the Primrose among the herbs for the kitchen, while Cowslips and Paggles (Oxlips) appear among "flowers for windows and pots."

As the green Primrose is the earliest recorded variety, and there are writers who are doubtful of its identity, it may be worth remarking that, along with the green Cowslip and Oxlip, it continued in both its single and double forms to be a favourite flower until at least the end of the seventeenth century. Parkinson, with his delightful habit of detailing with exactitude the slightest things, enables us to picture to ourselves from his word painting the light green shade of the single and the darker green of the double (or two-rowed) Primrose. Bacon, too, in "*Sylva Sylvarum*," refers to it, but in order to prove his contention that there was no such thing as a green flower, "There is," he remarks, "a *greenish Prime-Rosa*, but it is pale and scarce a green." Among the Elizabethan poets who may be said to have popularised the Primrose, Spenser is the only one who refers to the green variety:

Upon her head a Cremosin coronet  
With Damaske Roses and Daffadillies set,  
Bay leaves betwene,  
And primroses greene,  
Embellish the sweete Violet.

The Primrose in Drayton's "Garland," though sweet, was not a green one.

A course of Cowslips then I'll stick,  
And here and there (though sparingly)  
The pleasant Primrose down I'll prick  
Like pearls which will show rarely.

Gerarde mentions and figures a double white Primrose, but one is left to conjecture if he had the plant at all. It is certainly suspicious that it is not mentioned in the catalogue of 1599, nor do we hear of it elsewhere. Parkinson refers to the common double only and remarks that, though better known in the West parts of the kingdom and in the North, Primroses were not usual in the vicinity of London.

A quarter of a century later Rea introduces us to a great variety of sorts, "there being about twenty diversities of reds, some deeper and

others lighter, from blood red to pale Pink colour; some are of a bleuish Rose colour, sader and paler, some brick colour, some Dove colour, others of the colour of an old Buff coat and some hair colour." Then he goes on to more particularly describe "the fair red," "the Scarlet" and the "Red Hose-in-hose and the double red" "the rarest of all kinds," but not known to Rea himself. His son-in-law, the Rev. Samuel Gilbert, describes it as a "dull Horse flesh hue" and of no value.

Like the Cowslip, the Primrose would seem to have lost repute among florists, and very little is to be found regarding it all through the eighteenth century. Miller (1733) mentions, along with the common double, the Paper White, pale flesh, and double Paper White, and distinguished them as Primroses of Constantinople. Later, the latter appellation was withdrawn. An Edinburgh nurseryman in 1774 names three double sorts, viz., double yellow, double red and double velvet, which he described as "a great beauty, being almost of a crimson colour with a bright gold-coloured stamina."

Martyn in "*Flora Rustica*" figured a dingy-coloured variety which he called "Scotch Primrose," and asserted that the plant grew wild in Scotland, and in his dictionary he further remarks that it partakes to some extent of the nature of a *Polyanthus*. The pink or lilac double Primrose was figured by Curtis in the *Botanical Magazine*, and for a long time or till about the third decade of the last century the Primrose remained in almost a stationary condition. Since then many double and fine single varieties have been produced.

R. P. BROTHERTON.

(To be continued.)

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### POLYANTHUSES FROM CAMBERLEY.

Mr. J. Crook, The Avenue, Camberley, sends us a splendid lot of these charming spring flowers in many colours. One of an old gold shade is particularly pleasing, and the deep rich yellows are also very fine. This strain is a very good one indeed, and, as Mr. Crook is now making a speciality of these flowers, we may expect some extra good things from this source in the near future.

### ARCTOTIS ARBORESCENS FROM HERTS.

Mr. A. G. Gentle, gardener to Mrs. Denison, Little Gaddesden, Berkhamsted, Herts, sends beautiful flowers of this useful greenhouse plant. He writes as follows: "I am sending some *Arctotis arborescens* for the Editor's table. We have a dozen plants that have been in flower since the latter part of January. I think it excellent for cutting, as the flowers last a long time. It is a good greenhouse plant, as no insects, except green fly, attack it."

### DAFFODILS FROM MR PETER BARR.

Still another interesting and fragrant contribution of these beautiful flowers has reached us from Mr. Peter Barr, V.M.H., and which have been grown in the garden of his Scottish home. Among them were two flowers of *triandrus albus*, one grown under glass and the other in the open.

The latter was very pure, had the pale yellow markings in the perianth better developed, and had longer anthers and style. *Corbularia conspicua* (true) is a lovely little rich yellow flower. *Biflora hybridus*, collected at Nimes, had three flowers on a stem, these being rather small and pale cream coloured. The corona is very small and bright orange in colour. In the *Poeticus* section were *Cassandra*, rich red cup, which appears to come a better colour in the open than under glass; *Glory*, also deep red cup; *Almira* and *precox grandiflorus*.

Among the *Magnis* were the beautiful *J. B. M. Camm*, *Mrs. Camm*, the huge *Mme. Plemp*, *Glory of Leiden*, extra large; *Millie Barr* and *P. R. Barr*. In the *Barri* section *B. conspicuus*, *Lady Godiva*, *Maurice Vilmorin* and *Crown Princess* were all beautiful and good. *Princess of Wales* is a charming bright orange-cupped *Leedsii*, and others in this section were *Beatrice*, with rich cream-coloured cup; *Duchess of Westminster*, large, pale sulphur cup; *Mrs. Langtry* and *Katherine Spurrel*, broad open canary yellow cup. *Incomparabilis Catherine* has a very wide deep yellow cup with a much serrated edge; *I. Lulworth* is very handsome, the bright orange scarlet cup contrasting well with the cream perianth.

#### MUNSTEAD PRIMROSES FROM WATFORD.

Mr. Daniel Hill, Herga, Watford, sends excellent flowers of this strain of Primroses. The rich yellow and cream colours are very pleasing. He writes as follows: "I am sending for your table just a few Munstead Primroses. I noted them in Messrs. Sutton and Sons' last year's list and obtained a packet, sowed it early in February (1907), pricked the seedlings out in boxes, and planted them out when large enough in a somewhat damp and rather shady piece of ground, where they stood until early in February this year, when they were removed to their flowering quarters, being then very large plants with a big ball of soil to each. They commenced flowering at the end of March, and, notwithstanding being laid quite flat by the snow, are now a perfect mass of flower. There are only a few very deep orange varieties, and it is curious these individual flowers are much smaller than the others."

#### POLYANTHUSES FROM EPSOM.

Mr. George Boyd, gardener at Danehurst, Epsom, Surrey, sends a very fine lot of Polyanthuses. The blooms are large, and are evidently the result of good culture. He writes: "I am sending you a few blooms of Polyanthuses for your table. They are from seedling plants sown on May 1, 1907. Now is the best time to sow the seed if good strong plants are wanted for next autumn. It must be sown in good sandy soil in a pan. Place in a cool greenhouse till up, and when large enough to handle prick the seedlings out into seed-trays. Place in a cold frame, give plenty of air and shade from strong sun for about a month. Then face a frame towards the north, and put into it about 1 foot of soil composed of equal parts of garden soil, loam and well-decayed manure (old hot-bed is best). Plant out into this a few inches apart; the sashes can be removed altogether if the weather is very hot. Shade for a few days. Plant out in the open after the beds are cleared of summer plants. Give the bed a liberal supply of cow manure before planting."

#### CINERARIAS FROM SCOTLAND.

Miss Clark Cooper, Thornfield, Selkirk, Scotland, sends very fine blooms of an excellent strain of large-flowered *Cinerarias* with the accompanying note: "I forward a small box of sample flowers of large *Cinerarias* grown at Thornfield from one packet of seed procured from Messrs. Daniel Brothers, seedsmen, Norwich. The variety of colouring and handsome masses of bloom have been much admired."

## TREES AND SHRUBS.

### THE DOUBLE-FLOWERED GORSE.

NO one who sees a common or hillside covered with Gorse in full flower can fail to appreciate its beauty, and we can well understand such plant-lovers as Linnæus and Dillenius going into ecstasies of delight, as they are reported to have done, when such a sight first burst on their view after being acquainted with the plant from botanical material only. Although, however, it is found in such abundance in a state of Nature, we rarely find it in the garden, though, for certain positions, it, or better still, its double-flowered form, has few equals. The double-flowered variety is of more compact habit than the type, and is neater for garden work, while the fact of its being sterile is much in its favour, as the type becomes somewhat unsightly during summer when covered with burst seed-pods.

As a rule the double variety is met with as a dense bush 2 feet to 3 feet high of fairly uniform outline. It attains its greatest perfection in poor, gravelly soil in an open and sunny position; in fact, a far greater profusion of flowers is produced from examples growing in poor ground than from those planted in richer soil. The rich golden flowers open during April and May, and the plant is at its best from four to six weeks, during the greater part of which it is a blaze of colour. As it never produces seeds it has of course to be increased from cuttings. These are made from young wood taken in July or August, and should be about 4 inches in length. They are inserted in sandy soil in a cold frame or under a hand-light, and are left undisturbed save for an occasional watering until growth commences the following spring. The commencement of growth is a sign that roots have been formed, and at this period it is necessary to lift the tiny plants and pot each one singly into a 3-inch pot. By placing them in a cool frame as soon as potted, and keeping them close for a week or two, they establish well, and may then be plunged out of doors. By following this treatment first-rate results can be obtained; it is, however, inadvisable to give cuttings artificial heat as they cannot be hurried.

On no account should young plants be put out in nursery beds, as they transplant badly, but keep them in pots until placed in permanent situations. When preparing a position for a plantation simply dig the ground over to bury the turf or weeds, then tread it well and insert the plants. Be careful when planting to avoid hard, marginal lines, and try to obtain an undulated, natural outline, running into the grass or surrounding vegetation on all sides. If the clump is to be kept dwarf, it is a good plan to go over it as soon as the flowers are over, and cut out a number of the strongest shoots. When once established a clump will continue to give good results for many years, and will require very little attention.

W. D.

### A BEAUTIFUL WILLOW.

(*SALIX GRACILISTYLA*.)

NEARLY all trees or shrubs which bear catkins during the earlier months of the year deserve extended cultivation in our gardens, and many only require to be better known to be more largely appreciated. The Willows include numerous species and varieties of great merit, and who does not admire the common Goat Willow (*S. Caprea*) of the woods—the "Palm" of the woodland. The subject of this note is a Japanese species, sometimes known under the name of *S. mutabilis*, and in its catkin stage is probably the most beautiful of the whole family, owing to the exquisite colouring of the flowers and the great freedom with which they are produced. When they first appear they are silvery grey with a suffusion of red, but with age or the process

of expansion only the former colour remains. During the latter part of March and in April a good specimen is most pleasing. As a bush this Willow is attractive, but it is undoubtedly seen to much greater advantage when worked on to a stem of good height, so that the somewhat slender branches may form a pendulous growth. A position close to the water's edge should, if possible, be afforded this shrub, but failing this it will succeed in a damp soil. It may be easily increased by cuttings inserted during March in an open border. Unlike some varieties, which must be severely pruned annually to reveal their charms, this Willow requires little attention in this respect.

A. E. THATCHER.

## THE ROSE GARDEN.

### ROSE RUST OR ORANGE FUNGUS.

WHEN this pest was troublesome last year the plants should be sprayed at once with a solution of potassium sulphide. The bushes should be sprayed just when the leaves are expanding.

Already the rust is showing on the hedge Briars. Where it is seen in patches on the hard wood of Rose plants, a capital remedy is methylated spirit and water in equal quantities. Thoroughly rub this in with a piece of sponge. This rust will attack seedling Briars that are planted out for budding, and if not checked will cause considerable damage.

P.

### ROSE DOROTHY PAGE ROBERTS.

WE have in this beautiful Hybrid Tea a decorative Rose of charming colouring, reminding one of *Mme. Abel Chatenay* and *Mme. Eugenie Boulet*. There could scarcely be a more interesting combination of tints, and, judging from blooms exhibited, I should say this Rose will become a favourite. We all know how popular *Mme. Abel Chatenay* now is, and I think a search into the back numbers of *THE GARDEN* would show that we predicted this on its appearance, but it is remarkable how a Rose attains popularity, and equally remarkable that no new comer succeeds in dethroning the favourite. For instance, there was introduced, soon after the advent of *Mme. Abel Chatenay*, a variety named *Ferdinand Jamin*, very much like the former, and in quality of bloom oftentimes much superior, but somehow this Rose has never "caught on," and I question if many Rose growers know it. *Dorothy Page Roberts* has already attained a certain amount of favour, and I imagine it will be found in the front rank of beautiful tinted Roses, although it is rather devoid of petals. But many of these newer Roses are wanting in fulness, yet by their size of petal and exquisite colouring they make amends for this.

P.

### RAMBLER ROSES IN POTS.

Now that the sprays of bloom are showing, great care will be required in the matter of watering and feeding. These ramblers are very thirsty subjects. On a fine day they will need water three or four times, as they are usually grown in comparatively small pots, mostly 9-inch or 10-inch, and these are quickly filled up with roots if the plants are in a healthy condition. Where they had a dusting over with some good artificial manure in February, they will now benefit by liquid manure at least once a week. That made from cow manure and soot is as good as can be given; but where this is not practicable, then guano water is a good fertiliser applied at the rate of about 1 oz. to a gallon of soft water. The syringe should still be freely applied to the under side of the foliage, as red spider is specially partial to the *Crimson Rambler* and *Dorothy Perkins* tribe. As the blooms commence to unfold, they develop more beautifully if the plants are placed in a somewhat cool

temperature, such as a house with a north aspect. When employed for decoration in draughty positions, great care is needed that the plants are well watered beforehand. We have seen splendid plants ruined in a few hours by neglect of this simple precaution.

These ramblers can be grown in such a variety of ways that the skilled gardener has little difficulty in developing his taste in this direction. When Dorothy Perkins first came out it was grown as a bush, and most beautiful it was. Most of the sorts now grown can be made to bloom as dwarf bushes by simple pruning and pinching of the growths. Growers will find two and three year old own-root plants excellent for making these bushy specimens. Everyone must grow the new Tausendschon. Nothing finer has ever been raised. Its huge bunches of bloom measure fully 9 inches across, and they are such exquisitely beautiful individual flowers, quite 2½ inches over, with a lovely shading of white and cream on a lively Carnation pink ground. The blooms are very durable, and it is not unusual to have a plant in flower for a month if placed in a cool temperature. A charming dwarf companion to Tausendschon will be Aennechen Müller. This would make a groundwork to pillars of the former, either for indoor or outdoor decoration. P.

## COLOURED PLATE.

PLATE 1348.

### SWEET PEA EVELYN HEMUS.

**T**HIS charming Sweet Pea is the latest addition to the somewhat limited Picotee section, and was raised by Miss Hemus, Holdfast Hall, Upton-on-Severn, by whom it was exhibited last summer and to whom we are indebted for the flowers from which the accompanying coloured plate was prepared. The variety was granted an award of merit by the Royal Horticultural Society when exhibited before them last summer, a rather rare distinction for a Sweet Pea. As will be seen by the coloured plate, the flowers are large, with delicately-waved standards, the creamy buff ground colour being edged with bright pink. It will be interesting to note what position this variety takes in the National Sweet Pea Society's audit this year. Last season it was exhibited once only, owing, of course, to the raiser holding all the stock. Seeds of it were sold out at an early date this year, so that those who secured any may consider themselves fortunate. Miss Hemus was very successful with Sweet Peas last season, the magnificent flowers staged by her at Vincent Square attracting much attention. Although self flowers appear to be favoured most at present, the bicolors or fancies have much to commend them, especially when we have colours that harmonise so well as they do in the variety now under notice. How it will behave this summer grown in various soils and under varying circumstances can, of course, only be ascertained at the end of the season, but we hope that it will retain the excellent points displayed last year. Providing it is properly fixed and has a good constitution, this Sweet Pea should have a rosy future in store for it. As exhibited last season it had splendid stems, each carrying three or four blooms, these being well placed on the flower-stalks.

## THE FLOWER GARDEN.

### VENUS' LOOKING-GLASS.

(SPECULARIA SPECULUM.)

**T**HIS hardy annual resembles in general appearance some of the Campanulas or Bellflowers; indeed, several botanists have included it in that family under the name of *C. Speculum*. When the seed is sown in autumn, Venus's Looking-glass is one of the earliest and showiest annuals to flower in early summer. Coming into bloom as they do after the blaze of spring-flowering bulbs is past, and before the summer bedding is at its best, annuals such as the subject of this note are worthy of more general cultivation. When once grown in a garden, if the ground is not disturbed beyond weeding and lightly forking over the surface, the plants seed and come up year after year, requiring no attention beyond thinning the seedlings if too thick. Grown in small groups near the front of the mixed border, or for massing along the edge of a shrubbery border, as illustrated, this *Specularia* is an ideal subject. The

a solitary specimen, however good that may be. Then seedling plants are usually more vigorous than those from divisions, and, if the amateur has a small collection of species, he may profitably devote a little time and attention to hybridising and raising hybrids between some of the best of the species. There is no limit, or almost none, to the variety he may thus secure.

In raising these hardy Primulas from seeds an important consideration is the freshness of the seeds, and in the case of purchased seeds it is difficult to secure these absolutely fresh. It is well known to those of experience that the seeds of these plants germinate much more freely if they are sown almost as soon as ripe, but it is almost impossible to secure such from the trade, and it is thus generally necessary to depend on those ripened the previous year—and it may be an earlier one still—and only obtainable with other seeds in spring. In this case the seeds are generally a long time in germinating, and not only patience but some care is needed if a full measure of success is to be reaped. Some of these seeds may germinate the same year as they are sown, but many will remain dormant until the

THE WHITE-FLOWERED VENUS' LOOKING-GLASS: SPECULARIA SPECULUM ALBA.

plants grow 9 inches to 1 foot high; the flowers are bell-shaped and violet-blue in colour. The white variety, alba, the subject of the illustration, is even prettier than the type for massing. A. O.

### HARDY PRIMULAS FROM SEEDS.

THERE are many beautiful hardy Primulas which can be easily raised from seeds, but, in order to achieve a full measure of success, certain considerations must be kept in view. The writer has for many years raised a number of the hardy Primulas in this way, and an account of the methods he has found most profitable may be of assistance to many of the readers of THE GARDEN. It is almost unnecessary to say anything in favour of this plan of securing a stock of these beautiful flowers, many of which are comparatively expensive, and by means of seeds in a year or two quite a little colony of vigorous plants will be secured for what is often less than the price of an individual. The latter consideration is by no means to be despised, as a group of even half-a-dozen is much more effective and attractive than

following one, and it is thus necessary to prick out the seedlings very carefully, so as not to disturb the more tardy seeds and to leave the pans unemptied for another year. I have even found it profitable to wait for the third season before discarding the chances of additional seedlings; but it will be found that the exposure of these seed-pans to frost or snow for a week or two in early spring will frequently hasten the growth of the seeds and give one a better crop of seedlings.

#### SOIL TO SOW THE SEEDS IN.

In preparing the soil for the seeds it must be remembered that these will lie a long time, and that not only is ample drainage required, but it is advisable to bake or roast the earth so as to destroy the seeds of weeds and other growths injurious to the Primulas. This may be done by placing the soil in an iron shovel over the kitchen fire. Then the drainage requires to be very good. A large crock should be put over each hole in the seed-pan or pot, others over that again, then some smaller pieces, then a little moss or rough fibrous soil, and the pot filled up

ANEMONE (WINDFLOWER) NEMOROSA BLUE QUEEN.

to within an inch of the rim with sandy, open soil of loam, leaf-soil or a little peat and sharp silver sand. Press this gently down with a piece of flat wood and sow the seeds very thinly, pressing them down and covering with a little very fine and sandy soil, which, again, should be well pressed.

I have practised two methods of watering with satisfactory results, both at the time of sowing and to keep the soil moist afterwards. According to one plan the pots are dipped in water until the latter rises just through the soil. This is allowed to drain away, and then the seeds are sown and slightly covered with earth as already indicated. In the other way the seeds are sown first, and then the whole carefully watered. It will be found a good plan to put a piece of paper or small piece of wood on the top of the pan or pot, and on this the water is poured and allowed to soak through to the soil. In subsequent waterings I prefer the dipping method when time is available, but it is more tedious than the other.

#### AFTER TREATMENT.

After the seeds are sown the pans or pots are covered with a sheet of glass to prevent evaporation, and a piece of brown paper is put on the top to keep the seeds in darkness. As soon as any of the seedlings begin to appear, the paper and glass should be gradually removed and light and air thus admitted. When the young plants have made a pair of rough leaves, they should be pricked out into similar soil about an inch apart and grown on under glass, but with plenty of air, until the following spring, when they may be planted out.

In the management of the seedlings it must be observed that they have plenty of air, and, so long as under glass, be shaded from the full sunshine, but kept near the light. Green fly must be guarded against, and either checked by occasional fumigations or kept away by the use of a small brush and plenty of clean water. If these directions are carefully carried out and the seeds are of good germinating power, a considerable measure of success will follow, and the garden will be enriched by the possession of many very beautiful plants not too common in the garden of

the amateur. Among the hardy Primulas which can be successfully raised from seeds are japonica, Sieboldii, sikkimensis, denticulata and its forms, calycina, frondosa, involucrata, pubescens, villosa, viscosa, capitata, carniolica and, of course, the Auriculas, Primroses, Cowslips and their allies in great variety. S. ARNOTT.

### TWO RARE WINDFLOWERS.

#### THE APENNINE WINDFLOWER.

THE Apennine Windflower (*Anemone apennina*) is well known as one of the most beautiful of our lower-growing spring flowers, and as a plant particularly suitable for naturalising, as well as for borders and rockwork. It is naturalised with the most charming effect in the pleasure grounds of several mansions, and the writer has seen little wooded glens carpeted by the blue

flowers of this Windflower as thickly as some places are covered with our native Wood Anemone (*A. nemorosa*). This Windflower thrives splendidly under the shade of deciduous trees, while it also blooms freely in the open, giving its starry flowers in great profusion in either situation about March, April and May. Nor is it fastidious as to soil, as it will thrive freely in the vegetable earth to be found in most woods, in the ordinary soil of the border and in the somewhat stony material which forms the basis of the provision for plants grown in many rock gardens. In either it will flourish, giving its pretty, elegantly-formed foliage and its starry flowers well raised above the plant and from 6 inches to 9 inches high. The colour of the typical *A. apennina* is blue, but the plants have yielded some variation both in nature and under cultivation. The shades of blue vary, and there are also both white and rose varieties, all being beautiful in their own way. The newest of the coloured varieties of *A. apennina*, however, is that called *A. apennina purpurea*, a plant of which is illustrated. The colour is distinct from that of any other variety offered, being of a bright and pleasing mauve. The flowers are also large and elegant in form, and for cutting this variety should prove useful. It originated in the nurseries of Mr. C. G. Van Tubergen, jun., at Haarlem, and was sent out in 1906. It is as easily grown as any other variety, and the plant figured was cultivated in poor and stony soil at the lower part of a small rockery, which partly screens it from the midday sun. Planting should be done in autumn. Plant the tubers about 1 inch or a little more deep.

#### ANEMONE NEMOROSA.

Charming as is the *Anemone* of our woods, *Anemone nemorosa*, it is so plentiful in many districts that it is needless to take up the space of our gardens by planting this wildling, save for those who are out of reach of the sight of its fragile, starry flowers. There are, however, some exquisite forms of the Windflower which lend a charm to any garden, and some of these are of the most beautiful shades of colour or are noteworthy from some other feature which makes them distinct from the ordinary one. The most distinct of the white varieties are the double one (*A. nemorosa* fl.-pl.) and the curious *A. nemorosa bracteata*, the "Jack-in-the-Green" of the race, which has its white flowers surrounded by a ruff of green, and is quaintly pretty in its own way. The coloured forms are—many of them, at least—of great beauty, none being so well known, however, as *A. nemorosa robinsoniana*, which is one of the most charming with its opal-like shades of

THE PURPLE APENNINE WINDFLOWER: ANEMONE APENNINA PURPUREA.

tinting. It has been the parent of some very beautiful flowers, several of these having been raised by the late Mr. James Allen of Shepton Mallet, famed for his work among the Snowdrops. Mr. Allen raised some very beautiful varieties from *A. nemorosa robinsoniana*, one of these which bears his own name, *A. nemorosa Alleni*. This is a glorified form of its parent in size of flower, height and in warmth of colouring. His great desire, however, was to raise deep blue forms, and he succeeded in his object, that which is figured in the accompanying photograph, and called Blue Queen, being one of the best of all. It has remarkably deep, true blue flowers of good size, and freely produced on a good plant. I had the privilege of receiving from Mr. Allen this and others of his seedlings from *A. n. robinsoniana*, and all are beautiful, that called White Queen being even larger than *A. n. Blue Queen*. No difficulty is experienced in cultivating these Wood Anemones in ordinary soil in the garden, and they are obliging in other respects as well, as they can be cultivated in a sunny border or at the lower part of a sunny rockery as well as in the half shade of trees, the latter being, of course, the conditions they enjoy in their woodland haunts. When free from shade they are slightly dwarfer, and do not last quite so long in bloom. Plant in autumn.

Dumfries.

S. ARNOTT.

## GREENHOUSE.

### PRIMULA OBCONICA.

**A**MONG the many species of greenhouse Primulas it would be difficult to find one that is more generally useful than *P. obconica*, or the inversely cone-shaped Primula, the name being derived from the shape of the calyx. During recent years many fine varieties of it have been introduced, ranging in colour from the palest lilac to a very good blue. The size of the flowers and the length of the stems have also been greatly improved by selection and good cultivation. Plants are easily raised from seeds sown any time during spring, using well-drained pans filled with finely-sifted soil composed of loam and leaf-soil in equal proportions, with a good sprinkling of silver sand added. Make this moderately firm, scatter the seeds thinly on the surface and just cover them with silver sand. Water very carefully through a fine rose, cover with sheets of brown paper and stand the pans in a slight hot-bed or warm greenhouse. The paper must be removed as soon as the seedlings appear. When large enough prick off the seedlings into boxes or pans of similar soil and give them more air when established. When several leaves have formed pot the plants singly into small pots, using soil composed of two parts good loam, one part well-decayed cow manure and one part leaf-soil, with a good dash of silver sand. Shift on as the plants require it until they are in  $\frac{1}{4}$ -inch or 6-inch pots, in which they will flower the winter and spring following seed sowing. The plants are excellent for a slightly warm greenhouse, and also make fine subjects for a window. Gloves should always be worn when touching them as they are highly poisonous to some persons and on this account should not be placed where children can reach them.

## THE KITCHEN GARDEN.

### RUNNER BEANS FOR AMATEURS.

**T**HIS vegetable can be grown to great advantage by the amateur who has only a small garden, as in many cases a fence or wall may be covered by it, and the plants also answer admirably to cover a screen or fence if the roots have sufficient food and moisture. On the other hand, there are certain difficulties to cope with. Soils are often far from the best, and the worst is a heavy clay soil. Slugs, too, have to be got rid of. I have also seen far too much food given at the start, with the result the plants grow rampant in a season like the last,

depends upon the position of the border and other small details the amateur well understands. I am sure much better results would often be obtained if a little more attention was given to the soil at the start, and it should be borne in mind the labour is not lost, as it will grow the plants satisfactorily for years. In heavy land I have used old leaf-soil to advantage or spent Mushroom manure.

#### SEED-SOWING AND PLANTING.

The amateur frequently sows too early; only recently I saw Runner Beans sown the early part of March. I am aware every allowance should be made for mistakes, and that the amateur is anxious to secure early pods, but often this is retarded by too early sowing, growth not being sufficiently rapid when the soil is not warm enough to encourage root-action. I do not advise sowing earlier than the second week in May, and other sowings can with advantage be made until the end of the month. It is a good plan to make a drill or trench and sow the seeds in this 4 inches apart.

#### AFTER MANAGEMENT.

So much here depends upon the season. Last year a friend of mine lost much of the early crop by over watering with a hose; the weather was wet and cold and the soil heavy, and when watered every day the blossom dropped. In dry, hot weather, of course, it would be the reverse, and in a light soil plants in full bearing require liberal supplies of water and food, and the latter may be given in the shape of liquid manure or a good fertiliser, the last-named used as a surface dressing about every ten days and well watered in. Another point often overlooked is stopping the plants; it is often thought that the higher they run the better, but it is not so, as this growth is obtained at the loss of pods at the base. I certainly advise stopping or pinching out the points at 4 feet or 5 feet from the ground, or even less with a dwarf fence, as this induces the plants to throw out side growths and to fruit much sooner. The stopping must be continued as required through the season. This stopping does not apply later on in the season if a large space or height is required to be furnished. If the plants are allowed to grow as they please, the tops will double over after they get a few inches beyond the tops of the stakes and become badly bruised by winds and heavy rains. For plants on low

AN EASILY-GROWN GREENHOUSE PRIMULA: *P. OBCONICA*.

and the crop is by no means satisfactory; on the other hand, a very poor soil requires help.

#### PREPARING THE SOIL.

With heavy clay soil it would well repay the amateur to lighten it with fine old mortar rubble; failing this, use road sweepings, coarse sand, wood ashes or burnt earth. In many gardens a certain amount of success may be obtained in heavy soil by having a raised border if under a wall or fence, the only objection to this being that in a hot, dry summer more moisture is required. With a light soil a raised border is not advisable, and the amateur would do well to give a liberal amount of food in the shape of manure, cow manure being excellent if it has been laid in a heap for a few months. Soil at the foot of a wall or fence often dries quicker than in the open, and in this respect so much

fences or walls, the advice given above is specially applicable; but I would advise a trial of the Climbing French Beans. These are admirably adapted for limited space and low walls or fences. They resemble the Dwarf French in some ways, but run freely, and they are earlier than the ordinary Runner. There are some splendid sorts, such as Veitch's Climbing, Princess of Wales, Sutton's Epicure, Carter's July and Successor. Among Scarlet Runners we now have some very fine sorts. Carter's Scarlet Emperor is a variety that produces large clusters of very long pods; Sutton's Prizewinner is another that belongs to the long-podded section, and is splendid for exhibition; and Webb's Exhibition is also one that is capable of winning many first prizes. Other splendid varieties are Sutton's Best of All, Sutton's Scarlet (a good one for a hot season) and Carter's Jubilee Runner.

G. W. B.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**V**EGETABLE GARDEN.—Owing to the cold and unsatisfactory weather in the early spring many subjects are very backward. I am now thinning my Parsnips, leaving a space between them of about 1 foot. From a patch of Cabbage seed sown in early March and from seedlings subsequently pricked off I propose in the immediate future to plant them in their permanent quarters, observing a distance between the rows of 18 inches and 1 foot between the plants in the rows. The thinning of Carrots and Onions should not be delayed. The shorthorn Carrots should be thinned to about 2 inches apart, the intermediate varieties to 3 inches and the long-rooted to 4 inches apart. Subsequently it may be advisable to thin them again. If Runner Beans have not yet been sown, put them in at once. The earliest sowings are producing plants that are now making vigorous growth, and these will be staked at once.

*The Greenhouse.*—I am just now moving my Lilliums outdoors, standing them on tiles, boards, slates, &c., in a sheltered quarter of the garden. If stood on a good layer of coke breeze or sifted ashes the plants do well. The beautiful Arum Lily may be divided now and planted forthwith in specially-prepared quarters in the open. This operation was fully dealt with and illustrated in these pages some time ago. As the showy Pelargoniums go out of flower I am standing them outdoors for the growths to ripen preparatory to

1.—HIPPEASTRUM SEEDLINGS PRICKED OFF INTO A 5-INCH POT.

cutting them down. A later batch to succeed those just mentioned I am giving occasional applications of liquid manure. The manure water will be stopped when the blossoms open. Bushy growths on Petunias and Heliotropes may be secured by pinching out the points of the shoots; this must not be repeated, however, if really good results are wanted within reasonable time.

*Chrysanthemums.*—My late-struck plants are now being placed outdoors. The earliest batch are making headway in their sheltered quarters outdoors. We are now giving the plants rather more space, as air must pass freely through them and the sun's beneficent influence must also be experienced if good results are to be obtained next autumn. Pay careful attention to watering. Plants of the early-flowering sorts that have been thoroughly hardened off in the cold frames I am proceeding to plant outdoors in their flowering quarters. Give each plant plenty of room. The Japanese varieties require a space 3 feet square, the singles 2½ feet and the Pompons about 2 feet. Wherever possible, mass a few plants of one colour or one variety together.

*The Rose Garden.*—Suckers that so often develop should be removed at once, otherwise they may cause serious trouble or inconvenience. Maggots, grubs and caterpillars are sure to cause anxiety as new growth becomes more general. They must be dealt with at the inception of their depredations. Hand-picking is the best remedy, although syringing is often advocated. Syringing is efficacious in the case of aphides and may be followed with advantage. Weakly growths should be rubbed out, thus concentrating all the vigour of the roots on the stronger shoots that are retained. For flowering next year I propose to prune the climbing Roses under glass in the immediate future, by these means encouraging the development of stout and sturdy growths.

*The Window Garden.*—Plants in the window are benefited by being turned round from time to time; they become drawn and unshapely otherwise. Take advantage of fine days to afford window plants abundant ventilation. Plants that have well filled their present pots with roots should have an occasional application of manure water. Use preferably a well-known and reliable

patent or concentrated manure, as this is less likely to give off unpleasant odours.

*The Cold Frame.*—Plants raised in heat in the greenhouse should be transferred to the cold frame and gradually inured to hardier conditions. By these means I am able to transfer or plant outdoors later on quite a number of sub-tropical subjects for beautifying the garden through the summer season. Dahlias and other equally tender plants may be inured to hardy conditions of plant life by the aid of the cold frame. On fine days the frame-lights should be removed entirely.

D. B. C.

### HIPPEASTRUMS: THEIR PROPAGATION AND CULTURE.

THE varieties of Hippeastrum, or, to give it the more common name in gardens, Amaryllis, have become extremely popular during the last few years. This is not surprising when we consider what a glorious sight they are when in flower. For size and brilliancy of colour they are unsurpassed by any other bulbous plant. Few better examples of the skill displayed by

3.—AN EIGHTEEN MONTHS OLD SEEDLING, SHOWING THE EFFECT OF PLUNGING THE POT TO A DEPTH OF 2 INCHES IN LEAVES ON A HOT-BED.

hybridists can be obtained than a comparison of the many beautiful hybrids, and the wild species, both of which can be seen in flower at Kew in the spring. The crossing and intercrossing of the flowers is a subject which the amateur might very well make a hobby, for few plants are easier to grow and give better results. When once the bulbs flower, with proper treatment they continue to bloom annually, often producing two and occasionally three spikes of flowers.

The question which may confront the beginner is how to start their cultivation, whether to purchase a few bulbs or a packet of seeds. Bulbs of really first-class sorts are expensive. On the other hand seeds of really first-class strains can now be obtained from 1s. per packet upwards. Although this may mean waiting a couple of years for the first flowers, the results will more than justify the time spent in growing the seedlings to the flowering stage. When once flowering

2.—A THREE MONTHS OLD PLANT READY FOR POTTING UP INTO A 3-INCH OR 4-INCH POT.

bulbs are obtained, seeds may be saved from the best blooms and a few plants raised each year. The selection of the flowers from which to save seeds is important, the chief points to consider in the flowers being colour, form, substance and size.

*Propagation.*—The seeds ripen in autumn, when some growers sow the seeds. When the supply of heat is limited it is better to defer sowing till early spring, as the young plants will then have the whole summer in which to make good growth. Sow the seeds in pots of light sandy soil, just covering them with fine soil, and place them in a propagating frame if available, or cover the pots with sheets of glass and stand them in the warmest available position in the greenhouse. The seeds soon germinate. When large enough to handle they may be potted off singly in small pots or placed several together in a larger size—4-inch or 5-inch, as shown in Fig. 1. In a compost of equal parts loam, leaf-mould and peat, to which plenty of sand is added, the young plants will make rapid progress.

*Offsets.*—These grow round the sides of the old bulbs (Fig. 5) and should be removed at the time of potting or top-dressing. A typical offset is depicted in Fig. 6. Pot them up singly in small pots, using soil similar to that recommended for seedlings. They are sometimes left to grow in the same pot with the parent bulb, but as a rule the blooms are not so fine as when the bulbs are grown one in a pot. The flowers of the offsets are, of course, identical in colour with those of the parent plant; seedlings, although saved from blooms pollinated with their own pollen, vary in colour.

*Growing on the Young Plants.*—By giving them plenty of heat, moisture and rich soil it is possible to flower the seedlings in eighteen to twenty months. Amateurs, however, are seldom able to give them these conditions unless the whole greenhouse can be devoted to Amaryllises and plants requiring similar conditions. In the ordinary greenhouse it takes from two to three years to flower the plants from seeds. The next move for the plants potted up singly will be into 5-inch pots, while those growing several together, one of which is illustrated in Fig. 2, should be potted up singly in 4-inch pots. Fig. 3 shows a plant eighteen months from seed lifted out of the plunge bed. This is a method favoured by some

5.—AN OLD BULB WITH NUMEROUS SMALL ONES, OR OFFSETS, SURROUNDING IT.

4.—A WELL-GROWN PLANT, ONE YEAR AND NINE MONTHS OLD, FROM SEED.

growers, others cultivate their plants with equally satisfactory results on the ordinary greenhouse stage.

*Treatment of Flowering Bulbs.*—In March the drainage of each pot should be carefully examined, the soil thoroughly soaked with water and the bulbs top-dressed or repotted if necessary. Use soil composed of two parts fibrous loam, one part leaf-mould, one part peat and one part well-decayed manure, with a sprinkling of bone-meal and sufficient coarse sand to make the whole porous. Very little water will be necessary till after the plants have flowered, as they obtain sufficient moisture from the syringing morning and evening. Amaryllises make most of their foliage after flowering; this is a very important period, for it is the time to lay a good foundation to obtain good flowers the following year. The plants benefit by liberal feeding when growing vigorously. They should be given all the sunlight possible and be syringed at least twice daily. In autumn, when the season's growth is completed, the supply of water may be gradually reduced. Only sufficient water is necessary during winter to prevent the bulbs shrivelling.

#### THE DISTANCE BETWEEN PLANTS.

WHEN a collection of plants are put out in a border it is very important that a proper distance from plant to plant be allowed so that each will have sufficient space to develop in, then the plants will form fine specimens and fill up the whole of the border without being unduly crowded. The system of bedding-out which obtains at the present time, viz., of filling flower-beds with a combination of tall and dwarf-growing plants, is a very effective one when rightly carried out. The tall or dot plants, as these are called, are sometimes too numerous in a bed, and so the general effect is marred. In such a case the large plants smother the small ones.

*A Good Example.*—If Fuchsias are employed as dot plants, specimens which are about 2 feet high should be planted 3 feet apart. Then we will suppose that Violas are used as a groundwork; these should be planted 10 inches asunder, they will thus form a complete carpet of healthy plants, and the Fuchsias will be seen to the best advantage from all points of view.

*The Zonal Pelargonium Bed.*—As a rule Zonal Pelargoniums fill a bed by themselves and are more successful so grown than when mixed with tall-growing subjects, because air and light must reach them freely. Overcrowding and excessive moisture results in both leaves and flowers damping off badly. Good plants turned out of 3½-inch pots should be planted about 1 foot apart. At the end of June the leaves of the plants will touch each other, but overcrowding will rarely occur, and when cuttings are taken later in the season ugly gaps will not be made, and the removal of the cuttings will prevent any undue crowding.

*Tuberous Begonias.*—These plants should be put out about 14 inches apart if they are good specimens, as the leaves are large and quickly fill up the space.

*Edging Plants.*—Naturally dwarf-growing subjects are used for the edging or bordering of a

6.—AN OFFSET CAREFULLY SEVERED FROM FIG. 5 WITH A SHARP KNIFE SO THAT A NUMBER OF ROOTS ARE ATTACHED.

flower bed, and they should be put in more closely than flowering plants which occupy the body of the bed, so that they will form a compact line unbroken at any point. Such plants as Lobelias, Coleuses, Iresines, Violas, Grasses and Echeverias are so employed, and each one should be put in so as to allow of a few inches of open space between that will be filled soon after the bedding work is completed.

*Carpet Beds.*—The groundwork plants used in these beds must be arranged close together, so that the design will show up distinctly at once. Afterwards judicious pinching of the plants will be necessary to keep the design distinct. AVON.

## THE TOWN GARDEN.

**PLANTING DAHLIAS.**—These are very satisfactory plants for the town garden whose borders are sufficiently wide for their accommodation, but if they are to yield of their best the soil must be thoroughly prepared by deep digging and generous manuring in the second spit. When the station has been thus prepared, the strong central stake should be put into position, and in planting the plant should be placed close up to it. Healthy young plants from cuttings struck this spring are the most reliable, and if they have not been raised at home they can be bought quite cheaply from hawkers or shops making a speciality of plants. They will be in 3-inch pots and will be finely rooted. When the planting is completed there should be a wide, shallow saucer all round the stem, as this will facilitate watering and the application of liquid manure later on. If the soil is poor and it is impossible to adequately enrich it with natural manure, the show and fancy varieties or the Pompons should be grown and allowed to flower with little or no disbudding, but in good soil Cactus varieties are best.

**GERMAN IRISES.**—For planting in many positions in the town garden where other plants would either refuse to grow or merely exist, German Irises are exceedingly useful. In narrow forecourts where the soil gets practically no rain naturally and little sun, or beneath trees, they will prove especially satisfactory if they can once be established, but this essential point often causes trouble. The amateur who has planted and failed on more than one occasion and has not tried moving them immediately after flowering is over should do so, and the probabilities are that if the soil is well worked and water is given now and again afterwards, success will reward his efforts. They may not flower very freely for the first and second seasons, but subsequently will not fail the grower in that direction; and if they did they would still be entitled to a place on account of their handsome leafage. As it is not desirable to disturb them any more frequently than is imperative, the amount of food in the soil should be maintained by annual top-dressings of rich soil or sweet manure; the former can be applied after flowering or the latter in autumn. During June and July particularly heavy waterings are very beneficial.

**SURFACE STIRRING.**—This is one of the routine operations of gardening which must never be overlooked or neglected, as it aids one so materially on the road to success. In the generality of cases Dutch hoeing is the best form of cultivation, for at the same time as it opens up the surface it cuts down the weeds, but it is not always possible of adoption when plants are closely packed in the beds and borders and are making free growth. In this event the most useful tool is a planting fork attached to a long Ash handle. With this one can work in and out among the plants without the remotest chance of doing injury, but it will, of course, be necessary to do the weeding by hand. Such a tool as this comes in handy for several purposes and should always have a place in the set.

**VIOLAS.**—Those whose gardens are of light soil that dries out quickly are somewhat prone to hesitate whether to grow Violas or not, for it is generally understood that they prefer a stronger, moisture-rooting medium. No matter, however, what the soil may be they should always be grown, for they make a beautiful display, provided that they receive proper attention. Some manure should be worked into the soil and the planting must be done firmly. After that the principal thing is watering, and in well-drained gardens it does not appear to be possible to overdo this; if they have a really good soaking every alternate evening, they grow vigorously and flower with a freedom which other plants may equal, but certainly cannot excel. Favourite varieties of mine are Bullion (rich yellow) and True Blue. HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUIT HOUSES.

**P**EACHES AND NECTARINES that are ripe and ripening should have abundance of air, so that the flavour of the fruits is enriched. Tie in the young growths, especially those that shade the fruit, and the leaves which cover the fruits should be pulled or fastened aside while the fruits are colouring. Give plenty of water, and do not miss damping down several times daily. It is not necessary to stop syringing except for a very few days when the fruit is in the last stages of ripening. Trees in succession houses should be kept tied, and no more wood laid in than is absolutely necessary; the present is a good time to take out any barren growths and fill in with new. Plenty of room should be given for development of the foliage. In dull weather the temperature should be 60° to 65°.

*Vines* which are rapidly colouring should have abundance of air daily in fine weather, and a little chink, enough to dispel moisture, at all times. See that the borders are in proper condition of moisture, as the Vine takes a lot of water. Continue to stop the laterals till the Grapes are ripe, when they may be allowed to grow as they will shade and help keep the berries in proper condition. Keep Muscats at a good even temperature of about 75° to 80°, and put on a little air every morning at 6.30. Prick over the border when thinning is completed, give a good sprinkling of artificial manure, and follow with a thorough watering of tepid water as near as possible at the temperature of the house. Many a check may, I think, be traced to cold water. Houses containing late varieties should be well thinned, and when long shoulders are liked, these should be carefully tied up.

*Figs* that are yielding ripe fruits should be kept a trifle drier on the foliage, but not at the roots, or the second crop may suffer. As soon as the crop has been gathered, top-dress with manure and give a thorough watering to help along the second crop. Encourage succession houses in like manner. Tie in the growths and stop the ends of the shoots, except where longer growths are required.

#### HARDY FRUIT GARDEN.

*Peaches* that have set a good crop must be thinned early; if any curled or blistered leaves still exist continue to remove and burn them. Proceed with the disbudding as fast as possible, so that there is no undue strain on the tree.

*Apricots* will now require stopping, except where a tree is forming, then stop only those branches which are not required. Lay in exactly the number of shoots you have room for and no more. Stop the branches before they get hard, as the Apricot does not like the knife. Put the nets over the Strawberry quarters; this will ward off a degree or two of frost should any prevail.

#### KITCHEN GARDEN.

*Turnips and Parsnips.*—Thin these as soon as they can be conveniently handled; all crops are better if thinned early. Peas and Runner Beans should again be sown, and Carter's Michaelmas Pea sown the first week in June for latest crops. Sow Carrots every fortnight to have successions of young edible roots, also salading plants little and often.

*Vegetable Marrow Beds* should be made, and those planted out under hand-lights and in frames may have the lights removed on all bright days. Marrows do well on the flat ground if a hole is taken out and a few spits of good manure

dropped in, with a bit of good soil on the top to plant in. Prick off Celery now in quantity.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**HANGING BASKETS.**—When the roof of the stove or conservatory is not overcrowded with climbers the employment of hanging baskets will much improve the general appearance of the structure, and for this purpose some Ferns are most suitable. The old and well-known *Nephrolepis tuberosa* and the smaller-growing *N. pectinata* are both desirable. *Davallia tenuifolia Veitchii* is also excellent, and the beautiful lace-like fronds hanging over and around the baskets have a very attractive appearance.

*Pot Roses.*—Now that these popular flowers have given their main crop of blooms, we must work among them most assiduously if the best results are to be obtained for a future season, as success depends so much on present treatment and the class of growth secured. However well and carefully one may attend to the plants later on, it will be comparatively useless if they are neglected now.

#### FRUIT UNDER GLASS.

*Grapes.*—Second early Hamburgs and other summer Grapes will now be at the stoning stage, and, presuming all lateral growth has been closely pinched just before the process commenced, the work must now be temporarily suspended, or only carried on so as to prevent actual crowding of the foliage. Afternoon closing may likewise be postponed a little beyond the usual hour, as undue pressure in any respect is not advisable at this somewhat critical juncture.

#### HARDY FRUIT.

*Cherries on Walls.*—In exposed situations, owing to the prevalence of adverse winds and cutting frosts, the extremities of the new growth of various kinds of Cherries are liable to become infested with black aphid. On the first appearance the trees must be syringed (preferably with a hose) with soap-suds, this application to be followed by a second of clear water the following day.

#### KITCHEN GARDEN.

*Seakale.*—The sets inserted some time ago for the main forcing batch now being somewhat advanced in top growth should be gone over, and the new crowns reduced to about a couple on each set. Some growers never thin at all, but this practice is ruinous, as no sun or air can gain admission, and weak, puny produce, utterly unfit for forcing, is the result. After reducing the crowns use the Dutch hoe freely to keep down weeds.

*Newly-planted Rhubarb.*—Where new plantations were formed this season, and early sorts given a sunny position and warm soil in order to encourage early growth and ripening of the crowns for forcing, a good thick mulch must be given and water supplied to the roots, as many new fibres will now be at work. Upon no account pull any from these plants this season, as this would greatly weaken the crowns.

#### FLOWER GARDEN.

*Lilies.*—Newly-planted Lilies of the late flowering types will be all the better for a little protection to the early growths. If this protection can be afforded by growing shrubs or plants of any kind so much the better, but spray tips from Pea sticks answer very well, and they should be high enough to afford some shelter until the end of the month.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Crown Imperials (Constant Subscriber).

These things are very erratic in their behaviour, and it is not at all improbable that some of the bulbs may still be quite sound and firm, while others may have decayed. Impatient of removal generally, the bulbs, if long out of the soil and much dried, will take a long time to recover. As there is now so little growth apparent, we advise you to wait till July, then lift them for examination, replanting the sound ones at a depth of not less than 6 inches. As your soil is heavy brick earth, it would be well to lighten it with sand or grit before replanting, selecting a warm position when doing so. Only bulbs of the largest size flower; the others may remain without giving evidence of leaf-growth at all or producing but the merest apology for the same.

#### Belladonna Lilies flowering now (E. O. P.).

—We have never before known Belladonna Lilies to behave in the same way as yours. In our opinion their throwing up spikes in spring is mainly owing to the cold wet summer experienced last year. Owing to the absence of sunshine it is probable that the embryo flowers were only partially formed when growth was arrested, and consequently they did not possess sufficient vigour to make their appearance above ground at the proper time. As the stems are rotted off at the base they will not in any way interfere with the autumn flowering, no more in fact than if they had developed and expanded their blossoms last autumn. Belladonna Lilies need fairly liberal treatment, and it is possible that yours may be somewhat starved. A thorough watering with liquid manure for two or three times at intervals of a fortnight may be helpful. Give the first dose at once.

**Bulbs in grass (Ridgeway).**—If the bulb growth is good, liquid manure will be of some assistance, and this you may apply to suit your own convenience. If the growth is weak, it is highly probable that lifting and replanting are necessary. The diminished flowering may be due to two causes, viz., weakening growth or the lack of sun-beat in 1907. On the other hand, the Tulips may have descended by means of "droppers" to too great a depth, and in such instances do not flower till lifted and replanted nearer the surface. At the same time, we would point out that all classes of bulbs in sandy soil require more frequent attention in the matter of replanting than do those in cool or moist clay soil. If from this reply you are not clear what to do please lift a bulb and forward for our inspection.

**Information about Violets (E. Bates).**—Young plants of Violets may be obtained almost anywhere, and many firms advertise these things for sale in our columns. Some of the specialists are Messrs. Cannell and Sons, Swanley, Kent, and Messrs. I. House and Son, Westbury-on-Trym, Bristol. We are not sure to what you refer when you speak of "winter-flowering Begonias," and whether the newer varieties which originated with Messrs. Veitch and Sons, Limited, Chelsea, are intended or the smaller-flowered varieties of the Gloire de Lorraine group are meant. The latter are freely advertised from time to time, and such growers as Messrs. Cannell and Messrs. H. B. May, Edmonton, grow them freely, also Messrs. Peed and Son, West Norwood. Tubers of Gloxinias should have been started before now, but you may still obtain dry roots from the firms last named. A good way to grow Gloxinias is to raise the plants from seeds, and these, if sown in heat in January, would flower in six months if grown on quickly and well. Messrs. Cannell and Sons, Messrs. Peed and Sons and Messrs.

Sutton and Sons, Reading, would supply seeds of these plants and of a reliable strain. The dry tubers if planted now would be in flower about August, and later with ordinary greenhouse treatment.

**Garden plan (Norfolk).**—Were we desirous of planting a few things for lasting effect we should favour Hybrid Tea Roses, with bulbous plants such as Lilies and Daffodils, among them, and the surface of the beds carpeted with Tufted Pansies. By adopting a method such as this you could edge the beds with mossy Saxifragas or Aubrietias, or both, and plant Hepaticas, Adonis, Anemone blanda, alpine and other Phloxes, Polyanthus and such things freely. The Eucynthus as a marginal plant is so small a garden does not appeal to us, and we favour the idea of planting Tea or Hybrid Tea Roses rather thinly, one variety to each bed, then dibbling in a few inches apart at the right season good Narcissus, Lilies, &c., or even Fritillarias, and edging and planting the beds with the above-named subjects. The Roses need not predominate. Or by planting bulbous Irises, single and double Pyrethrums, Columbines, Lilies, Hepaticas, Anemones and other plants the Roses could be left out. Daphne mezereum, Forsythia suspensa, or a big group of Cydonia may occupy the centre of the bed to advantage. There would also be room for Lilies in these beds.

**Propagating Kniphofia caulescens and Erica carnea (C. G. O. B.).**—The deaths of your plants of Kniphofia caulescens are difficult to account for, as in much colder districts plants of this species stood quite well, even last summer. If your plants are on dry soil, which they should be, the probable cause is a little want of protection in spring, and a few boughs loosely placed about them will be helpful. The plants for propagation should either be heathered in late autumn or early spring long before flowering, as shoots cannot mature properly after flowering. The safest method of increase is by the shoots, or rather suckers, which should come from the base of the plants and not from the stems, which, we gather, are those you have used. The former will form a few roots naturally, and they can be taken off and put into a frame or into pots in a greenhouse for the first winter. If you try the shoots from the stems, take a little piece of the old stem with the shoots and strike them in gentle bottom-heat. Do this when they are 3 inches or more in length. The same remarks apply to K. Northia. As soon as Erica carnea has done flowering clip it back, and draw some fine soil about the stems for 2 inches or 3 inches up, working it well among them. Roots will be emitted into this, and the plants can then be divided in autumn, keeping some roots to each division. We are glad you find THE GARDEN useful.

### TREES AND SHRUBS.

#### Information about Almond trees (Wanderer).

—The Almond tree is quite hardy in this country and will thrive in almost any soil, provided it is well cultivated and is not waterlogged. They do not need any special treatment, and a good avenue of them should be a sight worth travelling far to see. The varieties are equally hardy, and any of them would do well in your locality. You could not successfully plant them now; prepare the positions during this summer and plant in the autumn, say, the end of October or early in November.

**Holly leaves spotted (Lea).**—The Holly leaves you send are attacked by the grubs of the Holly fly, which is known under the scientific name of Phytomyza ilicis. The fly bores a small hole in the leaf, deposits an egg, and leaves the rest to Nature. The eggs produce the grubs and they feed on the leaves below the surface, causing the brown patches. The way to clear out the disease is to pick off affected leaves and burn them, or to syringe the plants once a week during April, May and early June with an insecticide made by dissolving half a pound of soft soap and 2 pints of paraffin together, then adding 12 gallons of water. If steps are not taken to eradicate the pest, other Hollies in the vicinity will be attacked. The pest does not, however, attack other kinds of trees.

**Laurel leaves injured (A. E. S.).**—Your Laurel leaves have undoubtedly been eaten by some insect, and we have but little doubt that the author of the mischief is the caterpillar of one of the night-feeding moths. Probably it is that known as the silver Y moth (Plusia gamma), the perfect insect of which can be readily distinguished by a peculiar white Y-shaped mark on the brown ground colour of the upper wings. The caterpillar will eat almost anything, but we have never seen them attack the Laurel to the same extent as in the specimens sent by you. Of course the mischief was done long since. As these caterpillars feed during the night they must be sought for at that time. As you purpose clearing away the Laurels and getting rid of the accumulations of rubbish, the pest will in all probability give but little trouble in the future. As much of the rubbish as possible should be burnt, as by this means all insect life will be destroyed.

**Treatment for a Wistaria (C. S. P.).**—The only way you can induce your Wistaria to push out leaves on that portion of the stem which remains bare is to cut it back, say, to within 8 feet or 10 feet of the base. This will cause the production of new shoots, and as the plant is on a wall they can then be trained as desired till the required space is furnished. It would have been better had the cutting back been done earlier, but it is not too late even now to carry it out. If the plant is young and flexible, it may be bent back in such a manner as to arrest the flow of sap and cause the production of new shoots, but as yours is 40 feet long it is probably too old for this treatment.

**Name and information about a flowering tree (J. G. P.).**—The flowers you send are those of Prunus Padus (the Bird Cherry). The tree is a native of Britain, and in some districts is found either as a shrub or small tree in copses and hedgerows. It can be increased by means of seeds, which are produced freely and ripen in August. Cuttings can be rooted, but this method of culture is not usually adopted. Half-ripe shoots, 4 inches to 6 inches long, may be inserted in pots of sandy soil and placed in a warm and close case in July or August, or ripe shoots, 1 foot long, may be put in the open ground in October or November, in a similar manner to Currant cuttings. We have never seen it forced and doubt whether it would be a success treated as an indoor plant, its size being very much against it. There are many more Prunuses which are very much better subjects for forcing, P. japonica fl.-pl. and P. triloba fl.-pl. being cases in point. There are many varieties of P. Padus, one with semi-double flowers being specially noteworthy.

### ROSE GARDEN.

**Rose tree nearly dead (T. S.).**—We have little doubt that the trouble has been caused indirectly by the heavy dressings of manure that you mention. These would, as you say, induce the trees to make a strong, vigorous growth, which would not ripen up well last autumn, consequently the severe frosts experienced during the past winter has killed them. There seems to be a tendency now to feed Roses in an altogether unreasonable manner.

#### Exhibition Roses from cut-back plants (R. E. T.).

—There are some of our best exhibition Roses that are only reliable when budded annually. These are termed "maiden" plants, but the following succeed well from cut-backs, that is, plants that are planted permanently and pruned hard each year. We are not quite sure whether you desire the names of eighteen Hybrid Perpetuals, Hybrid Teas and Teas collectively or eighteen of each group, so have given the latter, and they may be taken as named in the order of merit. Hybrid Perpetuals: Frau Karl Druschki, Mrs. John Laing, Ulrich Brunner, Hugh Dickson, Mrs. Sharnan Crawford, Suzanne M. Rodocanachi, Captain Hayward, Helen Keller, Prince Arthur, François Michelin, Dupuy Jamain, Alfred Colomb, Mme. G. Luizet, General Jacqueminot, Duke of Edinburgh, Etienne Levet, Beauty of Waltham and Margaret Dickson. Hybrid Teas: Dean Hole, Caroline Testout, Mrs. W. J. Grant, La France, Lady Ashtown, Florence Pemberton, Killarney, White Lady, Melanie Souper, Lady Mary Fitzwilliam, Joseph Hill, Richmond, Mrs. Theodore Roosevelt, Gladys Harkness, W. Shean, Pharisae, Mrs. D. McKee and George L. Paul. Tea-scented: White Maman Cochet, Mrs. E. Mawley, Maman Cochet, Mme. Jules Graveraux, The Bride, Comtesse de Nadaillac, Souvenir de Pierre Notting, Medea, Catherine Mermet, Mildred Grant, Bridesmaid, Souvenir de S. A. Prince, Boadicea, Innocente Pirola, Mme. Hoste, Souvenir d'un Ami, Marie van Houtte and Mme. Constant Souper. A few varieties that are specially good as "maidens" are: Mildred Grant, Hybrid Tea; Horace Vernet, Hybrid Perpetual; Victor Hugo, Hybrid Perpetual; Marquise Litta, Hybrid Tea; Duchess of Portland, Hybrid Tea; A. K. Williams, Hybrid Perpetual; Ulster, Hybrid Perpetual; and Robert Scott, Hybrid Tea.

#### Young Rose shoots injured by insect (R. K.).

—We believe the injury to the young shoots is caused by woodlice, and the reason you cannot detect them at work is that the mischief is generally done at night. We advise you to examine the plants at night and you may catch the depredators at work. You may destroy the woodlice by placing some small pots about with a little moss inside, which attracts them, and the pots are emptied at intervals into some boiling water. Or some Paris green mixed with sugar placed about in the house

quickly kills the pests. Sometimes the tiny black grub will do immense damage among the young growths if not caught, but they usually work at the extreme ends of the shoots.

**Pruning Hiawatha Rambler (C. H. R.).**—The wichurana Roses require but little pruning, and we do not advise you to prune your plants at all this season seeing that their growths are but 3 feet to 4 feet long. They would answer very well partly pegged down, but should not be closer than 1 foot to the grass, or you would find that the grass would choke the young growth. It is always best to give the wichurana something to run upon, such as an old tree stump or some roots of some sort. A few hoops placed in the lawn and the growths of the Rose tied on to them would answer very well. We have formed a framework of osiers like the handle of a basket and tied the growths thereon, and very beautiful they appear with the sprays of bloom all over the growth. Most of this beautiful group lend themselves to almost endless ways of training, their growths being so pliant. They look very interesting trained as small pillars and dotted among dwarf Tea Roses.

**Sulphate of ammonia for Roses (T. A.).**—This is an excellent fertiliser for Roses, but it is best to apply it mixed with superphosphate. Give a good dressing at once at the rate of 3lb. of sulphate of ammonia and 1lb. of superphosphate to 40 square yards of surface. One application will be sufficient, but when the small flower-buds are seen some liquid manure should be applied. That made from cow manure and soot is an excellent stimulant. If you place two paraffin casks in an out-of-the-way part of the garden, these could be used for the liquid manure. Put about a bushel of the cow manure into one of the casks and fill it up with water. Into the other put two pecks of soot and fill up with water. Both the manure and soot should be in porous bags, then the liquid can be strained off almost clear. In applying this two parts of the cow manure liquid, one part of the soot liquid and three parts water should be mixed together, giving each plant about 1 gallon of the mixture once a week.

### MISCELLANEOUS.

**Gloxinia leaves injured (F. J. F.).**—The injury to the Gloxinia leaves is caused by thrips, which can be readily destroyed by vaporising with the XL All Vaporiser. Owing to the state the leaves are in a single vaporising will not be sufficient to clean the plants thoroughly, hence it should be done two or three times at intervals of ten days or a fortnight. The presence of thrips in such numbers suggests that the atmosphere of the house in which the Gloxinias were grown was much too dry.

**Road scrapings and clay soil (Anxious).**—There is no connexion whatever between what is known as finger and toe disease and dressings of road scrapings. If the road has been treated with tar or some similar dressing or is much frequented by motor-cars that drop petrol on the roads, the scrapings might be harmful or poisonous. But we assume yours are ordinary country roads, not so affected, and have surfaces of gravel or flint, which, being ground by traffic, forms rather fine grit. This is quite innocuous matter, but it is very poor, adding nothing to the fertility of the soil, but simply making it rather more open or porous. The greater the quantity of horse manure and road-side trimmings that may be in the scrapings the better for the soil, as those add fibre, and also as they decay become plant food. If your soil does produce the finger and toe fungus, your best course is to give it a dressing of gas-lime (40lb. to the rod) when uncropped in the autumn. Coal ashes do soil more harm than good, but wood or turf ashes make capital stiff soil dressings.

## SOCIETIES

### ROYAL GARDENERS' ORPHAN FUND.

#### A RECORD AND MOST INTERESTING GATHERING.

THE coming-of-age festival was held in the Victoria Room of the Hotel Cecil on the 12th inst., His Grace the Duke of Bedford, K.G., in the chair. As usual, the tables were most beautifully decorated with flowers sent by various nurserymen who are interested in the fund. The chairman, in giving the toast of "The Royal Gardeners' Orphan Fund," referred in sympathetic tones to the responsibility of those gardeners who are fathers, and mentioned that there seemed to be a general tendency by private employers to secure men "without encumbrances," and, although this might be advantageous from a private standpoint, it had also a serious national aspect. The fund was now maintaining and educating 116 children, and they might do more were the means available, and he appealed to them to see that the institution was always enabled to carry out its objects. Mr. Edward Sherwood, treasurer of the fund, in replying, stated that he hoped the present gathering was a record one. Mr. Sherwood announced that, to celebrate the passing of the coming of age of the fund, his father (Mr. N. N. Sherwood), his elder brother and himself had decided to establish a new section of the fund (£200) in honour of his father's little grand-daughter, Maybend Campbell, whose name this section would bear. The Mayor of Westminster (Mr. J. W. Dennis, J.P.) proposed the toast of "Gardeners and Gardening," referring in an interesting way to the work that gardeners were called upon to do. In replying, Dr. J. B. Farmer, F.R.S., pleaded most eloquently for Government recognition of

British horticulture. Other excellent speeches were made by Mr. W. Poupard, who proposed "The Visitors," and Mr. Arnold White, who responded.

Mr. Wynne, the secretary, announced that the record of last year in attendance and subscriptions had this year been surpassed, the total amount subscribed this year being £1,385, exclusive of the £300 from Messrs. Sherwood. The principal contributions to this sum were as follow: His Grace the Duke of Bedford, £250; Leonard Sutton, £100; George H. Cuthbert, £63 10s.; George Reynolds, £60 10s.; J. F. McLeod, £25 (including £20 from Messrs. Dobbie and Co.); R. B. Leech, £22 12s.; Lord Mountstephen, £20; David W. Thomson, £14 18s. 6d.; R. Hooper Pearson, 14 guineas; Whitpain Nutting, 14 guineas; T. W. Sanders, 11 guineas; W. Allen, James Veitch and Sons and Harry J. Veitch each 10 guineas; W. P. Thomson, £9 8s.; Thames Bank Iron Company, £10; James Douglas and J. Witty each 6 guineas; Cuthbert and Sons, J. W. Dennis, Alfred Watkins, S. Segar, Charles Dixon and George Bunyard each 5 guineas. The Covent Garden friends subscribed £260 13s. 6d. Mr. H. P. May proposed "The Chairman" and His Grace responded, thus terminating a very pleasant gathering.

### DAFFODILS AND TULIPS AT VINCENT SQUARE.

A most important announcement was made at the meeting of the Narcissus and Tulip committee on the 12th inst., namely, that the council had acted on their recommendation and appointed a sub-committee to draw up such a classification of Daffodils as might be useful for show and catalogue purposes and which the society itself might adopt at all its meetings.

This sub-committee has met and a start has been made, but the task is a big one and will necessarily take time; still, it is thought that the results will be available in time for the 1909 schedules. I fancy the general idea will be found to be the dividing up the whole of what may be called show Daffodils into about eight or ten main groups and then assigning each flower to its special division, much as the Sweet Pea Society do with their list of Peas of each colour. If the scheme can be successfully carried out, it will meet a want which each year's shows seem to emphasise.

An award of merit was given to Mr. Walter Ware for a very fine late Poet called Snowshoe (raiser, Mr. G. H. Engleheart). It has a tall, robust habit, and, being of good substance, its petals are very lasting. It is a little like *Almira* in shape, but the eye has the recurved colouring. No less than eight groups of either Daffodils or Tulips, or both, were in the hall, which was filled to its utmost extent. Unfortunately, the lateness of the season told upon the one and the cold, severe weather on the other, so the quality of bloom was rather below the average. Silver Flora medals were given respectively to Messrs. Barr and Son, Messrs. R. H. Rath, Messrs. R. Wallace and Co. and Mr. A. W. Wilson, and a bronze Flora medal to Miss Spurrell. Looking at the flowers one felt the end of the Daffodil season was not far off.

What a trying time it has been for many of us! Nothing can emphasise this more than to remind readers that neither the Rev. G. H. Engleheart nor Messrs. Pearson and Sons of Chilwell have been able to stage a single exhibit in London, nor the latter for that matter anywhere else. Certainly Mr. Engleheart did bring a box, and I was privileged to look into it. One flower it contained was very striking, a pure white Leedsii, like an immense Princess of Wales, only with a most pronounced citron yellow edge to the cup. It was a vision of what we may expect next year. Mr. Chapman has a remarkable flower called *Canari*, raised by the Rev. G. P. Haydon. It is an Ornatus with a primrose perianth. To me it was a great novelty, but Mr. H. Backhouse of Eastbourne told me he had seen one such flower once among a lot of wild ones in their native home, and that he now had it in his garden. *Canari* is not only remarkable, it is beautiful, the softness of its colouring being very pleasing.

There were some good single and double early Tulips. Princess Helen (a splendid white) and Hector (orange red, with soft yellow edge) on Messrs. R. H. Bath's stand were fine. So, too, were *Jaune Aplatie* (a yellow Rose Aplatie) and *Rose Luisante* (large rosy pink) in Messrs. Barr and Son's group. The Darwins were hardly grown enough, but the above two firms, and also Messrs. Wallace and Co. and Mrs. Benson, has some good standard varieties. Mr. Wilson had some well-grown blooms in front of his Daffodils. Stanley (or *Cramoisi Superbe*) is a lovely shade of rosy red and, as I saw it in Holland this year, very effective in a large mass. Sir Thomas Lipton (bright red) was in Messrs. James Veitch and Sons' group. It is excellent for bedding—durable and of good shape. There were but few "cottage" varieties. I hope this is only a pleasure deferred, and that the Temple Show will be found to be just timed this year to suit them.—JOSEPH JACOB.

### CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.

THE eighth annual spring flower show of this society was held at the Horniman Hall, Croydon, on the 6th inst. The committee have in view the fostering of a love of horticulture in the minds of all, and through the generosity of the society's supporters are able each year to give free admission to the general public. In response to such a kind invitation it is needless to say that the number of visitors attending is very great, and from the time the show opens at three o'clock till its close about ten o'clock the hall is full. No prizes are offered to the exhibitors, so that they are to be complimented on the enthusiasm they display in making the affair a success. From the gardens of the president, Mr. J. J. Reid, came a grand exhibit of *Schizanthus*, *Azaleas* and *Mignonette*, reflecting great credit on his head gardener, Mr. F. Oxtoby. Mr. J.

Pascall's gardener (Mr. A. Edwards) had a miscellaneous group of plants, including well-grown *Calceolarias* and double *Chicorarias*, and Mr. C. Lane, gardener to Mr. C. H. Coles, Caterham, put up some good *Hippeastrums* and *Cladiums*. In one corner Mr. J. J. Pittman's gardener (Mr. A. Dyer) staged an effective exhibit of *Cineraria stellata*, *Cyclamen* and white Stocks. Sir Walpole Greenwell sent cut flowers, including double and Regal *Pelargoniums*, *Cypripediums* and two fine sprays of *Cymbidium lowianum*, which his gardener (Mr. W. Smith) very effectively arranged. A very fine *Azalea* came from Mrs. Matthews of Anerley, and her gardener (Mr. C. Trower) evidently knows the cultivation of this class of plant, for it was a mass of flowers and measured 2 feet 6 inches in diameter. A pretty exhibit was made by Mr. Wateredge, gardener to Mr. Otto Hehnir, with *Cineraria stellata* in good colours and vigorous plants. Mr. Frank Allen's *Spiraeas* and *Hippeastrums* were also much admired, and the society welcomed a new exhibitor in his gardener, Mr. Beacon. Two cottagers contributed exhibits, Mr. J. R. Tice bringing some well-grown *Auriculas* and Mr. R. Cleveland a collection of Cacti. The trade was well represented. Messrs. J. Peed and Son had a collection of alpinas, these being arranged in boxes and adjoining a few Carnations, making an interesting exhibit. Alpines were also shown by Mr. J. R. Box, while the firm of Messrs. J. R. Box and Co. arranged a miscellaneous group of Tulips and Narcissi. Mr. P. Chaff arranged a miscellaneous group of plants, and the stage was tastefully decorated by Mr. T. Butcher. Messrs. E. W. and S. Rogers had a table of Hyacinths, including the best varieties, all of them having very fine trusses.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE usual monthly meeting of this society was held at the Horticultural Hall, Vincent Square, Westminster, on Monday evening, the 11th inst., Mr. Charles H. Curtis in the chair. Five new members were elected and one nominated. The death certificate of a late member was produced and a cheque passed for the amount standing to his credit in the books in favour of his nominee. The amount of sick pay for the past month was £25 12s. The amount of sick pay to May in 1907 was £199 11s., and to the same time this year it was £154 3s., being less by £45 3s. There are five chronic sick and five other members on the sick fund at the present time. The annual report and balance sheet has been posted to all honorary and benefit members. Will any member who has not received a copy please notify the secretary?

### ROYAL HORTICULTURAL SOCIETY.

#### ORCHID COMMITTEE.—MAY 12.

PRESENT: Mr. J. Gurney Fowler (chairman), Messrs. James O'Brien, de B. Crawshaw, H. Little, W. Boxall, R. Thwaites, F. Sander, A. A. McBean, J. Cypher, H. G. Alexander, Arthur Dye, F. J. Thorne, W. H. White, H. Ballantine, Gurney Wilson, W. Bolton, Norman C. Cookson, Harry J. Veitch, Walter Cobb, J. Wilson Potter, Stuart H. Low, F. Mentieth Ogilvie, Frederick J. Hanbury, H. Tracy and C. J. Lucas.

Messrs. J. Veitch and Sons, Limited, Chelsea, staged a very pretty group of Orchids, consisting chiefly of well-grown plants of *Odontoglossum Pescatorei*. *Dendrobium chrysotoxum* was also very fine, a grand specimen carrying four good-sized inflorescences of the rich yellow flowers. In the centre of the group was a magnificent plant of *Brasso-Cattleya Veitchii*, this carrying three huge, well-coloured flowers. *Dendrobium thyrsiflorum* and several fine forms of *Odontoglossum crispum* were also noticeable in this group. Silver Flora medal.

Messrs. Hugh Low and Co., Royal Nurseries, Enfield, staged a nice little group of Orchids, in which we noticed a fine specimen of *Lycaste lanepes*, which had ten large, well-developed creamy flowers. *Dendrobium thyrsiflorum* was also very fine, and a grand plant of *Cattleya Mendelii* was included.

From Messrs. Cypher and Son, Cheltenham, came a most attractive group of well-grown Orchids, these being tastefully arranged and comprising many choice subjects. *Miltonia vexillaria splendens* was very fine, and some grand plants of *Laelia purpurata* were particularly noticeable. *Leptotes bicolor*, *Cochlidia sanguinea*, *Cattleya Mendelii* and some good varieties of *Odontoglossum crispum* were also included. Silver Flora medal.

Sir Trevor Lawrence, Bart., K.C.V.O., Burford, Dorking (gardener, Mr. W. H. White), staged a very choice group of new Orchids, these including *Cattleyas*, *Dendrobiums*, *Odontoglossums* and *Epidendums*.

Mr. Maurice Mertens, Mont St. Amand, Ghent, put up a very pretty little group of Orchids in good variety. These included some very fine *Odontoglossum* hybrids, a fine plant of *Cattleya Mendelii* and a good *Miltonia*. Silver Banksian medal.

From Mr. H. S. Goodson, Fairlawn, West Hill, Putney, came a very choice and pretty little group containing many kinds in splendid condition. *Celogene pandurata magnificum*, with its green and black flowers; *Brasso-Cattleya Mossie digbyana*, *Masdevallia ignea* and *Cattleya Insseldorffii* undine were some of the best seen. Silver Banksian medal.

### ILFORD HORTICULTURAL SOCIETY.

THIS well-known suburban society has just held its second *Auricula* show at the Reading Rooms, High Road, Ilford, under the presidency of the Vice-President Councillor W. O. Sheat. There was a first-class attendance, and the display was of the best. During the evening the Rev. C. H. Vine, the "Nonconformist Bishop of Ilford," gave a much-appreciated lantern lecture on "Wayside Wonders."

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden. W.C.

## "COLOUR IN THE GARDEN."

ONE of the most practical and looked-for books that have appeared of recent years is "Colour in the Garden," by Miss Jekyll, who has been for many years working, to quote from the introduction, at these problems in her own garden at Munstead Wood, and "can venture to put them forth with some confidence." This work will, we think, influence the flower gardening of the future. The mixed border is generally "mixed," and it is impossible to cram four seasons into one strip of ground.

"I believe," Miss Jekyll writes, "that the only way in which it can be made successful is to devote certain borders to certain times of the year; each border or garden region to be bright for from one to three months." And at this season when the leaves of the bulbs are yellowing the mixed border is unsatisfactory. One cannot disturb the foliage without weakening the bulbs, and, therefore, one must wait patiently for that dying away which becomes wearisome when the summer-flowering plants are at hand to fill the places of the bulbs. "Nothing seems to me," Miss Jekyll writes—and we are in complete agreement with her remarks—"more unsatisfactory than in spring shows a few patches of flowering bulbs in ground otherwise looking empty, or with tufts of herbaceous plants just coming through. Then the bulbs die down and their place is wanted for something that comes later. Either the ground will then show bare patches or the place of the bulbs will be forgotten and they will be cruelly stabbed by fork or trowel when it is wished to put something in the apparently empty space." One of the pleasantest recollections of Munstead Wood is of the "main hardy flower border," a sumptuous mass of colouring for many weeks, and a revelation of the possibilities of producing brilliant effects. This border is "about 200 feet long and 14 feet wide. It is sheltered from the north by a solid sandstone wall about 11 feet high, clothed for the most part with evergreen shrubs—Bay, Laurustinus, Choisya, Cistus and Loquat. These show as a handsome background to the flowering plants. They are in a 3-foot-wide border at the foot of the wall; then there is a narrow alley, not seen from the front, but convenient for access to the wall shrubs and for working the back of the border." And the following notes on the scheme of colouring are interesting: "The planting of the border is designed to show a distinct scheme of colour-arrangement. At the two ends there is a ground-work of grey and glaucous foliage—Stachys, Santolina, *Cineraria maritima*, Seakale and Lyme Grass, with darker foliage, also of grey quality, of Yucca, *Clematis recta* and Rue. With this, at the near or western end, there are flowers of pure blue, grey-blue, white, palest yellow and palest pink; each colour partly in distinct masses and partly intergrouped. The colouring then passes through stronger yellows to orange and red. By the time

the middle space of the border is reached the colour is strong and gorgeous, but as it is in good harmonies it is never garish. Then the colour-strength recedes in an inverse sequence through orange and deep yellow to pale yellow, white and palest pink, with the blue-grey foliage; but at this, the eastern end, instead of the pure blues we have purples and lilacs.

"Looked at from a little way forward, for a wide space of grass allows this point of view, the whole border can be seen as one picture, the cool colouring at the ends enhancing the brilliant warmth of the middle. Then, passing along the wide path next the border, the value of the colour-arrangement is still more strongly felt. Each portion now becomes a picture in itself, and every one is of such a colouring that it best prepares the eye, in accordance with natural law, with what is to follow. Standing for a few moments before the endmost region of grey and blue, and saturating the eye to its utmost capacity with these colours, it passes with extraordinary avidity to the succeeding yellows. These intermingle in a pleasant harmony with the reds and scarlets, blood-reds and clarets, and then lead again to yellows. Now the eye has again become saturated, this time with the rich colouring, and has therefore, by the law of complementary colour, acquired a strong appetite for the greys and the purples. These therefore assume an appearance of brilliancy that they would not have had without the preparation provided by their recently received complementary colour."

These extracts show the character of this beautiful and most instructive book. It solves the problem of maintaining borders of colour throughout the year, even in winter, when the greys of Rosemary and Lavender give warmth to the garden. The illustrations are numerous, of great teaching value, and there are many plans drawn to scale showing exactly how to place the plants to obtain those beautiful colour effects we have longed to obtain, but are now within our reach.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

June 9.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1—6 p.m. Lecture at 3 p.m. Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

June 11 and 12.—Royal Horticultural Society's Exhibition of Colonial-grown Fruits and Vegetables (Fresh and Preserved), 1—6 p.m. Lecture at 3 p.m. by Mr. H. Hamel Smith on "The Cultivation of Cacao." King's Colonials' Orchestra. Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

**"The Garden" Flower Show.**—There seems some confusion in the minds of intending exhibitors as to how many coupons are required if more than one entry is contemplated. Only one set of coupons is required for any number of exhibits and in any classes. The object of the coupons is simply to ensure that only readers of THE GARDEN are competing.

**Plant importations into Germany.**—All plants, shrubs, &c. not belonging to the category of the Grape Vine, which have been grown in nurseries, gardens and plant houses may for the future only be sent via the Grand Ducal Mecklenburg chief Custom house at Rostock.

**Rhododendrons in the open.**—It may interest your readers to know that we have in flower outside several plants of Lady Skerimsdale, Mrs. James Shaw and Duchess of Sutherland. These delightful, white, sweet-scented plants have been planted out several years and generally become well set with buds, which, however, the early autumn frosts often cripple. They need high positions and moderate shade, with a free, well-drained, sweet soil. R. Gibsonii flowered freely last season and quite unprotected. Many species have been charming between the frost this season, and it was no uncommon sight to see the snow on one side and flowers on the other—the same with Camellias; in fact, while we had snow I gathered several from the protected side quite fresh and uninjured.—W. A. Cook, *Leonardslee Gardens*.

**A Rose show in Leipzig in 1908.** Under the protection of H.M. Friedrich August, King of Saxony, an exhibition of Roses will take place in the Leipzig Palmengarten, from June 27 to July 5, inaugurated by the Gärtner Verrin of that city. Applications should be addressed to Otto Moosdorf, jun., Leipzig, Lindenau. The exhibition will be international in character.

**Horticultural fete at Hanley.**—The twelfth annual horticultural fete is to be held in Hanley Park, Hailey, Staffs, on July 1 and 2, when many valuable prizes will be competed for. In addition to the gold and silver medals usually awarded to trade exhibits, a silver challenge cup, value £10 10s., will be presented by the committee for the best trade exhibit in the show. Classes are arranged to suit all kinds of growers, and the committee anticipate a record exhibition. Mr. William Poulson, Town Hall, Hanley, Staffs, is the secretary, and he will be pleased to supply full particulars about the show.

## PRIZES FOR READERS. JUNE.

THE BEST EIGHTEEN OUTDOOR-GROWN FLOWERS AND GRASSES FOR CUTTING FOR ROOM DECORATION, WITH DIRECTIONS FOR THEIR SUCCESSFUL CULTIVATION.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Tuesday, June 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE

(The Editor is not responsible for the opinion expressed by correspondents.)

**Daffodil leaf disease.**—I send a few Daffodil leaves to show what looks like a disease of some kind which has appeared upon the foliage of a few of my Narcissi, and I am at a loss to understand its nature or cause. It is not "yellow stripe" as I have scarcely any of that, and am getting less and less of it each year, and the plants that are affected by this were quite free from stripe. It is too soon yet for the foliage to be turning yellow naturally. I wonder if it could in any way be attributed to the terrible frosts the plants were subjected to during the snowstorm in April when they were in full bloom. This may have had a weakening effect upon the foliage, but the fact that only portions of one or two varieties are affected would incline to do away with that idea. I lifted an affected plant and found it apparently perfectly healthy at the roots. You will notice in the case of Sir Watkin and Princeps that it first appears as a small dark brown spot in the foliage, while it seems to develop in Horsfieldi without the preliminary spot, the leaves merely becoming prematurely withered and yellow. Princeps is growing in the grass and the other in cultivated ground, where they have only been two years planted, and the soil is an ideal one, being rich, stiff fibrous, well-drained fresh loam. The ground is a patch enclosed from an old pasture, and cropped for a couple of seasons with Potatoes previous to planting the Daffodils. The Daffodils have had no manure, of course, except a slight dressing of crushed bone last autumn. Up to the present they have grown magnificently with me; indeed, I have never seen finer blooms anywhere. The disease looks like a fungoid one of some kind, and, possibly, a powerful microscope would reveal its nature. I am afraid of it weakening the bulbs by prematurely destroying the foliage, and I am still more afraid of it spreading. I shall be exceedingly grateful if you can throw any light upon it for me and tell me whether it is dangerous or not, and how to deal with it. I should like to hear from you on the matter as soon as possible.—G. L. W.

[We sent our correspondent's letter to Mr. F. J. Chittenden, The Laboratory, Royal Horticultural Society's Gardens, Wisley, who replies as follows: "The browning and death of the Narcissus leaves appears to be due to the presence of the fungus Botrytis parasitica. This fungus lives part of its life at least upon dead vegetable matter, and is likely to pass from that to living leaves of certain plants, among them the Narcissus, if the conditions should prove favourable. Exactly what the favourable conditions are does not seem to be known, but speaking generally it may be said that anything that makes for abnormal development, such as the weather conditions mentioned by your correspondent, are likely to lay the leaves open to the attack of this fungus. It grows for a time in the tissues of the plant and may pass down the leaves to the soil and into the bulb, and if this occurs it is probable that in the succeeding year there will be a recurrence of the disease, for the fungus produces masses of mycelium, which are eventually of a blackish colour and which allow it to tide over periods of adverse weather conditions, and when suitable weather again prevails, these sclerotia, as they are called, give rise to mycelium, which spreads through the soil and attacks plants in its neighbourhood. The sclerotia are to be found both in the soil around the plants and on the bulbs as well as in the dead tissues of the leaves. None appear to have been formed at present, but there may be some on the bulbs which I have not seen. It would be as well to remove and destroy all leaves that are attacked to a marked extent, and to spray the remainder with a solution of potassium sulphide, made by dissolving 1 oz. of the substance in 3 gallons of water. If the

attack is only just beginning, this would probably prevent its very rapid spread."—Ed.]

**The Poeticus section of Narcissus.**—I have read "Poetaster's" remarks in THE GARDEN of the 16th inst., page 238, with considerable interest. I should like to ask him through you if he has ever seen a pure white form of it. I mean, of course, one free from all trace of colour in the rim and of the true Poeticus tone of white. I have one, raised from seed, of course, and I am curious as to whether it has any interest or value. I have raised many seedling Daffodils, some of which are very beautiful, but I think the one mentioned above is perhaps the greatest novelty. I may mention incidentally that I am a very old subscriber, having had, I believe, every issue since the paper started, and this is perhaps the main reason why I venture to trouble you with this enquiry. With many thanks for the pleasure and instruction your journal has afforded me.—JOHN W. GAUNT, *Summerfield, Bramley, Leeds*.

## THE EDITOR'S TABLE.

"THE LAST OF THE DAFFODILS FOR THE SEASON."

Mr. Peter Barr sends from Kird, N.B., "the last of the Daffodils for the season," and we thank him very much for the interesting series he has gathered for us this season. The last collection included such interesting sorts as Barri Ledington; the true Narcissus Poeticus (a large, beautiful flower of the purest white, with brilliant orange scarlet cup); Burbidgei Agnes Barr, Poeticus Cassandra, Burbidgei Vanessa, Barri Maurice Vilmorin, Poeticus tripodala (the three outer segments forming a tripod), Barri Mrs. C. Bowley, Poeticus Glory (a pretty flower of very refined form), Burbidgei Beatrice Heselton, Poeticus Almira, Leedsi Katharine Spurrell, Leedsi Minnie Hume, the now-popular Daffodil Queen of Spain, Nelsoni Berardii—Mr. Barr as he sends this flower writes, "I have never seen it with so much colour in the cup"—Barri Lady Godiva, Nelsoni Wolley-Dod, Nelsoni minor, Nelsoni major, Leedsi Duchess of Westminster, Nelsoni pulchellus, the famous Barri conspicuus, Incomparabilis Guyther, Leedsi Beatrice, the pretty biflorus hybridus, Incomparabilis Frank Miles, biflorus orientalis, Incomparabilis Stella, Incomparabilis Princess Mary, Leedsi Gem, Poeticus poetarum, Leedsi Mme. de Graaff (the stem sent having two flowers).

MIGNONETTE SUTTON'S RED GIANT.

Mr. J. S. Higgins, The Gardens, Rûg, Corwen, North Wales, sends magnificent spikes of this Mignonette. Although we have previously seen this variety well grown, we have never seen it better than in this instance: "The seed was sown on September 2 last in 6-inch pots, about half-a-dozen seeds in each pot, and placed in a cold frame and grown on as cool as possible and quite close to the glass. The middle of January it was moved to a warmer house (minimum temperature, 45°) to induce active growth, finally thinning at this stage to three plants in a pot. When the flower-spikes began to show the plants were moved to their flowering quarters, no heat being used except in the case of sharp frosts. The stimulant used was one pint of liquid manure to one gallon of clear water, only when the flower-spikes appeared. Watering during the dark, dull days is a point to be well studied, as if the soil becomes sodden and sour failure is certain. The soil used is one-half turfy loam, one part leaf-soil, one part spent Mushroom bed and sand, with old mortar rubble added to the amount of a 10-inch potful to a bushel of soil, and a few small bits among the crocks of the pots. In preparing the pots the soil should be rammed as hard as possible, as herein lies the secret of success. I never pot Mignonette on or stop it, and you see the result.

## THE GREENHOUSE.

### SALVIA SPLENDENS.

**A**MATEURS should grow *Salvia splendens* and *S. Bnanthi*, which is dwarfer in habit and brighter in colour, for the embellishment of their greenhouses and conservatories in the dull days of autumn and early part of winter. Two methods may be adopted in the growing of these plants: First, by retaining them in pots throughout the season; and, second, by planting them in the open border in summer and lifting and potting them early in September. By following the latter course larger and more bushy specimens may be obtained, and if they are carefully treated at the time of lifting and repotting the plants will not suffer.

#### INSERT CUTTINGS

made from young healthy shoots early in the spring. The cuttings should be about 3 inches long and severed immediately below a joint, the leaves from which must be cut off. The most suitable compost is one of rich, sweet loam two parts, leaf-soil two parts, and sufficient coarse sand to make the whole porous. Fill 5-inch pots with this compost, and also put some sand on the surface. Six cuttings may be inserted around the edge of each pot; plunge the latter to the rims in some loose material, such as Cocoanut fibre, placed on a slight hot-bed and the cuttings will quickly form roots. Directly sufficient roots have been made put the young plants separately in 3½-inch pots and keep them in a warm frame until they are established, then transfer them to a cool frame. Of course, warmer weather will now have come, and it is important that sturdy plants be grown.

#### PLANTING OUT.

Prepare a border in an open position, digging the soil deeply and enriching it with well-rotted manure. If the soil be of a clayey nature mix some sifted leaf-soil with it at the time of digging. In the meantime harden the plants by placing them on a bed of ashes in a sheltered place, then, when all danger from frost is past, put them out in rows 2 feet apart and 18 inches from plant to plant in the rows.

#### SUMMER TREATMENT.

This consists of watering, keeping the ground loose and free from weeds, and, early in the summer, pinching the point off the leading shoot to induce a branching habit. When grown in pots those 7 inches in diameter will be large enough for the final potting. Great care is needed in the matter of watering, and some feeding must be done when the pots are full of roots. Soot water in a clear state is a splendid stimulant. In any case it is not advisable to stop the shoots too severely, nor later than the end of July, as such severe pinching lessens considerably the size of the spikes of blooms.

#### LIFTING PLANTED-OUT SPECIMENS.

Prepare a good compost and suitable pots in readiness for lifting the plants early in September. Carefully preserve all the roots, and when the potting is completed put the plants in a cool frame or house, and keep the structure

rather close and shaded from bright sunshine for about a week afterwards. The plants will quickly get established in the pots, and then air may be admitted more freely. As the colder weather comes place the plants in a temperature of about 55° and give water judiciously at all times. AVON.

### MAIDENHAIR FERNS AS WINDOW PLANTS.

AMATEURS generally are very partial to these Ferns as window plants. During a somewhat lengthy experience in judging amateurs' gardens I have found that the owners frequently

THE GARLAND ROSE AT MUNSTEAD WOOD.

(From "Colour in the Flower Garden." See page 261.)

make mistakes in potting and watering these Ferns. The best time to repot a plant which is growing in a window is towards the end of March, when the young fronds commence to grow, but the work may be safely done till the end of May if care is taken.

#### THE COMPOST.

This should consist of fibrous loam two parts, peat one part and leaf-mould one part, with sufficient coarse sand to make all thoroughly porous. Then to a bushel of the above mixture add a 7-inch potful of charcoal broken into lumps rather smaller than sugar cubes and the same quantity of old mortar. Mix all the ingredients thoroughly and use clean, dry pots and crocks.

#### HOW TO REPOT THE PLANTS.

Carefully remove the old drainage crocks without injuring the roots and place a few lumpy pieces of the compost on the crocks before putting in the plant. The size of the new pot should allow of the fingers being pressed down between the ball of soil and roots and the side of the pot. Press down the compost with the fingers and leave sufficient space for water. Great care should be taken not to break off the young fronds, and also in watering the plants afterwards. Do not allow the pots to stand in water in saucers, as the stagnant water would cause the soil in the pot to turn sour and kill the roots. This is a mistake often made. But if the ball of soil is allowed to get very dry water passes away down the sides of the pots and does not enter the ball and reach the roots. If, however, a plant becomes very dry place the pot in a pailful of tepid water and let it remain so for a whole day; it is the only way to once more saturate the ball through to its centre. Common garden soil is often used for potting these Ferns in and the result is very unsatisfactory. Tiny slugs and woodlice will eat the young, unfolding fronds, so that close observation is needed to detect them. Old fronds should be cut off and not pulled out, else the young fronds will be destroyed also. AVON.

### HOW TO GROW THE SCHIZANTHUS.

DURING the last few years much has been done in the way of improving the *Schizanthus*. By the careful cultivation of plants grown from the fine strains of seed which are now procurable very distinct and elegant specimens are produced. As the plants are half-hardy annuals, they should never be subjected to a high temperature that is loaded with moisture, but should be induced to grow strong and sturdy from the first. Plants which are at their best during April and May were raised from seed in August and September. The young plants are grown on in a light, airy house from which frost is excluded, care being taken during the winter to prevent the plants suffering from overwatering. The most suitable pots for their final shift are 6-inch size, and these should be cleaned and well drained. A few of the strongest plants may be potted into 8½-inch pots; these are very useful in large conservatories where an abundant display of flower is required, also when used as single specimens for the adornment of rooms they are very attractive.

Seed may be sown now for providing a display of flower in late summer and autumn, also for the purpose of supplying plants for growing in the flower garden. The dwarf forms of *Schizanthus* are the most suitable for outdoor culture, viz., the various forms of *S. pinnatus* and *S. retusus*. A sheltered position and a rather firm, well-drained light soil are conditions under which the plants will flourish in the open garden. For pot culture the larger-flowered strains should be selected. The culture advised for the *Cineraria* will be found to suit these admirably. The one thing to aim at is to secure a good sturdy growth from the start, and this is best accomplished by keeping the plants well up to the glass and providing free ventilation whenever possible. C. RUSE.

## THE ROSE GARDEN.

### SEASONABLE WORK AMONG ROSES.

#### PLANTING OUT UNDER GLASS.

**T**HE present is a very suitable time to make preparations for planting out Roses under glass. Where a house can be devoted to this beautiful flower the best results follow from careful planting in well-prepared borders, far better than can be accomplished from plants grown in pots. The fine exhibition blooms that

that drainage is good, and trench it two spades deep, working in some quarter-inch bones with the lower spit of soil and some well-decayed farmyard manure with the upper spit. This trenching should be done at once, and then the borders will be ready for the plants by the middle of June. We usually afford plenty of space between the plants; not less than 2 feet apart. Later on, as plants develop, some will need to be cut out. If one were growing for market and anxious for a quick return it would be well to plant about 18 inches apart and tie the plants to Bamboo canes, but in private establishments the greater distance apart is best, for as the plants grow they may be bent slightly outward, which encourages the basal eyes to start, and from these one obtains splendid trusses of blossom.

The plants to purchase are those grafted this season on seedling Briar roots. Being in a growing state they lay hold of the soil at once and make remarkable growth if a moist warm atmosphere is maintained during the summer. A rest is given the plants in the autumn by withholding water for a time and affording plenty of air. In December, or earlier or later, according to when it is desired that the plants shall blossom, they are slightly pruned and started gently into growth. A period of about twelve weeks is allowed from the pruning to the blossoming. The hot-water pipes from the first should be painted with sulphur, which will keep down mildew and to some extent dread. A genial, steady atmosphere is best for Roses rather

than a fierce heat, and the best results always follow where such culture can be afforded.

Varieties are now so numerous that it is difficult to select, but there should be several plants of a sort to allow of a goodly number of blooms being out at one time for table or other decoration. The following would grow very well together in one house and are really a very select list: Liberty, Antoine Rivoire, Catherine Mermet, Mme. Abel Chatenay, Bridesmaid, Perle des Jardins, Richmond, Kaiserin Augusta Victoria, Joseph Hill, Lady Roberts, Lady Battersea, Pharisaer, Sunrise, \*Mrs. W. J. Grant, Joseph Lowe, \*Caroline Testont, \*La France, \*Frau Karl Druschki and Lyon Rose. If a second structure could be given up to Roses I would suggest that this be planted out with those sorts marked with an asterisk, adding Captain Hayward, Mrs. John Laing and Mrs. Sharman Crawford.

For the first two years a few ramblers in pots could be grown in these houses, placing them

where the light was not seriously obstructed from the dwarf plants. The pillars in the house should have a free-flowering sort planted against them. Useful varieties would be Niphetos, Souvenir de S. A. Prince, Crepuscule, Billiard et Barre, &c. A Maréchal Niel or two could be grown on the single rod system so as not to obstruct the light to the plants beneath. P.

### EXPERIENCES OF ROSES.

**AGLAI.**—A plant of this variety, six years after planting and never pruned, measures 15 feet high and the same in width. Last season it was one mass of pale yellow clusters, which, it is to be regretted, turn white as they age. It is on the north-west side of a house in a bleak position—one half of the tree faces due north—yet this was also covered with blooms. Since flowering last year at least eighty new stems were produced from the older shoots 5 feet to 8 feet in length, promising a cloud of colour for the coming season. It is quite useless to plant this Rose where it has not freedom to grow at will.

**Beryl.**—Three years ago a dwarf of this variety was placed with others of that section, but it is the same to-day as regards size and has only given a few poor "miffy" blooms.

**Rêve d'Or.**—A yellow Rose, but it opens so quickly from the bud stage to the expanded flower that it is almost useless for any purpose. It soon falls also.

**Mme. Bérard.**—A slow climber and shy bloomer, but the flowers are very fine when you get them. Makes a good standard, is hardy and blooms more freely in that form.

**Frau Karl Druschki.**—A splendid white Rose, strong grower, free bloomer, &c., but the moment a Rose of this calibre, but really double, arrives Frau Karl Druschki will be eclipsed; do not fill the garden with it.

**J. B. Clarke.**—The common experience need hardly be repeated.

**Gustave Piganeau.**—Quite a good grower when established and fine flower.

**Duke of Edinburgh.**—This Rose gives clear dazzling scarlet flowers at the top of the bushes, but lower down, shaded by the foliage, maroon specimens and shades between these two are gathered. Still one of the best scarlet and crimson Roses.

**Caroline Testout.**—The best all-round Rose. The climbing form is the best also of the so-called new "climbers."

**Climbing K. A. Victoria.**—Grows 10 feet in a season, but does not give ten Roses, and the slightest damp rots the flowers.

**Perle von Godesberg.**—A variety of Kaiserin Augusta Victoria, which, on well-drained, warm soils, gives really fine blooms and freely; stands wet fairly well and is a fair grower.

**White Maman Cochet.**—This rivals Caroline Testout, but if the roots are allowed to get too dry in a hot spell of weather the buds will split when opening. A beautiful Rose, and we want more of this type. Hardy and free.

**Fisher Holmes.**—Hard to beat as a dark sweet-scented Rose.

**General Jacqueminot** is a competitor, but is lighter in shade and smaller. Both are strong growers and free bloomers.

**W. A. Richardson.**—It is hard to understand the gush over this Rose, as it has colour only to recommend it. It will not give a good flower or grow at all on hot ground, but it will on heavy loam. Its colour is anything in most years, from a dirty greyish white to coppery yellow. When a pure deep-coloured bud is obtained it is good. Its stalk is very short and its growth straggling. Good as a bud in special situations chosen with care and knowledge.

**L'Idéal.**—A pretty Rose, but so far succeeds only as a standard. It simply will not grow away in the open, yet is described as a "climber."

*St. Albans.*

W. B.

FLOWER OF NARCISSUS HONNET. (Exhibited at the Birmingham Daffodil Show.)

are met with at the spring meetings of the Royal Horticultural Society are in a large degree grown from Roses planted out. Of course, this necessitates a structure to be allotted entirely to the Roses; but in these days of cheap horticultural buildings there should be no difficulty on this score, neither are expensive or elaborate houses necessary. In many gardens I know for a fact old vineries are being converted into Rose houses, and very suitable they are as a rule. It is sometimes said that the plants must be near the glass, but I know of one large commercial Rose-growing place where some of the houses are fully 14 feet to the ridge, and these were furnished with small plants from 4½-inch pots. I expressed surprise to the grower at the unusual amount of air space, and he said he was in favour of plenty of freedom for his plants, and certainly the growth they had made in a few months was wonderful.

Where the soil is good it is not necessary to import fresh, but it pays to have first-class soil. A good loam, inclined to be clayey, is best. See

## THE FLOWER GARDEN.

### TWO BEAUTIFUL NARCISSI.

FURNACE AND HORNET.

**P**ROBABLY there has never been a more brilliant and more perfectly-formed flower of its type shown than the charmingly distinct variety called Furnace, which was in the centre of Messrs. Barr and Sons' exhibit at the recent Birmingham show. The perianth is flat, firm, of grand substance and of a clear soft shade of yellow, and the crown, which is beautifully frilled and crimped, is of a colour which is most difficult to describe, the name Furnace being the very best that could have been chosen, for it speaks of glowing embers, and the crown or cup of this flower just glows. Unlike so many of the brilliant-crowned flowers, the colour in Furnace, true to its name, is more intense in the centre, where, as one might say, the fire is hottest.

Hornet is another of those flowers that one must go to Birmingham to see or not see at all. It is a seedling raised by Mr. P. D. Williams of St. Keverne, Cornwall, and was shown among the twelve varieties of seedlings with which he won the Bourne Cup. It stood out distinct and strikingly brilliant among all the exquisite blooms surrounding it. The perianth is of pale lemon, flat, very firm, overlapping, and of such grand substance that the flower was as good at the end of the second day of the show as it was when first set up. The flat, spreading crown is of orange red, beautifully crimped and frilled. I cannot help thinking that it was this flower that turned the scale in Mr. Williams's favour in the very close competition between him and Mr. Crosfield for the cup. W. A. WATTS.

### DAHLIA NOTES.

DAHLIAS much dislike being planted on the same land two years running; but as this is sometimes inevitable, the only way to ensure a good return is to dig in a quantity of fresh material either in the form of fresh loam or, as already mentioned, decayed refuse or manure. It is often said that the Cactus varieties require no manure if they are to flower freely, and only recently there appeared in print a recommendation from an experimentalist in Dahlia culture to withhold manure and water entirely from varieties which have a tendency to come shallow in the centre, and by this means full-centred flowers will be obtained. This is indeed a novel method, and as likely to succeed in the long run as a starvation diet would be to fatten a pig. On the majority of soils the more manure in reason the better. Although the plants may for a time be somewhat gross, yet the ultimate result will be not only quality, but quantity of bloom. In the case of Pompon Dahlias, if not wanted for exhibition, manure is beneficial, as much larger bushes will grow and a far greater quantity of flowers be obtained. It is surprising that these little Dahlias are not used in far greater numbers for planting in borders and odd places where a showy mass of flowers is seen to effect.

### PLANTS IN POTS.

To secure the best results, notably in exhibiting, young plants are now almost always the favourites, and yet there are now and then varieties which succeed best from old roots, and so it is advisable to retain a few and let them form a supplementary force as it were. When the day comes for cutting the flowers, many an unlooked-for bloom will happen to be in its prime on the old roots just when most needed. A common error is to pot up too much of the old tuber when dividing and potting up the old roots. A small portion potted deep enough to cover the crown is far preferable to the usual practice of ramming a lump of root into a pot

and leaving a couple inches of crown and the shoots above the soil.

Much the same thing occurs with young plants. In many instances which have come under my notice the object appears to be to get hard, stunted, pot-bound plants which are doubtless hardy and will stand the change from the comparative shelter of frame or corner to the open ground, but which will at the same time lose much valuable time in getting away into anything like free growth.

After noting the behaviour of many thousands of plants, we have come to the conclusion that a growing plant in a 5-inch pot is the best for transferring to the open. If larger, they feel the check too severely, and if smaller they have a lot to do to get a good foundation.

If plants are placed in 5-inch pots early in May and grown on in a frame, they should make sturdy, healthy stuff by planting time.

### INSECTS.

When Dahlias become at all root-bound they are almost sure to be attacked by thrips, and no enemy is more difficult to exterminate. Of course, everyone of experience would know at once that thrips were at work by the appearance of the plants, but we have been surprised at the number of growers who were totally unaware that the unhealthy condition of the very young leaves was caused by thrips, and scarcely believed it possible when shown the actual specimens. Dipping is the best remedy, as by this means it is impossible for the thrips to escape contact with the insecticide, which naturally not only destroys the thrips, but renders the plant obnoxious by coating the leaves with the destructive fluid. It is a great pity to transfer a lot of plants to the open ground if at all infested with vermin. Should a spell of dry weather set in the plants will be a source of endless trouble before they finally throw off the enemy, and even as late as August it is not unusual to see plants practically ruined by thrips. On sunny mornings the mature insects may be seen jumping about on the petals of the developed blooms, and the bases of such florets are usually semi-transparent and to a great extent spoiled. P. P.

### A FINE NEW PANSY.

THE large-flowered Pansies so beloved by our forefathers seem to be once more coming into general favour, and many improvements have been made in them during the past few years. We have never seen a better variety, however, than the one exhibited by Messrs. R. H. Bath, Limited, of the Floral Farms,

Wisbech, at the Royal Horticultural Society's meeting on the 28th ult. It is named Bath's Bronze Empress, the name fairly indicating the colour. The main, central portions of the petals are almost black with a rich velvety sheen, and this is edged by a band, rather more than one-eighth of an inch wide, of bright reddish bronze, thus giving the flower a rich yet refined appearance. The size of the blooms measured was  $3\frac{1}{4}$  inches in diameter, and they have that circular shape so beloved by the exhibitor. Added to these good qualities we have plants of great vigour and flowers that are faintly but pleasantly scented. The variety is said to come quite true from seed.

### CHRYSANTHEMUM MAXIMUM MARGARET MARWOOD.

NOT very many years ago it was seldom that one met with the large-flowered Ox-eye Daisy (*Chrysanthemum maximum*) in the majority of gardens; now there are but few where hardly flowers are appreciated in which it is not to be found in one or other of its forms. The facility with which the plant can be cultivated, and the value of the flowers as cut blooms or for border decoration, have rendered it increasingly popular, while the continuous flow of new varieties has maintained the interest in the flower. It is to be feared, however, that there are too many new varieties being sent out, and a search through a dozen or so of catalogues of reliable firms who sell this plant and its varieties, would, I feel certain, rather appal those who desired to make a choice of the best. That figured in the accompanying

NARCISSUS FURNACE. (Exhibited at the Birmingham Daffodil Show.)

photograph, which has been sent out by Messrs. Kent and Brydon of Darlington, is a beautiful variety, the reflexing of the ray petals giving the blooms a pleasing and more informal appearance than is presented by many of the varieties, while the purity of the flowers makes them of additional service as cut blooms. It is of medium height, about 2 feet or a little less, and it is one of the freest bloomers of a class of flowers which are unusually floriferous.

There are many other good varieties of *Chrysanthemum maximum*, some of those with fimbriated petals being very pretty indeed. One of the best of these for some time has been Robinsoni, but a still larger and newer variety called Snowdon has been raised by Mr. W. Angus of Penicuik, the raiser of King Edward VII., another well known and excellent variety,

by applications of Kilogrub, this being dusted on the soil and lightly scratched in wherever a likely place for alga to harbour in existed. Whether they have been killed or not I cannot say, but the fact remains that seedlings have been untouched since its application.

Insects, too, seem to be coming on in large quantities. Aphidea have already made their appearance, but prompt ayringings with a Quassia and soft soap solution have routed them for the present.

H. W. F.

## NEW PLANTS.

### AURICULA MAY DAY.

A YELLOW self of merit and refinement. In colour it is somewhat paler than "Daffodil," and in its

CHRYSANTHEMUM MAXIMUM MAROARET MARWOOD.

with blooms of great size. Snowdon is larger than King Edward VII., and in other respects is more graceful. Among other good varieties are filiformis, Earl Roberts, G. H. Sage, vomerensis (one of the finest of all), E. Johnson (the Munstead variety) and W. H. Gabb.

The cultural requirements of *Chrysanthemum maximum* are of the simplest kind, and they can be cultivated in any ordinary garden soil well dug and enriched with rotted manure. The flowers are much finer if the plants are broken up and replanted every two years or so, and a bed in the reserve garden will be found most useful in supplying plenty of blooms for house decoration.

S. ARNOTT.

## SLUGS, INSECTS AND FLOWERS

I do not remember ever before seeing such a plague of slugs so early in the season as I have encountered in my garden this spring, owing probably to the wet weather experienced earlier in the season. Seedlings of many choice flowers have been devoured in a wholesale manner, despite application of soot, lime, ashes, and even the so-called sawdust. The slugs are at present so small that it is impossible to hunt and kill them, an eye with hawk-like keenness being necessary to detect them. During the last fortnight their depredations have been stopped

way it is one of the most pleasing that we know. The central white paste is well defined. Shown by Mr. James Douglas, Great Bookham, Surrey. Award of merit.

### AURICULA CORONET.

A green-edged or show variety of sterling worth. The white paste is very finely formed and the centre is yellow. Exhibited by Mr. Douglas, Great Bookham. Award of merit.

### ASPARGUS FILICINUS.

Sir Trevor Lawrence, Burford, Dorking (gardener, Mr. Bain), exhibited this elegant new species from the Himalayas. The plant is of erect habit, the spreading frond-like side branchlets assuming a nearly horizontal position. The species is reputedly one of the hardiest of the genus, and, therefore, a welcome addition. Award of merit.

### NARCISSUS SNOWSHOES.

A late-flowering *Poeticus* with well-formed blossoms of good substance and a variety whose late flowering will render it of much value. The plant is obviously of good stature. Shown by Walter T. Ware, Limited, Bath. Award of merit.

All the above were exhibited before the Royal Horticultural Society on the 12th inst., when the awards were made.

## TREES AND SHRUBS.

### UNCOMMON EARLY-FLOWERING TREES AND SHRUBS.

**A**MONG trees and shrubs which bloom during late winter and early spring are several which stand out conspicuously among the remainder as subjects especially worthy of the attention of the garden enthusiast.

These are for the most part old introductions, but have never become really well known; hence their present scarcity in collections outside those of scientific establishments. This failure in the past to establish themselves among the foremost occupants of the garden does not prove that the plants have no pretensions to beauty or that they are unworthy of attention for ornamental gardening, for they possess many attractive features and are well fitted for garden adornment. One of the March-flowering shrubs to attract attention is

*STACHYRUS PRÆCOX*, a Japanese deciduous bush 3 feet to 8 feet high with reddish brown bark. Its most attractive period is throughout March and early April, when numerous axillary, pendent racemes of greenish yellow flowers appear. It thrives in light, warm loam into which a little peat has been dug, and should be given a position where it will be shaded from the early morning sun. Very rich soil is not to be recommended, as growth under this condition becomes too vigorous for successful flower production.

*PRUNUS SUBHIRELLA* is a Japanese Cherry which blooms during late March and early April; the flowers are small and delicate pink in colour. Rich loamy soil suits it, and planted in such material growth is rapid. Propagation is easily effected by means of cuttings in summer. It is not advisable to plant it in an exposed position, as the early, delicate flowers are sometimes injured by cold east winds. A companion plant to this is *P. pendula*. Its characteristic features are its weeping branches and pretty rose or pink unopened buds, which have been responsible for the common name of Rose-bud Cherry. As a lawn specimen for a sheltered position it has much to commend it.

*P. TOMENTOSA* is a pretty white-flowered species belonging to the Apricot section of the genus; it forms a large bush and blooms freely during early April. The flowers are about half an inch across, and are sometimes succeeded by scarlet fruits about the size of a small Cherry, but of Apricot appearance. It requires a sheltered position on account of its earliness of blooming and delicate petals.

*ERICA AUSTRALIS* is one of the brightest of the April-flowering section, the flowers being red, larger than those of most of the hardy set and borne in profusion. It ought not to be planted in cold districts, and should be given soil free from lime.

*SPIRÆA THUNBERGII*.—Of the various shrubby *Spiræas* this is the earliest to bloom, its tiny white, star-shaped flowers making it conspicuous during March and early April, while later on its dainty light green foliage warrants its cultivation as a foliage plant alone. It thrives in light, loamy soil.

*RHODODENDRON NOBLEANUM* is one of the earliest of the large-growing *Rhododendrons* to bloom, and it is not uncommon to find it in full flower during February should the weather prove mild. If, however, the weather is severe in February, it makes a good display in March. A good deep red form of this is known under the name of Handsworth Early Red, while a companion plant may be obtained in Handsworth Early White. Among trees,

*PRUNUS DAVIDIANA*, the earliest of the Almonds, blooms during February and March, while the white variety is also conspicuous during the same period.

# THE TEMPLE SHOW.

ONCE again the great Annual Flower Show of the Royal Horticultural Society is taking place, and once again it is an exhibition of rare interest and beauty. It is impossible to individualise, but we must congratulate the Council upon an alteration in the placing of the groups. The same exhibitors were not in exactly the same places, and there was less crowding, we think, in the tents. No exhibition in the world can approach in magnificence and downright interest this great annual gathering in the Temple Gardens, and such an exhibition would not be carried out so smoothly and successfully without Mr. S. T. Wright, superintendent of the Society's Gardens at Wisley, and Mr. Frank Reader. We owe much to these officials, but all work for one object—to make the exhibition a success. There seemed, however, a want of something, and it was the absence of the secretary, the Rev. W. Wilks, who is recovering, we rejoice to hear, from a somewhat serious illness. Her Majesty the Queen and H.R.H. the Princess of Wales spent over an hour in the tents, and the most important exhibits were pointed out by Sir Trevor Lawrence, Bart., the president, and Major Holford.

## ROSES.

Charming indeed was the large group of Roses at the end of the long tent on the Embankment. This came from Messrs. Hobbies, Limited, and included many of the delightful climbing and decorative Roses. Among the single Roses we noted Delight, Hiawatha, Kathleen and Paradise, and a beautiful lot of freely-flowered standards of the new Tausendschön.

Messrs. Frank Cant and Co., Braiswick, Colchester, set up a very long and representative group of all types of the Rose. Boxes of good exhibition sorts were superb, and pot Roses in great variety, including new and choice Roses that do so much to make the garden beautiful. Fine specimen climbing Roses were abundant and in excellent form and condition.

A pretty group of Roses was exhibited by Messrs. Benjamin R. Cant and Sons, Colchester, who staged charming forms of the double and single climbing varieties of all up-to-date sorts, also a box of beautiful Maréchal Niel Roses, and two large boxes of exhibition sorts in good condition.

Mr. George Mount, Canterbury, excelled in this department. His mounds of Roses were truly superb. The flowers were quite up to exhibition standard, and were beautifully disposed on long stems. Mrs. John Laing, the new Hybrid Tea Joseph Lowe, Liberty, Frau Karl Druschki, Richmond, Ulrich Brunner, Mrs. Sharman Crawford and Caroline Testout were exhibited in masses.

A large and handsome group of Roses of various types was quite a feature in the large tent. This was exhibited by Messrs. William Paul and Son, Waltham Cross. Hiawatha, Kathleen and Stella were good singles; Minnehaha, Lady and Crimson Rambler were the best of the climbers. Elaine, a creamy white Hybrid Tea that received an award of merit, is a large full flower of good form and very consistent. This was well shown. We had a special liking for Tausendschön, a beautiful climbing Rose.

From Messrs. Paul and Sons, Cheshunt, came a group of Roses that filled the south-east corner of the big tent. Lovely indeed were many of the standard specimens, and the groundwork of

good exhibition Roses borne on healthy plants made a grand display. Hybrid Teas David Harum, George Laing Paul, Rosalind and Old English were noteworthy kinds.

Messrs. Hugh Low and Co., Enfield, staged an outdoor group of beautiful climbing Roses in charming variety. The individual specimens were some of the best in the show, and included the more noteworthy sorts of recent introduction.

Mr. George Prince, Longworth, Berks, had a fine group tastefully disposed. All the better climbing Roses were nicely shown, as were also a box of fine Tea-scented Roses.

The charming display of Roses as made by Messrs. Cannell and Son, Swanley, saw this famous firm in a new light. The dwarf Polyantha Rose Mme. N. Levavasseur, a beautiful rosy carmine very free flowering sort, Hiawatha, Lady Gay and other lovely climbers were beautifully represented in a large group.

Mr. Charles Turner, Slough, exhibited a group of Roses in varying forms. Climbers, exhibition kinds and a charming variety of Tea and Hybrid Tea-scented Roses, all well grown, made a very attractive display. The disposition of the plants was commendable.

## CARNATIONS.

Messrs. Hugh Low and Co., Enfield, had one of the largest groups of Carnations, all in first-class condition. Their unique system of setting up the flowers was distinctly good, a mirrored background heightening the effect. Britannia, Winsor, White Enchantress, Beacon, Victory and Mrs. Burnett were all in grand condition. A unique group of splendidly-grown flowers.

A very pretty exhibit of Carnations was exhibited by Mr. W. H. Lancashire, Guernsey, White Perfection, Enchantress, Robert Craig, President, Mrs. T. W. Lawson and Mrs. H. Burnett being the best.

Glorious was the display made by Mr. H. Burnett, Guernsey. Very large vases were most artistically filled with flowers of high quality, the base of the stems being interspersed with Asparagus Sprengeri. Enchantress, Mikado, Mrs. H. Burnett, Winsor, Marnion, Aurora and Robert Craig were very fine.

A pretty group of Carnations in long, stately vases made a good exhibit from Mr. A. F. Dutton, Iver, Bucks. There was plenty of colour and the blooms were beautifully fresh. Aristocrat, White Perfection, Robert Craig, Pink Imperial, Winsor and Harlowarden were all good.

Carnations from Mr. S. Mortimer, Rowledge, Farnham, were very fine and were artistically set up in tall vases. Robert Craig, Flamingo, Fair Maid, Jessica and Mrs. T. W. Lawson were among the better specimens. The blooms were very fresh and clean.

Mr. C. Engelmann, Saffron Walden, Essex, staged a very nice series of vases of Carnations. The disposition of the flowers was good, the colours bright and pleasing and the quality good.

Mr. C. F. Waters, Balcombe, Sussex, was well to the fore again with the choicer Carnations. Malmaison Princess of Wales was grand, as were also the perpetual sorts as represented by President, Calypso, Prosperity, Britannia, Harlowarden, Lady Hermione, Nelson Fisher and others.

Mr. W. H. Page, Hampton, had a grand lot of flowers—Beacon, Enchantress, Winsor, Britannia, Mrs. T. W. Lawson, Aristocrat and Governor Roosevelt were all well done. The disposition of the flowers left nothing to be desired.

Messrs. Bell and Sheldon, Guernsey, had some of the finest Carnations in the show. The blooms were large, of good colour and of superb quality,

though lacking arrangement. Evangeline, President and Aristocrat were very fine indeed.

A group of well-grown Malmaison Carnations was exhibited by Mr. Cecil F. Raphael, Shenley, Herts (gardener, Mr. A. Grubb). King Arthur, Princess of Wales and a dark crimson were in the pink of condition and were well disposed in the handsome group.

Messrs. Thomas S. Ware, Limited, Feltham, staged a good group of Carnations; in the vase of one variety, Enchantress, there was associated pleasingly a pale Delphinium for effect.

## ORCHIDS.

Sir Jeremiah Colman, Bart., Gatton Park, Surrey (gardener, Mr. W. P. Bound), staged a marvellous bank of choice Orchids, which, for artistic effect, would be very hard to beat. This bank was some 10 feet high, graceful Palms towering over the top. Cattleyas, richly-coloured Masdevallias, Oncidiums, Cymbidiums, Odontoglossums and many other kinds vied with each other for the place of honour, the whole of the plants being in splendid condition and tastefully set in a groundwork of small Palms and Maidenhair Ferns. Among the rarer species we noticed Cirropetalum gamosephalum, C. Cummingii, C. pulchrum, Bulbophyllum Lobbi colossus, B. godseffianum, Octomeria diaphana, Epidendrum fuscum, Liparis corniculata, Oncidium monachium, Masdevallia O'Brieniana, M. cuculata (Gatton Park variety), M. muscosa, Spathoglossis soulterianum and Odontoglossum Lindenii. We were pleased to see Mr. Bound well maintaining his high reputation as a grower of these plants.

Messrs. Charlesworth and Co., Bradford, put up a very fine group indeed, containing a vast number of choice species, hybrids and varieties. These were staged in the form of a solid bank, with Palms for a background and Maidenhair Ferns forming a most pleasing setting. Cattleya citrina, Trichopilia crispa marginata, Odontoglossum crispum varieties, Cattleya Fantasia, some magnificent plants of C. Skinneri, Odontioda Charlesworthii (a magnificent bright rich crimson hybrid, the result of crossing Cochloda noetzliana with Odontoglossum harryana), with fine Miltonias were a few of the best in a very beautiful collection.

Messrs. J. and A. A. McBean, Cooksbridge, erected a pretty little group, in which Odontoglossum crispum forms predominated. We noticed one little plant of an Odontoglossum carrying one flower with distinct brownish crimson markings, and this we understand is a newly-imported specimen. Cymbidiums, a few Cattleyas and a Cypripedium or two completed an interesting exhibit.

From Messrs. Moore, Limited, Rawdon, Leeds, came a very prettily-arranged group composed of many interesting subjects. The old Dendrobium Victoria Regina, which is very rarely met with, was present, and we also noticed some very fine forms of Odontoglossum crispum, Masdevallia harryana exquisita (very rich colour), the green and black-flowered Celogyne pandurata, Odontoglossum Phoebe Queen of Spain (very handsome), Cypripedium bellatulum Queen of Spain, Cattleya Aelandiae and some very fine plants of Miltonia.

Messrs. Armstrong and Brown, Tunbridge Wells, adapted a rather pleasing arrangement with their group, many grand and interesting specimens being most tastefully displayed in two rather acute bays. In one of these Cypripediums in many choice forms were displayed, a superb plant of C. chamberlainianum magnificum being much commented upon. C. rothschildianum, too, with three splendidly shaped and huge

flowers, was also most noticeable. *Odontoglossum wilckeanum uranis*, *Cattleya Skinneri* Temple's variety, and *Odontoglossum crispum virginialis* were very fine indeed.

From Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Tetbury, Gloucestershire (gardener, Mr. H. G. Alexander), came a magnificent group of splendidly-grown plants, in which *Cattleyas* and *Odontoglossums* predominated. The plants were remarkably floriferous, and the arrangement, being in the form of a more or less solid bank, with Ferns and Palms intermixed, was such as to show the plants to their best advantage. *Cattleya Dusseldorfi* Undine, *Lælio-Cattleya Elva* Westonbirt variety, *L.-C. Lustre magnifica*, *Miltonia vexillaria* Empress Augusta Victoria and *Brasso-Lælio Minerva* were a few of the most notable subjects in this charming group.

Messrs. Hugh Low and Co., Royal Nurseries, Enfield, staged a very fine and comprehensive bank of well-grown and choice plants. These were artistically arranged with Palms and Ferns, the whole presenting a most pleasing appearance. We particularly noticed fine plants of *Cattleya Mossiae* The President, very large well-coloured flowers; *Bulbophyllum barbigerrum*, *Cirropetalum Colletti*, *Cattleya Mendelii* varieties, *Ærides Fieldingii*, *Odontoglossum crispum* varieties, very good indeed; *O. Pescatorei* virginale, *Dendrobium albo-sanguineum*, *D. Bronckhardtii*, *Cypripediums* in variety and *Epidendrum bicoloratum*. A really splendid group.

M. Ch. Vuylsteke, Loochristi, Belgium, staged a few of his wonderful *Odontoglossum* hybrids. These were a centre of attraction, especially to Orchid enthusiasts, the whole day. *O. infusum* is almost a blood red self, *O. laudatum* has deep purple markings, *O. crispum* Blushing Bride is deep blush on a white ground.

Mr. John Robson, Altrincham, put up a nice compact little group of *Odontoglossum* varieties, *Masdevallias*, *Cattleyas*, *Dendrobiums*, *Miltonias* and similar subjects. *Phalenopsis ramestediiana*, too, was very fine.

From Mrs. Collingwood, Lilburn Tower, Alnwick, came some well-grown and highly floriferous plants of *Vanda teres*.

Messrs. W. Bull and Sons, King's Road, Chelsea, staged a very pretty group of well-grown plants, in which *Lælia purpurea illustris*, *Cattleyas* and *Odontoglossums* predominated. *Cattleya Mendelii* Empress, *C. M. Princess of Wales*, *C. Mossiae* Prince of Wales and *C. M. Coronet*, with some unnamed *Odontoglossums* were particularly noticeable.

From Mr. F. Menteith Ogilvie, The Shrubbery, Oxford, came a very large group of remarkably well-grown plants, these being most tastefully arranged with Palms for a background and Maidenhair Ferns and moss for a groundwork. The *Miltonias* in this group were particularly fine, a beautiful bank of *M. vexillaria gigantea* forming one end of the group. We also noticed a fine plant of *M. v. Chelseensis*, *Cypripedium callosum* Sanderæ, *C. lawrenceanum* hyeanum, *Odontoglossum ordentissimum* (shrubbery var.), a huge plant of *Cattleya Skinnerii* in the centre and *Cattleya citrina* carrying enormous blooms. This group was awarded the Veitchian Cup.

The magnificent group staged by Messrs. Cypher and Sons, Cheltenham, was really beautiful. *Miltonias*, *Odontoglossums*, *Masdevallias*, *Phalenopsis*, *Dendrobiums*, *Cattleyas*, *Brasso-Cattleyas*, *Cypripediums* and many other choice kinds were presented in such a variety of colours, yet so well blended, that the group was continually besieged with a host of admiring visitors. *Miltonia vexillaria* with its varieties *leucoglossum*, *superbissima*, *virginialis*, *splendens* and *Augusta Victoria* made two splendid masses in the bank. Flanking these on either side were splendidly-grown plants of *Odontoglossum Rolfeae*, *Phalenopsis sanderiana*, *P. grandiflora*, *Cypripedium bellatulum*, *C. Gowerii* magnificum, *C. rothschildianum*, *Cattleya intermedia* alba, *Odontoglossum Pescatorei*, *Epiphronitis Veitchii*,

*Cattleya Dusseldorfi* and many other very choice subjects too numerous to mention.

In the splendid group erected by Messrs. Sander and Sons, St. Albans, there was quite a host of very choice and beautiful specimens, the whole, as usual, being in the very pink of condition. The arrangement was superb, delicate green Ferns being most judiciously intermixed with the Orchids, *Odontoglossums*, *Cattleyas*, *Miltonias*, *Cypripediums* and many other very choice kinds being displayed in a most lavish manner. *Cypripedium bellatulum* varieties, the green and black-flowered *Celogyne pandurata*, *Cymbidium Sanderæ*, *Diaerum* (*Epidendrum*) *bicoloratum*, the lovely *Dendrobium Bronckhardtii*, *Odontoglossum excellens*, *Cattleya Mendelii* formosa, *Lælio-Cattleya Rowena*, *Odontoglossum crispum Festivus*, *O. c. transcendens* and *O. eximium* were but a few among a host of extra good and interesting things.

#### MISCELLANEOUS GREENHOUSE PLANTS.

Messrs. W. and J. Brown, Stamford, made an interesting display embracing *Verbenas*, *Roses*, *Heliotrope* and *Zonal Pelargoniums*, all disposed in an artistic manner.

*Azalea rosæflora* represented by dainty plants were grouped on the table with a background of Palms for effect. This came from Messrs. J. Backhouse and Son, Limited, York.

Messrs. J. Veitch and Sons, Limited, of Chelsea, made one of their fascinating table groups of choice plants for which they are famous. This included such plants as *Lobelia tenuior*, *Gerbera Jamesoni* and choice *Gerbera* hybrids, *Kalanchoe kewensis*, *Streptocarpus*, *Richardias*, *Malvastrum grossulariifolium* and *Nephrolepis*.

Mr. W. J. Godfrey, Exmouth, exhibited show and fancy *Pelargoniums* in his usual fashion in baskets. The plants were well grown, freely flowered and pleasingly diversified; *Mars*, *Beauty*, *King Manuel* and *Bridesmaid* were conspicuous.

From the Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett), came a long table group of a fine strain of *Streptocarpus*. The well-grown plants were grouped in colours for effect, and the shades were very good. The flowers also were large and handsome, and reflected credit on this good gardener.

The King's Acre Nurseries, Limited, Hereford, made a very excellent table group of *Heliotropes*, *Petunia* Countess of Chesterfield, *Carnations* and *Schizanthuses*. The *Heliotropes* were very fine and the staging of the group excellent.

Prettily disposed among Ferns and *Panicum variegatum* were superb *Gloxinias*, selfs and spotted sorts being conspicuous. This exhibit was staged by Messrs. J. Carter and Co., High Holborn. A very large table group of *Gloxinias* was also set up by Messrs. John Peed and Son, interspersed among which were Ferns, backed by Palms, all very attractive.

From the Horticultural College, Swanley, was a small group of *Gloxinias* interspersed with Ferns and other foliaged plants. *Schizanthus retusus* was also well shown by this college.

A notable feature of the show were the dainty baskets filled so charmingly with the *Schizanthus* in varying form and colour. These were suspended from arches in attractive fashion. There were also numerous pot plants. This exhibit came from Messrs. James Carter and Co., High Holborn. Messrs. James Garaway and Co., Bristol, also staged these plants in excellent form, the colours being very diverse and they were well grown.

A very handsome lot of herbaceous *Calceolarias*, in wonderfully diverse colours and all well grown, was exhibited by Messrs. Webb and Sons, Wordsley, Stourbridge. This was a welcome feature of the show, and showed how fine is the strain represented by this well-known firm.

Messrs. H. Cannell and Sons, Swanley, Kent, well maintained their high reputation with a superb group, which included a representative

collection of Cacti, *Bougainvillea* Maud Chettleburgh, well-grown herbaceous *Calceolarias*, *Hydrangeas*, *Fuchsias* triphylla, other *Fuchsias* and a glorious bank of richly-toned *Cannas*.

In the group of Messrs. Richard Smith and Co., Worcester, among other things were *Carnations*, *Liliums* and herbaceous *Calceolarias*, all tending to make a fine show.

*Lilacs* in variety came from Mr. T. Jannock, Dersingham. This grower also had a grand bank of his superb strain of *Lily of the Valley*, the whole group producing quite a cooling effect in the warm tents.

The large group in the middle tent set up by Messrs. Sander and Sons, St. Albans, was a fine feature and included a large number of very choice plants—*Polypodium Knightiæ*, *Pandanus Sanderii* var. *superba*, *Pereskia godseffiana*, *Vitis atrovirens*, *Furcraea watsoniana* and the new *Croton* Fred Sander.

*Saracenias*, as exhibited by Mr. A. J. A. Bruce, Chorlton-cum-Hardy, are always a pleasing feature of this great show, and if the display was not quite so large as usual the quality of those plants that were staged was very good indeed.

Noble Ferns and other foliage plants made a most effective group as set up by Mr. H. B. May, Upper Edmonton. There were also numerous bunches of the better double and single *Zonal Pelargoniums*. Of the Ferns, *Nephrolepis exaltata* *superba*, *N. Whitmanii*, *N. Scottii*, *N. Amerpholii* and *N. elegantissima* were well represented.

At the north end of the large tent, Messrs. Sutton and Sons, Reading, had a series of undulating groups of choice flowering plants. Individual groups of their superb strains of *Cineraria stellata*, *Schizanthus*, herbaceous *Calceolaria*, flanked or fronted with a choice array of tuberous *Begonias*, *Gloxinias* and *Nemesia Suttonii* and the newer forms of *Nicotiana affinis* made at once one of the most comprehensive and interesting displays in the whole show. This exhibit well maintained the high reputation of this firm.

From Mr. Charles Turner came a pretty group of *Azaleas* in pyramidal form. The plants were well flowered, beautifully fresh and the colours were diversified.

*Azaleas* in beautiful variety were set up in a handsome group by Messrs. R. and G. Cuthbert, Southgate, N. This group is always much sought after, as the display is so choice and the colours so soft and beautiful. *Occidentalis magnifica* is grand; the varieties are so numerous and all good that it is quite invidious to mention them in this short note.

A group from Messrs. Bull and Sons, Chelsea, included many choice plants. *Heliconia illustris* was a central figure of great beauty in the group. This was exclusively confined to foliage plants of a choice nature.

*Caladiums* from Messrs. John Peed and Son, West Norwood, were not so numerous as usual, although the plants were large and generally of good colour.

The Hon. Vicary Gibbs, Aldenham House, Elstree, had a fine group of scented-leaved *Pelargonium* *Clorinda*. The plants were fine standard specimens, and were freely flowered. A groundwork of *Spirea japonica* heightened the effect.

Messrs. James Veitch and Sons, Limited, Chelsea, set up a large and attractive group of flowering and foliage plants. In this exhibit were included *Rhododendrons*, *Clematis*, *Cytisus Bearii*, climbing *Roses*, *Azalea mollis*, *Vitis Thomsonii*, *Ceanothus veitchianus*, *Viburnum* and numerous other flowering plants and shrubs.

*Clematis* from Messrs. George Jackman and Son, Woking, are always a great feature at these shows, and the present exhibit was even better than usual. Fresh and clean plants of high quality, bearing beautiful flowers in profusion, made a noteworthy display. *Fairy Queen*, *Jackmanni rubra*, *Lord Neville*, *Lady Caroline*

Neville and the bright Ville de Lyon were very good.

Peonies from Mr. W. James were very fine, and the large flowers, of splendid quality, were the admiration of all. It is a great pity that the varieties were not named.

The group of miscellaneous stove and greenhouse plants in the big tent from Messrs. James Veitch and Sons, Limited, Chelsea, is always a fine achievement, and the present is no exception to the rule. Caladiums, Crotons, Dracenas, Nepenthes, Carnations, Anthuriums, Nephrolepis, Ficus, Medinilla magnifica and numerous choice Orchids made a very handsome display.

At one corner of the big tent Messrs. William Cutbush and Sons, Highgate, N., and Barnet, Herts, made one of the most attractive groups. The groundwork was of Carnations and Roses, all grouped in mounds or as a carpeting, with the lovely Hiawatha and other climbing Roses in festoons pleasingly disposed.

Very beautiful Clematises made a grand group from Messrs. Richard Smith and Co., Worcester. Excelsior, Sensation, Marie Lefebvre and King Edward VII. were all noteworthy. Roses and Palms made a good background.

A fine group of rare exotic Ferns was staged by Messrs. J. Hill and Son, Lower Edmonton. Platycerium grande was in good form, Adiantum veitchianum was in excellent condition, as was also Polypodium lepidopteris sepultum, and numerous other choice plants, including a pretty case of Filmy Ferns.

Handsome Hippeastrums from Messrs. R. P. Ker and Sons, Liverpool, were exceptionally fine. The flowers were large and of good form, and the colours very diverse and most interesting. Margot, Jasper, Venus, Sunset, Pink Perfection and Nestor were fine specimens.

Messrs. Carter and Co. of High Holborn made one of the charming displays of Cinerarias for which they are famous. C. stellata, in which were many beautiful new Cactus forms, were beautifully disposed in great diversity of colour. There was also the ordinary stellata forms free and branching, and lovely plants and flowers of the large Brilliant prize forms.

#### TUBEROUS-ROOTED BEGONIAS.

Pleasingly staged were fine samples of the tuberous Begonias in variety, all double forms of high quality, which came from Messrs. Carter and Co., High Holborn.

Messrs. Blackmore and Langdon, Twerton Hill, Bath, staged a remarkably handsome group of these plants, the quality being of the highest and best and characterising all the plants and flowers. They were almost exclusively double sorts, except a few superb examples of frilled single varieties.

A fine group was staged by Mr. John R. Box, West Wickham and Croydon. Double sorts preponderated, but a little more variation in the colour was wanted.

A pretty group also came from Messrs. John Laing and Sons, Forest Hill. These were well-grown plants of good quality, but hardly so freely flowered as we are accustomed to see from this firm.

Mr. A. L. Gwillim, New Eltham, Kent, staged a group of Begonias of excellent quality. The flowers were large and of grand form and colour, and were growing on plants in good health.

Superb aptly describes the magnificent group staged by Messrs. Thomas S. Ware (1902), Limited, Feltham. The colours in this instance were most diversified and the quality of the flowers all that one could desire. The arrangement of the plants left nothing to be desired.

#### HARDY PLANTS.

An excellent arrangement of hardy plants on an improvised rockery, from Messrs. William Cutbush and Sons, Highgate, was one of the features in the open. In addition to the

rockery were groups illustrative of the water garden, the bog garden and the border. The latter on this occasion was given the central place, and Tree Peonies, Incarvilleas, Phlox Laphami, with Lilies, Eremuri, &c., in the background. In the water group were Aponogeton distachyon and the Bog Bean (Menyanthes) in capital form.

Mr. M. Prichard, Christchurch, Hants, displayed many choice alpine in boxes, among the gems being Saxifraga aizoon rosea, S. A. flavescens, Trifolium alpinum, Veronica rupestris alba, Polygonum sphærostachyum (with rosy crimson spikes), Thalictrum anemonoides rosea (a charming plant), Aquilegia Stuarti, and many more, all very good.

At the opening of No. 1 tent Messrs. Carter and Co. had a rockery arrangement on which were seen Saxifragas, Phloxes, Lithospermums, Heucheras, Anubrietas and the like.

William Artindale and Son, Nether Green, Sheffield, had a showy group of hardy plants such as Trollius, Primula pulverulenta, Gentiana acaulis, Gerberas, hardy Cypripediums, Primula Sieboldi and many more.

From Mr. R. Farrer, The Craven Nursery, Clapham, Yorks, came a delightfully arranged rockery filled with the choicest of alpine plants, such as Saxifraga aizoon flavescens, Androsace villosa, Ramondias, Primula farinosa and Daphne rupestris.

Messrs. J. Cheal and Sons, Crawley, set up an arrangement of natural rock pleasingly arranged with choice and suitable subjects. The rockwork itself was admirably done, and the naturally-disposed plants rendered it quite a feature. Ferns, as well as a great variety of alpine, entered into this excellent exhibit.

Messrs. George Bunyard and Co., Maidstone, had an extensive grouping of the most showy subjects, Irises, Pyrethrums, Poppies, Eremuri, May-flowering and Darwin Tulips, Lupines, Saxifraga pyramidalis, Trollius and the like, the whole making a most extensive display.

Mr. Amos Perry, Hardy Plant Farm, Enfield, had an admirable group of hardy flowers in great variety. For example, the Cushion and allied Irises and their hybrids formed a most delightful gathering worthy of special study. Again, Darlingtonias, Sarracenias and Water Lilies were interesting in the extreme, and quite naturally arranged. In a third group a collection of Primulas was worthy of much study.

Messrs. Bakers, Wolverhampton, had a rich display of Tufted Pansies and Violas, the blooms being of remarkable size and freshness.

Mr. B. Ladhams, Southampton, displayed many effective hardy plants, none so good perhaps as the large-flowered and spurless Columbine Aquilegia Stuarti, a lovely flower, much larger than is usually seen, and a great gain for the rockery.

The Misses Kipping, Hutton, Essex, had a small yet pleasing rockery arrangement, on which a great variety of alpine were judiciously arranged.

Mr. G. Reuthe, Keston, Kent, displayed a very beautiful lot of alpine and choice hardy flowers and shrubs. Species of Rhododendrons were quite a feature, while such things as Saxifraga brunoniana, Campanula Allioni, Saxifraga aizoon lutea, Lithospermum Gastoni, Oenothera tauricum (with golden flowers) and Androsaces, Ramondias, hardy Cypripediums and Primula sikkimensis were among choice things noted.

Mr. Godfrey, Exmouth, Devon, brought a large gathering of Poppies, varied in colour and in many ways beautiful and distinct from those usually seen.

Messrs. Gunn and Sons, Olton, Birmingham, had a small group of beautifully-grown Phloxes, such as White Swan and Mrs. Hunter being prominent.

Mr. R. C. Notcutt, Woodbridge, Suffolk, had a group of the more showy hardy flowers, such as Tulips, Trollius, Phlox canadense, Primulas, Pyrethrums, Incarvillea grandiflora, Viburnum

macrocephalum, Berberis Knightii, a strongly-spined species with golden flowers, and Azalea latifolia, presumably one of the Indian section, with white flowers, is said to be quite hardy.

Mr. J. Forbes, Hawick, staged Polyanthus, Pansies and Pentstemons in considerable variety and beauty.

The Misses Hopkins, Shepperton, displayed a rockery exhibit arranged with hardy plants and alpine in variety, including groups of Primulas, Orchises, Phloxes and Saxifragas of many kinds.

Messrs. Barr and Sons, Covent Garden, had a most extensive display of hardy flowers, embracing a very wide range of all that is good in hardy plants. We have no space for an extended enumeration of names, but we take the early Gladioli, the Cushion and allied Irises, the showy Columbines and Primulas, the exquisite and delicately toned Ixias, and the gorgeous Tulips as indicative of what was included in the display. The Tulips alone were a great feature and in perfect form.

A varied group of hardy things from Messrs. James Veitch and Sons, Limited, Chelsea, was arranged in the open, and in addition to Azaleas, Andromedas, Bay Laurels, the newer climbing Vines from China, Cerasus and other plants, we noted fine examples of Primula pulverulenta, Meconopsis integrifolia, M. punicea, towering spikes of Eremuri, Clematis montana rubens, Primula cockburniana, P. siberica, Delphinium nudicaule, and quite a host of other beautiful and interesting plants.

Messrs. R. Smith and Co., Worcester, had a mixed group of cut flowers in which English, May-flowering and Darwin Tulips, Peonies, Spanish Irises, Anemones, Carnations and other things were seen in very great numbers.

Messrs. William Bull and Sons, Chelsea, staged a pleasing group of Spiraea Queen Alexandra, together with a large and representative gathering of May-flowering and Darwin Tulips in great variety, the latter being particularly fine.

Messrs. George Jackman and Son, Woking, staged many good hardy flowers and chiefly those of a showy character, such as Primula japonica in variety, early Gladioli, Lupines, Heucheras, single and double Pyrethrums in great variety, hardy Cypripediums, Saxifraga granulata plena and a lovely lot of S. longifolia, some of which were in bloom.

A particularly interesting and varied group of seedlings of the blue Poppy Meconopsis racemosa was exhibited by Lady Northcliffe, Sutton Place, Guildford (gardener, Mr. J. Goatley).

The King's Acre Nurseries, Limited, Hereford, displayed hardy flowers and alpine on a rock-work arrangement. There were many good plants shown, such as Incarvillea, Saxifragas in variety, alpine and other Phloxes, Arenaria grandiflora, Primula cockburniana and others.

Mr. Howard H. Crane, Woodview Terrace, Highgate, N., had a lovely lot of the Tufted Pansies and Violettas displayed in the most natural manner in pans. There were some five dozen pans of these flowers in gold, yellow, sulphur-primrose, lilac and many shades of blue.

Baker's, Wolverhampton, had a remarkable exhibit of herbaceous and alpine plants displayed in imposing groups, such as Primula pulverulenta, Cypripedium spectabile, Dianthus neglectus, Anubrietas, Incarvilleas, Aquilegia Stuarti, Primula cockburniana and the like, all in goodly batches.

The Guildford Hardy Plant Company (Mr. A. R. Upton) had a delightful lot of hardy things, alpine, rock shrubs and the like in considerable numbers. Among the more effective were Daphne Cneorum, Lychnis Lagascae, Cobweb Houseleeks, Androsace sarmentosa, Ramondias, Oxalis enneaphylla, Geum rivale and Tulipa persica.

Mr. R. Gill, Penryn, Cornwall, had a lovely lot of Rhododendron Roylei, Tricuspidaria lanceolata, Clanthus puniceus, Embotrium coccineum and similar things. The exhibit was

among the most interesting and valuable we have seen.

Sweet Peas from Mr. Breadmore, Winchester, were splendidly grown and shown, and such varieties as Helen Lewis, Etta Dyke, Miss Willmott and others merit high praise.

Messrs. Gilbert and Son, Bourne, Lincolnshire, had a pleasing lot of Anemones and Messrs. G. and A. Clark, Dover, a small rockery exhibit, together with a variety of herbaceous plants of the more showy types.

The Tulips from Messrs. Hogg and Robertson, Dublin, were really superb, many of the Darwin and gesneriana forms being in the finest possible condition and giant flowers withal.

Another delightful lot of Tulips was that from Mr. Alexander M. Wilson, East Keal Manor, Spilsby, in which the richly-coloured W. T. Ware, May Queen, Fairie Queen, Mrs. Moon, Clara Butt and Maiden's Blush were seen to perfection.

Messrs. G. Stark and Son, Great Ryburgh, Norfolk, had a pretty group of Sweet Peas, such as the Spencer form of Miss Willmott and Nell Gwynne being noted among many sorts.

Tulips in wonderful variety and in splendid form came from Alex. Dickson and Sons, Belfast. The superb colour of the Darwins and their huge sometimes fully expanded flowers presented a sumptuous feast of these things rarely seen at the end of May.

Some good Anemones were shown by Messrs. Reamsbottom and Co., Geashill, King's County, Ireland, in pink, mauve, violet, scarlet and other shades, the flowers being of remarkable size.

Sweet Peas, Violas and early-flowering Chrysanthemums, each superbly grown and displayed in great variety, came from Messrs. Dobbie and Co., Rothesay, the Chrysanthemums being as good as one might expect in August.

Messrs. Pulham and Son, 71, Newman Street, Oxford Street, London, arranged a rather bold and interesting rock garden, with waterfall and the like. This was exceedingly good and naturally disposed, and, so far as is possible in these circumstances, well planted. In the suggestive character of these arrangements there is much still to be done.

Messrs. R. H. Bath, Wisbech, staged an admirable lot of Tulips and early Gladioli. Of the Tulips, Flamingo, pale pink, and Mauve Clair were among the novelties, Miss Willmott, Edmée (deep pink), Clara Butt, &c.

Messrs. Kelway and Son, Langport, had a beautiful lot of Tree Pæonies and Pyrethrums in single and double forms, and in many delightful colours in both instances. It is a great pleasure to see the lovely exhibits from this well-known firm, and we hope shortly to write more of the Pæonies and other flowers from Langport than is possible in a report such as this.

Mr. Robert Sydenham, Birmingham, staged a delightful lot of Sweet Peas in considerable variety and the best kinds of commerce. White Spencer, Primrose Spencer, Herbert Smith (orange), with many seedlings.

Messrs. R. Wallace and Co., Colchester, in the large tent grouped many beautiful plants, as *Primula japonica* in diverse colours. *Pæonia decora alba*, *Fritillaria sarana*, *Lilium rubellum*, *Dodecatheons*, hardy *Cypripediums* in variety, *Primula sikkimensis* (very fine), *Saxifraga cotyledon pyramidalis*, *Liliums* in variety, such as *Hansonii*, *testaceum*, *monadelphum*, *szovitzianum*, *Ixias*, *Irises*, *Eremuri*, early *Gladioli*, *Habranthus pratense* (very fine), with *Irises* of the *Regelia* and allied sections made a most effective and beautiful group. Messrs. Wallace also set up a fine assortment of Tulips.

#### ORNAMENTAL SHRUBS.

Mr. L. R. Russell, Richmond, erected a very fine group of various ornamental foliaged and flowering shrubs. These were splendidly grown and contained such things as *Acers*, *Ceanothuses*, *Vitis Coignetiae*, *V. henryana*, *Osmanthus*, *Elders*, *Cytisuses*, *Hedera Helix arborea flavescens* and similar subjects.

Messrs. J. Cheal and Son's group from Crawley was a most beautiful, varied and interesting one. Clematises, Aralias, Azaleas, Vitis, Oaks, Beeches, Maples, Rhododendrons and similar subjects were all most tastefully arranged.

Messrs. R. Smith and Co., Worcester, were well maintaining their high reputation with a very fine group of Rhododendrons and other flowering and foliage shrubs. Rhododendron Pink Pearl, *Pinus Montanum*, *Kalmia glauca*, Aralias, with various Maples and conifers, made up a most imposing collection.

The immense group of Rhododendrons and ornamental foliaged shrubs staged by Messrs. John Waterer and Sons, Bagshot, Surrey, was a very pleasant sight to behold. Rhododendron Pink Pearl was largely in evidence; and we have rarely seen *Kalmia glauca* better grown.

Messrs. Thomas Cripps and Son, Limited, Tunbridge Wells, were exhibiting a comprehensive and well-arranged group of their Maples.

Messrs. William Cutbush and Son, Highgate, were, as usual, making a good display of topiary work, the Box trees and Yews cut into all sorts of fantastic shapes appealing to some people.

Messrs. Barr and Sons, Covent Garden, made a very fine display with their Japanese pigmy trees, these being exhibited in many kinds and in a great diversity of forms.

Messrs. James Carter and Co., High Holborn, made an attractive display of Japanese pigmy trees and shrubs.

#### FRUIT.

Messrs. T. Rivers and Sons, Sawbridgeworth, were exhibiting a most interesting and comprehensive collection of fruit trees in pots, Peaches, Nectarines, Cherries, Lemons and Oranges being freely represented. Nectarine Cardinal, Peaches Duke of York and Duchess of Cornwall, and Cherries Early Rivers and Frogmore were the varieties displayed. The Grape fruit in the Citrus section attracted much attention.

Messrs. George Bunyard and Co., the Royal Nurseries, Maidstone, staged a wonderful collection of Apples in their usual first-class style. These were in a really splendid state of preservation and amply demonstrated what can be done with our native fruits when properly treated. No less than 100 varieties were staged, these including many varieties that are usually in season during the late winter months. Fruiting Cherry trees were exhibited by this firm.

Messrs. Laxton Brothers of Bedford exhibited a really fine collection of Strawberries, Peaches and Figs. The former were most extensively shown, gathered fruits and also some growing on plants being well represented. Royal Sovereign was naturally well to the fore, Laxton's Epicure, Bedford Champion and Laxton's Pineapple being other fine sorts.

#### VEGETABLES.

Messrs. Watkins and Simpson, Tavistock Street, Covent Garden, staged an interesting little collection, consisting of Cauliflower Early Sixweeks, Cos Lettuce Romaine, Carrot Early Frame, Turnip Early Long White Frame and Cabbage Lettuce Early French.

The exhibit of new Potatoes staged by the well-known firm of Messrs. Sutton and Sons, Reading, was a most interesting and instructive one. The sets of these were planted on February 26th and the tubers exhibited raised on May 20th, so that growth was of a most rapid character. Many of the tubers were considerably larger than hens' eggs, and all presented a most pleasing appearance. The varieties included May Queen, Ringleader, Ninetyfold, Epicure, Windsor Castle, Reliance, Satisfaction, Superlative and Abundance. Gladiator, a white kidney, was exceptionally good.

Mr. A. J. Harwood, Colchester, staged some very fine examples of Asparagus Harwood's Superb Giant. Mr. W. Godfrey of Colchester was also exhibiting good samples of Asparagus.

Mr. Stephenson, Burwell, Cambridge, put up four good bundles of this exquisite vegetable, these being of very fine quality indeed.

#### OFFICIAL LIST OF AWARDS.

*Veitchian Cup*.—Mr. F. Mentieth Ogilvie, for Orchids. *Gold Medals*.—Messrs. J. Veitch, for foliage plants, flowers, &c.; Messrs. W. Cutbush, for Roses, Carnations and alpinies; Messrs. Sander, for Orchids and foliage plants; Messrs. Charlesworth, for Orchids; Major G. L. Holford, C.I.E., C.V.O., for Orchids; and Messrs. Hugh Low, for Orchids, Carnations, &c.

*Silver Cups*.—Messrs. Sutton and Sons, for miscellaneous; Messrs. Barr and Sons, for herbaceous plants; Messrs. Bunyard, for herbaceous plants and fruit; Messrs. J. Waterer and Sons, for Rhododendrons, &c.; Messrs. May and Sons, for Ferns, &c.; Mr. L. R. Russell, for Clematis, shrubs, &c.; Messrs. R. Smith and Co., for Clematis and herbaceous plants; Mr. C. Turner, for Roses and Azaleas; Messrs. Paul and Sons, for Roses, &c.; Messrs. Jackson and Son, for herbaceous plants; Messrs. Pulham and Son, for alpinies, &c.; Messrs. J. Cheal, for trees, shrubs and herbaceous plants; Messrs. W. Paul and Son, for Roses, &c.; Messrs. T. Cripps and Son, for Acers, &c.; Messrs. R. P. Ker, for Hippeastrums; Mr. Amos Perry, for herbaceous plants; Mr. R. G. Cuthbert, for Azaleas, &c.; Hon. V. Gibbs, for Pelargoniums and Streptocarpus; Mr. C. F. Raphael, for Carnations, &c.; Messrs. Blackmore and Langdon, for Begonias; Messrs. R. Wallace, for herbaceous plants; Sir J. Colman, for Orchids; Mr. W. James, for Carnations and Peonies; Messrs. Cypher, for Orchids, &c.; and Mr. M. Pritchard, for herbaceous plants.

*Silver-gilt Flora Medals*.—Messrs. T. S. Ware, Limited, for Begonias and Carnations; Messrs. Cannell and Sons, for Roses, Calceolarias, Camias, &c.; Messrs. Carter and Co., for flowering plants; Mr. G. Mount, for Roses; Hobbies, Limited, for Roses; Mr. G. Reuthe, for herbaceous plants, &c.; Messrs. A. Dickson, for Tulips; Messrs. J. Hill and Son, for Ferns; Mr. A. J. A. Bruce, for Sarracenias; Messrs. Armstrong and Brown, for Orchids; Mr. H. Burnett, for Carnations; Mr. A. F. Dutton, for Carnations; and Mr. R. Ashworth, for Orchids.

*Silver-gilt Knightian Medals*.—Messrs. Rivers, for fruit trees in pots; and Messrs. Laxton Brothers, for Strawberries.

*Silver-gilt Banksian Medals*.—Messrs. J. Peed, for Caladiums and Gloxinias; Messrs. Bakers, for herbaceous plants; Mr. J. R. Box, for Begonias; Craven Nursery, for alpinies; Messrs. Fromow and Sons, for trees, shrubs, &c.; and Mr. Notcutt, for herbaceous plants.

*Silver Knightian Medals*.—Thatcham Fruit Farm, for vegetables; and Mr. Stephenson, for Asparagus.

*Silver Flora Medals*.—Messrs. F. Cant and Co., for Roses; Messrs. D. Russell and Son, for trees, shrubs, &c.; Messrs. J. Laing, for Begonias, Caladiums, &c.; Mr. C. W. Breadmore, for Sweet Peas; Mr. A. R. Upton, for herbaceous plants; Messrs. Webb and Son, for Calceolarias; Messrs. B. R. Cant, for Roses; Messrs. Dobbie and Co., for Violas, &c.; Messrs. Hogg and Robertson, for Tulips; Messrs. McBean, for Orchids; Messrs. J. W. Moore, for Orchids; and Mr. E. Gill, for Rhododendrons.

*Silver Lindley Medal*.—Mr. F. Mentieth Ogilvie, for Orchids.

*Silver Banksian Medals*.—Mr. J. D. Enys, for Myosotidium; Mr. W. P. Horton, for alpinies; The King's Acree Nurseries, for herbaceous plants; Mr. A. M. Wilson, for Tulips; Messrs. W. Bull, for Orchids and foliage plants; Mr. H. Crane, for Violas; The Misses Hopkins, for alpinies, &c.; Mr. F. Lilley, for bulbous plants; Mr. G. Prince, for Roses; Messrs. Watkins and Simpson, for vegetables; Mr. R. H. Bath, for Tulips and Carnations; Mr. A. L. Gwillim, for Begonias; Mr. A. J. Harwood, for Asparagus; Mr. Jannoch, for Lilies, &c.; Mr. B. Lathams, for herbaceous plants; Mr. W. H. Page, for Carnations; and Messrs. Bell and Sheldon, for Carnations.

#### ORCHID COMMITTEE.

*First-class Certificates*.—*Odontodia Charlesworthii*, Messrs. Charlesworth; *Cypripedium ventricosum*, Messrs. W. Cutbush and Son; *Laelio-Cattleya Elva Westonbirt* var., Major Holford; *Cattleya Mendelii* His Majesty, F. Wellesley, Esq.; *Odontoglossum illustre* var. *luxuriosum*, Ch. Vuysteke, Esq.; *Lochristi*, and *Odontoglossum eximium* Queen Alexandra, Ch. Vuysteke, Esq.

*Awards of Merit*.—*Odontoglossum Lindenii*, Sir J. Colman; *Cirrhopetalum pulchrum*, Sir J. Colman; *Odontodia St. Fuscien*, M. H. Graire, Amiens; *Odontoglossum laudatum*, M. Ch. Vuysteke; *Odontoglossum crispum* Kenneth, N. Cookson, Esq.; *Odontoglossum hibernicum*, Messrs. Charlesworth; and *Cattleya Mossiae* Le Président, Messrs. Hugh Low and Co.

*Botanical Certificate*.—*Bulbophyllum vibrans*, Sir J. Colman.

*Cultural Commendation*.—*Miltonia vexillaria*, Major Holford (grower, Mr. Alexander).

#### FLORAL COMMITTEE.

*First-class certificates*.—*Dracena Donceetti* de Grootel, Messrs. Veitch; Tulip Walter T. Ware, Mr. W. T. Ware.

*Awards of Merit*.—*Azalea occidentalis graciosa*, Messrs. Cuthbert; *Begonia* Empress Marie, Messrs. Blackmore and Langdon; *Croton Fred Sander*, Messrs. Sander and Sons; *Dimorphaea aurantiaca*, Messrs. Barr; *Pæonia decora alba*, Messrs. Wallace; *Rose Elaine*, Messrs. W. Paul; *Rose Tausendschön*, Hobbies, Limited and Messrs. W. Paul; *Rose White Dorothy*, Messrs. B. Cant and Messrs. Paul and Son; Tulip Duchess of Westminster, Messrs. A. Dickson.

\*. A description of the New Plants exhibited will be given next week.

*ACER RUBRUM*, a tall-growing tree, is very fine throughout late March and early April, by reason of its small, bright red flowers, which are borne in great profusion from almost every branchlet, while a contrast is gained from *A. opulifolium*, which bears yellow flowers.

In addition to these there are numerous other out-of-the-way trees and shrubs, all of which add beauty and interest to the garden. K.

### THE MONKEY PUZZLE IN WALES.

(*ARAUCARIA IMBRICATA*.)

THIS well-known hardy tree of striking aspect, commonly known as the Monkey Puzzle, should be included in every arboretum or shrubbery. It is largely grown in the valleys of Monmouthshire, and seems to be a great favourite, as one meets with it planted in many front gardens. This is a great mistake, as it is quite unsuited for small gardens, being far too large; the branches get very much disfigured with the wind blowing them against the houses or fences, so that the tree generally has a stunted and unhealthy appearance. But planted with other choice conifers in a pinetum or park, where there is plenty of room to develop, it is really a very handsome tree, and well worth cultivating.

While in Ynyoddu some time ago I saw a noble specimen of this tree planted in front of a house, where it had plenty of room to exhibit its great beauty. It measured about 50 feet in height and was well furnished with good healthy branches from top to bottom. This tree was planted by William Thomas, one of the most famous Welsh poets, who was born in Monmouthshire in 1832 and died in 1878. J. KENNEDY.

[Unfortunately, the tree is not a success in gardens, those we have seen, with few exceptions, having lost most of their branches. It is not a tree to be recommended for general planting.—ED.]

### AN INTERESTING RHODODENDRON.

(*RHODODENDRON RHOMBICUM*.)

THE deciduous section of the Rhododendron family is usually represented in gardens by the Chinese *R. sinense*, or *Azalea mollis* as it is frequently called, or by a set of the numerous garden varieties raised from the various North American species, such as *calendulaceum*, *nudiflorum*, *occidentale* and the Caucasian *R. flavum*. There are, however, numerous other deciduous species which are well worthy of attention from the gardener, and *R. rhombicum* is one of these. It is a Japanese plant, and has been known under the name of *R. reticulatum* as well as the one which heads this note.

In habit it is looser than the better-known sorts previously mentioned, while the more or less rhomboid foliage stamps it at once as perfectly distinct. It grows quite 4 feet high and forms a spreading bush. The flowers are produced in advance of those of most deciduous Rhododendrons, being at their best during early May. They are upwards of 1½ inches across, rosy purple in colour and borne a few together from terminal buds. When planting this species care should be taken to select a position sheltered from the east, so that in the event of late spring frosts, rapid thawing after a cold night is not brought about by bright sun focussed on the plant, D.

