v. 72

— TO THE —

REV. W. WILKS, M.A.,

VICAR OF SHIRLEY, SURREY, AND SECRETARY OF THE ROYAL  
HORTICULTURAL SOCIETY,

THE SEVENTY-SECOND VOLUME OF "THE GARDEN"

**Is dedicated.**

IT is with pleasure we are able to dedicate the present volume of THE GARDEN to one of the most enthusiastic and practical workers among the flowers of the present day. Much of the success of the Royal Horticultural Society is due to Mr. Wilks, who has been not only secretary, but an organiser of remarkable capabilities. The Royal Horticultural Society has been rescued from financial troubles; its influence for good in the world of Horticulture is immense, and the fortnightly meetings held in the spacious hall are filled not only with rare and beautiful exhibits, but they have fostered a deep love of gardening in the hearts of those that crowd to see them, especially in the height of the London season. Mr. Wilks for many years gave his services to the society, and in many ways has shown his interest in Horticulture. We think of his generosity in distributing seeds of the exquisite Shirley Poppies, famous the world over, to the Fellows of the Royal Horticultural Society, and of his love for the Church which he serves so well.

Mr. Wilks, who was born at Ashford, in Kent, on October 17, 1843, is one who requires understanding, but he commands respect and admiration—a straightforward, business-like, Christian gentleman—and of such men England may well be proud. An account of Mr. Wilks's life appeared in THE GARDEN of May 26, 1900.

## INDEX.

## A.

Achimenes and Tydeas, 271  
 Acidanthera bicolor, 523  
 Aconite, the Winter, 75  
 Adonis amurensis, 191, 446  
 Agapanthus, repotting, 69; umbellatus, 165  
 Agricultural statistics for 1907, 38  
 Almonds fruiting, 3  
 Alpines from seed, 93  
 Alstroemerias and their culture, 397, 555  
 Amaryllises and Chrysanthemums at St. Petersburg, 274  
 Anchusa italica, how to propagate, 427  
 Androsace sarmentosa in winter, 552  
 Anemone apennina, 482; blanda, 114, 226; coronaria, 163  
 Anemones naturalised in grass, 274; raising St. Brigid, from seed, 131  
 Annual, a hardy, for the bees, 201; a pretty and useful (*Collinsia bicolor*), 100; a quick-flowering (*Eucharidium grandiflorum album*), 226  
 Annuals and perennials under trees, 615; beautiful, for beds and borders, 85; for spring flowering, 389; sowing, 139, 305; in the open, 131; the best fifteen hardy, for summer effect (prize essay), 121; thinning, 145

 Bees in the garden, 3  
 Beet Carter's Crimson Ball, 215  
 Beetroot, cultivation of the, 227  
 Beetroots, how to grow good, 169  
 Beetles in Lily pond, 307; in Water Lily tank, 391  
 Begonia Gloire de Lorraine, a beautiful form of, 83; *kewensis*, 435; *Patrie*, 459; the tuberous-rooted, and its culture, 216; tuberous, Wm. Marshall, 30  
 Begonias, extra frilled, single, 103; fibrous-rooted, 52; propagating fibrous-rooted, 92; tuberous, from seed, 27  
 Bellflower, the Chimney, 459; the Dalmatian, 469  
 Bellflowers, two of the, 143  
 Berberis arguta, 481  
 Bibliography, the Florist's, 571  
 Blackberry preserve and Rowan Berry jelly, 501  
 Black scab in Potatoes, 506  
 Border, a mixed, for autumn, 122; in Sussex, 510; for a bed, 234; of picturesque beauty, 597; planting in autumn, 119; work in the herbaceous, 425  
 Borecole or Kale, 157  
 Botany, commercial, 86  
 Bottled Torture, 74  
 Bottles for fruit, 544  
 Box border, 23; edging, lifting and replanting, 600  
 Briars, Penzance, on arches, 201  
 Broom, the white Spanish, 276  
 Bulb nursery, an English, 271  
 Bulbs and plants, hints on forcing, 551; grown in fibre, 454, 607; in grass, 579; pot, treatment of, after flowering, 205; potting, for greenhouse decoration, 412; the flowering period of various, 473; three good, for pots, 576; uncommon garden, 522

## C.

Cabbage crop, a catch, 485  
 Cabbages and Turnips, clubbing in 628; planting spring, 401; some good, for spring, 479  
 Cacti and succulents, winter treatment of, 625  
 Cactus *Dahlia Satisfaction*, 509  
 Cajapat oil, a new source of, 235  
 Calceolaria, a beautiful new, 623; alba, 545  
 Calceolarias, how to propagate the bedding, 550  
*Caltha polypetala* at Glasnevin, 326  
 Campanula Allionii from seed, 159; portenschlagiana, 469  
 Canterbury Bells and how to grow them, 245; early sowing of, 410; in Truro Churchyard, 397  
 Carnation cuttings, 74; introduction of the Malmaison, 87; leaves diseased, 12; Irene, 383; the Perpetual-flowering as a summer plant, 238; Winsor, 50, 87  
 Carnations, about Malmaison, 60; best twelve for exhibition, 463; hints on growing, 397; layering, 455, 491, 545; perpetual-flowering, 154, 491, 631; outdoors, 583; planting border, 115; planting out young, 461; seedling, 590; winter-flowering, 32  
 Carrots, how to grow good, 157  
 "Casella A B C of Gardening," 233  
 Caterpillars on Gooseberry trees, destroying, 295  
 Cattleya Harrisonae alba Stanley's variety, 483; Mendell Queen Alexandra, 312

Cauliflowers, early, under cloches, 179  
*Celastrus articulatus*, 89  
 Celery, earthing-up, 389; how to earth, 512; trial at Wisley, 2  
 Cheal's nursery, 507  
 Cherries, some good late dessert, 432  
 Chicory or Witloof, 577  
 Christmas decorations, 621; Roses, lifting and flowering, 596  
 Chrysanthemum Hilda Lawrence, 563; table decorations for, 605; Maximum Margaret Marwood, 265; Marquis of Northampton, 2; Mme. Paolo Radaelli, 3; Mrs. J. Hygate, 14; Whitepoint, 40; Chrysanthemums, early-flowering single, 563; finest group in Scotland, 29; how to secure or retain buds of, 484; lifting, 537; National Society's show, 616; single-flowered in autumn, 572; some of the new, 51, 125; the final potting of, 292; twelve early-flowering, for a London garden, 95  
 Cigar ash for greenhouse plants, 59  
 Cineraria, the, 189  
 Clematis cotoneaster, 135; montana rubens, 534; the Mountain (*C. montana*), in New Zealand, 55  
 Clematises, hints on pruning, 549  
 Clibrans' nurseries, 583  
 Climber for brickwork under window, 43  
 Climbers for a greenhouse, 565  
 Clubbing in Cabbage family, 504  
 Cockchafer, the common, 163  
 Cockcombs and Celosias, how to grow, 223  
*Coleus thyrsoides*, 286  
 Colour in the garden, 261  
 Columbines and their culture, 76; history of the long-spurred, 321  
 Conifers, golden-leaved, for winter decoration, 608  
 Cosmos sulphureus, 619  
 Cotoneaster *agustifolia*, 48, 75; in Victoria, B.C., 186  
 Cotoneasters, four good, 16  
 Crane's-bill, the wood, 178  
 Crassulas, what to do with frozen, 48  
*Crataegus Pyracantha*, increasing, 580  
 Crinum, treatment of, 308  
 Crocus corms, moving, 195  
 Crops, the rotation of, 467  
 Crown Imperials, 259  
 Cucumbers, two good new, 324  
 Currants and their culture, 471  
 Cyclamen, frilled Persiau, 523; how to grow, 523; Low's Salmon King, 103  
*Cymbidium gattonense*, 72; Lady Colman, 94  
*Cyperus alterifolius*, 117  
*Cypripedium fairieanum* Black Prince, 16; Cookson's variety, 72; insignis, 40; and its varieties, 12; Mr. F. Sander, 72; Sultan, 64  
*Cypripedium* (Lady's Slipper), hardy, 16  
*Cystopteris fragilis*, 211

## D.

Daffodil, an Australian, 546; bulbs, dividing, 15, 39, 75, 123; leaf disease, 262; notes, 399, 407, 421, 446, 468; the Cyclamen-flowered, 223  
 Daffodils at Vincent Square, 195; Royal Horticultural Society's classification of, 381, 431, 442, 453, 466; Cornish, 315; forced, 86, 163; for early work, 109; free-flowering, 224, 275; in pots, 110; new, 394; planting, 499; three interesting, 445  
*Dahlia imperialis*, 619  
 Dahlias, about, 317; a selection of garden Cactus, 247; Cactus, in Victoria, Australia, 289; garden, 618; garden Cactus, 291; how to grow single from seed, 81; increasing, 104; new, 501; notes, 265; protecting, 485; the best, 141, 154  
 Daisy, the Moon (*Pyrethrum uliginosum*), 54; Trees, the, 409

Daisies, destroying, 311; increasing double, 269, 311  
 Damsous, Bradley's King of, 15  
 Daphne Dauphinii, 543  
 Dendrobium thyriflorum, a well-grown, 287; wardianum, 64  
 Dia-Cattleya Colmanae, 94  
 Dianthus Napoleon III., 413  
 Digging and trenching, 589  
 Dimorphotheca aurantiaca, 125, 311  
 Dipping wells, 384  
 Disa grandiflora, 288

## E.

Earwigs, 225  
 Edelweiss, the, 413  
 Edgings, suitable plants for, 596  
 Editor's table, 239, 251, 283, 307, 331, 385, 401, 413, 427, 429, 451, 463, 487, 527, 539, 543, 579, 626  
*Eleagnus macrophylla*, 549  
 Elephant's Foot from South Wales, 43  
 Elm, seedling of the English, 14  
 Epacris, the, 111  
 Erica carnea, 176; *codonodes*, 250  
*Erinus alpinus* on a wall, 177  
 Enterprise, an Anglo-French, 239  
 Eupatoriums, propagating, 284  
 Eupulea polyandra, 191  
 Evergreens, clipping, 315; for autumn planting, 470; how to prune, 117  
 Exhibitors, hints for, 293, 317

## F.

*Fabiana imbricata*, 545, 571  
 Fern, Maidenhair, fronds eaten, 14  
 Ferns for amateurs' greenhouses and rooms, 156; Maidenhair, as window plants, 263; Royal or flowering, 214; two good for pots, 32

 Grapes at Wisley, 430; how to grow in pots, 4; injured, 392; the outdoor culture of, 583; the Wisley collection of, 530  
 Greenhouse, hanging baskets for the, 169; heating a small, 35; management in summer, 317; plants, watering and ventilating in spring, 140; the unheated, 26; winter in the, 480, 492, 510  
 Grevillea Banksii, 435  
 Guernsey Lilies from the open, 539  
 Gunnersbury House Gardens in spring, 212

## H.

Heath, a beautiful, 176; garden, the, 199  
 Heather from seeds, 580  
 Heaths, hardy, in flower, 481; pruning, 591  
 Helleborus Peter Barr, 141  
 Heliotrope and its cultivation, 116  
 Heloniopsis japonica, 202  
 Hemerocallis Dr. Regel, 310  
 Hepaticas, raising, from seed, 175  
 Herbaceous border, 12  
 Hibiscus, a beautiful, 66  
 Hippocastans, their propagation and culture, 257  
 Hoe in the garden, the, 151  
 Holly berries, 618  
 “Holly, Yew and Box,” 614  
 Hollyhocks, 382  
 Honesty, 88  
 Honeysuckle, a white-flowered (*Lonicera Maackii*), 409  
 Horseradish, increasing and cultivating the, 564  
 House and frames, airing of, 69  
 Hutchinsia alba, 31, 278  
 Hyacinth bulbs diseased, 319  
 Hyacinths at Vincent Square, 187; growing in water, 524  
 Hydrangea cuttings, taking, 515; paniculate grandiflora, 560  
 Hydrangeas, 15; blue, 459, 490; producing blue flowers, 207

## I.

*Impatiens Holstii*, 619  
*Incarvillea Delavayii*, 421; forcing, 151; wintering, 415  
*Iris carthusiana*, 315; *Gatesii*, 422; *luteo-alba*, 138; *ochroleuca*, 622; *stylosa*, 611; *Vartanii*, 507; *warleyensis*, 635  
 Irises, notes on, 468, 482, 492, 562  
 Ivy, how to increase the, 460; not clinging to walls, 35

## K.

Kale, a new, 267  
 Kales, variegated, 86  
 Kew, notes at, 527; the Alpine House at, 175  
 “Kew Gardens,” 451  
 “Kew, the Royal Botanic Gardens,” 569

## L.

Lady's Slippers, hardy, 29, 83  
*Laelio-Cattleya Pizarro*, 153  
*Lantana salvifolia*, 548  
*Lavandula abrotanoides*, 619  
 Lawn, how to prepare and sow a, 100; making a tennis, 307; mowers, the care of, 329; removing fairy rings from, 592; the amateur's, 17  
 Laxton's nurseries, 385  
 Leeks, 287  
 Legal point: Fixtures, 295  
 Legal points, 627  
 Leonotis Leonurus (Lion's Tail), 112  
*Lespedeza Sieboldii*, 530  
 Lettuces, early, without glass, 145  
*Libouia floribunda*, 111  
 Lilac, a beautiful (*Syringa Emodi*), 16  
 Lilacs, the, 64, 89  
 Lilies of the Valley in winter, 601  
*Lilium giganteum* in New Zealand, 311; sulphureum, 523; to flower in August, 107  
 Lily, a beautiful, 499; of the Valley, forcing, 624; (Fortin's variety), 166; the beautiful orange (*Lilium croceum*), 42  
 Lime tree leaves with outgrowths, 391  
*Limnathes Douglasii* as an edging plant, 611  
*Linnaea borealis*, raising from seeds, 171  
 Lobelias, treatment of, 510  
 Loganberry, the, 471  
 Logwood (*Hæmatoxylon campechianum*), 384  
 “London Parks and Gardens,” 451  
 Lowberry, the, 470  
 Lupine, the many-leaved, 573  
 Lupines, the, 325  
 Lycaste Skinneri Orion, 94

## M.

*Magnolia hypoleuca*, 384  
 Maize, cultivation of the edible, 607  
 Malmalson, introduction of the pink, 175  
 Marguerites, how to treat, in winter, 525  
 Marrow plant, a prolific, 583; Tender and True, 215  
 Marsh Marigold, an uncommon (*Caltha polypetalis*), 150  
 Melons and Cucumbers, how to plant, 108; late, 324; some good, 456  
 Merryweather's nursery, 491  
*Metrosideros floribunda*, cultivation of, 502

Corydalis Allonii, 290

Cottage, a creeper-covered, 103

Cress, Rock (Arabis albidia) falling over rockwork, 67

Crocus biflorus, two pots of, 576

Cucumbers, two good new, 323  
 Cyclamen, a double-flowered, 191; frilled  
 Persian (*coloured plate*), 523; Low's Sal-  
 mon King, 101  
 Cypripedium fairieanum Black Prince,  
 16; insigne in the garden of Mr. W.  
 Tillett, 559; Sultan, 65  
 Cytisus albus at Kew, 276

## D.

Daffodil, a new, from Australia, 548  
 Daffodils in the grass in Mr. Kingsmill's  
 garden, 301; three interesting (*coloured  
 plate*), 445; three new (*coloured plate*), 391  
 Dablia Mrs. F. McQuade as grown in  
 Victoria, Australia, 289; Satisfaction,  
 508  
 Dahlias, increasing, 104  
 Daisy, the Moon (*Pyrethrum uliginosum*),  
 in Mr. A. Gill's garden, 54  
 Dalmatian Bellflower, a colony of, 460  
 Delphinium stem, a remarkable, 431  
 Dendrobium thysiflorum, 287; wardi-  
 anum, 64  
 Dipping well, an old, 384  
 Drosera burkeana, 213

## E.

Elephant's Foot raised from seed, 48  
 Epacris The Bride, 113  
 Erica carnea in Messrs. Bakers' nurseries,  
 176  
 Erinus seedlings on rock garden steps, 90  
 Encharidium grandiflorum album, 226

## F.

Fabiana imbricata growing in the open in  
 Cambridge Botanic Gardens, 511  
 Ferns for amateurs' greenhouses and  
 rooms, 157  
 Fig trees in pots, 129  
 Flower Show, THE GARDEN, general view  
 of, 386  
 Fruit, first prize collection at THE  
 GARDEN Show, 386  
 Fruit trees and bushes, summer pruning,  
 305  
 Fuchsias, how to propagate and grow, 68;  
 increasing the hardy, 448; some beautiful  
 (*coloured plate*), 229

## G.

Garden, a corner of a London, 411  
 Geranium sylvaticum album, 178  
 Geraniums, standard-trained window, 192  
 Gilia nivalis, 201  
 Gladioli, propagating choice, 193  
 Gladiolus stem attacked by a caterpillar,  
 68  
 Glories of the Snow, pink and white, in a  
 Scottish garden, 634  
 Gloxinias and their cultivation, 230; how  
 to grow (*coloured plate*), 202  
 Gooseberry Keepsake, 521; Whinham's  
 Industry, 75  
 Grapes, Black Hamburgh, prize bunches  
 from old Vine, 561

## H.

Hartland, Mr. William Baylor, 445  
 Heliotrope and its propagation, 116  
 Helleborus Peter Barr, 141  
 Heloniopsis japonica, 203  
 Herbaceous border, preparing and planting  
 the, 21  
 Hippeastrums: Their propagation and  
 culture, 256  
 Holly, the American, 8  
 Horseradish, increasing and cultivating  
 the, 564

Hutchinsia alpina, 31, 278  
 Hyacinths, bedding, a good potful of, 577;  
 growing in water, 524  
 Hydrangea, a beautiful, in Manby Church-  
 yard, 15; paniculata grandiflora, a  
 standard, 560

## I.

Iocarvillea Delavayii in the border, 421  
 Ionopodium acaule, 398  
 Iris carthusiana, 315; Gatesii, 422; ochro-  
 leuca in a Lincolnshire garden, 622;  
 warleyensis, 635  
 Ivy, how to increase the, 460

## L.

Lady's Slipper, Cypripedium insigne, 40  
 Lælia anceps, 79  
 Lælio-Cattleya Pizarro, 153  
 Lewisia Cotyledon, 290  
 Lilium auratum grown in a small garden,  
 443; giganteum in New Zealand, 311;  
 sulphureum in the garden of Mr. G. S.  
 Patey, 523  
 Lily, group of the orange (*L. croceum*), 43;  
 of the Valley, forcing, 624  
 Limnanthes Douglasii as an edging, 611  
 Loganberry, the, 471  
 Lowberry, the (*coloured plate*), 470  
 Lupines in Mr. William Hudson's garden,  
 325  
 Lupinus polyphyllus in Mr. William  
 Hudson's garden, 573

## M.

Maidenhair Fern, good specimen of, 32  
 Melon Superlativa, 456  
 Melons, a good crop of, at Paddockhurst  
 Gardens, Sussex, 519  
 Michaelmas Daisies, methods of increas-  
 ing, 204  
 Mint, lifting and propagating, 217  
 Mistletoe on Apple tree, 140  
 Montanoa bipinnatifida (*coloured plate*),  
 302

## N.

Narcissi, a good bowl of, in moss fibre, 607  
 Narcissus Barcarole, 278; Buttercup,  
 29; Furnace, 265; Hornet, 264; Mont  
 Cenis grown in a sitting-room, 164;  
 Paper White in pots, 576  
 Nelumbium speciosum Osiria, 457  
 Nepeta Mussinii, 563  
 Nephrolepis exaltata Amerpohlii, 111  
 Nevard, the late Henry, 615  
 Nigella Miss Jekyll, 125  
 Nymphaea caroliniana perfecta, 314

## O.

Odontioda Charlesworthii, 301; Goodson's  
 variety, 586  
 Odontoglossum crispum Leonard Perfect,  
 288; hybridum bingelianum, 51  
 Olearia macrodonta, 409  
 Omphalodes verna, 240  
 Onion plant over-potted, 9  
 Orobancha on a Pelargonium, 223  
 Osmunda regalis palustris, 215

## P.

Paeonia decora alba, 291; Delavayii  
 (*coloured plate*), 322  
 Paeonies in Dr. McWatt's garden, 419  
 Page-Roberts, the Rev. F., 621  
 Pampas Grass, a fine clump of, at Kew,  
 523; a fine plant of, in a Scottish  
 garden, 619

Pansies, a simple means of raising, 45 a  
 simple way of showing, 299; increasing  
 in the spring, 144; increasing the, by  
 cuttings, 498  
 Parsley, how to provide a winter supply of,  
 588; obtaining, in cold weather, 44  
 Path, a straight, flanked with herbaceous  
 borders and Yew hedges (second prize  
 photograph), 597  
 Pea Quite Content (*coloured plate*), 128  
 Pears, two good (*coloured plate*), 574  
 Peas, how to stake a row of, 269  
 Pelargonium, Ivy-leaved, and their pro-  
 pagation, 180; propagating Zonal, 56;  
 types of scented-leaved, 102, 118  
 Pergola, a newly-formed, in Mr. E. A.  
 Bowles's garden, 458; clothed with fruit  
 trees, 47; clothed with ornamental  
 Gourd, 19; entrance to, in Mr. Kings-  
 mill's garden, 303  
 Persimmon fruit grown out of doors, 574  
 Phloxes, increasing the herbaceous, 168  
 Plant, an old-fashioned border (Honesty),  
 89  
 Plum Coc's Golden Drop, 99; Myroblan,  
 good spray of, 507; Pond's Seedling, 87;  
 Purple Gage, 52  
 Pinks, increasing, 388; wild, in the garden,  
 243  
 Pittosporum undulatum in a pot, 152  
 Polyanthus Primroses (*coloured plate*), 423  
 Pool, a charming, in the Rev. T. S. Lind-  
 say's garden, 446  
 Poppies, the Welsh alpine, in rough steps,  
 91  
 Potato tuber, an old, producing new ones,  
 619  
 Potatoes, how to have new, at Christmas,  
 472; sprouting maincrop, 130  
 Primula frondosa in a pan at Kew, 167;  
 obconica, 255; o., a pendulous-flowered,  
 190; pedemontana, 166; Sieboldii grow-  
 ing in the open, 327; Webb's Snow  
 Queen, 234  
 Puff-ball, a giant, 467

## R.

Raspberries, thinning and transplanting,  
 537  
 Renanthera coccinea as grown by Mr.  
 Charles Hicks, 327  
 Rhododendron Hercules, 633; Pink Pearl  
 in South Africa, 228; rhombicum, 267;  
 Sapho in Ireland, 470  
 Rhubarb, dividing, 20  
 Rock garden, a charming, that was origin-  
 ally a wood, 7; a small, 42; near the  
 edge of a wood, 41; a town, one year  
 after its formation, 434; a winding path  
 in the, 41; in Backhouse's Nursery, 480;  
 in Walsgate Gardens, Louth, Lincs,  
 155  
 Roas, Mr. Charles, 585  
 Rosa Moyesii, 313  
 Rose Aglaia, over arches, 154; A. Hill Gray,  
 493; Alberic Barbier, a bank of, 386;  
 Dorothy Perkins, standard of, in Rev.  
 Page-Roberts's garden, 492; Dundee Ram-  
 bler on a garden arch, 53; Electra grown  
 in a mass, 575; Hugo Roller (*coloured  
 plate*), 177; La'ly Alice Stanley, 491;  
 Mrs. E. J. Holland, 535; Mrs. E. Mawley  
 as grown in Australia, 279; Paula, 433;  
 rugosa Schneelicht, 494; stem affected  
 by grey mould, 28; sucker, a, 304; The  
 Garland, at Munstead Wood, 263; The  
 Lyon (*coloured plate*), 548  
 Roses, a beautiful mass of, in the wild  
 garden, 610; a bowl of, gathered in late  
 October, 543; gathered on Christmas  
 Day, 28; Euphrosyne, Thalia and Aglaia  
 in Mr. Kingsmill's garden, 302; gathered  
 in November, 587; Messrs. George Paul  
 and Son's gold medal group, 495; Mr.  
 George Prince's gold medal group, 496;  
 protecting standard with old wine-bottle  
 cases, 6; Red Damask, and white Lilies,  
 497

## S.

Sage, a rare (*Salvia dichroa*), 78  
 Sandwort, the Majorca (*Arenaria balearica*),  
 66  
 Saxifraga Boydii alba, 177; Grisebachii,  
 215; longifolia, three years from seed  
 142  
 Scabious, tall double (*coloured plate*), 55  
 Seakale, easy methods of forcing, 612  
 Semele androgyna, 432  
 Shortia uniflora, 202  
 Shrubs, propagating evergreen, by cuttings,  
 424  
 Sinningia hybrida Dr. Maxwell Masters,  
 399  
 Smith, the late Mr. Martin R., 595  
 Snowdrop, a rare (*Galanthus Elwesii*  
*Cassaba Boydii*), 623  
 Sophro-Cattleya Doris, 609; eximia (Fow-  
 ler's variety), 5; warhamensis J. M.  
 Black, 423  
 Spirea Aruncus in Mr. Kingsmill's garden,  
 302  
 Strawberry Royal Sovereign, 385  
 Strawberries, layering, 316  
 Sweet Bay, Yew and Laurel, propagating,  
 436  
 Sweet Cicely and Butter Bur, natural  
 arrangement of, 18  
 Sweet Pea Evelyn Hemus (*coloured plate*),  
 253  
 Sweet Peas, 77; first prize, twelve bunches,  
 at THE GARDEN Show, 386  
 Sweet Sultan, white, 115

## T.

Thalictrum dipterocarpum, 435  
 Thorne, the Washington, 8  
 Thyme, methods of propagating, 244  
 Tulip La Merveille, 127  
 Tulipa kaufmanniana, a fine bed of, 190;  
 saxatilia, 214

## V.

Vanda anavis pallida, 188  
 Venus' Looking-glass (*Specularia specu-  
 lum alba*), 253  
 Verbaicum leianthum in the Botanic  
 Gardens, Glasnevin, 509  
 Vegetables, first prize exhibit at THE  
 GARDEN Show, 387; the gold medal  
 exhibit at THE GARDEN Show, 386  
 Viburnum Carlesii, 242  
 Vines, pot, in Hodnet Hall Gardens, 4  
 well grown, at Stanley House, 30  
 Viola gracilis, 202  
 Violets, single and double (*coloured plate*),  
 279; ways of increasing, 268  
 Violettas, how to increase the, 328

## W.

Walls, dry, for rock plants, 546  
 Water and rock garden, a small, 179  
 Water garden, plan of a, 179  
 Water Lilies, a beautiful group of white,  
 151; Portugal Broom and Arundo Donax,  
 effective grouping of, 314  
 Watsonia O'Brienii, 17  
 Wineberry, the Japanese, clothing a per-  
 gola in the gardens at Tyne Hall, 534  
 Wistaria multijuga at Cobham, Surrey  
 407

## Y.

Yucca gloriosa in a Kentish garden, 395;  
 in flower, 31

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With this object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

## GOOD EARLY PEAS FOR AMATEURS.

THE question often arises at this season of the year as to which are the best early Peas. Amateurs frequently have the means at command to get the best results, as the earliest sorts are usually small or compact in growth ; and if these are given a sunny south border and a friable, fairly rich soil, excellent dishes may be had in May and June, according to the locality. The old method to get early dishes was to sow in December, indeed, even earlier ; but this is not wise, as there are so many losses and the crop in our variable climate is so uncertain. There are two alternative plans, one which concerns glass or frame culture at the start, and the other growing entirely in the open.

### CULTURE.

Glass or frame culture has been referred to, and by this is not meant using fire-heat. Cold frames are preferable, but it may be necessary in January or February to cover the frames during severe weather, as the plants are not far from the glass. The seeds should be sown in 5-inch pots not too thickly, and only just covered with soil. The latter should be made firm in the pots before sowing, and it should have been under cover for a time so as to be in a workable condition. Smaller pots may be used if desired, but if so less seed must be sown, as it is a mistake to crowd the seeds, which should be evenly distributed over the surface. After this work is done stand the pots in the frame on a firm bottom, water very carefully and keep the frames shut quite close for a month, covering with mats at night to exclude frost. Any warmth from sun-heat is beneficial and will assist germination.

The after-management is most simple. As growth is made ventilate more freely. Early in March the seedlings are ready to plant out in their permanent quarters. A south border or under a wall is a good position, and the ground should have been deeply dug and enriched with manure some time in advance of the planting. The rows should be from 2 feet to 3 feet apart, according to the variety. It is best to draw a rather deep drill for these early Peas, as

this protects from wind at the start and facilitates watering in dry seasons. Care should be taken not to break the tender roots, and it is a simple matter when planting to open out or spread the plants a little ; plant firmly, covering the roots with the fine top soil.

### SOWING IN OPEN GROUND.

Many growers may not have frames at command, and the next best plan is to sow the same varieties in the early part of February, should the weather permit, on a well-drained sunny border, and in drills the same distance apart as suggested above. A sloping border should be given in stiff soil, but here it is advisable to lighten the land by a free use of old spent manure, fine mortar rubble, burnt garden refuse or wood ashes. The seeds require to be sown a little thicker at this season than they would three months later, but, should the plants be at all close, it is well to thin early, so as to give each plant room.

For this sowing a shallow trench or deep drill is recommended, and in covering the seeds it is not well to bury them under more than 2 inches of soil. In severe weather it is a great gain to place a little strawy litter over the rows, always removing it in fine weather, as if left on then it retards growth. Peas sown thus in good land will give dishes at the end of May or early in June, according to locality, and only a little later than those sown in frames.

### VARIETIES TO SOW.

These are very numerous, but only those with a robust growth are quoted. The small round white Peas which found so much favour years ago are not advised. Sutton's Pioneer is a splendid new Pea that grows nearly 2 feet high, is of unusually robust habit, and bears large pods. This Pea, sown early in March, was ready late in May. It is equal in quality to a maincrop Marrow, and is a remarkable cropper for such a rapid grower. Reading Wonder is also a splendid early Pea ; it is very dwarf, but bears a fine pod. Sown in February, it may be had for use by the middle of May. As this has a strong growth, it does grandly in a poor soil. Little Marvel is also a beautiful early variety, a great cropper and certainly rightly named, as last year it was our earliest variety. It is of splendid flavour and grows from 12 inches

to 18 inches high. The Peas are a dark green and the pods are closely packed. Early Giant is a little later and grows 3 feet to 4 feet high.

May Queen, 2 feet to 3 feet high, has splendid cropping qualities. Last season we had a splendid early Pea in Veitch's Langley Gem; this is one of the best for early borders. It has pods of the Chelsea Gem type, but larger, and is equal in quality to that excellent variety. It is also more robust, and constitutes a splendid forcing variety with branching habit. Veitch's Acme is also a fine early Pea of great merit, and Earliest Marrow is much liked. For forcing in frames or open ground, Carter's Eight Weeks is a grand variety and one of the earliest to mature. Carter's Early Morn and Daisy are also most reliable. G. WYTHES.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### APPLES COX'S ORANGE AND ALLINGTON PIPPINS.

Mr. Arthur Mountain of St. James's House, Grimsby, sends magnificent fruits of these two popular Apples, which would probably have taken first prizes at the Royal Horticultural Society's fruit show in October last. They are the best we have seen or tasted this year, which shows how excellent is our correspondent's system of culture, especially when it is considered where the trees are grown. Mr. Mountain writes: "I am again sending you a few Cox's Orange and Allington Pippins. I have, as usual, had an excellent crop of both varieties, good as regards flavour, colour and size. Last year and this I have taken nine firsts for dessert Apples with nine entries. The system on which the trees are grown is that of nine to twelve cordons very closely spurred, hollow centre, and little or no stopping of terminals. The result gives long straight branches studded with short spurs from bole to base of present season's growth."

### SHRUBS FLOWERING IN WINTER.

Mr. H. A. Tipping, Mathern Palace, Chepstow, sends an interesting collection of flowering shrubs, which he describes below; the Winter Sweet was particularly good. "This season's somewhat queer climatic conditions are causing some vagaries among my shrubs. I send you sprays of Winter Sweet in bloom and of Myrtle, *Ceanothus puniceus*, *Cydonia japonica* and *Ceanothus Indigo* in bud. The former is normal enough; I often get it in bloom by Christmas if the weather is mild, but why buds on the Myrtle, which bloomed, as usual, last summer? You will notice the same condition of things on the *Ceanothus* twigs; beyond the well-developed seed-pods of the summer flowering are trusses of flower-buds already showing the blue colour of the blooms. The *Ceanothus*, I regret to say, has every shoot of the whole of its 10 feet of height covered with buds, not one of which, I presume, can live through the winter to bloom in the spring."

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 6.—National Amateur Gardeners' Association.

January 12.—Royal Horticultural Society, Meeting of Committees, 12 noon; Horticultural Club, 6 p.m.

January 18.—French Horticultural Society's Annual Dinner, Mr. H. J. Veitch in the chair.

January 23.—Gardeners' Royal Benevolent Institution Annual Meeting.

**Coming of Age of the Royal Gardeners' Orphan Fund.**—The Coming of Age festival in aid of this charity will take place at the Hotel Cecil on Tuesday, May 12, when the president of the fund, the Duke of Bedford, K.G., has kindly consented to preside.

**Dedication to Miss Willmott, V.M.H.**—We are very pleased to learn that the Editor of the *Botanical Magazine*, Lieutenant-Colonel Prain, C.I.E., LL.D., F.R.S., has dedicated the new volume to Miss Willmott, V.M.H., of Warley Place, Brentwood, Essex, to whom he alludes in appreciative terms.

**Winter - flowering Carnation Society.**—The spring show of this society is to be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on April 1 next. During the afternoon a lecture will be given by Mr. P. Smith, on "The Winter-flowering Carnation."

**Kent, Surrey and Sussex Daffodil and Spring Flower Society.**—The annual show of this flourishing society is to be held in the Great Hall, Tunbridge Wells, on Wednesday, April 15. With Earl Cranbrook as treasurer and Mr. Herbert Chapman, 101, High Street, Rye, Sussex, as hon. secretary it is safe to predict a splendid show of bulbous and other spring flowers on the date named. Copies of the schedule are now ready and can be obtained from the hon. secretary.

**Rubber planting in Mexico.**—The October and November "Bulletin of the Department of Agriculture for Jamaica" contains a most interesting article on the cultivation of rubber in Mexico and Central America, an industry that many will be surprised to learn has already become fairly well established there. The author apparently makes out a good case for using the name *Castilla* instead of the generally accepted *Castilloa* as the genus of South American rubber-producing plants.