## THE KITCHEN GARDEN

### A USEFUL SPRING VEGETABLE—CHOU DE BEDFORD.

THE choice of vegetables from October till the spring Cabbages come in is by no means large, and any addition is worth noting. Recently I saw some excellent crops of Chou de Bedford, a plant which, as its name implies, largely partakes of the Cabbage. There is also another very similar variety called Chou de Burghley, raised by the late Mr. Gilbert, and this is a delicious vegetable, but more closely allied to the Broccoli than the first named. Chou de Bedford has a white solid heart which, when cooked, is quite free of the strong flavour that some of the larger Cabbages have. It is quite distinct, and forms a valuable addition to the winter vegetables; it is also most useful for an early spring supply to precede the early Cabbages. The plant is quite hardy and does well in exposed places. For a supply at the season named seeds should be sown in September, or earlier if required in the winter. The plant thrives where the Broccoli fails, and it is a vegetable well worth the attention of the amateur on account of its easy culture and hardiness. Sown in August there will be good plants by October, and these, if planted in rows 2 feet apart and 15 inches in the row, will give good heads for spring cutting.

### A NEW KALE—CARTER'S CHOU DE RUSSIE.

IN the early spring there is a dearth of good Greens; but to a great extent the void has been filled by the introduction of Carter's Chou

de Russie, a most valuable acquisition on account of its hardiness and excellent flavour. The new variety has a dwarf habit and a strong leg or stem, with a wide or spreading head, and this is divided into smaller ones of a distinct character. The leafage is deeply cut or laciniated, and the plant produces a large number of sprouts or shoots on the stems.

After a severe trial at Wisley by the Royal Horticultural Society, over fifty stocks of Kale being grown, the new variety was considered a great advance on older sorts, and not only received an award of merit, but the highest possible award and an unusual one for a Kale—a first-class certificate. When cooked this Kale is delicious and the colour is taking, but its hardiness commends it to all growers of vegetables who want those of the best from December to May. For that purpose I would advise two sowings—one in April, and another a month or six weeks later for the spring supply—the plants to be grown on an open quarter and planted out in a small state.

### A NEW TOMATO—LYE'S EARLY GEM.

THIS excellent new Tomato is worth a special note on account of its earliness, shape, colour and good quality. It was raised by Mr. R. Lye at Sydmonton Court, Newbury, and put on the market by Messrs. Cutbush, Highgate, having received an award of merit from the Royal Horticultural Society. There are so many Tomatoes at the present day that any new variety must be specially good to gain an award, and I am sure Mr. Lye, who is such a good cultivator of vegetables, has been most fortunate in raising such a distinct Tomato possessing splendid cropping qualities. It is one of the best and most compact growers I have seen. G. WYTHES.

ONE OF THE DECIDUOUS RHODODENDRONS; *R. RHOMBICUM*.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**G**REENHOUSE AND CONSERVATORY.—The Azaleas (*A. indica*) that are potbound should be repotted at this period. A suitable soil may be made up of five parts peat and one part sand. These plants I have grown successfully in a mixture of peat and turfy loam in equal quantities, adding

1.—A VIOLET PLANT AFTER FLOWERING LIFTED READY FOR DIVIDING.

thereto coarse silver sand at the rate of about a sixth of the whole. When placed in a temperature of from 60° to 65° the repotted plants do well. Apply water carefully for a time subsequent to the repotting. What the plants like is a spraying overhead pretty frequently with clear water. Should Azaleas be attacked by thrips, place the plants where they may be fumigated with tobacco paper, &c., on two successive days. To prolong the display of other plants in flower I observe the greatest care in shading them from bright sunshine. Tiffany strained across the roof, either outside or inside the glass structure, will answer well, as this may be removed at will. Of course, a roller blind is better than any other means of shading the plants, but everyone cannot afford this. Abundant ventilation is absolutely necessary on warm days, and even at night it is a good plan to slightly open the ventilators of these structures.

**The Vegetable Garden.**—On every hand there is plenty of work to do in thinning Carrots, Parsnips, Onions, Beet, Turnips and other crops, and this should not be left undone too long, otherwise they will deteriorate. Partially thin out the more crowded seedlings, at a later date completing this important work. I find the plants respond at once to a weekly hoeing between the rows, this aëration of the soil promoting growth of a vigorous character. I make a sowing of both Cos and Cabbage Lettuces at this season to furnish main summer supplies, I

sow in prepared beds outdoors, pricking off the seedlings before they get too long and drawn. The seeds should germinate within a week, and the plants be ready for use in about nine weeks from the date of sowing. I am filling up blanks in the bed of autumn-planted Cabbage with young plants raised from seed sown in the early spring. I am also planting a special bed of these recently-raised plants to succeed the earlier batch. Brussels Sprouts raised from seed sown in early March for late September and October supplies should be planted in their permanent quarters at once. Plant the dwarf varieties in rows 2½ feet apart, and the same distance between the plants in the rows. The taller varieties should be planted in rows 3 feet asunder, and the plants 30 inches apart in the rows.

**Chrysanthemums.**—The final potting of the more forward plants that are to produce large blooms should be proceeded with forthwith. Make up a compost embracing two parts turfy loam, one part leaf-mould, half a part of well-rotted manure from a spent hot-bed and a sufficient quantity of coarse silver sand or clean road-grit to make the compost porous. This is well mixed before using. To add to the fertility of this mixture I always apply a dusting of guano, crushed charcoal and bone-meal to the heap. Use clean pots and crocks; always wash them and allow them to drain dry. All plants should have been standing outdoors for the last week or two to complete the hardening off process. I accord my plants a sheltered position until they are finally potted in their flowering pots.

**The Flower Garden.**—Pansies that have been flowering for some time past should have the spent blossoms removed if the plants are to be maintained in health. Break out the flower-stalks low down—really out of the axils of the leaves. The Pyrethrums are developing their buds and blossoms at a great pace, and for this reason they must be staked and tied before the growths become unruly. The Everlasting Peas (*Lathyrus latifolius*) are also developing their vigorous growths, and their staking should be no longer deferred. All the growths should be under control if grown in the form of a clump. If permitted to ramble over a wall, trellis-work or the stump of an old tree the effect is very pretty. In late July and August this is a beautiful plant in the hardy flower garden. The pretty Aubrietias and Arabis may be lifted and divided at this time. I am now planting my earliest batch of Dahlias, beginning with flowering quarters that are well protected. To grow these showy plants well it is a good plan to dig out holes 1 foot deep and of a similar diameter. Place a layer of well-decayed manure at the bottom, covering this with 3 inches to 4 inches of good garden soil. Arrange each plant in position, and then fill in around with good soil, firming this with the hands and finishing off neatly afterwards.

**The Fruit Garden.**—The matter of layering Strawberries must soon receive attention. For making new beds with the object of planting in August and for forcing, strong, sturdy plants should always be available. At this period it is a good plan to shorten Vine shoots that are developing bunches of Grapes. I stop the shoots at the second leaf beyond the bunch. Continue to thin out young wood on Peach trees. I am planting Tomatoes outdoors against walls and fences with a southern aspect; here they do well.

## WAYS OF INCREASING VIOLETS.

ALTHOUGH it is now getting rather late to take in hand old plants of Violets for the purpose of increasing them, it is not too late, because the weather has been so very unseasonable that work of this kind has been deferred in many gardens. Generally speaking, the month of April is the all-important period during which the plants are lifted and divided. The old plants, however, are not lifted until they have ceased flowering, and this may vary considerably, owing to the seasonal influences or to the position in which the frames, &c., have been located.

**Dividing Old Plants.**—Fig. 1 represents an old plant that has been lifted for division. Observe the character of the growth, which represents a dense mass of foliage, crowns and roots, with one or two spindly runners. Before dividing the plant it is well to consider the future of the divided pieces. Instead of dividing the old plants into individual crowns, it may be considered more advantageous to separate them into pieces representing three crowns. Treated in this fashion, the plants become more quickly established and make fine, healthy specimens that are less likely to fall a prey to red spider or disease. The division of the old plants is a comparatively simple matter, provided care be observed in the operation. By inserting the thumb and fingers well into the mass of growths and roots, the latter will in most cases part asunder quite easily. Should there be any difficulty in this matter, however, a sharp knife will soon release any offending portion. Fig. 2 portrays a piece with three crowns. Observe the sturdy character of the crowns and the vigorous nature of the roots. There is also a runner left on this divided piece for the purpose of illustrating more clearly its character; but before planting this must be detached. This method of planting three crowns is not so often followed as that of dividing the old plants into single

2.—A PORTION OF FIG. 1 REPRESENTING THREE CROWNS.

D. B. C.

3.—DIVIDED PORTIONS REPRESENTING INDIVIDUAL CROWNS, EACH WITH ROOTS ADHERING.

crowns, by means of which a greater number of fresh plants are made, and that in most gardens is the chief consideration. It may be well to remember that it is better, even in such cases, to separate from the parent plant only the stronger individual growths, retaining the weaker crowns for the purpose of planting two or three together. Fig. 3 represents two illustrations of individual crowns. These are well developed and give promise of a successful future, provided they are treated properly. It is important to remember when dividing the plants not to allow the roots to become dry before they are planted; for this reason do not expose them to the open or to the sun, but keep them under cover in the cool until they are actually planted, and this should not be delayed.

*Planting the Divided Portions.*—The Violet may be grown successfully in almost any position, provided the grower is prepared to look well after the plants throughout the summer and keep the soil and surroundings in a moist condition. Quarters in north, east and west borders will grow these plants successfully, but for choice we would rather plant where the Violets can be screened from the sun during the warmest period of the day. Violets are very susceptible to the attacks of red spider, and this must be guarded against at all costs. Red spider is much less likely to cause trouble or inconvenience when the position of the border is a cool one and the soil is maintained in moist condition. The border should be deeply dug or trenched, and plenty of good partially decayed manure incorporated at the time. Previous to the planting it is a good plan, especially in heavy soils, to fork in a good layer of leaf-mould with a light dressing of soot. This should be done carefully and the surface levelled to complete the operation. In planting allow the pieces with three crowns a space of about 18 inches in the rows, and the latter should be the same distance asunder. In the case of individual crowns a foot apart in the rows should suffice. Plant firmly, subsequently giving water should the weather be dry at the time. Throughout the summer copious applications of water must be given when the weather is hot and dry, and frequently during the same period the quarters must be hoed over, using a Dutch hoe for the purpose. As the plants are making free growth the "runners" must be removed, in this way concentrating all the energies of the roots on the development of plants with sturdy crowns. In the event of red spider infesting the plants a dusting with soot and lime will eradicate the pest, but repeat the operation until the trouble is removed.

*After Treatment of the Plants.*—They should be lifted and planted in cold frames in September, for which purpose leaves should be accumulated in order to make up beds on which the frames are to be placed. Plant in soil composed of light

loam and leaf-soil, keeping the plants well up to the glass of the frame-lights, say, within 6 inches. Plant 10 inches to 12 inches apart each way. "Runners," before referred to, are shoots that issue from the plants during the summer time, and also while the plants are in the frames. They are easily managed during the latter end of the flowering season, as they may be pegged down, when they root very readily. They may be detached subsequently and planted outdoors in similar fashion to the crowns, giving them rather less room, however. Fig. 4 represents an unrooted and a rooted "runner." Good varieties of Violets: Single—Princess of Wales, The Czar, La France and wellisiana. Doubles—Neapolitan, Marie Louise, Lady Hume Campbell and Swanley White.

#### STAKING COOKING PEAS.

THE proper staking of culinary Peas is a matter that is little understood by the ordinary amateur or beginner in gardening, and as most people have a liking for this toothsome vegetable and usually devote a portion of their garden to this subject, a few hints on staking Peas may, perhaps, be welcomed. The use of brushwood or faggots, that are more generally known as Pea "sticks" or Pea "boughs," for the purpose is probably the most popular of all the methods adopted. Yet how often one sees the stakes or sticks inserted in anything but uniform order and in such a manner that they are of little support to the plants at a crucial period. First of all the grower should consider the height of the variety to be dealt with. It would be useless to insert stakes 3 feet to 4 feet in length for Peas that grow fully 5 feet or 6 feet in height. Do not insert the stakes in upright fashion, as with an experience of boisterous wind they are sure to be blown about and get loose at their base. The only really satisfactory way is to insert the sticks in diagonal fashion on either side of the rows. The illustration gives a very good idea of how this should be done. It will be observed that the stakes cross each other about midway between the ground and the apex of each of them. By staking the Peas in this

HOW TO STAKE A ROW OF PEAS: OBSERVE THE DIAGONAL ARRANGEMENT OF THE STICKS.

fashion they (the stakes) hold each other in position; as a matter of fact, they are locked together at their head and are perfectly steady when the winds are strong and gusty; this is no mean advantage and is worth striving after. Do not insert the stakes too near to the plants or damage to the roots may ensue; observe a reasonable distance, so that the rows of plants do not fall over as they attain a height of a few inches.

#### INCREASING DOUBLE DAISIES.

THESE charming little spring-flowering plants are not grown so extensively as their merits demand, and it is greatly to be feared that they are decreasing in popularity. This is a great pity, because when properly managed they are capable of producing flowers in abundance during the spring months, and for edging or carpeting beds of taller, thin-growing plants they are excellent. The colours now obtainable range from pure white to rich bright red, and the plants are not at fastidious as to soil.

4.—RUNNERS DETACHED FROM THE OLD PLANT SHOWN IN FIG. 1; THAT ON THE RIGHT IS SLIGHTLY ROOTED.

Division of the old plants is the easiest means of propagation, and this is best done when flowering is just over. If we now lift an old plant, we shall find numerous young offsets of a vigorous character surrounding the central, somewhat worn-out mass, and it is these offsets that are to produce our plants for blooming next spring. After shaking away the soil from among the roots, it will be an easy matter to pull off the offsets so that each has a few roots attached. These must be inserted in a bed of well-dug but not too rich soil of medium texture, planting them in rows 15 inches apart, and the plants 6 inches asunder in the rows. Make the soil rather firm, as a robust, hardy growth is the thing to aim at. If possible, a showery, dull day should be selected for this operation, but, failing this, do the work one evening and well water the young plants afterwards.

If hot weather prevails, shade must be afforded until the offsets are established and water must be given at frequent intervals. If it is possible to select a site that is shaded by a fence or building during the hottest part of the day, this will be most helpful. Keep down all weeds by frequently hoeing the soil between the rows, but do not disturb it close to the plants. By the end of the autumn good vigorous plants will be available for transferring to beds or borders where they are to flower next spring. This treatment will be found far more satisfactory than retaining the old plants from year to year, and, if carried out in a proper manner, these old-fashioned plants will soon regain their former status in our gardens. Double Daisies have such an old-world air about them that it would be a pity if the love for them should dwindle. A charming variety is the tender pink-coloured Alice, which the Misses Hopkins show so well. It would be a delight to have more of such dainty double Daisies as this.

## THE TOWN GARDEN.

**BEDDING-OUT.**—Although fashion tells us that the era of the Geranium, Calceolaria, Marguerite, Lobelia and other kindred plants that are used in summer bedding has passed away never to return, experience teaches that hundreds of thousands are annually planted in the gardens of London and other cities and towns of the British Isles, and whatever one's personal predilections may be candour compels one to admit that there are no plants that will make a more gorgeous display in the small enclosure than these. The central bed filled with splendid Zonals, such as Paul Crampel, white Marguerites and brilliant yellow Calceolarias, with an edging of alternate plants of Golden Feather and blue Lobelia makes a brave display; and the long, narrow borders planted with similar plants, in different varieties as far as possible, will certainly please the popular taste if it is too pronounced for the æsthetic mind. To those who dwell in the country and have pure air and plenty of space one would unhesitatingly say raise your own stock, but to the townsman whose space is rigidly limited one would say buy the plants, for they can be procured cheaply, and the market growers produce such grand stuff that no amateur, without excellent conveniences, could possibly grow its equal. Only four weeks ago I called attention to the dangers and disadvantages of loose rich soil in summer bedding and, at the risk of being accused of needless repetition, I venture to urge the importance of the point again. Procure thrifty plants which are not overburdened with buds or blooms, but are well rooted and hard, and plant them firmly in soil in good heart, and the reward will be beautiful flowers instead of large, handsome leaves. Later on, if it is thought that improvement would follow upon a little special feeding, it can always be afforded by the use of one of the many excellent fertilisers constantly advertised in the columns of THE GARDEN.

**WINDOW-BOXES.**—The town house without its window-boxes is unfinished, and although they may bring pain and worry at times through youths and men stealing the plants and flowers, I would still urge upon every householder to furnish his window-sills with boxes and plant them with bright summer flowers now. They will involve considerable attention in watering and other details, but they will afford immense satisfaction to the owner as well as to passers-by in the street. The width of the box will necessarily vary with the width of the sill, but it should be at least a foot in depth and have plenty of holes in the bottom, and, further, should stand on treads to keep the bottom clear of the stone. Each hole ought to be covered with a large crock, and over these smaller crocks must be placed; above this place moss or the rougher portions of the compost and then put in the soil. An excellent mixture consists of three parts of loam and one part of leaf-mould, with plenty of sharp sand. In this material the chosen plants should be firmly set, and in no circumstances must they be neglected in the matter of watering, especially if the aspect is a hot one. Or if it is considered more convenient, no soil need be put in the boxes, but plants in pots dropped in and the intervening spaces filled with light soil or Cocoanut fibre refuse. The fronts of the boxes can be painted, tiled or covered with virgin cork according to taste.

**HANGING PLANTS.**—Here is another direction in which we can adorn our homes and the streets in which we dwell. Procure some strong galvanised wire baskets and line them with moss; this done, put in soil similar to that already recommended for boxes, and they are ready for their occupants. Ivy-leaved Geraniums, with a good Fuchsia in the centre, look charming and make a brave display for a long time if they are regularly watered and occasionally helped with a little liquid manure or a top-dressing of an approved fertiliser. **HORACE J. WRIGHT.**

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FLOWER GARDEN.

**B**EDDING-OUT will now require attention, and plants that have been well hardened off will now be fit to be planted in the positions allotted to them. Begin by preparing the beds and borders, and, if necessary, add manure and leaf-soil during the process of digging. Good showy masses of Zonal Pelargoniums are very effective. Begonias, Fuchsias and Heliotropes also have much to recommend them. When planted in suitable positions, Dahlias, Gladioli, Marguerites, Streptosolen Jamesoni, Plumbagoes and Cannas are also noble subjects. See in planting that the roots are made firm, and to tall plants place a stake so that it can be supported against wind and rough weather. Hide the supports as much as possible, as these are at all times unsightly.

*Half-hardy Annuals*, such as Stocks, Asters, Zinnias, Nemesis and Verbenas, should be put now into good rich soil. Thin also the annuals that were sown in the borders. These are more effective when thinned so that each plant can develop fully. Mignonette especially must have ample room, and the main branches may be disbudded if wanted for cutting. Seed may still be sown for a later display if not already done. Sow seeds at once of Wallflowers, Myosotis, Silene, Pansies and Canterbury Bells for spring flowering. Sow in well-tilled soil, and as soon as large enough prick out 6 inches to 9 inches apart on a partially-shaded border and see that they receive sufficient water in dry weather.

#### HARDY FRUIT.

*Peach Blister.*—If the leaves of Peaches and Nectarines are attacked with blister, persistently attend to picking every piece off. Disbud the shoots, removing all superfluous growth. Syringe the Peach wall every day when no rain falls; this will help to keep the trees clean and healthy. Examine Plums, Cherries and Apricots for caterpillars. Open the closed leaves, destroy every pest and syringe with XL All Quassia Extract. This if used strong enough will rapidly cause them to disappear.

#### PLANTS UNDER GLASS.

*Winter-flowering Carnations.*—If ready, these should now be put into their flowering pots. Use good loam, with a little Mushroom-bed material or dry cow manure, and some Velthea and Carnation fertiliser—about 7lb. to a barrowful of soil. If rust should appear, destroy the plants, and as a preventive syringe with sulphide of potassium, but this must be applied outside and away from paint, as it discolours it. Stand the plants in a frame for a time, after which they may be placed outside entirely, but the best plan is to stand them in frames and take the lights off, as these can be easily put on in wet weather. The successional batch will probably require flowering pots in about a fortnight's time. Give abundance of air to all Carnations flowering and about to flower and manure little and often. Shade all flowering plants during the hottest part or the day, as they quickly fade and lose their colour. **W. A. COOK.**

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*CYCLAMEN.*—Plants from seed sown in August and September will now be ready for moving on into 6-inch pots. These will be found of sufficient size to carry them through their flowering season.

Use a mixture of loam and leaf-soil in equal parts, with plenty of lime rubble and sand added. Where a heated pit with a slight hot-bed is available, this will be found a most suitable quarter for them after potting. Keep the frame rather close for a few days, afterwards admitting a free circulation of air. Shading the plants from the brightest sunshine is most essential.

*Chrysanthemums for Small Pots.*—The end of May is a good time to strike cuttings of many Chrysanthemums for growing in small pots, to fill vases and to be used in the front of conservatory and other groups. They are of little trouble, and will be found very useful when grown either as single-stemmed dwarf plants with a cluster of flowers on top, or pinched to form neat little bushes a foot or so across. Three cuttings of one variety may be struck in a small pot, and shifted when rooted into 5-inch or 6-inch pots, according to the variety, potting very firmly, and standing them in the full sun and a very light position to ensure dwarf, stocky growth.

#### THE SHRUBBERY.

*Diervillas (Weigelas)* are among the most charming shrubs at present in bloom. Too often the plants are crowded together in a way to deprive them entirely of characteristic beauty. *D. Lovysmani aurea* is conspicuous for its golden leaves, a colour retained as a rule through the summer. What is needed as regards these plants is, in planting, not crowding them together, but placing them on turf, so that every shoot with its burden of flowers has free play. They will grow almost anywhere, as well in the suburbs as in the country, but repay for careful attention in the way of good soil, annual thinning out of weakly shoots and top-dressing.

#### HARDY FRUIT.

*Raspberries.*—As a rule the spaces between the rows of Raspberry plantations become at this time infested by a superabundance of suckers, emanating from the bases of the old stools. These are not only unsightly, but tend to impoverish the fruiting canes, and should all be removed as soon as they appear above the surface. It is also advisable to reduce at this date the number of young canes which cluster round the base of the plants, as if left until after the fruit is gathered they will have appropriated much of the strength which should have gone into the few which are to bear fruit next year. When the plants in exposed situations are making weakly growths, a little artificial manure sown broadcast in showery weather will aid growth, as also will a mulch of well-decayed manure.

#### KITCHEN GARDEN.

*Salads*, such as Mustard and Cress, Lettuces and Radishes, should be sown fortnightly, according to the demand. To assist rapid germination cover the seeds, taking care to remove this as soon as the seedlings push through the ground, giving also ample supplies of water.

*Early Leeks.*—Plants from seed sown in frames early in the year will now be strong, and will need planting carefully to preserve their tender roots. Lift them with a ball and plant in trenches with a good portion of decayed manure in single rows. Allow quite 12 inches between the plants and 3 feet between the rows.

#### FLOWER GARDEN.

*Wallflowers.*—I grow Wallflowers largely for spring bedding, and raise annually some hundreds of plants. The seed is sown towards the end of May on a piece of ground which is not considered good enough for vegetables, but which answers remarkably well for Wallflowers. On this comparatively poor soil, which, I may add, is always reserved for Wallflowers, the plants do not grow very tall after being drawn from the seed drills and transplanted; but they become dwarf and bushy, and cover the ground at once when transferred to the flower beds in the latter end of October.

**T. B. FIELD.**

*Ashwellthorpe, Norwich.*

## AN ENGLISH BULB NURSERY.

A VISIT TO BARR'S.

**W**E recently had the pleasure of visiting the extensive bulb and hardy plant nurseries of Messrs. Barr and Sons, King Street, Covent Garden, which are situated at Long Ditton, Surbiton. Here Tulips, Narcissi and Hyacinths are cultivated by the acre every year, and in the spring months the display of these flowers provides an optical feast that is worth travelling far to see.

At the time of our visit the Narcissi were nearly over, yet we noted a few excellent varieties that were doing their best to prolong what has been a rather brief and none too favourable season. The famous Peter Barr was still in good form, despite the fact that the flowers had been open several weeks, thus testifying to the excellent lasting properties of this grand flower. Eileen Mitchell is a superb pure white Leedsii that is sure to be a universal favourite when it is better known. The segments are of good substance and the corona is large, both being very pure. Calpurnia and George Phillip Haydon are two large trumpet varieties that are already known to some, the former being a bicolor and the latter a self. In Isolde we have another splendid large-trumpeted variety, but of rather drooping habit. The creamy white perianth segments are somewhat twisted and the trumpet is very large and deep cream in colour. Royal Star is a pleasing flower belonging to the Eagleheartii section, the pure white star-like perianth providing it with its name. The spreading cup is fiery red and contrasts well with the white.

Coming to the Tulips we found these represented by all types, and, notwithstanding the fact that last summer and the present spring have been most unfavourable for these plants, all were in excellent health, and scarcely a blank appeared in their ranks. Double Tulips appear to be increasing in favour, and Messrs. Barr had some splendid varieties in this section. Among others we specially noticed William III., fiery scarlet self; Titian, scarlet and deep yellow, very effective in a mass; President Grant, deep rich crimson, with stiff, erect stems; Murillo, a very pretty rose pink and one of the best; Imperator Rubrorum, rich crimson, very large; Henry Witte, deep rich scarlet, edged deep yellow; Voltaire, rich deep crimson, large and of grand substance; and Salvador Rosa, a mixture of pale and deep rose pink, very fine habit and rather dwarf. Some of the early singles or bedding Tulips were over, but we were able to see some very fine things in this section. Standing out from all others was a fine mass of that magnificent variety Prince of Austria. Were we confined to one single Tulip our choice would at once fall on this. Here we have vigour, superb shape, regularity in growth and, above all, a vivid orange scarlet colour that is almost dazzling to behold. Prince of Austria should find a home in every garden. White Swan is a splendid companion to the former. It is of dwarfer habit, but the pure white flowers possess that regular shape so dear to the heart of the Tulip enthusiast. Sparkler is a fine scarlet variety of medium height and good shape and was most effective in a mass. In La Réve we have a Tulip of rather unique colouring that is difficult to describe. Crushed strawberry or soft rose with orange and chamois glow are, perhaps, as near as one can get to its colour composition. It is a grand Tulip and one that finds much favour with the ladies. Queen of the Netherlands, a large pale pink variety; Rose Luisante, bright rose, good shape; and Bruneilde, very large cup-shaped flowers, white, flushed soft yellow, were other splendid varieties among the early singles.

The Darwin Tulips are those almost globular-shaped flowers with long stems that are so

largely in evidence at the Temple Show. At the time of our visit these were just coming on, and, judging by the enormous quantities grown by Messrs. Barr, there must be a large demand for them. Their excellent lasting qualities and long stems make them splendid subjects for cutting, while the large range of colours available enables all tastes to be satisfied. The Rev. H. Ewbank is a lovely silvery heliotrope variety of large size; Ruby is a rather small but interesting ruby-coloured sort; Admiral Togo, rich crimson; Valentine, heliotrope purple, very large and tall; Von Jehring, very deep maroon, of excellent shape; Seiraad Van Flora, very large, rosy cerise and very handsome in a mass; The Bride, crushed strawberry, pinkish white edges; Rose Queen, rather small but of a most charming rose colour; William Copeland, pale heliotrope purple; Circe, rose, shaded purple, very effective in a mass; Faust, very tall, dark maroon; Anthony Roozen, rose, silvery white towards the edges; Bride of Haarlem, deep cherry red, very large; Glow, brilliant glowing vermilion; Donders, a very good-shaped flower of deep crimson hue, slightly edged white; Loveliness, superb satiny pink of splendid shape; The Sultan, very dark maroon; Zulu, almost black; Farncombe Sandars, rich coral red, white centre; and Mrs. Krelage, soft blush, silvery margins, were a few among many of the best that we noted. All the above-named sorts are good, and among them will be found colours to suit everyone.

Among the species and cottage Tulips we noted acuminata, a curious yellow and red streaked flower, the petals of which are almost thread-like; retroflexa, the graceful canary yellow species with reflexed acute petals; elegans, similar in shape to retroflexa, but deep glowing scarlet in colour; and elegans alba, of the same shape as the type but white, with a very faint edging of crimson. Both in Daffodils and Tulips we were pleased to note the great care that is taken to ensure only the best stocks being put on the market, and the healthy condition of the plants was also a subject for comment. Those of our readers who are specially interested in Tulips would find it well worth their while to visit these nurseries during the next fortnight.

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Sowing seeds in holes in walls and pockets for the same** (*Wanderer*). Although seeds will frequently grow in crevices in walls without any soil, especially if the mortar is old and crumbling, it is desirable to put a little soil in where this is possible, and the holes and cracks can be deepened by using a chisel or other sharp instrument. The soil can be made moist and pushed in with the end of a thin piece of wood, and the seeds then sown, pressing them in; some put a little wall moss on the top. If the weather be dry and the wall not exposed to much moisture when it rains syringing should be resorted to, but seeds sown in autumn do not

require this as a rule. Where pockets are placed on outside walls they are generally made of stone, and the best plan to follow is to drive a spike partly into the wall, leaving a part projecting on which a flat stone is cemented and also cemented to the wall. On this other pieces of stone are cemented so as to form a little pocket for soil. Pieces of slate are sometimes driven into the cracks to form the base of the pocket, but these are more artificial-looking and not so satisfactory.

**Sweet Peas with browned leaves** (*F. P.*).—We have carefully examined the seedlings sent, and have come to the conclusion that the leaves have been burned or scorched by some substance. What this is we cannot, of course, say. Has any artificial manure been given to the plants? Many manures if allowed to rest on the leaves would produce a similar result. Dogs, too, will often cause such mischief. The root system and also the stems appear to be quite healthy. Remove the injured leaves, and then we think new growths will soon be formed.

**Moving Pheasant's Eye Narcissi** (*M.*).—It would certainly be harmful to remove the Narcissi as soon as they have done flowering, and we advise you to wait till the leaves have died down before doing so. You speak as an alternative of waiting till the autumn, but the bulbs may be safely lifted in the month of August. The production of seed has certainly a weakening effect upon the crowns of the Lily of the Valley, and there is no objection to gathering the flowers the first season after the bed is made; indeed, it can be regarded as helpful rather than otherwise.

**Daffodil for inspection** (*T. H. D.*).—The Daffodil is a very remarkable case of fasciation or the growing together of two more stems. In the example sent four stems had evidently grown together and thus formed one broad, flattened specimen. Cases of fasciation are rather common, but we do not often see so many stems united. It is a freak of plant life that is little understood. The cause of the injury to the Peach leaves we think is due to fumigating with too strong a mixture of some insecticide, or to an application of a wash in too strong solution. Plants of *Humea elegans* growing in close proximity to Peach trees have been known to produce similar results.

**Darwin Tulips for forcing** (*Nurseryman*).—Darwin Tulips may be treated for forcing very much in the same way as the ordinary early-flowering varieties are, the main difference being that they must not be brought into heat too soon. To begin with, we would introduce the first batch about the second week in February and watch the result, then the second batch a fortnight later. If you are successful with these the first year, you might try for them a little earlier another time. They do very well in boxes or pans, but as they make a good deal of leaf they should not be planted too thickly. The following are a few good sorts which do well under glass: Rev. Ewbank, lavender; Glow, brilliant crimson; Zanzibar, deep claret; Professor Rawenhoff, fine red; Margaret, bluish; Clara Butt, pink; Laudelle, rose, with a pink edge; La Candeur, white; Harry Veitch, deep crimson; Philip de Comminet, very dark; Pride of Haarlem, rose, very large flower; and Farncombe Sandars, immense scarlet. Of these some are much more expensive than others, and the price will probably be prohibitive unless they can command a high figure as cut flowers. Of the above dozen we should advise Rev. Ewbank, Glow, Margaret, La Candeur (White Queen) and Harry Veitch as good ones to start with. Do you mean Spanish Iris in your note?

## THE GREENHOUSE.

**Achimenes and Tydas** (*T. K.*).—In Achimenes the flowers as a rule have a slender tube and a very widely-expanded mouth, usually of some shade of white, blue, purple or scarlet. Generally speaking, the flowers are but slightly if at all veined. On the other hand, the flowers of Tydas have a much stouter tube, and, though spreading, the lobes of the flower do not extend to anything like the same extent as most of the varieties of Achimenes. Tydas, too, whether the ground colour be whitish, yellow, or red, are mostly veined in a very pronounced manner. In the red flowers the veining or netting is almost black. Lastly, the small underground rhizomes of the Tydas are stouter than those of the Achimenes, and this extends to the entire plant, leaves, stems, flower-stalks, as well as the flowers themselves. There is no work as far as we are aware that deals with Gesneraceous plants alone. In such comprehensive publications as "Nicholson's Dictionary of Gardening" all the genera are in turn dealt with, and, of

course, such a work would be of great assistance to you. In the last part of the "Journal of the Royal Horticultural Society," published January, 1908, there is a paper by Colonel R. H. Beddome, F.L.S., which contains an annotated list of the genera and species of the Gesneraceous plants which have been introduced into cultivation. The price of this number is 7s. 6d. to non-Fellows. Your little seedlings would certainly be greatly benefited by being pricked off into pots or pans. There is very little risk if this is carefully done. A mixture of equal parts of loam and leaf-mould or peat and half a part of silver sand will suit them well. If the soil is passed through a sieve with a quarter of an inch mesh the operation of pricking them out will be much simplified. One thing to be noted in connexion with Gesneraceous plants in general is that the names used in gardens are very seldom followed by botanists.

**Cyclamen with crinkled leaves** (*S. L.*).—There were marked traces of thrips on the two Cyclamen leaves, and these pests are no doubt answerable for much of the trouble. At the same time, their presence would indicate that the atmosphere of the structure in which the plants had been growing was too dry, as thrips readily increase under such conditions. Probably the roots are also in a bad state, and if so the trouble would be intensified thereby. Thrips can be readily destroyed by vaporising with the XL All Vaporiser, which is the safest material for the destruction of insect pests in the greenhouse. As the flowering season of the Cyclamen is now over, your aim will be to get them ready for another season. They may now be stood in a cold frame, and care taken not to overwater them. Under this treatment they will gradually go to rest, and soon after midsummer will be ready for repotting. In doing this the corms must be shaken quite clear of the old soil, and repotted in a mixture of loam, leaf-mould and sand, with a little brick rubble. Pots 5 inches to 6 inches in diameter will be a very suitable size for the corms. After potting, they may be again returned to the frame and stood on a hard ash bottom. When potted, watering must at first be very carefully done, but it may be increased as the roots take possession of the new soil and the leaves develop. They may be allowed to remain in the frame till the end of August, by which time they should be good shapely plants. After this they are better in the greenhouse.

## FRUIT GARDEN.

**Making new range of vineries and Peach houses** (*O. Oakley*).—We think that the disposition and the amount of 4-inch piping suggested by you for heating the new range will meet the case very well; but as you are proposing to grow fruit trees in pots in the late Peach house, we should have a return pipe under the ridge. It will help to dry, and give greater circulation and buoyancy to the air in early spring in the body of the house while the trees are in bloom, thus helping materially in securing a better set of fruit. We advocate the same arrangement for the early Peach house. Means, of course, must be taken of making provision that each house may be heated separately or all together, as desired, by an ample provision of bent valves in the flow and return pipes in each division. The front wall of the range should, we think, be built on arches, so that the roots of the Vines and Peach trees may have access to an outside as well as an inside border. The permanent success of both will be much better assured in this way than would be the case if the roots were confined to an inside border. In this case you could not have your pits fixed against the front wall of the range. We suggest it would be much better to build the pits 14 feet distant and parallel with the front of the range, thus allowing space for a 10-foot border and a 4-foot walk at the back of the pits. The expense would be a little more in building a back wall to the pits, but the advantage in time to come as regards the healthy growth and fruitfulness of the Vines and Peach trees would be so great that this trifling extra expense should not be considered. The heating of the pits a little distance away from the boiler would present no difficulty; a flow and return pipe could be taken in a channel underground from the east end of the vinery.

**Peach foliage diseased** (*C. O.*).—Your tree is suffering from a bad attack of the Peach blister disease caused by a fungus named *Exoascus deformans*. The foliage

appears attenuated and thin, giving one the impression that the tree was not in robust health to start with, and, therefore, the more likely to invite an attack from this disease. Nothing can be done to save the affected foliage; indeed, it had better be picked off and burnt to prevent the further spreading of the disease, afterwards dredging the whole of the tree thickly with flowers of sulphur, leaving it on for a couple of days, when it may be syringed off, shading the tree in the meantime. The sulphur will fall on the border, as will also possibly much of the fungus; it should be cleared away as soon as it is dry along with an inch of the surface soil, substituting for it a dressing 2 inches deep of best loam and fresh horse manure in equal quantities, with a little lime and bone-dust added to encourage better growth later on. Unfortunately, this disease has a tendency to reappear every year. The only way of preventing this is by infusing greater vigour into the tree, and to do this we advise you to replant the tree early in autumn, using the best turfy loam you can find, with a liberal mixture of lime rubble and a little bone-dust; also dressing the tree in winter with "Medila," a preparation of Messrs. George Bunyard and Co., and for which they claim that it is a complete cure for this disease.

## KITCHEN GARDEN.

**Putting out Cauliflower plants** (*Mullingar*).—When your now dibbled out Cauliflower plants are strong and from 5 inches to 6 inches in height, it should be quite safe to plant them out on to a warm border, especially the Snowball. These you may plant out in rows 18 inches apart and 12 inches apart in the rows, as they do not grow to any appreciable size. Transplant with a trowel, so as to preserve all the roots, and with them as much soil as possible. Make the soil about each plant quite firm. With respect to the Michaelmas Market variety, which is, no doubt, Autumn Giant under another name, plant these out with a dibber in rows 2 feet apart, and the plants in the rows 15 inches apart. Give these deeply-dug and well-manured soil to encourage good leaf-growth and fine white heads. If the ground has been dressed with manure and that dug in a month before planting, it is best for the crop, as then it is becoming soluble. A top-dressing put on when planting is done or soon after is of much less value.

**Vegetables absorbing fumes of Vaporite** (*Reader*).—We have used Vaporite and have never been troubled with vegetables absorbing the fumes, nor do we think they are at all likely to do so; certainly it is quite harmless to consumers when used on vegetable plots.

**Diseased Celeriac** (*Forth Bridge*).—If your Celeriac plants suffered from a severe attack of maggot last year, no doubt that conducted greatly to stunted growth, yet it is evident the roots sent are affected with a fungus which not only has caused decay in the rind of the roots in places, but has speckled the flesh also. Primarily the ground seems to have been sour or fungus-infested and needs a good dressing of finely-ground lime before any other crop is grown on it. Were it the autumn we should advise a dressing of gas-lime at the rate of two bushels to three rods of ground, well spread, left for a month, then dug in. If you put out Celeriac plants this year, dust lime freely along the drills or trenches when you plant, also give occasional dustings with fresh slaked lime about the plants during the summer and autumn. All the same give a liberal dressing of manure well dug in a couple of weeks before planting.

## MISCELLANEOUS.

**White worms for inspection** (*H. Backhouse*). The white worms that you found in the soil of your garden are the grubs of a two-winged fly belonging to the genus *Thereva*. I do not know that the insect has any English name. There is not much known about these grubs, but they are said to be carnivorous, and if so they are in no way injurious to plants.—G. S. S.

**Worms for inspection** (*H. Wright*).—The creature you enclosed is one of the snake millipedes (*Julus londinensis*). These are very injurious to the roots of many, if not most, plants, and they are very difficult to destroy, as they have such hard, horny skins that no liquid insecticides applied in the ordinary way has any effect on them. If you have many in the soil, I advise you to try Vaporite, a compound which, when mixed with the soil, gives out gases which, it is said, kill all insects, millipedes, &c., which they reach.—G. S. S.

**Worms infesting Strawberries** (*Clonagh*).—The worms that you sent are nearly allied to the common earthworms and belong to the family *Enchytraeidae*. They are very injurious to the roots of plants. Thoroughly soaking the soil in which they are with lime water will kill them. I expect your Strawberries and Beans were attacked by one of the snake millipedes and not by these worms, judging by what you say. The spotted snake millipede is of a very pale colour, and may easily have been mistaken for them. If they attack your Strawberries again, send a few up and I will tell you what

they are. I should have thought Vaporite would have killed both these creatures if it had been properly mixed with the soil.—G. S. S.

**Scum in pond water** (*P. S.*).—Any application sufficiently strong to kill the scum will probably kill or injure the Lilies. The scum is virtually inseparable from the water, and during the early months of the year makes its growth. If the pond water is stagnant it will be more troublesome in this respect. If you have a supply running in you might try a system of filtration through sand or gravel, and where this is not possible you had best have recourse to a net for clearing it out.

**Turf stacked in the open** (*O. S. M.*).—How long turf that is stacked in the open will remain good depends on what it has to be used for. Generally speaking, for potting large plants it is at its best when it has been stacked from six to twelve months, as the fibre then is in a partial state of decay. During the second year it would do for smaller plants, where coarse fibre is not needed. After two years the fibre will be practically gone and the loam will then only be suitable for seed-sowing or for small seedlings.

**Using coal ashes and road scrapings** (*Antious*).—We do not advise you to use sifted coal ashes in your soil for the purpose of lightening it or loosening it in any way. Coal ashes very often do considerable harm to many crops, especially those which are grown for their roots, such as Beetroot, Carrots, Potatoes and Parsnips. You need not have the slightest fear in using road scrapings in your garden. They will do heavy soil a great deal of good, especially if you collect them from roads made up with gravel, and providing the roads do not have a great amount of motor traffic over them. Certainly they will not fill the ground with wireworms.

**Plants for June exhibition** (*Constant Reader*). It is quite impossible for us to advise you in the middle of May as to what flowers you could bring on "for exhibiting in the beginning of June," and that without a greenhouse. You say nothing as to what plants you possess or the class of exhibition you refer to. There are many things, such as Primulas and alpine Phloxes, that could be flowered well with frame protection, but these require previous thought and preparation. If you have any special exhibition in mind and will give us the particulars we will help you. The size given for the Polyanthus is good, but mere size counts for little unless the quality of the strain is good also.

**Transplanting Roses** (*W.*).—Considering that this is a very late season you could safely transplant your Roses now if the work is taken in hand at once. Of course, the summer bloom would be all the better if the plants were not disturbed, but if it is a case of necessity we say move them. It will be well to dip their roots into some thin mud before replanting, and give each plant a shovelful of some nice compost. Tread them in very firmly, but in about a week from the planting go over the bushes and set the heel against them on each side. A little water may be given if the weather is hot and dry after the plants have been moved about a week.

**Affiliated gardeners' societies** (*W. L.*).—Provincial gardeners' associations can be affiliated to the National Sweet Pea Society, to the National Chrysanthemum Society and to the Royal Horticultural Society by payment of a small fee. We advise you to write to the secretaries of the various societies for full particulars. Mr. C. H. Curtis, Adelaide Road, Brentford, is the secretary of the National Sweet Pea Society; Mr. E. A. Whitty, St. James's Villa, Swain's Lane, Highgate, N., is the secretary of the National Chrysanthemum Society; and for the Royal Horticultural Society address your letter to the secretary, Royal Horticultural Society's Hall, Vincent Square, Westminster, S.W.

**Blood as manure** (*J. E. C.*).—Animal blood is a manure that chiefly promotes leaf-growth, as it is eminently of a nitrogenous nature, and, if considerably applied, might create too much leaf-growth and soft, sappy wood rather than firm, stout wood that should bear hard pruning and wintry weather. But if you wish to use blood, do so mixed with soil, also adding to it soot freely and bone-flour to give phosphates. A soil-bag might be made, say, 2 feet across, with a soil bottom of 6 inches to 9 inches deep, to soak up the liquid, and each time blood was added cast in soot and bone-flour also, and over it a thin covering of the outer soil. When what seems to be enough liquid and artificial has been added, cast over all the ridge of outer soil and well mix the whole. Let it lie for a couple of weeks, then turn and mix again, and by that time, the soil having well absorbed the liquid, the whole should make good manure dressing for Roses. The blood may also be mixed with moss litter or any other rather dry manure.

**Using a garden frame** (*E.*).—If you have ample room to grow vegetables, you could use your small frame to raise some seeds in shallow boxes, such as Cauliflower, Cabbage, Lettuce, Endive, Celery, Mustard and Cress or Broccoli. All such seeds raised under glass quickly would give you a good supply of plants to put out in the summer for autumn and winter purposes; or you may put a small quantity of well-decayed manure into the centre of the frame in a hole, and thus with soil heaped over it making a mound, and put out into it a couple of Vegetable Marrow plants if you purchase them at once. Later, you can lift off the frame and allow the Marrows to grow freely. If you prefer flowers, it is really not too late to sow in shallow pans or boxes filled with good fine soil seeds of Stocks, Asters, Wallflowers, Auriculas, Polyanthus, Snapdragons, Pentstemons, African Marigolds or any flowers that grow quickly, and when, later, they have become strong they can be planted outdoors, where they will flower in the autumn or next spring.

# THE GARDEN.

No. 1907.—VOL. LXXII.

JUNE 6, 1908.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## NEW ORCHIDS AT THE TEMPLE SHOW.

IT is to the above-named exhibition that we look for some of the best novelties of the year and usually we are not disappointed. Besides those that receive the coveted first-class certificates or awards of merit there are always a number of interesting things that the judges do not consider worthy of such honour, but which are nevertheless interesting. This year the Orchid committee granted first-class certificates to six plants, awards of merit to seven and a botanical certificate to one. The floral committee awarded the higher honour to two specimens and awards of merit to nine. In the Orchid novelties some very beautiful flowers were to be seen.

*Odontioda Charlesworthii* is the very richest-coloured member of this bigeneric race that we have ever seen, and it was a centre of attraction during the whole time the exhibition was open. The flowers are of the characteristic size and shape, but the colour is a very rich glowing scarlet, the effect being heightened by the rich yellow blotch at the base of the rather large reflexing labellum. The plant exhibited was not a large one, but the inflorescence was composed of four fully opened flowers and two buds. Messrs. Charlesworth and Co., Bradford, exhibited this charming plant.

*Lælio-Cattleya Elva*, Westonbirt variety, shown by Major Holford, is an Orchid of a most rich and refined appearance. The sepals and petals are of a rich rosy purple hue, the latter being rather a deeper colour than the former, and also reflexed in a curious manner. It is the labellum, however, which most appeals to one. This is of the richest velvety crimson imaginable, it broad, spreading character with frilled edges making it very striking. Added to this we have a deep yellow blotch on each side of the throat.

F. Wellesley, Esq., Westfield, Woking (gardener, Mr. W. Hopkin) staged a lovely form of the popular *Cattleya Mendelii*, named *His Majesty*. The flowers of this are very large indeed, especially the petals, which are nearly 3 inches wide and beautifully recurved. The colour of these and the lanceolate sepals is pale lilac. The large, grandly-shaped labellum is white, with purple and deep yellow markings in the throat, the margins being crenated in a most pleasing manner.

*Odontoglossum eximium* Queen Alexandra is an Orchid worthy of the illustrious name that it bears. The very rich bright purple colouring is most regularly placed on a white ground, the labellum having a blotch of dull crimson conspicuously placed upon it. Added to this we have flowers of exquisite form and a plant of great vigour.

Another beautiful *Odontoglossum* was *Illustre luxuriosum*. The flowers of this are of perfect shape, the predominating colour being rich reddish purple. All the segments are daintily edged pale white. Both these plants came from

M. Ch. Vuylsteke, Loochristi. Each of the above received a first-class certificate.

In Messrs. Hugh Low and Co.'s group was *Cattleya Mossie Le President*, a very beautiful variety of a well-known Orchid. The flower is very large, the sepals being long, lanceolate and reflexed at the tips. The petals are very broad and beautifully crenated. The colour of both is a deep rosy lilac, and this colour also predominates in the labellum. The latter is very large, broad, beautifully waved at the edges, with a broad band of very rich yellow at the top of the throat. In the centre of the lip the colour is very rich velvety purple.

*Odontioda St. Fuscien*, as shown by M. Henri Graire, St. Fuscien, Amiens, is a very pretty member of the bigeneric race. The ground colour of the flowers is dull yellow, and this is almost obliterated with orange scarlet spots. The sepals and petals all have a distinct edging of crimson. The medium-sized labellum is a mixture of old rose, yellow and dull orange. The flowers are about the usual size. This plant is the result of a cross between *Cochlidia noetzeliana* and *Odontoglossum Adrianae*.

Messrs. Charlesworth and Co. of Bradford staged a very handsome *Odontoglossum* named *O. hibernicum*. The sepals and petals are of a uniform lanceolate shape with reflexed tips, the canary yellow ground colour being thickly covered with large, dull brownish crimson blotches, except at the tips, which are left pure yellow. The labellum is large, roughly heart-shaped and of a pale cream colour except at the base, which is dull crimson.

In *Odontoglossum laudatum* we have a very handsome member of this genus, the good-sized, well-formed flowers having their white ground almost covered with large, dull, purplish blotches, the markings being of a very regular order. This came from M. Ch. Vuylsteke.

*Odontoglossum crispum* Kennaeth was exhibited by Norman Cookson, Esq., Oakwood, Wylam (gardener, Mr. Chapman). It is a lovely flower, the white ground being very heavily blotched with rich orange purple. The markings, however, are none too regular. The flowers are of good shape, and are well placed on a somewhat arching stem.

*Cirrhopetalum pulchrum* was in the large group staged by Sir J. Colman, Bart. (gardener, Mr. W. P. Bound). This is a large-flowered plant of these interesting and curious Orchids, the dull cream ground colours of the curiously-shaped blossoms being very heavily besprinkled with very dull carmine blotches. The fao-like inflorescence was composed of eleven fully-developed flowers. The same exhibitor was also displaying a splendidly-grown plant of *Odontoglossum Lindenii*. This plant had a long arching inflorescence composed of rather small canary yellow flowers, the petals of which were very much crimped at the edges.

*Cypripedium ventricosum* from Messrs. William Cutbush and Son, Highgate, is a very handsome plant, most closely resembling the better-known *C. macranthum*, and the twain are natives of Siberia. The plant now under notice differs from *C. macranthum* in having shorter petals and a handsomely inflated pouch much deeper in colour.

The predominant colour tone is purplish red, varying in degree in the individual examples.

An award of merit was granted to each of the above-named plants.

*Bulbophyllum vibrans*, as staged by Sir J. Colman, Bart., is a little plant that is more curious than beautiful. It had two tiny curiously-shaped flowers of a creamy brown and spotted character, and was awarded a botanical certificate.

\* \* Owing to the demands on our space we have been compelled to hold over the descriptions of new plants honoured by the floral committee until next week.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

June 9.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1–6 p.m. Lecture at 3 p.m. Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

June 11 and 12.—Royal Horticultural Society's Exhibition of Colonial-grown Fruits and Vegetables (Fresh and Preserved), 1–6 p.m. Lecture at 3 p.m. by Mr. H. Hamel Smith on "The Cultivation of Cacao." King's Colonials' Orchestra. Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

**The Gardeners' Royal Benevolent Institution.**—Sir Frank Crisp, LL.B., J.P., has kindly sent the sum of £31 6s. 5d. in aid of the funds of the above institution, this being a proportion of the proceeds of admission fees received for opening Friar Park, Henley-on-Thames, to visitors.

**Kew Guild annual meeting and dinner.**—The annual general meeting, followed by the usual dinner, was held at the Holborn Restaurant on Monday, the 25th ult. About fifty members attended the meeting, and the proceedings were of an enthusiastic character. In the discussion on a change of policy of the Guild, the old Kewites were firmly opposed to any change. The annual report and balance sheet are of a favourable character. We are sorry to learn that Mr. Bean, the assistant curator of the Royal Gardens, has retired from the editorship of the *Journal* and that in future the committee as a whole will assume that office. Mr. W. W. Pettigrew occupied the chair at the dinner, and, in the absence of Mr. Hensley, Mr. Daydon Jackson responded to the toast of the Guild. Mr. R. Hooper Pearson proposed, in eulogistic terms, "The Chairman." The enjoyment of the evening was greatly enhanced by the splendid vocal music supplied by Miss A. Walter, Miss I. Watson and Mr. T. W. Briscoe.

**National Rose Society's arrangements for 1908.**—We have received a copy of the publication containing details of the arrangements for the coming season, together with a list of members, schedules of prizes and bye-laws and regulations. The metropolitan exhibition is to be held as usual in the Royal Botanic Gardens, Regent's Park, on Friday, July 3. The provincial show is this year to be held at Manchester, in the Royal Botanic Gardens (White City), on Tuesday, July 21, and the autumn show is fixed for Thursday, September 17, at the Royal Horticultural Society's Hall, Vincent Square. As usual the committee are offering prizes in a sumptuous manner, and we fully anticipate record displays, providing the weather proves favourable for the development of the flowers. Full particulars can be obtained by applying to the hon. secretary, Mr. E. Mawley, V.M.H., Rosebank, Berkhamsted, Herts.

**M. Abel Chatenay.**—Wandering round the Paris Salon a few days ago we had our attention arrested by a finely-executed portrait of a gentleman we have had the pleasure of

knowing for some years past. Although no name is given in the Salon catalogue, but merely the No. 864, followed by the words "Portrait de M. A. C.," it is easy to recognise the features of the well-known French horticulturist and able secretary of the National Horticultural Society of France.

**Royal Lancashire Agricultural Society.**—The annual exhibition in connexion with this flourishing society is to be held at Platt Fields, Manchester, on July 30 and 31 and August 1 and 2. We have received a copy of the schedule of the horticultural section, and notice that many valuable cash prizes are offered for groups of plants, collections of alpine and hardy perennials, stove and greenhouse plants, Ferns, Caladiums, Fuchsias, Tuberosa Begonias, Orchids, cut flowers, bouquets, Roses and Carnations. Sweet Peas are specially catered for, numerous classes with good prizes being arranged for these. Ten official large silver medals will also be at the disposal of the judges for awarding to trade exhibits. In some classes the cash prizes are supplemented by silver cups. Copies of the schedule can be obtained from Mr. Edward Bohane, Derby House, Preston.

**A Rhododendron show.**—Messrs. John Waterer's annual exhibition of Rhododendrons will be opened on Wednesday next and remain on view throughout the month.

**Herbaceous Calceolarias at Farnham Royal.**—A beautiful display of Calceolarias may be seen now in the nurseries of Messrs. James and Son, Farnham Royal, Slough. The plants are admirably grown, and the colours remarkable for the variety of shades, the pink and salmon pink tints displaying a great contrast to the spotted types. It is the pink shades that attract us most, and in the future will probably undergo further development.

**Amaryllises and Chrysanthemums at St. Petersburg.**—In an interesting letter appearing in a German contemporary from the pen of Mr. H. M. K. Kühn, head gardener at Lewaschowa, near St. Petersburg, we note the prevailing taste for English varieties of Chrysanthemums with exclusively large blooms, while the pretty varieties of single-flowered Chrysanthemums are entirely neglected with the one exception of the Imperial Gardens. In other countries these small-flowered varieties are largely employed in making funeral wreaths; but in Russia only metal wreaths are the fashion, and it is not unusual to see, especially at funerals of important persons, magnificent hearse loads with metal wreaths, on which expensive ribbons are fastened, drawn by snow white horses. The number of varieties of Chrysanthemums grown for sale is very small, although the plants are cultivated in large numbers. The principal varieties are Princess Alice de Monaco, the chief variety; then come Mme. Paolo Radaelli, W. Duckham, Souvenir de Mme. Buron, Amy Ensol (very fine as a pot plant), Souvenir de Lombez and N.C.S. Jubilee. One which is likely to become a great favourite is Dolly Glide, an English variety. One great point in this variety is that the flower is not injured by rain. Dolly Glide begins with Mme. Paolo Radaelli to flower in the middle of October, and can still be had in fine condition at the end of December. Large-flowered varieties begin to flower at St. Petersburg early in the month of August; the late flowerers not so soon. As regards Amaryllises, scarcely any were grown there previously to Messrs. Ker and Son of Liverpool showing a large group of these plants at an international exhibition held in 1899. Now there is scarcely a garden in which thousands are not grown. So far is the cultivation of these bulbs extended that flowering plants are obtainable from September onwards to the spring. In conclusion, the writer of the article remarks that large-flowered Amaryllises and Chrysanthemums are eagerly purchased, but not so those of medium quality.—OBSERVER.

## PRIZES FOR READERS. JUNE.

THE BEST EIGHTEEN OUTDOOR-GROWN FLOWERS AND GRASSES FOR CUTTING FOR ROOM DECORATION, WITH DIRECTIONS FOR THEIR SUCCESSFUL CULTIVATION.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Tuesday, June 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**"The Garden" Flower Show.**—Will you allow me as a reader of your excellent paper to add my plea to that of "F. G. S.," which appears in THE GARDEN for May 16, for a class in your forthcoming show for town gardeners? I should be very pleased for one to enter as a competitor, and I have made up my mind to send some flowers, if possible, whether we have a class to ourselves or not. I have no doubt a class limited to town gardeners will be a matter of some difficulty to arrange; but I do not think it should be impossible, and I hope, sir, that you will give our suggestions consideration and see your way clear to adopt it.—RUS IN URBE, *Parson's Green, London, S.W.*

**Anemones naturalised in grass.** The note in THE GARDEN of the 9th ult. reminds me that *Anemone blanda*, with several allied species, are easily naturalised in grass and soon sow themselves thickly, forming groups which have a beautiful effect at this season. *A. apennina* is a beautiful hardy plant for the purpose, so is *A. ranunculoides*. *A. nemorosa* fl.-pl. is also a beautiful white one. All these will do quite well. A few years ago we planted some in beds. A few roots were left over, and these were planted under Beech trees. These have formed large masses and are seeding freely in the grass. Strange to say, these were bought for the ordinary *A. apennina*, and for the first year or two they came quite true. Now, however, there are a great many more white than blue, and I fear that in a short time the blue will have vanished entirely. I do not know whether it is the soil (limestone) which has influenced the colour; it certainly suits them very well indeed. Wherever the seed is scattered there will the plants grow and increase rapidly. *A. blanda* does not increase so quickly, but is a beautiful hardy and early plant.—T. ARNOLD.

**Destroying earwigs.**—In the article on "Earwigs" in your issue of the 9th ult., your able correspondent Mr. G. S. Saunders states "That it is difficult to suggest any method for destroying this insect except by trapping,"

which is, as we all know to our cost, a very slow and uncertain one. Now, might I suggest that among your many readers, a few with ample leisure and patience to record their results, should write to me, expressing their willingness to experiment with a new preparation and also with a beetle poison which is not yet introduced, being only in the experimental stage. If they will do so, free samples will be forwarded, and I venture to think that some wonderful results will be achieved by way of destroying pests which hitherto have been considered unexterminable.—JOSEPH LYTLE, *Freshfield Road, Formby.*

**A snow scene in April.**—You will doubtless remember that about two months ago you very kindly answered several questions which I sent to you. I have thought more than once that I should like in some way or other to acknowledge your kindness. On April 25 we had a heavy snowstorm here, and when awaking in the morning the snow lay to the depth of several inches on the ground in one vast white mantle. Being an amateur photographer, the thought struck me that I would try to take a snapshot of it in our local park. I had not wandered very far before I saw a very pretty nook, in which the trees blended beautifully with the surrounding scenery. This I took, and am forwarding to you the first print I have taken from the negative. I ask you to kindly accept it as a very small acknowledgment of your kindness to me. I wish you every success with your nicely-printed and very valuable paper.—VICTOR R. RICHARDSON, *Frome, Somerset.*

**Free-flowering Daffodils.**—Your correspondents' notes in THE GARDEN of April 4 and the 9th ult. concerning free-flowering Daffodils have been specially interesting to me. I have grown Daffodils for more than twenty years, and have now a large collection. So far as my experience goes, the largest return I have ever had in flowers from a single bulb occurred two years ago. This was from a single bulb of Weardale Perfection; it was a very fine bulb when planted in 1905, and the following year I had four grand flowers. Last year I fully expected that I should have had five or more. But history repeated itself; there were only four. This year there were five. I think that this seems to point to the fact that if one wants as large an increase as possible in flowers, the plan to adopt is to take up the bulbs as soon as possible after growth for the season is over and divide them, not, however, to divide them too hard and in too greedy a way to obtain as many offsets as possible, but only to part asunder those bulbs that will readily separate and those only that have the brown covering that surrounds every thoroughly-matured bulb. One assists Nature in this way. The contest for supremacy, as it were, and the struggle for existence is less keen, and every bulb has a better chance of giving proof by itself what it can do. Until I read your correspondent's note in THE GARDEN of the 9th ult. I almost imagined that my bulb of Weardale Perfection two years ago with its four blooms held the record for free flowering among trumpet Daffodils; but I was truly amazed to read that a single bulb of Emperor threw six blooms. This is a greater return than any I have ever read of or heard of before.—(Rev.) WILLIAM W. FLEMYNG, *Coolfin, Portlaw, County Waterford.*

**The Poeticus section of Narcissus.**—Kindly allow me space to inform "Poetaster" (page 238) that Aeme is certainly an absolutely pure Poeticus and bred between

two absolutely pure Poeticus varieties. To my eye—which, I suppose, has looked on a very great many more seedling Poeticus flowers in the past twenty-five years than anyone else can have seen—there is no suggestion in the form or colour of Aeme of any influence whatever outside true Poeticus. I could show "Poetaster" a score of seedlings with precisely the same red, which is a rare tone, but, nevertheless, occurs in a certain line of Poeticus descent. As to its white, no two varieties of pure Poeticus have precisely the same white, a thing which can at once be seen by a trained eye if the flowers are set against a dead white background. Broadly speaking, the earlier Poets are less white than the later; but no two are quite alike in this respect, whether early or late.—G. H. ENGLEHEART.

**Town gardening and cats.**—With reference to your correspondent's ("F. G. S.") criticism of "The Town Garden" column, as it was, I believe, at my suggestion that you adopted it, perhaps a few words from me will not be out of place. I am sorry he thinks so little of it. I cannot agree with very much that he says. My garden is a proper town garden, about 24 feet by 18 feet, and consists of a 3 feet border round three sides and a bed 5 feet in diameter in the

cure for the ant pest, with which insect I am overrun; they run and swarm over everything and are very distasteful on the grass, &c. If, as your correspondent says, he knows something about practical gardening, he should have no difficulty in making a selection for his garden. I know very little about gardening, except what I have learnt through your paper, and I find my greatest difficulty is in deciding what I shall grow. However, a bit of what I have made a start with in my "back yard" may not be amiss; possibly I have planted some with more hope than wisdom. My soil is light, very dark in colour, and I believe, inclined to be sour (any way it smells rather disagreeable when turned over). I have used no manure of any kind. The following is the list: Lilies in variety, good; Gladiolus brechenleyensis, good; Pinks, eighteen varieties, good; Michaelmas Daisies, very good; Carnations, sixteen varieties, moderate, the birds got at them; Campanulas, very good; Phlox, moderate; Doronicums, in full bloom; Harpalium, good; Persian Ranunculus, good; Iris, in full bloom; Chrysanthemums, not yet planted; Antirrhinums, not planted yet; and some others, the names of which I do not know, having had them given to me, and in

addition the following annuals all grown from seed: Stocks, Mignonette, Cupid Sweet Peas, Nasturtiums and Canary Creeper. What do you think of my list, Mr. Editor; surely not a bad one for a back yard? I may mention also that I have had a fine show of bulbs, such as Crocuses, Scillas, Hyacinths and Daffodils. I quite agree with "F. G. S." that gardening is somewhat expensive. I hope later to let you know what success I have and also some hints for "F. G. S." as to my method of cultivating the above.—RUS IN URBE, *Parson's Green, London, S. W.*

—"F. G. S." must not assume that town or suburban gardens are found in and around London only. I have a garden, if worthy of the name, fully 16 feet square, and in a thickly-populated part of Kingston-on-Thames, where at one time cats gave me immense trouble, doing great harm. For some reason or other they have almost entirely disappeared, no doubt some sensible and not too squeamish persons having assisted this clearance of the feline race by chemical means. But to guard my small garden I put up round portions of it most accessible to cats wire netting standing 2 feet above the usual fence and in other parts fixed up two and three strands of barbed wire. Cats have ever since fought shy of my enclosure. It is folly to be tender-hearted to these pests. In so small a space I grow on the fences Ampelopsis, Clematis montana (a splendid town climber), Ivies, seedling Vines, Brambles, &c.; and in the borders hardy Ferns, Daffodils, Anriulus, Creeping Jennys or other hardy things that will give little trouble and really grow well. It is useless to plant things which in such environment refuse to grow.—A. D.

**Sycamore seedling with four cotyledons.**—An uncommon seedling Sycamore has been sent to us by Mr. A. C. Onslow, Hill House, Bembridge, Isle of Wight. Instead of the cotyledons being two in number, as is usual with the Sycamore, four distinct cotyledons have been produced. They are rather smaller than the average size for the species, but are similar in shape and character. We have never observed this multiplicity of seed leaves in the Sycamore before, though it is not an uncommon occurrence with seedlings of some plants.

SCENE IN A SOMERSET PARK ON APRIL 25.

centre. It is situated well within the four mile radius of Charing Cross, and within about five minutes' walk of the Electric Railway generating station (with its four great shafts always belching forth great volumes of smoke), a gas works and a large brewery, so "F. G. S." will recognise that it gets its share of smoke. He says people in towns do not grow Lettuces, but if he lives in London he cannot go about and use his eyes much. What about all the little allotments filled with vegetables that the railway men cultivate? In this part of London every spare bit of land is cultivated, mostly for vegetables. He must remember that it is also for those that Mr. Wright has to write and advise. If he does know of any device for keeping away cats I will shower all the gratitude I can on him if he will tell us what it is; I have heard of nothing more practical than Mr. Wright's device yet. I grow no vegetables of any kind, and the only criticism I shall make of "The Town Garden" column is that there is so few varieties given for planting. I have tried Mr. Wright's remedy for worms in grass and it is capital. I, too, have a lawn; whether my grass will prove an annual remains to be seen; I have only just raised it from seed; I have hopes that it will prove perennial. By-the-by can Mr. Wright or anyone give me a

## TREES AND SHRUBS.

THE WHITE SPANISH BROOM.  
(CYTISUS ALBUS.)

THE numerous members of the Broom family compose a very important group of flowering shrubs, as nearly every one is of a most floriferous character and very ornamental. The white Spanish Broom (*Cytisus albus*) is found wild in both Spain and Portugal, where it has as a companion the yellow Spanish Broom, a plant that is not a *Cytisus* at all, but belongs to the allied genus *Spartium*. The shrub under notice is of graceful appearance, with thin, green, twiggly branches and three-parted leaves; the latter, however, are not borne in very great profusion. The flowers are produced during April and May, and are white and small. The illustration well defines the floriferous character of the plant. A variety is in commerce called *incarnatus*; in this the wing petals are reddish in colour.

Like most of the other *Cytisuses*, this one is at its best from three to ten years of age, and although plants will live for fifteen or twenty years, it is not advisable to keep them so long, as they become leggy and unsightly. With some shrubs it would be possible to cut the branches back when they became leggy, and so obtain a new foundation, but with Brooms this is out of the question. So long as cutting back is restricted to one year old wood it answers well, but is quite a failure when applied to old wood. Seeds are borne freely, and from these very nice plants may be obtained in two years. Stopping of the shoots is essential while the plants are young, so that a good foundation is formed. When planting out it is advisable to stake each plant, as the roots are usually out of proportion to the head and will not keep the plant firm until established. The plant thrives in almost any kind of soil.

W. D.

AN UNCOMMON SHRUB FOR  
FORCING.

(XANTHOCERAS SORBIFOLIA.)

WE have within the last few years seen many subjects forced into bloom whose adaptability to

that mode of treatment had not previously been considered. One of these (*Xanthoceras sorbifolia*) bids fair to become ere long very popular for the purpose, as it readily lends itself to this mode of treatment, flowers freely, and is not only decidedly showy but also quite distinct from its associates. The *Xanthoceras* (a native of Eastern Asia) is a sturdy growing shrub or tree with stout ascending branches, clothed with pinnate leaves of a bright glossy green tint. These leaves consist of seven to nine leaflets with serrated margins, bearing in general appearance a certain resemblance to those of the *Sorbus*, hence its specific name. The flowers, which make their appearance simultaneously with the leaves, are densely packed in shortish racemes, produced from the terminal buds of the preceding year's growth. Individually the flowers are about an inch in diameter, and are white with a coppery red centre, caused by the base of the petals being of that hue. In the open ground it is perfectly hardy as far as the winter's frost is concerned, but the young unfolding leaves and blossoms are quickly injured by harsh winds. For this reason its spring display out of doors is often a meagre one. Under glass, however, where the blossoms open well, it is very effective.

H. P.

## A BEAUTIFUL TREE.

(PYRUS FLORIBUNDA ATROSANGUINEA.)

Few flowering trees or shrubs can excel the well-known *Pyrus floribunda* for its wealth of bloom and beautiful appearance in the spring season of the year. At the same time, it is somewhat surprising that the excellent variety *atrosanguinea* should be very little known, as it possesses all the good qualities of the type, with a much more striking colour. The unexpanded buds are very showy, being so richly coloured, and when fully open are well described by the varietal name. This *Pyrus* is a fast grower when well established and soon forms itself into a handsome, small tree, well suited for a prominent position in the shrubbery, or, better still, in an open position on the lawn, where its long, pendulous branches have ample room to expand and reveal their natural grace. I do not know whether it is general, but the habit of the variety is naturally more pendulous with us than is the case with *Pyrus floribunda*.

A. E. THATCHER.

## THE FLOWER GARDEN

## WORK AMONG THE SWEET PEAS.

ON page 165 the treatment of the young plants up to the time of permanent staking was dealt with. The plants will by now have almost reached the tops of the short twiggly sticks that were placed in position to afford them temporary support, and it will be necessary to at once see about the permanent supports. What these shall consist of will depend, to a great extent, upon circumstances. Personally, I prefer good bushy sticks, but these are not always available. They are, however, more easily obtained in towns now than they were a few years ago, most seed or corn merchants stocking them.

It will be necessary in preparing the sticks to remove any branches that radiate at an awkward angle, and also to cut them so that they are as straight as possible. This, with the sharpening of the thick end and removing straggling tips will be all the preparation necessary. The length or height of the sticks must of course be taken into consideration. Six feet is a good average height; in many gardens the plants never grow so tall, and in others they grow much higher. The insertion of the sticks will need some care. Where the plants are grown in rows, the best way is to place the sticks about 3 inches away from the plants on either side, the distance apart of the sticks varying according to their width. Crowding must, however, be avoided. A point where amateurs often go wrong is in sloping the sticks so that the tops form a sort of ridge. The appearance for the time being is neat, but when the plants reach the top they have but little area of supports to cling to, and, consequently, suffer much from strong winds. The double row of sticks, when properly inserted, should be as wide at the top as at the base. Where clumps are concerned some growers prefer to place the sticks inside the circle of plants, but there is not any advantage in this. If placed outside, the plants quickly grow through the supports and cover them. Where a large stick of symmetrical form, such as a young Birch tree, can be obtained, this may be pushed into the middle of the circle and

allowed to form the sole support for the clump. The effect thus obtained is very pretty. Failing sticks, wire netting of large mesh (4-inch) makes an excellent substitute, and will last for years. It should be securely fixed to stout stakes firmly driven into the ground.

With the advent of hot weather will come the question of mulching, and where fine flowers are desired over a long period this is almost essential, especially if the soil is of rather a light nature. What the mulching shall consist of is a question that may be asked by some. Personally, I prefer rather long stable manure that has fermented well. This is excellent for preserving moisture and gradually yields up a small amount of food for the plants. Dwellers in towns will frequently find this difficult to obtain, and, as a substitute, Wakeley's Hop Manure is excellent. If it is mixed with an equal amount of soil and placed 2 inches or 3 inches thick along each side of the row it will be found to preserve the moisture and at the same time supply valuable food to the plants. Mulching of any kind should not be put on until the soil has had time to get thoroughly warmed by the sun, and it should be applied soon after a good soaking of rain, then heat and

THE WHITE SPANISH BROOM (CYTISUS ALBUS) AT KEW.

moisture will both be conserved. Feeding is another point that will soon need attention. Many good growers never feed at all, but rely upon thorough preparation and manuring of the soil to supply all the food the plants require. Where such work was properly done little feeding will be required, but should the plants appear to need extra help much good may be done by applying superphosphate at the rate of 1oz. to each yard run of row. This may be given just when the buds begin to appear. When a few flowers are open an excellent manure is made up of two parts superphosphate, one part sulphate of ammonia and one part nitrate of potash (saltpetre), using this mixture at the rate of 1oz. to each yard run of row. Weak soot water or weak liquid manure made from cow manure are both excellent. The artificial manures advised above may be applied in solution if desired, using half an ounce to a gallon of water. Where applied in a dry state they should be well watered in. Liquid manure must not be given when the soil is dry; water well with clear water, then apply the liquid manure a few hours afterwards.

Those flowers that have orange in their colour composition will need shading from the direct rays of the sun; tiffany blinds on rollers fixed over a wooden framework are the best, but anything that will afford shade without unduly excluding light will answer.

Green fly is sure to appear, and this pest must be promptly checked by syringing the plants with a solution of soft soap and quassia solution, or any of the excellent insecticides now advertised. Spot is a fungoid disease that causes much trouble in wet seasons; as soon as seen the plants must be sprayed with Bordeaux mixture or a solution of potassium sulphide (liver of sulphur), half an ounce to a gallon of water, repeating the operation if necessary. H.

#### AURICULA MILDRED JAY.

ONE of the most shapely alpine Auriculas we have seen; the blossoms, too, are of the largest size, of perfect outline and the colour shading well defined. The predominant colour is purple to a bluish shade, with well-formed cream-coloured centre. It was exhibited by the famous Auricula specialist, Mr. James Douglas, Great Bookham, Surrey, before the Royal Horticultural Society on the 12th ult., when it received an award of merit.

#### HISTORY OF THE PRIMROSE, COWSLIP AND AURICULA.

(Continued from page 251.)

##### THE AURICULA.

THOUGH comparatively not an old garden plant, the Auricula ranks among the most important

It became not only highly esteemed among florists, but gardeners cultivated it with great care. It may at once be said that the early Auricula had little in common with the plant of to-day, but it is one of the few things in the history of gardening concerning which no doubt exists that from the first it was cultivated with the greatest care, with also progress towards the perfect flower of the florist. Gerarde's Auriculas may be passed over, but when we arrive at the time of Parkinson (1629) there was a great variety of these "outlandish" flowers, which he tells us "encrease much

many florists being active—Bobart and Austen of Oxford, "Mistris Buggs" of London, Rickets of Hogsden and a dozen others whom Rea names. The varieties were now named, such as The Fair Virgin, The Matron, The Alderman, The Cow, The Red Bull and The Black Imperial. Two striped sorts are mentioned, a class which afterwards obtained great popularity. Rea, it may be mentioned, noted details of the method of cultivation pursued at that time, and alludes to the fact that the best sorts were set in pots. By 1683, when Gilbert's Vade Mecum appeared, the

striped varieties had largely increased, and to them was added a new section—that of doubles, which, as well as self coloured, were produced too in striped varieties, which, judging by the prices quoted (£4 to £5 each) were considered the cream.

Gilbert falls into rhyme over the Auricula, as follows: See how the Bear's ears in their several Dresses, (That yet no Poet's Pen too high expresses.) Each Head adorned with such rich attire Which Poole and Clowns may slight, whilst skill'd admire Their Gold, their Purples, Scarlets Crimson dies, Their dark and lighter hair'd Diversities. With all their pretty shades and Ornaments Their parti-colour'd Coats and pleasing Scents. Gold laid on Scarlet, Silver on the blue With sparkling Eyes to take the Eyes of you. Mixt Colours, many more to please that sense, Other with rich and great magnificence; In double Ruffs with Gold and Silver laced, On purple crimson, and so neatly placed, Ransack Flora's Wardrobes, none can bring, More taking Ornaments t' adorn the Spring.

Bradley, writing on the Auricula in 1717, remarks that a few years previously he had "known a root sold for 20 guineas, but that was indeed when they first began to appear in our climates," from which it may be inferred that a new strain had been introduced, probably from Holland. Bradley, moreover, is the first writer to give the "excellencies" of a good flower. "A good Auricula ought to have the following excellencies: First, that the flower-stem be strong and substantial; secondly, the footstalk of the flower must be short and capable of supporting the blossom upright; thirdly, that the Pipe or neck of each Flower be short; fourthly, that the Flowers be large and of a regular form; fifth, their colour should be bright and well mixt; sixthly, that the eye be large, round and

of a good white; and, lastly, that the flowers spread themselves flat and be no way inclinable to cup."

The above is repeated almost word for word in "Miller's Gardeners' and Florists' Dictionary" of 1724, while in that of 1733 it is noted additionally that "the Tube of the Neck be not too wide." It was at the latter date, according to Justice, a Scottish amateur, that the Auricula originated. Maddock in 1792 dates from about

A NEW ALPINE AURICULA: MILDRED JAY. (Natural size.)

delight in all sorts of the Gentry of the Land." The flowers at this time were all selfs, some with white centres, others with yellow, but as figured none of merit. Some of the colours mentioned are purple, blood red, violet, scarlet, rose, yellow, bluish and the inevitable green. At this time Tradescant and Master Tuggie of Westminster were the leading Auricula growers. The period between this and the date when Rea's book appeared was fruitful in good gardening work—

A FREE-FLOWERING ROCK PLANT: HUTCHINSIA ALPINA.

fifty years previously, while in a "Monthly Calendar" (1738), it is stated that "Plain flowers brought from Holland were sold for a great price." There is no reason to doubt that from one of these the seed was obtained which produced the plant from which the succeeding florists' varieties were raised. In 1738, however, the striped forms were still pre-eminent. They were "richly cover'd with a dusty meal"; perhaps Thomson's "Auriculas enrich'd with shining meal o'er all their velvet leaves." These were called "Painted Ladies," and later the stage Auricula was designated variegated to distinguish it from the self or "plain Auricula."

## GARDEN OR OLD AURICULAS.

The statement in "Hill's Eden" (1757) that the cultivated forms originated from a purple variety of the yellow-flowered *Primula Auricula* cannot, therefore, be entertained. Probably that versatile person was thinking of what we now term the alpine Auricula, for he remarks: "Their colour is a deep but glowing purple and the eye is yellow." From about the year 1740 to 1790 there is a break in the history of the flower, but at the latter date it had developed varieties which were still in cultivation at a recent period. Coloured illustrations of such varieties occur in Curtis's *Botanical Magazine*, Maddock's "Florists' Directory," and in "The Temple of Flora." Maddock's properties of the Auricula and Polyanthus form the basis of later standards of these flowers, and to him we are indebted for one of the technical words used to designate the umbel of flowers—a "truss." "Bunch" is a term previously in use, and this author uses both. Truss has survived and bunch is, perhaps, never used. Truss is obviously a colloquial corruption of thyrsis or thyrsus.

During the first half of the nineteenth century Auriculas were popular not only with florists but also with gardeners. Here and there, too, throughout the country, collections were kept together by some humble enthusiasts whose love for the flower was not eclipsed by the introduction of gayer flowers into our gardens, but Yorkshire, where a collection of Auriculas was called a "stud," and Lancashire were the chief homes of the plant.

Flower societies, which, by the way, can be traced back to the seventeenth century, main-

tained a spirit of rivalry and were important aids in keeping up the standard of flower form.

In Lancashire the Auricula went by the name of Baziers (Bear's Ears), and one of the songs

sang by Mayers in the end of April had as a refrain the line "The Baziers are sweet in the morning of May." It may be interesting to repeat here a list of twelve varieties given in 1833.

These are: *Green edged*—Booth's Freedom, Stretche's Alexander and Howard's Lord Nelson. *Grey edged*—Waterhouse's Conqueror of Europe, Grime's Privateer and Kenyon's Ringleader. *White edged*—Hughes's Pillar of Beauty, Lee's Bright Venus and Taylor's Glory. *Selfs*—Grime's Flora's Flag, Redman's Metropolitan and Schole's Ned Lud. Most of these are named in a larger selection given a decade later, when Page's Champion, Oliver's Lovely Ann, Syke's Complete and Metcalfe's Lancashire Hero are also named. Alpines, though perhaps always in cultivation, were not grown by florists until about thirty years ago.

The old florists were partial to a rich compost, some using as much as two-thirds of cow manure to one-third of soil; others dispensed with soil altogether. Night soil, sugar boiler's refuse, blood and Willow earth are other materials used, but it is fair to say that those of a manurial nature were completely decomposed, and, indeed, reduced to soil before they were used. Hogg of Paddington was perhaps the first to employ a simple compost, and this was improved upon by Dr. Horner of Hull, father of the Rev. Francis Horner, who used one of two parts loam, one of decayed cow manure with the addition of a little sand.

R. P. BROTHERSTON.

(To be continued.)

## NARCISSUS BARCAROLLE.

AMONG the many fine varieties of *Narcissus Poeticus* there is probably none finer than Barcarolle. The flower is well rounded and the eye is margined with red. Having grown this variety, I can say that it is of remarkably vigorous habit and quick to increase, so it will, no doubt, soon take a prominent place among *Narcissi*. Mr. Chapman of Rye holds the stock. W. A. WATTS.

## HUTCHINSIA ALPINA.

THIS delightful alpine was one of those mentioned in the prize essay "How to Make a Small Rock Garden," and therefore this brief description may be of interest. The plant was named after Miss Hutchins, a distinguished botanist. It grows to a height of from 4 inches to 6 inches altogether, and the flowers are in clusters on a stalk about 2 inches long. The season of flowering is from March to June, and when grown in large pieces in suitable soil and position it makes a magnificent display during these months. H. BUCKTON.

## COLOURED PLATE.

PLATE 1349.

## SINGLE AND DOUBLE VIOLETS.

**O**F recent years, through the introduction of the large-flowered single Violet, the love for this beautiful and fragrant flower has deepened greatly, and it is not unusual at the leading exhibitions to find delightful exhibits which, I am sure, have helped towards popularising the plant. At one time California, a large single flower of deep blue colouring, was largely grown; but all the single sorts have been superseded by Princess of Wales, which is in many gardens, except for a few double sorts, the only Violet accounted worthy of attention. These notes are appropriate, as a beginning may be made at this season. The way to obtain a plentiful supply of flowers is to select strong, healthy single crowns at this time, and plant them 1 foot apart on ground which has been liberally manured and deeply dug. Trench it in winter, giving at the same time any manure that may be available, or fresh manure will suffice. In March give a further dressing of short, decomposed hot-bed manure, forking it in. Early in April rake over the ground and set out the plants, pressing the roots firmly in the soil. Keep them free from weeds and runners, and, if the season is dry, mulch between the plants with any old potting soil. Old Mushroom beds broken up fine and spread evenly between the plants provide excellent material. This saves watering and encourages growth. The Czar variety grown in this way and planted at the end of September in a sheltered position at the foot of a wall or warm hedge will flower all the winter. Marie Louise, Princess of Wales, or any other variety, double or single, grown thus, and either potted up in September or planted in frames, will flower throughout the winter, the blooms produced under glass being clearer and finer than those from outside. The Russian varieties are frequently, however, very fine in sheltered borders. Plants under glass—that is, in cold frames—will need little water in winter, and they must be near the glass. Remove the lights in warm, dry weather, as anything like coddling treatment is fatal to success, and pick off dead or decaying leaves. With regard to Violet growing in the open air, it is a good plan to leave a bed or two undisturbed the second season, because this produces a wealth of flowers, but after the second year Violets deteriorate unless they have a change of soil. Red spider is troublesome in hot years, but mulching and an occasional soaking of water will generally vanquish the pest. Much has been written recently on the growing of Violets in THE GARDEN, and the prize essay I read with interest and profit. The variety Princess of Wales is the most valuable to me. VIOLET GROWER.

[The varieties represented in the plate are Baron Rothschild, single purple; Mrs. J. J. Astor, pinkish mauve; Comte Brazza, white; Lady Hume Campbell, mauve; Marie Louise, pale purple; Neapolitan, pale mauve, and the flowers were kindly sent by Mr. Weeks of Bodmin; they show excellent culture.—ED.]

## THE ROSE GARDEN.

## SEASONABLE WORK AMONG THE ROSES.

**I** DO not remember seeing the growth in a better condition for the time of year. The shoots must be carefully thinned now, so that the best we retain may have the main support from the roots. It is a great mistake to encourage a lot of very small spray growth on the what may be termed better-class Roses. Of course, on ramblers and the old-fashioned summer Roses this is not so material, but even with Roses of the Camoens type they are inclined to produce a superabundance of growth, so that a moderate thinning of the shoots from the centres of the plants

been heavily manured with farmyard manure this will not be necessary. A good general manure can be prepared as follows: Three parts superphosphate of lime, one part sulphate of potash and one part nitrate of soda. Apply about 4oz. to each square yard of surface. In country districts, where it is possible to obtain night soil and sewage, this is a splendid stimulant to well-established Roses. Draw drills between the plants and pour on the manure in a fairly diluted form, then cover in the drills, and the rains will take down the nutriment to the plants. The drainings from a heap of cow manure, with some soot added, is a splendid fertiliser, and to vigorous plants this may be applied, diluted with an equal quantity of water, once a week, until the buds show colour.

The hoe should be kept busy among the Roses now. Where the surface soil is fairly loose the push hoe is the best tool, then we do not tread on the soil. A good tilth to our Rose beds is the best cultivation we can give them now. Do not wait for weeds to come. Keep the hoe going frequently.

Wild suckers must be suppressed as soon as they appear. As a rule they are easily distinguished, especially the wild Briar, but the Manetti stock is not so readily identified. It has a pale grass green foliage and reddish wood and prickles. Sometimes these suckers predominate on a plant, and if not cut away will kill it.

The flowering dates of various Roses should be noted with a view to future use in the arrangement. This is very useful where ramblers are planted, as we might frequently so arrange their positions that they will harmonise the better for it.

Potting compost should be prepared for repotting Tea and other forced Roses as soon as the second crop of bloom has finished. The best soil is three parts good fibrous loam, one part well-rotted manure, preferably one year old, and about a 6-inch potful of bone-meal to each barrowful of compost. Throw this well up in an airy rain-proof shed in readiness for the repotting. After the repotting the plants are grown on for a time in the greenhouse, keeping them well syringed, and in July they may be plunged outdoors in a sunny position. P.

## ROSE MRS. EDWARD MAWLEY IN AUSTRALIA.

This lovely Rose is a great favourite in Australia and very often secures the much-coveted award of "best Rose in the show," especially in the Victorian associations. The bloom illustrated was grown by Dr. A. W. Marwood of Geelong, Victoria, and was one of the champions of 1907. Perhaps it will be information to some readers to know that all our Roses are grown in the open, and a glance at the form of this specimen, which is characteristic of a champion twelve or twenty-four, will, I think, prove that Roses thrive well in Australia. The Teas and Hybrid Teas do well in Victoria, and the growth of the bushes would, I think, surprise some of the English growers.

The Hybrid Perpetuals, I understand, thrive better in England, but I am looking forward with great interest to see the champions at your forthcoming shows and to judge how they compare with ours.

HOWARD HITCHCOCK.  
Geelong, Victoria, Australia.

ROSE MRS. EDWARD MAWLEY AS GROWN IN AUSTRALIA.

becomes advisable. This, of course, may be done by simply rubbing them off. Often three or four small growths cluster together. Thin these down to one growth.

Plants may be considerably aided now if the hard growths are slightly bent outward where such plants have a tendency to grow too upright. This applies more to old bushes and standards than to those recently planted, but where, even in old plants, the old wood has been severely discarded no trouble will arise on this score. Soft sucker-like shoots springing from the base of the plants should have their points pinched out. They are robbers and practically useless in producing bloom this year, but if pinched the growth hardens and comes in useful another season. A sprinkling of some good reliable artificial manure may be applied now, hoeing it in immediately. Where Roses have

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**ORCHIDS.**—Periodically I look over my plants to remove spent blossoms before they begin to overtax them. For some time past I have been repotting *Odontoglossums* that needed this attention. There are still some plants, however, that need repotting, and this I propose to do without delay. *Odontoglossums* do well in small pots that are half filled with crocks. The remaining half of these small pots I fill with a compost made up of two-thirds peat and one-third sphagnum moss, with some charcoal and sand. It is important to remember to keep the plants raised above the surface and to finish off with a layer of nice fresh live moss. These plants must be watered liberally throughout the summer, taking care, however, to use only rain water, but not rain water from glass houses where the roofs have been limewashed for shading purposes.

**Lawns.**—The warmer weather of late has made it imperative to give close attention to newly-turfed lawns. It is my rule to give an occasional soaking with water. The evening is an excellent time to apply the water, as the grass has the whole of the night and early morning to take advantage of it. Plantains and Dandelions are an eyesore. I get rid of them by cutting them off well into the soil and by subsequently placing a small quantity of salt on the stump left in the ground. Daisies are less troublesome, unless they are very numerous. Individual roots may be removed with a stout old knife. Lawn sand may be used with great advantage. If applied at the rate of 4oz. to the square yard the Daisies may be got rid of, but it may be necessary to give repeated doses.

**The Window Garden.**—The fresh, pale green fronds of Ferns in the window should be shaded

1.—A POT OF SEEDLING AURICULAS. THESE ARE VERY SMALL AT FIRST, BUT GROW QUICKLY.

from the direct rays of the sun. Fuchsias that may be regarded as ideal plants for the window prefer partial shade. As they commence to flower the well-rooted plants derive considerable benefit from periodical applications of weak manure water. Once a week is often enough, however. Several of the more interesting species of Cacti are coming into flower and others are giving the promise of flowering in the near future. These plants prefer a window in a sunny aspect while in blossom. After flowering I stand the plants outdoors in the sun to ripen the growths. Arum Lilies, Heaths, Azaleas and Genistas that are so highly valued in the spring and early summer are placed outdoors in a warm position. The Arum Lilies I plant in the open in a sunny quarter, and the other plants are stood on a bed of sifted ashes.

**The Flower Garden.**—Hyacinths and Tulips should be lifted from the beds and borders when the latter have finished flowering, in this way making room for other subjects. That good use may be made of the bulbs another season I lay them out in the sun for a few hours to dry. When quite dry they are placed in boxes and stored in some cool place until the planting season in the autumn. These same beds may be planted with some of the choicer and more tender subjects, such as the tuberous-rooted *Begonias*, *Heliotropes*, *Fuchsias*, *Cannas*, *Celosias* and *Zonal Pelargoniums* (*Geraniums*), besides many other bright though short-lived plants of a tender kind. To maintain the Pansies in good health I am removing spent blossoms and seed-pods. By these means the flowering period is extended and the blossoming of the plants made continuous. Wallflowers and Brompton Stocks to flower next spring I am sowing now on a warm border outdoors. Flowering plants that should be raised from seed on a shady border are the *Polyanthus*, *Primrose* and the *Hollyhock*. Plant *Dahlias* forthwith, giving each plant plenty of room, digging out a good hole first and filling this with prepared soil.

**The Vegetable Garden.**—The more forward *Cos Lettuce* need attention; the plants should be tied up forthwith. For successional supplies make another sowing. French Beans may be sown outdoors. Sow the seeds 2 inches deep in single rows 18 inches apart. I am just planting my first batch of Leeks in specially-prepared

trenches. They may be grown very successfully, however, in any good, rich soil, if planted 9 inches apart in rows 15 inches asunder. The hoe must be kept busy at this period, otherwise the weeds will soon get the upper hand. I am planting an early batch of Brussels Sprouts, leaving a distance between the plants of about 2 feet and 3 feet between the rows. Make a good hole for each plant and press the soil firmly to the roots by the aid of a good dibber. These plants should provide supplies in the autumn. For late summer and autumn supplies a sowing of Turnips should now be made. This crop matures in from eight to ten weeks. D. B. C.

## BORDER AURICULAS.

The culture of these plants is comparatively easy. They are equally suitable for the town and suburban or the country garden. Years ago they were more popular than at present, especially among the working classes in the North. In smoke-laden districts, in the shade of factory chimneys, the Auricula enthusiast who had no garden grew them on the window-sills in pots or boxes. The Auriculas are divided into two sections, the show and the alpine. It is to the latter section the border Auriculas belong; they differ from the former in having no meal or paste-like substance surrounding the tube in the centre of the flower. As this comes away on

3.—AN OLD PLANT AFTER FLOWERING. NOTE THE NUMEROUS OFFSETS.

the finger when touched, it shows at once that the show varieties are not suitable for culture in the open air.

The border Auricula is perfectly hardy; in fact, it thrives better in cold localities than in warm ones, the moist climate of the North of England and Scotland suiting the plant admirably. When planting border Auriculas avoid giving them a dry, sunny position. A north border sheltered by a fence or wall, but not shaded by trees, is very suitable. The ideal place for the border Auricula is in the rock garden fairly low down, thus securing a moist position and sheltered from the heat of the sun. In such a position they will grow and increase for several years without being

2.—A SEEDLING AURICULA TWELVE MONTHS OLD.

4.—OFFSETS TAKEN FROM FIG. 3, EACH HAVING SOME GOOD ROOTS.

disturbed. They are also very pretty grown in clumps or groups along the mixed border, or in the case of the commoner sorts as an edging to beds and borders.

#### SOIL.

Although Auriculas will grow in ordinary garden soil, they prefer a fairly heavy loamy compost. If the natural soil is light and sandy, it will pay to remove a few spadefuls and replace with heavy, almost clayey soil, thoroughly stirring it with that already in the garden.

#### PROPAGATION BY OFFSETS OR DIVISION.

Young shoots are produced freely round the base of most border Auriculas. Propagation is best done after the plants have flowered or in early autumn. The illustrations of a clump lifted for division (Fig. 3) and the offsets severed apart ready for replanting (Fig. 4) should convey to the beginner a good idea of how to proceed. Unless a larger stock of Auriculas is required, the plants should not be disturbed for several years. Cleaning the plants in early spring and top-dressing with loam and a little well-decayed manure (cow manure for preference) is all that is necessary. Having divided the clumps, plant them where they are to flower, or, failing this, they may be grown on a border shaded from the midday sun. Small offsets with few or no roots should be dibbled in pots or boxes of sandy soil and placed in the garden frame for a time.

#### SEED SOWING.

Raising Auriculas from seeds is very interesting work if the seeds are obtained from a reliable source or saved from good flowers in one's own garden. The seed ripens about the end of June or during July. It may be sown forthwith, or kept till the following spring. Sow thinly in well-drained pots or pans of light sandy soil, placing a layer of finely-sifted compost on the surface. Place in the garden frame or on the shelf in a cool greenhouse. Cover with a pane of glass and sheet of paper till the seedlings begin to appear, and at all times see that the soil does not become dry. Fig. 1 illustrates a pot of seedling Auriculas almost ready for pricking off in shallow pans or boxes. As the seeds germinate very irregularly do not throw the seed-pans away as soon as the first batch is pricked off, but return them to the house or frame, and others will most likely germinate in due course. Fig. 2 is a seedling plant one year old. Small beds of border Auriculas similar to the one illustrated in Fig. 5 are very effective in May. Anyone desirous of starting a collection of named varieties should try the following sorts: Celtic King, lemon yellow; Dean Hole, maroon-crimson; Firefly, crimson, darker shadings; Mrs. H. Turner, purple;

Mrs. P. Campbell, red; Queen Alexandra, yellow; Queen of the East, rosy red; and Uranie, red, paler shading.

#### MULCHES AND MULCHING.

THERE is no other operation in connexion with gardening that is capable of doing so much good or harm, according to whether it is rightly or wrongly carried out, as mulching, yet it is an operation that the beginner is apt to regard with a certain amount of awe, hence a little explanation as to its uses and misuses may be of assistance. In the first place we may with benefit consider what is a mulch. In garden phraseology a mulch simply means a top-dressing of some material applied with one or two ends in view. Often a mulch is given to prevent rapid evaporation of moisture from the soil, or it may be used solely as a means of supplying food to the plants, but usually it is intended to serve the double function. Mulching is also resorted to in a few instances for the protection of plants from severe frost in the winter months.

Naturally the character of the mulch will depend upon the duties it is expected to fulfil. Where it is solely intended for the preservation of moisture in the soil during hot weather it may well consist of short straw, lawn mowings, Cocoanut fibre refuse, or even dry dust or ashes, all these substances tending to check evaporation. Where, however, it is needed to supply food to the plants the above substances will be of little use. In this case partially-decayed stable manure is excellent, although it is apt to become rather untidy during dry weather. Very wet close manure is not advised, as, owing to its texture, air is excluded from the soil. Those who have small gardens, especially in towns, usually experience some difficulty in obtaining stable manure suitable for mulching, and all such should give Wakeley's Hop Manure a trial for this purpose. Used according to the directions it answers splendidly, the spent Hops which form its base rendering it porous.

Having thus considered the question of mulches we must now turn our attention to those subjects that are specially benefited by it, and also the time when it should be applied. Generally speaking all recently planted trees, whether fruit or otherwise, are greatly assisted by a mulching placed on the soil over their roots. The same applies to newly-planted herbaceous subjects and all established plants, such as Roses, Sweet Peas and Asparagus that delight in a comparatively cool, moist root run. On light soils practically all crops are greatly

benefited by mulchings applied at the proper time. It is in the time of application that many amateurs go wrong when mulching, a few well-defined principles needing consideration if the full benefit is to be derived from the material used. At the present time we need not consider the mulching of plants for the purpose of affording protection from frosts, the checking of rapid evaporation and the supplying of food being the most important now. It is a common but entirely wrong practice to mulch trees, shrubs and other plants in the spring before the soil has had an opportunity of becoming warmed by the sun, consequently the soil is retained cold for a long time, much to the detriment of the plants. Others again put on a mulch after a long period of drought, consequently when rain does come it is diverted from the roots of the plants that are dying for the want of it. To derive the full benefit from a mulch it ought not to be put on until the soil has become thoroughly warmed, then it should be applied as soon after a heavy soaking with rain as possible. If the soil is dry and rain is not likely to fall for some time thoroughly water it and apply the mulch soon afterwards. The thickness of the coating given will vary according to the condition of the material used. Fairly short stuff may be spread on 3 inches thick; long, strawy material twice that thickness. Trees are frequently given a thick mulching of short manure in the autumn as soon as planted, consequently the soil is kept sodden, air is excluded and the trees either succumb or make a miserable attempt at growing. The present is an excellent time for mulching, and if carried out now the operation will result in much good. Young trees and shrubs in pots, where the roots are necessarily cramped, derive great benefit from a mulch placed on the top of the soil in the pot. Many cultivators of pot fruit trees use a tin band several inches deep for placing round the top of the pot, thus forming a sort of receptacle for the mulching material. Frequently this consists of thoroughly decayed manure or rather rough fibrous loam, with some suitable artificial manure added. Besides mulching proper the good effects produced by frequently hoeing the soil should not be overlooked. Such work produces a tilth of fine soil on the surface, several inches thick, that is most valuable for the prevention of rapid evaporation of soil moisture. Besides this air is allowed free access to the roots of the plants, insects are exposed to birds that are always watching for them, and weeds are destroyed in a young state before they have had time to rob the soil of much nourishment.

5.—A BED OF AURICULAS IN FLOWER.

## THE TOWN GARDEN.

**THE LAWN.**—The grass plot, which we all prefer to dignify by the name of "lawn," will demand incessant attention on the part of the owner during the summer. It is always a matter of great difficulty to keep the Grasses in first-rate condition in limited areas, but where constant treading in distinct tracks can be avoided the trouble is considerably lessened. There are three operations which go far to ensure thick, permanent turf, and these are regular mowing, persistent rolling and generous watering. In respect of the first named it is well to cut closely up to about the third week of this month, and then raise the knives a little so as to reduce the danger of exposing the bases of the plants to the fiercest rays of the sun. Mowing will have to be done about once a week, but the precise intervals are governed by the weather. Rolling can scarcely be done too frequently, provided that the ground is not too wet, while watering with one of the excellent sprinklers advertised in *THE GARDEN* does an immense amount of good. The man who keeps up with these details will find his grass plot a great pleasure throughout the season, but he must not spare the water.

**PETUNIAS FOR A HOT BORDER.**—Those who have a hot, dry border on which plants are apt to run out too rapidly and have not tried Petunias should do so. On a narrow border of rather poor soil in my garden they thrive magnificently and make a display which cannot be excelled by any other plant as easily grown. Fine plants are procurable from vendors, and they should be planted at once and watered well in. After this the principal attention will lie in occasional watering, pegging down or tying up, according to circumstances, and the persistent removal of the blooms as they pass the zenith of their beauty. I have tried both single and double varieties, but find the former by far the more satisfactory. Last season was rather too damp for the most brilliant results, but the effects of the constant wet were militated against by keeping the soil very firm. As soon as possible after rain or watering the surface between the plants was trodden hard down, and then pricked over to a depth of half an inch or an inch with a bluntly-pointed stick. This kept the plants thrifty and floriferous, and created one of the best features of the garden.

**STAKING PLANTS.**—This is an operation to which the average amateur gardener does not attach sufficient importance, and the manner in which it is done in many cases completely destroys the charm of the small town garden, in which defects are far more conspicuous than in places of large extent. To put in one central stake and bunch all the shoots up to it entirely destroys the natural charm of the plant. By all means limit the supports to one at a plant if it can be made efficient, but sling each growth up to it separately and securely, and use strands of tying material that are as thin as is possible consistent with strength. If this work is done well, the garden looks tidier and the plants retain the native grace of habit to a considerable extent which they cannot do when the hideous bunching style is adopted. In all instances the stake should be placed as inconspicuously as possible, and green tying material should be utilised in preference to white or straw-coloured.

**ROOM PLANTS.**—During the summer these are apt to be neglected for the fuller charms of the garden, and they do not get the weekly wash that is the rule in the winter. It is certainly not as necessary, for the air now is purer than when we have November's special fogs; but on no account should they be allowed to become coated with dirt. Stand them out of doors during every warm shower, as this will cleanse and revivify them at one and the same time, but in addition sponge them over carefully now and again. Ferns which cannot be

sponged should be laid on their sides and vigorously syringed through the fronds from above. If they get dirty with insects, they should be dipped head downwards in weak insecticide.  
HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUITS UNDER GLASS.

**EARLY VINES**, with ripe and ripening fruit, should have ample ventilation, and take care that the borders do not get dry, otherwise red spider will make its appearance, and it is then difficult to eradicate when the fruit is ripe without disfiguring the berries. The Muscat house should be attended to regularly in the matter of damping down, and with a good syringing in the morning and at closing time. Shut up with a good sun-heat of about 90° and give plenty of liquid manure. Young Vines should not carry too much fruit at the expense of poor berries and small wood for next year's crop.

Vines planted this season should be tied up neat and straight and allowed to ramble freely in order that they may make plenty of roots. All late Grapes should by this time be well thinned, and as soon as the thinning process is complete give a good sprinkling of *Le Fruitier* on the border and water in. Keep all lateral growths pinched in regularly, so that too much has not to be cut away at one time.

**Figs.**—Where these have been gathered the house should be treated as for the first crop, as the second crop will now be swelling. Keep the growths tied in and pinched. Give frequent heavy waterings in bright weather. The house in which

**Melons** are ripening should have air left on at night, the fruits cut as soon as ripe and placed in a cool fruit-room. Successions should be treated as recommended for early crops, but no difficulty should be experienced in setting a good crop quickly. Seed should now be sown for the latest crop.

**Cherries** should have plenty of air all night, and nets be run around the ventilators to keep out depredators, or the fruit may be missing.

**Cucumbers.**—Carter's Model is a fine summer variety. Cucumbers should be sown often, so that they can always be had fresh, and old plants are apt to get red spider and produce distorted specimens.

#### PLANT HOUSES AND FRAMES.

**Winter-flowering Carnations** will now require to be placed in flowering pots. In all cases they should be protected, after the final potting, from heavy rains and extreme exposure to sunshine. Stop the shoots so that they break and make bushy plants. Stake the plants as soon as it becomes necessary.

**Malmaison Carnations.**—The main batch is fast opening its flowers. Neat rubber bands should be placed over the buds, and all the lateral ones and growths kept pinched off, so that all the strength is directed to the one flower. This also applies to borders, and, in fact, all Carnations. Keep the house cool and damped occasionally. Pot Cyclamen. Sow more Primulas and Cinerarias.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

In the stove house very little artificial heat will now be necessary, but, while more air

than was formerly given will be required in hot weather, the evaporation will be consequently increased, and, therefore, additional precaution must be taken to keep the air of the house sufficiently moist. The plants should be syringed overhead early in the morning and in the afternoon. On hot sunny days water should also be thrown along the paths. Shading from the more direct rays of the sun will prove beneficial, and for Orchids it is especially necessary.

#### FRUIT UNDER GLASS.

**Thinning Grapes.**—This operation is by some performed all at once, and by others at two different periods; that is to say, the bunches are partially thinned out as soon as the berries are the size of small shot, a secondary and final touch being given a week later. In the case of early and midseason Hamburgs, Foster's Seedling and similar Grapes I think one thinning is sufficient, as it is no drawback, but rather the reverse, especially where Grapes are used in quantity, if the berries do wedge each other slightly, as with a dry, airy atmosphere and a gentle warmth in the hot-water pipes damping off, and consequently gaps in the bunches, rarely occur. With later varieties, however, intended for hanging well into the new year, the case is totally different, and a second thinning is, I think, advantageous, inasmuch as it allows of a more correct judgment being formed of the exact space to allow between the berries to admit of a free current of air passing through them.

#### HARDY FRUITS.

**Trees against Walls.**—Where the borders are occupied with vegetables it is astonishing the amount of nourishment required to keep both going, for as the succulent crops take all the moisture out of the upper portion, there is nothing left for the roots of the trees to feed upon. In such cases mulching is impossible, and the only plan that can possibly be adopted is to feed the trees with liquid manure. Pears should now receive their final thinning, reserving only one at each cluster, and this the largest and best placed.

#### KITCHEN GARDEN.

**Tomatoes.**—Where the plants have been thoroughly hardened off, there should be no further delay in planting, provided the weather is genial. Each plant should have the lowest bunch of blossom showing. I do not care to have them more forward than this at planting time, for I have not found the desired freedom of swelling with fruits that have set in small pots, and think that more is lost than gained by getting them so forward.

**General Work.**—Thinning of main-crop Carrots, Beet, Salsify, Scorzoneria and Chicory should follow close on those things taken in hand earlier, as growth will now be rapid.

#### FLOWER GARDEN.

**Bedding-out** is the principal business now. Take the plants in the order of their relative hardiness, so as to keep back to the last moment all the more tender subjects such as Coleus and Alternanthera. Keep the lawns in the best order possible, and in the event of prolonged dry weather flood them with water at least once a week. Stake and mulch Dahlias. Look over mixed borders and provide supports for plants that are likely to be blown over.

**Hardy Annuals.**—Those sown early in May will now need thinning, first singling them out, and then, when danger from slugs has passed, reducing to the required distance apart, which is generally about double the distance usually afforded. The room taken by a well-developed plant should be the guide to this at all times. There is nothing in the culture of annuals that repays so well as early and systematic thinning.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
*Ashwellthorpe, Norwich.*

## SWEET PEAS AT THE TEMPLE SHOW.

**A**T the Temple show the lover of Sweet Peas usually expects to get his or her first view of the flowers in any quantity, and one may safely prophecy that, in addition to standard varieties, a few novelties will also be found. This year the display of flowers was hardly so lavish as usual, but this lack of quantity was compensated by the general good quality of the blooms staged.

Mr. Breadmore's magnificent group was a great surprise to most people. I have rarely seen Helen Lewis staged in better condition, even at the summer shows, than it was on this occasion, and Mrs. Collier was also put up in first-class condition. Some inflorescences of the first-named were composed of five large flowers, and this without any signs of fasciation. Elsie Herbert and Etta Dyke were also in grand form. Of novelties shown here, Kathleen MacGowan will probably become a universal favourite. It may well be described as a large sky blue Spencer, the standard shading off to lavender at the edge. Mrs. C. W. Breadmore is a dull cream or buff, slightly suffused and edged with pink.

Mr. R. Sydenham, as usual, had some very interesting things in his tastefully-arranged group. Primrose Spencer was here, and I noticed that it was labelled as synonymous with Clara Curtis. As exhibited, it is not so good as the last-named, but flowers grown under glass so early are not good for comparison. Mrs. F. R. Castle is a nice Pea. It somewhat resembles King Edward, but belongs to the Spencer section. The standard is also brighter, and the wings rather more highly coloured. Miss Millie Maslin is a lovely thing, the rich glowing crimson colour of the large flowers appealing to all. Paradise on this stand was superb, the colour of the flowers being well developed.

Messrs. Dobbie and Co. maintained their high reputation with a most interesting group. The King is a novelty that should become popular. It is a large flower, with a waved scarlet standard and rich rose carmine wings. White Spencer as shown here appears to be no better than, if as good as, Etta Dyke. Mid-Blue is a pleasing variety of the grandiflora type, the clear deep blue of the standards and the lighter blue of the wings producing a fine effect. Menie Christie was shown in good condition, and will no doubt give a good account of itself this summer. Mrs. A. Ireland is a bright-coloured variety that should be popular for decorative purposes. The highly-waved standards are of a distinct bright rose pink colour, the large wings being somewhat paler.

Messrs. G. Stark and Sons had two novelties in their group. Olive Ruffel is a Spencer, the colour of which may be described as a mixture of buff and pink, the wings containing more of the latter colour than the standard. Maggie Stark is a large Spencer, the pink standard containing a trace of orange when young. The wings are almost deep rose-coloured. H.

## MAY-FLOWERING TULIPS AT COLCHESTER.

TWO ACRES OF BLOOMS.

**T**HE various Tulips that come under the above heading have much to commend them to the flower-loving public, and the rapidly increasing demand for bulbs of this class may well be taken as a sign that growers are at last beginning to realise the many charms that they possess. It is impossible to visit such a collection as that grown by Messrs. R. Wallace and Co., Kilnfield Gardens, Colchester, without being greatly impressed with the immense wealth

of variety found among them, the unique colouring, form and huge stems rendering them valuable for many purposes. Compared with the early bedding Tulips, these late-flowering types score many points. Besides refinement in colouring and form, we have here flowers of grand lasting qualities, both in a natural and a cut state, the long, stout stems being specially suitable for arranging in vases and other receptacles. Another point that we fear is too often overlooked in connexion with these Tulips is that many of them are most delicately scented, a feature without which the most lovely flower is of little value to many people.

About two acres of these Tulips are cultivated by Messrs. Wallace at Colchester, and it speaks well for their robust growth when we remember that, only three weeks previously, they had been covered with about 10 inches of snow and subjected to 10° of frost, and only a few days before a severe hailstorm had tried its best to wreck the beautiful blooms, yet they had all come through it almost unscathed and presented a most vivid yet refined spectacle. The question of soil for Tulips is one that, perhaps, may trouble some. That at Colchester is a rather heavy loam, well and deeply cultivated; and here we measured many leaves that were 6 inches wide and of a corresponding length, while the stems in many instances were almost as thick as one's little finger, thus manifesting the excellent treatment accorded them by Messrs. Wallace.

As the term "May-flowering" may be rather mysterious to some, it may be well to mention that it includes all the late-flowering types, these being represented by the cottage, Darwin and gesneriana varieties. In the cottage section we have usually large flowers of somewhat irregular shape and pointed petals; the Darwins are of regular shape, have blunt-pointed petals and include many rare colours, such as violet, lavender, heliotrope and maroon, as well as the usual hues; while the gesneriana varieties have rather long, sharply-pointed flowers of bright colours. The Darwins are a comparatively new race, having been introduced to this country from Holland about twenty years ago. Mystery surrounds their origin, but we may safely assume that the old Dutch breeder Tulips were used in their production.

In the Darwin section we were very pleased to see a huge new one appropriately named Giant. Besides its immense size it has a beautiful rich violet colour and great vigour, so that it may be regarded as one of the Tulips of the near future. Those who like a dark-coloured Tulip will find a grand variety in Zulu, a beautifully shaped purple-black flower with a delicate waxlike bloom on the outer surfaces of the petals. Millet is another of the dark-flowered varieties, the deep crimson-maroon flowers being of perfect shape, and the plants of great vigour. Professor Rowenhoff is one that we particularly admire in spite of its somewhat unwieldy name. It is one of the strongest growing of all the Darwins, and many of the sturdy stems were 3 feet high. The cherry-red flowers are of immense size, grand substance, the base being a blue star resting on a white disc. Either individually or in a mass this Tulip is superb. Somewhat similar to the foregoing is Van Poortvleit, a beautiful deep rose-coloured variety. Whistler is a Tulip that at once attracts the eye, the fiery scarlet colouring toned down somewhat with reddish bronze on the outside of the segments rendering it excellent for massing. Clara Butt is, perhaps, the best known of all the Darwins, and Messrs. Wallace's strain is an excellent one, the salmon, rose and pink colouring being well blended, and the form splendid. The stock of King Harold noted here was a very good one indeed; the glowing crimson colouring, superb shape and immense vigour of this variety should make it a universal favourite. In Farncombe Sandars we have another dark crimson flower that is specially good when massed; a large bed of this is a sight not soon

forgotten. Antony Roozen is an early-flowering Darwin that we were just in time to catch. The deep rose colour shading to blush is most effective, and when massed is delightful to behold. Those who like the beautiful lilac-coloured sorts will find a grand flower in Melicette, a tall vigorous Tulip with beautifully-shaped blooms of a soft lilac hue.

In the cottage section so many good things were seen that it were an impossible task to note them all. A few, however, specially appealed to us, and these were noted for the benefit of readers. Walter T. Ware is the new deep yellow Tulip that created such a sensation when exhibited before the Royal Horticultural Society in 1906. It is quite the richest of the yellows and the shape leaves nothing to be desired. Flame is aptly described by its name. It was introduced to commerce by Messrs. Wallace, and the flame-coloured scarlet coupled with immense vigour and exquisite shape have quickly made it a general favourite. Inglescombe Pink, I. Scarlet and I. Yellow are three fine varieties, the colours of which, with the exception of the first, are described by their names. I. Pink is really a most delightful blending of pink, buff and salmon, with a green base. It is a grand flower and should find a home in every garden. Mrs. Moon is a fine rich yellow variety of most elegant shape, the long petals tapering beautifully at the points. So vigorous is this Tulip that it frequently produces large bulbils in the axils of the leaves. In Afterglow we have a lovely new variety that is splendidly described by its name, the golden yellow and scarlet flowers being of a most elegant and pleasing shape. Zomerschoon is a Tulip that will find favour with many, its striking markings at once commanding attention. The flowers are rosy red marked with sulphur. Those who like Tulips with Chameleon-like propensities should invest in Primrose Beauty and Nydia. The former is a pale primrose colour when the flowers open, this eventually passing off to almost pure white. Nydia opens a cream colour, changes to deep yellow, then turns pure white and finishes its existence adorned with well-defined deep pink markings on the outside of the flower. Both are dwarf and excellent for table decoration. Glancopis is also a dwarf variety, the pale rose-coloured flowers with a vivid blue spot at the base being quite unique.

Among the gesneriana varieties we must mention *g. aurantiaca*, beautiful bright orange red; *g. a. maculata* (Orange Globe), very rich scarlet flowers with a black base; *g. lutea*, a well-known beautifully-shaped yellow Tulip; *g. l. pallida*, paler yellow than the former; and *g. rosea*, rich carmine with black centre. A Tulip that will appeal to those who like flowers with unusual traits is *viridiflora*, the green-flowered Tulip, of which we saw a good stock.

Besides Tulips Messrs. Wallace devote many acres to choice hardy rock and border plants, Lilies and water plants, so that a visit to their nurseries at any time during the summer is sure to be well repaid.

## THE EDITOR'S TABLE.

FLOWERS FROM KNAP HILL.

Mr. Anthony Waterer sends from the Knap Hill Nursery, Woking, several interesting flowers for our table. One is the beautiful variety of the Japanese Quince (*Cydonia japonica*) Knap Hill Scarlet; the flowers are a pure scarlet and cluster thickly on the shoots. Then there is the variety of *Pyrus Malus* named *neidwitziana*, which should be more frequently seen in our gardens; its rosy purple colouring is unusually distinct, and the fruit is the same colouring as the bark of the wood. *Cerasus Padus* Knap Hill variety is remarkably fine, the racemes of flowers being of great length. This, Mr. Waterer informs us, was cut from a tree about 30 feet high and

much through. Also comes the double variety of the Bird Cherry, a tree of much beauty in May; the flowers are like little white rosettes.

#### A RARE SHRUB FROM IRELAND.

Mr. H. Armytage Moore of Rowallene, Saintfield, County Down, sends flowers of the beautiful and rare *Exochorda* or Pearl Bush called *Alberti macrantha*, which is one of the most beautiful of the flowering shrubs. Our correspondent says: "I send you a few flowering sprays of this shrub, which is as yet rarely met with. The snowy whiteness of the flowers, the freedom with which they are borne and its vigorous growth entitles it to rank among the most attractive of shrubs that are flowering now."

#### SPRING FLOWERS.

Mr. T. Arnold, The Gardens, Cirencester House, Cirencester, sends many interesting flowers, comprising *Rehmannia angulata*, *Tulipa retroflexa*, *Anemone Pulsatilla*, *Iris stylosa*, *Tulip* President Perrier (very fine scarlet), the double Marsh Marigold, a very fine form of *Primula obconica* called *gigantea*, a delightful gathering of *Primroses* of good colours, the yellow *Fritillaria pallidiflora*, the white Snake-head (*F. Meleagris alba*) and many other most interesting spring flowers. We must not forget the blue *Anemone robinsoniana*, which was in this spring gathering.

#### VIOLAS FROM SURREY.

We have received from Mr. A. Young, Oxted Nursery, Oxted, Surrey, some very fine *Violas*, comprising the following: *Virgin White*, one of the most lovely pure white rayless varieties we have seen for a long time; it is very free flowering, and has a sweet scent; another advantage which this also enjoys is its fine long stem; *Red Braes*, a delightful shade of golden yellow, also very free flowering, when massed together it must make a splendid show; *Royal Scott*, a beautiful rich purple, slightly rayed; *Marchioness Compact*, white, with slightly yellow rays; *Maggie Mott*, a beautiful shade of lavender, the flowers being of splendid form and size and sweetly scented, with strong stems; and *Primrose Dame*, as the name implies, is of a beautiful primrose colour. We understand from Mr. Young that the two first-mentioned received respectively a certificate and silver medal from the Scottish Horticultural Society.

#### LARGE AND FRAGRANT PANSIES FROM SUSSEX.

Miss G. B. Glanville, Sunnyside, Anstey, Cuckfield, Sussex, sends very fine flowers of *Pansies*, these being of good size, excellent form and of very pleasing colours. These were accompanied by the following note: "I am sending you some of my *Pansies*, as I thought I should like to have your opinion of them. The seed I got from Bath's, three sorts, viz., *Monarch*, *Empress* and *Lord Beaconsfield*. I sowed it the end of last June, but it came up very slowly owing to the cold July we had, and thereby made my plants rather backward for planting and early flowering. I sowed the seed in boxes, covered them with glass and placed in the shade; and when the seedlings were large enough, pricked them out again in boxes in a rather rougher soil containing new leaf-mould, to which the roots adhered, and when transplanting into the open ground, having some soil with them, they received no check. This final planting was, some in August, some September and the last in the first half of October. They have grown into magnificent plants, all the better, I think, for being raised entirely out of doors, and have been flowering for the last two months, and are now covered with blooms, which, unfortunately, the last week seem diminishing considerably in size. *Monarch* I have found the largest *Pansy*, in *Empress* the greatest variety of colour and *Lord Beaconsfield* the greatest length of stem."

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Sweet Pea plant for inspection** (*J. N. H. G.*).—We cannot say what it is that has eaten the seeds at the bases of your Sweet Pea seedlings, but it is undoubtedly the work of some ground pest, possibly woodlice. Yes, you must replant the seedlings as soon as they are large enough; in the meantime keep the boxes in which you have placed them in as open a position as possible so that sturdy growth results. Before replanting we advise you to dress the soil with either Kilogrub or Vaporite; these substances, if used according to the directions supplied with them, are excellent for killing ground pests, and are harmless to the plants. Had you written to us before lifting your seedlings we should have advised you to dress the soil with these substances without lifting the plants.

**Decayed Daffodil bulbs** (*Poppyland*). It is difficult to assign any cause for the one clump of bulbs having rotted if the other clumps in the garden contained the same variety and were planted at the same time. The bulbs sent look as if they had never made any roots since they were planted. The question then arises: When were they planted, and what was their condition when they were put into the soil? If they were sound, they were probably planted late and got caught by frost before they had time to produce roots. Probably, however, the bulbs were bad when planted, and the wet winter has naturally helped them to decay. It would be interesting to have fuller particulars as to variety, date of planting, condition when planted, and state of ground before and at the time of planting.

**Names and colours of early-flowering Chrysanthemums** (*G. Hurst*).—We are pleased to reply to your questions respecting the names, &c., of the early-flowering outdoor *Chrysanthemums* in the list submitted to us. The following varieties are *Pompons*: *Anastasio*, light purple; *Crimson Precocité*, bright crimson; and *Flora*, golden yellow. There are two single-flowered sorts, viz., *Pretty Polly*, orange and gold; and *Daisy Bell*, a pretty bluish. The others are Japanese: *George Wermig*, yellow; *O. J. Quintus*, rosy pink; and *Evelyn*, crimson bronze with gold points. *Martinmas* was once classified as a *Pompon*, but recently the National *Chrysanthemum* Society took the variety out of that section and placed it in a new one known as "decorative," most of which are like hybrid *Pompons* or enlarged forms of the smaller *Pompon* sorts.

**Polyanthuses and Auriculas for inspection** (*Yew Tree*).—The laced *Polyanthuses* are worthless from a florist's point of view, as both varieties are "plyed"—that is, the stigma is even with the mouth of the tube; except for this fatal defect the red ground variety has good properties. The *Auriculas* are nondescript things, neither alpine nor show varieties. They are the worst lot imaginable. Nothing in the way of the florists' type could be obtained from them. As border flowers, and if they please the owner, well and good, but they are

of no use whatsoever as exhibition flowers; better to purchase a few plants from a reliable source or obtain seed. The best seed is in small packets and often fails in the hands of the inexperienced.

**Semper Augustus Tulip** (*Florinet*).—This very famous Tulip was a "Rose," with broad atripea of bright colour and pointed leaves.

**Many-flowered Tulips** (*C. M. A. Peake*).—It is not unusual for Tulips to have secondary flowers, which branch from the main stem. La Tulipe Noir and Coronation Scarlet among the May-flowering varieties often exhibit this peculiarity. It is generally supposed that the reason for this is that they have "done themselves well" the previous season, and so stored up some extra energy, which they get rid of in this way. It should not be forgotten that there are one or two species where more than one flower on the main stem is the rule and not the exception.

**Agapanthus not doing well** (*M.*).—Apparently your plants of the blue *Agapanthus* were too small for the large tubs in which they were planted. *Agapanthus*, in common with practically all other cultivated plants, make far more satisfactory progress if they are shifted on into larger pots when necessary and allowed to become strong before they are put in the tubs. The soil and general treatment mentioned by you could not have been improved upon, and as you say the roots have increased, which shows that the plants are taking hold of the new soil, it is very possible that you will find a considerable increase of vigour during the coming summer. It is quite true that *Agapanthus* make a far better floral display when the plants are pot-bound than at any other time; still, good foliage and flowers may be reasonably anticipated before that takes place.

### THE GREENHOUSE.

**Propagating Eupatoriums** (*J. F. P.*).—*Eupatoriums* are very readily propagated by means of cuttings. This is a good time of the year to take the cuttings, which should be formed of the tops of the young growing shoots. A length of about 4 inches forms a very suitable cutting. It should be cut clean off just below a joint and the bottom pair of leaves removed when it is fit for insertion. Pots 4 inches to 5 inches in diameter are very suitable for the reception of the cuttings. These pots must be quite clean and well drained by means of a few broken crocks in the bottom. Ordinary potting compost, with the addition of a little silver sand, will suit the cuttings well. A 4-inch pot will hold about half-a-dozen, and the larger size a proportionately greater number. The pots being filled with cuttings, they must be watered thoroughly through a fine rose, enough being then given to settle the soil completely in its place. If you have no other glass accommodation but the conservatory, the cuttings may be readily rooted therein provided they are kept in a close case. A home-made one may be readily formed from a box about 8 inches or 9 inches deep with a square or squares of glass laid over the top. It must, of course, be shaded from the sun. Directly the cuttings are rooted the glass should be taken off. The young plants must then be potted singly into pots 3 inches in diameter in a mixture of loam, leaf-mould and sand. As soon as the roots take possession of the new soil the tops of the young plants must be pinched out to make them bushy. After a time the plants may be put in a cold frame, and throughout the summer they can be stood out of doors and given much the same treatment as a *Chrysanthemum*. Care must be taken to remove them under glass before the nights get too cold in the autumn. Violet plants can be obtained from the many advertisers in THE GARDEN who make a feature of hardy herbaceous plants.

**Fowl manure for pot plants** (*Bates*).—Fowl manure is not a good material to use for pot plant compost, but if it is old, as you say, it will be less hot than fresh poultry manure usually is. We advise you to spread your fowl manure out a few inches thick, to give it a heavy dusting with soot, then spread on to it the best potting soil you have, in bulk six times that of the manure, and then throw the whole into a heap, well mixing it. In a month from then, if kept dry, it should work freely through a coarse sieve and be suitable for potting. Still, for any plants, especially for large-leaved ones like *Cinerarias*, use rather small than large pots, as such a compost should be rather rich than poor. If you can use as soil unmixed good turfy loam, do so, also if the compost seems to be rather close or adhesive add to it one-tenth its proportion of sharp white sand.

## EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF **THE GARDEN**, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE BEST FLOWERS AND SHRUBS FOR TOWN GARDENS.

(First Prize Essay.)

**D**ESPITE the many difficulties to be contended with, there is no reason why, with good cultivation and a selection of suitable plants, town gardens should not be kept bright and interesting through the greater part of the year. Even in the heart of large towns and in the most smoky atmosphere and confined position there is a fair number of plants which may be depended upon to thrive and bloom freely, while under the improved conditions and comparatively pure air to be found in the outskirts a great variety of hardy shrubs, perennials, bulbs and annual flowers may be grown.

One great difficulty to be encountered in the cultivation of town gardens is the poor nature of the soil, and, before commencing to plant such a garden, it would certainly be good policy to lay in a quantity of short stable manure and as much mellow fibrous loam as is procurable, then, by deeply trenching the soil, adding manure freely to the lower spit and placing a few spadefuls of loam round the roots of each plant when placing in position, a good start is ensured. The subsequent cultivation consists mainly in keeping the surface soil loose and open by hoeing, in giving plentiful supplies of water in dry weather and in the frequent use of the hose or syringe, so that the foliage may be kept fresh and clean.

### SELECTION OF SUITABLE PLANTS FOR TOWN GARDENS.

**Hardy Shrubs.**—These should be planted thinly, bearing in mind that after two or three years' growth they will occupy considerable space and that they are always more effective when so planted that the natural outline of each can be seen from all points. Evergreen shrubs in particular are, I think, often used to excess in small gardens, and, although useful for forming a background of green foliage, they should not be employed to the exclusion of the many beautiful deciduous species. Those I would recommend are Euonymus (both green and variegated), Hollies in many varieties, Laurustinus, Berberis Darwinii with orange and B. atenophylla with golden yellow flowers, common Box and Aucubas, taking care to include a plant or two of the male variety of this latter in order to obtain a profusion of the beautiful berries on the female plants. In addition to these, Crategus Pyracantha, C. P. Lalandi and Cotoneaster Simonsii may be used as wall plants.

Of deciduous shrubs Forsythia suspensa is one of the best town plants, the slender shoots being covered with golden yellow flowers in March.

Daphne Mezereum, with fragrant pink flowers, usually blooms in February and will succeed in fairly open situations; it is a slender-growing dwarf shrub and should be planted in small groups to produce the best effect. Pyrus (Cydonia) japonica bears crimson flowers in April, and may be used either for training on a wall or grown as a bush in the open; the white variety should also be grown. P. Maulei is a dwarf variety with brick-red flowers. Prunus Pissardi is very effective with its white flowers and deep maroon-purple leaves, as is also P. triloba fl.-pl. with double rose pink flowers. A succession of bloom may be maintained by growing, besides the ordinary Lilacs, the Persian Lilac, a small-growing shrub very suitable for town gardens, the Diervillas or Weigelas, with crimson, rose or white flowers, and the Mock Oranges (Philadelphus). Other valuable shrubs for town gardens are the white Portugal Broom (Cytisus albus), Cytisus scoparius andreanus, with crimson and yellow flowers, and the double variety of the Jew's Mallow (Kerria japonica fl.-pl.). Azaleas of the mollia type will succeed if grown in peat or a mixture of peat and loam free from lime. To enumerate the many plants other than shrubs which may be successfully grown in towns would occupy so much space that I must content myself with mentioning a few which will grow and flower well in almost any situation, provided they are given good soil and cultivation.

For spring flowering there is a large choice of bulbous plants. Snowdrops, Scillas and Crocuses should be massed in clumps towards the front of borders or used as edgings for beds of other bulbs. Narcissi in great variety may be planted between shrubs or hardy perennials; Hyacinths and early Tulips are useful for beds, while the tall late-flowering cottage and Darwin Tulips produce a brilliant effect in herbaceous borders, and are valued as cut flowers. Of other plants Wall-flowers are indispensable, mauve and purple Aubrietias and yellow Alysum can be used for edgings and the double Arabis will produce sheets of white Stock-like flowers in April and May. The Doronicums are vigorous-growing perennials, with large yellow flowers, and are useful for planting between shrubs. In shaded positions Primroses, alpine Auriculas and Polyanthuses may be planted in light soil composed of loam and leaf-mould.

### Summer and Autumn-flowering Perennials.

From May to the end of October the garden may be kept bright with many hardy perennials. Irises, more particularly those known as German Irises, are very valuable town plants, and for planting in narrow borders or between shrubs are perhaps the most useful of any. Good varieties are the common blue Iris; Queen of May, rose lilac; Mrs. H. Darwin, white; Mme. Chereau, white, margined blue; and variegata aurea, yellow. Iris ochroleuca is a tall-growing species with cream and yellow flowers, and I. aurea is of similar growth, the flowers being golden yellow.

For the back row of borders the herbaceous Lupines are valuable, and should be planted in well-manured soil, and between them may be placed some of the Day Lilies, such as Hemerocallis flava, H. fulva and H. aurantiaca. Other

early summer-flowering plants are the Pæonies, both the old double red and the double and single Chinese varieties; Campanulas, such as *C. pyramidalis*, *C. persicifolia* and *C. latifolia*; Delphiniums, Oriental Poppies and such Lilies as *L. croceum*, *L. candidum*, *L. umbellatum* and *L. testaceum*.

For edgings in town gardens there are no better plants than Pinks, good varieties being Mrs. Sinkins, Albino, Her Majesty and Paddington. Carnations are also excellent town plants, more especially if raised from seed in preference to growing named varieties. Both the biennial and the perennial Evening Primroses (*E. nocturna*) succeed well in town gardens, while for shady borders the Funkias are useful for their handsome foliage and lilac flowers. *F. sieboldiana* major produces the largest and handsomest leaves, while some of the varieties of *F. lancifolia* have foliage margined or variegated with gold, white or silver.

Suitable plants for late summer and autumn blooming include Hollyhocks, Chrysanthemum maximum, with large white flowers; perennial Sunflowers; *Erigeron speciosus*, with mauve Daisy-like flowers; *Coreopsis grandiflora*; *Pyrethrum* (*Chrysanthemum*) *uliginosum*, a tall-growing plant with large white flowers; *Rudbeckia Newmanii*, which grows about 2 feet high and bears yellow flowers with dark brown cone-like centres; Phloxes in many shades of crimson, pink, purple and pure white: these require plenty of moisture in summer, and should be mulched with half-decayed manure to keep the roots cool and moist; *Sedum spectabile*, a handsome plant with glaucous leaves and large heads of rosy pink flowers; and Michaelmas Daisies in many varieties; these comprise flowers in shades of purple, lilac, rosy mauve and pure white, the plants varying from 2 feet to 5 feet or 6 feet in height, and, by a careful selection of varieties, a succession of bloom may be maintained from August to the end of October. Room must, of course, be found for some of the border Chrysanthemums, which are among the best of town plants, and will help to keep the garden bright during September and October; also in shady borders for *Anemone japonica*.

**Annuals and Bedding Plants.**—Space will only permit of a brief reference to these. Of half-hardy annuals Stocks and Asters may be raised from seed in spring and used for filling beds which have contained spring-flowering plants. Zinnias, Balsams, *Salpiglossis* and *Nicotiana affinis* may also be employed for this purpose. The soil for all these should be of a rich nature, and a dressing of decayed manure may be given before planting. Bedding plants such as Zonal and Ivy-leaf Pelargoniums, *Calceolarias* and *Petunias* flower best if the soil is not too rich. Cannas will succeed if planted in rich soil and kept well supplied with water, and good-sized beds of these plants are very effective. Nearly all the hardy annuals will grow well in towns. These should be sown thinly in good soil, and thinned out to 6 inches or 8 inches apart when large enough to handle. Those of medium height comprise annual Chrysanthemums, Shirley Poppies, Clarkias, annual Larkspurs, Godetias, annual Lupines and Malope grandiflora, while a few of dwarf growth are Indian Pinks (*Dianthus*), Viscaria, *Linum grandiflorum*, *Linum catharticum*, *Linum catharticum*, Dwarf Nasturtiums and Virginian Stock.

C. W. CAULFIELD.

Bridgen House, Park Crescent, Erith.

## FORTHCOMING EVENTS.

June 10.—Messrs. John Waterer and Sons', Limited, Rhododendron Exhibition, Royal Botanic Gardens, Regent's Park.

June 17.—Grand Yorkshire Gala, Jubilee Exhibition, Bootham Park, York.

June 24.—Gardeners' Royal Benevolent Institution Annual Dinner at the Hotel Metropole.

## PRIZES FOR READERS.

### MAY COMPETITION—AWARDS.

In this competition readers were asked to give a list of the best flowers and shrubs for town gardens. The prizes are awarded as follows:

The first prize of four guineas to C. W. Caulfield, Bridgen House, Park Crescent, Erith.

The second prize of two guineas to D. E. Elder, Tyne Green, Hexham.

The third prize of one guinea to L. Johns, St. George's Hostel, University College, Reading.

The fourth prize of half-a-guinea to Gilbert Walsham, 25, Griffiths Road, Wimbledon, S.W.

The number of essays sent in was not so large as in some competitions, nor could the quality be considered so good. Generally speaking, the lists of plants were weak. Those from the following were of more than ordinary merit, and deserve commendation: G. H. Webster, A. J. Long, Miss E. A. Patch, H. Butler, J. Wooff, E. Cummins, W. P. Wood, J. Glasheen, D. B. Allwork, Evelyn M. Kent, A. Jones and F. Bultitt.

## NOTES OF THE WEEK.

**Royal Horticultural Society's Gardens Guild.**—The first annual general meeting will be held on Wednesday, July 8, the second day of Holland House Show, at 7 p.m., in the Charles Dickens Room, Carr's Restaurant, Strand. It is particularly hoped that all who have at any time been students or employés in the Royal Horticultural Society's Gardens at Chiswick or Wisley will endeavour to be present and will give early notice of their intention to the acting hon. secretary, Mr. R. Wallis, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.

**Flowers at the Bath and West of England show.**—One of the most interesting features of the Bath and West of England Society's exhibition is the flower show, and the tent devoted to this section at Dorchester recently was well frequented by the visitors. There being no competition, every effort is made to render the collection pleasing to the eye, and the arrangement, as usual, was most tasteful. Messrs. John Waterer and Sons of Bagshot made an admirable display of Rhododendrons; and the Cedars Hardy Plant Nursery, Wells, staged a good collection of Carnations, including splendid examples of Mrs. T. W. Lawson and Fair Maid. Messrs. George Cooling and Sons of Bath added to a very pleasing show of Clematis, Roses and Carnations, some good Tulips and Irises and a choice collection of hardy rock plants. Colonel Brymer (gardener, Mr. J. Power) sent a large variety of Schizanthus and Orchids, to which his collection of Palms, Ferns and foliage plants served as an excellent foil. Messrs. W. H. Rogers and Son, Southampton, staged Acers, Genistas and Spiræas; and the Eames Floral Nurseries, Frome, sent, among other things, a few well-grown examples of *Anchusa italica* (Dropmore variety). Messrs. Jarman and Co., Chard, made a special feature of Pelargoniums, Carnations and Azaleas, and also showed the new Centaureas The Bride and Honey-moon. Messrs. Garaway and Co., Durham Down Nurseries, Clifton, had a section made notable by some very fine Lilies of the Valley and blue Hydrangeas; and Messrs. Heath and Sons, Cheltenham, achieved a distinct success with a collection of rock plants, as well as greenhouse and hardy plants; a few heads of Embotrium attracted much attention, being evidently unknown to many of the visitors. Messrs. R. Veitch and Sons of Exeter showed some nice Clanthus, and Lady Digby made a very fine show of Odontoglossums. Hardy plants and Roses in great variety came from Messrs. Paul and Son of Cheshunt, and Pelargoniums were well represented by Mr. Godfrey of Exmouth.

**Compounds (poisonous) for horticultural and agricultural purposes.**—The horticultural trade should now bestir themselves and approach their Members of Parliament and obtain support to Clause 2 of the Poisons and Pharmacy Bill when it reaches the House of Commons. The final issue between the Traders in Poisons Society and the chemists monopoly is fast approaching, and every effort should be made to secure a victory for fair trade. The Bill has this season passed its second reading in the House of Lords, and Clause 2 (which will make it lawful for nurserymen, florists and agricultural agents to stock and retail insecticides, weed killers, sheep dips, &c.) has been recommended by a joint committee to go forward. It is anticipated that the Bill will reach the House of Commons from the House of Lords within the next few weeks, and it is most important that support for the Bill should be obtained at once by the horticultural trade by writing to their Members of Parliament, claiming support of Clause 2, as the chemists are opposing most strenuously and canvassing Members of Parliament. All information as to the way to go to work can be obtained from Mr. T. G. Dobbs, solicitor, Worcester (secretary of the Traders in Poisons Society). In the interest of horticulture and for the convenience of the gardening public I trust that you will insert this letter in your next issue.—J. H. RICHARDS.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Early-flowering Roses.**—I think it would interest many fellow readers to compare notes as to which we find to be the earliest flowering Roses. I had three blossoms open on June 1 on two plants, *R. rugosa rubra*.—M. P. H.

**Mistletoe flowers.**—Noticing your request in THE GARDEN of April 25 last for male and female flowers of Mistletoe, we have much pleasure in sending you these gathered at our Langley Nursery, where we always cultivate a number of trees with Mistletoe growing on them.—JAMES VEITCH AND SONS.

**Amaryllis Belladonna flowering now.**—I read your note in THE GARDEN with interest. The plants here also sent up flower-spikes at the end of April. The stems rotted at the ground level, but I was inclined to attribute that to the frost and snow of Easter week. They did not flower last autumn.—G. M. ROBERTSON, All Saints' School, Blocham, Banbury.

**Viburnum Carlesii.**—Referring to the note on *Viburnum Carlesii*, which appeared in THE GARDEN of the 16th ult., I think it may interest some of your readers to learn that a plant which has grown in the open ground, in a shaded and somewhat sheltered place, at Ketton in Rutland, since 1906, has flowered both in 1907 and this year. It does not appear to have been injured by the cold of even the past rather severe winter.—SUSAN H. BURROUGHS, Stoughton Farm, Leicester.

**Coleus thyrsoides.**—Now is the best time to propagate this useful winter Coleus to produce nice sturdy plants. If struck too soon they become very leggy by their flowering time. I find they root easily in a case kept quite close in a temperature of about 65°, and no bottom-heat is required. When struck, pinch out the tips and secure three or four breaks; the plants will then be most useful in 5-inch pots, or larger as required. I have grown this plant since its introduction, but never could I see its merits till last winter, when I flowered it in a much lower temperature than usual, maximum 50°. The colour then was much brighter and lasted three times as long in bloom.—J. S. HIGGINS, Rigg Gardens, Corwen.

**The Gayton rake and Sproughton hoe.**—In a recent issue the use of the Gayton rake was recommended. Will some reader kindly explain its advantages? Last year I bought the Sproughton hoe, recommended by the Rev. Foster-Melliar in his "Book of the Rose," a book, by the way, in my humble opinion, of invaluable use to all amateurs. I have put the hoe to very little use up to the present, as I fear the long, dagger-like blade may seriously injure the fibrous roots so often found near the surface. Will some reader kindly give me the benefit of his experience and suggestions as to the proper use of the Sproughton hoe?—**SUBURBAN.**

**A well-grown Dendrobium thysiflorum.**—I am sending a photograph of a Dendrobium, and, as I do not know the variety, I have enclosed flower [D. thysiflorum. —Ed.]. My garden friends think it very good. Last year it carried sixteen sprays from 9 inches to 18 inches long. This year it had eighteen sprays, but snails destroyed four, which left it with fourteen, but we were unable to show them all in the photograph. The treatment I give it is to keep it in a warm greenhouse till growth is finished, then remove it to a cold house where frost is just excluded till the buds begin to move. Then I return it to the warm house again.—**F. TAYLOR, The Gardens, Southcliffe, Lee, Ilfracombe.**

**Saxifraga longifolia and offsets.**

Mr. Arnott, on page 225, enquires concerning the above, and as the enquiry is doubtless the outcome of an earlier statement of my own, I may be permitted to amplify, and at the same time verify, what I first said. I may say at once that, in dealing with large numbers of imported plants in the past I have more than once seen examples of this species, in robust health, producing a secondary growth. I am referring now entirely to the linear-leaved form everywhere recognised as the true *S. longifolia*. I do not say that instances of secondary growths are plentiful; indeed, they are rare, but I do say that such things occur and exist. To what I have already stated may be added the fact that, on the 13th ult., in the collection of Mr. E. Hambro, Hayes, I saw a very fine example of this Rockfoil with a good secondary growth or rosette. In the same collection was a slightly broader-leaved form also received as *S. longifolia* with four crowns. In the instances formerly seen the rosettes were usually of nearly equal size and most frequently placed back to back. In the Hayes collection the rosettes are of unequal size, and the presence of the smaller rosette in one instance has tilted the larger rosette to an angle of nearly 45°. In those instances where the two rosettes are of nearly equal size, I have, on consideration, regarded it as the result of injury, probably in the cotyledonous stage, the twin crowns having grown up in consequence. This could hardly be the case where the crowns or rosettes are of very unequal growth or development, one, say, of 8 inches diameter and another of 3 inches diameter, which is sometimes seen. In such instances I should, without much hesitation, regard the presence of No. 2 as the outcome of an adventitious bud or something akin. All the same, while I give the facts as these have appeared to me from time to time, the whole of my experience among choice alpinists points to one thing, viz., that much the finer panicles of bloom are produced by those plants having but solitary rosettes of leaves. In the wild state the species is a variable one, quite apart from the degenerate cross-breeds. This variability extends to the encrusted character, its density or sparseness, the length and breadth of the leaves, also their flat or distinctly arching character. But in all its phases the plant is a glorious one, and one to be grown by all lovers of alpinists. Seeds are produced abundantly, and only quite ordinary care is needed, with intelligence, to ensure complete success.—**E. H. JENKINS, Hampton Hill.**

## THE KITCHEN GARDEN.

### LEEK S.

**T**HERE is little doubt that the Leek is one of the most wholesome of vegetables, and has long been held in very high esteem by all classes of society. The date of its introduction is uncertain, but we know it was cultivated in Egypt some 1,500 years B.C. Strange to say, for many years the production of high-class specimens was practically in the hands of Scotch friends and the extreme North of England, and it is only during the past twenty years or so that the Southern growers have found out that it is not merely the climate, as was once supposed, but the proper treatment of the plant, especially in the early stages of its growth. Whether intended for competition or for home consumption, every endeavour should be made to produce these at their best, and one can only appreciate good specimens when comparing them side by side with badly-grown produce.

There is considerable diversity of opinion as to what constitutes a good Leek. Some believe a long length of blanch is essential, while others are of opinion that thickness and not length is

DENDROBIUM THYSIFLORUM.

what should be aimed at. But in my opinion an intermediate specimen is to be preferred, consisting of a blanched stem from 12 inches to 15 inches in length with a circumference of about 6 inches, uniform throughout and no tendency to bulbing. The most important item to observe in Leek culture is that the blanching should begin immediately the plants are put out, as by this means the stems are drawn up to the required height with suitable paper collars, which are easily made, or they can be purchased at a small cost. Far too many people even now are under the impression that the growth should first be made and the blanching done afterwards. This cannot be, as after the growth is once set nothing will induce the plant to run to the length required, the result being a short edible piece generally full of grit, which, of course, is objectionable.

The Leek requires much food and loves moisture, hence the trenches should be well prepared and three parts filled with good manure. Water should be given freely in a clean and liquid manure form and the tops damped over every fine afternoon. Fine soil should be drawn up to the blanched portion as the paper collar is raised higher, and to hold the soil in position boards should be placed upright on either side, leaving a space of about 8 inches between them. This is a method I have adopted

for the last few years with the greatest success. By so doing the roots are not buried to any great depth as when the soil is banked up in the usual way, and the plants can be fed and watered much more effectively, and very little bulbing will be found to take place. What first induced me to follow this plan was when lifting the specimens, after being treated under the old-fashioned principle, the roots were found largely in the banked up soil instead of at the bottom, where they should be. This often meant that the appearance of the specimen was very much marred. For a continuance of a regular supply through the winter and early spring three sowings and three plantings should always be arranged. The last sowing made at the end of March should be planted on a south border from the middle till the end of June. There is no more delicious vegetable than the Leek when properly cooked, and it is to be hoped such a wholesome addition to the table will become more popular. **E. BECKETT.**

## THE FRENCH SYSTEM OF GROWING VEGETABLES IN GLASS FRAMES AND UNDER BELL-GLASSES.

RELATING to the above, a correspondent writes: "Some articles have appeared in the daily Press on the subject of growing vegetables in frames and under bell-glasses. There seems a lot in it, and I should like to try my hand at it in my small patch." We have no doubt that our correspondent in his remarks voices the wishes of a great number of our readers; and in the interest of those who have suitable land available, leisure and a determination to cultivate such land to its utmost capacity under intensive culture such as that practised by our French neighbours, we have pleasure in submitting the following details of culture gathered from witnessing the system in operation in France, as well as from long experience in the culture of such subjects in this country.

Before entering on details of culture, it is only right that we should caution such would-be growers against extravagant expectations in regard to profits which may result from an amateur embarking in the business. It has been stated that as much as £500 has been extracted from the soil by the vegetable products of one acre in one year under this system of culture. On the face of it this seems almost incredible; but when we come to consider the cost of covering an acre of land with glass in the shape of frames and bell-glasses, the quantity of manure which must be forthcoming, as well as the cost of labour involved, we are not prepared to dispute the statement that, with this heavy disbursement, it is quite possible for this gross return to be obtained by experts in the business on land which had been highly manured and intensively cultivated for many years; but for an amateur starting for the first time in the business on comparatively poor land and without any experience to guide him, no such returns are possible.

However, with experience, confidence gained and close application to the work there is no reason why an English gardener (or amateur, for the matter of that) should not be as successful, or more so, than are the French gardeners. The climate for at least thirty miles round London is as favourable for the growth of these vegetables as is the suburb of Paris where most of them are grown. Without any appearance of boasting, it is safe to say that we have the best and most remunerative market in the world for such produce at our doors, which market in the past has been wholly supplied, in respect to the subject under notice, by French gardeners, to their credit and gain and, it must be admitted, to our loss and discredit.

The success of the system depends almost entirely on the quantity and quality of stable or farmyard manure available and on the use of glass, and of both commodities we have an

unlimited supply. The system has never had a fair and full trial in this country, but during the last year or two attention has been drawn to the subject by a market garden firm in the Vale of Evesham, and also in Berkshire, both parties engaging Frenchmen to carry out the work. This system of culture is eminently suited for the small holder, enabling him to secure a number of crops in the course of the year from the same piece of land.

It is essential for the position of the land to be open to the south and on a slight slope if possible, and to be sheltered from the north, north-east and east, and also that the soil should be of good quality and depth and well drained, and of a light rather than of a heavy nature, and, above all, to be deeply cultivated and well stirred with half its composition made up of rich well-decayed manure. The manure when received will be in the form of strawy litter fresh from the stables, in which condition it

## ORCHIDS.

### DISA GRANDIFLORA.

**A**S a grower of Disas I have, contrary to general experience, found their culture very easy. To begin with let the aspirant fully understand that Disas are really cool plants, and to place them in a warm house spells failure. The system I follow is very simple, and my results are always successful. Growth starts immediately the flowers begin to fade. At this stage I turn the plants out of their pots, removing all the compost and taking care to prick out any small tuber that may be among it. The largest tubers are generally flowering size. These I place in 5-inch pots and the smaller tubers go into less size. The soil I use is not an elaborate mixture, as it consists only of peat with the fine

pushing up their flower-spikes. The flowers remain in beauty from four to six weeks, and are always a great attraction.

*Penicuk.*

W. ANGUS.

### ODONTOGLOSSUM CRISPUM LEONARD PERFECT.

THIS is a very fine form of a most popular Orchid, and one that has given us many varieties during the past few years. The flowers are very large and of splendid shape and substance, the white ground being heavily mottled with brownish purple blotches. The plant exhibited was a very vigorous one and the inflorescence was enormous, this being composed of thirteen fully-developed flowers. The stem was as thick as a lead pencil, and the leaves very long and robust. Exhibited by Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne (gardener, Mr. H. J. Chapman), before the Royal Horticultural Society on the 12th ult., when it received a first-class certificate and a gold medal.

## THE ROSE GARDEN.

### A BEAUTIFUL NEW SINGLE ROSE.

**T**HE delightful new single-flowered wichuraiana Rose which Messrs. Barbier and Co. have given us under the name of Joseph Billiard cannot fail to become a favourite by all who appreciate these simple yet elegant Roses. The combination of colour is charming, as we might expect from a cross between *R. wichuraiana* and the lovely monthly Rose *Mme. Eugène Resal*. When in the bud and until the flower is half open the outside of the petals is a rich apricot yellow, the inner side of the petals revealing a bright rosy carmine tint. When the flowers expand they are fully 3 inches across. We then have a distinct white centre, which, together with the rich carmine of the remaining part of the petals and the golden stamens, makes up a most beautiful Rose, as pleasing in its way as the lovely hybrid of *Rosa sinica* known as *R. sinica Anemone*. Being so large a flower we could scarcely expect the clusters to contain many buds; they are produced three to five in a truss, but do not expand simultaneously. This Rose will be a delightful companion to *Jersey Beauty*, as it possesses a very bright and glossy foliage, but not quite equal to the latter in this respect.

P.

### A NOVELIST'S ROSES.

NOVELISTS are very fond of lapsing (or rising) into raptures about the Roses in a heroine's garden, but they seldom venture to give much information about the methods of culture or the most successful varieties. Mr. E. F. Benson, however, in his latest novel, "Sheaves" (but it may be only his latest but one by the time this can get into print) does—greatly daring—give us a catalogue, and a curious catalogue we find it. We begin, of course, on the high note. "As if he was [were] the conductor of some garden symphony, all the Roses had responded, as when a hundred bows are ready resting on the strings to that baton-beat, and had leapt on to a fortissimo." The catalogue follows.

"There was old-fashioned cabbage rose [denuded of capitals], homely to the eye but steadfast as a friend to the nostril; *La France* was there, perfect in line and scent; *Baroness Rothschild* was pinker

A BEAUTIFUL NEW ORCHID: ODonTOGLOSSUM CRISPUM LEONARD PERFECT. (Single flower natural size.)

is used for making up the hot-beds, and afterwards, when it has sufficiently decomposed, it becomes available as manure for the above purpose.

In France the frames used for the growth of Lettuce and other vegetables in winter are chiefly made on the ground by ordinary workmen. They are formed of rough boards, most of them dovetailed together so that they can be pulled to pieces and packed into small compass when not in use. They are usually 4 feet wide by 5 feet long, about 20 inches deep at the back and 14 inches in front. Glass lights to fit them may be obtained from horticultural builders by giving dimensions, with cloches or bell-glasses, the larger ones (and these are mostly in use) are from 15 inches to 16 inches in diameter and about the same in height. They are made of strong glass, and with care will last a lifetime, and there is no after cost entailed in the way of painting or repairs. The cloches are chiefly used for Cos Lettuce, and the frames for Cabbage Lettuce, because they can be grown nearer the glass.

OWEN THOMAS.

(To be continued.)

portions shaken from it, light loam broken into pieces, and a liberal quantity of sand so as to form a good open mixture. The soil is used neither too dry nor too wet; a practical man knows by the grasp of it. The tubers are placed in pots as described, the compost is worked in among them, finishing off by leaving the tuber entirely below the surface of the soil, and allowing a space of half an inch for holding water.

The best house I consider is a cool greenhouse, where they can have plenty of air and not too moist an atmosphere. I usually grow my plants in a greenhouse or a Peach house all the winter, where they are never without fresh air. The plants are flowered in a Carnation house, as the treatment for both suits admirably. This house has obscure glass, and a season like the one gone past I never had to use shading in any form.

In ordinary seasons it is always advisable to shade to preserve colour, and also to prolong the flowering season. When growth is in full vigour I feed liberally, but with judgment, with liquid manure. I find it most beneficial when they are

and more perfect in form, but with no other appeal; Richardson [presumably William Allen of that ilk] sprawled, desiring fresh trellises, where he could wrestle with the loose carmine pillar [justifiably loose after the annoying deprivation of his capitals also]; Beauté Inconstante showed copper, and yet maintained its value against the purer gold of Dijon [Gloire de Dijon]; Captain Christie [Christy] found an anchorage on this stormless margin of the Thames; and a company of alien ladies, Mme. Vidal, Mme. Rivot, Mme. Résal, agreed with Lady [Viscountess] Folkestone on the pleasantness of this Thames lawn."

Several things puzzle us here. If La France was "perfect in line," how could Baroness Rothschild be "more perfect in form"? It would be a very poorly-grown La France which could not beat a Baroness Rothschild in line or form, whatever the difference may be. And Captain Christy is not a delicate Tea "seeking an anchorage," but a strong garden Rose. But most puzzling are the "alien ladies." Mme. Résal we may, perhaps, assume to be Mme. Eugène Résal; Mme. Rivot might possibly be a large corruption of Antoine Rivoire. Mme. Vidal we give up in despair.

The natural conclusion would seem to be that Mr. Benson must join the National Rose Society at once, and spend July 3 in the Royal Botanic Gardens, so as to get a good Rose garden, with correct labels, ready for his next heroine, say, before the autumn. G. E. JEANS.

NEW PLANTS AT THE TEMPLE SHOW.

DRACÆNA DOUCETTI DE GROOTEL.—This very handsome plant came from Messrs. James Veitch and Sons, Limited, Chelsea, and may be said to resemble a well-variegated form of *D. australis* with longer and more rigidly inclined leaves. The specimen was upwards of 4 feet in height, and as an isolated example for the conservatory would make a showy and useful subject.

Mr. Walter T. Ware, Bath, had a remarkably fine cottage Tulip of the largest size named Walter T. Ware. The colour is deep golden orange. It is probably the most intensely coloured in this section. This very handsome Tulip had previously received an award of merit and was now given a first-class certificate, a similarly high award being also granted to the *Dracæna* described above.

A very pleasingly coloured *Azalea* (*A. occidentalis graciosa*) was shown by Messrs. R. and G. Cuthbert, Southgate, and attracted a large number of visitors by the delicate tone of its blossoms. The body colour is of a creamy white, tinted with pale pink or blush towards the outer edges of the petals.

*Begonia* Empress Marie, as shown by Messrs. Blackmore and Langdon, Bath, may be said to represent a near approach to perfection in double white-flowered varieties, and those of the *Camellia*-flowered group in particular. The variety is an exceedingly beautiful one, very pure in tone, and the handsome character of the flowers is greatly enhanced by well formed and shapely petals of much purity.

A richly-coloured *Croton* of the three-lobed section, named Fred

Sander, was exhibited by Messrs. Sander and Son, St. Albans. The upper parts of the leaves are dark olive green, the central portion and the base near the leaf-stalk being of a clear gold colour.

Not the least striking or beautiful subject among the new plants shown for certificate was the orange-coloured *Dimorphotheca aurantiaca* from Messrs. Barr and Sons, Covent Garden. The shining petals or ray florets and their refined colouring are quite an attraction. The exhibited examples of this pretty Cape annual were about 18 inches high. We regard it as a plant best suited to warm soils and situations, and in such should form a really attractive bed, not far removed in effect from a small-flowered *Gazania*.

New Roses are always regarded with favour, but on this occasion absolute novelties were not plentiful, the most chaste and beautiful being Elaine, as exhibited by Messrs. William Paul and Sons, Waltham Cross. It is a Hybrid Tea whose outer petal tips are strongly recurved, while the central portion of the well-modulated tapering blossoms is of exquisite form. A white-flowered variety of fragrance and merit.

Two other varieties of Roses call for mention among the certificated novelties, and these are White Dorothy (rambler), shown by Messrs. B. R. Cant, Colchester, and William Paul and Son, Waltham Cross, and Tausendschön, also a rambler, shown by Hobbies, Limited, Dereham, and William Paul and Son, Waltham Cross. White Dorothy has happily a descriptive name of its own, and further remark would be superfluous, unless it be to say the newcomer is a counterpart of the old. Tausendschön, however, will doubtless prove a stumbling-block to many a gardener until the correct pronunciation of the word has been conquered, but the handsome Oleander-like blossoms of rosy pink, broad

and shell-like in petal, will appeal to all who delight to have beautiful pillar Roses in their gardens.

*Pæonia decora alba*, exhibited by Messrs. Wallace and Co., Colchester, is a single-flowered variety of the species indicated. It is, we believe, a variety that the late Michael Foster had in his garden for some years. An illustration and description of it will be found on page 291.

Tulip Duchess of Westminster may be briefly described as a rose-coloured Darwin with a suffusion of palest pink near the edges of the petals. It is a showy and beautiful variety of much merit, and was seen in the group from Messrs. Alex. M. Dickson and Sons, Belfast.

To each of the foregoing novelties an award of merit was granted.

CACTUS DAHLIAS IN VICTORIA, AUSTRALIA.

SOME eight years ago I decided to go in for Cactus Dahlias and give them special attention for show purposes. Right from the start I was most successful from every point. Such good results were obtained that I not only secured the champion prizes at all the leading Victorian shows, but I had plants which gave me champion blooms, and also provided me with thousands of beautiful flowers for distribution among my friends.

Victoria, especially the southern part, is specially suitable for the growth of Dahlias. The green plants are put out about the middle of December (our summer), and three months afterwards they start to flower. For the next six weeks they make a grand show.

We are right up to date as regards the latest novelties. Personally I import the majority of them every season, and as we can flower them six months after you have flowered them in England, it can be seen we are not far behind the English growers with their new varieties. On the other hand, we raise a good number of very good varieties ourselves; in fact, so fine that over and over again they have beaten all the English varieties for "champion bloom in the show." If one has the room, a bed of seedling Dahlias is most interesting; and if a number are grown there will, as a rule, be two or three worth saving.

The *Pæony* Dahlia has also "caught on" as a desirable garden flower; but the old-fashioned show Dahlia is now a thing of the past, and is very rarely shown at any of the good Dahlia exhibitions in Victoria.

In connexion with the Geelong Horticultural Association the Dahlia show is a very popular one, and the competition in all sections is very keen. We have three classes, viz.: Open Class, open to all, nurserymen or amateurs; Amateur Class, open to amateurs only; Amateur No. 2 Class, open to amateurs with small gardens. We find this latter class most popular, and in order to encourage beginners give prizes to those who have never previously won a prize.

HOWARD HITCHCOCK.

CACTUS DAHLIA MRS. F. MCQUADE AS CROWN IN VICTORIA, AUSTRALIA.

## THE FLOWER GARDEN.

### PREPARING FOR SUMMER BEDDING.

**B**Y the time these lines appear in print the important work of preparing the beds for a display of flowers during the summer will demand attention. The selection of plants for the various beds should have first consideration, and care must be taken that a sufficient number of these are in readiness before the actual work of planting out begins. Excellent notes have been printed in *THE GARDEN* recently respecting a variety of plants suitable for this purpose with details of their arrangement. These may be followed with every confidence of securing a pleasing effect providing the planting is carefully carried out. An important matter is a suitable soil for individual plants. Plants which are intended for producing a wealth of flowers such as the Geraniums, although not needing an abundance of fresh manure added to the soil, must, however, be provided with sufficient food to keep them in robust health, so necessary for the continual and free production of good flowers.

This is especially important when the beds have been filled with plants during the spring, some of which, such as Wallflowers, require a lot of food, and therefore leave the soil in an impoverished condition. For enriching the soil of these beds give half-rotten manure and bury this deep enough to escape coming in contact with the roots of the plants. If no manure is applied in the case of light, shallow soils, the growth of the plants will not be satisfactory, and should a period of drought occur they quickly fail owing to the extreme porosity of the soil. With a deep soil, and when following a regular system of manuring the beds in the autumn, it is not necessary to apply manure now for the majority of bedding plants. There may be exceptions, however, as in the case of Dahlias (dwarf varieties of which are used with good effect in some bedding schemes), which require a rich soil. Other plants for which manure may safely be applied are Cannas, *Lobelia fulgens* and any of the strong-growing specimen plants where a bold effect is desired. Dwarf-flowering plants intended for producing a sheet of colour are best without fresh manure, as this promotes too much foliage. A sprinkling of some approved fertiliser

is, in many cases, sufficient, and even this may not be required if the soil is in good condition.

#### THE ACTUAL PLANTING.

Roots of all plants should be in a moist condition when planted. This is frequently advocated, but cannot be too strictly watched, especially when dealing with plants grown in pots. It is difficult to thoroughly soak the ball of soil after it is turned from the pot. Press the soil firmly round the roots and level the surface with the trowel as the work proceeds. After planting a bed, in the absence of rain, apply a copious watering, using a rose watering-pot for this purpose. Plants requiring supports should

be afforded neat, green painted sticks, and these should be placed in such a way so as to be as inconspicuous as possible. The soil between the plants should be frequently stirred during the season. Frequent watering has a tendency to produce a hard, caked surface, and if this is not broken with the hoe the plants suffer through the roots becoming unhealthy owing to the exclusion of air.

#### TIDINESS IS ESSENTIAL

throughout the season. Weeds, dead leaves and faded flowers must be removed, and every effort made to preserve neatness in the beds. Plants requiring tying to their supports should be regularly attended to, also those which require pegging down to the soil. When left too long and the growth becomes crowded the task is difficult, and there is always the risk of the plants getting broken. Plants carefully tended will give good results, and afford pleasure to all who see them.

*Munden Gardens, Watford.*

C. RUSE.

### TWO NEW HARDY PLANTS.

THE *Lewisia* family, which contains some very interesting and beautiful plants, is confined to North-western America and is closely allied to *Calandrinia*. One of the first to be introduced into cultivation was *L. rediviva*, a native of the Rocky Mountain region, where it is found growing alongside rivers on dry prairies.

The latest addition to the number of species of this genus in cultivation is *L. Cotyledon*, a beautiful plant from the Siskiyou Mountains of Northern California. As may be seen in the illustration, it forms a rosette of leaves not unlike those of *Saxifraga Cotyledon*, but greener, more fleshy and without the silvery edge. They are about 4 inches in diameter, while the much-branched stems reach a height of 6 inches. The flowers, 1½ inches in diameter, have eight to ten petals, which are rose-purple with a broad white margin. The photograph of the plant was taken when only the three primary flowers were expanded, but afterwards the stems developed and produced more flowers, four to six being out together on each stem. These later flowers, however, were slightly smaller than those first

A BEAUTIFUL NEW HARDY PLANT : LEWISIA COTYLEDON.

A NEW HARDY FLOWER : CORYDALIS ALLENI.

produced. A distinctive feature of the plant is that both bracts and sepals are fimbriated with reddish, glandular tipped hairs. It was found growing on well-drained rocky slopes, with a southern exposure.

So far the plants have been grown in pots in a cold frame, potted in very sandy loam, but there seems no reason why it should not be as hardy as the other species. All these, however, do not succeed in every garden, and some little care and attention is required in order to grow them successfully. The best position for most of the different species is one exposed to full sunshine, in a mixture of sandy loam and leaf-soil, with plenty of good-sized stones mixed with the soil. They require to be kept rather dry in the winter while they are at rest, and an overhanging stone will afford the necessary protection.

#### THE CORYDALISES.

All the Corydalises are pretty rock or shade-loving plants, some of the stronger-growing like *C. nobilis* being effective border plants, while others like *C. bracteata* and the lately-introduced Chinese *C. thalictrifolia* are graceful subjects for the rock garden.

The subject of this note and illustration is an earlier-flowering, stronger-growing form of the pale yellow *C. bracteata*. It is a plant of garden origin and there is a suspicion of hybridity about it, the colour of the flowers (yellowy white, with a tinge of purple) suggesting the influence of *C. tuberosa*. Flowering as it does some fortnight before *C. bracteata*, it is a welcome addition to our early spring plants. Judging from its behaviour so far it appears to be free growing, as it has already made an effective group. I have no knowledge of the raiser of *C. Alleni*, but the plants were obtained from Mr. Amos Perry of Enfield some two years ago.

Of the species of *Corydalis* worth growing in addition to the above, there is the well-known *C. nobilis*, with its deep yellow and purple-tipped flowers, and the pale sulphur yellow *C. bracteata*. An elegant species is *C. cheilanthifolia*, with Fern-like foliage and small yellow flowers. It makes great tufts and is quite a desirable plant for the rock garden. *C. thalictrifolia* is one of the best of late introductions from China, with bright, clear yellow flowers on long racemes, and it also has handsome foliage. It flowers all the summer, and continues till cut down by frost. *C. Wilsoni* is a beautiful plant with much-divided, almost white foliage and racemes of rich yellow flowers. All are easy to grow in well-drained, light rich soil, but the Chinese species are liable to damp off in winter unless protected by glass.

W. IRVING.

#### PÆONIA DECORA ALBA.

This is a single and beautiful white-flowered variety of the above-named species. The handsome blooms of 4 inches or 5 inches across are of a spreading cup-like outline, and have a tuft of quite pale yellow anthers surrounding the ovary. The petals are of satin-like transparency and impart a pleasing effect to the flower. The plant is 2 feet high or rather more, and the blooms, as is usual, are solitary. This good border plant was noted in the group of plants staged by Messrs. R. Wallace and Co., Colchester, at the recent Temple show, when it received an award of merit.

#### GARDEN CACTUS DAHLIAS.

Owing to varying circumstances, but especially that the plants were sent in too late in the spring, the trial of Cactus Dahlias conducted last summer in the Royal Horticultural Society's gardens at Wisley, under the joint auspices of the Royal Horticultural Society and the National Dahlia Society, had a very indifferent result, nothing specially worthy of mention for real garden decoration resulting. A section of the Dahlia committee, not so absolutely engrossed in the mere exhibition aspects of the Cactus Dahlias as some others, are anxious to see these most

beautiful flowers made as attractive in gardens as they are at exhibitions, and for that reason have induced their own society, in conjunction with the Royal Horticultural Society, to promote trials of the newer varieties at Wisley to test their fitness for garden purposes. It is too well known that with very few exceptions, these being chiefly found in what is known as the Pompon section of the Cactus varieties, that the plants under ordinary garden culture run too tall, and generally show gross dense growth. The flowers, while produced in abundance, are too much hidden by the luxuriant foliage, and the flower-stems are too weak or limp, not carrying the flowers boldly erect, such as is seen in the ordinary Pompon Dahlia, without doubt yet by far the most florally decorative section of garden Dahlias we have. Trade growers aver that to have Cactus Dahlias in gardens at their best the plants need much of both thinning and disbudding. But those necessities constitute the weakness of the section, as it is just so much trouble in garden plants everyone wishes to avoid. Thus it is seen that while raisers have in Cactus forms produced what may well be described as marvellously beautiful flowers, many, perhaps, ranking among the quaintest in form found in flowers, yet their energies

A NEW SINGLE

PÆONY : PÆONIA

DECORA ALBA.

seem to have been chiefly devoted to the production of exhibition varieties rather than those specially suited for and very beautiful in gardens.

The Wisley trial of the past season included varieties put into commerce from 1904 up to 1907. The ensuing trial for 1908 will include varieties sent out only since 1905 and inclusive. It is needful thus to limit the range of selection, as the primary object of the trial is not to include in it as Cactus Dahlias varieties that, however attractive in gardens, are yet not true to name, but only such varieties as produce flowers of the most up-to-date Cactus form. It is worthy of note that the next exhibition of the National Dahlia Society will be held at the Royal Horticultural Society's Hall, Vincent Square, on September 3, instead of at the Crystal Palace, as has hitherto been the case.

A. D.

## THE EDITOR'S TABLE.

### JACKS-IN-THE-GREEN PRIMROSES FROM WOODCOTE.

Mrs. Danvers Bidlake of Woodcote, near Stroud, sends fine flowers of this old favourite with the following note: "I brought some of the plants from Ireland some years ago. I had collected them there from one spot or another, generally from old cottage gardens. One or two varieties I have got about here in the same way, but as varieties seemed to have increased in my garden, some, I believe, have come from inoculation. I found them much more difficult to grow here than in Ireland; the soil is too full of lime and too much clay for Primroses and the summers too dry. I planted them in various parts of this garden when first we came nine years ago, and then watched to see where they

grew best, in the open or in the shade; and soon came to the conclusion they did best in a well-made rockery. I tried various experiments with manures and soils, and now use exclusively stable manure made of moss litter (a horse we had ate straw, and so we used litter instead) to grow them in; the more moss litter and leaf-mould the brighter the colours and the finer the foliage. I water them in the summer, and sometimes put shades over the more delicate plants. It takes trouble, but I am very fond of these and the Hose-in-Hose."

### ARENARIA GRANDIFLORA FROM ESSEX.

An anonymous correspondent sends flowers of this charming Sandwort with the following note: "I am sending a few sprays of *Arenaria grandiflora*, as at present it is one of the most showy subjects in the rock garden. The plant measures 15 inches across, and is a mass of white flowers."

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**T**HE GREENHOUSE AND CONSERVATORY.—Fancy, regal and show Pelargoniums that have made such a fine display of late are now fast going out of flower; I am, therefore, placing these outdoors in a sunny position so that the wood may be ripened. I avoid watering freely and when the leaves turn yellow

1.—A CHRYSANTHEMUM PLANT TURNED OUT OF A 5-INCH POT, WELL ROOTED, READY FOR PLACING IN ITS FLOWERING POT.

it is my custom to cut back the old shoots to within about 2 inches of the main stems. If these plants are left in the glass structure too long with other subjects they often get infested with green fly. Fuchsias are now coming on very fast; these should be watered with manure water occasionally to keep them in health and ensure the development of fine blossoms. As the days get warmer very little fire-heat will be needed, and such subjects as Maidenhair and other choice Ferns must be shaded from the hot sun, otherwise the delicate tones of green will be lost. The leaves of fine foliage plants must be kept clean and free from dust if they are to do well at this season.

**Roses.**—Plants that have ceased flowering indoors I am now standing outside. The present is a good time to propagate these indoor Roses. Plants in the beds and borders outdoors I am constantly overlooking, removing suckers immediately they are seen, otherwise they soon become a serious trouble. Insect troubles have to be contended with, caterpillars needing to be searched for before they begin their ravages of both foliage and buds. Aphides may be got rid of by syringing with any well-known and approved insecticide, of which there are now so many really excellent preparations. The plants will now appreciate occasional applications of manure water, or, what is better, a dressing of some good guano or concentrated manure. This latter is especially beneficial in moist weather.

**The Vegetable Garden.**—Early Celery that has been pricked off in boxes or the cold frame some time should be planted now, if possible during rainy weather. If the weather is dry give the soil in the trenches a heavy application of water some few hours before the planting is done. The trenches should be 3 feet or rather more asunder, and should run from north to south. The width of the trenches may be anything from 15 inches to 18 inches; the depth should be about 12 inches, filling in with 6 inches of good, well-decayed manure and covering this in turn with 3 inches of the garden soil. Plant from 6 inches to 9 inches apart in the trench, taking out the soil with a trowel and in this way ensure each plant being well embedded. Water in afterwards. Continue to thin out all vegetable crops, such as Beet, Carrots, Parsnips and Onions, giving each plant ample space to develop satisfactorily.

**The Flower Garden.**—I am completing the planting out of such annuals as Ten-week Stocks, Asters, and the sweet-scented Tobacco plant, as opportunity offers. Annuals that were sown where they are to flower I am thinning out in most drastic fashion. It is a great mistake to allow these to grow in too crowded clumps. See to the staking of all flowering plants forthwith, as they are now making such rapid progress. Continue to plant Dahlias that have been hardened off in the cold frame. Give the plants plenty of room and stake them at the time of planting. Pansies and Violas should have their seed-pods and spent blossoms rigorously removed throughout the whole of the summer season to maintain the plants in health. For next year's supply of Canterbury Bells I am now making a sowing on a sunny border outdoors. Wallflowers, too, I am giving the same attention, although I would rather have done this some time since.

**The Fruit Garden.**—Fruit trees against walls should be syringed pretty often at this period to keep red spider and aphides from giving trouble. This should be done in the cool of the evening. Place clean straw on the surface soil between the rows of Strawberries to keep the fruit clean. If fine fruit is required it will be necessary to thin out the weaker and smaller fruits that have set on such subjects as Apples, Pears and other hardy fruits. D. B. C.

### THE FINAL POTTING OF CHRYSANTHEMUMS.

ALTHOUGH beginners with the cultivation of the Chrysanthemum may have heard of the term "final potting" times out of number, they may be in doubt as to what this term really means. To give the plants the final potting, or, as termed by some authorities, "final shift," is really to place the plants in their flowering pots. This has to be done at its proper season, May and June usually being the best time. It is hopeless to expect to produce big blooms, or plants that are capable of developing a number of flowers of a decorative character, unless the plants are given sufficient root-room. Chrysanthemums vary in their character, some varieties being far more vigorous in their root-action than others; consequently a little discrimination is necessary when deciding in which size pots to place the respective plants. The more vigorous plants will do well if they are put into pots measuring 10 inches in diameter, those somewhat less vigorous into others 9 inches, and the somewhat weakly ones in pots measuring 8 inches across.

### HOW TO KNOW WHEN THE PLANT IS READY FOR THE FINAL POTTING.

Evidence that the plant is ready for the final shift is given by the quick drying of the soil and

the more frequent applications of water needed as a consequence. If the grower is uncertain as to this fact, he may turn the plant out of the pot, when, if the plant be ready for transference into its flowering pot, it will have a mass of roots round the ball of soil. Fig. 1 is a very good illustration of a plant that is ready for its final potting.

### SOIL FOR FINAL POTTING.

This must be well prepared and should comprise three parts of good turfy loam with plenty of fibre in it. This material should not be passed through a coarse sieve but should be broken up into little nodules. Add to this one part of leaf-mould and one part of well-rotted manure from a spent hot-bed, with a free admixture of road grit or coarse silver sand to make the compost porous. The foregoing ingredients should be well mixed, and to make the soil more fertile to every bushel of soil add a 5-inch potful of bone-meal and guano. The whole heap should be thoroughly mixed and turned over each day for several days before it is used.

### HOW TO FINALLY POT THE PLANTS.

Crock the pots with care, placing potsherds in an inverted position in the bottom of the pot in layers to a depth of about 1½ inches to 2 inches. These should be covered with some of the rougher portions of the soil or a piece of turfy loam to prevent the smaller particles of soil working down into the drainage. Place a few handfuls of the compost over this in turn and make fairly

2.—LATE STRUCK PLANT, PROPAGATED WITH THE OBJECT OF FLOWERING IT IN A 6-INCH POT.

firm, and the plant to be repotted should then be placed in position. With the fingers of the left hand placed round the stem of the plant to maintain it in position, fill in all round the ball of soil with the prepared compost with the right hand, making this very firm, ramming it down by the aid of a wedge-shaped wooden rammer. Take care, however, when ramming the soil not to damage the roots, otherwise serious trouble will

ensue. Continue this up to the level of the surface soil of the plant, which should be  $1\frac{1}{2}$  inches to 2 inches below the rim of the pot, otherwise adequate supplies of water cannot be supplied during the summer season. Finish off with a thin layer of soil on the surface, pressing this down with the palm of the hand. On no account should this be rammed or the surface roots will be damaged thereby. Insert a small stake for the support of the plant, and stand each one as it is done in slightly shaded quarters, where they should be allowed to remain for a week or fortnight until they have recovered from the check experienced in the repotting. Do not water the plants at once unless the weather be very hot and dry. After a few days give them a copious application of clear water by the aid of a fine-roset can, and do not rest content until the ball of soil is moistened throughout. It may be necessary to give two or three waterings in quick succession to achieve this.

#### POTTING UP LATE STRUCK PLANTS.

Fig. 2 serves to illustrate a cutting that was struck quite late in the season with the object of

4.—THIS PLANT WAS ROOTED EARLY IN MARCH AND HAS BEEN PINCHED TO MAKE IT BUSHY.

flowering the same in a pot 6 inches in diameter. It will be seen that the plant in this illustration is well rooted and ready for shifting into a pot of larger size. It may be either first transferred to a pot measuring  $3\frac{1}{2}$  inches in diameter, or be placed right away into its flowering pot measuring 6 inches in diameter. We would prefer to adopt the former course, although if the time be limited the second method is often practised. The illustration in Fig. 3 shows a plant struck slightly earlier than that seen in Fig. 2. The object of the earlier propagation was to obtain a plant of a bushy character. In order to do this the point of the shoot was pinched out a few weeks since, and in consequence of this treatment the plant has evolved two shoots where formerly there was only one. The illustration in Fig. 4 shows the plant in Fig. 2 finally potted in a 6-inch pot. Either of the methods above mentioned may be followed with the sure prospect of producing good results. Fig. 5 represents a plant that was pinched, i.e., the point taken out

of the plant, in late March, in consequence of which the plant has developed its branching growths earlier than would be the case otherwise. This is an advantage where the flowers are wanted early or where the plant is naturally late and the blooms are needed for an earlier display. The same rule is usually observed where large, bushy specimens are required for decorative uses.

#### SOME USEFUL HINTS FOR EXHIBITORS.

To the best produce the prizes are awarded, and exhibitors who have had considerable experience know how very important it is to try and grow every plant, flower, fruit or vegetable as well as possible when the object is to gain prizes at a horticultural show. I will give a few useful hints on essential points in connexion with the growing, packing and staging of different kinds of fruits, flowers and vegetables that amateurs may find of service to them.

#### ROSES.

As a rule a fair quantity of organic manure, in the form of manure from the cowsheds and stables, is dug into the soil at the time of putting in the plants. Where this has been neglected it may be well to put on a good mulch of rotted manure now, and not a littery mulch. The production of fine blooms is not absolutely dependent upon the large supplies of farmyard manure, but I always like to give the Roses a liberal quantity. At the present time give also one teaspoonful of sulphate of ammonia to each plant and well water it in. A week or ten days later apply a dessertspoonful of superphosphate to each plant. Then follow these applications with one of nitrate of potash, using  $1\frac{1}{2}$  oz. to 2 gallons of water. In all cases see that the soil is moist before applying manure in any form. The foliage must be kept free from aphides and caterpillars, else the most promising buds will undoubtedly be lost. I hope to give a few hints about the gathering, packing and staging of the blooms in a later issue of THE GARDEN.

#### PEAS (CULINARY).

These must have plenty of moisture at the roots right through their growing season. Numerous roots must be encouraged to grow, and to this end the rooting medium should be deeply trenched. Encourage strong growth and then the plants will bear large, well-filled pods if superphosphate at the rate of 1 oz. per yard run of row is scattered on the soil on both sides when the plants show signs of forming flowers and during the swelling of the pods. Phosphate of potash is also a grand food, 2 oz. dissolved in 3 gallons of water being a suitable dose for each yard of row. Do not forget to put on a timely mulch of half-rotted manure; it is a valuable aid in spells of dry weather.

#### SWEET PEAS.

Practically the same treatment is necessary in growing large blooms of Sweet Peas. It is now too late to sow seeds, but if the plants are growing in deeply-dug ground you must help forward the haulm by applying superphosphate as soon as possible at the rate of 1 oz. per yard run of row or per clump respectively. Put on the superphosphate during rainy weather. In the absence of rain give clear water first and afterwards wash in the stimulating food. Weakly sprays or those only bearing two blooms should be pinched off; and, furthermore, all faded flowers should be removed. On no account allow seed-pods to form on the plants. AVON.

#### WORK AMONG THE RASPBERRIES.

THESE plants will now be pushing up an abundance of vigorous young growths, and where the work has not already been done the thinning of these should be at once attended to. Healthy clumps always produce far more shoots than it is desirable to retain, and the early removal of those

3.—THE SAME PLANT AS SHOWN IN FIG. 2 FINALLY POTTED IN A 6-INCH POT.

that are superfluous is of much benefit to those that are left. Generally speaking it is a wise plan to retain three or four of the most vigorous and best placed suckers to each clump, and all others should be removed just below the surface of the soil, unless any are likely to be required for the formation of a new plantation in the autumn. Where such are needed those shoots that are pushed up some distance away from the clump should be retained, as they will be the best for lifting.

If not previously done a good 6-inch thick mulching of rather short manure should be placed along each side of the row, first giving the soil a thorough soaking with water if it is at all dry. Weeds must be kept down by lightly hoeing the ground, and any tying that is needed must be promptly attended to.

A point that is often overlooked by amateurs in the cultivation of this fruit is the early removal of the fruiting canes. As soon as the fruit is gathered from these they are of no more use to the plant, and, indeed, their presence is detrimental. They should be cut out immediately all the fruit has been collected, thus admitting sun and air to the young canes which are to bear the crop the following summer.

5.—A PLANT PINCHED IN LATE MARCH, IN CONSEQUENCE OF WHICH IT WILL FLOWER EARLIER

## THE TOWN GARDEN.

**CARNATIONS.**—These are among the most satisfactory of all plants for cultivation in town gardens, for, although they are severely attacked by sparrows in some places, they only demand reasonably good attention to ensure gratifying results. At the present time the plants are in excellent condition, the growth being abundant and healthy and the buds clean and numerous. As far as the latter are concerned, the main things are reduction of numbers and light but efficient support. In all instances it is desirable to do a little disbudding, and the rule should be to retain the principal bud, except in those cases where it is deformed. Light, green sticks should be used to support the flower-stems, and one will suffice to each plant, the several growths being slung separately to it, and not tied up in a solid mass with one ligature. The surface of the soil should be kept open by persistent hoeing or pricking over with a small fork or a stick, and water must be given when the soil is almost perfectly dry. If it is suspected that the soil is becoming deficient in food, weak liquid manure, made preferably from natural manures, should be given now and again after the soil has been thoroughly moistened with clear water. It is essential that a sharp look-out be kept for slugs or they will quickly play havoc with the plants.

**ROCKWORK.**—Whether the rockery be one of pretension, that is entitled to be designated a rock garden, or is of quite modest dimensions, it will demand attention at practically all periods of the year. Just now the owner will devote much of his energies to keeping down the weeds and giving water according to necessity; but it is imperative that he shall also keep close watch on the progress that is being made by the stronger-growing occupants. If these are permitted to spread unchecked they will steadily overrun their weaker neighbours, and, as the latter are often the choicest plants in the collection, the result will be most disappointing. However, this is one of those things that is always under the control of the grower, and if he will only give it regular attention it is unlikely that any of the specimens will suffer to an appreciable degree. It certainly requires some strength of mind to ruthlessly tear up vigorous clumps of plants in full flower, but it is a necessity if the rockery is to continue a source of pleasure for a considerable period.

**SEED SOWING.**—Such subjects as Antirrhinums, Canterbury Bells, Polyanthus and others thrive splendidly in town gardens, provided that strong plants are raised and placed into their permanent quarters in the autumn. Wallflowers grow well if the garden is large enough to ensure abundance of air, but where the supply is stinted they are weak and rarely pass safely through the winter. In these circumstances it is wiser to procure healthy young stock and plant in the spring. The present month and July are the best for seed sowing, and a special bed should always be made up for the purpose. Dig the selected area deeply, and then put on a layer of about 3 inches of leaf-mould, pricking this into the surface with a fork, as one thus provides a material to which the young roots will cling with great tenacity. Upon the completion of this, make the surface level and moderately firm, and sow the seeds as thinly and evenly as possible either in drills or broadcast, the former for preference. If the soil is moist, no water will be required for some little time.

**RED SPIDER.**—This is a terrible pest on plants grown against the hot walls of town gardens, and if it is allowed to multiply unmolested it soon does an immense amount of damage. The grower should look over the leaves of the plants at frequent intervals, and immediately a sign of the enemy is seen the soil at the roots should be heavily watered and the foliage and stems cleansed with water through a hose, using as much force as possible. **HORACE J. WRIGHT.**

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## PLANTS UNDER GLASS.

**M**ANY plants grown during the summer months for autumn and winter decoration are much improved if planted out in frames, and all such may now be put in their places. Solanums, Bouvardias, Salvias, Eupatoriums, Carnations, Callas and Leonotus should have a nice mixture of growing material and be allowed plenty of room to develop. Keep the plants well syringed on every occasion when it is desirable.

*Cyclamens* may now be put into their flowering pots. Use good sweet soil and do not give too much water till the roots have gripped the new soil; an important factor is that the roots and ball of the plants should be in a moist condition when potted. Keep the plants shaded from bright sunshine and syringe under the foliage as much as possible.

*Crotons* and *Dracenas* that were struck early and are now in 2½-inch pots require 5-inch pots at once. Give some good loam and leaf-soil, with peat and a good sprinkling of sharp sand; pot firmly and shade for a few days.

*Ixoras* may be fed with some stimulant when flowers are showing. *Ixora Duffii*, *I. Westii*, *I. Williamsii*, *I. Prince of Orange*, *I. Pilgrimii*, *I. coccinea superba* and *I. Fraserii* are among the most effective. These plants must be kept clean, as they are very liable to be attacked with bug and thrips, which must be destroyed by fumigating.

*Nepenthes* (Pitcher Plants) must have plenty of water and be kept well syringed in order to keep down thrips. Shut up the house and run the temperature up to 90° at closing time.

*Allamandas*, *Clerodendrons* and the like should have the growths strung up artistically and the weak shoots removed. Plenty of feeding must be adopted with old or established plants growing in small borders or tubs.

## HARDY FRUIT.

*Plums* and *Cherries* must be kept clean from aphid and maggot. Where the growths have become strong on walls they should now be pruned. The same may be said of Pears and, in fact, all fruits on walls. Finish off the disbudding of Peaches, and keep every portion of the tree free from aphid by constantly syringing with some approved remedy. Thin the fruits on Apple, Pear, Plum and Peach trees, especially on small ones, and it is well not to allow weak trees or newly-planted ones to carry any fruit at all, or the trees will suffer in subsequent years.

*Strawberries.*—If not already done, these should be mulched between with clean Wheat straw, so that the fruit may be had in perfect condition. Previous to strawing a good dusting of soot round the plants is a fine thing to kill slugs.

## KITCHEN GARDEN.

*Tomatoes* may now be planted out. Carter's Sunrise is one of the best, perhaps the best of all, for outside purposes, especially for profit, and it ripens early and is an exceptional good grower. These should be planted at least 2½ feet apart and have a good stout stake put to each at once. Prick out more Brussels Sprouts, Broccoli and Cauliflower. Continue to sow seeds of salads every week or as often as may be deemed necessary. Hoe all crops and keep down weeds, remembering that the ground cannot perfect two good crops at once.

## MELONS AND CUCUMBERS.

Continue to plant these for general succession; it will not be much good to plant Melons after this month.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**BOUVARDIAS.**—Where the planting-out system is followed, no time should be lost in getting these into their summer quarters. Well fork the ground in order that leaf-mould and manure may be thoroughly incorporated with the soil. A sunny border is the most suitable position for the plants. The earliest batch should soon be ready for the flowering pots, and, if well managed, will make fine specimens by the end of the season. Both for the plants inside and in the open the syringe must be freely used during the afternoons of bright days in order to keep down the red spider and to encourage growth. For this purpose I use soot water.

*Phyllocacti.*—Where repotting is necessary this should be done immediately the plants have flowered, but take care not to overdo this. It is far better to under pot them than to put them into pots several sizes too large. It is by no means necessary to repot each season; every third or fourth year is usually sufficient. The soil then used must be free and open, the following suiting most sorts admirably: Two parts sharp river sand, one part pounded charcoal or bricks and four parts good rich fibrous loam. Good drainage is an absolute necessity. Stagnation at the roots is fatal. For large-sized pots one-third of the depth should be filled up with broken crocks.

## FRUITS UNDER GLASS.

**Vineries.**—Should the spell of fine weather continue, it will be advisable to do without fire-heat altogether in the early vinery. The Grapes should not need it, except, perhaps, to dispel moisture and prevent damping of the berries. The less fire-heat used the longer the berries will remain plump, and the wood will ripen far better if the process is not hurried. Of course, a dry atmosphere should be maintained from the time the Grapes ripen until they are cut, and, if this and a cool temperature are persevered in, the bunches will hang in first-rate condition for several weeks. A light shade, too, will help to lengthen the season and to preserve the bloom on black Grapes, which, if exposed fully to the light, will gradually assume a red tinge.

## KITCHEN GARDEN.

**Summer Turnips.**—This is a good time to make another sowing of Turnips for summer use. The Milan varieties should be succeeded by a good strain of Snowball or Veitch's Red Globe. Do not depend upon one variety, as Turnips are much influenced by the season and are apt to run to seed.

**Celery.**—I always adopt the plan of getting the Celery trenches dug out early in the season. This allows of the ridges being used for quick-growing crops, such as Lettuce, Spinach and dwarf early-heating Cabbage, Cauliflower and French Beans, but, of course, due attention must be paid to watering, especially in light soils and dry seasons. Labour is economised and a good growth secured by sowing good dry-weather varieties of Lettuce down the centre of the ridges, merely thinning the seedlings out.

## FLOWER GARDEN.

*Aquilegia hybrids.*—The flowers of the hybrid Columbines are so varied and beautiful and so useful for decoration, either in the plant or in a cut state, that they deserve a place in every garden. A packet of seed from a reliable source will give hundreds of plants in all conceivable tints and gradations of colour, while the foliage itself is very beautiful. Mine are now in full beauty, from seeds sown in June of last year. They look well in the borders of the kitchen garden, and in various parts of the flower garden and grounds they are most useful.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## LEGAL POINT.

**Fixtures (Removal).**—Things annexed to the freehold, but which do not become part thereof and which are commonly designated "removable fixtures," are grouped as either agricultural, trade, ornamental and domestic convenience fixtures. Agricultural fixtures are governed by the Agricultural Holdings Act and other recent statutes; the law as to the rest is chiefly found in judicial decisions. The right to remove fixtures put up for trade purposes is certainly wider than that enjoyed by tenants who have merely affixed the article for ornament or domestic convenience, but a resemblance occurs in the fact that the right must be exercised before the expiration of the tenancy. The decisions on fixtures put up for purposes of ornament and domestic convenience chiefly relate to things put up in the house, but there is no reason why they should not extend to things in the garden, although up to the present gardening points of law have not been common. Rails, fences and hurdles have, however, been held to be removable. The right to remove in any individual case may be defeated by the mode and degree of annexation and the physical injury to the freehold which would ensue. From the description given by our present querist, we gather that there will be no permanent injury to the land, and we think removal would be justifiable.

ANSWERS  
TO CORRESPONDENTS

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Tulips diseased (Puzzled).**—The spots upon the Tulip leaves are due to an attack upon the plant by the fungus *Botrytis parasitica*, the cause of the Tulip disease. The fungus is abundant upon the leaves and flowers, but as yet does not seem to have invaded the bulbs. This will, no doubt, occur later, and then the resting form of the fungus will be produced in the form of black masses of mycelium known as sclerotia, and by means of these the disease will be carried over to another year. It would be well to remove all the leaves and tops of the plants affected in order to check the passage of the fungus down into the bulbs and burn them, not throw them upon the rubbish-heap. It is quite probable that weather conditions have contributed to the disease by so injuring the foliage as to lay it open to the attack of the fungus. Snow lying in the heart of the plant and perhaps freezing there would be a possible contributory cause.

**Primrose flowers and Rhododendron leaves for inspection (J. E. B.).**—The abnormal form of *Primula vulgaris* with a greenish corolla which you send is occasionally met with in various parts of the country, and at times the green colouring is much more pronounced than in your example. Numerous variations occur in this Primrose, some being very extraordinary in the shape, size and colour of the flowers. The injury to the Rhododendron leaves is most likely due to the reason you suggest, especially as last year was a bad ripening year. A great number of evergreens have been disfigured by reason of the leaves turning brown since the commencement of last winter. This, in many cases, can be traced

to bitterly cold winds following on the insufficiently ripening of wood and leaves. The same sort of injury is sometimes caused by drought, but this is more often due to drought during the growing season, and the results are noticeable in summer. Bad root action would also cause a similar effect. It is quite probable, however, that in your case the disaster was caused by the storm from the sea you experienced last autumn.

**American Violets (Wilmslow).**—Of the two small American Violets sent the pale blue one with the finely-cut leaves is *Viola pedatifida* or lobe-leaved, the other, having dark flowers, is evidently *Viola ovata*, having egg-shaped leaves. Grow your Violets, if possible, on rockwork and in cool, shaded positions. Possibly where you collected these plants in New England the site was a cool northern one. With us here Violets in a warm position are apt to be eaten up with minute insects.

**Carnation leaves blistered (J. E. W.).**—The shoots of Carnations sent have evidently had the leaves scalded in some way. The most probable cause is by the sun through the glass, or it could be done by an overdose of insecticide or too strong fumigation. There is no fungoid growth on them. The border Carnations are more hardy and would not feel the effects of sunshine or an overdose of fumigation so much as the Tree and Malmalson types. The only thing that can be done is to air the house freely and shade from bright sunshine after a spell of dull weather.

**Nitro-bacterine for Sweet Peas (Norah Unwin).**—If you wish to give your Sweet Peas some of the new bacterine material your best course will be to dissolve a very small quantity in water and pour it in very limited quantity in and about the Peas, doing so once a fortnight till the end of May. We have no practical knowledge as to its nature, but hope to learn more during the present year. Opinions greatly differ as to the value of the inoculation; your best course will be to use the solution on portions of your Peas or rows, and thus test for yourself its usefulness or otherwise. When you purchase the bacterine, instructions as to the relative proportions of that and water will doubtless be provided.

## TREES AND SHRUBS.

**Lilac plant drooping (Captain E. T. O.).**—The drooping of your Lilac is no doubt owing to the fact that, being planted only last autumn, the roots have not yet taken possession of the soil, and consequently a combination of hot sun and drying wind causes the young shoots to flag. This theory is further borne out by the fact that the plant quite recovered during the night, as it naturally would with the absence of sunshine and the increased amount of atmospheric moisture. As all outdoor subjects are now rooting freely, your Lilac will soon become thoroughly established, and we do not think that any further trouble will arise from the drooping of the shoots. Should it, however, occur again, give the roots a good soaking with water.

**Soil and situation for Judas tree (N. N.).**—The Judas tree is not a very fastidious subject with regard to soil and situation once it becomes established, for if given a position in full sun or in partial shade, in light or heavy loam, it grows satisfactorily. It cannot, however, be called one of the best plants to establish, and it often takes some little time to get over transplanting. If, as you say, your plant shows signs of growth, it will doubtless grow more vigorously presently. When planting shrubs in poor soil it is a good plan to excavate holes 5 feet or 6 feet in diameter, and give a little new soil at the time of planting.

**Information about Privet and other shrubs (F. J. P. H.).**—Strong three year old plants of the oval-leaved Privet can be successfully moved by the first week in October, in proof of which we may mention that two years since we planted a hedge of it by the second week in September and it is now in splendid condition. You can certainly plant standards of the two trees mentioned, but we should prefer them 12 feet apart rather than the lesser distance named. *Choisya ternata* will thrive against an east wall. Where Lavender bushes are required to form a neat shapely hedge, they should be pruned in the spring.

## THE GREENHOUSE.

**Treatment of Azaleas in pots (Young Gardener).**—It will not be wise to plunge your Azaleas outdoors until the third week in June. In the meantime give them an abundance of fresh air, so as to harden off the growth as much as possible. In plunging the worm trouble may be obviated to a great extent by placing a good layer of sharp coal ashes and soot under each pot. The plants must have copious supplies of water during hot, dry weather, and they will be much benefited by weekly applications of much-diluted liquid manure while growth is

being made. On the evenings of very hot days give the plants a light syringing overhead.

**Information about a Cyclamen (H. J. Harpenden).**—It is of course impossible for us to say definitely what species your Cyclamen is, but very probably it is *Cyclamen neapolitanum*. This is quite hardy and flowers in the autumn. Your better way will be to plant it out of doors in a sheltered and partially shaded spot, mixing some sand and leaf-mould with the soil. It will then probably soon push up leaves and ultimately flower, when its correct name can be ascertained.

**Winter-flowering Begonias (Enquirer).**—The best of the winter-flowering Begonias are Agatha, similar to the well-known Gloire de Lorraine, but the flowers are larger and richer coloured; Ensign, carmine-scarlet, semi-double; Gloire de Lorraine, rose pink; Gloire de Sceaux, bronzy green leaves, rose-coloured flowers; Haageana, handsome bronzy foliage, bluish white flowers; Ideale, bright rose carmine; John Heal, deep carmine; Julius, pink; Mrs. Heal, large flowers of a bright carmine-scarlet; Turnford Hall, bluish white form of Gloire de Lorraine; Winter Cheer, semi-double, carmine-rose; Winter Perfection, semi-double, bright rose pink. Most of these varieties were raised by Messrs. J. Veitch and Sons, Limited, Chelsea, from whom all of the above can be obtained.

**Stocking a greenhouse (L. F. B.).**—A minimum temperature of 45° during the winter months will be better for greenhouse plants in general than 5° lower. Your selection of plants for clothing the back wall is a good one, but for the border at the foot there are very few suitable plants other than Ferns, of which a good selection is herewith appended: *Adiantum cucuatum*, *A. decorum*, *A. formosum*, *Asplenium bulbiferum*, *A. Colensoi*, *Cyrtomium falcatum*, *Doodia caudata*, *Lastrea aristata*, *variegata*, *L. lepida*, *L. patens*, *L. Standishii*, *L. varia*, *Nephrolepis exaltata*, *Onychium japonicum*, *Osmunda palustris*, *Polystichum setosum*, *Pteris arguta*, *P. argyrea*, *P. cretica*, *P. c. albo-lineata*, *P. leptophylla*, *P. longifolia*, *P. major*, *P. serrulata*, *P. s. cristata*, *P. tremula* and *P. Wimssetii*. The only plants other than Ferns that we can recommend are the green and golden Creeping Moss (*Selaginella kraussiana* and *S. k. aurea*), *Aspidistra lurida* variegata, *Isolepis gracilis* and *Ophiopogon jaburan* variegatum. With regard to the plants to grow in pots on the staging, we advise you, as you know nothing of greenhouse management, to commence with subjects whose cultural requirements are simple. For flowering throughout the summer months, you have a wide choice of such things as *Fuchsias*, *Pelargoniums* of the different sections, but especially the double-flowered Ivy-leaved and Zonal classes, *Heliotrope*, *Lantanas*, flowering *Cannas*, *Begonias* (both tuberous and fibrous-rooted kinds), *Carnations*, *Calceolarias*, *Campanulas*, *Coleus*, *Celosias* and other plants. These can be obtained in the shape of thriving little plants at a cheap rate from the nurserymen who advertise in the columns of THE GARDEN. A suitable selection of cool house Orchids of comparatively easy culture is herewith given: *Coelegyne cristata*, *Cymidium lowianum*, *Cypripedium insigne*, *C. venustum*, *C. villosum*, *Lelia anceps*, *L. autumnalis*, *Lycaste Skinnerii*, *Madevalla harraryana*, *M. ignea*, *M. veitchiana*, *Odontoglossum crispum*, *O. Hallii*, *O. Pescatorei* and *O. triumphans*. Mushrooms may be grown under the greenhouse staging, and on this subject you will find a valuable illustrated article in THE GARDEN for November 23 last year. We have not space here to repeat it. Books that will afford you great assistance are "Gardening for Beginners" by E. T. Cook, 12s. 6d. net, from THE GARDEN Office; and "Pictorial Practical Greenhouse Management," by Walter P. Wright, price 1s. 9d. (Cassell and Co.).

## FRUIT GARDEN.

**Destroying caterpillars on Gooseberry trees (P. S.).**—Procure some Paris Green (Blundell's) and dissolve 1oz. in 10 gallons of water, taking care to have it well mixed. Then spray the trees with this mixture, using a syringe that will give a very fine spray for the purpose. Coat every part of the foliage with the liquid. It will be necessary to keep it well stirred while applying it. This substance is poisonous and must not be used within a fortnight of gathering the fruit. If you cannot obtain Paris Green procure some white Holleboe powder, freshly ground, from the chemist, and mix 2½lb. with 10 gallons of water, keeping it well stirred while using. Spray with this as advised for Paris Green. A week after the application of either mixture give the bushes a heavy syringing with clean water.

**Leaves of Apple tree curled (E. Diekmann).** The leaves of your Apple trees are infested by one of the Apple aphides (*Aphis pomi*). Now that the leaves are beginning to curl there is little chance of killing the aphides with any insecticide, as it is so difficult to make any spray reach them. In the autumn, just before the leaves begin to fall, the trees should be thoroughly sprayed with a strong solution of paraffin emulsion, and in the course of the winter they should again be sprayed, this time with a caustic wash or with an insecticide lately

put on the market and known as V1; but these washes must not be used after the buds show any signs of opening. In the spring, before the leaves begin to curl, if in any way you suspect that they are likely to be attacked, they should be sprayed with a weak solution of paraffin emulsion or an insecticide known as V2.—G. S. S.

**Book on grafting (H. S.).**—We know of no work exclusively devoted to grafting and budding, but the "Alphabet of Gardening," a useful little book, gives information on grafting, budding, pruning, hybridising and kindred subjects, with explanatory diagrams. This may be had from the *Gardener's Chronicle* Office, 41, Wellington Street, Strand, W.C. Price 1s. 9d.; cloth, 2s. 3d.

**Grapes and Vine gone wrong (Mr. Nicholson).**—The Vine foliage and bunches of Grapes have all the appearance of having been scorched by a burst of hot sunshine acting on an inadequately ventilatedinery. The weather lately, having been dull for so long, has caused the growth of Vines under glass to be attenuated and weak, compared to what it is when exposed to more sunshine, and consequently more easily injured by this cause. We have had many similar complaints. Sometimes a cheap, bad pane of glass in the roof of theinery will cause such scorching. We can find no trace of disease or of injury from insect attack.

**Pear blooms injured (H. H. Jones).**—The description you give of your injured Pear blossoms and the appearance of the sample bloom sent would lead us to the conclusion that they had been injured by frost. It is not necessary for the bloom to be fully developed to be injured by extreme cold and rough weather. Very frequently the heart of the bloom where the stigma or embryo fruit is situated, is injured while in the bud state, and turns black and falls, as in your case. We can only surmise that your tree of Pitmaston Duchess is growing in a more exposed position than the others. It sometimes happens that the anthers on the flowers of the Pear are devoid of pollen and are barren in consequence. We presume your trees are not near enough to the sea to be affected by sprays of salt water.

**Louise Bonne of Jersey Pear—young fruit diseased (F. W. E.).**—The young fruit received is no doubt suffering from a bad attack of *Eladosporeum dentriticum*, a fungus which grows on the leaves and young twigs as well as on the flowers of the Pear, preventing the fruit from properly setting and swelling, in fact, rendering it useless. The most destructive agent to use against all forms of fungoid diseases on fruit trees, in our experience, has been Bordeaux mixture, and as an application of this mixture seems to have been at least partially successful in protecting the leaves of your tree from the fungus this year, there is reasonable ground for hoping that, by perseverance in spraying the trees in winter, immunity in time may be had from its ravages. It is a singular, well known and interesting fact, and borne out by your experience, that wherever there happens to be a Louise Bonne Pear tree in a collection, this fungus will always attack this variety in preference to any other.

**Vine leaves diseased (F. B. M.).**—The disease from which the Vine leaves are suffering comes under the term of "scorching." It is caused by too moist and close an atmosphere during the night, this causing the extremely tender leaves at this time to be heavily coated with condensed moisture towards morning, and which is not sufficiently dispersed before the early sun causes a sudden and great rise of temperature, and which is accountable for the mischief. The more healthy and robust the Vines are, the more likely they are to suffer from this cause, and in our experience the Black Alicante variety is the most liable to suffer. The remedy lies in the admittance of a small chink of air (front and back) all night while the weather is favourable and growth is so active, at the same time applying a little extra warmth to the hot-water pipes to prevent the temperature falling too low, and also to prevent the deposit of so much moisture in the foliage by the freer circulation of air and the greater buoyancy of the atmosphere. At one time we suffered much from the same complaint, but since we have adopted the plan above recommended we have had no recurrence of the trouble.

**A sailor's Vines (Lieutenant, R.N.).**—If you will add perseverance and application to your evident enthusiasm for gardening, the small matters, which appear at first puzzling and difficult, will soon come easy to you. For ainery 30 feet long twelve canes or rods is the correct number to have. This will leave each rod a little less than 3 feet apart. The trellis to which the Vines are trained should be 2 feet from the glass, and should be fixed to the rafter under which each Vine is growing from the front of theinery to the back (not crossways). The trellis should consist of three wires arranged in a bracket and fastened to the rafter 9 inches apart, the brackets to be 3 feet asunder. The side shoots of this year's growth should be 15 inches apart on either side of the Vine, and each one should be stopped at the seventh leaf. The young lateral growths which will emerge from these shoots during the summer must be stopped at the third leaf. By attending to this work the growth of the Vine will be kept under control and prevent the overcrowding of leaves and branches. Whether the young shoots are showing bunches of Grapes or not, they must be retained if wanted to make up the shoots on either side to 15 inches apart. The shoot which has no fruit on this year will probably have a better bunch next year. The leaf sent is no doubt suffering from mildew. It is very small and poor; let us hope that by diligent attention to watering, ventilation and stopping the shoots a marked improvement will take place next year. If you write us in the autumn, quoting the page on which this reply appears,

we shall be glad to point out the best winter treatment to adopt. The best way of destroying the mildew is to sprinkle flowers of sulphur on the base of the walls and paths thickly on the afternoon of a warm day, closing theinery after syringing a little after 4 p.m. when the sun is shining, so that the temperature will rise to from 83° to 88°, leaving the house closed until the next morning. The Rose is evidently of the summer-flowering class, which bears only one crop. Send us a flower next year and we will tell you its name.

**Apple trees with bulbous growth on trunk (Stroud).**—1. These excrescences are termed "galls," and are common on many trees, including the Oak and the Apple. They are also found on the roots of some trees, such as the Oak, the Elm and Beech. They are produced by the deposit of the eggs of insects in the bark of the tree. When cut the gall is found to enclose a number of granules, each containing a minute larva, corresponding possibly to the dark spot you mention. Our experience of these galls is that they practically do no harm to the trees, and also that it is very doubtful if the seat of the mischief can be got at by cutting the gall, and thereby running a risk of causing a nasty wound in the bark of the tree without any compensating good, therefore we advise their being left alone. 2. There is no better way of killing ants than to watch carefully their return journey home in the evening and then to pour boiling water into their nests. 3. Your greatest care should be to help the young tree to make a free, healthy new growth this summer for the production of a good crop of fruit next year. This can best be done by allowing each new branch it makes to grow to its full length without stopping it, tying or nailing the branches to the wall as they grow, being particularly careful not to allow the new branches to overlap and become too crowded, cutting the weaker ones away when this is the case. Cover the roots with short decayed manure at the end of this month to the depth of 3 inches, and in dry weather give a soaking of clean water once a fortnight. In exceptionally severe frost in winter the roots and branches of the tree should be protected by mats, straw or Bracken Fern. 4. The book on "The Enemies of the Rose" may be had for 2s. 6d. from Mr. E. Mawley, Rose Bank, Berkhamsted, Herts.

## ROSE GARDEN.

**White flies upon Roses (J. H. M.).**—The small yellowish white flies are known as thrips. They are very destructive to the foliage, sucking out the juices by means of a small proboscis. We recommend you to syringe the plants with paraffin emulsion or Quassia extract, either of which you can obtain from your seedsman. You will find that diligent spraying, preferably in the evening, will keep them in abeyance. For cloches try Messrs. Pilkington Brothers, Limited, Horse Shoe Wharf, 10, Upper Thames Street, London, E.C.

**Mildred Grant as a pot Rose (W. Williams).**—We agree with you that Mildred Grant is a fine pot Rose. We have had similar experience of this Rose as you relate, and although the quantity of blossoms are not numerous the quality is superb. To all who have a greenhouse we would recommend a trial of this splendid Rose. We have had similar experience with Bessie Brown. This grand Rose is almost a failure with some individuals. It grows freely enough outdoors, but the blossoms are too double to open freely. Under glass the flowers develop into superb specimens, and although given to hang its head this can be remedied by means of a neat stick.

**Rose with injured buds (A. Reid).**—The Rose blossoms and buds you sent were not from Gloire de Dijon but William Allen Richardson, and it is quite a common occurrence to find the buds of this Rose malformed in various ways. We could detect no injury from any insect, and we think you will have little cause to complain when the buds are fully developed.

**Growth of Crimson Rambler turning black (H. P. M.).**—This is a fairly general occurrence with Crimson Rambler this year. It is the effect of the winter frost upon the old wood. We have some plants upon pillars in the open where all the old wood is quite black. At pruning time these were suffered to remain to see how they would behave. They have steadily got worse, and they will now be removed. The growths made last year are perfectly sound. You will do well to cut away the growths just below the blackened parts, and rely upon the young wood for your blossom. The hedge of the same Rose having escaped injury is probably owing to the more sheltered situation, or they may not have continued to grow so late in the year as the pergola plants, consequently the growths were more matured. These blackened growths have nothing to do with the tying, it is simply a matter of frost, and you must take a hint from this, and see that most if not all of the old wood is removed from this Rose as soon after flowering as practicable. It is a variety that needs to be annually

treated something like Raspberries, i.e., cut away all old wood and allow several canes per plant of the young wood to replace that removed.

## MISCELLANEOUS.

**Royal Caledonian Horticultural Society (Competitor).**—No particulars have been received by us concerning the results of competitions arranged by the above society.

**Diseased Mint (F. B.).**—The fungus affecting your Mint is known as *Puccinia Menthae*, also known as Mint rust. It is, unfortunately, a somewhat common disease, and once it gets possession of a garden is difficult to eradicate. The Pansy family suffers from it often in the same way. You seem to have tried several remedies. We can but advise to run a hoe over the bed and cut off every piece hard to the ground, rake it off and burn it, then give the bed a good dusting with fresh slaked lime, and with it some flowers of sulphur as a possible remedy.

**Using poultry manure (Somerset).**—This manure may be used to fertilise soil for almost any kind of vegetable or flower, but it should not be applied in a fresh state. To have it in good condition mix the manure each time it is removed from the hen-house with fully its equal quantity of soil obtained from any source. If you can add to it a good quantity of soot to destroy the insect life commonly generated by poultry manure do so. Mix the whole and let it lie in a heap, adding more manure and soil from time to time and occasionally turning the whole heap. At the end of some three or four months the dressing may be applied to soil thinly and be well dug in before the ground is cropped. Add soot as freely as you well can.

**Late cropping a garden (Wallflower).**—Your best course to take with a garden that much needs renovation is to have the soil liberally manured and deeply dug, burying down all small weeds, but forking out all coarse ones. Then, so fast as you get ground thus prepared, you can crop it. Thus you may yet sow some good 3-feet Pea quite thinly in drills 4 feet apart; also you can sow Scarlet Runner Beans. If you can get tall sticks, let the rows be 5 feet apart. If you have no sticks, then let the rows be 4 feet apart, so that as the plants grow they can be pinched to make them bushy. You can also sow in drills, 2 feet apart, dwarf French Beans, the seeds in the drills being 3 inches apart. It is too late to sow Parsnip seed, but you may sow in drills, 12 inches apart, Early Nantes Carrot, Snowball Turnip, tap-rooted Beet and Salsify. You had better get from your locality strong Onion plants to put out now, also Leeks in trenches and Celery plants for the same purpose. You may sow seed of Savoy and white Cabbage, and get plants also of Cauliflower, Cabbage, Brussels Sprouts and Kale to plant out, also white and purple sprouting Broccoli. It may not be too late to plant Potatoes, especially early ones such as Puritan or White Beauty. You will do well to read our calendar of garden operations, and a vegetable book such as the small one on "Vegetable Culture," price 1s., published by Macmillan, London, will greatly help you. Any bookseller can get it for you. As to purchasing plants, call on Mr. W. Baylor Hartland, 24, Patrick Street, Cork, and no doubt he will supply you with what you want.

**House sewage for garden (A. H.).**—In disposing of a considerable quantity of house sewage, largely liquid, it is unfortunate that yours is a stiff, retentive soil with a clay base, as such soil needs less artificial watering than does a porous soil on sand or gravel. While in ordinary light soils liquid sewage, which must be disposed of somehow, may be given to trees and shrubs during the winter, it may be harmful to do so in your case with such a water-holding soil. The cesspool liquid has the very slightest manurial value. In dry weather it may be given to anything growing, even to lawns, with usefulness, but such use in wet weather would be harmful. Even when used, it is evident from your statement that it is very hard and that the cesspool should have a small force-pump fixed to it, and a large tub close to it into which the liquid could be pumped each night after being emptied, so that by twenty-four hours' exposure to the air it may soften. With respect to the dry matter from the earth closet, dry soil, if obtainable, would be far better than coal ashes. Cannot you provide a cement enclosure or receptacle in a covered place, where that matter as it accumulates can be put and the real house slops added to it? If with that were added soot occasionally, the whole being now and then turned and mixed, you would have an excellent manure. Your cesspool badly needs an overflow drain, thus enabling the solid matter to settle for clearing out once a year, while the mere liquid could pass off to some distance and disperse itself in woods or where it can in time soak away. Of course, in the summer months every drop of liquid after exposure to the air as advised may be utilised on fruit trees, Roses, shrubs or borders.

**Name of fruit.**—W. G.—We regret that we cannot name the Apple sent; please send a better fruit when you gather them this year.

**Names of plants.**—Miss L. H.—*Osmanthus Aquifolius latifolius*.—J. H. P., *Ledbury*.—1, *Prunus Padus* (the Bird Cherry); 2, *Crataegus coccinea*.—C. W., *Worstead*.—1, *Pedicularis sylvatica*; 2, *Menyanthes trifoliata* (Bog Bean).—W. D., *Lonicera alpeigena*.—J. Dixon, *Anchusa sempervirens*.—W. F. ## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## DRYING, MOUNTING AND PRESERVING PLANTS.

**D**URING the summer months many readers will be visiting remote country districts, famous gardens, or, perhaps, taking a trip abroad, and it frequently happens on such occasions that plants are secured which one may desire to press and preserve as dried specimens. Although many plants are comparatively simple to thus preserve, there are others that will give considerable trouble if not handled properly, but if the following hints are carefully observed these difficulties may readily be overcome. If one intends preserving plants in this way on an extensive scale a wire lattice work press should be obtained. This ought to consist of two frames measuring approximately 18 inches by 13 inches, these being held together by four wooden cross-bars (two at each end), which must project about 3 inches over each side of the frames. Through these projecting ends holes are bored so that a bolt and thumb-screw can be used at each end of the cross-bar for tightening the whole. A more simple plan is to use a good stout pair of leather straps for the purpose. In addition to the press a good supply of paper, folded to the size of the press, will also be needed. Although tough blotting paper is much the best for aquatic plants and those of a succulent nature, old newspapers will answer admirably for the majority of plants.

Having thus made the necessary preparations we must now see about securing the plants. The nature of these will, of course, depend upon the object for which they are intended. Where possible, a complete specimen should be preserved, i.e., one possessing roots, stems, leaves and flowers. It is always advisable, where possible, to secure a few extra flowers and fruits for drying. Of course, many plants will be too large for this, and in these instances portions of each organ should be used. Much trouble will be avoided if the plants reach the press in a fresh condition. Roots must be washed clean, and where thick stems, bulbs or roots exist these should be split lengthways, so as to considerably reduce their thickness.

In placing the specimens in the press first lay one of the wire frames flat on a table or the floor, then place several thick sheets of paper on it and then spread out the specimen so that every root, stem, flower and leaf is seen to advantage. Leaves and flowers are often troublesome, as the segments frequently have a tendency to curl up, but any trouble taken with them at the outset will be amply repaid later. A slip of

paper bearing the name of the plant and when and where collected should be placed with the specimen, which is then covered with several thicknesses of paper and another plant placed thereon, the process being repeated until all have been dealt with, when the press is strapped or screwed moderately tight and placed in a hot or sunny position. Where the plants are of a sticky nature they should be first placed between tissue paper, this being retained on the plants until they are quite dry. The press must not be filled too full at once, a total thickness of plants and paper of 5 inches being sufficient.

For the first few days the paper ought to be changed every day, using dry paper to replace those used, and taking care to bring those plants that are in the centre of the press one day to the outside the next, and *vice versa*, the object being to get them dry as quickly as possible. After, say, five days, it will suffice with most subjects if the papers are changed every other day.

When the plants are quite dry they may be either mounted at once or placed between dry sheets of newspaper, each with its label, and the papers tied into a bundle and stored in a dry place until mounting can be done. The regulation size of the papers on which plants are mounted is 10½ inches by 15½ inches, and it is wise to use white paper of stout texture. Where large plants have been dried it will, of course, be necessary to mount them in sections on a number of sheets. Although any good paste will do for mounting, gum arabic is the best, this being used in a rather thick condition. It should be applied to the whole of one side of the plant with a small brush, the specimen being then placed on the sheet of paper and firmly pressed down with a clean cloth. A reasonable amount of care will be needed in this operation, as many plants are very brittle when dried. Where possible one or more leaves and flowers should be mounted so as to show the under surface. Where thick stems and roots exist, it will be necessary to use narrow strips of thin but strong paper to keep them in place, these being secured by each end to the mounting sheet with the root or stem underneath.

A mistake that many novices make is to mount the plants as nearly as possible in the middle of the paper, with the result that when a number have been done the pile of papers and plants is much thicker in the middle, this causing the sheets to curve badly. This is easily avoided by placing some specimens towards the sides of the sheets. As each plant is mounted a neat label, bearing the name of the plant and any other desired particulars, should be pasted

on, and where extra flowers and fruits were secured, they should be placed in a small envelope, which must also be pasted to the sheet. These extra flowers and fruits are very useful for a botanical examination, if such should at any time be desired. The novice will be wise to experiment with a few common plants, both as regards drying and mounting, before dealing with any that are rare or valuable.

## NEW PLANTS.

### MILTONIA ST. ANDRE.

HERE we have a very large yet refined-looking flower. The pure white ground of the petals and labellum is marked with deep purple and brownish crimson, two large purple blotches being situated at the base of the petals, and a heavy striation of brownish purple at the base of the labellum. Shown by Baron Schröder, The Dell, Egham. First-class certificate.

### ODONTOGLOSSUM QUEEN ALEXANDRA CRAWSHAYANA

This is a grand variety of a very good Orchid and is a great advance on the type plant. The broad sepals and petals are of a rich brown hue, delicately marked with bright yellow. The labellum is large, the creamy white ground colour being heavily marked with rather small bright purple blotches. The plant exhibited had one raceme composed of five fully-developed blooms. Shown by de B. Crawshaw, Esq., Rosefield, Sevenoaks. First-class certificate.

### ODONTOGLOSSUM PHOEBE THE DELL VARIETY.

This is one of the many good things that have been raised by Baron Schröder's clever gardener, Mr. H. Ballantine. The specimen exhibited was a grand one, the long arching raceme being composed of twelve fully-opened flowers. The white ground of these is heavily besprinkled on all the segments with good sized rosy purple blotches, with a deep rich yellow blotch at the base of the labellum. In addition to the handsome colour combination it has flowers of superb form and a plant of robust character. Shown by Baron Schröder, The Dell, Egham. First-class certificate.

### MILTONIA BLEUANA STEVENSII.

This is a very beautiful variety of a well-known Orchid, and is particularly noticeable on account of the purity and refinement displayed in the flowers. The pure white ground colour of the large blooms has a blotch of deep rosy lilac placed at the base of each petal, the large labellum being heavily striated with dull brownish crimson. Shown by W. Thompson, Esq., Walton Grange, Stone. Award of merit.

### ODONTOGLOSSUM GLORIOSUM DELICATULUM.

As indicated by its varietal name, this Orchid is a very delicate flowered member of a large and popular family. The rather small pale citron-coloured flowers are borne in profusion on a long, rather arching stem in the form of a compound raceme. The ground colour is blotched with faint green markings, and the segments are very much pointed and reflexed at the tips. Shown by Messrs. J. and A. A. McBean, Cooksbridge. Award of merit.

### DEUTZIA WILSONII.

A new species from China with oppositely placed, lance-shaped leaves serrated at the margin. The pure white starry blossoms are freely borne on terminal and axillary clusters, several of the 4-foot-long shoots being simply crowded with buds yet to expand. The individual flowers are of large size. A valuable plant for the garden. Shown by Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

### PHILADELPHUS LEMOINEI ROSACE.

The pure white semi-double blossoms of this plant give one the impression at first sight of a

Rambler Rose, in which the inner petals are much narrower than the rest. Hence it is very distinct. Only small cut branches were shown, but these gave all the evidences of great freedom of flowering. Shown by Sir Trevor Lawrence, Dorking. Award of merit.

### CARNATION SNOWBALL.

A full-petalled variety of good shape. It is not a pure white, and is inclined to a quite pale blush. The variety is said to belong to the tree section. Shown by Mr. H. Burnett, Guernsey. Award of merit.

### PYRETHRUM LANGPORT CRIMSON.

A very handsome single-flowered variety of large size and of a velvet crimson-scarlet shade. Shown by Messrs. Kelway and Sons, Langport. Award of merit.

### RHODOTHAMNUS KAMTSCHATICUS.

This is a dwarf-growing deciduous shrub with slightly hooded or cupped flowers, which rise but 3 inches above the rather woolly leaves. The whole plant as shown is not more than 6 inches high. Exhibited by Mr. G. Reuthe, Keston, Kent. Award of merit.

### STOCK VEITCH'S MAGENTA STRAIN.

A very excellent strain of these popular flowering plants came from Messrs. R. Veitch and Son, Exeter, an award of merit being granted for the strain.

*Iris carthusiana*, *Zephyranthes aurea* and *Rosa Moyesii* each received an award of merit, and we shall describe and illustrate these in a future issue.

All the above were exhibited before the Royal Horticultural Society on the 9th inst., when the awards were made.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

June 24.—Gardeners' Royal Benevolent Institution Annual Dinner at the Hotel Metropole.

**Royal Horticultural Society's committees at Windsor.**—On Wednesday, the 10th inst., by gracious permission of His Majesty the King, the members of the Royal Horticultural Society, council and standing committees paid a visit to Windsor, when the first item on a most pleasant programme was a lunch, most hospitably provided by His Worship the Mayor of Windsor, E. Bampfylde, Esq., in the historic banqueting saloon of the Town Hall. About 100 guests were present, among whom were Sir Trevor Lawrence (president of the Royal Horticultural Society), the Rev. W. Wilks (the indefatigable secretary), Sir John T. Llewelyn, Bart., V.M.H., Sir Albert Rollit, Sir George Watt, the Rev. the Vicar of Windsor, Father Bampton, Canon Fowler, S. K. Tahourdin, the Hon. James Boscawen, Colonel Holford, Messrs. Harry J. Veitch, J. Gurney Fowler, A. Mackellar, A. T. Nutt, Spencer Pickering and A. W. Sutton. As the programme involved an inspection of the State apartments, as well as the beauties of Frogmore Gardens, brevity was a necessary characteristic of the speeches in connexion with the toasts of the King and Royal Family, proposed by the Mayor in happy terms, and followed by that of the guests from the same source and the health of the host who presided, proposed by Sir Trevor Lawrence and received with all honours. The party then proceeded to the castle and were escorted through the magnificent suites of State apartments, filled with priceless treasures of art of all branches and of all nations. The private gardens adjoining the castle were then inspected, and with the majestic castle as a background and bathed in the sunshine of an ideal summer day, their freshness, verdure and skilful design formed a delightful picture and example of high-class gardening. Mr. Mackellar, the head gardener,

then accompanied the visitors across the park to Frogmore Gardens, where the immense range of conservatories, all filled with the choicest and most up-to-date examples of horticulture, were fully appreciated by those best able to judge, and the skill of the gardener was recognised throughout. Melons, Vines, Strawberries, Grapes, &c., claimed the attention of the fruit committee, the Orchid houses that of the many specialists in that particular line and the general floral judges had an even wider field in the infinite variety and charm of non-orchidaceous blooms, while the tree-loving arboriculturist was often absorbed in admiration of the noble specimens of Oak and Beech and the conifer tribe, the latter including one of the most magnificent *Salisburias* in existence.

**Franco-British Exhibition.**—The flower show in connexion with the Franco-British Exhibition, to be held from the 24th to the 26th inst., will be arranged in the spacious Palace of Music, in the Court of Honour, the most prominent and central position in the exhibition. No. 3 entrance, Wood Lane, will be the most convenient way of approach for exhibitors' vans, &c.

**Rhododendrons at Regent's Park.**—Londoners and visitors to the Metropolis are much indebted to Messrs. John Waterer and Sons, Limited, Bagshot, Surrey, for the splendid exhibition of Rhododendrons held annually by the firm in the Royal Botanic Gardens, Regent's Park. This year the show opened on the 10th inst., and, as usual, the interior of the huge tent, covering nearly half an acre, was a mass of well-arranged flowers and foliage. About 2,000 plants were so disposed as to form natural borders and beds, the somewhat subdued light in the tent showing the delicate colours of the flowers to perfection. As usual, Pink Pearl was in grand condition, and Gomer Waterer, white, slightly blushed, and Mrs. E. C. Stirling, delicate blush pink with no markings in the throat, were other favourites. Cynthia, pale shell pink; Michael Waterer, scarlet-crimson; Kate Waterer, rosy crimson, large yellow blotch; Lady Clementina Walsh, white, edged pink; and Mrs. William Agnew, pale rose, yellow blotch, were other specially noticeable varieties. The interest of the exhibition was greatly added to by the display of Japanese pigmy trees and herbaceous plants and flowers made by Messrs. Barr and Sons, Covent Garden. The Japanese trees were especially attractive, those that were growing several kinds in the crevices of one piece of rock attracting much attention.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Worms in lawns.**—Having been asked by several readers of THE GARDEN the best way to get rid of worms in lawns, and seeing that Mr. Horace J. Wright on page 232 recommends lime water to reduce them, I may say I have tried lime water and also several other cures, but at last I have got a real effective one in Sutton's worm destroyer. It is the simplest, safest and most efficient cure you can find. There is not the slightest danger of harming the turf, no matter how you use it, and that is a great point in its favour, as there are certain cures which are no doubt harmful to the worms, but at the same time damage the turf. If Messrs. Sutton's directions are carried out there is not the slightest fear of damage, and it greatly enriches the turf and improves the grass generally. Apart from the improvement in the condition of the lawn, the question of labour also comes into consideration, as a lawn freed from worms does not require to be brushed or rolled daily, and, what is more, you will not be troubled with worms in the lawn for the next twelve to eighteen months.—THOMAS BERRIDGE, *The Kew Club, Mortlake Road, Kew, Surrey.*

**A new Guelder Rose (*Viburnum Carlesii*).**—This *Viburnum*, illustrated in THE GARDEN for May 16, is undoubtedly entitled to rank as a most desirable acquisition among flowering shrubs, and one, I think, soon destined to become popular. As a supplement to the note in THE GARDEN, a slight sketch of its history may be of interest. It was first brought under my notice by a characteristic woodcut in THE GARDEN as long ago as September 6, 1902. The illustration was prepared from a photograph sent from Yokohama, the plant having been previously obtained from Corea. At that time the plant, I believe, was not in this country, but in the autumn of 1905 it was announced for distribution by the well-known firm of MM. Lemoine et Fils of Nancy. In their catalogue it was stated that they had obtained the entire stock from M. Louis Boehmer of Yokohama. At Kew in 1906 it flowered, as far as I know, for the first time, while last year it attracted a good deal of attention. In the early part of May of this year I was fortunate enough to find it in full flower, despite the wintry weather experienced just before. The delicious fragrance of the blossoms is a very notable feature. It is pleasing to record that this delightful shrub is perfectly hardy, for the specimens that were shown on April 14 had been expanded under glass. So highly do I value this *Viburnum* that I have but little doubt that the award of merit bestowed upon it will, before many years are past, be increased to a first-class certificate.—H. P.

**Tulips at Colchester.**—I was very interested in your article on the above (page 283), and would be glad if you would kindly allow me to make a few remarks upon it. It appears to me to be hardly correct to differentiate *gesneriana* varieties from Cottage Tulips. They are Cottage Tulips if any are; and it would be better to describe them as a section of the Cottage Tulips just as we do the *billietiana* group, instead of something different to them. It is certainly, too, not quite correct to say that they have "sharply pointed" flowers. This description would be more appropriate for *Didieri* and *maculata* forms. *Farncombe Sanders* is not a dark crimson; from the description it would appear that it is somewhat darker than *King Harold*, whereas it is of the brightest rosy red colour imaginable, and whenever I have picked out the brightest spot of colour in a Tulip field I have invariably found it to be *Farncombe Sanders*. It is a grand Tulip. The article mentions *Zulu* as a very fine deep purple-black *Darwin*. It is. It deserves every bit of praise it gets. One thing I might mention about it is that it remains in good condition a very long time, and seems better able than most to withstand the vagaries of our springs. I am rather at a loss to understand why *Primrose Beauty* was singled out for its chameleon-like propensity. It does become much paler as it grows older; but the change is not so marked as in *Vitellina*, and nothing to be compared with the remarkable change that turns *Isabella* from a primrose, edged and flushed with pink, into an almost entire deep rose, nor to the alteration of Messrs. Wallace and Co.'s new May-flowering *Lord Curzon* (syn *Singularis* of Hogg and Robertson) from rather an ugly reddish purple-edged bloom into a handsome self. This change, which is quite common in the late-flowering sorts, is one of the factors which make the Tulip so interesting.—JOSEPH JACOB.

### A SIMPLE WAY OF SHOWING PANSIES.

THE accompanying illustration depicts a simple yet effective method of exhibiting Pansies or Violas, as adopted by Mr. Howard Crane at the recent Temple Show. As may be seen, the blooms were lightly arranged in flat bowls, with a few sprays of the common Hawthorn for garnishing, one variety only being included in each bowl.

## THE FRUIT GARDEN.

### THE CULTIVATION OF THE STRAWBERRY.

**U**NDER good cultivation the Strawberry seldom fails to give a satisfactory crop. The early flowers are sometimes damaged by late frosts; but it is unusual—in the south, at least—for the entire crop to be damaged in this way. Perhaps it is the most certain of all our hardy fruits, and as it is so greatly valued, both for dessert during summer and as a preserve during winter, it is one of the most important crops in all good gardens, both large and small. To

#### FORM A NEW PLANTATION

a sufficient number of rooted runners must be secured as early in the season as it is possible; these with good treatment will give a good return the first season after planting. Do not propagate from old, worn-out stock. If there are no young, healthy plants from which runners may be taken, it is far better to purchase the

should be taken in hand as soon as the ground is vacant, so that the young plants may be placed in their permanent quarters before becoming stunted in the pots. Light soils should be firmly trodden down before planting is commenced. A loose soil is not suitable for the Strawberry, and after the plants become established it is advisable to tread around the plants occasionally; this is especially necessary in winter after a spell of frosty weather. In the absence of rain, water the plants carefully to settle the soil about their roots.

#### THE DISTANCE OF PLANTING

varies considerably, but when determining this point the relative vigour of the varieties and also the nature of the ground must be considered. Varieties of moderate growth, such as *Fillbasket*, may be planted in rows 2 feet apart and 18 inches in the rows. More vigorous sorts, such as *Royal Sovereign*, require more room, and should be allowed from 2½ feet to 3 feet between the rows. Some growers with a good supply of plants at command set them out 1 foot apart each way, and after the first crop is gathered every alternate row is removed and every alternate plant in the rows which remain. This leaves the plants

A SIMPLE WAY OF SHOWING PANSIES.

young plants from some reliable firm who make a speciality of these fruits. Providing some good varieties are at hand from which a number of runners are required to form a new plantation, the work of preparing these should be undertaken as soon as they are far enough advanced to be handled. This can be determined by examining the runners, and when the emission of roots is noticed they are in a suitable condition for layering. A number of 2-inch pots should be prepared by filling them with good turfy loam. This should be pressed rather firm in the pots, the runner placed in position and secured either by a neat peg or a stone, and the pot plunged for half its depth into the soil. By adopting this latter plan the plants are less liable to become disturbed, and it is also an aid in maintaining the soil in a moist condition, which is most essential for the quick establishment of the plants.

#### THOROUGH PREPARATION OF THE LAND

is most important, and by planting early excellent results are secured the first season. The ground which has been cleared of an early crop of vegetables, such as Potatoes or Peas, is suitable for planting with Strawberries after it has been trenched and heavily manured. This work

2 feet apart each way. The ground should then be lightly forked over and a heavy application of manure afforded. The

#### MANAGEMENT OF AN ESTABLISHED PLANTATION

consists of three important items, viz., keeping down weeds, applying abundance of water during dry weather, and removing all runners which are not required for propagation as fast as they appear. Early in May place some litter around the plants; this is chiefly for the purpose of keeping the crop clean, but is also to some extent a protection against frost. After the crop is gathered cut off all the old large leaves.

Although in some cases Strawberry plantations remain profitable for six or seven years it is seldom advisable to allow them to remain more than three years. It is a good plan to make a new plantation annually, destroying the old and exhausted bed. There must be no stint of manure in successful Strawberry cultivation. A heavy mulch should be afforded the beds annually in January or February, and on light hungry soils this may be followed by heavy applications of diluted farmyard manure water during the spring.

Munden Gardens, Walford.

## THE KITCHEN GARDEN

### THE FRENCH SYSTEM OF GROWING VEGETABLES IN GLASS FRAMES AND UNDER BELL-GLASSES.

(Continued from page 288.)

**F**OR commencing operations under this system the season begins in September, and, as Lettuces are probably the most important and lucrative crop, we will first speak of them. The area of land to be planted must be determined by the space the grower has at his disposal, bearing in mind to reserve enough land for successional crops from winter to spring. The border, if possible, should be formed with an inclination to the sun by giving a border, say, 6 feet wide a rise of 18 inches at the back. Six feet is a convenient width for one of these borders. This will afford room for four cloches in a row across the border, with a little room to spare, and the same with the 5 feet long frames. Sow early in the month across the border at one end one row of Cos and the same of Cabbage Lettuce, drawing a drill for this purpose rather more than half an inch deep and sowing thinly, covering the seed with fine soil. The quantity of seed to sow at one time will depend on the extent of the ground to be planted. These two rows (6 feet long) will provide plants to furnish a large-sized border.

As soon as the young plants are large enough to handle they must be planted in the rich border prepared for them. If they are permitted to remain too long in the seed row in an overcrowded condition, the seedlings will soon become permanently damaged. Before beginning to plant mark four spaces across the border from top to bottom, within 2 inches of one another, by pressing one of the cloches into the soil and forming a ring. Into each of these spaces plant five Cabbage Lettuces, one in the centre and four round the side, not too near the glass, or, if Cos Lettuces are preferred, three only of these should be planted. If it is intended to use frames instead of cloches to cover the Lettuces later on, the same distance between the plants must be allowed as in the cloches. This crop planted thus early may mature without the aid of glass, but the probabilities are that the weather towards the end of October will be so broken and cold as to necessitate the use of the cloches. After the end of this month no ventilation of the cloches will be necessary, as the slight heat of the sun shining on the glass will help to develop the full growth of the Lettuce and to greatly improve its quality. The more forward of these Lettuces will be fit to cut early in November and the later-developed ones will keep the supply going well on to Christmas. As the season advances and hard frost may be expected, provision must be made for protecting the crop; this is secured first by pressing the cloches rather deeper and firmly into the ground and by placing dry leaves or litter between them half the way up, pressing it down rather firmly and by covering with mats at night and taking off in the day.

This first crop is a valuable one and has been grown with little expense, and should be made a large one by those who grow for market. A similar sowing to the above may be made three weeks later, and if the weather remains open and favourable will be found forward enough to follow the last crop, with the help of glass placed over them about the end of October and well protected from cold, as described for the other. It may be found that this crop is too late for maturing in the open ground in the winter, in which case it must remain dormant until spring, protecting with a thin layer of leaves or straw in very hard weather and placing the cloches or frames over at the end of March or as soon as the plants have started well into growth.

OWEN THOMAS.

(To be continued.)

## RIVIERA NOTES.

**THE TREE PEONY** is a shrub that should be in every garden on this coast where it can be given good soil and a fair amount of shade and moisture, though it is most enduring of drought when fully established. In England no variety seems better and more free than the bright red *Reine Elisabeth*. Here it is not so, as it becomes very lanky in habit, and its heavy flowers weigh down the branches. Had I to plant only one variety it should be the handsome growing *fragrans maxima*, with splendid salmon rose double blossoms. Next to it comes the equally vigorous *Souvenir de Ducher*, a rich plum-purple of enormous size. *Stuart Low* is the most gorgeous flame colour, neat and vigorous in growth, and decidedly the best in this colouring: an universal favourite. Of double whites there are: *Koch's Weisse*, very neat and free in growth and fine double white blooms; *Bijou de Chusan*, a weakly doer, but with fairy-like petals that are deeply lacinated. It opens pure white, but is pale pink in the bud, so it is worth a place near the front. *Caroline de Italie* is a grand flesh white, and *Souvenir de Maria Leguenot*, a cream white of remarkable beauty, which is rather new as yet, and so is not very well known. *Louise Marechelet*, *Comtesse de Tuder* and *Ville de Versailles* are all magnificent in flower and in shades of pink and rose; but their habit is tall and straggling in comparison to those I have mentioned.

The Japanese single and semi-double varieties are neat in habit and most surprising in their new shades of colour. They are grafted on a stock that suckers very badly, and, unless carefully watched in spring, the stock shoots deprive the graft of nourishment and kill the variety; but *Milliet* and other French growers are now grafting them on the European stock, and so avoid this serious drawback. It is much to be hoped that European equivalents of their Japanese names may be published, for the vigour and beauty of their varieties must be seen to be fully appreciated, and the foliage is as remarkable as the flowers. One deep blood red flower has rich bronze leaves. One copper red flower has apple green leaves of the most startling shade. There is a grand double pure white flower with bronze leaves. There is a creamy white flower that resembles the white *Lotus*, but is even more beautiful. There are two ethereal blush pinks, one that has apple green leaves and the other deep bronzy red leaves; indeed, the number of varieties is so bewildering that it needs someone to classify them so that buyers may know what they are getting; but one thing is certain that if anybody plants them in suitable positions in this climate they will give each year a series of surprises and gain notes of admiration from all.

**THE FINE LATE-BLOOMING WISTARIAS** (*W. multijuga alba* and *W. brachybotrys*) are so distinct and so beautiful that they should both be more frequently planted. *W. multijuga alba* is the most elegant of all the Wistarias; it flowers with its fresh green leaves, and its long and most delicate sprays of fragrant white flowers hang in such profusion that the bright green leaves do not hide them unduly. I could not counsel anyone planting this in England, for the least moisture spoils the delicate flowers directly. Here in most seasons it succeeds admirably. *W. brachybotrys* is a very vigorous and handsome late-flowering Wistaria that somehow is little known or grown; but it is in my estimation the most desirable of all, as it flowers later than the others and so escapes the storms of early spring. Its colouring is decidedly deeper and bluer than *W. chinensis*, and the quantity and compactness of the flower-spikes makes it far more effective in the mass than that old favourite. This should certainly be given a good trial in English gardens, where it should

flower with the common False Acacia or Robinia, and would make a pretty effect when trained up its trunk and allowed to grow among the branches. Another distinct feature about this Wistaria is that it seeds freely and the seedlings have occasionally flowered the third year from sowing, so that in this climate it is easily propagated.

**A NEW BOUQUAINVILLEA** (*Mand Chettleburgh*) has been one of this year's surprises, and is a plant to take notice of for the future. It is a very vigorous form, larger and brighter in colour than *B. Sanderae*, and, like it, a good winter bloomer, decidedly a hardier plant than *B. spectabilis*, which it should replace in all but the most sheltered nooks. Its blooming period is so long that I am myself pulling up a large specimen of *B. spectabilis*, which flowers so much later and so frequently suffers from a few cold nights that I think this new variety is more desirable. The colouring of the bracts is almost identical with *B. spectabilis*, and their size is quite a quarter larger.

**PTERONIA INCANA**.—The "Queen's Bush," as it is called by those who know how delighted Queen Victoria was with the fruity fragrance of this pretty Cape shrub, is in great beauty this year. It loves a dry, sunny bank and where its slender, hoary branches and stiff little tufts of fragrant yellow flowers may bask in the sun and fill the air with fragrance during April and the first part of May. It requires propagating by layers, as cuttings root with difficulty; but otherwise its cultivation is of the easiest, and once established on a dry bank will take care of itself for many years.

Nice.

EDWARD H. WOODALL.

## INSECT PESTS.

### ANTS IN GARDENS.

**T**HE following is one of several letters we have recently received from readers: "Our garden, made last year, is infested with ants. They eat the fruit, and have now taken to eating the Rose buds. What can I do to prevent this? I have tried *Quassia* with no effect, and have got pots filled with grass under the trees as advised in "Gardening Made Easy"; but meanwhile they are feasting on my Roses."

One can hardly help placing these insects among those that are injurious in gardens, though the amount of mischief they do is very small, and it is only when they make their nests at the roots of a plant that any harm is done, and that only indirectly, as they do not feed on the roots; but these are injured by not being in such close contact with the soil as they should be. It will nearly always be found that if an ant's nest be made among the roots of any plant the roots are attacked by one of the root-feeding aphides. This position has been selected in order that they may the more easily feed on the sweet secretions of these insects. When this is the case the plant should be taken up, its roots carefully washed and freed from the aphides, and then replanted elsewhere. The ant's nest may then be destroyed by pouring boiling water, diluted carbolic acid or paraffin oil into it. If it be undesirable to remove the plant, take a good-sized garden pot, stop up the hole at the bottom, half fill it with leaves and place it bottom upwards on the ground close to the plant, then water the plant copiously every day, so as to keep the soil thoroughly saturated. The ants will soon begin to move their nest to the shelter of the pot, which in about a fortnight's time may be taken carefully away, when it will be found to contain the nest. Ants are often of service by showing when a plant is attacked by aphides or scale insects, for if several ants are found on a plant it is almost certain that it is infested by one of these insects.

## THE FLOWER GARDEN.

## HISTORY OF THE PRIMROSE, COWSLIP AND AURICULA.

(Continued from page 278.)

## THE POLYANTHUS.

**T**HE Polyanthus, as already stated, was the latest section of popular Primulae to be evolved. Hill and Hanbury, late eighteenth century authors, attributed its source to Turkey, no doubt being misled by Parkinson (*Theatrum Botanicum*), Ray and other botanists, who refer to it as a kind of Primrose with trusses, and as having been received by Tradescant from the Levant. Botanists long contended whether the Polyanthus was a distinct species or merely a variety. Darwin thought it to be a variety of the Cowslip, but two centuries ago it was unmistakably associated with the Oxlip. In present-day collections there are to be found two distinct types, one carrying flowers characteristic of the Primrose, the other of the Cowslip or Oxlip, only much larger. Not improbably the "red Cowslip" or Oxlip of Rea was a Polyanthus. It was "of several sorts, all of them bearing many flowers on one stalk, in fashion like those of the field, but of several red colours, some deeper, others lighter, some bigger like Oxlips, others smaller like Cowslips." "The variable scarlet" had an orange centre, the edges being cinnamon; others were shades of scarlet. Ray, too, describes the flowers as having yellow orange centres with outsides coloured. They carried many flowers umbel fashion on the same stalk, were scented like the wild Primrose, and frequently Hose-in-hose varieties were to be found among them. In Bradley's "New

DAFFODILS IN THE GRASS IN MR. KINGSMILL'S GARDEN. (See page 302.)

Improvements" the earliest description of the plant as Polyanthus is found. They are there stated to be Cowslip Primroses, single and double, Hose-in-hose, Pantaloon, Feathers, single red, white, purple, yellow, sometimes violet, frequently variegated, the latter expression referring almost invariably to edged or laced flowers.

Pantaloon had "green leaves about their blossoms which are sometimes variegated with the same colour of the Flowers they encompass." "Feathers seem to have been at first design'd by Nature for hose-in-hose, and have their Blossoms so split and curl'd that they something resemble Bunches of Feathers." Another writer remarks of these: "Others have the Husk that the Flower

grows in split in Pieces, and finely colour'd and the Flowers split likewise, which are call'd Shags, Feathers and scatter'd Polyanthis." These must have become extinct shortly after this period, and have never been revived.

The Polyanthus became very popular, and to some extent superseded the Auricula in gardens, rain, as one writer remarks, not affecting the flowers injuriously as it did the Auricula. Not much can be said of the plant until towards the end of the eighteenth century, but it may be noted that Hill gives a good description of it (in 1757) in "Eden" and an accompanying figure of an edged flower.

James Madock, the fore-runner of the modern florist,

records in "The Florists' Directory" (1792) that the Polyanthus had been greatly improved "within the last twenty or thirty years; and the sorts known fifty years ago are not now in cultivation." The pip of a laced variety illustrated the forward stage the Polyanthus had reached.

The varieties of laced Polyanthus either deteriorate or die out sooner than the Auricula, for not one of the sorts named in Hogg's catalogues of 1822 is in existence at the present day. In lists of 1833, however, George 4th and Bang Europe appear, and a few years later Cheshire Favourite and Formosa. The last-named was so profitable to its raiser that, according to Mrs. Loudon, he was able to build a cottage from the results of its sale. By 1860 the cultivation of the Polyanthus had reached a low ebb, and about 1870 and a little later letters appeared in the *Florist and Pomologist* deploring the loss of the old varieties, while a little previously correspondents were advised by another journal to try Lancashire as the only likely part in England where they could be procured. At the same time, here and there laced Polyanthus from seeds continued to be grown, but their unfortunate habit of dying in the course of a year or two, especially if the soil was dry, no doubt hastened their almost total extinction. The introduction of the Fancy or Bunch Polyanthus caused the old sorts to be little missed, and it is questionable if to-day a collection can be found in Great Britain.

I have already mentioned whence the word "truss" as applied to the Auricula is derived, and it may be interesting to state that the word "pip," which, as far as I have been able to discover, was first used by Hill in 1757 to distinguish the individual flowers of a Polyanthus, in course of time came to include not only the tube, but every part of the flower. "Lace" originally is the same as "ribbon," the ribbons by which brides were led to church in olden times being called "bride-laces." R. P. BROTHERSTON.

## ODONTIODA CHARLESWORTHII

THIS beautiful little Orchid was a centre of attraction during the first and second days of the recent Temple show. It is the result of a cross between *Cochlidia noetzliana* and *Odontoglossum harryanum*. The flowers, of which our illustration is natural size, are of a rich glowing scarlet colour with a rich yellow blotch at the base of the labellum. It certainly ranks as the brightest coloured of all this ever-increasing bi-generic race, and added to its unique colouring it has a habit that is exceedingly graceful. It was exhibited by Messrs. Charlesworth and Co., Bradford, and received the high award of a first-class certificate from the Orchid committee.

ODONTIODA CHARLESWORTHII, A RARE BI-GENERIC HYBRID EXHIBITED AT THE TEMPLE SHOW. (Natural size.)

## A GARDEN IN HARROW WEALD.

It is many years since we visited Mr. Kingsmill's pretty garden, The Holt, Harrow Weald, and it was with delight we renewed our acquaintance with the many interesting trees, shrubs and hardy flowers with which it is planted. The view from the house is one of the most beautiful in Middlesex, and the whole setting to the garden is as perfect a framework as the most critical could desire. A sweep of turf throws into relief the masses of flowers, the purple of *Aubrietia*, the white of *Arabis*, and the many shades which the hundred rare plants contribute to the gaiety of the garden. Around are Scots Pine, Beech, and woodland, and the wonderful view across to Hampstead Heath from the flower-stained terrace.

The garden has been a labour of love for many years, and Mr. Kingsmill has gathered round him a collection of great rarity and charm, many of the plants the gifts of friends to remind him of the pleasant hours spent in the gardens of those who rejoice in the brotherhood of gardeners. There is nothing formal in the setting out, as the illustrations from photographs taken by Mr. Clarence Elliott suggest, the clouds of colour from the *Roses Euphrosyne*, *Thalia* and *Aglaia* being typical of the effects that may be seen here. It is impossible to mention all the plants that Mr. Kingsmill grows, but that they are of more than ordinary interest our readers are aware from the instructive notes this keen gardener occasionally sends to this paper. *Papaver cambricum* was one of the brightest plants in flower early in June, and other things we noticed of rare interest were *Rosa pimpinellifolia*, *R. altaica*, *R. Brunonis* (running over a Holly bush) and many other rare species and hybrids. *Tropæolum speciosum* or the Flame Nasturtium is a wonderful success; it is a weed, if one can call so glorious a flower by so harsh a name. The writer wishes he could coax this somewhat fractious plant into behaving respectably; a cool root-run and shade for the young growths is what it most desires, and then it will grow with great vigour, sending its thin, graceful, light green shoots into a thicket of stems and leaves.

A BOLD CLUMP OF SPIRÆA ARUNCUS IN MR. KINGSMILL'S GARDEN

A flower pointed out to us as one of the bluest of the blue is *Cynoglossum nervosum*, but it is rarely seen in gardens. *Ranunculus Lingua* or the Great Spearwort is a noble flower, which we first remember in Mr. William Robinson's garden, Gravetye, Sussex. It was by the lakeside, and the writer remembers the charming coloured plate of it drawn by the late Mr. H. G. Moon. It is one of the finest of all the Buttercups, and the plant to group by the waterside. The stem is strong and straight, and holds flowers of the deepest golden yellow. Mr. Kingsmill's group is one of the most vigorous we have seen of recent years. *Thalictrum glaucum*, the Bronze-leaf (*Rodgersia podophyllum*) and *Achillea Kelleri* we also noticed in luxuriant health. Near the house there is a collection of plants, a friendship garden, and these will give a new interest to the sur-

roundings, when they become more established. Any description of The Holt would be incomplete without mentioning the beautiful trees and shrubs, flowering and evergreen, which throw into relief the masses of flowers set out in the most charmingly informal way. *Spiraea Aruncus* is represented in one of the illustrations, and there are such interesting trees as the cut-leaved Beech, the purple-leaved Nut, *Pyrus himalaica*, one of the noblest and most silvery of its family—a tree that though rare will, we hope, become common—*Olearia macrodonta*, crimson Maples, *Rubus nutkanus*, *Ceanothus azureus* and *Solanum crispum*.

## COLOURED PLATE. PLATE 1350.

### A BEAUTIFUL WINTER-FLOWERING PLANT.

(*MONTANOA BIPINNATIFIDA*.)

At the meeting of the Royal Horticultural Society held on December 10 last year an award of merit was given to this *Montanoa*, and judging by the remarks overheard at the time, it was practically unknown to the numerous visitors. A group of plants was contributed by Messrs. Paul of Cheshunt, the specimens composing it being from about 2 feet to 5 feet in height. It forms naturally a stout, erect stem of a half-shrubby character, clothed with large, oppositely arranged, much divided leaves, the divisions in their turn being deeply cut, hence the specific name of *bipinnatifida*. It is a member of the huge Composite family, and the ray florets which go to form a bloom of about 3 inches in diameter were in the specimens pure white, although "The Dictionary of Gardening" states they are yellow.

*Montanoa bipinnatifida* is a native of Mexico, and has been long known in this country, but chiefly regarded as a foliage rather than a flowering plant. Under the name of *Polymnia grandis* it is often used for sub-tropical bedding. Other names for it are *Montanoa heracleifolia* and *Polymnia heracleifolia*.

This *Montanoa* is readily propagated by cuttings or seeds, and the plants may during the summer months be placed out of doors. Care must be taken to remove them under glass before the nights get too cold.

H. P.

ROSES EUPHROSYPNE, THALIA AND AGLAIA IN MR. KINGSMILL'S GARDEN.

## THE ROSE GARDEN.

### NEW ROSES FOR BUDDING.

**W**HERE a few hundred stocks can be set apart for new Roses there can be no more interesting spot than this plot when these plants are producing their fine maiden blooms. One may see at a glance what a Rose is worth from these budded plants, and it would serve a useful purpose because we could then plant largely such sorts as prove themselves worthy of such increase. New Roses will never lose their charm if they are genuinely distinct, and the variety in the Rose seems to be infinite. Although pink novelties predominate, who can say that they do not want both Lady Ashtown and Joseph Lowe? They are both described as pink, yet how distinct! It is the same with many other novelties. We must not too hastily say they are too much like other Roses until we have grown them side by side. It is worth anyone's trouble to plant 200 or 300 half standard Briars every year and bud them with novelties. These can be purchased in pots with nice buds upon them, or if procured in good time and given a shift into a larger pot quite a lot of buds will be available by the end of July if the plants are put into strong heat and kept well syringed and watered.

Taking the matter up from an exhibitor's point of view, I would advise all to bud some of each of the following dozen sorts, which I believe to be the best novelties obtainable: Lady Helen Vincent, Lyon Rose, Mme. Constant Souper, William Shean, Albatross, Queen of Spain, Beatrice, Elaine, Mrs. Myles Kennedy, Renée Wilmart-Urban, Harry Kirk and Frau Ernst Borsig. Then, if there are still some stocks to spare, bud them with all or some of the following: Betty, Joseph Lowe, Frau Alfred Mauthner, Grossherzogin Alexandra, Dorothy Page Roberts, Königin Wilhelmina, Lady Falmouth, Lohengrin, Laurent Carle, La Vendemoise, Lucien de Lemos, Mme. Maurice de Luze, Mrs. Stewart Clark, Marichu Zayas, Marquise de Sinety, Melanie Souper, Jenny Gillemot, Mrs. Aaron Ward, Celia, Dora, Mrs. Peter Blair, Nadia, Rosomane E. P. Roussel, Simone Beauniez, Souvenir de F. Vercelline, Souvenir of Stella Gray and Yvonne Vacherot. This seems to be a large collection to add, but if space is available they are all worthy of being grown, and most, if not all, are of first-rate constitution.

We are not only improving in this matter, but in size and substance also, although it must be admitted many novelties are too thin. But who would refuse to grow Betty or Irish Elegance because of their want of fulness? We obtain delightful blendings of colour, which should always be remembered when we feel tempted to blame raisers for introducing these thin Rosea. Happily, we do not all regard Roses from an exhibitor's standpoint. P.

### ROSE LADY ROBERTS EARLY IN THE YEAR.

If one would see this fine Rose in its best form it should be grown under glass. Under artificial

conditions the flowers are a glorious colour, a rich reddish apricot, absolutely distinct from all other sorts. It is an example of the value of sports, for it is well known to have originated from Anna Olivier, and both in its excellent growth, beautiful shining foliage and fine long buds it resembles this variety.

Under some conditions outdoors the flowers of Lady Roberts become so pale that one cannot distinguish them from those of Anna Olivier, but this seldom happens upon old plants. I have not grown Lady Roberts in a cool house, but I used to have wonderful blooms of Anna Olivier upon standard plants in a cold house. The petals developed to an enormous size, and I see no reason why Lady Roberts should not be equally and even more beautiful under similar conditions. Mme. Hoste is another fine Rose, which some think is a sport of Anna Olivier. It is wonderfully like it in growth and foliage and excellent for forcing, one of the best of the pale cream

as the Rose is not specially full this arrangement is seen to perfection. Then how can one describe the colour? The inner tint is of a rich and deep shell pink, almost carmine, with a tendency to orange, a colour that reminds one of Mme. Jules Grolez. Then, to add to its beauty, there is a distinct whitish edging to the centre petals. All Rose growers must be indebted to Herr Lambert for this flower. P.

## THE GREENHOUSE.

### A FRAGRANT GREENHOUSE SHRUB.

(MICHELIA FUSCATA.)

**A**LTHOUGH the flowers of *Michelia fuscata* are not so showy as are those of many of the species of *Magnolia*, to which it is related, they compensate for lack of size and colour by the delightfully refreshing perfume which they exhale when the sun shines on them. An old garden plant, *Michelia fuscata* was figured in the *Botanical Magazine* just over 100 years ago under the name of *Magnolia*, and from the text accompanying the plate we learn that it was "introduced to this country from China by Mr. Evans of the East India House, in whose valuable collection it first bloomed in 1802."

The name *Michelia* is in commemoration of the Italian botanist Micheli, and the specific name *fuscata* is descriptive of the brown-coloured buds and young wood, which are clothed with a soft pubescence, and the reddish brown flowers. The essential points which distinguish *Michelia* from *Magnolia* are the position of the flowers (which, instead of being on the ends of the branches, are in the axils of the leaves) and the number of seeds (of which there are two in each carpel in *Magnolia* and more than two in *Michelia*).

About a dozen species are known, and these are inhabitants of South and South-western Asia, including the islands of the Indian Archipelago; but *M. fuscata* is the only one in general cultivation. In the Southern States of North America, where it is perfectly hardy and frequently cultivated, it is known as the "Banana shrub" on account of its Banana-like perfume. It requires the protection of a cool greenhouse in

this country, and succeeds best when planted in a bed of good loamy soil, in which position it will attain a height of from 5 feet to 8 feet. Cuttings of the ripened wood root readily if inserted in sandy soil and placed in bottom-heat.

*Michelia fuscata* is an evergreen shrub clothed with ovate, lance-shaped leaves 4 inches to 6 inches long, strongly veined on the under surface and alternately arranged on the branches. The flowers are produced from early spring till September. They are about 1 inch to 1½ inches in diameter, composed of six perianth pieces of a reddish brown colour, edged with carmine and cream-coloured on the back. In the absence of light they remain in a half-opened condition until they fall, but on a bright day they expand fully, forming star-shaped rosettes with a central tuft of stamens and a pointed pistil, and fill the whole house with their fragrance, which suggests Bananas according to some opinions, and according to others Pine-apples. H. SPOONER.

ENTRANCE TO THE PERGOLA IN MR. KINGSMILL'S GARDEN.

section. It is rather remarkable that many of our best forcing Roses are sports. There is The Bride and Bridesmaid, both sports of Catherine Mermet; Sunset, a sport of Perle des Jardins; Sunrise, a sport of Sunset; and Souvenir de S. A. Prince or The Queen, a sport of Souvenir d'un Ami. The question that arises in my mind was whether the high temperature induced a sporting propensity. I have seen Liberty give off blooms almost the colour of Mme. Abel Chatenay. All who force Roses in quantity should keep a sharp look-out for sports. P.

### ROSE FRAU ERNST BORSIG.

(HYBRID TEA.)

This is one of the good things among the novelties of last year, and will become a favourite perhaps as much for its exquisite form as for the clearness and loveliness of its colouring. The form is so beautifully regular and of that circular arrangement of the petals that we admire so much, and

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE FLOWER GARDEN.**—My herbaceous Phloxes are beginning to feel the effects of the warm weather. I am therefore lightly forking over the soil between the plants, applying copious applications of water from time to time and giving them a good watering with manure water once a week. Old plants I am mulching with a good dressing of well-decayed manure. In districts where dry weather is severely felt it is a good plan to give similar attention to Hollyhocks, Pansies, Roses and Pinks. I am now making a sowing of Delphiniums, Aquilegias, Sweet Williams, Hollyhocks, Pansies, Anemone Coronaria and other equally interesting hardy flowers. The seeds should be sown in light, sandy soil, well prepared, and in cold frames. Sow thinly, keep the soil moist, and after the seeds have germinated admit plenty of air, shading from bright sunshine for a time. Ultimately remove the frame lights altogether. I am now lifting plants of London Pride and Creeping Jenny that have made such an excellent edging just lately: the plants are being divided and bare places filled in.

**Chrysanthemums.**—These plants need special attention at the present time. If large blooms are desired in November and December next the plants must be well grown and be flowered in pots measuring either 9 inches or 10 inches across. The plants, if well rooted in their smaller pots, should be finally potted into those of the measurement above described. Use good soil of a lasting character and carry out the work as fully described and illustrated in these pages a week or two ago.

**The Vegetable Garden.**—In showery weather I make it a rule at this season to plant winter greens. April-sown seeds of Broccoli, Borecole, Savoys, Cauliflowers and Brussels Sprouts are now in splendid condition for plants. Plant in

rows. Those for Brussels Sprouts should be 3 feet asunder and the plants 30 inches apart: Cauliflowers and Broccoli may be planted in rows about 30 inches asunder and 2 feet apart in the rows. The dwarf Savoys should be planted in rows 15 inches asunder and about 1 foot apart, the larger varieties in rows 2 feet asunder and 18 inches apart in the rows. Borecole does very well in rows 2½ feet asunder and the plants 2 feet apart. Continue to thin vegetable crops. Carrots, Parsnips, Turnips, Onions and Beet need continually looking after in this respect. The frequent use of the hoe between growing crops is highly beneficial at this season. Anticipate the attacks of the Celery fly by dusting the leaves with soot, moistened by the aid of a syringe or water-can with a fine rose placed thereon, and subsequently applying the soot. If this be done in the cool of the evening it is better and more efficacious.

**The Fruit Garden.**—For providing a fresh plantation of Strawberries layer runners without delay. Fill small pots with good soil, placing a runner with the base of the plant on the surface, maintaining this in position by placing a small stone on the runner itself. Keep the soil moist and useful plants will very soon be ready. To make good Raspberry canes for another season I find it a good plan to retain about five or six stout shoots on each plant. It may be that only four good strong shoots are available; in any case remove the weaklings. Plums, I fear, will not need much thinning this season, but these fruits and others, such as Apples and Pears, should be thinned while it is possible to obtain the benefit of this timely work. Peaches that are ripening their fruit should be kept rather drier at the roots or the flavour will suffer in consequence. Continue to syringe fruit trees growing against walls to prevent attacks of aphides and red spider. Grapes should be thinned out at this period, and take care to ventilate the house in the early morning, otherwise trouble will most assuredly arise.

D. B. C.

### BRIAR SUCKERS UPON ROSE PLANTS.

Most of the cultivated Roses now grown are budded upon the root-stem of seedling Briars, and they have the appearance of being on their own roots. The term "own root" means that the plant was produced from a cutting, and, of course, in such cases all growths are of the Rose proper, consequently there can be no wild suckers, which are only produced upon budded plants. The amateur is often at a loss to distinguish these suckers, and we have prepared an illustration of a Briar sucker and also a typical one of a garden Rose, which we trust will assist those who are in doubt about the matter. These Briar suckers are readily distinguished from Tea, Hybrid Tea and Hybrid Perpetual Roses by their colour, which is usually of a dull grey-green, both in the stem and leaf, and, moreover, the leaflets are produced in sevens, whereas the tribes named have rarely more than five on a stalk.

There is such a vast difference in colour and in size of leaf between the Briar sucker and the Rose proper that there should never be any doubt as to which to cut away. When they first appear the Briar sucker is a little more difficult to discern; but a careful observation and comparing the young growths to those in the hedge-rows will soon make the beginner proficient in their detection, and we need hardly say that they should be removed as quickly as possible by the aid of a sharp spud, which any ironmonger will

A ROSE SUCKER: ONLY FIVE LEAFLETS TO EACH LEAF AND THE GROWTH MORE REFINED.

supply. Standard Roses frequently produce a lot of Briar suckers from beneath the ground, and these should always be removed early.

We recommend own-root plants, especially of the Rambler Roses, as they produce in many cases seven leaves and are not so readily distinguished from the Briar sucker if the plants are budded on Briars. There is another stock often used for Roses called the Manetti stock. Although readily observed by the practised eye, it is often overlooked by the beginner. These suckers are usually quite upright, the foliage a grass green and the stems a ruby red colour, with very numerous reddish thorns. If suckers of Briar or Manetti are not carefully suppressed when first seen they become an incessant source of trouble, as they will send out another growth below where cut off. Some may wonder how it is these suckers appear from the root, but the Briar is so full of vitality that if pieces of the roots were cut up quite small each one would make an attempt to grow and in time make a Briar plant.

### HOW TO GROW FINE SALADS IN SUMMER.

THE hotter the weather the greater is the demand for fresh crisp salads, and it is at such a time that many beginners find a difficulty in growing high-class produce. The great heat of the sun quickly dries up the soil, and if young plants are allowed to lack moisture they become tough, drawn, or otherwise unfit for use in the salad bowl. Given proper treatment, the hot sunshine will greatly facilitate the growth of the plants.

**Position.**—Of course in spring-time the warmest and most sheltered border is generally selected for the raising of the earliest crops of salad plants; but in summer-time there is no

A BRIAR SUCKER: NOTE THE COARSE GROWTH AND THE SEVEN LEAFLETS ON EACH LEAF.

special reason for making use of such borders. Any open quarter in the garden will do if the soil is of fairly good quality. It is necessary to have deeply-dug soil, well tilled and enriched with rotted manure.

**Lettuces.**—The seeds of these plants are cheap and plentiful, and, consequently, they are generally sown too thickly, the only good seedlings being those growing near the edge of the bed. Sow the seeds very thinly, keep the resultant plants well watered and duly transplant them in a well prepared border. Do not pull up the young plants forcibly, but while the soil is moist raise them with the aid of the garden fork and plant them with a trowel, thus preserving all the roots intact. If well watered the young plants will quickly form big specimens, and if neatly tied up while the leaves are dry the inner portion of each plant will be well blanched.

**Radishes.**—Tough roots are useless. If they are a long time in growing or receive any check the roots will be tough and stringy. Sow the seeds thinly broadcast, and if the soil is very dry thoroughly saturate it prior to the sowing of the seeds. Surface sprinklings while the plants are growing are useless. Moisten the soil through deeper than the roots.

**Mustard and Cress.**—The seeds must not be buried with soil, but sown thickly on the surface of a rich loam and pressed into the surface slightly with a wet piece of board. Raise these plants on a border facing the north. It will be necessary to maintain the soil in a moist condition, and this can best be done when the position is such that the sun does not shine upon it during the middle of the day. Sow seeds every week and thus keep up a regular supply of young plants, as the latter should be cut while they are in their seed leaves.

**Endive.**—The young plants may be raised in the same way as Lettuces are, and should be similarly treated while growing to a fit condition for use, but the blanching is done by the laying on of clean boards, tiles or slates; and before frosts come a number of plants should be lifted and replanted fairly close together in a frame. A temporary frame will answer the purpose.

**Cucumbers.**—The shoots of frame and ridge Cucumbers should be trained about 1 foot apart over the surface of the bed. By pinching the shoots at one joint beyond the one from which fruits are growing, new shoots will grow, and in due course bear fruits, so that a regular supply of tender Cucumbers will be available. AVON.

1.—A PLUM TREE BEFORE SUMMER PRUNING. NOTE THE MASS OF GROWTHS.

## SUMMER PRUNING FRUIT TREES AND BUSHES.

THERE are few operations in connexion with the cultivation of hardy fruit trees and bushes capable of giving such good returns for the labour expended as a judicious course of summer pruning, yet this is a task that is often left entirely undone by the beginner. The main object of this work is to admit an abundance of light and a free circulation of air to all parts of the tree, so that those shoots which remain shall derive the full benefit of these important factors and thus become well ripened for the following year.

A vigorous fruit tree or bush will always produce far more shoots than it is desirable to retain, and the removal of these during the summer months cannot fail to benefit the tree. The exact time at which summer pruning should be carried out is a debatable point among cultivators, but generally speaking early in July is as good a time as any. If the work is done earlier it frequently happens that secondary growths are made, and these in turn have to be removed, but if the operation is delayed until the time stated above there is not much likelihood of this happening.

Summer pruning must be divided into two distinct styles, according to the trees or bushes to be dealt with. Thus in most Apples, Pears, desert Cherries and Red and White Currants, where the fruits are borne principally on lateral spurs, a shortening back of the lateral growths will be the chief needs; but with Gooseberries and Plums, where the fruit is produced on both spurs and young wood, a thinning and shortening back of laterals will be necessary. In the case of the Morello Cherry, where the fruits are borne only on wood of the previous year's growth, a thinning only is required. This summer pruning is not intended as an actual substitute for, but rather an aid to, the winter pruning, although in the case of stone fruits many growers now make it almost entirely take the place of the winter pruning as gumming is supposed to be thereby avoided. If we examine a vigorous young Apple or Pear tree or Red or White Currant bush early

in July we shall find that lateral shoots have been evolved in profusion from the main growths, and it is to these laterals that we must look for our future spurs. In the ordinary way these shoots, except in the case of those needed to fill up gaps, would be spurred back at the winter pruning to within two or three buds of their bases, but with summer pruning it is not advisable to shorten them severely. The best course is to cut them so that about four or five leaves and buds remain, then at the winter pruning they can be cut to the proper distance. If they were pruned to within two buds or leaves of the main branch, secondary growths would be more likely to come. Of course, there will be many laterals that are weak and misplaced, and these may, with advantage, be entirely removed. The leading shoot of each main branch is left

2.—THE SAME TREE AFTER SUMMER PRUNING. NOTE THAT MOST OF THE LATERAL SHOOTS HAVE BEEN CUT TO WITHIN THREE OR FOUR LEAVES OF THEIR BASES AND THAT THE LEADERS ARE LEFT ENTIRE.

untouched, as also are any side or lateral growths that are needed to fill up any blank spaces in the tree or bush.

In the case of Plums and Gooseberries, *i.e.*, where the latter are grown for fruiting chiefly on the young wood, it will be, as previously stated, be necessary to somewhat vary the above methods. In the first place, all weak and obviously misplaced growths should be entirely removed, then those that are intended to eventually form spurs are cut back as advised for Apples and Pears, taking care to leave a sufficient number of well-placed and sturdy young growths to furnish the bush or tree, leaving each so that it stands well apart from its neighbour. Here, again, the leading shoot of each main branch should be left untouched by the knife.

In the case of the Morello Cherry no spurring back is done, the operation consisting in removing entirely all weak and misplaced shoots, and also thinning out the others so that sufficient only are left to well furnish the tree with fruiting wood another season.

For fruit trees that are growing on walls this summer pruning is especially valuable; it is no uncommon thing to see these trees a mass of growth in the summer months, with the result that they do not become properly ripened and a poor crop of fruit only is secured the following year. Fig. 1 depicts a Plum tree on a fence before it has been summer pruned, and Fig. 2 shows the results of summer pruning. It should be borne in mind that all flowers for next spring are formed in the buds this autumn, and that the two chief factors in their formation are sun and a free circulation of air. In the event of secondary growths being pushed from the laterals these should be pinched back to within two leaves of their bases as soon as possible.

## SOWING ANNUALS.

MANY amateurs and gardeners wisely retain a little seed of annuals in the packets when making the main sowing in the spring, and if these seeds are sown at once a fine autumn display of blooms will result, providing the weather is at all favourable in the meantime. Practically all hardy annuals may be thus treated, and even Asters and Stocks have given good results when sown as late as this. It will be necessary to keep the soil well watered after sowing and while the plants are small, as it is most desirable that the plants be kept growing right on without a check. Thin the seedlings early so that they are able to branch to their fullest extent.

## THE TOWN GARDEN.

**SHIRLEY POPPIES.**—There are few more delightful annuals for the town garden than these charming Poppies, provided that the plants are thinned out sufficiently to allow them to branch and develop their full powers of flower production. Although the individual blooms are extremely fugacious, the succession is persistent as long as the fading flowers are promptly removed. For use as cut flowers the buds should be secured prior to expansion, as they open freely in water and last a fair time. When the plants begin to show signs of passing their best, the soil should be heavily watered with clear water and an hour or two subsequently with weak liquid manure; as soon afterwards as the surface has become dry enough it should be pricked over with a small handiork or a pointed stick. It must not be assumed that this will completely restore the plants, but it is usually effectual in ensuring a further supply of blooms. If it is desired to have Shirley Poppies late in the summer, seeds sown now and the seedlings thinned early and widely enough apart will provide splendid results. The soil must be deeply worked and moderately firm, but it should not be made excessively rich by the addition of natural manure.

**THE ROSE MAGGOT.**—Notwithstanding the fact that Roses are acknowledged to be among the most unsatisfactory of all plants for the town garden, it is more than probable that every amateur essayer their culture at some time or another, and he is seldom disheartened by one or two failures. One thing is quite certain, viz., that those who have any Roses in their gardens have also a supply of the wretched Rose maggot. As far as its own comfort is concerned this pest is quite sensible, for it ensconces itself in such a position in the growths that it is impossible for the grower to apply any powder or liquid dressing which will destroy it without at the same time killing the shoot itself. It is, therefore, imperative that hand-picking shall be had recourse to, and while it is tedious, it affords some substantial pleasure as one firmly pinches each enemy to death between the thumb and finger. Personally, I do not remember to have seen the infestation more serious than it is this season, and where many plants are grown it means hours of unwearying effort to keep it in subjection. The searcher should examine the point of every growth, and in the youngest unfolded leaves he will find the maggot carefully encoased. To leave one means ruination to the blooms; to leave many means to spoil the first display of flowers from the plants for the season.

**WATERING AND HOEING.**—These operations are of the utmost importance in the town garden, and they should always go hand in hand. As far as the former is concerned the rule should be a thorough soaking when water is wanted and no more until the soil again approaches dryness, while the latter should invariably follow as soon subsequently as the surface has become dry enough for the blade of the tool to work freely. In addition to the watering there should be frequent sprinklings, preferably through a hose, with a view to the removal of the dust, which accumulates upon the plants so quickly during dry weather; this may be done each evening or every alternate evening, according to convenience and necessity.

**PEGGING DOWN.**—In the case of many plants, of which one may mention *Phlox Drummondii* as a typical example, it is possible to much improve the effect of the display by pegging the shoots down to the surface of the soil. Some care is, of course, required in carrying out the operation or the growths may be broken off; but if this is given the results will be so much better that the time expended will be most generously repaid. The pegs utilised for layering Carnations answer admirably for the present purpose, but any form can be employed at the will of the cultivator.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FLOWERING SHRUBS.

**T**HOSE shrubs that have flowered should now have the seed-vessels picked off and any pruning done that may be required. Any plants that have become overgrown or untidy should be cut back into shape. Prunus of various types, Berberis, Azalea, Ceanothus and many others are all the better for being thinned at this season. All seed-pods ought to be gathered from Rhododendrons of the earlier varieties, taking care not to injure the young growths. The flowers of many of these are now over, and this operation should be effected at once. Other shrubs may be assisted with a mulching of manure; this will assist the development of the flowers and keep the roots cool and in good condition.

Roses should be mulched and manured, and when extra-sized blooms are required the flower-buds must be thinned. Keep them free from aphids and maggot.

#### ALPINE GARDEN.

*Saxifrage*s and many other things should now be propagated by cuttings and seed collected and sown as soon as ready. Keep plants that are located in dry positions supplied with moisture, and see that shade-loving plants get the required amount in the middle of the day when the sun is at its hottest. Branches of Rhododendrons, common Laurel or Erica will answer very well for this purpose. Ramondias have been most charming this season; they do not last nearly so long if exposed to much sunshine. Continue to prick out seedlings into small pots and pans, and keep them shaded. Many seedlings are lost through inattention to this seemingly small detail.

#### FRUITS UNDER GLASS.

*Vinerias.*—Give an abundance of air to houses containing ripe fruit and allow the shoots to grow more freely. Pinching need only be done to keep them free of the roof. Keep the atmosphere of the house cool and dry, but still maintain the moisture right in both inside and outside borders, or red spider may make its appearance. Late Grapes should be looked over often and have the laterals pinched, and if any berries have been left that are not required take them out carefully with Grape scissors. Feed the roots at every other watering. Muscats must be kept warm (70°) now at night, so as to correspond with the high day temperatures; it is well to look over these carefully and frequently, stopping and tying down the laterals.

#### KITCHEN GARDEN.

Owing to the late heavy rains and tropical heat vegetables and weeds have grown at a great rate, and what appeared to be a late season has now so far become quite normal. Prick out all Broccoli, Cauliflowers and Brassicas generally for the autumn and winter. Sow Carrots, Lettuces and Turnips frequently. Thin out all crops, allowing room for proper development. Earth up all Potatoes at the earliest moment, and keep all plants and walks free from weeds.

#### SWEET PEAS.

The early crops of these are bearing very fine flowers. Stake with tall sticks all the later sowings. I am afraid we are getting too many varieties. As soon as one class of anything in the garden becomes popular it is overdone, and I have noticed that some varieties vary in different soils very considerably. Whites, reds and blues are the best for general purposes. The Countess Spencer varieties seem to take precedence with some. John Ingman, Dorothy

Eckford, King Edward and Queen Alexandra are most beautiful sorts. A good sowing now will produce fine late blooms.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**DENDROBIUMS.**—The majority of those with the habit of *D. Phalenopsis*, *D. bigibbum* and others in this section are now starting into growth, and the present will be a good time to repot or rebasket any that may require it, or to surface-dress any that are in fair condition at the roots and do not need disturbing. Although greatly alike, species and varieties in this class need a little different treatment; but I find the greater number like small perforated pans or shallow baskets better than any other receptacle.

*Indian Azaleas.*—Plants that were forced in the early part of the year, and have since been in heat to encourage them to make growth, should now be removed to a cooler house, where they will remain until growth hardens and the flower-buds are well set. Syringe frequently to keep red spider in check and to also help the flower-buds to develop steadily. Reduce somewhat the supply of stimulants to the roots.

#### KITCHEN GARDEN.

*Asparagus.*—Where sowings of this to supply plants for making new beds or for forcing were made early in April, attention must now be turned to thinning out the seedlings. This must be done with a free hand, as if left thickly the growth will be weakly and a difficulty will be experienced when the plants are lifted for transplanting. A soaking with farmyard liquid manure once or twice during the summer will be of great benefit to the plants. Beds which were made last year for forcing in the coming year will now be advanced in growth, and liberal feeding must be resorted to in order to secure extra strong crowns for early work. Weeds must be kept closely down, either by means of hand weeding or by the application of moderate dressings of salt two or three times during the summer.

#### HARDY FRUIT.

*Gooseberries.*—It is but very seldom that there is any attempt made to grow a distinct lot of bushes to provide green fruit for cooking, and where such bushes are not grown it is the custom to go over all the bushes to find fruits for this purpose. This is not a bad system, provided the finest fruits are left for ripening, but the general practice is to pick the largest and leave only the smaller fruits to remain for dessert, the consequence being that there is a want of size about the ripe fruits that reduces them below mediocrity and brings the Gooseberry into bad repute as a dessert fruit.

#### FLOWER GARDEN.

*Double Wallflowers.*—Now is the best time for putting in cuttings of the double Wallflower. They strike freely under handlights in light, sandy soil in a shady situation. When rooted plant them out into beds. They will grow and bloom in very barren soil, but to have a long continuance of bloom they must have rich, dry ground.

*Nemophila insignis.*—Where a splendid mass of blue is the object for a couple of months in autumn, this is the most effective thing. It quite eclipses *Lobelia speciosa* seen at a distance, and in cold localities it is, perhaps, superior to the *Lobelia*, especially when the latter is from seed. To have a fine bed of it in August and September, sow the seed now, and when well up thin out to 6 inches. I find this interesting subject does best in a dry soil.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## THE EDITOR'S TABLE.

## DOUBLE-FLOWERED WELSH POPPIES FROM ARMAGH.

Mr. J. McWalters, The Mall, Armagh, sends a beautiful contribution of these charming flowers, the bright orange and yellow blooms providing excellent material for vases. Mr. McWalters' strain is one of the best we have ever seen. He writes as follows: "The double and semi-double *Meconopsis cambrica* seedlings are now making a great show in the garden here; hundreds of plants combine to make a brilliant stretch of colour, and groups and single plants set in pretty foliage are effective in the rock garden. As for cut flowers, I send a few for your table."

## TREE PEONIES FROM FRANT.

Mrs. C. Malden, Henley House, Frant, sends excellent blooms of the Tree Pæony with the following note: "I have seen several times lately suggestions that those who grow the Tree Pæony well might, with benefit to others, give an account of how the plants are situated and treated. I have a very large bush standing about 10 feet to 11 feet high; it has at the time of writing seventy-eight blooms or buds on it. It would have been a truly splendid sight if a thunderstorm had not shattered the flowers. I send you two to judge of the size. The border is a long-shaped oval. Tall bushes or almost trees grow at the back and shelter the Pæony from the south. I enclose a little of the soil from the border. It has only been manured once in the last twelve years, but it is dug over twice a year. All my Pæonies are growing on the north side of borders, and get the early morning sun. I believe the best place for them is where they are kept cool in the spring, so that they do not begin their growth too soon. Also, I do not believe in too much manure, as it makes the growth rank and soft."

## ROSES FROM THE ISLE OF WIGHT.

Lady Thorneycroft sends from Steyne, Bembridge, a box of beautiful Roses, representing several varieties we treasure in our gardens, and the following interesting note: "I am sending you a few Roses which it may interest you to see. Mme. Alfred Carrière has been in full bloom for more than a week, and I could pick hundreds of Roses of this variety, which here comes into bloom early and goes on blooming into November, and as a climbing decorative fragrant Rose is difficult to beat. Mme. Lambard on a stone wall had some blooms fully out in Easter week and is now in great beauty, the pink Roses looking particularly pretty on the greyish white stone wall. A bed of General Shablikine has been covered with Roses. The first are nearly over, but the plants are covered with buds, and we find that this Rose is a particularly good autumn one here. We have many other Roses coming into bloom well, and already with one or two blooms fully out, but Mme. Alfred Carrière, Mme. Lambard and General Shablikine are the three varieties which are already giving us a profusion of flowers."

## PYRETHRUMS FROM LANGPORT.

Messrs. Kelway and Sons, Langport, Somerset, send us some beautiful blooms of their famous Pyrethrums, which remind us of the value of these plants both for border and house decoration, the richly coloured and beautifully shaped flowers with their long stems rendering them most suitable subjects for many purposes. Of single varieties we were particularly pleased with the beautiful crimson-scarlet variety called Langport Scarlet. General Buller and General French are similar in colour and make excellent companions. Roseen is an exquisitely-shaped flower, the colour

of which reminds us of Rose La France, and Snow White is a pure white variety. Seduction is a huge double flower of beautiful rich crimson, and Lord Rosebery and Captain Mars are similar in colour. Empress Queen and Lady Kildare are blush pink sorts, and excellent whites are represented by Aphrodite and Souce. Among those of a deep rose colour we were particularly pleased with Millie Fowler and Evelyn.

## HARDY BROOMS FROM NEWRY.

Mr. T. Smith, Daisy Hill Nursery, Newry, sends us some of the newer forms of the hardy Brooms of which he makes a speciality. The examples sent show a marked advance on the older sorts and ably demonstrate the value of these hardy shrubs in the flower garden. Firefly and Mayfly are two that somewhat resemble the old andreas, but they are decided improvements, both in the size of the flowers and clearness and brightness of the colouring. The wings of the first named are rich mahogany crimson, and in Mayfly this colouring is much paler. In each instance it contrasts well with the rich yellow colour of the other parts of the flower. Daisy Hill has pale cream flowers with rosy crimson wings; Newry Seedling is canary yellow with rosy crimson wings; Moonlight has large flowers of pale golden hue and Butterfly has blooms of the richest gold colour slightly suffused with crimson on the wings.

## PINKS AND FLOWERING SHRUBS FROM LEONARDSLEE.

Mr. W. A. Cook, gardener to Sir Edmund G. Loder, Bart., Leonardslee, Horsham, Sussex, sends us a fine collection of Pinks (*Dianthus*) and a few of the choicer flowering shrubs. The Pinks comprise *Dianthus fimbriatus*, *D. cæsius*, *D. anernensis*, *D. alpestris*, *D. multiflorus roseus*, *D. alpinus*, *D. arenarius* and *D. deltoideus*. Among the shrubs were sprays of the Bottle-brush Tree (*Metrosideros floribunda* or *Callistemon salignus*), gathered from a tree measuring 6 feet in diameter and 10 feet high; *Rhododendron ferrugineum album*, *R. hirsutum album* and *Deutzia discolor grandiflora*, all gathered from plants in the open on the 10th inst. All these were in fine condition, thus testifying to the generous and judicious treatment accorded them by Mr. Cook.

## RARE SHRUBS FROM CHELSEA.

Messrs. James Veitch and Sons, Limited, Chelsea, send us a collection of the rarer flowering shrubs, many of which are most beautiful additions to existing varieties. Perhaps the most interesting of all were three varieties of Lemoine's Mook Orange (*Philadelphus Lemoinei*), named respectively Avalanche, with beautiful large white flowers; purpureo-maculatus, white, purple centre; and Manteau de Hermine, a very refined-looking flower. *Rubus nuthkanus*, *Deutzia discolor major*, the lovely-scented Rose Mrs. Anthony Waterer, a reputed cross between General Jacqueminot and rugosa; *Weigela* or *Diervilla* Abel Carrière; the Moonlight Broom, *Cytisus pallidus* or *C. scoparius sulphureus*; *Ceanothus thyrsiflorus*, *Rhododendron fragrans*, *R. govenianum*, *Viburnum plicatum*, *Lonicera Maackii* and *Polygonum baldschuanicum* were a few others among the many beautiful things sent, all of which are worthy of a place in English gardens.

## EARLY SWEET PEAS.

Mr. R. C. Notcutt, The Nursery, Woodbridge, sends excellent flowers of Sweet Peas with the following note: "I beg to enclose you some blooms of Sweet Peas grown from seed inoculated with nitro-bacterine, which have been three months and five days from the date of sowing; they are far ahead in this soil of varieties which have not been inoculated. I thought it might interest you to see them."

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Lily of the Valley (K.).**—The soil of the bed in which these things are planted must be lacking moisture or the requisite supplies of food for the plants. Partial shade, too, is important. If the leaf growth is small, or thin and poor looking, apply liquid manure freely and note the results. You do not say if the bed is an old one or not. It is possible, too, that overcrowding is also a cause of the present condition of the plants, but you give us no clue to guide us in helping you.

**Water beetles in Lily pond (K.).**

The introduction of newts into your Lily pond will probably have the effect of clearing it of the water beetles which are destroying your Nymphæas. The manure you speak of ought not to have an injurious effect on the newts. It is difficult to suggest any other method of clearing the pond, for if anything very strong is applied it will most likely kill the Lilies as well as the beetles. Newts, during the greater part of their lives, live on insect life and are only vegetarian during the very earliest stages of their existence.

**Plants for rockery (A. K.).**—You cannot do better than add some of the following plants, all of which are suitable for the purpose: *Campanula muralis*, *C. garganica*, *C. g. alba*, *C. pumila* and its variety *alba*, *C. turbinata* and *C. G. F. Wilson*; of dwarf Phloxes, any of the *P. subulata* forms, such as *frondosa*, *atropurpurea*, *The Bride*, *Nelsoni* and *Vivid*; *Saxifraga oppositifolia*, *S. o. major*, *S. granulata plena*, *S. sancta* and *S. apiculata*, *Lithospermum prostratum*, *Cyclamen repandum*, *Acantholimon glumaceum*, *Crucianella stylosa*, *Iberis* and many more. A capital way of reducing the slugs is by paying night visits, and with the aid of a pointed stick and a small bucket of salt and water a large number might be disposed of. If you can possibly apply salt to them at sight, nothing is more fruitful of good results. Kilogrub, if used according to the directions, is also excellent.

## TREES AND SHRUBS.

**Making a tennis lawn (A. E. B. F.).**

Presumably you purpose allowing the 30 yards' length of lawn on the upper side of the whole to remain. In making the remainder, roughly 100 yards, which now slopes gently to an ultimate depth of from 6 feet to 9 feet, we assume you wish to make of that length two other levels, thus necessitating steps from higher levels to those below. Your course will be in the autumn to remove all the turf, having it properly cut and rolled, from the 50 yards which immediately adjoin the upper untouched and level portion. Then you will need a long, perfectly level edged piece of wood, 2 inches wide and 4 inches to 6 inches deep. This may be some 10 feet to 12 feet long, and the upper and lower edges should be absolutely even. Place that lengthwise on the ground the way of the slope, and on its centre an ordinary spirit level; lift the lower end of the wood on bricks or blocks till the spirit stands quite in the centre of the level. By that means you would be able to note exactly how many feet at the lower end of the 50 yards the soil would need raising to make the required level.

If, for instance, 18 inches depth gradually running out to nothing at 25 yards were wheeled from the upper end of the 50 yards to the lower end, raising that end to 18 inches and running off to nothing in the centre, the desired level on which to relay the turf would be found. Even an ordinary bricklayer's plumb-bob level would do almost equally well. The second or lower 50 yards would then be treated in the same way. October and November are excellent times to do work of this kind.

**Removing Elm suckers (R. H.).**—The suckers of these trees are often very troublesome, and the only effective way of getting rid of them is to dig down to the roots from which they originate and remove the root at a point nearer the tree than that from which the suckers are produced. It is little use to cut them off, as they will soon sprout again.

**Rhododendrons gone wrong (J. A. W.).**—From the appearance of the leaves and buds of Rhododendrons you send, we should say that there is something radically wrong at the roots. Drought causes such an effect, and sour soil also. If you remove the soil from about the balls you may perhaps discover the source of the injury. In some places Rhododendrons were injured during the winter on account of insufficient ripening last autumn; but the injury was more in the nature of destroyed shoots than damaged leaves. The critical time with regard to water is the period during which new growth is being made. If the balls are allowed to become dry at that time leaf injury usually occurs. The reason for buds going wrong as yours have done may frequently be traced to sour soil or bad ripening of the wood.

## THE GREENHOUSE.

**Treatment of Crinums (W. B.).**—We think that most probably your Crinums are *C. Moorei*, the most generally grown of the greenhouse species, and one of the most satisfactory under cultivation. Where conveniences exist for planting it out in the greenhouse or conservatory *Crinum Moorei* will do well treated in this manner. Still, in many places this cannot be done, and then the plant may be grown in pots, and when large masses exist tubs are preferable. A compost consisting of two-thirds loam and the remaining third made up of manure, leaf-mould and sand is very suitable. Repotting when necessary is best done in early spring before growth recommences, but with regard to this it may be pointed out that large plants will remain in the same pots or tubs for years and flower all the better for this treatment. Briefly, the cultivation of *C. Moorei* may be summed up in keeping it quite dry in a structure from which frost is just excluded from October to March, when it must be watered and will quickly start into growth. As the noble head of foliage develops give occasional doses of liquid manure. About midsummer many of the plants will show signs of going to rest, after which the flower-stems will soon be pushed up and the blooms quickly open. When the flowering season is over the plants may be stood under a south wall or in some similar position in order to thoroughly ripen the bulbs, but they must be removed under cover before autumn frosts set in. This *Crinum* may, if desired, be allowed to stand out of doors throughout the whole of the summer.

**Name of, and information about, an Orchid (B. M. J. de la F.).**—The name of the Orchid sent by you is *Cymbidium lowianum*, a native of Burmah, from whence it was sent to this country in 1877. It is not a particularly good form of the species, and it is impossible to say the value of such a plant without seeing it. At all events, it should be well worth a guinea. We think that your plant needs repotting, and the best time to carry this out is as soon as the flowers are over. In the case of this *Cymbidium*, they remain fresh so long as to put a considerable strain on the plant, hence it is a good plan to cut off the entire spike when the flowers show signs of fading. Directly after this the potting should be done. The most suitable compost is equal parts of good fibrous loam and peat, with a liberal sprinkling of rough silver sand and broken crocks. This compost will remain sweet for a very long time, which is an important consideration, for during the growing season this *Cymbidium* needs a liberal amount of water at the roots, yet it is very impatient of stagnant moisture. For this reason the pots must be effectually drained with broken crocks to about one-third of their depth. *Cymbidium lowianum* is essentially a cool house Orchid, and in winter a temperature of 50° to 55° suits it

well. No fire-heat will be needed throughout the warmest part of the summer. Very large old plants are apt to get hollow in the centre, and consequently unsightly. When this happens the better way will be to divide up the plant into as many pieces as there are separate growths and pot them singly.

**Planting *Primula obconica* outdoors (H. J. C.).**—*Primula obconica* may be safely planted out of doors for flowering during the summer. It is not hardy, and therefore will, in all probability, perish in the winter, but from now till the autumn frosts set in is a period of some months, and throughout the whole of that time it will, under favourable conditions, maintain a display of bloom. Of course, very young plants, such as those raised from seeds this spring, will not be suitable for planting out this summer.

**Bouvardia leaves spotted (F. T.).**—The spots on the Bouvardia leaves may be caused by the smoke from the furnace, but in our opinion a more likely cause is the sun shining brightly on the leaves while they are still wet. Such spots are by no means uncommon at this season of the year, not only in the case of Bouvardias, but also of many other greenhouse plants. The explanation of this is that during the winter the leaves have no special strain put upon them, and consequently they remain fairly fresh and bright; but when the sun gains power they are unable to withstand the additional strain, and therefore soon suffer. The leaves now produced are not likely to be injured to the same extent. Of course, the roots may be in a bad state, and the leaves therefore rendered more susceptible to injury; but on this point we cannot say without personal inspection. At this season of the year Bouvardias need to be shaded from the direct rays of the sun during the hottest part of the day.

## FRUIT GARDEN.

**A simple method of bottling fruit (V. S.).**—Select firm, well-ripened fruit, carefully wipe and place in clean, dry bottles or jars. Place these in a warm oven, fill up the jars with a syrup made of 1 lb. loaf sugar to 1 pint of cold water, slowly cook until the fruit looks slightly shrivelled. Take from the oven, and when cold tie down in the ordinary way and store in a cool, dry place. Patent bottles for this purpose, with full instructions for using same, may be obtained from Messrs. Whiteley's, Westbourne Grove.

**Grubs attacking Strawberries (F. E. Mayhew).**—The only means of killing the grubs which are attacking your Strawberry plants without disturbing the plants is to make some holes, say four, round each plant with a dibble or stout stick about 6 inches in depth; then put 1 oz. of Vaporite into each hole and fill up the latter again. The Vaporite when in contact with the moist earth gives out certain gases, which permeate the surrounding soil and kill all insects which are under their influence. Watering with any insecticide which would kill the grubs would also kill the plants. Taking up the flagging plants and picking out the grubs is of course the more certain way of destroying them.—G. S. S.

**Peach and Nectarine leaves diseased (G. L. K.).**—The foliage received is suffering from a fungoid disease to which Peaches and Nectarines when grown out of doors are, unfortunately, very subject to. It is commonly called the Peach blister, and is supposed to be caused by sudden and violent changes in the weather such as we have lately had. It is seldom or ever met with on trees cultivated under glass, and the best way of getting rid of it is no doubt by erecting glass over the trees. For the present the best thing you can do is to cut off the leaves which are most affected and burn them, and then dredge the trees thickly with flowers of sulphur (having first moistened the trees by gently syringing), leaving the sulphur on the trees for a couple of days, when it may be syringed off with water, and as soon as dry again scraped off the soil and burnt. The sulphur will kill all the fungus it comes in contact with, and this gives the tree a chance of developing healthy foliage again during the summer. But the best way of killing it right out is by a winter application of a fungicide invented by the firm of George Bunyard and Co., nurserymen, of Maidstone, who claim for it that it effectively prevents an attack from this most destructive pest. The name of the antidote is "Medila."

**Fig fruits mildewed (Harry Low).**—The past cold and changeable weather has probably helped to cause

the fruit of your Fig trees to become mildewed, and your want of fire-heat at the same time has, no doubt, helped to aggravate the mischief by your not being able to create a free circulation of air in the house for the want of the adequate heat. There is no doubt that a too cold and sluggish atmosphere has been the cause of the attack. We have suffered in the same way on many occasions, and the remedy of extra heat in the pipes, with increased ventilation and less moisture in the air, coupled with sulphuring the pipes when hot, has always had the desired effect of preventing further mischief. If you cannot increase your fire-heat, we advise you not to start the trees into growth so early next year. The loam it seems to us is excellent.

**Vine foliage diseased (Vectis).**—The Vine foliage sent is suffering from a bad attack of mildew, and if the berries are similarly attacked the crop will be virtually ruined for the season. The best way of destroying the mildew is by heating the hot-water pipes to that degree that you can scarcely bear your hand on the pipes, then have ready some flowers of sulphur mixed with water to the consistency of thin paint, and wash the pipes over while hot. The resulting fumes will destroy the fungus, if not on the first application, it will on the second given the following night. The operation should be carried out in the evening, the weather should be calm, and of course the ventilators and doors of theinery sealed as close as possible to prevent the escape of the fumes. The sulphur should be allowed to remain on the pipes for some time, as slight fumes will continue to rise and help to ward off another attack.

**Insect-infested Gooseberries (T. M.).**—The only insects we could find in the box sent, which also enclosed a very tiny and stunted piece of a Gooseberry shoot with leaves, were red spider, a minute sucking insect which infests and preys on the leaves. That your bushes are not in a robust, healthy condition seems to be evident if the small portion sent indicates the character of general growth. It is so very evident that the soil must be very poor and needs liberal manure dressings. The bushes need to be daily heavily syringed with water to wash off the insects, and once a week a good spraying with a solution of Sunlight soap, dissolved at the rate of 1 lb. to ten gallons of boiling water, would do great good. The trouble, however, all seems to come from poverty of soil. Even now, if the bushes have no fruit, we would advise cutting them hard back low down, giving a dressing of manure and liquid sewage to compel new, strong, clean shoots to form.

**Blenheim Orange Apple and Peach tree unsatisfactory (C. J. D.).**—It is characteristic of the Blenheim Orange Apple that the tree bears fruit sparingly while young; but as it has been planted seven years it should by now be bearing fair crops, provided the conditions for growth are favourable. By your description of the practically leafless condition of the tree we are led to think that the cause of its being in this condition is owing to its being planted in unsuitable soil, either too poor, too wet or too heavy. An Apple or any other fruit tree which does not make a free and robust growth becomes an easy victim to the attack of fungoid and insect enemies, and we suspect that the cause of the defoliation of your Apple, as well as your Peach tree, is an attack of red spider or mildew. Should this be so, syringe the trees with flowers of sulphur mixed in soft water, half a pint of sulphur to a gallon of water. In the autumn (early in October) lift up your Apple and Peach tree, trench the ground 3 feet deep and in doing so add a good proportion of turfy soil (with the grass cut off), some well-decayed farmyard manure and a gallon of bone-meal to the soil in which each tree is replanted, mixing all well together, removing the worst of the soil to make room for these additions. Replant carefully, placing the new soil round the roots with the hands, pressing firmly as the work proceeds until finished, and in a year or two you will be rewarded by your trees coming round to good health and fertility.

**Young Vine shoots and leaves diseased (Harry Low).**—From a careful inspection of the Vine shoots and leaves sent us, we find that the leaves are large, of succulent growth and very tender, and we think that the injury to them has been caused by the hot rays of the sun shining on them while moist with condensed vapour of the night and before adequate ventilation had been given in the morning. We can find no trace of fungoid growth or of spider. The remedy in this case another year lies in leaving slight ventilation (top and bottom ventilators) all night as soon as the weather is favourable in spring, with, of course, sufficient heat in the pipes to secure a free circulation of air. As regards the young shoots, the disease from which they suffer is more obscure. Our Vines have suffered occasionally from the same malady, and we always found that its attack was confined to young Vines in robust growth, and always to the tenderest and softest shoots the same as in your case, and it always seemed to favour the varieties Alicante and Gros Colman for its attack. At first we attributed the cause to some form of mildew, but with further experience we were satisfied that a minute species of red spider was the cause, and we were afterwards confirmed in this opinion by the decision come to by the scientific committee of the Royal Horticultural Society to the same effect. It is a most tiresome and dreaded thing, and what is worse, is the fact that it will recur every year unless it is stamped out. We recommended you to cut away most of the affected parts and to dredge sulphur thickly over those remaining, leaving it on for two or three days, then syringing off and, when dry, to burn it, as the disease is said to be epidemic. By doing this and keeping a vigilant look-out the following spring for its reappearance and immediately applying sulphur, we were enabled to stamp it out. How it originated with you it is hard to say; possibly from the manure, as you suspect.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## PROSPECTS OF THE COMING ROSE SEASON

I HAVE written a few notes on this subject, more particularly, perhaps, with reference to the National Rose Society's metropolitan show, during the last few years; and at the request of the Editor I contribute the following with rather more pleasure than usual:

Last year, writing at about this time, Roses looked well, but were late and needed what, as a matter of fact, they never got—a few hot days—to bring them to perfection. They had, it was true, a slight check in May, caused by frost, but they had formed better than usual, only the abnormally cold June of 1907 ruined (or nearly so) what promised in the early days of the month to be the best Rose season of recent years. But what of 1908! I quite agree with Mr. Mawley, the Rose clerk of the weather, that the early part of the Rose season is more affected by the weather of the preceding month than it is by the autumn, winter or spring weather, he the latter what it may. To go back to the autumn, we had, after a fine September—which enabled the finest lot of autumn Roses to be exhibited at the autumn show of the National Rose Society as we are likely to see for some time—a very wet October, which caused the growth then making to be unduly sappy, and a large portion of which never ripened, at any rate sufficiently to withstand the terrors of Jack Frost, and consequently this season Roses generally pruned badly. There were numerous complaints throughout the country of dead wood, brown pith, &c., necessitating in some cases pruning to the ground level or below it before sound wood was reached. With regard to the exhibition flower, this cannot be considered much of a loss; but to the garden or decorative section it was more serious, as many of these Roses produce their flowers on the wood of the second year. The spring we have passed through was cold, and everything up till mid-May was very late; but the hot weather of the last fortnight, coupled with the occasional showers, has made a very considerable alteration, so much so that the prospects are that we shall not only have an early Rose season rather than a late one, but a very good one too.

Circumstances over which the National Rose Society had no control compelled the alteration of the date of the metropolitan exhibition from July 9 to July 3, and what at one time looked like a misfortune will turn out, I think, a blessing in disguise. Writing of the Roses in the south metropolitan district, they promise to be not only early but particularly good. This year they have entirely escaped the late May and even June frosts that sometimes have played havoc with them. Until May was nearly out they grew slowly but without a check; since that date they have grown fast, and now look as well as I can remember seeing them.

Speaking of my own garden, green fly and mildew are both conspicuous by their absence, but there has been an unusual quantity of maggot, caterpillar and Rose beetle about, as

if to justify the appearance of the society's last publication, "The Enemies of the Rose." But where hand-picking has been systematically carried out these plagues are dealt with before much damage is done, and the foliage is now looking both clean and healthy—exceptionally so, I think. Then there is an almost entire absence of that *bête noir* the blind shoot, due largely to sudden changes of atmosphere, so that from the exhibition Rose standpoint the prospects are excellent.

Garden Roses look uncommonly well, but are distinctly early in this part of the country, so much so that many sorts will be over before the month is out; but so extensive is the area from which the society draws its exhibitors that I have little doubt that this section will be unusually well represented at the show on the 3rd prox. The feature of such Roses as have put in an appearance at this early date has been their high colour, which always means robust health. To sum up the situation in this district, given decent weather between now and the date of the show, I venture to think we shall have a record show at the Royal Botanic Gardens on July 3 next, both as regards quality and quantity of flowers.

I have endeavoured to gather the opinions of the leading exhibitors throughout the country, and quote a few of some from the letters I have received for the benefit of your readers. I hope the show may prove a record in one other respect beside these above referred to, namely, in attendance. Especial precautions are being taken to provide for the comfort of visitors. The catering, always the most difficult matter to arrange satisfactorily, is having unusual care bestowed on it. The finest military bands have been engaged, and, given a fine day, the Royal Botanic Gardens will be at their best when the queen of flowers knocks at the gates on the 3rd prox., and the combination will be worth a long journey to go and see.

The president of the society, E. B. Lindsell, Esq., writes from Hitchin: "I think my Roses look promising, and that they will be fairly out by July 3. Only genial weather is required to realise an excellent promise."

My other Hitchin correspondent says: "My Roses never looked better. We should have a grand show on the 3rd."

From Hitchin to Colchester, where the leading amateur in this district says: "The garden varieties are well above the average, and I think it will be found that July 3 will be quite late enough for most amateurs. Rain is wanted. Fly and mildew not much in evidence, but I have never seen so many maggots. Teas promise well, the Coquets are really fine and Hybrid Perpetuals and Hybrid Teas promising."

The trade speak even more confidently. One of the leading firms write me: "I think the prospects for the coming Rose season are distinctly bright. Roses will be in good time; plants are strong and healthy, carrying fine buds on nearly every shoot, which has not been the case of late years, and are free from blight and insects. The National should see Roses at their best, especially in the exhibition sorts, but some of the singles and garden varieties will be over."

A leading amateur south of the Thames writes: "Roses are looking better than they have done for some years; the plants are wonderfully clean and healthy, and the buds look very promising. All flowers out have been very highly coloured. The season is early here and there should be some fine flowers by the 3rd. Gardens will be very fine."

From Sutton I hear that "all the growers in this district appear to be thoroughly satisfied with their plants and the promise they hold out of good blooms for the first week in July. A late start was followed by forcing weather, and at the present time the plants are on the forward side. I certainly anticipate a very fine show on the 3rd."

Hertfordshire.—From the headquarters of the Rose in this county I had a long letter; a brief extract says: "We think the present season will prove one of the finest Rose seasons of late years. The early species and garden Roses are finer than usual; colours are particularly intense. The exhibition sorts are opening most promisingly, and only require a good rain to be quite first-rate. Maiden plants are exceptionally vigorous. There are very few blind shoots."

From Berkshire and the Reading district the story is equally satisfactory. Oxford writes: "Hybrid Perpetuals are rather late, but garden Roses are coming into bloom fast and are very satisfactory. Teas, too, will, I think, be just about right for the 3rd, and Roses generally should be at the zenith of their glory."

Further west our leading amateur in this part of the country writes me: "My Roses are looking exceedingly well and should be quite ready for the London show. The Teas are much more forward than at this time last year and all are looking strong and well. I notice particularly how deep the colour is in most flowers seen up to now."

From the Midlands: "Hybrid Perpetuals are late, so are the maidens. Gardens promise unusually well. No May frosts of consequence; Teas are therefore much better than usual. You should have an excellent show on the 3rd, judging from appearances here."

From Peterborough: "The National Rose Society's exhibition on July 3 promises to be the best yet held by the society. Roses in this district are well forward and look more vigorous than for some years."

I will conclude with extracts from a letter from Mr. Edward Mawley, who writes: "My Roses are looking most promising and were never at this season more free from green fly. The temperature the last few weeks has been very changeable, but at no time have the spells of cold weather lasted sufficiently long to arrest the growth of the flower-buds. There is every prospect of our National Show in the Royal Botanic Gardens, on July 3, being an exceptionally fine one."

In conclusion, I may say not since I started making these enquiries some four or five years ago have I received such unanimous replies from my correspondents; there is not a single unfavourable reply from any quarter. May I take this opportunity of thanking all of them for their prompt replies to my enquiries.

Purley.

HERBERT E. MOLYNEUX.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

June 30.—Sonthampton Horticultural Society's Exhibition; Canterbury and Kent Rose Society's Exhibition.

July 3.—National Rose Society's Metropolitan Exhibition, Regent's Park.

**Hemerocallis Dr. Regel.**—This somewhat new variety of Day Lily is a beautiful addition to the early-flowering section of herbaceous plants, and one that should find a place in all good collections. Although it only makes growth of moderate size the flowers are

large, of good substance, and the colour a deep golden yellow. If a small group is planted in the border, a much better method than "dot" plants, a good display is obtained, for though the individual flowers are short-lived, the plants produce flower stems over a considerable period. I find that a partially shaded position is preferable to one in full sun. The *Hemerocallis* are easily propagated by division of the roots in autumn or early spring, and this variety is quite happy in a loamy soil, though after being split up it must be allowed one season to become re-established.—A. E. THATCHER.

**The National Rose Society's metropolitan exhibition.**—This, the leading Rose show of the season, which will be held on Friday, July 3, in the beautiful gardens of the Royal Botanic Society, Regent's Park, promises to be one of the finest the National Rose Society has held for many years. The previous weather conditions which, as a rule, mar most Rose shows are late spring frosts and a long continuance of cold weather in June. This year both of these conditions have been absent, for seldom has there been so few frosts late in the spring, while during the present month the cold periods have never lasted more than a day or two, so that the growth of the plants has at no time received any serious check. Among other interesting new features of this exhibition will be competitive groups of the varieties which obtained the first, second and third places in the recent ballot for the best dwarf and climbing Roses for ordinary garden cultivation.—EDWARD MAWLEY, *Hon. Secretary, National Rose Society.*

**The Neill prize.**—There will be general approbation of the award made of the Neill prize of the Royal Caledonian Horticultural Society which has just been announced by the council. It has been given to Dr. John H. Wilson, the talented lecturer to the University of St. Andrews, and a celebrated botanist who has done much practical work in investigating the diseases of certain plants valuable to horticulturists and in conducting a remarkable series of experimental work in hybridising. Dr. Wilson's early days were spent among horticulturists, and after some time at St. Andrews he was for some years in the Edinburgh Botanic Gardens, and since that time has filled several prominent posts in connexion with botanical and horticultural studies. His work in hybridising has gone on for a number of years and the Royal Horticultural Society awarded him a Banksian medal for this as far back as 1899. The Neill prize consists of the interest of a fund left by the late Dr. Patrick Neill, and is awarded to men distinguished for their work in horticulture and botany. It has been held by some of the most able men of their day in Scotland, but none will rank higher than the present recipient, Dr. J. H. Wilson.

**Gardens in general.**—Seldom of late years have gardens generally looked fresher or more beautiful in the middle of June than now. A really glorious steady downpour of rain lasting for twelve hours during the night of the 16th and morning of the 17th inst. so thoroughly refreshed all vegetation that everything seems green, vigorous and full of beauty. The grass is rich in colour, dense and charming to look upon. Trees are in glorious leafage; shrubs the same; Roses clean and full of large buds. Hardy flowers of every description seem to be specially luxuriant. Sweet Peas have made remarkable growth of late, and already are blooming abundantly. Fruit trees and bushes carrying what promises to be excellent crops are, in spite of complaints as to insect pests, yet looking remarkably well, and Strawberries promise a grand crop of fine fruit. Vegetables of every description promise well, and rarely have looked better. Such is the general condition of gardens in Surrey. I trust the description may fit gardens elsewhere. In spite of some early climatic drawbacks gardening this year promises well.—D.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Sproughton hoe.**—Your correspondent "Suburban" need have no fear in using this most excellent tool; of all the hoes on the market, for Rose culture at any rate, it has no superior. It loosens the top surface expeditiously and thoroughly, and it is, from its very shape, difficult to drive deep enough into the soil to injure the fibrous roots. Its only weakness is a tendency to bend at the neck, which must be rectified at once if the work is to be done properly. If only everyone would banish the hose and use the Sproughton hoe or any other hoe for that matter the gain to their gardens would be tremendous.—H. E. MOLYNEUX.

**Hoes, rakes and Roses.**—Your correspondent "Suburban," in THE GARDEN for the 13th inst., asks about the proper use of the Sproughton hoe. I have used it regularly for many years and never imagined "the long dagger-like blade" could be considered dangerous. It is not intended to stab the ground, but to be pushed or drawn through the surface soil after the manner of using a Dutch hoe, with the advantage over that hoe of being able to draw it towards you as well as push it from you. Having a support only on one side of the blade it can be easily worked all round the bushes. The sharpened point is very useful for breaking up any hard lumps of earth that are brought to the surface. After reading in THE GARDEN about the Gayton rake I sent to Cheltenham for one. I think it will prove a useful tool when the top of the ground is caked after heavy rain. Hitherto I have used for this purpose a home-made tool, which is simply an old worn-down four-pronged digging fork fixed to a long handle, with the prongs bent at a right angle to form a drag rake with teeth about 3½ inches long. It does the work in a capital manner, but I find that the Gayton rake, being so much lighter, is less fatiguing to use and gets over the ground quicker. So far the Rose season here in Worcestershire has begun exceedingly well with the climbing and pillar Roses. Fortune's Yellow, on the south side of a low stone wall, had eighty blooms out at once in the early part of June. L'Idéal, on the south wall of the house, has finer blooms than I have seen for the last three or four years. The more easily grown Roses, like Mme. Alfred Carrière, Bardon Job, Carmine Pillar, Ards Rover and Claire Jacquier are doing as well as possible.—JOHN J. BURTON.

**Destroying queen wasps.**—A determined attempt has been made to destroy queen wasps at Great Limber, in North Lincolnshire, this spring. Two years ago the fruit in Mr. A. G. Soames's garden was nearly all destroyed by wasps, and Mr. A. Dutton (Mr. Soames's head-gardener) received instructions to pay 2d. each for queen wasps during the months of April and May, and the number of queen wasps killed amounted to 1,518 this spring; the number brought in last year amounted to 450. As this reward was only paid for wasps caught within a radius of two miles, the figures given are very striking. Have any of your readers known of queen wasps in such large numbers being caught in one locality before; and can any state if it is probable that they would all be produced in the immediate neighbourhood, or would they be likely to keep coming into the district to supply the deficiency caused by the disappearance of queens in this particular locality?—A. D.

**Wellingtonia struck by lightning.**—A singular incident took place at Whitbourne Hall, Worcester, on the 3rd inst. During the terrific thunderstorm a large Wellingtonia about 70 feet high was struck. The tree is one of a row on the east side of the grounds at the bottom of a slope. On the higher ground there are several large Oaks—one fine tree about 50 feet away from the struck

Wellingtonia; not one of the Oaks are damaged. The lightning appears to have struck the Wellingtonia at the very top and run more than half way around the tree in its descent; the bark is thrown several yards away, and, as far as I can tell, the wood is uninjured. It is the first tree of the kind I have ever known to be struck by lightning.—J. WILLIAMS.

**Wall gardening.**—In passing Crossgar Railway Station, County Down, one can notice in the wall there several bunches of Red Valerian; the roots have got well into the chinks between the stones, and seem to derive sufficient nutriment from the mortar to sustain them. There were also many Snapdragons and Wallflowers growing in the same wall. The Valerian, therefore, should be noted as a wall plant.—WALTER SMYTH, *Holywood, County Down.*

**Dimorphotheca aurantiaca.**—No doubt many very beautiful and simple plants suffer from hard, long and difficult to pronounce names. This plant is one most certainly, and doubtless it is yet little known. I saw a batch of it in pots, raised from seed sown under glass early in the year, flowering abundantly at Long Ditton just recently, and of all single Marguerite bright rich yellow flowers those of this plant, borne on long stems, are the most perfect in form and the most beautiful. It should make a charming pot plant for any purpose, but without doubt will bloom and do well outdoors during the summer. It is an annual from Namaqualand, and its average height in bloom is 12 inches. The plants need ample sunshine. Just what the red or similarly-coloured flowers of *Gerbera Jamesoni* are in form and grace and beauty, so are the rich yellow flowers of this lovely annual. It badly needs some common name.—A. D.

**Lilium giganteum in New Zealand.**—I am sending with this a photograph of a *Lilium giganteum* grown here in Mr. Percy Smith's garden. It was a very beautiful sight, the leaves being almost as much admired as the flowers. I thought you might like to see it, even if it will not reproduce. We very much enjoy THE GARDEN, besides getting many useful hints from it.—ROSE E. PATON, *Momona, New Plymouth, New Zealand.*

**Destroying Daisies.**—Now that the Daisy season is again with us, perhaps you will allow me to let your numerous readers know how to get rid of them, for, although they are very nice in their own place, in lawns and greens they are a terrible nuisance and eyesore. One of the main reasons why Daisies and other weeds are so generally found in lawns is poverty of soil, caused by cutting the grass year after year, without in many cases even the thought of applying nourishment to the distressed lawns. Another prominent reason is that the Daisy multiplies at an enormous rate by self-sown seed and delights in poor land, so that to have our lawns renewed without disturbing the turf, something that will kill the Daisies, enrich the starved land and nourish the grass is the ideal that is wanted. Fortunately, that ideal can now be easily procured. Some years ago I was at my wits' end. The lawns then under my charge were in a fearful state with Daisies and other weeds, especially Daisies, and every year getting worse. We got a trial order of Climax Lawn Sand, and it proved so surprisingly successful that we put on 40cwt. of it that year with the most flattering results. I am using a large quantity of the sand on the lawns here this spring. I consider May the best month to use it, as the grass quickly recovers from the temporary browning at this time. I also believe in putting it on rather heavier than the makers state in their directions, as, although it adds somewhat to the cost, it makes a surer job and saves any trouble for years; in fact, till the soil begins to get poor again. I shall be pleased to answer any enquiries in the matter, provided a stamped addressed envelope is enclosed.—C. T. COLE, *The Gardens, Craighead, Bothwell, N. B.*

**Increasing double Daisies.**—I thank you for the article in THE GARDEN for May 30 on the Daisy subject. It was the very thing I wanted to know, and was thinking of writing to Messrs. Barr (from whom I had my seed of their giant double, which has turned out splendid) to know how best to continue the perfection, by slips from old roots or to sow seed annually? After reading your article, I shall try the offset way of increasing, or rather in my case decreasing, but continuing my stock for next spring. I only had a small packet of seed; they soon came up, and as soon as I could handle them I thinned into wider spaces. Through the summer, and as soon as I could in the autumn, a few at a time, I got them permanently placed in a border all round my beds, consequently there is at least 100 feet of nearly a foot wide of blossom now. They are a sight worth looking at, as is shown by the admiration evinced by passers-by. Personally, I should say the seed sowing is quite as easy, but I shall this year try your method; I shall put the offsets at once into

A GOOD SPECIMEN OF LILIUM GIGANTEUM AS GROWN IN NEW ZEALAND.

permanent quarters. I am also so glad to read about the subject of Polyanthus culture; I want to increase my small stock of the good ones I have. I must tell you I only put one Daisy root at intervals of about 4 inches, and yet there is this splendid show. I think my borders are likely to set a taste for Daisies. If Mr. Barr reads this I am sure he will be pleased.—M. CLOKE.

#### WHAT AN ARTIST NATURE IS!

EVERY uncultivated and wild place, every spot left entirely to her, if only man keeps his rough hands off it, she decks forthwith in the most tasteful way, clothes it with plants, flowers and shrubs, whose unfettered growth, natural grace and charming grouping are evidence that they have grown up not under the disciplinary rod of the great egoist, but that Nature has here had her own free way. Every neglected spot, however small, becomes forthwith beautiful. Hence is derived the principle of English gardens, which

is, to conceal art as much as possible, so that they may look as if Nature had here been allowed her own way. For only so is she perfectly beautiful, *i.e.*, does she most clearly show the objectification of the still unconscious Will-to-live, which here displays itself with the utmost naïveté, because the forms are not determined—as in the animal world—by outside aims, but solely and immediately by soil, climate, and that mysterious third thing which imparts such diverse forms and characters to the many plants that owe their origin to the same soil and the same climate. The great difference between the English (or more properly, Chinese) and the old French gardens—these are now becoming rare, though a few fine examples are still to be found—lies in the last resort in this: that the former are laid out in an objective, the latter in a subjective, spirit. In English gardens the Will of Nature, as it objectifies itself in tree, shrub, hill and stream, is brought to the purest possible expression of these her [Platonic] ideas—that is to say, of her very essence. In French gardens, on the contrary, is reflected only the Will of the owner, which has subjugated Nature and made her wear not her free ideas, but badges of slavery, forms forced upon her by the owner's whims—clipped hedges, topiary work, straight avenues, pergolas and so on.—SCHOPENHAUER ("World as Will and Presentment," Chapter XXXIII.).

#### WATERING.

WHAT TO DO AND WHAT NOT TO DO.

IT goes without saying that on most soils some watering must be done in any ordinary summer, though its necessity may be very much lessened by a proper system of deep cultivation. In one dry summer I had a bed of herbaceous Phloxes, moisture-loving plants, which stood the whole of the drought without flagging, though they were never watered, simply because the bed had been dug right out the previous autumn to a depth of 2 feet, thus giving them an extensive root run. In another part of the garden of similar aspect and with similar natural conditions, except that the ground had not been so treated, the leaves of some clumps of Phloxes hung limply down the stem for a good part of July and August. This practice will obviate the necessity of watering most herbaceous plants, but of course it is not always practicable.