**Celery trial at Wisley.**—A meeting of members of the fruit and vegetable committee of the Royal Horticultural Society was held in Wisley Gardens on the 18th ult., Mr. O. Thomas presiding, and a full quorum being present. The special object of the visit was to examine a large collection of Celery. This being the last trial of the year, some forty-four stocks of Celery and four stocks of Celeriac had been planted in trenches and in double rows, the Celery being well moulded up; but, because of the breadth of double rows, the tops of the ridges were flat, not a defect in dry weather, but with so much rain as has fallen of late it did serve to collect too much of it to the detriment of the outer leaf-stalks of those varieties that were rather of soft or hollow texture. In any case no variety or stock showing the latter defect obtained an award. Of those so honoured, all, with one exception, were coloured varieties, that one exception being the good old dwarf White Incomparable, put into commerce many years since by the late Charles Turner, and which so far has never had an award. This stock came from Nutting and Co. It was agreed that this and a stock named Sandringham Dwarf White were identical. Awards of merit were unanimously granted to the following: Early

Rose (Veitch and Sons), William's Matchless Red (Veitch and Sons), Grove Pink (Nutting and Co.), Pink Beauty (Barr and Sons), New Solid Pink (Barr and Sons); and previous awards to Standard Bearer (James Carter and Co.) and Ivery's Non-such Pink (Veitch and Sons) were confirmed. Evidently coloured Celeriac stand excessive wet better than white ones do, and generally seem late to show best flavour. Of the four stocks of Celeriac, one, the best, came from Veitch and Sons, and that had an award of merit also. Some four plants from every row were lifted, cut through the middle to expose the heart, and all rigidly examined. In no case was the name of the sender of the stock given until after the award to it had been made.

**A new Pear.**—A fine new Pear was placed before the fruit committee at the Royal Horticultural Society's meeting in December last. It was shown by Messrs. Cheal and Sons. The committee unanimously voted it an award of merit with an alacrity which was quite refreshing to witness, as it is so seldom that the committee is moved to enthusiasm by exhibits placed before it. The opinion generally expressed afterwards by those who had tasted the fruit was that this variety will at once take its place in the front rank of high quality Pears. It is named *Beurré de Nagan*, is of large size, pale golden in colour, reminding one a little of *Duchesse d'Angoulême* in size and outline, but infinitely superior to that variety in the texture of its flesh, being buttery, mellow, juicy and perfectly free from grittiness or hardness at the core, while for a Pear of its size the flavour is very sweet. It is a Continental variety, and if its other attributes, such as hardiness, free growth and fertility are equal to its appearance and flavour, there is no doubt whatever we have a valuable acquisition.—OWEN THOMAS.

**A beautiful new Chrysanthemum.**—A beautiful *Chrysanthemum* which will doubtless become popular is the *Marquis of Northampton*. This is a sport from *W. A. Etherington*. The flowers are of a lovely golden bronze colour, a colour that is particularly welcome to many lovers of *Chrysanthemums*. This new *Chrysanthemum* was awarded the first-class certificate of the National *Chrysanthemum* Society on November 18, 1907, when it was exhibited by Mr. A. R. Searle, Castle Ashby Gardens, Northampton.—C. RUSE.

## PRIZES FOR READERS. JANUARY.

### THE BEST POTATOES AND HOW TO GROW THEM.

A First Prize of FOUR GUINEAS,

A Second Prize of TWO GUINEAS,

A Third Prize of ONE GUINEA,

And a Fourth Prize of HALF-A-GUINEA

are offered for the best essay on "The Best Potatoes and How to Grow Them."

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Friday, January 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**The Tree Poppy (Romneya Coulteri).**—The Rev. E. M. Hill, Holy Trinity Rectory, Dorchester, sends a photograph of this beautiful shrub; but, unfortunately, it will not make a good reproduction. The following note, which accompanied the illustration, is interesting: "I am sending you a photograph of Romneya Coulteri, and am sorry it does not give a better idea of the extreme beauty of the plant. It flourishes exceedingly well here in a cold soil with chalk subsoil, but no wall or other shelter near it. The plant measures 42 feet round, and some of the shoots are over 6 feet high. We attribute our success with this plant in a great measure to the fact that the original plant was by chance placed where there had been an old path; it now spreads rapidly, and throws up shoots at a great distance. It dies off every year, and we cut down the old shoots in the spring, just before the young ones begin to shoot up. At one time (last September) there were almost 100 blossoms out at once, and it flowered freely from July till the heavy rains in October stopped further blooming. Considering how very hardy Romneya Coulteri is, it is strange that we do not see it grown oftener, the plants being now quite moderate in price. It seems to flourish in the open much better than near a wall, where I have often seen it doing very badly."

**Almonds fruiting.**—With reference to the correspondence about Almond trees, we picked some Almonds on December 16 from our trees and they were quite good to eat.—ALDERSHOT.

**Bees in the garden.**—One or more hives of bees should be in every garden, both large or small, for, apart from the advantage of always having a supply of wholesome honey for home use, much interest and benefit may be derived in various ways. In the first place, they are profitable when well managed. In this neighbourhood honey is readily disposed of to the retailer at 9s. per dozen 1lb. sections, and I have no doubt that a remunerative price may be obtained in other localities, provided that the sections are full of light-coloured honey and are presented to the purchaser in an attractive manner. During summer bees do a vast amount of good in the fertilisation of fruit blossoms, besides visiting daily other flowering vegetable and fruit crops. Even in glass structures containing various fruit trees, besides Cucumbers and Melons, the bees will enter when they are opened in sunny weather, and carry on their good work, which would otherwise need to be done by hand. There are many kinds of hardy flowering plants that the bees abstract large quantities of honey from.

**The best winter Pear.**—The belief has been hitherto pretty general that to grow Winter Nelis Pear to perfection the assistance of a warm wall is necessary. In warm and favourable seasons the best results are to be obtained from this variety on pyramid trees grown in the open. Growers should make a note of this fact, and hasten to plant this, certainly one of the best and most indispensable winter Pears in cultivation, in some warm corner or other of their garden. It will be well to qualify the above by saying that in cold and unfavourable seasons this variety is a disappointment in the open, and therefore a reserve of trees on a warm wall should be provided where possible.—B.

**Planting shrubs against walls.** As many gardeners and amateurs will still have some shrubs to plant against walls, it may be well to remind them that the colour of the walls and the flowers or fruits of the shrubs should be considered. The other day I saw a splendid fruiting plant of the Fire Thorn (*Cratægus pyracantha*), that was entirely spoiled by the dull red brickwork to which it was nailed.—H.

## THE GREENHOUSE.

## FREESIAS.

**T**HESE sweetly-scented flowers are exceedingly beautiful, and also useful in winter and early spring. Potting should be done in good time, so that the plants can be got forward as needed. Nearly all the failures met with in trying to flower the Freesia are from one cause, which is late potting. They should be potted early in August, and grown on as cool as possible, as the longer they are kept in a cold frame and the more air they have so much sturdier will be the growth, while the flowers will be finer and more lasting. The soil should be light and rich, consisting of three parts of turfy loam to one part leaf-soil, with a sprinkle of sand added. This will suit them admirably, other conditions being favourable. Five-inch and 6-inch pots are most suitable, with nine to twelve bulbs in a pot, covering them with about half an inch of soil. If the soil be fairly moist no water need be given until some signs of growth are seen. After potting, place them in a cold frame where they should remain as long as the plants continue to grow, giving air on mild days, and covering up with mats in case of severe frost. Under this treatment the plants should be ready to remove into a cool greenhouse about the first week in November, where they should be kept near the glass and plenty of water given.

At this time the plants will need staking, which should be done with very thin sticks and fine raffia or the effect of the plants when in flower will be spoilt. When the pots are full of roots and the spikes are forming weak liquid manure about twice a week will be of great benefit. If forcing is resorted to it should of the very gentlest description, otherwise both plants and flowers will be a failure. The best sort is *F. refracta alba*, white, sweet scented. After flowering is over is a critical time for Freesias, as then the new bulbs are just swelling and finishing growth. Between the dropping of the flowers and the beginning of the leaves changing colour the plants should be given liquid manure when required until the foliage dies down. When this has taken place the pots should be placed in a position, no matter how hot or dry, and let the bulbs roast in the pots until potting time comes again. A shelf in a vinery or similar place will answer where rain cannot penetrate. The following season the bulbs should be sorted and the best potted and grown in the same way, when the result will be most satisfactory and pleasing.

Elsham Hall Gardens, Lincoln. G. SIZER.

## WHY GROW SO MANY SCARLET GERANIUMS FOR SUMMER BEDDING?

AMATEUR gardeners, and jobbing gardeners especially, nurse up with expensive fires and a great amount of trouble hundreds of cuttings year after year, and the resulting sameness of the bedding out becomes very monotonous to those who look for variety in the annual garden plan. It may be of interest, therefore, to indicate a change of tactics in the preparations for the ensuing summer, instead of so much of this now customary red Geranium bedding. What could be more beautiful and novel than a scarlet bed of the lovely *Sutherlandia frutescens*, named after the compiler of a botanical catalogue. This splendid species was grown last year in Finsbury Park (throughout a bad summer), reaching the highest state of perfection. Some few seasons ago a plant of this species was seen growing out of doors in a pot in grand style, and this seems to point to its coming usefulness for our summer bedding out. The writer secured a packet of seed and has been growing the plants along ever since, with

the result that, at the moment, they have become fine specimen standards already nearly 3 feet high, while the seedlings, some of which have only just been sown, will be brought on as dwarf plants to use next season for the groundwork of the bed, in which, to add further brightness, will be planted standard pink *Lantanas*, *Cyperus Natalensis* (ornamental grass), yellow *Begonias*, *Anthericum variegata*, blue *Lobelia* and the edging all round the bed will be *Alternanthera versicolor grandis*. Another good bed for effect which was found to grow to perfection last year was planted as follows: One standard *Heliotrope* in the middle, two *Kochia Scoparia* round the *Heliotrope* to hide the stem, two *Eucalyptus cordata* and two *Artemisia abrotensis* in front, the latter's most beautiful silvery leaves just rising like a bouquet around below the umbrella of the standard *Heliotrope*. In front of this was planted the *Sutherlandia frutescens*, *Solanum pyracanthum* (Holy Thorn) and *Cnicus Chamæpence Diacantha* (cultivated Thistle) alternately. The edging used round the bed was white *Alyssum Koeniga maritima* grown from cuttings, and here is a point: Do not grow this from seed or you will find the plants anything but compact. The effect given by this bed was much admired by many gardeners. For his part, the writer will certainly aim more and more at this style of bedding in the future, and this in spite of the fact that he grew some fine beds of Cannell's Paul Crampel *Geranium* last year with blooms more than a hand across and petals over 2 inches wide. It should be mentioned that *Sutherlandia frutescens* is quite easily grown from seed sown at the beginning of December and in practically a cold greenhouse. Keep the seedlings close up to the glass and frequently syringe when the plants are about 2 inches high, then, as the days draw out and the sun's rays become more powerful, remove the plants to a cooler situation.

H. SELBORNE BOOME.

Holwell Hyde, Hatfield, Herts.

## PLEROMA MACRANTHUM.

THIS beautiful flower is often met with under the name of *Lascandra macrantha*. It is suitable for the conservatory or cool greenhouse, and should be planted against a wall where it has plenty of room to develop. Its value is very much increased by the fact that it flowers during winter, a season when flowering roof plants are very scarce. Here it is growing over the roof of a corridor, where its beautiful deep violet-purple flowers are very attractive. It is planted in a shallow border in a mixture of turfy loam and peat. During the summer months when growth is active plenty of water is needed, and old-established plants also enjoy stimulants. After flowering the growths are shortened back near their base, and the plants given a short season of rest till growth is again active. It is easily propagated from cuttings taken from the plants in a half-ripened condition during the spring.

Frogmore.

E. H.

## CHRYSANthemUM MME. PAOLO RADAELLI.

THIS is a grand variety, and the raiser (Calvat) may well be proud of the high position it has occupied since he first sent it out. Its deep yellow sport (Mme. G. Rivol) is also a flower worthy of its parent, and there may possibly be a whole family of sports, as there have been with some other well-known show flowers. At the recent Paris Show an exhibitor staged a large number of blooms from another sport of Mme. Paolo Radaelli called Mlle. Marthe Raffard. The flowers are reddish buff, the build and form of the sport otherwise resembling the parent. It is worthy of note that Mme. Paolo Radaelli was awarded the second prize for the finest bloom in the Paris Show.

C. H. P.

## THE FRUIT GARDEN.

### HOW TO GROW GRAPES IN POTS.

**T**HE pot Vines in fruit represented in the illustration are one year old plants, or sixteen months from the "eye," to the time the fruit was ready for use. The most important point connected with the fruiting of Vines in pots is to have well-grown and well-ripened canes. To produce fruiting canes in one

trained up the back of the house, which is a three-quarter span. As soon as they have grown about 8 feet they are "stopped," and all laterals stopped at the first leaf. I like to have them potted in their fruiting pots as early in August as possible; the pots used are 14 inches in diameter.

In these they can be cropped for two seasons with success. The soil for this potting is made somewhat richer than before by the addition of some half-inch bones and Thompson's Vine Manure, and some brick or mortar rubble should also be added. After potting they

are placed in a cooler house, the house in which they will fruit the following year. Here they are tied up to the wires, fully exposed to sun and light, where they remain until the beginning of October.

By this time the pots should be well filled with roots and the canes beginning to ripen. They are now placed out of doors in a sheltered position, where the pots can be covered in the event of frost or heavy rains. About the second week in December they are brought into the house again (having been pruned a month or six weeks previously), and started in a temperature of 50° to 55°, allowing a rise of 5° when the buds begin to break, gradually increasing it to 70° by the time they are in flower, always allowing a further rise by sun-heat. Very little water will be required at the roots for the first few weeks. As soon as the buds are seen to be breaking well, the back and front of the pots and the intervening spaces are packed well up with leaves and stable litter; this will assist root-action and also prevent the soil from drying so quickly in hot weather. As regards stopping, ventilating, &c.,

they will now require the same treatment as permanent Vines. When carrying a crop of fruit, they will require abundant supplies of water and plenty of liquid manure. For a change I find Thompson's and blood manure very beneficial.

The varieties in the illustration are Black Hamburgh and Foster's Seedling. The heaviest bunch of Black Hamburgh weighed 2lb. 15oz.; the two best bunches totalled 5½lb. No doubt such varieties as Black Alicante and Madresfield Court could be grown much larger, but I have not tried them.

W. R. CATT.

## COLOURED PLATE.

PLATE 1340.

### HOW TO GROW SWEET PEAS.

**I** AM frequently asked whether the present popularity—it is sometimes miscalled a boom—in Sweet Peas will ever wane, and while I should not like to positively affirm that they will always enjoy the remarkable position to which they have attained during the past seven or eight years, I most certainly do not think that they will ever fall into a low estate. They are essentially the summer garden flowers for all, as they will thrive and produce hundreds or thousands of blooms in conditions in which other plants, equally as cheap to purchase and simple to grow perhaps, would do little more than eke out a bare and unsatisfactory existence. I am firmly of the opinion that if the craze for the distribution of novelties, more or less good and distinct, is not carried to an extreme degree, and that those which are sent out are properly fixed (this, however, seems an almost impossible matter with some of the waved standard forms) that the Sweet Pea will be a far greater favourite at the end of the next decade than it is at the present time.

It is to be feared that some growers will become tired of the constant increase in the number of varieties, especially when they find three or four that are so close that it is practically impossible to distinguish the one from the other when they are apart. What is far more desirable with varieties that are almost identical with others already in commerce, is a still further reduction in numbers, so that growers may feel when they are ordering that they will be sure to receive something that is at once good and perfectly distinct. There is little doubt in my mind that when the floral committee of the National Sweet Pea Society gets fairly settled down to work it will go far to clear up all matters in connexion with varieties, and I am perfectly certain that, no matter whence it comes, the new variety that receives the first-class certificate of the National Sweet Pea Society will be of outstanding merit, and that such distinction will come to be regarded ere long as a reliable hallmark of excellence. The start this season was full of promise of the greater and better work that is to follow year by year as long as the society continues in its present course of prosperity.

#### SOIL PREPARATION.

In the successful culture of Sweet Peas, whether they are grown for the adornment of the garden or for exhibition, I do not think that there is any point more important than this. To attempt to grow the finest plants in shallow soil that is in poor heart is to court comparative failure, but to sow the seeds or set the plants in deep land that is in perfect heart is to have taken a long stride towards success. The minimum depth to which the soil should be worked is 2 feet, and if it is possible to go half as deep again so much the better. As far as the addition of manure is concerned I would urge the desirability of generosity tempered with judgment, and especially the thorough incorporation of the material with the soil, as I do not consider the laying of manure in solid masses is wise or advantageous. With the second spit natural manure may be mixed in digging, working it in as early in the year as possible, that is to say, where the work was not done in the autumn. If manure is put in the surface soil it should be perfectly sweet, and if it has had its more active virtues taken from it by Mushrooms or some other crop, it will yet serve the Sweet Pea in excellent stead.

#### SEED SOWING.

Whether the seeds are sown in single or double lines the drills should always be flat-bottomed, and never cut triangularly with the corner of a

POT VINES IN HODNET HALL GARDENS.

season, they require much care and attention. Our method here is as follows: The eyes are inserted singly in 3-inch pots in the early part of February and placed in the propagating frame. As soon as they have rooted sufficiently they are potted into 6-inch pots and grown on in a temperature of 65° to 70°, keeping them well syringed morning and afternoon. As soon as these pots are well filled with roots, they are transferred into 8-inch pots. A suitable compost for this potting is three-parts good fibrous loam, one-part well-rotted manure and wood ashes, with a little charcoal. After this shift the pots are plunged to the rims in leaves and the shoots

draw hoe as is sometimes done. For double lines the flat drills, more correctly perhaps trenches, should be at least 15 inches in width and 2 inches in depth, and a row of seeds should be set 1 inch from each side. I say that the seeds should be "set" and not sown continuously along the entire length, as the latter practice involves waste of seeds, and it is seldom when they all germinate that an individual will be found with sufficient courage to thin them out to the proper distances. For single lines the flat drills should be 5 inches or 6 inches wide and 2 inches deep. If the seeds are placed 3 inches asunder the seedlings should subsequently be thinned as necessary until each has from 12 inches to 18 inches of space in which to grow. Thus it will be seen that we shall sow some five or six times as many seeds as we require plants, and allow a margin for the birds and slugs to have the share to which they apparently think themselves entitled. Of course this practice is only possible of adoption with standard sorts, as when we come to anything under a dozen seeds for 1s. it is not wise to permit the natural enemies to have any at all, and steps must be taken to prevent them from doing so.

It is common and excellent practice to sow seeds in pots and place them in cold frames in January and February, and when this is done I would again urge the necessity for hardy culture. To treat the plants as though they were tender is an error that is certain to be followed by disastrous results, and it should be strenuously avoided. Fill 6-inch pots to within 1 inch of the rim and place five seeds round the sides of each; or put one seed in the centre of a small pot. Have the soil pleasantly moist at the time of using, stand the pots in a cold frame, never putting on the light except during snow or torrential rain, and the progress will be steady and strong. As soon as the seedlings appear the frame should be covered with fine-meshed wire netting to keep the birds at bay, or they will top the plants quickly and effectually. The soil in the pots should never become sodden.

#### STAKING THE PLANTS.

This is another operation to which the amateur does not always attach sufficient importance. No matter what the variety may be or where it is growing, the young plant ought to have support when it is 3 inches or 4 inches high; this may take the form of twiggy stakes, such as the pieces from an old besom, and they should stand about 12 inches out of the ground. Before the plants have reached the top of these the permanent stakes should be put in position, and if necessary the growths should be lightly attached to them with bass, but this is not invariably essential. Hazel makes the best supports, and should be procured if possible, and there ought to be at least 7 feet clear of the ground—more in those climates where the plants attain to a height of 10 feet or 12 feet. Wire

netting of very large mesh answers splendidly as a support, and, although somewhat expensive at the outset, is cheap in the long run, as with care it will last for several years.

When a plant has ample space in which to grow, it will make a natural break close to the base and produce many shoots (my friend Mr. Apps of Hastings had one plant with twenty-five stems this season, and he sold the flowers from that one plant for 25s., at which price one does not mind giving 1d. or 2d. per seed), and these should be reduced to three, four or five, according to judgment, this reduction being done in stages so as not to cause a severe shock to the plants.

#### TIMES OF SOWING AND PLANTING OUT.

Both of these operations are largely governed by the weather, as it is far better to be either a few days early or a few days late than to put the

article readers are referred. I should like, however, to say just a little about St. George. This is the brilliant scarlet-orange-coloured variety that received the first-class certificate and silver medal of the National Sweet Pea Society in July last. That it is superior to any of its shade I have little doubt, but I am not by any means satisfied that it can fairly be termed a waved variety, although I have several times seen it described as such. In this respect it appears to be somewhat unstable, for some flowers show signs of waviness, while others have perfectly smooth standards. I am awaiting the next flowering season with much interest, as the point will then be quickly settled. If, as is said, the blooms do not burn, all will agree that St. George is one of the most desirable Sweet Peas that has been introduced during recent years. Sutton's Queen, of which a coloured

plate is given, is a new variety that was shown last summer; it is a beautiful sort, the flowers being very large, waved, of a cream colour, delicately edged with pink. Under the provisional names of Mrs. Rothera and Miss Hilda Chamberlain it received an award of merit from the National Sweet Pea Society and a first-class certificate at Wolverhampton.

Many other new varieties are excellent, and one might quote many names. The thing to aim at in the future will be the retaining only of those new varieties that are a decided advance in habit, colour, size and form on those now in existence. The Spencer or waved sorts seem to be the most favoured at present, and Mr. Cole considerably changed the form of the flowers when he introduced that still charming variety Countess Spencer. The grandiflora sorts, however, still find many favourites, their bold, upright standards giving them quite a distinct appearance. No matter what type we favour most, our object

should be to grow the plants as well as we possibly can. H. J. WRIGHT.

[We are indebted to Messrs. Sutton and Sons for the flowers from which our plate has been prepared.—ED.]

SOPHRO-CATTLEYA EXIMIA (FOWLER'S VARIETY).

seeds or plants out when the climatal conditions are not favourable. For out-of-door sowing in the spring about the end of the third week of March gives excellent results, and successive sowings may be made if necessary up to the end of April. Plants from seeds sown under glass in spring or autumn should be put out into their permanent positions as soon as the weather and soil are suitable towards the end of April.

#### FEEDING THE PLANTS.

As soon as the plants are well in bud, never earlier, feeding may commence if it is considered necessary; but as long as the plants grow strongly and appear to be getting abundance of good food from the soil, there is no advantage in having recourse to special feeding. When it is done let the liquid, whether it is made with natural manures or concentrated fertilisers, be given in a weak state when the soil is pleasantly moist; if it is applied when the soil is dry at least half of its virtues will be lost to the plants.

#### SELECT VARIETIES.

I do not purpose taking up valuable space by naming a selection of varieties, as Mr. Alexander Malcolm gave an admirable review of the best in THE GARDEN for November 2, 1907, and to this

#### SOPHRO-CATTLEYA EXIMIA (FOWLER'S VARIETY).

This is a lovely form of the hybrid Sophro-Cattleya eximia, the parents of which are Sophronitis grandiflora and Cattleya bowringiana. The result is a dwarf plant that has more the habit of a Cattleya than a Sophronitis, while the flowers partake of both. This variety is of larger size, and constitutes an all-round improvement on S.-C. eximia. The flowers measure about 2½ inches in diameter, the sepals and petals being of a lovely magenta-crimson hue. The lip is rich crimson streaked with rich gold at the base. It was shown by Mr. J. Gurney Fowler, Glebelands, South Woodford, before the Royal Horticultural Society on December 10, when it received a first-class certificate. As will be seen in the illustration, two flowers were borne on a rather stout stem.

## THE ROSE GARDEN.

### WILD ROSES (SPECIES).

**M**AY I put in a plea for the increased planting of some of the more interesting and beautiful forms of the wild Roses that have been obtained from all parts of the globe, and which, when rightly planted (referring more particularly to situation) flower, as a rule, before the cultivated varieties, which generally satisfy the requirements of most Rose-lovers? Apart altogether from the interest which they possess as the parents (in some cases) of our garden Roses, they are in many instances deserving of culture for their own sakes, and it adds immensely to the interest of one's Roses if one can find room for a few of the very many wild Roses that can now be obtained from most Rose nurserymen worthy of the name, some of whom, at any rate, of recent years have made a speciality of the species.

There is an excellent article on this subject in "Roses for English Gardens," which book I would recommend to all your readers who may not have come across it as the best all-round Rose book yet published, of which I should like to see a second edition, revised and brought up-to-date with detailed descriptions of our best exhibition and garden Roses. Perhaps the proprietors of the *Country Life* library will take the hint. Allowed to grow naturally, unpruned in the ordinary sense of the word, with an occasional thinning out of the old wood, some of the species grow into most beautiful garden plants that are quite a revelation to those who do not know them. The majority of them flower early, and only once; but they quite make up for this by their wealth of Rose hips of all kinds, colours and shapes and their often beautiful foliage. I can recommend any and all of the following varieties to those who like to have something out of the ordinary (and who does not?) in their garden; they can be obtained, as a rule, at a cost of 9d. to 1s. 6d. per plant.

*Rosa acicularis* (the Needle Rose) is a native of Siberia, and in the winter months might easily be mistaken for one of the various forms of *rugosa*, as its stems are as thickly covered with sharp spines, but it is distinct at other seasons. Its flower is a bright deep pink of medium to large size, and the foliage might be termed glaucous, and the flowers generally appear by the middle of May; it is, therefore, one of the early Roses; sweetly scented. Its good points do not end there, as its fruit is quite distinct, being long and Pear-shaped, not round like the *rugosa*s, with a few spines seen on the fruit, so that it might be termed the Prickly Pear Rose. Coming as it does from Siberia, there is no doubt about its hardiness. Best on its own roots, and not difficult to raise from cuttings.

*R. alpina* (the alpine Rose, not the flower which goes by that name in Switzerland, which is a species of *Rhododendron*) is a native of Europe, and there are at least three distinct forms, of which I have only two—the type, always the earliest Rose to flower with me (often weeks before our native Dog Rose). The stems of one year's growth assume a reddish hue, and are almost without thorns. The flowers are bright rose-pink in colour, and can generally be picked in an ordinary season the first week in May. The type is the parent of the Boursault Roses; there is a double form of it that is free and of good habit. Another variety that comes from the Pyrenees, and is so called, is of much dwarfer habit, and a good subject for the rock garden. It, unlike the type, has spiny foliage, and has been sent to me under the name of *nitida*, which, however, is something quite distinct, having round hips instead of the very long ones that are typical of all forms of *alpina*.

*R. altaica*.—A native of North Central Asia and China, allied, no doubt, to *Rosa spinosissima*, but of more robust growth. This makes a

fine bush; it can also be recommended for a hedge. Fairly early, this season it bloomed twice with me, quite a number of flowers being produced in August; its beautiful pale lemon-white flowers are always much admired. Small foliage that turns to a pretty variegated brown shade in late autumn, which contrasts well with the small deep black hips.

*R. arvensis* (Native).—The variety known as Miss Jekyll's is the only one I have. (The type can be met with in most of our hedges). It is rather larger in flower than the ordinary type, and is a very rampant grower. *R. arvensis* is the parent of our Ayrshire Roses, those free-

PROTECTING STANDARD ROSES WITH OLD WINE-BOTTLE CASES.

flowering ramblers of which Bennett's Seedling is probably the best.

*R. Banksiae* (China).—Too well known to need comment. All who have a warm sheltered corner should grow the small yellow-flowered variety against a wall. It is exactly one hundred years since this Rose was introduced into England, and the centenary might well be celebrated by planting it largely. There are, I believe, four varieties, but the double yellow and the double white are the most popular. It rarely flowers the first season after planting; but if left alone and not pruned will well reward you for the necessary patience. Thornless.

*R. beggeriana* (Central Asia and the Himalayas). Not particularly beautiful; interesting owing to its unpleasant smell; the small white flowers are produced in July.

*R. blanda* (North America).—This and its double form (fl. pl.) are both worth growing. It makes a good bush; its flowers are salmon pink in colour, and of rather larger size than usual with these wild Roses. It is sometimes called the Labrador Rose.

*R. bracteata* (China and Central Asia).—One of the most beautiful of the species, one might almost say of all single Roses. It is very distinct, and also very tender, must have a sunny, sheltered wall, and is well worth taking care of. Practically evergreen, it objects strongly to be covered with a mat, but protection is absolutely necessary. The flowers, which are freely produced on established plants, contrast well with the beautiful dark green shiny foliage. There is a double form called Marie Leonida, which is not, to my way of thinking, half as beautiful as the type. One misses the contrast of the yellow stamens and the white petals.

*R. Carolina* (North America).—This somewhat resembles *Rosa lucida*, but it has the advantage of flowering right through August and September when all the species have finished. The flowers are freely produced and are of a light pink shade; it makes a fine bush and will grow 6 feet high; the foliage is thick and the leaflets long and narrow. Smooth wooded with few thorns.

*R. cinnamomea*.—I am not sure of the native habitat of this Rose. The flowers are small, flattish, and produced on yellow-brown wood, not very freely, and are of a pale pink in colour; it will grow into a medium bush.

*R. Fendleri*.—The feature of this scarce species is the colouring of its foliage in the autumn, helped by the bright stems; it is then a very pretty picture.

*R. gallica* (centifolia  $\times$  damasceana).—The ancestors of our modern Hybrid Perpetuals, hence here grouped together, although quite distinct otherwise. Their varieties are numerous, and cover all the Damask, Cabbage and striped Roses of our forefathers. Mostly sweet-scented. Ballata, a variety of centifolia, is sometimes known as the Lettuce-leaved Rose, and the foliage is distinct. Mrs Orpen is a good type of Hybrid Damask, large single pink flowers, and Rosa Mundi, sometimes, but erroneously, called York and Lancaster, a type of the *gallica*. Otto of Roses is largely made from a variety called Kazanlik, one of the Provence Roses allied to this group.

Purley.

HERBERT E. MOLYNEUX.

(To be continued.)

### PROTECTING STANDARD ROSES.

THE accompanying photograph, kindly sent by Mr. F. Sanderson, Bower Mount Road, Maidstone, shows a method of protecting standard Roses with the straw covering from wine bottles.

### MAKING FIRM ROSE ARCHES.

MAY I offer a small tip for a sound foundation for Rose arches, pillars and so on? Worried with the decay of the wooden plugs to which the iron rods used to be secured causing fungus on the Rose roots in addition to the general collapse, I cast about for a better plan, and hit upon the following: Take a drain-pipe, say, 6 inches or 8 inches in diameter, fill with concrete and insert, say, three pieces of old gas-pipe. When properly set, place in its position, then insert your iron arch—in my case a triangular one with three rods—level properly and pour in a little liquid cement. In a little while the whole thing is as firm as need be and will last as long as the ironwork or the Rose.

Suthampstead

J. T. STRANGE.

### ROSE LINA SCHMIDT-MICHEL.

I HAVE an impression that this will become a general favourite as a decorative Rose. It is one of those large-flowered, semi-double sorts we all admire so much, especially when possessing, like this one, lovely colouring. We naturally look for something good from a seedling of Mme. Abel Chatenay, and I am sure one will not be disappointed. It is a fine bold grower and just the sort of Rose to plant in an isolated position on the lawn; have them well cared for, but spare the knife. We want to encourage the growing of more of this type. It is quite a pleasure to meet now and then real good large bushes a blaze of flowers, and there are numbers of Roses suitable for such a mode of culture. There is a novelty of last season's introductions, which will become, if I mistake not, a general favourite. Its name is Sarah Bernhard. Its colour is as vivid as that of Duke of Edinburgh; the blooms, however, are semi-double. It will be a gorgeous garden Rose if it proves to be free-flowering enough. We should be thankful for these large-flowered, semi-double Roses. They provide some beautiful groups of colour. For instance, where can we surpass Bardou Job?

P.

## THE ROCK GARDEN.

### THE ROCK GARDEN IN WINTER.

**I**N midwinter the appearance of a rock garden is certainly not very attractive, owing to the many bare ledges and pockets which in the spring and early summer months are occupied with plants showing beautiful patches of colour. Apart from the Christmas Rose, one of the most beautiful and welcome of our hardy flowers which is now about at its best, and the Algerian Iris, with its lovely purple and white flowers, there is little else to be seen in bloom. However, the place is not entirely devoid of interest, with the silvery cushions of crusted Saxifragas, and the bright green carpets of the mossy sorts, to say nothing of other evergreen plants such as Stonecrop (Sedums), Sempervivums, Pinks, Galax, and Shortia, with their various forms and shades of colour. At the same time there are the Snowdrops, Winter Aconites and Anemones ready to push their way up and unfold their welcome flowers with the least encouragement of mild and sunny days.

#### WORK TO BE DONE.

All through the winter months there is much to be done in the rock garden. If not previously done in the autumn, all plants that require it should be top-dressed, using a mixture of fine soil, leaf-mould and sharp sand. Many plants, like some of the Primulas, have a tendency to form stems and grow away from the surface of the ground, with the result that they appear leggy. If top-dressed, fresh roots are emitted higher up the stem, and thus the plants benefit to a great extent by this being periodically performed. Mossy Phloxes, Achilleas, Aubrietias and other similar carpeting plants should have a like compost worked in between their prostrate stems. Where there is room between the plants, the soil should first be stirred up slightly with a handfork and all weeds cleared off before putting on the top-dressing. A sharp look-out must be kept at all times for

#### SLUGS AND SNAILS,

which have their special favourites among alpine plants. Among those especially liable to attack are Omphalodes Luciliae, Aster alpinus, Campanulas of the smaller sorts like C. Saxifraga, Crepis aurea, and other kinds which have succulent leaves and buds. If neglected, the growing points are liable to be eaten off, with the result that there is no flower the following season.

For smaller choice things a good protection is a zinc hoop about 3 inches deep placed round the plant. A good method of catching slugs is to put down here and there little patches of bran covered with a piece of slate or glass to keep it dry. This forms an attraction for them, and they can be caught in great numbers at night. One of the best ways of keeping down their numbers is to frequently examine their known favourite plants at night when they come out to feed.