Annuals and bedding plants generally, however, are different, and, whatever method of cultivation is practised, they will suffer from a severe drought, though good cultivation is helpful. In addition to deep digging, a gentle hoeing or loosening of the surface checks the rise of moisture from below and consequent evaporation. This is just the reverse of what happens when surface watering is practised, when, all the water being in the top 2 inches or 3 inches of soil, which is of close nature, it is rapidly evaporated by the sun's heat. The obvious inference from this is that the best thing to do is to water seldom, and only when absolutely necessary, and then do it in such a way that the soil is saturated to a depth of at least a foot—deeper if possible.

This can be done, as regards beds and borders, in two ways. The soil can be very lightly loosened at the surface, and the water put on with a fine rose at intervals of half an hour during a long summer evening, the intervals giving the water time to percolate down, and lessening the liability of the soil to run together. The alternative is to cover the soil with a layer of short manure and half turn it in, when, the soil being in such a rough state and kept open by little pieces of very porous stuff, it will absorb any amount of water, which may be poured on with as coarse a rose as you possess, the manure feeding the plants at the same time. This is a more satisfactory method than the former, and scarcely takes up more time, while the ground can be watered so thoroughly that it will need no more

water for two or three weeks, perhaps not again during the summer if an ordinary amount of rain falls. For Marrow beds, outdoor Cucumber beds, clumps of Sweet Peas, Dahlias and other

#### MOISTURE-LOVING PLANTS.

a different course can be adopted. If a flower pot is sunk in the ground up to the rim with a few pieces of broken pot underneath, water can be poured into it even with a pail and it will run into the ground, and there is the satisfaction of knowing that nearly all the water will be absorbed by the roots, very little of it being evaporated from the surface of the soil. This is a specially advantageous practice where the ground has been raised to make a bed, as, for instance, a Marrow bed. For some special things which it is desired to water occasionally, such as Lilies, a mulching round the stems with light manure partly turned into the surface soil is the best practice, as it lets the water run quickly into the soil, and has not the unsightliness of a flower-pot let into the ground, which, however, does not show among the Marrows or underneath spreading things like Dahlias.

Where rain water is available it should by all means be used, hard water, especially very hard water, not only not helping to dissolve the food material of the soil, but caking the ground together to a worse extent than rain water, and shutting out the air, the carbonate or sulphate of lime in the water solidifying between the particles and cementing them together, thus forming a hard crust, in pretty much the same way as the inside of a kettle becomes encrusted by the boiling of hard water, the pure water going off as steam and the solid matter in the water remaining.

A. P.

## THE FRUIT GARDEN.

### THE SUMMER STOPPING OF THE SHOOTS OF VINES.

**F**AILURE in the growth of good Grapes by amateurs is often caused by the want of knowledge of how and when to stop (meaning, to cut off) the young growth on the green shoots of Vines in early summer when growth is so active. So rapid is the growth of the Vine at this time of the year that, if the work of stopping is neglected, the roof of the vinery soon becomes one tangle of useless and wasteful shoots, shutting out light and air so necessary to the well-being of the Vine and to the success of the crop of Grapes, and at the expense of uselessly wasting the energies of the Vine. This subject of stopping the Vine is so simple and entails so little labour that, once well understood, a child could do the work without trouble, so that there is no sort of excuse for its being neglected. The new shoots which emerge in spring from the shoots of last year's growth, which were pruned back in winter, should be 15 inches apart (on both sides of the Vine) on Vines of moderate growth such as Black Hamburgh, Muscat of Alexandria, Foster's Seedling and Buckland Sweetwater, and 18 inches on the stronger-growing sorts such as Gros Colman, Gros Maroc and Alicante.

The bunch of Grapes on these shoots generally appears after the third leaf of the shoot has been developed. As soon as three other small leaves have been formed above the bunch is the time to stop the shoot by pinching out the point or heart

with the finger and thumb. This will leave six primary leaves on the shoot, which must be guarded and kept healthy until the crop is ripened and gathered, as on the health and vigour of these leaves the success of the crop greatly depends. The result of stopping the shoots will be that several other small shoots will emerge from the axils of the leaves below. These in their turn, as soon as they have formed two leaves, must be stopped in the same way, and so must also all the young shoots which will emerge from the stopping of these sub-shoots, which are termed laterals. By the time this third stopping will have taken place, growth of foliage will be on the wane and the Grapes colouring, and then this lateral growth may be permitted more freedom, with advantage, stopping them at the sixth leaf instead of the second. This summer stopping of the shoots is of the greatest importance, and amateurs

frequently err in either not doing the work properly or leaving the growths alone. I hope, however, the few notes I have made will be helpful to readers of *THE GARDEN*. Vine-growing is very interesting, and, when the simple rules of culture are observed, it is not difficult. Some varieties, of course, are more easily managed than others. OWEN THOMAS.

### THE CULTIVATION OF THE STRAWBERRY.

(Continued from page 299.)

#### FORCED STRAWBERRIES

REQUIRE careful management, and the earliest runners that can be procured should be selected for this purpose. Many growers now layer the young plants at once into their fruiting pots, and experience teaches that this plan answers admirably. No intermediate shift is needed, and less labour is required in their preparation. Suitable sized pots are those measuring 7 inches in diameter; these must be clean and well drained. Place a sprinkling of soot over the drainage and fill the pots to within an inch of their tops with the best loam procurable. A 7-inch potful of bone-meal may be added to each barrowload of the loam and thoroughly mixed. The soil must be made very firm in the pots. When layering endeavour to leave the space between every alternate row of plants quite clear; by attention to this plenty of room is afforded for the convenience of watering and cleaning, and the beds will also present a better appearance when the work is completed. Never allow the plants to suffer through becoming dry at the roots.

When the young layers become established in the pots they may be detached from the old plants and the pots arranged on a bed of ashes in an open and sunny position, where they may remain until the end of October. The best place for the plants during winter is in cold frames, where the pots may be plunged in ashes, which will prevent them becoming injured during severe frost. Air must be admitted whenever the weather permits. Strawberries must be forced slowly; to place the plants direct from the frames into a high temperature is to court disaster. A temperature of 45° to 50° is suitable for a start, gradually increasing this to 60° as the flowers open. As the plants are removed from the cold frame a top-dressing of loam with a teaspoonful of some approved fertiliser (Clay's and Willis's Universal have proved excellent) should be applied to each pot. Six or seven berries are enough to allow on a plant, and when these have formed the remaining flowers should be removed. At this stage a temperature of 65° by night, rising to 70° during the day, should be maintained. Weak manure water at this time should be applied to the plants about three times during the week.

As the berries swell and commence to colour the temperature during the day may, with the aid of sunshine, rise to 80°, but this should not be exceeded in any case. The flavour of the berries is improved if the plants are removed into a slightly lower temperature just before they are thoroughly ripe. The plants must always be kept close to the glass, and will require abundance of water; if the leaves are allowed to flag they seldom recover. It is a good plan to place a layer of half-rotten manure on the shelves and stand the plants on this as an aid in keeping the roots moist, but even then frequent waterings are necessary.

Morden Gardens, Watford.

C. RUSE.

### CATTLEYA MENDELII QUEEN ALEXANDRA.

THIS Orchid is a very chaste and beautiful form of the old *C. Mendelii*. In addition to its excellent size and form the labellum is pure white ornamented with a central marking of soft rosy purple. It was exhibited by Messrs. William Bull and Sons of Chelsea at the recent Temple Show, when it attracted much attention.

CATTLEYA MENDELII QUEEN ALEXANDRA. (Much reduced.)

## THE ROSE GARDEN.

### PROPAGATING ROSES BY SOFT-WOODED CUTTINGS.

**N**OW that the propagating cases are comparatively empty many who have such at their disposal and who also have Roses that they wish to increase the stock of may, with interest and profit, devote some time to the propagation of these subjects by means of cuttings formed from half-ripened wood. Such cuttings of many of the species and most of the rambler varieties root readily, and doubtless Teas, Hybrid Teas and Hybrid Perpetuals might also be propagated in this manner.

The operation is a simple one. Secure some 5-inch or 7-inch pots, place crocks in them to one-third of their height and then fill in to within half an inch of the rim with rather finely-sifted soil that contains a good percentage of coarse but clean sand. This soil must be made moderately firm, and before inserting the cuttings place a thin layer of sand on the surface. It is in the selection and preparation of the cuttings that the greatest amount of care must be exercised. Shoots 6 inches to 9 inches long that do not terminate in a flower-bud are best, and these should be detached with the thinnest possible heel of the older wood adhering. Smooth over the base and remove a few of the lower leaves with a sharp, clean knife, and also remove the very soft tip so that when finished the cuttings will be from 4 inches to 6 inches in length, these being the most convenient sizes. Care must be taken not to let these cuttings flag in the least before inserting them in the pots, rapidly in gathering, making and planting them being an important point.

A 5-inch pot will take comfortably five cuttings, and a 7-inch will accommodate two more, the best way being to place them near the edge. A point where many fail is in planting the cuttings too deeply; those 6 inches long may go 1½ inches deep and the longer ones 2 inches. It is absolutely essential, as in the case of all cuttings, to make the soil quite firm at the bases of the shoots, otherwise roots will certainly not be omitted.

After inserting the cuttings give them a gentle watering in through a rosed can and then plunge the pots to their rims in Cocoanut fibre in the propagating cases and shut them close. The temperature, if the weather is warm, may well be a natural one; or if a slight bottom-heat can be afforded rooting will be considerably facilitated, but excessive heat must at all times be avoided. Each morning the glass of the lights should be wiped dry and a chink of air left on for about half-an-hour so as to dissipate any superfluous atmospheric moisture. Any dead or decaying leaves must be promptly removed. If the soil shows signs of becoming dry water is necessary; but care must be exercised in applying it, as wet soil is not desirable. It is necessary to keep the fibre moist. Rooting will be effected in from two to three weeks, and as soon as growth is noticed as being active the pots may be removed from the cases and stood on a shelf near the glass, taking care to avoid cold draughts or mildew will sure to appear. After-treatment will consist in the general routine of watering and gradually inuring the young plants to a cooler and drier atmosphere, so that they are quite hardened off for planting out in nursery beds in the autumn.

By adopting the above system of propagation nearly a year is saved, as the plants by this time next year will be nearly as forward as are those from cuttings inserted last autumn. Even those who do not possess the orthodox propagating cases might try this system, using deep boxes partly filled with fibre for plunging the pots in and covering them with sheets of glass. F. W. H.

### ROSA MOYESHII.

THIS is a very delightful new single Rose from China, giving one the impression of an exceedingly thorny, vigorous-growing species. The colour is very exceptional and of a ruby red tone, much more intense in the opening flowers. The blossoms are about 2 inches across and the petals of very firm texture. The leaves are also of firm

The plant is in a fairly sheltered corner that gets the benefit of all the sun that is to be had up to midday—and what a dainty little flower it is, not only the flower, but the whole plant is unique; the flower, of a pure satiny white, is interesting because it has only four petals arranged in the form of a Maltese cross, the plant is unusual because, first of all, the enormous thorns on the young wood are blood-red in colour; and,

A NEW ROSE SPECIES: ROSA MOYESHII. (Natural size.)

texture, long, usually eleven lobed, the lobes oblong, ovate, dark green and thorny on the under sides. Should the plant prove to be a free bloomer it will create a sensation in the garden, and in any case it will be of inestimable value to the hybridist for some time to come. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea, before the Royal Horticultural Society on the 9th inst., when it received an award of merit.

### EARLY-FLOWERING ROSES.

YOUR correspondent "M. P. H." on page 286 thinks a few notes on the above might interest some of your readers, and I have much pleasure in sending you the following. At the same time, situation of the Rose garden, as well as of the particular plant in it, may easily make all the difference between an early and a normal blooming period. For early-flowering Roses we have to depend largely on the species and one or two hybrids; by early flowering I mean May. The season this year, at any rate in the early part of May, was late (practically ten days, or a fortnight possibly); but, nevertheless, my first Rose flowered earlier than usual—two days earlier than last year, and, curiously enough, on a plant that, although early, is generally a good way down the list that I generally keep. *Rosa sericea pterocantha* occupies the place of honour this year, and its first flower opened on May 9.

secondly, because the leaves are produced in such a way as to have a delicate, almost fan-like, appearance. Altogether the Rose is entitled to a high place among the interesting Roses. Only two flowers made their appearance on the date named, and the month was drawing to its close before the plant was in full flower, but they were sufficient. *Alpina*, which for years has always been the first Rose to flower, waited until the 12th before it opened its first bloom—one day later than in 1907. It is quite regular in the habit, and has never failed to produce flowers with me before the end of the second week in May. The plant, however, refuses to grow very much, and is not much bigger than when planted some six or seven years ago. Naturally smooth wooded, under cultivation this Rose occasionally produces thorns. Why, I wonder? The 15th saw two more species join in the race—*Altaica*, sometimes called *Spinossissima maxima*, surely one of the most beautiful of these early-flowering Roses, and a single yellow form of one of the Scotch Roses. By the 20th the bushes of *Altaica* were in full flower and covered with hundreds of beautiful blossoms; it makes a fine hedge, and, unlike most of the early Roses, gives a few flowers again in the autumn. *Nuttalliana*, the first pink Rose came out on the 18th; it is very beautiful, its large single flowers freely produced of a most pleasing shade of soft pink with golden stamens,

making a fine contrast. Virginiana variety Moodsii, Xanthina, Harrisoni, Copper Briar, and several varieties (white, pink and yellow) of the Scotch Roses were all in flower by the 24th. On the 25th Conrad F. Meyer opened its first flower, and what a glorious Rose it is. I cut over fifty flowers of it on May 30, and they literally perfumed the house. The great branches seemed overweighted with the enormous flowers, and had to be staked well to prevent them doing themselves irretrievable damage, the thorns literally tearing the foliage and flowers to pieces where this is not done. Some dozen varieties of Rugosa were in full flower by the end of the month, notably Blanc Double de Coubert, Mercedes delicata, Chedane Guinoisseaux, Rose Apples, &c. No Hybrid Perpetuals favoured me in May; but the following Hybrid Teas were all in flower before June 1: Gustave Regia, Antoine Rivoire, Grace Darling, Viscountess Folkestone, Amateur Teyssier, Lady Ashtown, Betty, Lady Waterlow and Climbing Mrs. W. J. Grant. Sinica Anemone was not out on June 1, and since then my garden is getting quite gay. Jersey Beauty and Gardenia among the wichuraianas; Leonie and Eugénie Lamesch, Petit Constant and Kleiner Alfred are in full flower of the Pompons. Teas are quite plentiful and too numerous to mention. Rosa canina and arvenais are just coming out in the hedges, and are a little later than last year; all of which forces one to the conclusion that my garden is earlier than most. As to the prospects of the coming Rose season, I hope to write you next week; at the moment they are excellent.

H. E. MOLYNEUX.

## THE FLOWER GARDEN.

### WATER LILIES AND THEIR CULTURE.

I AM well within the mark in ascribing to the Water Lily a charm and grace such as few other plants dare hope to equal, much less excel. Being aquatics the cultivation of the many varieties necessitates the existence of water of suitable depth, and the greatest measure of success follows when the plants can be planted out and permanently established, as neither the foliage nor the flowers are so freely produced when the plants are in confined areas. Such marvellous lives have even the

ONE OF THE MOST BEAUTIFUL OF NYMPHÆAS—N. CAROLINIANA PERFECTA.

choicest hybrid Nymphæas that small basins or submerged tubs will sustain the plants in vigorous health for several years with ample remuneration in flowers, but whenever a paucity of bloom becomes evident no time should be lost in renewing the compost in which they are planted. This may consist of two parts old maiden loam to one part of thoroughly decayed manure, the whole to be carefully mixed before using.

May is the best month for planting Nymphæas, but as most dealers in water plants hold their stock of these in pots amateurs may safely plant up to the end of June; at the same time there is some advantage in planting at the latter date, as then one may see the earliest flowers of the season and choose such colours as appeal to the individual taste, for though no Water Lily may be said to produce flowers of a doubtful colour yet their variety is exceedingly great, and the combinations which occur in some of the flowers really require seeing, as words cannot adequately do justice to their rare beauty.

For practical purposes Nymphæas are grouped according to the depth of water in which they are found to succeed in best. Pygmea and Helvola are miniatures for planting in shallow water of a depth of 12 inches or so; all the others

succeed in water 2 feet to 4 feet deep, though only the most vigorous need be given the latter depth. One of the salient points in successful Lily culture is the temperature of the water, which in the open depends upon solar heat for its warmth, and as this never becomes excessive in our climate every ray should be husbanded and the water inlet to the pond be governed, where possible, by a niggard hand.

Water Lilies revel in abundant sunshine, so that little or no good can be expected from them when planted in positions overshadowed by trees or buildings; under such conditions leaf growth is excessive and the flowers are few and imperfectly coloured.

THOMAS SMITH.

Walmgate Gardens, Louth, Lincs.

### PERMANENT EDGING PLANTS.

WE possess a number of plants that are eminently adapted to form permanent edges to large beds and shrubberies. In large gardens and parks, whether private or public, enormous quantities of edging plants are required annually, and their production entails no inconsiderable amount of time and labour. I do not wish to infer that the majority of the beds should be planted with a permanent edging; but one-third may be so treated, which will both lessen the work and add variety. I have found that two rows of *Megasea cordifolia* planted 9 inches apart each way speedily form a splendid belt, handsome at all times and strikingly beautiful when in flower. *Funkia subcordata grandiflora* is a superb subject as an edging to a large foliage or sub-tropical bed, and if Winter Aconites are planted on either side of them the edging at least is permanently furnished.

The Golden Ivy is not appreciated as it should be, and a 1 foot wide belt kept strictly in position and clipped each spring is nearly as effective as the golden-leaved Creeping Jenny (*Lysimachia nummularia aurea*). In planting the last named the ground should be raised 2 inches from 1 foot to the outer edge and sloping towards the edge. *Antennaria tomentosa* should be similarly treated. Bare patches will occur during winter, especially if we experience excessive rain and fogs; but this is easily remedied by the removal of a few tufts from the well-furnished portion or with plants from the reserve garden. The variegated form makes a very handsome edging, and should be pegged in position. The golden-foliaged Stonecrop is very fine; small tufts or even single growths planted 2 inches apart over a 1 foot wide surface of well-manured soil will develop into a dense carpet the same season, and now is the time to carry out the work. *Heuchera sanguinea* makes a bold display as seen in a 15-inch belt, and it is

AN EFFECTIVE GROUPING OF WATER LILIES, PORTUGAL BROOM AND ARUNDO DONAX.

hardly necessary to dwell upon the extreme beauty of the plant.

If less desirable, the old and persistent *Armeria maritima* is not to be despised, and small pieces afford a dense edging with astonishing rapidity. It is superfluous to speak of *Cerastium tomentosum*, and failure to clip it at the proper time will account for the straggling masses often seen in amateurs' gardens. Drastic measures must be employed, and as soon as the flowers fade it should be cut off to the ground level and subsequently clipped to maintain a fairly compact habit or appearance.

Many of the *Saxifragas* lend themselves to this work and are effective when planted on a raised and sloping surface, and, perhaps, *S. hypnoides* is as good as any. It is literally smothered with dainty white flowers in summer, while it presents a very cheerful and fresh appearance during the dull season. *Alyssum saxatile compactum* is useful as an edging to *Rhododendron* and shrub beds; an important point is to remove the flower-spikes as soon as they fade, as the ripening of the seeds induces a weedy and undesirable habit. The improved forms of *Pinks* yield a wonderful harvest of inflorescence when employed in this way and fully exposed to light and sun, and, provided the ground in close proximity to them is richly manured each season, many years will elapse ere they exhibit signs of deterioration. *Iberis sempervirens* forms a fine white mass, and the best way to keep it in order is to clip back sharp after flowering and encourage new growth by an application of artificial manure.

WALTER H. AGGETT.

### IRIS CARTHUSIANA.

THIS is a beautiful cross-bred variety, said to have been raised from a cross between an unnamed species collected near Mardin in Syria and the handsome Flag Iris *I. pallida dalmatica*, the latter being the pollen parent. The subject of our illustration most closely resembles the pollen parent, except that the blossoms are of a more uniform character, while the rich golden colour of the beard and the reticulations near the base of the falls also render it distinct. The prevailing colour is bluish mauve, and the variety possesses all the good attributes of the *I. pallida* set, the fine stature and generally bold appearance. In this way it is a useful addition to a family already endowed with many excellent garden plants. It was exhibited by Mr. J. W. Marshall, Charter House, Godalming, before the Royal Horticultural Society on the 9th inst., when it received an award of merit.

### CORNISH DAFFODILS.

**D**URING a spring visit to Cornwall visits were made to some of the leading Daffodil gardens in the county. At Ludgvan Rectory N. cyclamineus in the rock garden was a beautiful sight. Large clumps were in full bloom, a sheet of bright yellow. Here it seeds itself freely, and numbers of self-sown seedlings are springing up around the parent plants. An early white trumpet Daffodil, somewhat after the style of *Mme. de Graaff*, but far more precocious, was noticed. In Mr. C. Dawson's garden at Rosemorran King Alfred was in fine bloom, and *Mme. de Graaff*, of which Mr. Dawson holds by far the largest stock in England, was looking very healthy.

Though during the past season there may not have been any very marked advance in new seedling Daffodils, there have been some very striking flowers exhibited. Besides the beautiful collection of Mr. J. C. Williams at Truro, some new and distinct flowers were shown by Mr. P. D. Williams of Lanarth. Among these were, notably, a lovely *Poetaz*, with pure white petals and a large scarlet eye. The petals were flat and evenly overlapping, and the eye was of almost pure scarlet, brighter in tint than any other known variety. This flower was named *Sparkling Beauty*. *Inga*, also raised by Mr. P. D.

Williams, with white petals evenly overlapping and an eye of pure orange buff. *Jasper* was a flower of similar shape, but with yellow petals and a very deep crimson eye. *Marshall* is a flower that should in time take the place of *Lucifer*, with a cup of intensely deep orange scarlet. The stock is, however, very small, and I understand that Mr. P. D. Williams does not intend to part with it. No doubt this will be an extremely valuable flower for the purpose of the hybridiser. *Aphrodite*, which created such a sensation at Birmingham last year, was not ready, nor was it in time for the Birmingham show this year, but, notwithstanding this, Mr. Williams was able to annex the Bourne Cup. *Bernardino*, an enormous *Lulworth* seedling raised by Mr. Worsley, was a very striking flower on Mr. C. Dawson's stand. This flower was also exhibited by Mr. Dawson in fine form in London at the Royal Horticultural Society's Show at Vincent Square on April 14, as was also *Victory*, which is probably the largest *incomparabilis* ever shown. *Pearl Diver*, also exhibited by Mr. Dawson in London, was pronounced to be the whitest flower yet produced. It was raised by Mr. Dawson. Another flower of the same raiser's is *Redcap*. This puts *Will Scarlet* altogether in the shade and is an infinitely better-shaped bloom. This appears to be a flower that hybridists would do well to secure.

The beautiful *Buttercup*, figured in THE GARDEN on page 229, was shown in London by Mr. Dawson, and the same blooms were also exhibited at Birmingham and yet again at the Royal Horticultural Society in London on April 28, this speaking volumes for the stamina of the flower. This variety was originally raised by Mr. Engleheart, but I understand that the entire stock has been acquired by Mr. Dawson, and the manner in which this variety is grown at Rosemorran is a proof of the robustness of the plant. Space does not permit of a description of the many fine varieties growing at Rosemorran, but among the best may be mentioned such as *Cossack*, *Home-spun*, *Imari*, *Incognita*, *Moonbeam*, *Pilgrim* and *Tennyson*, with fine beds of *Weardale Perfection* and *Mme. de Graaff*, before alluded to. Many beds of three, four and five year old seedlings must prove of intense interest in the future with their infinite possibilities of success and failure, for the anticipation of their flowering has to recognise the possibility of disappointment as well as of good fortune, and probably but few out of the many will attain a standard of the highest excellence. Mr. Crosfield at Birmingham showed many beautiful seedlings, and doubtless this raiser has as many surprises in store for the lover of *Narcissi* as anyone. The season has been unfavourable to many and Mr. Engleheart has been severely handicapped, having been quite unable to stage exhibits of his usual phenomenal quality, and the same remark applies to Messrs. Pearson and Sons.

South Devon.

S. W. FITZHERBERT.

**Clipping evergreens.**—Where evergreens, such as *Box*, *Yew* and the like are used as hedges, or as solitary specimens clipped into shape, this will be a good time to commence the summer clipping. *Box* may safely be clipped fairly hard now, as the new growth will have time to ripen before winter, but any subsequent operations should be confined to keeping stronger growths within bounds, for in cold districts new growth made late in the year often suffers badly in winter.

A NEW HYBRID IRIS: *I. CARTHUSIANA*.  
(Two-thirds natural size.)

Williams, was a most refined flower that justly received first prize as the best of the *Parvi-Coronati* in the show. It is a most perfectly

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE WINDOW GARDEN.**—Those who have not yet replenished their window-boxes with summer-flowering plants should see to this without further delay. Our window-boxes were completed in this respect two or three weeks since. Among the many plants that succeed in such are Pelargoniums, Petunias, Heliotropes, Marguerites, Fuchsias, Lobelias, Tropæolums, Calceolarias and Ivy-leaved Pelargoniums, the latter so useful for overhanging the sides of the boxes. Our boxes of Pansies have always been admired. We plant the last-mentioned in soil of a rich and lasting character and persistently remove the spent blossoms; by these means the display is maintained over quite a long period. Window-boxes in sunny aspects should be watered in the cool of the evening. Watering in such positions in the morning is of little value. Well-established plants should be occasionally watered with liquid manure. I find this acts as a splendid stimulus to the plants.

1.—OLD STRAWBERRY PLANT, SHOWING RUNNERS SUITABLE FOR LAYERING.

Most plants in pots will derive considerable benefit from an application of manure water twice a week at this season.

**The Flower Garden.**—This is, perhaps, the busiest period of the whole year in the flower garden. Weeds are a constant source of trouble; on no account must they be allowed to develop unchecked. I make a rule to go through the border at least once a week, doing the weeding thoroughly and going through the border systematically. Most plants need to be staked and tied, otherwise the growths may fall over and assume anything but a pleasing appearance. When staking the plants see that the stakes are of a suitable length for the respective subjects, that they may not become an eyesore. Also endeavour to preserve the natural beauty of the plants. This may be done by avoiding overtight tying, and in some instances, such as in the case of the Michaelmas Daisies, thinning out the weak and attenuated growths. I am continuing to thin out the more crowded annuals; it is a great mistake to allow the plants to remain in the border so close to one another. For a display next spring I am just now pricking off in prepared beds seedling Wallflowers; it is astonishing how much the young plants progress when treated in this fashion.

**Garden Frames.**—As opportunities offer I have the necessary painting and reglazing done, so that

the frames are in a better state of preservation for the winter season. My Carnations that are growing in rather deep frames in pots have been carefully staked and tied. Their appearance has been improved of late by frequent syringing with clear water; I much prefer rain water, and use this daily in this way when the weather is warm. I am expecting a beautiful display in late July and August. Cucumbers in frames must have constant attention. Growth is very rapid just now owing to the warmer weather. Plants bearing fruit quite freely should be assisted with frequent applications of manure water.

**The Vegetable Garden.**—I made my last sowing of Short Horn Carrots and Parsley for winter supplies a short time since, but it is not too late to make a sowing even at this period. I am busy putting out all kinds of winter greens, giving the plants plenty of room and watering them in with copious applications of water. Celery and Leeks should be planted; the sooner they are in their permanent quarters the better. Tomatoes, both outdoors and in the greenhouse, are receiving special attention just now. The plants are progressing rapidly; I am therefore removing all side shoots, keeping the plants to single stems. So many beginners keep the soil too moist, which promotes unnecessary and undesirable growth. Keep the soil on the dry side and apply manure water when the fruits have set, which will assist the fruits to swell.

**The Fruit Garden.**—Strawberries should be layered at once. I prefer to layer my plants in pots, as they are so much better handled when severed from the old plants after rooting. Cherries should be netted where the fruits are beginning to ripen, otherwise the birds will soon spoil the crop. Remove suckers of Raspberries, except those that are to be retained for next year's canes. Plums that have set their fruits freely need looking after. Fruits that are beginning to swell where they are crowded should be thinned out to some extent, in this way ensuring the development of a goodly number of fruits of better quality.

D. B. C.

### LAYERING STRAWBERRY PLANTS.

STRAWBERRIES are increased by runners that are rooted in June and July, and the earlier this work is done the better, as by these means strong plants are developed which should produce fruits in abundance next summer. There are various methods by which the plants may be layered, and that the beginner may understand what a runner is and when it is time to deal with them, Fig. 1 gives a very good indication of the character of an old Strawberry plant during June. Thereon will be noticed numerous runners, each of which has a small Strawberry plant actually developing at its end, and which may be rooted with comparative ease.

The young plants may be layered either in 3-inch pots or in the open ground, or on pieces of turfy loam 3 inches or 4 inches square, and this kept moist throughout the rooting period. Any of these means may be used by those who desire to increase their stocks; but the more popular method is that of layering these plants in pots, as they may be detached without injury from the main plant when properly rooted.

Fig. 2 shows the same plant as represented in Fig. 1, with two or three pots brought into use, on which the runners are layered. This is very simply done. All that is necessary is to place the end of the runner on soil that has been properly prepared, and maintain this in position by placing on the runner itself a small stone,

which will not only assist to keep the soil moist, but will also keep the plant sufficiently rigid. The same rule may be observed with pieces of turf cut in round or square fashion, and on the same old plant there will be noticed two illustrations of runners pegged down to these. When the layers are well rooted they should be severed from the old plants. It is important, however, to remember that the soil must be maintained in a moist condition, otherwise the progress of the plant will be retarded and their future well-being to some extent jeopardised. Fig. 3 shows a plant that has been severed from the old plant after becoming well rooted. It will be observed in this case that small runners are already developing in the crown of the plant. These should on no account be allowed to remain, but must be pinched off in order that the energies of the roots may be concentrated on the development of crowns of promising nature.

The plant in Fig. 4 is one of the runners that were rooted from the plant in Fig. 1. Note the healthy character of the plant and its strong-

2.—THE SAME PLANT WITH RUNNERS LAYERED IN POTS AND ON PIECES OF TURF.

rooting character. This is in an ideal condition for planting outdoors or for being potted up into pots in which they are to flower and fruit. In this case, too, the runners are observable evolving from the crown. These should be pinched back to within 2 inches of the crown of the plant, in order that the plants with crowns of ideal character may be developed.

### QUARTERS FOR STRAWBERRY PLANTS.

Many people labour under the mistake that the Strawberry is a shallow-rooting subject, but we are quite convinced that this is an erroneous impression. They delight in soil that has been deeply dug and well manured, and we have never had any hesitation whatever in trenching the ground fully 2 feet deep, breaking up the soil thoroughly and incorporating with it a very heavy dressing of partially-decayed manure. This is left in the rough for some little time previous to planting, and subsequently the surface soil is broken up, levelled and made ready for planting the recently-rooted plants.

Fig. 5 shows how the planting should be done, August or September being the best months. Plant in rows 2½ feet asunder, and the plants 18 inches apart in the rows. Take out a good hole, so that each plant may be properly embedded and so that the soil is quite level with the crown of the plant. Press the soil well round the ball of soil of the embedded plant. Arrange

3.—STRAWBERRY RUNNER ROOTED IN A 3-INCH POT AND RECENTLY SEVERED FROM THE OLD PLANT. THE SMALL "WIRE" ON THE RIGHT SHOULD BE REMOVED.

the plants in the rows alternately. Fig. 5 gives a clear indication as to how this should be done. By planting alternately in the rows the plants are able to take full advantage of the space allotted to them, and are less crowded in consequence. Subsequent to planting out in the Strawberry bed give the plants a thoroughly good watering, so that the ball of soil and roots is quite moist.

#### ABOUT DAHLIAS.

A DAHLIA plant will grow in comparatively poor soil and bear flowers freely, but it will not withstand a prolonged period of drought without showing signs of distress, notwithstanding the fact that the tubers are fleshy and full of moisture. Thousands of amateurs grow Dahlias and carefully preserve the tubers during the winter time. Some persons like the show Dahlia best, others prefer the Cactus and single-flowered, and Pompon types find favour with some. Every year there are fresh recruits being added to the ranks of growers, and where exhibiting is the chief object in view the inexperienced person is often at a loss to determine the features which mark the different types and make mistakes in the selection of the blooms. The following notes will prove useful to intending exhibitors:

**Show Dahlia.**—This is a large double self-coloured flower, or the base of the florets may be of a light colour edged with a darker shade. In the latter case the flower is called edged.

**Fancy Dahlia.**—This is similar as regards size and form, but has two or more colours or florets tipped with a lighter shade.

**Bedder.**—This is a show type, dwarf, with erect flowers.

**Pompon.**—The Pompon resembles the show and fancy type in shape, but has much smaller flowers and is very free.

**Cactus.**—A true Cactus Dahlia should have long, narrow, pointed spiral florets which radiate from the centre.

**Decorative.**—These are distinguished from the Cactus by being flatter in both the florets and the flower.

**Single.**—The single Dahlia consists of but one row of flat florets evenly arranged.

#### HINTS ON GROWING AND EXHIBITING GARDEN PRODUCE.

(Continued from page 293.)

In continuing my remarks on this subject, I will deal with those kinds of flowers, fruits and vegetables that require special treatment during their early stages of growth in order to have the very best produce when the crops are matured. Of course, all kinds require good treatment, but the following will be worthless as regards showing—if they are neglected in the least now.

**Pansies.**—It is always a pleasant sight to see our Pansies in full bloom; but if large flowers

are required, the earliest buds must be removed so that the plants will grow strongly and not become exhausted through bearing many blooms. Fanny plants will continue to flower throughout the season if all faded blooms are regularly picked off; but to obtain large flowers of great substance it is a wise plan to remove the earliest buds, and, later on, about one month before the cut blooms are required, to also disbud, that is, leave one bloom on each strong shoot and remove the others. Before you allow the flower-buds to develop put on a rich top-dressing of loam and rotted manure and loz. of superphosphate to each square yard of ground. Furthermore, keep the soil in a moist condition. If allowed to become very dry the blooms will be small.

**Window Plants.**—A nice, well-balanced specimen is more likely to secure a prize than a tall, ungainly plant. Foliage plants, of course, must possess fine leaves of good substance, so, also, should the leaves of flowering plants be large and healthy. But in growing the two different kinds the same treatment does not exactly answer our purpose. The foliage plant should not be permitted to get too much pot-bound, else there will be more difficulty experienced in keeping the leaves healthy than while the roots are still feeding on new soil; but manure water and artificials should not be given until the pots are well filled with roots. A flowering plant, such as a Zonal Pelargonium or a Fuchsia, should be

4.—YOUNG PLANT ROOTED IN A PIECE OF TURF LOAM READY FOR PLANTING OR POTTING UP.

retained in as small a pot as possible consistent with getting a fully-grown plant by at least one month from the date of the show. If such a plant is somewhat pot-bound at that period, flowers will be produced in profusion, and feeding may be done with grand results. A teaspoonful of superphosphate will be sufficient for three plants in 6-inch pots, and the same quantity to the same number of pots of nitrate of soda will prove beneficial in the case of foliage plants. A dose once every ten days will be ample.

(To be continued.)

#### GREENHOUSE MANAGEMENT IN SUMMER TIME.

AMATEURS often experience some difficulty in keeping their plants throughout the winter on account of excessive moisture in the greenhouse. In summer time, however, the interior of the house is kept too dry for the plants to do well in it. Furthermore, they are subjected to extreme heat and sudden chills, and the

result is scorched foliage and rapid spread of insect pests.

**Ventilation.**—It is not possible to admit air in the morning too early. By slightly opening the top ventilators very early—before the sun shines on the house if possible—and gradually increasing such ventilation, then also opening the front ventilators as the sun gains power, the temperature will not become almost unbearable. When it does, be quite sure that the conditions are unsuitable to plant life. The safety valve in ventilating a greenhouse in summer time is the leaving of the top ventilator open slightly all night. It is better to err in keeping the house a little too cool than too hot at this season. In the afternoon, according to the state of the weather, the ventilation should be gradually reduced. If the weather is very hot and the house is in an open position, five o'clock will be soon enough to commence the reduction. If cool and the house be in a partially shaded position, reduce the ventilation at four o'clock.

**Atmospheric Moisture.**—Of course plants which are suitable for the greenhouse do not require as much atmospheric moisture as stove plants do. But it is a mistake to think that the atmosphere in a greenhouse should be kept quite dry. Such plants as Fuchsias, Tuberous Begonias and even Zonal Pelargoniums thrive better when the atmosphere is moderately charged with moisture than when it is absolutely dry. Of course one must have some guide as to what amount of moisture is desirable. To the novice this is a difficult problem. The solution is best given to such a person as follows: Damp down the floor and under the stage before eight o'clock in the morning, again at ten o'clock, once more at noon, and finally in the middle of the afternoon on a hot, bright day. Two dampings will be sufficient on a day of moderate brightness, one on a rather dull day, and not any in showery weather.

**Watering.**—This is another important matter, and requires much careful thought. One examination of the pots each day is not sufficient in summer time. The plants should be examined three times during the day, namely, in the morning, at noon, and in the evening. In this way the soil will not be allowed to get too dry. Do not feed newly-potted plants, but only those specimens which have filled their pots with roots. It frequently happens that plants which have been recently repotted droop their leaves during the hottest part of the day, and this is taken as a sign that they need water. This is not always the case, as the soil may be quite moist; in such instances give a light syringing overhead with a slight shading. AVON.

5.—SHOWING HOW PLANTS SHOULD BE ARRANGED ALTERNATELY IN THE ROWS WHEN PLANTED OUTSIDE.

## THE TOWN GARDEN.

**PINKS FROM PIPINGS.**—There are few plants which make a more delightful border in the town garden than white Pinks, for the flowers are exceedingly useful for cutting and the fragrance is charming. Unfortunately, some town gardeners appear to think that when once the plants have been placed in position they do not demand any further attention; this is quite wrong, and the man who would have really gratifying results quickly learns that the management entails regular attention in maintaining the soil in good condition and in the renewal of the border at least once in three years. This can be effected by division if preferred, but it is more satisfactory to raise entirely fresh stock from pipings, and the present is an excellent time to take them. Clean, healthy, flowerless growths should be chosen and drawn out of their sockets by a sharp upward pull; if they are inserted in light, sandy soil firmly they will root quickly and grow into splendid little plants with which a new border may be formed in the winter or spring according to convenience. It is an advantage either to insert the pipings in a cold frame or place a hand-light over them for a time if they are in the border. Her Majesty is a grand variety, but it has not yet succeeded in ousting the old favourite, Mrs. Sinkins, from our gardens, and it is not likely to do so for some years.

**SWEET PEAS.**—Where the young plants received correct attention in the early stages, the Sweet Peas are now looking the picture of health and the promise of abundance of excellent flowers a little later on is rich. Buds will have been in evidence for several days, and it is now that the grower can commence feeding with every prospect that the food supplied will prove beneficial to the plants. No doubt many people have had recourse to special feeding before now, but the policy is not good and is quite unnecessary where the soil was efficiently prepared at the outset. It is far better to wait until the plants are well in bud and have made sound growth before manures are used, for they are always apt to cause the growth to become soft and sappy, and, as a consequence, unable to develop flowers of the finest size and substance. In feeding, the conveniences of each grower must be considered, and it really does not make any material difference what is used, provided that as many changes as possible are afforded and that whatever is applied is not too strong. In any case clear water should be given between every two applications of liquid manure and the quantity should be sufficient to soak down below the roots—say, from three gallons to five gallons to the square yard, according to the nature of the soil, more being wanted on a light than on a heavy land. Soot water is excellent as an alternative to other things.

**HEDGES.**—If it is desired that these shall present the brightest possible appearance throughout the summer months it is important that they shall not be too closely cut from now onwards. If the shears are allowed to go down into the hard wood it is a considerable time before this again breaks freely, and the result is that the hedge looks brown and bare, but if the cutting is restricted to the removal of shoots that are advancing too rapidly, the hedge will always be green and attractive. It is excellent practice, where it is possible of adoption, to thoroughly soak the soil in which the roots are working about once in every ten days, and if it is convenient to apply weak liquid manure a few hours after the watering, the results will be all the more satisfactory. For this particular purpose I have not found anything more generally useful than guano water, but if this is not at command, liquid manure from any natural excrement can be pressed into service. A hedge is always pleasant to see when it is well cared for, not otherwise.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**T**HIN out the weak growths of such plants as Allamandas; these are now showing fine flowers. Give manure water occasionally, as this will assist to prolong the flowering period till well into the autumn. Clerodendrons should have the dead flowers taken away when all beauty has passed. Stephanotis may be cut back now that flowering is over. Pot on Gloxinias, Begonias and similar plants that were raised in February; these will make good successions to those that are flowering now. *Azaleas and Camellias*, where grown under glass, may now be placed outside under a north wall on a bed of ashes, or stand the pots on planks: this is to keep worms from getting into the pots. Keep them well supplied with tepid water and syringed twice daily in hot weather, in order to keep down thrip and promote healthy growth.

**Pitcher Plants (Hepenthes).**—Afford these tropical heat and plenty of moisture and syringe twice daily. Pot on such plants as *Jacobinia chrysostephana*, *Plumbago rosea*, *Thyracanthus rutilans* and *Gardenias* for autumn and winter. *Gloriosa superba* and *G. grandiflora* should have the run of a pillar or wires under the glass roof, when they will prove most useful and interesting. *Eucharis* that have been flowering should be rested for a month or six weeks.

*Cyclamen* ought now to go into the flowering pots; use the best loam and leaf-soil obtainable, with plenty of sharp sand. Do not bury the corms too deep in the soil, about half being the best system. Pot firm and shade from bright sunshine, and syringe well under the foliage in sunny weather to keep down thrips.

**Tree Carnations.**—Pot the last batch for winter flowering into the final pots. The tops may yet be pinched to make them bushy. Pot into 2½-inch pots *Primulas* of all sections. Sow more *Cinerarias*. Pot winter-flowering *Geraniums* into the flowering pots and stand in the open on a bed of ashes, and do not over-water till the roots have found and got well hold of the new soil.

#### FLOWER GARDEN.

Keep this department smart and as gay as possible, and let soft colours be the leading feature; these are more pleasing to the eye and more artistic. All dead and decaying foliage must be picked off and herbaceous plants nicely staked before they fall about, taking care to hide the stakes as far as possible. Rock, alpine and aquatic gardens should be kept free of weeds and as far as possible each plant free of its neighbour.

#### HARDY FRUIT.

Continue to pinch or prune trees against walls or fences, and keep them free from aphids. Tie in the growths of Peaches and Nectarines, but not more than is required for next season's crop. Layer Strawberries for the earliest crop, rooting them in small pots being the best method. Keep the plants well watered and they will soon grow away. Gather Strawberries early in the day or late in the afternoon, as they can then be sent to table in much nicer condition than when gathered in the heat of the day.

#### KITCHEN GARDEN.

**Lute Peas.**—Mulch and stake these, and if required run a string along each side of the rows to guard against damage by wind. Continue to pick out Broccoli, Cauliflowers, Leeks, Savoys and finally plant out all Brussels Sprouts. Sow Endive, Lettuces, Turnips and Dandelions for winter salad. Thin Seakale heads to one crown. Plant out Celery now in quantity, first

placing plenty of well-decayed manure at the bottom of the trenches. Cease cutting Asparagus and tie up any large growths as they appear, so that they are not broken by the wind. Sow Beans for a late crop; Canadian Wonder and Ne Plus Ultra are the best varieties.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)

Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**SHOW PELARGONIUMS.**—As these plants go out of bloom they should be placed in a cold frame or in the open air in a somewhat sunny position to ripen the wood. Water should be withheld, so that the wood may become hardened and in a condition to make cuttings. If placed round the sides of pots filled with a sandy compost and kept in a cool frame and shaded, so that the soil does not dry rapidly, the cuttings soon root, when they can be potted singly into medium-sized pots, using a compost containing leaf-mould and sand. Winter the plants in a greenhouse.

**Greenhouse Rhododendrons.**—The present is a very good time to propagate these Rhododendrons by means of cuttings, which are not at all difficult to root, all that is needed being to form the cuttings of the half-ripened shoots; finish them at the base with a rather sloping cut and then dibble them into pots prepared for that purpose. The pots should be well drained and filled firmly with very sandy peat. Care must be taken that the soil is well pressed around the cutting, especially guarding against any cavity at the base of it. After being watered they must be placed in a close propagating frame in an intermediate house temperature, and in this way they may be struck, potted into small pots and established before winter.

**Chrysanthemums.**—Now that the plants are all in the pots in which they are to flower, provision must be made for getting them into their summer quarters without delay. Usually at potting time they are stood close together in a sheltered corner until all are potted. By that time the most forward will have become nicely established in their large pots and will be ready to undergo the usual routine of summer management. A position sheltered from the south-west and the full blaze of the midday sun, and as long as it can be obtained during the other parts of the day is the best that can be chosen for the plants. The best position of all is beside paths near the water supply, where abundance of light is assured.

#### FLOWER GARDEN.

**Pinks.**—Cuttings of these may now be put in as the different varieties go out of flower. A bed should be prepared at once for them, and I prefer to make it in an extemporised frame, where they may be shaded for a time if necessary, or get the benefit of all the sunshine available should the weather prove dull and showery. Soil turned out of pots and boxes at the time of planting out summer bedding stuff will do very well for the cuttings of Pinks, Violas and alpine Phloxes. If the soil be dry it should receive a good soaking of water the day before the cuttings are inserted, previously adding a little fresh leaf-soil and sand, and incorporating the same with the old potting soil. Some 4 inches of soil resting on a hard bottom is much better for cuttings of the above plants than to allow a considerable depth. Under the latter conditions the roots will ramble far afield and the plants suffer proportionately when they are lifted to other quarters. The Pink is one of the most welcome of summer flowers, and such varieties as Mrs. Sinkins produce a wealth of blossom at this time.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Carnations dying** (*Dunruadh*).—There is no disease in the Carnations sent. In every collection a few will die off in a similar manner. It is generally attributed to over-watering, or allowing the plants to become dry and drenching them with water afterwards.

**Iris for name and treatment** (*C. E. Brunton*).—The Iris of which you send a flower and foliage is the pretty *I. sibirica*. You give us no indication of the treatment that you have accorded it. This Iris thrives best by the side of a pond or pool of water where the roots are partly submerged. Given such a position it is not at all fastidious as to soil, and will produce an abundance of its pleasing blue flowers.

**Hyacinth bulbs diseased** (*Suffolk*).—Your bulbs are badly cankered at the base, and the whole of the area from which the root-fibres are usually emitted is extended and deepened in a most unusual manner. The general appearances of the bulbs, too, display something of a prior grossness of growth, and we are disposed to think that you have poisoned the soil by the very "large proportion of bonfire ash" you have used. We have known instances where the soil by similar applications has been for years rendered unfitted for the cultivation of bulbous plants, and we strongly recommend you to refrain from such free applications of these things in future. When the bulbs are more fully matured, lift them, and when dry endeavour to divest them of the cankered part and replant at the proper time in fresh soil quite free from the burnt ash. It is doubtful whether such bulbs as those you send will ever pay to grow again. Your soil also appears to be infested with slugs and other ground pests, and you should use Vaporite or Kilogrub to clear them out. These are not the primary cause of the trouble, however. The Star of Bethlehem (*Ornithogalum umbellatum*) appears to be suffering from some fungoid attack, but the leaves were quite rotten when received.

**Double Tulip to name** (*Mrs. Paterson*).—We regret to say we are unable to name the variety sent. We have seen similar doubles or semi-doubles growing in old gardens; but as they were small, like yours, and not of any striking shade of colour, they have never been cared for. It is exceedingly improbable that the variety is in commerce; and if this is so, it follows it would have no generally recognised name.

**Tree Peony diseased** (*Hampshire*).—The stems and leaves are affected by a fungus, and you cannot do better than cut away and burn all diseased portions at once. Then if you write to Messrs. Cannell, Swanley, for a supply of their fruit tree wash, and use it according to directions about once a month, you may, in a year or so, get the upper band of the disease. A north-east position for these plants is about as bad as could be chosen, and one facing south-west would be far better. The best time for replanting is at the end of August.

**Three Tulips for naming** (*Colonel J.*).—No. 1 (pink) is one of the many Darwin varieties, but it is a small flower. We have compared it with a good many, but cannot find any absolutely the same. It is exactly the same shade as Parthenope, but the base is rather more white. Still, for practical purposes they might be considered the same in a garden. No. 2 (white, tinged green). It is a pity that a perfect flower was not sent,

for the green in the petals is a defect. It is an old garden variety very seldom seen nowadays called *Alida*. No. 3 (yellow, edged red). This is the good old variety called *Golden Crown*. A larger pink Tulip of the same shade as No. 1 is *Kate Connor*. It is one of the old English breeder or mother Tulips, and has an excellent constitution. Another which is of a similar shade but with a more pronounced paler edge is the *Darwin Mrs. Krelage*. This is a fine handsome flower.

**Information about Anemones** (*Mrs. S. I. W. S.*).—*Anemone apennina* can be procured in roots or tubers from any of the bulb dealers, and the variety *purpurea* from Mr. C. G. Van Tubergen, jun., Zwanenburg, Haarlem, Holland. He has also some of the varieties of *A. nemorosa*, mentioned in the article to which you refer, and it is possible that you may get tubers of some of the newer ones from Mr. T. Smith, Daisy Hill Nursery, Newry, Ireland. The latter can supply you with *Omphalodes verna* and with seeds and plants of a number of the wild Pinks.

**Tulips and Daffodils** (*A Constant Reader*).—The fading blossoms of the Tulips may certainly be removed with impunity, but most of the varieties shed their petals naturally about the same time. It is the seed-pods maturing that are calculated to most weaken the plant. There is not the smallest reason why the Tulip and the Daffodil may not revert at times, but wholesale reversion is by no means usual. The Daffodils are apparently passing a stage in the evolution of the flower which is not "turning back to doubles," but, from your remark, the reverse order of things. You do not say whether during this change the bulbs have remained planted or have been lifted and cultivated in the usual way. The Lily of the Valley could only be cultivated in full sunshine with success if planted in rich and quite moist ground. In any case the plant delights in shade and produces in such places and under the best treatment its finest spikes of blossoms. Some of the finest we have ever seen were growing in a Thames side garden, where the river at high tide occasionally overflowed its banks and flooded the garden. The plants were in deep soil and had the thin shade of Apple and other trees.

### ROSE GARDEN.

**Remedies for Rose mildew** (*F. A. N.*). We have found that this fungus can be checked, if not actually cured, by syringing the plants with a solution of carbolic soap, half a bar of Lifebuoy soap being dissolved in three gallons of soft water and applied with a very fine sprayer, such as an Abol syringe. It must be remembered that the young soft foliage is always susceptible to mildew, so that as fast as it appears it should be sprayed. In the excellent little work entitled "The Enemies of the Rose" the authors recommend spraying Roses with sulphuric acid (commercial), one part to a thousand parts of water. Constant spraying is needed to keep the pest in check. It is a good plan to spray the plants three days in succession and then follow this up by spraying once a week. Use a very fine sprayer. This is important, as we want the liquid to remain on the leaf, not to drip off, as it will do if applied with a coarse sprayer. Wherever any variety such as *Her Majesty* and *Killarney* are observed to be specially addicted to mildew such plants should always be under observation and sprayed whenever required, for insects have the power of transferring the mildew spores from infected to healthy plants.

**Rose bushes planted last autumn** (*E. H. A.*).—Providing the plants are growing well there is no reason why they should not be allowed to bloom. As soon as the flowers have faded they should be cut off about 1 inch below the seed vessel, for if allowed to seed a great and unnecessary task is imposed upon the plants. Any small plants should have all the flower-buds removed from the present time until the end of July. After this, if perpetual varieties, they would doubtless be strong enough to carry a few autumn flowers.

### FRUIT GARDEN.

**Vines in small vinery unsatisfactory** (*F. P., Monmouth*).—The chief cause of the failure of your Vines in bearing fruit must, we think, be attributed to the fact that the roots are far too close together, especially as you say that they are mostly strong growing. Sixteen rods in the space of 24 feet is contrary to all successful experience and good practice in Grape culture. We advise you to take a bold course and reduce the number of rods by as many as will increase the distance between each Vine to at least 2½ feet. As your rafters are so short (only 7 feet) it would be better to cut out altogether one or more of the most unsatisfactory

varieties rather than reduce the number of rods on so short a rafter—Duke of Buccleuch, for instance. To grow this grand Grape successfully it should have a house to itself, where it can be grown and pruned on the extension system. It will not fruit satisfactory if spur-pruned, and one or two of the least satisfactory of the others might be sacrificed in the same way. We have no doubt that the increased exposure to light and air, which would result from this thinning-out process, with the admission of abundance of air into the vinery during late summer and autumn to properly ripen the wood, would result in inducing your Vines to bear fruit freely.

**Gooseberry diseased** (*C. B., Henbury*).—The American Gooseberry mildew is not present, and it would seem, from the symptoms described and the appearance of the lower part of the dead shoot, that the cause of the shrivelling of the branches as they appeared was traceable to some wrong condition at the roots.

**Grape Madresfield Court scalding** (*Geo. Tucker*).—This grand Grape is subject to this complaint. The way to stop the malady is by admitting more air into the vinery during the day, and to have a little on as well, back and front, all night until the Grapes are ripe, with just a little heat in the pipes to keep the air moving. This Vine succeeds best under what is termed the cool system of Vine culture.

**Nectarines failing to swell** (*Norfolk*).—The cause, in our opinion, of your Nectarines failing to swell is to be found in the fact of the trees being weakened by the heavy crops borne last year (as you state). Nature will have her revenge, and you may depend upon it that if you take too heavy a crop one season you will not have the chance of doing so in long succession. The better way is to secure a moderate crop every year by judicious thinning. In this way better fruit is secured and disappointment at the loss of an occasional crop avoided.

**Strawberries mildewed** (*D. P. S.*).—This has been an unfavourable spring for the forcing of Strawberries in consequence of the long continued cold and unless weather we have had. In your case the attack of mildew was most likely brought about by suddenly exposing the plants to too much cold air, causing a chill to the foliage and thereby courting an attack of mildew. This is the most frequent cause of attack, both in forced Strawberries and Grapes in spring. Yes, we think *Omphalodes verna* would answer the purpose you wish fairly well. *St. John's Wort* is also an effective plant for this purpose, but the best plant of all for carpeting the ground under such trees is *Euonymus radicans variegatus*. In spring it is clothed with small foliage of the colour of green and gold and in late summer and winter green and silver. The plant grows from 5 inches to 7 inches high. It does not produce flowers of any value.

**Rust on Strawberries** (*J. B.*).—This mildew is a terrible scourge when it attacks this fruit, either in the open air or under glass, and what is worse, the injury is inflicted so quickly and is so fatal to the quality of the fruit that, once the attack has taken place, nothing can be done to save it. The only thing is to avoid creating conditions surrounding the growth of the plants which are known to favour its attack. The long continuance of dull, cold weather such as we have had for a long time past has, no doubt, encouraged its presence, especially in creating cold draughts by incautious ventilation. Another frequent cause is to be found in the night temperature being too cold after the foliage has been excited into growth. Still another cause, as you suggest, is to be found in the too wet and sodden condition of the roots, as also in the opposite extreme of over-dryness at the roots and in the atmosphere. But the most common cause of its existence is to be found in the fact that the mildew is often present on the foliage before the plants are taken under glass. The remedy here is self-evident: examine the plants carefully, and if mildew is suspected dredge the plants heavily with flowers of sulphur. There is no other known remedy.

### MISCELLANEOUS.

**Grubs for inspection** (*Anxious*).—The grubs you sent are those of a two-winged fly, one of the drone flies belonging to the genus *Eristalis*, which you often see in gardens and sometimes on the windows of houses. To the uninitiated they are often mistaken for bees. The grubs are perfectly harmless to plants. They live in stagnant water and breathe through pores at the end of their long, rat-like tails. I cannot say what is the cause of your young Pears dropping without seeing them and some of the shoots which bear them.—G. S. S.

**Grub for inspection** (*J. C. L. Du C.*).—The grub you forwarded is that of the daddy-long-legs. They are most troublesome pests, as most insecticides have little or no effect on them. They will ruin any plant on whose roots they feed. Sometimes they can be trapped by laying bricks, tiles and pieces of board or turf near the plants they are attacking as they will often hide under such things at night. Vaporite mixed with the soil in which they are said to kill them. You might try it by making four holes with a stout stick, say, 6 inches deep round the plant, placing some Vaporite at the bottom of each, and then filling up the holes again. The gases emanating from the Vaporite will kill the grubs in the surrounding soil.—G. S. S.

**Destroying Polygonum (F. K.).**—The plant of which a specimen is sent is one of the annual *Polygonums*, commonly called *Pluk Persicaria*. It is, botanically, *Polygonum Persicaria*. It should, to destroy it, be pulled up so soon as seen, as it seeds freely. With respect to the perennial *Polygonum*, which grows so plentifully in your pond or on its margin, have it chopped down and removed to a heap to decay so soon as new growths or suckers appear. Keep them cut down hard with a sharp hoe. Persist in that course, never allowing the growths to make leaves, and in time the plants will disappear. You can, of course, use salt freely after this cutting down, but, because the roots run deep, we cannot say that such dressing will destroy them. Lime will not harm them. If you were to remove much of the surface soil and give the roots a good dressing of liquid wood-killer, that may destroy them, replacing the top soil again. Still, in any case, persist in preventing suckers from growing.

**Cactus flowers (Mrs. K. E. J.).**—Although the Cactus flowers cannot be regarded as superior to, or even the equal of, some of the existing varieties, they are very pretty and especially interesting as the result of intercrossing the two flowers whose blooms you send. When the plants flower another season you will probably find them considerably improved from this year, as they are rarely at their best the first time. If in your place, we should await the flowering of the others with especial interest, for the variability that occurs in seedlings, even when raised from the same pod, is very great.

**Names of plants.**—*W. A. C.*—Your Larkspur is *Delphinium consolida*.—*Miss J. M. L.*—*Meconopsis racemosa*.—*Ponderosa*.—The plant you send is *Smilax maculata*. *Dracena godseffiana* is a native of the West Coast of Africa.

## SOCIETIES.

### FLOWERS, FRUIT AND VEGETABLES AT THE YORK JUBILEE GALA.

#### A GREAT EXHIBITION.

THE horticultural exhibition held in connexion with the York Jubilee Gala on the 17th, 18th and 19th Inst. was a great success, despite the very heavy and continuous downpour of rain which occurred on the opening day. Flowers generally were very good, the large groups arranged for artistic effect being mostly of high order. Fruits were moderately good, but vegetables on the whole were poor and but sparsely shown. Now plants were very disappointing. A deputation of the Royal Horticultural Society visited the exhibition on the first day and granted silver cups and medals to various exhibitors.

#### COMPETITIVE SECTION.

##### SPECIAL JUBILEE COMMEMORATIVE CLASSES.

Four classes were arranged for in this section, a special cash prize being offered in each case. In Class A, for the most imposing and meritorious festival display (on ground) of plants and flowers grouped for effect, size 30 feet by 11 feet, three competitors entered, and Mr. W. A. Holmes, West End Nurseries, Chesterfield, appropriated the first prize of £40 with a marvellous combination of grandly-grown plants. Tall Palms formed a background, and then rambler Roses, pyramidal Crotons, a few Japanese Maples and *Dracenas* were stood rather thinly in front. Among these, and forming a sort of carpet, were *Verbena*s, dwarf Crotons, *Coleuses*, Ferns, *Caladiums*, *Orchids*, *Carnations*, *Lilies* of the Valley, scarlet *Anthuriums* and similar things, the whole being most artistically combined for colour effect. The second prize fell to Mr. Joseph Pickersgill, Barton Hill, Westwood, Leeds (gardener, Mr. J. Donoghue). Here Roses were used in profusion, the long branches of the ramblers being trained to canes in pendulous fashion. Two baskets filled with spikes of *Odontoglossum*s were suspended from tall semi-circles, excellent plants of Crotons, various *Orchids* and *Dracenas* being freely employed. Mr. William Vaise, Warwick Street, Leamington, was awarded the third prize, this group also being a good one but rather densely arranged.

In Class B, for the most meritorious combination display of horticultural products, arranged for effect and instruction, on table, space not exceeding 20 feet in length by 6 feet in depth, one frontage, height unlimited, there were three entries, and the first prize went to Mr. C. E. Simpson, 21, Spurlinggate, York (gardener, Mr. F. Nutbrown). This was a wonderful combination of artistic skill and good culture, the whole exhibit being of a unique and high order. White and rose-coloured *Pinks* were placed on wire frames to form Prince of Wales's Feathers, a huge cross, wreaths and a miniature font. Then *Grapes*, *Cherries*, *Peaches* and *Nectarines*, *Pine-apples*, *Melons*, *Bananas* and *Tomatoes* were most beautifully displayed with a few cut flowers and foliage. Quite different in style and contents was the second prize group, arranged by Messrs. William Artindale and Son, Sheffield. The centre-piece was "gates ajar," formed of *Roses* and white *Stocks*. Flanking this on the right was a large harp composed of deep lavender Sweet Peas, and on the left masses of *Carnations*. Baskets, wreaths and other designs formed the background. The third prize went to Messrs. J. Backhouse and Son, Limited, York, for a very fine display of flowers and fruits, the lady's hat and muff, composed of white *Stocks*, *Statice* and *Roses*, attracting much attention.

In Class C only one exhibit was staged, and this was only considered worthy of fourth prize.

In Class D, for gardeners and amateurs resident Yorkshire only, the best and most meritorious display of the produce of Yorkshire gardens, the only exhibit came from Lord Londesborough, Market Weighton (gardener, Mr. J. C. McPherson), and this received second prize. It contained good *Grapes*, medium *Peaches* and *Nectarines*, *Carrots*, *Beans*, *Tomatoes*, &c., with *Crotons* and *Sedum* for a background.

In Class I, for a group of miscellaneous plants in or out of bloom, arranged for effect, there were five entries, the first prize being awarded to Mr. J. W. Conlthurst, Gargrave House, Leeds (gardener, Mr. M. Skinner). This group was composed of large Crotons, *Humans*, two good specimens of rambler *Roses*, *Hippeastrums* and *Orchids*, a small pool of water being in the front. The arrangement was rather heavy and sombre, and the colours not at all well balanced. The second prize went to a much brighter group staged by Mr. J. S. Sharp, Valley Nurseries, Almondbury, Huddersfield. The general comment was that this group fully deserved the premier award. Certainly it was a most tastefully-arranged exhibit, and the variety of plants used was excellent. Mr. James Blacker, Thorpe Villas, Selby (gardener, Mr. Walton Curtis), secured third prize with a good display; and the fourth award went to Messrs. R. Simpson and Son, Brook Street, Selby.

In Class 2, for a group of miscellaneous plants in or out of bloom, arranged for effect, artistic arrangement being considered the chief point, the display was very good indeed. "The finest exhibit in the whole show" was the verdict of the Judges concerning the magnificent first prize group staged in this class by Messrs. J. Backhouse and Son, Limited, York, and consequently it was granted the special Jubilee gold medal offered for the best group. Mere words fail to describe the magnificence and artistic ingenuity displayed here. Generally speaking, a huge bay some 10 yards long and 5 yards wide was formed, with large rocks placed in a natural, irregular fashion. In the front and bottom of the bay the faintest of water-gardens was arranged, with stone steps leading through a charming little bog garden to it, with a small shell path running round the base of the cliff at the back. *Primula sikkimensis*, *Ramondias*, *Heavenly* *Delavayi grandiflora*, *Dianthus neglectus*, with hairy *Orchids* and many other choice alpine and rock plants freely draping the rocks, made this group one that was full of interest. The second prize went to Messrs. Artindale and Sons, Sheffield, this exhibit also taking the form of a rock garden, with a beautiful display of herbaceous and rock and alpine plants intermixed. Mr. J. Wood, Boston Spa, York, was third with a very attractively-arranged rockery and water garden; and the fourth prize went to Mr. G. Cottam, Alma Gardens, Cottingham.

#### GREENHOUSE AND STOVE PLANTS.

In Class 3, for nine stove or greenhouse plants in bloom, distinct (*Orchids* excluded), Messrs. Cypher and Sons, Cheltenham, secured the first prize with magnificent specimens, including *Erien ventricosa* magnifica over 4 feet in diameter; *E. cavendishiana*, 6 feet in diameter, and a plant of *Bougainvillea sanderiana*. The same firm also took several firsts in the single stove plant classes with really wonderful specimens.

For a group of *Pachisthas* in flower, arranged for effect, Mr. William Kettlewell, 41, Horner Street, York, was first with some very good well-flowered pyramidal plants, the double-flowered varieties being particularly good. The second and third prizes went respectively to Mr. J. W. Clarke, Clifton, York, and Mr. George Lee, York.

For a group of *Carnations* in bloom the first prize was secured by Mr. Joseph Pickersgill, Barton Hill, Westwood, Leeds (gardener, Mr. J. Donoghue), with some well-grown specimens of *Malmalson Carnations*. Messrs. Walshaw and Son, Scarborough, were second with good plants rather loosely arranged, and the third prize went to Mr. J. E. Skaffe, York.

#### ORCHIDS.

In the class for a table of *Orchids*, 12 feet by 5 feet, Messrs. J. Cypher and Sons, Cheltenham, almost, if not quite, created a record in first prizes, this firm securing first prizes in four classes. The specimens staged were very fine indeed, especially the *Miltonias*, *Cattleyas* and *Vandas*, huge plants of these really covered with flowers being freely displayed.

Messrs. J. W. Moore, Limited, Rawdon, Leeds, were equal first in the above class with Messrs. Cypher. It is rarely that such a tie occurs, especially in a class of this description. The arrangement in this case was very good, tall pillars being freely bedecked with *Orchids* in flower. All the specimens were excellent, and evidently the result of good culture.

The magnificent group staged by Lieutenant-Colonel G. L. Holford (gardener, Mr. H. G. Alexander) was admittedly one of the finest ever seen. In addition to the special gold medal offered by the York Gala committee the deputation of the Royal Horticultural Society also awarded it a gold medal and the first prize for a collection of twelve *Orchids* exhibited by an amateur. *Miltonias*, *Cattleyas*, *Cypripediums*, *Vandas* and, indeed, practically all *Orchids* now flowering were incorporated, the plants being the picture of health.

#### ROSES.

Generally speaking the *Roses* were not good, owing probably to the early date, many collections contained a few good flowers and a host of inferior blooms.

In Class 32, for a collection of *Roses*, in pots or ent blooms, arranged on table, there were four entries. Mr. George Prince of Oxford coming out a good first with a very charming exhibit. *Roses* of all sections were most tastefully displayed and the condition and form in which they were displayed left nothing to be desired. The second

prize group staged by Messrs. W. and J. Brown was also a very good one and came in close to the first prize group; the arrangement, however, was rather crowded. Mr. George Mount of Canterbury put up the third prize group, in which were excellent blooms of Richmond, Frau Karl Druschki and Joseph Lowe.

In Class 33, for a collection of *Roses* in bloom in pots, grouped for effect, the competition was good, and some excellent groups were displayed. Mr. J. E. Skaffe, Barton Lane, York, was the champion with a very pretty exhibit. *Crimson Rambler* formed an arch at the back, *Hybrid Perpetuals* and *Hybrid Tens* being placed in the foreground, surmounted with a small standard of Dorothy Perkins. Mr. William Todd, 19, Vyner Street, Haxley Road, York, secured second honours with well-grown plants that needed at least another week to develop their flowers. The third prize went to Mr. George Mount, Canterbury, for a very pretty group composed of *Polyantha* varieties.

Class 34, for a group of *Roses* in bloom, not less than twenty pots, the competition was rather keen, some very nice groups being staged. Mr. W. Langstaffe, Sydney Street, York, won the first prize in good style, his group comprising well-grown plants of *Polyantha* and other *Roses*. Mr. J. E. Skaffe, York, was second, his plants carrying blooms of much substance. The third prize went to Mr. H. Pybus, Wormald Green, York, the plants here being rather backward.

In Class 40, no less than seventy-two *Roses*, single blooms, not less than thirty-six varieties, were asked for. Messrs. D. Prior and Sons, Colchester, were the champions in this class, their good blooms fully deserving the first prize. *Maréchal Niel*, *Mildred Grant*, Mrs. John Laing, Captain Hayward and Mme. Jules Gravenex were the best. The second prize was withheld, but Messrs. B. R. Cant and Co. of Colchester secured the third. We noticed good flowers of Mrs. E. Mawley, Aimée Cochet and Maman Cochet. The fourth prize was allotted to Messrs. Harkness and Sons.

In Class 47, for forty-eight *Roses*, single blooms, not less than twenty-four varieties, Mr. George Mount of Canterbury was awarded the premier position for a good lot of large blooms. Rev. Alan Chenes, Mrs. John Laing, Aimée Cochet, Richmond, Captain Hayward and Frau Karl Druschki were some of the best flowers. The second prize went to Messrs. D. Prior and Sons, Colchester; and the third to Messrs. B. R. Cant and Co., Colchester.

Class 48, for thirty-six *Roses*, single blooms, not less than eighteen varieties, was well contested, hence Messrs. Harkness and Sons, Hitchin, may be congratulated on winning the first prize. The blooms here were a uniform lot and good all through. White Lady, Lady Ashtown, Mrs. David McKee and Mrs. E. Mawley were very fine. Blooms of fair quality were staged in the smaller classes, but lack of space forbids detailed mention of these.

#### HARDY CUT FLOWERS.

Class 55 was the principal one in this section, a collection staged on a space not exceeding 15 feet by 6 feet being asked for. Messrs. G. Gibson and Co., Leeming Bar, Bedale, Yorks, were first here with a fine exhibit, the splendidly-grown blooms being staged in first-class condition and comprising such things as *Irises*, *Pyrethrums*, *Paeonies*, *Poppies*, *Lupines* and *Columbines*. The second prize went to Messrs. Harkness and Sons, Hitchin; and the third to Messrs. William Artindale and Sons, Sheffield.

#### FRUIT.

Class 67 was a most popular one and was very keenly contested. A decorated table of ripe fruit, not to exceed fourteen dishes nor less than ten dishes, and not more than two distinct varieties of a kind, was asked for. The first prize here went to His Grace the Duke of Portland, Welbeck Abbey (gardener, Mr. J. Gibson). This was a very fine exhibit, first-class *Melons*, *Peaches*, *Strawberries*, *Cherries*, *Figs* and *Grapes* being most artistically arranged with suitable foliage and flowering subjects. The second prize went to the Earl of Harrington, Elvaston Castle, Derby (gardener, Mr. J. H. Goodacre). The fruit used here was very fine indeed, the *Peaches* and *Figs* being splendidly finished. The third prize was won by the Marquess of Northampton (gardener, Mr. A. R. Searle).

Class 68 was for a collection of fruits, ten kinds, only two sorts of *Grapes*, two bunches of each, being allowed. Lord Londesborough, Market Weighton (gardener, Mr. J. C. McPherson), was first here with a good collection containing very fine *Strawberries*, *Grapes* and *Pine-apples*. The Earl of Harrington (gardener, Mr. J. H. Goodacre) was second, and we specially noted a good dish of early Green Gage Plums in this exhibit. The third prize went to Messrs. Colebrook Brothers, Burton-on-Trent.

The smaller fruit classes were generally well contested, especially those for *Grapes* and *Melons*, the quality being of a very fair order considering the early season.

#### VEGETABLES.

These classes were poorly contested, but some moderately good produce was staged. For a collection of vegetables to be grown from seeds supplied by Messrs. J. Backhouse and Son, Limited, the Marquess of Northampton was first and Mr. P. Neville second. For a similar collection grown from seed supplied by Messrs. Sutton and Sons the Duke of Portland was first and the Earl of Lathom (gardener, Mr. B. Ashtown) second; and for a collection grown from seeds supplied by Messrs. Webb and Sons the first prize went to the Hon. Viary Gibbs, Aldenham House, Elstree, Herts (gardener, Mr. E. Beckett). Pea Stourbridge Marrow, Tomato Webb's Sensation and Carrot Webb's Prize-winner were superb here. The second prize was awarded to the Marquess of Northampton and the third to the Earl of Lathom.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## HISTORY AND CULTURE OF A BEAUTIFUL FLOWER.

### LONG-SPURRED COLUMBINES.

#### HISTORICAL NOTES.

THE Columbine (*Aquilegia*) has been an inhabitant of British gardens for at least 350 years; it may be for an even longer period. In the days of herbals almost every part of the plant was thought to be efficacious for some particular complaint, and this was very likely one reason why it was included among cultivated plants in those early days. Once introduced, it would soon be noticed how much seedlings varied from each other and from their parents, and thus it would become a source of interest to watch the first flowering of a young plant. It is certain that there were a large number of garden varieties in the early years of the seventeenth century. As the rage was then for double flowers, we find numerous double forms depicted in the old flower books of that period. Two in particular are worthy of mention, and seem to have been highly prized: (1) *Aquilegia flore roseo multiplici* (double Rose-like flowered) and (2) *Aquilegia degener virescens* (degenerate Columbine). They were both spurless, and the former was like a double Larkspur or tiny double Rose, and the latter something after the style of those *Anemones* which have an outer circle of larger petals filled in with a number of smaller and narrower ones in the centre.

All these were forms of the common Columbine (*A. vulgaris*). No long-spurred varieties were known for many years afterwards. *A. canadensis* was introduced from North America in 1640 by John Tradescant, but although it has longer spurs than the old-fashioned *A. vulgaris*, it cannot be said to be really long spurred. This modern garden type of flower had its origin in (1) *A. cerulea*, introduced in 1864 from the Rocky Mountains; (2) in *A. californica* from North America; (3) in *A. chrysantha*, introduced in 1873 from California.

These different varieties seem to cross with one another very freely, so that it has become impossible to say where one begins and the other ends. They are all distinguished by their very long spurs, and in *cerulea* types the prevailing tones are blues, lavenders, purples and pinks, in *californica* red shades, and in *chrysantha* yellow and white (?) shades. Most seed lists catalogue *Aquilegia cerulea hybrida*, and a considerable number *A. californica hybrida* and *A. chrysantha hybrida*. Purchasers, however, should remember that owing to their freedom of intercrossing and generally unstable character these definitions and distinctions are only approximately true.

#### THEIR USEFULNESS.

Columbines are an indispensable adjunct to the flower border in June, "that season affording few other flowers," as that keen gardener John Rea observed so long ago as 1665. When Tulips are over we want something to take their place, and I would urge that there is no more graceful or easily-grown plant for this purpose than this comparatively modern race of long-spurred Columbines. They vary very much in their colouring. We get deep purples and pale lavenders, delicate pinks, bright reds, rich yellows, blues of many shades, and all borne in good strains on long, graceful stems, which in their turn spring from a nest of lovely Fern-like foliage. They are excellent as cut flowers. They are so elegant in themselves that they want but little arrangement, only a few of their own large leaves put in the bottom of the bunch. They are equally adaptable for large and small vases. And last, but by no means their least qualification, is that they last well. I tried some myself this year, and found that three vases of flowers which were put on my dining-table at midday one Wednesday remained quite fresh until the following Sunday, and then when I had cut a few old blooms away, went on for another two days. The only thing that was done to them was the keeping the vases full of water.

#### CULTURE.

The long-spurred race is not quite as robust as the old short spurred; still, it is quite hardy, and not at all fastidious about soil, provided it is not too light and dry. They enjoy a cool, damp-rooting medium, and although they will do well and flourish quite in the open, if they can be put where they will get a little shade from the hot afternoon sun their colouring will be more delicate. The one thing they dislike, and from which they must be protected, is wind. If they can be given a sheltered position, well and good; but if not the wise gardener will put strong, short stakes to support the flower-stems before the first bud begins to colour, otherwise, such is the brittle nature of the base of the stems, there will be breakages and unsightly plants before the flowering season is over.

Seed may be sown in gentle heat in mid-February and the seedlings pricked out in pans or boxes when they have made two or three proper leaves. They must be kept growing on in cold frames until towards the end of May or early June, when they should be nice sturdy little plants and may be safely transferred to a shady nursery border. Here they can remain (due attention being paid to watering and weeding) until September, when they can be planted in their permanent quarters. The following spring they will flower, but it will be nothing to what we may confidently expect the next year. I would advise everyone to have a few plants in a spare nursery bed, so that failures or poor flowers can be replaced after the first flowering. Personally I seldom keep any plants more than four years, often only three—new-raised seedlings are so much more vigorous and satisfactory. Seed should accordingly be sown every second year. If there is no accommodation for raising the young plants under glass, seed may be sown in a shady border in the open in well-prepared

fine soil any time after the severe frosts are over. It must, however, be remembered that, compared with that of many other plants, Columbine seed takes a long time to germinate, and one must not too hastily conclude, if it does not come up as soon as one expects, that it is no good. A similar routine of pricking out and planting must be followed with these open air seedlings as with those raised under glass.

Some firms now, such as Messrs. Dobbie of Rothesay, Messrs. Veitch and Sons, Chelsea, Messrs. Barr and Sons and the King's Acre Nurseries of Hereford make a speciality of these long-spurred varieties, and plants obtained from them in the autumn are sure to give good results if raising one's own seedlings is impossible.

#### AS POT PLANTS.

I have grown from twenty to forty Columbines in pots every season for the last few years, and each succeeding spring I seem to appreciate them more than the last. This is what I do: Early in September I get some good strong two year old plants and pot them up in ordinary good garden soil with some bone-meal with it. I cut all the yellow and dead foliage away, and when the operation is complete I stand them under a north wall, and there they remain until November or even December, when they are cleaned again and top-dressed and put into cold frames. I am careful to keep out frost, and about mid-February I bring the first batch into gentle heat. After a time, when they have well started, they are put into a warmer house. They are slow creatures to move, and I find they take at this early period of the year from six to eight weeks from the time they are taken out of the cold frame till they bloom. Green fly are very fond of the young growths, hence occasional fumigating is almost sure to be necessary to keep them in perfect health. As a rule, we put one plant in a 7-inch pot or three in a 9-inch or 10-inch, but, of course, everything depends on its size. Anyone who has had one year's experience will soon get to know what is best to do in this matter.

I cannot too strongly urge everyone who has not done so to give these long-spurred varieties a trial as pot plants. For cut flowers, as specimen plants in rooms or as a decoration for the conservatory or winter garden they are splendid, and their cheapness and the ease with which they are managed only need to be more widely known to make them more largely grown. J. JACOB.

## PRIZES FOR READERS. JULY.

### BOTTLING FRUITS AND VEGETABLES.

A First Prize of **FOUR GUINEAS**,  
A Second Prize of **TWO GUINEAS**,  
A Third Prize of **ONE GUINEA**,  
And a Fourth Prize of **HALF-A-GUINEA**  
are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Tuesday, July 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

July 7 and 8.—Royal Horticultural Society's Great Summer Show at Holland Park, High Street, South Kensington (by kind permission of Mary Countess of Iheater).

"The Garden" Flower Show.—We draw our readers' attention to the entry forms for our show which appear on another page. It will help us considerably if intending exhibitors will kindly fill them in and post them as soon as possible, and also if all rules are strictly observed. Judging by communications received the exhibition will be a most interesting one, and we hope as many readers as possible will exhibit and also attend the exhibition at Vincent Square on the 29th inst.

**Flower notes from the Franco-British Exhibition.**—In the French Garden and the Elite Gardens there is a goodly array of plants of various kinds from well-known French exhibitors, although in some cases the plants, especially Roses, Clematis, Gladioli, &c., were not yet in evidence. Messrs. Moser and Son of Versailles have several lots of Rhododendrons and Azaleas, among which we noticed in good form among the former Mlle. Therese de Vilmorin, Duc de Montpensier, M. Ch. Girault, Mme. Felix Guyon, M. Ch. Seguin, Claude Monet, Jacques Moser, M. Albert Viger, Ampère, Arago, Bengali and many others. Azalea pontica was represented by a number of President Carnot, Azalea hybrid de mollis by M. Hardy. Some fine plants of Azalea glauca stricta and Kalmia Pavardi were also included in the groups. Messrs. Millet et Fils of Bourg-la-reine showed Pæonies in goodly numbers; Albert Crousse, M. Calot, Mlle. Dessert, Marie Deroux, Flambeau, Emile Bourbon, M. de Chaunay, Pauline La Coquette, Louis Van Houtte, Mlle. Louise Calot and many more beside. The same firm showed an immense variety of Iris grandiflora. We can only note a few of them, Goliath, Druides, Virgilus, Edina, Empruss, Nigee, Sceptré, Verdita, Juliette, Haydeé, Aspaie, Calypso, Actéon, Bacchus, La Baronne, Louis Meyer, Justinian, Chloris, Orpheus, Alice, Soliman, Pajols, Victorine, Florentine, Amabilis, &c. M. Goyer of Limoges has a large display of Cannas, Roses and Clematis. At the present moment we can only note Pelargonium Paul Crampel and P. Alphonse XIII. The exhibits from other French nurserymen must be noted later in the season.—C. H. P.

### Roses and Sweet Peas at Kew.

No matter at what season of the year one visits the national gardens at Kew something of interest is always to be found and just now Roses abound everywhere. The sunk garden—appropriately known as the Rose Dell—that is situated close to the Pagoda, is at present a veritable dream of loveliness. Rose species and the stronger growing ramblers present themselves in the utmost profusion, that lovely variety Alberic Barbier being exceptionally good. Then the beds round the Palm House, wherein are planted those varieties of Teas, Hybrid Teas and Hybrid Perpetuals best suited for garden decoration, are a blaze of colour and a great centre of attraction. When one has had a surfeit of these, a short walk will bring the visitor to the pergola situated between the herbaceous ground and the rock garden. Here festoons of bloom present themselves in endless array, the colours in most instances being admirably blended. In the herbaceous border skirting the T range excellent clumps of Sweet Peas are producing their brilliant and fragrant flowers, and when one has tired of these a visit to the Berberis Dell is well worth while. Here huge spikes of variously coloured Foxgloves are towering over the blushing Pæonies, the rich colours of both these plants being admirably toned down by the purple and variously shaded green hue of the Barberries. Altogether

Kew is a place to live and be happy in at the present time, and this blending of the florists' and botanists' arts is a most pleasing and healthy sign of horticultural advancement.

## COLOURED PLATE.

PLATE 1351.

### THE YELLOW PÆONIAS.

(WITH A COLOURED PLATE OF P. DELAVAYII.)

FOR a number of years admirers of the brilliant Pæonia, than which there is no more handsome ornament to the flower garden, have desired one with yellow flowers. The species which for long most nearly approached that colour was P. wittmanniana, but it has not been found one of the best of growers with many, and it has also proved somewhat shy in blooming in many gardens, while its colour is not bright enough to meet the desires of those who sought for a really yellow flower in the race. We owe, however, largely to the researches of the Abbé Delavay in Yunnan the introduction of some species which give us flowers of a truer yellow, and these plants, first sent to France, have found their way into the British Isles, although only to be met with in the gardens of a few of the most enthusiastic seekers after new flowers. P. lutea, which was found in Yunnan in 1882, was sent to the Museum of Natural History in Paris, and has since been distributed, although still scarce and expensive. It has good yellow flowers, but it is in this respect surpassed by the variety major, which has more intense colouring.

Still another yellow Pæonia has been introduced, but under the cumbersome name of P. Makosewitsii, one sufficient to debar the plant from any garden were it not for its pleasing flowers. This, like the others named, has been cultivated in the garden of Mr. W. E. Gumbleton, Belgrove, Queenstown, to whom we are indebted for the flowers of Pæonia Delavayii, illustrated in the coloured plate, one of the latest to be introduced and also one of the best of its colour. Mr. Gumbleton is one of the most discriminating of flower lovers, and as he has made a special study of the yellow Pæonias for some years, it must be gratifying to him to have this species figured from flowers grown by him. The coloured plate speaks for itself and shows the beauty of this species, which, like several others, comes from China.

These yellow Pæonias require much the same cultivation as the ordinary herbaceous and Tree Pæonias, and prefer a rich soil and an open position, although they will also thrive in one which is shaded or semi-shaded. S. A.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### Primula obconica outdoors.

Having read in your "Answers to Correspondents" for June 20 a note on planting Primula obconica out of doors, it may interest you to hear that in the spring of 1906 I planted out in a border facing north two of these plants which had been flowering indoors. This was done experimentally, and I did not expect them to live through the winter, but both plants survived the winter of 1906-7, and when I was last at home I noticed that one of them was not only alive, but making fair growth and showing bloom. The position was fairly sheltered, but more exposed to a north-east wind than any other. The garden I am speaking of is that of Overbury Hall, Layham, Suffolk, and stands on rising ground exposed to the east and south, but is fairly sheltered by trees. T. H. DIPNALL.

**Ants in gardens.**—Referring to the note on the above subject in THE GARDEN of the 20th ult., it may be of use to some of your readers to know of a simple and effective way of exterminating these pests. I got the idea a year or two ago on a fruit farm at the Cape, where the ants were playing havoc among the tender young shoots of newly-planted Vines. We took a quantity of bran, sweetened and moistened it with golden syrup and water, and stirred in a small quantity of Paris green. This mixture we distributed among the Vines, putting about a teaspoonful at the foot of each. The ants quickly took to this pleasant mixture and—passed away! We prepared our mixture from no special recipe, but, as far as I can remember, used about half a medium-sized tin of golden syrup to a bucket of bran, with about two tablespoonfuls of Paris green and enough water to make all moist and crumbly. Here in England it might be advisable to protect the poison mixture, lest dogs, gardeners' children or birds should be tempted to eat it. At the Cape it was used quite freely in the open, and, as far as I remember, we had practically no fatalities, human or otherwise. As a matter of fact, for the killing of ants the Paris green may be used sufficiently diluted, and the mixture distributed sparsely enough to make the work of collecting enough to harm a child or a dog hardly worth while. Having seen the havoc ants will work among Peaches on a wall, I make no apology for sending this note.—CLARENCE ELLIOTT.

## NEW ORCHIDS.

### ODONTIODA × WICKHAMENSIS.

THIS is a very pretty little bigeneric hybrid, the result of crossing *Odontoglossum crispum* with *Cochlidia sanguinea*. It has rosy mauve flowers measuring about  $1\frac{1}{2}$  inches in diameter. The sepals and petals are ovate lanceolate, the rosy mauve ground colour being freely dotted with carmine spots. The flowers are produced rather loosely on a slender stem. Shown by Mr. G. W. Bird, Manor House, West Wickham. Award of merit.

### ODONTOGLOSSUM CRISPUM PRINCESS OF WALES.

This is a very fine variety of a most popular and variable Orchid, and has exceedingly large flowers of grand substance resembling somewhat in form the variety Prince of Wales. The sepals and petals are broadly ovate, the latter being beautifully serrated at the margin. The white ground is daintily suffused with purple. The labellum is of medium size, with dull, blood red and yellow markings. The habit seems very vigorous, the large flowers being placed rather thickly on a stout stem. Shown by Baron Schröder, The Dell, Egham. First-class certificate.

### DENDROBIUM JERDONIANUM.

A very pretty and rare member of this family, the deep golden yellow flowers being produced in rather dense clusters at the tops of erect, stout stems. The petals and sepals are very narrow and acute, and the labellum is nearly the same shape, but delicately crimped at the edges and of a deeper orange hue. The brownish grey stems are thinly clothed with rather small leaves. A handsome, well-grown and sweet-smelling plant. Shown by Sir Trevor Lawrence, Bart, K.C.V.O., Burford, Dorking. Award of merit.

### EPIDENDRUM VIRENS.

This, as its name implies, is a green-flowered *Epidendrum*, and it is also exceedingly free-flowering, the plant shown having four large compound racemes very freely clothed with medium-sized flowers of a pale green hue. The labellum is dull white, with faint, dull crimson pencillings. Shown by Sir Trevor Lawrence, Bart. Award of merit.

### BULBOPHYLLUM FUSCO-PURPUREUM.

A very curious little Orchid, the small purple and almost black flowers being borne on a pendulous stem. The sepals are comparatively large and very acute, the colour being dull purple. The two petals are represented by tiny thread-like organs, the blackish crimson labellum being the most conspicuous. Shown by Sir Trevor Lawrence, Bart. Botanical certificate.

### EULOPHIA NUDA.

A curious plant somewhat resembling a *Calanthe*, but with differently-shaped flowers. The rather small sepals and petals of these are bright green, and are erectly held. The lip is of medium size and white, with crimped or waved

TWO GOOD NEW CUCUMBERS: FAULTLESS AND EVERGREEN. (See page 324.)

margins. Flowers are placed rather thinly on stout, erect stems. Shown by Sir Trevor Lawrence, Bart. Botanical certificate.

### PHALENOPSIS LINDENII.

The plant shown was a well-grown specimen, and had a large, pendulous raceme of its pretty little purple and white flowers, which contrast well with the reddish brown line of the stem. Shown by Messrs. Charlesworth and Co., Bradford. Botanical certificate.

### LYCASTE TETRAGONA.

This has very curiously coloured flowers that are borne in a dense raceme on a short stem quite close to the soil, the large, erect leaves standing well above them. The dorsal sepal is very large and pouch-like, the large pitcher-shaped labellum resting snugly in this. The

colour of the sepals and petals is pale green, faintly marked with dull crimson, and the lip is cream and purple outside and rich purple inside. Shown by Messrs. Charlesworth and Co. Botanical certificate.

### VANDA PUMILA.

As its name implies, this is a very miniature member of the *Vanda* family. The plant shown was only a few inches high, and had two of its pretty little cream and purple flowers, the latter colour being represented by bright and distinct striations on the comparatively large lip. Shown by Messrs. J. W. Moore, Limited, Rawdon, Leeds. Botanical certificate.

All the above were shown before the Orchid committee of the Royal Horticultural Society on the 23rd ult., when the awards were made.

## "THE GARDEN" FLOWER SHOW.

### THE PACKING AND TRANSMISSION OF FRUITS, FLOWERS AND VEGETABLES.

THE date of THE GARDEN Flower Show, which is to be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Wednesday, July 29, is drawing near. Readers who intend exhibiting their produce at this exhibition will now be very busy making their final preparations. Many will be obliged to send their produce by rail; others will bring it with them and remain to enjoy the floral feast provided; but to all intending exhibitors the following hints will be of much service:

In the first place, I would impress upon them the advisability of carefully reading and complying with the rules printed for their guidance. By strictly adhering to these the exhibitors will benefit as well as the promoters of the show, the former by having their produce placed before the judges in good condition, and the latter by being able to devote equal attention to all exhibitors. If, for instance, some exhibitors fail to enclose their names and addresses with their exhibits, the officials would be put to much unnecessary trouble—trouble which can be avoided.

The following points should be remembered:

1. Strictly observe the rules.
2. Use stout, but not cumbersome, wooden boxes for packing the produce in.
3. Pack all goods firmly, so that they cannot move about and get bruised during transit.
4. Do not use cotton wool for packing cut flowers.
5. Do not pack flowers, and especially Sweet Peas, when the blooms are damp.
6. Have all packing material quite clean.
7. All boxes should be plainly labelled, "This side up, with care," and addressed to "The Manager, THE GARDEN, Royal Horticultural Society's Hall, Vincent Square, Westminster."
8. Boxes taken by the exhibitors themselves should be as carefully labelled, and every care taken to prevent mishaps.
9. See that each card is fastened to the particular exhibit for which it is intended, and do not lay the cards loosely in the boxes.
10. Do not put up five varieties nor seven where six are required. Put in the exact number specified, otherwise the produce may be disqualified.
11. Send the best produce, having regard to quality rather than mere size; but if you can combine the two, so much the better.
12. Consult time-tables and railway officials, and so be quite sure of having your goods at Vincent Square in good time.

**Cut Flowers in Water.**—Where cut flowers, such as Roses, are placed on show-boards in cups of water, care should be taken to prevent any water spilling. To this end the cups must not be filled too full, nor too little put in, as it would become exhausted during a long journey.

**The Condition of Flowers when Gathered.**—If a Rose bloom be cut on the morning of July 28, it should be in such a condition that by

the following morning it will be just sufficiently developed to show all its good points. If it is sufficiently developed on July 28, it will be too much developed on July 29. I simply mention this one case, but exhibitors would do well to apply the principle to all cut flowers.

*Selecting and Cutting Flowers.*—The early morning is the best time to cut flowers. The plants have been feeding and absorbing moisture during the night, and are much fresher than at the close of the day after exposure, maybe to brilliant sunshine. Cut all flowers with long stems attached at first, and place them in vases of water immediately in a darkened room which is cool. Do not place the vases on the floor, as there is a draught there, but on a table. Boxes painted green or black or brown attract the sun's rays, and then the flowers inside suffer more or less. Unpainted wood is best in summer time. If your boxes are painted any of the above colours, cover them with holland cloth.

*Fruit and Vegetables.*—It would be quite useless to send over-ripe fruit, as it would not be fit to stage on arrival at Vincent Square, but it should be as ripe as possible consistent with carrying well. Gather the fruits with their stems attached, and pack all in single layers in small, flat boxes, and then securely pack the latter in the travelling boxes. The small ones should not be nailed down—that is, the lids—but tied firmly with stout twine. Less trouble will then be experienced on arrival at the show building, and the contents will not be injured by the knocking in and taking out of nails. Use green leaves for packing the fruit in such as Gooseberries, Raspberries, Currants, Strawberries and Cherries. The first and the two last named should be placed each berry in a leaf. Plane, Fig, Vine and Lime leaves are suitable, also Strawberry leaves. The shallow boxes should be lined with leaves, and sufficient placed on the top so that when the lid is put on the fruit will be kept firmly in position. If possible, gather the Currants in clusters and deftly place leaves between each cluster. Apples, Plums, Pears and similar fruits should be wrapped singly in clean tissue paper and placed in the boxes, all vacant spaces being filled with cotton wool, and a layer of the same material put on prior to the fixing of the lid.

Although vegetables may be sent long distances by railway without being damaged, specimens intended for competition at a flower show should be as carefully packed as the most tender fruit or flower. It must be remembered that many persons are competing, that each one is sending up the best produce, and so every care should be taken to stage your vegetables in the best possible condition. For instance, as regards quality, certain dishes may be equal, but the one that is cleanest and freshest, being free from any bruises and discolouration, will be awarded first honours. So the difference between first and second prizes, and so on, may be determined by the packing.

Selection and preparation of the vegetables are two very important matters. The skins on Potatoes should be firm, not loose. When lifted expose the tubers to the air for one hour, then gently sponge off the soil and, directly they are dry, wrap each one in clean paper ready for the packing. Undue exposure to the sunshine and air would cause the skin to turn green. Turnips and Carrots should be raised from the soil with the aid of the garden fork. If violently pulled up the Carrots would be scratched by the stones in the soil. Sponge off the soil, do not use a brush. Leave the taproot on Turnips and some of the top growth as well, also on Carrots. Onions should not be peeled, simply remove the soil. Gather Peas early in the morning and pack the pods in boxes by themselves. Tomatoes should be packed similarly to Strawberries. Heavy vegetables, such as Carrots, Turnips and Potatoes, should be packed in the bottom of the box, and lighter kinds, such as Peas and Tomatoes, at the top. Do not confuse kinds and varieties. Avon.

## THE KITCHEN GARDEN.

### THE FRENCH SYSTEM OF GROWING VEGETABLES IN GLASS FRAMES AND UNDER BELL-GLASSES.

(Continued from page 300.)

**A**NOTHER method of preserving and protecting Lettuces in frames for winter use is to take up the full-grown plants with a bole of soil to the roots at the end of October and plant rather close together in these frames. By attention to picking off dead leaves and protecting from hard frost these Lettuces can thus be kept in fresh condition for months. A good way of obtaining an early spring crop of Cabbage Lettuces is by sowing early in January in pans or boxes, placing these in a heated frame or on the shelf of a greenhouse near the glass. Immediately the young plants are large enough to handle they should be transplanted 4 inches apart into these frames, which have been previously placed on a border in a sunny position, but not necessarily with a hot-bed under, where they will soon make good progress. Before the young plants touch each other every other one should be taken up carefully, with soil attached to its roots, and transplanted to a warm position on a rich border out of doors. Those left in the frame will soon make rapid progress, and be fit to cut early in May; those of the same age transplanted out of doors will soon follow. By sowing again at the end of January in a frame and pricking out on a warm border outside 5 inches apart as soon as large enough to handle, transplanting every other one before they touch each other as before, an unbroken supply can be obtained until Lettuces may be had in plenty in the open quarters. Half of the last sowing should be Cos Lettuce.

*Lettuces on Hot-beds in Winter.*—From the foregoing it will be seen that a long succession of Lettuce may be had in the course of the year in warm and sunny positions out of doors with the aid of these glass frames and bell-glasses alone. The time of most difficulty in obtaining a supply is from January to the end of April, and this is the time they command the highest price, for the production of which recourse must be had to the assistance of hot-beds and glass. The middle of November is a good time to commence the formation of these beds. They should be made up of fresh stable manure (well shaken and mixed beforehand) to the depth of 2 feet and 7 feet in width (2 feet wider than the frames are long) to allow of linings of warm manure in cold weather. The length of the beds will be determined by the number of frames used, allowing a space of 1 foot between each frame for lining. The frames are chiefly used for Cabbage Lettuce and the cloches for Cos varieties. The frames being 20 inches deep, the bottom part to the depth of 6 inches may be filled with the same manure as that forming the bed, treading it hard down and placing on this 7 inches of light soil well enriched with rotten manure, pressing it slightly down to plant the Lettuces in, thus bringing them within 7 inches of the glass and close to the light.

The seeds intended for this first winter crop should have been sown early in October in frames, and the young plants transplanted as soon as large enough, as recommended before, so that by the time the frames are ready they are good sturdy little plants, and if carefully planted 8 inches apart with a body of soil to the roots, they will immediately start into growth under the genial influence of the heat of the hot-bed, which should range at this time from 55° Fahr. to 58°, and to prevent its falling at any time below 50°, recourse must be had to filling the spaces round the frames with fresh manure as linings, and to covering the frames with mats or litter at night. More care is needed in the growth of these Lettuces than of those spoken of

before, on account of the moist heat in which they are growing and the susceptibility of the leaves to damp off. To prevent this a little air must be admitted on every favourable occasion and decayed leaves picked off as soon as discerned. In planting it is important to select the plants all of one size as near as possible; by doing this they are fit for cutting at the same time, and the frame immediately ready to receive another crop.

The seed for the next crop should be sown about October 20 in one of the frames on the hot-bed, and treated as before described, sowing again the middle of November and early in December for the last time.

The preparation of the beds should be the same for cloches as for frames, leaving spaces of 10 inches between each for linings. These linings may be planted in spring with Cos Lettuces when no longer wanted for warmth. The most common way of planting the cloches is with one Cos in the centre and four Cabbage Lettuces round it; these are fit to cut before the Cos, thus making room for it to develop into a large specimen.

The crops in the frames are over by the middle of May and occasionally before, and the question now arises what crops to grow in them to the best advantage during the summer and autumn. Melons, I think, are the most popular, and when well grown are as remunerative as most fruits. Two plants should be planted in each frame, and each plant stopped at the fourth leaf to induce it to form side shoots; two of the strongest should be selected and encouraged to grow prostrate on the soil. Each of these shoots (there being four from the two plants) should produce two fruits each, giving, say, from six to eight fruits to a light, and as it is quite possible to produce two crops of Melons before the end of October, each frame is capable, in experienced and industrious hands, of producing sixteen Melons, which at 2s. each and the value of the Lettuce crops would amount to a considerable sum. Those who are curious in the matter may find out for themselves approximately the returns which can be had from these crops under this system by finding out the number of frames it takes to cover an acre. OWEN THOMAS.

(To be continued.)

### TWO GOOD NEW CUCUMBERS.

It is seldom that we see two such excellent Cucumbers as those illustrated on page 323, and this pair is particularly interesting on account of their parentage. The one on the left is named Faultless, and is the result of a cross between Market Rival as the seed parent and Improved Telegraph as the pollen parent. That on the right is named Evergreen, and in this instance the same parents were used but the process of crossing was reversed, i.e., Improved Telegraph was used as the seed parent, the pollen being obtained from Market Rival. As will be seen, Faultless is rather the longer of the two, but both are of excellent shape. They were raised by Mr. S. Mortimer, Farnham, Hants, and shown by him at the meeting of the Royal Horticultural Society held on the 9th ult.

## THE FRUIT GARDEN.

### LATE MELONS.

**W**ELL-GROWN late Melons are generally much appreciated, and when one has suitable convenience for producing them special efforts should be put forth to ensure a supply during September and October. Generally speaking it takes from three to four months from the time the seed is sown till the fruits are ripe, according to the season and the methods under which they are grown. Probably no fruit varies so much in quality as the Melon, and practically everything

depends not so much on the variety but on the cultivation, for unless the fruit is properly matured and well ripened the flavour will be indifferent. Some of the oldest varieties are, in my opinion, quite equal to many of the newer sorts when grown to perfection, and though I do not wish to say one word in disparagement to those who have done so much in introducing the newer varieties, I am anxious to point out that however good these may be they are inferior when cultivated in an unsatisfactory way to the older varieties when well treated. In my opinion the chief causes of failure may generally be attributed to insufficient drainage, soil too close in texture and allowing the plants to become infested with insect pests such as mealy bug, red spider and black aphid. These are sufficient to account for deficiency in flavour and that highly finished appearance which all experts in Melon culture are only too well familiar with.

#### RAISING THE SEED.

Seeds should be sown singly in well-drained, clean 3-inch pots, and raised in a gentle heat. Immediately the young plants have made their appearance through the soil place them on shelves near the glass, and after the second rough leaf is made pot on into 5-inch and 6-inch pots; bury the stem to the seed leaf and make moderately firm. Place a neat stake to each and give the plants all the light possible to encourage a stout, short-jointed growth. I cannot say how long Melon seed retains sufficient vitality to germinate, but when kept under proper conditions I have known it to do so after fifteen years, but the older the seed the more care will be required in making it grow and little water must be given.

#### STRUCTURES.

Though Melons are a success both in heated pits and portable frames on hot-beds far better results are assured when suitable three-quarter or span houses are available, specially during late summer and early autumn, as the days get shorter and the sun-heat less.

#### COMPOST.

Few gardeners, and specially the less experienced, are fortunate enough to be able to say that they have never been troubled with what is known as canker or the rotting of the stem. This may occur in any part of the plant, either at the base, quite near the soil, or on any of the leading branches, and this generally happens about the time when the fruits are in the final swelling. Many remedies have been suggested as a cure, but I have never met with anything effective, the result being that the fruits, if sufficiently advanced, are prematurely ripened and are practically worthless. All sorts of causes are attributed to this, the chief one being the indiscriminate use of water, and many people take the utmost pains not to let any go near the base of the plant, but I have long been convinced that the chief and practically only cause is insufficient drainage, and especially a non-porous state of the soil. In my younger gardening days this troubled me considerably until an old gardener friend, who was a most successful cultivator and exhibitor, gave me some advice, which I have never failed to follow. Use plenty of drainage at the bottom of the bed, and instead of having all loam have one-half of this and the other half of river sand with a little finely broken charcoal added. Since then canker has never troubled us. The plants at first may not grow so strong but the fruits will set more readily, the water passes away quickly and when a good crop is assured feeding will soon put sufficient size and vigour both into foliage and fruit. The soil should never be allowed to become dry except in the last stages of ripening, the fruits being supported with either suitable nets or small wooden supports looped up to the wire at each corner. Every means should be taken to keep the foliage and growths clean and healthy till the ripening is completed.

Herts.

E. BECKETT.

## THE FLOWER GARDEN.

### THE LUPINES.

**B**ROADLY speaking, the Lupines may be divided into three groups, viz., annuals, perennials and those of a shrubby character, each alike valuable. The number of sorts met with under cultivation in gardens is comparatively few, those most frequently seen being either annuals or perennials. Taking them all in all, not only are they a beautiful and interesting, not to say useful, group of plants, but they are all of them of easy cultivation in any good garden soil. Especially beautiful and varied are the numerous varieties of annuals, which may briefly be described as among the most ornamental of summer-flowering plants. These may be sown in the open ground in March or April, or in successional batches in both months, where they are intended to flower, or they may be sown thinly in pots and transplanted. The perennial sorts are also among the easiest plants to grow, and given a good depth of soil

The shrubby sorts are of equally easy culture, and may be increased freely by seeds or by cuttings slipped off with a heel attached in summer time and inserted in sandy soil in a cold frame. In this way *L. arboreus* roots freely, or self-sown seedlings may be obtained in the vicinity of the old plants.

*L. arboreus* (the Tree Lupine) is a native of North America, from whence it came to our gardens just a little more than a century ago. The pale yellow and fragrant blossoms of the type are abundantly produced, and when the plant attains to a good size it is most effective either in the shrubbery or as an isolated specimen. When fully grown it is several feet high and often 6 feet through, while its silvery and somewhat downy leaves render it quite distinct. It is also an excellent plant against a wall having a western aspect. The best known of the perennial varieties are:

*L. polyphyllus*, shown in the illustration, a bold, free-growing perennial attaining 4 feet to 5 feet high and having handsome spikes about 2 feet or more in length, of blue, lilac, purple or white flowers. Raised from seeds this is a some-

LUPINES IN MR WILLIAM HUDSON'S GARDEN AT SURBITON.

into which they may root freely, they quickly form handsome bushes. These when in flower are most effective. The perennial varieties are readily increased by division and also by seeds. When dividing the plants it will be found a good plan to pierce the prong of a small hand fork into the woody rootstock and then wrench the plants asunder. This is a safer method than using a knife for many things, the latter often causing the loss of many valuable roots. In the case of a good strain of *L. polyphyllus albus*, for example, division is the only certain way of increasing it. Notwithstanding, good white strains are obtainable from seed, and though the white *polyphyllus* may easily be distinguished by the foliage alone, there is a good deal of variation in point of purity in the flowers.

It is a good plan with these late spring-flowering plants to propagate them by division early the previous autumn. By so doing they gather strength before flowering time comes round. There are few perennials capable of producing a finer effect in the garden than well-grown and equally well-flowered examples of this white Lupine. An old and common plant it may be, but one of the finest notwithstanding.

what variable plant in point of colour, while *L. grandifolius* is a distinct large-leaved form of this plant, also known as *L. macrophyllus*.

*L. nootkatensis* is a plant of dwarfier and more compact growth, seldom more than 2 feet high. The predominant colour is blue, mingled with more or less intense purple, with veins of a deeper hue. A neat and showy border plant.

The above are those most frequently met with in cultivation, while such sorts as *laxiflorus*, *leucophyllus* and *sub-carnosus* deserve to be more frequently seen than now. Among the more tender varieties *L. mutabilis* is deserving of notice as worthy of cultivation.

### ZEPHYRANTHES AUREA.

THIS is a very beautiful species from Peru, with erect, funnel-shaped blooms nearly 3 inches across and of a rich golden orange colour. The solitary flower is produced at the summit of a scape 1 foot high, having a slightly glaucous tendency. The narrow, deeply channelled, acutely-pointed leaves are about 1 foot long, shining, distinctly lined above and glaucous beneath for about half their length when this

characteristic passes away. The plant was originally received from a friend in Peru by Sir Trevor Lawrence's son in South Africa, and by him sent to England. At its first flowering the plant was leafless, while the example exhibited before the Royal Horticultural Society on the 9th ult. was well equipped with the foliage already described. It was shown by Sir Trevor Lawrence, Bart., Dorking, and given an award of merit.

### VIOLA ELATIOR.

A CHARMING *Viola* as yet but little known, although not by any means new to British gardens, is *Viola elatior*, a native of Northern Asia and the Orient, which must not be confounded with another *V. elatior*, now referred to as *Viola canina*. The true *V. elatior* is a very distinct and beautiful species, which I had for some years, but lost accidentally, and was glad to replace a couple of years or so ago. My own plants are in a semi-shady place, partly beneath the branches of *Cornus sibirica flavi-ramæa*, and in the half-shade the *Viola* is charming with its soft green foliage and delicately-coloured blue flowers with a little white in the centre. It is an erect grower and is of slender and graceful habit, and with me at present is about 9 inches high. *Viola elatior* does not seem to be at all common in the nursery trade, but it is a plant worth looking after by amateurs and also by dealers in hardy flowers.

Dumfries.

S. ARNOTT.

### PRIMULA SIEBOLDII OUTDOORS.

THE group of *Primula Sieboldii* illustrated on the opposite page is growing in Mrs. Jessopp's garden at Forty Hill House, Enfield. The soil there is deeper and more retentive of moisture than in my garden, and many plants that love cooler conditions flourish there in a manner that astonishes me and often makes me somewhat envious. *Erythroniums*, *Violas*, *Iris*es of the *Juno* section, *Narcissus cernuus fl.-pl.* and many forms of *Primula Sieboldii* all show a degree of luxuriance and a tendency to increase quite unknown, unfortunately, on this side of the road.

The group shown is one of several broad bands edging herbaceous borders. It is composed of the varieties known as *Miss Ryder* and *Bruce Findlay*. They have been planted about five years and face the south-east, but after midday they are shaded from sunshine by some stable buildings and sheds. *Miss Jessopp* tells me she gives these groups a good top-dressing of leaf-mould annually, preferably in autumn, but if not convenient at that season it can be deferred till spring. Other varieties that are doing equally well are *Ware's White*, *Maiden's Blush* and *Lilacina*.

E. A. BOWLES.

### GLASNEVIN NOTES.

#### CALTHA POLYPETALA.

THIS plant is a native of Asia Minor, and stands out as a giant among the Marsh Marigolds. Disparaging remarks may already be heard about *Caltha polypetala*, which shows it is not a plant for everyone, but if seen under favourable circumstances, as at Mr. Walpole's garden in County Wicklow, one must acknowledge the plant is all

that it claims to be, i.e., a bold, handsome and magnified version of the common Marsh Marigold.

At Glasnevin the plant grows very freely, but does not flower so profusely as the common one. It is planted in good rich soil in a bog bed, where it is often flooded during the winter, so there should be no doubt of its hardiness. The flower-stem reaches about 3 feet in height, bearing flowers of a bright golden yellow from 2 inches to 2½ inches in diameter. After flowering a great amount of growth is made, and some of the leaves are now 10 inches by 12 inches in width, rising on stout petioles to nearly 3 feet in height.

There is a peculiarity about the flower-stem which is worth noting, for it will be seen that

A NEW ZEPHYRANTHES: *Z. AUREA*. (Natural size.)

the nodes, where the stem branches, seem to emit roots with great freedom. Last year the flower-stems were pegged down and covered with soil, and from each node thus treated leaves appeared, and eventually young plants were formed, which have grown strong enough to flower this spring.

Seed was also saved and sown here last year, and a nice young batch of plants was obtained. Careful watching is needed to gather the seed, for the follicles split while almost green. The seed should be sown, soon after gathering, in pots placed in a cold frame, and if it is good the seedlings should appear in about six weeks.

C. F. BALL.

## THE ROSE GARDEN.

### SECRETS OF ROSE CULTURE.

ROSES that are let severely alone during summer will not prove glorious bloomers, and any autumn varieties among them will be especially unsatisfactory. It is necessary to give Rose trees food and drink, protect them from weather ravages and free them from insect pests, also sometimes cure them of diseases if they are to yield plentiful and perfect flowers. During the warm months the culture of Teas and Hybrid Teas is identical with that of Hybrid Perpetuals, Polyanthas and the various hardy Roses; it is only in winter that the delicate types require to be sheltered with Bracken Fern, moss litter, branches, sacking or other methods. Because Roses have been autumn planted in well-manured soil it does not follow, as is often believed, that they can do without feeding when they are lavishly producing buds and opening blooms. There are various encouraging kinds of artificial manures that do wonders when applied in April; but if this work has been neglected we must fall back upon other kinds that are suitable for use alternately twice a week until the end of August, or I should say until the middle of September, since our seasons appear to be changing and there are now prolific Rose displays during October.

A splendid liquid manure can be made with half an ounce of nitrate of soda dissolved in a gallon of water, and this is so simple that its concoction will not bother the least experienced gardener. More elaborate, but almost essential, is another made of half an ounce of superphosphate of lime, a quarter ounce of sulphate of iron, a quarter ounce of sulphate of ammonia, in 2 gallons of water. To use these alternately, one on Monday and one on Tuesday, will produce splendid results, or a reliable fertiliser will do as much service perhaps as the second of these manures prescribed if used at the rate of half an ounce to 1 gallon of water. Liquid manure must never be applied to dry soil, as its action will be scorching and far too powerful. If rain enough has not fallen to saturate the earth thoroughly, a canful of water, rain water preferably, should be given to each Rose, two canfuls or a pailful not being too much for a strong standard, large bush or tall climber. After the soil has dried up almost on the surface the liquid manure should be given, and will then go straight to the nourishment of the roots. I always employ soot water once a week in addition to manures, because I think it helps the foliage to maintain a healthy green and also sweetens the earth, ridding it of many insects.

It will generally be found that a fine autumn crop of Roses is gained from trees that have been copiously cut during the summer. There are two recognised pruning seasons, the end of March or early April and October, but I am of opinion that Hybrid Perpetuals and Teas cannot be expected to go on blooming well until the coming of winter unless they are considerably cut about the middle of August, or rather earlier, after the first blooming is done and the second has not commenced. As stated above, if the Roses have been freely cut, with long stems as

they look best in our vases, the trees will be in a fine healthy state to begin making new flower-shoots, and no summer pruning should be done. Some Rose lovers will not allow their flowers to be gathered, only snip off short-stemmed dead blooms, and are then foolishly surprised because there is no luxurious autumn harvest. Frequent hoeings of the soil are necessary to keep it from being baked hard by the sun.

As for watering Roses, it is essential; trees may live through spells of drought, but their productiveness is checked and their health ruined; they become liable to many kinds of disease and will soon be covered with vermin. Merely wetting the soil of a Rose bed does more harm than good, but twice a week at least thorough root soakings should be carried out and the liquid manures given afterwards.

Without making a profound study of Rose diseases the amateur gardener will be able to see when mildew has attacked foliage; every fragment of spoilt foliage should be picked off and burnt, not cast on the ground at the foot of the bush. There are plenty of good insecticides advertised, and to wash the leaves and stems with these often frees them from every sickness and pest for a whole season. Syringings are resorted to in large gardens, because washing every leaf and stem would be so great a work, but I believe the more thorough method proves less time-occupying in the long run, and ensures that no buds or blooms are spoilt by the liquid. The attacks of green fly are bound to come with the summer; the daily use of an aphid brush is the best remedy for this. The Rose maggot is equally sure to put in an appearance, but as it shows his presence by curling up some leaves, it can be easily detached and destroyed.

Growers of exhibition Roses take care to limit the number of buds and also of branches, because the nourishment that will produce enormous thick-petalled fully double blooms will not suffice to feed innumerable quantities of stalks and leaves as well. J. D.

#### ROSE BLOOMS WITH GREEN CENTRES.

We are receiving many complaints this year of Rose blooms coming with green centres. In our opinion they are the result of late frosts affecting the buds when in embryo. One remedy against this is to prune late, and when pruning cut past all forward shoots to good dormant eyes. Some Roses are specially given to these green centres, Annie Wood being notably so, and many of the

A CURIOUS ORCHID, RENANTHERA COCCINEA, AS GROWN BY MR. CHARLES HICKS, PATCHING, WORTHING.

very double Roses are prone to it. Sometimes indiscreet disbudding is responsible for the malformation. Obviously if the sap that supports five or six buds is suddenly diverted to one bud by the removal of the others, this sudden influx of sap is liable to cause distortion. Where the soil has been heavily manured we have found many blooms become ill-shapen, and we also think the trouble may be caused by the late spring frosts, although the flower-buds coming among the green centre points to a soil too rich for the plants. We advise the removal of the buds as they show these green centres and trust to the second crop of blossom for better results.

#### ROSE CONRAD FERDINAND MEYER.

ONE is constantly receiving excellent accounts of this grand hybrid rugosa Rose, and all who

know it must admit that it is a very fine variety, worthy of extensive planting. As an individual bush it is fine, especially where the last year's wood has not been pruned back very hard; but it appears best in a large mass in the wild garden, or anywhere in the garden where a bold, tall mass of colour and beautiful foliage is desired. I believe Dr. Müller first raised a seedling from a cross between Gloire de Dijon and Duc de Rohan, and this seedling was employed as pollen parent upon the rugosa Rose Germanica, a variety of Dr. Müller's raising, so that we have quite a mixed parentage. There can be little doubt that this sort of crossing and recrossing has given us some of our best recent novelties, and I believe Grüss an Teplitz originated in the same way.

In a very able paper read before the American Rose Society on March 27 of this year Mr. Alexander Dickson gives a most interesting account of some of his experiments, mentioning among other facts that Mildred Grant originated from a seedling which was obtained from Niphetos and Mme. Willermoz in the first instance and afterwards crossed again with another seedling not in commerce. M. Pernet-Ducher informs me that some of his wonderful coloured productions have been obtained by using as pollen parents one or two specially good seedlings from a colour point of view. This all goes to prove that there is much more in the cross breeding of Roses than one might imagine. P.

#### RENANTHERA COCCINEA.

THIS beautiful and curious Orchid is not met with very frequently, owing possibly to its being somewhat difficult to cultivate. As may be seen by the accompanying illustration, it is of a rather straggling habit and needs to be trained up the roof or on an old Tree Fern stump or similar support. It requires an even, warm, moist temperature with a light position. The beautiful and curiously shaped blood-red flowers are very attractive, and the long aerial roots give the plants quite a distinct appearance. The plant was introduced to this country from Cochin China in 1816. We are indebted to Mr. Charles Hicks, Patching, Worthing (who grew the plant), for the photograph from which our illustration was prepared.

PRIMULA SIEBOLDII, GROWING IN THE OPEN IN MRS. JESSOPP'S GARDEN, AT FORTY HILL, ENFIELD.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**ROSES.**—Constant attention is required at this period. Small details, such as removing deformed flower buds, carefully overlooking the plants for grubs and caterpillars—and this should be done pretty frequently—and thinning the more crowded clusters of buds. I am applying liquid manure in the case of all Roses that are well established. Should the weather be wet and showery, I invariably apply a light dressing of some reliable concentrated guano or manure instead of using manure water. Shoots that are infested with aphides should be syringed with quassia and soft soap solution. Another remedy is to boil for fifteen minutes 1lb. of soft soap in a gallon of water, then add a pint of paraffin oil and thoroughly stir the solution so that the whole of it is well mixed. When ready, place in a large air-tight vessel and use as required. A pint of the solution mixed with 7 gallons of water makes an excellent insecticide.

*The Flower Garden.*—Watering is important during spells of hot dry weather. Not only should the plants receive copious applications during these periods, but each should be followed with an equally free supply of manure water. Such attention assists the plants considerably during an important and trying season. Let the watering be done always in the late afternoon or evening; staking and tying must be observed continuously. As one subject succeeds another in the hardy flower garden, its requirements in this respect must be anticipated, otherwise the growths will soon become unruly and many shoots be broken and thereby lost. Dahlias need plenty of water just now, and to be staked and tied regularly. Take note of the better Pinks at this season, marking those it is desired to increase. The Pinks are increased by simply pulling the old plants to pieces in September, taking care, however, to retain a small portion of the old, firm wood. Plant these pieces firmly where they are to flower if convenient, and they should produce a beautiful display next season. Stake Carnations before they get unwieldy and difficult to control. Leave the tie loose though quite securely attached to the stake. Many hardy annuals may still be sown to flower in the late autumn. The Aquilegias (Columbines) and Wallflowers may be sown at the present time for flowering next year in the early summer. These

2.—DIVIDED PORTIONS OF THE PLANT SHOWN IN FIG. 1.

1.—PLANT OF A TYPICAL VIOLETTA, SHOWING ITS STURDY, SHORT-JOINTED GROWTHS AND IDEAL TUFTED HABIT.

plants prefer a sunny border outdoors, just covering the seeds with soil and maintaining the latter in a slightly moist condition during the period of germination. Mulch Phloxes, Starworts and other equally vigorous growing things.

*Trees and Shrubs.*—Privet hedges so frequently met with in suburban gardens are making rapid growth just now; for this reason see that they are trimmed pretty frequently and kept well under control. Laurels and Hollies need to be pruned at this season. Do not make the common mistake of using shears, but prune them into shape with a knife. Climbers on walls and fences should be properly trained and this work done in good time, otherwise the growths will get hopelessly entangled and the general effect spoiled. Cuttings, 4 inches to 6 inches in length, of the variegated Privet, if inserted now in a rather shady border, will root quite readily and make nice little plants by the autumn. Remove spent blossoms and seed-pods from the hardy Azaleas and Rhododendrons without further delay. Shrubs that have been growing in pots for window decoration should be plunged in their pots in the garden, taking care, however, to place a piece of slate or some other hard flat substance underneath them to prevent the ingress of worms through the hole in the bottom of the pots.

*The Vegetable Garden.*—The free use of the hoe is invaluable at this period, by these means keeping the weeds under and aerating the soil which promotes growth.

*The Greenhouse.*—Cyclamens that were sown at the close of last summer in boxes and subsequently pricked off into other boxes, then into 3-inch pots, are now being placed in those 5 inches in diameter, in which they are to flower.

Suitable soil for these plants consists of two parts good fibrous loam, one part leaf-mould, with plenty of coarse silver sand to make the compost porous, and a 5-inch potful of guano to every bushel of soil, all well mixed. Cinerarias and Chinese Primulas do well in similar soil. Shade flowering plants from bright sun or their display will be very short lived. D. B. C.

## HOW TO INCREASE THE VIOLETTAS.

The Violettas or miniature-flowered Tufted Pansies are a race of plants of which comparatively little is yet known, but which are so very beautiful and interesting that there is no reason why all interested in the hardy flower garden should not acquire a collection and make the most of the present season's opportunities. These miniature-flowered Tufted Pansies are the result of a cross made with the ordinary garden Pansies and *Viola cornuta* of the Pyrenees, the result of this cross giving us now quite a wide range of colours and flowers that in form are identical with the parent plant, which was named Violetta, and others differing in a more or less degree. These plants are specially well adapted for the rock garden, where, if planted in colonies of a dozen to twenty or thirty plants in each and the colours grouped with some consideration for colour effect, their beauty is most pronounced. They are plants of the simplest possible culture, and may be increased and perpetuated with comparative ease.

As an instance of the method by which they may be increased, the illustration portrayed in Fig. 1 shows a small plant that has been lifted from the open border, in which are revealed several sturdy, short-jointed growths. These

3.—VIOLETTAS GROWING IN A SEED-PAN.

plants may be propagated at almost any period, provided means be taken in the hot midsummer season to shade them from the trying sun and keeping the soil moistened immediately subsequent to the division of the old plant. We prefer to divide the old plant to any other method of increasing them, as by these means numerous pieces are obtainable from each plant, each shoot having roots adhering, which ensures speedy progress and the development of a useful plant in a comparatively short time. It is a simple matter to divide the plants, as they may be broken asunder quite easily, as the illustration in Fig. 2 aptly portrays. Here will be seen several pieces in various stages of development, some individual shoots, others with two or three sturdy shoots in one piece, and quite little tufts

4.—ROBBIE JENKINS, THE SMALLEST VIOLETTA IN CULTIVATION. THE FLOWER IS LESS THAN AN INCH IN DIAMETER AND OF SPLENDID FORM.

in others. Should stock be scarce and the grower desire to make a number of plants of any particular variety, each little shoot may be torn asunder from the main plant and will most assuredly root, and that quickly. The *Violettas* delight in soil that has been well tilled, and also well broken up. The plants desire a free root-run, and for this reason the ground should be trenched, if possible, and plenty of gritty substance worked into the soil, together with a good quantity of well-rotted manure. The plants may also be grown successfully in pans of deep structure; and Fig. 3 well portrays a number of specimens that are growing quite satisfactorily in a pan that was planted a few months since. These plants are so hardy and take so kindly to division and removal at almost any period of the year that pans may be made up at any time.

The illustration here referred to shows how free-flowering the plants are and their dwarf and sturdy growth, with the flowers carried well above the foliage. The soil should always be maintained in a cool condition, and the plants in pans will then continue to flower over quite a long period. If slight shade from the hot midday sun can be afforded, this will be greatly appreciated by the plants, no matter where they are growing.

In Fig. 4 we give an illustration of what is really the smallest *Violetta* in cultivation. It is distributed under the name of Robbie Jenkins, and is a free flowering dainty little plant. We have this growing in pans, and the appearance is something quite unique. The flowers are highly perfumed, and growing on the rock garden the effect is very sweet.

The following varieties are some of the most interesting: *Cynthia*, a pale blush lilac of oval form; *Diana*, a pretty primrose flower; *Eileen*, a charming deep blue flower; *Estelle*, the smallest of the miniatures, pure white; *Grace*, purest snow white flower; *Lavinia*, a beautiful blush lavender, veined a deeper shade; *Miss G. Jekyll*, a dainty little bicolor, orange and primrose; *Mona*, a charming little deep blue flower; *Olivia*, an interesting flower, colour white, tinted lavender blue; *Proserpine*, palest blush, almost white; *Purity*, an improved form of the original *Violetta*; *Queenie*, white, broadly margined, bluish lavender; *Robbie Jenkins*, one of the smallest *Violettas*, white, flushed yellow; *Rock Blue*, charming little deep blue flower, rayless; *Rock Yellow*, dense yellow; *Sweetness*, another minute blossom, white, tinted blush; *Thisbe*, beautiful pale blush flower; and *Vestal*, beautiful flower of the purest white.

## THINNING AND STAKING HERBACEOUS PLANTS.

Now that growth is very active among the stronger-growing herbaceous plants the task of thinning and staking the growths is one of the utmost importance, yet it is one that the beginner in gardening is frequently apt to overlook until much irreparable damage has been done. If we examine a vigorous specimen of perennial Sunflower, *Michaelmas Daisy* or similar plant at the present time we shall find a host of growths pushing their way upwards towards the light as best they can, and we shall also find that many of them have already become weak and attenuated and in risk of being entirely overwhelmed by their stronger brethren. Obviously it is useless to retain these weak shoots, as they will never be capable of producing flowers worthy of the name, and the nourishment they require for their sustenance may with advantage be diverted to the strong ones allowed to remain.

Just how many shoots should be left will depend, of course, on the individual plant, but for most subjects three, four or five growths to a clump will be ample. In any case, each growth that is left should stand quite clear of its neighbours, so that it has a good opportunity of developing its best traits. In removing weak and other shoots not required it is best to cut them just below the surface of the soil. Even then some kinds are apt to sprout again; but by the time they do so the growths left will have made such headway as to render these secondary shoots of little consequence.

Staking is an absolutely necessary adjunct to thinning, and it must be performed at a comparatively early stage of the plant's career if the subject dealt with is to derive the full benefit of the supports. Although staking has been written about very frequently indeed, one still encounters bad examples of such work, hence no apology is needed for describing it again. It will be obvious, even to the veriest tyro in gardening, that it is useless to thin out the growths of plants and then tie those that remain into a bundle that resembles more than anything else the umbrella so consistently carried by the famous Sairy Gamp, yet this is what frequently happens. A stake is thrust into the centre of a clump and all the shoots are drawn up rather tightly to it, with the result that growth is impeded to a very serious extent.

Far better is it to place a neat stake to each growth so that it may remain in as natural a position as possible. This system has its drawbacks on account of the number of stakes required, but it pays in the end. Those who live in the country may easily make one stake, or at the most two, suffice for each clump, but the right sort of stake must be selected. Where hedge-wood is available it will be a fairly easy matter to secure stout stakes that have rather thick lateral growths, and these latter should be cut so as to leave 6 inches or more of each on the central stake. When one of these is thrust firmly into the centre of the clump the lateral growths are splendid for tying the shoots of the plant to without unduly crowding the latter.

All supports should be so placed as to render them as inconspicuous as possible, as a garden in which stakes overwhelm the plants is most unsightly. Tying is another point where many amateurs go astray. Frequently one meets with plants which have been tied so tightly to the stake that the tying material is cutting into the growths. It should always be remembered that shoots

swell and lengthen, and room for this natural function must be afforded. With such things as *Carnations* there is a danger of the stems buckling seriously owing to tight ligatures, the leaves getting caught as the growth extends upwards. During recent years raffia or bast has been superseded by raffiatape, an excellent green material that has all the advantages and none of the disadvantages of raffia.

Unless early staking and tying are resorted to, the stems of plants will take a more or less recumbent position, after which it is well-nigh impossible to get them in presentable condition. All supports should be thrust firmly and deeply into the ground, and in wind-swept situations it is an advantage to place them at the opposite side of the plant to that from which the strongest winds blow.

## THE CARE OF LAWN MOWERS.

THE frequency with which one encounters these useful machines creating a noise that is far from musical, and certainly altogether different from the smooth, humming noise a properly managed mower should make, leads one to reasonably assume that the amateur, as a rule, gives very little attention to his or her machine, with the result mentioned above, coupled with inferior work. Consistent attention to a few small details will make all the difference in the running and life of a lawn mower, hence no apology is needed for drawing attention to them.

In the first place, the blade and knives must be set so even that one almost, but not quite, touches the other. There is no more important item in connexion with a lawn mower than this, but owing to the numerous makes of machines now on the market it would be useless to give detailed information on how to set the knives or blade. What the amateur should avoid is any tinkering about with these parts of a mower when the latter is performing its work satisfactorily. Should the knives or blade get out of gear it would well repay the inexperienced to get some practical gardener to readjust them.

Then, again, every time the machine is used each part ought to be thoroughly cleansed so that it is free from all dust, grass or other substances. An old spoke brush is very useful for this purpose, and after removing dirt all bright parts should be rubbed over with an oiled rag. All bearings, too, must be oiled and the quality of the oil used will make a considerable difference in the running of the machine. Only that of the finest quality should be used, and it will be found to keep the bearings much cleaner if a little paraffin is added to it. To get the best possible work out of a lawn mower the handle or handles should be movable, so that they can be adjusted to suit the height of the person using it.

5.—A NUMBER OF VIOLETTA FLOWERS, SHOWING THEIR DIVERSITY OF FORM.

## THE TOWN GARDEN.

**DEAD FLOWERS.**—To speak of dead flowers will, perhaps, cause some of my readers to think that we are approaching the end of the season instead of being on its threshold, but it is so important that they shall be removed early and regularly that the matter is referred to now. The rule should be to cut off every flower as soon as it has passed the zenith of its beauty, so as to preclude the possibility of any seed pod formation. Of course, this is more important with annual plants than it is with any others, but no exception ought to be made, for if the seeds do not materially prejudice the longevity of the plant's beauty they always create a more or less untidy appearance in the garden; therefore remove every one and do it early. On the score of neatness dead or decaying leaves should be similarly dealt with, and it is quite certain that the grower will find the time devoted to the operation generously repaid.

**LEAF-MINER IN MARGUERITES.**—This is one of the worst pests with which the grower of the graceful Marguerite has to contend. The grub tunnels in the tissues of the leaves and does serious injury by preventing the foliage performing its proper functions, as well as by making the entire border or bed in which the plants are growing look untidy and unkempt. It is not an easy enemy with which to deal, as when once the egg has been laid on the leaf it is impossible to apply anything that will be perfectly certain of destroying the egg or the maggot without at the same time damaging the leaves themselves. Prevention is indisputably the best course to pursue, and fortunately it is not difficult to manage, provided that the measures taken are followed up consistently. The grower can safely rely upon the popular soft soap, quassia and paraffin emulsion, or he can have recourse to a mixture of soot and wood ashes. The former should be applied through a spraying syringe and the mixture must be directed to the under as well as the upper surfaces of the leaves, while the latter should be thrown into all parts of the plants when they are damp either with rain, dew or artificial watering. In the latter course the cultivator must be especially persistent and put on fresh dressings after every rain, as the material used is quickly washed off. Where the maggot has hatched out, the only course open for adoption is to crush it between the thumb and finger.

**SHRUBS.**—These are most desirable in town gardens, but the atmospheric conditions are not favourable to their successful culture. The whole of the leaves become coated, both above and beneath, with sooty accumulations, and the pores are thus so closely sealed that they cannot perform their functions. It is, however, possible to considerably reduce the harm which accrues thereby if a hose and a plentiful supply of water are at command. Every evening after a hot, dry day the hose should be turned on to the leaves and stems of the shrubs, and it will be found that they can be comparatively easily cleansed, with the result that they grow more freely and healthily, and remain ornaments to the garden for a much longer time. It is also excellent practice to loosen the soil above the roots, apply water heavily, and subsequently to again prick over the surface. In some circumstances liquid manure may also be given, but it should always be in a weak state.

**CANTERBURY BELLS.**—There are few more desirable plants for town gardens than the single Canterbury Bells, for they grow and flower magnificently, either in pots or in the border. The present is an excellent time to sow the seeds thinly on a specially prepared bed on a cool border. The soil should be well dug and have plenty of leaf-mould incorporated into the top 3 inches or 4 inches before the surface is made firm and level, and the seeds are distributed evenly over it.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUITS UNDER GLASS.

**TEMPERATURES.**—Little fire-heat should be used now. When the heat can be kept up to 70° the fires may be dispensed with, but up to the present the nights have been cold. Melons require a warm temperature to finish. Muscat Grapes need a fairly high temperature, and where quantities are grown it is necessary to always maintain a steady supply of artificial heat.

**Vineries and Peach Houses.**—Where these are cleared of the fruit throw the lights open and expose the plants as much as possible, but do not neglect the watering. This is the season when Peaches get neglected, and consequently bud-dropping occurs in the spring. Avoid this by syringing twice daily and giving a thorough watering whenever necessary.

#### PLANTS UNDER GLASS.

**Chrysanthemums.**—Finish potting these as soon as possible, as plants that become pot-bound soon begin to deteriorate. All tall-growing varieties should have good stakes and be tied up straight. Do not put the stake in the pot and then tie it up to the wire to make it straight, else when taken down the plants will require to be restaked. The staking of plants cannot be too carefully done at this time. Allow each plant in the line room for proper development, and if the compost was enriched at the potting no manure will be required for some time.

**Callas** planted out in the open should be left severely alone till the foliage gradually dies away, when it may be cut off and the plants encouraged to grow by damping over with a fine-rosed water-pot in the afternoon.

#### KITCHEN GARDEN.

Continue to plant out crops that are fit, such as Celery, Cauliflowers and early Broccoli, and sow more Turnips, salads and a good border of Parsley for winter and spring use. A sowing of Cabbages now will provide nice dishes in the autumn. Sow good breadths of Coleworts for winter use, also curled Endive in quantity.

#### FLOWER GARDEN.

**Violets.**—Keep the hoe among the plants, and do not allow them to become dry, or they will get an attack of red spider, which, in order to get the best results, must be strenuously avoided.

**Shrubby Plants** that have flowered well should now be looked over and pruned. Clematis montana and its variety rubra has been a mass of flowers. The growths should now be pruned, the old flowering wood cut out and the new trained up.

**Flower-beds** must have the proper attention at the right time. Carpet or designed beds should have the growths pinched and the designs made quite clear, or all beauty is lost. Old flowers of Geraniums should be gathered and the beds kept smart. Intermediate and other Stocks may now be sown to flower in the winter and spring; there are some good varieties of these now, from which an excellent selection can be made.

#### HARDY FRUIT GARDEN.

**Peaches and Nectarines.**—Early varieties must have the fruit exposed in order to get a good colour. Water the roots copiously, giving some Le Fruitier at every other watering, and syringe the foliage well twice daily.

**Summer Pruning.**—Continue with this, but do the work carefully. Cut the shoots clean and just above an eye. Tie in all young shoots in the direction they are intended to go. Thin Apples and Pears, especially on cordon-trained trees.

See that all trees growing on walls have plenty of moisture.

W. A. COOK.  
(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**GLOXINIAS.**—Those that are now coming into flower should be removed to cooler quarters, for if allowed to remain too long in a high temperature the stems become drawn and the flowers will require staking. Spring-sown seedlings should now be ready to pot into 5-inch pots, then grown on a shelf well up to the light.

**Exacum macranthum.**—Spring-sown seedlings will now be ready for transferring into 2½-inch pots. This beautiful biennial does not require coddling. An airy intermediate house, with plenty of moisture on the staging and paths, suits it admirably. Soil of a free, open nature is necessary, while overwatering in the early stages of growth means certain failure.

**Zonal Pelargoniums.**—These should now be finally potted for winter flowering; after this has been done ten days or a fortnight an outside sunny position will be best for them. Keep all flower-buds removed as fast as they appear and see that there is no stagnation of water about the roots.

#### FLOWER GARDEN.

**Poppy Anemones.**—The present is a good time to sow seeds of the Poppy Anemones. In all instances the seed should be sown in the open ground in well-enriched soil of good depth. Select a somewhat sheltered position, such as a shady border, and sow the seed thinly either in drills or broadcast. Should the soil be dry, a good soaking may be given after the drills are drawn. Draw the drills at 8 inches apart, selecting a calm day for the sowing, and should the seeds be at all lumpy take a handful of sharp sand or fine earth and, mixing with the seed, rub them through the hand till separated, afterwards sowing soil and seed together in the drills.

#### FRUIT HOUSES.

**Muscat Grapes.**—The bright sunshine which we had during a greater portion of last month was very favourable to the ripening of Muscat Grapes, and those having them at that stage ought not to experience any difficulty in maturing them properly. Muscats require a high temperature, with plenty of light to finish the fruit perfectly. At the same time they must not be exposed to the direct rays of the sun, or the berries will scald. Where the foliage is robust and shades the bunches too much, they should be tied back to admit more light. If the atmosphere of the house be kept too dry, red spider sometimes attacks the foliage, causing much annoyance. The only way I find to get rid of this is to sponge the leaves with clean water, taking care not to touch the berries.

#### KITCHEN GARDEN.

**Turnips.**—Sowing may now be carried out more extensively than has been advisable up to date; the weather will in all probability be more conducive to the production of roots of good quality. I, however, advise rather small sowings for private use, for the quickly-grown roots that are not allowed to stand long after they have become full grown will invariably be found of better quality than those which are older. I also find that we get excellent roots from sowings made towards the end of July or any time up to the middle of August.

**General Work.**—Tripoli or other autumn-sown Onions which have not yet commenced ripening the top growth should be broken down at once preparatory to their being pulled and stored. If allowed to grow any longer, mildew is sure to attack them.

T. B. FIELD.  
(Gardener to Baroness Berners.)  
Ashwellthorpe, Norwich.

## THE EDITOR'S TABLE.

## FLOWERS FROM LOUTH.

Mr. Smith sends from Walsgrave Gardens, Louth, Lincolnshire, an interesting collection of flowers with the following notes: "I send you a few flowers of the following delightful plants which make the rock garden a veritable shrine of beauty in June, in the hope that fresh votaries may come to worship. I append the following notes. Taken in alphabetical order:

"*Allium acuminata* is a dwarf member of the Onion tribe, bearing rose-lilac flowers in umbellate heads which are carried by stout 18-inch stems.

"*Androsace lanuginosa* is singularly effective draping a rock, the myriad heads of bright Primula-like flowers are produced right into autumn.

"*Asperula hirta*.—This dwarf species of Woodruff flowers freely in sunny positions.

"*Armeria splendens* produces the deepest-coloured flowers in this family, and yields them over a long season.

"*Antirrhinum glutinosum* is one of the best of dry wall plants; flowers lemon and white on creeping downy stems.

"*Ethionema grandiflorum* makes a small bush smothered with long stems bearing carmine-red flowers.

"*Dianthus cæsius*, *D. alpinus* and *D. neglectus* form a well-known trio of beautiful dwarf rock Pinks. None of them exceed 6 inches in height, and the flowers are various shades of rose.

"*Erigeron aurantiaca* gives an uncommon colour among the rock plants; the flowers are large and bright orange.

"*Gypsophila repens monstrosa* is a magnified and vigorous form of the type.

"*Hypericum fragile* is a beautiful dwarf St. John's Wort. The individual flowers are very large and are produced on the terminal points of prostrate shoots. It make a capital subject for draping small rocks.

"*Lychnis pyrenaica* is a very small species, bearing white flowers upon erect wiry stems.

"*Lithospermum graminifolium* is a rare plant, which forms a charming group when liberally planted. The flowers are a fine shade of blue and are borne upon graceful arching stems some 9 inches in height.

"*Ononis rotundifolia* makes one of the finest rock garden shrubs, compact in growth, free in flowering, and a lovely shade of pale pink; the leaves form a trefoil, and are elegantly toothed and waved along the margins.

"*Onosma taurica* is the well-known Golden Drop.

"*Phlox canadense Laphamii* makes a first-rate garden plant, yielding sheets of colour with the charming pale lavender flowers, essentially a summer colour; it is seen at its best in June.

"*Ramondias* are inseparably associated with shade and damp, so that when grouped with dwarf Ferns they disclose such beauty as ranks them with the finest of hardy exotics. I have had a fine mass of blossoms from seedling *Ramondias* (*Pyrenaica* and *serbica*) sown less than three years ago.

"*Silene alpestris* bears small white starry flowers upon slender stems, and is an excellent dry wall plant."

## A RARE CLIMBER (SEMELE ANDROGYNA).

Mr. S. W. Fitzherbert, Kingswear, sends a leaf, or rather cladode, of this fine climber, with the following interesting note: "This is a native of Madeira and the Canary Isles, and in the first-named island is much used for draping the pillars at the entrances to quintas, where it has a charming effect. It was introduced into this country nearly 200 years ago, and was for long known as *Ruscus androgynea*. It is but rarely to be met with in the open in this country, but is grown in a few gardens in Devon and Cornwall. The leaves, or rather cladodes, are from 1 foot to 2 feet in length, and are furnished with

from twelve to twenty pinnate sections of brightly polished green. As these droop the glossy green is well displayed, and a wall completely covered with the handsome foliage is an attractive sight. The cladodes are very tough in texture, and often remain perfectly fresh for six or seven years. Strong, well-established plants push up vigorous Asparagus-like shoots from the base, which will sometimes attain a length of 40 feet in a season. In young plants these shoots often appear as early as November, but as they become established the shoots do not appear until the spring. *Semele androgynea* is a noble climber for a large, cool house. In the Temperate House at Kew there is a splendid specimen which has reached the roof, a height of over 30 feet. In the summer the plant presents an attractive appearance, since every pinnate section of the cladode bears, along its edge, clusters of small, yellowish flowers about an eighth of an inch across, some of these clusters containing as many as twelve blooms, and ten or more often being borne on one section. At the present moment every old cladode of the plant, which is growing on a north-west wall, is covered with these tiny blossoms, and the effect is quite pretty, though it is as a foliage rather than a flowering plant that this *Semele* is chiefly valuable. This year's shoots, which have already reached a length of about 20 feet, will not flower until next season. Red berries sometimes follow the flowers in the open in Cornwall, but my plant has not as yet produced fruit."

## A NEW MALMAISON CARNATION THE GALA.

Messrs. Hugh Low and Co., The Royal Nurseries, Bush Hill Park, Enfield, send a flower of a very striking new Malmaison Carnation, which it is proposed to send out under the name of The Gala. The flower is of immense size, very full, and a warm shade of pink. It was raised from the variety Lady Grimston fertilised with the variety Princess of Wales, a very difficult cross to make. The flower sent was cut from a last year's autumn layer. Another virtue of this variety is its fragrance. A Carnation without this is not much to our liking.

## STRAWBERRIES FROM RICHMOND.

Mr. Edward Montague, gardener to Colonel Biddulph, Grey Court, Ham, Richmond, Surrey, sends very fine fruits of Strawberry Royal Sovereign. These were of grand size and excellent flavour. He writes on June 19: "I am sending you a dish of Strawberries for your table. The variety is Royal Sovereign. I gathered the first dish outdoors on June 10, and have been picking every day since. The runners were taken the second week in June last year. They were not layered in pots as usual, but severed from the old plants and pricked out on a piece of ground which had been well prepared for them. They were carefully lifted the first week in August and planted in the bed, three plants in a clump, the clumps being 2 feet 6 inches apart in the rows, and the rows 3 feet apart. A dusting of soot was given occasionally to keep down the slugs; it also improves the colour of the fruit. Each truss of bloom was staked up, and where the fruit was very thick it was carefully gone through with the Vine scissors and the weakest and bad-shaped fruit removed."

## A NEW SWEET PEA FROM HISTON.

Mrs. R. H. Biffen, The Gables, Histon, Cambridge, sends flowers of a very pretty Sweet Pea called Zephyr, with the following note: "I am sending for your table a few blooms of a new Sweet Pea, Zephyr. All the sprays should be four-flowered, but at present the plants are too small to produce them at their best. The nearest approach to Zephyr in colour is Flora Norton, but even this is hardly so pure a blue. The colour never burns out, but becomes brighter in intense sunlight."

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Alpines mutilated** (S. L. Lee).—We do not think the soil grub to which you refer as having been found at the roots is responsible for the mischief you complain of, and it is far more likely to be done by birds at their nesting time, or subsequently when bringing up their young. At this latter period they work very busily in the endeavour to find suitable food for their offspring, and we are inclined to interpret the thing in the following way, viz., that the bird may have seen a grub or some insect upon the plant, and in the endeavour to catch it has pecked away the growth. We have many times seen both the robin and the wren perched upon the tufts of these alpine searching diligently for insect life. At these times a good deal of mischief may be done in a short time.

**Sweet Peas eaten off** (Miss C. H. F.).

So far as we can judge by the crushed specimens sent we think the mischief has been caused by either woodlice or ants. The weevils that you mention eat holes in the leaves and slugs also attack them in a similar manner, but yours, as you say, have been eaten through level with or just below the soil. We advise you to place some pots on their sides along the row, placing in some of these a little boiled Potato and cover it with dry hay or straw. This will attract woodlice. In other pots place small, clean, dry sponges, into the canals of which some Demerara sugar has been shaken. If ants are present they will quickly find the sugar, and they may be shaken out of the sponges into a bucket of some insecticide at frequent intervals, recharging the sponges with sugar each time. It is necessary to keep the sponges dry.

**Daffodils in grass** (Staveley).—You say nothing about the position, whether hot and dry, or moist, or even what varieties have failed to flower. A large number of Daffodils are moisture-loving, and their non-flowering may be due to a variety of causes of which we have no information. Please say what sorts you refer to and whether the growth is quite healthy, that is, the leaves free from brown tips, &c., how long the bulbs have been planted and in what class of soil. With these particulars before us we may give you advice that would prove helpful.

**Weeds on lawn** (C. L.).—The weed sent is a wild Centaurea and is related to the Cornflower. The most effective way of ridding the lawn of its presence is to trench the ground 2 feet deep early in the autumn, picking out every particle of the roots as the work proceeds and then sowing down with lawn grass seeds. The next best thing to do is to have a well-worn kitchen knife with a strong pointed blade, cutting the roots with it 3 inches below the surface, pulling up the plants and their roots together. By perseverance in this method of eradication for a few years the plant will become so weakened that it will naturally die away. The weed should never be allowed to flower and bear seed.

## TREES AND SHRUBS.

**Rhododendrons grown tall and straggling** (Dumpling).—Your Rhododendrons, as you say, ought to have had attention many years ago. We are afraid that if you cut them back into the thickest wood now you will not have very satisfactory results. Your best plan will be to cut some of the plants out bodily,

selecting the worst-shaped and worst-placed plants for the purpose. Then go over the remainder and prune them back 2 feet or 3 feet, taking care to prune in such a manner that the plants will push out new growths fairly equally. If the branches have not a diameter exceeding 2 inches they ought to break again readily. You cannot have a better period than the present for the work, and the sooner it is done the better. If you have a quantity of half-decayed leaves handy they will make a much better top-dressing than the peat. This should be applied as soon as the pruning is done.

**Abies nordmanniana diseased** (*Miss A. B.*). Your *Abies nordmanniana* is attacked by one of the aphides belonging to the genus *Chermes*; but, as I could not find a full-grown specimen, I am unable to give you the specific name. You should spray the affected parts with paraffin emulsion, not with the plain oil, or you might try a new insecticide which is very highly spoken of; "V 2" is the name under which it is sold.—G. S. S.

## MISCELLANEOUS.

**Names of plants.**—*W. M.*—1, *Helichrysum antenarium*; 2, *Andromeda* species; 3, *Cryptomeria elegans*; 4, *Lonicera involucrata*; 5 and 6, *Helleborus viridis* var.; 7, *Dianthus deltoideus*; 8, *Saxifraga trifurcata*; 9, *Muehlenbeckia varians*; 10, *Arenaria balearica*; 11, *Pittosporum tenuifolium* (?), cannot be sure without flowers.—*C. F. M.*—*Chelidonium majus*.—*E. B.*—*Lathyrus sativus*.—*Paddy*.—1, *Carex panicea*; 2, *Lycnis Viscaria flore-pleno*.—*A. B.*—*Deutzia scabra*.—*Mrs. B. B.*—*Antennaria dioica*.—*Col. F.*—*Crataegus punctata*.—*R. Bicknell*.—1, Probably *Iris setosa*, but the flowers were over; 2, *Heuchera sanguinea* var.; 3, *Saxifraga trifurcata*; 4, *Thymus serpyllum*; 5, *Veronica Teucrium* var. *dubia*; 6, *Geranium sanguineum*.—*Hants*.—1, *Tanacetum vulgare*; 2, *Silene* sp.; 3, *Kalmia latifolia*; 4, *Centranthus ruber*; 5, *Melissa officinalis*; 6, *Stachys lanata*.—*Miss E. A. H.*—*Alchemilla alpina*; *Tellima grandiflora*.—*J. E. L.*—1, *Diervilla Abel Carrière*; 2, *D. Eva Rathke*; 3, *Cupressus lawsoniana*; 4, *Thuja orientalis*; 5, *Cupressus lawsoniana*.—*S. D.*—*Roses*: 1, *François Crousse*; 2, probably *Countess of Derby*, but the bud had not developed, and one cannot name a Rose from the bud only.—*Rhagatt*.—*Thalictrum aquilegifolium*.—*R. J. M.*—Most of the *Pelargonium* flowers were represented by a heap of loose petals in the bottom of the box, so that it was quite impossible to tell to which they belonged. Some in rather better condition than others appear to us to be as follows, though one can be by no means confident on that score: 2, *Mazpie*; 3, *Triomphe de St. Mandé*; 6, *Lord Kitchener*; 8, *Hermione*; 9, *Mrs. Charles Pearson*. Before sending *Pelargonium* blooms the petals should be gummed to prevent them dropping.—*Ramsden*.—*Geranium pratense*.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY.

At the fortnightly exhibition of flowers and plants, held on the 23rd ult., at Vincent Square, S.W., the president and council of the society had the pleasure of receiving a deputation of about 100 members of the Société Nationale d'Horticulture de France and entertained them to a light luncheon. The visitors included the president of their society (*M. Viger*), *M. Lebouf* (treasurer), *M. Abel Chatenay* (secretary) and *M. Maurice Vilmorin* of Paris. A lecture was given by the Rev. Professor G. Henslow, M.A., F.L.S., V.M.H., on "The Absorption of Rain and Dew by the Green Parts of Plants."

### ORCHID COMMITTEE.

Present: Mr. J. Gurney Fowler (chairman), Messrs. James O'Brien, Harry J. Veitch, H. B. Little, W. Boxall, J. F. Acceck, Stuart H. Low, J. Sander, R. Thwaites, A. A. McBean, F. J. Hanbury, C. H. Curtis, Walter Cobb, J. Charlesworth, Arthur Dye, W. H. White, H. A. Tracy, H. Ballantine, Gurney Wilson, J. Wilson Potter, R. Brooman-White, Norman C. Cookson and de B. Crawshaw.

Messrs. Hugh Low and Co., Royal Nurseries, Bush Hill Park, Enfield, had a small group of well-grown Orchids, in which was a very fine plant of *Dendrobium clavatum*, the rich golden flowers of which were borne in profusion. *Lelio-Cattleya Dora magnifica*, *Oncidium leucociliatum* and *Cattleya Mossie Lowie* were other excellent plants in this group.

From Messrs. Stanley and Co., Southgate, N. came a very handsome group of *Cattleyas*, including a large number of *C. Mossie* varieties, all of which were in the best possible condition. *Cattleya Aclaudae*, *C. Mossie Heather Bell*, *C. M. Thompsonii*, *C. Warneri*, *C. M. triumphans*, *C. M. Bluebell*, *C. M. Fieldie*, *C. M. Duke of Marlborough* and *C. Warneri ignescens* were some of the best of a very interesting collection. Silver Banksian medal.

De B. Crawshaw, Esq., Rosefield, Sevenoaks (gardener, Mr. W. J. Stables), staged a very fine group of *Odontoglossum hybridum*, in which were some very beautiful and interesting things. The labellum in some of these has been developed into a large size, and the markings are quite remarkable; yellow and rich crimson brown are the predominant colours in these hybrids. Silver Flora medal.

H. J. Elwes, Esq., Coleshounne, staged a few well grown plants of *Thunia Marshallii* and some seedlings, all of which were in the very pink of condition, the handsome clusters of white orange flowers contrasting well with the pale green foliage. A very fine exhibit.

Messrs. Charlesworth and Co., Bradford, exhibited a most interesting group of choice plants that were all staged in very good condition. *Phalenopsis Lindenii*, *P. violacea*, *P. v. schrederiana*, *Odontoglossum williamsianum*, *Ornithocephalus grandiflorus*, *Miltonia flavescens*, *Lycaste tetragona*, *Pescatorea klabochorum* and *Promenaea citrina* were some of the most interesting in a splendid group. Silver Flora medal.

### FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, W. Bates, A. Dean, H. Parr, G. Reynolds, George Wythes, W. McIndoe, Owen Thomas, W. Pompart, A. H. Pearson, A. R. Allen, J. Davis and P. W. Tuckett.

Messrs. Dobbie and Co., Rothsay, staged a very fine group of Potatoes that had been grown in Cornwall. The tubers were planted in the open trench on February 3, and the Potatoes shown were of very good size and even shape, many of the kidney varieties measuring 5 inches in length. *Milothian Early*, *Milecross Early*, *Sir John Llewelyn*, *Russet Queen*, *Radium* and *Ideal* were some of the best whites, and *Cardinal*, *Climax*, *Rouge Royal* and *Beauty of Hebron* were the most noticeable coloured varieties. In addition to these this firm staged a representative collection of Radishes now in cultivation, the variability among these being well demonstrated. More of these instructive exhibits would be welcome. Silver Knightian medal.

From Messrs. James Veitch and Sons, Limited, Chelsea, came an interesting little group of Cabbages, Cauliflowers, Lettuces and Carrots grown under the French system. Cauliflower *Lambin* was very fine indeed, and Cabbage *Oxheart* was very firm and of good shape.

From the New South Wales Department of Agriculture came a good collection of Apples, Lemons and Oranges. These were staged in excellent condition and attracted much attention. The Washington Navel Oranges were very fine, and Apples *Grammy Smith* and *Munroe Favourite* were good. Silver Knightian medal.

S. H. King, Esq., Eastwell Park, Ashford, Kent (gardener, Mr. Weston), staged fourteen very good bunches of Grapes. All the berries were well finished, and we have seldom seen Grapes staged better at this time of year. *Black Hamburg*, *Muscot of Alexandria*, *Poster's Seedling* and *Gros Maroc* were the varieties represented. Silver Knightian medal.

### FLORAL COMMITTEE.

Present: Mr. H. B. May (chairman), Messrs. W. A. Bilney, James Hudson, J. Green, G. Renthe, C. Bick, R. W. Wallace, C. T. Drury, R. C. Notcutt, E. A. Bowles, J. Jennings, W. T. Ware, R. Hooper Pearson, Charles Dixon, Charles E. Pearson, E. T. Cook, William Cuthbertson, E. H. Jenkins, H. J. Cuthbush, J. W. Barr, James Douglas and R. C. Reginald Nevill.

The hardy plant and water garden exhibit from Mr. Amos Perry, Winchmore Hill, was an especially interesting feature, furnishing abundant proof of the value of the good grouping that might advantageously be carried out in not a few gardens. At right and left of this imposing group were seen bold masses of Larkspurs in many leading varieties in pale and deep blue and violet shades, the centre being occupied by a charming lot of Lilies, while in the central front an ingeniously arranged piece of water grouping and Lilies was seen, consistently margined by Ferns, Funkias, Grasses and the like. The Water Lilies were in every sense a delightful feature in a pleasing group. Silver-gilt Flora medal.

A very complete and valuable collection of garden Pinks grown in pots was staged by Mr. James Douglas, Great Bookham, Surrey, the plants being finely flowered and in the best of condition. Selfs and laced varieties were freely shown, among the former being *Snowdrift* and *White Queen*. The laced sorts were particularly attractive, and of these *Bookham Gem* (a fine flower of the true florist's type), *Lufra* (with very dark centre), *Rosy Morn*, *Tweeddale*, *Rosina* (white ground, dark ring, centre paling to rose) and *Ethel* (a rather heavily-edged variety) being among the best in a very interesting lot.

A table of well-coloured Crotons from Messrs. H. B. May and Sons evidenced the best possible cultivation, the excellent and well-furnished examples constituting quite a notable feature. Silver-gilt Flora medal.

Messrs. W. Cuthbush and Sons, Highgate, had a remarkably fine lot of Carnations of the Tree or American section, and also a set of *Malmaisons*. Of the former, Robert Craig was exceedingly fine, the clear scarlet dominating all others of its class. Other good sorts were *Euchautress*, *White Perfection*, *Mrs. Lawson*, *Fair Maid*, *Victory* and *Floriana*. The pink-flowered *Spirea Queen Alexandra* was especially good and well coloured, and demonstrated its value among these plants. Silver-gilt Banksian medal.

The Misses Hopkins, Shepperton, had a small exhibit of alpine plants on rockery, the alpine Pinks and Campanulas being the more prominent subjects.

Messrs. Cammell and Sons, Swanley, staged a fine lot of *Gloxinias* in a setting of Ferns. The plants were superbly flowered and representative of the best types of these popular flowering plants. *Mrs. Watson*, spotted; *Captivation*, rosy carmine and spotted; *Amiable*, pink and white; *Sherlock Holmes*, violet and white; *Miss Pope*, ruby red; and *Mrs. Collins*, the giant flower spotted uniformly with scarlet throughout, were some of the best. Silver Banksian medal.

Messrs. B. R. Cant and Sons, The Old Rose Gardens, Colchester, had some lovely Roses, such as *Jugo Roller*, *Warrior*, *Souvenir de Stella Gray*, a lovely orange and yellow shade, with perfect bud-like form; *Betty*, cream and peach; *Azeline Morel*, peach and white; *Countess of*

Gosford, clear shell pink; *Etoile de France*, deep crimson; *Irish Elegance*; *Dr. J. Campbell Hall*, deep pink; *Mrs. Ralph Brocklebank* and *Mme. Edmond Sablayrolles*. These were some of the best in an exquisite lot. Silver Banksian medal.

Messrs. James Veitch and Sons, Limited, Chelsea, staged an admirable group of flowering plants, such as *Cannas*, yellow-flowered *Callas*, *Gloxinias* of the highest excellence and in many shades of colour, *Kalanchoes*, *Lobelia tenuior* (lovely with rich blue tone) and *Swainsonia galegifolia*. Some of the scarlet and red-flowered *Gloxinias* were especially good, and in their strong self tones very attractive. A large batch of Spanish and English Irises were also staged by Messrs. Veitch, together with an interesting lot of autumn-sown annuals, such as *Tagetes*, *Candytuft*, *Diascea Barbaera* and *Rocket Larkspurs*, also a group of many other interesting plants. Silver-gilt Flora medal.

Bakers of Wolverhampton had a showy group of Irises, Poppies, Gaillardias, Columbines, Day Lilies and the like, with a small exhibit of Alpines. Silver Banksian medal.

Messrs. R. Wallace and Co., Colchester, in a group teeming with good and interesting plants, had a very remarkable lot of hybrid *Heucheras* in much variety of colour, *Larkspurs*, Spanish Irises, a very handsome lot of *Lilium monadelphus szovitzianum* and *L. Hansoni*, *Isias*, *Calochorti*, *Gladiolus Ne Plus Ultra*, *Iris Delavayi* (a rich blue-violet tone), *Thalictrum Delavayi*, with violet drooping flowers on a charming habit were also noted in a very fine display. Silver-gilt Banksian medal.

Mr. W. J. Godfrey, Exmouth, had a capital lot of decorative and Ivy-leaved *Pelargoniums*, the plants being exceptionally well flowered. *Lady Decies*, bluish pink; *Mrs. W. J. Godfrey*, pink with dark blotch; and *Dora Godfrey*, deep rose-pink, were extra good. *Solanum Wendlandi*, in excellent plants from 2 feet to 3 feet high, were displayed in good flower. Silver Banksian medal.