#### TRANSPLANTING.

If not previously carried out in the autumn, which is the best time for replanting early spring flowering plants, all transplanting should be finished off as soon as possible. Pockets that have got sour should be emptied and refilled with good soil, taking care to put plenty of drainage at the bottom. The stronger free-growing plants that show signs of having exhausted the soil of the pocket in which they are growing should be taken up and replanted in a larger one with fresh soil, while the pocket from which it came may be renewed ready for something else. Where there is danger of a choice plant being overrun by a coarser-growing kind, one or the other should be moved to a more suitable position, so that the weaker one will have a fair chance to develop.

#### LABELLING

is important, and usually occupies a great deal of time where large collections are to be kept

but a useful size is one with letters three-sixteenths of an inch. Except for larger plants this makes a plain enough label. After the letters are punched in the lead they are filled up with white enamel, the whole surface then being wiped over with a cloth so as to leave the letters clear and distinct. When dry the labels should be wiped over again with a rag saturated in linseed oil to preserve the lead from oxidation. All dead leaves and decayed matter should be cleared away from the plants, as it only harbours snails and slugs, and the rock garden should be made tidy ready for the promised display of beautiful sheets of flowers in the near future.

W. IRVING.

### NOTES ON A ROCK GARDEN.

THE rock garden shown in the illustration has been planned and made during the last five and a-half years by Mr. Montgomery, with the help of a willing and intelligent gardener, but without the aid of a landscape gardener. The space which the rock garden now covers was originally a wood, and the trees which still remain round the garden give great shelter from the north and east winds. To the left in the illustration is a large bed of Anemone japonica, which in a mass is very effective in September. The tall shrub nearly in the centre of the picture is the beautiful Spiraea flagelliformis. This specimen is over 5 feet high and each shoot is covered early in

June with clusters of white rosette-shaped flowers. The white flowers seen at a distance to the right are blossoms of Romneya Coulterii, which does extremely well in this garden, dying down in the autumn and coming up with renewed vigour every spring; it only requires a few branches as protection in the winter. The rock garden is approached by a stepping-stone path through a very damp piece of ground, and at the side of this path is a small pond, on the edge of which a large patch of Iris Kampferii flourishes.

### THE GLADWIN.

THIS Iris foetidissima is one of those good plants that is

much and undeservedly neglected, and it is much to be regretted. When in fruit the open capsules, showing their beautiful orange-coloured seeds, are most ornamental. When tastefully arranged in a vase, with some of its own foliage and fine grasses, the combination forms a useful room decoration for the winter season. This native Iris does well in almost any moist position. The spikes of seed vessels should be supported with sticks in early autumn to prevent them falling to the ground, which would probably spoil many of them.

A CHARMING ROCK GARDEN WHICH WAS ORIGINALLY A WOOD.

correctly named. Lists should always be made in fair weather of all plants that want relabelling, so that it is ready on wet days when one cannot work outside or in hard frosty weather. Various kinds of labels are used, one of the best being made of sheet lead, cut to shape. This makes a most serviceable label, which at the same time is not conspicuous enough to mar the general effect. For making these labels it is necessary to have a flat piece of iron or steel on which to lay the lead for punching in the letters. The size of the type is optional,

## GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**F**LOWER GARDEN.—In frosty weather, when the ground is hard, wheel on manure and fresh soil where digging operations are necessary. Now is an excellent time to prepare new beds and borders and to renovate old walks and make new ones. Relay or level turf and sweep and roll lawns during open weather.

**Roses.**—Protect dwarf, Tea and other Roses. Ample protection can be afforded by placing a plentiful supply of Bracken among them and by drawing the soil round the base of the plants. Standard Briars to be budded next summer should be planted now.

**Greenhouse and Conservatory.**—Keep the glass clean, as this greatly promotes healthy plant life. Plants in the cool greenhouse should be watered only when they are dry at the roots, and this should be done in the morning. Ventilate with care, as sudden bursts of sunshine unduly raise the temperature. Close the ventilators an hour or two before sunset, and thus conserve the warmth. Bulbous subjects for forcing may now be brought indoors in successive batches.

**Chrysanthemums.**—Propagation by cuttings may now proceed apace. Select shoots that are free from buds and that have developed 1 inch or 2 inches from the base of the old stems. Send orders for novelties and scarce sorts without delay, or there may be delay in executing the same. For decorative uses propagate batches of the singles, Anemones and Pompons. The best position to root the cuttings is in an improvised frame on the side benches of the greenhouse.

**Cold Frames.**—Open the frame-lights on every possible occasion, as an hour or two of such treatment of the occupants is beneficial. Remove

decaying foliage, and stir the soil between the plants and cuttings, as this does much good and saves many plants. Very little watering will be required at this season. Provided adequate protection can be afforded, Chrysanthemums may be rooted in small pots in the cold frame. Prepare for severe frosts by securing an abundant supply of litter and good mats.

**The Vegetable Garden.**—Ground intended for root crops, such as Carrots, Parsnips, and Beet, should be trenched without delay, frost and the weather at this season contributing so much to its value and fertility. Vacant ground generally should be dug over forthwith, incorporating at the time heavy dressings of good manure. Deep culture invariably answers well for vegetables; for this reason, therefore, let the ground be

THE WASHINGTON THORN.

deeply dug, and all kinds of decaying garden refuse be dug in. Leave the surface soil in a rough condition.

**The Window Garden.**—Window plants should be watered with rain-water that has been made slightly tepid. Water carefully, however, treating only dry plants to this consideration. The well-being of plants may be encouraged by periodically sponging foliage plants, using tepid water and milk. Window-boxes may be planted with small shrubs, in this way imparting a pleasing appearance to the windows. It is early yet to think of repotting plants that need fresh soil or pots of larger size; leave this operation until the end of February. The more tender plants in rooms should be removed from the windows in frosty weather, as the contrast between the day and night temperature is often very extreme. Plants may be screened from the cold by placing muslin or newspapers between the windows and the plants, allowing the screens

THE AMERICAN HOLLY.

to remain for some hours during the day if frost has reached the plants.

## TREES AND SHRUBS WITH ORNAMENTAL FRUITS.

## NOW IS THE TIME TO PLANT.

WHEN planting trees and shrubs the effect in spring and summer is too often the only consideration, the remaining six months of the year not being thought of. The fact, however, that a number produce ornamental fruits in autumn and winter must not be overlooked; they serve to brighten up the garden and give it an added interest during the dull season. Sprays of many of them can also be cut for indoor decoration, being especially useful during the Christmas season, forming a welcome relief to Holly berries. A number of the larger fruited Crabs can be utilised for making jelly when fully mature. Some of them, in addition to the highly-coloured fruits, are useful when in flower. The illustrations will give an idea of what the plants are like, but it is impossible to do them full justice, as most of the fruits are red, and this, as those who dabble in photography know only too well, is one of the worst possible colours to deal with, invariably coming out black.

**Crabs.**—These attain to the size of small trees. The best known with ornamental fruits is the Siberian Crab. The Cherry-like fruits are yellow, tinged with red. The Japanese Pyrus Ringo has small yellow fruits. There are a number of varieties of the White Beam Tree (*P. Aria*) with highly-coloured fruits, the variety *Majestica* being one of the best. Quite distinct in appearance to those already mentioned is the Mountain Ash (*P. Aucuparia*). This is sometimes met with in villa gardens and also occasionally as a street tree. It has large leaves and clusters of scarlet fruits. The upright growing form var. *fastigiata* can be highly recommended.

**Hawthorns (*Crataegus*).**—These can usually be depended on to carry a heavy crop of fruits. The

THE SEA BUCKTHORN.

Evergreen Thorn (*C. Pyracantha*) is the one most generally met with in gardens grown for the berries. It is no uncommon sight to see it trained up a dwelling-house 20 feet or more in height, and literally aglow with clusters of orange red berries in early winter. It is often necessary to hang nets over the trees to protect the berries from birds. Planted in the border it forms a nice bush. The Washington Thorn (*C. cordata*) attains the size of a small tree. The small red fruits often remain on the trees after many others have disappeared. There are a number of varieties of the Cockspur Thorn (*C. Crus-galli*). Like the last, this also grows into a small tree. The small scarlet fruits are edible, so that it is not advisable to plant it in the front garden, as small boys are very partial to them. In contrast to these, we have the Chinese (*C. pinnatifida*) with much larger fruits and *C. nigra* with black fruits. An interesting form of our common hedgerow Thorn has rich yellow fruits. Its botanical name is *C. Oxyacantha* var. *fructo luteo*.

*Sea Buckthorn*, or, to give the tree its Latin name, *Hippophae rhamnoides* is well shown in the illustration. A frequent cause of failure to

Planted in the open several of them are low-growing shrubs; they will also clothe low walls and fences when planted against them. *C. rotundifolius* is useful for this purpose; the small fruits are scarlet. *C. horizontalis* is naturally a low-spreading bush; planted against a fence it will grow 6 feet or more in height. *C. frigida* and *C. Simonsii* are more upright growing plants, having prominent fruits in autumn and winter.

The foregoing families by no means exhaust the list of trees and shrubs with showy fruits. The Roses have not been touched upon, as several illustrations and descriptive notes have appeared in the pages of THE GARDEN during the past year. The Snowberry is a very easy shrub to grow, with conspicuous white fruits in autumn and winter. The common Spindle Tree has reddish fruits enclosing orange-coloured seeds. There are several forms of the Prickly Heath, *Pernettya mucronata*, differing in the colour of the fruits, which are red, white, purple or pink. It forms a close-growing bush 2 feet to 3 feet high.

Where to obtain the plants written about is sometimes difficult. Readers need have no fear of being unable to obtain any of the plants named here from advertisers of trees and shrubs in the pages of THE GARDEN. A. N.

#### THE ONION PLANT.

THE Onion Plant, which rejoices, or otherwise, under the botanical appellation of *Ornithogalum longibracteatum*, is among the oppressed and downtrodden of the plant world, for one rarely indeed sees an attempt made to do the plant bare justice. Judging by the treatment generally meted out to this long-suffering flower-pot decoration, there would appear to be a popular idea abroad that it can live without soil or water, so little of either does the plant generally get.

But every rule has its exception, and in the illustration is shown a plant which has had too much of both soil and water. Too much soil began the trouble, and the owner was told that his plant required a bigger pot; he interpreted the hint too liberally. More soil, he thought, meant more water, and again his liberality outran his discretion. Result: the soil became sour and stagnant, and the plant drifted into the state of ill-health in which it is portrayed.

To remedy this state of affairs—not only with Onion, but with other plants—all the old soil should be shaken away, the roots washed in tepid water, and all brown and decayed ends cut off. Then the plant should go into a clean, well-drained pot only just large enough to receive it comfortably, some light and sandy soil used for filling up, and little water given for a few weeks. If slightly warmer quarters can also be given, the progress of the plant to robust health will be facilitated.

#### FORCING CHRISTMAS ROSES.

To force Christmas Roses in perfection the plants are best lifted and potted in October, and grown as cool as possible until their flower-buds show prominently, as do those in Fig. 1. But Christmas Roses are fairly good-natured plants, and one may even now lift them from the outside border and hurry them into flower in the greenhouse.

They should go into a deep pot or tub, according to their size, injuring the roots as little as possible in the process, and be well watered in. A week or fortnight in a cold frame will help them to get accustomed to their new quarters, and by that time they should have somewhat the appearance of Fig. 1, from which, by the way, the leaves have been removed in order to show the condition of the flower-buds.

Plants in this condition very soon open their flowers in a warm greenhouse, and rather less soon in a cold house or room. They must have plenty of water during their development, and an occasional dose of liquid manure will be appreciated; if in a living room, the plants should be taken to

CHRISTMAS ROSE AS TAKEN FROM COLD FRAME.

the scullery sink to receive their manurial stimulants. As showing that good plants and flowers may be grown in an ordinary sitting-room, it may be mentioned that the plant shown in Fig. 2 was grown entirely in dwelling-rooms; in a cold room until it had reached its first stage, and in a warm room to open its flowers. If placed again in a cold room when the flowers are about two-thirds expanded a good plant will remain in bloom several weeks.

#### FLOWER-BEDS AND BORDERS IN WINTER.

EXPERIENCED flower gardeners are quite agreed that the majority of the plants now used for making masses of bloom are very exhausting to the soil, and require to have a good foundation laid for their culture as do many of our vegetables. Few plants are more exhausting to soil than Verbenas, Heliotrope, Calceolarias and Geraniums, and the unsatisfactory appearance which these frequently present can be as often attributed to the want of liberal treatment as to anything else. If deep draining and cultivation are needed to produce good crops, certainly such conditions apply to the flower garden. An accumulation of water about a bed of flowers is productive of evils that will thwart the efforts of good management in all other respects; it will keep down the temperature of the soil, prevent the natural action of the atmosphere, and lessen the chances of getting the soil pulverised and sweetened. Every flower-bed that is wet should therefore be well drained, as this is the first step in successful flower gardening. As to deep cultivation, the benefits derivable from it are so many that it would be difficult to enumerate them all. It opens the soil so that the roots can penetrate it more easily, and in dry seasons go down where the soil is moist and escape to a greater extent the evils of drought. In wet seasons the water escapes more freely to the drains or subsoil.

CHRISTMAS ROSE: THE SAME PLANT IN FLOWER.

ONION PLANT OVERPOTTED, AND DECAYING IN CONSEQUENCE.

obtain fruits on this tree is that many persons are unaware that there are male and female forms. As fertilisation of the flowers must take place before berries are produced, two plants, one of each sex, must be planted together. One male tree, however, is sufficient to fertilise several females. Except when the trees are fruiting, an expert has a difficulty in distinguishing the two trees. In addition to the orange yellow fruits, the greyish green foliage is highly ornamental in summer.

*Holly*.—This is such a well-known tree that no description is needed of our common forms. The fact, however, that there is a variety with yellow berries is not usually known. The Latin name is *Ilex aquifolium* var. *fructo luteo*. Our common Holly is a native of Europe and Asia. An illustration of the American Holly (*I. opaca*) is given to show how nearly it resembles some of the forms of the European plant.

*Rose Box*.—This common name very well describes the members of the *Cotoneaster* family, for the leaves resemble those of the Box and the plant belongs to the great natural order *Rosaceae*.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**I**F the weather is wet or frosty work must be arranged accordingly. Walks may be mended or regravelled during wet or showery weather and the edgings made good, and if too wet for outside work the roots may be examined and any decayed specimens removed. Large labels for the vegetable quarters might be prepared. Painted well and clearly written much time may be saved and the work better executed if done on bad days. In frosty weather manure should be got on to the ground.

*Forcing Seakale.*—Put in more Seakale to force, and cut any crowns as soon as long enough. If more are desired stand the ends in dishes of water.

*Forcing Asparagus.*—Make up another frame of stable manure and leaves for a second lot of Asparagus. As soon as the temperature is about 65° to 70° the roots should be placed in thickly and covered over with 3 inches of fine soil. On the surface sow very thinly a pinch of Carter's forcing Radish, and endeavour to keep the temperature of the frame at 55° to 60°; if kept hotter the growths will be very weak and the bed not so lasting. Asparagus should be cut when about 6 inches long, tied in bundles, and placed in water till ready for cooking.

#### FRUIT HOUSES.

*Pruning.*—Continue to prune and clean Peach, Nectarine and Cherry trees; thoroughly wash the woodwork, wire and walls of the houses. This is very important, and after the painting or whitewashing of the walls see that the ventilating gear is in proper order. This work should be done at this season when the houses are empty, and nothing should be overlooked that may be likely to cause trouble later on. In pruning the Peach and Nectarine cut out as much of the old wood as possible and lay in the young shoots straight up from the base. The earliest Peach house may now be closed for forcing. See that the border has been well cleaned and prick it over with a fork. If it is at all dry give a thorough watering.

#### GREENHOUSES AND CONSERVATORY.

*Late Chrysanthemums.*—These structures should now be gay with late Chrysanthemums, Lily of the Valley, Spiræa, Cyclamen, Azaleas, Camellias and Roman Hyacinths. Keep the conservatory spotlessly clean and at a temperature of 55° to 60°, as this will suit most plants. The plants that require most heat, such as Poinsettias and that class, should be kept at the warmest end and be free from draughts. Chrysanthemum cuttings may now be put in. Bouvardias that have finished flowering should now be rested.

#### HARDY FRUIT.

*Pruning.*—Proceed with pruning the Pear and Apple trees, also with root-pruning. Do this thoroughly, as most probably a tap-root may have gone straight down under the centre of the ball.

*Current and Gooseberry Bushes.*—These may be sprinkled with lime mixed with petroleum. This is a very good way to keep birds from destroying buds, and they have already commenced. Another good plan is to put black cotton over the top of the trees. This I have found very effective, especially in isolated cases, such as Almonds, where they are placed for spring effect.

#### FRUIT ROOM.

See that all varieties are clearly labelled, as the owner may like to go and see them. This is always a distinct advantage. Each variety should be labelled when sent in for dessert. If

hard frost prevails, put up shutters to the windows, or, failing these, mats over, as a protection against frost. This will be found much better than fire-heat. In modern fruit rooms this is scarcely ever provided, but I know it is in some old-fashioned ones.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### KITCHEN GARDEN.

**TENDER VEGETABLES.**—There will now be more demand for tender vegetables than can be supplied from the open, unless some means are taken to eke out the supply. Brussels Sprouts and early Broccoli are not so plentiful as usual; Broccoli will lift well and give heads just the size needed if taken up before severe frosts check the growth. It is not safe after this date to rely upon tying up the leaves over the flowers; it is better to house the plants. The Cardoons this season have made a much later growth than usual; but it will now be well to lift them and place them under cover. They will remain good a long time in a cool store. Good use may now be made of the Large Batavian Endive as a vegetable if the plants are fully grown. Chicory forced in the same way as Seakale, if grown slowly and the growths out when 4 inches to 6 inches long, makes a good vegetable and an agreeable change. Vegetables stored some weeks ago must be kept as cool as possible. I find Potatoes are growing out badly, and it should be borne in mind that all roots that grow freely in the store will soon lose quality.

#### FRUIT UNDER GLASS.

*Early Vines.*—Black Hamburgh and Foster's Seedling which were started in November will now be moving into growth, and should be treated to a slight increase of both day and night temperatures, 55° at night and from 60° to 62° through the day will be suitable. With sun-heat the thermometer may be allowed to touch 70° before air is given, and if cold winds prevail allow the temperature to run up a little beyond the fixed standard rather than open the ventilators.

#### PLANTS UNDER GLASS.

*Double Chinese Primroses.*—The huge plants of these which are now to be seen in quantity, demonstrate in a forcible way the ease with which not only the finest varieties may be grown, but their exceeding value for supplying beautiful double flowers during the winter. The process of propagation, which should begin in January, is first to remove some of the outer leafage, then to notch slightly the bases of the crowns in layer fashion, then to drop the plants into pots a good size larger, and place round the tops an inch of fine sandy soil. If stood in gentle warmth rooting soon follows, and when each plant is lifted from the pot and the newly-rooted parts are severed from the old, then get into small pots and return to gentle warmth, very quickly are sturdy plants obtained. When shifted into larger pots later on, the best for them is a cool span frame, where, standing on a firm ash bed, good growth is continued. Eventually they may be got into 6-inch, or, if very strong, into 7-inch pots, and in these well established, soon begin to carry bloom.

#### FLOWER GARDEN.

*Getting Work Forward.*—Should the weather be favourable it will be advisable to take every opportunity of getting work forward in this department. Live edgings of all kinds may be planted at any time during the winter when the weather is suitable. In the formal part of the garden neatness is imperative, and all edging plants should be kept trim.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## THE KITCHEN GARDEN.

### TWO EASILY-GROWN WINTER SALADS.

**D**URING the dull, short days of winter there is always a scarcity of salads, but this shortage may be remedied to a great extent and with little trouble by those who are the fortunate possessors of a heated greenhouse. Mustard and Cress is a salad crop that is already largely grown by amateurs, but it is certain that the majority of them do not get the best possible results for their labour and expenditure. A few shallow boxes—1½ inches deep is quite sufficient—some finely-sifted but sweet soil, some crocks and a good supply of seed are all that is required. One good-sized crock over each hole in the bottom of the box will provide ample drainage. Old potting soil is frequently used, but this is not desirable, fresh soil, finely sifted and containing a large percentage of sand, being by far the best. Fill the boxes so that when the soil is pressed moderately firm the surface will be slightly below the edges of the boxes. Scatter the seed on the surface fairly thick and even, press it in slightly with the bottom of a clean pot or pan, give a watering with a fine-rosed can and stand in a warm, semi-dark place until germination is effected. Never cover the seeds with soil and do not use the same soil for more than one crop. Mustard and Cress are usually wanted together, therefore the former should be sown three days later than the Cress, as it grows faster and consequently becomes ready for cutting more quickly. After germination stand the boxes in full light and avoid watering overhead. If water is required it is much better to just dip the boxes in tepid water and allow the latter to permeate the soil from below upwards. This system of watering avoids damping off, a fungoid attack that is exceedingly prevalent among seedlings of all sorts during the winter. When ready for cutting insert the teeth of a coarse comb between the tiny stems and cut above this. Grit will thus be avoided and the Mustard or Cress can be transferred in an upright and attractive position to the dish.

Chicory or Witloof is the other salad that is easily yet seldom grown in this country. Seeds are sown in drills 1 foot apart in April in any good garden soil and the resultant seedlings are thinned to 9 inches apart in the rows. Summer treatment consists in keeping the hoe going frequently between the rows and seeing that the plants do not suffer for lack of water, this seldom happening except in very light soils, owing to the plant's deep-rooting proclivity. In late autumn some growers lift the large Parsnip-like roots and store them in soil in an outhouse or other position where they are easily accessible during the winter months, but the only advantage in this system lies in the fact that the roots can be readily got at during severe frosts. If some protection can be given to the bed wherein they are growing, so that the ground does not become frozen so hard as to make lifting them difficult, they may well remain in their summer quarters until required for forcing.

One of the easiest and simplest methods of forcing is to procure a deep box—a Tate sugar box answers well—make a few holes in the bottom, and cover them with good-sized crocks, and then put in about 3 inches of soil. This may well be the ordinary garden soil, providing it is not too wet nor of a heavy, close nature, or old soil from the potting bench, or even leaf-mould answers admirably, a rooting medium irrespective of nourishment being all that is required. Place the roots in this layer of soil crowns upwards about 6 inches to 9 inches apart all over the box, and fill in with soil made moderately firm to within 1 inch of the crowns. Give a good watering with a coarse-rosed can, leave a few hours for superfluous moisture to dissipate, and then

cover over with a clean mat or cloth of sufficient thickness to absolutely exclude light. The box or boxes may then be stood under the stages, or anywhere out of the way in a warm house, taking care, however, to see that water does not drip among the plants when growth is taking place. With a temperature of 50° the crop of white crisp leaves will be ready for cutting in about four weeks, less time being required for producing a crop the nearer we get to spring. A succession is easily kept up by filling a fresh box every nine days. A second crop of leaves is sometimes secured from the same roots after the first batch has been gathered, but unless the supply of roots is short this course is not advisable. It is also unwise to use the same soil for more than one batch of roots. Plants for forcing can occasionally be obtained from local nurserymen.

## RIVIERA NOTES.

*ROSA SINICA ANEMONE* is flowering in this month of December as freely and finely as if it were spring. When young it hardly ever showed a winter bloom, but each year it has proved a better autumnal till this year, when it has far exceeded its previous performances. It is flowering almost entirely on the older side shoots, while the long new summer growths are reserving themselves for the true spring. It seems probable this season that there will be no cessation of bloom all winter.

*Rose Noëlla Nabonnand* is another winter-blooming Rose of great beauty and freedom in sunny situations, but it requires plenty of space for its vigorous shoots, and summer-heat and drought to ripen them. Its rich velvety crimson petals and its remarkably powerful scent make it quite indispensable on a pergola near the house, where its colour can be seen and its fragrance felt. As a cut flower it is not so satisfactory.

*Nerine Manselli* has, I fancy, been raised in Japan as well as in England, for I got from Japan under the name of *Nerine tardiflora* a late flowering sort, which on blooming proved undistinguishable from *N. Manselli*, although slightly more vigorous in every respect. This has proved most useful as a hardy garden plant whether in pots or in the open ground, multiplying and flowering in December each year most abundantly. A plant that seems as if it would take care of itself, and when in quantity would be admirable as a cut flower.

*Acacia podalyriifolia*.—This pretty winter-blooming shrub or small tree, which has been adopted as the badge of Queensland, opened its first fluffy lemon yellow balls very early in December, and promises to continue a long time in flower. When better known it must prove a great favourite, as even on this coast a shrub or tree that is in fullest flower in December and January, and is, moreover, frost-proof to an unusual degree, is something that approaches to the impossible. Like its near relative *A. cultriformis*, it is a lime hater, and likes a dry soil; but grafted on the ubiquitous *A. floribunda* it will grow on all soils on this coast. Its very glaucous or silvery foliage and the abundant clusters of flower are quite fairy-like on a young plant. I wonder if it will prove useful as a cut flower, as *A. cultriformis* droops and dies when cut under any conditions. Should it prove fairly lasting in water, it will entirely displace any other winter-flowering *Acacia* and prove a plant for every garden.

*Bignonia venusta* is already in great beauty before the first breath of winter is felt. It is not seen or grown as much as it deserves, perhaps on account of its thin and straggling growths, but when allowed to run wild and clamber through Bougainvillea or any other vigorous and leafy climber it is a beautiful thing, and one, moreover, that stands 5° of frost without harm on a dry south wall.

*Thumbergia laurifolia*.—To my surprise this tender climber has survived the frosts of the last

two severe winters, though cut down to the ground each year. This seems to be the best way to grow it, for certainly the finest plant I know was apparently lifeless till last April, and now it covers a very large space on a south wall and is smothered with its lovely lavender flowers and handsome foliage, which would soon suffer if cold came. But if it can be cut down and cleared away at once without suffering when unsightly, it is a plant that should not be left out by those who come out before Christmas and enjoy their early winter flowers. An old and nearly-forgotten shrub of much beauty just now is the Cape Evergreen,

*Eriocephalus capensis*.—Its abundant heads of white Daisy-like flowers, with dark purple centres, are most attractive at this Christmas season, and later on, when the white petals die, the purple centres fluff themselves out into white woolly balls, which at a distance give the effect of flowers for several months. Like many Cape plants and shrubs, it needs a dry and sunny bank, otherwise it does not flower freely, and soon perishes from a frost when well wetted. Nevertheless, no garden in these parts should be without it.

*Clematis balcarica* is another pretty December flowering plant of great charm and freedom. As it is very hardy it may be placed in a cool and shady position where it can climb either among other shrubs or up a pole, where its pretty creamy white bells and finely-cut foliage will show to great advantage during the months of December and January. Like the *Eriocephalus*, its seed-plumes are silvery and persistent, so that it keeps ornamental till quite late in the spring.

Nice.

EDWARD H. WOODALL.

## TREES AND SHRUBS.

### DECIDUOUS TREES AND SHRUBS WITH WINTER BEAUTY.

ALTHOUGH during the winter months the majority of our deciduous trees and shrubs present their worst appearance, the leafless period has certain redeeming features. In the case of large trees, for instance, the outline of trunk and branches is hidden throughout summer by the leaf canopy; but during winter it is fully apparent, and is often very striking. Then in the case of trees that shed their bark, such as the Planes, the peculiar patchy appearance of old and young bark is seen to advantage during the leafless period.

The best winter effect is, however, produced by those trees and shrubs that have bright-coloured bark, and many of these are so beautiful that they are planted extensively solely for their winter appearance. With no great effort of memory we can recall very effective features on bright wintry days produced by the reflection of red and yellow-stemmed Willows in the water of lake or stream, or, again, by the silver trunks of the Birches standing out among the dark browns of Oak and Elm.

In addition to these there are, however, a large number of other plants equally effective. In the case of many plants the colour is most brilliant on the past season's wood, and when they are grown specially for their winter beauty this fact is taken into account. With such things as Cornuses and Willows the method of culture adopted to obtain the most satisfactory results is to plant them in masses in rich ground, and cut them down to the surface of the soil annually just as the young shoots begin to push in spring. This ensures a constant supply of strong young shoots without the darker and heavier effect of old branches. The colours most prominent during winter-time are red, yellow, green, brown and white. The best reds are furnished by the Dogwoods (*Cornus*), *Berberis* and Willows (*Salix*). Of the *Cornus C. alba* and its varieties *Baileyi* and *stolonifera* are the best.

As the types of these are not of any decorative value during summer, people who wish for shrubs with both winter and summer beauty should select the gold and silver variegated varieties of *C. alba*. The best of these are *Spæthii*, with golden variegated leaves; and *elegans*, with silver marked foliage. *Berberis virescens* is an effective shrub, the young wood being of a pretty red hue; it does well as a large bush without an annual cutting back. The red-stemmed variety of *Salix alba vitellina* is an excellent shrub for marshy ground, its branches being very bright. Among the *Roses* several sorts are notorious for their bright stems, two very conspicuous ones being *Rosa alpina* and *Rosa sericea pteracantha*; the latter is of recent introduction, and is chiefly conspicuous by reason of its enlarged bright red spines.

### YELLOW-STEMMED SHRUBS

are furnished by *Salix alba vitellina* forms, varieties of *S. fragilis* and a yellow-barked variety of *Cornus stolonifera*. Green stems are prominent in the *Cytisus* and *Genista* families, *Kerria japonica* and the *Ephedras* being also noticeable. Perhaps the best of the bright green-barked shrubs is *Lycocateria formosa*; this forms an excellent shrub for cutting back. Among the browns are several shrubs that are also very prominent as flowering plants. One of the very best is *Lemoine's Philadelphus*. This grows 2 feet to 3 feet high, and if cut back as soon as the flowers are over, strong young shoots are formed, which are effective for many months. Other *Mock Oranges* are also effective; in fact, all the species have bright-coloured bark. In addition to these, brown bark of various shades is produced by the various *Deutzias*, *Forsythia suspensa*, some of the *Ribes*, *Spireas*, *Rubus spectabilis*, &c.

### WHITE-STEMMED SHRUBS

are fewer in number, and the *Brambles* (*Rubus*) are possibly the most prominent. Such as *R. occidentalis* and *R. leucodermis* are effective, but they have to give place to *R. lasiostylus* and *R. biflorus*. Both these have quaint white stems, which have the appearance of having been whitewashed; in fact, the latter is known under the common name of White-washed Stemmed Bramble. Both of these should have the old stems removed as soon as new ones begin to grow, and it is essential that they should be given rich soil to secure robust growth.

Glancing at trees we find, in addition to the common Silver Birch, several others with silver trunks, notably *Betula ulmifolia* and *B. Ermanni*, *B. papyrifera* (the Paper Birch) is also a remarkable tree by reason of its reddish brown bark, which is constantly peeling off. Several of the Maples are remarkable, as their trunks are prettily striated with white. Two notable ones are *Acer Veitchii* and *A. Pennsylvanica*. A beautiful variety of the latter has recently been introduced under the name of *erythrocladum*; its special feature is its brilliant scarlet bark. The golden-barked Ash is an effective tree when denuded of leaves, all the young wood being of a golden colour. It may be had in two forms, one of upright growth and the other of weeping habit. Another beautiful effect is noticeable in winter by the

### BRIGHT FRUITS

of some deciduous trees, which are retained for a considerable period well into the new year. The Siberian Crab is very noticeable, as also is the Washington Thorn. Other Thorns, such as *Crataegus cordata*, *C. mollis*, *C. Carrieri*, *C. Douglasii* and *C. Crus-galli prunifolia* retain their fruit for a long time. Some sorts of *Roses* hold their fruits very late, as also do several *Cotoneasters*. As most of these fruits are bright red, scarlet or yellow they are very beautiful on bright days. A few deciduous shrubs open their blossoms during January, the various *Witch Hazels* (*Hamamelis*) for example, the *Mezerium* (*Daphne Mezereum grandiflorum*), winter-flowering *Honeysuckle* (*Lonicera fragrantissima*),

winter-flowering Jasmine (*Jasminum nudiflorum*) and the Winter Sweet (*Chimonanthus fragrans*) being the best.

With these subjects at hand it is not difficult to imagine that a garden may be made bright and cheerful with deciduous shrubs, even during the winter months. W. DALLIMORE.

### THE SHRUBBERY.

It will improve the general appearance of the garden if all dead leaves are removed from under trees and shrubs and the surface of the soil left clean. Recently-planted trees should be examined and where necessary new supports given them. In digging among the shrubs care should be taken to avoid damaging the roots. All dead branches should be cut from trees and shrubs, and if the growth is too crowded, remove with a sharp knife some of the branches. Established shrubberies which have become so crowded that no room is left for further development should be carefully gone through and the worst or least interesting plants entirely removed. This will allow space for the remainder to grow into handsome specimens, whereas if all are left the result in a few years will be an uninteresting wilderness.

Choice varieties of trees planted during the autumn should be given a mulching of strawy manure. This will protect the soil about the roots during severe weather, and by maintaining an even temperature of the soil new root-action is promoted. If in an exposed position, or the appearance of the manure is an objection, cover this with a layer of soil. As a pillar plant the yellow winter-flowering Jasmine is very striking when judiciously planted in the shrubbery, particularly when viewed from a distance. Tender subjects should be afforded protection when severe frost threatens. A neat protection for medium-sized shrubs may be arranged by enclosing them with wire netting. Place a layer of leaves around the roots and finally thread branches of some evergreen through the meshes of the wire. C. RUSE.

### ORCHIDS.

#### ONE OF THE MOST EASILY GROWN ORCHIDS.

(*CYPRIPEDIUM INSIGNE* AND ITS VARIETIES.)

**D**URING the last ten years the varieties of *Cypripedium insigne* have been greatly improved, and they have become very popular winter-flowering plants. They have much to recommend them, as they are easily cultivated and the flowers last for nearly three months in perfection during the duldest period of the year, and they stand well the injurious effects of fogs. The varieties are very numerous, and many of the finest forms have been raised by crossing two distinct varieties. There is plenty of scope to raise even better forms now that we have got such a noble variety as Harefield Hall to work upon.

#### CULTIVATION.

*Cypripedium insigne* will grow freely in an ordinary greenhouse where a temperature of 55° to 60° is maintained. The plants require plenty of atmospheric moisture during the spring, summer and autumn months, and should never be allowed to remain dry at the root, but they should always approach the stage of dryness before water is applied. Soft water about the same temperature as the house should always be used. From the end of February to October shade them from direct sunlight. Canvas roller blinds are most suitable for this purpose, and they should be raised 6 inches or 8 inches above the glass, so that a current of air will pass between. When the weather is dull these

blinds should be raised, and during the winter months keep the roof-glass clean inside and outside, so that the plants may get all the light procurable. On bright, warm days syringe them overhead, but this should not be done during the autumn and winter months.

#### POTTING THE PLANTS.

The best time to repot them is about the end of February, but this need only be performed every second year if good fibrous compost is used. Clean pots of a suitable size should always be selected, and crocked to about one-third their depth with clean crocks. Before placing the plant in its new pot, pick away all the decayed compost and cut off any dead roots that may be present.

#### SOIL.

The most suitable compost or soil for the purpose is two-parts good fibrous loam, one-part fibrous peat and one-part chopped sphagnum moss. Mix the whole well together and add a quantity of finely-broken crocks and a liberal sprinkling of coarse silver sand. Spread the roots out in the new pot, and press the compost moderately firm between and about them to the level of the base of the plant, which should be kept a little below the rim of the pot. Great care must be taken with the watering of the newly-potted plants. Until they become established they should be allowed to get moderately dry between each watering. Syringing between the pots should be done morning and afternoon, and damp the floors and stages as often as may be necessary to keep the atmosphere well charged with moisture.

#### PROPAGATION.

The usual way to propagate is by division of growths, and this should be done when they are turned out of the pots. Old flowered back growths will readily break if cut away from the plants with some roots and potted up separately. Many of the choice varieties, such as the beautiful yellow *C. insigne* Sanderæ, have been raised from seed. The seed takes about a year to ripen, and then it should be sown on the surface of newly-potted plants. It is a good plan to sow the contents of one capsule over the surface of several old plants, because the conditions on one pot are not always suitable for the seed to germinate, whereas in most cases the seed will germinate on one or more pots. These seedlings should be pricked off as soon as the second leaf is about a quarter of an inch long, and three or four should be made secure in small seedling pots in finely-chopped soil of equal parts fibrous loam, peat and sphagnum moss, with coarse silver sand added to keep it porous. These seedlings should be grown on in a temperature of 65° if possible, and, as soon as the plants are strong enough, they should be potted singly in small pots. Never allow them to get dry, but, on the other hand, if they are always kept saturated they will make very slow progress. It is quite easy to keep them moist by allowing them to become moderately dry before applying water.

#### INSECT PESTS.

The worst insect pests to *Cypripediums* are thrips and red spider; the former will soon spoil a batch of seedlings and check the old plants if they are not destroyed. This is easily done by fumigating about every second or third week with XL All or other good compounds. The plants should also be sponged occasionally with weak insecticide, in order to make them look presentable.

#### VARIETIES OF *C. INSIGNE*.

Some of the finest spotted varieties are Harefield Hall, montanum magnificum, holfordianum, berryanum, James Renwick, Aberdeen, E. Ashworth, Amy Moore, montanum anreum, Al. majestica, Victor, and Monk's Hood. The yellow varieties consist of Sanderæ, sanderianum, Dorothy, Laura Kimball, cobbiana, Amesia,

Johnsonæ, Chantini Lindenii, Ernesti, Balliæ and youngianum superbum. The majority of the above may be obtained from most of the Orchid nurserymen and are well worth cultivating.

W. H. PAGE.

#### Chardwar, Bourton-on-the-Water.

[Visitors to the December meeting of the Royal Horticultural Society will not easily forget the magnificent group of *Cypripediums* and other Orchids which came from Chardwar. No finer group has ever been seen before in winter.—Ed.]

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Carnation leaves diseased (*S. H. C.*).

The disease is of a fungoid nature and commonly known as "spot." As a rule, it is most prevalent and troublesome in those instances where the surroundings are too damp or cold. Plants in a closed or poorly ventilated frame would be especially susceptible to the disease, and in those instances where a frame is necessary the lights used for covering should never be closed down, but used merely to throw off the wet. Light and air are among the chief enemies to such pests as these, which are more easily kept at bay by these means than eradicated once they obtain a footing. If your plants are not near the glass place them there at once by standing them on pots, as in this way abundance of air will be circulated about them. Remove all the affected leaves and burn them; and, finally, dust a little black sulphur over the plants. Keep the frame-lights constantly raised, so that while a free circulation of air is admitted stagnant air is impossible. No water at the roots should be given until the plants are perfectly dry. The surface soil of the pots may be stirred occasionally with advantage.

**Herbaceous border (*O. C. C.*).**—We think the *Pæonies* would do well under the circumstances you name, but you do not give the width of the border, and we are, therefore, precluded from giving you a definite list of suitable subjects. Frequently a border facing north is a most valuable one, and with due cultivation we should not hesitate to plant the *Pæonies*, *Michaelmas Daisies*, *Heleniums*, *Sunflowers* of many sorts, *Trollius*, *Lenten Roses*, *Megaseas*, *Spiræa*, *Aruncus*, *Astilbe Davidii*, a great variety of herbaceous *Phloxes*, the entire group of *Flag Irises* with many species of the same family, *Oriental Poppies*, many kinds of *Lilies*, the bolder sorts of *Primula* as *P. Sieboldi*, *P. japonica*, *P. rosea*, &c. Any of the *Peach-leaved Campanulas* would do quite well, and there are others of equal worth. It is always best in the case of *Pæonies* and other things that are slow to establish that good plants be procured at the start. Are you convinced that the border receives the best cultivation, as it is unfortunate so good a border is not well planted? Did we know the width and other particulars as to the cultivation of the soil, we might assist you more definitely.

THE NEW SWEET PEA  
SUTTON'S QUEEN.

but some would choose *Syringa* (so-called), Apple blossom, Lime tree blossom, Almond, Acacia or the budding Larch. We do not put the scents in order as they come, but as remembrance conjures them. Of sweet-smelling shrubs among the most delectable is the old-fashioned red Ribes, with its strong Black Currant smell and taste, so pungent, so irresistible, that one cannot pass it without rifling the bush of just one leaf to play with.

#### SCENTED FLOWERS OF SUMMER AND AUTUMN.

Quite different in quality from flowers of spring are these. Roses, of course, come first, for they give us both scent and beauty as a rule, with equal generosity. Everyone loves Roses, and no one needs to be reminded of them, but there are fragrant annuals that are sadly neglected. Numbers of people omit sweet white Alyssum when they are making out their seed lists. It is sweet as honey, smelling very much like it, and goes on blooming till November. Stocks, Mignonette, Sweet Peas, Sweet Sultan and Sweet Scabious are in fairly common use; not so the aromatic herbs, however, many of which are well worth growing for their perfumes, either sweet or aromatic. Woodruff is a plant that might often be given a place, for the sake of the new-mown-hay-scented foliage that so prettily sets off its starry white flowers. And in early summer who can have too many beds of Lilies of the Valley or too many clumps of damask and pink Carnations, of the common Pinks, Heliotrope, Sweet Williams, Woodbines, clustering white Clematis, Southernwood, Lavender, Cottage Lilies, Day Lilies, Meadow-sweet, Sweet Cicely, Heart's-ease, Musk and best of all as regards fragrance the Lemon Verbena? All the sweet-leaved Pelargoniums, too, so out of fashion now, that we must never forget to take our own cuttings, for florists seldom keep them. Magnolia should have a west wall and Rosemary a south one. Honeysuckle and Jasmines should wreath the windows, intermixed with climbing Roses. Then when the summer wind blows in there will be scented draughts. What more delightful?

#### THE GARDEN OF SWEET-SCENTED FLOWERS AT NIGHT.

The hot day over and the western sun gone down, how happy then the flowers of night—moon-flowers, as some have called them. At dusk the Invisible must hold sway. We wander down the shadowy garden paths and cross the dim and fragrant lawns. All the dumb flowers have now found voices. The Evening Primrose opens out, the double white Rocket remembers his old message, and the Night-scented Stock says gently, "I am here!" Honeysuckles breathe out a richer fragrance and hawk-moths quaff deeply from their delicate drinking-horns; Nicotianas (please keep to the white ones) pour forth heavenly scent that does not in the least suggest Tobacco. Some of us have built castles in the air about having a special garden all of night-scented flowers; the Night-blooming scented Cactus is enough to tempt anybody, but really it is better that we should dot the flowers about in careless fashion and let them take us by surprise, like children who hide their treasures and then forget them on purpose, to have the pleasure of finding them again.

#### THE HEALTHFULNESS OF THE SCENTED GARDEN.

Floral and leaf odours are antiseptic, the essential oils of Rosemary, Lavender and Eucalyptus being among the most efficient. Perfumes made from flowers possess special health value. Why not scent cures? To smell Sweet Briar, they say, makes anybody cheerful. The perfume of a Rose will often take away a headache, and any scent in which Rose is the principal ingredient is highly tonic and invigorating. Lavender has similar refreshing qualities, and flowers of delicate perfumes soothe the nerves of invalids. "A Rose garden is no place for grief," said Sadi of old.

FRANCES A. BARDSWELL.

Mundesley, Norfolk.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 14.—Royal Horticultural Society, Meeting of Committees, 12 noon; Horticultural Club, 6 p.m., lecture by Mr. E. A. Bunyard.

January 18.—French Horticultural Society's Annual Dinner, Mr. H. J. Veitch in the chair.

**National Sweet Pea Society's Annual and Schedule.**—We are requested to notify our readers that the above interesting Sweet Pea publication will be sent free to members about the 16th inst.

**National Sweet Pea Society's trials.**—The following circular is being sent to members of the National Sweet Pea Society who are raisers of new varieties: "My committee propose holding a further trial of Sweet Peas at the University College Gardens, Reading, during 1908, and I shall therefore be very glad if you will assist us in making these trials as complete as possible by sending seeds of new Sweet Peas you may be distributing in 1908, or are getting forward for distribution in 1909. I need hardly add that the trial will be an absolutely independent one, and under the able management of Mr. Charles Foster. Not fewer than fifteen seeds of each variety should be sent, and they should reach Mr. Charles Foster, Assistant Director in Horticulture, University College, Reading, on or before January 14th, 1908. You will greatly oblige by indicating the colour section to which each variety belongs, whether it has waved or plain flowers, and whether you would care to have it tested by the side of any standard variety. This information should be on a separate sheet of paper, and a duplicate copy sent to me will further facilitate matters. My committee does not propose to make a charge for these trials, but suggests that a donation be sent to the honorary secretary to help defray their cost. The trials conducted in 1907 necessitated considerable expenditure and this was defrayed chiefly by private donations. No awards to new varieties will be made at the society's exhibitions in 1908; awards of merit or first-class certificates will be granted only to meritorious varieties tested in the society's trials at Reading. The value of these trials to all raisers and growers is so great that I trust you will kindly render whatever assistance you can."—CHARLES H. CURTIS, *Hon. Secretary.*

**Pear President Barabe.**—A dish of this Pear was submitted for the inspection of the fruit committee at the Royal Horticultural Society's Hall, on Tuesday, the 31st ult., by Mr. Allen of Gunton Park Gardens. Were it not that it had previously obtained a first-class certificate from the society one would have been granted to it on this occasion, as the committee were unanimous in their estimate of its great excellence from all points of view as a Christmas dessert Pear. In size it is moderate to large, of a deep golden colour, flesh melting and juicy and the flavour exquisite. Provided the variety is hardy, of free growth and a good bearer, then it ought to find its way into every garden.

**Seeding of the English Elm.**—The December number of the *New Bulletin* contains an interesting account of the seeding of the English Elm (*Ulmus campestris*), at Terling Place, Essex, the seat of the famous scientist Lord Rayleigh. Although some little doubt appears to exist as to the identity of the Terling Elms, the official description being that it "appears to be *U. glabra* with a certain leaning towards *U. campestris*," the fact of the trees producing fertile seeds was established beyond doubt. This is the first recorded instance of the English Elm producing fertile seeds in this country, but other instances may have occurred, and possibly have been noticed, without being recorded. It would, of course, be more interesting still could the trees have been declared the

true *U. campestris*, but possibly some of our readers will look out for seeds and seedlings in the future.

## PRIZES FOR READERS.

### DECEMBER COMPETITION—AWARDS.

In this competition readers were asked for essays on a garden of sweet-scented flowers. The prizes are awarded as follows:

The first prize of four guineas to Mrs. Frances Bardswell, Meadow House, Mundesley-on-Sea, Norfolk.

The second prize of two guineas to A. W. Podger, 1, Forest View Avenue, Whippis Cross, Leyton.

The third prize of one guinea to Miss Hopkinson, Sutton Grange, Wansford, Northamptonshire.

The fourth prize of half-a-guinea to Mr. James Pounsett, 22, Naunton Park Terrace, Cheltenham.

This was an exceedingly popular competition, the number of essays sent in being very large indeed, and all were of high quality.

These from the following, which we highly commend, were little inferior to the winning papers: Miss E. P. Martin, C. W. Caulfield, Thomas Gough, H. Rowles, A. L. Simpson, E. I. Lloyd Edwards, Miss Beatrice A. Hinton, P. Reid, W. H. Walters, Frank Lee, V. H. Lucas, W. A. Cook, W. L. Lavender, James Rae, J. Morton, H. Tomalin, R. McHardy, E. Montague, E. F. Davis, Arthur J. Cobb, T. E. Newman, S. Gordon, Major W. P. Bunbury, Mrs. E. Gaye-Hodge, Miss E. A. Patch and W. R. Dykes.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

### Chrysanthemum Mrs. J. Hygate.

In referring to the certifying of this new Chrysanthemum as an incurved variety, Mr. Crane does not tell his readers that the introducer catalogues it as belonging to the Japanese section, and believes it to be none other than a true Japanese of the incurving type. As far as I have seen all catalogues so class it. Such action by the central body, to which inexperienced persons look to for guidance, cannot be other than misleading. No person with any knowledge of a true Chinese Chrysanthemum could say this newcomer belongs to that type at all. Such a misleading example of using power cannot do other than place the floral committee in a sceptical position with those who do know how a flower should be placed in its proper section. Being at the close of the season the bloom produced from a later bud would be neater than earlier in the season, naturally, and to those of inexperience this error could have easily been made. Those who saw the variety at the November show at the Crystal Palace knew quite well to which section it should belong. Now that especial care is needed to keep an interest in the incurved section, such action by the central body is distinctly of a retrograde character.—E. MOLYNEUX.

**Apples for flavour.**—The letters which have appeared in THE GARDEN on the best six Apples to grow for a small garden have been very interesting. I think it would also be both interesting and instructive to have the various opinions of growers on, say, twelve of the best dessert Apples to grow for flavour, with particulars of each as to growth, cropping and faults.—I. M., *Leominster*. [We shall be delighted if our correspondent's suggestion is taken up by fruit growers.—ED.]

**Maidenhair Fern fronds eaten.** I suffered very severely from the above cause in the case of a house of *Adiantum cuneatum*, thousands of small transparent slugs inflicting the mischief. Orange peel laid among the plants

proved the remedy, the plants being well furnished with fronds again. I have no doubt if your correspondent will apply the same he will soon see his plants perfect again. Orange peel in the case of slugs of any kind is an excellent trap, both in plant houses and out of doors.—FREDERICK PERKINS.

**Hydrangeas.**—As I have read several letters about these shrubs in *THE GARDEN* lately, I am sending you a photograph of some that I have growing close to our church at Manby in Lincolnshire. This parish is about five miles from the sea, and the plants are growing in the corner between the buttress and wall of the church facing the south. Several of these plants every year have more than 100 heads of blooms on them, and they are about 7 feet high. I give them no protection whatever during the winter, and I do not water them at all in the summer (there being a spout above to carry the water from the roof), so that they are often in the summer very dry. To the best of my knowledge these plants are at least forty-five years old. I only cut off the dead flowers in the spring, just cutting them back to the first healthy and strong bud below the old flower. They are quite the admiration of people who see them.—(Rev.) F. D. HALL, *Manby Rectory, Louth, Lincolnshire.*

**Dividing Daffodil bulbs.**—I think much more remains to be said on this subject than appears on page 624 of *THE GARDEN*, Vol. LXXI. From the remarks of your correspondent "W. A. W." concerning the "embryo roots," and others to the same effect, it would appear that division, where this was necessary, was left much too late in the season. One notices, too, that root fibres are indicated on both the mother bulb and the offsets in the sketch accompanying the note. If this is really so, and the whole tenor of the note in question is well in line with the illustrated bulb, there is ample room for the remark that the operation has been performed at too late a date. Daffodils may be divided too early, to the detriment of the offset, and the same work may also be done too late, to the detriment—i.e., the subsequent progress—of the offset itself. Quite early in the Daffodil-lifting season of 1907 some Daffodil bulbs reached me displaying obvious injury to the basal seat of the bulb with the enquiry how the injury could in future be avoided. The injury in question consisted in the central basal cores being torn completely out of the offsets, and was due in its entirety to the undue haste and impatience—possibly not a little ignorance—of the operator. In the instance referred to the bulbs had clearly been lifted too early from the soil, and an attempt made to separate bulbs not reasonably ripe for the operation. These circumstances combined to an unsatisfactory result generally, and in the case of a rare variety would mean considerable loss. Taken at the right time such a bulb as the one depicted on page 624 could by finger and thumb be divided with the greatest of ease. Indeed, in a large number of varieties properly dried it would only be necessary, assuming the bulbs to be in a small heap, to rub the hand over the bulk to bring about separation of the most perfect kind. In no case should there be any attempt at separation so long as the offset is contained within the tunics of the mother bulb and these tunics remain unbroken. Attempts at separation at such a time are calculated to result in injury all round unless the work is being performed by an expert. Some varieties, more particularly if left in the soil, will reach the double or treble-nosed stage without revealing the least inclination to separate naturally. Other varieties, similarly situated if not actually separated, reveal a number of flatish or wedge-shaped members that only require the exposure consequent upon lifting and drying off to give them the freedom the soil has not permitted hitherto. The difference of varieties is considerable, however, hence the need for definite references thereto.—E. H. JENKINS, *Hampton Hill.*

## THE FRUIT GARDEN.

### RENOVATION OF OLD FRUIT TREES.

**D**URING the winter months in old gardens and orchards the question as to whether an old fruit tree is worth retaining or not is almost sure to crop up, and often, one fears, remains unanswered until the rushing work of the spring months detracts all thoughts from the subject. In the case of Plums little can be done in restoring vigour to an old specimen; but with Apples, Pears and Cherries good results may, with judicious treatment, be obtained from an old tree that has hitherto been regarded as a veritable lumberer of the ground. If it is decided to retain such a tree, the first operation must be to set about thinning its branches, cutting out all old worn-out wood and retaining only that which is of comparatively young formation. If it is a wall tree that is being dealt with, it may be, and often is, a good plan to remove entirely all the old spurs and depend upon the new shoots that will be produced for supplying a new set the following year. This will, of course, mean that no fruit

together and used at the rate of 4oz. per square yard. Top-dressings, whether of natural or artificial manures, should always extend from the stem of the tree to the outermost spread of the branches.

Liquid manure is often available in large quantities during the winter months, and much of it is often wasted. These old trees that are undergoing renovation will be enormously benefited if holes 18 inches deep and 18 inches apart are made among the roots by means of a crowbar or similar implement, and then frequently filled during the winter with the liquid manure, it being well nigh impossible to apply it too strong. In the spring the holes may be filled with good soil rammed firm. Old wall trees are especially amenable to this liquid manure treatment.

### BRADLEY'S KING OF DAMSONS.

FEW Damsons are equal to Bradley's King, and as regards quality, I give it first place. Damsons are not often grown for dessert, but this is excellent, being sweet though of a brisk flavour, and if left late on the trees the fruits are delicious, very juicy, and hang a long time. It may be

A BEAUTIFUL HYDRANGEA GROWING IN MANBY CHURCHYARD, LINCOLNSHIRE.

will be produced next summer, but the tree will benefit materially by this lapse.

After pruning must come a cleansing process, every scrap of rough bark, moss and lichen being removed. If much is present it will be necessary to use an iron scraper of some approved pattern, afterwards washing or spraying the stem and branches with the winter caustic wash now so well known, or else the still efficient and perhaps better-known dressing of quite fresh lime. If the tree is standing in an orchard and grass has been allowed to grow right up to the stem, the turf should be removed from an area corresponding with the spread of the branches, lightly forking over the soil afterwards. Where natural manure is available, it will do an immense amount of good to old fruit trees of any kind if a little of the surface-soil is removed from over the roots and replaced with a 6-inch thick layer of well-decayed stuff. But natural manure is not always to be had, and we must then fall back on artificials, excellent results having been obtained by the use of the following mixture used as a surface-dressing early in February: Four parts nitrate of potash, six parts superphosphate, three parts basic slag, three parts sulphate of lime and three parts nitrate of soda, the whole well mixed

termed a medium-sized fruit, and the tree is a great bearer; indeed, it is one of the best in this respect, and well worth the attention of amateurs who only have small space and require the best. Young trees soon bear, and as the fruits in a favourable season mature and ripen from early October or earlier in light soils, it should find room either for the dessert or cooking. It grows freely, and should, if possible, be planted in the open, at least not too much shaded by other trees. Grown thus, it rarely fails. Even when other stone fruits are barren in many localities, it is known as the King, and is a great favourite; it makes a delicious preserve. G. WYTHES.

### RASPBERRY PROFUSION.

I HAD this excellent variety on trial this season for the first time, and was surprised to note its excellence in a poor soil and in anything but a suitable position. Profusion differs from many others as the plant has such robust growth, and this in a poor fruit soil is a great advantage. It often happens that Raspberry canes do not thrive in some gardens as one would wish, and here I would advise a trial of the above, not only on account of its fine growth, but its admirable

fruiting qualities. It is rightly named, being a free and constant bearer and of rich flavour. To do it justice, the plant should have ample room on account of its vigorous growth. As this is the season for planting, I feel sure amateurs would do well to give it a trial, first well trenching or double digging the land and manuring, and by early planting secure a strong growth next season. W. M.

## HARDY LADY'S SLIPPERS

(CYPRIPEDIUMS.)

THE hardy Lady's Slipper Orchids are a puzzling group to grow, and although much has been written about them in recent years real successes in their cultivation are few in number. So far as one is able to judge neither the plants nor the climate are wholly responsible for the failures—such responsibility is shared by the collector, the vendor and the planter. The collector is none too careful in gathering his plants without serious injury to them, the vendor is not always successful in his methods of storage before sale, and the planter expects too much from his specimens in their first season of growth, without having due regard to the tax on the plant's powers of endurance in its transit from its native home to the planter's garden. "More consideration" appears to be a necessitous plea for the hardy Slipper Orchids, and the time has arrived for it to be put into practice. The supplies are already precarious, the difficulty in collecting such increases year by year in the ease of the better kinds, and there are rumours of restrictive legislation in at least one State wherein these plants abounded but now occur gregariously or in isolated examples in inaccessible places. Propagation by severance of the rhizomes may be practised with old-established plants without disturbance till the severed portions make crowns, and *C. humilis* makes offsets freely where it thrives till ten to twenty crowns are aggregated; such clumps are common in a wild state but rare in cultivation.

Preparation of the crowns and roots should be thorough. Dead particles of root and rhizome are best removed, even if only a few roots and the crown remains. If the stems flower and the plants that result appear weakly at the time, the flowers should be removed immediately or before they develop, the leaves being encouraged, by shading or watering if necessary, to remain on the plant as long as they will, for it is upon the duration of these that the establishment of the plant mainly depends, the new crowns and the wig of roots surrounding each being developed by the leaf action alone—no active roots ever survive collection. With the new crown and the wig of roots developed care practically ceases, for the plants are then able to help themselves, and provided they have the kind of soil and degree of moisture we know each species requires, and some shade for the bog-loving species, there is nothing that should interrupt the steady growth into clumps of which the gardener may be proud.

The group readily divides itself into two races. *C. humile*, *montanum*, *macranthum*, *guttatum*, *Calceolus* and *californicum* prefer loam freely mixed with sand, and they prefer conditions altogether drier than is good for the others. Limestone chippings are of use for *montanum* and *Calceolus*, but they grow just as well without this material if the loam is good. In wet, heavy soils, and particularly in harsh clays, the plants require to be lifted above the general level in order to maintain drier winter conditions.

The second race, comprising *C. arcticum*, *parviflorum*, *pubescens*, *candidum*, *japonicum* and especially *spectabile*, require a root-run of leaf-soil and peat and altogether wetter conditions. One cannot do better than suggest their association with *Trilliums*, *Osmundas*, *Ramondias*, the moisture-loving *Primulaceae* and grassy *Irises*, for where these plants thrive there should be no

difficulty in growing *Cypripediums* if they are carefully nurtured in the first season. Some of the slender growers are excellent for growing in crevices between damp boulders, and especially where such boulders act as retaining walls and are continually moist and shaded; indeed, the many ways in which one can grow hardy Slipper Orchids may be described indefinitely. All the kinds are valuable garden plants, hence there is no need for discrimination between worthy and unworthy types. Most of them are easily procurable, but the rarer forms of Lady's Slippers—*C. guttatum*, *C. japonicum* and the Siberian *C. macranthum*—travel so badly and are so rarely collected that intervals of a few years may elapse between good consignments; these plants one would naturally attempt to grow when fully successful with the less difficult sorts. *C. fasciculatum* I have never been able to learn anything about. M.

(To be continued.)

## CYPRIPEDIUM FAIRIEANUM BLACK PRINCE.

WHEN *Cypripedium fairieanum* caused such a commotion in the Orchid world a few years ago

CYPRIPEDIUM FAIRIEANUM BLACK PRINCE.

not many would have cared to suggest that it would soon become comparatively common, yet such is the case at present, owing to large importations from its native haunts. The first variety of it, named Black Prince, was shown before the Orchid committee of the Royal Horticultural Society on the 10th ult. by Messrs. Sander and Sons, the well-known Orchid specialists of St. Albans, when it received an award of merit. It is a handsome and distinct variety. The dorsal sepal is broader than in the type and is very heavily streaked with almost black crimson. The petals curve downwards, with the ends charmingly reflexed, the colour being greenish streaks on a white ground. The lip is projected well forward and is of a brownish red colour. Doubtless we shall soon be welcoming other varieties of this famous Orchid. Our illustration is from a sketch of the flower exhibited.

## TREES AND SHRUBS.

### A BEAUTIFUL LILAC.

(SYRINGA EMODI.)

AT the time of year when there are but a small number of flowering shrubs left us, among which may be counted the various Dogwoods (*Cornus*), one may sometimes come across a tall, handsome shrub which many would be puzzled to name, and which, indeed, would probably be identified by but few. A most ornamental shrub it is, with bold, dark green leaves and large panicles of creamy flowers, in appearance somewhat like a glorified Privet. It is distinct and noticeable, and is in some parts not very uncommon, yet is, nevertheless, not well known, and when the explanation is offered that this is one of the Lilacs, *Syringa Emodi*, the fact always meets with surprise.

Classed with the ordinary Lilacs and compared with these, which come out in late spring, it would never become popular, for it is not fragrant, nor has it the same profuse beauty of these lovely well-known favourites. Still, it is a handsome and very valuable shrub, flowering as it does so late in the season—the end of June and July—long after the time the Persian and common Lilacs are over and forgotten, and when our shrubberies can boast of but few flowering subjects. It retains its dark, glossy leaves, too, until well into November, and in every sense it is such a desirable addition to our gardens that it seems marvellous it should not be better known. For towns it is excellent, as is proved by the way it is flourishing in various parts of London parks, brightening up many a spot there in late summer, and again, in dull November days, showing its cheerful clean greenery. As a shrub for a dusty roadside garden it is also a good thing to plant, for the leaves do not retain the dust on their surface. It seems to be accommodating also, for I know of some excellent specimens which are growing in the semi-shade of the northern side of a shrubbery, where they are partly overshadowed by trees. When soil and aspect suit it attains the proportions of a very large shrub or small tree. We are at last getting more in the habit of referring to these shrubs as *Syringa*, the name so long and, unfortunately, still rather persistently applied in error to the *Philadelphus* (the Mock Orange). There is no danger that its well-known name of Lilac will ever get forgotten in consequence, although the beautiful old pronunciation of it, "Laylock," has passed entirely out of custom. One cannot but feel a certain regret that this old word has become so altered. E. CURGWEN.

### FOUR GOOD COTONEASTERS.

*C. ROTUNDIFOLIA*.—This is one of the best of the *Cotoneasters* for winter effect, and it is surprising that it is not more often seen, though none of the members of the genus find such favour in the eyes of the planter as they deserve. The above forms a small spreading shrub about 3 feet in height by nearly 6 feet in diameter, bearing bright scarlet berries about the size of a small pea. These are ripe in October, and remain on the shrub until the following March or April, and are rarely, if ever, touched by birds. The leaves are less than half an inch in length, round and of a dark, shining green. They are persistent as a rule, but in a hard winter the majority fall off, turning to a brilliant red before doing so.

*C. frigidula*.—This is a tall-growing kind, attaining a height of 12 feet or more, with long, woolly leaves, glaucous on the undersides, and clusters of scarlet berries borne after the manner of those of the Mountain Ash. Unlike the latter, however, they are rarely interfered with by birds, and hang on the plants during the greater part of the winter. I have found this

plant flower and fruit freely in partial shade even when hemmed in by Laurels, &c., but its greatest beauty is seen when it is in a moderately dry, sunny spot, which is also best for all the *Cotoneasters*, as they are sun-loving plants and do not mind a certain dryness at the root.

*C. microphylla*.—This is a dwarf, creeping plant suitable for the rockery or for training against a low wall. In the latter position it attains a height of 4 feet to 6 feet, with numerous branches clothed with tiny, persistent, dark green, shining leaves and bright crimson-red berries. Its greatest beauty is, perhaps, displayed when it is on a rockery, where its shoots can spread in all directions, clothing the stones with a carpet of glossy green and red.

*C. horizontalis*.—This resembles the preceding in growth and should be planted in similar positions, but it differs in being deciduous and bearing small, bright scarlet berries, which make up in numbers for their lack of size. The branches grow in a flattened fan-shaped manner and the small leaves turn to a bright orange red before falling off.

Bagshot, Surrey.

J. CLARK.

### FLOWERING TREES.

BESIDES the larger deciduous and evergreen trees hardy in this country, there is a considerable number of small trees that are valuable for their flowers, and should be freely planted wherever space permits. None of them attain to any very great size, but all are valuable, both for their free blooming and the ease with which they can be grown. The following list is not at all an exhaustive one, but is merely a notice of the best—those which can on no account be overlooked:

#### HORSE CHESTNUTS (*ÆSCULUS*).

The common Horse Chestnut (*Æ. hippocastanum*) is a well-known large tree in this country, but some of the other members of the family are smaller in growth and equally beautiful. *Æ. carnea* (*rubicunda*) is of hybrid origin, and bears bright red spikes of flowers in late May; but *Æ. carnea* var. *Briotii* is much brighter in colour and quite as easily grown, though it is not often seen. *Æ. californica* is a small tree with erect spikes of white, sweet-scented flowers, opening in May, and *Æ. indica* (the Himalayan Horse Chestnut) is a distinct and handsome tree, which will become popular when it is better known. The blooms are white with yellow and red blotches at the base of the petals, and open in July, when all the other Horse Chestnuts are past.

#### CATALPA.

All the *Catalpas* are handsome garden trees, and have an additional value from their time of flowering, which is during July and August. The commonest of them is *C. bignonioides* (*syringifolia*), which grows to a height of about 30 feet, with a spreading, symmetrical head. The leaves are 6 inches or so long by 4 inches wide, and the flowers are borne on erect, branching panicles, each *Gloxinia*-like flower being over 1 inch across, white, with yellow blotches and purple spots in the throat. *C. cordifolia* somewhat resembles the preceding, but is a larger growing and somewhat hardier tree, with larger panicles of flowers opening rather earlier. Both of these are natives of North America, while from Japan we get *C. Kämpferi*, which is often met with under the name of *C. Bungei*, a native of China, though it is doubtful if the latter is in cultivation. *C. Kämpferi* has yellowish brown flowers with purplish spots, but it is not so handsome a tree as the North American species. A hybrid between *C. cordifolia* and *C. Kämpferi* was raised some years ago by Mr. J. C. Teas in America, which bears white flowers with yellow and purple markings in enormous panicles much larger than any of the species. This hybrid is of strong and vigorous growth, and it is surprising it is not oftener seen.

Bagshot, Surrey.

J. CLARK.

(To be continued.)

## THE FLOWER GARDEN.

### WATSONIA O'BRIENI.

THE *Watsonias* are natives of South Africa and are beautiful bulbous plants, somewhat *Gladiolus*-like in appearance. In the colder districts they must be used for conservatory decoration, or, if they are planted out, must be lifted when the foliage dies down. In the south-west, however, they may be grown permanently in the open, though, when so treated, they rarely flower annually. The first white *Watsonia* was discovered by a man in the employ of Mr. Upjohn, a nurseryman of Rondebosch, near Cape Town, growing on the slopes of Table Mountain. The produce of this bulb eventually became the property of the Curator of the Botanical Gardens at Port Elizabeth, who passed them on to Mr. O'Brien, by whom they were distributed as *Watsonia* O'Brieni. After the lapse of a little time, Mr. H. M. Arderne of Cape Town, a most enterprising horticulturist, found a white *Watsonia* near Worcester, about eighty miles distant from Cape Town.

This bulb was propagated from and the produce sent out under the name of *Watsonia* Ardernei, but as *W. O'Brieni* and *W. Ardernei* are both white varieties of *W. iridifolia*, they are, needless to say, identical. However, they are still catalogued as distinct, and are quoted at different prices. There is no doubt that these white *Watsonias* should be known as *W. iridifolia alba* and not by their present specific titles. I myself, many years ago, found a white *Watsonia* in the Knysna district of Cape Colony, far distant from where *W. O'Brieni* and *W. Ardernei* were discovered, and intended to secure it on my return, but was, unfortunately, unable to visit the spot again. The flower-spike shown in the accompanying illustration was almost 6 feet in height and bore over fifty blossoms. The largest leaf was 4 feet 6 inches in length and 2½ inches in breadth. One thing against this *Watsonia* is that it produces its foliage in this country at the same time as it does at the Cape, namely, the autumn, which corresponds to the South African spring, while the flowers are several months later in their appearance. W

rosea, on the other hand, conforms to our seasons, its leaves dying down in the autumn and reappearing in the spring. If *Watsonia* O'Brieni would follow its example, instead of holding its leaves through the entire winter, it might prove a more consistent bloomer. Some writers affirm that wet is fatal to the corms, but, though the winter rainfall in Devon is heavy, my unprotected plants are perfectly healthy, and Mr. Arderne found his plant growing in "a boggy marsh," while the one that I discovered was in low ground close to the brink of a river.

South Devon.