The *Paeonies*, *Delphiniums* and *Pyrethrums* from Messrs. Kelway and Sons, Langport, filled a large table, the single and semi-double forms of the first-named being exceedingly chaste and beautiful. Of these we take *Moonlight*, white with pale lemon centre; *British Empire*, rose carmine with gold and rose tufts in the centre; *Prince Edward of Wales*, rosy red with golden yellow tuft of petals; and *Emperor of India*, similar in colour but with distinct centre, were among the best in a showy lot. Silver Banksian medal.

Messrs. William Bull and Sons, Chelsea, exhibited in much variety a collection of the Spanish Irises. *British Queen*, *Queen of Whites*, *Canary Bird*, *Cajaines* (rich yellow) and *Eldorado* (fine rich golden yellow) were among the best.

The Spanish Irises from Messrs. Dobbie and Co., Rothsay, were exceptionally well-grown examples, the tall stems and large, handsome blooms denoting the highest culture. *Soleil d'Or*, rich yellow; *Snrbiton*, yellow; *Belle Chinoise*, primrose yellow; *King of Whites*; *Leander*, golden yellow; *L'Unique*, blue, with white falls; and *L'Innocence* were among the best of a really superb lot. Silver Banksian medal.

Messrs. Barr and Sons, Covent Garden, exhibited many fine *Paeonies*, Irises, *Potentillas*, Spanish Irises, early *Gladioli* and other hardy cut flowers of a showy character, these being admirably arranged in a large group. Silver Banksian medal.

Messrs. Hugh Low and Co., Enfield, displayed a very fine lot of *Malmaison Carnations* in variety. *Mrs. Trelawney*, rose; *Duchess of Westminster*, pink; *Nell Gwynne*, white; *Yaller Gal*; *Maggie Hodgson*, crimson; and *H. J. Jones*, crimson, were especially noteworthy. Most of the plants were very fine examples. Silver Banksian medal.

Messrs. W. and J. Browne, Peterborough, had a capital lot of *Roses* in the cut state. *Mme. A. Chatenay*, *Mrs. Peter Blair*, *Souv. de Stella Gray*, *Queen of Spain*, *Wm. Shean* and *Mildred Grant* were all good. Silver Banksian medal.

Mr. George Mount, Canterbury, staged a lovely lot of *Roses*, such as *Ulrich Brunner*, *Frau Karl Druschki*, *Duke of Edinburgh*, *Joseph Lowe*, *Richmond* and *Mrs. John Laing*. A background of the rambler *Roses* gave a delightful setting to the entire group, which was greatly admired. Silver Flora medal.

Messrs. J. Laing and Sons, Forest Hill, staged a fine circular group of *Caladiums* with Ferns and other things. Silver Banksian medal.

Mr. George Renthe, Keston, Kent, staged a most interesting lot of hardy plants, such as *Pyrethrums*, *Lilies*, *Eremuri*, *Poppies*, *Kniphofia Tuckii* and *Campanulas*. The small alpine plants were numerous and good, and of these such as *S. cochlearis*, *S. c. minor* and *S. tyrolensis* were all beautiful and worth growing for their late flowering. *Bruckenthalia speculifolia*, with small Erica-like pink blooms on a plant 6 inches high was also notable. *Dianthus*, *Edelweiss*, *Incarvilleas*, *Isias*, *Androsaces*, *Rhododendron myrtifolium*, *Mitrisia coccinea*, *Tamarix odessana* and *Philadelphus purpurea maculata* were other good and interesting plants in this exhibit. Silver Flora medal.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, had an admirable lot of herbaceous *Paeonies* in many superb and good varieties. Among light coloured varieties we noted *Lady Carrington*, *M. Rousselon*, *Virginia*, *Pulcherima*, *Duchess de Nemours* and *Princess of Wales*, and there were many dark-flowered varieties of equal merit. Messrs. Paul also show exquisite *Roses*. Silver Flora medal.

Messrs. R. Veitch and Son, Exeter, had a basket of *Calceolaria Golden Glory*, a very fine new hardy hybrid that should be grown by all. The exhibited plants from the open ground had received no protection since being planted two years ago.

The Guildford Hardy Plant Nursery brought a most interesting lot of *Houseleeks* and *Sedums*, together with rock shrubs and the like.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## "THE GARDEN" FLOWER SHOW.

### IMPORTANT NOTICE.

WE have much pleasure in announcing the list of those who will act as judges at our forthcoming show, to be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, London, on the 29th inst. They are as follows: Messrs. E. Beckett, gardener to Lord Aldenham, Elstree, Herts; D. B. Crane, a well-known amateur; W. A. Cook, gardener to Sir Edmund Loder, Bart., Leonardslee, Horsham, Surrey; E. Jenkins, nurseryman and florist; H. E. Molyneux, treasurer of the National Rose Society; Owen Thomas, V.M.H., late gardener to Her Majesty Queen Victoria; Walter P. Wright, horticultural superintendent under the Kent County Council; and G. Wythes, late gardener to the Duke of Northumberland. All are horticulturists in whose judgment our readers may place the fullest confidence, and their decisions must in all cases be regarded as final.

We also wish to make it quite clear that we cannot undertake to return any exhibits, and those not called or sent for will be forwarded to a hospital. No prize money will be paid on the day of the show, but will be forwarded to successful competitors as soon after the day of exhibition as possible, therefore we hope that all competitors will write their full names and addresses as clearly as possible on the entry forms and also on cards sent with the exhibits. Visitors will be admitted to the Hall at 1 p.m. until the close of the exhibition on showing a coupon that will be printed in a future issue, and Fellows of the Royal Horticultural Society will be admitted free on producing their passes.

Several readers have asked whether, in the case of such flowers as single blooms of Roses being indicated in the schedule, several of a sort may be forwarded for those who are staging to select from. This will be allowed, as of course those who stage their own exhibits usually take more blooms than are actually set up in case of accident in transit.

Vases will be provided for all cut flowers except in the table decorations. Where exhibitors desire to show their blooms in boxes they must be brought to the Hall and staged in them. Exhibits may be brought or sent so as to reach the Hall the evening previous to the show.

We hope intending exhibitors will fill in and return the entry forms as soon as possible, and not leave them until the last day allowed. These entry forms were published in last week's issue.

## PROSPECTS OF THE SWEET PEA SEASON.

ALL lovers of the Sweet Pea are looking forward to the coming season with absorbing interest. It is not the extraordinary development of the flower during recent years alone which accounts for this. An element of uncertainty has been introduced by the singular and widespread sportiveness which showed itself last year. Growers hardly know what to expect. The impurity of the stocks was too general to be attributed entirely to carelessness on the part of growers. Nature was in one of her freakish moods, and few indeed were the growers who did not suffer in consequence. Novelties that were believed to be absolutely fixed threw all sorts of variations.

This impishness on the part of Nature is one of the things that "cut both ways." When it gives a person who has bought a so-called novelty only 20 per cent. of true flowers, the remaining eighty being an old sort, he naturally rises in his wrath and demands the head of the tradesman who has supplied him with the seed. When, however, it gives a grower who has purchased an old sort a series of new breaks, in which he scents awards of merit, things are different, and his complacency is unbounded.

There was an absolute, all-round break up of Sweet Peas in 1907, and one can only say of the prospects of the season, so far as the crop of novelties is concerned, that anything may happen. Prophecy is paralysed. To do justice to the occasion demands the sublime self-confidence of a turf tipster, who asserts his ability to make you a colossal future, while at the same time presenting in his own person every evidence of complete inability to earn a decent living.

I believe that we shall have more novelties exhibited in 1908 than were ever shown before, because large numbers of growers had new breaks last year, and my experience of human nature is that nine out of ten of these will consider that they have only to grow them and show them this year to take the world by storm. It may not be amiss to warn these optimists that the National Sweet Pea Society did not go about with its eyes shut last year; that it read the signs of the times; that it amended the rules governing the operations of its floral committee, where, in one vital spot, they were defective; and that the distribution of awards in 1908 will be safeguarded as it has never been before.

The behaviour of Countess Spencer and the trouble over John Ingman should in themselves suffice to convince raisers that the task of fixing and developing a good commercial stock of a new Sweet Pea is a work of immense difficulty in these days, but it is not an impossible one. There are not wanting firms that prove their ability to produce genuine novelties every year, and, what is more, to distribute stocks which, under independent trial, are practically pure.

Turning to a consideration of the prospects of the season from another point of view—that of the vigour of the plants and the quality of the

flowers—one is bound to strengthen one's own observation and experience with reports from growers in different parts of the country, if one's remarks are to have any general value. By common consent we have had one of the coldest springs on record. March, April and May were thoroughly uncongenial. Strong, biting winds, keen frosts and late hail and snow storms were rife. This weather, following an unusually severe winter, filled growers in what are known as "late" districts with the most gloomy forebodings. Their one crumb of comfort was that the National Sweet Pea Society's London show was much later than it had been in previous years. Had it chanced to be the first week in July, as has been the case in some previous seasons, long and loud would have been the wail of anguish. Even as it is, I do not envy those who trusted to outdoor sowings. There are, I suppose, still a few folk left in the world who have sufficient faith in the British climate to sow Sweet Peas in the open air and expect prize flowers in July; but I think that they must be a steadily dwindling band. Any way, the only plants that I have seen which are strong and forward from outdoor sowings are those in sheltered, enclosed gardens.

There is, naturally, considerable interest in the operations of the Scottish growers, who should be favoured by the later date of the "National" show this year and may make a very strong bid for the chief trophies. That well-known amateur, Mr. Alexander Malcolm of Duns, writes me: "The Sweet Peas in this district are doing splendidly, and a few varieties are showing colour in the bud at this (for us) early date (June 25). The early growths, owing to a partially-ripened condition of the seed, were thin, but when once the plants began to move into full growth they soon reached the standard of former years. I have some fine specimen plants, and in the district the promise is first-rate." The above is very cheerful reading, and points to a strong attack from Scotland this year.

Two well-known firms write me from East Anglia. Mr. John Green of Hobbies, Limited, Dereham, says: "There is every prospect of Sweet Peas being more than up to the average this year. If one gets the average amount of sunshine, the necessary amount of moisture demanded by the crop can easily be given. This is the state of affairs with us: We have enjoyed more than the average amount of sunshine; our crop promises to be timed about right for the meeting of the National Sweet Pea Society. We shall prune back the same crop for the supply of blooms for Shrewsbury. We find this answers well, but, of course, it entails a good deal of labour."

Mr. A. G. Stark of G. Stark and Son, Great Ryburgh, writes: "This has been a remarkable season. All autumn-sown seed went off and had to be sown again. Although the weather has been hot, some of our Peas are not doing well, but one field which has twelve rows of 200 yards long each is doing very well. We have had wireworm in abundance; in fact, some of the rows have been taken off completely. Having about three and a-half acres sowed, we shall have something to show worth seeing. . . . The seed crop generally will be small, especially field-sown stuff in light soils. We shall have a fair crop, because we keep cutting all flower-stems and feeding."

That famous Winchester grower, Mr. C. W. Breadmore, writes me in a very cheerful strain, in spite of early trials. He says: "We have had a very trying spring, during which the ravages of pests, new and old, have greatly troubled us; nevertheless, at the time of writing (June 24) the prospect is very good indeed. Peas planted out prior to the 2 feet of snow on April 26 have come away in a remarkably vigorous manner, and promise exceptionally well. They have come into bloom early and rapidly on account of the dry, brilliant time during June. The question of water supply hits us hard on our dry and chalky soil; given

a good ground rain during the next few days, I feel sure that some very fine stuff will be on show early in July."

A good deal of interest will, of course, be felt as to the prospects in the Reading district. Messrs. Sutton and Sons write: "Sweet Peas in this district are all very short in the haulm, and the growth is not strong. Owing to the very sunny weather which we have had during June the plants are showing bloom earlier than usual, and we anticipate that they will be in full flower towards the end of June, and probably last through the first and second weeks in July."

Mr. Robert Bolton of Carnforth is optimistic in the extreme. In a letter from him dated June 24 he says: "My Sweet Peas are the best lot I have ever had, very vigorous and strong. I had a look over the plants of the leading Northern exhibitors last week, and all the lot looked exceptionally well. It looks as if all records for big Sweet Pea blooms will be broken this year." Will Southern growers kindly note this and tremble?

Mr. Robert Sydenham of Birmingham thinks that the season will be late. He says: "In my own garden at Edgbaston I am very late. I went for a trip in Spain, Portugal, Tangier, the Canary Islands and other places in May, and when I came back at the end of a month things did not seem to have made the slightest headway. As far as I can see the season will be a late one, and we shall be very much troubled with 'rogues.'"

Messrs. Watkins and Simpson think that the prospects are fairly good provided we have a dry summer. A month ago the haulm was exceptionally short, and it is still dwarf, but it has improved during the past three weeks.

Mr. S. Cole informs me that the cold, wet days and nights in April and May kept the Sweet Peas at Althorp Park back, and he has been terribly harassed with slugs; but the plants are improving, and the early batch are throwing very fine flowers.

Mr. T. Stevenson, Woburn Place Gardens, Addlestone, thinks that in spite of the cold spring the plants will be in bloom early, and that the prospects are very good indeed.

Mr. W. J. Unwin of Histon, Cambridge, reports that he lost several acres of Sweet Peas through slugs; but later hatches, though small plants, are throwing very fine flowers.

Summing up, it may be observed that on the whole the Northern and Western growers are more cheerful than the Southern and Eastern ones. Does this foreshadow a wholesale defeat for the South at the National Show at Vincent Square on July 24? If so 1907 will be avenged, but the battle has still to be fought.

WALTER P. WRIGHT.

## NOTES OF THE WEEK

### FORTHCOMING EVENTS.

July 24.—National Sweet Pea Society's Exhibition, Royal Horticultural Society's Hall, Vincent Square, Westminster.

July 29.—THE GARDEN Flower Show, Royal Horticultural Society's Hall, Vincent Square, Westminster.

**Calla æthiopica in St. Petersburg.**—As a flower for cutting *Calla æthiopica* is considered to be of the highest value by the inhabitants of St. Petersburg, and it is becoming year by year a greater favourite. Until recent years the St. Petersburg florists imported the chief part of the Callas sold by them from foreign sources, and a portion of the trade drew its supplies from Hermann Köppe at Wilna, who cultivated the plant on a large scale. But in consequence of the heavy Customs' duties on the weighty blooms and the losses of the tender flowers on the long journey, the St. Petersburg

marketmen perceived the necessity of supplying their needs at home. The plants are grown during the summer months in the open air and dug up and potted at the beginning of September or late in the month of August, according to weather conditions, and are then placed in frames, which are kept close for fourteen days and then afforded air abundantly and the plants syringed daily. Early in October the plants are placed in light glass houses. The flowering period begins in that month and lasts till April. The spathes (flowers so called) are of most value in the months of November, December and January. The Russians cultivate for the cut flower trade *C. æ. deventiensis*, *C. æ. grandiflora* Nicolai, both flowering almost without a break; and *Perle von Stuttgart*, which, because of its compact growth and shortness of flower-stalk, is well adapted for pot culture.—OBSERVER.

**Forced bulb show.**—In connexion with the special prizes for Hyacinths and Tulips to be competed for on Tuesday, March 9, 1909, at the Royal Horticultural Society's exhibition, the council would be glad if this date could be made a general one for the exhibit of collections of forced spring bulbs, specially with a view to showing which varieties (of Daffodils, for instance) are best suitable for forcing. The council invite the exhibition of small collections from amateurs as well as from the trade.

**National Sweet Pea Society's outings and exhibitions.**—The two annual outings of the members of the above society will take place this week. On Friday, the 10th inst., the members journey to Reading for the purpose of inspecting the society's trials that have been conducted by Mr. Charles Foster at the University College Gardens, and on Saturday, the 11th inst., the outing is to Kelvedon and Marks Tey. A halt will be first made at Kelvedon to inspect the Sweet Peas grown there by Messrs. Hurst and Son, who raised the gold medal variety of last year, then the party will proceed to Marks Tey and view the extensive stock of Messrs. Dobbie and Co. The eighth annual exhibition in connexion with the society will be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on the 24th inst., and the second provincial show at Dublin on August 5. Full particulars of the exhibitions can be obtained from the hon. secretary, Mr. C. H. Curtis, Adelaide Road, Brentford.

## PRIZES FOR READERS. JULY.

### BOTTLING FRUITS AND VEGETABLES.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Friday, July 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Wellingtonia struck by lightning.**—Having noticed in THE GARDEN particulars of a *Wellingtonia* being struck by lightning, I may mention that, during the terrific thunderstorm of the 4th ult., a *Wellingtonia* in the grounds here, about 80 feet high, was struck, apparently at the very top, the lightning running down to within a few feet of the ground and then escaping off one of the branches at the bottom, the pieces of bark being thrown some distance from the tree.—A. COSTAR, *The Gardens, Redstone Manor, Redhill.*

**Destroying queen wasps.**—On page 310 of THE GARDEN for June 27 there is a paragraph on the above subject. I was told about a fortnight since that on a single plant of *Cotoneaster Simonsii*, in the neighbourhood of Pwllheli, forty-five queen wasps had been destroyed this season, and nearly as many last year. I doubted afterwards whether these really were queens, as I saw a good many on the *Cotoneaster* at the same time. Usually I see one queen by herself, and generally going to the foot of a plant or shrub. I have since thought that these reputed queens might be the occupants of a nest hanging from a branch. There have been several such nests here recently, generally about thirty or forty insects to a nest.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

**Wild Lupines on the banks of the Tay.**—The accompanying illustration, from a photograph taken by Lady Marjorie Dalrymple and sent to us by Lady Menzies of Menzies, is of more than usual interest, as it depicts a fine breadth of the Nootka Sound Lupine (*Lupinus nootkatensis*) growing wild on an island in the Tay. Although not a true native of Britain, this plant, according to the latest edition of "The London Catalogue of British Plants," is now established in seven counties, but we doubt whether it is often met with in such quantities as shown in the illustration. The island is situated at the junction of the Lyon and Tay, and the mountain in the distance is Schichallion. Undoubtedly the climatic conditions that prevail in Scotland render it an ideal home for many plants that need a certain amount of coaxing to induce them to grow further South.

**Fremontia californica.**—This beautiful shrubby climber is flowering most profusely in these gardens. It has a beautiful bright yellow flower about 3 inches across and rather flattish in shape. It has stood the winters with slight protection quite unharmed. I believe this shrub has been in England since 1854, when it was flowered at the Royal Horticultural Society's Gardens; but the plant is said to have died upon an attempt at removal when the Arboretum at Chiswick was given up. It is the only species of the genus. It is supposed to have been first discovered by Colonel Fremont's expedition to the Rocky Mountains in 1846.—W. A. COOK, *Leonardslee Gardens, Horsham.*

**Roses from cuttings in summer.** I was very interested in reading the article on Rose cuttings, by "F. W. H.," on page 313. The great drawback to growing Roses from cuttings in the usual way is the time it takes before one can transfer them to their permanent quarters, and it is nice to hear of quicker ways of producing them. I wonder if any of your readers have ever tried growing them by the water method, which is quite as quick and far easier than the way described by "F. W. H."? All one has to do is to take the cutting from the Rose desired, either Tea, Hybrid, or Rambler, and place it in a glass jam-jar with a wide neck, and fill it up with water, being careful that it remains full until the cutting is rooted, which will be in about three weeks. As many as twenty to twenty-five may be grown in one good-sized jar. They must have plenty of light, and

should, if possible, be placed in a cold frame or greenhouse. When well rooted they should be potted into 5-inch pots in good turfy loam, and for the first fortnight kept fairly wet, gradually drying off as autumn approaches. They may be planted into the Rose-bed in January or February next and should flower next summer. Some Dorothy Perkins I treated in this way grew 6 feet or 8 feet in the following summer. The wood used may be young or old, the old wood taking a little longer to root. It is most interesting to watch the roots forming. When I prune my Roses in March and April I always put a few in a jar, with fair results. A little charcoal in the water keeps it pure.—S. L. GREEN, *Chorley Wood.*

## NEW PLANTS.

STOKESIA CYANEA PRÆCOX ALBA.

THIS is a very good white-flowered variety of this excellent border perennial, the flower-heads

*P. Achievement*, which resulted from crossing the Zonal and the Ivy-leaved forms. Shown by Messrs. W. H. Rogers and Son, Limited, Red Lodge, near Southampton. Award of merit.

ANTHURIUM PRESIDENT VIGER.

One of the *A. andreaeanum* forms, the spathe being of an intense crimson shade and as though highly varnished. From M. A. Truffaut, Versailles. Award of merit.

CAMPANULA RADDEANA.

A very charming new species from Ural, with roundish, crenate leaves on 3-inch-long foot-stalks, the flowering stems, which are glabrous, bearing eight to ten drooping flowers of a deep violet hue and about an inch across. It is one of the most distinct Bellflowers we have seen, and as shown was barely 12 inches in height. From Mr. G. Reuthe, Keston, Kent. Award of merit.

ERICA CINEREA PYGMÆA.

A really delightful plant not more than 4 inches high and smothered with ruby red bells. An ideal carpet of the soil if it can be had in

THE NOOTKA SOUND LUPINE GROWING WILD ON AN ISLAND IN THE TAY.

being not unlike a white Sweet Sultan in form and fully thrice as large. From Mr. Amos Perry, Enfield. Award of merit.

ESCHSCHOLTZIA MIKADO.

The most brilliantly-flowered variety we have seen, the colour being that of a glowing crimson Poppy; very intense and showy. Shown by Mr. W. H. Gardiner, Mill Street, St. Osyth. Award of merit.

EREMURUS BUNGEI MAGNIFICUS.

A highly magnified *E. Bungei* in all its parts, and a noble plant withal. With this fine addition to the group it is now easy to foresee the yellow-flowered *Eremuri* with all the greatness and stature of the finest *E. robustus* forms. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

BEGONIA COL. LAUSSEDALE.

A dwarf-growing, double, yellow-flowered variety that should be of much value for bedding. It is not more than 8 inches high and very freely flowered. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

PELARGONIUM JAMES T. HAMILTON.

□ This excellent variety is of rich scarlet shade, and would appear to be of a similar parentage to

quantity. From Mr. George Reuthe, Keston, Kent. Award of merit.

SWEET PEA THE KING.

This excellent red-flowered variety is regarded as a Spencer King Edward VII., hence the name.

SWEET PEA MID-BLUE.

A showy variety of a clear deep blue shade. These were shown by Messrs. Dobbie and Co. of Rothesay, and each received an award of merit.

KNIPHOFIA GOLDELSE.

A pretty dwarf-growing hybrid variety, having *K. pauciflora* and *K. ruia* as its parents, the former being the seed parent. The long, cylindrical flowers are of a clear lemon yellow tone and very pleasing. From Messrs. R. W. Wallace and Co., Colchester. Award of merit.

DELPHINIUM CAMEYSES.

A showy and good plant with deep violet-coloured blossoms of large size, that are rendered the more conspicuous by a clear white bee-shaped centre. Exhibited by G. Ferguson, Esq., Weybridge. Award of merit.

All the above were exhibited before the floral committee of the Royal Horticultural Society on the 23rd ult., when the awards were made.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

## SEDUM CÆRULEUM.

Mr. Clarence Elliott sends from Six Hills Nursery, Stevenage, Herts, flowers of this interesting Sedum, with the following note: "I am sending a small piece of *Sedum cæruleum* for the Editor's Table. It is one of the loveliest and most suitable annuals one could possibly grow on the rock garden, yet how seldom annuals seem to be grown among alpine! The enclosed plant was collected this spring in Corsica, and was quite unknown to me until I took it to Kew to be named. There they have a pan of it in the Alpine House. The Kew plants are at present covered with starry sky blue flowers, as are mine; but the egg-shaped, fleshy leaves lack the brilliant red which makes my Corsican specimens so charming. This lack of colour in the Kew plants is probably due to their having been grown under glass. Grown in the open in a starved, sunny position on the rock garden, this blue-flowered Sedum would probably attain the scarlet leaves that it does in Corsica; but in any case it is well worth a trial, or, rather, an annual position on any rock garden. Probably the most suitable treatment would be to raise it from seed as *Portulaca* is raised, and plant it out as soon as large enough. I see it is described in one catalogue as a half-hardy annual; but my plants have flourished in the open since the end of March, and have survived not only heavy snow but severe frost. From this one would suppose that it might be sown *in situ* on the rock garden. For those who do not know this little-known Stonecrop, it may be described as growing from 3 inches to 6 inches high; leaves fleshy, egg-shaped, scarlet; flower-buds white, opening into starry sky blue flowers a quarter of an inch across. There are a good many true alpine annuals which might be more grown on rock gardens than they are. *Ionopsidium acaule*, for instance, with its countless tiny flowers of palest lavender white, is quite delightful, yet comparatively seldom seen. Once started from seed, however, it sows itself, and a succession of self-sown plants will blossom year in and year out."

## INTERESTING SHRUBS FROM CHELSEA.

Messrs. James Veitch and Sons, Limited, send from their Chelsea Nursery a most interesting collection of flowering trees and shrubs, showing the great wealth of bloom that is obtainable at this season of the year. It is to be hoped that such kinds as those named and mentioned in the following list will be more grown in our gardens. The three Mock Oranges (*Philadelphus*) sent are delightful, flowers of snowy whiteness and crowded on the slender stems. All are forms of *P. Lemoini*, and how great is our debt of gratitude to the great French hybridist for enriching our gardens with such treasures. A beautiful trio comprises those sent—*Conquetti*, *Fantaisie* and *Mont Blanc*—and these we commend for their beauty and effect. Then we picked out from the gathering the sweetly-scented *Robinia decussata* and the better known *R. hispida*. Among other things were the creamy *Spirea sorbifolia*, *S. corymbosa*, the lovely *Styrax japonica*, the flowers reminding one of the Snow-drop; *Escallonia philippiana* and one of the most

precious of its race flowering now, *E. langleyensis*, the flowers deep crimson and lining the long slender shoots; this is a shrub to make a note of. *Amorpha fruticosa*, the white-flowered *Abelia triflora*, *Andromeda speciosa cassiniaefolia*, *Cytisus nigricans*, yellow with bloom, one of the most valuable of all summer-flowering shrubs; *Olearia macrodonta*, *Colutea arborescens purpurea*, the yellow-flowered *Berberis vulgaris integerrima* and the rosy coloured *Kalmia latifolia*—a welcome gathering.

## ICELAND POPPIES FROM UPTON-ON-SEVERN.

Miss H. Hemms of Holdfast Hall, Upton-on-Severn, sends us excellent flowers of the popular Iceland Poppies. These comprise new shades of vivid orange scarlet, pale terra-cotta, cream and apricot. The flowers were large and of sturdy habit, evidently the result of good culture.

## PERPETUAL-FLOWERING PINKS.

Messrs. B. Ladhams, Limited, The Shirley Nurseries, Shirley, Southampton, send us a series of delightful Pinks, including several unnamed seedlings. Those that attract us most are *Favourite*, *Brightness*, *Charles*, *The King*, *Princess Christian*, *John Ball Improved*, *Nellie*, *Continuity* and *Monarch*. All these are of beautiful colours and very sweetly scented. Such flowers as these are a joy in the garden at this time of the year, and we hope Messrs. Ladhams will continue their good work of raising such varieties.

## THE FRUIT GARDEN.

## A NEW AUTUMN STRAWBERRY.

(LAXTON'S PERPETUAL.)

**T**HE autumn Strawberries are not grown nearly as much as they deserve to be, and, when their value is considered and the good return secured on a small space of land, it is evident that these fruits should find more favour with amateurs. The new variety named *Laxton's Perpetual* was raised by Messrs. Laxton of Bedford, and was the result of crossing the large summer fruiting *Monarch* with *St. Joseph*, a true perpetual. The result is even better than one could have hoped for, as, though the new variety is a true perpetual, fruiting continuously from June to November, the fruits are much larger than those of *St. Joseph* and also of excellent quality, having a sweet and aromatic flavour and a deep red colour. At the same time the plant is dwarf, and in this respect much like *St. Joseph*. This latter feature is a great gain, as the compact habit of the plant allows it to be grown quite close—18 inches apart will suffice between the rows—so that it will be seen it is excellent for gardens limited in size.

The older *St. Joseph* and *St. Antoine de Padoue* are also well worth attention, these being the best of the perpetual class, the last-named being larger than *St. Joseph*, but not equal to *The Laxton*. Messrs. Laxton inform me that they have several other seedlings on trial, and doubtless *St. Joseph* will be one of the parents. There appears to me to be a desire to secure size in the perpetuals, but I hope if this is done that flavour will not be lost sight of, as this is most important. I am glad to say that the flavour of *Laxton's Perpetual* is much better than that of *St. Joseph*.

Culture is extremely simple. Strong runners planted early in the spring will fruit in the autumn, but to do this it is well to get the plants well rooted and to remove the first flowers that show. Good land that has been well manured and an open border not much shaded with trees, planting in rows 18 inches apart and 9 inches to 12 inches between the plants, will ensure a good crop the following season. To get late fruits the blossoms must be removed until a later date in the summer. I have got successions by

change of quarters, but I find the latest lot must get full exposure in every way. It is also advisable to make a new bed annually, and, this done, the old one can be destroyed, as the fruits, though numerous, get smaller after the second season's crop. During the cropping season in dry weather the plants will repay liberal supplies of food in the shape of liquid manure. G. WYTHES.

## THE KITCHEN GARDEN.

## THE FRENCH SYSTEM OF GROWING VEGETABLES IN GLASS FRAMES AND UNDER BELL-GLASSES.

(Continued from page 324.)

**O**THE crops which may be profitably grown in these warm frames in winter (starting at the same time as the Lettuces) are early Carrots, sowing Radishes among them at the same time. The Radishes will be ready for pulling before the Carrots have made any appreciable growth. Afterwards two crops of Tomatoes may be had from the frame during summer, planting five plants in the bottom of the frame, growing them in a prostrate form on the ground the same as the Melons, taking care that the fruits are placed high enough on inverted pots in order to expose them to light and to prevent their being splashed by the soil in syringing and watering. This also applies to Melons.

Another highly remunerative crop which may be forced in this way is the Asparagus. Roots of three years old and upwards may be dug up from the beds outside and placed thickly together in the frames on a bed of ordinary soil and covered with fine soil to the depth of 3 inches about the middle of November (the same time as the Lettuces and Carrots), and from this planting Asparagus may be cut within a month. As soon as the cutting from these roots is exhausted, the roots may be thrown away and others brought in, so that a succession of four crops at least may be grown in these frames on hot-beds. (I am presuming that the roots are grown at home, when they cost but little beyond the slight labour entailed; it does not pay to buy the roots to force.) Another valuable use these frames may be put to in connexion with this vegetable is to lift them off the hot-beds in spring when winter crops are over and place them over the ordinary Asparagus beds in the garden. This will result in Asparagus being cut at least three weeks earlier than would be the case in the ordinary way, when the price obtained would be more than trebled.

I will only mention one other crop out of a large number which could be included as amenable to profitable growth under this system, and that is the Strawberry. It is a well-known fact that the time the Strawberry is the scarcest and in the greatest demand is towards the end of May, when the pot-forced Strawberries are practically over and before the outside ones are ripe. By the timely use of these frames and cloches (when their services are over as regards winter crops) in covering over Strawberry beds outside as soon as they have set their fruit, the ripening of the fruit is enhanced by at least a fortnight or three weeks, and the difference in price this makes is often as the difference between 3s. per pound and 9d. per pound. I have trespassed too long on valuable space and can only hope that what I have had the privilege of saying may stimulate further enquiry into this subject, pregnant as I believe it to be with enormous possibilities as regards the remunerative employment of labour in the growth of winter and early spring vegetables by our country people, as well as in the greatly enhanced value of land to its owners. In the Vale of Evesham there are upwards of 2,000 acres under Asparagus culture, the best of it commanding a rent of from £10 to £15 per acre per annum. OWEN THOMAS.

## THE GREENHOUSE.

### IMPATIENS HOLSTII.

**S**INCE the introduction of this brilliant-coloured *Impatiens* into cultivation from German East Africa in 1903 numerous attempts have been made to cross it with other species in cultivation. Apparently the most successful in this respect are Messrs. Haage and Schmidt of Erfurt. Between *I. Holstii* and *I. Sultanii* they have obtained a number of very beautiful hybrids, one of which is illustrated. The new colours are very distinct and come almost true from seeds. Cuttings also root readily at almost any season of the year. Robust in growth and very free flowering, *I. Holstii* and its hybrids seem likely to supersede *I. Sultanii*, both for cultivation in pots and outside in summer. The individual blooms are  $1\frac{1}{4}$  inches to  $1\frac{1}{2}$  inches in diameter.

When once the plants reach the flowering stage they are seldom or never absent from the plants, and for several months, practically throughout the summer and autumn, the plants are covered with flowers, as in the illustration. They thrive best in soil consisting of equal parts loam and leaf-mould, to which plenty of sand should be added. Seeds, which are best sown in March, can be obtained of the following colours in separate packets or mixed: Carmine, dark scarlet, lilac, dark violet, white tinted rose and white with red eye. A. O.

### MALMAISON CARNATIONS.

"SOME years ago (possibly twelve or more) you published in *THE GARDEN*, when it was in a larger form, directions for growing Malmaison Carnations. I wonder if you could let me have them again. They were most successful, and two groups of them I had photographed. Each plant had something like 150 blooms and buds. I have, unfortunately, lost the directions, which were issued in the form of an article, "How to grow Malmaison Carnations." My gardener has neglected them and I am so anxious to get up the stock again."—Mrs. A. H.

Some time ago there was a discussion about the origin and time of introduction of this distinct class of Carnations, but none of the correspondents went quite far enough back. I knew the original blush variety before 1870. I could not be quite certain, but it would be either 1867 or 1868 that we had the first three plants, and I may say that I have been interested in them ever since. These notes being in reply to an enquiry regarding their culture I must keep to that rather than history, except to say that the first came from France. The enquirer asks how to grow them? In the first place, clean healthy stock is necessary, and if the plants already in stock are weak and unhealthy they should be thrown away and fresh healthy plants procured. The Malmaisons require rather different treatment to the other varieties grown under glass. To start with propagation. Layering is the best method for all the true varieties of the original *Souvenir de la Malmaison*, but many of the hybrids may be readily propagated from cuttings.

The best time for layering is when the side shoots have made a good growth, and this is usually about July. My practice has been to sink the smaller pots into larger ones and clear off all the lower leaves, then carefully cut from the under side of the shoots, bringing the knife up through one joint and about half through the stem. The advantage of sinking the plants is that the soil can be brought up to where the stem is cut, and it is dangerous to try to bend the shoots down much for they easily split off from the stem. When done in the open ground the plants may be laid down sideways, and in good ground they do better perhaps than in pots.

As soon as rooted they should be taken up and potted. Soil is of some importance, and although

I have grown them well in various soils, fibrous loam, leaf-mould and some well-decayed stable manure, with firm potting, will be found best; or if the loam is not fibrous, some peat may be added. Sand may also be necessary. In potting be careful that the soil is as firm at the bottom of the pots as on the surface, and do not press the surface down. Leave it loose so that the water can penetrate easily. Pot on into larger pots before the plants become pot-bound or stunted, and always give good drainage. In watering be careful when it is given that it penetrates to the bottom of the pots, but do not overwater. Position is a great point, while under glass they should stand on a moist bottom and have plenty of air above. During the winter the temperature may be kept up to 50° Fahr., and with sun may rise above. Avoid giving too

much fire-heat in dull weather, as it only weakens the plants and does not advance the flower-buds.

The same plants may be grown on from year to year, and some of the best I have had have been from three to five years old. The great point is to be careful in cutting the flower-stems out; they should be cut quite close down to the shoot that remains. They flower when grown naturally from early in May until the middle of June, and it may happen that while in flower they suffer from heat. I do not believe in much shading. A little may be given, and plenty of moisture under the stages or between the pots, with air above to prevent damp settling on the flowers. Sulphur and lime may be dusted about freely, and will keep away mildew and rust. It is generally when plants have done flowering that they get neglected, and where plants are to be grown on from year to year it is the most critical time. All old foliage should be cleaned off and the plants repotted before they get weak or stunted. With the older plants some of the soil may be removed, but this will depend on the condition of the roots. With good soil very little manure will be necessary, but when the pots are full of roots some may be given. Liquid made with cow manure and guano or soot may be added, but it should be made some time before required for use and allowed to settle down so that it can be used in a clear state. It is better to use it frequently in weak doses than to give it strong and less frequently. There is no secret in growing the Malmaisons well. Regular attention and potting at the right time are the chief items.

I may add that some growers keep them under glass all the year through, but they are better in the open during July and August if a suitable

position can be given, but should not stand where they may be flooded in case of heavy rains.

### VARIETIES.

The old introduction is still to be found, and is as good as when first introduced. It was not long after its introduction that we had a sport of a deeper colour; then we had Lady Middleton, a striped variety; and I believe it was a little later that Mr. C. Turner sent out a rosy pink variety. The variety now popularly known as Princess of Wales is certainly the best and most appreciated of all the Malmaisons, and in the market makes the highest prices.

Some time ago I visited the nurseries of Messrs. Hugh Low and Co., Bush Hill Park, Enfield, where I found all the varieties, including the hybrids, were being well cared for, upwards of

IMPATIENS HOLSTII AS GROWN AT KEW.

fifty varieties being grown. From these it is difficult to make a selection; but I must say that I believe some should not be included. The true Malmaisons have the peculiar habit of giving a second lot of florets from what should be the ovary. It was owing to this peculiarity that H. J. Jones, the fine crimson, was classed with the Malmaisons. Among those which I noted at Messrs. Low's were Princess May, similar to Princess of Wales; Lady Rose, a fine variety of a different shade of pink; and Nell Gwynne, the best or perhaps the only white—it is a little defective in habit, but the flowers are large and have the true scent of the Malmaisons. I might give a good many other names, but it would be better for anyone interested to visit a nursery such as Messrs. Low's or any other large grower and select for themselves.

I find on reference to notes that those I have seen and thought good a few years ago are now rarely seen. When I first grew Churchwarden it was good, but a year or two later I could not get good blooms. It has been the same with other hybrid varieties, yet the old true stock still remains as good as ever. I include the sports and not the seedlings, for my experience is that they are all doubtful. A. HEMSLEY.

### A BEAUTIFUL SEA LAVENDER.

(STATICE SUWOROWII.)

THIS is perhaps the showiest of all the Sea Lavenders when in flower, and one of our very best hardy annuals for autumn or spring sowing. Its greatest value, however, is as a pot plant for greenhouse decoration. Grown under glass the tall flower-spikes thickly clothed with mauve-pink blossoms attain to the greatest perfection. The oblong-lanceolate light green leaves lie almost flat upon the pot, and above them, rising to a height of 2 feet to 3 feet, are the many-branched flower-spikes. It is recorded that exceptionally well-grown plants have produced flower-spikes 5 feet in height. The tallest plants are raised from seeds sown in autumn, the plants being kept in a cool greenhouse or frame during the winter. The plants flowering in the greenhouse at Kew, one of which is illustrated, were grown from seeds sown in January. Their cultural requirements are of the simplest; well-drained pots, ordinary potting soil and cool greenhouse treatment being necessary. The plants do not make an abundance of roots, so that overpotting must be guarded against. A very good method is to grow several plants in a pot.

To flower in the open air the seed may be sown where they are to bloom in autumn or spring, or the young plants can be raised under glass and planted out at the end of April. The latter method is adopted in Hyde Park, where a bed composed largely of this beautiful Sea Lavender attracted considerable attention. Another valuable property of the flowers is that they are "ever-lasting." Cut with long stems when the flowers are fully open and hung in a cool place the stems will dry rigid and the flowers retain their beautiful tint for a year or more. For the decoration of rooms in winter they are very valuable in this state. A. O.

### A BEAUTIFUL NEW SALVIA.

(SALVIA SPLENDENS PRIDE OF ZURICH.)

DURING the last generation we have seen the flowering period of many plants greatly extended, and in some instances at least turned quite topsy-turvy, the flowering of *Lilium speciosum* in the spring from retarded bulbs being a case in point. In some cases, however, this change has been brought about by selection, as in the above-mentioned *Salvia*. The typical *Salvia splendens*, introduced from Brazil in 1822, has for the last half century, or perhaps more, been an extremely popular subject for the embellishment of the greenhouse or

conservatory during late summer and in autumn, at which season its bright scarlet-coloured flowers and bracts serve to lighten up the comparatively pale tints of so many of the *Chrysanthemums*, which form the bulk of the greenhouse flowers at that season. This newer form is much earlier flowering than the type.

Apart from its early-flowering qualities, this *Salvia* is also dwarfier in habit than the older type. It is highly spoken of as a subject for bedding out during the summer months. Exception may perhaps be taken to my reference to this *Salvia* as new, but it is really of recent introduction, and so little known as a decided break away from the type that the term new may not appear altogether out of place. It is already a favourite with those who know it, and one may safely predict that this plant has a rosy future in store for it. All the *Salvias* of this class are as readily struck from cuttings as a *Fuchsia*, and they grow away freely in any good potting compost, a little peat and sand mixed with good loam being much enjoyed. H. P.

A PRETTY SEA LAVENDER (STATICE SUWOROWII) IN THE GREENHOUSE AT KEW.

## THE FLOWER GARDEN.

### REVIVAL OF THE LACED PINK.

HOW much we owe to Mr. James Douglas, Edenside, Great Bookham, for giving to our gardens much of their flower beauty! At a recent meeting of the Royal Horticultural Society we were charmed with one of the most interesting groups of Laced Pinks we have ever seen, not the varieties we remember years ago, but seedlings raised by this famous florist. The flowers were of many shades, some exquisite in subtle colouring, and others perhaps more conspicuous for beauty of form. One we illustrate, *Bookham Gem*, a worthy name; the flower is of perfect shape, the edge deep rose purple, a warm shade, which seems to agree with the rich fragrance. The time for propagating these old favourites is now with us, and the operation of taking pipings or slips and inserting them in pots, boxes, or beds of sandy soil is a very simple one indeed. We heartily congratulate Mr. Douglas upon his success in raising these beautiful flowers.

### ERODIUM CARUIFOLIUM

THERE are some pleasing plants among the *Erodiums* or Heron's Bills, and the foliage in itself is usually very beautiful, the finely-cut leaves of the greater number increasing the attractions of the plants. Some are excellent rock garden plants, while a few are a little too large for any save the larger rock gardens. *Erodium caruifolium* seems to occupy the border line between the border and the rock species, but in districts where such plants grow vigorously it really ought to be a border flower. Its height is given as from 6 inches to 10 inches; but this season it is fully the latter height with me, even on a dry and sunny part of the rock garden.

It is a good plant, however, with its flowers of a red-purple, each about half an inch across and borne in umbels with sometimes as many as ten blooms together. If in the border its stems will need some support where they grow to more than 6 inches or 8 inches, but on the rockery they may be allowed to trail over a stone and show off the bright flowers. A hard and dry soil will help to keep it dwarf and will induce floriferousness, whereas a rich one would produce leaves at the expense of flowers. It is quite hardy, and can be increased by division after flowering or by seeds sown in spring.

S. ARNOTT.

### A BEAUTIFUL LATE-FLOWERING LILY.

(LILIUM SPECIOSUM.)

THIS is one of the most popular of all Lilies for pots, as in the first place it flowers naturally towards the latter part of August and in September, and is on this account particularly valuable for the greenhouse at a time when many summer-flowering subjects are on the wane and before the *Chrysanthemums* come

# THE NATIONAL ROSE SHOW.

THE annual show of the National Rose Society was held on what had been so far the hottest day of the year, and the flowers suffered accordingly. The heat was terrific, and many of even the prize blooms collapsed before the afternoon. It was distressing to see the effect of the tropical weather upon the decorative Roses, many of which were withered in an hour. But the exhibition was in every way a complete success, and, as our report shows, the competition was keen in most classes. The new Roses were interesting and two gold medals were awarded, both the sorts coming from Ireland. We must heartily congratulate Mr. Edward Mawley upon his unselfish and untiring work, and on the hon. treasurer, Mr. H. E. Molyneux. Without these helpers the society would not be in the proud position it is to-day. Her Majesty the Queen visited the exhibition in the morning and remained nearly two hours. Mr. E. B. Lindsell, the president, won the amateur challenge trophy, and Messrs. Prior and Son of Colchester the trophy in the nurserymen's division, both, it is needless to say, with superb exhibits.

## NURSEYRYMEN.

### GENERAL SECTION.

In the nurserymen's championship class, which is really the head contest in the United Kingdom, seventy-two blooms, distinct, are asked for, and five competitors entered, hence Messrs. D. Prior and Sons of Colchester may be most warmly congratulated on securing the championship. Certainly their blooms were superb, the whole being a very even and well-developed lot, the colour also leaving nothing to be desired. William Shean, White Maman Cochet, Robert Scott, Bessie Brown, Mme. Delville, Oscar Cordel, Oherhöfgartner Terks and Mrs. Theodore Roosevelt were a few of the very best. Messrs. R. Harkness and Co. of Hitchin came in a good second. Among their flowers were grand blooms of Florence Pemberton, Jean Soupert, Alice Lindsell, J. B. Clark, Yvonne Vacherot, Lady Moyra Beauclerc and Horace Vernet. Third honours went to Messrs. B. R. Cant and Sons, Old Rose Gardens, Colchester. We noticed Bessie Brown, Mme. Jules Gravereaux, Maman Cochet and Mildred Grant in fine condition in this exhibit. The fourth prize was awarded to Messrs. Alex. Dickson and Sons, Limited, Newtownards.

In Class 2, forty distinct varieties, three blooms of each, were stipulated, and competition was very good. Messrs. B. R. Cant and Sons, The Old Rose Gardens, Colchester, are to be congratulated on winning first prize here. Taken on the whole their blooms were very good, especially considering the scorching hot weather. Mildred Grant, Mme. Jules Gravereaux, J. B. Clark, Marie Baumann, Ben Cant, Souvenir de Pierre Notting, Dean Hole and A. K. Williams were a few that particularly appealed to us. The second position was allotted to Messrs. Alex. Dickson and Sons, Newtownards, whose flowers were also of high order. Mildred Grant, Bessie Brown, Princess Marie Mertchersky, Mrs. Bateman and William Shean were superb. Third honours fell to Messrs. D. Prior and Son of Colchester, some particularly good flowers of Dean Hole being staged in their exhibit.

For forty-eight blooms, distinct varieties, the first prize was won by Messrs. J. Burrell and Co., Cambridge, in strong competition. The flowers here were very good, and we specially noticed J. B. Clark, Mrs. Theodore Roosevelt, Mme.

Phillipe Rivore, Lady Ashtown, Mildred Grant and Mme. C. Soupert. Second honours fell to Messrs. G. and W. H. Burch, Peterborough, whose flowers were also excellent. Horace Vernet, J. B. Clark and Mme. Jules Gravereaux were exceptionally well formed and highly coloured. The third position was secured by Mr. George Mount of Canterbury. Mr. Hugh Dickson, Belfast, was considered equal third, and consequently an extra prize was awarded to his exhibit.

In the class for twenty-four distinct varieties there were six entries, the blooms staged by Mr. H. Drew, Longworth, Bucks, being granted first honours. Bessie Brown, Mildred Grant, Robert Scott and Dean Hole were the best. Mr. C. Turner, Royal Nurseries, Slough, was a very close second, his blooms of Her Majesty, White Maman Cochet and Mrs. E. Mawley being superb. Mr. E. Hicks, Twyford, Berks, was third.

For sixteen distinct varieties, three blooms of each, there were six entries, the first prize going to Messrs. G. and W. H. Burch, Peterborough, for a collection of extra large and well-finished blooms. Her Majesty, Mildred Grant, J. B. Clark and Alice Lindsell were particularly large and attractive. The second prize was well won by Messrs. J. Burrell and Co. of Cambridge, whose blooms of Mildred Grant were particularly good. Messrs. John Jefferies and Sons, Limited, Cirencester, were third.

### TEA AND NOISETTE SECTION.

For the D'ombrain Cup, twenty-four blooms, distinct varieties, had to be staged, and four competitors entered. Mr. G. Prince, Longworth, Berks, appropriated the cup with a beautifully-finished lot of flowers. Souvenir de Pierre Notting, Maman Cochet and Mrs. E. Mawley were the best. The second position was allocated to Messrs. B. R. Cant and Sons, Colchester. Bridesmaid, Mrs. Myles Kennedy and Maman Cochet were extra fine in this exhibit. Third honours went to Messrs. Frank Cant and Co. of Colchester.

For twelve blooms, distinct, there were also four entries, the first prize being well won by Mr. John Mattock, Headington, Oxford. He staged a very good bloom of Mme. Jules Gravereaux. Messrs. Paul and Son, Cheshunt, were placed second, their dozen containing grand flowers of Maman Cochet and Mme. Constant Soupert; third honours went to Messrs. J. Burrell and Co., Cambridge.

For fourteen distinct varieties, three blooms of each, to be shown in fourteen vases, there were seven entries, hence Messrs. B. R. Cant and Sons of Colchester may be congratulated on securing the first prize. Their exhibit contained excellent flowers of White Maman Cochet and Mme. Jules Gravereaux. Mr. H. Drew of Longworth, Berks, was second, and Mr. G. Prince third.

### EXHIBITION ROSES IN VASES.

In Class 9, twelve distinct varieties, to include not more than six varieties of Teas and Noisettes, seven blooms of each were demanded. This class was a very keenly fought one, and Messrs. Alex. Dickson and Sons, Limited, of Newtownards, were adjudged the champions. Their blooms were really a delightful lot, the form and colour being superb. Mildred Grant, Bessie Brown, Grace Molyneux and Lady Derby stood out prominent. Messrs. D. Prior and Son, Colchester, were a very good second. Maman Cochet, Mildred Grant and Bessie Brown as shown here being superb. Third honours went to Messrs. Frank Cant and Co. of Colchester.

In a similar class for quantities of Teas and Noisettes, the competition was not quite so good. Mr. Henry Drew, Longworth, Berks, was first with rather small but beautifully-coloured flowers. Maman Cochet, White Maman Cochet and Souvenir d'Un Ami were the best. Mr. John Mattock, Headington, Oxford, was second, and Mr. G. Prince third.

### SECTION FOR DECORATIVE ROSES.

For thirty-six distinct varieties, not less than three or more than seven trusses of each, Mr. John Mattock was first with a tastefully-arranged group of well-grown blooms; second honours went to Messrs. Paul and Son of Cheshunt, the flowers staged here being very fine indeed.

In Class 12, for eighteen distinct varieties, not less than three or more than seven trusses of each were asked for, and the competition was very good. Messrs. William Spooner and Son of Woking being first with well-grown stuff. Rubin and Jersey Beauty were particularly good. Second honours went to Mr. Charles Turner of Slough, and third to Mr. John Barrow of Oadby, Leicester.

For eighteen distinct varieties of summer-flowering Roses, Hybrid Perpetuals, Hybrid Teas, Teas and Chinas not admissible, Mr. G. Prince of Longworth, Berks, took the premier award with a tastefully arranged lot of flowers. Rubin, Himalaica and Mrs. Flight were very pretty. Messrs. G. Cooling and Sons of Bath were a good second and Messrs. Paul and Son of Cheshunt were placed third.

Eleven distinct varieties, not less than three sprays of each, was an interesting class, Mr. J. Mattock, Headington, Oxford, taking first prize. Mme. Abel Chatenay and Lady Battersea were very good here. Mr. G. Mount was second and Messrs. J. Jefferies third.

### GROUPS OF ROSES.

For a representative group of Roses on the floor, pot plants and cut flowers, Hobbies, Limited, Dereham, Norfolk, staged the first prize group. This was a really superb exhibit and fully deserved the honour. Such Polyanthas as Dorothy Perkins, Hiawatha and Lady Gay were fully represented at the back and in the centre, excellent cut blooms of various sorts being tastefully arranged in front and the whole edged with Maidenhair Ferns and Isolepis gracilis. Messrs. Paul and Son, Cheshunt, were second with a group that was little inferior to the first prize lot, all the material used being of high order.

In the class for a representative group of cut Roses, to be placed on staging, to include as far as possible Hybrid Perpetuals, Hybrid Teas, Teas, Noisettes, China and Polyantha varieties, the exhibits were very pretty indeed, and filled one whole side of a long tent. The first prize and gold medal here were won in fine style by Mr. George Mount of Canterbury. This group was a very beautiful combination of artistic arrangement and cultural skill, the flowers being in the pink of condition. Richmond, Killarney, Joseph Lowe, Laurette Messimy and many other beautiful sorts were freely displayed. Mr. F. W. Bradley, Peterborough, secured the second prize and silver-gilt medal also for a beautiful group of well-grown material. Frau Karl Druschki was very good. The third prize and silver medal were awarded to Messrs. W. and J. Brown of Peterborough.

### GENERAL SECTION.

OPEN TO ALL NURSEYRYMEN AND AMATEURS.

For eighteen blooms of any crimson Rose Messrs. R. Harkness and Co., Hitchin, were the

champions with splendid flowers of Ulrich Brunner. Second honours went to Messrs. B. R. Cant and Sons, Colchester, for the same variety, and the third prize was won by Mr. Hugh Dickson with Richmond.

In the class for eighteen blooms of any white or yellow Rose nine competitors tried conclusions, the premier prize being appropriated by Mr. John Mattock, Headington, Oxford, with superb flowers of Bessie Brown. Messrs. R. Harkness and Co., Hitchin, were second with very full flowers of Florence Pemberton, and third honours went to Mr. Hugh Dickson of Belfast. Comtesse de Nadaillac was the only yellow variety shown.

For eighteen blooms of any Rose other than white, yellow or crimson the first prize went to Messrs. Frank Cant and Co. for a delightful lot of Mildred Grant. Messrs. S. Bide and Sons, Farnham, were second with Queen of Spain, and third honours went to Mr. Hugh Dickson of Belfast.

In the class for twelve blooms of White Maman Cochet five competitors entered. Messrs. Frank Cant and Co., Baiswick Rose Gardens, Colchester, took first prize for a very highly-developed dozen. Mr. C. Turner of Slough was a good second and Messrs. B. R. Cant and Sons came third.

Class 21 was for twelve blooms of Frau Karl Druschki and twelve blooms of J. B. Clark, the flowers to be arranged alternately. The effect was very beautiful indeed, as no less than nine competitors staged blooms. Mr. George Mount of Canterbury was the champion with grand flowers. Second honours were splendidly won by Messrs. G. and W. H. Burch of Peterborough and the third prize was secured by Messrs. Frank Cant and Co. of Colchester.

For nine blooms of any new Rose the first prize was secured by Messrs. Alex. Dickson and Sons of Newtownards, Ireland, for a magnificent box of William Shean. The silver medal for the best Hybrid Tea staged by a nurseryman was awarded to a superb flower shown in this lot. Messrs. Frank Cant and Co., Colchester, were second with fine flowers of Mrs. Theodore Roosevelt, and Messrs. B. R. Cant and Sons and Messrs. S. Bide and Sons were equal third with Mrs. T. Roosevelt and Queen of Spain respectively.

The class for twelve blooms, distinct varieties, of new Roses, offered for the first time in the spring of 1905 and subsequently, was a most interesting one and the competition was good. Messrs. Frank Cant and Co., Colchester, were first with excellent flowers. We particularly liked Mme. Constant Soupert, Mrs. T. Roosevelt, J. B. Clark and Mrs. Myles Kennedy. Messrs. B. R. Cant and Sons were placed second, Countess of Derby, William Shean and Colonel K. S. Williamson being good here. Messrs. A. Dickson and Sons were third.

#### NEW SEEDLING ROSES.

For not less than six trusses of any new seedling Rose or distinct sport, Messrs. Alex. Dickson and Sons of Newtownards won a gold medal with Mita Weldon, a beautiful Tea of large size and rather flat shape, the colour being creamy white, tinted apricot. An equal honour was secured by Dr. J. Campbell Hall for a lovely Tea named Mrs. J. Campbell Hall. This has a delicate combination of cream and pink colouring, the petals being rather acute at the apices. Cards of commendation were granted to Shower of Gold, a yellow rambler variety shown by Messrs. Paul and Son of Cheshunt; W. R. Smith, shown by Mr. Hugh Dickson, and an unnamed Tea and a lovely variety named Grace Molyneux, both shown by Messrs. A. Dickson and Sons, Newtownards.

Earl of Gosford, a carmine Hybrid Tea, staged by Messrs. McGreedy and Son, was also granted a card of commendation. In shape it resembles J. B. Clark.

#### DECORATIVE CLASSES.

In the class for twelve varieties of single-flowered Roses, Messrs. George Cooling and Sons

of Bath were first. Their flowers were staged in excellent condition and contained fine examples of Lady Curzon, Andersonii and Stella. Messrs. Paul and Son of Cheshunt were second, Royal Scarlet and Irish Glory being very fine here.

For twelve vases of Mme. Abel Chatenay, seven trusses in a vase, Mr. G. Mount of Canterbury took first honours with some very large and fresh-looking flowers. Messrs. W. Spooner and Son of Woking were second, and Messrs. D. Prior and Son third. A group here that would have taken first prize was disqualified as being not according to schedule.

#### THE NICKERSON DIVISION.

For a representative group of the twelve Roses to which the recent ballot had entitled each of the raisers of those varieties to a silver cup, value five guineas, presented by Mr. W. E. Nickerson of Cambridge, Massachusetts, U.S.A., the first prize went to Mr. J. Mattock, Headington, Oxford, for a tastefully-arranged lot of flowers. Mme. Ravary, Dorothy Perkins and Caroline Testout were all good. Mr. G. Mount of Canterbury was second, and Messrs. Paul and Son of Cheshunt third.

In Class 98 a representative group of the twelve Roses occupying the second position on the balloting list was asked for. Mr. G. Prince, Longworth, Berks, was first here with very good flowers. Mme. Abel Chatenay, Una, Grüss an Teplitz and Marie Van Houtte were particularly noticeable. Mr. George Mount was third.

For a representative group of the twelve Roses occupying the third position on the balloting list, Mr. J. Mattock was the champion here with well-grown flowers of such varieties as Mme. Jules Gravereaux, Souv. de Pierre Notting and La France. Second and third prizes went respectively to Mr. G. Mount and Messrs. Paul and Son of Cheshunt.

#### BEST BLOOMS IN THE SHOW.

*Open Section.*—Hybrid Perpetual A. K. Williams, shown by Mr. George Mount of Canterbury; Hybrid Tea William Shean, shown by Messrs. Alex. Dickson and Sons, Newtownards; and Tea Mrs. Myles Kennedy, exhibited by Messrs. George Cooling and Sons, Bath.

*Amateurs' Section.*—Hybrid Perpetual Her Majesty, shown by Mr. E. J. Holland, Sutton, Surrey; Hybrid Tea Dean Hole, staged by Mr. E. B. Lindsell; and Tea White Maman Cochet, shown by Mr. Conway Jones.

#### AMATEURS' GENERAL SECTION.

In the amateur champion class for thirty-six blooms, distinct, for the Amateur Champion Trophy, value 50 guineas, there were seven entries. Leading honours fell, as usual, to Mr. E. B. Lindsell, Bearton, Hitchin, Herts, for a bright and beautiful exhibit. Oberhöfgartner Terks, Ulrich Brunner, Dean Hole, Nadaillac, Alfred Colomb, White Maman Cochet, Maman Cochet, Mildred Grant, Horace Vernet (grand), Ulster, Queen of Spain, Duchess of Portland, Mrs. John Bateman, A. K. Williams, Countess of Gosford, Marchioness of Londonderry, Marie Baumann and others were all very handsome. Second prize was won by the Rev. J. H. Pemberton, Havering-atte-Bower, Essex. Third prize went to Mr. F. Dennison, Rosecroft, Kenilworth, for bright flowers, and Mr. Conway Jones, Hucclecote, Gloucestershire, was fourth.

Mr. A. Tate, Downside, Leatherhead, was a good first in the class for twenty-four blooms, distinct, showing neat and even flowers of Mildred Grant, Dean Hole, Countess of Derby, Frau Karl Druschki and Florence Pemberton. Mr. E. B. Lindsell had to be satisfied with the second place, showing fresh and beautiful blooms of the best sorts. Third prize was secured by Mr. F. Dennison with a fresh lot of beautiful colour.

The class for twelve trebles was well contested, the competition being very keen. Of the eight entrants, the president (Mr. E. B. Lindsell) again

led with a superb exhibit. Mildred Grant, Duchess of Portland, Dean Hole, Florence Pemberton, White Maman Cochet, Mrs. J. Laing, Bessie Brown and Ulrich Brunner were the best varieties staged. Second prize was secured by Mr. E. J. Holland, Sutton, Surrey, also with a superb lot. Mildred Grant, Mrs. W. J. Grant, Maman Cochet, Dean Hole and George Laing Paul were striking examples. A good third was found in Mr. A. Tate's lot.

There were but four entries in the class for nine blooms of any Rose except Tea or Noisette shown in vases. Mr. F. Dennison was a good first with lovely flowers of Mildred Grant. Second prize was secured by Mr. G. A. Hammond, Cambrian House, Burgess Hill, Sussex, who staged lovely blooms of Dean Hole, and third prize was won by Mr. E. M. Eversfield, Deane Park, Horsham, with Florence Pemberton.

#### OPEN TO GROWERS OF LESS THAN 2,000 PLANTS OF EXHIBITION ROSES.

In the class for twenty-four blooms, distinct, there were but four entries. Leading honours were secured by Mr. W. O. Times, Hitchin, with a capital even lot of blooms; Mildred Grant, Ulrich Brunner, Mrs. J. Bateman, O. Terks, White Maman Cochet, Marie Baumann and Dean Hole were among the best blooms. Second prize was secured by Mr. Thomas B. Gabriel, Hart Hill, Woking, for a nice fresh lot; Killarney, Maman Cochet and Caroline Testout were good. Third prize was won by Mr. C. C. Williamson, Wilstead, Ethelbert Road, Canterbury. The winner of the first prize won the challenge cup, value 10 guineas, presented by Captain Christy.

Only three exhibits were forthcoming in the class for eighteen blooms, distinct. First prize was won by Mr. G. Speight, Market Harborough, with a very interesting series. W. Shean, J. Ruskin, Caroline Testout and a few others were charming. Second prize was secured by the hon. secretary, Mr. E. Mawley, Rosebank, Berkhamsted, with a bright box of blooms; and third prize went to Mr. Richard E. West, Reigate.

In the class for eight trebles, the six exhibits made a fine show. Mr. Speight was a good first, having superb examples of Florence Pemberton, Mrs. J. Laing, Caroline Testout, Mme. Jules Gravereaux, Gladys Harkness, Dean Hole, White Maman Cochet and Bessie Brown. Mr. G. Hammond's second prize lot were good, Dean Hole, Lady Ashtown, Oberhöfgartner Terks and Bessie Brown being very fine. Mr. W. O. Times, Hitchin, was an excellent third.

In Class 38, for seven blooms of any Rose except Tea or Noisette, Mr. Speight took the first prize with good blooms of Florence Pemberton. Mr. Times was second with Frau Karl Druschki, and Mr. A. W. Metcalfe, Luton Hoo, Luton, third.

#### OPEN ONLY TO GROWERS OF LESS THAN 1,000 EXHIBITION VARIETIES.

The seven entries in the class for twelve blooms, distinct, for the Grahame Memorial Prize, value 5 guineas, were very good. Dr. Charles Lamplough was a splendid first. White Maman Cochet, Dean Hole, Her Majesty, Mildred Grant and Gladys Harkness were all very praiseworthy. Second prize was well deserved by Mr. M. Whittle, and the third prize went to the Rev. J. B. Shackle, Dropmore Vicarage, Maidenhead, with a fresh series.

There were only four entries in the class for five blooms of one variety of any Rose except Tea or Noisettes. Mr. C. F. H. Leslie, Epcombs, Hertingfordbury, Hertford, was a good first with Caroline Testout, the Rev. J. B. Shackle was second, and the Rev. F. R. Burnside, Great Stourbridge Rectory, Essex, third.

The first prize in Class 41 for twelve blooms, distinct varieties, was the Ben Cant Memorial, value 5 guineas. This was won by Mr. William Upton with large fresh blooms of Countess of Caledon, Dean Hole, Caroline Testout, Mme. Jules Gravereaux, Mildred Grant, Bessie Brown

and others. Second prize was won by Mr. H. Robins, Ingatstone, Essex, with a neat series, and Dr. T. E. Pallett, Earl's Colne, Essex, was a good third. There were eighteen entries in this class.

The sixteen exhibits in the class for five blooms of one variety, except Tea or Noisette, made a fine display. First prize was secured by Mr. George Moules, Hitchin, Herts, with a grand lot of Mildred Grant. Mr. Bostock, Springfield, Northampton, was a good second with Florence Pemberton, and Viscountess Enfield, Dancers Hall House, Barnet, was third with fine examples of Caroline Testout.

The three entrants for six trebles in Class 43 were a pleasing feature. Dr. Lamplough again excelled, showing in grand form flowers of Frau Karl Druschki, Mildred Grant, Dean Hole, Florence Pemberton, Caroline Testout and Bessie Brown. A beautiful second was seen in the exhibit of Dr. T. E. Pallett, who had Killarney and J. B. Clark in rare form. Third prize was awarded to Mr. Joseph Wakeley, Rainham, Kent, with a bright series.

#### OPEN ONLY TO GROWERS OF LESS THAN 500 EXHIBITION VARIETIES.

For nine blooms, distinct, Mrs. E. Horne, Park House, Reigate, was first of the four entrants; Mr. J. Nightingale, Sutton, second; and Mr. V. Rolt third.

The ten exhibits in the class for six blooms distinct made a good display. Messrs. Burrell and Co.'s prize, value 2 guineas, was won by Mr. H. C. Baker with a charming box of blooms. Second prize was won by the Rev. H. S. Arkwright, and equal thirds went to Mr. Courtney Page, Enfield, and Mr. W. Upton.

In the class for five blooms of one variety, except Teas or Noisettes, the eleven exhibits made an excellent display. First prize was won by the Rev. H. S. Arkwright with superb examples of Florence Pemberton. Second prize went to Mr. Courtney Page for Bessie Brown, and third prize to Mr. Vivian Rolt for Mrs. John Laing. The president's prize, value 5 guineas, for twelve blooms, distinct, was well won, in very keen competition, by Mr. C. F. H. Leslie with a beautiful series of blooms. Mildred Grant, Ulrich Brunner, Maman Cochet and Florence Pemberton were superb. The Rev. H. S. Arkwright had beautiful blooms for second prize, J. B. Clark and Dean Hole being grand, and Mr. M. Whittle was third.

#### OPEN TO GROWERS OF LESS THAN 350 EXHIBITION VARIETIES.

Mr. E. F. Brown, Lynton, Slough, led the eleven competitors in the class for nine blooms, distinct. Killarney, Dean Hole, Earl of Warwick, Mildred Grant and Princess Marie Mertehersky were all noteworthy blooms. Second prize was awarded to Mr. E. L. Dixon, Sutton, Surrey, and third to Mr. George Lewis, Bushey.

The class for five blooms of one variety found ten competitors. Mr. E. F. Brown was placed first with Florence Pemberton, Mr. Alan Searle second with Dean Hole and Mr. W. P. Panckridge, M.P., Petersfield, Hants, third, with Frau Karl Druschki.

The class for four trebles was a pretty one, the seven boxes being very good. First prize was awarded to Mr. H. C. Baker. Dean Hole and Florence Pemberton were grand. Mr. Upton was a good second and Mr. R. H. Gifford, Edensor, Slough, a charming third.

#### OPEN TO GROWERS OF LESS THAN 200 EXHIBITION VARIETIES.

The fifteen entries in the class for six blooms, distinct, made a brave show, leading honours falling to Mr. C. G. Barron, Charnworth, The Avenue, Hitchin. This exhibit secured the piece of plate offered by Messrs. George Bunyard and Co. Mildred Grant and Dean Hole were good blooms. Second prize was won by Mr. W. G. Pedley,

Hoddesdon, Herts; and third prize by Mrs. E. A. Moulden, Bandra, Stevenage, Herts.

No less than seventeen boxes were staged in the class for six blooms in not less than four varieties. First prize was won by Mr. W. Bentley, 21, Lombard Street, E.C.: second prize by Mr. H. F. Matthews, Berkley House, Stevenage; and third prize by the Rev. J. F. Kershaw, Corsley Rectory, Warminster.

Twenty exhibitors staged in the class for five blooms of any Rose except Tea or Noisette, and made a grand display. First prize was won by Mr. C. G. Baron, Charnwood, The Avenue, Hitchin, with beautiful examples of Bessie Brown; second prize for Florence Pemberton went to Mrs. F. Pridham, Rickmansworth; and third prize was secured by Mr. G. W. Heaton Armstrong, Westcliff-on-Sea.

There were only three exhibits in the class for four varieties, three blooms of each, and the leading position was taken by Mr. Alfred H. Williams, The Moat, Harrow, who had a pretty series; the Rev. J. T. Kershaw was a good second, and Mr. F. A. George, Redhill, Worcester, third.

#### METROPOLITAN DIVISION.

The class for six blooms, distinct, brought out eleven exhibits. Premier honours rested with Mr. A. E. Clark, Mottingham, Kent, for a beautiful exhibit; second prize was secured by Mr. A. T. Booth, Westbury Road, Woodside Park, N., with a very attractive set; and third prize went to Miss B. H. Langton, Hendon, N.W., for a really handsome lot of flowers. This class was for the challenge cup offered by Mr. E. K. Smith.

There were only three boxes of blooms in the class for six flowers in not less than four varieties; Mr. W. D. Cony, Wandsworth Common, S.W., was first, Mr. A. Wilkinson, Granville Road, North Finchley, N., second, and Miss B. H. Langton third.

The fourteen entrants in the class for twelve blooms, distinct, was a pleasing feature. Mr. J. Hart, Little Heath, Potter's Bar, won first prize—a piece of plate offered by Messrs. D. Prior and Sons—with a really very excellent lot of blooms for a novice. Mr. Harold Peerman, Nantwich, was also a very good exhibitor for second prize. Third prize was secured by Mr. E. L. Dixon, Sutton.

For nine blooms, distinct, the two competitors dividing honours were, first prize to Mr. A. M. Darling, Tonbridge, and fourth prize to Mr. H. W. Sell, Kempton Villa, Luton.

The sixteen exhibitors in the class for six blooms, distinct, made an excellent competition. First prize was awarded to Mr. G. W. Heaton Armstrong; second prize to Mr. R. M. Munro, Mill Fields, Nantwich; and third prize to Mr. J. Smart, jun., Stevenage, all showing well.

#### OPEN TO AMATEURS WHO HAVE JOINED THE SOCIETY SINCE THE LAST METROPOLITAN SHOW.

The ten exhibitors in the class for six blooms, distinct, made a first-class effort. The piece of plate presented by the Misses Langton was won by Mrs. J. M. Bell, Haileybury, Hertford, with a neat lot. Second prize was won by Mrs. Wainwaring, The Lodge, Bembridge, Isle of Wight; and third prize by Mr. A. Talbot, Southend-on-Sea.

#### EXTRA CLASSES FOR AMATEURS GENERALLY.

For twenty-four blooms, distinct, Mr. Mahlon Whittle was placed first, winning the piece of plate offered by Mr. James Brown. Second prize was secured by Mr. E. M. Eversfield, Denne Park, Horsham, with a pretty series, and Mr. G. A. Hammond was third. In this class Mr. E. J. Holland was, unfortunately, disqualified.

The fourteen exhibits in the class for twelve blooms, distinct, made a grand display. First prize was well won by Mr. E. J. Holland with superb specimens. Second prize was won by Mr. E. B. Lindsell with a handsome series in

fine condition, and third prize went to Mr. W. Leggett, Colchester, with lovely blooms. The Hackness Cup was offered in this class.

For nine Teas and nine Hybrid Teas, the seven exhibits were most noteworthy. First prize was secured by Mr. A. Hill Gray, Newbridge, Bath, for a really lovely lot of flowers. Bessie Brown, Mme. Melanie Soupert, Comtesse de Nadaillac, Florence Pemberton and Alice Lindsell were superb. Second prize was won by Mr. Leggett with a beautiful series, and third prize was secured by Mr. E. M. Eversfield.

The class for six blooms of new Roses, distinct, was well filled. First prize was won by Mr. E. J. Holland, Mrs. John Biteman, Mrs. Theodore Roosevelt, Mme. Melanie Soupert, William Shean and Mrs. Myles Kennedy being shown in exquisite form. Second prize was won by Mr. F. Dennison, and the Rev. J. H. Pemberton was third.

For a collection of Roses there were four competitors. First prize was well won by Mr. H. L. Darlington, Potters Bar, with a really pleasing and interesting lot. Mrs. E. M. Wightman, Bengoe, Herts, was second and Mr. D. L. Freeland, Snodland, Kent, third.

#### TEA AND NOISETTE SECTION.

There were six competitors in the class for eighteen blooms, distinct, Teas and Noisettes. The challenge trophy and replica was well won by Mr. A. Hill, Grays, with a really delightful box of blooms; Mme. C. Soupert, La Boie d'Or and Maman Cochet were lovely. Second prize was awarded to Mr. O. G. Orpen, Colchester, with a dainty lot of blooms, and Mr. Conway was third.

Six boxes of blooms were shown in the class for twelve Teas and Noisettes. Mr. A. Tate won first prize—the Prince Memorial piece of plate—with an excellent lot of Roses. Mr. Eversfield was second and Mr. A. Hill Gray a very good third.

The class for eight trebles was very fine indeed, although there were but four exhibitors. Mr. A. Hill Gray was again first, showing the best sorts in charming form. The Rev. F. R. Burnside was second and Mr. Conway Jones third.

For seven blooms of one variety, Mr. A. Hill Gray was again first with Maman Cochet, Mr. Eversfield second and Mr. Orpen third.

Twelve Teas or Noisettes found eight competitors. Mrs. B. Fortescue led with a pretty lot of blooms of good colour, the Rev. J. B. Shackle second and Dr. T. E. Pallett third.

Seven entries were forthcoming in the class for nine blooms, Teas or Noisettes, Mr. Alfred Evans, Marston, Oxon, being first with a fairly even lot of blooms. Second prize was secured by Mr. Mahlon Whittle, 60, Belgrave Annexe, Leicester, who was close up, and third prize was awarded to Dr. Charles Lamplough, Alverstoke, Hants.

In the class for six blooms, Teas and Noisettes, Dr. F. H. Cooke, Colchester, was first of the ten entrants, showing well Cleopatra and D'Elise Vardon. Second, Mr. W. Upton, 16, Claremont Street, Belgrave, Leicester, also with a beautiful series. Third, Mr. H. C. Baker, Bayfordbury, Hertford.

For five blooms shown in a vase the Rev. H. S. Arkwright, Binfield Rectory, Bracknell, was placed first, with good blooms of Mme. Jules Gravereaux. Second to Dr. Cooke and third to Mr. H. C. Baker.

For six blooms Teas or Noisettes, distinct, there were fourteen boxes, a pretty series gaining first prize for Mr. Alan Searle, Ashton Lodge, Basselt; Empress of Russia and Mme. C. Soupert being very pretty. Second prize was won by Mr. V. Rolt, Storrington, Pulborough, and third prize went to Mr. H. F. Matthews, Berkley House, Stevenage.

In the class for nine distinct varieties, five blooms of each, there were seven very handsome exhibits. First prize was won by Mr. G. A. Hammond, Burgess Hill; second, Mr. E. M.

Eversfield; third, Mr. W. Leggett, Colchester. This is a pleasing break away from the more formal method of exhibiting, the blooms being arranged in vases.

#### DECORATIVE SECTION.—AMATEUR LADIES.

The table decorations were a most welcome feature, and were set up in a separate tent. There were fourteen exhibits, the leading table being that arranged by Mrs. O. G. Orpen, Colchester, who had a lovely rosy blush single with dainty buds deftly arranged with trailing growths of the Rose as an embellishment. Irish Elegans was the variety used. Second prize also for single Roses was won by Miss J. Langton, Hendon, N.W. Third prize was secured by Miss West, Reigate, for a brilliant crimson Rose embellished with Asparagus foliage and sprays of Rose foliage.

The eleven bowls of Roses were a most attractive feature of the show. Mrs. Orpen again scored with Damask Rose Mrs. O. G. Orpen charmingly disposed; Miss J. Langton was second with an exquisite display; and Mrs. W. Munt, Welwyn, Herts, third.

In another class of a similar character the seven exhibits were very beautiful. Miss J. Langton was first with a superb exhibit; Mrs. H. G. Molyneux, Purley, second; and Lady Wilmot, Bracknell, third.

Vases were very pretty, no less than thirteen being staged. First prize was won by Miss J. Langton with a charming arrangement; Mrs. E. Mawley, Berkhamsted, second with Liberty; and Lady Wilmot third.

## SOME OTHER ROSE SHOWS.

#### NORWICH ROSE SHOW.

ALTHOUGH styled "Rose show," the Queen of Flowers by no means monopolises the majority of exhibits at Norwich summer shows; indeed, this year Roses were rather scarce, this being due, no doubt, to the intense heat of the previous week, and also to the date being that before the great National Rose Society's Exhibition. Crown Point Park, the seat of Russell J. Colman, Esq., although some little distance from the city, was a great place for the show, and with the ideal day the attendance showed an advance over last year of nearly 1,500. A new feature of this year's show was an extra tent devoted entirely to Sweet Peas, which fully warranted its introduction, being filled with exhibits. The perennials were a great feature, as were also the Strawberries and Grapes, and, generally speaking, the exhibits were in advance of last year.

The principal awards were as follows: Forty-eight Roses, Messrs. B. R. Cant and Sons; forty-eight varieties, three blooms of each, Rev. J. A. Fellows; eighteen Teas, Messrs. J. Burrell and Co.; twelve blooms, not less than eight new varieties, Messrs. J. Burrell and Co. Amateur classes: Thirty-six blooms, Mr. R. Steward; twelve Teas, Mr. R. Steward. Growers under 500 plants: Twelve blooms, Mr. F. Valentine; six Teas, Lieutenant-Colonel Danby; twelve blooms, one variety, Mr. R. Steward. Confined to the county: Twenty-four blooms, Mr. R. Steward; twelve bunches of garden Roses, Sir F. Adair; best Tea, a Mrs. Edward Mawley shown by Mr. R. Steward; best Rose any other than Tea, a Mildred Grant shown by Mr. F. Valentine.

Miscellaneous cut flowers.—Twelve bunches, exotic, Mr. Lewis Smith, gardener to Robert Fellowes, Esq., who was also first for forty-eight bunches of herbaceous flowers with a grand collection admirably grouped. Six bunches exotic, B. E. Fletcher, Esq. Thirty-six bunches perennials, Mr. W. Chettleburgh, gardener to Colonel Rous, Westwood Hall; twenty-four bunches, Mr. H. Gonde, gardener to E. Reeve, Esq., The Grange, Catton, a new exhibitor in this section, who has made a splendid first impression; twelve bunches, B. E. Fletcher, Esq.; six bunches, Right Rev. Bishop Fisher. Flowering shrubs, Mr. W. Chettleburgh. Iris, Mr. L. Smith. Border Carnations, Mr. Henley, gardener to Sydney Morris, Esq., Wretham Hall. Sweet Peas, twenty-four bunches, the Mayor of Norwich; twelve bunches, Rev. R. F. Taylor; six bunches, Mr. F. H. Smith; twelve bunches, Messrs. Daniels Brothers, Limited, prize for their varieties, Mr. E. G. White. Messrs. Stark, Ryburgh, and M. R. Holmes, Tuckswood Farm, Norwich, made a big display of new varieties of Sweet Peas.

Pot plants, including Rex Begonias, greenhouse Ferns and Coleus, six plants of each: In all these classes Mr. W. Rush, gardener to F. P. Hinde, Esq., Thorpe, came out at the top. Celosias as shown by Mr. H. Gonde were much admired.

Fruit.—Collection, Mr. W. Shingler, gardener to Lord Hastings, Melton Constable. Three bunches black Grapes, Right Rev. Bishop Fisher; single bunch, black, Sir F. Adair, who was also first for three bunches of white, the

single bunch of white and for six Peaches. Mr. L. Smith was first for a collection of four varieties of Strawberries. Melon, Mr. P. Wright, gardener to W. J. Kirkbeck, Esq.

Peas, Beans, Cucumbers, Tomatoes and Onions were much in evidence in the vegetable department, with one or two nice groups of both vegetables and salad from Mrs. Lubbock, Mr. E. G. White and Mr. W. Chettleburgh.

Messrs. Daniels Brothers, Limited, of Norwich made a bold, comprehensive display of choice subjects from their nursery, and Mr. R. Notcutt staged a choice collection of herbaceous flowers.

#### SUTTON (SURREY) AND DISTRICT ROSE SOCIETY.

The twenty-seventh annual exhibition in connection with the above society was held in the Public Hall, Sutton, on the 1st inst., when a very fine display of blooms was made. We have rarely seen Bessie Brown and Mildred Grant shown in better condition than in some of the collections staged on this occasion. The arrangements were excellent and reflected great credit on the hon. secretaries, Messrs. F. J. Borland and E. L. Dixon, and the chairman and hon. treasurer, Mr. E. J. Holland.

In Division A, open to all nurserymen, the Sutton Challenge Cup, for forty-eight blooms, distinct, was won by Messrs. Frank Cant and Co., Colchester, with a splendid lot of blooms, Frau Lilla Rantenstranch, Lady Ashtown, Bessie Brown, Ulster, Mme. Jules Gravereaux and Mme. Constant Souper being exhibited in very fine form. The bloom of Bessie Brown secured the silver medal offered by Mr. Holland for the best flower in the division. Messrs. R. Harkness and Co. of Hitchin came in a good second. We noticed Mildred Grant, Papa Lambert and Mrs. Myles Kennedy very good in this collection. Third honours fell to Messrs. G. and W. H. Burch, Peterborough.

For twenty-four blooms, distinct, Messrs. G. and W. H. Burch were awarded the premier prize for a splendid two dozen. We noticed a huge flower of Bessie Brown and excellent blooms of J. B. Clark, Mildred Grant, Alice Lindell, Papa Lambert and Helene Guillot. Messrs. Frank Cant and Co. of Colchester were second with well-coloured flowers, and the third prize was allotted to Messrs. R. Harkness and Co.

For twelve distinct varieties, three blooms of each, Messrs. Burch were again awarded first prize, the flowers staged being of large size and substance. J. B. Clark, Her Majesty and Lady Ashtown were particularly noticeable.

In the class for eighteen blooms, Teas or Noisettes, Messrs. Frank Cant and Co. were the only exhibitors, but their blooms were considered worthy of the first prize.

In Division B, open to all amateurs, Mr. E. J. Holland, Sutton, was the winner of the Vice-President's Cup offered for the first time this year for twelve blooms, distinct. The flowers exhibited here were superb, being of good size, shape and colour. William Shean, White Maman Cochet, Bessie Brown, Horace Vernet, Mme. J. Gravereaux, Dean Hole, Mildred Grant and Her Majesty were all very fine indeed. The second honours fell to Mr. A. Tate of Leatherhead. We noticed particularly good blooms of White Maman Cochet, Comtesse de Nadaillac and Mildred Grant in this exhibit. The third prize went to Mr. E. M. Eversfield, Horsham, and an extra fourth prize was awarded to Mr. T. B. Gabriel of Woking.

For twenty-four blooms, distinct, Mr. E. J. Holland once more appropriated the first prize with grand flowers. His flower of Mildred Grant was magnificent, and won the medal offered by the National Rose Society for the best bloom in the division. Bessie Brown and Horace Vernet were also very fine. Mr. A. Tate, Leatherhead, was second, and Mr. E. M. Eversfield third.

For eight distinct varieties, three blooms of each, Mr. E. J. Holland was again a decided first, and rarely have we seen a better trio of Mildred Grant than those shown here. Bessie Brown and Dean Hole were also very fine indeed. Mr. A. Tate was second, and third honours went to Mr. E. M. Eversfield.

For twelve blooms, Teas or Noisettes, distinct, Mr. A. Tate of Leatherhead was the champion. His blooms included good ones of Souvenir de Pierre Notting and Bridesmaid. The second honours went to the Rev. F. R. Burnside, Great Stamburgh, Essex, who staged grand blooms of White Maman Cochet and Souvenir de Elise Vardon. Mr. E. J. Holland was third.

In Division C, open only to amateurs growing less than 1,000 plants, for twelve blooms, distinct, Mr. W. R. Hammond, Burgess Hill, was placed first. His flowers contained excellent examples of Mildred Grant and Dean Hole. Mr. E. E. Grimson of Sutton was second.

In the class for four distinct varieties, three blooms of each, Mr. Hammond was again the champion, the second and third prizes being awarded respectively to Mr. V. Rolt, Pulborough, and Mr. Lewis S. Pawle, Harrow.

For nine blooms, Teas or Noisettes, distinct, the premier honours again fell to Mr. Hammond, his best bloom being a rather small one of White Maman Cochet. Mr. V. Rolt was second and the third prize went to Mr. S. F. Jackson, Epsom.

In Division D, open only to amateurs growing less than 500 plants, the challenge cup offered by E. E. Grimson, Esq., for six blooms, distinct, was appropriated by Mr. V. Rolt of Pulborough with a really good half-dozen. Bessie Brown, Dean Hole and Helene Guillot were the best. The second prize fell to Mr. E. L. Dixon, Sutton; and the third to Mr. F. J. Nightingale, Sutton.

For six blooms of any one variety, Mr. S. F. Jackson was a good first with splendid flowers of Mildred Grant; Mr. L. S. Pawle, second, with Florence Pemberton; and Mr. V. Rolt, third, with Bessie Brown.

Mr. F. J. Nightingale, Sutton, was the winner of the Alexander Clark Challenge Bowl for nine blooms, distinct.

His flowers included good ones of Caroline Testout and Dean Hole. The second prize went to Mr. E. L. Dixon of Sutton, whose exhibit included the best bloom in Classes 15 to 18. This was a full flower of Florence Pemberton, and it secured the National Rose Society's silver-gilt medal. The third prize went to Mr. E. E. Grimson, Sutton.

In the division for local competition, Mr. Nightingale was also the winner of the piece of plate offered as first prize by Messrs. R. Harkness and Co. for twelve blooms, distinct. The second prize in this class went to Mr. E. L. Dixon.

The Ladies' Challenge Cup, offered for six blooms, distinct, was also appropriated by Mr. Nightingale, the second prize going to Mr. H. G. Morrish, Sutton, whose exhibit contained superb flowers of Mildred Grant and Frau Karl Druschki. The latter was awarded the National Rose Society's silver medal for the best bloom in Classes 19 and 20, and also a silver medal offered by A. E. Farnden, Esq., for the best bloom in the whole of the local classes. The third prize went to Mr. C. W. Edwards of Sutton.

For nine distinct varieties of Sweet Peas, shown in bunches, Mr. E. J. Holland was first with a good lot of flowers. Countess Spencer and Helen Pierce were excellent. Mr. H. Churcher was second and Mr. W. R. Hammond third.

For six distinct varieties, in bunches, Mr. E. T. Baker was first with fair flowers, Mr. H. E. Whistler being second and Mrs. C. G. Johnson third.

#### REIGATE ROSE SHOW.

A HIGHLY-CREDITABLE exhibition was held on the 27th ult. Competition on the whole was very keen, the exhibits evoking considerable interest. In the first division (open to nurserymen) the Reigate Challenge Cup for forty-eight distinct varieties fell to Messrs. R. Harkness and Co., Hitchin, who staged a very fine lot of blooms, including Queen of Spain, Mildred Grant, J. B. Clark, Hugh Watson, Kaiserin Augusta Victoria, Hugh Dickson, Earl of Dufferin and Mrs. Myles Kennedy. Messrs. Frank Cant and Co., Colchester, came second with a good collection, some of the finest being Dean Hole, White Maman Cochet, Bessie Brown, Mildred Grant, Mme. Jules Gravereaux, Duchess of Portland, M. Joseph Hill and Duke of Edinburgh. Messrs. B. R. Cant and Sons, Colchester, were third.

For twenty-four distinct varieties, Messrs. G. and W. H. Burch, Peterborough, were first, with fine blooms of Helen Keller, Mrs. John Laing, Kaiserin Augusta Victoria, Countess of Caledon, J. B. Clark and Queen of Spain. Messrs. B. R. Cant and Sons were second; and Mr. E. J. Hicks, Twyford, Berks, third.

For twelve bunches of garden Roses, Messrs. Spooner and Sons, Woking, came first with a lovely display, Eda Myer, Mme. Abel Chateaufort, Richmond and Mme. Chédane Guinousseau being very fine, followed by Messrs. F. Cant and Co. and Mr. G. Prince, Longworth, Berks.

In the amateurs' classes the Challenge Cup for twenty-four distinct varieties went to Mr. E. J. Holland, Sutton, who had particularly fine blooms of Mildred Grant, Horace Vernet, Bessie Brown, Gustave Piganeau, Fisher Holmes, Hugh Dickson, William Shean and Laurent Carle. Mr. A. Tate, Leatherhead, came second with good blooms of Antoine Rivoire, Mildred Grant, Victor Hugo, Mrs. Edward Mawley and White Maman Cochet, the last named receiving a medal as being the finest specimen bloom in the division. Mr. E. M. Eversfield, Horsham, was third.

For twelve distinct varieties, Mr. E. J. Holland was again first; Mr. G. A. Hammond, Burgess Hill, second; and Mr. E. M. Eversfield third.

For eight distinct varieties, three trusses of each, Mr. E. J. Holland was the champion, showing good flowers of Bessie Brown, J. B. Clark, Florence Pemberton and Mrs. W. J. Grant. He was followed by Mr. E. M. Eversfield, with good blooms of Dean Hole, Hugh Dickson and Lady Ashtown. Mr. G. A. Hammond was third.

For twelve Teas or Noisettes, Mr. E. M. Eversfield came first; Mr. A. Tate, second; and the Rev. J. A. Fellows, Attleborough, third.

For eighteen distinct varieties (amateurs growing less than 2,000): First, Mr. F. Slaughter, Steyning; second, Mr. R. E. West.

For nine distinct Teas (amateurs growing less than 2,000), Mr. F. Slaughter again took premier award with excellent flowers of Maman Cochet, White Maman Cochet (medal bloom of the division), Roadicea, Mme. de Watteville and Caroline Küster. Mr. J. B. Gabriel, Woking, was second.

For twelve distinct varieties (amateurs growing less than 1,000), challenge cup: First, Mr. W. R. Hammond, Burgess Hill; second, Mr. D. L. Freeland, Snodland.

For twelve distinct varieties (local competition) challenge cup: First, Mr. F. C. Morrison; second, Mrs. C. Horne; third, Mr. A. C. Brown.

For nine distinct varieties (local competition), challenge cup: First, Mr. F. C. Harrison; second, Mrs. R. Adams.

For six distinct varieties (local competition), challenge cup: First, Mrs. R. Adams; second, Mr. C. B. Haywood; third, Mr. F. C. Harrison.

For six blooms, not less than four varieties (local competition), challenge cup: First, Mr. A. F. Blades; second, Mr. W. H. Gattier; third, Mr. J. S. Motion.

Table decoration, challenge silver Rose bowl: First, Mrs. Codd, Reigate, with a splendidly-arranged exhibit, consisting solely of one variety, Mme. Abel Chateaufort, with its own foliage. The award was richly deserved. Miss West was second, with Miss J. P. Pearson and Miss Spreckley third and fourth respectively, several others receiving commendation.

in; next, no Lily is less liable to be attacked by insect pests; and, thirdly, the blossoms have not the heavy fragrance of some Lilies, which in a confined place is often overpowering.

The bulbs of *L. speciosum* as sent from Japan are, as a rule, from about 8 inches to 12 inches in circumference. If the bulbs are potted singly, pots from 6 inches to 8 inches in diameter are suitable, while effective masses may be formed by putting several bulbs in large pots or tubs. Australian butter tubs, square in shape, a foot in diameter and the same in depth, are very suitable for the culture of these Lilies, and indeed many other plants. They are stout and strongly made, and the wood of which they are composed does not decay quickly.

Four years ago I obtained two of these tubs, bored five half-inch holes in the bottom of each, and gave them three coats of good oil paint. When thoroughly dry a layer of broken crocks with the concave side downwards was placed over the bottom, then some soil, and in each tub five bulbs were placed at an equal distance from each other.

The potting soil, which is of more importance than some imagine, was made up of one-half rather heavy fibrous loam, the remainder consisting of leaf-mould, dry cow manure and rough sand in about equal proportions. Such a soil is an ideal one for most Lilies. The bulbs were placed in the soil at such a depth that the upper part was 2 inches below the surface, and at the same time a space of 3 inches was left to the rim of the tub. This was not, as might be supposed, to allow for watering, as 1 inch or a little more would suffice for that, but as the stems of *Lilium speciosum* develop they push out a number of roots from their base, and then a top-dressing is useful, as it supplies an additional rooting medium just as it is required.

These tubs of Lilies, which are in summer used to decorate a small terrace, have flowered beautifully for the last four years. They are simply protected during the winter by two or three old sacks thrown over each. Then, before growth recommences, a little of the old and exhausted soil is taken from the top and some fresh put in its place. The drainage is still perfect, and everything points to a good display for another year, the buds being now visible. At first each bulb threw up one vigorous shoot, but now the stems are much more numerous. They are, however, less vigorous than the original ones.

Though these tubs just referred to are always out of doors, such treatment is not advisable when the plants are needed for the greenhouse. For this purpose the bulbs when potted had better be placed in a cold frame, that is to say, without any artificial heat, but they must be protected from sharp frosts by a few mats or other covering material. Sufficient water should be given to keep the soil slightly moist, but care must be taken not to overwater till the roots are active. As the stems, leaves and flowers develop more water will, of course, be required. By March or soon after the succulent shoots will push through the soil, and from that time it is necessary to see that they are not allowed to become drawn and weak. To obviate this the growing plants will need plenty of light and air.

When all danger from frost is over the plants may be stood or plunged out of doors, taking care that they are not allowed to suffer from want of water. When the pots are full of roots a little weak liquid manure occasionally will be helpful. Taken into the greenhouse just before the earliest flowers expand a few plants of this Lily will form an attraction for a considerable time.

After flowering they should be stood out of doors, watering them as before till the stems die down. When sharp frosts threaten the pots had better be removed to the frame, and when repotting is needed it should at the latest be done soon after Christmas. As a rule bulbs kept for the second season flower ten days or so earlier than freshly imported ones. A common error is that of drying off the bulbs during the winter, as it

PINK BOOKHAM GEM. (Natural size.)

is most injurious to those bulbs with loose scales, such as *Lilium*.

The varieties of *Lilium speciosum* are: Kratzeri, a yellowish coloured bulb with rather pale green leaves and white flowers; coloured kinds—*rubrum*, with rosy red-tinted blossoms; and *Melpomene*, in which they are of a deeper hue. This last is from its richness of colouring most attractive.

The flowers of *Lilium speciosum* which are so attractive in the florists' shops throughout the winter and spring months are obtained by retarding the bulbs beyond their normal season of growth by keeping them in refrigerators. As soon as these bulbs are taken into a more genial temperature and potted they grow away rapidly and then flower.

H. P.

## THE ROSE GARDEN.

### HYBRID BRIAR ROSES.

Is there not one among the multitude of British rosarians who will take up the work so ably begun by that indefatigable hybridist Lord Penzance towards the improvement of our native Briar? It is true he worked mainly upon the European species, *R. rubiginosa* or Sweet Briar, but, I believe, his aim was also to improve the bloom of *R. canina*. We all know the splendid results of Lord Penzance's labours with *R. rubiginosa* and the charming colours to be found in the sixteen varieties he named. Where is there a more delightful gem than Lady Penzance, with its tints of apricot and orange, or the glowing scarlet of Anne of Geierstein? To read this hybridist's account of his successes and failures in the "Rosarian's Year Book" for 1892 compels us to wish such an enthusiast were with us to-day. In 1896 we find him writing in the "Rosarian's Year Book" that he had established one great fact, which was that different races or families, however opposed, were capable of uniting in a common progeny. Have we not seen this verified? Look at the marvellous mixture of *Rosa wichuraiana* and an Hybrid Perpetual, which gave us Dorothy Perkins, or, still more marvellous, that of Persian Yellow crossed with Antoine Ducher (H.P.), which produced Soleil d'Or.

M. Pernet Ducher has not been slow to utilise his creation of Soleil d'Or in still further successes by crossing some of his splendid Hybrid Teas with seedlings from Soleil d'Or, for we have announced for this year the Lyon Rose, which should prove quite the novelty of the year if the report of those who have seen it is correct. M. Jules Gravereaux has also been working upon Persian Yellow, and his Lea Rosuti, a cross between the latter and a seedling, should be good.

One of the most beautiful results, in my opinion, of the crossing of *Rosa canina* with a Tea Rose is manifest in the variety Una. Here we have all the lusty vigour of *R. canina* with a delightful Tea-like bud of delicate cream opening to a large single bloom of wondrous beauty.

In Gottfried Keller, Dr. Muller has given us a marvellous combination. First we have Mme. Berard crossed with Persian Yellow, then this seedling crossed with another seedling from Pierre Netting and Mme. Berard, and this again crossed with Persian Yellow. The result is a delightful single Rose of perpetual Tea-like characteristics, but a flower nearly single, reminiscent of a large blossom of Lady Penzance. I am very anxious to see Herr Lambert's novelty Parkfeur, which is said to be more dazzling than Grüss an Teplitz.

It is evident to me that there is a vast unexplored field for the hybridist among Roses alone, and it is a most fascinating work for one with leisure, only my advice would be, do not attempt too much. Set to work on some given object, say, the improvement of the Scotch Rose, perpetuating the *wichuraiana* or multiflora groups, or the beautifying of our hedgerows by producing rich coloured Dog Roses.

All who grow the Penzance Sweet Briars should take the hint given by Lord Penzance and have spent blossoms removed and all seed-pods; they would then obtain a good number of flowers in autumn.

P.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**G**REENHOUSE AND CONSERVATORY.—Seeds of the herbaceous Calceolarias may be sown now to provide plants for flowering in May and June next year. I make a sowing of these seeds in light sandy soil that is finely sifted, thinly distributing the seeds on the surface, which should previously be made fairly firm. Lightly cover the seed with fine sand, and place a piece of glass over the pan until germination takes place. These plants may be raised in a cool greenhouse or cold frame, shading the pans from bright sunshine. Plants in the greenhouse and conservatory need to be overlooked pretty often just now. Fuchsias, Heliotropes, Petunias, Geraniums, Liliums and quite a host of other subjects that are now well rooted require water more often than formerly. An occasional application of liquid manure will greatly assist the plants. Cuttings of the showy regal, fancy and show Pelargoniums may be

1.—A CLUMP OF DOUBLE DAISIES LIFTED READY FOR DIVISION.

*The Flower Garden.*—Mulching the stronger-growing subjects in the border should be done without delay. As far as possible let the watering be done in the late afternoon or evening, as the plants are able to take more advantage of liquid plant food applied at this time. Do not just sprinkle the surface with a rosed watering can, but apply the water or liquid manure quite freely to the roots of each plant. The free use of the hoe between the plants is highly beneficial atill, aerating the soil, keeping weeds under and also assisting the soil to absorb the moisture applied and the plants to benefit thereby. Several well-known and reliable annuals may still be sown for providing flowers in the early autumn. Shirley and other Poppies, Candytuft, Mignonette, Nemophila insignis, Virginian Stock and Gypsophila elegans are excellent for this purpose. Should the soil be very dry give the quarters a good watering over night, sowing the seeds on the anucceeding morning. Sow thinly.

*The Vegetable Garden.*—Continue to plant winter greens and finish this work as soon as possible; plant firmly, giving the plants plenty of room, as advised in earlier issues. I am now making a sowing of Parsley for winter use, selecting a sheltered border where the soil is nice and friable. Sow in drills 1 inch deep and 1 foot to 15 inches asunder. In a few weeks the seeds should germinate, after which progress will be comparatively rapid. Shallots in many gardens will be quite ready for lifting. Should the weather be wet or showery, place them out on the greenhouse bench or in a shed to dry. If the weather is fine they may be spread out thinly in the open and afterwards stored away in some cool and airy place until required for use. Ridge Cucumbers in the open will now need plenty of water to keep them in health. Take the chill off the water first if it has not been exposed to the sun's influence for long. D. B. C.

### DIVIDING SPRING-FLOWERING PLANTS.

Now that most of these have finished flowering, our thoughts naturally turn to their future treatment. If the plants are doing well and we do not want a larger stock all that is necessary is to cut off the old flower-stems and clean the plants. Next fork over the soil between and

top-dress with a little fresh soil in which a small quantity of well-decayed manure has been placed. This is all the attention they will require, except keeping them free from weeds and watering occasionally when the weather is dry. In addition to the desire to obtain more plants, it may be advisable to lift them because they are crowded or because the plants are degenerating through growing in the same position for some years and the plant-food becoming exhausted.

*How to Divide the Clumps.*—Fig. 1 shows a root of the double white Daisy lifted after flowering. Having shaken most of the soil from the roots, it will be found to consist of a number of growths similar to those illustrated in Fig. 2. These readily divide up into pieces as shown, and each, if planted separately, will grow into a nice plant to flower next spring. The position to plant them depends on the ground available. They may be either planted where it is desired for them to bloom or on a spare piece of ground, preferably sheltered from the sun for an hour or two during the middle of the day. Previous to planting the ground should be dug and well manured. When planted on a spare border temporarily they may be moved to their flowering quarters in autumn or early spring. Subsequent treatment will consist in watering the plants during dry weather, syringing them after hot days till growing freely and stirring the surface soil between the plants. The variety illustrated in Fig. 3 is named Monstreuse and has pure white flowers 2 inches to 2½ inches across. Rob Roy (red), Longfellow (rose) and Alice (pink) are all good sorts for the garden in spring.

The following subjects may also be divided at the present time. All are easily grown in ordinary garden soil, and will be found very useful for growing in small beds as illustrated in Fig. 3 and Fig. 5, as a groundwork for spring-flowering bulbs, groups, or edgings for the mixed border or for filling pockets in the less favourable positions in the rock garden.

*Rockfoils.*—Several of the Saxifragas or Rockfoils are delightful plants for the garden in spring. One of the best is Wallace's Saxifrage. A small round bed illustrated depicts this plant forming a perfect carpet of small white flowers in May. London Pride (*Saxifraga umbrosa*) is about 9 inches to 1 foot high when clothed with pinkish blossoms. The Mossy Saxifrage

3.—A SMALL ROUND BED FILLED WITH THE DOUBLE WHITE DAISY MONSTREUSE.

propagated forthwith for next summer's display. Any light sandy soil may be used, inserting the cuttings around the edge of small pots, and these stood outdoors in a sunny position to root. Apply water sparingly.

*Roses.*—These are now making a beautiful display, although there are instances where insect pests are causing anxiety. I syringe my plants with clear water heated to about 120°, this effectually ridding the shoots of green-fly. I am now proceeding with the budding of my Rose Briara. I believe in getting this work done in good time. Roses intended for greenhouse culture in the winter and spring should be repotted without delay. These plants revel in a compost made up of two parts good fibrous loam, two parts well-rotted manure and one part charred earth and clean road-grit, all thoroughly mixed together.

*Orchids.*—The hot weather at this period makes it imperative that the grower should shade more heavily than usual all cool house Orchids. Air, too, must be admitted to the glass structure quite freely at this season. The value of maintaining the greenhouse paths and benches in a cool, moist condition is invaluable just now, and this can only be achieved by constantly using the rosed watering can and syringe.

(S. Rhei) forms a dense mass of bright green growths, which are refreshing throughout the year. It is especially suitable for an edging to a border. In May the plants are studded with small pink and red flowers.

*Double Primroses.*—The beautiful old double Primroses have lost much of their popularity. This is to be regretted, for they are delightful subjects for a moist shady border. In the North of England, Scotland and Ireland they are met with more frequently than in the South. By lifting the plants now and dividing them they will, with proper attention, make nice clumps for flowering next spring. The names by which they are known in gardens are mostly descriptive of the colour of the flowers. These include *alba plena*, white; *lilacina plena*, deep lilac; *purpurea plena*, purple; *rosea plena*, rose-coloured; *sulphurea plena*, sulphur yellow; and *rubra plena*, red.

*Siebold's Primroses.*—The varying tints of the flowers of these plants are among the most delicate and chaste in the garden in spring. They are easy to grow, the colours are numerous, and the plants are very free-blooming. The plants prefer a light rich soil in which plenty of leaf-mould and a little well-decayed manure

4.—A CLUMP OF WALLACE'S SAXIFRAGE LIFTED READY FOR DIVISION.

enthusiast to produce these roots in abundance from the middle of October onwards until the plants begin to run for seed, providing large roots are not needed.

Those who have had any experience in growing Carrots for seed purposes will know that it is the usual practice to sow the seeds for stock plants at the end of July or early in August, the plants being allowed to remain in the seed beds until the following February, when they are lifted and planted in the seedling quarters. A slight modification of this system will give us the roots we require for use in the winter and early spring, compared with which the old, large roots are much inferior.

It is necessary to select a well-drained site on rather light soil and a position where Peas or early Potatoes have been removed from will answer admirably. This must be thoroughly dug and all large lumps broken, but manure will not be necessary, as sufficient will have been left by the previous crop to supply the one we now have under consideration. Tread the ground firm and rake it level, so that a fine tilth is secured, then draw shallow drills 1 foot apart for the reception of the seeds.

If the soil is very dry, as it probably will be, it is a good plan to well water each drill before sowing the seeds. Scatter the latter rather thinly and then cover and tread down in the usual way. Sowing for this crop is best done about the middle of July. Germination will be greatly facilitated if some slight shading can be afforded, and where the bed is not a large one this should certainly be done, using brown paper, old fish netting, leafy boughs, or any other material for the purpose. When the seedlings are well up all weeds must be removed and the young plants thinned so that each stands well by itself. If left very thick, water is apt to stand round the crowns during the winter, and the plants suffer accordingly. During a spell of very frosty weather a slight protection will be needed, old Bracken, straw, Spruce boughs or similar material answering admirably for the purpose.

#### ROSES FOR THE AUTUMN.

WHETHER we obtain a good autumn crop of flowers from our Rose bushes or not will depend to a great extent on the treatment meted out to them now, and those beginners who are anxious to have late flowers will do well to pay attention to one or two very simple details.

The tyro in gardening is so very apt to spare the knife and spoil the plant that it is little wonder that this frequently happens with the Rose. When cutting summer blooms do not be

afraid of securing a good length of stem with them. By doing this the flower is rendered more valuable for many purposes and a crop of autumn flowers is practically assured. This hard cutting induces dormant buds to break at the base of the stem, and it is the shoots which spring from these that will bear those flowers so welcome in September.

In addition to a bold use of the knife, the plants must have ample supplies of food, as it is clearly evident that a double crop of blooms means an extra strain on the plants; therefore, frequent waterings with clear water and liquid manure must be resorted to, supplementing these with some approved artificial or natural manure.

#### SOWING SEEDS FOR EARLY SPRING FLOWERS.

THERE are no flowers more appreciated than those that greet us in the spring, and, fortunately, many of them are so easily raised and grown that nobody with a garden plot need be without them. Prepare an open sunny patch of ground by levelling with a rake, draw shallow drills, taking care that they do not exceed 1 inch in depth, and sow the following seeds at the end of July: Sweet Allysium, white; Virginian Stock, various colours; Candytuft, white and crimson; Larkspur, blue and white; *Nemophila insignis*, a beautiful blue edging plant; *Limnanthes Douglasii*, a 6-inch high yellow and white flower, grand in a mass; *Saponaria calabrica*; the Calabrian Soapwort, pretty white and pink starry flowers; *Viscaria cardinalis*, glowing crimson scarlet flower resembling a Flax in shape, 15 inches high; *Collinsia bicolor*, pretty flowers of mingled blue and white; and *Silene pendula compacta*, a splendid rose-coloured flower that blooms in masses in warm and sheltered gardens. All the plants mentioned should be thinned out in the seed-bed if they come up quickly, and may be planted where they are to bloom in October.—E. J.

6.—A DIVIDED PORTION OF WALLACE'S SAXIFRAGE. THE ARROW DENOTES THE DEPTH TO PLANT, AND THE ROOTS SHOULD BE CAREFULLY LAID ROUND IN A SHALLOW HOLE MADE WITH A TROWEL.

5.—A BED OF WALLACE'S SAXIFRAGE AT THE END OF MAY.

has been mixed. The leaves die off in autumn, the young foliage pushing up in early spring. Among the numerous varieties the following half dozen are distinct and recommended: *Alba magnifica*, white; *clarkæflora*, magenta; *lilacina superba*, lilac; *grandiflora*, creamy white, flushed rose; *Maiden's Blush*, pink; and *Sirius*, red, white centre.

*Leopard's Bane (Doronicum).*—This is a showy early-flowering plant with large yellow Daisy-like blooms. As they will thrive in almost any soil or position, the *Doronicums* are generally planted in the less favourable spots in the garden. They range in height from 1 foot 6 inches to 2 feet 6 inches. The commonest species is *D. plantagineum*, of which the variety *excelsum* or *Harpur Crewe* is the best; this flowers in May. *D. austriacum* flowers in April, and as early as March in favourable localities; it grows about 18 inches in height.

#### YOUNG CARROTS IN WINTER AND SPRING.

A CROP of fresh, sweet young Carrots during the winter and early spring months is one that does not need any recommendation, as it would be very welcome indeed in every household where these roots are esteemed. How to secure such a crop is a question that may be puzzling to many, yet it is comparatively easy for any gardening

## THE TOWN GARDEN.

**BUDDING ROSES.**—Although it cannot be asserted that Roses rank with the most satisfactory of flowers for the town garden, there are large numbers of amateurs who, despite many failures, still essay their culture, and it must be acknowledged that some of them achieve great success when allowance is made for the circumstances under which they labour. And those who grow Roses invariably desire to raise some of their own plants by budding. This is the time of year to put the operation in hand. I would urge everyone to try it, for the process is simple and full of interest. At the outset two things must be considered. First the condition of the stock, and, second, the state of the bud. As far as the former is concerned it is imperative that it shall be in such condition that the bark will rise easily to admit the bud. In reference to the bud it is essential to study the small slice of heart wood which is found inside the bud sheath when this is cut from the plant. It is necessary to remove this, and upon the manner in which it comes out one decides upon the prospects of success. If it hangs very tightly in position, the bud is unripe, while if it flies out instantly, the bud is over ripe, and neither condition is favourable. If, however, it hangs up a little and yet can be withdrawn it is safe to assume that the bud is just right and that it will grow satisfactorily. Directly a man has mastered the art of knowing when the bud is right he will have complete success. The cuts on the stock are first an upward one some  $1\frac{1}{2}$  inches to 2 inches in length and next a cross cut at the top about half an inch or less in width; as soon as these have been made the bark on each side should be carefully raised with the handle of the knife and the bud slipped into its place. With the necessary tying in the operation is finished.

**LAYERING CARNATIONS.**—These delightful flowers have their season of beauty at the same time as the Rose, and they thrive so excellently in town gardens that they should always be represented. It is true that the sparrows will demand a heavy toll unless they are circumvented, but by black threading the plants efficiently in the spring they can be kept at bay, and growth will be unchecked. It is common and good practice to try one or two new varieties each season, and when these bloom one decides upon those that are to be kept and marks others to be discarded. The favoured ones must be increased, and the best method for adoption is by layering, which should be commenced as early as possible so as to ensure splendidly-rooted plants to pass through the winter. A compost of three parts of loam and one part of leaf-mould, with an addition of sharp, clean sand, should be prepared and mounded up round the plants to be increased, and into this the shoots should be pegged after cutting. The latter work requires a sharp knife and a steady hand. The shoots selected must have a few of the lower leaves removed, and the knife should be inserted underneath and drawn upwards through one joint; the tongue thus formed must be pegged down into the special mould in such a manner that it is well opened. If the soil is kept pleasantly moist, roots will be emitted quickly, and perfectly-rooted young plants will be secured for potting to winter in frames or planting out in beds or borders.

**THE LAWN.**—To keep the grass in good condition it is imperative that it shall be attended to regularly, as well in respect of watering as of mowing and rolling. As far as watering is concerned it is of the utmost advantage to have a sprinkler, this being allowed to run for several hours, moving it occasionally to cover the entire surface. Mowing should be done about once a week, and in the hot weather the cutters should be set rather high so as not to expose the base of the plants.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**P**RIMULAS of the stellata section and others grown for winter decoration should now be potted up and kept close for a few days. Keep the frame nice and moist. Cinerarias may also be placed in pots; these should be kept cool and heavily shaded till they recover from the shift. A frame under a north wall will suit them for the next three months. Give Begonias of the Lorraine type another shift and stake as soon as necessary; one stick in the centre will suffice at this period.

*Liliums* coming into flower should be removed to a cool house, and one that is shaded, then the blooms will last in good condition much longer. Later batches should have a sheltered place outside, or a very cool house with a north aspect.

*Azaleas* and *Camellias* that have made their buds will be better if placed outside on a bed of ashes. They should, however, be shaded from hot sun, and syringed every afternoon after a hot day. *Ericas*, *Libonias* and *Rhododendrons* should all be treated similarly, and the watering be carefully done twice daily; if by any chance a plant becomes very dry it must be plunged in a tub for a few minutes.

*Coleus thyrsoides* and *Moschosma riparium* should be got into the next size pots. Small plants of these in 6-inch pots I have found to carry the best flowers, and for smaller plants in 3-inch pots there is yet time to propagate.

*Calanthes* that are now making good growth need extra care in watering till the plants have made a pot full of roots. *Dendrobiums* making good growths should be watered carefully, especially newly-potted plants. Give them a syringing twice daily and damp the spaces between the pots several times a day.

#### KITCHEN GARDEN.

*Tomatoes* should have the growths neatly tied to sticks and all the side laterals pinched out as soon as they appear. Carters' Sunrise is a fine Tomato for outside work and is setting a fine lot of fruit.

*Turnips* may be sown often to maintain a regular supply, and French Beans on a warm border for a late crop. Lettuces and Radishes should be sown frequently and afforded water regularly so that the plants will be crisp and tender. Sow Endive in quantity. Keep the hoe well going among all growing crops, and if the weather is hot and dry afford water in quantity. Continue to plant out Celery and Cauliflowers and prick out Broccoli so that the plants will have nice little balls of earth when lifted to be planted in the final positions.

#### HARDY FRUIT.

All fruits that are ripening must of necessity be protected from the birds. Nets should be placed high enough above the trees so that they clear the growth. Continue to layer Strawberries in small pots for forcing and planting out; those layered a week or two since will soon be ready for severing if they have been kept well supplied with water as advised. When severed they should be kept in a shady place for a few days to keep them from flagging. It is a good plan to change the stock now and again and, if expenses are a point to be considered, buy in a dozen of the varieties wished and plant out on a good border expressly for getting a new stock. Waterloo and President Lobet are good late varieties. Royal Sovereign, Leader and President are sorts that still hold their own.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CAMPANULA MEDIUM CALYCANTHEMA.**—For the decoration of the greenhouse or conservatory but few plants can surpass in beauty and usefulness these highly ornamental Canterbury Bells. They are invaluable either as pot plants or if grown for cuttings and the flowers range through a wonderful variety of colours. The culture of these plants is not at all difficult. Seed may be sown in July to produce flowering plants the following summer. When the seedlings are growing well, instead of potting them on an excellent plan is to plant them out in the garden as one would Wallflowers, and then pot them up in autumn.

*Abutilons*, grown for their flowers alone, do not appear to be so popular as they once were, yet they are very pretty subjects for the greenhouse or conservatory. Those remarkable for richly-marked leafage appear to be replacing the flowering section to some extent, and this is chiefly owing to the variety of uses to which they may be put. Small plants are very useful for the decoration of dinner-tables, and under artificial light they bear comparison with many flowering plants. Cuttings root freely, and if inserted towards the end of July will make good plants in small pots for use in the house during late autumn and winter.

#### HARDY FRUIT.

**Summer Pruning.**—Shortening the growths of all trees which are trained in the various forms of wall trees, pyramids, espaliers and the like, is a necessary part of the season's work, and the time has now come for extensive operations in this way, for there will now be no fear of the shortened shoots breaking into growth from the back buds and throwing the trees out of gear. No hard and fast lines can be laid down as to the proper number of leaves which shall be left on each shoot at the summer pruning, as this will vary with the individuality of the trees, but as a general rule it may be said that not less than five leaves should be left on a shoot, and if the tree is naturally a strong grower more still should be left.

#### KITCHEN GARDEN.

**Transplanting Celery.**—It matters very little how stocky and healthy the young plants of Celery may be, satisfactory results cannot be expected unless due care is taken at the time of removal into the trenches. A very common mistake is lifting the plants while the roots are in a semi-dry state. Many of the roots then snap off and are left in the bed. Moreover, the plants soon flag if exposed only for a short time to sun and wind, also losing their lower leaves. Then, again, the trench is often insufficiently moist and watering after planting is performed in a half-hearted manner.

**Lifting Shallots.**—These are often lifted much too early, and the old adage to plant on the shortest and lift on the longest day, though good advice in some seasons and in early localities, will certainly not do this year in the North and North Midlands. When they are harvested they should lie in the sun until thoroughly dry, and the cottager's plan of hanging them on a sunny wall is a very good one.

#### FLOWER GARDEN.

**Brompton Stocks.**—July is a good time for sowing the seed of this useful Stock, and a moist, shady border is the best position for them. The seedlings must be well thinned out when fit to handle, this being important to avoid weak, leggy plants. If possible, the border or bed intended for their final quarters should be made ready a good while beforehand, as a loose root-run is apt to produce a sappy growth.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN

**Pæonies and Lilies of the Valley diseased** (Thos. R.).—The Pæony appears to be affected by the fungus named *Botrytis Pæonia*. The stems attacked are best removed at once and burnt. Fresh manure or large quantities of organic matter of any kind should not be applied to plants, especially when there is only a small amount of lime in the soil, for the addition of the organic matter makes the conditions suitable for the development of the disease, and the young stems as they push through the earth become attacked by the fungus, which finally leads to their death. The addition of lime to the soil is a useful means of checking the progress of the disease where it is possible to apply it. The remarks made above apply equally in the case of the Lily of the Valley, where the principal cause of the trouble is the fungus named *Botrytis parasitica*.

**Hardy plants for late bloom on wall** (Miss D.).—The number of plants of the kind you desire suitable for late bloom is limited, but some of the earlier flowers, if planted on the shady side, will flower much later than in the sun. You do not mention whether the wall has soil in the centre or is of the usual stone or brick and mortar construction, so that it is more difficult to select good plants. Good blue flowers are *Ceratostigma plumbaginioides* (*Plumbago* Larentia), to be grown in sun, and *Veronica corymbosa*, in either sun or shade. *Silene Schafta*, red, sun or shade, is excellent, and for the top of the wall *Sedum spectabile*, red, and the dark variety *atropurpureum* are good. The following, for sun or shade, except where indicated, should flower late: *Campanula garganica*, blue; *Coronilla varia*, pink; *Lotus corniculatus*, fl.-pl., yellow; *Silene maritima*, fl.-pl., white; *Sedum Ewersii*, pink; *Mecanopsis cambrica* and the double variety, yellow, for top; *Linaria cymbalaria*, lilac; *Arenaria balearica*, white, shade; *Anthemis Aizoon*, white, sun; and *Achillea Clavennæ*, white, sun. The double *Helianthemum* called *venustum plenum* or Mrs. C. W. Earle, red, and *Jubilee*, yellow, will give blooms much later than the other Sun Roses, and should have sun. We regret that there are so few good blue flowers, but you might sow seeds of the little blue *Stonecrop* (*Sedum cæruleum*) another season, and also of the bluish *Ionopsidium aculea* at the same time, May, for autumn bloom. Some of your flowers which bloom early in the sun will probably grow and flower later in the shade.

**Climbing plants dying** (Reader).—As you say the soil is good we cannot understand why your *Ampelopsis* should have died. Sometimes when building operations are going on and there are certain holes and pits to fill up rubbish is used to fill up with that may contain poisonous materials, and when the roots of the plants reach such materials they, of course, succumb to its effects. Or it may be there are chemical works near you that would account for the mortality you speak of. We advise you to dig up a plant with its roots and send it to the Scientific Committee of the Royal Horticultural Society, Vincent Square, S.W., and give them as many details as possible. If, as you say, many creepers in the

locality have failed, this points to some serious local conditions which can only be explained by an examination of the roots of the plants.

**Romneya stem diseased** (Mrs. E. W.).—The *Romneya* has been attacked just where the shoot leaves the soil by a fungus which has caused the rotting of the shoots. The fungus which is at work cannot yet be identified, but it is probable that it is present in the soil and that the surrounding conditions are such as to enable it to develop well. It would probably be wise to remove the top 2 inches or 3 inches of soil and replace it with fresh which has some lime and a little flowers of sulphur mixed with it.

### TREES AND SHRUBS.

**Bunches of purple Broom growing on Laburnum Adami** (Rev. A. R.). The purple Broom you send is *Cytisus purpureus* and it is quite natural to find branches growing on *Laburnum Adami*; in fact, it is the great feature of the *Laburnum*, the production of yellow and purple *Laburnum* flowers and typical shoots of *Cytisus purpureus*. *Laburnum Adami* originated as a graft hybrid. *Cytisus purpureus* was grafted on to a *Laburnum* and a hybrid resulted, which produced all three kinds of flowers, and this has been perpetuated. Graft hybrids such as this are very rare and this particular instance has furnished an engrossing subject for scientists.

**Lavender plants dying** (L. S. Owen).—Your Lavender plants appear to have been fed too liberally after being enfeebled by the winter. On account of the cold and damp summer and autumn of 1907 a great number of shrubby plants were not properly ripened and suffered badly during winter, plants which pass through far more severe winters without injury if the wood has previously been well ripened. Yours would probably have started away again had the lime and superphosphate not been given while the plants were in a weak state. It is quite improbable that they will grow again: the one you sent was quite dead on arrival. Your best plan is to commence with fresh plants; cuttings will root readily in August.

**Copper Beech leaves infested** (Mrs J. E.). The leaves of your Copper Beech are attacked by one of the aphides (*Phyllaphis* fagi). Spray as you suggest with Abol, paraffin emulsion, or a new insecticide known as "V 2" at once, and again in the autumn, when many of the leaves have fallen, with a winter wash sold as "V 1" or a caustic wash. This should be repeated twice when the leaves have all fallen.—G. S. S.

**Clematis for inspection** (Mrs A. C. D.).—The *Clematis* you send is *C. montana rubens*. If you have purchased it for a scarlet-flowered variety you have been under a misapprehension, for it is not a scarlet colour at all. The flowers you send are slightly paler than is usually the case, which may be due to soil or some other local condition. There is a scarlet-flowered *Clematis*, but it is of herbaceous habit and produces urn-shaped flowers. It is called *C. coccinea*. *C. montana rubens* was introduced from China a few years ago by Messrs. Veitch.

### ROSE GARDEN.

**Roses with rolled-up foliage** (R. G. B.).—Of late years Rose growers have been completely mystified by the appearance of a number of their Rose plants with the foliage rolled in a cylindrical manner as described by you, and, although it is illustrated and commented upon in the new book, "The Enemies of the Rose," published by the National Rose Society, it still remains to many minds a mystery. The authors of the book mentioned say it is caused by the leaf-rolling sawfly, and "if one of the folds is opened we find inside one or more green larvae." We must say we have unrolled many leaves and have never found the said green larvae. It is said the leaf rolling is accomplished by the larvae, but sometimes it is aided by the incisions made by the females when they lay the eggs. It is hinted that the trouble may arise when suckers have been allowed to grow, and some think it is imported to our gardens on the roots of Briars. Can it be that foreign Rose plants have brought the "disease," which it appears to us to be, into the country? for we never remember seeing this leaf-rolling until comparatively recently. The

authors of "The Enemies of the Rose" say that the sawfly appears in May and June, the colour is black and shiny, the legs black with whitish knees, tibiae and tarsi, wings dusky and iridescent, length one-sixth of an inch. The following treatment is recommended: Hand-pick the folded leaves when first seen and destroy, and afterwards spray the Roses with arsenate of lead. What we cannot understand is, that if the trouble arose from the roots, how is it there are usually a number of healthy leaves on the shoot with a few of the rolled leaves above them? It may be caused by late frost and brilliant sunshine following next day. We should be glad of the opinion of Rose experts on this subject, for it is one of considerable importance.

**Budding seedling Briars** (A Novice).—You were ill-advised in cutting away the weak growths. It is always best to allow as much growth as possible to remain on the Briars, excepting the extreme ends. These are shortened just a few inches. By allowing the growth to remain the plants are enabled to grow stronger, as the more foliage there is to enable the plant to develop the better and the stronger will be the Rose plants next year. Do not think of removing any basal eyes, but just allow the Briars to grow as they like this summer. The buds are inserted in the root-stem just beneath the branches, or where you have marked B on your diagram. It is not necessary to insert more than one bud; but you may insert two, one on front and one on back of this root-stem, if you prefer to do so. You may cover the buds in November with a little fine soil, or, better still, with burnt garden refuse or burnt earth, and this can remain until April. It often saves the buds from being killed by hard frosts.

**Cutting Rose blooms off young bushes** (E. H. A.).—There are no definite rules as to what length of stem may be cut with a Rose bloom, but it must always be remembered that to remove foliage during the growing season is a serious tax upon the plant's vitality. Many old-established plants are quite ruined by the reckless cutting of the blooms with long stems. Whenever these are required for decorative purposes we always advise that a special plantation be made for cutting, and as Rose plants are now so very cheap, it pays to renew such plants whenever necessary. By so doing we allow our permanent beds to develop as they should do in order to be really decorative. From young bushes we should not cut more than 2 inches to 3 inches of growth with each bloom or bud, but it will be best to refrain from cutting at all as far as possible the first year.

**Rose shoots damping off** (Guernsey).—Possibly the cause of the shoots damping off is an excess of strong stimulants, which has checked root action. The bloom sent was certainly a very hard opener, one too full of petals, and the wet weather we have had would be a likely cause of the bloom damping; but this could hardly be the cause of the shoots behaving like this. We can only recommend you to keep the soil well hoed, not scratched over, but hoed 2 inches or 3 inches deep. Do this once a week. Thin out the growths if very numerous, removing the weakest from the centre of the plants. Where two or three buds are produced on one stalk reduce to the one which is the best formed. We believe you have in Guernsey very heavy dews at night. Possibly this is a contributive cause to the damping of very double varieties. Plant more of the less double sorts, such as *Caroline Testout*, *Mme. Ravary* and *Pharisæer*.

**Treatment of rambler Roses after flowering** (M. F. W.).—As your plants are now in 9-inch pots they will not require to be repotted this year. As soon as the blossoming is over cut back the laterals to one or two eyes and remove entirely one or two of the oldest growths, then put tall Bamboo canes into the pots and tie up the remaining growths into an upright position. The canes should be about 8 feet high. To have really nice well-flowered specimens next year, three or four growths would be ample, but we should not remove too much growth now. Encourage, as much as possible, three or four of the most prominent of the young growths, and keep them tied up and well exposed to the sun. They will make a much longer growth than the Bamboo cane, but do not curtail such growth until pruning time. When they reach the top of the cane allow them to drop over and tie them up to the roof of the house. Early in August remove the plants to a sunny position outdoors. In front of a greenhouse is best, as the object of putting them outdoors is to thoroughly harden the growths. They must be well syringed and freely watered while in the greenhouse, but when outdoors water should be sparingly given, although they must not be deprived of what is necessary. The plants should be placed in a cool house by the end of October, and then pruned about the end of the year. If three or four growths some 8 feet in height are retained this will be better than a greater height, and you should

obtain some very fine graceful trails from such growths. You must see that the plants do not lack water. In these 5-inch pots the plants, when in full growth, would require watering two or three times a day. You did quite right in not pinching the laterals. The great beauty of these wichuraiana Roses is the length of the trails of blossom, and they can be so arranged that you may have a pillar of blossom such as were seen in many instances at the recent Temple Show.

### KITCHEN GARDEN.

**How to treat Tomato plants under glass (W. H. R.).**—No, do not shade your Tomato plants no matter how hot the weather may be. We never have too much sunshine in this country for these subjects. Train the plants at least 1 foot from the roof glass, remove all side shoots which grow from the main stem, admit air freely, especially through the front ventilators, on hot days, and when the fruit commences to ripen maintain a dry atmosphere. Commence feeding when two or three trusses of fruit are set. Probably the discolouration of the fruits was caused by scalding through maintaining a too close atmosphere.

**Peas failing to grow (J. Arthur).**—The cause of the failure of your Peas is, we think, attributable to wireworm in the soil eating the roots. To find out if it is so or not, bury out pieces of Carrots, Turnips or Potatoes about 2 inches deep in the soil and examine them daily for a few days, when you will probably find the wireworms feeding on the roots.

**Peas turning yellow (H. Bostock).**—The soil in which the Peas are growing is teeming with a small white worm, one of the Enchytridae, which very frequently attack the roots of plants and kill them. The soil contains very little lime indeed, and this is probably at the root of the mischief. The worms are never so abundant where lime is plentiful and no doubt better results will be obtained if attention is directed to this matter before sowing Peas again.

**Pale-coloured Pea plants (J. L. B.).**—Most certainly the Pea plants sent, both of William the First and of Ne Plus Ultra, present unusual features; indeed, cursorily, it might be assumed that the plants were developing variegation, as they were partly becoming in their stems and leaves almost yellow. The obvious conclusion is that there is in your soil, as well as in that of your neighbours', a lack of nitrogen, as the plants are failing to create chlorophyll or the essential colouring matter of leafage, which is also a product of robust health. Your district is one having generally a deep chalk base, and our conclusion is that the soil is too full of lime, such as chalk is in its natural condition, to suit Peas, and needs, to do Peas well, to be deeply excavated and replaced with loam from an alluvial soil. We have washed out and carefully examined the roots, and fail to find any evidence of insect or fungoid injury while, as should be found on the roots of all Pea plants, there are the customary little swellings or nodules, through the agency of the bacteria existing in which the free nitrogen of the air is converted into soil nitrogen, and hence root food. But what good is thus done seems to be more than neutralised by the too-abundant presence of lime in the form of natural chalk. It is not too late now to have a trench 20 inches wide and 2 feet deep taken out and refilled with good loamy soil and some well-decayed manure, then sowing on the trench thinly a single row of Peas. No other solution of the trouble presents itself.

### MISCELLANEOUS.

**Clematis montana as a pot plant (M. P. W.).**—Now that the plant has ceased flowering pot it into an 8-inch pot and keep it growing in your greenhouse for a time, then plunge it outdoors in full sun. By plunging we mean sink the pot up to the rim in soil or ashes; but it will be necessary to look it over now and then so that any water needed may be afforded. No pruning will be required.

**Keeping Lily ponds clean (A. E. B.).**—For keeping Lily ponds clear of Algae, &c., a solution of copper sulphate has been recommended. It should, however, be carefully used, as injurious effects have resulted to Nymphaeas and other aquatic plants after it has been applied. The strength required to be effective is in the proportion of 1 lb. to 1,000,000 gallons of water. Another method, and a safe one, is to use a kind of shrimping-net made of canvas to skim the surface of the water frequently.

**Destroying Thistles (A. H. R.).**—By the constant use of a garden roe or of a spud having at its base a sharp chisel-like end, either tool being kept freely in use to cut off all Thistle-like growths close to the ground, Thistles can in time be eradicated. If all leaf-growth be thus stopped the roots must eventually die. As yours is a grass field, you could, as rapidly as each Thistle head was cut off, as low down as possible by one person, have a second one to follow with a can containing weed-killer, sulphuric acid or paraffin, and with a brush allow a few drops of the liquid to fall on the top of each of these severed root-stems. The process may seem a slow one, but it would ultimately prove effectual. We know of no instrument by which roots can be extracted; indeed, these run horizontally as well as vertically. Follow up

what we have advised for a season, and you should find excellent results.

**Names of plants**—H. J. King.—1, Duke of Edinburgh; 2, Mme. Plantier; 3, Gloire des Polyanthes.—Mrs. E. A. B.—Iris sibirica orientalis.—H. Moore.—Ceanothus azureus.—H. J.—Rose Mme. D'Arday; Asystasia bella.—J. Mills.—1, Carex remota; 2, Lysimachia nemorum; 3, Sanicula europaea.—G. W. E.—1, Lathyrus sativus; 2, L. s. umbellatus.—W. H. Cox.—Ligustrum japonicum.—S. Smith.—Kalmia latifolia.—Mrs. Gill.—Spiraea discolor.—F. Jones.—Iris versicolor.—J. Moffatt.—Dictamnus albus.—C. Morgan.—Sisyrinchium angustifolium.—Miss O. P.—Spiraea cantoniensis flore pleno.—R. H. Salop.—1, Pteris serrulata; 2, P. s. var. cristata, 3, Selaginella kraussiana; 4, Oxalis corniculata; 5, Fuchsia procumbens; 6, Salvia species, cannot name without flowers; 7, Abelia species, cannot name without flowers.—S. H. B.—Philadelphus microphyllus.—W. H. J. S. Scorrer.—1, Eupatorium riparium; 2, Ceanothus integrifolius; 3, Salvia species, cannot name without flowers; 4, Cannot name without flowers.—J. England.—Calycanthus glaucus.—A. S. Whittaker.—Semele (Ruscus) androgyna.—C. Jones.—Iris sibirica.—Newcastle.—Loniceria involucrata; L. tatarica variety without flowers.—Hoburn.—Odontoglossum triumphans. May be worth from 3s. 6d. upwards, according to size and condition.

## SOCIETIES.

### RICHMOND HORTICULTURAL SOCIETY.

THE thirty-fourth annual exhibition of flowers, fruits and vegetables was held in the Old Deer Park, Richmond, Surrey, on the 24th ult., when a very good display was made. The weather was ideal and the arrangements reflected much credit on the hon. secretary, Mr. W. J. Cook, and his committee. Roses were superb and pot plants generally were very good. Vegetables and fruits were rather weak.

#### COMPETITIVE CLASSES.—ROSES.

For forty-eight Roses, distinct, three blooms of each, the first prize went to Messrs. D. Prior and Son, Colchester, for a magnificent collection of highly-developed blooms. The colour and substance were superb and the form of the majority of flowers left nothing to be desired. Alice Lindsell, Ulrich Brunner, Mildred Grant, Helen Keller, A. K. Williams, Bessie Brown, Mme. Cusin, Innocente Rivola, Lady Ashdown and Duke of Wellington were the best among a very fine lot. The second prize went to Messrs. R. Harkness and Co., Hitchin, the blooms shown in this exhibit being also of very high order. We specially noticed Mrs. E. Mawley, William Shean, Dean Hole, Mildred Grant and Mrs. W. J. Grant. The third prize was awarded to Messrs. Frank Cant and Co., Colchester, whose flowers were of good form and colour, but rather small.

For twenty-four Roses, distinct, three blooms of each, competition was very good, and Messrs. B. R. Cant and Sons, Colchester, appropriated the first prize with a splendid lot of blooms. We specially noticed William Shean, Bessie Brown, Comte de Raimbault and Mildred Grant as being extra good. Second honours fell to Messrs. G. and W. H. Burch, Peterborough, in whose exhibit we noticed William Shean, Mildred Grant and Suzanne Marie Rodocanachi in excellent form. The third prize was awarded to Messrs. D. Prior and Son, Colchester.

Twelve Roses, distinct, three blooms of each, was a popular contest, and the premier prize was secured by Messrs. B. R. Cant and Sons of Colchester with blooms of grand size and colour. Bessie Brown, Mildred Grant, Aimee Cochet and Dean Hole were superb. The second prize was awarded to Messrs. W. and J. Brown, Peterborough, and the third to Mr. E. J. Hicks, Twyford.

For twelve Hybrid Perpetual Roses of one variety, Messrs. D. Prior and Son, Colchester, appropriated the first prize with a splendid dozen of Mrs. John Laing, the form, colour and substance of which was grand. Second honours went to Messrs. Paul and Son, Cheshunt, for superb flowers of Frau Karl Druschki, and the third prize went to Messrs. R. Harkness and Co., Hitchin, for Hugh Dickson.

In a similar class for Teas the first prize was awarded to Mr. E. J. Hicks, Twyford, Berks, for a very fine dozen of Mme. J. Graveaux. These flowers were very full and beautifully coloured. The second prize went to Messrs. D. Prior and Son, Colchester, for highly coloured flowers of Maman Cochet, and the third award was given to Mr. J. Brown, Peterborough, for Mme. Jules Graveaux.

For twenty-four Roses, distinct, open to amateurs only, competition was very good. The first prize was secured by Mr. E. J. Holland, Silverdale, Sutton, who staged a very even lot; Gustave Piganeau, Bessie Brown and Comte de Raimbault were extra good. Second honours went to the Rev. J. H. Pemberton, Havering-atte-Bower, for flowers of large size; Gustave Piganeau, Bessie Brown and Florence Pemberton were excellent. The third prize was secured by Mr. W. Leggett, Colchester.

In a similar class for twelve Roses, distinct, the first prize collection was staged by Mr. E. J. Holland, Silverdale, Sutton, the blooms being of good size and colour but rather lacking in form. We noticed excellent flowers of J. B. Clark, Dean Hole and Bessie Brown. The Rev. J. H. Pemberton, Havering-atte-Bower, was a very close second, his flowers of Frau Karl Druschki, Dean Hole and Mme. Jules Graveaux being very good. The third prize was granted to Mr. W. C. Romaine, The Priory, Old Windsor.

#### SWEET PEAS.

The principal class was for nine distinct varieties in bunches. The first prize was secured by the Earl of

Dysart, Petersham (gardener, Mr. T. F. Conway), for a well-grown collection, in which Paradise, Henry Eckford, Black Knight and Helen Lewis were very good. The second prize went to E. Moccatta, Esq., Addlestone (gardener, Mr. Thomas Stevenson), for well-developed flowers; and third honours fell to Mr. H. Compton, Kingston Hill. Generally speaking, the Sweet Peas in the other classes were poor.

#### PLANT GROUPS.

These were well arranged, but some rather inferior material was used in their composition. In Class 1 the Hon. Sir C. Swinlen Eady, Oaklands Lodge, Weybridge (gardener, Mr. James Lock), was the champion here with a very tastefully-arranged group of well-grown material. Crotons, Liliums, Orchids, Roses, Clerodendrons, Palms, Ferns, Carnations and Crassulas all played a part in the colour scheme of this group. Second honours went to Mr. William Vause, Leamington, well-grown Crotons being the chief feature, these being judiciously intermixed with Orchids, Hydrangeas, Ferns and similar plants.

In Class 3 Lady Waechter, The Terrace House, Richmond, won first honours with a very tastefully arranged group, in which Liliums, Hippeastrums and Orchids predominated. The second prize went to Mr. C. M. Bartlett, East Sheen (gardener, Mr. C. Hicks), and the third was awarded to Mr. William Vause, Leamington.

#### VEGETABLES.

For a collection of twelve dishes of vegetables, distinct, the first prize went to the Earl of Dysart, Ham House, Petersham (gardener, Mr. F. F. Conway). This was a very fine group indeed, the Tomatoes, Beetroots, Onions, Peas, Carrots and Potatoes being extra good. The second prize went to Sir C. Swinlen Eady, Oaklands Lodge, Weybridge (gardener, Mr. James Lock). Tomato Best of All and Potato May Queen were very fine here. The third prize group was very inferior.

For the best collection of vegetables, nine distinct varieties, grown from Carter's seeds, the first prize was also won by the Earl of Dysart. Peas, Tomatoes, Carrots and Beetroots were very good in this exhibit. Second honours went to Mr. R. Keene, Richmond, for a loosely-arranged exhibit, and the third prize to Mr. J. Munro, Richmond.

For a similar collection of eight distinct kinds, grown from Webb's seeds, the Earl of Dysart was the only exhibitor, but the group was considered worthy of first prize. The Carrots, Beetroots and Tomatoes were very good indeed.

#### FRUITS.

The Grapes were the best feature in this section. For the best three bunches of black Grapes, H. J. King, Esq., Eastwell Park, Ashford, Kent (gardener, Mr. J. G. Weston), was first with grand bunches of Black Hamburgh, these being of large size and the berries well finished. Second honours went to Sir W. Greenwell, Marden Park, Caterham (gardener, Mr. W. Lintott), for the same variety, and the third prize went to Mr. W. E. Wells, Hounslow.

In a similar class for white Grapes the first prize was appropriated by Sir W. Greenwell (gardener, Mr. W. Lintott), for three very good bunches of Foster's Seedling. The second prize went to Sir C. Swinlen Eady, Weybridge (gardener, Mr. James Lock), and the third prize to H. J. King, Esq., Ashford, Kent.

#### NON-COMPETITIVE GROUPS.

Messrs. T. S. Ware, Limited, Feltham, staged a good bank of herbaceous cut flowers, which included excellent Peonies, Liliums, Delphiniums, with tall pillar Roses in the centre. A fine batch of Spiraea Queen Alexandra occupied the end facing the entrance. All the material used in this group was really first class. Gold medal.

Messrs. J. Peed and Sons' group consisted of well-grown Carnations of the perpetual-flowering section, with Roses, Delphiniums, Irises, Peonies and similar subjects. Silver-gilt medal.

Messrs. William Cutbush and Son, Highgate, N., staged their Carnations in fine condition, the blooms being large and well coloured. The perpetual-flowering varieties were very freely represented. Messrs. Cutbush and Son also arranged a very pretty little group of pot plants on the floor, this comprising such things as Begonias, Geraniums, dwarf Roses, Spiraea Queen Alexandra and Carnations, all in good condition. Silver-gilt medal.

The bank of Roses staged by Messrs. W. and J. Brown, Peterborough, was a very fine one, many excellent blooms being shown in bunches in vases. Silver-gilt medal.

Mr. William Thompson, Sheen Nurseries, Richmond, arranged a very fine group of flowering and foliage plants on the floor. Palms, Hydrangeas, Dracenas, Spiraes, Crotons, Geraniums, Japanese Maples and similar subjects were artistically combined to form an attractive exhibit. Gold medal.

The beautiful group of Roses put up by Messrs. James Veitch and Sons, Limited, Chelsea, was a centre of attraction the whole day. Splendidly-grown pot Roses of all sections were most tastefully arranged, with a few good specimens of Lilium aratum intermixed. Gold medal.

Messrs. Eggitt and Son, Thames Ditton, exhibited a choice and comprehensive little group of Ferns.

The magnificent group staged by Mr. Amos Perry, and consisting of Delphiniums, Liliums, Irises and similar plants, with a dainty water garden containing hybrid Water Lilies in the foreground, was much admired, as it fully deserved to be. Gold medal.

Mr. E. J. Hicks, Twyford, exhibited a very pretty group of well-grown Roses. Long-stemmed blooms were tastefully arranged with foliage in virgin cork at the back, other good blooms being shown in boxes in the front. Silver medal.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## "THE GARDEN" FLOWER SHOW.

SEVERAL questions have been addressed to us in reference to our forthcoming show, which is now close at hand. Vases and dishes will be provided, but not boxes for showing such things as exhibition Roses. These, of course, must be brought by the exhibitors, as in the case of the National Rose Society's and similar exhibitions. These flowers may be exhibited in vases, and in the case of flowers being sent vases only will be used.

No exhibits can be received after nine o'clock on the Wednesday morning, the day of the show, but those bringing exhibits can stage them up to ten o'clock, judging beginning at eleven o'clock. The Hall will be open at eight o'clock in the morning on the day of the show, and up to seven o'clock or eight o'clock on the previous evening. All exhibits not being brought personally must be sent addressed to the Manager, THE GARDEN, Royal Horticultural Society's Hall, Vincent Square, London, S.W., the nearest stations being Victoria, Charing Cross and Waterloo.

As mentioned in previous notices, one coupon will secure admittance, and that coupon is published in our issues of July 18 and 25. This will admit readers and their friends. There will not be the slightest difficulty in obtaining admission, but, of course, as we have pointed out, all exhibitors must have the series of coupons already issued, which must be sent or brought with the exhibits and not sent with the entry form.

## OUTDOOR-GROWN GRASSES AND FLOWERS.

THE BEST EIGHTEEN FOR CUTTING FOR ROOM DECORATION.

(First Prize Essay.)

ALMOST every lover of flowers has his or her special favourite, valued above all others for cutting; to many the Rose, on account of its fragrance and its diversity in form and colour, will appeal most strongly, while others will prefer the Carnation or, perhaps, the Narcissus or Lily. There are so many flowers suitable for cutting for indoor decoration that it is a matter of some difficulty to make a selection of the best eighteen, but in doing so two things should be borne in mind: First, that the flowers chosen should be of lasting quality, that is, they should remain in good condition for four or five days at least, if not more; and, secondly, that the stems should be stiff and firm in texture, so that the blooms will remain in the position in which they

are first placed and not droop under the influence of heat or artificial light. The stems should also be of sufficient length to allow of a graceful arrangement of the flowers. Fragrance is, of course, another point to be considered, adding greatly to the attractiveness of bowls and vases of cut flowers, and many of the best kinds for cutting are sweet scented; on the other hand, there are others which should not be omitted for want of this quality. The manner of arrangement is a question of individual taste and hardly comes within the scope of this article, except to mention that while many flowers, including Roses, Narcissi and Sweet Peas, are most effective when arranged with their own foliage, others, such as Carnations and Aquilegias, show to the best advantage when associated with one of the many slender tall-growing Grasses, either wild or cultivated.

### SELECTION OF FLOWERS FOR CUTTING.

**Roses.**—In addition to the Hybrid Perpetuals, Teas and Hybrid Teas one may have long-stemmed sprays of the single varieties which have now become so popular. If cut when the buds are half open, these will keep fresh for some days. Then there are the wichuraiana and multiflora varieties and the China Roses, which furnish many delicate and beautiful tints. The cultivation of Roses is too well understood to need much description. Planted in November in good loamy soil which has been deeply dug and well manured they will produce quantities of flowers. Tender varieties, such as the Teas and Hybrid Chinas, should be protected from frost by earthing up the stems to a height of 9 inches or 10 inches with dry soil. The spring and summer cultivation consists in keeping the surface soil loose by frequent hoeing and in removing all suckers which may appear. A mulch of half-decayed manure should be given in spring, and, when the plants are well established, the colour and quality of the blooms will be improved by applications of weak liquid manure after growth commences. Severe pruning is not necessary unless very large flowers are required.

**Narcissi.**—There are no plants to equal these for cutting in spring, and by growing a number of varieties a long succession of bloom is ensured. Narcissi will grow well in most soils, but prefer a deep, moist loam without the addition of manure. Planting should be carried out in September, covering the bulbs with from 4 inches to 6 inches of soil, according to size. The bulbs may be allowed to remain for two or three years, or may be taken up annually when the foliage has died down, dried, and replanted in August or September.

**Sweet Peas.**—For furnishing cut flowers in July and August, a sowing should be made about the middle of March in deeply dug soil well enriched with manure. A second sowing may be made at the end of April for autumn blooming. The seeds should be sown 3 inches apart, and the plants afterwards thinned out to 6 inches apart. Stakes must be provided when

the plants are 3 inches high; water should be given freely in dry weather, and a mulch of decayed manure will prolong the blooming period. Spent flowers should be removed daily.

**Carnations.**—Many beautiful varieties may be raised from a packet of good seed sown in pots or boxes in May and placed in a cold frame; the young plants should be planted out in early autumn in good rather rich soil and will bloom the following summer. Named varieties and choice seedlings may be propagated by layers in August; these will be well rooted early in October and may then be detached from the parent plant and planted out.

**Aquilegias.**—Many of the best varieties come true from seed, which should be sown thinly in pots or boxes in May; the seedlings may be pricked out into a bed of prepared soil when sufficiently large and transferred to their permanent positions in autumn. The soil should be of a fairly rich nature, and a situation selected which is not reached by the early morning sun, or the flowers may be destroyed by spring frosts injuring the buds.

**Lilies.**—Nearly all the Lilies are suitable for cutting, but the best for this purpose is, undoubtedly, the Madonna Lily (*L. candidum*). Bulbs of this species should be planted in August and succeed best in good and rather moist soil. *L. croceum*, *L. umbellatum*, *L. tigrinum* and *L. testaceum* are among the easiest to grow. The varieties of *L. speciosum* should be grown in a mixture of loam and peat, and are best planted among Rhododendrons, Azaleas or Pæonies, so that the lower part of the plant is protected from the summer sun. Where possible, all Lilies should be planted in autumn, and, with the exception of *L. candidum*, which ought to be planted about 3 inches deep, they should be covered with from 6 inches to 9 inches of soil.

**Lily of the Valley.**—For this plant a prepared bed of loam, leaf-mould and well-rotted manure is preferable, and single crowns should be planted in autumn 5 inches or 6 inches apart. The position must be open but shaded from the south. The vigour of the plants will be maintained by annual dressings of well-rotted manure applied in autumn.

**Tulips.**—The early Dutch varieties are practically useless for cutting, but the tall-growing May-flowering varieties are invaluable, and many of them also possess the advantage of fragrance. These Tulips should be planted in October and November 5 inches or 6 inches deep, and are all the better if taken up when the leaves have died down and dried in the sun for a week or two. They may then be stored in a dry place and replanted in autumn.

**Pæonies.**—Both the single and double varieties are beautiful when arranged in large bowls with their own foliage. The best time for planting is September, and the deeper and richer the soil the better will the plants grow. Liquid manure may also be given with advantage in spring and summer.

**Pyrethrums.**—The single varieties are the best for cutting, but the double are also useful. Pyrethrums should be planted in autumn or early spring in rich, deep soil.

**Irises.**—Most of the bulbous species are excellent for cutting. *I. reticulata* and its varieties should be grown in light, rich soil and a warm, sheltered position. Then there are the Spanish and English Irises flowering in June and *I. juncea*, with golden flowers, which should be grown in a dry, sunny situation in light, sandy soil.

**Michaelmas Daisies.**—All the numerous species and varieties of Michaelmas Daisies can be used as cut flowers for indoor decoration. The plants grow best in rich, deep soil and should be taken up every second year and divided, replanting, if possible, in fresh positions.

**Chrysanthemums.**—The many border varieties, including some of the early-flowering single kinds, may be largely grown for cut flowers. Propagation can be effected either by cuttings or by division of the old plants in spring. Good

loamy soil, not too heavily manured, is the most suitable. The surface soil should be frequently stirred and the plants securely staked early in the season.

**Solomon's Seal.**—This is a most graceful and effective plant; the long, arching stems may be associated with tall Tulips or other flowers. A shady position must be selected, and the plants grow best in soil composed of loam, leaf-mould and well-rotted manure. The stems should not be cut too freely till the plants are well established.

THE FOLLOWING GRASSES ARE AMONG THE BEST FOR CUTTING:

**Pampas Grass** (*Cortaderia argentea*).—The large handsome plumes of this plant are highly valued for indoor decoration in winter. It should be planted in very rich, deep soil, and, if possible, a sheltered and rather damp situation should be selected; till well established it must be freely watered in dry weather and a mulching of manure should be given in early summer. The flowering stems are best cut when just open and hung head downwards in a dry place for a week or two before being arranged in vases.

**Miscanthus japonica.**—This is a handsome Grass with green leaves striped with white and grows about 4 feet high. It should be planted in rather rich, deep soil.

**Blue Lyme Grass** (*Elymus arenarius*) is valuable for its bluish grey foliage. It reaches a height of about 3 feet and should be planted in deep soil in a rather moist situation, such as the margin of a pond.

**Feather Grass** (*Stipa pennata*).—This Grass is useful for mixing with Carnations or other flowers. It grows 2 feet high and succeeds best in deep sandy loam. C. W. CAULFIELD.

Bridgen House, Park Crescent, Erith.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

July 22.—National Carnation and Picotee Society's Annual Exhibition, Royal Horticultural Society's Hall, Westminster.

July 29.—THE GARDEN Flower Show, Royal Horticultural Society's Hall, Vincent Square, Westminster.

### Exhibition of home-bottled and preserved fruits and vegetables.

On November 26 and 27 next the Royal Horticultural Society will hold their annual exhibition of home-bottled and preserved fruits and vegetables at the hall of the society in Vincent Square, Westminster, and now that the fruit-preserving season has again arrived it may give added zeal to the lovers of this skilled domestic art to prepare fruits for award at this exhibition.

Dried or bottled fruits of any kind may be shown, subject to the conditions of (a) there being no chemical preservative or (b) artificial colouring matter used, (c) of their being tasted by the judges, and (d) provided they have been grown in the British Islands. The schedule contains classes for bottled fruits, home-dried or evaporated fruits, preserved vegetables, jams, fruit jellies and cheeses, foreign jams and miscellaneous appliances, preserving bottles, &c. The exhibits will be judged by the most competent authorities, and the medals of the society and prizes of money awarded accordingly. One class is specially attractive, and, it is believed, quite original. It invites for exhibition three bottles of British-grown fruit (of which one must be Raspberries) bottled and shown by amateurs. These will be examined by the judges and left in the care of the society until November, 1909, and a silver cup and other awards given. A complete schedule and further information may be obtained from the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S. W.

**Turin Exhibition.**—Preparations are being made to celebrate the fiftieth anniversary of the proclamation of the Kingdom of States by

holding in 1911 an International Industrial Exhibition in Turin. Three flower shows will be held in connexion with the exhibition, one in May, one in September and one towards the end of October.

## PRIZES FOR READERS.

### JUNE COMPETITION.—AWARDS.

In this competition readers were asked to name the best eighteen outdoor-grown flowers and grasses for cutting for room decoration, with directions for their successful cultivation. The prizes are awarded as follows:

The first prize of four guineas to C. W. Caulfield, Bridgen House, Park Crescent, Erith.

The second prize of two guineas to F. J. Landsdell, Desford, Leicester.

The third prize of one guinea to Miss Ruth B. Cannon, St. George's Hostel, Reading, Berks.

The fourth prize of half-a-guinea to G. H. Webster, Oak Cottage, Woolton, Liverpool.

This competition proved a popular one and a large number of essays were sent in. The quality of these, however, was not very high. Those from the following were above the ordinary and deserve commendation: E. Cummins, Miss Hopkinson, Miss S. Keep, Mrs. E. Anderson, W. H. Shaw and C. H. Walkden.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### The fruiting of Pear trees.—

Staying at Lee Abbey, Lynton, a few weeks ago I came across the following record of the crops of some of the Pear trees growing in the garden there, and as such a long and careful record is probably unusual, I send you a copy, thinking it may be of interest.—A. L. FORD, Gwynnall, Lynmouth, Devon.

\* Standard broken by snow and destroyed in 1903.

† Espalier. ‡ Wall. § Wall, over fifty years old.

The blanks imply that no fruit ripened sufficiently to be gathered.

**A useful garden tool.**—It might be interesting to some of your readers to know that I have found that a small hand-fork put into a long handle far more useful than any hoe, as it breaks up the surface to any depth—from half an inch to 3 inches—does not injure the roots, and can be used on any beds or borders, no matter how full of plants, with perfect safety. For hoeing round Rose trees there is nothing better. —F. HESSEL.

**French Carnations.**—Many of the English visitors to the recent flower show held at the Franco-British Exhibition on the 24th ult. must have been disappointed with the French exhibit of Carnations. The grand blooms shown

by Messrs. Hugh Low and Co. and Mr. W. H. Page, to say nothing of those by some of the other English exhibitors, were perfect in finish and in colour. The French blooms were certainly wanting in brightness, many of them had hard, deformed centres, the calyces of others were burst, and altogether there was a lack of taste and artistic refinement in the display. This seems rather strange, considering that long before the middle of the seventeenth century the Carnation was a popular flower in France and has been grown there for centuries. Probably the very first independent monograph on any florist's flower was one on the Carnation by a French author in 1647, since which time numerous treatises in separate form and in various works on floriculture have been published by French authors. There is no doubt that Carnations can be well grown in France, for we have often admired the large and beautiful groups staged by Messrs. Lévêque et fils of Paris at the French shows, and there are others who make a speciality of the flower.—CELLESTISTE.

**Judging table decorations.**—I think the system of judging table and cut flower decorations at shows is wrong. I should like to see a committee formed for judging these composed of six or eight persons and the prizes awarded by vote. When left to one individual the prize is awarded to some arrangement which appeals to his or her personal taste. A committee such as suggested would prevent such unfairness.—T.

**Wistaria multijuga.**—I am sending you a photograph of a *Wistaria multijuga* that is growing in the gardens of G. W. W. Blathwayt, Esq., Melksham House, Melksham, Wilts. It flowered most profusely, having 184 long racemes of bloom of fine colour in the latter part of May and early June. The height of the plant is 3 feet 9 inches from the ground. It was planted in its present open position, fully exposed to north and north-east winds, three and a-half years ago. The first year it had eighty heads of bloom, the second year not so many, but this year there was a very fine show.—R. H. LEGG, *Melksham House Gardens*.

**Plagianthus Lyalli.**—Three years ago I received a small plant of *Plagianthus Lyalli* from New Zealand, and finding it just alive put it out in the open garden. Here it made good growth, and is now over 6 feet in height. Last year it bore a few flowers, and this year it is blooming freely. The pure white, cupped flowers are very pretty, having a central cluster of pale yellow anthers tipped with pink. They also have a pleasant perfume. The largest of the leaves is 5 inches in length and 3 inches in breadth. They are heart-shaped, with a smooth upper surface, but hairy on the reverse. The blooms are about 1½ inches in diameter, and are borne on foot-stalks of the same length. Here the shrub is deciduous, but in the lower elevations in New Zealand it is said to be evergreen. In its native country it flowers in January, but here it blooms in June and July. I saw a fine specimen growing against a wall at Canon Ellacombe's at Bitton Rectory which was a sheet of white bloom. My plant is growing as a shrub in the open with no wall near it. It is said to form a small branching tree from 20 feet to 30 feet high in the mountain district of the middle island of New Zealand.—S. W. FITZGERBERT.

**Wellingtonia struck by lightning.**—Your correspondent J. Williams (page 310 of your issue of the 27th ult.) will be interested to know that a *Wellingtonia* (*Sequoia*) was struck by lightning here in 1905. The storm occurred in the afternoon of Saturday, August 5, the tree being struck at a quarter to two o'clock. The tree, which was about 56 feet in height, stood on the lawn, there being an Oak tree about 20 yards away and two Spanish Chestnuts nearer to the *Wellingtonia*. The lightning appeared to enter the tree close to the top, running round the trunk in its descent and completely splitting the stem into several pieces

right the way down. Some portions were picked up at a distance of 40 feet from the tree.—WILMOT H. YATES, *Rotherfield Park Gardens, Hants.*

## THE KITCHEN GARDEN.

### NOTES ON TOMATOES.

THERE are constant additions being made to the already long lists of this popular esculent, but it is doubtful whether very much improvement has really taken place of late years. I make a point of trying one or two new varieties each year, or rather I should say sorts that are new to me, for the numbers of varieties are now legion, and it is next to impossible to fairly keep pace with them. Messrs. A. Dickson and Sons, of Rose fame, this spring sent me a packet of their new Tomato Liberty, and I am very favourably impressed with its merits. It sets very freely and the fruits are of medium size, while the plants are healthy and robust. The flavour is quite distinct from anything I have previously tasted, being more acid than in any other variety. This characteristic will recommend it to many palates, and it certainly is most

THE RARE WISTARIA MULTIJUGA.

refreshing and thirst-quenching. Carter's Sunrise is a wonderful cropper, as practically every flower sets, but grown in pots, as I am compelled to grow it, the fruits are small. The flavour is good, and the fruits are a fine colour and very solid. Freedom, an American variety, is one of the handsomest fruits I know, and for growing in pots has few superiors. It is a free setter, the fruits are large and well shaped, while colour and flavour are excellent. Magnus, another American sort, is a little like Sutton's Peachblow, especially in colour. Here it is considered to be the finest flavoured of all Tomatoes. The foliage is quite distinct from any other I know, but the fruits, although of fine size and shape, are never very numerous.

Sparks's Earliana is yet another American that I have grown for some years. It ripens as soon as Sutton's Earliest and is quite as prolific as that excellent sort. It is rather peculiar in shape, and the foot-stalks are very long. In colour it is a dull scarlet, while in flavour it is the sweetest of all Tomatoes, as far as my experience goes. I got a few seeds of a variety named Keelings this season, but I fail to find the name in any catalogue. Are any readers of THE GARDEN acquainted with it? It seems a little coarse, and is certainly late, as no fruits had ripened on June 27. Stirling Castle, although not a large fruit, is a wonderful bearer and always reliable.