S. W. FITZHERBERT.

### THE AMATEUR'S LAWN.

In the majority of cases on taking a residence the amateur gardener, who of all things wishes to have a smooth perfect grass lawn, usually finds either one-half weeds or coarse grass and very uneven or, perhaps, one quite worn out, starved and mossy.

To purchase new turves and thus recast the lawn is out of the question—the cost is too great. Still, so far as reasonable cost is concerned it will be willingly met. What, then,

WATSONIA O'BRIENI.

is the best course to take? Patching does little good and too often leads to great irregularities of the surface. It may be well where an old lawn is not too weedy to have every possible weed extracted and very much of the coarser grasses, then to give the whole lawn a top-dressing of fine gritty soil, with which is added soot, basic slag and wood ashes, all screened, then well raked in to fill all holes and level up irregularities. But even in such case it is important the soil used should not be from a weedy surface, as if so it will assuredly contain weed seeds in abundance. If it be found that is so, the only course is to allow all such seeds to germinate in the early spring, and as soon as high enough cut them down or pull them up, thus leaving the dressing clean for the pasture seed sowing, which may be left in such cases till the end of April. Where, however, the whole lawn surface has been forked over several inches deep, all grass weeds and roots removed and a dressing of fresh, fine soil cast over it, with soot, basic slag and wood ashes, as before advised, the whole again forked in, leaving the surface clean, fine and level, also the

an absence of needful grass-producing food, the presence of moss, a common feature in lawns, shows that the soil is sour and needs draining. Generally, however, to keep lawns in good condition, apart from regular and careful mowing, annual dressings with fine soil and some manure should be given. D.

#### NATURAL CONTRAST IN PLANTING.

THE charming grouping of our wayside and woodland wild plants offers a lesson to any gardener who has herbaceous borders or a wild garden to arrange. In Nature's garden, a pleasing irregularity is the rule, for the planting is done by the wind and the birds, and their irresponsible scattering of seeds results again and again in groups of such great beauty that the object-lesson thus given is not one to be ignored.

Besides this informality, the beautiful contrast of form must be noted, for Nature almost invariably seems to associate those plants which, from difference in habit of growth, form of leaf

## THE ROSE GARDEN.

### ARRANGEMENT OF ROSE BEDS.

#### A SCHEME OF COLOUR.

**Q**UITE an important point when planting Roses is arranging and blending different sorts nicely. In case any readers of THE GARDEN have not yet got in their Roses for 1908, here are a few suggestions for beds (particularly small beds) cut out of grass lawns. Several beds cut out of one of my lawns and given up entirely to Roses I planned like this, and they were greatly admired last year. In the case of small round beds, plant one standard in the centre, round this three or four dwarfs, and then edge all round with dwarf Polyanthas. Oblong beds, and, in fact, beds of almost any shape, the same idea can be carried out, employing more standards and dwarfs according to the size and shape of them.

1.—Frau Karl Druschki, 4 feet standard; ditto dwarfs, round same, and edge all round with dwarf Polyantha Katherine Zeimet.

2.—Hugh Dickson, 4 feet standard; Charles J. Grahame, dwarfs, round same, and edge all round with dwarf Polyantha Mme. N. Levasseur.

3.—Dean Hole, 4 feet standard; ditto, dwarfs, round same, edging with Gloire de Polyantha.

4.—Mme. Abel Chatenay, 4 feet standard; ditto, dwarfs, round same, edging with Mignonette.

5.—Countess of Derby, 4 feet standard; ditto, dwarfs, round same, edging with Georges Pernet.

6.—Lady Roberts, 4 feet standard; ditto, dwarfs, round same, edging with Perle d'Or.

7.—Mme. P. Perny, 4 feet standard; ditto, dwarfs, round same, edging with Anna Marie de Montravail.

8.—White Maman Cochet, 4 feet standard; G. Nabonnand, dwarfs, round same, edging with Schneewitchen.

9.—Mme. Berard, 4 feet standard; Joseph Hill, dwarfs, round same, edging with Eugenie Lamesch.

10.—Countess Festetics Hamilton, 4 feet standard; Morning Glow, dwarfs, round same, edging with Leonie Lamesch.

11.—Lady Ashtown, 4 feet standard; Gustave Grunerwald, dwarfs, round same, edging all round with dwarf Polyantha Philippine Lambert.

12.—Clio, 4 feet standard; Augustine Guinois-seau, dwarfs, round same, edging with Clothilde Soupert. Q.

#### HINTS ON PLANTING ROSES.

I HAVE recently received from the National Rose Society "Hints on Planting Roses." I hope I shall not incur the charge of presumption if I venture to offer a few remarks, as the handbook is put forth, "not for experienced rosarians, but for those who wish to grow Roses but do not know how to set about it." I do not pretend to be a "rosarian," but, as I have grown Roses with much success for a few years, experience has taught me something. In planting I dig 2 feet, put a turf at the bottom or any old decayed garden rubbish, then some well-rotted cow manure, and fill up to the required height. When the roots are carefully spread out I work in some well-sifted Oak leaf-mould, over that a little fine soil, over that, again, a sprinkling of basic slag and bone-meal, well mixed, and then some soil trodden firmly. The result in all

A BEAUTIFUL NATURAL ARRANGEMENT OF SWEET CICELY (MYRRHIS ODORATA) AND BUTTER BUR.

whole being well trodden all over, then raked afresh and again levelled, the sowing of grass seed may be made early in April, as it is desirable to secure a grass crop as early as possible.

When so much trouble is taken, and it is wisest to take ample trouble at the first if a good lawn is to be secured in time, the only other chief element to success is that the grass seed be of the best quality for such purpose. A good selection to secure a lawn of fine quality is small-leaved perennial Italian Rye grass (*Lolium perenne*), 12lb.; Red Fescue (*Festuca rubra*), 9lb.; Hard Fescue (*Festuca duriuscula*), 9lb.; Crested Dog's-tail (*Cynosurus cristatus*), 6lb.; Sheep's Fescue (*Festuca ovina*), 6lb.; *Poa pratensis*, 3lb.; and *Poa trivialis* and *P. nemoralis*, 3lb. each. That is held to be a good selection for soil of medium character. These quantities represent what are usually advised for an acre of ground, but it is well to add fully one-third to each quantity, as there may be some failures and birds may claim a share of the seed. While bare, thin and weedy lawns indicate poorness,

or flower, help to show up characteristics in each which, were they growing alone, might easily pass unnoticed.

A familiar example is that of the Primrose, the Wood Hyacinth and the Anemones. The leaves and low growth of the Primrose make an effective foil for the graceful, arching stems of the Hyacinth and the deeply-cut leaves of the Anemones.

Examples such as these can be recalled by most of us; but it is when we come to the taller and stronger growing plants that the contrasts are most striking. The illustration is of a group of the Sweet Cicely (*Myrrhis odorata*) with a foreground of the large handsome leaves of the Butter Bur. This serves to show what a splendid effect is to be obtained from contrasting a simple-leaved, low-growing plant with one possessing Fern-like foliage and a tall, graceful habit of growth.

This lesson of Nature's ought to be applied in every garden, for the contrast of form is quite as important as the happy blending of colours. I. S. TURNBULL.

cases is strongly-grown plants. For winter protection I spread a little cow manure all over the bed, and on that 6 inches of leaves, and, to prevent them blowing about, I put over them strong stakes or branches of trees. Once in the Midlands I had the leaves swept off the lawn on to a bed of fifty-six plants, covering them up 1 foot deep, and when the leaves were removed at the end of March the stems of many of the trees were of a bright green colour, and the growth that summer was immense.

I observe that the handbook does not mention whether standards, half-standards or dwarfs are recommended. Some Roses do better grown one way and some another, *e.g.*, La France and Viscountess Folkestone do much better on standards, but that lovely Rose M. Joseph Hill does best as a dwarf. Messrs. Frank Cant and Co. write in their catalogue:

"Few would grow such varieties as Comtesse de Nadaillac, Souvenir d'Elise, Ethel Brownlow, &c., for the adornment of their garden without courting failure, &c." The handbook advises the inexperienced amateur to grow for exhibition purposes Comtesse de Nadaillac and others. I very much doubt their being pleased with the result. Bessie Brown grows strongly and produces plenty of buds, but most of them ball and rot. Mildred Grant is fine the first year, but not of any account afterwards. Florence Pemberton grows strongly, spreads widely, is full of buds, but produces few good openflowers. The Maman Cochets are grand when they do well, but they hang their heads and often ball and rot. The Bride, Muriel Grahame, Catherine Mermet and Bridesmaid are tender and shy. Souvenir de Pierre Notting burns and shrivels on the outside—out of a multitude of flowers I have rarely had a decent one. Mrs. Edward Mawley will not grow in this neighbourhood. Mme. Jules Gravereaux is grand, but it sprawls all over a bed. It is a climber and should be planted against a high pole. I am surprised that the list does not include Antoine Rivoire and G. Nabonnand, two of the very best garden Roses. A nurseryman in this neighbourhood told me that he sold more of Antoine Rivoire than of any other Rose: Mme. Abel Chatenay next. I venture to recommend strongly Liberty, Papa Gontier, Rainbow, Lady Roberts, Lady Battersea, Beryl and Peace, and suggest that Etoile de France be refused, also George Laing Paul, because it turns to a bad colour, and tender plants like the lovely Duchess of Portland. Indeed, sir, it would be a great kindness if, before the planting season is quite over, you would out of your large experience, give a hint as to the Roses that should be avoided. That which you once wrote me about the behaviour of Mildred Grant proved true, and the list you once sent me I have found admirable. Notwithstanding the great number of new Roses, I think if I were limited to three they would be Fran Karl Druschki, Mme. Abel Chatenay and Marquise Litta.

W. J. CHAPMAN.

Eldene, Sawthurst Road, Tunbridge Wells.

### THE MARECHAL NIEL ROSE.

AMATEURS often fail to grow this Rose, but I find it is as popular as ever with the general

public, and here give my mode of culture. I have tried plants put out in beds, inside a greenhouse and also in outside beds, training the branches under the roof glass from the main stem, which passed through a hole in the wall of the structure.

I know that many prefer to have plants on other stocks. I have tried both these and specimens on their own roots and now I do not hesitate to choose the latter. Ample provision should be made for drainage before any soil is put in the border. For one plant a space 5 feet long, 3 feet wide and 20 inches deep is necessary for the roots, though large plants may be grown in a border half the size if there is not sufficient room to spare. Broken bricks, clinkers and similar material may be put in for drainage. On this place whole turves grass side downwards and fill up with chopped

is harmful; so long as frost be excluded from the structure the plant will be safe. Train the shoots at least 15 inches from the glass to allow of a free circulation of air between them and the roof. Thin out weakly shoots in August, not in winter or spring, and rub out any young growth which may appear after such pruning before they attain a length of 1 inch. The stronger branches should be trained about 9 inches apart and be left their entire length. Grown under glass the wood will ripen well and a bloom will be forthcoming from nearly every bud on each shoot. In summer time as much air as possible should be admitted. From an ordinarily-sized young plant I have gathered 260 beautiful flowers the third year from date of planting. Canker of the main stem does not, as a rule, show before the eighth year, and not even then if every precaution be taken against bruising the bark or allowing it to press firmly against a stage or other part of the structure. AVON.

A PERGOLA CLOTHED WITH ORNAMENTAL GOURDS.

turf which has been cut from an old pasture and stacked for two months. The turf should be fibrous and neither too light nor too clayey. With the exception of one peck of well-rotted, sweet leaf-soil to two bushels of loam, no other kind of ingredient need be put in. Great care should be taken in selecting the plant; it should have a clean stem with whole bark. Bruised bark on young plants would mean canker development the second year after planting. Equal care must be observed while planting and fastening up the branches, so as to avoid bruising the bark.

The roots should be spread out evenly and covered with soil 3 inches deep, and the whole surface of the border with half-rotted manure to a similar depth. The exposed portion of the stem should be wrapped in hay bands from November to April. A very high temperature

## ORNAMENTAL GOURDS.

WE so seldom find the ornamental Gourds used in the pleasure garden that the accompanying illustration will enable readers of THE GARDEN to form an estimate of their merits in this respect. The prominent features of these Gourds is their brightly-coloured and quaintly-formed fruits, which, given a season of ordinary sunshine, ripen readily and become as hard as a stone, so much so that when severed from the plants they remain in perfect condition for seven or eight months, retaining their bright colours throughout the winter.

The cultural requirements are exceedingly simple, and should be readily mastered by those having a limited experience in gardening. Seed is sown singly in 2½-inch pots from the middle to the end of April. Light soil is necessary for seed-sowing, employing a richer compost as the plants are moved into larger pots, and finally planting out in well-manured ground in June. Good garden soil enriched with well-decayed farm manure is excellent, into which the roots readily penetrate and the plants grow away in a fashion proverbial with Gourds. They delight in copious supplies of moisture when in full growth,

so that a plentiful supply of water and liquid manure greatly assist in their rapid development.

Strong supports must be provided when planting, to which the "vine" is trained, and almost daily attention is required to secure the leading shoot. When grown upon single poles it is necessary to "stop" the laterals or side shoots immediately beyond a fruit. The flowers of Gourds represent both sexes. The female flowers are readily recognised by the embryo fruit forming at the base of the coloured petals, and these must be carefully retained at pinching. The pergola illustrated was a prominent feature in these gardens last summer, owing much of its success to the distinct leafage of the Gourds, which in their turn were helped out by Michaelmas Daisies and annual Sunflowers.

THOMAS SMITH.

Walmgate Gardens, Louth.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**C**OLD GREENHOUSE.—Remove bulbs from the quarters in which they were plunged in pots, and place them in the cold greenhouse. Roses on the greenhouse roof should be pruned. Cut out dead, weak and useless shoots, leaving the strong, well-ripened growths to produce blooms. Complete the tying of Roses at the same time. The Chimney Bellflower (*Campanula pyramidalis*) is a charming plant for the cold greenhouse. Pot up a few strong plants in 9-inch or 10-inch pots.

**Plants in Rooms.**—Do not allow plants to stand in draughty positions. The Fern *Pteris tremula* is excellent for dark corners. Should any plants get frozen, remove them to dark quarters where they may thaw gradually. This is best accomplished when the air is dry and still. Water plants with the greatest caution, using slightly tepid water. Avoid the use of stimulants and manure water at this period.

**Heated Greenhouse.**—Growths of *Plumbagoes* should be shortened to admit light and air and for the benefit of plants immediately beneath them. *Fuchsias* may be pruned and started into growth where early cuttings are wanted. Soft-wooded plants may now be propagated by cuttings and they are less liable to damp off if a small portion of the old hard growth be detached at the heel. *Geraniums* for an early display should be placed in their flowering pots. Pot up a batch of *Tuberoses* and *Lilies*.

**Hardy Flower Garden.**—The present is an excellent time to prepare beds and borders for the reception of the plants later. New rockeries may also be formed now. *Carnations* planted in the autumn may be unduly loose around their base, for this reason slightly firm the soil.

**The Vegetable Garden.**—Hot-beds may now be made, assuming the materials have been properly turned over and sweetened. The hot-bed should be made up firmly and the situation should be a warm and sheltered one, preferably a south aspect. See that the materials stand out at least 1 foot beyond the sides of the frames. Hot-beds may be utilised for raising early supplies of Carrots and for raising various seeds. It is a

simple and inexpensive method of raising plants. Exhibition Onions are obtained by making a sowing at the present time on a hot-bed; Ailsa Craig is an ideal type of Onion for this purpose. Lift Rhubarb for forcing. When manure to quarters it is intended to dig in the near future.

2.—THE CLUMP DIVIDED.

**Fruit Garden.**—There must be no further delay in completing the pruning, nailing and

tying of all fruit trees and bushes. Young standard Apples and Pears need to be pruned with considerable care. If possible select about five shoots of equal strength standing out equidistant from each other, shortening back, according to whether they are weak or strong, to a bud

1.—CLUMP READY FOR DIVIDING.

pointing outwards. Strong shoots may be left from 12 inches to 16 inches long.

**Chrysanthemums.**—Propagate decorative varieties by cuttings. The earliest batch of plants should be given a position in the cool greenhouse on shelves near the glass and free from draughts. Order novelties forthwith.

### INCREASING RHUBARB.

Rhubarb is always in demand in the earlier half of the year, and in all good gardens arrangements are invariably made to lift roots for forcing, to maintain the clumps in good health, and for periodically forming fresh beds. To the novice in gardening matters little is known of Rhubarb and how to deal with it successfully. It may surprise some readers to learn that Rhubarb is deep rooting, and for this reason the plot in which it is to be planted should be trenched quite 2 feet to 3 feet deep, incorporating at the time the trenching is done a liberal quantity of good manure. Manure that is well decayed is of little use. For this reason, therefore, fill in the trenches with solid manure; in fact, the best that can be procured. Some of the finest Rhubarb we have seen was grown on ground that had been trenched to a depth of 5 feet.

**Dividing the Roots.**—The best time to lift Rhubarb for the purpose of division is February, and we prefer to do this early in the month when the weather is free from severe frosts. The huge clumps that some of the old plants are represented by should be first divided up into convenient sizes, so that the crowns may be more easily detached. To divide a few plants is not difficult, as they split very readily, and pieces containing one crown or more may be detached suitably for replanting with little trouble. Frequently, pieces containing a crown or two may be detached from old clumps without the necessity of lifting the latter for the purpose of division. Assuming the new plantation or beds are to be planted in the near future, sufficient time will be allowed in the interval in which the new quarters may be properly prepared. Rhubarb will do well in the same quarters for ten years, but to keep the roots in good order, it is necessary to mulch them periodically with manure. When the clumps appear to be exhausted,

which will be denoted by weak and sickly growths, remove the surface soil round about the roots and apply liquid manure or sewage copiously, following this with a heavy dressing of partially decayed manure. Subsequent growths will prove how beneficial such treatment is

**Planting Rhubarb Crowns.**—Assuming the new quarters are prepared in the way just suggested, a fine day in February should be selected for replanting the crowns. When the weather is dry and the soil friable the work is much more satisfactorily carried out. Plant the crowns in rows, the latter being 3 feet apart, with the same distance between the crowns. Where a smaller plantation is being made, arrange the crowns 3 feet apart each way. One strong crown will be quite sufficient, but three smaller ones should be requisitioned if strong individual crowns are not forthcoming. Observe special care when adjusting the crowns in position. See that they are just level with the surface soil, and press the soil firmly round each one. To promote growth, mulch the replanted crowns with littery matter, preferably strawy litter from long manure. As the warmer days approach, apply water at intervals, this timely attention ensuring their well-being. By following this simple means of propagation growth in the succeeding year should be strong.

**Forcing Rhubarb.**—Anyone with a few spare roots of Rhubarb may have an early supply with little trouble. Roots lifted at the present time should be ready for use within a month, more or less. Those who have a Mushroom house may utilise this for forcing Rhubarb, but a more popular method is to place a few roots under the greenhouse staging where the temperature can be maintained at from 55° to 60°, or, where there is little or no glass, the roots may be placed in a tub or box, covering them with any old potting soil and mulching the crown with a quantity of warm manure and leaves. The clumps should be kept in the dark as much as possible. Those who have no glass house will find a warm cellar answer well; in fact, any protection that can be afforded should be taken advantage of, and this means of forcing may be enhanced by a liberal covering with leaves or long stable litter as fermenting material. Good sorts are Royal Albert and Early Red for earlier

3.—GOOD SINGLE CROWNS FOR PLANTING.

supplies, and Myatt's Victoria and Hawke's Champagne for succession.

### PREPARING AND PLANTING A HERBACEOUS BORDER.

It is to this border that many amateurs devote their attention during leisure hours. With

AFTER TRENCHING THE BORDER LAY THE PLANTS ON THE SURFACE IN THE POSITION THEY ARE TO OCCUPY.

comparatively little trouble flowers can be obtained from early spring until late autumn.

**Position.**—The villa garden is usually small. A border 4 feet or 5 feet wide round the boundary fences or walls will make an ideal herbaceous border, provided it is not overhung with trees. This does not mean shelter or slight shade during a portion of the day; these are often beneficial rather than detrimental to some plants. If convenient, a wider border, say, 10 feet or 12 feet, should be made at the bottom of the garden. This will accommodate many of the taller plants, which would look rather out of place in a border of less width. The planting may be done during favourable weather from October to March, preferably not later than January. When making a new border it should be trenched, if possible, to a depth of 3 feet. When once the border has been well made, it is not necessary to dig it so deep again for a number of years. The illustration shows the digging of a border three spits (about 2 feet) deep. The soil in the bottom, marked by the spade on the right hand, is turned over and left at the bottom of the trench, not brought to the surface. Deep cultivation such as this is only necessary or advisable every second or third year. In a herbaceous border there are always a number of plants which are better left undisturbed for several years. Delphiniums (perennial Larkspurs), Japanese Windflowers (Anemone japonica), Torch Lilies (Kniphofias), Liliums and Rose trees are examples of plants which dislike frequent removal. Lifting and replanting of these once in five years is ample.

**Planting.**—The ultimate effect of the border when the plants are in flower must be continually borne in mind when planting. The height the plants grow, the time of blooming, and the colour of the flowers must all be considered. Three to eight or more plants in a long border grouped together are more pleasing, and exhibit the true character of the plants better

than when they are dotted singly. We read in gardening papers and elsewhere of a June border or a July border; these are all filled with plants flowering in those particular months. Another style is to plant a border with subjects, the flowers of which are all of one colour, as the white border, the blue border, &c. Gardens in towns or suburbs where such schemes can be carried out are few and far between. In the mixed border the pride of many amateurs is that the plants which flower in June should be distributed as far as possible equally along the border, treating those which flower in other months in the same way. Plants which flower in September, if placed in close proximity to those which flower early in the summer, will develop and cover some of the space occupied by the latter when in bloom. When planting dig the holes wide enough to permit of the roots being spread out. Avoid burying the crowns too deep, especially in heavy soils.

**Dividing the Roots.**—As the right and wrong methods of dividing rootstocks were fully dealt with in THE GARDEN of the 7th ult., it is not necessary to discuss that subject again.

**Other Methods of Propagation.**—Many herbaceous plants are readily increased by cuttings in spring, when the young growths push up. Michaelmas Daisies, autumn-flowering Chrysanthemums and the Japanese Stonecrop are good examples. It is always advisable to thin out the growths of herbaceous plants when too thick, so that by taking cuttings one is improving the prospect of a good display and increasing the stock of plants at the same time. Most of our herbaceous plants can also be increased by seeds sown in April and May.

**The Reserve Border.**—Whenever possible a few late-flowering plants should be grown, to be

WHEN PLANTING KEEP THE COLLAR OR NECK OF THE PLANTS NEAR THE SURFACE.

lifted and planted in the border when the early-flowering ones are over. The young plants propagated by cuttings mentioned above are admirable for the purpose.

**Twelve Tall-growing Herbaceous Plants for the Beginner.**—Michaelmas Daisy, Moon Daisy (Chrysanthemum uliginosum), Rudbeckia laciniata, perennial Larkspur (Delphinium), Hollyhock, Everlasting Pea (Lathyrus latifolius), Helianthus Miss Mollish, Goat Rues (Galega officinalis and var. alba), Lupinus (Lupine) polyphyllus, Helium autumnale and herbaceous Phlox.

**Twelve of Medium Height.**—Bergamot (Monarda didyma), Peach-leaved Bellflower (Campanula persicifolia), Lychnis chalcedonica, autumn-flowering Chrysanthemums, Chrysanthemum maximum, Columbine (Aquilegia) Crown Imperial, Gypsophila paniculata, Flame Flower (Kniphofia), Lilium candidum, Anemone japonica and Sneezewort (Achillea Ptarmica The Pearl).

**Twelve Dwarf-growing.**—London Pride, Japanese Stonecrop (Sedum spectabile), double Daisy, Veronica gentianoides, Pink, Carnation, Pyrethrum, double Arabis, Thrift (Armeria), Viola, Musk and perennial Candytuft (Iberis sempervirens).

In addition to the above there are a number of other plants grown in the herbaceous border, although, strictly speaking, they are not herbaceous plants. Others, such as Gaillardia, Coreopsis grandiflora and Sweet Williams, which, although strictly speaking herbaceous plants, are better treated as biennials, i.e., raised from seeds sown in May or June to flower the following year.

**Bulbs.**—Narcissi, Tulips, &c., are also planted. Dahlias, Rose trees, Lavender bushes and Irises, unless grown in the mixed border, would have to be excluded from many gardens. To take the place of the Tulips and other early-flowering bulbs, annuals, such as Asters and Stocks are dibbled in between the decaying foliage in June. The foliage of the Narcissi can be tied in a knot till sufficiently ripe to cut off.

HOW TO PREPARE THE BORDER FOR PLANTING.

## GARDENING OF THE WEEK.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ALLAMANDAS.**—These very useful plants if kept too dry when in moderate-sized pots are often apt to die back far too much. This weakens the plants, and should be avoided. It is better to keep them moderately moist with a few leaves retained in a fresh state. Even when in large pots it is not well to keep them absolutely dry, or the same thing will sometimes occur. If these plants are not kept in a stove proper, see that they are not subjected to a lower temperature, otherwise the consequences will be serious. *Clerodendrons*, both climbing and shrubby, are quite as sensitive in this respect. *Bougainvillea glabra* will stand 10° less with tolerable safety.

**Calanthes.**—These are among the most useful of our Orchids for a midwinter display. Anyone who has the convenience of a warm, moist house may have a fine display with very little trouble. A great mistake is to leave the plants about after flowering in cold or draughty places in the dwelling-house or elsewhere. The pseudo-bulbs so treated never start so well or produce such fine growths as others that have been properly treated by keeping them quite dry in a house kept at a minimum temperature of 50° or thereabouts. They get then the thorough and complete rest that is so necessary to their well-being, yet the eyes are not chilled or checked, and therefore start away vigorously in spring.

#### HARDY FRUIT.

**Pruning.**—Push on the pruning of all hardy outdoor trees and bushes in open weather so as to get this work completed before spring.

**Fig Trees** on walls in exposed positions may now require extra protection. It is an easy matter to tie the branches together, and cover with dry Bracken or straw and with mats securely fastened to the walls; indeed, in some cases I have taken the trees from the walls, laid them at the base and covered them during very hard weather.

#### KITCHEN GARDEN.

**French Beans.**—These can now be forced more readily than if sown a month or two back, as Beans sown at that period fail to produce a sturdy growth. I prefer 6-inch or 7-inch pots at this season, allowing only half-a-dozen plants in a pot. I have seen French Beans sown in boxes and transplanted, but do not advise it. For later use it is a good practice, as the longer days and greater warmth soon cause new root action, but early in the year the transplanting gives a check, causing delay and at times total loss.

#### FLOWER GARDEN.

**Mimulus.**—I make it a rule to sow seed of *Mimulus* early in January on fine sandy soil in shallow pans, and leave it to germinate in a comparatively cool house. In a few weeks there will be hundreds of strong seedlings to lift. Prick these out into other pans or boxes, and in these they would be ready to pot up singly if desired early in April, or by the middle of the month planted on a cool border outdoors, where they will on good ground produce a most brilliant mass of flowers. A really fine strain of *Mimulus* presents features of beauty such as few other flowers give. If the seedling plants have been well hardened before planting out so early, the foliage simply gets discoloured, but the late frosts do little or no harm to them.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### GREENHOUSE.

**WINTER CARNATIONS.**—The first batch of cuttings should now be put in if not already done. Take strong cuttings and place three or four in a small pot, inserting them near the edge. Use plenty of sand; in fact, they will root readily in all sand. *Enchantress* is very good just now, and this colour finds much favour. Carnations in flower should be kept in a somewhat dry and airy house, with just enough heat to keep the plants moving—55° to 60° suits them very well. *Malmaison* varieties should be kept somewhat cooler, and young plants are best in a cool, dry temperature, with just enough heat to dispel damp.

**Cyclamen.**—Seed of these charming flowers may yet be sown. Prepare pans of rich soil—which must be well drained—dibble the seed in regularly over the pan about a quarter of an inch deep and place in a temperature of 60°. Seedlings sown in October should now be potted singly. Seeds of *Grevillea robusta* and *Gloxinia* may be sown if very early plants are required.

#### FORCING HOUSE.

Introduce more Lilacs, Prunuses, Deutzias, Spireas and bulbs. These should be put in now at intervals, so that a break may not occur in the supply. The plants subjected to forcing should, however, be introduced to heat gradually and the same treatment afforded when leaving the forcing house. By so doing the plants last in flower much longer.

#### KITCHEN GARDEN.

Vacant ground should now be dug or trenched up rough, so that if the weather becomes frosty it will be pulverised. Place some early Potatoes on ends in boxes, and take away all but the strongest eye or shoot. Place the boxes in a warm and light position for either planting in frames or pots. A pinch of Onion seed may now be sown for exhibition bulbs, scattering the seed thinly and placing the boxes in a warm and light position. Put in more roots, such as Sea-kale, Dandelion, Chieory, &c., to force in order to keep up a daily supply.

#### HARDY FRUIT.

Continue to prune and train trees as the weather admits of so doing; all old ties should be removed. Trees on walls should be dressed if they have been attacked by any vermin, and if the walls require repairing now is the time to do it. Plant new trees during fine weather so that the soil is not pasty when pressed in about the roots; if trees are planted during wet weather the ground will crack when it becomes dry. When selecting trees the purpose for which they are intended must be borne in mind so as to get a judicious selection for the various seasons.

**Strawberries** may now be introduced into a warm house. The plants should be cleaned and top-dressed and the pots washed. Strawberries in the open ground should be mulched, treating both old and new plantations. See that no weeds are existing; if any are present they ought to be cleared away before mulching.

#### LAWNS AND PLEASURE GROUNDS.

These should be kept clean, especially when in view of the mansion. Lawns should be rolled occasionally. Any planting may be carried on during fine weather. Where shrubs have become crowded they may be thinned out or cut hard back. The present is a good time to carry out any improvements or alterations. *Azaleas*, *Camellias*, *Rhododendrons*, &c., can be moved any time now up till the end of March. Any large specimens which need top-dressing should be attended to. Palms, Bamboos and similar plants may also have fresh soil added to them; this should be done by taking out a trench a distance from the roots, gradually working it

away till the roots are reached, when a mixture of leaf-soil, peat and cow manure should be given. *Camellias* are benefited by a good sprinkling of bone-meal and soot in addition. *Roses* may be planted, and the tender varieties of *Teas* should have the protection of a little Bracken or other such material to guard against frost.

#### ORCHIDS.

*Calanthes* in flower should be kept dry or the flowers will soon damp. *Cypripediums* should be kept somewhat drier, especially those in flower. Spray the shingle on which they are staged twice daily in order to keep down thrips. *Dendrobiums* that have been resting may now have a little more warmth. *Cymbidiums* that are showing flower-spikes should not have too much heat.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## WHAT TO DO WITH FROZEN PLANTS.

It is safe to state that there is not a winter passes by without a number of plants being destroyed by frost in the United Kingdom, pot plants in particular, many of which could undoubtedly be saved did their owners know what to do with them when King Frost holds them in his icy embrace. "Pitch them on the rubbish heap," used to be the general verdict when more or less tender plants became frozen, but during the last decade or two science has come to the aid of the practical man, and informed him that it is not the actual freezing that is fatal so much as the after treatment.

In order that we may the better understand the treatment of frozen plants, it will be wise to briefly consider what happens when frost reaches them. The liquid contents of the cells become frozen and expand, the cell walls are ruptured, and the plant's tissues in general are disorganised. It is now a fairly well-known fact that a plant whose cells contain only a comparatively small amount of water will stand, without injury, several degrees more frost than a similar plant whose cells are turgid with liquid, therefore it is excellent practice, as a preventive of injury by frost, to keep plants as dry as possible without injury during the winter months.

But supposing a plant or plants have been badly frozen what are we to do to save their lives? The whole answer is given in three words, viz., thaw them slowly. It has been proved over and over again that if a plant is thawed sufficiently slowly the cells are able to once more absorb their contents that have been displaced by expansion, and the plant is little the worse for the disorganisation that has occurred. If it is a window or room plant that is affected, stand it in a very cool corner where the temperature is only slightly above freezing point, and keep it there until it has thawed.

The occupants of cold frames are often badly frozen, and if a sudden burst of sunshine is allowed to reach them much damage will be done. Keep the mats or other covering over them until a slow or gradual thaw takes place. But it is when the whole of the occupants of the greenhouse, owing to some defect in the heating arrangements, become frozen that the most destruction is likely to occur, and prompt measures must be taken if any of the plants are to be saved. As soon as such a condition is noticed take care that the heating apparatus does not right itself and thus send up the temperature quickly. Then cover the glass with thick mats, straw or other shading material in case the sun comes out and causes a sudden thaw. After these precautions have been taken secure a good supply of very cold water and syringe the plants, pots, staging and glass with it until the whole are drenched. This will cause a very gradual thawing to take place, and many plants will be

saved. Leaves will probably be lost, and the plants will need several weeks to recover from the shock, but better this than a total loss.

Half-hardy plants growing in sheltered positions out of doors are often ruined by the removal of the protecting material as soon as a thaw sets in. Such protection should be left on until all signs of frost have gone from the plant under notice. If such a specimen has had no protection before frost occurred much good might be done by covering it with mats after it is frozen but before it thaws. In concluding, it may be well to emphasise the statement that to safely bring plants through the ordeal of being frozen they must be thawed slowly.

THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

WINTER FLOWERS FROM SOUTH DEVON.

Mrs. F. L. Carslake sends from Daracombe, Newton Abbot, a most interesting box of flowers gathered in the garden on December 26, all grown outdoors and unprotected. There are no less than seventy-two different specimens, and many other plants are in bud. Some of the rock Roses have quantities of buds on them. Mrs. Carslake writes: "It is not a bad list for Christmas. Can any of your other readers show a longer one?" We hope our correspondent's letter will be answered. The list is as follows: *Corydalis*, *Polyanthus*, *Ceanothus Indigo*, white *Marguerite*, *Sedum*, *Gazania*, *Antirrhinum*, *Coronilla*, *Iberis sempervirens*, *Harebell*, the large green *Hellebore* (too large to send), *Abelia rupestris* in full bud, also in large bud *Magnolia grandiflora*, in flower and fruit *St. Joseph Strawberry*, showing colour, but not quite open *Pink Oxalis*, *Mesembryanthemum*, *Solanum*, *Abutilons* (various), large *St. John's Wort*, *Hellebore* (*Lenten Rose*), *Christmas Rose*, *Pittosporum Tobira*, *Arabis*, alpine *Pink*, *Choisya ternata* (*Mexican Orange Flower*), *Pentstemons* (various), yellow *Alyssum*, *Geum*, *Carnations*, *Jasminum nudiflorum* (winter-flowering *Jasmine*), alpine *Wallflower*, (*Enothera*, *Senna*, blue and the red *Periwinkle*, *Snowdrop*, *Violets* (single blue, double blue and white), *Laurustinus*, *Sweet Rocket*, *Diplacus*, *Auriculas*, *Escallonia macrantha*, *Escallonia* (white), *Anthemis tinctoria*, red *Salvia*, *Pansies*, *Primroses* (various, white, blue and coloured), *Fuchsia miniata*, *Hydrangea*, *Campanula pyramidalis*, *Shasta Daisy*, *Schizostylis*, *Roses* (various, *Macartney*, *China*, *Liberty* and another), *Chrysanthemum Source d'Or*, *Mignonette*, *Cobaea scandens*, *Cytisus*, *Heaths* (white and red), *Gorse*, *Berberis Darwinii* and five varieties of *Veronica*.