Laird's Supreme for all-round qualities I have never seen equalled, and I grow it in larger quantities than any other sort. It is a grand setter, carries good-sized, fine-shaped fruits, and the flavour is excellent. C. BLAIR.

*Preston House, Linlithgow, N.B.*

## NEW PLANTS.

**ODONTOGLOSSUM ELEANOR WESTONBIRT VARIETY.** This is the result of a cross between *O. cirrhosum* and *O. Uro-Skinneri*, the result being medium-sized flowers with beautiful markings. The sepals are lanceolate with very acute apices, the petals being somewhat broader and frilled at the margins. The labellum is comparatively large, the white ground being beautifully striated with rich crimson. The sepals and petals have a yellow ground colour freely marked with dull brownish crimson blotches and dots. Award of merit.

**Laelio-Cattleya Clivemagnifica.**—A cross between *Laelio præstans* and *Cattleya aurea*. We have in this bigeneric hybrid a flower of rare beauty and refinement, but of good size also. The shape of the sepals and petals is quite normal, and the colour is of the richest rosy mauve or pale purple. The labellum is very conspicuous; it is large and very broad at the top, with delicately fringed margins. The colour is the richest velvety crimson imaginable, with very rich golden yellow inside the throat. First-class certificate. Both were shown by Lieutenant-Colonel Holford, Westonbirt, Tetbury, Gloucester, before the Orchid Committee of the Royal Horticultural Society at Holland Park on the 7th inst., when the awards were made.

**Viola Ernest Needham.**—A fancy variety, white, rayed, with a heavy margin of violet and mauve. From Messrs. W. Artindale and Son, Sheffield. Award of merit.

**Begonia Frilled Queen.**—A lovely variety of the crimped class, the flowers large and of a pleasing shade of pink. From Messrs. Blackmore and Langdon, Bath. Award of merit.

**Begonia Duchess of Cornwall.**—A double-flowered variety of an intense glowing crimson hue; certainly the richest of its colour we have seen. From Messrs. Blackmore and Langdon. Award of merit.

**Delphinium Statuaire Rude.**—A delightfully toned flower of the softest mauve in a noble columnar spike of great beauty and excellence. It is one of the finest Larkspurs we have seen. From Messrs. Blackmore and Langdon. Award of merit.

**Tunica Saxifraga fl.-pl.**—Those who know the typical species of the above can form an estimate of the merits of this semi-double variety with its blossoms of a deeper pink hue. For rockwork, walls, ruins and the like this plant will be as welcome as it is delightful. From Mr. G. Reuthe, Keston, Kent. Award of merit.

**Rose Molly Sharman Crawford.**—A very fine white-flowered Tea Rose of great purity and excellent form.

**Rose Mrs. David Jardine** (Hybrid Tea).—A charming flower, rosy peach in colour, the form being excellent.

**Rose Florence Edith Coulthwaite** (Hybrid Tea). A delightful Rose of salmon and cream colouring, the flowers flushed with pink.

**Rose George C. Waul** (Hybrid Tea).—A very handsome Rose of a cherry scarlet hue and of beautiful form. The above Roses were exhibited by Messrs. Alex. Dickson and Sons, Newtownards, County Down, and each received an award of merit.

**Delphinium Progression.**—A white-flowered variety of considerable purity and merit, representing an advance upon existing white-flowered varieties. Shown by Messrs. R. W. Wallace and Co., Colechester. Award of merit. All the above were exhibited before the Royal Horticultural Society at Holland Park, on the 7th and 8th inst., when the awards were made.

## TREES AND SHRUBS.

## SHRUBS FOR THE SEASIDE.

## THE TAMARISKS.

**T**HE Tamarisks, or species of *Tamarix*, possess some considerable importance from a decorative standpoint, particularly in gardens situated in the vicinity of the coast, for they thrive quite close to the high-water mark, and are rarely, if ever, discoloured by salt-laden winds. In some towns various sorts of *Tamarix* are cultivated as hedges, and as such they have much to commend them. At Southport many such hedges may be seen in the public gardens situated between the esplanade and marine lake, and they have a particularly bright appearance. It is not, however, as a dwarf shrub or hedge plant that the Tamarisks are always met with, for some grow into large specimens of tree-like proportions, the trunks sometimes being from 1 foot to 1½ feet in diameter, and the examples 15 feet or 20 feet high. Such specimens are to be met with in various parts of England, many fine ones existing at Abbotsbury Castle, Dorset, while in the vicinity of the sea they are frequently found. Some parts of the Kentish coast are thickly dotted with Tamarisks, while numerous large examples are to be found wild in the Isle of Wight. It is not, however, in the neighbourhood of the sea only that the Tamarisks are to be found, for fine specimens exist in many inland gardens, and when well grown the beauty of their bright green foliage, graceful habit and pink flowers is always appreciated.

One of the best of the stronger-growing members of the family is *Tamarix gallica*, the French Tamarisk. Under favourable conditions this grows at least 20 feet high, with a trunk of considerable proportions.

A closely allied plant is *T. anglica*, another European species, which is widely distributed through the western portion of the Continent and is also found in England; it assumes large proportions, and is somewhat like the former plant. *T. chinensis* is a Chinese species peculiar by reason of its elegant plumose habit; growth is more luxuriant in the case of young plants than is so with many other sorts. The flowers are pink and borne freely. It is an excellent plant for use in shrubberies or for groups in prominent places on lawns. In height it is very similar to *T. gallica*.

*T. pentandra* is found in Eastern Europe and parts of Asia, and of late years much attention has been directed to it, or rather to a plant whose name is really a synonym of this. The plant referred to is *T. Pallasii rosea*, or *T. hispida æstivalis* as it is sometimes called. This is without doubt one of the most beautiful flowering shrubs we possess, and it has the advantage of producing its flowers during late summer. Although when mature it forms a large bush, it can be kept small by pruning back each spring. This results in shoots 3 feet or more in length being formed, which bloom from end to end, the flowers being of a very delicate shade of pink. The flowering period extends over a space of six weeks. It is seen at its best when planted in rich soil in moderate-sized masses.

*T. tetrandra* is a free-growing, free-flowering plant suitable for massing in prominent positions. It is of loose, elegant appearance, and the combination of light green leaves and pinkish flowers is very pleasing. It blossoms during late spring. The German Tamarisk (*T. germanica*) really belongs to another genus, the correct name being *Myricaria germanica*. It is less suitable than any of those previously mentioned for ornamental gardening.

For general purposes intending planters cannot do better than select *T. gallica* and *T. chinensis* of the larger-growing sorts, and *T. pentandra* and *T. tetrandra* for other purposes. Although the Tamarisks will grow and do well in poor

sandy soil, they grow more vigorously and attain larger proportions in good loam. Propagation may be effected during winter by making cuttings 9 inches to 12 inches long from the previous year's wood and inserting them in a shady border out of doors in a similar manner to Currant and Gooseberry cuttings.

## THE TULIP TREE.

## (LIRIODENDRON TULIPIFERA.)

This is a native of North America, and is one of the most ornamental of the larger hardy deciduous trees we have. In its native habitat it is found in moist bottoms and alongside rivers, where it attains a height of 120 feet to 150 feet, with trunks having a diameter of 3 feet or more. The wood is described as being white, hard and heavy, and easy to work. The heart-wood is of a lemon yellow colour, and is strong and durable enough for almost any purpose. It would probably hardly pay to grow it for timber in this country, its chief value here being as an ornamental subject for the lawn or park, where it requires a fairly moist spot and plenty of room to develop, some of the older specimens in this country being nearly 100 feet in height, with a proportionate spread of branches.

The leaves are about 5 inches long by 6 inches wide, four lobed, the lobes being arranged in two pairs on the sides of the leaf, while at first sight it looks as if there was another lobe missing at the apex of the leaf, where the two lobes nearest the tip project further than the centre of the leaf. The autumn colour of the foliage is intense golden yellow and is rarely absent on established trees, whatever the season may be. The creamy yellow flowers open in June and July, but are usually too high up to be much noticed. They are, roughly, the size and shape of a Tulip, from which the tree has been given its common name. The bark, especially that on the larger roots, has a distinct odour and a very bitter taste, and has certain medicinal properties; it is also used in the manufacture of beer for giving taste and smell.

Propagation is effected by seeds, which germinate readily outdoors if sown in a moist spot in spring. The young plants require transplanting every year for the first three years, when they can be allowed to stand for two years without removal, unless, of course, they are planted in their permanent quarters. Transplanting is best done in early April or just as the young buds show signs of moving, as, like its near ally the Magnolia, the Tulip Tree makes rather fleshy roots, which are apt to rot if they are disturbed in cold, wet weather. There are some five or six varieties, of which *L. t. aureo-marginata*, with leaves margined with silver in spring, changing to yellow later on, and *L. t. fastigiata*, a strong-growing, upright tree, are the best.

Bagshot, Surrey.

J. CLARK.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

## SWEET PEAS AND PINKS FROM BERKSHIRE.

Mrs. de Lacey-Lacey sends from The Garden House, Stamford, Dingley, splendid flowers of Sweet Pea Eckford's Giant, cut from plants which have been inoculated with nitro-bactérine.

We have seldom seen finer specimens, and this refers not only to the individual bloom but the spike itself. With these also came a collection of seedling Pinks of Messrs. Ladham's (Southampton) strain; the laced forms were very charming and the self of much beauty.

## COLOURED PLATE.

## PLATE 1852.

## THREE NEW DAFFODILS.

## (BEDOUIN, FIREFLAME AND SUNRISE.)

**I** AM afraid to say how many hundreds of named varieties of Daffodils are known to-day to experts. We have Long Trumpets and Short Trumpets, Big Cups and Little Cups, Large Eyes and Small Eyes in every gradation of size and shape, with the result that show committees and judges are harassed and worried to know where one class ends and the other begins. Disputes arise, as at Truro and Birmingham in this present year of grace. Catalogues differ. The charming Sunrise of the plate is listed by Miss Currey as an *Engleheartii* and by Messrs. Barr and Sons as a *Barri*! Could there be a more timely illustration of the necessity for some definite classification to which all of us would yield a willing acquiescence, as "Bridgers" do to the rules of the Portland Club and cricket players to the laws of the M.C.C.? Daffodil people naturally look to the Narcissus committee of the Royal Horticultural Society in their dilemma, and I am very happy to say they will not look in vain. It is pretty well known that a sub-committee has been sitting his summer under the able guidance of one of the grand old—and yet up-to-date—men of the Daffodil world, the Rev. William Wilks, on purpose to classify all existing named flowers. The result of their deliberations will see daylight very soon, and I feel sure will be helpful to many, but it must not be regarded as a final effort. On the contrary, it is but a first attempt, and no one, I know, more than the committee themselves will realise its imperfections and its tentativeness.

But I must pass on to the more immediate subject of these notes, viz., the coloured plate of the three new red-cupped varieties—Bedouin, Fireflame and Sunrise. Bright colour is always noticeable in Daffodils. The white or yellow of the perianth is such a good foil no one can help being attracted. I can remember when good red cups were rare. Now, however, they are much less uncommon, thanks to an ever-increasing army of hybridisers. The three blooms figured in the plate are excellent examples of their latest efforts. Bedouin is altogether an exceptional flower, and was one of the very best in Mr. Dawson's gold medal collection at Vincent Square on April 14. It is a large, striking incomparabilis, something after the style of *Flora Wilson*, which I believe is one of its parents. The large and rich orange scarlet cup is surrounded with a broad overlapping ivory-white perianth of quite 4 inches in diameter and of much substance. It is one of the most beautiful red cups that we have; price only £30. Sunrise is a seedling of Mrs. Backhouse. It has a flattish orange cup, with a red edge, and is distinguished by well-defined yellow flames on the white petals. This marking is, I believe, unique. It is a tall grower, and when I saw it in London thought highly of it as a decorative variety. Fireflame is also a 1908 introduction. From its general appearance it suggests *M. J. Berkeley* × *Poetorum* parentage. Blackwell is a fairly well-known flower of a similar type. Their distinguishing features are earliness and brightness, and because of these qualities they are very useful either in the border or as cut flowers. Everyone should have a few of these early bright varieties in their collection to prolong the season of red cups.

J. JACOB.

## THE FLOWER GARDEN.

### RAMONDIAS (ROSETTE MULLEINS) AND THEIR CULTURE.

**A**T the present time, when the *Ramondias* are in flower, it is difficult to imagine anything more daintily pretty than a group of these little alpinas happily situated in the crevices of rocks. In the Kew Rockery an ideal place is found for them on the shady side of a Bay, and there these Pyrenean plants enjoy a cool, moist position, shade without the drip of overhanging trees and, as they are planted with their rosettes of leaves in a vertical position, one can see them to the best advantage.

At Glasnevin Botanic Gardens they grow with great freedom and probably are a little more vigorous, and in the moister climate here obtaining do not seem to require quite so much shade. In a sunken path, with masses of Ferns rising on either side, irregular blocks of stone are placed to form steps leading to a higher part of the rockery. The crevices of these steps are numerous and ample, and are planted with the *Ramondia*, so that the steps are studded with their crinkled rosettes of leaves, from which rise a quantity of dainty purple and white flowers with orange eyes, borne upon slender stems. Here, if planted in a place where the water does not collect, they thrive equally well planted in the ordinary position as in a vertical one. Writing of planting in crevices, one has to see that these are not merely blind holes, for alpinas love good drainage and a deep root-run. Many of them, though so dwarf in stature, have tremendous roots in proportion to the amount of foliage.

*Ramondia pyrenaica alba* is a beautiful pure white variety and worthy of special care. Mr. Perry claims to have distributed this really good plant, having found it growing wild with the commoner form in the Pyrenees, where, in the same neighbourhood, he found several other albino forms of alpinas. *R. pyrenaica rosea* is also a delightful plant, but there seems to be intermediate shades between the pure white one and this rose-coloured variety.

*R. serbica* is a more uncommon species from Servia, having flowers of a pleasing shade of mauve. The rosettes of leaves have a more grassy green appearance, while the individual leaves are more attenuated at the base than in *R. pyrenaica*. *R. serbica* var. *Nathalie* is a fine variety of the former, with deeper-coloured flowers, and found on the Carpathian Mountains. Both this Servian species and its variety will grow in similar positions to the Pyrenean one, while all of them seem to enjoy a peaty soil.

*Ramondia* (*Syn. Jankwa*) *Heldreichii* from Thessaly is rather a difficult plant to grow. The silky white hairs of the leaves give it an interesting appearance, and possibly denote a dislike of dampness. So far, though the plant lives, it has not been a success here. The *Ramondia* belongs to the natural order Gesneraceæ, and several of the genera are remarkable for the ease with which they strike from leaf-cuttings. The *Gloxinia* and *Saintpaulia* may be cited as familiar examples, while the *Ramondia* also shares this characteristic. Sound, firm leaves should be selected in the autumn and taken off close to the base of the old plant. Pots or pans should be prepared as for cuttings, using a compost of sandy peat and the leaves inserted by the petioles, the pots then being placed in a cold frame or a greenhouse with a slight bottom-heat. The leaf-cuttings usually just form roots through the winter, then in the following spring form new little rosettes of leaves, when they may be potted up separately. The seed of the common *Ramondia* ripens and germinates here very freely, so that leaf propagation is only useful for the good forms.

Glasnevin.

C. F. BALL.

### BROMPTON STOCKS.

THE art of raising the beautiful Brompton Stocks, which were the pride and delight of our forefathers, seems to be almost lost in the garden of to-day. Ten Week or German Stocks there are in abundance in most gardens, and the brave and sweet display they make is very acceptable; but still we miss the dear old Bromptons with their towering spikes of bright and richly-scented blossoms borne in early spring. Probably the difficulty of keeping the young plants through the winter is the chief cause of the decline of the Brompton Stock in popularity, and on a heavy

situation the difficulty is a real one. There are, however, hundreds of gardens that are neither very exposed nor very wet. In these the famous old flower could be grown with perfect ease. A packet of seed will give sufficient plants for most gardens, and it should be sown before July is out. Make a shallow drill by treading a rake handle horizontally into a plot of fine soil, scatter in the seeds very finely, return the soil with the rake, tread lightly, rake and again make level and water in. If thin sowing is practised, the plants may remain in the seed row until planted in permanent quarters at the end of October, or they may remain and be planted out permanently in early spring. E. J.

### THE CUSHION IRISES.

THERE are Irises for every garden and for every position in a garden, and growers with wide experience may be disposed to share Mr. Reginald Farrar's invective, frankly believing that the Cushion Irises are beyond the ambition of any but experts and favoured gardens. That this section embraces some species difficult to regard as permanent occupants of our borders cannot be gainsaid, but, at the same time, there are a few which amateurs may attempt with confidence, and few plants surpass in beauty those gorgeous and majestic coloured flowers which, once deigning to reward the ardent cultivator, seem to act as incentives to future efforts.

Originating within the western limits of Asia, these *Oncocyclus* and *Regelia* Irises are peculiar to the localities in which they are indigenous. They flower with us, for the most part, in May and June, and in a few weeks more the growths are matured for the following year's display,

and it is generally accepted that after flowering a baking treatment until October or November ensures the fullest measure of success. In practice this may be secured by covering the plants with sashes so elevated as to admit air and yet prevent water reaching the plants. Planted in November or December, growth becomes active at once. None of them can endure sodden surroundings, and anything which promotes dryness at the root in winter will add correspondingly to the future well-being of the plants.

The Cushion Irises are pre-eminently subjects for natural well-drained soils, and a sun-baked spot at the foot of any low wall will almost

ONE OF THE CUSHION IRISES: I. IBERICA.

guarantee success, for such a position is sure to dry out naturally as soon as flowering is completed, and then only in an occasional year will the border feel the influence of returning moisture too soon in autumn, when the lights may be employed to ward off excess. Soil for these Irises should be rich, and that which is most conducive to success is a natural fertile loam. Soil artificially compounded may at times be unavoidable: then preference should be given to old meadow turf that has been stacked for some time, employing this as the staple, to which is added a quantity of shingle, crushed limestone

or chalk. The plants should be set deep and firm, with the rootstock about 1 inch below the surface, and they are best left undisturbed afterwards.

The illustration shows *Iris iberica*, a beautiful species from the Caucasus and one which amateurs unacquainted with this section might well obtain on trial. The standards are pale lilac and white, with deeper veins; the falls are chocolate brown, mottled with an amber colour; and the throat is marked by a deep velvety maroon blotch. The flowers are borne upon stems 12 inches to 15 inches in height, though the plant itself is only 6 inches high.

THOMAS SMITH.

*Walmgate Gardens, Louth, Lincs.*

### TREE PÆONY IN A LINCOLNSHIRE GARDEN.

THE illustration is reproduced from a photograph kindly sent to us by the Rev. F. D. Hall, Manby Rectory, Louth, Lincolnshire. It represents a Tree Pæony in the rectory garden there, which carried at one time over 234 blooms.

### VERONICA ALLIONI.

AMONG the Veronicas are many beautiful little alpines, and of these one of the prettiest is *V. Allioni*, not now much seen, although a spurious plant of much inferior value is substituted. It is a low-growing subject with greyish green leaves and small closely-arranged spikes of dark blue flowers not more than 6 inches high. The arrangement of the flowers on these spikes is so close that a somewhat matter-of-fact catalogue compiler has said they are "like lead pencils." In any case, the whole plant is one to be coveted by the alpine grower, and as it is not difficult to cultivate, even in an exposed part of the rockery, it might be added to many collections with profit. I find that *V. Allioni* does well with me at Dumfries on an elevated place in the rock garden, and in loam and grit with plenty of small stones about it and in full sun. It is increased by division in spring or autumn. S. ARNOTT.

## THE GREENHOUSE.

### HERBACEOUS CALCEOLARIAS.

**M**R. A. DAY, gardener to A. J. Brandon, Esq., Redfields Gardens, Church-Crookham, Hants, sends us a photograph of five herbaceous Calceolarias, three of which together measured 5 feet in diameter. Unfortunately, the photograph was not quite suitable for reproduction, but we give below the accompanying note: "I am sending you a photograph of five herbaceous Calceolarias which were grown here this season; you will see the size of the plants by the tape measure. I sowed the seed on July 1 (last year) in a shallow pan partly filled with loam, peat and leaf-soil in equal proportions, covering the pan with a piece of glass and standing it in a cool frame in the shade. I turned the glass each morning till the seedlings appeared. As soon as large enough to handle they were pricked off into 2½-inch pots, using loam and leaf-soil with the addition of a little peat. When they had filled these pots with roots they were shifted into 3-inch pots, using two parts loam and one part leaf-soil and decayed manure from an old hot-bed. The next shift was into 5-inch pots, using soil as before, and from these they were moved into 8-inch pots (in which they flowered), still using similar soil, with the addition of a little *Le Fruitier*, about a 5-inch potful to a bushel and a-half of soil.

When the flowering pots were well filled with roots I commenced using weak liquid manure, only just colouring the water, or for a change putting a tablespoonful of *Le Fruitier* to 1 gallon of water, letting it stand a few hours before using. I always used clear water at alternate waterings. The plants were grown in a frame till October, when they were placed near the glass in a cool greenhouse. I fumigated occasionally to keep down green fly, and took care never to shift the plants before the pots

were well filled with roots, or give them too large a shift, as these, with overwatering, I regard as the chief causes of failure."

### A PRETTY GREENHOUSE HEATH.

(ERICA PROPENDENS.)

As far as my knowledge of greenhouse Heaths extends there is not one which can when in flower be in any way confounded with this, while in addition to its distinctive characters it ranks among the most beautiful members of the genus. Introduced from South Africa in 1800, this Heath was twenty years ago comparatively unknown; but since that time it has made considerable headway in popular favour, and in 1899 it was given an award of merit by the Royal Horticultural Society. It belongs to that section of greenhouse Heaths known as soft wooded, that is to say, the class to which the popular *Erica hyemalis* belongs. In build it is somewhat after the manner of that well-known plant, but the growth is more slender and the habit dwarfer. The flowers in their shape, colour and arrangement are, however, totally different, for they are of a decided bell shape, and are suspended singly on slender stalks each about 1 inch long.

The colour of the flowers is difficult to define, being of a pinkish hue with a suspicion of mauve and lilac. At a little distance, or viewed in a subdued light, a mass of flowers such as that presented by a plant in good condition has a curious misty appearance, but at the same time decidedly pleasing. This Heath has of late joined the limited number of those taken in hand by the cultivators that supply Covent Garden Market with flowering plants. H. P.

### ARUM LILIES AND THEIR TREATMENT.

THESE exceedingly useful and attractive subjects should be given good treatment if large, elegant flower spathes are required, together with healthy foliage. Our plan of growing them probably does not differ from that of many others who are successful with their culture. Some gardeners I know grow them in pots during the summer, but I prefer planting them out in the open on a piece of well-manured land at this season. As soon as they have finished flowering they are divided and planted out at 16 inches apart, and but little attention is necessary through the summer, except to keep the soil among the plants free from weeds and giving the roots a thorough soaking at intervals in dry weather with manure water. The old leaves will soon die down, to be succeeded by a fresh healthy lot.

About the middle to the end of September the plants may be lifted and potted up, using pots of various sizes to suit the size of the plants. Before lifting them, however, it is well to give the soil a thorough soaking with water if needed, and after the potting is finished the plants are stood in a rather shaded spot and kept well syringed at intervals should the weather prove dry and warm.

When potting them be careful not to damage the roots more than can possibly be helped, and when the roots have well filled the pots, feed freely with liquid manure; but if smaller blooms are wanted less feeding is desirable. H. MARKHAM.

A LARGE TREE PÆONY IN THE GARDEN OF THE REV. F. D. HALL, LOUTH, Lincs.

## THE ROSE GARDEN.

### NOVELTIES IN BEDDING ROSES.

IT is not every novelty that appears of which one can say "it is a good garden Rose," but of late years decorative varieties have predominated among the large output from the numerous raisers now engaged in the work of cross-fertilising this flower. In these few notes I propose to name some really good sorts that will supply that variety which is so dear to the lover of the garden, and anyone may safely plant in quantity the sorts named herewith, for they are the *crème à la crème* of the recent introductions. It would be a large garden that could accommodate beds of one variety of the many excellent sorts, but I would suggest that they be planted in small groups, say, threes or fives, a plan that would show at a glance which would be most acceptable for making larger plantations. I do not pretend to name the Roses in order of merit, because I consider they are all good of their respective classes.

One of the first to notice is Mme. Melanie Soupert, a variety of great beauty, with huge flowers, not very double. The conical form of the half-open blooms is very attractive, and the colouring of salmon yellow and carmine is most exquisite. It is quite one of the best of recent novelties which that prince of raisers, M. Pernet Ducher, has given us. His other novelty, Marquis de Sinety, is, perhaps, up to the present moment the most remarkable colour yet obtained. It seems like a glorified Ma Capucine, with the fiery orange colour even more conspicuous than that. Charlotte Klemm must be grown by the hundred. Its colour is most gorgeous, the effect of a mass being almost as brilliant as a bed of Henry Jacoby Geranium. It is a China Rose with a very large semi-double flower of quaint formation.

Friedrichsrit is a deep blood-red colour and a grand full flower, sweetly fragrant. Every shoot seems to blossom, and this should prove a real good thing, for we are in need of brilliant bedding Roses that have individual flowers of good quality and yet freely produced. I think this character may be claimed for M. Pernet Ducher's latest novelty, Château de Clos Vougeot, a Hybrid Tea with brilliant velvety scarlet flowers shaded with fiery red. It is said to keep its colour well under a hot sun. A tendency to lose their wonderful colouring under hot sun is characteristic of many recent Roses. If this one maintains its colour it will become immensely popular.

Mrs. Aaron Ward yields the most delightful buds imaginable, and somewhat like a Lady Roberts. This variety is peculiar in having two or three different colours on the one plant, but in older bushes this may be overcome. Mrs. Peter Blair is a grand addition to the yellows, although not very rich in tint. Its beautiful trusses of buds show up well on the upright stems. Hugo Roller is a wonderful Rose that has quite caught the public fancy. The lovely blending of yellow and crimson is so very pronounced that one is drawn to it at once. As the variety yields its blossoms on good erect stems it cannot fail to be a good bedding sort, with a flower nearly large enough for exhibition. William Shean is,

the two in colour; but it is in the erect habit of Mrs. E. G. Hill which makes it superior to the older Rose. Hon. Ina Bingham has such wondrous petals that we can forgive the want of fulness in the flower; in fact, one rather admires the Rose as it is, for we have quite enough double flowers, and these semi-doubles have a special beauty on the plant. The colour is a warm shell pink. Gustave Grunerwald has so firmly established itself as a garden Rose that it must be placed in the front rank for this purpose. The colour might be a little more taking, but the yellowish shade on the rich rose-pink ground has a great attraction, and not less so is its vigorous growth and free-flowering qualities.

Queen of Spain can either be utilised as a garden Rose or for exhibition by freely dis-budding it. The blooms have great substance, and although it is not all that we expected of it, yet there is a future for this Rose. In Elizabeth Barnes we have a marvellous Rose of very rich colouring. It is like a Mme. Abel Chantenay. Farbenkönigin and Beauté Inconstante all blended in one flower, and, being of robust habit, it must prove a general favourite. Dora is a flower almost as large as a Paul Neyron, of beautiful form, and of a colour midway between Captain Christy and Lady Mary Fitzwilliam. Souvenir de Stella Gray is an exquisite mixture of apricot and orange tints, with red splashes and shadings, long-pointed buds and vigorous growth. P.

### ROSE REFULGENCE.

THIS is a new hybrid Sweet Briar of much vigour and promise. The blooms are inclined to be semi-double, 3 inches or more across and of an intense glowing crimson shade, the colour appearing the more pronounced by reason of the rich velvety sheen seen on the petals. Strong and vigorous in growth, with the firm leafage that would almost suggest *R. rugosa* influence, we have here one of the best additions to the Sweet Briar that has yet appeared. The good

attributes we have mentioned above are but strengthened by remarkable freedom of flowering and the pronounced Sweet Briar fragrance emitted by the plants. We regard this Rose with much favour, not merely as a good garden plant for the few, but good alike for beds or groups, and capable of affording beauty of a rare kind when planted as a hedge or dividing line in the best positions in the garden. This excellent variety was raised by Messrs. William Paul and Son, Waltham Cross, and exhibited before the Royal Horticultural Society on the 23rd ult., when it received an award of merit.

THE NEW HYBRID SWEET BRIAR ROSE REFULGENCE SHOWN BEFORE THE ROYAL HORTICULTURAL SOCIETY BY MESSRS. WILLIAM PAUL AND SON, WALTHAM CROSS. (Natural size.)

perhaps, the largest flower yet obtained among the Hybrid Teas if we except Mildred Grant. It is a huge flower of deep pink colour and massive petals. It will be one of the best for show purposes, and I believe it cannot fail to prove satisfactory as a bedding Rose.

Warrior is a much deeper Papa Gontier, with a superior growth to this latter. It will grow as vigorously as a Marie van Houtte. This year its deep blood-red buds are coming a marvellous rich colour. Mrs. E. G. Hill will become a formidable rival to that lovely Rose Grand Duc de Luxembourg. One can scarcely distinguish

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**G**REENHOUSE AND CONSERVATORY.—The present is an excellent time to sow seeds of the beautiful *Primula Sieboldii*. Sow the seeds as soon as they are ripe in a compost made up of light loam, leaf-mould and silver sand in equal parts, this being passed through a sieve with a rather fine mesh. Mix the soil thoroughly, and after

1.—MANURE SHAKEN OUT FOR A MUSHROOM BED. THE HEAP ON THE LEFT REPRESENTS THE SHORT MATERIAL WITH WHICH THE BEDS ARE MADE, AND THAT ON THE RIGHT THE LONGER STUFF FOR COVERING THE BEDS.

carefully crocking the pans or boxes in which the seedlings are to be reared fill in the compost and sow the seeds thinly. Thoroughly moisten the soil by holding the pan or box in a vessel of water, with the surface soil just above water level. For flowering early next spring the present is an excellent time to repot *Arum* Lilies that are grown in pots. The compost for these plants has frequently been given in these pages. Plants of the Indian *Azaleas* that have recently shed their blossoms, and are standing in a cool house to harden, should now be placed outdoors for the summer months. Choose a warm but protected situation, and if they are kept moist at the roots their progress will be quite satisfactory. The greenhouse and conservatory must be freely ventilated during the next few weeks. *Hydrangeas* may now be propagated by cuttings. I find it a good plan to insert cuttings singly in small pots in light loamy soil and then place them in a handy little propagating frame or under a bell-glass in a shady quarter of the greenhouse.

**The Flower Garden.**—The layering of *Carnations* should proceed apace for next year's supply. I always do this work in good time so that the layers may be severed and nicely established plants be raised by the autumn. The same remarks apply to the beautiful garden *Pinks*. Their fragrant blossoms are always welcome, and there are many choice sorts comparatively unknown. If pieces of these plants be pulled off with a slight heel on them and dibbled in in some shaded quarter they root readily enough. At this season I make it a rule to rigorously remove spent blossoms and seed pods from all plants that are not required for seed purposes. By these means the period of blossoming of the different subjects is prolonged.

**Window Gardening.**—To maintain a neat and pleasing appearance dead foliage and flowers should be promptly removed from all window plants. This not only applies to plants in the window, but also to the occupants of the window-boxes. Take pains to water the plants as they need it, and if any plant has got dry at the roots

immerse the whole ball of soil in a vessel of water so that it may become saturated.

**Vegetable Garden.**—I am just making my sowing of spring Cabbage in a border outdoors that has been well prepared and thoroughly moistened beforehand. Seed germinates very quickly at this season, so that good plants should be ready for planting in a comparatively short time. I have just lifted both Shallots and Garlic, the foliage having turned yellow, which is always an indication that they are ready for this treatment. Before placing them indoors in a cool place we spread them out to dry in the sun; in this way they keep much better. *Cos* Lettuce should not be allowed to grow too long before being tied rather loosely. Leeks, if not already planted, should be put outdoors in their permanent quarters at once. Our earliest plants are already doing well, and we are feeding them as growth proceeds. We prefer that they should be planted 6 inches apart in the rows, and the latter should be about 1 foot asunder. If planted in trenches similar to those prepared for Celery, Leeks invariably do well. The quarters recently assigned to Turnips are receiving attention. I am now dusting the surface soil in the early morning with soot, this warding off attacks of the Turnip fly and to a large extent ensuring the success of the crop.

**Fruit Garden.**—Peaches, the fruits of which are now swelling, should be given a thorough soaking with liquid manure. This must not be left too late, otherwise its application may be harmful. It is before they approach the ripening stage that they can appreciate liquid manure. Summer pruning of the fruit trees should be done as soon as possible, otherwise the different subjects will not derive the full benefit from it.

D. B. C."

## CULTURE OF MUSHROOMS IN THE OPEN.

This is a subject in which many beginners are no doubt interested, but have in the past been deterred from taking up the cultivation of Mushrooms because they have felt it is a matter quite beyond them, and one with which they could not very well succeed. We wish to dispense this fallacy at once, and endeavour to lay down simple rules by which Mushrooms may be grown quite successfully. Mushrooms may be grown very successfully in the open air, although with greater certainty under cover. They may be grown in almost any position, provided they are protected with plenty of litter against cold and uncharitable weather and other deterrent influences. Horse manure is the all-important essential, and unless this can be obtained in sufficient quantity it were better to leave the subject alone. However, where a supply of horse manure is available or can be procured, Mushrooms may be grown with comparative ease, especially if the manure be good and such as is obtained from horses that are well fed, in which case the manure is rich in food for Mushroom culture. The manure must be fresh and new, and be dealt with immediately on its receipt from the stables. We would absolutely eschew manure having sawdust, shavings and peat moss litter in it, as these are deterrent influences and can only be used successfully by growers with considerable experience.

**How to Prepare the Manure.**—As this is received it should be placed in a heap arranged as near to the quarters where the beds are to be made as possible. See that the quarters are quite clean and free from weeds. Shake the

heap over well, placing the longer littery matter—pieces 1 foot or more in length—in a heap by itself, and all the shorter material in another heap. The longer littery matter is kept apart for the purposes of covering the ridges once the Mushroom beds are formed. The shorter manure must be turned over repeatedly, and, should it be somewhat dry on its receipt, it is well to give it a good watering. Frequent waterings will not be needed if the manure be given one good watering in the first instance. Naturally, the more frequently it is turned over the drier it becomes, and it would then be too late to apply water without running considerable risk, largely rendering previous efforts null and void. From October to February it may be safely said that no water whatsoever will be needed. The case is different, however, in the month of September or later than February. In dry weather water must be applied at these periods, but only in sufficient quantity to moisten all the dry parts. It is not necessary to saturate the manure, but just sufficiently well to moisten it throughout. The heap may be turned again on the following day, assuming the manure is fairly new and fresh, but if not in this condition two days may elapse before it is necessary to turn the heap again. In subsequent turnings work the heap over in such a way that that which was formerly on the outside of the heap is placed in the centre, and *vice versa*. Generally speaking, three turnings will suffice. What the grower has to bear in mind is to so deal with the manure that the heap may be thoroughly sweetened throughout. Fig. 1 shows how this material should be prepared.

**When the Manure is Ready for Use.**—The manure that is properly prepared for Mushroom beds should give off no offensive odour, but should smell quite sweet and not unlike that of the Mushroom itself. It must not be wet, but sufficiently moist for one particle to adhere to another without exuding moisture. Of course, it must be hot, and if the manure was in good condition at the commencement the heat should be right when the beds are made up. Manure that is wanting in heat after preparation will be less likely to give good results, as the temperature always goes down after the beds are made up.

**Making Up Ridge Beds Outdoors.**—The beds must be made up according to the space available

2.—A BED MADE UP PREPARATORY TO SPAWNING.

and the quantity of manure prepared. Beds of this character may be made up any length from 3 yards and upwards. Ridge beds should be about 2½ feet in width and of the same height, tapering to their apex, at which point they should be about 6 inches in diameter. Beds of larger dimensions are too warm, and smaller beds very soon lose their heat. In cold weather, however, we should be disposed to make the

beds larger. With a garden line it is easy to determine the limits of the beds, and the ground plan having been fixed upon, proceed forthwith to shake out the manure in layers of 6 inches, treading it firmly, finishing each successive layer of 6 inches before proceeding with the next one. When the bed is about 2 feet high rake down the sides with a fork, in this way removing all loose matter and placing this ultimately on the top of the ridge, finally beating this down, at the same time treating the sides of the beds in similar fashion to consolidate them, which in the end should have the appearance of the bed represented in Fig. 2.

*What to Do Preparatory to Spawning.*—We must now await the spawning period. A thermometer inserted here and there in the bed to a depth of 2 inches to 3 inches will assist the grower in determining when it is ready for this work. At first the heat will be somewhat high, and ultimately it will reach a figure at about 130° Fahr. Should the temperature be beyond this it is too high, and must be reduced by more beating and treading. After a while the temperature

4.—BEDS COVERED WITH THE LITTERY MATERIAL.

which has been at 130° will gradually fall, and when this ultimately reaches 85° spawning may begin at once.

*Spawn* is made up of a mixture of manure and soil, permeated throughout with very fine white threads. The white threads are the live parts of the spawn, and really constitute the Mushroom plant in a dormant state. Sixteen cakes of spawn go to a bushel. It is essential that the spawn be of the very best, and this can only be ensured by purchasing this product from a reliable source.

*How to Spawn the Beds.*—Break up the spawn into pieces, so that eight to ten pieces are procured from each brick of the spawn. These pieces may be inserted here and there, 9 inches apart, on the top of the bed and in the sides. A cavity should be made for the insertion of each piece, so that its flat side is level with the surface soil. Adjust it in position and press the manure firmly to it, so that no cavity exists in which the moisture may settle, as this may cause the spawn to rot.

*Covering the Beds with Soil.*—The ridge beds should be covered with soil to a depth of 1½ inches about three days subsequent to the spawning, except in very wet weather, when the covering should take place immediately after the spawning. The soil for covering the beds should be of a friable character and absolutely free from decaying vegetable matter.

3.—A BED AFTER SPAWNING COVERED WITH SOIL AND MADE FIRM PREVIOUS TO COVERING WITH LITTERY MATERIAL.

Soil that has been recently manured is quite unsuitable for the purpose. We prefer, if possible, to use good loam from an old pasture, but when this is not available any other soil that is not rich will answer the purpose almost as well. Make this firm by using the back of a spade. Fig. 3 represents how a ridge bed in the open should be covered with soil.

*Subsequent Treatment.*—The only thing that now needs to be done is to cover the beds with the littery matter previously conserved with the prepared manure in the first instance, and the beds should be covered with this so as to conserve the warmth and to protect the ridges from rain. Should the surface soil be dry previous to the covering with the littery matter it must receive a slight watering; but if it be moist on no account apply the water. Within six weeks the beds ought to come into bearing, and from this time forth we may look forward to a continuation of the supply. In the case of beds in exposed and cold situations an extra covering of littery matter must be applied, and, if it be possible, the beds should be screened from strong winds by covering them with mats and other available covering. July, August, October, December and January are the best periods in the year to form beds outdoors. We like beds running from north to south, as in this way they get all the sun possible. Fig. 4 represents a series of beds covered with littery matter after spawning.

#### WORK IN THE VEGETABLE GARDEN.

The most important work in the vegetable garden is the planting out of the various winter greens, such as Broccoli, Cabbage, Brussels Sprouts and Kale. The ground needs no special preparation for this crop, but a plot that has carried Peas or early Potatoes may be levelled with the fork and planted; digging is not necessary, as these plants like a firm root-run. It is customary to pull young Cabbage and similar plants from the seed-bed, but many roots are torn off in this manner and a check is given to the plant. The better way is to loosen the plants with a fork, when they will come up with roots intact. Where a limited number of plants is dealt with, the trowel may well take the place of the popular dibber as a means of inserting the tender-rooted seedlings.

A small packet of Radish seed scattered broadcast on any vacant plot will give useful salad in a few weeks. If the seedlings come up very thickly pull out a portion and eat the young green tops before bulbs form. Turnips may be sown in a moist semi-shaded portion of the garden, either in a drill or scattered broadcast. Often a place beneath the shelter of a row of Peas or Runner Beans can be given, and this will suit the crop admirably at this season. Thin sowing and dusting with soot or lime to keep slugs at bay are essential to successful Turnip raising. Parsley sown now will yield a picking all through the winter and until late in spring. A well-drained position should be chosen, such as alongside a walk or under a wall which keeps off heavy rains, and the plants

should be thinned out 6 inches apart. The old country superstition as to bad luck attending the transplanting of Parsley may well be ignored, and any gaps in the row made good from places where the plants are too thick. E. J.

#### SUITABLE SOIL FOR ROOM AND WINDOW PLANTS.

Too often the idea obtains that any ordinary garden soil will grow window plants; this fallacy generally finds a home with the person who has had no experience of greenhouse plants. Once the attempt to grow greenhouse plants is made the necessity of using good soil is realised and the ordinary medium of the garden is never allowed to grace or disgrace a flower-pot. If good soil is necessary for greenhouse plants, then it must be even more so for window and room plants, and I should like at the outset to impress this fact very strongly on readers' minds. The strongest plant will dwindle and die in unsuitable compost; the weaker ones will never have a chance of living.

The realisation of the necessity of good soil brings us to the consideration of what good soil is. Here let me say that when soil is employed in a gardening sense it rarely means soil pure and simple; it is invariably a mixture of various ingredients, such as loam, peat, leaf-mould, sand, charcoal and occasionally other substances. The whole is collectively termed compost, and this is really a better term than the generally used one—soil. With a view to assisting the tyro, a brief explanation of what is meant by loam, peat and the other ingredients forming a compost may well be given.

*Loam* is, as I know from a wide experience, the biggest puzzle that one can set a gardening novice to unravel, and yet, fundamentally, loam is the simplest of the simple. Take a spade out into a field or common, thrust it down some 9 inches with the foot and bring away the soil displaced, and there you have loam in its purity and its most desirable form. To make this loam fit for potting purposes it is wise to stack it, layer upon layer, grass side downwards, in a heap outdoors. This serves a double purpose, i.e., it causes the grass to decay and forms what is called humus—the most valuable ingredient of all soils—and also starves out such animal and insect pests as wireworms, millepedes, cockchafer grubs and leather jackets, all deadly enemies of the gardener, practices he indoors or out. About twelve months should be allowed to accomplish these desirable objects, but loam stacked for six months may often be safely employed. The above is loam in the generally-accepted sense of the word, and such is always intended when the word is used by writers in the horticultural Press, but occasionally one may hear a jobbing gardener speak of the top spit of a cultivated garden as “loom.” E. J.

(To be continued.)

5.—A GOOD CROP GROWN IN THE MANNER DESCRIBED.

## THE TOWN GARDEN.

**THE QUEEN OF FLOWERS.**—This is essentially the time of the Rose, and those town dwellers who are so fortunate as to be able to persuade the plants to thrive will now have to be giving them some attention so as to ensure the full enjoyment and pleasure from the blooms. Green fly will assuredly have put in an appearance, and it must be promptly exterminated or serious injury is certain to accrue. A pinch of snuff is excellent in those gardens where the plants are not numerous, or the pest can be cleared out by the aid of one of the many washes or powders which are advertised in *THE GARDEN*. The surface soil must be kept loose and fine, or a dressing of short, sweet manure applied so as to conserve all moisture in the soil. When water is necessary the soaking should be so thorough that it will pass down below the roots, and, rising again, bring with it the food for the plants. Climbing Roses on walls will be especially benefited by heavy waterings and also by judicious applications of weak liquid manure, although I have never noticed any substantial advantage follow upon the use of this in the case of plants in beds and borders. As town dwellers who grow Roses seldom do so for any other purpose than the adornment of the garden, it is unnecessary to have recourse to anything beyond the most perfunctory disbudding. Hybrid Perpetuals should be cut over after flowering and encouraged to throw up new shoots, as these will give welcome flowers later in the season.

**INSECTS IN THE GREENHOUSE.**—At this period of the year, when work in the flower garden presses so severely, the greenhouse and its occupants are apt to be neglected, with the common result that many of the plants become infested with green fly, red spider and other pests. This should never be allowed, for it is imperative that the plants shall be kept clean and in perfect health if they are to afford satisfaction in due course. In some cases it is probable that sponging will have to be done before matters can be again properly adjusted, but as a rule fumigation on two or three successive evenings will do all that is necessary. The house should be closed so as to confine the fumes long enough for them to effect their purpose. Tobacco is, of course, excellent; but the special preparations now on the market are so efficacious and so much pleasanter to use that the former has practically fallen into desuetude. When all is clear the ventilators should be wide open in the daytime and almost wholly so during the night, while the floors and other surfaces may be advantageously damped at frequent intervals, watering receiving regular attention.

**ROOM PLANTS.**—Showers are not as frequent as we should like them, especially for the occupants of the garden; but when they do come they should be taken full advantage of on behalf of the room plants. Whenever a warm rain is falling stand these out of doors to enjoy it, and they will not only be cleansed, but also reinvigorated by their sojourn in the open. Failing showers, it is good practice to stand them out and sprinkle them through the rose of the water-pot or hose. It is imperative that they shall not be neglected in the matter of watering, and that the leaves shall be kept scrupulously clean by frequent gentle spongings with pure or soft soapy water.

**TOMATOES ON WALLS.**—Up to the time of writing these have done splendidly this season, but they must not be overlooked, especially in the matter of removing all the young shoots that appear in the axils of the leaves, in watering and in feeding as may be necessary. When the plants are well set with fruit weak liquid manure will help them immensely, but if it is given strong the plants will rush quickly to leaf and succeeding clusters will suffer as a consequence. Clear water must be given frequently.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUITS UNDER GLASS.

**VINES.**—Keep the temperature as low as possible where ripe Grapes are hanging, and keep sufficient moisture about the floors to prevent attacks by red spider. Where Grapes are cut the Vines may with advantage be syringed copiously twice daily, and the use of an approved insecticide will be an advantage. Later houses must be looked after very closely during hot weather. See that all places are damped thoroughly several times daily, but do not syringe the bunches, as if the water is not perfectly clean it will spot the berries. Keep the border in a good moist condition.

**Peaches.**—Where there are moveable lights over the early house these may at once be taken off. Keep the trees, however, well supplied with moisture, and on no account allow them to suffer from drought. Keep late houses well supplied with moisture, and to trees carrying heavy crops give some stimulant at every other watering. Prop the fruits up near the light to enhance the colouring. The latest house should have all the ventilators open during warm weather both day and night.

**Melons** will set very easily now, and those in cutting should be good owing to so much sunshine. Plant for the last crop in a house that can be kept warm during September should the weather prove cold.

#### HARDY FRUIT.

Take up and burn all old Strawberries that have become worn out; the ground can be utilised for Broccoli or other greens. Pot up Strawberries that were layered in small pots for forcing, using good loam, with some manure added, and ram the soil well, so that the growth will be solid. Look over all crops and thin where there is a superabundance. Many amateurs do not thin the fruit enough and in consequence it is small and the trees or bushes suffer for the succeeding year. Net all fruits before they get to a ripening stage; it is much easier to keep birds away when they have not tasted the fruit. Keep a sharp look-out for any insect pest and apply remedies at once.

#### KITCHEN GARDEN.

**Tomatoes** should be secured to the stakes as they grow. Take out the lateral growths as fast as they appear. These plants are doing well outside this season, and Carter's Sunrise has already got a fine set of fruits, which are swelling away rapidly. Continue to plant out Leeks and Celery if possible on dull days or during the afternoons of bright ones, watering thoroughly before and after. Mulch Peas and Beans after a thorough watering. Sow Carrots for autumn use. Thin all crops, so that those left may develop thoroughly.

#### FLOWER GARDEN.

**Carnations** are earlier than last season, so that layering with some varieties may be got on with at once. Place a quantity of good sharp fresh soil around the plants to be layered. Use a very sharp knife and wire pegs and make the latter quite firm.

**Lavender** flowers must be collected as soon as the spikes are fully open. Keep all beds and borders smart by constant picking off dead and decaying inflorescences. Maintain the ground free from weeds and Roses well watered and mulched where this is practicable. Give an occasional watering of guano and syringe well on the eve of a hot day, and if any rust or mildew puts in appearance syringe with potassium sulphide.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ROOF CLIMBERS.**—Many of these will now be making robust growth, and a dull day should be selected to overhaul them. All gross and superfluous growths should be removed, and those selected loosely and gracefully suspended, exposing to view as much flower as possible. There is a tendency with these plants to grow upwards and a desire to flower where they cannot be seen.

**Hydrangea Thomas Hogg.**—This is a noble plant when grown as a large specimen, and will produce a flowering truss from almost every bud when well ripened. In the formation of large plants the annual growth must be encouraged to form in the full sun. Neat little plants are secured by inserting cuttings now or later on in the autumn, after the embryo truss has formed. As soon as rooted the plants must be grown in full sun in the open air, after being repotted and finally established in 5-inch pots.

#### FRUIT UNDER GLASS.

**Melons.**—The season so far has been most favourable for these fruits, but there is still a necessity for continued warmth in the hot-water pipes, as there are times when the temperature is much lowered owing to rain and other causes. Should canker make its appearance, keep the plants drier, and dress the affected parts with fresh quicklime, sulphur and finely-powdered charcoal. Closely watch ripening fruits, and remove them just as the stalk is cracking.

#### KITCHEN GARDEN.

**Cucumbers.**—Plants growing in frames or hot-beds that have been bearing since April will now be showing signs of giving out, especially if they have been heavily cropped, and it will be necessary to thin out a lot of the old foliage so as to allow room for new growth to form. The surface soil should be slightly disturbed, and 1 inch or so of light, rich, porous compost given, to which should be added a slight sprinkling of soot. If the soil is heavily charged with moisture through constantly sprinkling the foliage, withhold water for a time. Plants which have been rather severely pruned should be kept close and shaded for a few days and the foliage dewed over morning and evening. If the roots are healthy new growth will soon form. This must be kept pinched at about the third leaf and regulated over the surface of the bed.

#### FLOWER GARDEN.

**Roses.**—These have had a very trying time in many places through the drought. Where there is a good water supply it will be helpful to the plants to give them a good soaking. All old flowers should be picked off directly they have passed their best. Strong, flowerless shoots, which often appear, should be shortened back level with the flowering shoots.

**Antirrhinums.**—Where flowers of gorgeous hue are in request at this season of the year, one of the best things available is the tall-branching Antirrhinum. From seed sown last July we have plants now 3 feet high with the first spikes just at their best, the shades in selfs varying from white and yellow to deep crimson and maroon, besides very striking mixtures, as dark scarlet with golden lip, and crimson and carmine striped on a yellow ground. To obtain plants for next season it is advisable to start soon. Prepare boxes by filling with a rather light compost, and give a good soaking before sowing, cover the seed lightly, place in a cold frame and shade from hot sun. Transplant into nursery beds as soon as the seedlings are of sufficient size, and plant out in autumn or early spring, as may be most convenient.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## BOOKS.

**Gardens of England.**\*—"Gardens of England, Present and Future," one is inclined to think would be a good title for this interesting volume, for the notes appended to the pictures are rather thoughts suggested by them than merely descriptions of the actual gardens shown, and Mr. E. T. Cook has dipped largely into his recollections of many beautiful gardens in England other than those pictured here, given us of his own experiences in the garden; lastly, and best of all, compressed into a comparatively small space simply numberless suggestions, based on broad lines, whereby we all, given we are possessed of that infinite capacity for taking pains which amounts to genius may, failures notwithstanding, become possessors of gardens, beautiful to their utmost capacity, whether they be great or small. Passing, for the moment, over the first few chapters, pride of place must be given to the Rose, and here, in "Amongst the Roses," we have one of the most, perhaps quite the most, interesting chapters of the whole book, while of the pictures which give rise to these notes that of "The Pergola, Brantwood, Surbiton," besides making a charming picture of itself, serves to show what may be done with Roses in a garden in the suburbs where expert knowledge and unceasing care has been brought into play, as here. Miss Parsons has been very happy in the moment she has chosen for her sketch, the clustered pink Roses against the deeply blue sky and the sunlit foreground forming an altogether beautiful scene. Mr. Dowdeswell, of Art fame, is the owner of this delightful garden. The author gives a goodly list of Roses, containing most of those best worth growing, dwelling more particularly on climbers and Chinas than is usually the custom. We join him in admiration of beds of Laurette Messimy and Mme. Eugène R  sal; these two associated make perfectly delightful beds when carpeted with Tufted Pansies, either cream or palest mauve. The picture he gives of the rosy flowers of Camoens peeping out from under the snow, in his own garden, reminds us of a letter we once read from an Englishman living in Persia to his mother, in which he exclaimed at the curious sight presented by the fields of "Attar" Roses, the ground covered with snow, while the Roses were in full bloom. This, we believe, is no uncommon sight there, and is not considered in any way detrimental to their use for perfume. But it is impossible to dwell at length on the various chapters in their turn. The beauty of simple grouping. We are in perfect agreement as to the undesirability of planting in lines; still, that there can be no hard and fast rule is emphasised here by the fact that one of the daintiest colour sketches in the book faces these suggestions for simple grouping, that of "Waxwell Farm, Pinner," in which rows of Daffodils nod over a grass alley, and is, as Mr. Cook says, entirely charming. The last four chapters, "Spring," "Summer," "Autumn," and "Winter in the Garden," the last contributed by Mr. S. W. Fitzherbert, are of much interest, and full of useful suggestions for the garden that is still to be; but we cannot now do more than give special commendation to some of the illustrations not yet mentioned. The first, "The Sundial, Woodside, Chenies," is extremely tender and delicate in tone; "The Dovecote," equally good, strikes a deeper, richer note; while the last of all, "Moonlight, Golder's Hill," is endowed with a quiet restfulness which is wholly pleasing. If we have any fault to find with this book, it is its weight to hold, but where so much that is good is given, it is, perhaps, ungracious to find fault at all. M. H.

\* "Gardens of England." Painted by Beatrice Parsons and described by E. T. Cook. Published by Messrs. A. and C. Black, London.

## LEGAL POINT.

## MARKET GARDENER'S CLAIMS.

[In reply to "D. S. O."]

THE rights of a market gardener to compensation for improvements, &c., depend very much on whether he is entitled to claim the benefit of the Market Gardeners' Compensation Act or whether he has merely the rights of the Agricultural Holdings Acts, 1883-1906. It is very troublesome to put any meaning on an Act which does not put out the new legislation clearly, but by reference to previous statutes; but it appears to be that the Market Gardeners' Act only applies if either it has been "agreed in writing" that the holding, if created on or after January 1, 1896, shall be treated as a market garden, or if created before that date it was on the commencement of the Act used or cultivated as a market garden with the knowledge of the landlord. In the earlier holdings the improvement for which compensation is given, or a right of removal is allowed, must have been executed prior to the date last mentioned without the tenant having previously received notice of the landlord's dissent. Before dealing with some general points, we may as well point out to our correspondent that he gives no information on the date when the tenancy which he took over in 1901 was originally first created. This point is of some importance, as he steps into the shoes of the former tenant, while the present landlord similarly takes over the rights and obligations of the former landlord.

"Sheds," if erected by the tenant, are comprised in the words "erections or enlargement of buildings." If the 1895 Act applies as described above, the tenant can demand compensation; but if only the Agricultural Holdings Act is applicable, then there is no compensation unless the erection was with the written consent of the landlord, although there may be the right of removal as a fixture in certain cases. "Green-houses" are governed by the same rule, and as regards these there might be a right of removal, even at common law, although it is otherwise generally in a residential tenancy.

As regards "crops," under the Agricultural Holdings Act the only claim to compensation which could arise would be in connexion with "fruit bushes" placed on the holding with the landlord's consent in writing, while under the Market Gardeners' Compensation Act, 1895, written consent is immaterial and the list of crops is somewhat extensive. There is a right under the later Act as regards Strawberry plants, Asparagus and other vegetable crops. As regards fruit trees and fruit bushes, there is a right to compensation if they are permanently set out; but if not permanently set out there is a right of removal only, which is to be exercised before the termination of the tenancy. The time for removal in this case resembles the right of removal of an ordinary tenant at common law as regards his fixtures, differing from that under the Agricultural Holdings Act, which can be exercised within a reasonable time after its termination if the landlord has not availed himself of his option of purchase. BARRISTER.

## ANSWERS TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Foxglove raceme with curious terminal flower** (*G. Francis and others*). It is not very unusual for Foxgloves to appear with a large, bell-like flower at the top of the raceme, and every season brings its quota of these. They indicate a freak of Nature, and little is understood about them. It is generally accepted, however, that they are the result of high cultivation continued through several generations. They certainly are not the result of a cross between Foxgloves and Canterbury Bells, as such a cross is impossible.

**Phlox stems diseased** (*M. H. C.*).—The stems of the Phlox showing the thin growths are teeming with eelworms (*Tylenchus devastatrix*) and to the presence of these the poor growth of the plants is due. This eelworm is very often spread from place to place in manure, especially when horses have been fed on Clover hay. It is a pest extremely difficult to deal with, and attacks a very wide range of dissimilar plants, Onions, Clover, Beans, Hops, Oats, Stocks and Wheat being among them. Probably the best method of getting rid of the pest is to apply a manure that will urge the plants into vigorous growth, and it has been found that in certain cases a mixture of sulphate of potash (three parts) and sulphate of ammonia (one part) applied to the soil in the spring at the rate of 1½ oz. to 2 oz. the square yard has had beneficial results and checked the progress of the pest, but probably the best thing to do, especially if the plants are very badly attacked, would be to burn them and give the soil a thorough dressing with lime.

**Information about window-boxes and caterpillars** (*Subscriber*).—Yes, window-boxes are used outside the window. Their size and shape varies according to the size of the sill outside, as they are usually made to fit this. They should, however, always be at least 9 inches deep. Wood is chiefly used in the construction of these boxes, boards three-quarters of an inch in thickness being best for the purpose. Sometimes a metal casing is placed inside the wooden box, especially when plants in pots are plunged in the boxes. The usual way in this country is to make a number of holes half an inch or more in diameter in the bottom of the box, then place in a 2-inch thick layer of broken pots, bricks or other rough material, and finally fill in to within 1 inch of the top with good turfy soil, such as is used for potting, the plants being put direct from pots or boxes into this. If it is desired to retain plants in their pots, the latter are stood in the box and packed round and up to their rims with Cocoanut fibre. Each box should have three bars of wood 1 inch thick nailed under the bottom outside, so as to raise the bottom of the box a little way from the window-sill. Various methods of ornamentation are employed for the fronts of these boxes. Fancy tiles are sometimes used, other growers prefer to paint the front of the box, but the most general system is to nail pieces of virgin cork in a rough and natural manner to the fronts. A good plan is to have one permanent box and about three others to fit into it. The latter are then taken out of the windows when shabby and replaced by others that have been prepared in reserve. We cannot advise you as to the best plants to use, as we do not know the climatic conditions in your country. To destroy the caterpillars procure some Paris Green (Blundell's) and dissolve 1 oz. in 10 gallons of water, taking care to have it well mixed. Then spray the plants with this mixture, using a syringe that will give a very fine spray for the purpose. Coat every part of the foliage with the liquid. It will be necessary to keep it well stirred while applying

it. This substance is poisonous, and must not be used within a fortnight of gathering the fruit. If you cannot obtain Paris Green procure some white Hellebore Powder, freshly ground, from the chemist, and mix 2lb. with 10 gallons of water, keeping it well stirred while using. Spray with this as advised for Paris Green. A week after the application of either mixture give the plants a heavy syringing with clean water.

### FRUIT GARDEN.

**Cherries casting their fruit** (W. J. S.).—The casting of the fruit in the way you mention is a sure indication of something being wrong at the roots. The Cherry succeeds best in a deep, well-drained, cool and rather heavy soil. Yours is probably of a light and warm nature, and therefore deficient in some essential constituents necessary to successful fruiting. If our surmise is correct, we advise you to give your trees a good soaking of manure water (from the stable or farmyard) every three weeks during the summer, and in the autumn (early in November) to remove the surface soil until a good body of roots is come to, then add a top-dressing of good heavy loam mixed with an equal quantity of rich, well-decayed manure from the stable or cowyard, and apply it 6 inches deep over the roots, treading it firmly down. Give the trees another soaking of water just before they show signs of growth in late winter. The overcrowding of the trees in summer with superfluous growth must be avoided or the fruiting shoots and buds of the trees cannot be properly developed and ripened.

**Pear dropping its fruit** (Skatta).—The failure of your Pear tree to carry to maturity its crop of fruit must, we think, be attributed to imperfect fertilisation of the flowers, on account of the want of pollen on the anthers. To prevent similar failures in future you should give particular attention to the summer pruning of your tree, in order to expose the current season's growth to the action of light and heat by cutting away needless growth and thereby preventing overcrowding of branches, bearing in mind that the success of next year's fruit crop depends very greatly on the proper development and ripening of the shoots and buds of this year's growth.

### MISCELLANEOUS.

**Names of plants.**—*E. S. M.*—1, Possibly Vandal, an old Gallica Rose; 2, Blairi No. 2; 3, Pitord, an old Hybrid Perpetual; 4, Pride of Waltham; 5, Sanchette, an old Gallica Rose; 6, Nepeta violacea.—*W. Scott.*—1, Campanula pusilla; 2, C. portenschlagiana; 3, Allium Moly; 4, Polemonium caruleum album; 5, Lotus uliginosus.—*M. P. Holt.*—1, Cannot identify; 2, Félicité Perpétue; 3, Climbing White Pet.—*A. M. C.*—1, Begonia Rex variety; 2, send better specimen; 3, Senecio articulatus; 4, Sidalcea candida; 5, Campanula glomerata dahurica; 6, Lathyrus sativus.—*E. S.*—The Dianthus is Crimson Bedder.—*H. Inman.*—Polygonum cuspidatum.—*E. L.*—1, Hypericum calycinum; 2, Juglans nigra (the Black Walnut).—*J. H. M.*—The Rhododendron is a well-known variety, its name being R. fastuosum flore pleno.—*W. de H. B.*—The Rose sent is Reine Olga de Wurtemberg. It is not at all a good autumnal bloomer. There are one or two stray flowers produced.—*F. W. D.*—The Rose is Killarney.—*H. Inman.*—A variety of Rosa alba, probably Mme. Audot.—*Rose Bloom.*—Could you send us a more developed bloom with a longer piece of the growth and foliage? The buds sent we are unable to identify.—*E. G. P.*—The large Tea Rose is White Maman Cochet, and the climbing variety Alberic Barbier.

#### ROYAL HORTICULTURAL SOCIETY.

HOLLAND PARK SHOW, JULY 7 AND 8.

##### ORCHIDS.

FROM MESSRS. HUGH LOW AND CO., Bush Hill Park, Enfield, came an extensive and artistically arranged group of splendidly grown plants. *Cypripedium macrochilum* giganteum, *Coleogyne dayana*, with its long drooping raceme of curiously coloured flowers; a very fine batch of *Cypripedium niveum*, *Cattleya Mossiae* *armoldiana* Snee's variety, *C. M. Neptune*, *Bulbophyllum claptense* and a large plant of *Coleogyne pandurata* were a few of the most noticeable in a really remarkable collection.

Messrs. Stanley and Co., Southgate, N., put up a small group of well-flowered plants of *Cattleyas*, chiefly Mendelii and *C. Mossiae* varieties. Many of the flowers here though were evidently past their best.

Messrs. Moore, Limited, Rawdon, Leeds, had a very pretty little group, the arrangement of which deserved the highest praise. Three large pillars draped with Maiden-hair Ferns and Orchids were erected at the back with

beautiful examples of choice Orchids tastefully placed among suitable greenery in the front. *Brassia verrucosa*, *Cypripedium bellatulum*, *Cattleya gaskiana* alba, *C. gigas* (very fine indeed), *C. Rolfe* magnificum, together with some very interesting botanical specimens, including fine plants of *Zygopetalum rostratum* were well shown.

Messrs. Sander and Son, as usual, put up a very extensive and comprehensive group of plants in the finest possible condition. The arrangement was in the form of an undulating bank, with bays filled with the choicer dwarf-growing types. *Cypripedium bellatulum* was displayed in profusion, and numerous *Odontoglossum* hybrids, finely coloured flowers of *Laelio-Cattleya Martinettii* Rex, *Miltonias*, *Cypripediums* and many interesting botanical specimens.

From Messrs. Charlesworth and Co., Heaton, Bradford, came a very beautiful collection of superbly-grown plants, these being remarkably floriferous. Such things as *Cattleyas*, *Miltonias*, *Odontoglossums*, *Laelio-Cattleyas* and many others were profusely displayed. *Cattleya Warneri* alba, *Laelio-Cattleya Golden Oriole*, *Lycaste Skinneri* alba, *Barkeria elegans*, *Trichopilia backhousiana*, *Bartholina pectinata* and *Stanhopea tigrina* were a few that especially appealed to us.

##### CARNATIONS.

Messrs. James Veitch and Sons, Limited, Chelsea, had a very fine group of Malmaison Carnations, containing splendidly-grown and well-flowered examples. A few of the best were Duchess of Westminster, Mrs. Trelawney (rose scarlet), Albion (rose salmon), Maggie Hodgson (crimson), H. J. Jones (crimson), Dragut (cherry red), Miss O. B. Simpson and Yaller Gal (yellow shades), both being very good.

Messrs. Hugh Low and Co., Enfield, had a sumptuous lot of Malmaisons, among which Irene, a salmon pink variety, the result of crossing Lady Grimston and Princess of Wales, stood out very conspicuous. Certainly it is a very charming flower. The Colonel, a red-scarlet flower, and a seedling yellow named Amber were also fine. Lady Mary Hope, with orange shading, is an exceptionally good flower, and apart from these were many seedlings of great promise.

Sir George Faudel-Phillips, Bart., Ball's Park, Hereford (gardener, Mr. Fitch), had a grand display of pot-grown Malmaisons, superb examples of the best-known varieties, in some instances carrying two or three dozen flowers each.

Messrs. Peed and Sons, West Norwood, S.E., also exhibited finely-grown examples of pot-grown Malmaisons in variety.

Sir Daniel Gooch, Hylands, Chelmsford, was an exhibitor of Malmaison Carnations, the pot-grown plants displaying much cultural skill.

Messrs. William Cutbush and Son, Highgate, N., had a very extensive and comprehensive exhibit of the best American Carnations with others of British origin. Princess of Wales, King Arthur, Mrs. H. Burnett, Trojan, Victory, My Maryland, Yaller Gal and White Perfection being among the best. Messrs. Cutbush also displayed Roses of the rambler class in great beauty and much variety.

Mr. James Douglas, Great Bookham, Surrey, had a few of his superbly grown Carnations, such as Germania, scarlet; Peregrine, fancy; Lady Linlithgow, rose; Miss Willmott, scarlet; Mrs. Trelawney, salmon; and others.

Mr. John Ree, Rickmansworth, also exhibited a group of Carnations in variety.

Mr. A. F. Dutton, Iwer, Bucks, had a sumptuous group of cut Carnations, representative of Malmaison and the cream of American varieties, a really superb gathering of all that is most desired in these ever-popular flowers. A capital lot of border Carnations also came from this exhibitor.

Messrs. Bell and Sheldon, Castel Nursery, Guernsey displayed a grand lot of these flowers superb in size, quality and freshness. Britannia as shown by this firm was a marvellous flower, and some five or six dozen of its flowers in a vase fully displayed its worth. The President, Winsor, Mrs. Lawsoo, Aristocrat and Mrs. Burnett were all of grand size and colour.

Mr. H. Burnett, Guernsey, was another of the leading exhibitors of Carnations, his flowers commanding attention by their size and beauty. Winsor and Mrs. Burnett were especially good.

Mr. W. H. Page, Tangleby Nurseries, Hampton, had a capital lot of Carnations, chiefly of the American tree section, and associated with Lilies in variety made a very effective display.

##### ROSES.

The Roses from Mr. George Mount, Canterbury, were very fine, and consisted of bold groups of Fran Karl Druschki, Liberty, Joseph Lowe, with masses of White Maman Cochet, Mildred Grant, W. J. Grant and many more in the finest condition.

Messrs. H. Merryweather and Sons, Southwell, Notts, had many good Roses in great variety, Betty, Dean Hole, Florence Pemberton, Mrs. Peter Blair, Mme. E. Souper, Mrs. E. Mawley and others being shown in charming condition.

Messrs. Alex. Dickson and Sons, Newtownards, County Down, had a delightful lot of new Roses. Duchess of Wellington, orange and salmon; Lady Helen Vincent; George C. Wand, cherry red; Molly Sharman Crawford, fine white; Mrs. David Jardine, salmon pink, very charming; Grace Molyneux, flesh pink; and Harry Kirk, yellow and cream, were among the best.

Mr. Robert Chaplin, Joyning's Nursery, Waltham Cross, staged a very fine lot of Roses on a table extending to 60 feet in length, and representative of the best types of this flower in its many and diverse sections.

Messrs. B. R. Cant and Sons, The Old Rose Gardens, Colchester, exhibited a capital lot of Roses, such as Hugh

Dickson, Charles J. Grahame, Antoine Rivoire, Mildred Grant, Gottfried Keller, White Maman Cochet, together with a delightful lot of garden Roses in many shades of colour.

King's Acre, Limited, Hereford, displayed Roses in really superb style, those of the rambler class and others, such as Mildred Grant, Mrs. E. Mawley, Caroline Testout and Souvenir de Pierre Notting contributing to a fine display.

Messrs. George Jackman and Son, Woking, had an admirable lot of Roses, Tea, rambler and garden varieties in great variety making a very charming group.

Rose American Pillar, a new single-flowered variety, exhibited by Messrs. Cannell and Son, Swanley, promises to be one of the most delightful of all pillar Roses. The flower is of large size, rose carmine in colour, with nearly white base. An ideal Rose for the garden.

Messrs. R. and G. Cutbush, Southgate, had a very fine group, in which Lilies, Humeas and Roses, the latter chiefly of the rambler and Polyantha class, combined their delightful fragrances in one pleasing whole, at the same time affording, by the grace and elegance of the plants employed, a rather unusual display.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, filled a delightful corner in tent No. 1 with the choicest of pillar and garden Roses, those such as Jersey Beauty and White Himalaya being exceptionally good as pillar sorts. Wallflower, also a rambler, was in excellent form. Of other good sorts we select Fisher Holmes (dark red), White Maman Cochet, Marquise de Sinety, Hybrid Tea (flesh yellow), Mrs. W. J. Grant, Mme. Melanie Souper (flesh pink), White Maman Cochet, Mrs. Paul (a glorious cluster Rose with large flowers), Mme. Ravary and Frau Karl Druschki were all noticeable and good.

Messrs. William Paul and Son, Waltham Cross, exhibited a very fine lot of Roses in pillar form and in the cut state. We noted Waltham Rambler, Earl of Warwick, Merveille de Lyon, Dr. William Goodson, Victor Hugo, Jersey Beauty, Kaiserin Augusta Victoria and Celia (a lovely pink flower) among many charming varieties.

From Messrs. Hobbies, Limited, Dereham and London came a very remarkable display of Roses, rambler and other sorts prevailing in standards, arches and pillar groups, while in many diverse ways were seen such as Progress, Mme. A. Chatenay, Dean Hole, Liberty, Sunset and the like, a really choice exhibit arranged with taste and skill.

Messrs. Frank Cant and Co., Braiswick Nursery, Colchester, had a magnificent lot of Roses, needless to say in the height of perfection. White Maman Cochet, Frau Karl Druschki, Pharsaer, Maharajah, Dean Hole and Mrs. Aaron Ward were all superb examples in a really splendid lot.

Mr. Charles Turner, Slough, had many beautiful Roses. Souvenir de Catherine Guillot (a lovely orange and salmon), White Maman Cochet, Maman Cochet and quite a host of garden and decorative Roses.

##### FRUIT AND VEGETABLES.

Messrs. Hugh Low and Co. of Bush Hill Park exhibited berries of the new Blackberry named Low Junior. This is a reputed cross between the Loganberry and Blackberry. It has the vigorous habit and the same shaped fruits as the former, the colour and flavour, however, being that of the Blackberry. A very beautiful and commendable fruit.

From S. Heilbut, Esq., Holford, Maidenhead (gardener, Mr. G. Camp), came a handsome group of fruit trees in pots, Figs, Cherries and Nectarines being shown in very fine condition, the Cherries being particularly well fruited.

Messrs. J. Veitch and Sons, Limited, of Chelsea exhibited some grand examples of fruit trees in pots. Figs, Peaches, Nectarines, Currants, Gooseberries and Grapes were shown in all the latest varieties, the trees being most remarkable on account of the very prolific manner in which the fruits were borne.

Fruit trees in pots also came from Messrs. George Bunyard and Co., Maidstone. These were splendid examples of high-class culture and reflected much credit on those responsible for their well-being. Apples, Plums, Peaches, Nectarines and Cherries were very freely shown. Strawberries were also shown in splendid condition by this firm, the varieties Latest Laxton, Louis Ganthier, The Bedford, Goliath and Waterloo being particularly attractive. The few dishes of Apples grown last year and included in this exhibited were most interesting.

Messrs. Adam Parker and Co., Waltham Cross, staged fruits of Tomatoes Comet and Sunrise. These were an even, well-finished lot with beautifully clear skins.

From Mr. S. Mortimer, Rowledge, Farnham, Surrey, came a beautiful and extensive exhibit of Melons, Tomatoes and Cucumbers. The Melons were a very well-finished lot, and included such good varieties as Sutton's Invincible, Sutton's Windsor Castle, Hero of Lockinge, Royal Favourite and Blenheim Orange. Tomatoes Sunrise, Hanwell Glory and Up-to-Date were well represented. The two new Cucumbers, Faultless and Evergreen, were also well displayed, the fruits being of very perfect form.

Lord Llangattock, The Hendre, Monmouth (gardener, Mr. Comber), exhibited a very fine collection of Pine-apples and Strawberries, all the best varieties of the last-named being staged in very fine condition. President Loubet, The Bedford, Bedford Champion, Fillbasket, Reward, Laxton's Latest, Givon's Late Prolific and Trafalgar were all in superb form. The Pine-apples were represented by the variety Queen.

The exhibit of vegetables shown by the Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett), was admittedly the best of its kind in the show. First-class produce of all kinds was most artistically arranged, Cucumbers, Potatoes, Broad and French Beans, Lettices, Turnips, Vegetable Marrows, Spinach, Cabbages, Beetroot, Tomatoes, Radishes, Celery, Cauliflowers and numerous other kinds being shown in all the latest varieties.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## "THE GARDEN" FLOWER SHOW.

IN connexion with the above exhibition, which is to be held on the 29th inst. in the Royal Horticultural Society's Hall, Vincent Square, Westminster, London, we repeat what we said last week regarding the sending and staging of exhibits. The Hall will be open on the afternoon and evening previous to the day of the show, and exhibits that are sent must reach there not later than 9 a.m. on the day of the exhibition. Those bringing exhibits will be admitted until 10 a.m., and all exhibits must be in readiness for the judges at 11 a.m., when all exhibitors must leave the Hall. Readers and their friends will be admitted at 1 p.m. until 7 p.m., on presenting the coupon published in THE GARDEN for July 18 and 25. Exhibitors will, of course, be readmitted at 1 p.m. Exhibits may not be removed until 7 p.m. We wish to impress on all intending exhibitors that the 25th inst. is the latest date on which the entry forms can be received. A full report of the exhibition will be given in our issue dated August 8.

## TRIALS OF SWEET PEAS.

FRIDAY and Saturday, the 10th and 11th inst., were important dates in the history of the now-popular Sweet Pea. On the first day the floral committee and members of the National Sweet Pea Society inspected the trials of varieties so ably conducted by Mr. Charles Foster in the gardens of the University College, Reading, and which constitute the official trials of the society; and on the second date over fifty members inspected the trials made by Messrs. Hurst and Sons at Kelvedon and Messrs. Dobbie and Co. at Marks Tey. Probably there is no other horticultural society in existence which conducts trials similar to those held at Reading during the past and present year, trials that have been rendered necessary owing to the sportive character of the flower in whose interests the society exists.

It augurs well for the future of the society that eleven out of the twelve members of the floral committee, under the chairmanship of Mr. Walter P. Wright, travelled to Reading for the purpose of adjudicating as to the merits of varieties grown there, Mr. Martin Hitchins having to come from St. Austell in Cornwall, Mr. Malcolm from Duns and Mr. T. Jones from Rnabon, the other members also having more or less long journeys to undertake. The results of

their judging may have been disappointing to many who had novelties on trial, as every raiser of what he considers to be a new variety is apt to regard it in the same light as a mother considers her first babe, yet this reticence to give awards only serves to enhance their value when they are granted and, moreover, gives the public the right to expect something good in the varieties honoured.

The silver medal and a first-class certificate were unanimously awarded to a variety named George Stark, sent to Reading by Mr. A. G. Stark of Great Ryburgh, Norfolk, by whom we believe it was raised. It is really a Spencer or waved form of Queen Alexandra, and we need only say that it is more vigorous and produces more stems carrying three flowers than the older variety. First-class certificates were also granted respectively to the varieties Mrs. A. Ireland and Mrs. H. Bell. The former was raised and sent to Reading by Messrs. Dobbie and Co. of Rothesay and Marks Tey. It is a delightful Spencer bicolor, the white and deep blush colouring being most charmingly diffused. Mrs. H. Bell came from Mr. Robert Bolton, Carnforth. It is a beautiful variety of rich cream and pink colouring. Kitty Lea, sent by Mr. F. E. Hallam, Moseley, Birmingham; and Romani Ronnii, sent by Mr. Hugh Aldersey, Aldersey Hall, Chester, were considered by the committee to be synonymous with it. Constance Oliver, a deep pink and cream variety sent by Mr. W. Lumley, Down Nurseries, Denvilles, Havant; and Paradise Ivory, a beautiful ivory-coloured variety from Miss Hemus, each received an award of merit.

Many varieties were so badly mixed that it was quite impossible in the case of novelties to make out which flowers were correct, and the task of fixing even the older varieties seems to be an almost impossible one. The following are a few sorts that were considerably better than most, and were as true as one can reasonably expect—if all were as true growers would have little to complain of in this respect: Evelyn Hemus, from several sources; Elsie Herbert, from Mr. C. W. Breadmore; Princess Victoria, sent by Messrs. Dobbie and Co.; Marbled Blue, from Messrs. Sutton and Sons (Hester, from Miss Hemus, is synonymous with this variety); Helen Pierce and Miss Willmott, sent by Messrs. G. A. Bunting and Co.; Herbert Smith and Helen Lewis, from Mr. R. Sydenham; Hannah Dale, from Messrs. Dobbie and Co.; Helen Lewis, from Messrs. E. W. King and Co.; St. George, from Messrs. Hurst and Son; Queen Alexandra, from Messrs. Bunting and Co.; The King, from Messrs. Dobbie and Co.; Mrs. Harcastle Sykes, from Mr. R. Bolton;

John Ingman, sent by Mr. F. E. Hallam and Messrs. Dobbie and Co.; Gladys Unwin, from Messrs. Bunting and Co.; Countess Spencer, from many sources; Enchantress, from Mr. F. E. Hallam; Clara Curtis, sent by Mr. W. Bolton; Mrs. Collier and James Grieve, from several sources; Paradise, from Miss Hemus; Nora Unwin, sent by several; Etta Dyke, from Mr. C. W. Breadmore; Chrissie Unwin, from Mr. W. J. Unwin; May Perrett, White Waved, H. J. R. Digges and Purple King, sent by Mr. H. Eckford.

Many varieties, especially in the cream, pink and white shades, seemed to be very much alike, and probably the society will later on publish a further list of too-much-alike varieties. A resolution was passed by the floral committee to the effect that in future novelties be only accepted for trial from the actual raisers, and we should like to see those represented by numbers only also excluded. Mr. Leonard Sutton very kindly entertained the visitors to lunch, and an excellent tea was provided by Mr. Owen Ridley, chairman of the college council.

Among the members who visited Kelvedon and Marks Tey on the second day were Messrs. Arthur and Leonard Sutton, Mr. W. A. Bilney, Mr. Robert Sylenham, Mr. John Green, Mr. C. W. Breadmore, Dr. Boxall, Mr. Titt, Mr. Moss, Mr. E. W. King, Mr. Malcolm, Mr. Martin Hitchin, Mr. T. Jones, Mr. W. P. Wright, Mr. William Deal, Mr. Herbert Smith and Mr. G. Stark. The visitors were received by Mr. N. N. Sherwood and Messrs. William and Edward Sherwood and Mr. Cuthbertson at Kelvedon, and conducted over the Sweet Pea trials by these gentlemen. St. George, the gold medal variety of last year, was the most interesting variety here, owing to the fact that it was raised by Messrs. Hurst and Son at Kelvedon. In addition to the vast stock of Sweet Peas, an extensive and most interesting trial of culinary Peas was inspected by those interested. At the lunch kindly provided by Mr. N. N. Sherwood and Mr. Cuthbertson reference was made by the former to the fact that it was owing to a conversation held on the farm, where the morning had been spent, that the National Sweet Pea Society was called into being. After lunch the visitors were conveyed to Mr. Sherwood's pleasant home known as Prested Hall.

On arriving at Marks Tey an inspection of the Sweet Peas grown there by Messrs. Dobbie and Co. was made under the able guidance of Messrs. William and David Cuthbertson and Mr. A. Ireland. Many beautiful things were seen, and the health and vigour of the plants was freely commented upon. Mrs. Bieberstedt is a beautiful French grey variety, resembling Frank Dolby in general colour, but being less rosy in the standard and belonging to the plain or unwaved section. Mrs. A. Malcolm was the deepest cream-coloured sort seen, and it, undoubtedly, has a good future in store for it. Mrs. A. Ireland, described above, was in grand form, its freedom of flowering rendering it specially valuable for decorative purposes. The Unwin stock of Etta Dyke was very fine, and Mid Blue found many admirers. It is a deep heavenly blue-coloured variety.

After inspecting the Sweet Peas the visitors were kindly entertained to a welcome tea by Mrs. Miss and Mr. Cuthbertson. The value of such trials as these cannot be over estimated, and those at Reading constitute one of the best features of the comparatively young, but lusty, Sweet Pea Society. The arrangements of both outings were exceedingly good, and reflected great credit on the hon. secretary, Mr. C. H. Curtis.

#### FORTHCOMING EVENTS.

July 28.—Southampton Royal Horticultural Society's Carnation Show.

July 29.—THE GARDEN Flower Show, Royal Horticultural Society's Hall, Vincent Square, Westminster.

## NOTES OF THE WEEK.

### Horticultural Education Association conference.

—The second annual conference in connexion with the above association was held on Friday and Saturday, the 17th and 18th inst., at Ridgmont and Bedford, under the presidency of Mr. A. E. Brooke-Hunt, chief inspector of the Board of Agriculture. The members were met at Ridgmont Station by Mr. W. F. Neild, manager of the Duke of Bedford's experimental fruit farm, and conducted by him to the farm, where they were met by the director, Mr. Spencer Pickering, who conducted the visitors round the farm and explained the various experiments that are being carried out. Tea was kindly provided, and eventually the members left for Bedford. After dinner at the Embankment Hotel a paper was read by Mr. J. C. Newsham on the illustration of horticultural lectures. A brisk discussion followed, in which all the members present took part. On Saturday morning a visit was made to Messrs. Laxton Brothers' nurseries, where the numerous stocks of Strawberries, Raspberries, Apples, Currants and other hardy fruits were inspected under the guidance of Messrs. Edward and William Laxton and Mr. Anderson. Excellent arrangements were made by the hon. secretary, Mr. Walter P. Wright.

**Report on agricultural education.**—The report of the Departmental Committee on Agricultural Education, of which Lord Reay was chairman, has been signed and presented to the President of the Board of Agriculture and Fisheries and will be published shortly.

**Electricity and growing crops.**—Much has been heard during the past few years concerning the application of electricity in various forms to growing crops, the experiments being attended in each case with more or less good results. Sir Oliver Lodge has recently described in the daily Press some experiments that have been carried out with gratifying results in connexion with farm and garden crops. Without going into any technicalities, the system is briefly to stretch over the field or plot to be treated a number of slack wires fixed to posts high enough for loaded waggons and other farm implements to pass underneath. The wires are supported on the posts by high tension insulators and then fixed to a generator that supplies positive electricity at a potential of 100,000 volts. The cost is said to be very small. Under the treatment Strawberries showed an increase of 35 per cent., Mangolds 25 per cent. and Raspberries showed a marked increase of crop on young plants but scarcely any on old plantations. Wheat also showed an increase in one instance of 40 per cent.

**Strawberry exhibition and conference.**—A highly interesting and useful conference and exhibition of Strawberries took place in the Goold Hall, St. Andrew Square, Edinburgh, on the 14th inst. under the auspices of the Scottish Horticultural Association. At the exhibition there were about fifty exhibits on view, some of these coming from a great distance. The fruit was generally of capital quality, and some of the exhibits were specially fine. The best of the old standard varieties were shown, as well as the newer ones which have just acquired a reputation. A seedling raised by Messrs. James Grieve and Sons received a favourable mention from the judges. Among the leading exhibitors to whom awards were made were Messrs. W. Smith, R. Aitken, Galloway; A. MacKinnon, Moffat; and Mrs. Vass. Mr. W. Smith, Lambton Castle, sent a fine dish of Reward, which was awarded a certificate of merit. Several awards were also made to new culinary Peas sent by Mr. Stewart, Panshanger, Herts, these being remarkably good and likely to gain favour when put into the market. There was also a good attendance at the conference which was held later, when the president, Mr. James Whytock, occupied

the chair. A number of those present took part in the discussion, and several practical points were well put by some of those present. On the call of Mr. M. Todd, hearty votes of thanks were accorded to the exhibitors and to Mr. Whytock for his services in the chair.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**A pretty Rose for a bed.**—Mme. Tillier is the name of a very pretty Rose growing in these gardens, and I suppose it is a Polyantha. Be that as it may, it is a free-flowering dwarf Rose of a most distinct and sweet colour which I cannot describe, neither have I met anyone who could, but it has been likened to crushed strawberry. As to flowering, the quantity of blooms one is able to gather during late autumn is astonishing, and I think the colour is then more pleasing than earlier in the season. It also appears quite hardy. It lasts well, and has very prettily-shaped buds indeed, which when half expanded are delightful.—THOMAS ARNOLD.

**The summer treatment of Christmas Roses.**—We often hear complaints of Christmas Roses not flowering satisfactorily and also at the present season of the plants losing their foliage. I am convinced that the two chief causes of this are too much sun and want of moisture in the early part of summer. Christmas Roses should not be exposed to the full glare of the sun. They enjoy semi-shade and an abundance of moisture, and occasionally this should be in the form of liquid manure from the cow-shed, with a little soot added. We had the greatest difficulty with these plants for some years, and were told by local experts that this was all due to unsuitable soil—too much free lime. However, we persevered, and by finding a partially shady place and fairly good soil, and observing a few details here given, our bed of Christmas Roses has improved year by year, and I think it looks more promising than ever before at the time of writing. What we do is as follows: As soon as the plants finish flowering the surface soil is lightly pricked over. A thorough dressing of a well-decayed mixture, consisting of lawn-mowings, leaves and old spent hot-bed, with a little soot added, is placed all over the bed. I know of nothing which will retain the moisture so well in hot weather as this. The young leaves come up through this dressing strong and healthy. We take especial care that the plants do not become dry during the growing season. During the past spell of very hot weather we have given these plants an abundance of water and an occasional soaking of liquid manure. They are now looking well, and I hope we shall see a good crop of flowers soon after Christmas Day. The variety is *Helleborus niger maximus*, which is a good one, with long stems and large white flowers. The ordinary one with short flower-stems and small leaves is very poor compared with *maximus*. I think that early summer is the time to pay a little extra attention to these Roses. A crop of flowers will most certainly follow a good crop of leaves, and we can only have the latter on this limy soil by giving the plants attention during the summer months.—THOMAS ARNOLD, *The Gardens, Cirencester House.*

**Carpenteria californica in Scotland.**—In the south-west of Scotland the beautiful *Carpenteria californica* is quite a success in gardens near the sea and in mild places further inland, and it is gratifying that it is proving amenable to the conditions which prevail there. The other day I saw a large plant of it in bloom in the garden of Mr. W. D. Robinson-Douglas at Orchardton, close to the Solway

and a few miles to the south of Dalbeattie, Kirkcudbrightshire. There it has been grown on a south-west wall for several years, and this season, despite the somewhat trying weather conditions of last winter and spring, it has passed through these unharmed and is flowering with great freedom. The charming white flowers are heightened in beauty by the freshness and the profusion of the foliage with which this plant was clothed. *Carpenteria californica* also does admirably in the garden of the Right Hon. Sir Herbert Maxwell, Bart., at Monreith in Wigtownshire, but the conditions there are a little more favourable than those at Orchardton.—S. ARNOTT.

**Dimorphothea Ecklonii aurantiaca.**—We grow these very easily under glass with masses of flowers, and afterwards plant them out, cutting them right over, when a new lot of bloom follows very shortly. For a succession of plants we grow from cuttings and pot on. No doubt the present hot, sunny weather is just what the plant needs to bring it to such perfection.—N. B. PULFORD, *Netherwood Bank, Dumfries.*

**Sweet Pea prospects.**—The account of the "Prospects of the Sweet Pea Season," by Mr. Walter P. Wright, is one of the very greatest interest to all lovers and growers of this delightful plant. The arctic weather of this spring lowered the hopes and aspirations of the cultivator down to zero, but since the advent of May the plants have made such marvellous growth that here we have been able to cut blooms three weeks earlier than has been the case for the last six years. Plants put out of pots the first week in May never grew so quickly and at the same time built up such strength that they are now able to produce some really wonderful flowers—three flowers to a raceme, and in many cases four, while two is the exception. The account of the sportiveness of the plant given by Mr. Wright I can bear out in all its details. The old theory of cross-fertilisation by insects must be dismissed, seeing how the flowers are fertilised, and in many cases the legume or pod has made some growth before an insect is able to open the flowers. My theory is this: In a few isolated cases there might be sports retaining those characters for ever which they possessed on first appearing, but in the majority of cases they are dormant characters, reappearing from a variety of a far back generation of the parents of, say, for demonstration sake, Gladys Unwin. My way of thinking may be wrong, but they are without a doubt recessive characters reappearing. If raisers of new varieties would give a little more time to the growing they would at once see if the colours were really dominant or not, instead of growing them for a year or two and then booming them as settled. Take for instance Countess Spencer, which I have growing in a clump of fifteen plants. Six are true, four are a dreadful-looking magenta, two are white, three have a tendency towards mauve. If this variety had been grown for some years instead of putting it into commerce, I think the raiser would have been so disgusted with it that he would have relegated it to the refuse fire. After this season I shall bid farewell to Countess Spencer, with the conviction, after some years of deep disappointment with her, never to again extend to her kindness in any way. I suppose after the National Show on the 24th inst. we shall hear what the opinions of the various growers are regarding the introduction of the bacillus to the soil in producing exhibition blooms; those opinions when they appear I am afraid will be a surprise; but more about this later. If the observations of the different growers, North and South, are reliable, then I think all growers will for once meet on an equal footing, and let us hope the tug of war will be such that the judges will have to call in an arbitrator to make peace between them (the judges).—G. CLAPHAM (gardener to E. Woodhouse, Esq.), *Calverley, near Leeds.*

## TREES AND SHRUBS.

### SOME INTERESTING TREES AND SHRUBS.

**VIBURNUM TOMENTOSUM.**—This is a fine flowering shrub, and grows as flat as a table, with enormous masses of flowers. *Viburnum plicatum* is now a perfect picture, with large balls of flowers as white as snow; a most beautiful plant for the shrub garden. These plants need liberal treatment to bring out the best results.

**Shuartia pseudo-camellia.**—This was introduced from Japan and is a handsome shrub, almost a tree, for there is in Sir Edmund Loder's garden a specimen upwards of 25 feet in height; it bears creamy white flowers resembling a single Camellia and is very free in flowering; the foliage, in addition, is very handsome.

**Styrax obassia and japonica.**—The latter is a very effective shrub in early summer, and usually bears myriads of flowers, which hang downwards. The plant is hardy. *S. obassia* flowers much later and has considerably larger leaves, which are heart-shaped and sometimes 8 inches to 10 inches in diameter. The flowers are sweet scented, pure white and hang in long racemes. Seed was saved from these last season. Both of these plants ought to be grown by all lovers of hardy shrubs; they are quite hardy and are of easy culture.

**Eucryphia pinnatifolia.**—This beautiful flowering shrub from Chili should be in every garden. It blooms quite freely in August. The flowers are white, and have stamens in profusion after the style of a St. John's Wort (*Hypericum*). It is not difficult to grow, and it does not object to being transplanted if this is carried out in the early stages sufficiently often. We have moved many this season and have no reason to anticipate any ill effects; it is easily raised from seed or layers.

**Desfontainia spinosa.**—This is an exceedingly interesting plant, which bears during the end of June and through July and August long, tubular, bright scarlet flowers tipped with bright yellow. We have found it hardy, although it is tender in most counties. It has stood 20° of frost with only a similar protection to that given to Tea Roses, viz., a little dry Bracken. This beautiful plant was introduced through Mr. Lobb, and I believe it first produced flowers at Exeter.

W. A. COOK.

*Leonardslee Gardens, Horsham.*

### LEMOINE'S MOCK ORANGE (PHILADELPHUS LEMOINEI) AND ITS VARIETIES.

THE recent editorial remarks in reference to these beautiful shrubs on page 307 and the fact that an award of merit was lately bestowed upon the variety *Rosace* should serve to direct renewed attention to these dwarfier forms of the Mock Orange. From the small space they occupy these *Philadelphuses* are particularly adapted for small gardens, and their simple cultural requirements commend them to the amateur whose space and knowledge of flowering shrubs is not extensive. The birth, so to say, of these dwarfier Mock Oranges dates back for more than twenty years, as it was in the autumn of 1887 that the first *P. Lemoinei* was distributed. It was a happy thought of M. Lemoine of Nancy to cross the small-growing *Philadelphus microphyllus* (then recently introduced) with the European Mock Orange (*P. coronarius*). The result was *P. Lemoinei*, which still remains one of the most popular. Since then numerous other varieties have been distributed, that known as *P. Lemoinei erectus* being sent out soon after the other. It is more upright in growth than *P. Lemoinei* itself, but in other

respects is a counterpart. Others of this section which, as far as my experience extends, are among the best include *Avalanche*, a large, single flower; *Boule d'Argent*, double white; *Gerbe de Neige*, more vigorous than *Lemoinei* and with larger flowers; *Manteau d'Hermine*, semi-double flowers, borne in great profusion; and *Rosace*, above alluded to, with large double flowers. Beside these a great many other varieties have been distributed by M. Lemoine, notably, *purpureo maculatus*, which stands out from all the Mock Oranges in general cultivation by reason of the purplish blotch at the base of each petal. This, we are told by the raiser, owes its colour to the influence of *P. Coulteri*, a Californian species, too tender for general cultivation in this country. At all events, *purpureo maculatus* does not inherit any of the tenderness of its ancestor and is in every way a desirable form. The typical *P. microphyllus*, which has played such a prominent part in the production of the dwarf race of Mock Oranges, has flowers with the fragrance of ripe Apples. This fragrance is, to a great extent, reproduced in all the *Lemoinei* section, which renders them preferable to the stronger-smelling *P. coronarius*. In the cultivation of *P. Lemoinei* and others of that set the best results are obtained by cutting the plants back hard immediately after flowering and thus encouraging the annual production of stout, wand-like shoots. These will be well developed by autumn, and the following season will flower profusely. After cutting back a stimulant, either in the shape of liquid manure or a top-dressing of well-decayed manure, will be found helpful. H. P.

### INSECTS ON IVY.

Ivy is always associated, in our mind, with old walls, quaint gateways, ancient trees, venerable house fronts and similar respectable environments in harmony with our ideas of restfulness and peace and the dignity inseparable from age. An "Ivy-covered wall" conjures up the picture of a time-worn secluded enclosure of artistic beauty, hallowed by a pervading sense of sentiment and quiet, and one cannot but express a feeling of regret that flies should have such an unfortunate affection for this plant, although no doubt the fancy has sufficient reason and attains useful results.

Even as late as the second week in November last year bushes of Ivy were swarming with a large fly of the appearance of a blue-bottle, making the plant one on which we can only look with disfavour.

There is something rather repulsive about flies, more especially those of the blue-bottle variety, and it is distinctly an unpleasant surprise when one is first confronted with this seething buzzing blue-black mass on a bush of such quiet picturesque refinement as our well-beloved Ivy.

It seems to be entirely the flower-heads which form the attraction, though the whole plant, leaf and all, is covered with the insects, except on misty damp days, when everything is wet. On several occasions I have noticed another fly of very venomous aspect, like an attenuated horse-fly, also apparently regaling itself on Ivy food, and when this is so an insect murder is nearly certain to be enacted, the victim being, in all cases I have observed, the blue fly.

It does not appear that the ripe blossom is the entire object of their visit, for I have seen them in crowds over a bush on which there were but two or three flower-heads open, and yet from their movements they seem to be in search of food. Their partiality seems to be chiefly for the common Ivy, but I am not yet quite convinced that there is any Ivy immune from their attentions.

The fact should be borne in mind, I think, when one contemplates planting it on a house front or as a bush in close proximity to a dwelling, for where an insect congregates in such numbers as to be a disturbing element it becomes a real nuisance. E. CURGWIN.

## THE FRUIT GARDEN.

### BLACKBERRIES AND THE LOGAN-BERRY.

**I**T is only during quite recent years that much attention has been given to the Blackberry as a garden fruit, the inhabitants of the United Kingdom having previously contented themselves with the fruit as it was produced in a wild state.

That even this differs to a considerable extent is a fact well known among country children, some

berries being much more fleshy and possessing a considerably superior flavour to others. With the introduction of some larger-fruited varieties from America fruit growers began to see the possibilities of the Blackberry, and in most good gardens one or more varieties now find a place, the Parsley-leaved being a great favourite with many. It was only natural that when the Blackberry came to be recognised as a legal inhabitant of gardens that hybridists should turn their attention to it, and a reputed result of their labours was the now well-known Loganberry, said to be the result of a cross between the Raspberry and Blackberry.

This is now recognised as a valuable plant for producing fruit for preserves of various sorts, but the acid flavour of the fruits render it of little use for dessert. This trouble has now been overcome by a further cross between the Loganberry and the Blackberry, the result being fruits resembling the Loganberry in shape and size but possessing the colour and flavour of a first-class Blackberry. Fruits of this were exhibited by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, before the Royal Horticultural Society at Holland Park on the 7th and 8th inst., when the fruit committee granted it an unanimous award of merit. It is named Low Junior, and the illustration is from a sketch and is natural size.

Both the Loganberry and its new ally delight in a deeply worked rather moist soil, and they are eminently suited for training on arches, pergolas and pillars. Their culture is really very simple, this consisting in removing the old fruiting canes as soon as all fruit is gathered and retaining young ones to take their place, precisely as in the case of Raspberries. Copious supplies of water and weak liquid manure during the summer, with a mulching over the roots of well-rotted manure during hot weather, is greatly appreciated. The Loganberry is very easily

propagated by pegging down the young canes in summer so that the tip of each touches the soil. Roots are soon emitted from the shoot at the point where it touches the soil and a young plant is quickly formed. This may be severed when large enough and planted into a nursery bed or odd plot to eventually develop into a large specimen.

In addition to being useful for training over arches or pergolas the Blackberries and the Loganberry may also be grown in rows and trained to wires or tied to stakes, the same as practised with Raspberries. Being of a vigorous character they naturally need more room in which to

THE NEW HYBRID BERRY  
CALLED LOW JUNIOR, SHOWN  
BY MESSRS. HUGH LOW AND  
CO. AT HOLLAND PARK  
ON THE 7TH AND 8TH INST.

(Natural size.)

develop, a point that should not be overlooked when planting is done, 3 feet between each plant and 6 feet between the rows being none too much.

The introduction of the Berry Low Junior suggests that we have at present only touched the fringe of a new and useful race of fruiting plants that may in the future take a prominent position in the great fruit industry of this country. I believe that Messrs. Laxton Brothers have a new fruit which is the result of a cross between the Loganberry and a Raspberry, but probably we shall hear more about this later.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### AN INTERESTING CONTRIBUTION FROM HERTS.

Mr. Clarence Elliot, Six Hills Nursery, Stevenage, Herts, sends several interesting border subjects. He writes: "I am sending a box of flowers for your Editor's table. The gorgeous *Gerbera Jamesonii* is very fine with me just now. Too often this plant is starved in pots. Far better plant it out in the cool greenhouse or frame, or even in the open, with good mellow loam well enriched with cow manure. If grown in the open it should be given a warm, sheltered position and the protection of ashes or such-like in winter. When any difficulty arises in keeping it through the winter in the open it is a simple thing to lift the plants in autumn, pot them and so store under cover till the following spring. *Gerbera Jamesonii* is invaluable as a cut flower, for the large, gorgeous, vermilion-scarlet blossoms are of a fine Marguerite form, and borne singly on strong, slender, graceful stems 1 foot to 18 inches long, they seem to 'arrange themselves' and last two or three weeks in water. Perhaps if required for cutting only it would be best to grow them planted out in a frame. In any case they must be given plenty to eat and drink during the growing period. *Tunica Saxifraga flore-pleno* is a newcomer, and promises to be a great acquisition on the rock garden. In fact, it is an acquisition, for I have a group of it here and it is quite charming. It may be classed with the double form of *Gypsophila paniculata* and the double white *Arabis* among those few plants which are really improved by doubling, or rather which, through doubling, give us something distinct from the type, valuable and attractive, beautiful though the type remains. My plants are literally covered with the lightly-borne double pink blossoms. The

other flower which I send is the little-known, seldom-grown *Michauxia campanuloides*. The plants grow from 4 feet to 6 feet high. First a rosette of narrow, reddish, serrated leaves, then a tall stem, from which are thrown innumerable branches, forming a narrow pyramid, and then come the flowers, hundreds of them. The buds open curiously. The petals lengthen into a closed, pointed balloon, then they split from one another except at their tips, so that there is a pointed, egg-shaped balloon of white slats, with spaces between. One by one the white petals free themselves and curl back till the flower resembles a large Martagon Lily, pure white, slightly tinged with purple and with a very prominent pistil. This lovely plant is quite hardy, and should be grown in good loamy soil in a warm border. Like most of the Campanulas, it dislikes severe drought."

#### THE TULIP TREE.

Mr. H. Henderson, The Gardens, Brookman's Park, Hatfield, Herts, sends flowers and foliage of the beautiful Tulip Tree, which adds so much interest to our gardens at the present moment. Our correspondent mentions that the tree in the park is 80 feet high and covered with flowers.

#### DELPHINIUM FANNY STORMONTH.

Messrs. J. Stormonth and Son, Kirkbride, Cumberland, send flowers of a very beautiful perennial Larkspur or Delphinium, which they well describe as a glorified *Delphinium Belladonna*, from which the senders raised it some years ago. It has all the properties of its parents, viz., loose arrangement of bloom, lovely colour and freedom of flowering. The bloom is large and of great substance, and the plant is strong in growth. We think it will supersede all others of this type. It is unequalled for cutting, and provides a colour which is all too scarce.

#### A NEW BLACK CURRANT.

Messrs. Hugh Low and Co., Royal Nurseries, Bush Hill Park, Enfield, send us a fruiting branch of a new Black Currant named *Resister*. This appears to be a very free-fruited variety, the medium-sized berries being of good flavour. The raisers claim for it that it is a resister of the dreaded big bud, and are prepared to supply a few plants for trial at a low cost to anyone who has trouble with the big bud pest.

#### VIOLAS FROM SUSSEX.

Mr. J. Barnes, Storrington, Sussex, sends good flowers of bedding Violas. He writes: "Kindly find enclosed a few of my Violas. These are from plants grown in the ordinary way in my garden. The white is a seedling I raised in 1907, and the striped blue and white is a sport from Lady Grant, of which I have made several plants. You will see how the hot sun has faded the edge of Mrs. Chichester. These were grown on a hot, sandy ground with no shade whatever. The only thing I am surprised at is that any of them lived, but now it is cooler I hope to get better blooms. I do not claim that these are good flowers, but I thought you would like a few for your table."

#### FINE SPRAYS OF SWEET WILLIAM.

Messrs. C. S. Daniels and Son, Wymondham, Norfolk, send us some of the most remarkable varieties of Sweet Williams we have ever seen. The flowers are not only large, but the colour is delightful—warm crimson with a white edge to the individual bloom. We hope such Sweet Williams as these will be largely grown in English gardens, as they are certainly worthy of a place alike in the humble cottage plot and the gardens of the wealthy.

## POPULAR CONFUSION IN NOMENCLATURE.

### NASTURTIUM—TROPEOLUM.

THIS is one of the most flagrant instances of the extraordinary manner in which a name has been given to the wrong plant and the inexplicable persistency in the application once the false christening has been effected. Here there is no real confusion but only in the mind of the uninitiated. The matter is quite clear and well defined, but the public has not yet grasped the distinction in technicalities, and still persists in error in spite of the wide diffusion of garden literature which by now should have put the case straight. In the ordinary amateur garden world it is next to impossible to inculcate the fact that what is called *Nasturtium* is not a *Nasturtium* at all, and has not the remotest connexion with it. "*Tropæolum*" is the only possible term applicable to this delightful plant, and even of those who habitually use this term many will refuse to repudiate the other. I should wish to see a firm stand made by all who have a love of flowers and like to have them dignified by their own proper titles.

So frequently is the suggestion resented as an unnecessary pedantry when the Latin name is put forward as the only claimant, more especially as it is not an easy word either to spell or speak. However unwilling to flourish Latin or Greek names in the face of the general populace, it is in this case imperative to designate correctly. The English name is stated as "*Indian Cress*," which substitute we are not very likely to adopt, and the plant belongs to the family of *Geranium*. A *Nasturtium* with a right to that name is a totally different plant, one quite insignificant and uninteresting, whose English equivalent is "*Water Cress*," the origin of the name arising from the effect this plant has when eaten, *Nasus tortue*—tormented nose. Moreover, it is allied to the Wallflowers.

Why we should deny the name to the well-known esculent and apply it to another sort of Cress is curious, yet the anomaly continues to be perpetuated year after year. But, once we begin to teach our children to apply the titles correctly and get our gardeners to appreciate the designation it will not take very long to uproot the persistent error, and we shall wonder retrospectively how it came to have so long and sturdy an existence. E. F. C.

## THE ROSE GARDEN.

### ROSE KLEINER ALFRED.

#### (DWARF POLYANTHA.)

IN the cross-fertilisation of Roses nothing strikes the worker more than the wonderful vagaries that result totally different from what one might reasonably expect. I know years ago rosarians were very sceptical as to the statement sometimes made that a certain Rose originated from a certain cross, but I would advise all who so doubted to have a try themselves, and I guarantee they will quickly be undeceived. The announcement by Herr Lambert that this lovely Rose originated from Anna Marie de Montravel, crossed with Shirley Hibberd, one is inclined to doubt, seeing that it is a flower more after the style of *L'Idéal* in colour; but evidently we never know what we may obtain and there is no telling what novelties may yet be in store for us from the increasing interest which the cross-fertilisation of the Rose is evoking. Kleiner Alfred would seem to me to spring rather from Leonie Lamesch than Anna Marie de Montravel, as it is a far better grower than the latter. In

any case it is a charming addition to this very pretty race of diminutive perpetual-flowering Roses.

This Rose would make a delightful groundwork to standards and pillars of *L'Idéal*, especially where this latter succeeds well, which is not always the case. Where it does, there is no sweeter or prettier Rose. It may be successfully grown as a bush for bedding, pruning it rather long and tying over any long shoots that spoil the evenness of the bed; but to see it in perfection I would suggest half-standards for it. The heads are then a mass of bloom. A little but very charming single Tea Rose that could be mingled with the two sorts named, especially as an edging, would be Miss Willmott. This has the beautiful admixture of tints found in *L'Idéal*, with a very small single flower.

### LYON ROSE.

THIS remarkable novelty was well exhibited at the meeting of the Royal Horticultural Society on April 28, by Messrs. William Paul and Son, Waltham Cross, and it was evident, from the interest it aroused, that it is going to be a popular favourite. As with many of the Hybrid Teas possessing the apricot or ochre-red tints, some blossoms were more intensely coloured than others. Those highly coloured were of remarkable richness in this almost undefinable shade of colour. The flower reminded me very much of Paul Ledé in the intensity of its colouring, but with a form between Kaiserin Augusta Victoria and Mme. Souper. Some blossoms were more like the latter, others like the former, and in some instances the blossoms were a salmon tint with the ochre-red suffusion. In a cool season this beautiful novelty will be grand enough for exhibition, and at any time it must take a foremost place as a garden Rose, and also as a unique variety for pot culture. It is said that M. Pernet-Ducher produced this novelty from a cross between Mme. Souper and a seedling from Soleil d'Or, and one can readily detect the influence of the latter in the wood and foliage, although the perpetual-flowering propensity of the Hybrid Tea predominates. The vigour of the plant and its general erect growth renders this Rose one of the most valuable introductions of recent years.

### THE WICHURAIANA ROSES.

SINCE the advent of *Rosa wichuraiana* a considerable change has been brought about in the free-growing or rambling garden Roses. The Japanese *Rosa wichuraiana* has only been made use of in gardens for about fifteen years, and even now it is not nearly so well known as its numerous offspring. Its chief characteristics are its prostrate habit, long scandent shoots (which in a single season may grow anything between 12 feet and 20 feet in length), glossy green sub-evergreen leaves and panicles of white, fragrant flowers, which are borne later than those of most Roses, being at their best in July and August. It was quickly taken in hand by the hybridist, and a remarkable race of free-growing and free-flowering Roses is the result.

In the earlier days of crossing the Polyantha Roses were largely used for the second parent, but during late years the Tea section has been called into requisition. Some of the earliest American-produced hybrids were extremely beautiful, and mention need only be made of such things as Pink Roamer and South Orange Perfection to emphasise the fact. A little later we find such varieties as Jersey Beauty and Gardenia, containing Tea blood and extremely beautiful when in bud; then came the various hybrids of European origin with which the names of Transon and Barbier are identified. These have the floriferous character of the Tea Roses, with delightful fragrance and bud colouring,

the flowers being borne from axillary buds and also in terminal panicles as in the Japanese parent.

One of the most lovely of all the varieties is Alberic Barbier, a variety with cream, open flowers, which in the bud stage are buff and beautifully formed. The leaves are rich in colour and are carried throughout mild winters. A good companion plant is Auguste Barbier, a variety with red flowers. Elise Robichon is an exceptionally free-flowering sort with pink flowers, while other good sorts are Edmond Pronst, flesh: Clothilde Soupert, white, flushed pink, very double; Paul Transon, yellow and red in bud, pinkish white when open; and Adelaide Moulli, cream, flushed pink.

A further group of wichuraiana Roses is represented by Dorothy Perkins, at present one of the most floriferous varieties we possess, and a favourite with everyone by reason of its delicate pink flowers. For forcing it is doubtful whether it has an equal, while under certain conditions it

grow these Roses is to bud them on stocks 6 feet to 8 feet high. If this is done, beautiful weeping plants result, the pendent branches being perfect cascades of flowers. Grown in this manner they make excellent subjects for specimen plants on lawns, or are useful to break up the formality of beds of dwarf-growing Roses. Like other Roses they rejoice in rich, loamy soil, and pay for an occasional application of rotten manure or manure water. R. wichuraiana is the easiest possible Rose to propagate, as cuttings of half-ripe wood in summer or ripened shoots in winter root with freedom; cuttings placed in pots of sandy soil in slight heat in July root under a fortnight. This trait in the character of the parent is also noticeable in the case of the progeny, for all can be increased without difficulty. K.

#### ROSE GARDENIA.

ALTHOUGH one of the first of the hybrids obtained from R. wichuraiana, this beautiful variety is

ROSE GARDENIA ON A BANK IN COLONEL H. MOORE'S GARDEN AT HIGHER WOODCOMBE, MINEHEAD, SOMERSET.

does equally well out of doors. A companion to it is found in Lady Gay, while other good varieties are Hiawatha, with single, deep red flowers; and wichuraiana rubra, with single, pink flowers. The varieties Crimson Rambler and Carmine Pillar have been used largely by the hybridist, and numerous pretty hybrids are abroad which have not been distinguished by separate names.

These free-flowering and free-growing Roses are eminently fitted for planting in positions where they can practically grow at will, and if they are given some old fence, bush or tree to ramble over, so much the better, for they are never more favourably placed or more demanding of admiration than when growing in riotous luxuriance over some informal support, the flower-laden branches intertwined with dark foliage or hanging in elegant streamers from high tree branches. Another delightful way to

still one of the best. Just now upon a four-year-old plant there are some 300 or 400 buds, which, when developed, will be quite as large and of a similar tint of canary yellow to the Tea Rose Mme. Chedane Guinoisseau. These Roses require a deep root-run of good loam, and should be given a few tree stumps to scramble over. They are full of healthy vigour, the buds being set off by glistening leaves. A variety which resembles Gardenia is Alberic Barbier, but the buds are of a paler tint and the expanded flowers nearly white. No one should miss an opportunity of adding both these to their collection, and if they have a few spare Briar stocks insert a few buds on those with the tallest stems. They make perfect weeping trees, and are fitting companions to Dorothy Perkins, Euphrosyne, Aglaia and such like. The Rose illustrated is in Colonel Moore's garden, and the branches have rooted in the ground, forming a series of own-root plants.

## THE FLOWER GARDEN.

### PERENNIALS FROM SEED.

**S**IMPLEST methods of culture often succeed to perfection, an instance of which is the ease with which immense quantities of herbaceous plants can be obtained from seed sown during July and August out of doors. When failure in this branch of gardening has to be recorded, it is generally owing to a sour condition of the soil or the neglect that causes even the best soil to become bad. It is necessary to give water in times of drought and to constantly use the hoe, both to subdue weeds and to create a porous condition of the earth. Naturally, this hoeing can be more safely performed when the seed has been sown in drills, for the spaces in between can be kept clear of all vegetation and the discriminating eye will not be needed to determine whether a new green sprout of growth belongs to weed or cultivated plant. In the drills hand-weeding alone can be pursued, and every weed should be pulled up while still in its infancy.

The best position for seed-beds is undoubtedly a semi-shady one at this season of the year, but an open piece of ground can be used if sheets of brick-weighted paper are used to protect the drills. A reliable method is to lay a single row of bricks 3 feet apart on either side of a drill or couple of drills, place sheets of newspaper upon these, then add another brick on the top of each already in position, which will effectually hold down the paper even in the windiest weather. Only one row of top bricks need be lifted when the papers have to be turned back and watering performed. As soon as the seedlings are a few inches high, shading can be dispensed with so long as the soil is kept cool and moist by a mulch of loam and leaf-mould and constant evening waterings. The mulch can be applied just along the drills, worked up around the seedlings, not all over the bed.

Pansies and Violas can be sown for a fine show early next summer, and in nearly all localities will be strong enough to put out in ornamental beds and borders this September or October. When they are a long time appearing, so are quite small plants then, or where the winter is likely to prove exceedingly damp and cold, it is wise to leave the plants growing in the drills 6 inches to 8 inches apart until March. The magnificent colours obtainable in Pansies from seed

nowadays should be taken advantage of for lawn and front garden beds as well as borders, while Violas prove delightful for the same purposes. For carpet hedging or the formation of neat edgings it will be best to use cutting-raised plants of varieties noted for dwarf habit, since vigorous seedling Violas are generally tall.

Polyanthuses and hybrid Primroses flourish from outdoor sowings if shaded while young; the silver and gold-laced Polyanthuses are reckoned exceedingly meritorious and come remarkably uniform from seed, while giant yellow and red are always sure of appreciation. Dean's hybrid Primroses are of innumerable lovely colours and most floriferous.

Myosotis in all its varieties, Iceland Poppies, Aquilegias, Anubrietas, Arabis, Alyssum, Daisies and Crucianella stylosa sown now will give plenty of blossom next year without involving

SWEET ROCKETS BY PATH IN AN OLD FARM GARDEN.

much labour; indeed, it is surprising how few gardeners raise perennials in this fashion, but prefer to employ pans and boxes under glass. Of course, seed-sowing in frames and cold greenhouses in summer is very certain work, yet there is often difficulty in finding sufficient space, and the appearance of the glass houses at their floral season is sacrificed for the sake of hardy seedlings that do not require protection.

All the beautiful perennial *Dianthus*es that prove so valuable for bedding out can be safely sown in shaded drills and planted out in September, or left to grow on undisturbed; this saves having to raise them in February and March in heat. *Antirrhinums* (both tall and dwarf), *Sweet Williams*, *Brompton Stocks*, *Campanulas* of all heights, *Honesty*, *Foxgloves* and *Mimulus*es may be dealt with in perfect confidence of happy results.

Lastly, a seed-bed in semi-shade that can be left undisturbed should be used to sow *Anemone coronaria*; the soil must be rich and the seed barely covered with sand. Seedlings can be moved if great care is exercised, or may be left 6 inches apart, to provide a harvest of cut flowers. E. J. D.

### THE ROYAL FERN.

(*OSMUNDA REGALIS*.)

A CORRESPONDENT writes asking for information about raising *Osmunda regalis* from spores. This, commonly known as the Royal Fern, is by no means a difficult subject to increase by means of spores if a few simple items are borne in mind. In the first place, the spores are often shed before (to a superficial observer) they appear to be ripe. The fertile fronds should be gathered directly the earliest spore cases commence to open, and if laid in a piece of paper in a dry place the others will quickly reach that stage and discharge their contents. It will be noted that the spores

be about half an inch below the rim of the pot. Next stand the pots nearly up to their rims in a vessel of water so that the soil becomes completely saturated. Then take them out and stand to drain for a little time, and while the surface is still wet sprinkle the spores very thinly thereon and cover with a pane of glass. This will maintain the regular moisture necessary for germination. When water is needed stand in a vessel as before. A nice shady spot in the greenhouse is best for these Ferns. If they come up too thickly they must be soon pricked off.

### THE SWEET ROCKET.

I ENCLOSE two photographs of my garden that I think may be interesting to some of your readers, for they show a walk of the old-fashioned Sweet Rocket, which, I am sorry to say, seems to be far less planted than was once the case. This year it has flowered very freely with me, and the walk which the plants border has been a really beautiful sight. I sowed seed last spring, and transplanted seedlings later in the year and others early this spring until I grew tired of doing so, when I threw away a great many. When I left my week-end cottage on the Chiltern Hills at the end of May the plants were beginning to grow big and strong, but it was a complete surprise to me to find, when I went down three weeks later, that the whole border, which I suppose is about 20 yards long, was one mass of bloom, so much so that I cut down a large number of plants, and the discarded blooms when laid on the lawn made a heap at least 3 feet high. I am, naturally, more than satisfied with my threepennyworth of seed, and cannot help saying that I think it is a pity this beautiful and decorative flower should be neglected. H. P.

SWEET ROCKETS AFTER CUTTING DOWN.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**T**HE GREENHOUSE AND CONSERVATORY.—I am putting in another batch of cuttings of the fancy, show and regal Pelargoniums that should provide plants for flowering in the late spring and early summer next year. To encourage growth Bouvardias should be given every attention. From this time forth I refrain from pinching back the growths, otherwise their flowering period will be delayed. I am potting up a batch of young plants, placing them in larger pots and in rich soil. Lilies that have flowered under glass I am standing outdoors in a partially-shaded position. Cinerarias that were pricked off as recently advised should in most instances be ready for their first pots. Use soil made up of good yellow loam two parts and one part of leaf-mould and coarse sand well mixed. At this stage I should use rather more leaf-mould should the loam be inclined to be heavy.

Roses may be budded. Select, if possible, showery weather and bud carefully. I have recently plunged my pot Roses outdoors in a sunny position for the growths to ripen. Well-rooted plants will appreciate a liberal top-dressing of manure. This is a good opportunity for removing old and useless growths from dwarf Roses, as well as the weakest shoots that can never be of much service.

*Chrysanthemums*.—These will need more attention from this time. Plants of the late-flowering sorts must not be pinched back or stopped again this season. Grow on to the terminal buds, i.e., the last series of buds that are developed, and these will make a beautiful display in mid-winter. Those who wish for large blooms of the November-flowering varieties should retain the "crown" buds during August. Side shoots must be removed from the axils of the leaves,

1.—BRIAR STOCK, SHOWING TWO VIGOROUS SHOOTS READY FOR BUDDING.

in this way concentrating all the energies of the roots on the development of plump buds and handsome flowers subsequently. Keep the soil between the plants of early-flowering varieties in the outdoor garden hoed over at least once a week, also see that all plants are staked and the growths secured by a loop-like tie, as we are sure to experience boisterous winds in the near future.

*The Vegetable Garden*.—Continue to plant Celery, taking care to see that the soil in the trenches is kept well moistened. Now is a good time to make a sowing of Tripoli Onions for next year's supply. Sow in quarters that have been deeply tilled and liberally manured. Greater success follows when the seed is sown thinly. I am lifting my early Potatoes, planting the same quarters immediately subsequent thereto with winter Greens. Seeds of the spring Cabbage should be sown immediately if this has not been done already. For winter use I am now making a sowing of Brown Cos Lettuce. Plants from an earlier sowing should be planted out without delay. My early Celery is growing away freely, being benefited by frequent applications of liquid manure. Mushroom beds may be made up outdoors at this period; a recent article dealt with this subject in detail.

*The Flower Garden*.—To maintain plants in health seed-pods should be removed most persistently. The layering of Carnations should now proceed apace. This is a very sure and ready means of increasing stock of these plants. The earlier Narcissi may be planted. Bulbs of new sorts should be acquired in good time, as the results are invariably better when this work is carried out at this early period. Sow seeds of the perpetual-flowering Stocks on a warm border. Primroses, Polyanthus and Daisies may be divided with comparative ease. This is a simple way of increasing stocks of these showy hardy plants. The beautiful yellow Tree Lupine (*Lupinus arboreus*) is a more or less shrubby plant. There is also a very beautiful variety named Snow Queen. I prefer to sow the seeds in a box or pan, afterwards placing it in a frame. When sown outdoors they fall a ready prey to slugs.

*The Fruit Garden*.—Old beds of Strawberries should be done away with, and the quarters trenched and heavily manured previous to planting with spring Cabbage later on. New beds of Strawberries must be planted in the immediate future. This work should be done in good time. Continue to layer Strawberries until a sufficient supply has been obtained. During this month Pears, Apples, Plums, Peaches and Cherries may be budded.

D. B. C.

### HOW TO BUD STANDARD ROSES.

EVERY beginner who is an enthusiastic admirer of the Queen of English flowers, the Rose, aims at being able to bud his own Roses, notwithstanding the fact that he quite fully realises that it is a matter requiring some application of thought. It is a simple matter after all, provided proper means be taken to prepare the stocks and buds beforehand, and that the work be done in good time. The most suitable time to carry out this operation is during the months of July and August. It is a most interesting and fascinating occupation, as we derive by union with the common Briar Roses of the most delightful kind, providing we have the necessary buds of the different types and varieties.

We have endeavoured by the photograph represented in Fig. 1 to show the ordinary Briar

2.—ROSE BUD ON LEFT AS REMOVED FROM A ROSE SHOOT. ON THE RIGHT THE LOWER FIGURE ILLUSTRATES THE SAME BUD WITH LEAF-STALK SHORTENED, AND THE UPPER FIGURE THE BUD WITH PITH AND WOOD REMOVED READY FOR INSERTION.

that was taken from the hedgerow last year. Here will be seen two vigorous shoots that have sprung from the main stem, and these are in fine condition for dealing with at the present time.

The first thing to acquire is a supply of suitable buds, and each of these should be plump and easily seen. Buds of this kind are usually to be obtained from nice free-growing shoots of an old or vigorous Rose tree. The first thing is to cut the leaves away, except perhaps about half an inch to an inch of the lower portion. This makes a very convenient handle with which to control the bud. This is severed from the free-growing shoot before alluded to, and when detached from the Rose the shoot should be about 1 inch long, and should be cut away with a sharp knife. The bud it will be observed in Fig. 2 is of shield-like form, and the centre of wood or pithy substance should be removed therefrom, taking great care, however, not to damage the "eye" in the operation. As a matter of fact the centre portion of the shield may easily be removed with the thumb nail by holding the shield in the left hand and using the thumb nail to effect this end. The great thing, however, is to carry out the work promptly, and if this cannot be done and the bud be injured in the course of dealing with it, it is better not to use it at all but to select another one. An incision is then made in the bark of the stem it is proposed to bud, and the illustration in Fig. 3 gives a good indication of how this should be done. The incision in the illustration is shown on the side of the shoot in order that the would-be operator may see for himself how this should be done. It should really be made on the upper part of the growth and not on the side as indicated in the illustration. It really represents an elongated letter T. The cut should be about 1 inch long, and should be done with the greatest care, so that the knife does not cut too deep. In the case of the cross cut, if made much below the bark there is just a risk that the strong winds may snap the shoot and destroy one's prospect of success. The insertion of the bud in the incision made requires a little care. The bark should be raised on both sides with the bone end of a budding knife, taking care in the operation not to split the bark, otherwise the result may not be satisfactory.

The illustration in Fig. 4 shows the shield-like bud inserted in position ready to be tied, and if

this be trimmed off at the top, in the case of it being longer than the incision made in the bark, the top end must be detached so that the bark of the bud is absolutely and entirely submerged in the incision made.

The next thing is to securely tie the bud in position. This may be done by the aid of raffia. The second illustration in Fig. 4 shows exactly how the ties should be made. Do not tie the bud tightly, but only moderately tight, leaving the eye just visible after the ties have been made. In the event of very dry and trying weather succeeding the budding operations, it is a good plan to give the roots of the Briar a good application of water. In the course of a month or so, the eye, which was the new Rose shoot in embryo, should begin to swell, and when this is visible it is well just to loosen the tie to prevent the bark becoming cut, but care must be taken

#### LIME IN THE GARDEN.

THE value of lime in the garden is apt to be overlooked by the amateur, yet it forms one of the most valuable substances that we can procure for many purposes, and a well regulated garden should never be without a good supply. Made into a wash it is most valuable for applying to the stems and main branches of fruit trees during the winter for the purpose of destroying lichen and insect pests, and applied to the inside walls of greenhouses and frames it answers a similar purpose. Where a cheap shading for glass structures is desired lime wash applied to the outside of the glass by means of a syringe affords an effective though temporary shading, and where slugs abound it may be mixed with soot and used as an excellent deterrent of these ravenous creatures. In conjunction with sulphate of copper and water it forms the famous fungicide known as Bordeaux mixture. However, the principal use of lime in the garden is as an application to the soil. Many old gardens exist where the ground has been heavily manured year after year, with the result that it has become what gardeners term "manure-sick" or sour, and it is with soil of this character that an application of lime is likely to give the best results. Its action on plant foods is to render them quickly available for the plants, and to reduce any harmful acid that may be present to a non-harmful and oftentimes beneficial condition. It is safe to assert that the majority of gardens, except where Rhododendrons and similar plants are grown, would have their fertility considerably increased by a judicious application of lime.

When and how to apply it are questions that naturally accrue. Lime proper should always be applied when the ground is vacant, as then there is no fear of tender roots being injured. A good dressing for ordinary purposes is half a pound to a square yard. This is best applied as slaked lime. A good plan is to place the fresh lime in small heaps on the plot to be dressed and allow it to remain thus until by the action of the air it falls into a fine powder, when it should be distributed evenly over the surface and then dug in, taking care to mix it with the soil as thoroughly as possible. A crop may be planted on the plot a few days afterwards without any fear of injury. Where clubbing in Cabbages, Turnips or allied plants is troublesome this application of lime should always be given when the plot is prepared for these crops, as it is one of the best preventives known of this terrible disease. It may be applied at any season of the year to vacant ground, but where used among the roots of fruit trees it is best applied in late autumn or early winter. Stone fruits often fail to swell their crops properly owing to a deficiency of lime in the soil, the fruits dropping off in large quantities during the stoning process.

For herbaceous borders and other places permanently occupied by tender-rooted subjects a safer dressing is chalk. This has not the burning properties of lime, and may be used among ordinary plants at the rate of 1lb. to the square yard with advantage. It should be crushed as fine as possible and worked into the soil by means of a handfork or similar implement.

#### SUITABLE SOIL FOR ROOM AND WINDOW PLANTS.

(Continued from page 353.)

PEAT is not so indispensable as loam; indeed, if a loam possessing plenty of fibre—i.e., decayed and decaying roots of grass and other herbage—be obtained, peat is rarely necessary. Its chief use is for Ferns, Azaleas, Heaths, foliage plants and any subject that likes a hard, close root-run and is likely to occupy the same pot for a considerable time. Peat is obtained in the same way as loam, viz., it is taken from the top of a common. It, however, differs in character from loam in that it is brown or blackish, full of fibre, sand-

4.—ON THE RIGHT IS A PORTION OF STEM SHOWING HOW THE BUD IS INSERTED, AND ON THE LEFT THE BUD IS PROPERLY SECURED IN POSITION BY RAFFIA TIES.

and strong roots, and of a light, spongy nature. In using peat, the thick, fleshy roots encountered, which are those of the Bracken Fern, should be removed and thrown away.

Leaf-mould is the residue from a heap of leaves after decaying. Leaves, preferably Oak or Beech, are collected from a wood, stored in a heap and tightly trodden down; a piece of fairly fine meshed wire-netting may be placed round the heap for a few weeks after its formation to prevent the leaves blowing away. When very dry weather follows the leaf collecting, it is sometimes wise to throw a few pails of water over the leaves to settle them down and hasten their decay. Turning once or twice at intervals of six weeks may be practised with advantage, and the decayed leaves should be ready for use in from nine to twelve months. E. J.

(To be continued.)

5.—A YOUNG STANDARD ROSE TREE, THE RESULT OF BUDDING A BRIAR LAST YEAR.

3.—PORTION OF BRIAR STEM SHOWING THE SHAPE OF THE INCISION. IN ACTUAL PRACTICE THE INCISION IS MADE ON THE UPPER PORTION OF THE LATERAL AND NOT ON THE SIDE AS SHOWN.

not to expose the bud fully until it is growing away freely. Some buds are rather quicker in their development than others, and in many cases they will remain in a dormant state all the winter, especially when the budding is done quite late in the summer. In the succeeding spring, the Briar shoots may be cut back quite close to the Rose buds that have been inserted, and as the sap rises in the early summer the Rose shoots will grow away freely, but should be secured as they grow, as there is always a danger that the wind may cause the buds to break out until they are well established.

Fig. 5 is a good illustration of a budded standard Rose the first season after the Briar was budded. Two shoots will be observed growing away freely, and each with several Rose buds well developed.

## THE TOWN GARDEN.

**BORDER CHRYSANTHEMUMS.**—These plants are so serviceable for the town garden, and, moreover, are so easily grown that it is a matter for surprise that they are not far more frequently seen. By making a judicious selection abundance of flowers can be had from the late summer until the threshold of winter, and they will always be welcome for cutting as well as for the embellishment of the borders. Unfortunately, many people who have them find them so accommodating that they think the plants are perfectly well able to look after themselves, and the result is that after planting they are not accorded any attention. This is an error for which the grower must pay a price. During the present and the early portion of next month each plant should be gone over thoroughly with a view to the removal of shoots for which it is clear that there is not ample space, and also for watering with clear water and liquid manure as may be deemed necessary. In regard to the latter, it may be pointed out that the plants are like those grown for exhibition in their partiality for good food, and this must be provided. After the plants have been heavily watered and had their soaking of liquid manure the cultivator should wait until the surface has become sufficiently dry for loosening, and then apply a mulching of sweet manure above the roots. The water that is given subsequently will pass through this covering and the food contained therein will be carried down into the soil, while the dressing will also prevent the waste of food by the constant evaporation. One of the greatest pests with which one has to contend in the culture of these plants is the maggot which burrows in the leaves, and when the attack is severe considerably weakens the plants and effectually prevents perfect flowering. I make it a rule to spray once in every two or three weeks with a weak solution of paraffin, soft soap and quassia, and even then some maggots are sure to gain a footing; but these do not live long, for they are promptly crushed between the thumb and finger.

**CLIMBERS ON WALLS.**—The town garden gains so immensely by the inclusion of climbers on the walls that it is quite imperative that they shall receive the best attention it is possible to give. In the matter of pruning I should always say the less the better, as it is the free, rampant habit which makes the plants so delightful, but it is seldom wise to neglect it entirely, as they are then apt to become thickets of growth which can never produce satisfactory blooms. Therefore, let discretion be used and only allow sufficient shoots to comfortably occupy the allocated space. It is, however, in the matters of watering and feeding that the majority of climbers come worst off, for many otherwise careful amateurs never give a second thought to the climbers. To facilitate the application of water and liquid manure make a wide, shallow saucer round the stem, loosen the soil a little and fill time after time as may be required, following later with liquid manure; this done, fill in the saucer with two or three inches of short, sweet manure and the work is done.

**PANSIES.**—It has become customary to rely almost exclusively upon the raising of seeds for the supply of Pansies, but when one has a variety of which one is especially proud it is essential that cuttings shall be rooted, as seedlings will not come true. The present is an excellent time for insertion to produce plants that will bloom early next season, and later on other cuttings can be inserted for succession. Short-jointed shoots springing from the base should be chosen and inserted firmly in some convenient position; as the losses during the winter may be severe it is well to take about three times as many cuttings as are really wanted.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## FLOWER GARDEN.

**AQUATICS AND BOG PLANTS.**—These should have the weeds pulled away from the roots, so that they have plenty of room for making proper development. *Spiraea palmata*, *S. astilboides*, *S. japonica*, *S. gigantea* and many others are now in perfection, and *Butomus umbellatus* is flowering unusually well this season.

**Hardy Ferns.**—These require an amount of moisture, which in hot seasons must be supplied by artificial means. Do not use the water cold from a tap, as this may give the plants a check. Ferns require a certain amount of shade, but not darkness, and when grown under large trees see that sufficient light is afforded by cutting away some branches. A mulching of leaf-soil, to which a little bone-meal and soot has been added, makes a capital top-dressing.

**Shrubs and Roses.**—Flowering shrubs which have finished blooming should be pruned back into the required size and shape. Some need but little pruning and others a lot. Roses must have all seed-pods removed as soon as possible after the flowers are over, so that subsequent blooms have all the strength possible. Give copious supplies of water, both sewage and clean, and a little guano.

## KITCHEN GARDEN.

**Horn Carrots.**—Sow these for pulling during the autumn. If the soil is dry, thoroughly soak it before drawing the drills, and a few mats may subsequently be placed over for a few days should the weather be hot and sunny.

**Celery.**—Water this well and syringe with insecticide to keep off an attack of maggot. Get late batches planted as soon as possible, and do not let the plants flag. Get in more seeds of Endive and Lettuce and prepare ground for sowing Cabbages next week and again ten days afterwards.

## PLANT HOUSES AND FRAMES.

Pot on all kinds of winter-flowering plants, such as *Bouvardias*, *Carnations*, *Cyclamen* and *Poinsettias*, also *Primulas*, *Cinerarias*, *Campanulas* and *Geraniums*. Repot *Roses* that require it, and keep all pot *Roses* well supplied with manure water and keep down all insects. It is better to plunge the pots in ashes.

## HARDY FRUIT.

**Peaches and Nectarines.**—Expose the fruits of early varieties to the sun as much as possible, so that they get a good colour. The young growths should be kept tied or nailed in, and the trees syringed twice daily during very hot weather. Peach growing will then become a pleasure. Some good short manure should be placed over the roots to keep the soil cool.

## FRUIT HOUSES.

**Melons.**—Continue to set the flowers of these in houses and frames, and water with liquid manure when the fruits start swelling.

**Peaches** must not be allowed to suffer from drought; water copiously and often all trees carrying heavy crops. Allow plenty of air, top and bottom, to late houses.

**Late Grapes.**—The houses containing these must be damped thoroughly several times daily, especially during hot, sunny weather, and where borders are outside and in let both be mulched with some short manure. The outside border may also want more water than the inside, especially when in full exposure to the sun.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**CHRYSANTHEMUMS.**—Plants grown as trained specimens must now be regulated and tied. They will by now have filled their pots with roots, and will require feeding. With the large number of shoots and flowers these specimens are expected to perfect, naturally more liberal feeding will have to be indulged in than is the case with plants which have to produce only a limited number of flowers. Thoroughly syringe the plants two or three times daily, and damp the surface of the ground on which they are standing frequently during hot, dry weather. Dust the undersides of the foliage occasionally with black sulphur to ward off attacks of mildew.

**Orchids.**—Admit plenty of fresh air during the hottest portion of the day. Close the top ventilators in the warm house early in the afternoon and give the plants a good syringing overhead on every favourable occasion. Reduce the bottom ventilation towards the evening in order to avoid much fire-heat.

## FRUITS UNDER GLASS.

**Strawberries.**—When once the runners have become fairly well rooted in their pots, these should be cut away and moved to a position where they will be shaded from the midday sun and stood thickly together for the first few days, as the pots then prevent each other becoming too hot and dry, and the young plants are thus inured gradually to the loss of sustenance they incur through being cut away from the parent plants. As they become able to bear it, it is advisable to stand them more thinly preparatory to potting them into their fruiting pots, which should be done by, or very soon after, the end of the month. Before potting it is advisable to turn the young plants down on their sides and to syringe them thoroughly on the undersides with water in which a good quantity of flowers of sulphur has been mixed.

## KITCHEN GARDEN.

**Spring Cabbages.**—I am no advocate of very early sowings of this important vegetable. I make my principal sowing at the end of July, and, provided good seed is used, it need not be sown thickly; in fact, thick sowing is ruinous. I make a second sowing from the middle to August 21 of good second early varieties, and plants that are to be wintered in frames will be quite forward enough if sown at the beginning of September. If sown earlier, large, ungainly plants which lift badly and are prone to run to seed after flagging from removal in spring follow. Sow the Red Pickling Cabbage at the second sowing, and it is also advisable to sow a little with the third for frame protection.

**Rhubarb.** Do not be led away with the erroneous idea so often entertained that in order to make the best jam and wine Rhubarb ought to be in a semi-withered condition. Those who desire quality in either will do well to take the sticks which result from the secondary growth, which occurs in most vigorous Rhubarb beds and is now at its best.

## FLOWER GARDEN.

**Herbaceous Borders.**—Many inmates of the borders show unmistakable signs of the effect of the continued drought, and in all cases where watering is practicable a thorough soaking should be given. Tufted Pansies, for instance, are not likely to throw cuttings in quantity unless they get more moisture than is this year naturally provided. A good soaking will also be necessary to secure a second growth and display of flowers on the *Pyrethrums*; at present they are not moving an inch. Seed-boxes of herbaceous plants sown during May or June will want attention in the way of watering.

T. B. FIELD.

(Gardener to the Baroness Berners.)

*Ashwellthorpe, Norwich.*

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Boltonia latissquama and Michaelmas Daisies** (Cape Colony).—As the popular name of Michaelmas Daisy is confined to the perennial Asters, you cannot properly exhibit *Boltonia latissquama* as a Michaelmas Daisy. A list of the best tall-growing varieties of Michaelmas Daisies is difficult to give without knowing whether you prefer small or large-flowered varieties, or both, while the number available is exceedingly large. The following, growing 3 feet or upwards in height, are all first-class: *Coombefishacre Brightness*, lavender, medium; *cordifolius Ideal*, lavender, small; *Edwin Beckett*, lavender, medium; *ericoides Sensation*, white, small; *gracillimus*, rose pink, small; *King Edward VII.*, mauve, medium; *lævis*, blue, small; *Novæ-Angliæ Mrs. J. F. Rayner*, crimson, large; *Novi-Belgii Captivation*, pink, medium; *N.-B. Edna Mereia*, rose; *N.-B. Fairfield*, white, large; *N.-B. F. W. Burbidge*, heliotrope, large; *N.-B. William Marshall*, mauve, large; *punicus pulcherrimus*, bluish, large; *Shortii*, lilac, small; *turbinellus albus*, white, large; and *Osprey*, pink, small. The *Amellus* varieties should also be grown, but these are not tall growing.

**Information about Pœonia Cambessedesii** (W. West).—*Pœonia Cambessedesii* is a native of the Balearic Isles and Corsica. It was first found in the Island of Majorca in 1896, and then introduced into cultivation in this country. Plants flowered at Glasnevin in April of 1907, and it was figured in the *Botanical Magazine*, t. 8161. Its nearest ally in the genus is *P. corallina*.

**Diseased Ostrich Plume Asters** (M.).—The Asters have been attacked by a fungus, probably a species of *Fusarium*, but they were packed so that it was quite impossible to investigate them properly. Whether the fungus is a parasite or merely a follower of some other cause of death must, in the absence of suitable material for investigation, remain a mystery. All plants should be carefully packed in tin boxes, and on no account should they be wrapped in cotton wool; damp moss is much better.

**Information about a Sweet Rocket** (E. Ashton).—The Rocket has evidently taken on a fasciated growth, a by no means unusual occurrence in flowering plants and shrubs, and due in all probability to a breakdown or rupture of certain cells, or at any rate some interference with the normal conditions within the plant. In the Rose, Sweet William, *Euonymus* and *Lily* numerous instances occur each year, the freak becoming more or less permanent in the latter group at times. In all cases it ranks as a disfigurement, and the blossoming is by no means improved by its presence.

### TREES AND SHRUBS.

**"Orange" plant in the open** (Mrs. C. M.).—The sprays you send are those of *Ægle sepiaria*, a plant which has many synonyms, one of the commonest names in gardens being *Citrus trifoliata*. You appear to be very successful in the culture of rare shrubs, and there are a great many things which would thrive excellently in your garden. The following *Rhododendrons* are worth trying: *Grande*, *Falconeri*, *Hodgsonii*, *barbatum*, *griffithianum* (Aucklandi), *arboreum*, *campylocarpum*, *glaucom*, *yunnanense*, *racemosum*, *cinnabarinum* and *Thomsonii*. Other suitable plants are *Escallonia macrantha*, *E. rubra*,

*E. langleyensis*, *E. philippiana*, *Ceanothus veitchianus*, *Tricuspidaria dependens*, *Jasminum primulinum*, *Mertens Ugni*, *Magdolia Watsonii*, *M. parviflora*, *M. Campbells*, *Grevillea sulphurea*, *Myrtles* in variety, *Eucalyptus* in variety, *Fuchsia Riecartoni*, *Cordyline australis*, *Eucryphia pinatifolia*, *Styrax japonica* and *S. Obassia*.

**When to prune Rhododendrons** (C. S.).—You do not say in what condition your *Rhododendrons* now are. If they are, on the whole, shapely bushes, you will not need to do more than remove odd, straggling branches here and there, and that is best done in April. If, on the other hand, your plants are very loose in habit, they will require well cutting back to induce a more bushy character. You will not need to remove old branches if they are healthy; new growths may be expected from quite old wood. The flower-heads should always be removed from *Rhododendrons* before seeds have time to form.

**Holly leaves attacked by insects** (W. S. B. Pirbright).—Your Holly hedge is suffering from an attack of the Holly fly (*Phytomyza ilicis*). The fly punctures the leaves and lay eggs in the tiny holes. These eggs hatch, and the resulting grubs feed on the inner portions of the leaves, causing the brown, dead patches. It is a difficult thing to deal with, and your best plan at the present time will be to gather up and burn as many as possible of the old leaves, and syringe the hedge once a week for six weeks with a liquid composed as follows: Mix 1 lb. of soft soap and 1 pint of paraffin together to form an emulsion, then place the mixture in 8 gallons of clear water, stir well up and spray over the whole of the hedge. Next year repeat the operation, but commence the spraying about the early part of April.

**Ampelopsis Veitchii dying** (Barn Rocks).—It is impossible to say what is the matter with your *Ampelopsis Veitchii* without seeing the plant. It not infrequently happens that large and, to all appearances, perfectly healthy plants suddenly die without any apparent reason. Sometimes this plant is attacked by scale insects rather badly and that eventually causes death. Some root injury, too, may have taken place or the soil it is growing in may have become sour. The most likely thing to suspect, however, is root injury. It is improbable that it will start into growth again.

### FRUIT GARDEN.

**Young Gros Colman Vine diseased** (J. R.).—The malady from which your Vine is suffering is a disease little known, but from time to time we have had experience of its ravages, which has been invariably confined to young Vines, and generally to the varieties *Alicante* and *Gros Colman*. We have always attributed the cause to an attack by a very minute species of red spider, and this also was the conclusion come to some years ago by the scientific committee of the Royal Horticultural Society. Mr. Barron, in his "Book of the Vine," says of this disease that the late Mr. Blackmore of Teddington, who had directed special attention to this malady, had suggested that in lack of an authorised name it should be termed "diphtheritis," as he suspected it to be of a fungoid nature. Mr. Barron very truthfully describes the first symptom of the disease as "a contraction of the margins of the half-grown foliage till the leaves become like a cup inverted; then the stem loses its crisp, clear substance, goes dull and is channelled with lines of shrinkage, the tips of the shoots become flat and flaccid, all the gloss is lost and the vigour gone, and the disease descends from leaf to leaf until the whole tissue is hardened and the young wood becomes of a dirty black tint." We would advise you to cut away the parts very badly attacked, and to steep the affected shoots remaining in a strong mixture of sulphur and soft water. Those branches which cannot be steeped should be painted over with the mixture, which is best left on for three days. This treatment we have found to be effectual in stamping out the disease

without harming the Vines. Encourage new growth in the Vines during summer by every means in your power, and they will come round all right in time. Keep a vigilant look-out for the disease next spring, as it is almost sure to reappear for a season or two, and apply the same remedy before serious damage has been done.

**Branch of Ribes with abnormal growth** (H. B.).—The curious growth on the stem of *Ribes* is of the nature of a burr or knaur, and these are usually caused through the effort made by the plant to heal up a wound made by insect attack or some other cause, such as a chance cut by a knife, hail and so on, while in many cases their origin is very obscure. In the present instance it appears that a callus was first formed and then the cambium went on forming new tissue, both wood and bast, as in the stem, until at last this great swelling was produced and the exciting wound completely obliterated and the cause of the wound entirely hidden. It is not a gall in the sense that it is made by an insect, or rather through an insect, for a dwelling-place, as somewhat similar growths on Oaks are.

**Plum trees to bud** (A. B. C.).—Provided the stock in question is growing freely and in good health, and the sap running freely at the time of budding, there is no reason why you should not be successful in budding any variety of Plum you wish on the stocks you mention. The middle of August is a good time to carry out the work. If bush trees are required, the buds should be inserted a few inches above the ground, and higher, of course, if standard trees are desired. The stock is prepared for the insertion of the bud by making an upright cut (in a smooth part of the bark)  $1\frac{1}{2}$  inches long, with a transverse cut at the top 1 inch long, the two cuts together forming the letter T in this position. The edges of the bark on both sides of the upright cut should be lifted gently up by the handle end of the budding-knife prepared for this purpose, in order to receive the bud, which must have been previously prepared. The way to do this is the following: Cut off a branch of the current year's growth of the variety you wish to bud, cutting the leaves off at the top of the stalk (not at the bottom), and place immediately in water. Select a plump bud and cut out with a sharp knife (deep enough to secure a thin piece of hard wood underneath the bud) something in the shape of a wedge, retaining the leaf-stalk attached. When the bud has been cut out as directed, gently raise the bark, commencing at the base of the bud, stripping it off the piece of wood to which it is attached. This must be done with much care, as if the centre or the eye of the bud is damaged in the operation the whole of the work will be nullified. All you have to do now is to carefully insert the bud in the slit prepared for it, taking care that the edges of the bud are well lapped over by the bark of the slit part, leaving the eye of the bud at the end exposed with the leaf-stalk still attached, finishing off by tying down with soft matting firmly, but not too tight. In winter the top of the stock must be pruned back down to the inserted bud, and the growth from this bud for the first year must be protected by tying to a stake fastened to the stock or pushed into the ground.

**Peach, Apple and Pear leaves diseased** (C. A.).—The leaves from your Peach tree are suffering from the attack of aphides. Syringe or spray the tree with a solution of paraffin emulsion or an insecticide sold as "V 2" at once, again in the course of a week, and again just before the leaves fall. When all have fallen, and before the buds show any sign of opening in the spring, spray with a caustic alkali wash or "V 1." Your Apple trees are attacked by the caterpillars of the winter moth (*Cheimatobia brumata*); at least, that was the only insect I could find on them. Spray the leaves with arsenate of lead or Paris green, and, if the trees have been very badly attacked by these caterpillars, early in October place sticky bands round the stems of the trees and keep them in working order until no more moths are about. These bands should be long enough to go quite round the stem and to slightly overlap. They are best made as follows: Take a strip of calico or some similar material of the requisite length and about 6 inches wide, lay it in a strip

of waterproof paper such as buttermen use, of the same length but rather wider, turn the edge of the paper over the calico, and place the hand with the paper underneath round the stem some 4 feet or 5 feet from the ground and tie it with two strings (at the top and bottom) tightly round the stem so that the moths cannot crawl underneath; then smear the calico thickly with cart-grease in which there is no tar. The object of the hands is to prevent the female moths, which have no wings, from making their way up the stems. If the paper is stout enough, the grease may be put on it without using any calico, but the grease must be kept off the bark. The leaves of your Pear tree are apparently infested by a fungus named *Entomospodium maculatum* (the leaf-scald fungus). Spray with diluted Bordeaux mixture and collect and burn all dead leaves.—G. S. S.

**Removing wireworms from viney border (W. D.).**—The wireworm as a rule feeds near the surface on surface roots, and the best way we know of killing it is by burying (a few inches deep) pieces of Carrots, Turnips or Potatoes, sticking a skewer through each piece to indicate where they are for daily examination. This, if persevered in, will rid the border in time, as they prefer this food to the roots of trees. No insecticide we know of may be used strong enough to kill this grub without endangering the safety of the roots, but we have known good results to follow an application of lime, soot and guano to the border in driving them away. Mix these ingredients up in equal quantities, say, a gallon of each, and spread fairly thick over the border, having lightly forked it before watering the same copiously in. Vapourite and Kilogrub, if applied according to the directions, ought to effect a clearance.

### KITCHEN GARDEN.

**Mint Diseased (J. E. K.).**—The specimen of Mint you send is badly affected with a deadly fungus commonly called cluster-cups, which also sometimes attacks Anemones. We fear that the only way to stamp it out is to dig up the whole bed and burn every portion of the plants. Then procure a fresh stock and form a new bed as far away from the old one as possible. You may, if you like, try cutting off all diseased growths just below the ground and burning them, then thoroughly spraying the soil and the remaining growths with weak Bordeaux mixture. This will sometimes effect a cure.

**Black spots on Tomato fruits (J. M. and also H. W. D., Sussex).**—This is a disease from which the Tomato suffers, and is of the same nature as the Potato disease, a fungus well known by its occasional terrible ravages on that tuber. Generally the cause of its attacks on the Tomato is the applying of too much water at the roots and too close and humid an atmosphere in the house in which the plants are growing. There is no cure for the spot once it has attacked the fruits, and the best way is to pluck off and burn all affected Tomatoes. To prevent its spreading give more air night and day, providing a little heat in the pipes at the same time. Water the plants carefully and give them plenty, but never let them be over-soddened at the roots. Take some of the old surface soil away near the stems and replace it with a dressing 2 inches deep of sweet loamy soil, mixing with it a little fresh horse manure. The plants will soon make new roots in this material, and, we hope, soon grow away from the disease.

**Mushrooms: Failure in their growth (H. A.).**—We think the fatal mistake you made in forming your bed was in the use of droppings alone in its composition. Thus formed it would heat too quickly and violently, and afterwards collapse into a cold, sodden mass of useless dung (for this purpose) with no warmth or life in it. You should have mixed with the droppings at least one-third of its bulk of the short straw litter which always collects with the droppings; this helps to moderate the heat, and also to add to its long continuance. It is difficult even for an expert to grow Mushrooms successfully in the height of summer, either in out of door beds or sheds, and we would advise you to defer beginning until the last week in August. This is too big a subject to deal with in an answer to a question, but we hope to refer to the subject in some detail before the time stated. In the meantime, we would recommend you to buy a very useful work on the subject by John F. Barter, a man with a long life's experience in

the growth of the Mushroom for market. Post free 1s. 2d. Address: J. F. Barter, Mushroom grower, Napier Road, Wembley R.S.O., Middlesex.

**French market gardening (E. R. M.).**—We have pleasure in giving the names of two market gardens in which the French system of gardening is carried out. There is another establishment in the Vale of Evesham, Worcestershire, of which, however, we have not the address. The Manager, Anglo-French Garden, Thatcham, Newbury, Berks; Paul Aquatius, French Market Garden, Mayland, Essex.

**Cauliflowers attacked at the roots (C. West).**—I have carefully examined the root of your Cauliflower plant, and cannot find any trace of insects or fungi. The tap root was extremely hard and woody, so much so that it was quite difficult to cut it with a knife, which would point to defect in their cultivation. Perhaps they were checked in their growth when first planted out by the weather. The ants could not have been the cause in any way.—G. S. S.

### MISCELLANEOUS.

**Climbing Roses for wooden wall (E. C.).**—Two fine varieties would be Mme. Jules Gravereaux and Françoise Crousse, but if the wall is a dark colour we should replace the latter with Mme. Hector Leulliot.

**Destroying Nettles (H. C. E.).**—We do not know of any means of destroying Nettles beyond constantly hoeing up the annual varieties and digging out and burning those of a perennial character. The Narcissi bulbs which have been in the ground for some years should be lifted at once, all the small offsets removed, and the large bulbs planted 6 inches apart in September. The smaller offsets would be best planted rather thickly in a nursery bed for a year or two until they attain flowering size.

**Suckers from budded Roses (M.).**—The reddish shoots sent are from what is known as the "Coster" stock, a stock much used in France to bud Roses upon. You must be on the alert to remove the suckers as soon as you observe them, for they will soon kill a plant owing to their great vigour. The following six climbing Roses would be found very suitable to grow on a south-west wall to flower late in the autumn: Mme. Alfred Carrière, Dr. Rouges, François Crousse, Kaiserin Friedrich, Mme. Hector Leulliot and Lady Waterlow.

**Pelargonium leaves diseased (W. Hay).**—The Pelargonium leaves look as if they had been badly attacked by aphides and thrips which had been destroyed by the petroleum emulsion, but which in its turn had injured the leaves and caused the spots thereon. Although there are traces of fungus, it appears to us to have originated after the injury, and is therefore not the cause of it. Spraying with a solution of potassium permanganate will check the fungus. Beside this, the piece of stem enclosed was deformed after a manner that is often to be found in some varieties of Pelargonium. The cause of this trouble is somewhat obscure, but it is generally regarded as owing to the varieties most affected having been raised by a long course of in-and-in breeding, thus leading to a weakly constitution. This trouble has caused the bright-coloured varieties of the show section to almost drop out of cultivation, as from their debilitated state it is next to impossible to obtain a satisfactory specimen.

**Learning the nursery business (Enquirer).** If your circumstances in life will admit of your paying a premium as a nursery pupil, then your best course would be to seek for admission as such into some good nursery at once, such as that of Messrs. Hugh Low and Co., Bush Hill Park, Enfield, Middlesex, or Messrs. Paul and Sons, Waltham Cross, Herts. Of course, there are many other nurseries round London; whether they would take a pupil we do not know. We have assumed that in mentioning "nursery" work you mean an ordinary tree, shrub, fruit tree, greenhouse and hardy plant nursery such as are those named. As an articulated pupil you would not only be taught the business, but you would have ample leisure to become familiar with the names of all the things grown in the nursery, how raised, their cultural requirements and very many other things, for nursery work covers very wide ground indeed. Assuming, further, that you cannot enter a nursery as a pupil, you would have to seek admission as a labourer, and, as you appear to be quite ignorant of the work, we fear a long time would elapse before you could earn wages. But if without means no other course is open to you. It is of little use at your age to get into a private garden, because the knowledge obtained there would be of little use in a nursery. If you could have started in a nursery as a boy you would have gleaned much useful knowledge by this time. As it is, under any circumstances it will need ten years' close application to fit you to control a nursery. It does, indeed, need such a wealth of experience and knowledge. Our leading nurserymen to-day are those who have grown up in the business from childhood.

**Names of plants.**—B. H.—*Iris fetidissima* variegata; 1, Rose Bouquet d'Or; 2, Rose, cannot identify.—W. Angus.—*Habenaria bifolia chlorantha*.—S. H. Bickham.—*Sedum Cepica*—H. Jones.—1, *Adiantum cuneatum elegans*; 2, the typical *A. cuneatum* or a slight seedling form; 3, *A. c. lawsonianum*.—J. L. Cox.—*Pisum elatius umbellatum* (the Crown Pea). It is not usually grown for culinary purposes.—A. Buckingham.—1, *Larix Lepolepis*; 2, *Quercus lucombeana* (the Lucombe Oak); 3, *Q. lucombeana* var.; 4, *Q. rubra* (the Red Oak).—G. Hodgekins.—The fruiting specimen is *Staphylea pinnata*; the other is *Polygonum cuspidatum*.

## SOCIETIES.

### COLCHESTER ROSE AND HORTICULTURAL SOCIETY.

THE annual summer show of the above society was held on the 8th inst. in the Castle Park, the old castle forming a splendid background to the show tents. At the entrance Messrs. R. Wallace and Co. had a delightful exhibit of Water Lilies and rockwork set in growing Grasses and hardy plants. Roses, as one would expect, formed the leading feature, and here was a feast indeed, the Rose giants at home contributing their best, and that well-known amateur Mr. O. G. Orpen taking no less than five firsts in strong competition. The amateur classes were very fine, and the table decorations a striking feature. Fruit was only an average quality, but vegetables were good and plentiful, and the splendid Asparagus staged by Mr. A. J. Harwood was most noticeable.

#### ROSES.

For forty-eight blooms, distinct, there were some grand flowers, Messrs. B. R. Cant and Sons being first, Messrs. Prior and Son second and Messrs. Frank Cant and Co. third. It will be noticed that Colchester held its own, and this remark applies to most of the open classes.

In the class for eighteen distinct varieties Messrs. B. R. Cant and Sons, Messrs. Frank Cant and Co. and Messrs. Prior and Son won in the order named. For twenty-four garden or decorative Roses Messrs. B. R. Cant and Sons were first and Messrs. F. Cant and Co. second. The Mayor of Colchester's Rose medal for the best Rose in the open classes was taken by Messrs. B. R. Cant with a grand bloom of *Gyovone Vacherot*, a perfect bloom of porcelain white with pink markings. Mr. W. Leggett, Colchester, was first for a grand stand of eighteen single distinct trusses, and Mr. O. G. Orpen a close second. For garden or decorative Roses the Rev. J. H. Pemberton, Havering-atte-Bower, was first with splendid blooms, Mr. O. G. Orpen second and the Hon. W. Lowther-Campsea, Campsea Ash, Wickham Market, third. Dr. Pallett, Earls Colne, was first in the smaller amateurs' class, and secured the medal for the best Rose other than Tea with a very fine bloom of *Frau Karl Druschki*. Mr. O. G. Orpen took the medal for the best Tea with a magnificent bloom of *Maman Cochet*.

#### GROUPS AND PLANTS.

The best group arranged for effect was a fine exhibit staged by Mr. T. Hetherington, Borechurch, Colchester, Mrs. Larpent, London, being second. For a table of plants the premier award was secured by Mr. T. Hetherington, Mr. W. Olle being second and the Right Hon. J. Boun, Birch Hall, Theydon Bois, Colchester, third. For the best plants for table work Messrs. W. Diaper, Colvin and Mumford were successful in the order named. For baskets of plants the leading exhibit came from Messrs. Saltmarsh and Sons, Chelmsford, Mr. H. Kettle, Colchester, being second and Mrs. Larpent third.

#### CUT FLOWERS.

A very large area was devoted to these. Sweet Peas were staged in profusion and herbaceous flowers were good. For twenty-four bunches, distinct, of herbaceous flowers Messrs. R. W. Wallace and Co., Kilnfield Gardens, Colchester, had a very fine exhibit, Mr. A. J. Harwood, Colchester, being a good second and Mr. C. Jacobs, Ipswich, third. In the smaller class the Hon. W. Lowtherby was first with very choice flowers well set up, Dr. F. H. Cooke being second. For Sweet Peas in the large class Mr. T. Cross, Messrs. Saltmarsh and Sons and Messrs. E. W. King and Co. won in the order named. In the smaller class Captain Cantley and Major Buckle won, and also in several other Sweet Pea classes.