FLOWERS PICKED IN A SMALL GARDEN OVER 500 FEET HIGH, NEAR EWHURST, SURREY, ON CHRISTMAS DAY, 1907.

The following flowers from "C. R. S." were gathered on Christmas Day and kindly sent for our table: *Antirrhinum major*, *Arabis*, *Aubrietia* (the common mauve), *Candytuft* (*Iberis*), *Ceanothus Gloire de Versailles*, *C. azureus*, *Clematis Anderson Henryi*, *French Daisy*, *Cyclamen*, *Carnation*, *Fuchsia* (pink and white—I have not the

name of the variety), *Geranium* (purple *Crane's-bill*), *Pelargonium Henry Jacoby*, *P. Souvenir de Charles Turner*, *Heartsease* (various large-flowered), *Hypericum calycinum*, *Jasminum nudiflorum*, *Laurustinus*, *Linaria maroccana purpurea*, *Mignonette*, *Primula Giant* (various colours), *P. vulgaris* (common *Primrose*), *Poppy* (large mauve *Oriental*), *Roses* (eighteen varieties)—*Dorothy Perkins*, *Frau Karl Druschki*, *Fairy Rose* (from seed sown in the spring), *Lady Macartney*, *Liberty*, *Mme. Abel Chatenay*, *Mme. Jules Grolez*, *Mme. Ravary*, *Kaiserin Augusta Victoria*, *Louise Richard*, *Penzance Briar*, *Monthly* (both pink and red), *Hermosa*, *Perpetual Thalia*, *Pride of Waltham*, *George Nabonnand*, *Reine Olga de Wurtemberg* and *Ulrich Brunner*—*Scabious*, *Schizostylis*, *Tobacco*, *Veronica* (common purple), *Vinca major*, *Violet* (two varieties, single), *Wallflowers* and *Watsonia alba grandiflora* (in full flower).

CHRISTMAS FLOWERS IN THE ISLE OF WIGHT.

Mr. Collister, gardener to Sir John Thorneycroft, Steyne, Bembridge, Isle of Wight, writes: "I enclose a list of plants and shrubs that were in bloom on Christmas Day last in the garden here. I thought it would interest readers of your valuable paper. It is wonderful the number of things that are in flower, showing the mildness of the autumn and congenial climate. Some of the plants mentioned are covered with flowers. Plants—*Wallflowers*, *Stocks*, *Erysimum Golden Gem*, *Lychnis coronaria*, *Marguerite Carnation*, *Limnantes Douglasii*, *Arabis alpina*, *A. a. fl. pl.*, *Polyanthus*, *Primroses*, *Sweet Peas*, scarlet *Geranium*, pink *Ivy Geranium*, *Marguerites*, annual *Chrysanthemums*, *Violets*, *Antirrhinums*, *Nicotiana*, *Gazania splendens*, *Iberis sempervirens*, *Pansies*, *Mignonette*, *Convulvulus minor*, *Pentstemons*, *Alyssum saxatile compacta*, red *Valerians*, *Hellebores*, *Chrysanthemums*, *Roses* in great variety and *Campanulas* in variety. Shrubs—*Hydrangea*, *Coronilla glauca*, *Genistas*, double *Gorse*, single *Gorse*, *Escallonia macrantha*, *E. montevidensis*, *Spartium junceum*, *Garrya elliptica*, *Laurustinus* in variety, *Myrtles*, *Veronicas*, *Solanum jasminoides*, *Fuchsias*, *Spanish Broom* and *Jasminum nudiflorum*."

PRIZES FOR READERS.  
JANUARY.

THE BEST POTATOES AND HOW TO GROW THEM.

- A First Prize of FOUR GUINEAS,
  - A Second Prize of TWO GUINEAS,
  - A Third Prize of ONE GUINEA,
  - And a Fourth Prize of HALF-A-GUINEA
- are offered for the best essay on "The Best Potatoes and How to Grow Them."

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Friday, January 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

ANSWERS  
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

FLOWER GARDEN.

Box border (E. M. L. B.).—If by a Box border a Box edging is meant, then the shrub form would be useless for the purpose, the sort employed for edgings being quite distinct and remaining dwarf, hence its adaptability for the purpose. Box for edgings may be purchased from any of the nurserymen who specialise in hardy trees and shrubs, and may be planted at any time from October to April. An old Box edging may be taken up and divided for the same purpose, the work of "laying," as the replanting is termed, requiring a little intelligence and care to get it into a proper position. The *Carnations* and other plants should be freely dusted with soot and lime in equal parts without delay. If the slugs are at all numerous you should, in addition, lay some flat boards or slates about to encourage them thither, and when congregated together destroy them. Messrs. Hunter and Gow, 46, Thomas Street, Liverpool, have a special preparation in the form of a powder, which is most effectual in killing slugs, wireworm and other pests of this kind.

Plants for herbaceous border (Velsa).—There are quite a number of plants suitable for the purpose you name, but, unfortunately, you have omitted the size of the border, a somewhat important item in the circumstances. Of brightly-coloured subjects you might at will select from such groups as *Pyrethrum*, single and double; *Pæonies* in like manner, *Delphiniums*, *Gaillardias*, *Trollius*, *Campanulas*, *Kniphofias* or *Torch Lilies*, *Michaelmas Daises*, which would prove invaluable for late summer and autumn, and the whole of the *Iris* family, more particularly those known as *Flag Irises*, and those beautiful groups of summer-flowering sorts known as *Spanish* and *English Irises*. To these could be added a large number of *Iris* species, such as *aurea*, *Monnieri*, *gigantea* and others. Other important subjects include the *Day Lilies*, *Perennial Pea* in white and rose varieties, *Stenactis speciosa*, herbaceous *Phloxes*, *Alstromeria*, *Sunflowers*, &c. In addition the more showy *Narcissus* could be planted in groups, also *Lilies*, particularly such sorts as *croceum*, *Hansoni*, *tigrinum*, *speciosum*, *colchicum*, *testaceum*, &c. Had we known the width of the border we could have given you a more helpful reply.

Weedy lawn (W. T.).—Of the lawn weeds sent, one with its fine grass-like growth is *Spergula pilifera*. Others are *Hernaria* and *Veronica* reptans. Very severe stirring these creeping weeds with a sharp toothed iron rake should help to destroy them easily. Such use of a rake also greatly helps to destroy moss, and in so doing gives the grass a better chance to grow. The wire-like grass sent, though more difficult to recognise now, is probably one of the coarser *Poas*, but which it is not easy to say. Such a coarse or tall-growing grass it should not be difficult to chop out with a hoe, and thus destroy it in quantity. Evidently the soil is very poor, and badly needs manure dressing. First make every effort to tear out moss and weeds, then dress the lawn with well-decayed manure, if to be had. If not, then use soil well spread about, and on that add soot very liberally and basic slag at the rate of 4lb. per rod, all well worked in with a rake; and in April

next follow with a dressing of sulphate of ammonia, 3lb. per rod and finely crushed.

**Meconopsis Wallichii** (*M. Denison*).—This plant may be obtained from any of the hardy plant dealers such as Messrs. Barr and Sons, Covent Garden; Wallace and Co., Colchester; Amos Perry, Enfield, and others. The plant delights in deep loamy soil of an open nature, or loam and peat in equal parts, and a position sheltered from cutting winds. A cool rooting medium is of importance. As the plant is of biennial duration only a better flowering is usually secured by raising the plants from seeds sown in January, planting out in May or early June for flowering the following year. In this way large rosettes are produced, and upon these a good flowering depends.

### THE GREENHOUSE.

**How to propagate Pitcher plants—Nepenthes** (*Doubtful*).—The best time of the year to propagate *Nepenthes* from cuttings is during the months of April and May, though in nurseries where rapid increase is essential it is carried on from February to the end of the summer, that is to say, whenever cuttings are available. The best cuttings are formed of the points of the shoots, and if your plants have but one main shoot and the top of that is taken to form a cutting, most probably the old plant will in time push out one or two shoots in the place of that removed. When these are about 4 inches in length and have lost some of their succulent character they form very desirable cuttings. The various sorts of *Nepenthes* are not difficult to root, providing a few simple facts are borne in mind. In the first place, the better way is to insert each cutting singly into a comparatively small pot. This must be effectually drained, and it is very necessary that the soil, which must be pressed down moderately firm, be of an open nature. Peat and sand, with a little sphagnum moss and a few nodules of charcoal, form a very suitable mixture. When each cutting is potted it should be secured to a stake, taking especial care that any young leaves with undeveloped pitchers are not injured in any way. The cuttings should then be plunged in a gentle bottom-heat in a close propagating case in the stove, for in the cultivation of *Nepenthes* a considerable amount of heat and atmospheric moisture is very necessary. The cuttings need not have a heel of old wood attached to them.

**When to graft Aralias** (*Doubtful*).—During April and May is the best time of the year to graft *Aralia Veitchii* and its allies, though in one nursery that we know, where very large numbers are propagated in this way every year, it was last year, owing to pressure of business, not carried out till June. The results were perfectly satisfactory, but the plants are not now quite so large as they have been in former years. The stock employed is *Aralia reticulata* (a species with plain strap-shaped leaves), which will strike very freely from cuttings. Side or veneer grafting is the method generally employed. For this purpose the stock plants, which are young and furnished with leaves nearly to the base, are headed back to about 4 inches or 5 inches from the pot, and the grafting is done as low down as possible. The stocks are all established in small pots, and the tops which are cut off are put in as cuttings to yield stocks for another year. The best scions are formed of the points of the shoots, but, where large quantities are needed, any plants that have grown too tall or are in any way unsuitable for sale are cut up into single eyes, each eye with its attendant leaf and piece of stem below it forming a separate graft. If these are too stout to fit the stock, care must be taken that one side fits exactly. After the scions are tied securely in their place, the grafted plants must be put into a close propagating case in the stove and kept carefully shaded. The lights of the case must only be opened for a short time each morning to inspect the contents. No grafting-wax will be required, hence the process of union may be easily watched. As the grafting is done close to the ground, the young plants

when potted can be sunk somewhat deeper, and the point of union will then be almost, if not quite, covered. When the grafts are quite joined, the remaining portion of the stock can be cut away.

**Repotting Plumbago** (*A. G.*).—The best time to repot *Plumbago* is from the middle of March to a corresponding period in April, according to the structure the plants are in. If a cool house the last-named date will be the best. At the time of potting any straggling shoots may be shortened back. *Plumbago capensis* will not thrive in an unheated greenhouse, for to keep it through the winter the thermometer should never fall below 40°.

**Begonia Gloire de Lorraine** (*Lancashire*).—This most valuable *Begonia* was, reputedly, raised by M. Lemoine of Nancy, France, and was put into commerce about 1890. Its parents were the bulbous-rooted species *Begonia socotrana* and the fibrous-rooted species *B. Dregei*. It was at first doubted whether this parentage could have produced the now famous hybrid, but later experiments with the same species were found to give similar results. *B. socotrana*, in conjunction with tuberous-rooted varieties, is the prime parent of the singularly beautiful race of winter-blooming *Begonias* put into commerce by Messrs. James Veitch and Sons, who are the raisers.

**Germination of Palm seeds** (*H. G. W.*).—It is possible the *Keutia* seeds you have found so difficult to germinate were old, and had been for some time kept in a dry place, the shells thus becoming very hard, and with a consequent loss of vitality in the germinative organs. The best thing to do where such hardness exists is to soak the seeds for twenty-four hours in at first quite warm water, as such soaking helps the softening of the seed shells, although it can do little to create germinative power. Generally Palm raisers find their seed to germinate fairly well, but no doubt they obtain fresh supplies. Even when soaked it may be wise to treat the seeds as you suggest, laying them on decayed leaves 3 inches in thickness, covered with mats until sprouting is seen, then to lift each one singly and get them into small pots.

**Information about a warm fernery** (*J.H.*).—In determining the proper temperature for a greenhouse fernery much depends on whether the Ferns are tender kinds or whether they be of greenhouse or comparatively hardy nature. For quite tender Ferns the temperature should range from 60° to 70°. For greenhouse Ferns, such as most of the *Adiantums*, *Pteris* and similar forms, a temperature ranging from 50° to 60° in the winter does very well, but, necessarily, would be higher in the winter. Why your potted Ferns in the greenhouse fernery do so indifferently it is not easy to say, because nothing is said as to kinds or conditions. Most likely the soil in which they are potted is not suitable, and may be deficient of peat which is an essential element. The atmosphere may be kept too dry, or your water contain too much lime or iron, hence be unsuitable for the Ferns. If your gardener is as you say a good man, he should certainly be able to give some reason why the Ferns do so badly. Have the hot-water pipes been coated with some offensive compound.

**Drying off Hæmanthus albiflos** (*Doubtful*).—It is not necessary to dry off *Hæmanthus albiflos* so thoroughly as to cause the roots to perish; still, during its resting period the soil should be kept almost dry. *Hæmanthus albiflos* as a rule flowers during the autumn, and after that makes its growth. Such being the case it needs throughout the winter, to be given a good light position in the warmest part of the greenhouse, or even in a structure kept at an intermediate temperature. It will at that time need to be watered whenever the soil is dry. If such treatment is continued till spring is well advanced, or even till the summer, the plant should have made good growth, and will probably show signs of going to rest. During the summer a sunny spot in a garden frame and a very limited amount of water will suit it well. By the end of August or thereabouts signs of growth should be seen, when more water may be given and the plant or plants removed into the greenhouse. The flower-spike will then very probably soon make its appearance.

### ROSE GARDEN.

**Soot as a preventive of mildew on Roses** (*E. M. D.*).—The soot should be mainly applied to the ground round about the plants, but it would be advisable to give the branches a good dusting also. At those seasons of the year, namely, November and March, there would be no tender foliage to injure, so that it may be applied without any fear of injury. We have syringed indoor Roses with a weak solution of soot water with very beneficial results. Some years ago we had a large quantity of budded stocks dressed with soot in May, and there was no sign of mildew that year. We were careful only to apply it to the land, as at that time the young foliage was in a very tender condition. Besides acting as a preventive of mildew, soot itself is a general fertiliser, and may be applied with much benefit to the plants.

**Soot as a preventive of mildew** (*W. R. M.*).—Sprinkle the soot on the surface of the soil round each

Rose tree, not too much, just a light dusting, say on November 1 and again on March 1. Be sure and use old soot.

### FRUIT GARDEN.

**Trees cankered** (*H. S.*).—No doubt this is due to your cold soil. Under the circumstances we are afraid that a complete cure is hopeless. We have known trees badly cankered to go on bearing well for many years by going over them carefully every year and cutting the cankered part out. We have seldom known any of the variety you mention to canker, and we hope they will remain free from it. To kill all kinds of fungoid or other parasitic growth on fruit trees, spray in winter with the caustic alkali wash.

**Protection of bush fruit trees** (*Rubrum*).—To be effective the mesh must not be larger than 1 inch and the size or gauge most convenient to handle in forming the enclosure is that of 3 feet wide. We have seen many failures in the growth of bush fruit trees inside such enclosures, the failure being attributed to the absence of birds in spring and summer in ridding the trees of aphids and other destructive tree pests. We would suggest that the sides only be formed of galvanised netting, and that for covering the roof herring netting be substituted. This could be applied in winter as a protection from bullfinches and taken off in spring and summer until wanted again for protecting the ripening and ripe fruit.

**Fungus on fruit trees** (*H. B.*).—For the destruction of fungus or other growth on the stems and branches of fruit trees, we know of nothing more effective than spraying the trees in winter with caustic alkali wash, the composition of which is as follows: 1lb. of commercial caustic soda and 1lb. of crude potash. Dissolve both in water, afterwards mixing the two well together, then add three-quarters of a pound of common agricultural treacle, stir well and add as much rain water as will make up 10 gallons. The wash has a burning effect on hands and clothes, and care must therefore be exercised when spraying the trees at the end of January or the beginning of February. This wash will also rid the trees of all blight it may come in contact with.

**Fruit room not satisfactory** (*Buckshaw*).—From the particulars given we can find no fault with the construction of the fruit room, excepting that the tiled roof is a mistake. There is nothing so damaging to the preservation of fruit as the frequent alternating of temperatures, which the tiled roof favours. Therefore we would advise the roof to be thatched outside and the sides and ends also with straw or long Heather 10 inches thick. The temperature will then be uniform and slightly warmer, which will suit the Pears better, and evaporation will also be stopped, which is important, as it tends to destroy the juices of the fruit. The room will then require no artificial heating even in the coldest weather. Thatched portable shutters should also be made to fit the skylight and windows for protection in very cold weather.

**Apples for cooking** (*H. B.*).—1. The Grenadier.—One of the very best of the Codlins; ripe in September. 2. Lord Grosvenor.—Excellent for early use and very hardy; ripe in August. 3. Lord Derby.—Fine cooking sort, heavy cropper, and especially suitable for growing in cold districts. 4. Royal Late Cooking.—The tree is very hardy and free bearing, the fruit large and handsome; ripe in February. 5. A well-known free-fruited and reliable late cooking sort. 6. Newton Wonder.—This is probably the finest late cooking Apple of the present day. It is a cross between Wellington and Blenheim Orange, and partakes of the good qualities of both. The tree is robust, hardy and prolific, the fruit large, of brilliant colouring, and will keep in good condition until May. It is profitable to grow for market.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## SWEET PEAS IN POTS.

A CORRESPONDENT sends the following interesting and practical note upon Sweet Peas in pots. The Sweet Pea has gained the affections of all who love their gardens, and a description of any way of growing it successfully is welcome.

"Sweet Peas are much more amenable to pot culture than might generally be supposed, and give very little trouble, while they keep up a bright display for a considerable period, and may be grown in pots by those who have little or no convenience for growing them in the garden. Varieties are now so numerous that it is difficult in making a selection to include all that are worthy of recommendation, but for those who would like to confine themselves to a dozen varieties the following will be found to be a good selection, viz.: Dorothy Eckford, white; Lovely, pale flesh pink; Lord Nelson, blue; Miss Willmott, orange pink; Gladys Unwin, pink; Hon. Mrs. Kenyon, almost a true yellow; Lady Grisel Hamilton, pale blue or mauve; Gorgeous, scarlet with a salmon shade; Horace Wright, violet-blue; Countess Spencer, pink; Evelyn Byatt, orange salmon; and Phyllis Unwin, rose-carmine. The seeds may be sown any time till the end of February, about seven or eight in a 5-inch pot. Good loam with a liberal addition of manure may be used, and it should be pressed moderately firm. The seeds should be covered with the soil. After sowing the pots may be placed in any light open position in a frame or cool greenhouse; care must be taken that there are no mice about. After the seeds begin to germinate, light and air, with a moderate supply of water, is all that is needed until the seedlings require some support. A few short twigs may be used at first, and these will hold them up until they begin to make tendrils, and as they advance a few tall sticks and twine placed around will hold them up well. If they are inclined to become too tall they may be stopped, and this will not delay flowering more than a few days. After they are well advanced they may be potted on into 8-inch pots, and after they begin to show flowers manure may be used freely.

"The above is the most simple method of growing Sweet Peas in pots, but they may also be grown singly. Sow early and pot off the seedlings as soon as ready, and stop from time to time until they have formed bushy plants. They may be tied up to a single stick. Six-inch pots are large enough for single plants.

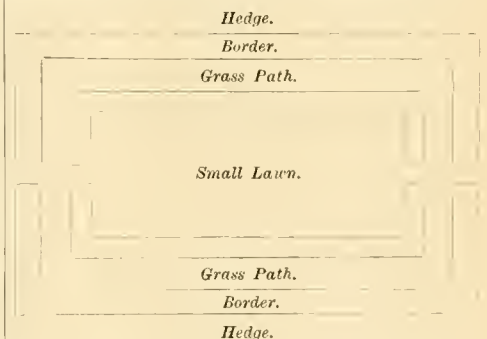

## A GARDEN OF SWEET-SCENTED FLOWERS.

(Second Prize Essay.)

WHAT visions the title brings back to us of old-fashioned gardens, the air drowsy and warm, and every breeze bringing some new scent to our notice. A garden of sweet scents must be, I think, essentially a summer garden, a garden of

blue skies and lazy days, quiet, sheltered from all outside influences—a dream garden, yet one we can realise if we will.

Let us imagine our dream garden in the making. An oblong piece of ground with sheltering hedges and grass inside shall be the start, as large or as small as our fancy permits. An entrance at each end through the hedge and a broad border inside, let us say, 10 feet wide. Then a grass path all round, then a bed about 8 feet wide following the line of the border, with a small lawn in the middle. The following rough sketch will make my meaning clearer.

In the centre must be a sundial, as our dream garden will be warm and sunny. Our sheltering hedge must be of sweet-scented shrubs—Lilacs, white and blue; Syringas, both dwarf and tall; white and crimson May, and plenty of Penzance Briars; these last grown at first on a rough fence or trained to poles. We will thoroughly trench both borders and beds, deepening them, adding good soil and manure and seeing that the drainage is right. In such a garden there ought to be a summer-house, not a varnished or painted one, but one made of plain Oak, which we can cover up with two plants of Rose Aimée Vibert or, perhaps, Honeysuckle. Then, for choice, I would plant the centre beds entirely with dwarf Roses, for this is to be chiefly a summer garden, and no flower equals the Rose.

Plant the Roses 2 feet apart, prune them hard the first spring, then allow them to grow into large bushes. I would plant the ends of the beds with Hybrid Perpetuals and the sides with Teas and Hybrid Teas, growing each sort together. Hybrid Perpetuals: General Jacqueminot, Hugh Dickson, Mrs. J. Laing, Dupuy Jamain, Ulrich Brunner and Charles Lefebvre. Hybrid Teas and Teas: La France, Marie van Houtte, Mme. A. Chatenay, Mme. Hoste, Pharisier, Prince de Bulgarie, Liberty, Killarney, Viscountess Folkestone, Betty, Countess Annesley, Caroline Testout, Mme. Ravary and Gustave Grunerwald.

I think the best way is to grow the perennial plants in the border to form the basis, as it were, in irregular groups or bays, avoiding formality, and filling up the spaces between with annuals, our choice of perennials that are sweet scented being somewhat limited. In one place we will add some peat to the soil and plant some Azaleas, and among these try some Lilium auratum, but we must take care that neither lime nor any rank

manure is present. At the back of the border, in front of and among the shrubs, we will plant plenty of white Narcissus, both double and single varieties, carpeting the ground above with Sweet Woodruff, and on these and plenty of Wallflowers we will rely for our earliest flowers.

Two dwarf shrubs that can be confidently recommended for their fragrance, should the soil be fairly light and peaty, are *Daphne Cneorum* and *D. Mezereum*. Then we must have a generous planting of the Madonna Lily (*Lilium candidum*), associating them for choice with pink China Roses. *Lilium croceum*, *umbellatum*, *testaceum*, *elegans* and the hardier *speciosum* are all fairly easy to grow, and will add considerably to the beauty as well as to the fragrance of our garden. For an edging to the border nothing can be better than white Pinks, such as Mrs. Sinkins. Sturdy plants put in about 9 inches apart will develop into a continuous border, producing masses of flowers. They will only need dividing and replanting every third year, and are very fond of a little road grit mixed with the soil. *Hemerocallis flava*, the sweet-scented Day Lily, is one of the easiest of all plants to grow.

Carnations, too, we cannot do without, especially the old-fashioned Cloves, and for a border such as I am describing I would recommend groups of seedling plants instead of named varieties. Seedling plants are cheap, flower so abundantly and we can easily retain, by layering, any we specially like. We must have some Bergamot, a very easily-grown scarlet perennial, and Lavender, Rosemary and Southernwood must find a place in our garden. We must find room somewhere for a plant or two of white Jasmine. If there is any shady corner, mix some leaf-mould with the soil and plant some Lilies of the Valley, and, except for replanting every four years, an annual mulching of decayed manure will be all they require.

For bold groups clumps of Sweet Peas should be arranged in early March, each clump containing about a dozen seeds 3 inches apart, and each clump of one colour and variety. If we have room, a few herbaceous Pæonies may be added, some of which are very fragrant, though the flowers are not very lasting. Pillars or large bushes of Roses *Gustave Regis* and *Griiss* an *Teplitz* will be an acquisition, grouping round them some dwarf Moss Roses. The Tree Poppy (*Romneya Coulteri*) and the yellow Tree Lupin might be tried if our garden is exceptionally warm and the soil light and well drained. The old-fashioned Sweet Rocket, both double and single, should be planted, also Sweet Sultans, and we have a large choice of varieties among the Evening Primroses. The white Musk Mallow, too, will grow almost everywhere, and Violets may be planted under the hedge, as they succeed best in shady places. The spaces between the perennial plants may be filled, when all danger of frost is past, by Verbenas, Stocks, Oak-leaf Geraniums and Heliotropes, and we must have a plentiful supply of Mignonette.

Do not forget the white Tobacco Plants. These, especially if planted in good soil and given plenty of room, will fill the whole garden in the evening with their fragrance, and wherever there is room put in a few seeds of the Night-scented Stock (*Matthiola bicornis*). This shuts up during the day and looks altogether insignificant, but as the evening comes on the little mauve flowers open and the whole air is laden with perfume.

There is a certain limitation in a garden of sweet-scented flowers, but it is far better to grow a few varieties and grow them well than any amount of flowers that do not realise their full beauty. But, in conclusion, such a garden by reason of its very limitation can be made more interesting, and certainly more delightful, than the usual mixed one, far too often planted without regard to either the general effect or the beauty of the individual flowers. A. W. PODGER.

1, Forest View Avenue, Whipps Cross, Leyton

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 18.—French Horticultural Society's Annual Dinner, Mr. H. J. Veitch in the chair.

January 21.—National Amateur Gardeners' Association.

January 23.—Gardeners' Royal Benevolent Institution Annual Meeting and Supper, Simpson's, Strand, 2.45 p.m. and 6 p.m.

**The Gardeners' Royal Benevolent Institution.**—The annual general meeting of members of the above society for the election of pensioners will be held at Simpson's, 101, Strand, London, W.C., on Thursday, the 23rd inst. At 6 p.m., at the same place, the annual friendly supper of friends of this institution will be held, under the presidency of Mr. Martin H. F. Sutton. Full particulars can be obtained from the secretary, Mr. George J. Ingram, 175, Victoria Street, London, S.W.

**East Anglian Horticultural Club.** The annual report of this up-to-date provincial horticultural club for 1907 and the schedule for 1908 is now being issued to members, and provides interesting reading for those who are interested in the various branches of horticulture. The net increase in the membership for 1907 is three, forty-four new members having been enrolled and forty-one lapsed. The finances are in a sound and satisfactory condition, although there is a small deficit on the year's working, due to rather heavy demands on the benevolent fund. The exhibitions have been of a very high and satisfactory character, although the entries in the flower and vegetable sections have been rather less than those of 1906, but the fruit entries show an increase of twenty-seven. The exhibitions in connexion with the special classes have been particularly good, much interest being taken in all the classes. The non-competitive exhibits and the essay competitions have all been of a very satisfactory order, while the high standard of the addresses and non-competitive papers has been well maintained. The annual outing was, by the kind invitation of the late Lord Battersea, to The Pleasaunce, Overstrand. Particulars of the interesting competitions to be held during 1908 are given. The secretary is Mr. W. L. Wallis, 12, Royal Arcade, Norwich.

**Adelaide Botanic Gardens.**—An interesting official souvenir of the Jubilee celebrations of the Adelaide Botanic Gardens, held on October 19 last, has been published by the Board of Governors of the gardens, and we have derived much pleasure from a perusal of its pages. The main features of the gardens are admirably portrayed by pen and camera, these being followed by a historical sketch. It was on October 18, 1854, that the Government voted the sum of £3,000 for the year 1855 as a first instalment for the creation of the Botanic Gardens. On March 8, 1855, Mr. George Francis was appointed secretary *pro tem.*, and on June 8 in the same year he was appointed superintendent. On October 26, 1860, it was decided that Mr. Francis's title of office be altered to director and secretary. On August 9, 1865, Mr. Francis, the first director, died, and on September 14 following Dr. Schomburgk assumed office in his stead, a post that he held until his death, which occurred on March 25, 1891. An interesting account is given of the first Victoria Regia grown in Australia. This was planted in the gardens on July 22, 1867. In the course of six months it produced no less than fifty-four leaves, the largest of which was 6 feet 4 inches in diameter, and forty-one flowers, averaging nearly 13 inches in diameter, were also produced. During 1871 much damage was done to plants belonging to cool countries by the hot winds that prevailed, the thermometer rising to 115° in the shade. Dr. M. W. Holtze, Ph.D., F.L.S., the present director, was appointed in 1891. The Jubilee

celebrations were held in the gardens by moonlight, the conservatories and plant houses being illuminated for the purpose.

**Resignation of Mr. P. Murray Thomson.**—Deep regret will be felt by all in any way connected with the Royal Caledonian Horticultural Society or its shows at the resignation of Mr. P. Murray Thomson, S.S.C., who has for a number of years been the secretary and treasurer. Mr. Murray Thomson has received an important estate appointment in England, which is the cause of his resignation. While his improved position is cause for congratulation to Mr. Thomson, it is a source of regret to the many who have come in contact with him in his duties in connexion with the Royal Caledonian Horticultural Society. He is ever courteous and obliging, and many have reason to remember his willingness to give any information and assistance in his power. A testimonial to Mr. Thomson is being promoted, and subscriptions are being received by Mr. J. W. M'Hattie, secretary and treasurer to the committee, at his office, City Chambers, Edinburgh.

**Windsor, Eton and District Rose and Horticultural Society.**—At a committee meeting held on the 11th inst. the date of the annual exhibition was fixed for June 27. The report for the past year was considered satisfactory, the number of subscribers having increased, while the number of exhibitors' entries was greatly in excess of all previous years. The hon. secretary (Mr. C. H. Burt, 3, Clarence Gardens, Windsor) announced with much satisfaction that two additional silver challenge cups would be offered for competition in the coming schedule, one given by Mrs. Fortescue, Dropmore, the other to be known as "The Islet Challenge Cup." An important alteration was made at the general meeting, when Mr. Romaine proposed that, considering the progress the society had continuously made, the time had arrived when its radius might advantageously be extended and Rule 7 be amended so that in future it should be: "That the district comprises the County of Berks and all within a radius of ten miles from Windsor."

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Flowers from the open on Christmas Day.**—One sometimes reads in THE GARDEN of flowers out of season being used for indoor decoration. I think it may be interesting to note that on both Christmas and New Year's Day our breakfast table was liberally decked with Primroses, Wallflower Cloth of Gold and Violet Marie Louise, all from the open garden.—G. JOHNSON, *Bishop's Waltham, Hants.*

**The unheated greenhouse.**—In reading an article on the relative hardness of certain plants, the locality in which the writer is situated must be taken into marked consideration, as this is always of great importance. An illustration of it occurs in the essay on "The Small Unheated Greenhouse," in THE GARDEN of the 21st ult. The writer, situated on the South Coast of England, gives a list of different flowering subjects that may be had during the winter in such a structure, yet I venture to say that over three parts of this country any attempt to reproduce this winter display would end in absolute failure. The average individual situated in Lancashire or Yorkshire, or even in the London district, would look upon it as a joke to read of Cinerarias, Acacias, Genistas, Indian Azaleas, Chinese Primulas, Cyclamen, &c., flowering during the winter in a greenhouse without any artificial heat. The fact that many plants will thrive out of doors in Cornwall, Devon and Dorsetshire that need greenhouse protection elsewhere, will, to a great extent, explain the apparent discrepancy. For a cold

greenhouse the plants require to be hardy, as they may be often frozen. Even then there is a considerable choice of subjects, including Hyacinths, Croci, Tulips, Muscari, Narcissi, Lily of the Valley, Liliums of sorts, Spiræas, Wallflowers, Clematis, Roses, *Dielytra spectabilis*, several Saxifrages, Christmas Roses, hardy Cyclamen, early-flowering bulbous Iris and many other hardy plants that are benefited by a certain amount of protection. The smaller hardy shrubs, too, such as *Deutzias*, *Azalea mollis*, *Staphylea colchica*, Lilacs, *Andromeda floribunda* and *Rhododendrons* are also well suited for such a purpose.—H. P.

**"New" Apples.**—In THE GARDEN for December 14 last a selection of new Apples for amateurs was given, in which occurs a rather amusing but yet perhaps natural mistake; still, a mistake which should not have been made. That old Apple *Ross Nonpareil* is credited to Mr. Charles Ross as one of that raiser's seedlings. Really it was put into commerce many years ago, and was raised in Ireland, having been sent to the Royal Horticultural Society by a Mr. Robertson of Kilkenny. The word "Ross" is doubtless intended to indicate the Apple's birthplace. In the list of Apples given as new is included *St. Edmund's Russet*. If by this title is meant *St. Edmund's Pippin*, and I know of no other variety bearing the saint's name, then it is rather old, as it received a first-class certificate so long since as 1875. This is a Russet fruit, but not a great cropper. The list does not include *Charles Ross*, Mr. Ross's best-known seedling variety, neither does it include *Lord Hindlip*, one of the very best of the late-keeping dessert Apples we have, yet new.—POMONA.