#### TABLE DECORATIONS.

These were a special feature and strongly contested, Roses mostly being employed for the work. The premier award was secured by Mrs. Butcher, Ipswich, with a delightful arrangement of Tea Roses and coloured foliage. Miss Bunting, Tolleshunt d'Arcy, was a close second with single Roses and Mrs. Hitchcock, Witham, Essex, third, there being thirteen exhibitors. Mrs. A. J. Harwood was granted an extra award. The prize for the best *epergue* was awarded to Miss A. F. Harwood, Mrs. Waller-Copford being second.

#### FRUIT AND VEGETABLES

The best six dishes of fruit were staged by Mr. Andrews, gardener to the Hon. W. Lowther. The best Grapes came also from Mr. Andrews, who staged very well finished Hamburgs. Mr. Osborne exhibited large Muscats, but these were not quite ripe. The last-named exhibitor had the best Peaches, Mrs. Larpent being second. The best dishes of Strawberries came from the Hon. W. Lowther in all the three classes, both for flavour and size. The collections of vegetables were remarkable for quality and required close judging, the premier award being secured by the Right Hon. J. Boun (gardener, Mr. Bishop), Mr. Andrews being a close second with even dishes, but losing two points only in the Peas.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE quarterly meeting of this society was held at the Horticultural Hall, Vincent Square, on Monday evening, 13th inst., Mr. Thomas Winter in the chair. Six new members were elected, making a total of forty-five this year so far. The usual quarterly grants were made to old age members on the benevolent fund. The amount of sick pay for the month was £41 18s. This is rather heavy for this time of the year. The meeting closed with a vote of thanks to the chairman.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## EXPERIMENTS AT THE DUKE OF BEDFORD'S FRUIT FARM.

MUCH has been written in the past about the remarkable results which have been obtained from experiments carried out at the Duke of Bedford's experimental fruit farm at Woburn, under the directorship of Mr. Spencer Pickering and the management of Mr. W. H. Neild. Many statements that have been made respecting these experiments have been on the one hand exaggerated or on the other misunderstood, so that many erroneous ideas have been circulated.

We recently inspected the many trials or experiments now being carried on, and a few particulars concerning the more important of them may be of interest to our readers. We wish it to be distinctly understood that we, nor those responsible for the carrying out of these experiments, do not advocate the general adoption of all the methods that have given good results at Woburn, because on different soils and in different localities the results might not be nearly so satisfactory. So far as we could ascertain, every possible precaution is taken to conduct the experiments on strictly scientific and practical lines, nothing being left undone that is likely to make the results obtained reliable.

It has, of course, long been known that grass growing over the roots of fruit trees is detrimental to their well-being, and elaborate experiments carried out at Woburn fully confirm this. Even where trees were well established before the grass was allowed to grow, the ill effects were plainly seen, and records kept show that the fruit crop was considerably reduced. Where the roots of the trees were grassed over immediately after planting, or before the trees had become well established, the ill effects were even more pronounced. It is not known exactly in what way the grass harms the trees, but it has been conclusively proved that it is not by the exclusion of air nor the extraction of food or moisture.

This summer a series of experiments in spraying trees in full leaf with various neat petroleum spirits have been conducted and the results have certainly been most surprising. One spraying with these spirits was made on June 28 at midday during bright sunshine. It was found that White Rose paraffin, while killing all insect life, was not injurious to the foliage. Motor and other lighter spirits damaged the leaves very much, as also did oils heavier than

White Rose, such as solar distillate. In the former case the damage was visible within half-an-hour of the spraying, but in the latter it was not noticeable for several days. Other sprayings made with the same oils at 6.30 p.m. in damp weather gave similar results.

Manuring experiments carried on during the past fourteen years have been rewarded with remarkable results. Apples, for instance, of similar varieties, of the same age, and given similar treatment, except as regards manuring, proved that the manure applied during the last fourteen years has done no appreciable good. In each instance a normal plot is retained and this has artificial manure equivalent to twelve tons of animal manure to the acre annually. Other plots are given artificial manures equivalent to an amount of manure under or over this quantity, and others again are given natural manure over or under the twelve tons per acre. Other plots had no manure at all. The records kept for fourteen years past show that none of the plots during that time have varied more than 2 per cent. or 3 per cent. in their crops. On a light sandy soil elsewhere similar experiments have proved that a normal dressing of manure was beneficial.

Gooseberries at Woburn gave quite different results. Some bushes planted fourteen years ago have been the subjects of experiments in manuring ever since. Some have had no manure and they have practically died out; others have had twelve tons of manure to the acre each year and others, again, thirty tons to the acre. The amount of fruit in the last two instances has not varied much, but where the thirty tons per acre were used the bushes have made much more wood. Artificial manures used at rates equivalent to those of the natural manures have given very little better results than no manure at all, the bushes having almost died out. In the case of Strawberries artificial manures and animal manure have given equally good results.

Pruning is a subject that is often much discussed. At Woburn the experiments have proved that in the case of newly-planted trees it was best to cut them back before the buds burst. Those that were not pruned until a year after planting had only produced half the crop over a certain number of years as compared with those pruned the first winter after planting. Some trees planted ten years ago have never been pruned since, others were pruned at planting time and have not been touched again, some have been lightly pruned annually, and some have been cut severely every year. The trees that have had the least cutting have given the best and heaviest crops, but the growth of those not pruned at all is too dense, and, in the case of some varieties, rather straggling. Most of the

trees experimented with were of bush form on the Paradise stock.

Planting has long been regarded as an operation that needs a considerable amount of care if good results are expected, yet the experiments at Woburn are quite in opposition to this. All sorts of planting have been tried, and the best results have attended what we should term a very bad method. Small holes, just large enough to cramp the roots into, were made, and after inserting the roots the soil was rammed quite hard around and over them. Trees planted thus have given better results than those planted in orthodox fashion, although for the first six months after planting growth was not so rapid. The growth of these trees has averaged nearly 50 per cent. more than from those planted in the usual way.

One more experiment must suffice for the present. Some small nursery stock of Apples infested with woolly aphids had to be dealt with, and it was found that the simplest, safest and most efficient method was to immerse the plants, roots and all, in water maintained at a temperature of 115° Fahr. for ten minutes. We give the above results of experiments so that readers may hear both sides of what have long been debatable points, and we have no possible reason for doubting their accuracy. The Duke of Bedford in financing this experimental station is doubtless doing a work that has long been needed, and, although the experiments and results are in many cases in opposition to generally-accepted ideas and practice, they are, at least, worthy of consideration by all those engaged in the culture of hardy fruit.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

August 4. — Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster; 1 p.m. to 6 p.m.

**"The Garden" Flower Show.**—At the time the paper is going to press, the flower show organised by THE GARDEN is being held in the Royal Horticultural Society's Hall in Vincent Square. The entries have exceeded our anticipations and many beautiful collections are staged, especially in the classes devoted to hardy flowers. It is impossible to give a report of the show this week, but a full account will appear in our next issue.

**Hedgerley Flower Show.**—A pretty village show took place in the grounds of Mrs. Stevenson, Hedgerley Park, near Stoke Poges, last Wednesday. There are few sweeter places in England. It was one of those flower shows with the village sports, which have such an influence for good in out-of-the-world corners where there is little to interest the inhabitants.

**Midland Daffodil Society.**—The general meeting was held at Birmingham on the 20th ult. Professor Hillhouse presiding. Mr. E. M. Crosfield was elected president for 1908-9. The new show classification of Daffodils as compiled by the Royal Horticultural Society was adopted as the basis of the 1909 schedule. The accounts showed a satisfactory balance of nearly £70. Mr. R. Sydenham was re-elected as treasurer, and the Rev. Joseph Jacob and Mr. Herbert Smith as joint secretaries.

**Scottish Horticultural Association's excursion.**—A party of between twenty and thirty members took advantage of the opportunity afforded by the annual excursion of the Scottish Horticultural Association on the 18th ult. to visit Drummond Castle, Crieff, in conjunction with the Dundee and Broughty Ferry Horticultural Associations and the Bridge of Earn Horticultural Society, the whole forming a good-sized company. The noted gardens of Drummond Castle were viewed with much pleasure, and the members were impressed with

the excellent manner in which they are maintained by Mr. J. Jeffrey, Lord Ancaster's gardener. The gardens have been described so frequently that it is unnecessary to give further detail, but it will be sufficient to say that all the old distinctive features have been maintained and a number of improvements effected, apart from the formal gardens, within recent years. Splendid weather was experienced.

**The fruit trade in Perthshire.**—The prospects of this year providing a profitable one for the Perthshire fruit-growers are most unpromising, the low prices which are being obtained for Raspberries being the cause of great disappointment. Some Raspberries are being offered retail at prices so low as to be unprecedented. There are signs, however, that better prices may soon prevail, although much uncertainty exists. Apart from the cost of picking and general cultivation, the high rents paid for suitable fruit farms make the present situation an anxious one for many fruit-growers.

## PRIZES FOR READERS. AUGUST.

### THE BEST ROSES FOR AUTUMN FLOWERING.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essays on the above subject, with hints on the management of the hybrids and varieties mentioned. The object of this competition is to encourage the cultivation of the Rose for the enrichment of the garden in the late months of the year.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Monday, August 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinion expressed by correspondents.)

**The Tulip Tree (Liriodendron tulipifera).**—The notes in THE GARDEN for July 18, page 348, on this beautiful tree may perhaps be supplemented by the following additional notes. With regard to the beauty of the trees there can be no two opinions. Nicholson, in his "Dictionary of Gardening," describes it as "a splendid tree, resembling an erect growing Plane in habit." It may not be generally known that the genus Liriodendron is Monotypic, that is, having only one species, namely, tulipifera. Though the tree is a favourite one in English plantations, it is said not to produce its flowers before the age of twenty to thirty years. Some years ago a very fine tree grew in the Royal Gardens, Kew, not far from the Cumberland Gate. Near the base of the trunk a large burr had formed, which, on being cut through,

was found to present no special character of figure, the ingrowing bark being interwoven with the knots which would unfit it for inlaying purposes. Some examples of these burrs or veins do, however, show a fine figure which would quite fit them for furniture work. It is, however, for the plain, even grained wood of the tall trunks that the commercial value of the Tulip Tree has been established, under the various names of American Whitewood, Canadian Whitewood, Canarywood, Yellow-wood or Yellow Poplar. The wood is now very extensively imported into Liverpool from New York for cabinet work, joinery, turnery and many other purposes. For ebonying it is said to be peculiarly adapted in consequence of it taking the stain well. The hulk of the wood when freshly cut is white, and is very easily worked, but the yellow wood, hence the name Canarywood, is somewhat harder, and is said to be produced by trees growing in moist, low-lying ground.—JOHN R. JACKSON, Clarendon, Lympstone, Devon.

**Rose Monsieur Tillier.**—The Rose mentioned by Mr. Thomas Arnold on page 358 is Monsieur, not Madame, Tillier. It is a Tea Rose, and was raised by M. Bernaix of Lyons in 1891. I always regret that it is not better known and more generally grown in England. I first saw it in the Paris Exhibition of 1900, and have grown it largely ever since, as it is never out of flower, and its singular and brilliant colour, described by M. Bernaix as "carmine red, shaded with brick red," makes it a most conspicuous object in the garden. No one seems to know it, and everyone admires it.—ROSE G. KINGSLEY, Keys, Eversley, Winchfield.

**The seasons when plants flower.** As one who reads a good deal on gardening matters, both books and periodicals, and sees most of the trade catalogues, and tries to keep abreast with the times, it has often struck me that in describing flowering shrubs and plants in general, and herbaceous plants in particular, how seldom the time or month of flowering is given. All other information is there. The name (and often the synonyms), history, pedigree, habitat, height, colour, shape and growth of flowers, and the best way of cultivating and increasing the stock, its utility and so forth are described, but never a word about the month in which it may be expected to flower. To those who require their gardens to be looking their best at a particular time of the year it is an important matter to know. Personally I always want my garden to be at its best and a wealth of colour in every direction through May, June and July, and I sacrifice a great deal to achieve my ambition. Every flower has its season, sometimes a long one, but generally very brief, and the knowledge of these seasons is a thing that a good gardener must make himself acquainted with. Many people do not enjoy the country till rather late in the year, and so their appetite for garden colour is supplied by the beautifully-laid-out parks, and then on retiring to the country they hope and expect to find their own private places at their best in July, August and September. How often they are disappointed and find that the Rose garden is bare and the herbaceous border untidy, overgrown and a waste, and little left to see except a few Michaelmas Daisies, Dahlias and Chrysanthemums, and the Sweet Peas a tangled mass of seed-pods. Others like to enjoy their gardens in the spring and try to make a display with Hyacinths, Daffodils and Tulips, and take an immense amount of trouble over the rock garden. It is not everyone by any means who resides in the country that enjoys his garden all the year round, but even those who do like to know the season of the flowering of the plant or shrub of which they read, and perhaps hesitate to purchase because they do not know when it flowers or what to plant alongside of it. I know personally that this fact has often proved a quandary to me till I had to buy my experience, and waste a couple of years perhaps. One might

write *ad lib.* on this subject, but I should just like to throw out a hint to those who write on these subjects.—A. E. S.

**Iris Kämpferi.**—Lovers of these beautiful Japanese Irises would have experienced a great treat could they have seen the superb show made by them in the Royal Horticultural Society's gardens at Wisley recently. Not merely in scores or hundreds, but literally in thousands were they to be seen, and all in contiguity to moisture. On the margins of the small ponds close to the wild garden they have bloomed superbly, so also on the margin of the large pond on the other side of the grounds, and then they fill the whole of the small stream which runs for several hundred feet through the grounds. Here they seed freely and reproduce themselves in that way. Should any inferior form present itself it is pulled out. That these beautiful flowers do thus seed shows how thoroughly they have acclimatised themselves at Wisley. It would be a kindly act on the part of the council of the society if it authorised the garden superintendent to furnish notice through the gardening papers beforehand as to when any specially attractive feature at Wisley would be at its best.—A. D.

**Lupines at Trusley Manor.**—The Lupines here make a grand show in rough shrub beds; of course, it is the quantity that makes the effect, which from a distance is charming. I planted them some three or four years ago, the plants being raised from Carter's mixed seed in the spring. The beds are very large, the plants are allowed to seed themselves and young ones come up in hundreds. We have them in flower nearly the whole year, as the seedlings flower the same season. The colours vary much, from pure white to dark purple.—E. CLEMENTS.

## SWEET PEAS AND OTHER FLOWERS AT SUTTON'S.

**N**O matter what time of the year one visits the extensive trial grounds of Messrs. Sutton and Sons at Reading there is always something of interest to be seen, but it is perhaps during the summer and early autumn months that the grounds are most attractive, as then the numerous annuals and other hardy flowers, for which the firm is so famous, are at their best. We recently inspected the various stocks of flowers there, and to mention all the good things seen would occupy several pages.

Sweet Peas naturally came in for a large share of attention. In addition to all the good standard varieties, which were well represented, some trial rows, the results of various crosses, were most interesting. Readers who are interested in these flowers will all remember the beautiful variety known as Sutton's Queen that the firm exhibited last summer, and of which we gave a coloured plate some time ago. Apart from several other merits that this Sweet Pea possesses, it can claim to be the precursor of a new race, noted particularly for the graceful form, delicate colouring and large size that the flowers possess. We saw quite a number of rows, the result of crossing Sutton's Queen with other varieties, and in practically all of them the parentage of this variety was highly manifest. Some exceedingly pretty flowers were among them, and if they can only be fixed the Sweet Pea world will be

considerably enriched. Gladys Unwin is another sort that has been employed extensively for crossing, and this work has also given some interesting and good results.

Pansies and Sweet Williams are specialities at Reading. A bed of the former, from seeds sown last autumn, were still producing good flowers, a plot occupied with spring-sown specimens just coming on to take their place, so that by sowing twice in a year flowers can be had the whole summer through. It is surprising how easily a display of these charming plants can be obtained from a packet of seed, no glass being required at any time in their career. Sweet Williams are old-time favourites that appeal to all, especially as they have been so much improved during recent years. Sutton's Giant White is a type that attracted our attention. The flowers are pure white, with smooth edges, the huge trusses of flowers reminding one forcibly of Phloxes. Many of the individual flowers easily covered a florin. The firm's large-flowered mixture contains some beautiful varieties with even larger

pink shades so much desired. Of the Opium Poppy varieties, The Cardinal, a bright scarlet sort, and White Swan were a pair that we liked very much. Both have large, beautifully fringed flowers which are produced in abundance.

Clarkias, again, are old favourites that have gained much by careful selection and crossing. In the elegans section we saw a beautiful double variety with rich salmon scarlet flowers that will be a most useful and welcome addition when it is obtainable. Double Salmon is much paler in colour, but a good variety all the same. Brilliant Rose in the integripetala section is really a lovely thing, the dwarf plants being freely clothed with flowers that do not contain any of the objectionable magenta hue found in older sorts. These flowers are excellent for cutting, as also are the beautiful annual Chrysanthemums. Morning Star, Evening Star and Eastern Star are a trio that no garden can afford to be without. The first-named has primrose-coloured flowers, with a deep yellow zone at the base of the petals and a rich yellow eye. Eastern

LUPINES AMONG SHRUBS AT TRUSLEY MANOR, ETWALL, DERBYSHIRE.

flowers, while Sutton's Pink Beauty is a variety with medium-sized flowers of graduating shades of salmon pink.

Sutton's hybrid Nemesis are now well known, the vivid colours and rather compact habit rendering them excellent for massing in beds. Magnificent plants that we saw were the result of seeds sown where the plants were standing. It may not be generally known that these can be easily and successfully lifted when in bloom and potted up for conservatory decoration.

Godetias are hardy annuals well known to most people. A dwarf form of the white Duchess of Albany was particularly good, and a long stretch of that lovely variety, Satin Rose, was most effective. Good as this variety is, Sutton's Dwarf Pink is even more attractive. Crimson King is a deep crimson variety that will appeal to many.

Poppies, despite the transient character of the flowers, are still favourites with us all, and Messrs. Sutton's strain of the beautiful Shirley varieties is particularly rich in those soft salmon

Star is similar, except that it has a prominent dark eye. Evening Star is a uniform deep rich yellow colour. Anchusa Annual Blue is also a plant for every garden where cut flowers are needed. The flowers are practically the same shade of vivid blue as the well-known Anchusa italica.

Californian Poppies, as the Eschscholtzias are popularly called, are just the things for rather poor soil, and they may now be had in a variety of colours. Mandarin is a beautiful rich orange sort that is now fairly well known, Ruby King has flowers of the prettiest ruby shade and Rosy Queen is paler. Miniature Primrose is a small flowered variety specially suitable for the rockery, where it should prove a real gem. Sweet Sultans, Lavateras and Malopes were doing remarkably well. The former is readily obtained in bright yellow, pure white and various shades of lavender blue. We have never seen a prettier Mallow than Lavatera rosea splendens. This has the most delicate rose pink flowers imaginable and forms a most exquisite plant. For poor soil

*Malope grandiflora* is the annual. The strain we saw at Reading was exceedingly good and the plants remarkably floriferous.

Stocks are still grown extensively, their sweet scent rendering them quite indispensable. Messrs. Sutton have nearly discarded the old Brompton, which is notorious for the large percentage of single flowered plants produced, in favour of a strain known as the branching Brompton. The plants of this branch near the ground and each shoot produced a fine truss of flowers, mostly doubles. Spring bedding Stocks form a race of hardy subjects specially suitable for bedding purposes. They are obtainable in various colours and also pure white. East Lothian and the ordinary German or Ten Week Stocks were also seen in good condition, and that beautiful little white flowered variety known as Sutton's All the Year Round, was quite at home in an open bed.

A selected strain of the Shasta Daisy growing beside the ordinary variety was most interesting. It has much larger and more graceful flowers and is even better adapted for cutting than the type. Some hybrid Lupines, the result of crossing *Lupinus arboreus* with *L. polyphyllus*, were of special interest, many of the flowers being of a most pleasing shade of yellow. Those on the look-out for uncommon plants should secure some of these and also the pale yellow-flowered Foxglove known as *Digitalis Primrose Yellow*. The name aptly describes the colour, which, of course, is quite unique in these plants. *Antirrhinum Carmine Pink* is a Snapdragon that will in future find a place in our garden. The colour is the most taking we have ever seen in these old favourites. If space permitted we could easily double the above list of good things seen, but we must just mention some fine sample lawns from seed sown last autumn. The turf of these is now quite close and already possesses that soft carpet-like texture so much desired.

In a range of glass houses we noticed a magnificent strain of the frilled tuberous *Begonias*, the many colours of which provided an optical feast that was worth travelling far to see. No expense or trouble are spared by Messrs. Sutton to ensure that their stocks are as true and good as human ingenuity and experience can make them, and the success obtained from their seeds fully justifies this rigid selection.

## THE ROSE GARDEN.

### TEA ROSE MOLLY SHARMAN CRAWFORD.

**W**HITE MAMAN COCHET has long held a proud position as a white exhibition Tea Rose, although it is really a pale cream variety. Molly Sharmar Crawford is a better white, and will doubtless find its way among the best exhibition Tea Roses before many years have passed. As will be seen by the illustration, it has superb form and depth of petal. It was one of four novelties shown by Messrs. Alex. Dickson and Sons of Newtownards, County Down, at

THE NEW WHITE TEA ROSE MOLLY SHARMAN CRAWFORD, EXHIBITED BY MESSRS. ALEX. DICKSON AND SONS AT HOLLAND PARK ON THE 7TH AND 8TH ULT. (Natural size.)

Holland Park on the 7th and 8th ult., when it received an award of merit.

### THREE GOOD ROSES.

**ROSE RENE ANDRE.**—This, one of the oldest of the *wichuraiana* group, has been remarkably fine this year. I was surprised at the quality of the blossoms which this Rose has

yielded; some were fully 4 inches across. It may readily be imagined what a beautiful picture a young pillar plant bearing such blossoms made, for the colour is a most delightful mixture of pink, yellow and orange, tints it obtains from *L'Idéal*, the pollen parent of the variety. On a tall stem this grand sort is seen to much advantage. The taller the stem the better, for its vigorous growths will soon reach the ground. Ordinary standards of *Réné André* are also most interesting, as indeed all the tribe are; but the absence of a perpetual flowering habit detracts from their usefulness, although we obtain stray blossoms on some of the sorts right through the season. *Paul Transon* is very good as an autumn Rose and it yields splendid large flowers equal to *Réné André*. *Debutante* will also blossom a second time, and its lavender-coloured clusters are always welcome although not very durable.

**ROSE GROSSHERZOGIN ALEXANDRA.** This will be a fine decorative Rose, perhaps surpassing *Kaiserin Augusta Victoria*, which it resembles, for its growth is decidedly more vigorous. This latter will grow well enough in some gardens, in others it is a failure; but the variety under notice should grow anywhere. There is not the exquisite form which we obtain in the older Rose, as the open flowers come rather irregular in shape, but the buds and half open blooms are pretty. It reminds one much of the old Rose *Narcisse*, only that the blossoms are larger. As a standard it is fine, making a good spreading head which cannot fail to be very effective when established two or three years. *Grossherzogin Alexandra* is reputedly a cross between *Merveille de Lyon* and *Kaiserin Augusta Victoria*. There is something about the old Rose *Merveille de Lyon* that enables it to produce grand seedlings. It was from this Rose crossed with *Caroline Testout* that Herr Lambert obtained that wonderful Rose *Frau Karl*

*Druschki*. It would seem that all the *Baroness Rothschild* tribe (of which *Merveille de Lyon* is a conspicuous variety) is capable of yielding great novelty when hybridised. It is said that the late Mr. Henry Bennett obtained that great production of his, *Her Majesty*, by crossing *Mabel Morrison* (a sport of *Baroness Rothschild*) with the yellow Tea Rose *Canary*; if so it is a wonderful cross. But all who are engaged in the fascinating work

of cross fertilising the Rose know full well the wonderful divergence there is in the results obtained.

**ROSE HIAWATHA.**—The lovely golden centres of the half-open flowers of this Rose give that marvellous distinct character to the variety that will place it far ahead of other crimson ramblers. There is an elegance about the beautiful clusters that is wanting in such heavy masses of colour that the old Crimson Rambler produces, and I can almost imagine this newer variety displacing the older sort to a large extent. It may not be generally known that Hiawatha makes a delightful bedding Rose if its growths are supported by about 3-foot Bamboo canes. The shoots may be shortened back to this height when pruning, and they will be covered with glorious wreaths of blossom that in the distance appear like some giant scarlet Verbena. Such plants will produce a number of running growths from the base, which may next year take the place of those now flowering. Hiawatha makes also a delightful standard and half standard, and, of course, it is *par excellence* as a weeper on a 6-foot stem, but as an ordinary standard, in which form it is more easily procured, it is a real boon to our gardens in mid-July, providing that bit of colour needed through the waning of many of the high-coloured Hybrid Perpetuals. It is this later flowering habit that renders both it, Lady Gay and Dorothy Perkins so valuable, and when we have the white Dorothy well established, and perhaps a yellow Dorothy, there will be no need to complain of the want of colour on our pergolas and arches in the August months. The flowers of Hiawatha are so wonderfully durable, which places it at the head of single Roses, for one great fault of Carmine Pillar and Jersey Beauty is the transient nature of their blossoms. Another fact worth noting is that it seems indifferent to rain. P.

## THE KITCHEN GARDEN.

### WINTER GREENS FOR AMATEURS' GARDENS.

**T**HE number of plants of Winter Greens that should be put out depends upon the size of the garden and the number of persons constituting the household. At the present time amateurs will be busy filling up vacant spaces, occasioned by the clearing away of Pea and Bean haulm and the lifting of Potatoes, with plants of Winter Greens. Due allowance must be made for losses through accident and weather conditions, especially frosts.

The number of plants necessary for the supply of six persons from November to June, inclusive, as here given, will prove a reliable guide in the case of fewer or more persons to be provided for. Self-protecting Broccoli, 150 plants; these will be the first to turn in along with Brussels Sprouts, of which 200 plants should be grown. Savoy is also useful for autumn and early winter gathering, and they are always sweeter after being exposed to slight frosts; 250 plants will be required. Broccoli should be planted for gathering from Christmas to June, early, medium and very late varieties being selected for this purpose; 150 plants of each variety, or a total of 450, should be put out. Cottagers' Kale: Of these 100 plants will be sufficient, as nearly all the leaves may be used; and the same number of Sprouting Broccoli will answer the purpose. The best of the produce may be used, and will prove quite adequate for the servants also and visitors. If space does not admit of the planting of the above numbers without undue crowding, it would be better to put in fewer plants and allow them sufficient room to grow in. The soil should be very firm and not too rich, as hardily-grown specimens withstand severe weather better than those with soft, sappy stems and extra large, succulent leaves. Avon.

## THE FLOWER GARDEN.

### SPARAXIS IN THE OPEN.

**O**NE of the chief advantages possessed by dwellers in the South-West is that they are able to grow in the open air plants that in the colder districts have to be cultivated under glass. Numbers of plants, natives of South Africa, New Zealand, Australia, Asia Minor, South America and other portions of the globe, may be seen in as vigorous and free-flowering a condition as if they were growing in their natural homes. The bed of Sparaxis illustrated has been planted ten years and has never been disturbed or manured, yet it never fails to produce a profusion of blossom in each succeeding May. In the same garden it is naturalised on a steep, grassy bank, where it is apparently as happy as its neighbours the Narcissi. Ixias also make a brave display in the spring, the lovely *I. viridiflora* being especially charming.

Other bulbous plants that do well in the district are the Zephyranthes of several species;

Bluebell Creeper, is already in full flower, with self-sown seedlings springing up around it; and around the verandah *Mandevilla suaveolens* is clambering, with tiny buds showing everywhere that in August will have perfected into clusters of scented white flowers. *Cassia corymbosa* will soon be a sheet of deep yellow, and will remain in beauty until late autumn; and in September the South African *Leonotis Leonurus* will be decked with whorl above whorl of scarlet flowers, some of the whorls over 14 inches in circumference. Pages might be written of the tender climbers, shrubs, trees and plants that are absolutely at home in the South-West, but for the present these few short notes must suffice.

South Devon.

S. W. FITZHERBERT.

### TWO BEAUTIFUL ANNUAL FLOWERS.

I do not think many people realise what a charming annual is the *Clarkia*, both for beautifying our borders and for decorating the house. The best kinds are Salmon Queen and the double and single White. The colour to avoid is that maenta shade which is often described

A BED OF SPARAXIS IN MR. FITZHERBERT'S GARDEN.

the blue Chilean Crocus, *Tecophylaea cyanocrocus*, which perfects its gentian blue blossoms in the early spring; *Cypella Herbertii*, with apricot yellow, Tigridia-like flowers, borne through several months; the lovely blue *Marica carulea*; the stately *Watsonia Ardernei*, with tall, white flower-spikes often nearly 6 feet in height; the *Cyrtanthus*, including the white *C. McKenii* and the orange Flambeau; in September the Guernsey Lilies, *Nerine Fothergillii* major, glowing scarlet, and the new pink *N. Bowdenii*; the lovely scarlet *Habranthus pratensis*, from Chili; the crimson *Jacoea Lily*, *Sprekelia formosissima*; and occasionally *Bessera elegans* and *Milla biflora*.

Of rare and tender non-bulbous plants that flourish in Devon and Cornwall an extensive list might be given, but it must suffice to indicate a few. The giant Honeysuckle, *Lonicera hildebrandiana*, is now covered with buds that in August will develop into blossoms 6 inches in length and 5 inches across the mouth. *Buddleia Colvillei* is blooming profusely, and *Abelia floribunda*, both against walls and in hush form, is a sheet of cherry rose. Soon *Mutisia decurrens* will bear its large flowers of glowing orange, and *Bowkeria gerardiana* its white Calceolaria-like blooms. *Sollya heterophylla*, the Australian

in the seed catalogues as "rose," which, when purchased, leads to much disappointment. *Clarkia* can be sown in March and April, either where it is to flower or the seedlings transplanted when 1 inch or so high. The great thing is to allow the plants plenty of room as they are of a branching growth. Twelve inches each way is not too much. One gets no idea of the beauty of this annual when hundreds of seedlings are crowded into a small space. A large clump of Salmon Queen *Clarkia*, backed by perennial Delphiniums, is a most striking sight in the border. *Clarkias* ought to be sown two or three times for succession, as I always find they are valuable plants for cutting and charming for the dinner-table arranged with *Gypsophila elegans*.

Another delightful annual is Sutton's Rose Larkspur; it comes into flower rather later than the *Clarkia*, and is really at its best at the end of August and September. It is invaluable for cutting, lasting well in water. I have always found that it is somewhat difficult to protect the young seedlings from the depredations of the slugs, so I sometimes sow the seed in boxes and transplant them when large enough into their permanent quarters, allowing plenty of space between the plants. P.

## THE FRUIT GARDEN.

### FRUITING VINES IN POTS.

**T**HE Vines shown in the accompanying photograph are two year old canes, that is to say, they have been cut back once, and each cane is carrying from five to six bunches or about 8lb. of Grapes.

To produce canes capable of carrying such a crop the method to pursue is as follows: The very strongest dormant eyes are chosen when pruning the established Vines. The eyes or buds are prepared practically the same as one would prepare a Rose-bud for budding purposes, the only difference being that the old wood is left in the bark and not drawn out as in the case of the Rose. Some gardeners do not split the wood in half as above described, but insert it whole in pieces about 1 inch in length; but my method is the first-named, because there is a greater surface from which roots are emitted and the buds therefore get a stronger start, which is important.

When prepared, and the best time to do this is January, the eyes are laid thickly in saucers of sand, or placed singly in small pots, and pressed in so that the bud is just level with the surface of the soil, and eventually watered in. The saucers or pots should then be plunged into a bottom-heat of 80° with a top temperature of from 65° to 70°. As soon as roots begin to grow well each eye should be potted singly and must suffer no check in this respect. They must afterwards be potted on as required until 7-inch or 9-inch pots are in use, these sizes being found sufficient for the first year. The soil used should consist of the best rich yellow loam procurable, a little lime rubble, wood ashes and either bone-meal or some kind of Vine manure. As the canes begin to ripen off they should be allowed plenty of air and the benefit of all the light and sunshine possible until the leaves begin to fall.

Some of the strongest of the canes will carry a crop the next season, but my practice is to cut all down to three or four eyes or buds. This operation should be performed as soon as the canes have ripened off thoroughly, for if it is

delayed they commence to bleed as soon as they are brought inside to start, and this bleeding is very difficult to stop, hence a great portion of the vitality which should go to support the resulting growths is lost.

As soon as the buds of these cut-back plants have burst into growth the weakest should be rubbed off and the plants repotted, shaking off a large portion of the old soil and potting into such sized pots as will just hold the roots, and again potted on as required into 10-inch or 12-inch pots, using a compost as advised previously. They should be very liberally fed with some good Vine manure specially prepared for building up strong-wooded, short-jointed fruiting canes. I have found Bentley's Vine Border Compound excellent for this purpose, especially the fine grade, this being the more easily assimilated by the roots. This feeding should be withheld as the canes begin to ripen, when they may be placed in the open air and exposed to the full benefit of the sun.

It is my practice to stop the cane when growing to the required length, say, from 6 feet to 8 feet, and so dispense with any pruning back and thus obviate the danger of bleeding. The Vines are brought into a cool house or into a temperature of from 45° to 50° about November to start. At this time water must be very sparingly applied, and indeed great care must be practised in this matter for some time. As the foliage growth is greatly in advance of root action, no manure should be applied until the roots are active, otherwise the soil becomes sour and the roots decay. A capital position is a shelf or narrow stage over hot-water pipes, training the rods up the roof. The temperature should be increased with the progress of growth. As soon as they commence to make new roots a turf may be placed under each pot (the drainage hole having been previously made larger), and the roots will make their way into this. Narrow strips of turf should also be laid around the rims on the tops of the pots. This gives more room for watering, and also soon becomes filled with roots.

They will require copious supplies of water and liberal doses of manure. The finest manure

I have used for swelling up the berries and giving them a perfect finish is Le Fruitier; but too much care cannot be taken in the application of this and in watering; carelessness in these matters will spoil the best crops. Retain as much foliage as possible, for in the case of black Grapes the shade is necessary to give them a good colour and finish. Through a bright spell of sunshine it may be necessary to shade them with canvas or other artificial covering. Artificial manures should be withheld as the Grapes approach ripeness. Their whole general treatment will be similar to that of permanently planted Vines, but more care must be exercised in the matters which have been specially mentioned.

If the Vines are wanted for decorative purposes, they can be grown erect and staked out, or can be trained to any wire support. If it is wished to have them in smaller pots for table decoration, all that is necessary is to split a 6-inch pot in half, making this secure around the cane at the desired height, preferably at a joint where adventitious roots are emitted, filling up with soil made moderately firm. This pot when in position has the appearance of the cane growing through it, and soon becomes filled with roots. When the fruit is ripe and the Vine required, the cane can be severed just below the pot and the growing Vine potted in the desired size and used for decoration.

The Vines in the photograph are growing in 10-inch pots, and the varieties are Black Hamburg, Muscat Hamburg and Grizzly Frontignou. Other varieties which may be grown with equal success are Muscat of Alexandria, Foster's Seedling, Black Alicante, Madresfield Court and Royal Ascot. These Vines could be used for planting out, but our usual practice is to raise a batch each year. This is the most certain way of ensuring a crop. The photograph was taken during June of this year. Such plants are useful for many decorative purposes, and a well-fruited specimen is always interesting and attractive. Many people like to gather their own Grapes, and when these pot plants are available the operation is a very simple one, as the Vines can be taken to any place where they are required.

Ladies especially greatly appreciate this. Of course, the plants must be kept scrupulously clean when required for decorative purposes.

Brocklesby Park, Lincolnshire.

POT VINES AS GROWN BY MR. F. C. STAINSBY AT BROCKLESBY PARK, LINCOLNSHIRE.

## COLOURED PLATE

PLATE 1353.

### ORIENTAL POPPIES.

**D**URING recent years a great deal has been done in the improvement of the handsome Oriental Poppies, as the varieties of *Papaver orientale* are popularly called. Among the best of the new sorts is that known as Jennie Mawson, raised by Messrs. Mawson Brothers of Windermere, and of which we give a coloured plate. The flowers of this variety are held erect on stout stems, and a clump makes a most welcome addition to the hardy plant border. Unlike most Poppies, the variety now under notice travels well, the blooms that were exhibited before the Royal Horticultural Society on June 25 last year having been exposed to heavy rains before cutting, yet they were staged in such excellent condition as to secure an award of merit from the floral committee.

## TREES AND SHRUBS.

## AUTUMN-FLOWERING HEATHS.

**T**HE various autumn-flowering Heaths are responsible for almost as effective a display during the latter half of the year as the spring-flowering sorts produce during the earlier season. In some instances the colouring is richer and more striking than is the case with those which bloom from February to May; but the plants are shorter and denser in habit than such species as *Erica lusitanica*, *arborescens*, *mediterranea* and *australis*, and they do not possess the striking personality of those plants. When, however, large areas are clothed with species such as *cinerea*, *vagans*, *ciliaris* or *Tetralix*, they form a glorious feature, and last in good condition from late July onwards for two or three months.

Some of those most suited for garden work are really British plants, and while some are found in restricted districts only, others are prevalent in almost all parts where Heathworts thrive. Selection has, however, done much in the provision of well-marked forms, and while in a state of nature a species may possess but one prevailing colour, the horticulturist possesses forms which show numerous colour changes.

As is the case with the early-flowering sorts, the autumn ones are most effective when planted in large informal masses, each mass being formed of one sort only or composed of a mixture of several species and varieties. Where room is no object large areas may be given over to such sorts of *E. cinerea* or any of those previously mentioned; but for small gardens a very pretty bed may be made up of a mixture of the various sorts, half-a-dozen or so specimens of each being grouped together. No elaborate cultural details are required providing soil fairly free from lime is given, with, if possible, a little peat at planting time. When established it is a good plan to go over the plants in spring and remove the old flower-heads; this has the result of keeping the plants dwarf.

The largest growing of the autumn-flowering section are *E. multiflora*, *E. stricta* and *E. vagans*. The latter is well known under the common name of Cornish Heath, and is met with in a wild state in the southern parts of Cornwall, being very abundant in the immediate neighbourhood of the Lizard. It is found from 1 foot to 3 feet in height, and from July to October may be found bearing a profusion of pink flowers. There is a variety called *alba* with white flowers, while the varieties *grandiflora* and *rubra* are distinguished for their floriferous character and dark coloured blooms respectively. *E. multiflora* is somewhat similar in appearance, but it is more floriferous than the typical *E. vagans*. Like the foregoing, *E. stricta* is a South European plant. It is less dense in habit and more upright. The flowers are red. Although it is stated to be somewhat tender it stands uninjured at an elevation of 1,100 feet in Derbyshire. Of the dwarfier plants, *E. cinerea* is the best known. It grows from 6 inches to 12 inches high and is resplendent in autumn with its rich reddish purple flowers. There are numerous varieties

which are recognised by means of their white, dark purple, red, rose or scarlet flowers, and they are known respectively as *alba*, *atropurpurea*, *atrosanguinea*, *coccinea* and *rosea*. *E. ciliaris* is a somewhat weak scandent habitated plant with hairy leaves and rather conspicuous red flowers. The variety *mawiana* is of denser, more erect habit, with upright, branched inflorescences of dark red blossoms; it is a very conspicuous variety and worthy of extended culture. *E. Mackailii* is a pink-flowered Heath, showy in its season. The cross-leaved Heath (*E. Tetralix*) is interesting by reason of the curious arrangement of the leaves; it has reddish flowers, but there are forms in which the flowers are pink and others white.

Taken as a whole, these several Heaths constitute a most important item in garden

are pure white, more so, indeed, than in the case of the old favourite *Viburnum opulus*.

Evidently this shrub is not well known yet, judging by the enquiries made. T. ARNOLD.

*The Gardens, Cirencester House.*

## THE GREENHOUSE.

## A RARE PLANT IN GARDENS.

(WITSENIA CORYMBOSA.)

**T**HIS pretty South African plant is extremely difficult to procure in this country, and after vainly endeavouring to purchase it from British nurserymen I eventually obtained it from the Continent. It is a very rare plant in gardens, and I know none at the present time except my own where it is grown in the open. It was introduced into this country from South Africa rather over 100 years ago. When New Holland, hard-wooded plants were largely grown under glass it was fairly common in greenhouses, but has now, apparently, quite passed out of cultivation. In conservatories, in the old days, it generally flowered late in the autumn, its Gentian blue blossoms contrasting prettily with the *Chrysanthemums* then in bloom. The plant, which is allied to the *Irises*, is very distinct in habit, the stem being erect and of a firm, woody texture, while the sword-shaped leaves are arranged in a fan-like form at the extremities of the shoots. My plant has now been in the open for three years, and is growing in sandy peat at the foot of a south wall. In the winter it is protected by evergreen branches and has come through the last two winters, which have been exceptionally severe for this locality, without harm. The branching clusters of starry, deep blue flowers, almost 1 inch across, protrude beyond the tips of the leaves, and are very freely borne. Last year the plant in question bore fifty-five flower racemes, each holding from fifty to sixty blossoms, and was an exceedingly pretty sight when in full bloom. Curiously enough this specimen flowered in August, whereas under glass it usually bloomed in November. It is now 2 feet 2 inches in height. It is a slow grower and appreciates abundant moisture during the summer months. This *Witsenia* is now

WITSENIA CORYMBOSA, A RARE AND INTERESTING GREENHOUSE PLANT.

adornment during autumn, and would well repay attention from those horticulturists who do not already possess a collection. K.

## A GOOD FLOWERING SHRUB.

*VIBURNUM PLICATUM* is one of the best flowering shrubs we have in our gardens. Few will last so long in flower, and this season it was in full beauty with us for a month. It was said a few years since that it was useless planting this shrub in the full sun, as the leaves would scorch to such an extent as to weaken the growth. This, however, has proved wrong. I know of no shrub which enjoys the sun so well; indeed, this is absolutely essential in order to ripen its growth and cause it to flower freely. No flowering shrub found so many admirers as this during the past season here, and many enquiries were made as to name and treatment required. The flowers

held to be an *Aristea*, but is far superior to *Aristea Ecklonii*, also grown in this garden, its flowers being considerably larger and remaining open the whole day, whereas those of the *Aristea* generally close about two o'clock and are far less profusely borne. It may be propagated by removing the small leaf-tans at the base of the stem, each with a little of the old wood clinging to it and placing these around the edge of a pot in very sandy peat, surfacing the pot with a layer of sand and watering well. A bell-glass must be placed over the pot and the cuttings should be shaded and kept close until rooted. If gentle bottom-heat be applied it will induce quicker growth.

The plant is worthy of a place in any garden, but in most localities it would probably need the protection of a cool greenhouse or frame, especially during the winter months.

*South Devon.*

S. W. FITZHERBERT.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**CHRYSANTHEMUMS.**—What are known as crown buds should now be developing in the points of the shoots, and those who wish to produce large and attractive flowers must retain the buds as soon as they are large enough to handle. To retain a bud is to break out the small shoots that evolve immediately round about it. It is not wise to break these out all at one time, but to let it be a gradual process. Plants that have well filled their flowering pots with roots—and this is generally determined by the speedy drying of the soil—should never be allowed to suffer for want of water, and in the case of plants where the buds have been retained feeding with manure water should now be the rule. In our case we apply the liquid manure in weak doses and often.

**Cold Frames.**—These are a most valuable adjunct of the garden, and in many cases they are not much used at the present time. I make a rule to give both the frame and frame-lights a coat of paint at this season, this preserving them and rendering the surroundings sweet for the occupants when the frames are brought into use. I am just potting up seedling Cinerarias and Primulas. The earliest batch require larger pots at the present time, and these plants must have cool conditions such as the cold frame affords. The present is an excellent time to sow the seeds of a large variety of hardy perennials. I make good use of seed-pans and shallow boxes, sowing the seeds thinly in these, and, when the seedlings are sufficiently large to handle, prick them off in other boxes preparatory to planting them in specially-prepared beds outdoors.

**Flower Garden.**—This should be a busy period in layering Carnations and Picotees, and even the garden Pinks that are so fragrant and beautiful may also be layered, although it is customary in many gardens to break off pieces with a small heel attached and to root these in a shady border outside, or in frames where they may be shaded. Dahlias are growing freely, in consequence of which I am giving frequent applications of weak liquid manure. It is important that these plants be staked and tied with more than ordinary care, as their growth is so very rapid, and the branching shoots so cumbersome, that unless they are

1.—ROSE SHOOT OF THIS YEAR'S GROWTH. IT IS FIRM AND WILL MAKE TWO CUTTINGS.

secured in good time many valuable shoots will be lost. Weak and superfluous growths should be cut out to let air into the plant, by which means the growth becomes ripened and better flowers develop in consequence. Delphiniums and other flowering plants that are past their best should have the old flowering spikes removed, as they draw upon the resources of the soil so very considerably, which is undesirable when seed is not required. Delphiniums should flower again later on in the year when this treatment is afforded, and their blossoms are often much valued.

**Greenhouse and Conservatory.**—Winter-flowering Carnations must be staked and tied, and any varieties that the grower is short of may now have the cuttings inserted. The beautiful Funkias, with their showy foliage and flower-spikes, may be stood outside after the blossoming period. In this way they get a fresh stimulus and invariably do well subsequently. Hydrangeas should be propagated by cuttings also at the present time. I always insert the cuttings singly in small pots, placing them in a propagating frame or under a bell-glass, in which case they root very readily. The present is an excellent time for sowing Mignonettes for winter flowering. I always sow the seeds thinly, and keep the plants cool in their early stage, and thus avoid them becoming drawn.

**Vegetable Garden.**—For late spring and early summer supplies, sow the seeds of the spring Cabbage and Coleworts. The seed germinates quickly at this period, and if not sown too thickly the plants may be pulled later on with little inconvenience to themselves. Turnips sown some few weeks back will now need thinning. They should be left at least 6 inches to 8 inches apart if the plants are to do well, and if this be done speedily the welcome roots will be available in a little while. For later supplies and for winter use a further sowing may be made at the present time. Onions that it is hoped to lift in

the near future should have the tops bent over close to the neck of the bulbs, as this has the effect of causing them to mature much quicker, and when the roots are ready and well ripened it is a good plan to lift at once. Early and semi-early Potatoes should be lifted as soon as possible. It is useless to leave them in the ground once the crop has matured, as the same quarters may be turned into use again and planted with Winter Greens or other vegetables. Lift when the weather is dry. Mushroom beds outdoors should be made at the present time. An article on this subject appeared in these pages recently, and this should be followed in every detail. D. B. C.

### PROPAGATION OF ROSES BY CUTTINGS AND "EYES."

We recently dealt with the budding of standard Roses, but as there are so many beginners who would perhaps prefer to raise Roses by other means, we have deemed it wise to give a series of illustrations showing how Roses of all kinds may be raised by cuttings and by the aid of "eyes." Roses are very easily propagated at the present time by cuttings, and this work may be continued for some weeks to come. Much depends upon the selection of the material used. Cuttings are made from shoots of the present year's growth, and they should not be too stout, but be nice and firm. The stoutness of a quill pen is an ideal size. It is possible, of course, to obtain shoots of varying length, but the illustration shown in Fig. 1 is a fair example of what

3.—THE TWO PIECES OF GROWTH MADE INTO CUTTINGS. NOTE THAT THE LOWER LEAVES HAVE BEEN REMOVED.

may be obtained from any ordinary dwarf plant of a Hybrid Perpetual Rose. It will be observed that it is a growth on which blooms have developed, and of sufficient length to make two or three cuttings. The length of the cuttings should be anything between 4 inches and 9 inches, but 6 inches is the most convenient length. A sharp knife, of course, is indispensable, as the cutting through of the stem must be quite clean. The illustration in Fig. 2 shows the same shoot as represented in Fig. 1 divided into three distinct pieces. The two lower pieces of the shoot will make excellent cuttings, while the small portion on the top is of no use whatever, and should be discarded. With the other two proceed to remove the leaves from the two lower joints leaving three to four leaves above in each

2.—THE SAME SHOOT SEVERED INTO SEVERAL LENGTHS FOR CUTTINGS. THE SMALL PIECE AT THE TOP IS USELESS.

4.—PORTION OF SHOOT, SHOWING METHOD OF CUTTING OUT A BUD OR "EYE."

instance, and if the shoot be cut through immediately below that point from whence the lower leaf was removed such shoot will make an ideal cutting. The prepared cuttings as portrayed in Fig. 3 show the same shoots as represented in Fig. 2, with the leaves trimmed off and the cuttings prepared in readiness for their insertion in proper soil.

We prefer to embed our cuttings in a cold frame, and in such a receptacle we usually place on the surface soil 3 inches to 4 inches of light sandy soil specially prepared. This soil is passed through a sieve with a half-inch mesh, and the ingredients thoroughly well mixed before spreading the compost on the surface. This should be levelled and beaten down firmly preparatory to the planting of the cuttings. Insert the cuttings 3 inches apart to the depth of the second joint, from which it will be remembered the leaves were removed. Press the soil firmly round about the base of the cuttings, otherwise the chances are they will not root. Give them a good watering in by the aid of a fine-rosed can, and keep the cold frame closed, shading the same for a few weeks, by which time they should be rooted, when air must be gradually admitted, thus inuring them to more hardy and natural conditions, when their progress will go on unhindered.

In warm weather sprinkle the cuttings lightly with clear water occasionally, as this maintains them in a fresh condition and also checks the attacks of insect pests which might otherwise be found troublesome. If no cold frame is available the cuttings may be placed in pots and covered by hand-lights or bell-glasses, but in each case the cuttings must be shaded from the bright sunshine and be treated to a sprinkling or syringing overhead with clear water at intervals. It may be possible that some beginners who are anxious to raise a stock of Roses on their own roots have no cold frame or even a hand-light. They need not be discouraged, however, as Roses may be raised from cuttings quite easily outdoors if a rather shady border be selected in which to make up a bed of light, sandy soil and the cuttings be inserted therein. Early October is, however, the best time for planting cuttings in the open ground.

There may be growers who prefer to raise a stock of Roses on their own roots from what are known as "eyes." This is a very easy and simple method, and quite a number may be raised from a comparatively small quantity of Rose shoots. To propagate Roses by "eyes" the growths should be removed in the form of a shield, as clearly depicted in Fig. 4. Here, it will be observed, is a portion of a shoot with three or four Rose leaves and "eyes" in embryo

in the axils of the leaves. If the leaf-growth be cut out in shield-like form, as clearly depicted in the photograph in the severed portion above the stem. These "eyes" may be inserted in sandy soil, and will root with comparative ease. The leaf must be severed intact, and not be interfered with in any way. We prefer to insert these "eyes" in very sandy soil in pots or shallow pans, just bringing the shield with the "eye" thereon immediately underneath the surface soil, which, by the way, should be covered with coarse silver sand, and the soil pressed firmly round about them. If the soil be moistened with care the pots or pans may be placed under a hand-light or bell-glass or in a propagating frame where moist conditions may be made to prevail. In this case, too, the "eyes" must be shaded from the sun and the leaves sprinkled twice a day with clear water.

#### SUITABLE SOIL FOR ROOM AND WINDOW PLANTS.

(Continued from page 365.)

**SAND.**—Everybody knows what sand is, but for gardening purposes there is sand and sand. Two sorts of sand should be obtained whenever possible, both white, but one so coarse that it is possible to count the component grains; the other sufficiently fine to pass through a coarse pepper-sifter. The coarser sand is indispensable in promoting porosity and free drainage for water in the compost. The finer sand is employed to sprinkle on the surface soil of pots to prevent green, moss-like growth forming, and is also used in striking cuttings and sowing fine seeds. The other ingredients which enter into soil or compost occasionally call for no special mention here, but may well be referred to when their employment is indicated.

#### SOIL SUBSTITUTES.

Having considered the matter of suitable soil at some length (page 353), we may well give a little thought to soil substitutes, *i.e.*, substitutes that can be employed when the more orthodox or better suited ingredients are not forthcoming. Of course, it will be understood that the use of these substitutes is only advocated when the proper soil, leaf-mould, &c., are unobtainable, though some of them, dried manure, for instance, are, to use the shopkeeper's phrase "just as good."

**Substitutes for Loam.**—The easiest way to get a substitute for loam, or, in fact, for the whole of the potting ingredients, is to consult a good nurseryman, state to him plainly the facts of the case, and negotiate with him for a bushel or sack of compost. In this case I would counsel the purchase of two kinds of compost, one for flowering plants, the other for foliage subjects. Let me, however, advise readers to obtain the various ingredients and mix their own composts. They will learn to take as much pleasure and feel as much pride in compounding the various soil concoctions as does a cook in the evolution of one of her *chefs-d'œuvre*. Gardening without compost mixing is like photography without developing—like love without kisses. Instead, then, of consulting the nurseryman, cast round for substitutes nearer home. In my part of the country we can obtain an excellent loam substitute almost for the asking. This is the tufts of grass called tussocks, raised in the grass meadows by ants. These are cut off level with the ground by the farmer's men with stout hoes and generally left lying in a heap in the fields. When decayed they make an excellent potting compost, and one that is, undoubtedly, the richer for the deposit of formic acid left in the soil by the ants. Failing these tussocks, most dwellers in country, and even in suburban districts, have the chance of acquiring road trimmings at a very moderate figure. By road trimmings I mean the portions of grass and soil removed in the autumn from the banks, ditches and greens by the roadside by the orderly men employed by the local authorities or county council. These trimmings

often contain a goodly proportion of road grit, and also, when stored by the roadside, horse manure, and form an admirable substitute for loam when rotted down. If all other sources fail, recourse must be had to the garden soil, and often this may be made into a not-to-be-despised compost. Its chief objection generally is its fineness, which causes it to lie too closely in the pot and impedes the free passage of water. The addition of dried and thoroughly-decayed horse manure, coarse sand, broken brick, or lime rubbish will counteract this want of porosity.

**Substitutes for Leaf-mould.**—The most natural and the best of these is peat; it is, however, generally so much more expensive than leaf-mould or more difficult to obtain, it should only be used in case of necessity. The chief function of peat and leaf-mould is to build up the stem and leaves of plants, and no compost can be considered complete in which both are lacking. Decayed horse or stable manure, from which all traces of straw have vanished, is another splendid substitute for leaf-mould. It should be thoroughly dried in a warm place and then rubbed through a fine-meshed sieve. This will reduce it almost to powder, in which state it may be used at the rate of one-sixth part to the bulk of compost. Only one other substitute need be mentioned, and that is rotten wood. When this is in a dry and powdery form it is an excellent plant food, and used at the rate of one part to four parts of compost gives good results.

**Substitutes for Peat.**—Although peat is a good substitute for leaf-mould, leaf-mould can scarcely be considered as a good substitute for peat. The latter is employed almost as much for its elastic, moisture-defying properties as for its manurial ones. Leaf-mould, on the other hand, possesses none of the elasticity or springiness which makes peat so valuable for Ferns and what are known as hard-wooded plants, and is easily destroyed by water, whereas peat is practically indestructible as long as pure water only is brought into contact with it. All things considered, there is only one really satisfactory substitute for peat, and that is the fibrous part of good loam.

**Substitutes for Sand.**—As sand has no fertilising or manurial properties whatever, but is used solely to promote porosity and drainage, it is obvious that any sharp, not easily caked, substance may displace it in the potting compost. Charcoal, broken into portions as large as Peas, is the favourite substitute, followed by crushed mortar rubbish, broken soft brick, road grit, sweepings from gravel walks and sifted coal ashes. The latter three are cheap and generally easily obtainable, and answer quite as well as sand for potting large specimens or plants which grow quickly and only occupy their pots for a few months. Coal ashes, broken brick and lime rubbish should all be sufficiently fine to pass through a quarter-inch meshed sieve, and all should be kept dry. E. J.

5.—A NUMBER OF BUDS OR "EYES" INSERTED IN LIGHT SANDY SOIL IN A SHALLOW PAN.

## THE TOWN GARDEN.

**SWEET PEAS.**—In one respect these flowers are similar to Roses, they do not thrive as well in town gardens as we should like. This season my plants have flowered satisfactorily, but the stems have seldom exceeded 14 inches in length, although a few have been as much as 17 inches. The plants are now passing over as far as the first crop of flowers is concerned, and I am about to cut them hard down, with a view to the production of new shoots and additional blooms in September. Each one is cut down to within about 20 inches or 2 feet of the ground, and the plants are subsequently generously watered and fed, and it is surprising how quickly they will respond to this treatment, especially if it is found convenient to hose them after every hot day. The disadvantage is that so many growths start away, and it is imperative that the majority of these shall be removed, or it is quite certain that the rows will become such a perfect thicket that it is impossible for beautiful flowers to be produced. Plants from late sown seeds which are still in full vigour should have water and liquid manure as may be deemed necessary, and the blooms must be kept closely picked.

**WINDOW BOXES.**—These demand regular attention if they are to produce a bright and attractive display for several weeks. It is thought by some amateurs that they call for almost more time than the results merit, but this is not so, for if they are neglected they soon become shabby and are then the reverse of an ornament to a house. The grower who attends assiduously to the removal of dead and dying blooms and leaves, and who sees that the soil never becomes as dry as dust, will derive the utmost satisfaction to himself as well as conveying pleasure to others. It will probably be wise to have recourse to the use of weak liquid manure or to light applications of concentrated fertilisers occasionally from now onwards, and, provided that these matters are attended to with the judgment to which their importance entitles them, it is perfectly certain that the efforts put forth will be generously repaid in the near future.

**ROMAN HYACINTHS.**—It will soon be possible to procure bulbs of these most exquisite plants, and the sooner the earliest can be potted up the better, as it is impossible to have blooms too soon or over too long a period. If only three pots can be made up at a time in succession at intervals of about three weeks, the results will be most pleasing, as there are few plants so easily grown which bloom at such a welcome season of the year. Procure sound bulbs from a reliable source and place four in each 5-inch pot, and satisfaction is bound to accrue. A suitable compost consists of three parts of loam and one part of leaf-mould, with an eighth of sharp sand all thoroughly mixed; the pots must be well drained and a little moss should be placed over the drainage material. In potting, care is essential that the soil beneath the bulbs is made firm, but not so hard that the roots will not penetrate it, as when this is the case they are lifted right out of the pots; when the operation is completed the nose of each bulb should be nicely showing through the surface. After potting they should be plunged in a bed of Cocoanut fibre refuse or put in a dark place so as to allow of roots being produced in advance of leaf and flower growth. Double Roman and Paper White Narcissi should be dealt with in a similar manner, potting up in succession in order to maintain a protracted display of blooms. Of the two the second-named is justifiably the more popular, but the double flowers are always welcome and they must never be omitted from the bulb order. These bulbous plants will stand reasonable forcing, but it is imperative that this shall not be had recourse to until such time as the plants have made good root progress by a sojourn in the dark.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## HARDY FRUIT.

**FRUIT-ROOM.**—If not already done, let the fruit-room have a thorough cleaning. Scour the benches with soap and hot water. Any fruits, such as Peaches and Melons, should be taken out while the process is in operation, and subsequently leave plenty of air on the ventilators. These can always be left open at this season if the outer covering be of perforated zinc.

**Raspberries.**—Norwich Wonder, Superlative, Hornet, Baumforth's Seedling and Semper Fidelis have done well this season, and the fruits have been very fine; these are a good selection for anyone making a new plantation. Where the fruit has been all gathered cut out the old canes so that more light and air can reach the new ones, which should then be tied up and the roots mulched with any manure, such as hot-bed refuse. This will keep them nice and moist and in a growing condition.

**Strawberries.**—Plant these out as soon as the ground can be made ready for them. Give plenty of room, or plant thicker and take out every other one after the first year. Make the plants firm in the soil and see that they do not suffer from want of moisture. Old Strawberry beds can now be destroyed. The old plants should be raised with a fork (not cut off) and burnt, and the ground cleaned and made serviceable for late Broccoli or similar crops.

## KITCHEN GARDEN.

**Seed-sowing** will be an important item for the next few weeks. Good Cabbages for spring cutting are Carter's Early, Heartwell, Model, Sutton's Earliest, All Heart, Tender and True, Favourite and April, and they form a good succession. Quantities of Turnips should now be sown for the autumn and winter supply, making several sowings at intervals of a week, according to the climatic conditions. Spinach may be sown. The ground should be made rich for this crop and the plants afforded plenty of room; sow again in the third week of the month. Sow Onions Ailsa Craig, Record, Tripoli and White Spanish. These ought to be in by the end of the second week, unless the weather is very hot and dry.

## PLANTS UNDER GLASS.

Sow a good batch of Mignonette. Place the seed in 4½-inch and 6-inch pots, which should be filled with rich soil. When the seedlings appear reduce them to about five, and if large spikes are wanted keep all the lateral growths picked off.

**Roman Hyacinths.**—As soon as these are received pot up a good batch. Use fairly good soil, and place them in an open space under a wall or shed and cover over with 6 inches of fine ashes. Early varieties of Narcissi should be treated the same as Roman Hyacinths.

**Greenhouse Plants** in flower should be kept cool and shaded on all bright days. Keep climbers clean and in a presentable condition. Water with manure water all plants carrying quantities of bloom. Cut down fancy Pelargoniums as soon as the wood is ripe enough to make cuttings for next season's stock.

**Carnations** should be exposed now for a month or two, according to the weather. I find the winter or perpetual varieties get very much stronger by being exposed. The earliest batch now filling the flowering pots with roots should be afforded soot water occasionally, and any plants that require stakes must have them at once.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**EARLY-FLOWERING BULBS.**—As soon as the Roman Hyacinths, Freesias, double Daffodils and other bulbs which usually flower early come to hand get them potted and plunged outside in ashes or Cocoanut fibre. By potting early the flowers come stronger and are produced early without forcing. Early-flowering bulbs are mostly grown in rather small pots, as they are wanted for the rooms, and the 4½-inch or 5-inch is the best size for them, but for the conservatory, where it is necessary to have masses of one colour, an 8-inch pot filled with Roman Hyacinths, double Narcissi or Freesias make a conspicuous object. The compost for bulbs should be sweet and open. Two-thirds loam, one-third old Mushroom manure or good leaf-mould, with plenty of sand, suits them well.

**Schizanthus.**—Where this useful plant is required for an autumn display a sowing should be made at once. Sow the seed thinly in a pan filled with light compost, placing it in an unheated frame until the plants are large enough for pricking out; three to five may then be pricked off into a 5-inch pot, in which size they will flower. A cold frame is a most suitable place to grow them in, and when required to bloom in the autumn transfer the plants to the warm end of the greenhouse or conservatory.

## FRUIT UNDER GLASS.

Owing to a sudden change from sunshine to dulness extra judgment and care will be necessary in the management of houses containing crops of Hamburg Grapes and in which no fire-heat is being employed. Moisture must be supplied in very small quantities only, and in cases where plants occupy the house no further supply than that which is given by watering the plants will be required.

**Melons in Frames.**—Melon plants now swelling off crops of fruit in frames must not be treated to overhead syringing during the prevalence of dull, sunless weather, nor must the surface dampings be practised. If during the hot weather water was regularly supplied, the plants will not be liable to suffer in this respect for some little time to come. Should cauter make its appearance the old method of applying lime in a dry state to the affected parts must be resorted to.

## KITCHEN GARDEN.

**Winter Spinach.**—As regards the date for sowing this crop the cultivator must be guided by circumstances. The value of a good breadth of this vegetable throughout the winter months is great. To keep up a supply till the spring sown comes in I advise two sowings, one now and another a month later. The earlier sowings will give the early winter supply and the later will bridge over an awkward period should a warm spring follow a mild winter.

**Late Broccoli.**—No time should be lost in getting out a good breadth of late Broccoli. The present planting may be considered fully late, but from close observation I have noticed that the smaller plants have pulled through severe winters when the larger ones have been killed.

## FLOWER GARDEN.

This has been a bad season for getting up seeds of perennials and biennials. A few of the quick-flowering annuals may still be sown for autumn blooming. These will include Nemophilas, Virginian Stocks, Clarkia pulchella alba, &c. Where seeds have failed from drought sow again now. Intermediate Stocks are lovely for early flowering. Sow thinly, pot up in autumn and keep in cold frames during winter. Only a part of the stock need be potted. Very often they winter safely outside.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## NEW PLANTS.

**STANHOPEA TIGRINA SUPERBA.**—*Stanhopea tigrina* is one of the most handsome Orchids known, but the variety now under notice even surpasses the type in size and colour markings. The large broad sepals and narrower petals have their rich cream ground colour beautifully marked on the basal portions with the deepest rich maroon crimson. The huge labellum and arching column have the paler cream ground thickly besprinkled with maroon dots. The flower shown measured about 7 inches in diameter, and was on a most healthy plant. Exhibited by Messrs. Charlesworth and Co., Heaton, Bradford. First-class certificate.

**Odontioda Thwaitesii.**—This is a very pretty little member of a useful family. The flowers are of ordinary size and shape, the sepals and petals being of a deep velvety maroon colour. The labellum is comparatively large, and is conspicuous on account of its magenta-carmine colour, the base and the column being of a rich yellow hue. Shown by R. G. Thwaites, Esq., Chessington, Christchurch Road, Streatham. Award of merit.

**Angrycum angustum.**—This is a native of North-East Rhodesia, and will probably prove a useful addition to this small family. The flowers are small and pure white, with very long, drooping spurs. The blooms are sparsely produced on a rather slender, arching stem. The plant has leaves and the aerial roots characteristic of the genus. Shown by Sir Trevor Lawrence, Bart. Award of merit.

**Epidendrum costatum.**—As shown this is a dwarf species, producing small flowers of a chocolate crimson hue, the labellum having a blotch of dull green in its centre. Shown by Sir Trevor Lawrence, Bart. Botanical certificate.

**Geodorum purpureum.**—A plant with large, Calanthe-like foliage and a raceme of small, white flowers with the scoop-like labellum dotted freely with tiny purple dots. It is a dainty little subject and should be useful. Shown by Sir Trevor Lawrence, Bart. Botanical certificate.

**Nelumbium speciosum var. Osiris.**—This is one of the most beautiful and fascinating aquatics of our acquaintance, and a plant to be grown by all. The *Nelumbium* or "Sacred Bean" is well known for its giant leaves and flowers, and the above-named variety is a splendid advance on the type. Frequently the huge peltate leaves reach a diameter of 2 feet and the handsome blossoms about half that size, and we doubt not the new-comer will quite equal these measurements when fully established. The blossoms as shown were about 10 inches across, the petals of a clear rose colour, deeper at the tips and white at their bases; a really superb variety whose beauty must be seen to be realised. The flowers of the *Nelumbium*, like the giant leaves, are borne on 3-foot-high stems, and these, standing clear above the surface of the water, are seen to the best advantage. Exhibited by Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. J. Hudson). First-class certificate.

**Astilbe Arendsii Ceres.**—A very beautiful variety, with plume-like inflorescences of a deep pink colour.

**Astilbe Arendsii Pink Pearl.**—Quite a distinct variety and of a pale pink hue. These were shown by M. Georg Arendt, Rosdorf, Germany, and each received an award of merit.

**Summingia hybrida Dr. Maxwell Masters.**—This is reputed to be a bigeneric hybrid between *Gloxinia* and *Gesnera*, the rose-coloured flowers somewhat resembling a drooping *Gloxinia*. The foliage is handsome and quite distinct from the *Gloxinia*. Exhibited by M. Ernest Benary, Erfurt, Germany. Award of merit.

**Begonia Kewensis.**—A white-flowering variety of considerable freedom, and a plant well suited for growing in baskets and in other ways where plants of drooping habit are required. From Messrs. James Veitch and Sons, Limited, Chelsea. Award of merit.

**Coriaria japonica.**—A valuable and ornamental berry-bearing shrub, especially suited for growing against a wall or even in open positions in the more favoured parts of England. The reddish orange or coral red berries, which are freely produced in axillary clusters, render the plant decidedly attractive. From Mr. M. Prichard, Christchurch, Hants. Award of merit.

**Carnation Cardinal.**—A superb border variety of a rich clear scarlet, an ideal flower in every way, and without doubt the finest type of a scarlet self at present known.

**Carnation Splendour.**—A border variety of a clear bright purple colour, with excellent substance and form.

**Carnation Hercules.**—This is one of the largest-flowered varieties we have seen, the colour being of a maroon-crimson shade. This variety is said to be the result of crossing an American tree variety with one of the Malmaisons. The above set of three varieties were from Mr. James Douglas, Great Bookham, Surrey, and each received an award of merit.

**Rose Lady Godiva.**—A very pretty variety of the wichuraiana group, the medium-sized blooms being fully double and of a pink colour in the centre, shading to a flesh tone at the edges. From Messrs. Paul and Son, The Old Nurseries, Cheshunt. Award of merit.

All the above were shown before the Royal Horticultural Society on the 21st ult., when the awards were made.

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Sweet Pea plant for examination (Alert).**—Your Sweet Pea plant is attacked by the disease commonly known as "streak." What it is or by what it is caused no one seems to know. We believe that the National Sweet Pea Society are investigating the matter. Last year we tried all sorts of fungicides and insecticides, but none did any good. The only thing to do with an affected plant is to pull it up and burn it as soon as the disease is noticed. We hope that some of our scientists will soon discover a remedy or at least a preventive.

**Delphiniums, Clarkias and Sweet Peas for examination (E. S. B., Germany).**—We have carefully examined the portions of plants that you send, and can find no trace of disease, hence we come to the conclusion that the trouble is of a local character. Do dogs have access to the garden? If so, they may be responsible for the mischief. The obvious remedy if this is so is to keep out the dogs. It may be that the soil in those particular spots where the plants turn yellow contains some injurious substance, but if this is so it ought not to affect plants for three years in succession. The only thing that we can suggest is to water the plants with weak solutions of any nitrogenous manure and thus try and induce them to grow out of the trouble. Soot water for Sweet Peas or any other plants should be diluted until of a golden brown colour. The best way is

to make up a strong solution by placing soot in a canvas bag and immersing the whole in a tub of water, allowing it to remain for a fortnight, shaking the bag round well each day. Dilute as required for use. For a row of Sweet Peas 6 yards in length you could safely use 12 gallons, diluted as advised, once a week, first watering well with clear water.

**Planting a bank (A. S. K.).**—In all the circumstances we think you might succeed in naturalising such things as Snowdrops, Crocuses and a number of single Trumpet Daffodils, such as *Princeps*, *Golden Spur*, *Queen of Spain*, *Pallidus precox*, *Poeticus ornatus* P. fl.-pl., *Horsfieldii* and any of the single incomparabils. In addition you might also plant *Muscari conicum*, one of the most beautiful of blue flowered plants. The bulbs should be planted in autumn, quite thinly and very irregularly, and when completed sow the bank with grass seed. In this case the grass should not be cut till the foliage of the bulbs has died down.

### FRUIT GARDEN.

**Cherries withering on trees (F. M. D.).**—Both branches sent seem to indicate by their half-withered appearance that your trees are suffering from gumming or canker, or from extreme dryness at the root, either of which would account for the wasting away of the fruit and the damage to foliage. If our surmise is correct, the remedy in the first two cases would be to replant your trees in better soil this autumn (end of October), and in the latter case to give a copious supply of weak liquid manure once a week and to place a mulch 2 inches thick on the surface of the soil as far as the roots extend.

**Strawberry fruit failing to swell (J. H. M.).**—The flowers of your Strawberry plants appear to us to have been destroyed by some species of mildew, which has also blackened and killed the stalk of the flower-spike down to its base; but, strange to say, the leaves you sent appear healthy and unharmed. Have the plants been suffering from dryness at the root while in flower? If so, this condition would be ruinous to them at that stage, and would, moreover, be a strong encouragement to a fungoid attack. The variety Leader being exempt from injury may be accounted for by its being an exceedingly hardy and strong-growing variety. We cannot name varieties of Strawberries by their leaves. If you can send a sample fruit as well as a leaf we will endeavour to do so.

**Berries of Foster's Seedling Grapes diseased (T. R.).**—Foster's Seedling Grape is one of the easiest Grapes to grow of any we have. Under ordinary conditions of treatment nothing comes amiss to it. We think you have overdone the Vines with artificial manures, causing a certain cessation of healthy root action. Withhold any further supply for the present, and ventilate more freely day and night, so as to give the Vines more rest for a time, when we hope the mischief will be abated.

**Cherry fruit not swelling (Anxious).**—The cause of the Cherries refusing to swell may, no doubt, be attributed to imperfect fertilisation of the flowers, in consequence, we think, of injury to the bloom by frost or by the long continued spell of cold weather at the time of flowering, and the cause of the strong growth of branches they are now making is in consequence of a lack of restraint of growth which the swelling of a crop of fruit would have exercised. We should at once cut all the side shoots emanating from the main shoots to within seven leaves of their base, and the main shoots we should shorten by one-third of their length. The cause of the tips of the shoots of your other tree dying is, we think, because the roots have penetrated to an uncongenial subsoil. The application of lime was quite right, as the Cherry luxuriates on lime or chalk land.

### KITCHEN GARDEN.

**Celery damaged (F. D.).**—Your Celery is suffering from a bad attack of the Celery fly. A dusting in early morning (when the leaves are damp with dew) with soot will prevent the fly from lighting on the leaves, as they dislike the taste of it. Once the fly has deposited its eggs on the leaves and the maggot is formed inside the only cure is cutting the worst part away and crushing the grubs within the remaining leaves with the finger and thumb.

**Grubs on Cabbage plants (Mrs. Corbett).**—The grubs attacking your Cabbage plants are those of the Cabbage fly. After the crop is over the soil

should have a good dressing of fresh gas lime or Vaporite, and it is better not to grow any plants of the Cabbage tribe on it next year. I presume from your letter that when your gardener used gas lime the plants were already planted, so that he could not give the soil a proper dressing. The parent flies lay their eggs on the plants just below the surface of the soil. Dipping the plants in a puddle of soot, clay and water, or laying soot or sand soaked with paraffin oil round the plants, is useful in keeping the flies away. Some persons have tried with much success cutting a central hole in a piece of card and passing the stem of the plant through it; the card lying flat on the ground prevents the flies from getting to the roots to lay their eggs.—G. S. S.

### MISCELLANEOUS.

**Using sulphide of potassium for mildew on Roses (Spray).**—The proportion in which to use this is half an ounce of the sulphide to a gallon of water. It is best to dissolve the sulphide in a quart of hot water and then make up to the desired quantity by adding cold water.

**The Royal Horticultural Society's examinations (Tutor).**—Having a copy of the syllabus and instructions relating to the examinations in horticulture held by the above society, we have sent it to you, as it gives much useful information. Your request relates to the general examination, which is held each year in April. The copy sent is of 1907, but that for the ensuing year will be the same, but the questions set are different, of course. To test your knowledge, you can have the whole of the questions set since the examinations began, information as to which you will have found on the syllabus sent you. Of course, the questions—portions of which are of a scientific character, the rest relating to practical horticulture—get rather harder each year. You will have seen that for all three examinations no less than forty books are recommended for study, but just one or two on each specific subject would be ample. While something would depend on your knowledge of the sciences of botany and plant or vegetable physiology, much also would depend on your knowledge of practical horticulture, knowledge which can be indifferently obtained from books, but which, where that knowledge exists through garden training, books greatly assist. The prices of the books named and their publishers are stated in the list sent. Neither of the three you name are included, yet they give to any student very valuable information. The school teachers' examination is less hard, but in relation to that some questions of a scientific kind are set, and a few at least of these must be answered. Should you need further information, write again.

**Names of plants.**—E. S. Martin.—1, Paul Neyron; 2, Anguste Rigotard; 3, Senateur Vaisse; 4, Viscountess Folkestone; 5, Mme. Welch; 6, Anna de Diesbach; 7, Mrs. W. J. Grant.—W. J. Ingram.—The very dark variety we believe to be Baron de Bonstettin, and the other *Triomphe de Caen*.—A. C.—*Rosa polyantha simplex*.—N. G. S.—Roses: Pink, Caroline Testout; white, Perpetual White Moss and Double White Scotch.—Miss Busden.—1, Mrs. J. Laing; 2, Victor Hugo; 3, Marie Baumann; 4, Clio; 5, Mme. Ravary; 6, Captain Christy; 7, Francisca Kruger; 8, Duke of Edinburgh.—Hants.—1, Helene; 2, Bennett's Seedling; 3, Mme. N. Levassieur; 4, probably Dawn, but the blooms had fallen; 5, Tom Wood.

**Name of fruit.**—F. C. C., East Sheen.—Your Raspberry appears to be Bannforth's Seedling, but the fruits were very crushed when received, so we cannot be sure about it.

## SOCIETIES

### THE NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW, MANCHESTER.

#### AN INTERESTING DISPLAY.

THE National Rose Society held its northern show at Manchester on Tuesday, the 21st ult., making its sixth visit to that city, the first having been made as long as twenty-eight years ago, and it was an interesting fact that three of the exhibitors at the initial show of 1880 were also present and exhibiting on this occasion, namely, Mr. Edward Mawley (the secretary), Mr. Mahlon Whittle of Leicester and the Rev. J. H. Pemberton. The exhibition was held this year in the same grounds but under different auspices, the old Botanical Society of Manchester having ceased to exist and its garden passed into the hands of the White City Company, Limited, under whose auspices the show was held. Fortunately, the show was favoured with fine weather, but the flowers showed signs of the rough treatment they had experienced during the last week, and rough petals were numerous; in fact, it was a matter of general surprise and comment that so many good flowers had survived the ordeal. The majority of the Southern gardens being over, those in the Midlands and North had their turn; but the best Roses in the show came from Ireland, Messrs. Hugh Dickson of Belfast and Alexander Dickson and Sons of Newtownards carrying all before them, the first-mentioned firm winning the Jubilee Trophy of the National Rose Society with a splendid box, good in colour, weight and form, that just beat the boxes of Messrs. Alexander Dickson of Newtownards. The amateur trophy was again won by Mr. E. B. Lindsell, the president of the society, but Mr. Eyles of Leicester ran him very close. The class for new seedling Roses was well filled, and again the Irish Roses were well to the fore,

Messrs. Alexander Dickson of Newtownards being awarded a gold medal for a brilliant-coloured red Hybrid Tea of excellent form and quite strong perfume named G. C. Wand, after the president of the Salsaire Rose Society. It was the best exhibition flower staged, and deservedly got the coveted award. Messrs. Hugh Dickson of Belmont also received a gold medal for a large pure white single Rose named Simplicity, a beautiful Clematis-like sort that we believe was exhibited at Salsaire last year. Here it was shown in improved form in two large stands, and was one of the features of the show, the flowers being 4 inches and 5 inches across. We understand that Kaiserin Augusta Victoria is one of the parents. The third gold medal was awarded to Messrs. B. R. Cant and Sons of Colchester, who staged a beautiful pure white sport of Dorothy Perkins that should prove very useful in the garden. They had six fine Roses that showed the flowers to advantage. Altogether there were ten exhibits for the gold medal. The committee thought the following worthy of a card of commendation: Messrs. Hugh Dickson and Sons, Hybrid Tea; Miss Ward, a good-shaped Lady Ashtown-like Rose, yet quite distinct from that beautiful variety; Messrs. S. McGredy and Sons of Portadown for a red Hybrid Tea called F. W. Moore (after the curator at Glasnevin) that promises well. This exhibitor also had a very pretty yellowish pink flower called Mrs. Alfred Tate that seemed an improvement on Countess of Gosford.

The awards in the principal classes were as follows: Class 1, the Jubilee Trophy Class: Cup and first prize went to Messrs. Hugh Dickson and Sons of Belmont for a beautiful lot of flowers. A Hugh Dickson in this stand appropriately won the silver medal for the best Hybrid Perpetual in the trade section. Messrs. Alexander Dickson of Newtownards were a close second, with Messrs. R. Harkness and Co. of Hitchin third, whose stand had some fine Hybrid Perpetuals. Messrs. Frank Cant and Co. of Colchester were awarded an extra prize. There were three other competitors and the class as a whole was a very good one.

Class 2, seventy-two blooms, distinct: Here again the Irish Roses carried the day, Messrs. Hugh Dickson being first, Messrs. Alexander Dickson second and Messrs. Frank Cant of Colchester third.

Class 3, twenty-four distinct varieties, three blooms of each: Messrs. Alexander Dickson were first with a first-rate box, some of the trebles being very fine, Messrs. Frank Cant a close second, with a beautifully staged and contrasted box, the flowers being a little smaller, and Messrs. Hugh Dickson of Belfast third.

Class 4, thirty-six blooms, distinct varieties, Division B. Mr. W. H. Frittingham was first, King's Acre Nurseries second and Messrs. G. and W. H. Burch of Peterborough third.

Class 5, sixteen trebles: The same three firms again divided the honours, Messrs. Burch taking second prize instead of third and Mr. Frittingham again winning with a good level box.

Class 6, Teas and Noisettes, eighteen blooms: Mr. George Prince of Oxford was first with some good Roses. The majority, however, showed signs of the weather on their outside petals. Messrs. Frank Cant of Colchester were second and Mr. Henry Drew of Faringdon third.

Class 7, twelve blooms: Messrs. Mattock were first and Messrs. Burch of Peterborough second.

Class 8, twelve blooms, new Roses: This is always an interesting class and there was strong competition. Messrs. Frank Cant of Colchester were first, and their box contained good flowers of J. B. Clarke, Mrs. H. Armytage Moore, William Shean, Mrs. T. Roosevelt, Queen of Spain, Richmond, Mme. Melaine Souper, M. H. Walsh, C. J. Grahame (an excellent flower), Mme. P. Rivoire, Mrs. John Bateman and Countess of Annesley. Messrs. Alexander Dickson and Sons of Newtownards were second, and their box contained many novelties not yet in commerce—William Shean, Conway Jones (a new dark red of globular shape), Lady Faire, G. C. Wand (a beautiful orange red scarlet), S. T. Wright, Mrs. G. W. Kershaw, S. P. Cowan (an excellent pointed crimson that will be wanted), Harry Kirk, Mrs. David Jardine (a Mrs. T. Roosevelt-like flower, but deeper colour and finer point), Eric Dickson (a beautifully-shaped flower of clear colour—deep crimson), Lady Ursula (pale flesh colour) and Grace Molyneux (a flesh-coloured Rose with peach centre); third, Messrs. B. R. Cant and Sons of Colchester. Messrs. Hugh Dickson of Newtownards had a fine box that the judges had to pass—as it contained a flower of Lady Ashtown, which was not eligible—that would have certainly been in the prize list. It contained a pretty flower of the new Lyon Rose, that was awarded (we think in error) the silver medal for the best Hybrid Tea in the show. Its colour could have been its only recommendation, as there were many finer Hybrid Teas, notably, a Mrs. Theodore Roosevelt in Messrs. Frank Cant's stand.

Class 9, twelve blooms of any white or yellow Rose: This was a very strong class, Messrs. Frank Cant of Colchester again securing first prize with a good box of White Maman Cochet, which also contained the silver medal bloom for the best Tea in the show. Messrs. Alexander Dickson were second with Fran Karl Druschki, and the King's Acre Nurseries of Hereford were third with the same variety. There were many other competitors.

Class 10, twelve blooms of any light pink or rose-coloured Rose: First prize, Messrs. Hugh Dickson, with a beautiful box that won easily of Mrs. Theodore Roosevelt; second prize, the King's Acre Nurseries, with fine coloured young flowers of Mrs. John Laing; third, Messrs. Frank Cant of Colchester, with a good box, close up, of Dean Hole, that might have changed places with second. Possibly the colour was not so good but the flowers were certainly better.

Class 11, for twelve blooms of any crimson Rose: This was again a very strong class and caused the judges some

trouble. Messrs. Hugh Dickson eventually won with a very fine box of Hugh Dickson, good throughout; the King's Acre Nurseries were second with Alfred Colon b; and Messrs. Burch of Peterborough third with Horace Vernet.

Class 12, exhibition Roses in vases: Here Messrs. Alexander Dickson of Newtownards were an easy first with Hybrid Teas predominating; second, Messrs. Prior and Sons of Colchester; third, Messrs. Burch of Peterborough. Class 13, for new seedling Roses, we have already referred to.

Class 14, twelve trebles, Teas or Noisettes: The Teas generally throughout the show seemed more susceptible to the weather, and were rough and damaged in consequence. Messrs. Frank Cant were an easy first, but showed their flowers in vases instead of the orthodox box; Mr. G. Prince was second; and Mr. H. Drew third.

In the section for decorative Roses one missed the usual table decorations, bowls and vases that were so popular and always create a lot of local interest; we think they might well be added another year. The trade came forward strongly in the two classes for eighteen and twelve distinct varieties, and the Roses shown were excellent in every way; in fact, created quite a sensation, so that it was difficult to approach the stands. In Class 15, for eighteen distinct bunches, Messrs. Frank Cant and Co. of Colchester were first with a beautiful clean lot of flowers, of excellent quality throughout. Minnehaha (a pink wichuraiana), Rosette Legion d'Honneur in fine form, Lady Gay and Dorothy Perkins were excellent, and the bunches were not too thickly crowded. Messrs. Paul and Son of Cheshunt were second, and the judges must have had a hard task to divide them. We were particularly struck with a beautiful Rose of Lady Godiva, a new sport from Dorothy Perkins, pale flesh with deep centre. Marquise de Sinety, a fine yellow, was also prominent. The vase of Griss an Teplitz was the only weak spot in a beautiful exhibit. Messrs. Mattock were third with beautiful clean flowers, the smaller Tea section largely predominating; fourth, Mr. G. Prince of Oxford, an exhibit quite good enough to win in the ordinary way. There were several other exhibitors.

In Class 16, for twelve bunches, Messrs. Mattock were first with well-staged flowers in first-rate condition; Messrs. Frank Cant and Co. second; and Mr. Prince third.

Class 17, the Jubilee Trophy, for amateurs: First, Mr. E. B. Lindsell of Hitchin, who had a good stand, wonderful really considering the weather of the preceding days. Mrs. E. Mawley in this box secured the silver medal for the best Tea in the amateur's section; second, Mr. William Boyes, close up, only lost in the last three or four blooms, which were small. Mildred Grant in this stand secured the silver medal for the best Hybrid Tea; third, Mr. Dennison.

In Class 18, thirty-six blooms, the competition was not quite so keen. First, Mr. R. Park of Bedale; second, the Rev. J. H. Pemberton; third, Mr. H. V. Machin of Workop.

Class 19, eight trebles: Mr. Machin was first, and his box contained a fine Horace Vernet that secured the medal for the best Hybrid Perpetual; second, Mr. Leggett of Colchester; third, Mr. R. Park of Bedale.

Class 20, nine blooms of any Rose except Tea or Noisette: Mr. Dennison won well with Horace Vernet, Mr. Machin second with Fran Karl Druschki and the Rev. J. H. Pemberton third with Dean Hole.

In Class 21 Mr. G. Speight was first for eighteen blooms, distinct. We could find no other entries in this class.

In Class 22, six trebles, the same exhibitor was awarded first under similar conditions.

In Class 23, six blooms of any Rose except Tea or Noisette, Mr. Speight was again first and Mr. C. Burgess second.

Class 24, twelve distinct Roses, for growers of under 1,000 plants: First, Mr. Mahlon Whittle of Leicester with a good box.

Class 25, nine blooms: Mr. E. H. Russell was the only exhibitor and was awarded a first prize.

Class 26, nine blooms, for growers of less than 500 plants: First, Mr. Upton of Leicester; second, Mr. S. Price.

Class 27, six blooms: First, Mr. A. M. Buxton of Branchall; second, Mr. C. G. Baron of Hitchin; third, Mr. Munro of Nantwich.

Class 28, four trebles: Mr. Upton of Leicester was first and Mr. S. Price second.

Class 29, six blooms of any Rose except Tea or Noisette: First, Mr. R. M. Munro of Nantwich; second, Mr. M. Whittle; third, Mr. S. Price.

Class 30, for six blooms of new Roses was disappointing, the flowers being small. The Rev. J. H. Pemberton was first, Mr. Leggett, Colchester, second and Mr. H. V. Machin of Workop third.

Class 31, twelve Teas, distinct, Messrs. R. and T. Park of Bedale were first, Mr. Leggett second and Mr. W. Byles third.

In Class 32, nine Teas, Messrs. Park were again first.

In Class 33, nine Teas, for growers of less than 500 Teas, the Rev. J. H. Pemberton was first.

Class 34, six blooms, for growers of less than 200 Teas: There was more competition in this class and the flowers were better; Mr. W. Upton of Leicester was first, Mr. M. Whittle second and Mr. T. G. Russell third.

Class 35, six trebles: Messrs. Park first and Mr. Leggett second.

Class 36, six blooms of one variety: Mr. Mahlon Whittle was first, with the Rev. J. H. Pemberton second.

Class 37 was for decorative Roses, and here the Rev. J. H. Pemberton was an easy first with well-staged flowers; second, Mr. H. V. Machin.

The local section was not well filled, and the Roses were only of medium quality. Mr. C. Burgess of Knutsford won the first prize in each class for twelve Roses and six blooms distinct. No doubt the weather had much to answer for.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Gar W.C.

## "THE GARDEN" FLOWER SHOW.

AS one of the oldest readers of THE GARDEN I was much interested in the novel and original idea of a flower show being held under the auspices of a horticultural journal in London, exhibitors being confined exclusively to its own readers. I must say that I felt somewhat perturbed in mind as to whether the idea could be successfully carried out, as many difficulties seemed to present themselves against the possibility of organising a successful exhibition on these lines. However, no sooner had I entered the Royal Horticultural Society's Hall, Vincent Square, where the show (of upwards of 600 entries) was held on July 29, than these fears and doubts vanished and proved groundless. For what did I see? The great Hall practically full of beautiful flowers, ripe fruit and splendid vegetables. Many of these exhibits would have done credit to some of our great premier shows in the provinces or in London.

*Table Decorations.*—These were arranged down the centre of the Hall occupying its whole length. A most interesting and charming feature it proved to be. Many of the tables were arranged with exquisite taste and true artistic knowledge. The Sweet Peas were another great attraction. One might have been pardoned for supposing that for the moment one had gone back to the National Sweet Pea Society's exhibition, held in this same place a few days before.

It is late for Roses, and the weather has been against them lately. These were not so strongly represented as we had expected; but Messrs. William Paul and others came to the rescue with honorary exhibits, which were greatly admired and much appreciated. Hardy herbaceous flowers were well represented, Messrs. Barr and Sons, among others, putting up a superb honorary exhibit. Vegetables proved to be one of the strongest features of the show, the gold medal offered for the best exhibit in the show going to an excellent collection effectively arranged. The fruit classes were well filled with excellent specimens, one collection proving a strong second favourite for the gold medal.

It was remarked by many what a contrast the hall presented to the usual fortnightly meetings. Instead of the ordinary habitués attending these meetings we found a totally new class of exhibitors—mostly new faces, and evidently facing a new experience, many of them possibly for the first time—displaying much ardour in their work and a keen desire to make the most of their exhibits. Truly a pleasant and inspiring sight

to see, and, as the editor of THE GARDEN happily remarked, a notable GARDEN family party.

For the general improvement of the art of gardening, and more especially for the greater diffusion of the love of flowers among the masses of our country men and women, no influence has been more potent than that of flower shows. Why, then, should not this ideal show of THE GARDEN, appealing as it does to many thousands of readers, become in time a powerful factor in still further greatly stimulating the love of a garden, with all its attendant delights, pleasures and profit?

ONE OF THE JUDGES.

## DAFFODIL NOTES.

THE NEW ROYAL HORTICULTURAL SOCIETY'S CLASSIFICATION.

THE new classification has not been actually published at the time of writing these notes, but its general principles have been made known, and two show committees (the Devon and the Midland) have adopted it as the basis of their 1909 schedules. As far as possible every known Daffodil has been labelled and given a place in one or other of the seven divisions into which the family is divided. It is pleasant to know that English names have been adopted in every case for this now peculiarly English flower, for such, at any rate, we can claim it to be as far as almost all the wonderful hybrids are concerned. It is to the advent of these that the modern Daffodil holds its present position in the world of flowers. The seven divisions are named as follows: (1) Long trumpets, (2) short trumpets, (3) large cups, (4) small cups, (5) flat cups, (6) double flowered and (7) bunch flowered. I will have some more remarks to offer when the list actually appears.

EARLY PLANTING.

I cannot insist too strongly or too often upon the desirability, if not the actual necessity, of early planting if the very best results are to be obtained. There is no doubt that better flowers are obtained from two year old clumps than from those planted late in the previous autumn, and which have not been a year in the ground. Anyone can easily prove this for himself, and it is well worth trying if there is the least doubt about its truth. For show purposes, if possible, plant in August. I always make a point of getting all my very best bulbs in the ground as soon as I can directly July has gone. This applies with double force to varieties with Poeticus blood in them. These never seem to have any resting season, for dig them up when you will it will nearly always be possible to find new roots as well as the old.

For ordinary garden purposes it is practically impossible to plant before September. The beds are full and there is still a wealth of flowers. Luckily for a very large number of garden lovers Daffodils are so accommodating that they do quite well enough for all ordinary purposes if we

can get them planted any time during this month. When, however, October comes in no time must be lost, or we shall see a decided falling off in size and quality of bloom in the spring.

#### WHAT TO BUY.

It is impossible to say much about the best sorts to get for showing. The best thing anyone can do who wants to begin a "show" collection is to get the schedules of those societies who publish a list of all the winning flowers, such as the Lincolnshire, the Midland, and the Kent, Surrey and Sussex. There the beginner will see the varieties that are included in the winning stands, and then, after providing himself with the bulb lists of four or five of the best firms, he can "cut his coat according to his cloth," and work out a selection of which the price comes within his means. Personally I would very much like to see all Daffodil societies include this most interesting and useful information when they issue their new schedules. It is of great value now, and it cannot fail in years to come to be of historical interest as well. I hope in future notes to deal with what to buy for the garden, for pots and for naturalising in grass.

JOSEPH JACOB.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

August 11.—Exmouth Horticultural Society's Show (two days).

**National Carnation and Picotee Society—Northern Section.**—The annual exhibition of the above society will be held in the White City, late Botanical Gardens, Old Trafford, Manchester, on Saturday, August 15, 1908. Full particulars can be obtained from the hon. secretary, Mr. T. W. Prescott, Murray Street, Great Ancoats.

**Preparing for alterations.**—No time should now be lost in planning any alterations or schemes of planting that may be in contemplation during the coming autumn and winter. Nothing saves time and trouble like having a well-thought-out plan, so that when the moment comes there is no doubt or hesitation about what is to be done. Moreover, if ground is to be moved or levelled, or even level ground trenched for planting, it should be done soon enough to allow the earth to settle. It is unfair to shrubs and trees to plant them in deep masses of newly thrown up earth. For some time it will be in movement, till it finally settles to its place. The shifting earth drags the roots and prevents them from taking good hold. Haste and scurry are fatal to all good work in this as in all things else. Often the garden designer or planter is urged by the owner of a place to begin, even after Christmas, and to get on as fast as possible, as he does not want to lose a season. There is no better way to lose a season than to plant too late, or, what is still oftener urged, to plant too large. A plantation of young trees 2 feet high put in at the right time (as early as possible after the leaves have fallen), will often overtake one that is planted late with larger trees. If some good and careful garden scheme is to be carried out there should be the best possible understanding between the owner of the place and the garden artist who is to take in hand its form and planting. If when the scheme is first put on paper there is any doubt whether it can be properly done, it is much better to make a fresh design of obviously less cost than to lop or skimp or make compromises when the work is well on the way. It should also be remembered that it is extremely difficult, in many cases impossible, to give anything like an accurate estimate of cost. Local conditions vary so much that experience in one place or even a dozen may be but little guide in the thirteenth. An ample margin should, therefore, be allowed,

and this should be clearly understood. If these matters are thus adjusted the work will be a source of satisfaction to both employer and employed, and will in itself be all the better for the harmonious conditions in which it is done. Take carefully to heart these words (see Mackail's "Life of William Morris," vol II., page 22): "Be careful to eschew all vagueness. It is better to be caught out in going wrong when you have a definite purpose than to shuffle and slur so that people cannot blame you because they don't know what you are at. Hold fast to distinct forms in art. Don't think too much of style, but set yourself to get out of you what you think beautiful, and express it as cautiously as you please, but, I repeat, quite distinct and without vagueness. Always think your design out in your head before you begin to get it on paper. Don't begin by slobbering and messing about in the hope that something may come out of it. You must see it before you can draw it, whether the design is of your own invention or Nature's."

## PRIZES FOR READERS. AUGUST.

### THE BEST ROSES FOR AUTUMN FLOWERING.

- A First Prize of **FOUR GUINEAS**,  
A Second Prize of **TWO GUINEAS**,  
A Third Prize of **ONE GUINEA**,  
And a Fourth Prize of **HALF-A-GUINEA**

*are offered for the best essays on the above subject, with hints on the management of the hybrids and varieties mentioned. The object of this competition is to encourage the cultivation of the Rose for the enrichment of the garden in the late months of the year.*

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The essays must reach this office not later than Monday, August 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

*(The Editor is not responsible for the opinions expressed by correspondents.)*

**The Flame Flower.**—Visiting to-day (July 28) a cottage garden in a very secluded lane at Lingfield, Surrey, I was greatly interested to see the front window of the cottage, which looks north, entirely encased in luxuriant growth of *Tropeolum speciosum*. Not only was the entire base of the window and sides a mass of growth and flower, but the strong growths were being carried along over the window also. The soil is almost pure sand. How difficult some persons find establishing this beautiful climber, while others can do it apparently with the greatest ease. *Tropeolum tuberosum* was also growing freely in the same garden. I remember seeing the Flame Flower growing most freely on a southern aspect in the gardens of Frensham Hall, Haslemere, at that time the residence of

the late Hon. Charles Ellis, and a wondrously beautiful garden. There, on sand and in a warm position, it seemed to be almost a weed.—A. D.

**Hollyhocks.**—There can be no doubt as to the importance of the place that these grand plants have in our gardens. Their great stature, picturesque beauty and varied colouring of the flowers entitles them to the most careful consideration we can possibly give, and though they are already extremely popular plants and widely grown, we should like to see them even better treated. The scourge of the Hollyhock fungus which attacks so many plants of the Mallow family has of late years deterred many from growing them. No one can suffer more from this than the present writer, in whose garden, on dry, sandy soil, the pest is rampant, and Hollyhocks cannot be grown to anything like perfection. Still they can be grown to a certain degree by means of liberal feeding, and though when the spike is in flower the lower leaves are lost, there is still the grand bloom. In this case they are placed so that they rise among other plants and the defect at the base is not seen. We are informed by a nurseryman who grows these fine plants largely that growing them in a quite open place, where the early leaves get hardened by exposure to sun and air, is a safeguard against disease; still, in garden use, such a place cannot always be given. It is much to be wished that some nurseryman or patient amateur who lives upon the cool loamy soil where the pest does not thrive would take in hand the raising of these grand plants in the form that is the most beautiful for gardens. In answer to our request, one of the first Hollyhock growers lately sent us a series of blooms of their best varieties. They were superb in colour and culture, but from the garden point of view they were, with one notable exception, distinctly not so beautiful as they might have been. There can be no doubt whatever that the florist's Hollyhock, from the point of view of beauty, is much too round and tight and full of petals. In many cases also the spike is too much crowded with bloom. Of course, no one wants a thin or empty spike in a garden Hollyhock. There is just a point where the most supreme beauty of which the plant is capable culminates, both in the fullness of the spike and in the fullness of the individual bloom. In obedience to a false ideal, the florist's Hollyhock has been pushed beyond this point, and is no longer so good a thing in a garden as many a chance seedling that has no claim to good breeding. In the show flower the petals are too much crowded, and the whole flower too round and ball-like. Beauty in a garden flower is better than tightness or even than rotundity. This case of the Hollyhock is only one of many in which the influence of the show is unhelpful, even if not harmful to garden progress. But surely the Hollyhock is, above all things, a garden flower. We feel quite sure that growers will be only consulting their best business interests if they will give attention to producing the kind of flowers that are now wanted. Any grower who could be the first to establish a strain of plants answering to the present needs would be astonished at the healthy demand for the plants that would ensue. What is wanted is a wide flower with a large and distinct guard petal, and that the mass of petals in the middle of the flower should not be so closely packed as to prevent the play of light and shade, or hide its wonderful effect of the value of the colour. This play of colour in the shaded depths of the flower adds materially to its brilliancy; when it is shut out by the closely-folded packing of the inner petals one of the most charming of its beauties is entirely lost, and an important source of brightness when seen at a little distance is destroyed. The favourable exception mentioned above was in the case of a flower of deep and pure sulphur colour, whose looser centre and distinct guard petal made the bloom stand out among its fellows as a thing of rare and refined beauty.

### Sweet Pea prospects and fertilisation of Sweet Peas.

—In an interesting note on the above subject by Mr. G. Clapham, published in *THE GARDEN* on July 25, he touches once more on the very debatable question of sporting and fertilisation, and seems to have settled it to his own satisfaction, but I am afraid he will have some difficulty in convincing others so easily. He says "the old theory of cross-fertilisation by insects must be dismissed, seeing how the flowers are fertilised," and he goes on to suggest that the blooms are so formed as to make it impossible for insects to get to the fertilising organs before the flower performs the operation for itself. Now, in the old-fashioned Eckfordian type this may be so, and everyone will admit that this so-called sporting was hardly ever heard of before the introduction of Countess Spencer, the first of its class. What must we deduce from this? Simply that there is a difference in the shape of bloom of the two types, the former having the wings and keel well overlapping and shutting up the organs inside, and in the latter both are comparatively open, and in a great many instances I have observed the style or stigma protruding from the keel long before the pollen on the anthers was ripe, thus making it not only possible but probable for it to be cross-fertilised, whether by insects, wind, or any other agency does not matter here. Mr. Clapham takes, for instance, his clump of Countess Spencer which has only six out of fifteen plants true, and he seems to take it for granted that everybody is in the same predicament. My packet of Countess Spencer, which I obtained from Mr. Bolton, did not contain one rogue. How do I explain this and square it with my other argument *re* shape of flowers. Well, my theory is that when Countess Spencer first appeared some of the blooms were more open than others, and, consequently, were cross-fertilised, while those more closed would be self-fertilised, and so on every succeeding season, the different results in Mr. Clapham's clump and mine being simply a process of roguing and selection on Mr. Bolton's part until now the keel is fairly close and so less liable to cross-fertilisation. This is only my idea, and I do not want to force it on anyone. Mr. Clapham's theory may be the right one; but, anyway, an exchange of ideas will do no harm. I fancy Mr. Cole and a few more raisers could clear up a lot of the mystery if they would.—J. F. BARWISE, *Lancaster*.

### NEW MALMAISON CARNATION IRENE.

The accompanying illustration is of a charming new Malmaison Carnation called Irene. When first shown by Messrs. Hugh Low and Co. it was under the name of Gala, but subsequently this was changed. The colour is a most pleasing shade of soft pink, and the shape and habit of the plant leave nothing to be desired. The illustration shows what a shapely specimen this variety forms when given good treatment.

### POPULAR CONFUSION IN NOMENCLATURE.

**T**IMES are propitious for remedial measures as regards incorrect terminology of plants. It is a generation in which practically all classes are making a general exodus into the country, when "Back to the Land" is the whimsical cry one hears on every side, in sense perverted from the original meaning. Back to the land, not to till and furrow, not to sheaf and plough, but to flee the city sights and sounds and smells and obligations, to luxuriate in quiet peace and leisure, to cultivate the charms of every flower and to form a lovely haven and retreat around us in which to spend our days reposefully. The rich flock to the

country, the poorer to the towns! Reversal of conditions of husbandry is to receive the desired and necessary encouragement for our country's welfare.

Still, there it is, the fever—a never-ending stream of town-bred families departing from the streets and traffic and the swirl of life, a competing crowd for ever hotly searching for "week-end" cottages, for desirable small estates within touch of the teeming cities. A constant rush outwards of one class which but desires beauty for its surroundings, the other class leaving pasture land and corn, orchard and the farm, filling up the gaps thus vacant in the lines and rows of bricks and mortar. One sure effect might be expected from this, that familiarity should induce a knowledge of our plants and lead to better naming of them. But how slow is the process! Ignorance is still as yet quite lamentable, haphazard, colloquial nomenclature, a mixed interchange of titles, a real not simulated indifference to the true significance of names, all most obvious and irrefutable.

We must hope that, however slow yet surely can we bring about a change for the better, conditions are so hopeful. The children live in the atmosphere of flowers, garden books are plentiful and cheap, plant portraits are traced for adults and for youngsters, on all sides do we see the signs of wider knowledge possible of attainment at very little cost of trouble and money. Horticultural colleges are open right and left, where our youth can train and our gardeners, too, can prove themselves more scientific, more interested than the old-time man of twenty years ago. This, then, is, I say, undoubtedly the time to stamp out and eradicate all possible errors that have crept so insidiously, so capriciously, into our garden nomenclature.

Till recently it has been regarded as somewhat in the light of affectation if one designated a well-known plant by its true term, which happened to be foreign, whereas its popular name might be absolutely erroneous. Latin and Greek names, &c., are invaluable, forming as they do a universally-understood medium, and I am convinced that the more we cultivate flowers and the more our knowledge and interest in them grows, the more will we make general use of such terms in preference to the local or common names, which leave such an enormous margin for error and which more frequently than not prove misleading rather than helpful. People use proper names more generally than they are aware, and without giving the matter a thought, names being not few in number which either have no English equivalent or pet name, or one that is very little known, as, take for instance, *Lupine*, *Tamarisk*, *Berberis* and *Calceolaria*.

A feature often noticed and much to be deplored is that some nurserymen endeavour to introduce into their catalogues fancy descriptive titles, and where none are already current invent a likely one to catch the public taste. Again that execrable habit, which of late has seemed to gain in popularity, of abridging a recognised word, for example, let us state at once almost the worst, where the beautiful and genuine name *Chrysanthemum* is reduced to a dreadful "mum," or take the docked and discordant vulgar "veg."

The journals should not for a moment countenance the entry of such retrogression into their pages. In certain minds there seems an inborn and involuntary tendency to begrudge the smallest expenditure of time and effort on pronunciation, and a disinclination to waste any by giving full value to a name, and this growing habit of "clipping," obnoxious in ordinary life, is unpardonable when introduced into the harmonious garden world. Before it becomes a settled custom let us try to stamp it out, disallow it on every occasion, refuse it in our books, in our journals, our societies, our shows and in our conversation. It is still a youngling, stunt it and let it languish of inanition. Right is right, and plants have their just claim to proper recognition, and now is the time to do our best to unravel all the tangles and set the matter straight for the future, so that the growing generation shall find a smoother way and lead their followers to a clearer view. Sometimes the ignorance shown is quite astounding, and

THE NEW MALMAISON CARNATION IRENE.

yet, if one considers the ripe old age some of the wrongful claimants have attained, perhaps it is not quite without excuse.

In a volume, the date of which goes back to nearly 230 years, I see some notable examples of a changeling name which still exists to-day. And to state only one instance of confusion, what vague and uncertain conjecture hangs around that dear and charming old-world name of "Gillyflower," to which how many of our sweetest flowers have not been put forward as owner! It must not be supposed that I am in favour of discarding the ancient sobriquets, old friends to which we have become attached. Indeed, far from it; for, apart from sentiment, there is often much practical meaning in the prebotanic names which one would be loth to lose. Still, a certain amount of chaos exists among them, and it is the elucidation of the puzzle that I urge on the present flower-loving generation, and particularly to be more careful when we use the foreign term that we do not misapply it.

E. CURGWEN.

## TREES AND SHRUBS.

LOGWOOD (*HÆMATOXYLON CAMPECHIANUM*).

**L**OGWOOD, though introduced into this country as a Dyewood so long ago as Queen Elizabeth's time, and used as such more or less ever since, and though the plant itself was introduced in 1724, it is seldom seen, except in economic collections. A native of Central America, Colombia and the West Indies, it is naturally a stove plant. Its racemes of yellow flowers and abruptly pinnate leaves of a bright green colour tell at once that its natural order is Leguminosæ, the genus, *Hæmatoxylon*, being a monotypic one and the species *campechianum*, referring to Campeachy, which was formerly the principal mart for Logwood. The tree grows up to a height of 50 feet. The heartwood is very hard and dense, of a deep red colour when freshly cut, but turning to a dull black on exposure to air and light. As imported in logs, from which the sapwood has been roughly chopped off, and as seen stacked in piles in the West India Docks, it might readily be taken for firewood. In Jamaica, where it has recently been stated that the output of Logwood represents about one-fifth of the world's supply, the usual age for felling the tree is ten years. The roots of previously-felled trees also form an important article of export.

Formerly the principal use of Logwood was for dyeing raw wool and woollen goods, and it was also said to have been extensively used for dyeing the material for gentlemen's silk hats, as it gave to it a special lustre.

Aniline dyes, however, have largely replaced Logwood, though it seems there are still many uses for it, both in textile and leather dyeing, for which it seems peculiarly adapted. It is worthy of note that not long after its introduction Logwood fell into disrepute, owing to the want of knowledge of the dyers in fixing the colour, so that an Act of Parliament was passed, entitled an "Act for Abolishing Certain Deceitful Stuffs Employed in Dyeing Cloths," which law remained in force till its repeal in 1661. In medicine Logwood has a place as an astringent and tonic.

JOHN R. JACKSON.

## MAGNOLIA HYPOLEUCA.

**T**HIS is one of the large-leaved Magnolias, being in this respect somewhat in the way of the North American *M. tripetala*. The creamy white, fragrant blossoms, which are borne during the month of May, are said in Japan to be from 6 inches to 7 inches in diameter, but in this country they have not reached these dimensions. In this species the bright-coloured anthers also form a notable feature. This Magnolia is said by Professor Sargent, in "The Forest Flora of Japan," to reach a height of 100 feet, with a trunk 2 feet in diameter, that is, in the rich moist districts, while in others its extreme height is about 30 feet. In the above-quoted work it is referred to as "one of the largest and most beautiful of the deciduous-leaved Magnolias; and in the early autumn, when the

cones of fruit, which exceed those of any of our species in size, and are sometimes 8 inches long, and brilliant scarlet in colour, stand out on the branches, it is the most striking feature of the forests of Hokkaido, which in variety and interest are not surpassed by those of any other part of the world." Some years ago Mr. Goldring visited Japan, and he spoke of *M. hypoleuca* as unquestionably the finest tree he saw during the month of May. This will probably prove to be one of the most useful of the Magnolias for hybridising and also for garden decoration where choice plants are appreciated.

## TWO BEAUTIFUL PYRUSES.

**T**HE *Pyrus* family, although including many highly ornamental trees and shrubs, does not contain two more notable examples than the subjects of these notes.

*Pyrus Scheideckeri*, a hybrid between *P. floribunda* and *P. prunifolia*, has semi-double

AN OLD DIPPING WELL.

flowers of a deep blush colour, which are a rich crimson when in bud. It is very free flowered, the flowers being produced in clusters the whole length of the branches. It is stronger in growth than *P. floribunda* and makes long erect shoots. Flowering in May, it retains its beauty much longer than most of the *Pyruses*, the semi-double flowers being better able to withstand the weather. Beautiful when planted in clumps in a mixed shrubbery, or as an isolated specimen in the open, it is also amenable to culture as a wall shrub. It is not so frequently met with in gardens as it deserves to be.

*P. niedzwetzkyana* was introduced into this country in 1891 from Siberia. It is ornamental during the whole year, for its bark is dark purple in colour, the young leaves at first red becoming green with red veins as they get older, and in the autumn changing again to reddish purple, while its fruits when ripe are bright crimson. The flowers, which are produced in

clusters very freely during May, are deep rose, darker than those of any other of the *Crabs*. It forms a small tree when reaching maturity. Lovers of hardy flowering trees and shrubs when planting should certainly not overlook these two *Pyruses*, more especially as they are of easy culture, growing freely in almost any soil. Of the two mentioned, *P. niedzwetzkyana* is decidedly the best.

G. BATES.  
*Sotherton Hall Gardens, Aberford, Leeds.*

## DIPPING WELLS.

**S**URELY these may be called the friends of those who "follow the broad road," or bear the burden of the heat of the day. Here are no barriers to be laboriously overcome by the weary traveller, no water lying fathom deep, out of reach, but in these country dipping wells the fount lies cool and dark at our very feet, bubbling from rock or sandy bottom and set about with fair, green moss and dripping Fern, with, possibly, an arch of weather-beaten stone. Here the water-sprites and pixies give with both hands, inviting us to the cool retreat of mossy bank or time-worn slab, where we may listen to the almost inaudible voice of the well, murmuring long-forgotten legends and, possibly, catch a glimpse of the wild folk from the surrounding woods, or watch the villagers who come leisurely to fill their broad-mouthed pitchers, and who relate legends full of quaint humour and set with shrewd comments, and hold a fast belief in things uncanny. Often the wells have myths of their own, their special saints and magic powers. Unfortunately, some are "improved," Heaven save the mark! so that their charm and dignity is hopelessly lost. What sweet saint would remain the same stripped of her simple robe and dressed in the latest local fashion? Poor Saint Anne! Patient Saint Catherine! Even the children who sailed leaf-boats on your holy waters scramble for pennies among the strangers, who no longer come to pray but merely out of curiosity. Happily, however, there are still some quaint old wells left us, where the village girl drinks on Midsummer Eve, in all good faith that so will she keep her love true, and where the waters still retain their power of healing in the local

mind. Indeed, the subject of our illustration was accounted "properly marvellous" in the matter of restoring failing eyes. What charm there is about a dipping well! It has an individuality—it is friendly, smiling—the sun dances on its circling ripples, it is cool and still or mysterious, murmuring darkly to itself in its shadowed hiding, and this delightful friend one might meet more often if those blessed with running water in their grounds would make good use of their opportunities. It is not difficult to arrange a dipping well with all its charm, provided one allows Nature to direct and take "simplicity" for one's keynote. The smallest trickle of water will serve to furnish an old-world garden with its picturesque dipping well, and one may have still water, moss-grown rocks and worn stone steps to delight the eye and bring gladness to the hearts of the wild folk, those small people of the woods, ever ready to give thanks with song, or to show their charming ways to one who has given them refreshment.

## MESSRS. LAXTON'S NURSERIES AT BEDFORD.

**T**HE name of Laxton and Strawberries have been so closely connected of late years that in any notes on the above Strawberries will naturally find a leading place. Other leading features may be seen at their Goldington Nurseries, as here Roses, fruit trees and herbaceous plants, and numerous glass houses for forcing purposes occupy a large space and are well done as regards culture. Messrs. Laxton Brothers were the raisers of that popular and well-known Strawberry Royal Sovereign, and they have of late years persistently striven for better things, a process requiring much care and patience. In the soil here the Rose makes a splendid growth, and the plants are remarkably healthy. Considerable space is devoted to the bush and standard types, and all the best pillar and garden or decorative Roses are also grown in great quantities, the ramblers forming splendid objects. I noticed a large break of the charming Mme. Abel Chatenay, and the plants for their age were remarkable. Liberty was splendid, and is not nearly as much grown as it deserves. The lovely Mme. Jules Gravereaux and Mme. Vermorel, a very fine flower with beautifully shaded coppery yellow centre, produced on long strong stems, making it excellent for cutting, were others that I noticed. Bessie Brown made a shorter growth than some, but the rows of Mme. Jean Dupuy suggested that it would make a splendid bedder.

The herbaceous plants grown in an open position adjoining the Rose quarters were in robust condition, the Pyrethrums being very fine. Here was a new variety of great merit named Lord Rosebery, a very fine crimson and a great advance on the older varieties. Some very fine quarters of Delphiniums were seen, and the new seedlings adjoining showed some very charming colour and variety.

### STRAWBERRIES.

These are naturally the leading feature at these nurseries. The new varieties of this year were first noted. Pineapple, as its name implies, has a brisk touch of Pineapple flavour. It is a rich fruit, luscious, and, though not large, is an excellent midseason variety, with good growth and a yellow orange flesh. Epicure was next on the list, and this tested with British Queen came out favourably. It is the result of crossing British Queen with Fillbasket, and has the rich Queen flavour with the free growth of the last-named. The fruits vary in shape, some being conical, others inclined to wedge shape, but it is a delicious fruit and should be a popular variety. Connoisseur, another of the new varieties, is a bright vermilion scarlet. It had Scarlet Queen as one of the parents, and the other was Fillbasket. It has bright pink flesh and a good flavour. Profit is the result of crossing Countess, an excellent old variety, with the well-known Sir J. Paxton, and the cross has given us a large midseason fruit, with a good deal of the Countess flavour and the firmness and cropping qualities of Sir J. Paxton, the plant being vigorous and the leaves thick and leathery, thus making it a good variety for poor soils.

Of other seedlings introduced earlier, The Cropper will, I think, prove of great value. The plants were remarkable for their crop and vigour, and in this respect it may be classed as an improved Fillbasket. It is one of the best for forcing to follow Royal Sovereign. In Reliance we have quite a different fruit, a main-crop, and one that anyone can grow to advantage. It is quite a new break. The old Vicomtesse Héricart de Thury was used as one parent, the perpetual St. Joseph being the other. It may be classed as a larger Vicomtesse, with its good flavour. In this cross I should have expected a later fruit. Progress, a seedling from British Queen and Latest of All, is an excellent late variety,

and should be most acceptable on account of its fine Queen flavour and free growth. Bedford Champion, a very large fruit, stands out well and is a great favourite this season, having borne wonderful crops. The large trusses well repay thinning.

Other varieties one cannot omit to mention are Reward and Laxton's Latest. The first named is, I consider, one of the best Strawberries raised, and is the result of crossing Royal Sovereign and British Queen. It has the vigour of the first named and the flavour is really fine, the fruits large and handsome, mostly wedge-shaped, and of a deep crimson colour. Laxton's Latest is valuable for its late crop and good quality. The fruits are rich and much better than other old late sorts. It is a free grower and a decided acquisition. Other varieties worth notice are The Bedford and The Laxton, but these are well known. The new Laxton Perpetual is also largely grown, and others of this type are being tested. Messrs. Laxton think that a valuable new type will be introduced from these.

### OTHER FRUITS.

A new berry called the Laxton Berry, a cross between the Loganberry and Raspberry Superlative, promises well. The fruits were not ripe, but the plants were cropping enormously. Messrs. Laxton think highly of this. The fruit is not so acid as the Loganberry and leaves the stalk freely like the Raspberry. A new Red Currant called Laxton's Perfection is well worth notice. A quarter of this variety grown alongside of Fay's was most noticeable for its free growth and crop.

Special interest was centred on some fruit tree crosses—Pears, Apples and other fruits—and the large quantities of trained trees, such as Peaches, Nectarines and others were specially good. Cordon-trained trees occupied considerable space, and there appears to be a good demand for these trees now, Gooseberries and Currants also being grown in this style. Some fine breadths of the Black Currant Boskoop Giant were noticeable; this is the best black and almost free from the mite. Large quantities of Raspberry Superlative, one of the best reds, are grown, also the Loganberry is largely cultivated.

I have not space to go into the glass department in its various phases, but my note would not be complete without referring to the good work carried on by Mr. W. Laxton in raising and perfecting culinary Peas. The late Mr. Thomas Laxton many years ago did splendid work in this direction, and gave us some good things in

the early Marrowfats; the excellent Gradus, one of the firm's introductions years ago, still holds its own. G. WYTHES.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### VIOLAS FROM CHINGFORD.

Mr. W. Beeching, Rosemeade, Sewardstone, Chingford, sends some very fine named Violas, which are undoubtedly the result of careful and intelligent cultivation. He writes: "I enclose a few of my Violas for the Editor's table. Your excellent paper has had so many directions as to the cultivation of Violas that I need not add thereto. The very hot weather in June was not favourable to their growth, but the recent rains have brought them out again."

ROYAL SOVEREIGN, ONE OF THE MOST FAMOUS OF MESSRS. LAXTON'S STRAWBERRIES.

## THE ROSE GARDEN.

### A ROSE BANK AND ITS MAKING.

**L**ANDSLIPS in a garden are not desirable things as a rule, but in one case at any rate an occurrence of this sort has been the cause of making a successful bank of Roses as shown in the photograph. The case in question is in a garden in Lincoln belonging to Mrs. H. W. Hutton, the garden being so near the town that Roses do not do at all well generally. On one side of this garden is, or rather was, a high stone wall, being part of the old close wall built in the time of Edward III. On the garden side of this wall the soil came up to within a few feet of the top, while on the other side was a deep drop, so that there was a considerable pressure on one side of the wall.

In the year 1904 the foundations of the wall having been loosened, the whole wall began to slip and to fall outwards till there was imminent danger of its falling down bodily. To relieve the pressure on the top of the wall, the earth was dug away all along the side to a depth of some 10 feet, leaving a large chasm right along the garden to be dealt with somehow. Later on the top half of the wall was pulled down and a long sloping bank made down to it in the garden, with a brick walk at the bottom. This bank faces south, but as there is a tall building close to the wall on the other side it gets a considerable amount of shade both from the sun and wind. The Rose Alberic Barbier was chosen to cover this bank, and was planted in the autumn of 1905, both at the top and bottom, those at the bottom having grown much the best.

The bank itself is 15 feet from top to bottom, and this year (1908) some of the plants from the bottom had not only grown up the bank but were going a good way up the posts of a pergola at the top. The plants were quite small when received from France, from the firm whose name they bear, so that they have grown very quickly. Their foliage is peculiar, being extremely smooth and shiny, looking almost like an imitation leaf, and is nearly evergreen. The flowers are at their best when just coming out, when they are a delicate yellow colour, and if picked then they

look very well as cut flowers; soon afterwards they open out into a rather loose white Rose.

From their rapid growth, the small amount of trouble and the immense quantity of flowers, they have been a most satisfactory covering for what looked like being an unsightly object.

F. H. HUTTON.

### ROSE CHARLES LEFEBVRE. (HYBRID PERPETUAL.)

**W**ELL might the Rev. Foster Melliar, in his excellent book on Roses, call this variety the King of Crimson. How grand is the formation of the blossoms, every row of petals beautifully circular and as regular as a Ranunculus. Then what a colour it is! a splendid brilliant velvety crimson. It is a variety rather addicted to turning "bluish," a tint so much objected to, but this is only when the old flowers are suffered to remain instead of being cut off ere they reach this objectionable colour. Charles Lefebvre has produced one very fine sport in Sir Rowland Hill, a flower of a maroon and claret colour and very distinct and beautiful. This is one of the few good purplish coloured Roses we have. There used to be a beautiful variety grown years ago named Jean Cherpin. Its buds were of the colour of a Black Hamburg Grape. To see Charles Lefebvre in perfection it needs to be budded each year, or pruned back very hard and early, say by the end of February. Cut it well down to one or two eyes from the base. By so doing the strength of the roots are concentrated in about two eyes or buds, which are quite enough if quality is desired. Margaret Brassac and Paul Jamain are so very much like Charles Lefebvre that only an expert could see a difference. Charles Lefebvre was raised by Lacharine and sent out in 1861. Just about this time and during the following three or four years the collection of Hybrid Perpetuals had some grand additions, the like of which had never been seen before nor since. This fact is very puzzling to raisers. Why cannot they produce equally good Hybrid Perpetuals as in the past? Can anyone supply the answer? These very dark crimson Roses appear to be favourites with most people, especially those of a velvet-like texture and strong scent. A well-formed, deep crimson Rose is a flower that wants a lot of beating.

P.

## THE FLOWER GARDEN.

### HARDY WATER LILIES.

(NYPHÆAS.)

**N**YMPHÆAS, or Water Lilies, have existed through many ages, and no other class of plants is more widely distributed at the present time. Species are indigenous in almost all parts of the world, and such diversity of flower-colour as white, blue, yellow, red and many intermediate shades is found in the genus.

Until the introduction of the coloured hardy hybrid Water Lilies, our water-gardens were little thought about, and contained merely a few of our native aquatics, including our own native Water Lily (*Nymphaea alba*). But with the advent of the coloured Water Lilies our garden waters began to improve, and have continued to do so up to the present day. Judging from the many beautiful and marvellous groups of aquatic and waterside plants which have been exhibited at our horticultural shows throughout the country during the past few years, perhaps in no other branch of horticulture have popularity and progress been more rapid than in the cultivation of aquatics. Another proof of this progress is found in the special lists and the many pages of catalogues now devoted to this class of plants by the different nurserymen who make a speciality of them.

Although we have a number of beautiful Nymphæas from various growers and raisers, it is to M. Latour-Marliac we owe, perhaps, the heaviest debt of gratitude, for he was the first to give us hybrid hardy Water Lilies; and, while others have since been introduced, the Marliac hybrids hold their own, and for general utility are still unsurpassed. Now that our lakes and ponds may be studded over with these dainty Water Lilies, resembling, as it were, brilliantly-coloured stars, swaying to and fro in the breeze, and in brilliance of colour rivalling the Nymphæas of the tropics, it may be said that no present-day garden is complete without some of these floral gems.

The cultivation of aquatics is of the very simplest: All they require is some good soil or the mud such as is found at the bottom of natural lakes. This is the natural food of Nymphæas. Given this to grow in and plenty of water above them, they soon establish themselves and grow into handsome specimens, covering the surface of the water with a wealth of beautiful foliage intermixed with star-like flowers. But though the culture of Nymphæas is so simple, it must not be thought that, once planted, there they are to remain for ever undisturbed or uncared for. No! Just as the perennial Asters and Sunflowers and other plants of our herbaceous borders require to be dug up and divided when they become too thick or get out of bounds, so with Nymphæas. After growing for a few years, some, such as the Marliacea section, being very vigorous growers, become so crowded, and produce so much foliage, that the leaves grow right out of the water, and so completely hide what flowers are produced. It is only when all the leaves are floating that the true beauty of the plants can be appreciated.

Lakes or ponds exposed to the sun, but sheltered from rough and cold winds, provide the most suitable home for Water Lilies, although, failing possession of a natural piece of water, these charming plants may be grown in cement tanks, or even in tubs. A lake for the cultivation of choice aquatics should be free from all coarse weeds, and in all cases the natural mud will be the best soil in which to plant. Where it is impossible to lower the water for planting, this difficulty is soon got over. All that is necessary is to procure shallow baskets of various sizes, and place the plants in these with some soil; then put a few small stones on the surface

A BANK OF ALBERIC BARBIER ROSES.

# "THE GARDEN" FLOWER SHOW.

**T**HE long-looked-for exhibition of garden produce, for our readers only, was held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Wednesday, the 29th ult., and proved an unqualified and gratifying success. The large building was well filled, as no less than 650 exhibits were entered, only a few of which did not appear. Mr. E. Penfold, Kingston Road, Leatherhead, won the silver medal in the amateurs' section, and Mr. J. Tomlin, gardener to Mrs. Goldingham, Anningsley Park, Chertsey, in the open classes. The gold medal for the best competitive exhibit in the whole show went to R. H. Comyns, Esq. (gardener, Mr. Waterton), Heath Farm House, Watford, for a grand collection of vegetables staged in the open section.

## SWEET PEAS.

By common consent the Sweet Peas were the most remarkable section of the show. Alike in the number of competitors and the quality of the blooms they were remarkable. In the amateurs' class for twelve varieties there were twenty entries; in that for six, thirty-two; in that for three, thirty-six; and in that for one, no less than forty-five! The open section was not quite so strong numerically, nevertheless there were twenty-two entries in three classes. Truly readers of THE GARDEN are pronounced lovers of Sweet Peas!

We will deal with the amateur section first. In Class 11, twelve bunches, distinct, E. T. Baker,

Esq., 63, Brigstock Road, Thornton Heath, was victorious with a magnificent collection made up of the following varieties: Frank Dolby, St. George (splendid), Mrs. Walter Wright, Helen Lewis, Evelyn Hemus (very fine), Elsie Herbert (very beautiful), Burpee's Primrose Spencer, White Spencer, Mrs. Hardeastle Sykes, Bolton's Pink (excellent) and John Ingman. The second prize went to E. Burnett, Esq., 1, Sutherland Villas, Cedar Park Road, Enfield, who also had a charming lot of flowers, conspicuous among which were Lord Nelson (very rich colour), Mrs. H. Sykes, E. J. Castle, Frank Dolby, Duke of Westminster and Helen Lewis. The third prize was secured by G. Davidson, Esq., Elm Grove, Quadrant Road, Thornton Heath, who had a very good set.

The first prize for six was secured by Mrs. Paul, 11, High Street, Brentwood, who had Audrey Crier, George Herbert and Helen Lewis in very fine condition; and Mrs. H. Sykes, Helen Pierce and Dora Breadmore excellent. Mr. E. T. Baker followed up his victory in the large class with a highly creditable second. His best varieties were Evelyn Hemus, Elsie Herbert and Frank Dolby; but Countess Spencer, Helen Lewis and George Herbert were also very good. W. A. Voss, Esq., Eastwood Road, Rayleigh, Essex, was a capital third.

The Rev. J. B. Shackle, Dropmore Vicarage, Maidenhead, won with three, having a lovely trio composed of Constance Oliver, Mrs. Collier (in grand colour) and Evelyn Hemus. L. B. Ellis, Esq., Oakmead, Sharnbrook, Beds, was a very close second.

Victory in the class for one bunch fell to E. Penfold, Esq., Kingston Road, Leatherhead, who had an exquisite vase of Frank Dolby. Mrs. H. Agar, Orchard House, West Byfleet, was second with a capital lot of Henry Eckford, which is a difficult Pea to do well.

There were some huge flowers in the open classes. In the class for eighteen, victory fell to Mr. S. Glide, gardener to D. E. Higham, Esq., Coombelands, Addlestone, Surrey, who had immense blooms on very long stems, but not quite clean in one or two cases. His best varieties were Countess Spencer, John Ingman, Audrey Crier, Navy Blue, Mrs. Collier, Frank Dolby, St. George and Mrs. H. Sykes. Mr. A. T. Paskett, gardener to E. J. Johnston, Esq., Burr's Wood, Groombridge, was a good second, also with large blooms. His best varieties were Evelyn Hemus, Audrey Crier, Elsie Herbert, Mrs. H. Sykes and Black Knight. The third prize went to H. A. Sell, Esq., Kempston Villa, Cromwell Road, Laton, whose flowers were small but very bright.

The class for twelve brought out an excellent collection from Mr. J. Tomlin, gardener to Mrs. Goldingham, Anningsley Park, Chertsey, in which Frank Dolby, Nora Unwin, Countess Spencer, Helen Lewis, Sutton's Queen and Primrose Spencer were conspicuous. The second prize fell to E. Franklin, Esq., 4, Belmont Road, South Norwood, who was best represented by Helen Lewis, Mrs. W. Wright, Countess Spencer and Queen of Spain. Mr. Paskett was third.

With six bunches Mrs. T. H. Barnard, Kempston Hoo, Bedford, scored. She had John

GENERAL VIEW OF THE SHOW—JUDGING TIME, BEFORE OUR READERS WERE ADMITTED.

Ingman (under the name of George Herbert), Countess Spencer (named Enchantress) and Helen Lewis extremely good. Mr. Paskett was second with Elsie Herbert, Black Knight and Audrey Crier very fine.

## ROSES.

### AMATEURS' SECTION.

For eighteen Roses, distinct, the first prize was won by the Rev. J. H. Pemberton, Havering-atte-Bower, with a splendid even lot of blooms. His finest examples were Dean Hole, Florence Pemberton and William Shean. The second prize went to Vivian Rolt, Esq., Brook House, Storrington, Pulborough. Beautiful specimens of Mrs. E. Mawley and White Maman Cochet were shown in this lot. Third honour went to Gulliver Speight, Esq., The Square, Market Harborough.

In Class 2, for twelve Roses, distinct, the first prize again went to the Rev. J. H. Pemberton, Havering-atte-Bower, who had another beautiful lot, in which were grand flowers of White Maman Cochet, George Laing and Florence Pemberton. G. Speight, Esq., The Square, Market Harboro', was placed second, and the third prize went to Mr. A. Brice, 4, Providence Terrace, Highbury, Hitchin. C. A. L. Brown, Esq.'s exhibit from Hatfield Peverel was very

position. This was a very fine lot in which we noted lovely flowers of Frau Karl Druschki and George Laing Paul. Mr. H. L. Sell, of Luton, was awarded third prize.

In Class 4, Mr. W. E. Fielder, gardener to W. Hudson, Esq., The Lodge, Surbiton Hill, was the only exhibitor, but he staged a dozen good blooms and received the first prize.

In Class 7, for six Hybrid Perpetual Roses, distinct, H. Matthews, Esq., of Betchworth was first; Mr. E. Clements, The Gardens, Trusley Manor, Etwell, Derby, second; and Mr. H. L. Sell of Luton third.

For six Tea Roses, distinct, Mr. W. E. Fielder, gardener to W. Hudson, Esq., The Lodge, Surbiton Hill, well won the premier prize with good flowers. Mr. H. L. Sell, Luton, was second with some moderately good blooms.

### GARDEN FLOWERS.

The class for twelve bunches of garden flowers (amateurs) brought nine competitors, and the quality and the arrangement of the exhibits were excellent. The first prize was awarded to George Cheney, Esq., Broadway, Kettering, who had excellent examples of Carnation Lord Roberts, Rose Anna Olivier, Phlox, Montbretia, Stocks and Gaillardias. The second prize was allocated to Lady Susan Trueman, Bayman

Mr. E. C. Curtis, The Old Rectory, North Petherton. Carnations, Sweet Peas and Gladioli were superb. A pretty series won second prize for the Rev. H. A. Soames, Lyncroft, Bromley, Kent, and the third prize was awarded to Mr. E. Clements, The Gardens, Trusley Manor, Etwell, Derby.

A special first prize was awarded to Mrs. T. H. Barnard, Kempton Hoo, Bedford.

### CARNATIONS.

The class for six vases of border Carnations, three blooms in each (amateurs), brought together a dozen competitors, the first prize going to an admirable lot of blooms from R. Morton, Esq., Grange Dean, Woodside Park, N. Second honours fell to A. Childs, Esq., Brown Candover, near Alresford, Hants, whose flowers of the Maid (yellow) and Hildegard (white) were excellent. H. E. Greef, Esq., St. Andrews Terrace, Cambridge, was a good third.

For three vases of border Carnations, three blooms of each (amateurs), the Rev. J. B. Shackle, Dropmore Vicarage, Maidenhead, was placed first with good blooms of Sir Bevy's, crimson; Miss Audrey Campbell, yellow; and Ketton Rose. The second prize went to Mr. C. Cox, Farnham Common, Slough; he exhibited very fine blooms of scarlet, pink and fancy sorts.

FIRST PRIZE COLLECTION OF FRUIT (OPEN SECTION). (Shown by Mr. M. Webster, gardener to E. J. Preston, Esq., Kelsey Park, Beckenham, Kent.)

highly commended. There were eleven exhibits in this class.

Class 3, for nine Tea Roses, distinct, G. Speight, Esq., was the champion with nice clean specimens, those of Souvenir de Pierre Notting and Mme. C. Soupert being particularly good. The second prize went to the Rev. J. B. Shackle, Dropmore Vicarage, Maidstone.

For six Tea Roses, distinct, the Rev. J. H. Pemberton, the Rev. J. B. Shackle and D. L. Freeland, Esq., Snodland, Kent, won in the order named. There were eight exhibits in this class, so the prize-winners may be congratulated on their success.

In Class 6, for six Hybrid Perpetual Roses, the first prize went to Mrs. E. Penfold, Kingston Road, Leatherhead, and the second to George Cheney, Esq., Kettering.

Class 7, for nine Hybrid Tea Roses, distinct, the Rev. J. B. Shackle was the champion. He had grand flowers of Princesse Metchersky, J. B. Clark and Dean Hole. G. Speight, Esq., was second, and D. L. Freeland, Esq., third.

Class 8, for six Hybrid Tea Roses, distinct, the Rev. J. B. Shackle was again first. Mrs. A. Brice, Highbury, Hitchin, was second. In this class two exhibits were disqualified as being not according to schedule.

### OPEN SECTION.

Class 1, for twenty-four Roses, distinct, the Rev. J. H. Pemberton occupied the premier

Manor, Chesham, Bucks, whose chief exhibits were Ceanothuses, Alstroemerias, Fuchsia globosa, Bocconia, Phlox and Hollyhock. The third prize was taken by A. Childs, Esq., Alresford, Hants, whose chief exhibits were Scabious, Scarlet Phlox, Dorothy Perkins Rose, Bocconia cordata and Stenactis.

In a similar class, for six bunches (amateurs), the first prize was taken by the Rev. J. B. Shackle, Dropmore Vicarage, Maidenhead, whose vases of Sweet Peas, yellow Carnations, Alstroemeria and Mme. Abel Chatenay Roses were very charming. The second prize went to E. Penfold, Esq., Leatherhead, who displayed Lavatera, Candytuft, Chrysanthemum coronarium and Sweet Peas in excellent form. Third honours fell to G. Cheney, Esq., Broadway, Kettering.

The four exhibits in the class for twelve bunches of garden flowers (open) made a brave show. A beautiful series won first prize for Mr. W. E. Fielder, gardener to W. Hudson, Esq., The Lodge, Surbiton. Phloxes, Carnations, Mme. Abel Chatenay Roses, Ceanothus, Godetias, Zinnias, Stocks and Sweet Peas were splendid. A good second was found in Mr. Sell, who had fine Achilleas, Roses, Lathyrus, Erigeron and Gaillardias. The third prize was well won by Mr. R. Brown, gardener to Lady Tress Barry, St. Leonards Hill, Windsor.

For six bunches of garden flowers (open) there was a spirited contest. The first prize went to

H. E. Greef, Esq., St. Andrew's Terrace, Cambridge, was again third.

The class for twelve vases of border Carnations, distinct, three blooms of each (open), brought three fine groups, the first prize being awarded to R. Morton, Esq., Grange Dean, Woodside Park, N., who staged a most beautiful lot of flowers in selfs and fancies, the entire lot denoting the best culture. The second prize went to F. Fairlie, Esq., Springfield Road, Acton, who had a choice lot of blooms. E. C. Curtis, Esq., The Old Rectory, North Petherton, secured the third prize.

For six vases of border Carnations, three blooms of each (open), there were seven competitors, the premier award once more going to R. Morton, Esq., Woodside Park. His scarlet and yellow selfs were superb flowers. J. Fairlie, Esq., Acton, was second and H. E. Greef, Esq., St. Andrew's Terrace, Cambridge, third.

### VIOLAS, PANSIES AND ANNUALS.

For six Violas (Tufted Pansies), distinct (amateurs), E. Moseley, Esq., Brisbane Road, Ilford, was first with Goalkeeper, Immortalité, Mrs. J. W. R. Johnstone and others. The second prize went to W. Poulteney, Esq., New Barnet.

In the class for six fancy Pansies, three blooms of each (amateurs), the first prize was well won by T. Hamilton, Esq., Coatbridge, Lunark, whose

THE GOLD MEDAL EXHIBIT. (Staged by Mr. Waterton, Heath Farm)

flowers of Robert Melville, Tom McCullum and Alice Lister were very fine indeed. Second prize went to V. Rolt, Esq., Storrington, near Pulborough, Sussex, for capital blooms of David Wilson, W. H. Clark and R. C. Dickson.

For twelve *Violas*, three blooms of each (open), W. Compston, Esq., Higher Hurdfield, was first with large and good flowers, the second prize being awarded to Mr. H. L. Sell, Luton, Beds.

For nine kinds of annuals (amateurs), first prize was appropriated by H. Cox, Esq., Jersey Lodge, Maidenhead, for excellent vases of *Zinnias*, *Nigella*, *Marigolds*, *Stocks*, *Salpiglossis* and *Godetias*. Second honours fell to Lady Susan Trueman, Chesham, Bucks, whose best vases were *Chrysanthemum burbridgeanum*, *Shirley Poppies* and *Eschscholtzias*. G. Harrow, Esq., Ponder's End, Enfield, was placed third.

For twelve kinds of annuals (open), the first prize went to Mr. J. Tomlin, gardener to Mrs. Goldingham, Anningsley Park, Chertsey. He had good vases of *Godetias*, *Sweet Peas*, *Lavateras* and *Marigolds*. Lady Tress Barry, St. Leonard's Hill, Windsor (gardener, Mr. R. Brown), was a good second. Third prize was awarded to Mr. G. Harrow, Ponder's End, Enfield.

#### TABLE DECORATIONS, BASKETS AND BOUQUETS.

There was only one competitor in the open class for a table decoration of *Roses*, Dorothy Perkins being used in association with *Asparagus*. This was exhibited by Mrs. H. L. Sell, Luton.

In the open class for a table decoration of any flowers there was only one competitor, Mrs. Sell being once again awarded first prize. The display was very pretty indeed, pink and cream *Sweet Peas* and dainty foliage beautifully arranged well meriting the distinction.

For a table decoration of *Roses* (ladies only), Mrs. Sell was again the only competitor, securing first prize for a fine exhibit.

In the class for a table decoration, any flowers (ladies only), Mrs. H. L. Sell was the first of the three exhibitors with a really charming display. Cream and lavender *Sweet Peas* with pale green *Asparagus* fronds and pieces of tanned Hornbeam judiciously worked in made a striking exhibit that fully deserved leading honours. Second prize was secured by Mrs. Edwards, 2, Warwick Terrace, Sydenham, who had *Henry Eckford*, a cream *Sweet Pea*, deftly disposed with foliage. Third prize was placed to the credit of Mrs. H. J. Kybert, 74, Heigham Road, East Ham,

whose *Sweet Pea* flowers were very pretty, but rather formally arranged.

There were four charming table decorations of *Roses* in Class 20 (amateurs), a really charming table of *Irish Elegance*, single, winning leading honours for Mrs. A. E. Cullis, 52, Ellerby Street, Fulham, W. Dainty buds and lovely foliage made a most artistic decoration. The second prize was secured by Mr. W. H. Turner, 66, Victory Road, South Wimbledon, with pink and cream *Roses* deftly disposed. Third prize went to Mrs. E. Esdaile, St. Leonards, Crescent Road, New Barnet, clusters of *Dorothy Perkins* making a pretty decoration. The green centre cloth spoilt this display.

No less than nine exhibitors entered the class for a table decoration of any flowers (amateurs), nearly all of them using *Sweet Peas*. First prize was secured by Mrs. L. Jones, 100, Marsala Road, Lewisham, S.E. *Enchantress* or a similar *Sweet Pea* made a lovely exhibit, and this was improved by the addition of *Asparagus*, *Gypsophila* and *Grasses*. Second prize was well won by Mrs. H. L. Sell, Kempton Villa, Luton, Beds, the combination of colour and the subjects used being all that could be desired. Third prize went to Mr. C. C. Rowland, Muckleton Manor, Gloucester.

There were four baskets of flowers in Class 31 (ladies), pretty *Sweet Peas* and a few sprays of other subjects winning first prize for Mrs. A. Swann, Ramsden Heath, Billericay, Essex. Mrs. Sell, Luton, was a good second, the yellow colouring being rather overdone, otherwise the basket was very pleasing. Mrs. Alex. Stenning, Hoathley Hill, East Grinstead, was third with an interesting basket that must have been very pretty earlier in the day.

Of the two bouquets shown Mrs. Sell was an easy first prize-winner, having *Roses*, *Carnations* and *Sweet Peas* artistically disposed among *Asparagus* foliage. Second prize was awarded to Mrs. J. W. Lightfoot, 256, Friern Road, East Dulwich, for a bouquet of *Roses*.

Of the six entrants for a lady's spray *Sweet Peas* superbly arranged with pretty foliage won first prize for Mrs. Sell. Mrs. Edward was second with a spray of *Odontoglossum* and *Asparagus*, and third prize for *Raby Castle Carnation* went to Miss E. H. Ekins, Rushden, St. Albans.

There were seven competing in the class for a gentleman's buttonhole, Miss Ekins winning first prize with three pretty buds of a *Noisette Rose*; Mrs. Edwards was second with an *Odontoglossum* and a bud of *William Allan Richardson* won third for Mrs. A. Swann.

For the best greenhouse or window plant Mr. W. G. Child was first with *Manettia bicolor* and Mr. W. Bignell second with a small, well-grown *Palm*.

FIRST PRIZE EXHIBIT OF TWELVE BUNCHES OF SWEET PEAS (AMATEUR SECTION).

## VEGETABLES.

The class for a collection of vegetables, not less than nine kinds (open), brought seven competitors, whose exhibits denoted the highest cultural skill; indeed, it is not too much to say of the leading groups that the collections would have occupied winning positions in any competition in the kingdom. The first prize in a close contest was awarded to R. H. Comyns, Esq., Heath Farm House, Watford (gardener, Mr. W. Waterton), who staged fourteen distinct sorts, including Prize-winner Pea, Canadian Wonder Dwarf Bean, Mammoth Longpod Broad Bean, Cauliflower Magnum Bonum, Vegetable Marrows, Perfection Tomato, Windsor Castle Potato, Ailsa Craig Onion, Carrots, Cabbage, Leeks, Celery and Cucumbers as his best. This exhibit from Messrs. Sutton's seeds also received the gold medal awarded "for the best competitive exhibit in the show." Little inferior was the collection staged by Mr. W. Gaiger, gardener at Kendall Hall, Elstree, Herts, which received second prize. In this group some fifteen kinds were staged, and great excellence marked the exhibits throughout. The third prize was awarded to Mr. Tomlin, gardener to Mrs. Goldingham, Anningsley Park, Chertsey. For six dishes of Peas, distinct (open), Mr. W. Waterton, gardener to R. H. Comyns, Esq.,

For two Cucumbers (open), T. Jackson, Esq., North Hill, Highgate, N., was first, Mr. W. Waterton, gardener to R. H. Comyns, Esq., Watford, coming second.

There were no less than seventeen collections of vegetables in the amateurs' class for not less than six kinds. First prize was secured by Dr. A. H. Boyes, The Grange, St. Albans, Herts, with a really creditable display. Cauliflowers, Longpod Beans, Carrots, Scarlet Runners, Beet, Peas, Marrows and Potatoes were all well done. Mr. C. C. Rowland won second prize with a very fine display, this following the leader closely. Onions, Cauliflowers and Celery were superbly shown in this exhibit. Third prize was won by Mr. F. J. Gentle, Bedmond, King's Langley, with a capital exhibit.

The seven exhibits of three dishes of Peas (amateurs) were a good feature of the show. First honours went to Mr. A. Childs, Brown Candover, near Alresford, Hants, for a splendid trio. Mr. F. J. Gentle was a close second, and Mr. C. C. Rowland third.

Seventeen dishes of Peas made a capital display in the amateurs' single dish class, Mr. H. Matthews, Brookham Green, Betchworth, Surrey, being first with Quite Content. Second prize was secured by Mr. R. H. Lessware, East Barnet Road, New Barnet. We were pleased to see so fine an exhibit of vegetables.

Childs was placed first with an example of New Scarlet Intermediate and Dr. A. H. Boyes second with a beautiful example of Carter's Summer Favourite.

No less than fifteen exhibits of three Beet-roots (Turnip-rooted) were shown in a class for amateurs. First prize was won by Mr. W. J. Child, Thornton Heath, with a clear trio, followed in the second place by Mr. H. Hayter, Fieldhurst, Addlestone.

## FRUIT.

Competition in the open section was good in most classes, and the amateurs also staged some very fine dishes.

For a collection of fruit, consisting of Gooseberries, Currants and Raspberries, Mr. Mark Webster, gardener to E. J. Preston, Esq., Kelsey Park, Beckenham, Kent, showed five varieties of Gooseberries, two of Raspberries and Red, Black and White Currants, all in magnificent condition. Second prize was awarded to Mr. Clements for a really interesting exhibit.

For three dishes of Strawberries, Mr. E. Clements was the only exhibitor and was placed first. Laxton's Latest, The Bedford and Waterloo were the varieties shown.

Four entered for the collection of Gooseberries, Currants and Raspberries (amateurs), and made

a highly creditable display. First prize was won by Mr. A. Child with the Currants (Black, White and Red) well represented and superb Raspberries. The Gooseberries were, nice and ripe. A close second was found in Mr. W. Bignell, 5, Castle Yard, Highgate, N., who had a capital series; and third prize was won by Mr. H. Bass, 22, High Street, Highgate, with a comprehensive display.

Four exhibitors showed in the amateurs' class for two dishes of Gooseberries, Mr. Penfold winning with splendid fruit. Mr. H. Bass was placed second with much smaller though ripe fruit, and Mr. Bignell was a good third.

Mr. E. Penfold was a capital first for two dishes of Red Currants in handsome form and condition, and Mr. Rowland was placed second.

The same order was observed in the class for two dishes of White Currants, the exhibits in both cases being meritorious.

For two dishes of Black Currants, distinct, Mr. H. Bass was a good first with handsome fruits. Mr. C. C. Rowland had beautiful fruit for the second prize, and Mr. Bignell was close up for third honours.

Splendid fruit was shown in the amateur class for a dish of Raspberries, and seven entries were forthcoming. Mrs. A. M. Platt, Ken View, View Road, Highgate, N., was a good first with large bright berries; Mr. William Lamprey, King's Sutton, near Banbury, second; and Mr. H. Matthews third.

Three capital exhibits were shown in the class for three dishes of Currants—red, white and black. Mr. C. Cox was an excellent first, Mr. Penfold second with a good series and Mr. R. J. G. Read, Cadbyrie House, Ealing, W., third. For a dish of fruit not mentioned in any other class Lady Susan Trueman, Bayman Manor, Chesham, Bucks, was placed first for a splendid Melon and Mr. Rowland second with large Bigarreau Cherries. There were ten entries.

Reference to Trade Exhibits will be found on page v.

FIRST PRIZE COLLECTION OF VEGETABLES (AMATEUR SECTION). (Shown by Dr. Boyes.)

Heath Farm House, Watford, was first. He had fine dishes of Masterpiece, Duke of Albany, Quite Content and Prize-winner. Second prize was won by Mr. E. Clements, gardener at Trusley Manor, Derby, and the third prize went to Mr. H. L. Sell, Luton, Beds.

A similar class for three dishes brought eight collections, the first prize going to Mr. W. Gaiger, gardener at Kendall Hall, Elstree, and second to Mr. W. Waterton, gardener to R. H. Comyns, Esq., Heath Farm House, Watford.

In the open class for three dishes of Potatoes seven competitors entered. Mr. R. Brown, gardener to Lady Tress Barry, St. Leonard's Hill, Windsor, was the champion. His dishes of Superlative, May Queen and Gladiator were superb examples. An equal second prize was awarded to A. H. Boyes, Esq., The Grange, St. Albans, Herts, and Mr. W. Waterton, gardener to R. H. Comyns, Esq., Heath Farm House, Watford. Snowdrop, Centenary, Duke of York and Superlative were specially noticeable in these exhibits.

The class for one dish of Tomatoes (open) brought eight competitors, Mr. J. Tomlin, gardener to Mrs. Goldingham, taking first prize with Sunrise. Second prize went to Mr. W. Gaiger, gardener, Kendall Hall, Elstree, Herts.

Nine exhibits of three dishes of Potatoes (amateurs) were a meritorious lot. Superbly fine tubers secured first prize for Dr. A. H. Boyes, The Grange, St. Albans. They were without a blemish, and were represented by Carter's Surprise, Duke of York and Snowdrop. We have never seen finer Potatoes so early in the season. Mr. A. Childs had an interesting series which secured second prize for him, and third prize went to Mr. C. C. Rowland with a nice lot.

There were sixteen entries in the amateur's class for a single dish of Potatoes, these making an excellent contest. Mr. F. J. Gentle, Bedmond, King's Langley, was placed first with Windsor Castle. Mr. E. Penfold, Kingston Road, Leatherhead, was second, and Mr. W. B. Child, Front Road, Thornton Heath, third.

For a bunch of autumn-sown Onions, there were seven competitors, Mr. E. Penfold being the champion with grand Ailsa Craig; Mr. Gentle was second.

Ten exhibits of Vegetable Marrows made a good show in the amateur class for a single Marrow. Mr. Gentle was first with a capital example of Sutton's Long White and Mr. C. Cox, Bucklands Cottage, Farnham Common, Slough, second with a pretty exhibit.

Carrots were well shown by amateurs, no less than eleven exhibits being in evidence. Mr. A.

or a few ties across the basket to keep the plant from floating out. Each plant can then be sunk where it is intended to grow, and before the basket has rotted away the plant will have rooted through and secured itself to the bottom. Large plants may also be planted by fixing a stone or other weight to the root and dropping the whole in where the plant is required to grow. In artificial ponds or tanks a copious inflow of water is not at all desirable; a trickle of water sufficient to keep things wholesome is all that is needed, and is, indeed, far better than a constant inrush. In small tanks a layer of soil to the depth of 10 inches or 12 inches might be spread over the bottom, and in larger structures little mounds or hillocks, made by placing a few turves together, should be formed.

When planting, secure the plant with a peg or weight to prevent it floating. The soil in which *Nymphæas* are to be planted should be prepared some months before it is required, and should consist of good turfy loam which has been cut and stacked for at least twelve months, plenty of half-decayed leaves and some sharp sand, and the compost should be kept dry until it is wanted for use. The use of manures in any form I do not advocate, as they only excite rank leaf-growth and predispose to disease.

#### THE BEST TIME FOR DIVIDING OR PLANTING NYPHÆAS

is the spring, about the end of April or beginning of May, although they may be safely moved at a much later period. If planted at the time stated the plants make sufficient progress to give a supply of bloom before the summer is gone. The flowering season for established plants begins early in June, reaches its height in August, and in good years lasts well on into October.

The depth of water required for the culture of *Nymphæas* may vary from 18 inches to 4 feet or 5 feet; but, although I believe some of the stouter-growing ones would do in a much greater depth, it is not wise to plant them so deeply, for they could not be got at without a boat or raft, and when it became necessary to divide and transplant them the water would have to be lowered, and this is not always an easy matter. I should, therefore, never plant choice *Nymphæas* in a greater depth of water than I could get at with a pair of wading-boots, with the tops made long enough to come well up under the arms. Four feet of water above the crowns of any of the stronger-growing varieties is quite enough, and not less than a foot above the lesser-growing ones.

A crowded water-garden is often a matter of necessity; but where space is at command the plants are best in bold groups and far enough apart to keep them quite distinct, while allowing for effective contrast in colour. All the *Marliacea* section, being of strong growth, together with similar strong-growing kinds, should be placed in the deepest water, but should not be put so far out that their beauty cannot be seen from the margin of the pond or lake. Drawing nearer to the margin, where the water will naturally be a little more shallow, we may plant the *Laydekeri* section and some of the American hybrids, which will be admirably suited for this position; and for planting nearest to the margin we have the lovely *odorata* section and the *pygmæa* forms. To give

A LIST AND DESCRIPTION OF THE NYPHÆAS in cultivation at the present day would occupy far too much time and space. They are accurately described by those who make a speciality of them. But a few might be mentioned which stand out above all others. The first is *N. gloriosa*, which is beyond doubt a grand variety, rich carmine-red in colour, with abundance of bright orange stamens, and the only *Nymphæa* with five sepals. *N. Marliacea chromatella* and *N. odorata sulphurea* are still the best yellow-flowered varieties we possess; *ellisiana*, *atropurpurea*, *sanguinea* and *William Falconer* are some of our best dark-flowered varieties; and for

rich rosy crimson we have *James Brydon*, quite one of the best American varieties; *lucida* and *Robinsonii* are also good in this shade of colour. Of white-flowered varieties there is none better than *gladstoniana* and *Marliacea albida*. The *odorata* section, of which *rosacea*, *rubra* and *exquisita* are some of the best known, are all sweetly scented. The last-named section will soon deteriorate if confined in small tanks, and I have sometimes heard of failures with it under such conditions, which can only be attributed to confinement. The *odorata* section is easily distinguished from all others, as the varieties have long, wiry-looking rhizomes, or root-stocks, sometimes measuring 4 feet or 5 feet in length. Where space can be found for them to grow freely on the bottom of large or medium-sized ponds, they are bound to succeed.

Although *Nymphæas* are naturally sun-loving plants, yet I have always noticed that the water-garden is seen at its loveliest on dull, showery days, when the water is clear and the leaves and flowers are thickly set with diamond drops that glisten and sparkle like rubies, topaz and garnets. The flowers vary as to opening and closing, and while on bright days, in the beginning of the season, they open in early morning and, unless the weather is dull, mostly close about three or four o'clock in the afternoon, as the season advances just the reverse takes place—they open later in the day, and sometimes keep open even into the early moonlight of a summer's night.

(To be continued.)

#### THE PLUME POPPY.

(*BOCCONIA CORDATA*.)

THIS is a handsome perennial introduced into this country from China in 1795. It is a noble, hardy plant, valuable both for its foliage and for its inflorescence. It throws up a mass of close-growing stems, often to a height of 9 feet or more, these being clothed with silvery grey, deeply-veined leaves, which are deeply lobed. The tall stems are terminated by panicles of creamy white flowers. Some of the terminal panicles are often almost 3 feet in length, and the flower-shoots also throw out lateral bloom-sprays. After the blossoms fade they turn to an amber-brown colour, which has a pleasing effect.

No garden should be without this excellent plant, which is at once bold, handsome and picturesque. It is especially suited for massing, when a noble picture is secured, or for planting in isolated positions on the lawn, in the front of

THE PLUME POPPY (*BOCCONIA CORDATA*) IN A DEVONSHIRE GARDEN.

shrubberies, or anywhere where abundant room may be given it for future development. Growing at the back of wide herbaceous borders, associated with such plants as *Arundo Donax* and the graceful *Spiræa lindleyana*, its effect is very distinct and ornamental, the towering stems with their great feathery plumes shaded from ivory white to reddish brown being unique in tint and form, while the green of the upper surface of the lobed leaves contrasts pleasingly with the silvery white of their woolly reverse.

The plant requires some time to become thoroughly established and to attain its rightful proportions, but when once thoroughly naturalised is indifferent to soil, throwing up stems exceeding 9 feet in height even on a bank of light stony staple, which is persistently robbed by the roots of neighbouring *Fir* trees. The *Bocconia* is worthy of a place in all gardens that can afford room for it. When once established it must, however, be kept within bounds, as it is a veritable land-grabber, and if unrestricted its suckers will encroach on the surrounding ground, greatly to the disadvantage of its neighbours. The nut brown stems of the withered blossoms should never be cut away, but allowed to remain, when they will provide an autumn picture as pleasing as the gradations of tones one gets earlier in the flowers. The *Bocconia* is a capital plant for the wild garden, as when once well established it will hold its own with the native vegetation. It may be easily raised by root-cuttings 2 inches in length placed in porous soil in pans and kept moderately moist under glass. It was at one time known as *Macleaya cordata*.

South Devon.

S. W. FITZHERBERT.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**THE FLOWER GARDEN.**—The Erythronium (Dog's-tooth Violet) is a pretty subject to plant at the present time. Although not fastidious as to soil it does not succeed very well in heavy clay. I plant it in well-worked soil, 2 inches deep and 3 inches apart, in colonies for effect, choosing semi-shaded quarters. I am

1.—SHOOTS SUITABLE FOR MAKING INTO CUTTINGS OR PIPINGS.

busy layering Pinks and Carnations, which will be severed from the old plants when well rooted. Gladioli, the spikes of which are growing vigorously, may be improved by frequent applications of liquid manure, and Asters and Stocks also take kindly to this feeding. Geraniums, Calceolarias and similar bedding plants may now be propagated by cuttings for next season's supplies. The former may be propagated in a bed in the open, using light sandy soil, or they can be inserted in similar soil in boxes. Select firm growths and trim off the lower leaves.

**The Window Garden.**—The white and blue Campanulas should now be making a beautiful display in the window. See that the soil does not get dry or their period of blossoming will be shortened. Do not allow the plants in the window to remain in one position continuously; they should be turned round from time to time as they benefit considerably thereby. Those who wish to raise a fresh batch of Fuchsias, Geraniums and similar plants should insert healthy cuttings at the present time. A warm window and a bell-glass or a box covered with a sheet of glass will make an excellent propagator. Always remember to use fairly light sandy soil, and press the soil firmly at the base of each cutting. The showy Guernsey Lilies and Vallotas may now have copious applications of water.