**How to treat frozen plants.**—I quite agree with the writer of the article on this subject that appears on page 22 of THE GARDEN, and would like to emphasise the remarks made there. With window and room plants it is a good plan to place as many as possible in a corner of the house on the floor and cover them with many sheets of paper and also some scrim or tiffany and leave them so covered until the frost has gone. If the foliage of such plants as *Zonal Geraniums* is dry the frost will not seriously damage them if they are not exposed to the sunshine while in a frozen condition. I find that many amateurs expose their frozen plants to the sunshine with the idea of thawing them, but this is a grave mistake. It is the same with regard to vegetables in the open border. Those covered with snow while severe frosts are prevalent do not seriously suffer. Others that are exposed to both frost and sunshine do suffer very much, so that the best thing to do is to put on Bracken or dry straw in the absence of snow. During a severe frost late in spring one year recently I had a frameful of *Castor Oil* plants (*Ricinus Gibsoni*) badly frozen. A young man in attending to his work uncovered and opened the frame, and so I found all the plants drooping down like mops. I immediately broke the ice in a cistern near by and thoroughly syringed the frozen plants with the icy water, then closed the frame and covered the glass with heavy mats. All remained in this condition for three days, until the frost had quite gone. When I examined the plants I found one leaf only with a brown patch on it, all the others were quite healthy, but if the plants had been left exposed to the air and sunshine while they were frozen all would have perished. These timely hints may prove of service to many inexperienced readers.—AVON.

## THE GREENHOUSE.

### TUBEROUS BEGONIAS FROM SEED.

VARIETIES of tuberous Begonias are now so well established in popular favour as bedding and greenhouse subjects that a few hints as to the means of obtaining a good stock of vigorous plants at a quite nominal cost may not, at this season, be out of place.

The plan usually adopted for increasing the plants is either by taking cuttings during the season of active growth or by means of seeds. It is only with the latter method that it is now proposed to deal, this being by far the most satisfactory way of raising a batch of sturdy vigorous plants which will give a gorgeous display of bloom for several years, whereas the

passed through a half-inch sieve. The loam used should not be of a too heavy or clayey nature.

A flower-pot should next be scrubbed scrupulously clean, a crock with the concave side downwards placed over the drainage hole, and the pot then filled with broken crocks or coal cinders (not coke) to within about 3 inches of the top, the smaller pieces being placed on the surface. On this put some rough fibrous material or moss to prevent the soil washing down into the crocks and thus choking the drainage, and place on this a good inch of compost with the finer particles on top, making sure that the surface is carefully levelled. Next take some pure leaf-mould which has been well baked until quite dry to destroy insects and fungus spores, and pass it through a fine sieve—such as is used by cooks for straining gravy—or rub it up in the hands.

The pot containing the soil should then be placed in a vessel of water, the level of which should reach to within half an inch of the top of the soil, and when the whole is thoroughly moistened it should be covered with a bare quarter of an inch of the prepared leaf-mould and then taken out to drain. In a short time the moisture will soak up into the dry top layer, when, making sure that the surface is quite level, the seed may be carefully and thinly scattered thereon. Begonia seed being exceedingly minute, it is as well to mix it with an equal bulk of fine silver sand, as it is otherwise somewhat difficult to scatter it at all evenly. It is not necessary to cover the seed, but the merest dusting of fine leaf-mould may be given. The pots should now be plunged in some moist Cocoanut fibre refuse, with, if possible, a bottom-heat of 70° to 80° Fahr. (10° lower will do, but germination will then be slower) and covered with a pane of glass, over which a piece of brown paper has been placed.

The glass must be removed for half-an-hour morning and evening, as if the soil be kept too close a minute fungus is apt to develop on its surface, which, if unchecked, will soon destroy seeds and seedlings. Probably after the first thorough soaking, if the surroundings be fairly moist, no further watering will be required until the seeds begin to germinate; but either then or at any other time the best way to apply it is by placing the pot in a pan of lukewarm water reaching to within about half an inch of the surface of the soil. If it be roughly applied to the surface the seedlings will "lie down," and many never get up again. It should be borne in mind that the water used should never be

cold, but as near as possible of the same temperature as the soil in which the plants are growing.

#### TREATMENT OF THE SEEDLINGS.

As soon as possible the seedlings should be pricked out about 1 inch apart into pans or boxes, using a compost as described above, the best time to do this being while the first pair of rough or true leaves are in process of formation, as the tiny rootlets have then not had time to run far, and a severe check is thus avoided. The handling of these tiny seedlings requires some patience and care, and this can best be done by cutting a V-shaped notch in a thin, narrow strip of wood, such as a plant label, using this to lift them with, while they are carefully levered out by means of a small-pointed stick, which may also be used for making small holes in the earth to plant them in, carefully prodding the soil round them afterwards. When this operation is finished, the whole should be again stood in a vessel of water as described above until well

A BEAUTIFUL DOUBLE WHITE TUBEROUS BEGONIA FROM SEED (SECOND YEAR).

plants procured from cuttings very soon begin to deteriorate.

#### SOWING THE SEED.

The months usually chosen for seed-sowing are January and February; later sowings may be made, but the resulting plants can hardly be expected to flower the same year, and with generous treatment plants raised from sowings made during these months will usually begin flowering in late June and July, and make a fine display, either out of doors or under glass during the rest of the growing season. In order to meet with a fair measure of success the amateur must be able to command a growing temperature of from 65° to 75° Fahr., and if this is not available in the greenhouse recourse must be had to one of the various forms of propagator on the market. The seed being obtained, the next proceeding is to prepare a soil suitable for its reception. This should consist of well-decayed Oak leaf-mould three parts, coarse sand half a part, and good fibrous loam two parts, the whole being well mixed and

moistened, and then kept rather close for a week or so to enable the roots to get well hold of the new soil. As soon as the seedlings have four or five leaves apiece and are beginning to touch one another, they should be again transplanted, this time singly into 2½-inch pots, using the same compost as before, but slightly coarser.

#### WHAT TO DO WITH THE PLANTS.

As the plants increase in size, the next shift should be given, this time into 4-inch pots, the old drainage being carefully picked from among the roots which have run down into it, so as to damage them as little as possible. The plants may now be gradually hardened off, which, supposing the seed to have been sown in the latter part of January, should be about May, and about the middle of June those intended for bedding out may be placed in their permanent quarters, provided the weather is suitable. Those plants intended for growing on in the house should be shifted into 5-inch or 5½-inch pots as soon as the roots begin to work well round the sides of the smaller ones.

Any additional food required may be supplied in the form of liquid manure as the plants come into bloom and the pots become crammed with roots. A suitable soil for the final potting consists of good mellow loam with plenty of fibre in it, two parts; Oak leaf-mould, one part; coarse potting sand, half a part, with a few nodules of charcoal to keep the soil more open and sweet, while a sprinkling of Clay's, Thomson's, or some other well-tried fertiliser may be added with advantage, the whole being thoroughly mixed several days before it is required for use. In conclusion, a word as to the selecting of seed. Always buy from good and reliable houses. It takes six months at least to produce a flowering plant from a seed, and it is just as easy to raise a plant fit for exhibition in the early stages as a worthless one, and the little extra one pays for reliable seed is money well spent.

RODIER HEATH.

*Bruton, Westham, Weymouth.*

A ROSE STEM BADLY AFFECTED BY GREY MOULD (BOTRYTIS CINEREA).

## ROSE GARDEN.

### GREY MOULD ON ROSE TREE STEMS.

WITH the ordinary mildew found on the leaves of Roses most cultivators are familiar, and to the casual observer this does not greatly differ from that shown in the illustration; but this latter is quite different in its effects and much more deadly, so that it behoves every Rose grower to keep a sharp look out for it. It generally attacks the older portions of the plants, such as the main stem or the larger branches, and by this trait is easily distinguished from the common Rose mildew, as that confines its attentions to the leaves and the young shoots.

This grey mould, or *Botrytis cinerea* as the mycologist calls it, is generally associated with decay, being, apparently, powerless to harm a healthy, vigorous shoot. If a wound is made in the bark of a Rose or any other tree and nothing is done to exclude parasitic fungi, the grey mould will probably be one of the first visitors.

In the illustration is shown the patch of grey mould magnified, and the wound round which it is clustered may also be plainly seen. This is in the main stem of the Rose, and its effect is to cut off all supplies of sap from the roots. The best way to prevent this trouble is to avoid making wounds on the stem, either with the sécateurs at pruning time or with the garden fork at digging, mulehing and other times. Should the fungus put in an appearance, its progress can generally be arrested by rubbing a mixture of two parts of flowers of sulphur and one part of unslaked lime into the affected area; but this should be done in the early stages of attack to be effectual.

### ROSES GATHERED ON CHRISTMAS DAY.

ROSES, we know, will often keep flowering until the end of October, and a stray bloom or two may occasionally be gathered during the dull days of November, but it is not many of us that have the pleasure of gathering even a single bloom out of doors on Christmas Day. The charming bouquet illustrated was gathered from plants in the open on December 25 by Mrs. G. E. Scaramanga, Rushetts, Crawley Down, Sussex, to whom we are indebted for the photograph from which our illustration has been made. Doubtless the mild weather that has been until quite recently experienced in that locality was responsible for this pleasing departure from the normal.

### CLIMBING ROSES UNDER GLASS.

[In reply to "R. G. B."]

YOUR question is a very timely one, and we have pleasure in replying to it. Many Rose growers have discarded the old *Maréchal Niel* as an indoor Rose, owing mainly to its tendency to canker, but also to its unfitness for providing a fairly continuous supply of flowers. Without a doubt it is still the king of golden Roses, and when grown upon a half-standard Briar and the entire structure devoted to the Rose nothing can equal it in beauty. We know of some old vineries where *Maréchal Niel* on short standards have been planted to supersede the Vines, and these houses yield their owner a handsome profit. Although there is an inherent tendency to canker,

A BOWL OF ROSES GATHERED FROM THE OPEN ON CHRISTMAS DAY.

it cannot be denied that the Rose is often so much overcropped that disease of some kind is sure to follow. We have been very successful with this grand old Rose under glass by budding it upon a free-flowering sort already established in the structure, and, although some advocate severe pruning after flowering, we have had most success when the Rose has been very sparingly pruned. The tendency of the free-growing sorts when grown under glass is to make wood so luxuriantly as to prevent them giving a continuous supply of bloom, but there are a few varieties that would provide you with the summer shade desired, from which you could expect more flowers than from *Maréchal Niel*. The following, we think, would answer your purpose, and we have placed them in the order of merit: Mme. Hector Leuilliot, Bonquet d'Or, Billiard et Barré, Mme. Jules Gravereaux, Climbing Belle Siebrecht, M. Desir, François Crousse, Mme. Moreau, Crepuscule, Mme. Boursin and W. A. Richardson. The best Roses to plant under glass to provide a long season of flowers are the Tea-scented and Hybrid Teas, groups of what are known as the non-climbing section. If one can exercise a little patience and wait a year or two, while the plants are developing, they would soon cover the roof of any ordinary greenhouse. We should recommend a trial of such Roses. If the house is a lean-to and there is staging in front, you could have a large pot or tub placed in one corner, into which an extra-sized pot plant could be planted. Such plants are usually from 2 feet to 3 feet in height from the top of the pot. Provide the pot or tub with plenty of drainage, and fill up with good loam (three parts) and well-decayed manure (one part) thoroughly mixed together. Two or three handfuls of bone-meal added would also prove helpful. Transfer the pot plant, and before planting just rub off the edges of the ball of earth and slightly prod the sides to release the little roots, when they will be the better able to lay hold of the new soil. Little or no pruning will be required the first year or two, for these plants are usually well ripened when received, and the growth under glass facilitates the ripening each year. You could have several of such plants placed about 4 feet apart, removing every other one as space becomes filled out. We have seen plants of such a Rose as Mme. Lambert entirely covering the roof, and rarely was the owner without beautiful buds and blooms. If it is not practicable to have the plants on a front staging, standard plants could be planted in a well-prepared border beneath; but we would advise pot-grown specimens in preference to those from the open ground. A top-dressing about twice a year, using bone-meal liberally when the

plants are established and watering freely during the growing period, will ensure a strong and vigorous growth quite sufficient for ordinary requirements. We are certain that if such Roses were planted they would give far more satisfaction than the orthodox climbers. A few varieties we can recommend are Mme. Abel Chatenay, Lady Roberts, Joseph Hill, Pharisæer, Mrs. Aaron Ward, Mme. Constant Souper, Perle des Jardins, Mme. Hoste, Richmond, Lady Battersea, Sunset, Sunrise, Souvenir de Pierre Notting, Mme. Lambard, Liberty, Niphetos, Souvenir de S. A. Prince, Kaiserin Augusta Victoria, Mme. Ravary, Mrs. David McKee, Prince de Bulgarie, Mme. J. W. Budde, Marquise de Sinety and Gustave Grunerwald.

## HARDY LADY'S SLIPPERS.

(CYPRIPEDIUMS.)

(Continued from page 16.)

*CYPRIPEDIUM ARIETINUM* (the Ram's Head Lady's Slipper) is a dainty, slender plant, too delicate for general treatment out of doors, and better grown in a sheltered nook amid rare Ferns or in pans in a cool house. It generally grows in tufts a few inches high, bearing small flowers scarcely an inch across, with ruddy brown sepals and petals more or less freely marbled with yellowish green. The pouch is a dainty slipper-like process coloured white, closely veined pink and horizontally poised. It is too small to be considered showy and the colouring varies with different specimens.

*C. Calceolus* (the common Lady's Slipper) is a well-known plant, easily grown and at one time a native of our limestone pastures. Its root-growth is gnarled and distinct from the long, straight roots of the bog-loving types. The stems reach a height of 2 feet when fully established, and they bear on an average two fragrant flowers, the sepals and petals of which are brownish red, slightly twisted and often chequered with yellow. The yellow lip is in the form of a distended pouch less than 1 inch across. The whole flower spans 2 inches to 3 inches, and they last well in good condition if water is prevented—by a sheltering light—from entering the pouch. This is quite an easy plant to grow, and one should endeavour to re-establish this pretty species in damp pastures overlying chalk, either by roots or by seeds.

*C. californicum* (the many-flowered Lady's Slipper) is a rare plant and one of the best of its group. The leaves are like those of *C. Calceolus*, and the stems support spikes of five to ten flowers, with yellow segments and a white pouch veined or sometimes flushed with rose. The plant is vigorous and showy, but very susceptible to decay at the collar in cold and wet winters. Collectors in its native country report it as a bog plant, but the soil exported with the plants is pure loam, and the probability is that a marshy place submerged in the growing season for a few inches is intended. Under cultivation it resents too much wet, preferring the drier loams in winter and to be well watered in its growing season. Its roots agree with the species from loamy soils, and they are quite different from the spectabile-pubescent group.

*C. candidum* (the white Lady's Slipper) is a dainty species of slender tufted growth that one could associate with Sundews, Sarracenias, Disas and kindred plants in cool structures. It appears far too delicate to grow in the open. The plant's long slender white roots indicate a root-run of sphagnum or mossy peat rather than soil, and it suffers from extremes of heat and cold. The stems are half a foot high, and they bear one to three flowers each, the segments of which are brown, shading paler near the bases. The slipper is pure white, and the whole flower averages less than 1 inch in diameter.

*C. guttatum* (the spotted Lady's Slipper) is a rarity from Siberia, white flowered, the lip being splashed with crimson.

*C. humile* [See Fig., THE GARDEN, Vol. LXIV., page 41].—A plant gardeners will more readily recognise as *C. acaule* (the stemless Lady's Slipper), one of the curiosities of the vegetable world. It is a pretty, and in some respects showy, plant, very interesting in its singular formation, and it will be familiar to many who attend the Royal Horticultural Society's fortnightly meetings. The roots are stout, fasciated, not fleshy, the stems, i.e., flower-stalks, are 9 inches high, bearing one (rarely two) flowers on each, 3 inches across the "wing" segments, which are lance-shaped, rigidly flat and the upper petal is hooded. The pouch is a loose bag-like process of rosy purple colouring, veined on the inside, quite 2 inches long and much contracted at the base. A slit from top to bottom of the lip reveals the coloured interior and the edges are turned back to render this colouring more attractive. As a garden plant *C. humile* finds its greatest use in damp rockeries associated with creeping Bellflowers (*Campanulas*) and Arenarias between stones. It grows well in the cool house treated like a Disa, and one can grow the plant well in pots in Belgian leaf-soil or in Jadoo fibre.

*C. japonicum* rarely finds its way to this country in good condition, and its flowers are

THE FINEST GROUP OF CHRYSANTHEMUMS SHOWN IN SCOTLAND LAST YEAR.

rarely seen. Newly-imported specimens may flower once, but rarely develop a second leafy growth. The leaves, there are but two, are arranged in a shuttle-cock-like vertical, neatly plicated, and the flower has wide converging segments and a curious warty lip in the way of *C. humile*, but with a rounded aperture at the centre and a few parallel raised processes at the tip. The whole plant is hispidulous. THE GARDEN published a coloured plate of this curious species several years ago. M.

(To be continued.)

## THE FINEST GROUP OF CHRYSANTHEMUMS IN SCOTLAND LAST YEAR.

MR. WILLIAMSON, Glasgow, sends a photograph, which we reproduce, of the finest exhibit of Chrysanthemums in Scotland last year. This record display was to be seen at the Glasgow Corporation Camphill Gardens. Forty-one varieties are represented, and, as our correspondent says: "It stands unequalled in Scotland, perhaps in Britain, and reflects great credit on Glasgow's Parks Department."

## THE FRUIT GARDEN.

### PEARS AND APPLES FOR THE NEW YEAR.

THERE are many new varieties of Apples and Pears in these days of novelties. Some are old but introduced with new names, others are the results of hybridising, the cross of which sometimes is not so good as existing varieties, and in the New Year some of the old Apples and Pears are very difficult to beat. I should like to know what is better than a good well-ripened Blenheim Orange or a Ribston or Cox's Orange. There is not a new Apple that can beat them, and if these fruits are well ripened, that is, allowed to hang on the tree till they part readily from the spur, their condition at Christmas is superb.

Many of the new Apples are in season at the time of the autumn shows; they get admired and are bought and planted largely, and in a year or two it is found that the old ones were really better than the new. Most of these inbred or crossbred sorts produce weak-growing trees, as the plants have been pushed rapidly to get a supply

of scions for multiplying the stock for commercial purposes. For instance, that good variety Allington Pippin is not wanted when one has Cox's Orange Pippin, as it is inferior; it is softer in texture and does not keep so well. Edward VII. is a new variety from which much was expected, but I cannot see any improvement. We have several trees in bearing, so that I am not speaking from hearsay, but from actual experience.

Pears in season at this time are few in number; the same mistake often occurs. People plant varieties they see at the autumn shows. Easter Beurré can be had in fine condition now by introducing the fruits into a warm room about twenty-four hours before they are wanted for consumption. If a smaller Pear be in demand, then by all means grow Winter Nelis and bring it on in the same manner. In some catalogues they tell you Thompson's is a good December Pear, but I have found it is gone long before Christmas; nevertheless, it is well worth growing.

Doyenné du Comice.—This is the best Pear in November and the first and second week in December, but cannot be said to be a Christmas Pear, as it does not keep after the second week, or very rarely. Our last fruits of this variety are

rarely gathered before November, and even then they fail to go on till Christmas.

Fondante de Thirriot is a good Pear for December; it has a green skin, and here and there is covered with patches of russet, but it is most delicious and is a good grower.

Glou Morceau or Beurré d'Handenpont is always a good Pear at this time; it is buttery, rich and delicious, and finishes its fruit best on a wall or some sheltered situation.

Charles Ernest, a large handsome fruit, is another reliable variety now in season. It grows well as a cordon or as a fan-trained tree on a wall.

Beurré de Jonghe is another Pear always ready for the New Year, and can be kept five weeks later. There are many others which I will enumerate on another occasion by permission of the Editor. It must be borne in mind that all Pears at this season are the better for dessert when placed in a warm temperature for a little while.

Of course, only by much experience can the precise time be dictated in each case. A few hours only are enough for those that are mature, and, as a rule, they are useless afterwards, so that only as many as are required should be served up under this process.

W. A. COOK.  
*Leonardslee, Horsham.*

## WELL - GROWN VINES.

THE illustration represents two vineries, early and late, with six Vines in each. Each Vine contains from four to six rods. There are nine varieties, as follows: Two Black Hamburgh, two Muscat of Alexandria, two Frontignans, with one each of Foster's Seedling, Golden Champion Alicante, Gros Colman, Mrs. Pince and Lady Down's Seedling. As near as I can find out they have been planted about forty years and at times have been badly neglected and heavily cropped, so when I took charge of them three years ago I found a great deal of shanking among them, my employer, the Rev. Meyrick Jones, having taken the place some little time before then. I generally apply a good dressing of rich farmyard manure in winter after cleaning down the houses. Two or three waterings of weak liquid manure are given and a dressing of Thompson's Vine Manure. They now seem to have taken a new lease of life.

H. PROTHERO.

*The Gardens, Stanley House, Stonehouse,  
near Gloucester.*

## THE OLD GREEN GAGE PLUM.

AMATEURS will doubtless continue to plant the real old Green Gage, or what is sold to them as such, and become resigned to its failure to fruit, even when it flowers freely nearly every year. Market growers also will continue to plant it, as it still remains unsurpassed, and perhaps unequalled, by any of the more recent introductions, even of the Gage type, and where the soil and situation does just suit it the lucky possessor has a fortune. Perhaps its greatest merit, from a market point of view, is that the man in the street knows it and will buy it, or what looks like it if labelled Green Gage, whenever and wherever he can get it. There are other Plums, e.g., Early

Transparent, Denniston's Superb, Jefferson, Golden Drop and others, all of the highest excellence, all unsurpassed by any other unless it is the Green Gage, and all bearing four or five times as well as the latter, which is said to bear only once in seven years. Yet it is, and doubtless will remain, one of the first the inexperienced amateur plants.

Like many of our most excellent fruits, its origin is lost in obscurity. It is supposed by some authorities to be a native of Greece and by others of Caucasia. It is said by some to have been introduced at the beginning of the eighteenth century by Sir Thomas Gage of Hengrove Hall, near Bury St. Edmunds, who procured it from his brother then resident in Paris; others say it was introduced earlier than this. In France, which may be said to be the modern home of the Gages, they are known as Reine Claudes, e.g., R. C. de Bavay, R. C. Violette, &c. Dr. Hogg enumerates twenty-five synonyms of the old Green Gage. It comes fairly true from seed as a rule, though there are innumerable variants all sufficiently alike to be called Green Gage, while there are a dozen or more well-marked

On those rare occasions when a tree is thickly set with fruit it pays to thin it in June, for if left to ripen too heavy a crop, not only will the fruit be small, but deficient in flavour. It is useless planting this tree in the open near woods or where bullfinches are very troublesome, as they take all the best fruit-buds in winter. I know of standard trees near woods where the blossom-buds are almost entirely removed every year.

It is said that wall trees often bear much worse than they would do through want of water, and winter watering is recommended. I have practised this, and have had better results since. I am inclined to think it is a case of cause and effect. It must be borne in mind that not only does the wall keep off a deal of rain when the wind is behind it, but that it absorbs a great deal when the rain is blown directly on the face of it, this being lost by evaporation during the first few dry hours afterwards. ALGER PETTS.

## STRAWBERRY FORCING.

ASSUMING that the plants are thoroughly ripened and developed, the difficulties attending successful

Strawberry forcing are very few, providing proper convenience is at command. Comparatively few gardens can boast of a Strawberry house, or any house that can be devoted to Strawberry culture alone. Where space is very limited we would advise deferring Strawberry forcing to a more favourable season, when the chances of failure will be considerably less. At this early date it no easy matter to get a good percentage of plants to flower; but this difficulty may be lessened if a heated pit is available and the plants can be plunged in a bed of leaves of moderate warmth. In so doing, the roots are encouraged into action correspondingly with the leafage. To restrict leaf growth until the flower spikes are visible a little air should be admitted on the top and

bottom of the pit on all favourable occasions. It is the undue hastening of the plants into luxuriant growth that causes so many to become blind.

## COLOURED PLATE.

PLATE 1841.

### TUBEROUS BEGONIA WILLIAM MARSHALL.

THIS Begonia is, perhaps, the most handsome scarlet tuberous Begonia in existence. As may be seen in the coloured plate it is a very full double variety of exquisite shape with handsome, robust foliage. It was raised by Mr. Pope at Messrs. T. S. Ware's Bexley Heath Nurseries in 1903, and is named after Mr. William Marshall, V.M.H., chairman of the floral committee of the Royal Horticultural Society. The habit of the plant is very erect, yet robust, and it will undoubtedly become a very popular variety. Messrs. Ware, Limited, make a speciality of tuberous Begonias, and have introduced many sterling varieties during recent years.

WELL-GROWN VINES AT STANLEY HOUSE.

and distinct forms of it varying in size, colour, shape, quality, season, &c.

Like most of the Gages, the old Green Gage is a very strong grower, and when grown as a wall tree or dwarf tree of any form it requires vigorous root pruning to get it into bearing condition. I know some bush trees twenty years old 8 feet high and as many in diameter which have never borne a crop of fruit, and never will as at present managed, being cut in close every year; in fact, clipped into shape. A chalky soil on high ground is perhaps best suited for it, and in such positions it is well grown in some parts of Kent.

The flower is more than ordinarily susceptible to damage by frost, such a long time elapsing before the embryo fruit begins to swell, and that is why it is best on high ground. In some places it does better as a standard in grass than anywhere else. The fruit is smaller from a standard than from a wall, but often of richer flavour, while somewhat different in appearance, the fruit from a wall being brownish green and orange, with a beautiful bloom upon it, while that from a standard is often destitute of bloom, but is marked with russet patches and reddish dots, the latter, however, sometimes appearing on wall trees as well.

## THE FLOWER GARDEN.

## HUTCHINSIA ALPINA.

**M**OST of us are familiar with the accommodating way in which *Aubrietia* and *Arabis* increase in our gardens, and though not so large in its parts as either of these *Hutchinsia alpina* is equally willing to make itself at home. It belongs to the great group of Crucifers or Cress family, and its dainty beauty is accentuated by growing a large patch. *Hutchinsia alpina* is remarkably free in flowering; it makes sheets of snow white flowers in May and June, though it is rarely without flowers the greater part of the summer. One of its greatest charms is the soft green colour of the foliage throughout the winter, which refreshes the eye and reminds one of spring. One can imagine no more pleasing edging to a spring garden than a broad ribbon of this plant, for it is easily propagated by small tufts placed in sandy soil in a cold frame, so that the idea is easily practicable in small gardens. The height of the plant is about 3 inches, attaining to a height of 6 inches when in flower. It also makes a delightful carpet when studded with the flowers of *Chionodoxa* (Glory of the Snow) or some of the smaller *Narcissus*, like *N. triandrus*. The group illustrated is grown upon the steep slope of a rockery in light, chalky soil, facing south, and is two years old from cuttings.

THOMAS SMITH.

Walmsgate Gardens, Louth, Lincs.

## A FINE YUCCA.

THE illustration shows a very fine flowering specimen of the Mound Lily or Adam's Needle (*Yucca gloriosa*). This plant is a native of the United States of America, but specimens are met with in many of our gardens, especially in the South of England, where they prove quite hardy. They are but little trouble to grow if a well-drained and open soil is provided. Planted in a bed on a lawn they assume a majestic appearance and always prove attractive. Inflorescences are not produced very freely, but when they do appear they are decidedly attractive, the hundreds of good-sized, whitish flowers lasting for many weeks. Propagation may often be effected by means of suckers that are produced naturally, or old pieces of stems may be placed in a warm propagating case during early summer, when side-shoots will be formed.

These may be taken off with a slight heel and inserted in well-drained pots of sandy soil, keeping these plunged in a temperature of 65° until the cuttings have rooted.

## HARDY FUCHSIAS.

Who will give us a race of hardy Fuchsias that shall include all the beautiful colours and variations of those which now grace our green-houses? Fuchsias equal in size and hardiness to *F. Riccartonii*, which in most English counties soon makes a fine shrub. What a boon they would be in late summer, when shrub borders are always rather sparse of flower and colour, and how charming their graceful and brightly-coloured flowers among the changing foliage in the more sombre days of the waning year.

YUCCA GLORIOSA IN FLOWER.

Unlike many other flowers the Fuchsia seems but little affected by the heaviest downpour. Its flowers move with the wind and so escape, while the umbrella-like corolla prevents any moisture trickling to the centre. True the branches of some varieties are rather brittle, but others, such as *F. macrostemma gracilis* are fairly tough and might be used by the hybridist to add suppleness where it is now lacking. Nor is it impossible to intermarry hardy and tender species and still retain the hardiness of the former, with the addition of the bright colours of the latter. What has been done by M. Marliac for the *Nymphaeas* can surely be accomplished with the Fuchsias.

There are already several species quite or almost hardy. From one of these (*F. globosa*) a seedling, viz., *F. Riccartonii*, was raised in 1830.

One would have thought the increased hardiness, size and brightness in the flowers of this variety would have proved sufficient incentive for further effort; seventy-seven years have, however, passed since then and very little has been done. Of the species before-mentioned many are well worth the small amount of protection they need in the more northern parts of the country. The seaside, even in the exposed Eastern Counties, seems to suit them admirably. In colder districts a sheltered situation, such as the side of a house, shed or wall should be chosen in which to plant. Not that they ought to be shaded in any way; provided the soil is fairly moist below, they cannot have too much sun. In winter a covering of cinders, Heather or evergreen branches may be placed over the roots, though in many places this is not necessary. Young plants should, however, be carefully protected; they are far more liable to be frozen the first winter after planting than when they have become established.

Propagation is easily carried out by means of cuttings, which root readily, preference being given to those shoots without flower-buds in the axils of the leaves. All Fuchsias prefer a light, well-drained soil, but heavy land, if not too wet, can easily be made suitable by adding leaf-mould or old potting soil. Plant in April; if the plants have been kept very cool and rather dry they will be dormant, and as the weather becomes warmer will soon make rapid growth, but if they have been kept in a greenhouse their tender foliage must be carefully inured to outside conditions before planting out towards the end of the month. With the exception of *F. Riccartonii*, they are best treated as perennials, pruning them to the ground level early in March, giving at the same time a top-dressing of manure.

## THE BEST SORTS.

Among the hardest species and varieties may be named *F. macrostemma gracilis*, hardy, good habit, flowers red and purple, produced freely; *F. m. coccinea*, late-flowering, tubes and sepals long, scarlet, corolla purple; *F. m. globosa*, dwarf, flowers red and purple, rather dull, free-flowering; *F. m. pumila*, 12 inches to 15 inches in height, neat and compact; *F. corallina*, a robust, large-leaved, free-growing sort; *F. Riccartonii*, a hardy shrub of highly decorative character. Another fine variety, one which passed through last winter in the open border quite unharmed, is *Mme. Corneillon*; the flowers

are of good size and shape, scarlet sepals, tinted on the under side with pink, veins of the same colour beautifying the white corolla. Its habit is good, it grows freely and flowers profusely; a small plant put out here in April, 1906, was on October 12 a mass of flower, 3 feet 6 inches in height and nearly as much through. Others might be mentioned, but my purpose is to awaken an interest which will not be satisfied with those already in cultivation.

If this is achieved we may see beautiful flowering plants adorning our shrub borders during the late summer with flowers almost as large as some of those we now grow under glass. I think everyone will agree that there is room for improvement.

J. COMBER.

Handcross, Crawley.

ONE OF THE CRESS FAMILY (*HUTCHINSIA ALPINA*).

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**FLOWER GARDEN.**—In open weather plant German Irises. When the weather is frosty prepare new beds and borders for hardy plants and deeply dig or trench new ground intended for shrubberies. Deciduous plants and climbers may be pruned now, rearranging growths of the latter, and carefully nailing them to the walls and fences as the work progresses.

**Vegetable Garden.**—Prepare hot-beds for forcing early crops of Carrots, Asparagus and Radishes. Where stable manure is plentiful, this way of raising early crops and seedlings has much to commend it. A sheltered situation should be selected for the hot-bed, where protection from cold winds can be provided. Early Peas may now be sown on warm, protected borders, but in other positions such work must be deferred for a few weeks. Quarters intended for Carrots and other root crops should be trenched or deeply dug as soon as possible, using well-rotted manure, which should be placed as a layer at considerable depth below the surface.

**Frozen Window Plants.**—Should any plants get frozen, place them in a cool dark cellar or room and sprinkle them with cold water. On no account attempt to thaw them with warm or tepid water or place them near to a fire to thaw. The earliest bulbous flowers should now be making the window gay.

**Greenhouse and Conservatory.**—Keep the fire going steadily to dispel damp and prevent injury from frost. Give water carefully to all plants. Repot Lilies. The golden-rayed Lily (*Lilium auratum*) and *L. speciosum*, if potted up in a soil made up of loam, leaf-mould, peat, well-rotted manure and sand in equal parts, will do well. Cuttings of such plants as Geraniums, Lobelias,

for many plants that are fast developing their blossoms. Keep the frames carefully and securely matted up at night and throughout the day when frosts prevail. Freesias and other bulbous-rooted subjects in cold frames should be staked and tied, as they require support. On bright, warm days the frame-lights covering bulbs and Violets should be thrown off for an hour or two, and any plants suffering from damp should have the affected leaves or petals removed. Violets require plenty of air, and this should be afforded them when the weather is not too severe.

**Chrysanthemums.**—Early-flowering decorative and Pompon sorts may be propagated freely. Insert cuttings of these sorts in shallow boxes and 3-inch and 5-inch pots, using a compost of loam and leaf-mould in equal parts, with the free addition of coarse silver sand or clean road-grit. Sift these soils. The cool greenhouse is an excellent place in which to root the cuttings now.

### TWO GOOD FERNS FOR ROOMS.

**THE AUSTRALIAN BRACKEN.**—This, the Quivering or Trembling Fern, *Pteris tremula*, is closely related to our native Bracken, *P. aquilina*, and constitutes one of the very best and handsomest Ferns for growing in rooms. Immense quantities of it are raised in nurseries annually from spores, a very easy means of propagation in this instance. Young plants in 2½-inch pots can be easily and cheaply purchased, the middle of April being a good time of the year to secure a supply. As these will in most cases have been grown on rapidly under comparatively hot and moist conditions, some special care is needed for a week or two after they are bought, giving them the warmest position in the room and sheltering them from drying draughts. A mistake that amateurs almost invariably make with these newly-bought young Ferns, and one that often proves fatal, is to repot them into a larger pot as soon as they are received from the vendor. No doubt the purchaser is tempted to do this by the pot-bound condition of the roots that usually prevails, but it is much wiser to keep them in their small pots until they are thoroughly accustomed to their new surroundings. They may then be given larger-sized pots with advantage, providing perfect drainage and using the same soil as advised below for the Maidenhair Fern.

**Maidenhair Fern.**—This is too well known to need description. The illustration shows a good specimen that has evidently been well treated. The best time to repot established plants is about the middle of March, using soil composed of three parts very fibrous loam, one part peat, and one part coarse sand. Keep rather close for a fortnight afterwards and be

very careful with the watering until the plants are established in their new quarters.