**The Vegetable Garden.**—I am just about to earth up my earliest batch of Celery. This is done in a variety of ways. One method is to first place 3 inches of soil round the base of the plants, taking care to avoid pressing the soil too closely. Subsequently—say, in about a fortnight—repeat the operation, and from time to time add soil until completed. Another method is to tie pieces of brown paper, 6 inches wide, at intervals of a few weeks; in this way the bleaching is beautifully done without the unpleasantness that accompanies the moulding up with earth. Before either method of bleaching is begun, remove all offsets and damaged stems and leaves, and also

draw all the stems moderately close together with raffia. Recently-sown Turnips for autumn supplies must be thinned in good time; 8 inches apart is a good distance to allow. I am sowing Tripoli, Rocca and White Lisbon Onions at the present time. The last-mentioned is a capital variety for saladings during the late autumn and winter, and the two former sorts will make large bulbs for harvesting next July.

**The Cold Frame.**—This useful adjunct of the garden should now be in frequent and almost continuous use. Have ready in good time the quarters intended for Violet culture. Although the Violets are not lifted and planted until September, the soil must be settled and ready for their reception in good time. Place the frame on a bed of leaves 2 feet or 3 feet from the ground, and tread this all over firmly. Fill in, after placing the frame in position, 10 inches deep with a compost of three parts light loam and one part leaf-mould, and, after mixing, level and make firm. Growers in the neighbourhood of London should not attempt to grow Violets, as the impure air renders it almost impossible. Primulas in frames should be maintained in a moist, close condition, and this may be contributed to by lightly syringing the plants in the evening. Shade these plants from the sun during the day.

**Hardy Fruit.**—Strawberries for next summers' supplies should be planted without delay. Old and exhausted plants should be uprooted and the quarters planted with Cabbage. Raspberries need attention forthwith. Canes that have borne fruit during the present season should be cut out, and the weaklings of this year's growth must also be removed. Stools represented by about five strong canes are most desirable.

**The Greenhouse and Conservatory.**—The perpetual-flowering Carnations should have their final shift without delay. The plants must have outdoor treatment until the closing days of September. Stand them on a thick layer of sifted cinder ashes to prevent the ingress of worms. The beautiful variety Robert Craig is one of the exceptions to the general rule; this plant must be kept under glass both winter and summer. The present is a good opportunity for painting these structures. Repairs to the roof are also matters that should have speedy attention, as everything must be in good and sound condition before bad weather is experienced. D. B. C.

### INCREASING GARDEN PINKS.

THE Pink is one of the old-fashioned garden flowers that never fails to interest and please lovers of the hardy flower garden, and, as it is a plant of comparatively simple culture, the wonder is that these fine old flowers are not more often met with than is now the case. Many flower-lovers prefer the garden Pink to the Carnation, chiefly on account of its propensity to flower freely, and also because of the fragrance of the dainty blossoms. They have this advantage, too, that they are extremely hardy and will live in the neighbourhood of large towns, where many other so-called hardy subjects fail to winter well. July and August, and even September in special situations, are the recognised months during which the Pink may be increased. They may be propagated by two or three different methods, viz., by simply pulling the old plants asunder and heeling in the pieces thus divided, or by the use of pipings (cuttings), by which means quite a large stock can be brought into effect, and by a system of layering as is successfully adopted in

the case of increasing Carnations. Each of these methods have a value peculiarly their own, and each one has many adherents.

We will first deal with lifting and dividing old plants. If they are torn asunder with what is known as a "heel" on them—that is, a portion of the old stem adhering thereto—they may be firmly dibbled or laid in along the edge of the border in light sandy soil, and in such a position will root with the greatest readiness. It is a good thing to choose showery weather for this purpose. It must be admitted that this is a very rough and haphazard way of increasing these plants, but it is followed with considerable success.

The second method requires rather more care. The Pinks may be raised, as we said before, in large numbers by the aid of cuttings or pipings, a term more popular with Pink growers. Doubtless, in many gardens there may be a few clumps available from which cuttings or pipings can be obtained, and these growths are represented in Fig. 1. The shoots are about 3 inches or rather more in length. Fig. 2 represents the same cuttings or pipings prepared in readiness for their insertion in specially-prepared soil in frames, pots, pans or boxes, using whatever means are most convenient in each individual case. It will be observed that the pipings are cut through immediately below a joint, from which the leaves have been removed. The lower leaves should be removed for an inch or so from their base. In some cases well-known growers make a practice of cutting off the tips of the leaves, but we have raised them very successfully without doing anything of the kind. The great thing to remember is to cut through the stem immediately below a joint, as it is at this portion of the stem that the roots are emitted. The shoot on the left of the illustration is slit up at the end; this is a practice that is sometimes adopted, but the cuttings will root very satisfactorily without this being done.

Leaf-mould, loam and sand in equal parts should be the ingredients of the compost, and in such material the cuttings will root readily. Insert the cuttings firmly 3 inches apart. The soil must be pressed firmly at their bases in order that it may adhere thereto, otherwise rooting will be somewhat delayed and they may even fail altogether. If a frame is not available a small bed or series of beds made up in any shaded position, and an ordinary hand-light or bell-glass placed over them will answer equally

2.—THE SAME SHOOTS PREPARED READY FOR INSERTION. NOTE THAT THE LOWER LEAVES HAVE BEEN REMOVED.

well, and in this way quite a number of useful plants may be raised with ease. Those who possess neither frame, bell-glass, nor hand-light need not despair, because if a bed of light sandy soil be made up in a shady spot in the garden the cuttings can be dibbled in here in like manner and should root within a month or so. It is important to remember that the cuttings should be shaded from the sun, so that tiffany or some other shading material must be used.

It is important to see that the soil does not get dry; it should always be kept in slightly moist condition. We have shown in Fig. 3 a few cuttings inserted in a 3-inch pot, because it is possible in some small gardens that growers may not have a piece of ground available. If cuttings are inserted in pots in the manner indicated here, and if a hand-light or bell-glass be placed over them the beginner may raise his plants quite satisfactorily.

The illustration in Fig. 4 is a typical plant after a year's growth. Readers will be careful to note the robust character of the clump from which numerous pieces of grass (shoots) have been developed.

In the illustration in Fig. 5 a growth of fairly good length has been selected for layering. Shoots are trimmed exactly in the same way as is customary in layering Carnations, and here it

3.—CUTTINGS INSERTED IN A 3-INCH POT; A METHOD SUITABLE FOR SMALL GROWERS.

own, and, as will be seen in Fig. 4, it forms a compact, dwarf mass such as is essential for edgings.

#### EARTHING UP CELERY.

THIS moisture-loving vegetable is a great favourite with most people, and rightly so, as a fine, solid, crisp head is something worthy to grace any table and provides a welcome change, both as a salad and a vegetable, during the late autumn and winter months. Many amateurs take an immense amount of trouble over rearing the plants, preparing the trenches, and subsequently tending the plants until earthing up time, when the tendency is to give them too much attention, and so to a great extent undo the good work of the previous months.

There is no doubt that eight out of every ten amateurs or beginners in gardening earth up Celery much too early—as soon, indeed, as the leaves are long enough to gather well together. The worst of this treatment is that the plants' subsequent behaviour is such as to lead the cultivator to imagine that his treatment is correct, as growth in an upward direction is soon most pronounced. It is, however, when the crop is lifted that disappointment usually ensues. Instead of the plump, thick, solid plant with a good white heart, the grower finds a long, attenuated specimen possessing the leaves that were present at the first earthing, and little else besides.

The reason for this state of affairs is easily explained. When the outer leaves are long enough to gather together very little heart has been formed, and when earthing up is performed at this period the inner leaves, which in the ordinary course eventually form the heart, have very little chance to develop. Instead of being in a hurry to earth up the plants, amateurs would do well to wait until a good number of the inner leaves have attained a considerable size; then plump hearts are practically ensured.

The actual earthing will vary according to fancy and circumstances. It should be borne in mind that the principal reason for doing the work is to blanch the leaf-stalks without injuring them, and any method that results in this cannot be far wrong. All offsets from the main plant should be removed, and if the soil in the trench is dry, as it almost certainly will be, it should be thoroughly soaked with water a few hours before earthing is performed, taking care to let the plants themselves get quite dry before the work is done. The simplest and most satisfactory way of placing the soil round the plants is to get a lad to gather all the leaves of one plant moderately close together, and hold them thus while the soil is banked around them,

taking care to break up all large lumps as the work proceeds. Failing this, the leaves may be tied rather loosely together near the tops, but it is advisable to remove the ties after the work is done.

Two operations are quite sufficient for all ordinary crops, the second one usually following about three weeks after the first. At the second earthing care must be taken to make the ridge pointed and firm so as to ward off heavy rains, as wet does the plants far more harm than frost. Some people use brown paper or other substances for blanching the plants, these being tied round the leaf-stalks. Although this system answers very well under careful management, the plants lack that crispness so much appreciated in earthed-up specimens.

#### ANNUALS FOR SPRING FLOWERING.

SILENE, Poppies and similar plants which are being grown for flowering next spring should be very carefully looked after at the present time. Some persons hesitate to transplant seedling Poppies, fully believing that they would not succeed so treated; but they may be successfully transplanted, a moderately dry border being the most suitable for them, but it is necessary to give water in order to establish the young plants. Afterwards they will take care of themselves as it were.

Amateurs who do not like to transplant their seedling Poppies should sow the seeds in patches or in prepared beds where the resultant plants are to bloom. The necessary thinning out must not be neglected. Silene plants will thrive well if left in the same beds where the seeds were sown, but here again I strongly advise a novice to transplant a number of seedlings in a nursery bed where they will form beautiful strong tufts which in spring will form veritable cushions of lovely blossoms. If the soil in the garden is of a clayey nature, raise the beds in which the seedlings are to be wintered and mix a quantity of road grit, leaf-soil (half decayed) and coarse sand with it. The young plants have in such circumstances a much better chance of surviving severe weather than when they are planted in a cold medium. It is well worth taking the extra trouble.

AVON.

4.—A ONE YEAR OLD PLANT WITH NUMEROUS SHOOTS. IT MAY BE DIVIDED INTO PIECES, EACH OF WHICH WILL QUICKLY FORM A PLANT.

will be noted the lower leaves have been trimmed back and an incision made in the stem just at a joint. With one peg the stem from the main plant is held in position, and by placing a second peg, secured by raffia round the layer, the growth is held in a correct position. If soil be placed round this, and maintained in a moist condition, the rooting process should take place within three weeks, more or less, at which time they should be severed and planted in their flowering quarters. The following is a selection for the beginner, and may be relied upon as containing the very best: Ascot, pink, deep red centre; Beauty, large full flowers, well formed petals, rosy crimson centre; Constancy, very full flowers, heavily laced rose red; Ernest Ladhams, rosy blush, claret centre, large flowers; Fairy, vigorous plant, well formed flowers, deep crimson centre; Her Majesty, large pure white flowers; Homer, fringed rose, dark crimson centre; John Ball, a well formed, correctly laced variety; King, a charming laced pink, dark centre, evenly laced rose-red; Lufra, maroon centre, deep red lacing, flowers large and of fine quality; Mrs. Lakin, white, pink centre; Snowdrift, flowers large, fine form, rose flush in centre; and Mrs. Sinkins, large pure white early flower.

Pinks are splendid subjects for edging large beds or borders, as when the flowers are over the glaucous foliage has an attraction of its

5.—THE METHOD OF LAYERING PINKS, SIMILAR TO THAT ADOPTED FOR CARNATIONS.

## THE TOWN GARDEN.

**PROPAGATING ZONAL PELARGONIUMS.**—Although the era of formal bedding has to some extent passed away, and it is scarcely likely that it will ever return to the same power that it has recently enjoyed, there are many thousands of Geraniums still grown, for the plants succeed splendidly in hot, dry seasons and make a really brilliant display. Those who desire to propagate their own stock for next year's bedding out should put the work in hand forthwith, as the earlier the cuttings are rooted the better. No doubt someone will object to such an early start on the score that the plants are still in flower and that interference will spoil their beauty. This, however, is not the case, for, if the cutting is done with care, it will not be easy after two or three days to see where the plants have been touched. Do not strip any plant, but draw the necessary growths from several, and the results are sure to be satisfactory in every respect. The lower leaves should be removed, the shoot cut squarely beneath a joint, and insertion may be in a sunny position in the open border, where rooting will be rapid, and as much trouble will not be involved as when the cuttings are put into pots or boxes. The soil should be light and firm and the base of each cutting must rest upon the base of the hole. As soon as they are well rooted they can be lifted and placed singly in 2½-inch pots, in which they may remain for the winter, a position on a light shelf being afforded. If the cuttings are put in small pots at the outset the compost should be light and sandy, and the soil never made too wet.

**FREESIAs.**—These fragrant flowers are favourites with everyone, and it is seldom possible to grow too many pots or to have blooms over too long a season. As soon as bulbs are procurable potting must commence, and to ensure a succession other batches should be put in at intervals of two or three weeks, according to requirements and conveniences. Six-inch or 8-inch pots are the most generally serviceable, and a soil mixture of three parts of sound, fibrous loam, one part of leaf-mould and about a tenth part of sharp sand will answer admirably. The pots should be well crocked and almost filled with the soil mixture, making it moderately firm; the bulbs can then be taken and pressed in until all except the extreme tip is beneath the surface. Although the compost must be pleasantly moist at the time of use, it is excellent practice to water immediately after potting. With the majority of bulbs generally grown by amateurs it is wise to plunge the pots in beds of Cocoanut fibre refuse or ashes, but this is neither necessary nor desirable with Freesias, which should be kept in the light and encouraged to make steady, healthy progress towards flowering. The most popular Freesia is still *refracta alba*, but the beautiful *Leichtlini* is well worthy of consideration as a companion.

**ANNUALS FOR SPRING.**—Annuals are so easily grown and so exceedingly accommodating in the matter of soil and situation that one cannot wonder at their wide popularity for culture in small gardens, and, fortunately, the majority of them thrive well in town enclosures, especially when the seeds are sown, as is usually the case, in spring. They, however, have another use to which sufficient importance is not attached by many amateurs, and this is for flowering in the spring. In the country it is easy to sow the seeds during the present and next months, and keep sturdy plants alive through the winter, but in the smaller town garden it is more difficult, as fresh air in good quantities is needed to ensure strong, stocky growth; but the experiment is well worth trying. I have found *Clarkias*, *Silenes*, *Saponaria calabrica*, *Eschscholtzias* and others stand well, provided that the seeds were sown in August and that thinning and transplantation were done as early as possible.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## FRUITS UNDER GLASS.

**G R A P E S.**—Muscats approaching maturity should be given more air, and if the roots were well fed at the last watering they will not need any more stimulating material. Keep a keen look out for spider, and if any make an appearance have the leaves sponged with insecticide at once, and the pipes (hot-water) may be dressed with sulphur and heated to nearly boiling point, when the fumes thrown off the pipes will arrest the attack. Late Muscats should have frequent waterings, and if the borders are old use plenty of stimulating manure. The same process must be observed with *Alicante*, *Gros Colmar*, *Lady Downes*, &c.; but be extremely careful to water *Madresfield Court* after the last swelling, or the berries will be liable to split.

*Peaches and Nectarines* should have plenty of air, as it is now a question of retarding more than forcing, and the more air the better will be the quality of flavour. *Dymond* is a very fine mid-season Peach, perhaps the best if only one is required, either out of doors or in.

## PLANTS UNDER GLASS.

**Carnations.**—Pot the last batch of winter-flowering sorts, and take cuttings as soon as possible for next year's stock. Cuttings struck in the autumn are much better than weakly ones in the spring. Pot on *Begonias* of the winter-flowering section and keep them in a clean and growing atmosphere. Put in a batch of *Browallia elatior* major for winter flowering. Pot on more *Poinsettias*, *Enphorbias* and plants of this kind and adopt clean methods for all.

## FLOWER GARDEN.

After the recent rain much picking off of dead flowers will be necessary. Clear at the same time all small weeds which soon become untidy if left. Cuttings must soon be taken from *Zonal Pelargoniums*. Make notes of any new plants that may be necessary, as some improvements can always be made. Collect seed of any pet subjects and dry before putting them away.

**Violets.**—See that these are kept free of runners and keep them well syringed during hot weather. All other plants that are planted out with a view to winter flowering should be grown well, which necessitates regular attention.

## HERBACEOUS BORDERS.

Clean and cut away all dead and decaying foliage. Stake and tie any plants that may require it. Cut back shrubs that have exceeded their bounds. Clip hedges and put in cuttings of *Roses*. Most ramblers do much better on their own roots. Use half-ripened shoots and make them very firm in the ground. Remove all old seed-pods from *Rose bushes*, and thin the blooms that are showing. Keep away mildew by syringing with XL All mildew preparation.

## KITCHEN GARDEN.

Continue to plant out Broccoli, Savoy and greenstuff generally, and hoe the ground between plants that are already becoming established. Sow Cabbages, Lettuces and Turnips. Carefully attend to the requirements of Tomatoes and Vegetable Marrows. Water Scarlet Runners if the weather proves hot or the bloom will drop. Gather the pods before they develop seed, and any surplus should be pickled in brine, as they make nice dishes in the winter. Water late Peas if necessary, as this will prolong their cropping.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**FERNs.**—Among the many varieties of *Adiantum* I find *A. fragrantissimum* to be the most useful as a pot plant. Its light green, elegant fronds are most attractive when grown for house decoration. It is a vigorous plant, doing well in sandy loam with a little peat. It also does well against the wall if kept in position with wire netting with moss and peat to grow in. I find many of these free-growing Ferns grow amazingly if watered frequently with manure water when the pots are full of roots, but when thus treated they are of no use to pot on for specimen plants.

*Solanum jasminoides.*—Though hardy in a few of the more favoured districts, I always find that this *Solanum* does best in the greenhouse. One thing in its favour is that when grown as a roof plant the light is in no way obstructed, as the foliage is not dense; a very desirable feature in a climbing plant. Planted out in a bed of good rich loam and given plenty of head room, it may be had in flower for six consecutive months, and by pinching it can be had in bloom at Christmas, when its pure white flowers will be found valuable for cutting.

## HARDY FRUITS.

**Strawberries.**—Where it is desirable to have good crops of the finest and earliest fruits next year, a sufficient quantity of plants should be put out on wall borders where the soil has been dug, manured and well prepared for their reception. Early planting has a great influence for good on these plants; indeed, it is the only way in which the maximum of success may be obtained. As the plants on these borders are, as a rule, only expected to give one crop, they may be put out thickly, and for some of the close-growing varieties 18 inches apart is quite sufficient. In planting take care that the ground is firm, either from being well trodden or from having been allowed time to settle naturally.

**Figs.**—Fig trees, though late in starting, grow rapidly, and the soft, pithy wood easily gets injured by high winds, so should be secured early to their supports. Surplus shoots may either be stopped or entirely removed, whichever seems to tend most to the benefit of the fruits, which need exposure to give them the needed colour. In the South of the country it is usual and wise to allow a considerable amount of latitude to the growth of outdoor Figs, and breast-wood may be allowed to grow freely; but in the more Northern latitudes they have to be rigorously reprimed and the trees trained well if we are to expect any fruit from outdoor trees.

## FRUIT HOUSES.

**Winter Cucumbers.**—Towards the end of this month a well-heated house should be set apart and prepared for growing these in. A lean-to house and one that is partly sunk in the ground is best, as such is more snug and less draughty than if built on the surface, while it also tends to economise fuel during cold weather. A good start with a clean house and good healthy plants will go a long way towards keeping matters right if cultural details are properly attended to. In the meantime sow seed and raise the requisite stock of plants, which should be grown well up to the light to prevent them becoming drawn.

## FLOWER GARDEN.

**Dahlias.**—Just now these will claim more attention than any other plant, especially if the weather is dry. Dahlias cannot possibly make headway in a dry soil; they must have moisture and plenty of it, or there will be no blooms fit for the exhibition stand. Give them a good soaking of manure water two or three times a week in the evening. Examine the stakes and tie-bands, and disbud where too many buds make their appearance.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
*Ashwellthorpe, Norwich.*

## ANSWERS TO CORRESPONDENTS

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN

**Violet-Pansy for inspection** (A. Newnham).—So far as can be seen from the material forwarded, your plant is possibly a Violet-Pansy hybrid as you describe; it is, however, impossible to give a definite opinion on the subject without more complete material. If you have not sufficient to send you might be able to obtain more definite information by inviting some local expert to see your plant.

**Beetles in Water Lily tank** (Kent). By no means introduce beetles into your Water Lily tank. They will do nothing towards clearing the water, and may do considerable damage to your plants. If you can run the water off occasionally, do so and fill with clear water, and if possible keep the water continually running. It does not need to run fast, but a constant supply of fresh water will do good. Water that is left stagnant for a few days in a tank is very apt to become green, especially in warm weather.

**Aster leaves curled** (Miss E. M.).—The Aster leaves have apparently suffered a chill, and this has checked the development so that some parts of the leaves have grown more rapidly than others, with the result that the leaves have become curled. Earwigs are best dealt with by finding the nest and pouring boiling water upon it. Better still, carbon bisulphide may be poured into a hole made as near as possible to the nest; but great precautions must be taken with this, as the vapour is very inflammable, and must on no account be brought near a light, not even that of a cigar.

**Sweet Pea for inspection** (H. T.).—Your Sweet Pea is not a sport from Helen Lewis, but is a rogue in the clump. It is a variety known as America, and if you like it you can purchase seeds very cheaply. We do not know of any book devoted to the subject of hybridising or, rather, the crossing of Sweet Peas. As you are so interested in these beautiful flowers, why not join the National Sweet Pea Society? The annual subscription is 5s., and you would then be in touch with all the Sweet Pea world. The hon. secretary is Mr. C. H. Curtis, Adelaide Road, Brentford, Middlesex, from whom all particulars can be obtained.

**Plants for border—colour scheme** (H. P. M.).—You might get the desired tone of dark crimson in a Cactus or Pompon Dahlia, the latter, perhaps, being the best in the circumstances. For pink for early summer you cannot do better than employ the single Pyrethrum Hamlet or Monarch. These grow about 2½ feet high, so may not be quite tall enough for your purpose. The same group also provides good shades of crimson, such as James Kelway (single) and Captain Nares (double), and there are many others. Maroon-crimson is found in the annual Scabious, but usually of a dark shade, and possibly too dark for your requirements. A red-toned flower is Rudbeckia purpurea and that known as the Winchmore

Hill variety is of deeper hue. Dark crimson shades, too, may be found in the single and double Pæonies, P. tenuifolia and P. officinalis fl.-pl. If by wine-coloured flowers you mean port wine colour, we think you would get nearest to this in the Celosia. We think you might select the more definite shades you now require by a few visits at various seasons to some of the larger nurseries, where the established examples in flower would be seen to advantage.

**Bedding arrangements** (G. L. H.).—It will very much depend upon the size of your plants as to what good uses these things may be put. The following, however, are a few examples: 1. Standard red Fuchsia for centre and clumps of not less than five of the Lobelia cardinalis 4 feet away, scarlet Celosia in the same way alternating and nearer the margin and the ground covered with white Tufted Pansy. 2. Standard Heliotropes with Heliotrope pegged for a ground. 3. The Ivy-leaved Pelargonium five in a group to form a pyramid in the centre, around the whole having a groundwork of the same plant pegged down. 4. Calceolaria amplexicaulis for pyramids, and, as in the last, with occasional small groups of Eulalia and blue or mauve Viola groundwork. 5. Salvia splendens Glorie de Zurich bedded with white-leaved Centaurea and yellow Coleus pegged or yellow Viola as groundwork. 6. Crimson Begonia, with Fuchsia gracilis and white Alyssum as groundwork. 7. Plumbago in groups of five to form a pyramid and a Viola to match for groundwork.

### TREES AND SHRUBS.

**Box edging failing to grow** (William H. Thomas).—We regret to report that we are unable to say what is the probable result of your Box edging failing to grow. The plant you send is quite dead, roots and branches. Try removing a space of soil, say, 1 foot in width, from your borders and replace it with soil from another part of the garden; fresh soil may have a beneficial effect. It is impossible to say whether the fumes from the chemicals you mention have killed the plants; if the same thing occurs in the majority of gardens in the district it may possibly be the cause, but this can only be decided by someone who is tolerably conversant with local conditions. Possibly you could get an expert opinion on the question if you apply to the Yorkshire College, Leeds.

**Lime tree leaves with out-growths** (J. W.).—The curious, reddish, nail-like growths on the leaf of the Lime are due to the attacks of a mite known as Eriophyes tilia. The attack of the mite upon the leaf causes an extra flow of sap to the irritated spot and the growth of a gall which is open towards the lower surface and hollow within, the mouth being closed by numerous hairs. Among the hairs and inside the gall the animals live. It is possible that the galls may recur another year, but sometimes a tree which has been badly attacked in one year is practically free the next. Of course, a certain amount of the food that the tree would make use of in the ordinary course of events for its own nourishment is diverted to the nourishment of the mites, and their presence reduces the amount of leaf exposed to the light of the sun, but otherwise they seem to do little harm. There is no practical means of dealing with them except by removing all the leaves, which would probably do more harm than the galls will.

**Swellings on Genista roots** (A. Houghton).—We are unable to detect any eelworm about the Genista roots you send; the swellings are similar to those found on the roots of all leguminous plants.

**How to prune a Beech hedge** (G. G.).—You may clip your Beech hedge at once in the same way that you would clip a hedge of Whitethorn. Do not let it grow too rapidly in height, or it will become thin at the bottom, and if it once becomes thin while it is young you will have a difficulty in getting it to furnish itself in after life.

**Information about Ericas** (Rev. K. M. P.).—The shape of your Heath bed is purely a matter of taste; we should think that a triangular bed would fit the position better than an oval one. Remove the soil to a depth of 1½ feet, and fill up to within 6 inches of the top with sandy soil free from lime. On this place 6 inches of peat and fork it into the sand. About October obtain ten plants each of Erica mediterranea, E. m. hybrida and E. carnea, five each of E. m. alba and E. Veltchii, and three each of E. lusitanica (codonodes) and E. australis. These will well fill the bed. E. lusitanica may be put in the

centre; then the red and white E. mediterranea may be spread over the bed, reserving places in front for E. carnea and E. mediterranea hybrida. E. australis and E. Veltchii may be used as dot plants. The work should be done as early in the month named as possible.

### THE GREENHOUSE.

**Repairing a greenhouse** (G. A. G.). In our opinion, your most economical plan will be to employ a glazier and joiner to carry out the work under your own supervision. Of course one cannot say much without an inspection of the entire structure, but it should be done at considerably less than the amount named by you. One point to be particularly observed is on no account to use top putty for keeping the glass in its place, for though often employed it is always a source of trouble. The glass must be well bedded in putty, which should be finished off smooth at exactly the same level as the glass. In this way painting is very easily and quickly done, as in the angle formed by the glass and roof bar the paint brush can be passed rapidly, and the vulnerable point, that is, just at the sides of the squares of glass, receive the greatest amount of paint. For holding the glass in its place small brass brads, such as shoemakers use, are the best, as iron ones quickly rust and the water in this way gains an entrance.

**Hydrangeas with blue flowers** (Foreman, Salop).—Mix some iron refuse from the blacksmith's shop with the soil in which the plants are potted, and when the pots are well furnished with roots water them occasionally with alum water. The alum must be crushed and dissolved in hot water to the extent of 1oz. to a gallon of water. It must be discontinued when the flowers show colour.

**Plants for a cool greenhouse** (Smiler).—As you give no particulars whatever concerning your greenhouse, it is impossible to advise with certainty as to the plants likely to succeed therein. If by cool greenhouse you mean a structure without fire-heat during the winter months, the plants therein must be quite hardy. As it faces the north-east it will, of course, get very little sun, in which case it is very probable that you would derive the greatest amount of pleasure from growing a collection of hardy Ferns, which would do well.

**Treatment of an Aspidistra** (C. C.).—These plants invariably thrive best in shade, as that is their natural condition. A room on which the sun little shines suits them admirably. The leaves should, if the plant is kept in a dwelling-house, be sponged clean every week, and if the plants be stood out of doors now and then and have a good overhead washing it does them good. Generally they need ample moisture, but must not be overwatered. When the plants become too large for their pots they should be shifted into larger ones.

### ROSE GARDEN.

**Roses attacked by weevils** (J. Street).—Your Roses are injured by the weevil known as the clay-coloured weevil (Otiorhynchus picipes). These beetles generally feed only at night, hiding themselves very carefully during the day. Shaking the bushes over a white cloth or newly-painted or tarred board after dark will probably enable you to catch a number of them; but they fall at the slightest disturbance, so the cloth or board must be placed in position before the bush is touched or any light thrown on it. They may also be caught by providing them with hiding-places. Small balls of hay or dry moss tied to the stems or laid on the ground near the plants make good traps, and they should be examined every morning.—G. S. S.]

**Roses with curled foliage** (Miss K. D.).—The leaves enclosed have been attacked by the leaf rolling sawfly. It has been very prevalent during the last two years. The leaf rolling is supposed to be caused by the female when laying its eggs. The green caterpillar you found is a larva of this special sawfly. The sawfly appears in May and June, its colour being black and shiny. The eggs are laid on the leaf. When the green larvæ are full grown they fall to the ground and enter the soil in August, and at once form a cocoon, in which they remain as larvæ until February or March, when they pupate and a fresh batch of sawflies emerge and attack the plants in early summer. The best plan to eradicate this pest is to hand pick the

rolled leaves as soon as seen and burn them. Probably this insect is introduced into the Rose beds on the roots of Briars in the cocoon form; it would, therefore, be advisable to wash all roots of Roses before planting them.

**Crimson Rambler with blighted shoots** (*A. A.*).—Your plants are badly affected with mildew. Those that are not bearing flower trusses we advise you to cut away past this blighted part, but those with flower sprays could be syringed or dipped in a solution of Mo-Etic, an excellent remedy for mildew. We do not think you need fear Dorothy Perkins taking the disease, for it is seldom affected in this way, but it is well to attempt to remedy it at once. Sometimes a hot, dry position will encourage mildew on Crimson Rambler.

**Rose Souvenir de Malmesdon with green centres** (*Miss Wakefield*).—When this occurs early in the season it is almost invariably the result of cold weather and late frosts. To remedy this, prune your plants later, say, end of March, and cut them back rather hard to within 3 inches or 4 inches from their base. The green centres are very bad this year among such Roses as Mme. Isaac Pereire, and we have traced it, in our case, to the error of leaving some growths extra long. The growths started out early and the cruel frosts crippled them when in the embryo stage.

**Rose blooms with green centres** (*M. P. Holt*).—In the case of the buds sent, we consider the early frosts are responsible for the trouble. You probably left the growths a greater length than was advisable instead of pruning past the forward shoots, and these forward shoots had their flower-buds crippled by frost. In some instances these green-centred blooms are the result of overfeeding; the soil is too rich and the buds become malformed in consequence of deranged root action. Your best plan will be to remove the crippled buds and trust to getting better results from the next crop in the autumn. Do not be too drastic in removing all, for we have found sometimes the blooms of certain sorts, although showing these green centres, will outgrow it when they develop their blooms. Do not on any account take up the trees now.

**Liquid manure for Roses** (*Roses*).—It must be remembered that cultural notes given in THE GARDEN are written for the benefit of readers residing in widely different localities. For instance, in Scotland Roses are very backward, so that when our correspondents give certain advice as to liquid manure it is given on general grounds, and they would not advise affording it when the buds begin to show colour. We prefer to commence the application of liquid manure as soon as the buds are the size of small marbles, then it may very well be discontinued when they show colour. A watering or two again after the first flowering is also of great help to the next crop. If the mulching is applied as advocated by our correspondent, a gentle stimulant is afforded every shower we get, and this of course can do no harm; on the other hand, it is very helpful.

## FRUIT GARDEN.

**Grapes injured** (*T. Allen*).—The leaf, as well as the Grapes, bears every indication of having suffered from what is commonly termed scalding. After heavy syringing at 5 p.m., with no air on the house until next morning, we fear the Vines could not be overdry by the time the sun shone on the house next morning. At the stage of growth the Vines are now at both the foliage and surface of the berries are most tender and easily injured. Did you mix any insecticide in the water? The berries affected will be disfigured and damaged for the season, but we hope not many are like those sent. The best treatment to adopt now will be to give air liberally during the day and a fair amount at night, both back and front, frequently syringing the borders and walls of the vinery on fine days in order to encourage them to make a free growth. Have a little heat in the hot-water pipes on dull, cold days and at night.

**Gooseberries and caterpillars** (*Scotland*).—The greatest damage to the Gooseberry is to be feared from the magpie moth. The habit of the caterpillars of wintering in leaves still hanging on the bushes, or sometimes lying among any shelter on the ground beneath, must be taken advantage of to get rid of the pest. At pruning time the bushes should be carefully gone over to make sure that there are no leaves which may hold a caterpillar, and the soil to the depth of 2 inches should be scraped and wheeled away from under the bushes and burnt, as many spun together will be found in this soil. A dressing of lime and flowers of sulphur in equal proportions is the most effective remedy we know of to fetch the grubs down from the trees or to prevent their attack if applied in good

time. It should be applied to the trees when moist. After coming in contact with Hellebore, we should advise that the Gooseberries be carefully washed to make sure that no traces of the Hellebore remain.

**Name of caterpillar on Apple trees** (*H. J. Patrick*).—Your Apple trees and hedges are attacked by the caterpillars of the small ermine moth (*Hyponomeuta padellus*), an insect which appears to be unusually common this year. Cut out the webs whenever possible, holding something underneath to catch any caterpillars that may fall out during the operation, or where this is not possible break up the webs by a strong jet of water and then spray with a solution of paraffin emulsion or arsenate of lead so as to poison the leaves on which the caterpillars are feeding. The caterpillars eventually become chrysalides, enclosed in little cocoons within the web or nest. When this happens it is too late to use any insecticide, and the cocoons should be pulled or cut out and crushed.—G. S. S.

**Apple leaves diseased** (*M. Tgy*).—The Apple leaves are badly attacked by the fungus named *Fusicladium dendriticum*. This fungus also attacks the fruit (causing the well-known Apple scab) and the young shoots. It is one of the three worst pests to which the Apple is subject in this country. It is present on the leaves all through the season, and through the winter on the fallen leaves and on the shoots. From these it passes to the fruits, infecting them by means of the spores, which are produced in profusion upon the olive green patches such as the leaves sent exhibit. In bad cases the fruits are caused to crack, and sometimes, as in the present instance, the leaves are killed by the fungus. Little, perhaps, can be done in the present season, though no doubt the spread of the fungus may be checked by spraying with a diluted solution of Bordeaux mixture, say, half the strength of that used for spraying Potatoes. In the winter the trees should be sprayed with an acid solution of iron sulphate, made in a wooden barrel by pouring 1 pint of sulphuric acid on 25 gallons of iron sulphate and diluting with 50 gallons of water. Just before the buds burst, and again after the petals have fallen and a third time about the second week in June spray with the Bordeaux Mixture mentioned above.

**Growth on main stem of a Vine** (*Ieto*).—The growths that you send are adventitious roots, and they do not have any pronounced bad effect on the Vine. They are generally produced on plants that are very robust and where the atmosphere of the house has been maintained in a damp condition for some time.

**Mites on Plum tree** (*Mrs. H. S. S. T.*).—The mites which you find on your Plum tree are not red spiders, but one of the beetle mites belonging to the family Oribatidae. They live on the small lichens or other vegetable growths so common on bark, and will in no way injure your tree. Whatever may be the cause of the branches dying, cutting off and burning them is a good thing to do. Perhaps if you would send up some pieces of the diseased branches I could tell you what was the cause.—G. S. S.

**Figs ripening** (*George Brood*).—It is quite natural for the Fig to show a second crop before the first is ripe. To secure the proper ripening of the first crop see to it that the leaf and branch growth is not too thick and dense. If this is so, do not hesitate to cut out altogether some of the weaker shoots of this year's growth, in order to admit more light and a better circulation of air among the fruit and branches. Admit more air in the daytime on sunny days and leave a good proportion all night as well. Keep the atmosphere rather drier while the fruit is ripening and not too wet at the roots, but immediately the first crop has been gathered give a good soaking of manure water and keep the house closer and warmer and more moist, in order to encourage a free growth in the second crop.

**Planting a twelve-acre orchard of Apples** (*H. W. S.*).—Seeing that you confess to an entire absence of knowledge on the subject of planting an orchard, or on its management, we advise you to protect yourself in the first place against loss and disappointment in the future by taking counsel, before starting on so important and technical a work, with a competent expert in orchard and planting management. The future success of the orchard depends on so many things which it would be impossible to learn from a book, however well written, such as position of land, quality of the soil and the cultivation which would best suit it preparatory to planting. A few hours' conversation on the subject, on the spot, with

such an expert would, we feel sure, prove invaluable before you started on your project. "The Book of the Apple," by H. H. Thomas, *Gardeners' Chronicle* Office, 141, Wellington Street, Strand, W.C., price 2s. 9d., is reliable and an up-to-date work.

## KITCHEN GARDEN.

**Weakened Asparagus beds** (*G. S. N.*).—As you seem to have liberally manured your Asparagus beds and have kept them free from weeds, only two reasons seem left to explain their present weakness. One, and possibly the right one, is that they have been too hard and too late out to supply heads for the table. Nothing weakens beds so greatly as over-cutting, as unless there is ample time left for growth to be made, and quite strong growth too, during the summer and autumn, the heads or shoots made the following spring will be proportionally weak. If beds show signs of giving out, the cuttings should be severely limited to enable strength to be regained. Then a second possible reason is the beds may be old, too old in fact, and new ones may be planted to grow into strong ones in a year or two. But all the same, if the old beds are to be saved, dress liberally with liquid and solid manure, and cut very sparingly for the next two years.

**Plants for back wall of a Cucumber and Tomato house** (*A. H.*).—We know of nothing in the way of useful flowers which you could successfully grow in association with Cucumbers excepting *Stephanotis floribunda*, a stove climbing plant bearing a profusion of pure white and fragrant flowers. The great heat required for Cucumbers would be fatal to the Roses. Gardenias would also succeed with Cucumbers, provided they could be fixed on a shelf or planted in a border not too far from the glass. Roses would stand a fair chance of succeeding if planted against the wall of the Tomato house, as this should be much cooler than that in which Cucumbers are grown. The following are good varieties: Climbing Niphetos, Climbing Perle des Jardins, Maréchal Niel, Climbing Papa Gontier, Climbing Devonensis and Climbing Mme. Lambard. Plums and Cherries are the only fruits which do well on a north wall, but both would have to be netted. It is also an excellent position for a border of Raspberries. The *Wistaria chinensis* does remarkably well in such a position, as do also many of the more robust-growing Roses, as well as many varieties of Clematis, such as montana, Flammula, Vitalba and the hardest and best of the Jackmanii types. The best varieties of gold and silver variegated Ivies make a fine covering for such a wall. If an evergreen plant is preferred, *Crataegus Pyraeantha* would do very well. It berries freely when grown in such a position.

**The Cucumber spot** (*Spot in Leaves*).—It is the spot that your plants are suffering from, and there is no cure for it. You may keep your plants growing for some time by pulling off the worst of the leaves and destroying them; but if the plants are very badly affected it will be better to pull them up and burn them, while there is time to grow crops of Tomatoes or Melons in the house. It is not safe to plant Cucumbers again in the same house for some time, or otherwise the disease will be sure to reappear.

## MISCELLANEOUS.

**Names of plants.**—*J. W. Dixon*.—1, *Cupressus lawsoniana*; 2, *Thuya plicata* aurea; 3, *Cupressus lawsoniana* Alumi; 4, *C. pisifera* aurea; 5, 6, 9 and 10, *C. lawsoniana* varieties; 7, *Juniperus communis* hibernica; 8, *Buxus sempervirens*; 11, *Cupressus lawsoniana* gracilis aurea; 12, *Thuya occidentalis*; 13, *Cupressus lawsoniana* gracilis aurea (probably); 14, *C. p. patula* (probably); 15 and 16, *Ilex aquifolium* varieties.—*Botanist*.—1, *Ballota nigra* (common Horehound); 2, *Cheopodium album* (Goosefoot); 3, Please send when in flower; 4, *Polygonum aviculare* (Knotgrass); 5, *Fumaria capreolata* (Fumitory); 6, Please send when in flower.—*Grain*.—1, *Holcus mollis* variegatus; 2, *Spiraea discolor*.—*M. M. Miller*.—*Gloriosa superba*.—*Miss C.*—1, *Funkia ovata*; 2, *F. stiboldiana*.—*Erantree*.—*Ophiopogon spicatus* aureo-variegatus.—*A. West*.—1, Bouquet d'Or; 2, Reynolds Hole; 5, Prince Arthur; 6, Merveille de Lyon; 7, Abel Carrière. The spotted petals are caused by the late rains.—*Ayayga*.—*Statice Suworowi*. More material is required of the *Spiraea* to enable us to name it correctly.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## BOTTLING FRUITS AND VEGETABLES.

(First Prize Essay.)

ALTHOUGH the art of preserving soft fruits in bottles has been known for many years, it is only since the introduction of the "clamp" bottles that it has become a general practice. This has made it a very simple proceeding, as under the pressure of boiling water they become air-tight, and so preserve the contents for almost any length of time. As a means of preventing waste and using up surplus produce it has much to commend it, but it must not on this account be thought that anything will do. The material ought always to be supplied from the main pickings, and preferably of medium size, clean and free from husks and stems, and in the case of fruits *under* rather than over ripe; in a word, the best to be had. If these details are attended to the fruit will keep intact and of a good colour and flavour.

### FRUIT—ORDINARY WAY.

Under this heading comes green Gooseberries, Black Currants, Red Currants, Raspberries, Plums, Damsons and Cherries. In all cases it is best to pick into the bottles. This saves two or three times handling, and prevents the skins from becoming bruised. Fill the bottles up to the top; a little settling will be sure to ensue in transit from the garden to the house. On the top of the fruit put one tablespoonful of sugar and pour in boiling water until it runs over, then put on the clamps. A fish-kettle should be in readiness (I prefer a large turbot kettle). This should have a layer of straw or hay on the bottom and enough lukewarm water to cover the bottles up to the necks. Place the bottles in this, and pack straw or hay between them to prevent breakages. Bring the water slowly to the boil and let it boil gently for half-an-hour. When cold they are ready for storing. I have used fruit preserved by this method fully a year old, and in all cases it was everything that could be desired, both in quality and appearance.

### FRUITS IN SYRUP.

Apricots, Greengages, Peaches and Figs are best preserved in syrup, this is made by boiling 1lb. of sugar with each pint of water required. To prepare Apricots cut the fruit in halves and stone them, place them in the bottles whole side uppermost so that they can be tightly packed, which prevents them from smashing, put in a few kernels to impart a brisk flavour, and pour in the hot syrup until it runs over; then put on the clamps and place in the kettle as recommended for the other fruits, and boil gently for half-an-hour. They are then ready for storing when cold.

Greengages should be put into the bottles, hot syrup poured over them, and then boiled until the skins are seen to begin to crack. Peaches

must not be soft, but ripe. Skin them by pouring boiling water over them (the skins will easily pull off), put them into the bottles, after they have been cut in halves and stoned, flat side downwards, pour syrup over them and boil the same as Apricots for half-an-hour. Figs should be of medium size or small and only just ripening, but they should be packed as close as possible in the bottles, the hot syrup poured over them and boiled for three-quarters of an hour. Citrus sinensis (Chinese Orange). This fruit is grown chiefly for ornament, but it makes a delicious dessert dish if preserved in the following way: Boil the fruit whole until tender, take out and drain, put them into a jar and pour over them a syrup made by boiling 1lb. of sugar with half a pint of water, pour this on hot and seal the jars at once.

Strawberries may also be preserved in syrup, but many people prefer them made into jam. It is always better to use the best sugar when preserving fruit, but if cheap sugar is used all scum should be taken off as the syrup boils before it is put on the fruit, as this spoils the colour.

### BOTTLING VEGETABLES—PEAS, FRENCH BEANS AND TOMATOES.

After all, these are the only three vegetables which may be said to be within the meaning of this paper, i.e., for bottling at home. Others, of course, may be preserved by pickling, and Asparagus and Mushrooms may be bought in bottles, but the home supply of these two latter vegetables is never sufficiently plentiful for this, as they are more appreciated in the fresh state.

*Peas.*—First get them as much the same size as possible, then throw them into boiling water in which is the salt and soda and a little sugar, the same as cooking them for the table, but only cook them 5min.; strain and put them into the bottles, put on top one teaspoonful of sugar and the same of salt, pour boiling water on them, close up the bottles, put them into the kettle, as recommended for the fruit, and boil slowly for half-an-hour.

*French Beans.*—Top and tail them and string the sides, but not cut them; cook them the same as the Peas, but these will have to be placed in the bottles lengthways; put one teaspoonful of sugar and salt on them and finish the same as for Peas. Sulphate of copper is often used to keep them green, but I do not think that is necessary if one pays attention to the water they are first boiled in; have the water boiling rapidly, throw in the salt and sugar and a little common washing soda, wait until the scum rises from this, take it off, throw in your Peas or Beans, wait beside them and take off any scum that rises at once, for it is this that makes vegetables a bad colour if allowed to boil into them.

*Tomatoes.*—Let 3lb. of Tomatoes and 3lb. of sugar stand together overnight, peeling the Tomatoes first. Drain off the syrup and boil it, skim well, put in the Tomatoes and boil gently for twenty minutes. Take out the Tomatoes, put them into jars, boil the syrup until it thickens, add the juice of one Lemon just before you take it off the fire, then pour over the Tomatoes and seal them up when cold.

Peas and Beans should be picked in the same stage as for cooking, not too young, and the Tomatoes should be just ripe. Fruit may be bottled without water by putting a layer of fruit and a layer of sugar in the bottles and boiling until you see the skins crack, but I prefer the use of hot water as it is more economical. There are different kinds of bottles. I have used the clamp that you press into the bottle—when you turn it and it fits into a groove on the outside of the bottle: the one that has a glass stopper to put on the top of the fruit with a zinc screw, which screws outside the bottle, and the ordinary bottle with the corks. If the latter are used they should have a piece of bladder tied over the top of the cork round the neck of the bottle and be placed in the kettle cork downwards. After they are finished the bladder should be taken off, and if any of the cork is sticking out of the bottle cut it off and seal over with sealing-wax.

(Mrs.) EMILY ARNOLD.

*The Gardens, Sauchieburn, by Stirling, N.B.*

## COLOURED PLATE. PLATE 1354.

### NEW DAFFODILS.

THE following notes refer to the varieties illustrated in this week's coloured plate, which was prepared from flowers sent by Messrs. Barr and Sons of Covent Garden.

*Czarina* is the largest and finest of the giant Leedsii varieties and is a flower of immense size, measuring 5 inches across, with broad white perianth elegantly twisted at the apex and a very large, delicate, citron crown or trumpet, with bold, open mouth. This variety was raised by Mrs. Backhouse of Sutton Court, near Hereford, but was acquired by Messrs. Barr and Sons.

*Queen of the North*.—This is a grand new seedling, with a large flower having a very broad white perianth and a prettily fluted lemon cup. It is one of those varieties remarkable for the purity of its colour, and is altogether a very chaste flower.

*Seraphin*.—This grand trumpet Daffodil was raised lately in Messrs. Barr and Sons' Ditton Hill Nurseries, and is a flower of great size and beauty. The perianth is creamy white, broad and with an elegant twist at the apex; the trumpet, which is very large and broad, is a soft delicate lemon, with a broadly-crempled, open mouth.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

August 18. — Royal Horticultural Society's Meeting.

August 19. — Shrewsbury Show (two days).

**Messrs. James Veitch's pot fruit tree exhibit.**—The splendid exhibit of fruit trees grown in pots at the Royal Horticultural Society's meeting on the 4th inst., sent by Messrs. Veitch and Sons, Limited, from their Langley Nurseries, Slough, calls for special notice. The trees were in perfect condition, the Fig trees alone being worth the award given; they were the best we have seen for some time both with regard to variety and quality, especially Negro Largo, Brown Turkey, White Iechia (a mass of fruit), Early Violet and Osborn's Prolific. There were also very fine trees of Peaches—all the best varieties being represented—Nectarines, Pears, Apples and Plums. The trees were remarkable for their heavy crops. The pots were small and the trees clean and healthy, certainly an object-lesson, as here one could see what can be done in growing fruit trees in this form. Amateurs should grow pot fruit trees more largely; the

culture is easy and several crops of fruit can be grown in the same house by having sets of trees. For instance, Plums of the best quality may be had from May to September and varieties of the Peach or Nectarine superior in flavour to those grown outdoors.

### Beautiful Violas or Tufted Pansies.

—The sight of Mr. Howard Crane's charming stand of Violas at THE GARDEN Show in the Horticultural Hall reminded me of a magnificent display of those flowers in Messrs. Dobbies' nurseries at Mark's Tey, which I saw on the occasion of the National Sweet Pea Society's outing. The beds were made up of a considerable number of sorts, and some of these struck me as being exceptionally good. Taking the rayless whites (a most delightful class) first, Purity, Snowflake, White Empress and White Beauty were all worthy of mention. The former pair were of the average height, say, 9 inches to the top of the flowers, and the latter pair were dwarf. A beautiful half-dozen of this class could be made up, if the number were not too great, by adding Mrs. A. D. Parker, dwarf, and Virgin White, rather tall. Of the rayed whites, Alexandra and Duchess of York, the former normal height, the latter dwarf, were as pleasing as any. The comparatively small class of whites with large yellow eye enjoys favour with some, and for their benefit I may mention Pencaitland and Christiana. The former, which is dwarf and exceptionally fragrant, is a valuable bedder. There were three excellent creams, one of which, Sylvia, is an old favourite. Her companions were Cream King and Devonshire Cream. The yellows might be divided into four sections, namely, primrose, light yellow, rayless yellow and rayed yellow. Of the first class, Primrose Dame and Sulphurea (dwarf) were two of the best; of the second, Ardwell Gem and Grievii (dwarf) may be mentioned; of the third, I like Redbraes, yellow (dwarf), King Cup and Royal Sovereign; and of the fourth, Walter Welsh, Bullion and Klondyke were noteworthy. In connexion with the yellows it is interesting to note that Ardwell Gem and Bullion seem to be still capable of holding their own in the best company, after many years of service, and in spite of the introduction of newer sorts. I will divide the blueshades into four sections. A very pretty pair of lavenders were Kitty Bell and Florizel, the latter dwarf. Maggie Matt (a rather tall grower), Mauve Queen and Blue Duchess were three striking light blues. Of dark blues, Charles Jordan, Royal Scot and the old dwarf bedder True Blue were excellent. In the purple and violet section Councillor Waters (dwarf), Jubilee and Archie Grant (tall, a splendid old sort) were pre-eminent. Crimson Bedder (purplish crimson) and William Keil (pale rose) were the only noteworthy representatives of their respective classes. I was interested to see the old variety Lilacina, which I thought was one of the most effective of all; but, as Mr. William Cuthbertson pointed out, it should really be classed as a bedding Pansy, because it has three distinct blotches on the deep lilac ground. Several of the fancies arrested my pencil, and I reproduce the names of the following: Glencoe, bronze; Countess of Kintore, the old white and blue; Blue Cloud, white, edged blue; White Duchess, white, edged heliotrope; Ada Anderson, white and rose; Mrs. Chichester, white, heavily edged with violet; and Iris, cream and rose. The plants were put in during October, 1907, probably, therefore, they began blooming in May; and here, well on in July, they were a dense carpet of flowers, in spite of the long spell of hot, dry weather. It would be difficult to imagine any lowly floral picture more cheerful or more winning. So far as culture was concerned, there were few special points. The beds had been mulched with peat moss manure in May, watered occasionally when very dry. Beyond this there had been nothing except the removal of dead flowers to prevent seed-setting; but that, of course, is a host in itself.—W. P. W.

## PRIZES FOR READERS.

### AWARDS IN THE JULY COMPETITION.

In this competition readers were asked to describe the best methods of bottling fruits and vegetables. The prizes are awarded as follows:

The first prize of four guineas to Emily Arnold, The Gardens, Sauchieburn, by Stirling, N.B.

The second prize of two guineas to Mildred I. Clayton, Eversfield House, St. Leonards-on-Sea.

The third prize of one guinea to S. Jackson, Clinton House, Kingsland, Shrewsbury.

The fourth prize of half-a-guinea to C. Elliot, 87, Etnam Street, Leominster, Herefordshire.

Highly commended, Emma Lithgow, Knoll Villa, Linthorpe, Middlesbrough, Yorkshire.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Longevity in seeds.**—The enclosed Sweet Pea is from some two or three seeds which were given me, having come out of a mummy coffin some thousands of years old. I thought it might interest you to see it. I have grown them in my small garden. The green is very fleshy and grew very fast, with these pretty blooms about 5 feet high.—(Miss) MAY C. DEARE. [Our correspondent's letter brings the old question again to the front: Will seeds, said to be taken from the old Egyptian tombs, germinate if sown? The reply to this question is Yes, they certainly will. But before this reply can be taken as an answer to the question as to whether seeds will germinate after being buried for some 3,000 years, another question must be asked: Were the seeds which germinated actually buried at the same time as the corpse? To which the reply is that they were certainly not, but that they must have found their way accidentally into the tomb through some aperture in the ground or have been carried in by some animal, or, what is more likely, been placed there by some unscrupulous person with the view of selling them afterwards to some credulous traveller. It is well known that the statements of most vendors of "curios" in Eastern countries are not to be relied upon, and that their guarantee as to the genuineness of their wares is absolutely valueless; and most probably the seeds had never been near a tomb. In no single instance have seeds which have been buried at the same time as the mummy been known to germinate. Grains of Wheat which have been taken from mummies by persons whose veracity is undoubted have, when sown, never shown any signs of life, and when examined under a microscope the embryo has always been found to be decayed and sections of it to crumble to pieces. The starch grains do not, however, seem to perish, as when treated with iodine they become stained a violet colour, just as recent starch grains do. A few years ago some very interesting experiments were made by M. Becquerel with the object of determining for how many years seeds can retain their vitality; these were really a continuation of some experiments made by A. de Candolle for the same purpose many years ago. M. Becquerel experimented with the seeds of nearly 550 species belonging to the most important families both of monocotyledons and dicotyledons, which had been gathered from 25 to 135 years previously. Ten seeds of each species were used, and no trouble was spared in trying to make them germinate; but of the seeds which were eighty or more years old only those of three species showed that they had not lost their germinating power. If these experiments were properly carried out—and there is no reason to suppose that they were not—it is perfectly clear that no seeds buried in the old Egyptian tombs at the time at which they were made can possibly germinate.—G. S. S.]

**Fruit trees at the Franco-British Exhibition.**—Everyone who takes an interest in the growing of fruit trees must have been struck with the really wonderful exhibition of these by a French firm at the Franco-British Exhibition, shown, of course, outside. Anyone who knows anything at all about this kind of thing must have wondered at the amount of time and patience that has been spent in bringing these young trees to such perfect and, in many cases, quaint and pretty shapes. After all, one would like to know, does it pay for all this extraordinary trouble? Do the young trees bear a larger crop? If not, is it done merely for the sake of exhibition and to show what can be done? We all must admit this side of the Channel that the French are cleverer than we are in getting more out of the soil in a limited space for profit. A great deal is talked just now about how the French make wonderful profits by growing vegetables under hand-glasses. French people are proverbially practical in horticulture. Is this tree-training another example of practical and remunerative horticulture, we would like to know?—A. E. S.

**Rose blooms with green centres:**  
**A note from America.**—Referring to the article entitled "Rose Blooms with Green Centres" in *THE GARDEN* of the 4th ult. (page 327), it seems to be something of a coincidence that this trouble should have appeared for the first time this year in my garden, or, at least, for the first time to be of enough importance for me to have noticed it; hence this note. The varieties most affected were Florence Pemberton, Mme. Philippe Rivoire and Queen of Spain. As this was in the earlier part of the season I attributed it to a late frost, although having no recollection of there being one; but later, about the second week in July, after the first flowering period was over, I found a bloom of Mme. Ravary with a green centre. This was somewhat of a surprise to me, as I had never heard of a thin Rose like the variety mentioned being troubled in this way, and also because the shoot from which the bloom was cut was of a too recent growth to have been affected by any frost; neither had I done any disbudding in this case, though in regard to the Roses first mentioned disbudding may have had something to do with it.—ALFRED L. SQUIRE, *White Plains, New York, U.S.A.*

**Yuccas in a Kentish garden.**—I enclose a photograph taken last August of a group of *Yucca gloriosa* in flower in a Kentish garden, in case you care to insert it in your paper.—E. W. HUSSEY, *Scoiney Castle, Lamberhurst.*

**Popular confusion in nomenclature.**—"E. F. C.'s" account of the "Popular Confusion in Nomenclature" I have read with unusual interest. It is one of those confusions which seems to me to die very hard. If you should at any time point out in a nice and gentle way that a mistake has been made the reply is, "Oh no, it is in so and so's catalogue." If seedsmen will continue to give plants wrong names, how are you going to convince the public interested in these things? Take the case of *Centranthus* and *Valerian*. How often do you hear the former given its proper name? It is generally called *Valerian*. I have been looking through the catalogue of a well-known firm which makes a speciality of herbaceous plants, and on looking up *Centranthus* it says "*see Valerian*." Well, on finding *Valerian*, the description was "beautiful herbaceous plants, colour rose and

white, height 2 feet." Now such a description would confuse any intending buyers; in fact, they would not know if it refers to *Valerian* or *Centranthus*. I will admit these plants belong to the same natural order, but there is a difference in height, shape of leaf, also colour of flower, which, on being placed side by side, is very obvious. In *Centranthus* the corolla tube is spurred at the base and has only one stamen, while in *Valerian* it is not spurred and possesses three stamens. Another confusion is in the case of *Spiraea japonica*, which is not a *Spiraea* proper, but a species of *Astilbe*, belonging to a totally different order of plants. These are only a few of the glaring confusions in our nomenclature, but they could be added to, thus making a very long list.—P. CLAPHAM.

**Autumn-sown annuals.**—"Sown in autumn will be a glowing sheet of colour in the early summer." Thus the seed catalogues; but in my experience reality seldom corresponds. Will successful sowers tell me what and when they sow.—H. M. C.

**Sweet Pea prospects and Countess Spencer.**—I cannot allow Mr. G. Clapham's remarks to pass without protest. His tirade against Countess Spencer is most unjustified. I can only say his experiences are singularly unfortunate. I have grown Countess Spencer (true) now for several years from Messrs. Eckford's strain, and am happy to say that I have never had a single one that was not absolutely true. It is, to my mind, the Queen of Sweet Peas.—E. F. OAKELEY (Captin).

**Hardy flower book.**—"A. E. S." may not have come across "A Concise Handbook of Garden Flowers," by Mrs. Stephen Batson (Methuen, 3s. 6d.), in which is stated, with much practical cultural information, the season of flowering of all the herbaceous and perennial plants treated therein. In the same series are similar handbooks on shrubs and creepers, in which also these necessary details are given. The first-named book is probably such an one as "A. E. S." requires.—B. M. H.

## THE FRUIT GARDEN.

### MILDEW ON VINES.

**J**UDGING by the many complaints and enquiries we have received with reference to mildew on Vines, we conclude that its ravages are more general this year than usual. The extraordinary fluctuations in the weather, alternating from hot to cold and cold to hot within very short intervals of time, must in a great measure, we think, be responsible for it. The foliage and fruit of the Vine are tender and sensitive at this stage of their growth, and a sudden rise or drop in temperature of 20° Fahr., such as we had in July, checks and chills the Vine, thereby predisposing it to attacks of mildew and other diseases.

The conditions which bring about an attack of mildew are frequently caused by errors of judgment in ventilation, on the one hand causing a chill by the too sudden and too wide opening of the ventilators when the wind is cold, on the other hand by inadequate ventilation; a sluggish, cold and damp atmosphere is the result, and forms an ideal medium for the breeding of this fungoid growth.

The way to avoid an attack in future is to be careful to admit air gradually as the heat of the day increases, leaving a small chink for the passage of air in the front and back ventilators all night unless the weather happens to be very wet and cold, coupling with this a modicum of heat in the hot-water pipes on cold days, and always at night, at least until the berries have attained their full size (before colouring), when the growth will have become harder and more capable of resisting the disease. The slight heat in the hot-water pipes causes a free circulation and gives greater buoyancy to the air.

The way to kill the mildew when Vines are badly affected is to heat the hot-water pipes to boiling point and then dress them with sulphur and water made like thick paint. This should be done on the afternoon of a still day, and of course all ventilators and apertures in the vinery

YUCCA GLORIOSA IN FLOWER IN A KENTISH GARDEN.

likely to allow the escape of the fumes from the sulphur must be closed. One application is not always fatal, but a second on the following afternoon generally is, provided the pipes are hot enough when the sulphur is put on.

OWEN THOMAS.

### A GOOD LATE STRAWBERRY.

ANYONE in search of a good late Strawberry could not do better than try Givon's Late Prolific. The fruit deserves the name late, is of good size, rather pointed shape, fine colour and of splendid flavour. Although of large size, it ripens at the point as quickly as it does at the base, and so is free from a fault very prevalent in late Strawberries. The soil here is rather heavy, with a great quantity of stones. We commenced gathering this variety on July 2, and there is a good prospect of the supply holding out until the end of the month. Some fruits gathered the first week weighed fourteen to the pound. This is not unusual, but speaks well for the variety, as we can only give them very ordinary cultivation.

Layers are obtained as early as possible, potted into 3-inch pots and planted out in the autumn on well-manured soil. The plants are not allowed to bear the first year, and the result is the production of a strong plant and an excellent crop the next season. A new plantation is made each year, and the plants are destroyed when they have fruited two or three times. A good mulching of half-decayed manure is given before the hard weather comes in the winter, and manure water is supplied once or twice before the plants come into bloom. In gardens much troubled with slugs it is a good plan to give a rather heavy dressing of soot, well dusted into the plants, a few weeks before they come into bloom. This helps the plants as a fertiliser, in addition to keeping down the slugs. The placing of clean straw beneath the fruit, to protect it from damp and dirt, is an economic necessity.

Preserving the fruit from the birds is another important item. Here we simply drive stakes into the ground round the beds, about 6 feet apart and about 2½ feet high, over which nets are stretched. It is an easy matter to throw back the netting from one side of the bed when gathering fruit. The method is improved by having boards cut into 2-inch or 3-inch widths and placed on the top of the stakes, with a nail projecting here and there to catch the netting.

It is a bad plan to dig among the plants at any time. By so doing many of their most useful roots are destroyed. A good occasional stirring with the hoe will keep the soil in healthy condition and also destroy the weeds.

T. H. WORLD.

*The Gables Gardens, Boxmoor.*

### THE SUMMER CARE OF SMALL FRUITS.

It is a fact, often forgotten in the busy days of summer, that next year's crop of small fruits depends very largely upon the treatment received by bushes and plants this year. The fruit being gathered, Strawberry beds are often left to take care of themselves until autumn. All runners should be removed as soon as sufficient have been secured for the formation of new beds. Keep the surface soil well stirred with the hoe, and should very dry weather set in one good watering may save the plants from drooping and also from being a failure next year. Hard, plump buds in the centre of the crowns formed this season are as necessary to next year's success as the fruit-buds of Apple and Pear trees.

The old Raspberry canes should be removed as soon as they have done fruiting to give the young canes all the light and air possible. When the young canes are crowded and in excess of what may be ultimately needed cut away all the weaker ones. The short grass from the lawns can be advantageously used as a mulch

among them, unless the soil is very wet and retentive.

Gooseberries and Currants should be kept free from caterpillars and other insects. If they are greatly crowded with new growth (a probable fact this season), it will be well to remove some of the new growths to within 2 inches or 3 inches of their bases. Other growths should be left entire until winter and then pruned in the ordinary manner. Black Currants, a shy crop in many places, can be greatly improved by having some of the older branches cut clean away. This is all the pruning they need, and it can be done very well after the bushes have fruited. It will increase the chances of success next year.

THOMAS H. WORLD.

*The Gables Gardens, Boxmoor.*

## THE ROSE GARDEN.

### A DWARF ROSE FOR POTS.

MME. NORBERT LEVAVASSEUR.

**W**HAT a pretty little Rose this is when grown in small pots under glass! The flowers are quite a bright pink, just the colour so much in demand for interior decorative schemes. I have no experience with it as a Rose for forcing, perhaps the colour of the flowers would not be so good; but when grown cool it forms a most charming plant, and one that can be brought into use for many decorative purposes. This is surely a Rose for those who have not the accommodation for varieties of strong, rampant growth, as plants in 4½-inch pots can be grown from 10 inches to 12 inches in height, carrying six or more trusses of their pretty little pink flowers. This Rose was introduced in 1902, and is often known as the Baby Rambler, owing to its resemblance (when grown outdoors) to the well-known Crimson Rambler, the difference being in its dwarf habit and perpetual flowering.

*Munden Gardens, Watford.*

C. RUSE.

### A GOOD ROSE SPORT.

It sometimes happens that a Rose sport is more beautiful than the parent variety, and I think this is so in the case of the variety named Rosslyn. It is a sport of Suzanne Marie Rodocanachi, which, as everyone knows, is a beautiful glowing rosy cerise, but the sport is a charming rich salmon pink. It is a particularly brilliant colour that appeals to everyone by reason of its clearness. Both of these Roses should be grown, as, although scentless, they are very free flowering, and possess the even, regular growth of the Victor Verdier race. The form of the flower has not been changed in the sport. It is just the same charming globular shape that has helped the exhibitor to win many prizes. There are two other sports from the old Rose named above. These are Muriel and Marie Corelli, but I think Rosslyn is the best of the three. Suzanne M. Rodocanachi makes a fine pot Rose, yielding grand flowers of massive size and fairly long stems if pruned back hard. There is a climbing sport of this old variety which would make a useful pillar Rose. Most of the climbing sports of Hybrid Perpetual Roses are useful when grown in this form, for they are not really climbing, the difference merely being a somewhat extra vigour of the shoots. They invariably make splendid standard plants. P.

### ROSE MME. CHARLES DE LUZE.

I WOULD like to speak a good word for a Rose which I first saw and admired at the Regent's Park show last summer, but which does not appear in any of the catalogues of British or Irish growers that I have received, and for which I had to send to France; that is Mme. Charles de Luze. With me this Rose has proved a great

success so far as my trials have gone. Though planted only last autumn, I was able to cut a number of beautiful blooms during the earlier part of the season; and even now, when we have been having exceptionally hot and dry weather—the thermometer being in the nineties nearly every day for a month—I have been able to cut some very good blooms. Sent out by Pernet-Ducher in 1904, Mme. Charles de Luze does not seem to have attained the popularity it deserves. With me the colour is something similar to Mme. Ravary, or perhaps more like Franz Deegan, but of beautiful form and large size, while the blooms are held upright on long footstalks. The foliage is good, and, as I said before, it has stood the hot weather admirably, though, like all yellow Roses, it loses its colour somewhat in the sun; but even then it does not have a mused appearance, as do some other varieties, but remains clean. Another excellent quality is its delicious fragrance. Of course, it is possible that a longer acquaintance may modify my enthusiasm; but, should it do as well in England as it has done with me thus far, I feel sure it will well reward anyone who may give it a trial.

ALFRED L. SQUIRE.

*White Plains, New York, U.S.A.*

### HYBRID TEA ROSE LAURENT CARLE.

THIS is a grand addition to the red Hybrid Teas. There is a clearness about its colour that one cannot but admire, although it is not so brilliant as Roses of the Liberty type. The colour is a velvety carmine, something like what we get in Countess of Oxford, but the flower is not so coarse. By disbudding I should say this Rose will attain exhibition size, and should make a very useful variety for the middle row. It is sweetly fragrant, and it is also a good grower, producing its flowers on upright stems. This variety and Mme. M. de Luze are quite new departures in colour from what their raiser, M. Pernet Ducher, has been giving us lately, and one may hope he has more in store and equally as good. P.

## NEW PLANTS.

**SOPHRO-CATTLEYA WURNHAMENSIS** J. M. BLACK (*Sophonitis grandiflora* × *Cattleya amethystoglossa*).—This is a very beautiful bigeneric hybrid of a distinct and novel shade of colour. The sepals and petals are ruby red, the drooping tip of the acutely-pointed lip shaded crimson and carmine, the throat and base being of a deep yellow shade. Exhibited by R. G. Thwaites, Esq., Streatham. First-class certificate.

**Vanda amena** var. *Sanderi* (V. *Roxburghii* × V. *caerulea*, natural hybrid).—A distinct and striking form, in which the influence of V. *caerulea* is strongly in evidence. The colour is quite novel and approaches to bluish violet, the lip being a deep violet-blue. From Messrs. Sander and Sons, St. Albans. Award of merit.

**Rose Paula** (Tea).—A delightfully fragrant Rose of dwarf habit and great freedom of flowering. It is also said to be very hardy. The colour and not a little of the form somewhat approach that of a pale Mme. Hoste. The flowers, too, are large and full, while their pronounced fragrance should render it extremely popular. From Messrs. Paul and Son, The Old Nurseries, Cheshunt. Award of merit.

**Carnation Countess of Pembroke**.—A border Carnation of excellent size and form and of a bluish tone, the flowers being supported on strong stems. A chief recommendation, however, is the exceptional Clove-like fragrance, and for this alone it will doubtless be in great demand. From Mr. T. C. Challis, The Gardens, Wilton House, near Salisbury. Award of merit.

All the above were shown before the Royal Horticultural Society on the 4th inst., when the awards were made.

## THE FLOWER GARDEN

### HINTS ON GROWING CARNATIONS.

**P**ERHAPS next to the Queen of Flowers—the Rose—the Carnation is the most valued of our garden flowers. Fortunately, the garden or border varieties are not difficult to cultivate, and seldom fail to give a plentiful supply of flowers if the routine treatment is carefully carried out.

Failures may often be traced to badly-drained soil, to the attacks of wireworm or the Carnation maggot, larva of the fly called *Hylemyia nigrescens*. It is fortunate that the latter pest gives but little trouble in many gardens, because there is no known precaution which will prevent its attacks, and unless a very close watch is kept on the plants they are attacked and destroyed before one is aware of the presence of the foe. The fly deposits its eggs on the young leaves of the plants. The maggot when hatched works its way down under the outer skin of the leaf until it reaches the shoot, then slowly proceeds to eat its way down the centre of this, and so on until it reaches the centre of the stem, into which it bores and eats out the very heart of the plant, which, of course, quickly fails and eventually dies. If a brown mark is noticed down the leaf, this denotes the track the maggot has taken. Although the shoot is apparently healthy, this must be cut off at the first joint, and if the stem is hollow the maggot has passed on, and it may be necessary to cut a slit into the stem of the plant before the enemy can be secured. This may cripple the plant, but it is the only way in which it can be saved, and with choice varieties the loss of a plant should, if possible, be avoided. If a close watch is kept, the maggot may be caught in the leaf and taken out with the point of a pin. This is by far the best way, as when once it reaches the main stem the chances of the plant surviving are poor, and when the foe is thus caught and despatched one has the satisfaction of being well repaid for his vigilance.

In wet soils drainage must be provided; the Carnation is never satisfactory in heavy, sour soil. Although it is always best to secure thorough drainage throughout the garden, this, for various reasons, cannot always be carried out, but for small or medium-sized

#### BEDS OF CARNATIONS

the following plan has proved successful. Throw out the soil to a depth of 2½ feet, and place 9 inches of broken bricks or limestone in the bottom for drainage. If turf can be procured, place a layer over the stones, grass side downwards. As the soil is being returned, mix with the same some old mortar or plaster rubbish; failing this, wood ashes or crushed charcoal. Half a barrowload each of old mortar and wood ashes may be added to about eight barrowloads of the soil. Horse manure and a small quantity of soot should also be added. On wet soils

#### PREPARE THE BEDS

during the autumn or winter months and plant out in the spring. When dealing with naturally-drained light soils, deep trenching and incorporating of manure are matters which need attention.

#### AUTUMN PLANTING

is recommended by some growers, and in some districts has proved successful; but as a rule the amateur will do better by planting in the spring, especially the choice varieties, which should, if possible, be potted up in the autumn and wintered in cold frames. The most important work in connexion with Carnations at the present time is

#### LAYERING,

which is the best mode adopted for the propagation of varieties of established plants. Remove a few of the bottom leaves from each individual

shoot which has not produced flowers, using a sharp knife for this purpose. Then place a little prepared light sandy soil around the plant, cut each shoot halfway through from a low joint in an upward direction for about 1 inch, then bend the stem and carefully insert the tongue formed by this upward cut into the prepared soil, and secure the shoot in position by means of a neat wire peg. Finish off by placing a little of the prepared soil on the stems above the tongue, and give a gentle watering through a fine-rosed watering-pot. Care should be taken when layering not to cut the stems too far through nor to break them in the act of bending them down to the soil.

### CANTERBURY BELLS IN TRURO CHURCHYARD.

THE planting of flowers in the cemeteries of towns has long been practised, but it is only during recent years that such decoration has been carried out to any extent in the country churchyards. There is no gainsaying the fact that many a "hallowed acre" might be rendered far more restful and beautiful by the judicious use of flowers. Our illustration is from a photograph

CANTERBURY BELLS IN ST. PAUL'S CHURCHYARD, TRURO.

kindly sent to us by the vicar of St. Paul's, Truro, and depicts a flowering mass of Canterbury Bells growing beside the church there.

### ALSTROEMERIAS AND THEIR CULTURE.

OF the many beautiful exotic flowering plants which render the flower garden bright and attractive at this season of the year, few fail to call forth more admiration than the Alstroemerias. In order to appreciate their full beauty it is necessary to devote a whole bed to them, or they may be effectively massed in the mixed border or on the margins of the shrubbery. Providing they are planted in a sunny position, and the soil is not of a too retentive nature, they will continue to increase and thrive for an indefinite period. The delicate markings and delightful shades of colour afforded in the flowers of this unique race of South American plants render to them a charm of their own.

One of the most beautiful species is undoubtedly *A. aurantiaca*. The slender stems of this plant attain to the height of 3 feet and are clothed with glaucous foliage. The flowers vary in colour from a clear yellow to a warm orange red, with dark markings on the petals. *A. pelegria* is a dwarf plant about 1 foot high, bearing large pink flowers spotted and striped. *A. pulchella*, *A. hemantha*, *A. psittacina* and the many beautiful hybrid

varieties which may be obtained at the present day, are all worthy of a place in every collection of hardy plants.

F. G. TUTCHER.

7, St. Eligius Street, Cambridge.

### HARDY WATER LILIES.

(Continued from page 387.)

THE varieties also differ as to earliness and length of season. *Alba rosea* is always one of the first to flower, but soon goes to rest; this is followed by the *Laydekeri* section, all of which are good, for not only do they begin early, but keep on flowering all the summer, and as late as any in autumn. *Laydekeri rosea prolifera*, lately introduced by Mr. Perry, is one of the best of this section, and quite bears out its name. *Colossea*, quite the giant of all *Marliac's* hybrids, together with *gladstoniana*, *Robinsonii*, *gloriosa* and the many other hybrids, are some of the best for effect through a long season. The common white Water Lily (*Nymphaea alba*) is two or three weeks behind the earliest hybrids, showing a gain in length of season, which is even more remarkable in autumn. It is the end of June or beginning of July before the forms of the *odorata* section are much seen, and *odorata sulphurea* often waits until August; but when once started this class

flowers well into the autumn, with such others as *pygmaea Helvola* and *Laydekeri rosea*. *Nymphaea odorata sulphurea* I have always noted to be the last in flower, and quite a bold one it is, with large yellow Vanilla-scented Cactus-like flowers rising well out of the water. In colour some of the *Nymphaeas* vary from day to day. *Aurora* and the *Laydekeri* section open pale in colour and darken each day with age, so that sometimes three distinct colours are seen upon the same plant; on the other hand, the *Marliacea* section grow paler from day to day.

Not only are those hardy Water Lilies valued on account of their beautiful flowers, but for their handsome foliage as well; for in such varieties as "*Arc-en-ciel*," *Andreana*, *lucida*, *Robinsonii*, *chromatella* and *odorata sulphurea* the leaves are beautifully marbled and spotted.

Though some of the finer hybrids make a few side crowns, and thus increase very slowly, others grow very rapidly and may be freely divided, the offsets being cut away with a piece of the old rhizome or root-stock attached. Those of the *Laydekeri* section are extremely difficult to propagate, as they make but few offsets; but some produce seed freely, and are easily increased in that way, the seed being sown as soon as it is ripe. Many are sterile, and can only be increased by division of the roots, which work is best accomplished in the spring, and when new growth is assured.

IF A POND OR WATER GARDEN IS IMPOSSIBLE many of these charming plants may still be grown in tubs. For this purpose the Laydekeri section and pygmæa form will be most suitable, as they are of compact growth. Tub or half-casks for Water Lilies should be as wide as possible and about 2 feet deep, allowing for soil, with not less than 1 foot of water over the crowns. A very pretty effect can be obtained, if a grass plot is available, by sinking the tubs into the ground, forming a background with Bamboos, Arundos and Eulalias and other foliage plants, with a few tubs of other aquatics, such as the single and double-flowered arrow-head, the flowering Rush, *Typha minima*, &c. If it is possible to do so, and for convenience in keeping the tubs filled, a trickle of water might be made to pass from one to another, and so both time and labour might be saved. By sinking the tubs frost is easily kept out by a covering of boards overlaid with straw, reeds or mats whenever necessary. With regard to the hardiness of all these beautiful hybrid Water Lilies, there can be no doubt. I know of places where they are cultivated in tubs not sunk in the ground and without any protection in winter. They have been frozen in solid blocks of ice, yet the plants have not been injured in any way. It would be better, however, not to run this risk with any valuable varieties.

#### ENEMIES OF THE WATER LILY.

Though free from many enemies of the garden, Water Lilies have foes of their own which must be held in check. All waters in which they grow must be kept free from weeds, as they not

common brown rat will sometimes attack and eat both rhizomes and flower-buds; therefore a sharp look-out must be kept for these pests or they may do considerable damage before one is aware of their presence. From some unknown cause the root-stock or rhizome of *Nymphæas* will sometimes develop into a flat fasciated-like form, and when growth begins a dense cluster of small leaves, without the sign of a flower, will be the result. So far I have been unable to find any means to prevent it, but when such growth is noticed it is best to lift the plant and cut the rhizome into very small pieces, leaving two or three leaves attached, plant thickly in shallow baskets, and in a few years the majority of them will make flowering plants.

Though we have already such a large number of beautiful hybrid Water Lilies, of all sizes and nearly all colours, white, yellow, rose, salmon, peach, flesh, rose purple and red in all shades to deepest crimson, there is no doubt that we have by no means come to the end of their development, and before long we shall be hearing of a hardy blue-flowering *Nymphæa*, which at present we are without. The difficulty of obtaining the blue colouring in the hardy plant is that the blue kinds are natives of the tropics; but there seems good reason to suppose that this difficulty will be got over, for there are also blue *Nymphæas* from the Cape and Australia which will no doubt play their part in the production of new garden varieties.

#### THE VIOLET CRESS.

THE Portuguese annual (*Ionopsidium acaule*), popularly known as the Violet Cress, is a delightful

about a quarter of a mile distant, where it had never been sown. Probably a few seeds were adhering to some plant or bulb that was brought to that garden from the one in which it was established, but its appearance was welcomed, and it has now spread widely over its new home.

It is an excellent plant for surfacing bulbs, and many beautiful colour-schemes are possible where the two are associated. Here in one place it veils the ground beneath a colony of the gorgeous *Tulipa Greigii*, and the effect of the carpet of soft lavender, about 2 inches in height, spreading beneath a couple of dozen great scarlet blossoms of the *Tulips* is extremely lovely. In another spot it carpets a large group of *Chionodoxa sardensis*, whose deep blue flower-scapes gain an added charm from their lavender setting. In a third instance it has taken possession of a bed of early bulbous *Irises* about 10 feet in length and 3 feet in breadth, and last winter covered the surface of the ground so thickly that not a particle of earth was visible. The *Irises* and the *Ionopsidium* bloomed simultaneously, but the latter remained in full beauty long after the *Irises* had ceased to flower. This is the colony shown in the accompanying illustration.

Here, as it is allowed to reproduce itself at will, seeds fall to the earth at all seasons of the year, and in almost every month certain plants may be found in bloom. The *Ionopsidium* will not, however, succeed in all soils, for in some, even though it be raised from seed, it will not reproduce itself. A light, dry soil is the best for it, and in staple of a clayey nature it often fails. It sometimes dies out suddenly without apparent cause. In Mr. Archer-Hind's garden, where I first saw it, sheets were to be seen in bloom through the winter and early spring; but about six years ago, in a mild winter, it almost completely disappeared, only a few stray plants being in evidence out of the thousands that usually spread a veil of soft colour over the borders.

South Devon.

S. W. FITZHERBERT.

#### THOUGHTS ON TULIP SPECIES.

PEOPLE who take up Tulips as their particular speciality will find, as I am doing, so much that is interesting in connexion with their past that before long they will become aware that the pleasure which they afford as growing plants is equalled, if not excelled, by the fascination of trying to learn their history and of solving the many difficult problems which that history unfolds. Take just one or two which appropriately fall under the present heading. How came *Tulipa gesneriana* to be what it is to-day? Is there any wild species known to botanists that can with certainty be claimed as its forefather? Is it not far more likely to be a garden hybrid?

Another matter of interest is to endeavour to trace the path or paths by which such species as *T. sylvestris* or *T. clusiana* came from their Eastern homes. Another, again, is how to account for the sudden appearance of new varieties in quite recent times in habitats which have been well known to botanists for many years, and where their presence could not possibly have been overlooked. How came *T. Didieri* or *T. mauriana* to be growing in the neighbourhood of St. Jean de Maurienne in Savoy, or *Stragulata* near Bologna, or *Maleolens* near Florence? Then, to branch off in quite another direction, there is the opening up of Central Asia by the Russians about thirty years ago and the explorations of Dr. Regel, and, later still, of the botanical expeditions organised by Mr. C. G. van Tubergen of Haarlem. *Greigii* and *kaufmanniana* are direct results of the former, and *tubergeniana* and *fosteriana* of the latter.

But Tulip species are not all new comers. We have only to turn to the Tulip articles and illustrations in our immortal Parkinson or Gerard and learn from them how *T. sylvestris* was known and *T. clusiana* and *T. oculis-solis* cultivated in English gardens 300 years ago. If after the first introduction of Tulips to Western Europe there

THE VIOLET CRESS (*IONOPSIDUM ACAULE*).

only choke the Lilies, but keep the water cold and too stagnant for the promotion of good growth. Aphides, green and black, will sometimes be found troublesome, and must be washed off with hose or syringe or the leaves dusted with Tobacco powder to rid them of these pests. As a rule plants generally outgrow these troubles, and have more to fear from rats and water-fowl at all times. It is impossible to grow *Nymphæas* in any water to which swans, ducks or other water-fowl have access. The water or moorhen is also very destructive, both to foliage and flowers, pecking them to pieces and even carrying them off to build their nests. The water-rat and

plant in the garden. When once sown it needs no renewal, for it reproduces itself from self-sown seed year after year. When sown in the late spring it flowers in the summer, and the scattered seed from these plants produces other colonies that come into flower in December and remain in bloom until mid-April. Here it was sown six years ago and has quite taken possession of the garden, springing up in borders, paths, and even on the tops of walls. Being surface-rooting it is harmless to its neighbours and is never disturbed, wherever it may come up, except to make room for new introductions. A few years ago it appeared in another garden

was a long interregnum, if during this epoch fanciers thought of nothing but how to still further refine refined gold, there were nevertheless all the time in unknown lands gems of the purest water waiting to be found—waiting to be called from their Eastern haunts to come and beautify our Western homes; and how well they do it, what colour they give us! Take ostrowskiana with its peculiar intense yellow-scarlet colouring. I saw a picture of it among Mr. Frank Galsworthy's beautiful flower paintings in Vincent Square last November, but it did not do it justice, and no one knew

better than the artist himself. "I am not going to be beaten," he said; "I will tackle it again next year, even if I have to make a colour." That is what it will come to, I think, for many of these magnificent scarlet-coated gentlemen have got garments of quite new hues; nothing is exactly like them. Sealing-wax red does not adequately describe the charming little linifolia; nor does "an uncommon light vermilion-scarlet" quite fit in with the glorious præstans. There is a depth and intensity about them all that is wanting in paint. Get them and grow them if you must know what they are like; this is what I am endeavouring to do. Each year I try a few new ones, for I cannot be content to look on them from afar—to see them only at shows, or in the Alpine House at Kew, or in some nursery or private garden. I like them so much; I want them as personal friends who will come and live in my garden—at least, all that are not too homesick in their strange, new surroundings of soil and climate.

The Savoy or Næo-Tulips, as they are frequently called, must be there too. They have not the same gorgeous colouring, but they have compensations. They are easy to grow, and generally soon settle down to their new life. They are by no means without beauty.

J.

## DAFFODIL NOTES.

THE public have at last appreciated the fact that, given suitable varieties, Daffodils are splendid subjects for pot culture. Two notable facts seem to bear this out. First our neighbours in Holland are finding the sale of Hyacinth bulbs steadily decreasing, and it is in order, if possible, to check this that the bulb growers of Haarlem are offering the valuable prizes, both for amateurs and the trade, that are to be competed for next spring at Vincent Square. Somehow I feel that will only be a case of the Danish King and the sea repeated; the effort will be powerless to stop the ebbing trade of Dutch Hyacinths, for the very obvious reason that neither as subjects for single pots nor for

growing in masses are they to be compared to Daffodils. The second fact is that the Royal Horticultural Society are going to have a field day on March 9 next, for forced bulbs and more especially for Daffodils. Now that everyone includes a few pots among forced bulbs, it is becoming increasingly important to find out which of the newer kinds lend themselves best to this purpose. As Mr. Engleheart remarked at the Daffodil committee meeting when the recommendation for such a show was passed, it by no means follows that the ones we think the

same time. It is a small edition of Henry Irving, and can be used effectively in small-sized pots.

Golden Spur is the best of all yellow trumpets for forcing, and follows closely upon Henry Irving and Tenby. It is a magnificent deep yellow self, very free and easily grown. For a later variety still nothing surpasses the well-known Emperor. It is as good indoors as out of doors, and no praise can be higher than this.

Turning to bicolors, pride of place must be undoubtedly given to Victoria. It is very free, and has a strong stem and large flower, with exceptionally handsome foliage. The perianth, too, under glass comes a pure dead white. Empress and Horsfieldii are also good; but as a contrast is generally desirable, for a second variety I would grow Mrs. Walter Ware. It is equally free, but it is not such a large flower, and the trumpet is a deeper shade of yellow. J. B. M. Camm is a pale bicolor. It is a most lovely thing under glass, not very large or tall, but most delicate and refined in shape and colouring. It should be grown in medium-sized pots. Now that it can be had at about half-a-crown a dozen everyone should give it a trial. It should not be forced hard. I must not omit Princeps or its variety Cervantes, with their yellow trumpets and deep primrose twisted perianths. They are very graceful and light-looking flowers and very cheap. The late bicolor for pots is undoubtedly Grandee. A good batch of this might be grown wherever possible to carry on with till the outside flowers begin.

Among the white trumpets nothing equals Mme. de Graaff. Unfortunately, it is expensive to use for forcing, so if a cheaper white is desired I would go for either albicans or Mrs. Thompson. Both are good old-fashioned flowers, and in medium-sized pots look very pretty. W. P. Milner is a dwarf variety that I am exceptionally fond of when forced. It is a diminutive magni, quite white under glass and just the thing for small pots. Five bulbs in a 5-inch pot make a very charming display. I strongly advise a trial. The cup sections, including the posts and the doubles and bunch-flowered varieties, I hope to deal with next week.

JOSEPH JACOB.

## SINNINGIA HYBRIDA DR. MAXWELL MASTERS.

THIS plant is a reputed bi-generic hybrid between a Gloxinia and a Gesnera, and certainly it promises to be a most useful greenhouse subject. The flowers are of a delicate rose colour, and several are borne on a branching stem some inches from the ground. It was exhibited by M. Ernest Benary, Erfurt, Germany, before the Royal Horticultural Society on the 21st ult., when it received an award of merit.

A NEW HYBRID PLANT: SINNINGIA HYBRIDA DR. M. MASTERS. (About two-thirds natural size.)

best from their behaviour outside will be found most suitable. Hence I look forward to this show with the most intense interest, and I would advise everyone who, like myself, likes to have some pots in the greenhouse, to pay it a visit.

### VARIETIES TO GROW IN POTS.

Speaking broadly, I think the large trumpets are, on the whole, more effective than the smaller "cups"; so when I come to consider the other sections it will be found that I do not include as many as might be imagined from their large numbers. There is no difficulty in having a pot of Daffodils in full flower on New Year's Day, if only they are potted in August or early in September and the right kinds chosen. Henry Irving is the variety I rely upon, and I always try to get bulbs that have been ripened early. This makes a very considerable difference. I often think dealers do not attach as much importance as they might to this fact in offering varieties for specially early work. It is a medium-sized yellow self with stiff, well shaped perianth. The Tenby Daffodil is also good, and can be had in flower almost at the

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**R** OSES.—I am continuing to bud Roses, although I must admit the sooner this work is completed the better. Briars that were budded in early July are now having the ligatures loosened. Rigorously remove suckers from Rose trees, and see that this is done before they attain any size. To promote the

1.—YOUNG FLOWERLESS SHOOTS OF THE ANTIRRHINUM SUITABLE FOR CUTTINGS.

ripening of shoots of Roses under glass abundant ventilation should be given to the structure.

*Chrysanthemums*.—For the next few weeks these plants will need more attention than at any period of the year. In all cases where large blooms are desired buds should be retained from this time forth. Retain what are known as "crown" buds by removing the tender points that surround them at the apex of the shoots. Terminal buds, which mark the termination of the plant's growth, will begin to develop within a week or two, and until the end of September it is safe to anticipate a continuation of their development. For the most interesting results just slightly thin out the more crowded clusters of buds. As soon as the buds are retained and they appear to be well set apply weak soot water regularly each day, and twice a week dissolve half an ounce of Peruvian guano in a gallon of water and water with this preparation. Soot water is made by placing a peck of soot in a bag and immersing this in a vessel containing twenty gallons of water. Should any plant get dust dry first apply clear water and then soot water.

*The Window Garden*.—Our plants of *Campanula isophylla* in both blue and white forms are a picture just now. They are easily managed and make ideal plants, either in hanging baskets or in pots in the window garden. They must be kept moist at the roots. Plants in window boxes need constant attention. The hot and trying weather of our late summer causes the soil to dry quickly, and on this account the plants need to be watered freely and often. In anticipation of the dull winter days I am about to pot up a few bulbs for early displays. The beautiful white single Roman Hyacinth is easily grown and may be purchased at the present time. Three bulbs in a pot 5 inches in diameter answers very well; some of the smaller bulbs may be placed five in a pot. Use clean, well-drained pots and a compost of loam, leaf-mould and sand.

*The Fruit Garden*.—Wasps and flies are already beginning to give trouble. Plums appear

to be their chief attraction at this period. An excellent method of reducing their depredations is to make up a mixture of beer and treacle or sugar, and to partly fill wide-necked bottles with the solution. The bottles should be secured to a Plum tree, in which case the mixture will prove a greater attraction than the fruit. Tomatoes growing on walls and fences should have the points of the leading shoots pinched out. This will have the effect of diverting the flow of sap to the fruits that formerly promoted growth. Ground that it is intended to plant with fruit trees in the ensuing autumn should be got ready in good time. Too often this preparatory work is put off until it is next to impossible to do it properly. The quarters allocated for this purpose should be dug two spits deep, and the bottom of the trench should also be forked over. Glass houses in which Grapes are ripening need careful management at this period. The atmosphere should be maintained in a dry condition, and this may be effected by careful ventilation. If plants of other subjects in pots are growing under the Vines, I should be disposed to move them or else water them with great care, so that the drainings from the pots may not create a very moist condition of the atmosphere.

*The Flower Garden*.—Plants in beds and borders are improved by a frequent use of the hoe or any other implement that will stir the soil between them. Weeds are kept under by the same means, and this is no small advantage. I usually prepare special nursery beds at this period in which to transplant hardy plants raised from seed a short time since. Such subjects as Sweet Williams, Foxgloves, Forget-me-nots, Sweet Rockets, Pansies, Pansies, Primroses, Polyanthus and other plants of a similar character are transplanted a few inches apart in these beds, where they quickly become established. These same plants may be planted in their permanent quarters in the early autumn or spring, and in either case will do well. Stately plants, such as the Lilies, Gladioli and Kniphofia (Red-hot Poker Plant), in exposed situations will need the support of stakes, to which they should be securely looped.

*The Vegetable Garden*.—For late autumn and early winter use I am making a small sowing of Cabbage Lettuce. The Black-seeded Cos Lettuce may be sown at the same time, as in a favourable season this will also do well. All the Year Round is a very good Cabbage Lettuce for this purpose. The seed must, however, be sown in a warm, sheltered border to do well. Lift Tripoli Onions without delay in dry weather, leaving them in the open to dry off. For next summer's supply make a sowing of Giant Rocca and any of the giant white Italian forms. Select well-matured and deeply-dug quarters. D. B. C.

### PROPAGATING ANTIRRHINUMS AND PENTSTEMONS BY CUTTINGS.

The above-mentioned subjects are well-known and popular garden plants, and are easily grown. *Antirrhinum majus*, the species from which all the charming varieties of our gardens have sprung, is raised from seed year by year, and many beautiful results are thus obtained; but there are numerous instances where certain well-known forms are so excellent in every particular that it may be desired to perpetuate them. While we may raise the Snapdragons (*Antirrhinums*) in batches of different colours, there is almost certain to be many variations from the original when we trust to seeds.

*When to Insert the Cuttings of Snapdragons*.—Opinions differ as to when the cuttings should be detached and inserted in suitable soil. We have found after considerable experience that during the late summer and early autumn is a good time to do the work. At this period shoots of the right kind may be obtained from many flowerless plants. It is after the flower season is practically over that numerous fresh young shoots are developed on the old plants.

*Soil for Propagation Purposes*.—Like many other subjects, these plants may be rooted quite readily in sandy soil. We prefer a compost made up of loam, leaf-mould and sand in equal parts, and if these ingredients are riddled through a sieve with a half-inch mesh and the heap well mixed before using, it will answer well.

*Where to Root the Cuttings*.—There are several ways in which the cuttings may be rooted, and for a beginner we wish to make the matter quite simple. If a large number of plants are required, it would be well to use a cold frame. Here, assuming the soil has been dug over, a layer of the light sandy soil above mentioned should be spread over the surface to the depth of 3 inches to 4 inches. This should be carefully levelled and made fairly firm, and watered by the aid of a fine-rosed can. Leave it for some hours before proceeding to insert the cuttings.

*Cuttings and How to Make Them*.—Fig. 1 shows two growths that have been detached from an old plant. This is the kind of growth to procure, hard shoots near the apex of the plants being of comparatively little value. To prepare these it is necessary to trim off the lower leaves and cut through the stem just below a joint. A joint is that portion of the stem where the leaf-stalks adhere to the stem itself. Fig. 2 shows the same two shoots as in Fig. 1 properly prepared for insertion.

*Other Methods of Rooting Cuttings*.—In addition to rooting the cuttings in cold frames where they should be arranged in rows 3 inches apart and 2 inches asunder in the rows, they may be

2.—THE SAME SHOOTS AS REPRESENTED IN FIG. 1 PREPARED READY FOR INSERTION.

inserted in pots 2 inches to 3 inches deep or in seed-pans or boxes. In the latter instances the limited demands of small growers are perhaps better served. Use soil of a similar character for filling the pots and boxes, taking care, however, to crock these receptacles with the greatest care. When inserting the cuttings first make a hole of sufficient depth to embed the cutting about 1½ inches and always take care to press the soil firmly at the base of each one; this is an essential factor in successful propagation.

3.—YOUNG SHOOTS OF THE PENTSTEMON SUITABLE FOR CUTTINGS.

When propagating in boxes, &c., the cuttings may be inserted close together;  $1\frac{1}{2}$  inches apart and the rows 2 inches asunder will answer very well. Gently water in the cuttings with water from a fine-rosed can. Place the boxes in a cold frame or else under a handlight or bell-glass. Maintain fairly close conditions while the rooting process is going on, and in a few weeks when new growth is apparent give air to the structure, increasing this from time to time. Here they may remain until planting-out time in the spring, affording covering and protection in the cold and trying weather however.

*Treatment of the Pentstemons.*—These beautiful plants may be treated in similar fashion to the Antirrhinums, the mistaken notion of propagating them in heat accounting for many failures. They must be matted up in cold weather as a protection against severe frosts. The cuttings are made from growths that develop quite freely on the plants, and Fig. 3 is a good illustration of typical shoots to use for this purpose. The prepared cuttings in Fig. 4 show the shoots that are represented in Fig. 3 with the leaves trimmed off and otherwise prepared in readiness to be dibbled in the light sandy soil. Pentstemons succeed remarkably well where the ground has been deeply dug and well manured, yielding wonderful spikes of blossoms under such conditions. They are of simple culture and may be raised from seeds, cuttings or divisions. We prefer to increase the plants by cuttings during the period above mentioned.

#### PLANTING SPRING CABBAGES.

Young Cabbage plants are always plentiful in the autumn. In some gardens they are too plentiful, in the sense that, being overcrowded in the seed-beds, they become weakly and drawn and do not withstand the winter weather very well. The young plants should either be freely thinned out while in their seed quarters, or, better still, be transplanted in nursery beds before being finally put out. The plants cannot be too sturdy. Persons who purchase the plants should insist upon being supplied with good ones. Spring-raised plants are far superior to weakly autumn-raised specimens, as the former grow more freely and form better hearts.

*The Preparation of the Soil.*—By this I do not mean deep digging or trenching and heavy manuring. It would be a mistake to do all this in the autumn, as the result would be gross growth, injury by frosts and loosely-formed hearts in spring. No elaborate and expensive preparation of the ground is necessary. Simply select a plot on which Potatoes, Peas or Beans have grown during the summer months. Manure has been put in for the benefit of all these crops and so the soil will be quite rich enough for the spring Cabbages, as you should remember that these plants may be lightly fed in spring, when they will reap all the benefit of the feeding given. Having chosen the best quarter for the

plants, remove all old haulm or other matter from it and level the surface soil. Then scatter sufficient soot on the ground to just darken the soil and forthwith point it in 3 inches deep. If the soil be light and in a dry condition, tread it down firmly before planting is done.

*The Planting.*—This work should be done with a hand trowel so that the roots of the plants may be well spread out and neatly covered with soil. Make the soil firm around the roots. Small compact growing varieties should be planted 16 inches apart in rows 18 inches asunder. The larger growing sorts require 2 inches more space each way. Earliest of All, a good variety of fine quality; Early Offenham, a good all-round sort, reliable; Ellam's Early Dwarf, one of the very best; Nonpareil, dwarf, early and compact growing; Wheeler's Imperial and Enfield Market, both good and reliable; Mein's No. 1 and Heartwell Early Marrow are varieties which, if properly treated, will never disappoint the grower. The novice should grow a few rows of each variety rather than confine himself to one or two sorts, then a prolonged supply will be assured in spring.

#### TREATMENT OF TOMATOES IN THE AUTUMN.

A SPELL of dry, hot weather in June and July is very favourable to a good set of fruits on the plants. The month of June was an ideal one: July was not so favourable, but during two weeks we had a fair amount of sunshine.

*Outdoor Plants.*—Any fruits which set after August 10 on plants growing in the open air are practically worthless, as they do not ripen, so it is a wise plan to cut off the top of each plant then. The fruits already formed will receive all the nourishment and, in due course, mature. If the plants are not cut back they will continue to grow and produce flowers and young fruits, but the latter will not ripen and they will rob the earlier-formed fruits of much nourishment.

*Indoor Plants.*—There is a risk of the Tomato disease attacking the plants grown under glass in the autumn, but this may be avoided if some of the main leaves are removed and also all young side shoots before the latter attain to a length of 2 inches. Then a good circulation of fresh air will pass through the house and benefit the plants. In cases where the houses are fitted with hot-water pipes the latter should be warmed every evening, and all necessary watering done early in the morning and not at night. As days and weeks pass less water will be needed.

AVON.

#### THE EDITOR'S TABLE.

##### SWEET PEAS FROM HAMPSTEAD.

Miss Glanville, Lyndhurst Road, Hampstead, sends good flowers of various Sweet Peas. These are some of the best we have seen grown so near London. The following note accompanied them: "I am sending you a few of my Sweet Peas as I should like to have your opinion of them. They have been grown in a small suburban (Hampstead) garden. In sending them I should like to mention what treatment they have undergone. I sowed the seeds first in pots at the end of February, in most cases putting seven seeds in a  $4\frac{1}{2}$ -inch pot, and kept them in a cool greenhouse. As soon as the seedlings appeared above the soil I placed the pots on a shelf near the glass to prevent the plants becoming drawn. At the end of March the pots were put in a frame, the light being gradually left off during the day but kept on at night. By the middle of April I planted the Peas in their flowering quarters, and at this time they were about 6 inches high and branching well. The soil where they were planted was dug and well manured last autumn. I planted them mostly in clumps, five plants in each clump, at a

distance of 5 inches apart. Soon after they were in the ground I trembled for them, as we had such severe weather at Easter, but the snow seemed to rather benefit them than otherwise. I have kept the plants well staked, and picked the first flowers about the third week in June; since that time they have flowered in profusion. Occasionally I give them a little soot water and keep the ground well hoed round them, and never let any dead flowers remain. The Peas I am sending are Dorothy Eckford, King Edward and Bolton's Pink. The seeds were from Eckfords. I used to commit the mistake of most amateur gardeners, that of sowing the seed too thickly, but, by experience, I have seen the mistake of doing so."

##### DOUBLE CLARKIAS FROM BICKLEY.

Mr. G. Ansten, The Gardens, Nunholme, Bickley, sends excellent spikes of double Clarkias. He writes: "I am sending you a few spikes of the double-flowering Clarkia. The seed I saved myself from one or two plants I had last year of the pink variety. This I sowed in early March and duly pricked off and grew on in a cold frame, and as soon as they had made nice sturdy plants I planted them in the borders. They have now made fine plants, and have been in bloom for some time. Some of the plants are over 3 feet high and 2 feet through, and form perfect pink pyramids. Like all annuals, they are easily grown, but pay for a little extra attention. I have also enclosed a spike of a good double white one which came up among the pink ones."

##### PERPETUAL-FLOWERING CARNATIONS FROM DEVON.

Mr. E. Cummins, Ringmore Road, Shaldon, Devon, sends flowers of two good perpetual-flowering Carnations. He writes: "I herewith send blooms of two of my new perpetual-flowering Carnations. They are seedlings from the American tree variety Lady Bountiful, and were produced by crossing that variety with Nelson Fisher. Although this is what I term a violent cross, the result has been most satisfactory. During twelve years' experience with the culture

4.—THE SAME SHOOTS AS IN FIG. 3 PREPARED READY FOR PLANTING.

of Carnations I have made hybridising a special feature, and I have always noticed that the most pleasing results are produced from this kind of cross, there always being a greater variation of colour and a better chance of producing something distinct and really worth growing. These blooms were cut from plants growing entirely in the open ground, where they have stood the severity of two successive winters without protection of any kind. (I may say that the blooms are shaded from the hot rays of the sun.) Next season I shall work them for blooming during the winter inside, for which purpose I think they are worthy. You will note that the variety Mrs. E. H. Wolfe has not been disubbed, hence the reason the flowers are not so large as those of the variety Devonia."

## THE TOWN GARDEN.

**PLANTING DAFFODILS.**—It is not the general practice for town gardeners to lift and store their Daffodils after flowering in the spring, but those who make it a rule to do so are recommended to plant them during this month if possible and if not then early in September. There is no doubt that bulbs planted early thrive better and consequently produce superior flowers to those which are kept out of the soil until the middle or end of November, and every opportunity of planting should be taken. In beds it is, of course, impossible, as the summer occupants are still in splendid form, but it is often easy to find empty spaces in borders, and these should be promptly occupied with the home-stored Daffodils. If the stock comprises a mixture of small and large bulbs, I would urge grading, placing the finest bulbs in the most conspicuous positions, as they will produce the best flowers, and the remainder in less prominent places.

**FEEDING CHRYSANTHEMUMS.**—Practically every amateur gardener in town and country must have a few Chrysanthemums in pots, for their blooms are more than welcome during the dull months of November and December. In towns the plants flourish grandly and superb blooms are produced in circumstances which are the reverse of favourable, but this is only where the grower makes a special study of his subject and devotes a large proportion of his spare time to the plants. In any case it will now be essential to attend regularly to watering and feeding. At least twice, and preferably thrice, a day each pot should be tested to see that the soil is pleasantly moist, and about twice a week the watering should be followed by an application of weak liquid manure. This can be made up of any material that may be convenient, but it must not be of too stimulative a nature, or the plant will grow too grossly to be satisfactory. Soot water of the colour of weak tea, liquid from any natural manure, or that from one of the excellent concentrated foods advertised in *THE GARDEN*, used strictly according to the directions supplied by the vendors, will answer admirably, but care must be taken to check the propensities of the majority of amateurs to give such things too frequently and too strong.

**PROPAGATING ZONAL PELARGONIUMS.**—Growers who take their own cuttings of Zonals should put the work in hand forthwith, as if it is done carefully the appearance of the beds will not be prejudiced in the least, and it will be easy to strike the cuttings in a sunny position in the border and thus reduce the necessity for much attention in watering. Sturdy, short-jointed shoots should be chosen, and after having had two or three of the lower leaves removed must be cut squarely beneath a joint; this done, they should be firmly inserted in the position chosen, care being taken that the base of the cutting rests on the bottom of the hole. If growths are taken judiciously from the plants it will not be possible to see any difference in the effect of the beds, but if one plant here and another there are stripped of all their shoots the display will be at once destroyed. If it is preferred, the cuttings can, of course, be placed singly in small pots or several in those of larger sizes.

**PAPER WHITE NARCISSUS.**—Although Roman Hyacinths are by far the most popular of all the earliest bulbs, this Narcissus is invaluable, and should always be used in conjunction with the Hyacinths. It will now be possible to procure bulbs, and as soon afterwards as can be managed the first batch should be potted, and in this respect, as well as in management, they should be treated in precisely the same manner as the Romans. Purchasers are strongly advised to procure their supplies as soon as they can, and to go to a source that is absolutely reliable rather than search assiduously for the lowest prices.

HORACE J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## HARDY FRUIT TREES.

**C**URRENTS have been good and plentiful, and the bulk of them will have been gathered. If, however, any are required late, these must be netted, or the birds will very quickly devour them; even wasps and bees attack them in this warm locality. In the latter case wasp-proof netting must be placed over the trees. The bushes may be pruned into shape, thinning out unnecessary growths. This will help those that are left.

Gooseberries must be covered with tiffany or wasp-proof netting in order to preserve the fruits.

Cherries must have protection also; even the Morellos are eaten ravenously by birds. The growths should be nailed or tied in, or they may get broken by gales.

*Peach and Nectarine Trees* in full bearing should receive copious supplies of water and the shoots be tied in neatly, exposing the fruits as much as possible. Many sorts of Peaches ripen in August, and I will mention a few for the guidance of would-be planters: Early Alfred, beginning of August; Dymond, mid-August; Early Grosver Mignonne, third week of August; Early Silver (a beautiful fruit and of the best flavour), end of August; Goshawk, first week of September; Noblesse, Stirling Castle and Violette Hâtive, mid-September; Sea Eagle and Princess of Wales, the latest. It is necessary to well syringe the trees twice daily, especially on light soils. Water with farmyard manure occasionally and about twice with Wood's Le Fruitier, but when the latter is used it is advisable to dispense with nitrate of soda. Nectarines that do best outside are Cardinal, end of July and beginning of August; Lord Napier, August; Rivers's Orange, Violette Hâtive and Pineapple, September; and Victoria as the latest.

*Early Apples* will want looking over. See that these are sufficiently thinned. Irish Peach and Mr. Gladstone will soon be ripening, and, if at all dry at the roots, a watering will help them materially in the last swelling. Beauty of Bath, Quarrenden and Lady Sudeley will also require watching, as the birds attack them very readily, especially in dry weather. It is an excellent plan to water and mulch all fruit trees carrying good crops, especially those on walls, fences and in confined areas. Those in more airy and exposed positions will not require so much attention.

Pears, such as Citron des Carmes, Jargonelle, &c., will also require similar attention to the above.

## PLANTS AND FRAMES.

*Chrysanthemums* will now require a lot of attention, and must be looked over several times daily. Attend to taking away the side shoots or disbudding, also to tying up to the stakes. Syringe the plants each night after a hot parching day, and once a fortnight syringe with insecticides to keep down aphides, mildew and rust. Those planted out should have copious supplies of water when dry, as if they are allowed to flag the flowers will be of poor quality. This is a good time to get plant frames and houses cleaned and painted if necessary. Anyhow, a good scrubbing with soap and water will benefit the plants, and the walls should have a cleaning and a good coat of limewash to prevent and destroy insects.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslée, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**ZONAL PELARGONIUMS.**—Time must not be lost in getting in a good batch of cuttings of the best-named varieties for next season's display. These may be inserted either singly in 2-inch or 2½-inch pots, or five or six cuttings in a 4-inch pot. I frequently place the strongest and best cuttings in the former, and the smaller and weaker ones in the latter. Light loamy soil, with a little leaf-mould and some sharp sand added, suits them well. Cuttings of the Ivy-leaved sorts may be treated in the same manner. Cuttings of the large-flowering Pelargoniums that were inserted early and are now rooted and growing again should be potted off singly, using pots proportionate to the size and strength of each. Pot firmly, and keep them rather close in a cool frame or pit for a week or two till established.

## HARDY FRUIT.

*Raspberries.*—The old fruiting canes should not be allowed to remain after the fruits are cleared, as those with the fruit crop will have impoverished the plants. Raspberries being surface rooters will now pay for food in the form of a mulch, and the more decayed the manure the better.

*Fruit Nets* which were placed over bushes should be removed as soon as the fruit has been gathered, and dried and stored away for future use. This is not only necessary for the preservation of the nets, but their removal from the bushes will enable the leading growths to again assert themselves and a free circulation of fresh air to pass through and around the foliage.

## KITCHEN GARDEN.

*Open-air Tomatoes.*—The earliest lot of these will need attention in the way of securing the leads either to wires, where the walls are furnished with such, or to stout stakes fixed firmly in the ground. Remove all laterals as they appear, and in the case of those plants that are plunged in the pots and are showing surface roots, top dress moderately, but postpone liberal feeding until the first lot of fruit is set. Avoid cutting away the foliage wholesale in order to hasten maturity, as this is a positive loss and tends to weaken the plant and lessen the aggregate weight of the crop.

*Late Dwarf Beans.*—A small sowing of any early variety, such as Ne Plus Ultra or Syon House, will give late dishes when other varieties are over. These will necessarily need protection. The best plan is to sow according to the means at hand to protect them. In sowing it is advisable to select a warm border facing south or south-west, and sow thinly or thin well when up.

## FLOWER GARDEN.

*Lilium chalcidonicum.*—Few subjects are finer in the garden about the middle of July than the rich flowers of the scarlet Turk's-cap Lily. Sound, healthy bulbs should be obtained, and, if possible, plant them quite by the end of August or transplant them about this time in a position free, or nearly so, from the midday sun. A rather stiff, holding loam suits this Lily well, and is much better than a light, sandy soil so freely recommended for growing bulbs in.

*Intermediate Stocks.*—Now is a good time to make a sowing of these in a cold frame for planting out in the early spring. These will flower before the Ten-week sorts.

*Roses.*—The present is a good time to prune many varieties of climbing Roses, such as the Crimson Rambler. Of course, it must not be understood that I mean final pruning, as this cannot be done until the early days of next year. Much good may be done, however, by a pruning now. Directly the last blooms have faded is the time to remove all old growths and any that are weakly and in any way likely to overcrowd the young rods, which must be retained full length.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Wallflowers (F. Hurrell).**—The seed was sown too late in the year to admit of making plants of sufficient size for flowering in the spring of 1908, and at this season will not flower. But as you have now some extra large plants a good flowering should result in 1909 by allowing the plants to remain where they are. Seeds of the Wallflower should be sown in the springtime about April, so as to obtain nice bushy plants by the end of September for planting out for flowering. In certain instances the seeds may be sown later than the above-named date, and where it is necessary to protect the young plants in frames during the winter season a somewhat later sowing would answer quite well. On the principle that a good-sized plant produces the best results at flowering time, the early sowing of seeds has much in its favour and also provides a hardy type of plant.

**Asters diseased (E. M.).**—The Asters are attacked by a species of *Fusarium*, a fungus allied to that which causes the "sleepy disease" of the Tomato and to others which produce similar symptoms in various other plants. The attack begins just at the collar or just below the level of the soil, and the tissues of the plant higher up are killed as well as the root, though the top of the plant appears quite green and healthy. Now the fungus has reached its fruiting stage and is producing small masses of pinkish colour consisting of myriads of thin curved spores. These spores are set free and in all probability remain in the soil through the winter ready to infect another batch of plants in the succeeding season. The only thing that can be done is to carefully remove the affected plants from the bed as soon as possible and burn them immediately. If possible, avoid planting Asters next year near where these are growing and take particular care that the soil in which the seed is sown is not such as has been open to infection by the fungus.

**Sowing seeds of *Cypripedium spectabile* (F. L.).**—Seeds of this should be sown as soon as they are ripe. Use a compost of peat, leaf-soil and sand. Make the surface of the soil very fine and sow the seed thinly all over it. Do not cover with soil, but place a sheet of glass over the pan or pot, and place it in a shady, moist position. When it needs water, do not water overhead, but dip the pot in a pail of water, but not deep enough to cover the surface of the soil or the seeds will float away. The plant you send is *Cornus capitata*.

**Astilbes and Spiræas (Hector).**—The genus *Astilbe* is only separated from *Spiræa* by slight botanical differences, and the members of both genera need exactly the same treatment, the whole of them being moisture lovers. Of the plants enumerated by you the only *Astilbe* is *japonica*, all the others being true *Spiræas*. A great many *Spiræas* are of a shrubby character, indeed, the members of this section are among the most beautiful of our flowering shrubs. The true *Spiræa japonica* is a shrubby species, forming a rather upright bush, which is, from the early part of July onwards, studded with clusters of bright rosy red blossoms. It is often met with in cultivation under the specific name of *callosa*, and as a late summer-flowering shrub is particularly valuable. We have little doubt it was the nitrate of soda which injured your plant; the fact that some others were not affected may be, in the first place, owing to the circumstance that it possibly received a little more than the others, and,

secondly, the soil was perhaps too dry when the stimulant was given, for these strong manures should never be applied when the roots are dry. You may safely give a solution of Peruvian guano, and thus encourage it to make good free growth, as in this way the flowers, which will develop next year, are built up.

**Climbing plants for east and north walls (Ignoramus).**—The following climbing Roses will succeed very well: *Aimée Vibert* (white cluster), *Ard's Pillar* (rich crimson), *Blush Rambler* (a grand new climbing Rose), *Turner's Crimson Rambler*, *Climbing Mrs. W. J. Grant*, *Dorothy Perkins*, *Electra*, *Gloire de Dijon*, *Mme Alfred Carrière* (white) and *William Allen Richardson*. Also the following Clematises: *C. Jackmanii*, *Marcel Moser*, *Mrs. Hope*, *President*, *Princess of Wales*, *montana*, *Vitalba* (*Traveller's Joy*), and the *Wistaria*, the grandest of all climbing plants, will succeed in such a position.

**Delphiniums and Roses (H. F. P.).**—The Delphinium sent is what is known as Cambridge Blue. It certainly is far from being True Blue. Probably it is a seedling. As to budding Roses to produce maiden plants, you can only procure these by planting out in February some stocks such as seedling Briars, Briar cuttings or Manettis and budding them the following August. The non-flowering of the Carnations may be due to the plants being wrongly named. Probably you have been supplied with seedling plants under the names you give. The *Gentiana acaulis* flowers best on a rockery in rather poor soil. It seems to need elevation, although it may frequently be found flowering freely by the side of a garden walk where the soil has been well worked. The Rose Mrs. David McKee is, as you say, a first-rate sort. It grows well and is most showy and beautiful, and a more useful Rose than Kaiserin Augusta Victoria for outdoor growth.

**Increasing Pansies (Ignoramus).**—Pansies are propagated from cuttings planted at the end of August in a warm, shaded border in sandy soil. The cuttings should be taken from the centre of the plant and be about 3 inches long. Cut off all the leaves close to the stem, excepting three or four at the top, and insert firmly in the soil. They will be ready for planting in the border by October. They require no protection. They like a rich soil and a cool aspect and should be planted 12 inches apart. Intermediate stocks may be sown in the open ground now and potted into 5-inch pots when large enough to handle. These must be wintered in a cold frame and protected in very cold weather by mats or some other covering. They should be planted in the borders at the end of March. They may also be raised in spring by sowing the seed in heat early in March and growing in frames (in pots) until large enough to plant in the borders.

**Weedy lawn (S. R.).**—We fear your informant as to the source of the weed which now so largely infests your lawn is right. It is known as the Hawkbit, and its botanical name is *Apargia autumnalis*. It is presumably an autumn bloomer, but in poor soils is much earlier. Like all the Thistle family, this weed seeds freely, and the seeds being light are easily carried on the wind good distances. If your lawn was in the direct path of the wind when these Hawkbits were seeding, a big share of them would fall upon it. Previously you had no spare soil on which the seeds could germinate, but after using the lawn sand to destroy broad-leaved weeds, there was ample soil space, and the lawn sand is really a manure. We fear that, so long as the poor grass land is near, do what you will, you may be troubled with weeds. Your only course is to have the lawn well forked over in the winter, all weeds and grass forked out and removed, a dressing of fully decayed manure forked in, then the whole allowed to lie until the end of March. Then sow fairly thick with good lawn grass seed and well roll. If the grass gets to cover the soil densely, there will be little chance for weed seeds to find soil on which to germinate.

### TREES AND SHRUBS.

**Jessamines flowering irregularly (H. M. C.).**—It is impossible to account for one of your Jessamines flowering and the other not, as they are growing under the same conditions. If your white Jessamine is a young plant that may account for it, especially as you say that it grows vigorously. Try root-pruning next autumn. Remove some of the soil from around the roots and cut through a few of the larger ones. This will tend to weaken growth a little and may induce it to flower. The aspect is favourable for it.

**Destroying stumps of Elders (Alford).**—The Elders can be destroyed by boring large holes in the trunks near the ground line and filling them with common salt. After the salt has been inserted the openings should be corked up.

**Dead Ampelopsis (R. R. G.).**—The sudden dying of Virginian creepers, and especially old ones, is one of those things which seem to baffle explanation. The white mould within the dead bark of the stem of your twenty year old and now dead climber evidences the existence of fungoid growth, but that after all may be but a consequence of the decay and not the cause of death. We have seen many such deaths, and especially of *Ampelopsis Veitchii*, the close-growing one. Possibly the stem near the ground may get some injury, or some emanation of gas or other poisonous matter may kill the roots, or the soil may be quite exhausted. It is even

possible that severe frost may do the plant harm. There is no end of conjecture, but very little of reliable evidence. Possibly seedling-raised plants are more enduring than are those propagated by cuttings or layers. Still, a fungoid attack may be the real cause after all.

**Information about tender plants (J. Metcalf).**—If, in your part of Ireland, such plants as *Cordylina* (*Dracena*) *australis*, *Tricuspidaria dependens*, *Myrtles*, &c., thrive in the open ground, it is quite probable that *Araucaria excelsa* and the *Camphor Tree* will do so. About the *Shasta Daisy* there is little doubt, as that thrives in many parts. The *Watsonia* will most likely grow well if given a sunny position at the foot of a wall in a well-drained border of sandy soil, but it is doubtful whether the *Pepper Tree*, *Papyrus* or *Wigandia* will thrive very satisfactorily. If you have plenty of plants it will, however, be worth trying them, for occasionally certain plants succeed in places where no one expects them to do so.

**Information about *Pinus insignis* (A. Mackenzie).**—Though *Pinus insignis* is a very beautiful species, and harder than many suppose, it is not a success in many parts of these islands. In their "Manual of Conifers," Messrs. Veitch say that its value as a subject for British arboriculture is restricted to the area which may be roughly defined to be that part of England south of the Thames and west of the Severn, Ireland generally, and the south-western counties of Scotland. Such is also our experience, and we find that this species thrives particularly well within the influence of the sea breezes. Of *Abies webbiana* there are many fine specimens scattered throughout the country, but it is a well-known fact that in many places its culture is not attended with success. The main trouble seems to be owing to the fact that this beautiful Silver Fir begins to grow so early in the year that the new growth is often killed by spring frosts, which quickly injure the tree beyond repair. In its Himalayan home the snow lies on it for months together, but when it melts and growth takes place there is no return of frost that season. *Abies grandis* is by many experienced arboriculturists regarded as one of the most promising of the North American Silver Firs, and many large specimens are to be found in various parts of these isles. Its price, however, as noted by you, is by no means cheap. The Japanese Larch (*Larix leptolepis*) is looked upon as one of the most promising trees of recent introduction, being by many considered disease proof, while its comparatively quick growth is commented on by all. We shall be pleased to learn later on whether your diseased tree of the common Larch has in any way affected its Japanese relative.

**Shrubs and climbers for plan (F. S.).**—The following shrubs are all likely to suit your purpose: *Berberis steophylla*, yellow, May; *Carpenteria californica*, white, May; *Choisya ternata*, white, May; *Chimonanthus fragrans*, white and brownish, January; and *Cydonia* (*Pyrus*) *japonica* in variety. Of the last-named we should recommend half-a-dozen varieties, as their beautiful flowers are all produced in early spring, and in colour they vary from white to deep crimson. In addition there are *Ceanothus rigidus*, lavender blue, April and May; *C. veitchianus*, blue, May; *Clematis montana*, white, May; *C. m. rubens*, rosy red, May; *Deutzia Lemoinei*, white, May; *D. discolor purpurascens*, pink, May; *Exochorda grandiflora*, white, May; *Forsythia suspensa*, yellow, February and March; *Hamamelis japonica*, old gold, January and February; *H. j. zuccariniana*, citreous yellow, January and February; *Jasminum nudiflorum*, yellow, winter; *J. primulinum*, yellow, spring; *Hydrangea volubilis* (climbing *Hydrangea*), white, May; *Magnolia stellata*, white, April; *Prunus triloba*, rose, April; *P. sinensis alba plena*, white, April and May; *P. s. roseo-plena*, pink, April and May; *Rubus deliciosus*, white, May; and *Viburnum plicatum* (Japanese Snowball Tree), white, May. For the stretch of wall on the left, which does not get much sun after midday, the most suitable plants are the *Cydonias*, *Forsythia suspensa*, *Jasminum nudiflorum*, *Hydrangea volubilis* and *Viburnum plicatum*. The only preparation needed will be to thoroughly dig the border before planting. As the soil is a fairly good loam, it is not likely to need any addition, for, owing to the limited height of the wall, you do not want the plants to grow too vigorously.

### THE GREENHOUSE.

**How to treat Ivy-leaved Pelargoniums (Mrs. Gurney).**—If you merely wish to have pyramids of these in the open, as in the bedding arrangements seen in the public parks and gardens, the simplest way would be to arrange a pyramid of stout stakes or Bamboos and plant five, seven, or even more plants around and train them thereto. To do this successfully the cuttings rooted in the autumn of 1907 and grown on make good tall plants for the purpose, or cut-back plants would do equally well. Similar pyramids could be grown in large pots or tubs for terrace decoration by planting several around the inside edge of the receptacles named and training them into shape. This method of forming pyramids of such things as *Heliotropes* and the Ivy-leaved *Pelargoniums* has much to recommend it, and the plants when shortened back are readily wintered in a

temperature of 45° if kept rather dry at the roots. The dark-flowered *Heliotrope President Garfield* is a good one. Pots of 10 inches and 12 inches across would be large enough to grow handsome examples, and such as these with careful treatment and judicious supplies of liquid manure would remain good for two years at least.

**Malmaison Carnation buds destroyed** (*M. Fell*).—There is no doubt that the Carnation blooms are eaten by caterpillars of some kind. You do not speak of finding any, but the mischief may have been done some little time ago, and when you noticed the damage these pests may have entered upon the chrysalis stage. Again, the authors of the mischief may be the larvae of one of those small yet very destructive moths whose caterpillars feed only during the night and remain in hiding throughout the day. You will probably be too late to find any caterpillars, unless a second brood takes possession of the plants. The buds of double-flowered *Geraniums* are often scooped out by caterpillars in the same way as your Carnation buds are.

**Calceolaria for inspection** (*Miss C.*).—There are now so many garden varieties of *Calceolaria* in cultivation that we cannot possibly say whether yours is quite distinct from others. At all events, it is a very beautiful variety, apparently a cross between the ordinary herbaceous *Calceolaria* and one of the smaller-flowered forms. It may be said to stand in the same relation to the herbaceous *Calceolaria* that the stellata section of *Cineraria* does to the ordinary florist's varieties, that is to say, it forms a taller and more graceful specimen combined with a great profusion of bloom. The flowers sent were of a rich golden yellow heavily spotted with crimson, and as a succession is kept up for so long, it should prove of great value for the embellishment of the greenhouse or conservatory. It appears to us so good that we should certainly advise you to bring it under the notice of some specialist.

**Applying chemical manures** (*W. M.*).—We fear it is of little use to apply any general mixture of chemical manures to your garden now, unless you use them as liquid manures. To so apply them get a large tub holding from 20 gallons to 30 gallons of water, fill it, then put in a coarse bag a mixture of 3lb. of superphosphate, and 2lb. each of kainit and nitrate of soda or sulphate of ammonia. Let them lie and soak for twenty-four hours, then use the liquid to freely water crops, and refill the tub. Use the water again the next day, and when refilled add a fresh lot of the manure. It would in that way necessitate your getting in perhaps 1cwt. already mixed in the proportions we have named. Soot in a bag, a peck to a tubful of water, makes good liquid manure, but the chemicals are best. A good dressing of, say, 6lb. of superphosphate and 4lb. of kainit per rod should be dug in during midwinter, and nitrate of soda applied in the spring.

**Information about Fuchsias and Campanulas** (*G. A. L.*).—Some of the seedling Fuchsias will in all probability flower towards the end of the summer or early in the autumn if they are kept in the cool greenhouse. At the same time, seedlings seldom show their true character the first season, so that however unpromising some of them may appear it will be wise to keep them till next year before you make up your mind to discard them. The Campanulas will not flower this year, and your better way will be to lift them early in September, pot them up and winter them in a cold frame, protecting from frost during the winter. The month of October or the first half of November is the best time to make a new Raspberry plantation. Your enquiry re *Cyclamen* corns refers, we presume, to *Cyclamen persicum*. If so July is better than August to obtain dormant corns for potting, but a more satisfactory plan is to obtain growing plants, which can be procured from a nursery anywhere during the autumn and winter. You omitted to send your name and address.

**Information about double tuberous Begonias** (*A. R. D.*).—In reply to your first question it will be quite impossible to increase your double *Begonias* by cuttings at the present season, for should a few of them strike root they will not have time to form a tuber before winter and will consequently then perish. The time to take cuttings is in the spring, when the young shoots are from 2 inches to 3 inches long. They must then be dibbled into clean, well-drained pots of sandy soil and placed in a propagating case in a warm greenhouse temperature, care being taken not to overwater them, as from their succulent nature they are very apt to decay if kept too wet. Division of the tubers can be carried out when two or more shoots are produced from one tuber. This should be done in the spring, when the young shoots are 1 inch or a little more in length, the tuber being divided in such a manner that each shoot has an equal amount of tuber attached thereto. These divided portions must then be potted and treated the same as the uncut tubers. You may, if you wish, save seed from your double *Begonias*, though in this way you cannot depend upon perpetuating the characteristics of any individual. The double flowers are the male ones and the single the female. All that is necessary is to

take some pollen on a small brush and apply it to the stigma of the female flowers. True double blooms seldom produce pollen, but it may often be found on semi-double flowers. At all events the more double the flower from which the pollen is obtained the greater percentage of true double flowers is likely to occur among the progeny.

**Information about a Salvia and Abelia** (*R. H.*).—The *Salvia* is in all probability the Pine-apple Sage (*Salvia rutilans*), whose leaves have a warm aromatic fragrance. You may cut your plant down immediately to within 9 inches of the pot. So treated fresh shoots will be pushed out before winter, at which season it must be kept in the house. It may be placed out of doors till the end of August. The *Abelia*, probably *A. chinensis*, or *rupestris* as it is often called, is quite hardy if planted out in the open border. A sunny yet sheltered spot and a well-drained soil are the best conditions for it. The *Dentzia* is quite hardy, and may be planted out under the same conditions as the *Abelia*.

## ROSE GARDEN.

**Mildew on Roses** (*G. F. T.*).—We advise you to cut off the most affected parts of your plants and then syringe them with a solution of carbolic soap. This is made with half a bar of Lifebuoy soap to three gallons of soft water. When thoroughly dissolved syringe with a very fine sprayer on the under and upper sides of the foliage. Repeat every few days until the mildew disappears. Ants may be trapped by sinking some glazed jars into the ground near their nests and putting some syrup into the jars. They should be rather less than half full. The ants will fall into them and fail to get out again, when they can be emptied out and the trap reset until the nest is destroyed. If you can trace the nest, pour some paraffin into it; but you must take care that it is not near the roots of any plant.

**Rose Conrad F. Meyer not flowering satisfactorily** (*C. L. A.*).—This Rose is apt to grow so vigorously that unless grown as a pillar plant or pegged down it will not flower very freely. You might remove a few inches from the flowerless shoots at once, but we do not think you will get many blooms from them this year; it will help to ripen them, however, and they should bloom next year. In pruning next year leave the growths made this year from 3 feet to 4 feet in length, and if necessary loop them up to sticks. Some of the growths bend over arch-like and others horizontally. Keep them about 2 feet from the ground. A good plan to check the exuberant growth is to lift the plants with a spade and place them again into the same position, making the soil firm about their roots. This should be done in October. This Rose flowers very freely on standards, and we have had it bloom grandly this year upon plants put out two years ago. In pruning we retain the wood almost the entire length that it made last year. Some of the plants might be trained in a fan shape upon a trellis formed with Bamboo canes. The check to the flow of the sap would induce it to flower.

**Roses for a new Rose garden** (*M. M. M.*).—As you say Roses do very well with you, we take it that you are able to give them a fair depth of soil, although there is rock beneath. It is always well to provide Rose plants a depth of some 2 feet of soil, and more if possible. Where 2 feet cannot be provided, you could raise the beds 8 inches to 10 inches, and turf over the sides of the raised portion. Your idea of planting three of a sort is a very good one, and, of course, you will want a large number of sorts to fill such a piece of land, but you will, no doubt, lay out the land into beds of various designs. You could have some arches and pillars of Roses, also a bed of standards, to break up the flatness. As regards continuing the hedge of China Roses, we think this could be done without spoiling the effect. We append the names of some very free-flowering sorts, which will enable you to have plenty for cutting purposes. White and pale flesh colours: Admiral Dewey, Anna Olivier, Antoine Rivoire, Augustine Guinoisseau, Clara Watson, Frau Karl Druschki, Florence Pemberton, G. Nabonnand, Hoh. Edith Gifford, La Tosca, Peace, Pharisar, Prince de Bulgarie and Viscountess Folkestone. Pink of various shades: Celia, Captain Christy, Caroline Testout, Earl of Warwick, Grace Darling, Gustave Grunerwald, Killarney, La France, Mme. Edmée Metz, Mme. Leon Pain, Mrs. John Laing and Mrs. R. G. Sharman Crawford. Yellow and apricot: Dr. Grill, Francisca Kruger, Gustave Regis, Joseph Hill, Lady Roberts, Le Progrès, Mme. Charles, Mme. Hoste, Mme. Pernet-Ducher, Mme. Ravary, Marie van Houtte, Paul Lide and Sulphurea. Rose colour and

salmon: Camoens, Countess Cairns, Lady Battersea, Mme. Abel Chateau, Mme. Jules Grolez, Mme. Lamhard and Mrs. W. J. Grant. Red and crimson: Captain Hayward, Corallina, Liberty, Marquise Litta, Papa Gontier, Richmond and Ulrich Brunner. Dark red: Charles Lefehvre, Commandant Felix Faure, Duke of Connaught, Duke of Wellington, Earl of Pembroke, Ella Gordon, Fisher Holmes, Jubilee, Victor Hugo and Warrior. The following Polyantha and China Roses would yield some lovely sprays of bloom. Polyantha: Aenech Müller Aschenbrödel, Eugénie Lamesch, Katharine Zeimet, Mme. N. Levavasseur, Mrs. W. H. Cutbush and Perle d'Or. China or Monthly: Aurore, Comtesse du Cayla, Baronne P. de St. Cyr, Charlotte Klemm, Mme. E. Resal and Queen Mab.

**Rose Jean Liabaud failing to open** (*Anatole. Alexandra Park*).—This is always a very difficult Rose to grow, and it is rarely satisfactory. The petals are so very numerous that unless we have a hot season they will not unfold, and then, unless shaded, they are burnt by the sun. You will find that the autumn blooms are much the best, although not very numerous. Probably if you planted the tree in a rather warm position you would be more successful with it. If you have a liking for very dark Roses, try Jubilee, Abel Carrière or Baron de Bonstetten. These are all good, so also is Dandy. If the old growths are thinned out in autumn and the strength of the plants confined to the young wood, you should be able to grow these dark Roses very well, providing you prune carefully in the spring, cutting back to plump eyes.

**Pruning Roses in summer** (*E. S. M. and others*).—As the writer of the reply to "E. H. A." page 343 of THE GARDEN, re "Cutting Rose Blooms Off Young Bushes," I maintain that it is contrary to Nature to cut away a quantity of growth when the plant requires the foliage for its sustenance. I cannot agree with "J. D." page 326, that it is advisable to cut Roses copiously with long stems during the summer, in order to ensure a fine autumn crop. This might succeed one year, but it would soon tell its tale in decrepit plants in the near future. You cannot make a shy-blooming Hybrid Perpetual bloom freely in autumn by hard pruning. The reverse is the case. It will merely make strong flowerless wood that will be unripe and totally unfit for flowering well another year. If Tea and Hybrid Tea Roses are in a good rooting medium they will continue to send up plenty of young wood without any pruning whatever, and this can be considerably aided by partly bending over or pegging down the growths, rather than cutting them away. In the reply to "E. H. A." young plants are referred to. Plants established some years can have more growths removed in summer than newly-planted ones, but any good gardener knows full well the risk that is run in severely pruning Roses during the growing period. If a good autumnal display is desired from newly-planted bushes, I should advise pinching off all the bloom buds until the end of June. Many first-class gardeners ensure a good autumnal crop from their Teas and Hybrid Teas by cutting off all blossom from their plants immediately their employers have gone away, but they never think of removing a lot of unnecessary growths and foliage.—P.

## FRUIT GARDEN.

**Berries of Foster's Seedling Grapes diseased** (*Thomas Ross*).—Foster's Seedling Grape is one of the easiest Grapes to grow of any we have. Under ordinary conditions of treatment nothing comes amiss to it. We think you have overdone the Vines with artificial manures, causing a certain cessation of healthy root action. Withhold any further supply for the present and ventilate more freely day and night, so as to give the Vines more rest for a time, when we hope the mischief will be abated.

**Gooseberry bushes attacked by insects** (*H. A. Martin*).—The Gooseberry leaves have been attacked by red spider, which often does much damage to Gooseberries. A thorough syringing with water will do much to check the increase of these pests upon the bushes, especially if the work is done early when the trouble first appears. Even better would be syringing with potassium sulphide solution made by dissolving 1oz. of potassium sulphide in 2 gallons or 2½ gallons of water. The syringing should be repeated at intervals of a few days, as the solution will not kill the eggs of the pest. The black chrysalis with gold rings is the chrysalis of the magpie moth which feeds upon Currants and Gooseberries. The rolling of the leaves of the Rose is due to the presence of the larva of one of the sawflies (*Blennocampa pusilla*), and each of the tunnels formed by the rolled leaves shows traces of the presence of that insect though only one of the larvae was present. Standard Gooseberries may be obtained from most nurserymen.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## AMONG THE ROSES.

**B**EFORE the introductions of the last two decades we had few Roses of merit during August and September. Thanks to the vast improvements in Teas and Hybrid Teas we now have varieties that flower more or less continuously throughout July, August, September and October, and a good many of these are never seen to better advantage than when the majority of Hybrid Perpetuals and climbers are over. Very beautiful and dazzlingly bright is

*Ecarlate* at present, and it will continue so until well into October unless we have an unfavourable autumn. *Ecarlate* makes a capital bedding Rose, favouring Marquis of Salisbury and Camoens in growth and habit—it is a seedling from the latter—and has been a mass of deep scarlet from the end of June. It does not throw up strong and uneven growths, but keeps almost as uniform as the Zonal Pelargoniums. Both this season and last it has taken the eye of all who have seen it.

*Mme. Antoine Mari* is another that continues to flower from mid-June until stopped by frost. A very pretty coat flower this, opening into a good decorative Rose that lasts for several days. Ideal in habit as a bush, and about our best for beds where a very soft rose colour, tinted with carmine on the edges, is wanted, and one that is sure to please.

*Mme. Jean Dupuy* is stronger in growth but compact, and during the bright days of autumn has the deep carmine edges found in *Marie van Houtte* and *Homer*, only more intensified. The chief colour is a deep and warm rosy yellow. This variety is as hardy and certain as *Homer*.

*Mme. Jeanne Phillippe* is another good nankeen yellow, reflexed with carmine, carried boldly erect and in immense trusses; quite distinct and will be welcomed everywhere for decoration.

*Mme. Philippe Rivoire* is comparatively new, and supplies a grand deep apricot yellow on a clear nankeen ground, beautifully tinted with carmine on the edges. It is also very fragrant, a good bedder, and gives capital coat flowers throughout the season, while the fully-blown bloom is fit for the exhibition box.

*Mrs. David McKee*, a very free-flowering creamy yellow, much clearer than most of the cream-coloured Roses, is a grand one for the exhibition box as well as the garden. It has a bold habit, lasts well and is very sweet.

*Mrs. Myles Kennedy* reminds me of *Souvenir d'Elise* when at its best in form and size. It is a lemon yellow, shaded with buff, and almost as distinctly edged with carmine as *Mme. de Watteville*,

*Instituteur Sirdey* has been very good this season, throwing up some grand trusses of deep golden yellow with a touch of brick red in the centre.

*Le Progrès* is another that has surpassed itself this month. Large, full, a very deep golden yellow and exceptionally sweet-scented. I wish this Rose would look stiffer and bolder. For some years it has been a surprise to me that

*La Tosca* is not more generally grown. Resembling *Viscountess Folkestone* in shadings, it is carried perfectly upright, produces large trusses, and is not over directly the bloom has burst. It is also one of what I call all-season Roses, and has never once disappointed us. Hon. Edith Gifford, *Mme. Abel Chatenay*, Lady Ash-town, *Pharisaer*, *Mme. Ravary* and

*Mrs. Theodore Rooserelt* have come in capital form. The last-named is about the best in its colour. Creamy white, reflex of petala clear pale rose; a flower that always looks clean, stands up boldly, is perfect in form, of good size and with the fragrance of *La France*, a Rose it seems to have an affinity with.

*Dean Hole* has also been exceptionally good, giving us a touch of *Maman Cochet*, *Mrs. Edward Mawley* and *Earl of Warwick* in a bolder form, and yet quite distinct from either. The season at present has suited

*White Maman Cochet*, and I have seldom seen it better. It is hard to beat this Rose when grown upon short standards, a form which many varieties need to see them at their best, especially those with a tendency to droop through slowness of stem compared with the weight of bloom.

*Etoile de France* is coming better again now. This Rose rather disappointed me at first. I expected more from *Fisher Holmes* and *Mme. Abel Chatenay*, especially where the pedigree was so marked; still it is among our best dark sorts for late cutting and stands remarkably well. I notice we have several plants of *Dorothy Perkins* throwing a white sport much after the

*White Dorothy* now coming into commerce. A good number of quite new varieties are under close observation, and some of them promise well; but more of these later on.

*Rhea Reid* is doing well with me out of doors. Although recommended as an improved *Richmond* under glass, the blooms we have are not so at present; but outside it is far superior. It is too early to decide, as it was only procurable this season. Another new Rose, *Molly Sharman Crawford*, promises to be a really grand white. *Evangeline* and *Hiawatha* are two

Newer *wichuraianas* that are quite distinct, but several queries have reached me as to "which was which?" By some means *Evangeline* has

been distributed as Hiawatha. I do not think this was done intentionally; but both coming from the same raiser and sent out about the same time, with great similarity of growth when in their younger stages, may account for it. Hiawatha can always be distinguished from Evangeline, whether in flower or not. The first-named has perfectly straight prickles, and the last are hooked as much as Fortune's Yellow and Maréchal Niel. Evangeline is a beautiful single Rose, clear, shiny flesh pink, with large stamens, and is difficult to beat when growing on tall standards or drooping from walls and rockeries. It does not continue in bloom so long as Hiawatha, but has given a six weeks' show this season. Stella is a much deeper and brighter form of Leuchstern, flowering the full length of its growths and lasting against all weathers for many weeks. It takes the eye at once and comes in very early. So far we have not been troubled with

#### ROSE PESTS

to any great extent here. Early in the season there was rather more Rose maggot than usual, but hand-picking soon put a check to this. Mildew is making its appearance, no doubt caused by the extreme changes of temperature experienced lately; hot in the daytime and cold early in the morning. It is those who get up a little before the sun who realise the great difference between sunrise and midday. Others will scarcely credit it. I have invariably found mildew after these changes. Green fly has given us no trouble whatever, and at the time of writing we are free from thrip, a blackish brown pest that quite spoils our light-coloured Roses during many summers, more especially after a spell of hot and dry weather.

Since writing the above I have had one more look at the newer varieties and the following are certainly first class. Mrs. Aaron Ward is a deep Indian yellow, washed with warm salmon rose, tinged with the deep coppery yellow found in Prince de Bulgarie and Monsieur Joseph Hilt; erect in growth and flowers carried boldly above the foliage. Mlle. Simone Beaumez is a large, well built up flower, rosy white in the centre and tinged with saffron yellow that becomes more intense as it reaches the edges. Mrs. Peter Blair, chrome yellow, golden yellow centre, large and quite distinct. The

*Lyon Rose* has been talked about a great deal, and so far as it has come with us deserves all praise. It is a cross from Melanie Soupert and Solfaterra, the pernetiana that was claimed as the precursor of a new race. Unlike Solfaterra, the *Lyon Rose* has already proved its perpetual qualities, and takes after its Hybrid Tea parent in many respects. It is very large, long in the bud, and opens into a grand flower, made up of extra large shell-like petals. Both in the open and under glass it has pleased us, and is certain to be largely grown for some time. Its foliage is good and without traces of mildew here, the colour coral red, tinted with chrome yellow at the base. The raiser describes it as "shrimp red" at the edge of the petals, but it has more the clear colouring of prawns than shrimps, very sweet, keeping its colour in sun or shade.

*Sussex.*

RIDGEWOOD.

#### NATURE THE ARTIST.

It is surprising how beautifully and picturesquely trees and plants, even the commonest, will group themselves the moment they are freed from man's control. We see this in any spot that has been thrown out of, or never taken into, cultivation, even though it bear only Thistles, Briers and the commonest of flowers. In corn-fields and market-gardens, on the contrary, the æsthetic effect of the plant-world sinks to a minimum.—SCHOPENHAUER (2 "Parerga," page 459).

#### FORTHCOMING EVENTS.

September 1.—Royal Horticultural Society's Exhibition, Vincent Square, Westminster, S.W.

## NOTES OF THE WEEK.

**Co-operative Flower Show, Crystal Palace.**—The flower show to be held at the Crystal Palace on Saturday, the 22nd inst., in connexion with the Coming-of-Age Co-operative Festival, promises to be very successful. Entries are being received from as far north as Northumberland, and there is every prospect of a very good show being got together. In addition to the flower show, the programme includes concerts, choir contests, big co-operative exhibition, dramatic literature performances, athletic sports and many other attractions.

**The National Chrysanthemum Society at Windsor.**—The annual country meeting of the National Chrysanthemum Society was held at Windsor recently. In the morning the party paid a visit to the Royal Gardens, and afterwards assembled at Layton's Restaurant. The president of the society, Sir Albert Rolitt, took the chair at luncheon, which was served in the two largest rooms in the restaurant, nearly 200 guests being present. The Mayor of Windsor, Alderman E. Bampfylde, occupied the chair on the right of the president. After luncheon the chairman proposed the royal toasts, and afterwards "The National Chrysanthemum Society," which, he said, had for half a century done a great floral work in promoting the cultivation of a flower which was beautiful, of easy culture and decorative in the autumn of the year, when its varied colours were without rivals, and when there was a dearth of other inflorescence. The Windsor branch of the society had also been most successful, as he knew from his local associations. He urged support of the society by the proposal of new members. In proposing the toast of "The Mayor of Windsor," Sir Albert said their honoured guest was a pattern Mayor. As a member of the Royal Horticultural Society he could say that the Mayor's recent luncheon to them at the Windsor Town Hall had been most hospitable; while recently he had the honour, with Lord Desborough and his Olympic athletes, of having been entertained by the Mayor before the start of the Marathon Race from the castle.

**Potato Sutton's May Queen.**—Those readers of THE GARDEN who require a really good early Potato, valuable alike for frame or open air culture, should make a note of the above for the coming year. On a sheltered border in light and rich soil excellent tubers were dug in eight weeks from the planting, and a few days later the yield was as good as one could wish, the tubers handsome in appearance and very clear skinned. The flavour, too, is of the best. A large number of the tubers I have lifted have been of good exhibition size and quality, but the largest and most shapely tubers I have yet seen were in the first prize collection of six sorts at the recent GARDEN show in the Royal Horticultural Hall on July 30. These were indeed a superb-looking sample and came from Mr. R. Brown, gardener to Lady Tress Barry, St. Leonard's Hill, Windsor.—E. H. JENKINS.

**The Gooseberry mildew.**—Mr. Henry Cannell of Swanley sends two letters, with specimens of Gooseberry, showing the effect of his "One and Only Perfect Wash" in checking the mildew. The specimens were of great interest; the one previously dressed was in perfect condition, but the other was covered with the fungus. Mr. E. S. Salmon of Wye College, who has taken so determined a step in bringing this disease before Gooseberry and fruit growers generally, recently lectured before the Maidstone Farmers' Club. He reported on the recent outbreaks of Gooseberry mildew in Kent, expressing the opinion that this disease had been in the county for two, and probably three, years, and said it had made its appearance at Crockehill, Sutton-at-Hone, Swanley, and Southfleet, in which district over 200 acres were affected. The mildew is causing much anxiety

in the Swanley district. The opinion has been expressed that the trouble is due to infected fruit baskets being brought into Kent. If this be accurate, the first precaution should be to disinfect the baskets by dipping in some wash. It is stated that on several of the farms the infected plantations are being successfully treated by Mr. H. Cannell, sen., of Swanley with the "One and Only Perfect Wash" already mentioned. One letter is as follows: "I have great pleasure in writing to you with reference to your 'One and Only Perfect Wash.' I have tried it on Apple, Plum and Pear trees—Apple sucker and aphid, Plum aphid and scale (both very bad). After two applications, on careful inspection not a single pest could be found alive. My Gooseberry bushes were simply covered with caterpillars. After spraying in the evening, on examination next morning the ground was literally covered with dead pests. It is just as effective for mildew. My Roses are a picture of health and vigour after two applications. It is in the highest degree effective. It is also harmless to the trees (non-poisonous). There is no risk or discomfort to the user. It is economical in cost and, above all, absolutely reliable.—JAMES STEPHENSON, *The Gardens, Sutton Scarsdale, Chesterfield.*"

**The annual borders at Carton, Maynooth, Ireland.**—For a number of years quite a feature has been made of annuals in the borders flanking one of the main walks in the kitchen garden of the Duke of Leinster, at Carton, Maynooth. This kitchen garden, which, by the way, has within its walls ten acres of ground, is beautified with borders of flowers, and in its season those devoted from year to year to annuals are most effective. This season they are doing well, and the show is very fine indeed. *Salpiglossis*, *Asters*, *Godetias*, *Clarkias*, and, in fact, almost all the good annuals of the day, are cultivated in generous masses in these borders, and the display is evidence of the real value of these annual flowers at this time of year. The borders occupy each side of the main path running along the garden, and the effect has been and is very fine indeed.—S. A.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Gooseberry mildew in Kent.**—By a clerical error the notice sent on the 13th inst. by the Board of Agriculture and Fisheries referred to the recently-discovered case of American Gooseberry mildew as having occurred in Kent. The particular case referred to occurred in Essex, and the Board would be glad if the notice could be amended accordingly.

**Rose Marechal Niel and canker.** I sent a short note to the "Rose Annual, 1906," of the National Rose Society about the freedom from canker of an old Maréchal Niel grown by a neighbour of mine. Its freedom from this pest he attributed to the fact of its being budded on Isabella Gray, which I pointed out was one of the reputed parents of Maréchal Niel. I have lately had a letter from a Mr. Kemp of Clapton, who said he had been told that the parents of this our best yellow Rose were Isabella Gray and Solfaterra. Certainly, from my memory of the latter's perfume and habit, this pedigree would not be unlikely. Can any of your readers give me any information on this interesting subject? Perhaps Mr. Kemp when he sees this letter may be able to add to the information he gave me. To the best of my recollection Isabella Gray had a most pernicious habit of splitting, and, like several Roses of that date, frequently came with a green centre and had the same rather full, rounded calyx as the Maréchal.—J. T. STRANGE, *Sulhamstead, Berks.*

**Lilium candidum and the disease.**—You were kind enough last year to give me advice about my *Lilium candidum*, which were badly attacked by fungus. I followed your directions, sun-baking the bulbs and then rubbing sulphur well into them before replanting. The result has been most satisfactory and I have had a nice show of bloom, whereas last year not a single plant bloomed. I wish to thank you for your advice.—EMILY O. PARR, Bromley.

**Wistaria multijuga.**—Noting the illustration of *Wistaria multijuga* in THE GARDEN for the 18th ult. I herewith send you a photograph of a plant growing on the lodge at Millfield, Cobham, Surrey. Unfortunately, it was impossible to photograph the whole of the plant, as the *Viburnum* in the picture obstructed the view of the finest racemes, many of which were 36 inches in length. For years it never flowered until I adopted the plan of pinching the shoots in summer, so that practically there was no spring pruning to do.—F. W. PEARCE (gardener to Mrs. Hansard).

**The variableness of Spencer Sweet Peas.**—The assumption that the well-known variableness of Sweet Peas of the Spencer type is due to insect or atmospheric cross-fertilisation is by no means assured. Whatever may be the exposure of the point of the stigma in many flowers there is, in the first place, no assurance that prior to that exposure self-fertilisation had not already taken place, and, second, there is the fact that the pollen cases still remain covered by the keel just as much in the Spencer type as in the Eckford strain. But how easy it is for any one another year to put this matter to the test. Let them sow or plant out from pots in the open six or more of the Spencer varieties that are known to have sportive or variable characters in clumps of ten or twelve plants. Allow each plant to flower first to see if true to name or otherwise, and have all plants untrue pulled out. Then have every expanded bloom cut off and at once envelop each entire clump in fine muslin through which light and air can penetrate but no insects or pollen grains. Have the whole of the seeds produced, saved and carefully sown the following year. If each lot come true to name then would it be certain that the variableness now so common was due to external fertilisation; if the variableness still was evidenced then must it be attributed to heredity of character. How much all Peas, for many years after being put into commerce, show this sportive tendency is well known to all seedsmen, and only the very closest and constant oversight in rogueing stocks, no matter how extensively, will keep them true. Sometimes, as we see in edible Peas especially, the variableness results in producing an improved stock, which is called an improved selection, though that character is less plentiful than is the backward tendency. Few persons who grow Peas in their gardens know how much they owe to the seed grower or Pea expert for the excellence of the stocks sold to them. There seems to be some stocks of the Spencer type of Sweet Peas that remain true to name. That being so, if external fertilisation be the cause of variation why do these varieties escape? When it is remembered that Sweet Peas are now the product of "in and in" breeding, that many of them have in them the blood of numerous progenitors in varying colours, is it any cause for wonder if variableness does evidence itself so markedly in the progeny? It would be well if some independent authority, such as the floral or scientific committees of the Royal Horticultural Society, conducted next year experiments with the object of testing the matter fully. Certainly the future of the Sweet Pea is not dependent on any such test, but at least it might set at rest the question as to how far natural variableness or external fertilisation produces these sports, which are so unpleasantly numerous.—D.

## DAFFODIL NOTES.

LARGE AND SMALL CUPS FOR POTS.

**A**S I said in my previous notes, the large trumpets somehow seem to be more suitable for pots than either the large or small cups. Just for curiosity I turned up some old Midland Daffodil Society's schedules to see how the pots for competition were generally made up, and I found in both the sixes and the twelves that in every case the large trumpets outnumbered both the other sections put together. This bears my remarks out, and is a fair criterion of popular taste. Hence in making a selection I would not advise more than five out of twelve pots to be made up with these cupped varieties. Sir Watkin, the giant Welsh incomparabilis, is the best of all and can easily be flowered early in February. Autocrat is an excellent one to come in a little later; it is a beautiful soft yellow self with a nice stiff perianth, and is a particular favourite of mine. The orange red and red edged varieties never appeal very much to me; their colour suffers more or less from being grown under unnatural conditions, and I generally give them the cold shoulder. Nevertheless, for coming in in March they may be got fairly in character. Barri conspicuus and Crown

flowered and well grown is exceedingly handsome. The Phenixes too are effective, and are frequently grown in pots; probably Orange Phenix is the most popular.

POLYANTHUS AND POETAZ FOR POTS.

Three of the best Polyanthus Narcissus are Maestro, Mont Cenis and Sir Isaac Newton or, as it is more often called, Newton. The latter has a yellow perianth and an orange cup, whereas the others have white perianths, and in the case of Maestro an orange red cup and in that of Mont Cenis a rich yellow. Both are exceedingly floriferous. The above three make an excellent trio for those who admire this type. Very many object to their strong scent, and it certainly is overpowering in confined spaces. Muzart orientalis I grew for the first time last year, and I was charmed with it. It is a late flowerer naturally, so I would only advise it for late forcing. In its general appearance it is more like the Poetaz type, as the stem is tall and does not carry many flowers; there are seldom more than three. The perianth is white, and the cup a dull deep orange something like the colour we get in *M. Madeleine de Graaff*. It is not very free, so the bulbs may be planted fairly close together. Before very long the old-fashioned Polyanthus will be seldom grown. The new race of Poetaz is in every way superior. All that I wrote about it in THE

WISTARIA MULTIJUGA AT MILLFIELD, COBHAM, SURREY.

Prince are good representatives of the red edged, and Gwyther and Lulworth of the red orange cups. The latter is a dwarf-growing plant and is especially effective in small pots. "There is no rule without an exception," and the exception here is the old Leedsii type, with their white perianths and lovely pale citron or creamy white cups. They are good in pots, and their delicate colouring and refined look always form a delightful contrast to the trumpets. Of the cheaper ones, Minnie Hume and Mrs. Langtry are the best; of the more expensive ones, Duchess of Westminster and Katherine Spurrell. I believe Seagull is good too, but I have not tried it; the price is now much lower than it used to be, but half-a-sovereign a dozen is prohibitive for many of us. Everyone should include a few pots of Campernelle Jonquils. It is a matter of taste whether the ordinary type or the rugulosus type is chosen. Some prefer the stiffer and more regular rugulosus, while others like the looser flower of the type. Poeticus ornatus does well, but if several Leedsii are grown I do not think it is really wanted. Poeticus recurvus will not force.

DOUBLES FOR POTS.

Whether it is for sentimental reasons or not I am unable to say, but the old double yellow (*Telamonius plenus*) has a good many admirers, and I must admit that a good large pot nicely

GARDEN last autumn I can fully confirm. The head of a large wholesale bulb and seed firm told me that he had had a small private show of Narcissi for his customers this spring, and that he was surprised at the way they all went for the Poetaz. Let me enumerate some of its advantages: First, its looser and less stiff habit; secondly, its more pleasing scent; and, thirdly, its hardiness. Compared with the Polyanthus type, this new decorative class has taller flower-stems and bigger individual blooms, although there are not so many in a truss. They are most effective in pots. Elvira has white petals with a rich golden yellow cup, and there are generally three or four flowers on a stem. It is the latest of the Poetaz. Ideal has from four to six flowers, and the perianth is white and the cup a decided red orange. Klondyke has about the same number of flowers, but the perianth is pale yellow and a good deal turned back; the cup is a deeper shade of yellow. Jaune à Merveille is exceedingly handsome, and may be described as a sort of yellow Elvira. Unfortunately, this variety at present is very scarce; last year, although I wanted about a hundred and fifty, I was only able to buy twenty-five. I would strongly advise everyone to give this new type a trial, and, when the flowers are done, not to throw the bulbs away, but to plant them out just as you would a pot of Emperor.

JOSEPH JACOB.

## THE ROSE GARDEN.

### CLIMBING TEAS AND NOISETTES ON PERGOLAS.

WITH the passing of Dorothy Perkins, Hiawatha and other late-flowering ramblers our pergolas will present a rather dull appearance during September and October unless we have had the forethought to plant some of the climbing Teas and Noisettes. Unless the garden is much exposed there are few of these lovely Roses that could not be utilised. I have seen in a comparatively cold garden such a tender sort as Climbing Devonensis thriving most successfully, sending out its long reddish growths in great luxuriance. But I should not recommend this particular sort, as it is rather a shy bloomer; there are numerous and good varieties that would give their blooms freely until the frosts come to check them.

That cheerful cherry red Reine Marie Henriette has not yet been surpassed in its own particular colour, and if it is provided with a good deep root-run, as all Rambler Roses should be, we should find less of that mildew that frequently mars the beauty of this Rose. François Crousse is one of the most brilliant sorts, its flowers being as rich in colour as our A. K. Williams; but, unfortunately, it is scentless. Waltham Climber No. 3 is deliciously sweet, and a well-shaped double flower, the colour a fine tone of crimson. Souvenir de Mme. Joseph Metral has a splendid large bloom, quite of exhibition size and form, and it is the most lovely shade of rosy carmine imaginable.

Climbing Captain Christy should be planted where a cheerful pink is wanted, and its blooms are more elegant in shape than the original dwarf form. Mme. Hector Leuilliot is splendid; its huge orange yellow flowers appear likely to displace W. A. Richardson, although in the bud state there is no fear but that the old favourite still holds the field. Mme. Alfred Carrière is a beautiful flesh white; it is not so pure a white as Aimée Vibert, but it is more vigorous. However, both should be grown and mingled with Grüss an Teplitz and Longworth Rambler, the quartette making quite a beautiful show in themselves. Mme. Jules Siegfried is another of the hardy Teas with a delicate creamy flower not unlike Enchantress. Jaune Desprez is old, but it is still beautiful and so luxuriant in growth that it should not be ignored. Rêve d'Or, although not very free-flowering unless allowed to grow unpruned over a lofty south wall, is yet too good in foliage to be omitted for pergola work, and when its fine golden flowers peep out amid a mass of brownish foliage it is a pretty object. Zepherin Drouhin is such a delightful shade of rosy pink that one must find space for it, if only on the pillars of the pergola, and its sweet fragrance supplies what some of the other varieties lack.

A glorious bit of colour is provided by planting Bardou Job on one of the upright supports of the pergola, and it is one of the best autumn Roses we have. Kaiserin Friedrich is a pink-tinted form of the old Gloire de Dijon, and most charming it is in the autumn days, reminding one of Marie van Houtte in its beautiful blending of cream and pink. Somehow the old Gloire de Dijon seems to be neglected, and for why I cannot conceive. We have yet to produce a better all-round Rose than this one when it is grown as it deserves to be, but it is so hardy and free that I am afraid we sometimes imagine it does not require artificial aid. This old Rose, like all the rambling and climbing Roses, well repays us for liberal waterings with liquid manure, both before the summer bloom and also afterwards to help the autumn crop.

In planting Roses for their autumnal blooming the pretty hybrid Musk Roses should not be

overlooked, especially that valuable novelty Trier. This is a lovely Rose with its pyramidal sprays of buff and white blooms. Another useful novelty of the same group is Snowstorm, a Rose not unlike Pissardii. All of these would be very suitable to make a low hedge between the pergola supports, and to add to their number the Perpetual Thalia should not be overlooked for the same purpose. P.

### ROSE AUGUSTINE GUINOISSEAU REVERTING BACK.