### WINTER-FLOWERING CARNATIONS.

THESE plants have become so very popular of late that all gardens worthy of the name appear to be incomplete without at least a small collection of the better varieties. English raisers are now

viewing with their American rivals in the introduction of new and beautiful flowers, and as a consequence of this praiseworthy effort we are now in possession of quite an interesting list of named varieties. The Tree or Perpetual-flowering Carnations, by which description the winter-flowering sorts are more generally known, are flowers partaking of a great diversity of colouring, and their form is pleasingly varied. They are

THE AUSTRALIAN BRACKEN (*PTERIS TREMULA*).

not difficult to cultivate if the grower is quite prepared to give them the conditions in which they invariably do well. Some of the newer sorts are, of course, expensive, but the older varieties, which are almost as good as many of the novelties, may be raised in large numbers when one is in possession of a plant or two with which to make stock.

**How to Make Carnation Cuttings.**—Much depends upon the character of the individual plant that is dealt with. The proper length of a cutting is about 3 inches, though half an inch less is quite long enough. These may be detached quite freely in the late winter as the plants go out of flower, the frequent cutting back of the plants having the effect of inducing them to evolve fresh young shoots from time to time. Always use a sharp knife and make a clean cut through. Remove the lower leaves by simply pulling them down, and cut through the joint, just leaving the eye, immediately below which the roots are emitted. A joint is that part of the stem where the leaf-stalk forms a junction with the cutting.

**Propagating Winter-flowering Carnations.**—Propagation of the winter-flowering Carnations may be done in January and in subsequent months as cuttings are available. There are several ways of rooting the cuttings, but the simplest method is that of inserting them in pots filled with sandy soil, and placing them in a propagating frame where genial bottom-heat can be provided. The cutting may be rooted exclusively in sand or in very sandy soil. In sand of a reddish or sandstone character the cuttings root with great freedom, and we prefer to use this to any other. Where this is not available, make up a mixture of sandy loam, leaf-mould and clean road-grit or sharp sand of some sort, using half a part of each of the two first-mentioned soils and one part of the road-grit. Mix these ingredients thoroughly

A GOOD SPECIMEN OF MAIDENHAIR FERN (*ADIANTUM CUNEATUM*).

Ageratums, Heliotropes and Petunias should be inserted now. Lily of the Valley, *Deutzia gracilis*, *Azalea mollis*, Solomon's Seal and *Spiraea japonica* should now be placed in a light position and watered moderately.

**Cold Frames.**—Cyclamen and other somewhat tender plants should be placed in the cold frames as they go out of flower. This will make room

CARNATION CUTTING WITH LOWER LEAVES REMOVED READY FOR INSERTION.

before using the material. Pots of a size to suit the requirements of each individual grower should be used, and, where possible, the cuttings should be inserted singly in  $2\frac{1}{2}$ -inch pots. However, we prefer to avail ourselves of a propagating frame in a warm greenhouse where the bottom-heat is about  $70^{\circ}$  to  $75^{\circ}$  and the temperature of the glass structure some  $10^{\circ}$  to  $15^{\circ}$  less. If the propagating frame is filled in 6 inches or 7 inches deep with reddish sand, the cuttings may be dibbled in freely and will root within about three weeks. No frame-lights should be placed over the cuttings, as this predisposes them to fail. When inserting the cuttings, always see they rest on the sand in the bottom of the hole and press the soil firmly at their base; 2 inches between the cuttings will suffice. Water in with a fine-rosed can, using tepid water.

*Potting Up the Rooted Cuttings.*—As soon as the cuttings are rooted they should be potted up into small pots. On no account must they be allowed to remain long in the propagating case after they are rooted. Evidence of rooting will be given by fresh growth of a pale green kind. Two and a-half inch pots are quite large enough for the first potting, and these should be clean and crooked with potsherds. Place a small quantity of soil over the crocks; then proceed to lift each rooted cutting, disturbing the roots as little as possible, and subsequently arranging them carefully before filling in the compost. Make the soil fairly firm from bottom to top, as the non-observance of this rule is a frequent source of failure. When the young plants are finished they should be stood together in the same glass house where a moist bottom and a free circulation of air can be provided. When established they should be transferred to a glass house where less close conditions prevail. The soil for this first potting should consist of good sandy loam, leaf-mould and clean road grit.

*Subsequent Repottings.*—As soon as the young plants are nicely established in the ordinary greenhouse they will need another shift in a little while, and this time into pots measuring  $3\frac{1}{2}$  inches to 4 inches in diameter. Subsequently it will be found advantageous to give them another shift into 6-inch pots, or those a trifle less in diameter. A good soil for these later repottings should consist of good fibrous loam, to which should be added some well-decomposed horse manure and a free sprinkling of bone-meal. Should sandy loam be used, little road grit will be needed; on the other hand, heavy loam should have mixed with it plenty of coarse sand

or road grit. Plants should be overlooked before repotting, and those that are dry should be well watered. During the summer months, say, from June onwards, the plants may be stood in cold frames or pits, but be removed to the greenhouse in August.

*Later Treatment.*—After housing the plants always give plenty of top air. It is a great mistake to excite the plants into growth by keeping them unduly warm or close. The temperature of the glass structure should be maintained at about  $50^{\circ}$  to  $55^{\circ}$  at night and  $60^{\circ}$  to  $65^{\circ}$  during the day. Watering must be done with care, using common-sense. Apply water to

A ROOTED CARNATION CUTTING, SHOWING HAIR-LIKE ROOTS.

the plants when the soil is nearly or moderately dry, and err on the side of caution in wet, cold and foggy weather. Manure water may be given to the plants when they are well rooted and buds are formed, but always err on the weak side.

*A Few Good Winter-flowering Carnations.*—Robert Craig, bright scarlet, large; Mrs. Burnett, lovely salmon pink; Mrs. S. J. Brooks, pure white; Britannia, scarlet; Duchess of Portland, soft pink of medium size and lovely form; Fair Maid, large, light pink; Enchantress, beautiful flesh pink, large; Harlowarden, deep crimson; Nelson Fisher, intense cerise, large; Mrs. T. W. Lawson, a beautiful pink, sweet scented; Mrs. Robert Norman, a grand pure white sort; Mrs.

William Cutbush, bright rose-pink; Windsor, beautiful pink; and Mikado, white with distinct crimson blotches.

#### SEASONABLE HINTS ON THE CARE OF ROOM PLANTS.

THE winter is a very trying time for these occupants of our homes. The extra firing and burning of gas that has to be resorted to tends to render the atmosphere of the rooms dry and dusty, and this is far from being beneficial to healthy plant life. Some people who are aware of this evil try to avoid it, and do what is equally detrimental, namely, allow the plants to remain in seldom-used rooms; and, of course, these get too cold for them. Of the two drawbacks the former is the lesser, so long as the plants are kept from being directly under the gas or in front of the fire. The dryness of the room and dirty appearance of the plants must be counter-balanced by more frequent spongings. These remarks apply to Palms, Aspidistras, India-rubber Plants, Castor Oil Plants and others of a similar character.

Geraniums and Fuchsias can be kept through the winter even without the aid of green-houses, though with them much easier, providing a spare room or its equivalent space, from which the frost can be kept, is available. Practically all foliage will come off the Geraniums and Fuchsias at this season; but this need not alarm anyone, as they quickly make new leaves in the spring if we can preserve the roots and stems alive. To do this it will be necessary in very severe weather to burn a lamp or small oil stove in the room so as to keep the temperature from falling below freezing point. Another very important point for the safe wintering of such plants is to keep them well on the dry side during the cold, frosty weather, as by so doing they are much less likely to take any ill effects. When watering must be done, choose a mild day. Water thoroughly, and do it in the morning, so that the plants may be well drained before night time. The Fuchsias will not need more than a couple of waterings through the winter, and, being hardier than the Geraniums, may be stood under a table or in a corner. The Geraniums need all possible light, and therefore should be placed where that will be obtainable. C. TURNER.

ROOTED CARNATION CUTTING ESTABLISHED IN A "THUMBE" POT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FORCING DEPARTMENT.

**S**OW a few Cucumber and Melon seeds of approved varieties to give an early supply, and to do this effectively now care should be taken in preparing the soil, which should be of the best quality and free from worms, grubs and other vermin. Take sufficient into a warm house for the purpose, sow in small pots and when the seedlings are well rooted transplant or pot on into a larger size, disturbing the roots as little as possible. Some good fibrous loam, with a portion of leaf-soil and decayed manure, will be the right material. Keep up a supply of bulbs and plants for the conservatory and house decoration by introducing plants each week.

**Vines.**—The earliest Vines may now be kept 5° warmer by day and night, and on bright days syringe them twice or thrice daily. If the rods show signs of breaking too freely bend the top down to induce growth at the bottom. A second house may now be started by shutting it up. All Vines should be pruned by this time or they may bleed, which is very weakening.

**Peach House.**—This house may now have a little more heat, but proceed with caution, and as soon as the blooms begin to open allow a little circulation of air, and on bright days the trees should be sprayed with a very fine jet. This I have found the best way of procuring the most satisfactory set of fruit. A second house may now be closed. Each fruit house should be scrupulously cleaned before being started, cleanliness in Peach growing being one of the principal elements of success.

#### FLOWER GARDEN.

**Sweet Peas in Pots.**—Sow a batch in pots and place in a cool house or frame. Only the best varieties should be grown. As soon as the seedlings are up keep them very close to the glass to prevent a drawn growth.

#### FERN HOUSE.

Keep Ferns a little drier, except those that are in active growth. The new types of *Nephrolepis* are excellent for decoration and are readily increased. They must not, however, be grown in too much heat, as they are apt to run back to their old-fashioned parent.

#### THE GREENHOUSE.

**Primulas and Cinerarias.**—Give these supplies of manure water and a pinch of artificial manure occasionally. Cyclamen should be now looking very fine, and when a house can be devoted to them they are very effective. A batch of

**Amaryllis** should now be started. Shake out the soil and pot in fresh material. Give very little water till active growth begins.

**Roses.**—Get a batch of these in now and force steadily. Top-dress and clean the pots, and write fresh labels and prune fairly hard, except the Teas, which should have all puny weak growths entirely removed.

#### KITCHEN GARDEN.

**Carter's Eight-week Pea.**—This is an extremely early variety and crops well. Choose fine days for sowing, and if the ground is very pasty get on it by the aid of long planks.

**Seakale.**—Take up all that is required for forcing inside. Dig the ground deeply, so that all the roots are collected, and prepare strong thongs for next season's supply. Lay them in bundles of fifty in ashes, which, however, should be protected from frost.

**Mustard and Cress** should be sown as often as required. Plant

**Potatoes** in pots and frames that were stood on end, as recommended in my first calendar.

Carter's First Crop is a perfect type of Potato for this purpose, as the crop matures in a short time. Sow

**Broad Beans.**—Extra Early Long Pod is a grand variety for early sowing. Sow also on a warm border

**Autumn-sown Peas** should have some ashes put around them to keep worms and slugs away. If

**Broccoli** are turning in seasonably they should be lifted and placed in sheds or frames, as a frost soon spoils the head; if lifted they last a long time.

#### HARDY FRUIT GARDEN.

**Pruning and Cleaning of Trees.**—This work should now be pushed forward. Apricots may be tied or nailed in position. Nail in some nice young branches to take the place of old ones. Reduce old spurs that have become long and at a distance from the wall. Cherries, Plums and Pears should be treated similarly or they do not get that protection intended. Give bush trees a good spraying of Alkali Wash to kill lichen and vermin, and one of soluble petroleum will assist in protecting the buds from the birds. Mulch Gooseberry, Currant and Raspberry quarters with manure. This should not be neglected if fine fruit is expected; it should be wheeled on the ground in frosty weather. See that all stakes are made good, such as will last through a season. Wooden stakes should be dipped or boiled in creosote. This puts five to ten years on the life of the stake. The best system of training Raspberry canes is stout posts, either iron or wood, with strong galvanised wire and tie with fine tar string.

**Autumn-fruiting Raspberry.**—A few stools of that famous autumn-fruiting sort Belle de Fontenay should find a place in every garden. The fruits are very pleasant for dessert or flavouring in the autumn months and are very much appreciated.

#### FRUIT ROOM.

Keep a sharp look-out for decayed fruits, as these soon spoil the sound ones, especially Pears. Ne Plus Meuris is just now in fine condition. Apples and Pears are keeping pretty well.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**DRACÆNAS FOR PROPAGATING.**—Any stools that can be spared, such as leggy plants which are going shabby, should now be cut up for propagation. Remember that the most vigorous wood, and the healthiest also, make the best material for starting afresh. When the wood is cut into short pieces, a joint is sufficient for a young plant. It should be soaked in tepid water and then plunged in Cocoanut fibre refuse upon bottom-heat. Growth will soon begin. Injury from cockroaches must be guarded against, as where these exist they seem fond of young shoots, and will soon eat them off under the surface. Plenty of moisture is, however, a good deterrent.

#### FRUIT UNDER GLASS.

**The Earliest Peaches** will now, in most cases, be on the point of unfolding their flowers, and from the time this begins overhead syringing should cease and the atmosphere kept fairly dry and buoyant. It has been claimed for the syringe that its use on Peaches and Nectarines in flower is the best way of securing a good set, but with this I cannot agree, and feel sure that any trees which set their fruit under such conditions at this time of the year could do as well, or better, without it. Some advance the plea that showers do good to trees grown outside, for these flower at a time when there is an ample amount of daylight and some power in the sun, while at this time of the year short days and dull skies are the rule. A humid atmosphere only accentuates

the difficulties with which the trees have to contend.

#### HARDY FRUIT.

**Planting.**—Very little if any of this ought to remain unfinished, but where, through some unavoidable cause, there is any still on hand, it should be brought to a close as soon as possible. Fruit trees of all kinds are far better planted as soon as the leaves have fallen, and those who are unable to get such work done before the buds begin to swell had far better leave it alone until another autumn than do it in the spring. The old adage in this respect still holds good, that "trees planted in the old year will look after themselves, while those planted in the new require to be taken care of." However, it is a good policy to get all such work done now as soon as possible. After planting, mulch the ground with short manure to prevent the frost penetrating the soil, as by so doing the ground will be kept much warmer, and root action will be more active in spring.

#### FLOWER GARDEN.

**Christmas Rose.**—The later varieties of the Christmas Rose are still freely blooming in sheltered spots, and where, as is often the case, they are protected by a frame, which in severe weather may be covered over and the plants thus protected from the effects of frost. During heavy gales and rains some covering is advisable for the clumps, or the white flowers get sadly soiled by earth stains. Where a span-light is not available a sheet of glass large enough to extend well beyond the radius of the plants may be fixed over each clump by driving four strong wooden pegs securely into the ground at the four sides and slipping the edges of the glass into deep notches cut for the purpose on the insides of the pegs.

#### KITCHEN GARDEN.

**Potatoes.**—Where room can be found for Potatoes grown in pots, the present is a good time to see about potting them up for the purpose of a supply to come in before the earliest lot grown in frames under the hot-bed system. They are most acceptable for this purpose, as the postponement of planting in frames for another week or two will have a beneficial effect on the crop, which will not only be larger, but of better quality, through the delay. Potatoes will not bear hard forcing, and a position in a Peach house or vinery just started, where a sufficient temperature is kept up to enable the tubers to start gently into growth, will be the best that can be found for them at present. Later on, when these houses are kept hotter, the pots may be moved into successional houses. Eight-inch pots are sometimes used for the earliest lot, but I prefer 10-inch or even 12-inch ones, as the runners have more room to spread in these larger sizes and the crop is heavier.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## THE EDITOR'S TABLE.

#### NEW POTATOES DUG ON CHRISTMAS EVE.

Mr. E. Gray of Ventnor, Isle of Wight, writes as follows: "I am sending you a few Potatoes which were dug here by a market gardener, Mr. I. Plumbly, on Christmas Eve. He had about a gallon off five roots of British Queen, all of them self-comers, and although there were other varieties besides this one, viz., Supreme, Hebron and International, this was the only one to crop. In the gardens at Woolverton Manor, Mrs. Morgan's, I have *Vihurnum macrophyllum* in bloom for the second time during 1907. It is only a small one in a pot, but it has now three blooms on it, and I only took it into the cool house a week ago, when the cold winds first made their appearance." [The Potatoes were a splendid sample.—ED.]

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Ivy not clinging to walls (W. M.).

Your question is a most difficult one to give advice upon, as it is well known that Ivy and other self-clinging plants have a particular dislike to clinging to surfaces composed of various materials. Cement is one of these, either in the form of "harling" or otherwise. Your house is, however, probably harled with lime, which is, as a rule, not so obnoxious to creeping plants as cement harling. It is quite probable that it is the fresh whitewash which the Ivy objects to, and you might try the effect of leaving the part upon which the Ivy is to be grown free from whitewash for a year or two. The writer had great difficulty in a somewhat similar case, but duresco was employed instead of whitewash. By leaving this unrenewed for a couple of years or so the Ivy was induced to grow, and it clung all the more freely in after years when a greenish moss had begun to grow also. It was necessary, however, to fasten the Ivy up with shreds and nails for some time until it had secured a hold. This is more easily done in a damp district than in a dry one, and the writer has seen what you speak of, not only in Ireland but in Scotland. The fresh whitewash being in layers, scales off freely, and the rootlets of the Ivy have no solid material to which to attach themselves. You could have a portion of the wall scrubbed with a hard brush and water to remove any whitewash from the place you try first, and you would then be able to observe the effect. Your desire is to be commended, and your success would well repay the trouble this would involve.

#### Making a pond for Water Lilies

(Colonel B.).—If you are satisfied that the bottom of the pond is water-tight, the sides could be rendered secure by puddling with clay or by using concrete and cement. In any case it is hardly likely that a satisfactory or lasting job will be made of it with the water coming in as you describe. Have you no means either of diverting the course of the water or of effectually damming it back or preventing its entering the old pipes to which you refer? With the water entering into the excavation so rapidly it is highly probable that the present water level is maintained to a large extent by the saturated condition of the soil, and it rarely happens that a soil that "will not puddle" can be depended upon. But if your experience on the spot is to the contrary, then we suggest that you either divert the course of the incoming water or, if this is not possible, to make the pond in sections, beginning with the end farthest removed from the intake or supply. But if by means of a trench at the upper end you can keep the water from coming in upon the work as it proceeds, things may be more easily arranged. According to your sketch the sides of the pond shelve off at A, and if this is so the concrete could be placed thereon easily enough. Concrete made of clean ballast and cement—three parts ballast to one of cement—would be suitable if laid on in a 6-inch

thick layer. A 4-inch layer of two parts ballast and one cement would do; this could be reduced both in strength and thickness as the top is reached. If you cannot get the water away from the bottom, you had better, as a precautionary measure, fix a plank at an angle of 40° or 50° to the bank and at a few inches below the point marked A for receiving a band of strong concrete. We suggest this because we are strongly of opinion that a seam or substratum of sand, sandy clay or gravel exists between point A and the present water level, and is really responsible for the fact that it does not apparently vary. In these circumstances a perpendicularly-cut trench beside the pond for testing purposes should afford a good guide. If you bring the cement and concrete to the surface, let it be hidden by turfing down to and over it, and further by grouping Reeds and other things to produce a natural margin.

**Information about Gladioli (E. F.).**—Your best plan will be to write to Messrs. Kelway and Sons, Langport, Somerset, and describe the varieties as near as you can, when in all probability they will be able to supply others like them. If you cannot obtain them in this way, send the firm a flower or part of a spike when the varieties in question flower. We cannot answer your question concerning the kaint, as you do not say for what crop or purpose you require it. If you send us these particulars we may be able to help you.

### THE GREENHOUSE.

#### Roman Hyacinth bulbs unsatisfactory (H. S.).

—We have carefully dissected and examined the bulbs of Roman Hyacinths sent, and cannot find any traces of flowers ever having been formed in them. As far as size is concerned, they are, of course, sufficiently large to flower well, and we can only conclude that the cold, wet summer of last year, which we believe was not confined to England, caused a deal of soft growth and was answerable for the non-production of blooms. We should not hesitate to say that the failure of the Lily of the Valley crowns was caused by some decided check, but as there are many probable ways in which this might occur, it is, of course, impossible for us to put our finger on the particular one. They may have been kept out of the ground too long before potting or allowed to become too dry after this was carried out, while an escape of sulphur into the house in which they were placed would also cause the injury. At all events, the crowns sent are very fine ones, and the spike which has grown a little has a considerable number of blossoms in embryo.

#### Maidenhair Fern fronds gone wrong (A. E. L.).

—The fronds that you send are in a very bad condition indeed. They are infested with brown scale insects and also with thrips, the latter being small, long, dark objects not very easily seen. The best thing to do with plants in this condition is to cut off all the fronds at once close to the surface of the soil and burn them. Then keep the plants in a cool but frost-proof structure until the first week in March, when they may be taken into a warmer house to start new growth. Water will probably only be required three or four times during the period when the plants are resting, but this will depend upon the surrounding temperature. Only give them water when there is a danger of the soil becoming dust-dry. There is little doubt that the moss growing on the surface is due to overwatering in the past. This would cause the plants to become unhealthy, and thus allow the insect pests named above to gain a strong foothold. When young fronds are about 2 inches high, as they should be by the middle or end of March, it will probably be advisable to turn the plants out of their pots, remove nearly all the old soil, and repot them into clean, well-drained pots, using a mixture of very fibrous loam (three parts), peat or partly-decayed leaves (one part) and coarse sand (one part). If this is done, the plants ought to go into pots the same size as those they now occupy. The atmosphere of the

house should be kept very humid for several weeks after such drastic but necessary treatment.

#### Heating a small greenhouse (Mrs. S., County Cork).

—The most successful, and in the end the cheapest, way to heat a greenhouse of the dimensions given will be to have one 4-inch flow and return hot-water pipe fixed against the front wall under the stage, with a small boiler fixed in the wall at the point where the pipes enter. A useful boiler for the purpose is a small cheap one sent out some years ago by Messrs. Messenger and Co. of Loughborough. Another way of heating such a greenhouse would be by using a good-sized paraffin stove, the same as is used for heating dwelling-houses. This would be the cheapest in the first instance and also easier to manage, but the heat would not be so well diffused throughout the house neither would the health and progress of the plants be so well assured. Referring to Strawberries—it depends on the strength and the healthy condition of the plants and also on the time of the year when you wish to have the fruit ripe. If the plants are strong and well grown and ripe fruit is desired by the middle or end of April the plants should be introduced into heat from the middle to the end of this month. The temperature to start with should be 45° at night, rising to 55° by day; a month later to 55° at night and 65° by day. For a later supply successional plants should be introduced into heat every fortnight. As the season advances the temperature should be increased to 60° and 65° at night and to 70° and 75° by day. The plants should be left out of doors until wanted for forcing, protecting them from frost by plunging the pots in ashes or leaves.

**Plant for a cold house (L. F.).**—The Lapageria would in all probability do quite well in the house, as the plant succeeds in conservatories and other places but little heated, and occasionally in the open air in favoured localities. The white form is the more hardy, we think; but the red, of which there are several superior varieties, is not far behind it in this respect. Do not hamper the plant in a pot or tub; plant it in a well-prepared border of loam, peat, brick rubble and sand, and in a perfectly drained position.

#### Lycaste Skinneri going soft and brown

(J. M. W.).—Your Lycaste has undoubtedly received a check of some kind, but what that is it is, of course, quite impossible for us to say. An intermediate structure is very suitable for it, but the temperature may have fallen too low or the atmosphere of the house been allowed to get too dry, while dryness at the roots would be equally injurious. There yet remains another probable cause, and that is perhaps the correct one. Within the London district the fogs so often experienced during the winter contain a considerable amount of sulphur, and they affect Lycaste blooms exactly as you have described. We do not know how you are situated in this respect, but should imagine that in the neighbourhood of Oldham the fogs would contain a considerable amount of impurities.

#### Information about a small conservatory

(Broadgates).—We are not certain that we rightly grasp your ideas, but if the structure is to be a combination of billiard-room and conservatory the plants selected must be such as require but little atmospheric moisture for their well doing. Foliage plants alone must be principally depended upon, and of these the better class of Palms, a judicious selection of Ferns, and such subjects as Aralia Sieboldii, Cyperus alternifolius, Araucaria excelsa, Aspidistras, &c., would be effective at all seasons, and the comparatively dry atmosphere necessary for the billiard table and its appliances would not hurt them. You cannot expect to grow flowering plants in such a structure, as plenty of light and air, when the weather is favourable, is very necessary for them. Still, if you have anywhere else to bring them on, they might serve a turn in the conservatory and be returned to their quarters before they had suffered any permanent injury. Such a structure as you suggest should be built for the sum named. One great point to bear in mind is that as much light as possible is necessary for successful plant growing, on which account your conservatory must not be too dark or shaded. Even where plants need artificial shading in summer they are all the better for as much sunshine as possible in the winter. If there is a suitable position for it, a large Wardian case might be made an object of interest and beauty throughout the entire year. If small, the better way will be to furnish it with Ferns grown in pots; but a large case or frame may be made doubly interesting by arranging some rockwork therein and planting Ferns of different sorts, including some creeping ones, a selection of Selaginellas and a few of the Rex Begonias to yield some lighter tints. If the body of this case is made of zinc with a tap in the lowest part to drain off any superabundant water, it may be stood anywhere without injuring the floor in any way. A good light position is the best place for it, but at the same time it must not be exposed to direct sunshine.

**How to grow *Cypripedium insigne* successfully** (*Mrs. S.*).—*Cypripedium insigne* needs to be treated in a more liberal manner than many Orchids in order to obtain the best results. With regard to temperature it succeeds best where a minimum of 50° is maintained throughout the winter months. If repotting is needed it may be carried out in February or March, the most suitable soil being one third good fibrous loam, one third peat or Belgian leaf-mould (now much used in the cultivation of Orchids) and the remaining part made up of charcoal, sphagnum moss and silver sand. This material must in preparation be pulled to pieces with the hands and not sifted in any way, for it is very essential that the compost be as open as possible. In potting, rounding up the soil, as is done in the case of many Orchids, need not be followed with this *Cypripedium*, for it is far better potted below the rim of the pot as plants in general are. It is by no means necessary to repot annually; indeed, some successful cultivators repot only about once in three years. In this case, however, the plants are assisted with liquid manure during the growing season. If, however, they are allowed to remain longer without repotting, the plants are apt to get starved, and their flowering consequently suffers. Throughout the summer the plants will do well without fire-heat, but, of course, a little will be needed as autumn advances. As above stated, a minimum temperature of 50° will suit them well. *Cypripedium insigne* is sometimes treated as a stove plant, in which case the repotting may be done earlier than the time above recommended. One great point to bear in mind is that it must be watered regularly all the year round and not subjected to a period of drought as many Orchids are.

## ROSE GARDEN.

**Removing Rose plants next June** (*E. B. L.*).—We have seen Roses dug up and transplanted from one part of the garden to another during June and even July, but there is considerable risk in this. When the plants have to be taken to another garden we certainly would not recommend this practice. The best plan is to dig up the standards and bushes at once and pot them into 8-inch and 9-inch pots, the standards in the latter size and the bushes in the former. You should put a fair amount of crocks in the pots, or, failing crocks, some broken clinkers would do. The soil may be that in which the Roses are now growing, but as this is most likely in a very wet condition it would be better to obtain some loam or garden soil that is not wet. If a little well-decayed manure is available mix about one part with two parts of soil. You can prune back the growths a little and remove all foliage before digging up the plants, then finally prune at the end of March. When they are dug up, remove any suckers and cut back the roots a little. No roots need be more than 6 inches long. Preserve all the fibrous roots possible. Pot very firmly and give stakes to support the standards. After potting you might plunge the pots into the ground, first placing some ashes or stones for the pots to rest upon. Cover the pots right over with soil and about 2 inches above the rims. Here the plants can remain until ready for removal. When arrived at their new quarters it would be best to plunge the plants again into the soil until October or November. They may then be transferred from their pots to the new position, preserving as far as possible the ball of earth surrounding the roots. Should the summer prove a dry one water must be applied occasionally to the plants, but being well plunged they will require but very little. When transferring the plants by rail or otherwise great care must be taken that the roots are not disturbed in any way.

**Information about Rose Imperatrice Alexandra Feodorowna** (*F. L. B.*).—Your correspondent asks for some information as to this Rose and whether it is synonymous with Empress Alexandra of Russia. I have never grown the Rose in question and am afraid, therefore, that I can give but little information with regard to its habit and growth. It has passed out of cultivation to a very large extent and is not now to be found in the catalogue of any English grower, and only in two of the numerous Continental catalogues that I have filed. I find that it was raised by M. Nabonnand in 1854, that its colour is described as clear pale yellow, with the outer edge of the petal sometimes tinged carmine, centre of the Rose deepening to peach, of good shape, but not very large and its growth is described as medium—all of which, being freely translated, means, I am afraid, that Imperatrice Alexandra Feodorowna is no longer worth growing. It certainly is not synonymous with Empress Alexandra of Russia; in fact, it has nothing in common with it, except a resemblance in the name.

The latter Rose was sent out by Messrs. Paul and Son of Cheshnut in 1897, and would be a good Rose if it was free flowering and did not hag its head so badly, as its colour is still unique among Roses, being of a terra-cotta reddish lake, and it has a large globular flower that I have often seen exhibited.—H. E. M.

**About mulching Roses that are planted in sandy loam** (*Ignoramus*).—Certainly mulch your Roses early in April, using thoroughly-decayed farmyard or stable manure for the purpose. This will prevent the evaporation of moisture from the soil during the hot summer months, and the plants will be much benefited. You ought to have protected them from severe frosts with dry Bracken or other light material. Mildew might possibly be caused by mulching where the soil is of a very heavy nature, but in your case there is no danger.

## FRUIT GARDEN.

**Treatment of newly-planted pyramid Apple trees** (*Holroyd*).—The side shoots on the main branches of your trees must be cut back now to within two or three buds of their bases; then next summer the shoots that grow from them will need pinching back to within 1 inch or 2 inches of their bases. This treatment will tend to produce spurs. The main branches should be cut back so as to leave only a third of the growth that was made last summer. When pruning side shoots or laterals for the production of spurs, cut to a bloom-bud if one is situated near the point where you wish to cut, but the main branches and leader must be pruned to wood-buds, choosing those that are pointing in the direction that the shoots are intended to take.

**Mealy bug on Vines** (*A. H.*).—The destruction of this pest on Vines is a most difficult and tedious process, and evidently our correspondent has found it so by the number of remedies he has tried and found wanting. The difficulty lies not so much in killing the fully grown and visible pests, but in finding out and destroying the embryo insect concealed in crevices of the bark and other places during winter, and which emerges into life with surprising activity with the return of spring. We have no hesitation in saying (and that statement is based on a long life's experience in the growth of the Vine, as well as considerable experience of the difficulty in getting rid of this curse, for it is nothing else), that there is no known remedy that will rid a vinery of this pest by winter dressing alone. We have seen the floors of badly affected vineries thickly strewn over with dead bugs after a strong application of sulphur fumes in winter while the Vines are dormant, but even then some will escape and reappear in spring. After cleansing and washing the Vines in the usual way in winter, perhaps one of the most effectual ways of getting rid of it is by painting every particle of the Vine (eyes and all) with clay puddle reduced to the consistency of thick paint, adding half a pint of strong tobacco water to half a gallon of the stuff. This sealing or casing of the whole surface of the Vine is supposed to asphyxiate the insect and so get rid of it in that way. Whatever remedy is applied in winter must be supplemented by vigilant and constant search for their reappearance in spring, and also through the summer, touching every little one seen with a drop of paraffin from the point of a small soft brush. By persevering in this way throughout a whole season, mostly by the light of a bull lantern at night when they are the most active, we once succeeded in clearing three good sized vineries that had been badly affected.

**Information about Mulberry trees** (*Mrs. D. G.*).—With regard to the tree thirty years old, planted on a lawn and bearing very small fruit which never ripens, this tree, the Black Mulberry (*Morus nigra*), ought to do well in your county; it always thrives best though in sheltered gardens in deep soils. It is a beautiful lawn tree; but, where possible, give it a free, deep and rather moist soil. Evidently your tree has got its roots into poor soil. Give at once a heavy mulch, *i.e.*, top-dress with well-rotted farmyard or stable manure 6 inches to 9 inches deep, and when applying the same it is advisable to leave a circle a few inches wide round the trunk, as injury might be caused by heaping up any material round the base of the tree. Respecting the small tree which has never

fruited, on a wall, it is only advisable to grow the Black Mulberry against a wall in cold localities. You might root-prune this specimen, and, if it is in heavy soil, improve the same by the admixture of road scrapings, wood ashes or leaf-mould.

**Nectarine roots diseased** (*W. P.*).—The roots are suffering badly from canker, usually the result of growing in cold and uncongenial soil. The white spots, we think, are indications of decay in those parts on which they rest. It is a fungus which is generally found on dead or decaying wood, and is not a root pest. We presume the tree is old by the appearance of its roots. It may improve in health by the treatment you have adopted, which is quite correct, excepting that we should not have used any of the old soil with the new. No fruit tree derives greater benefit by occasional replanting in new soil than does the Peach and the Nectarine. Should your tree prove disappointing again, we should root it up and throw it away, replacing by a healthy young tree in the autumn.

**The caustic soda solution** (*A. P. W.*).—What you term American potash is probably the same thing as is purchasable as pearl ash or common potash. We have not previously heard of any potash so named. The term "caustic" is applied to the soda, and that is the ingredient in the solution which it is useful to guard against when being used, as it burns the skin. With 1 lb. of each of these ingredients use 20 gallons of water, so as not to err on the wrong side. In spraying trees wear old or worthless clothes and boots, also leather gloves to protect the hands, and even a veil tied under the chin to protect the face from the spray. It is advised in spraying to stand on the windward side of the trees, but that cannot be always done if the trees are to be properly sprayed all round.

## MISCELLANEOUS.

**Kerosene flares as counteracting frost** (*Cardiff*).—Your question as to the use of kerosene oil to create heat to ward off frost from football grounds is to us very novel, and one, with the limited experience of to-day, practically incapable of getting a satisfactory reply. No doubt the safest, and probably cheapest, course in the end, to preserve football grounds from being frozen is to put over them a thick coating of straw litter, much of which if removed just prior to play could be replaced so soon as play was over. The practice referred to of creating kerosene fires or flames to ward off frost from fruit tree bloom in the spring is more common in Canada than with us, but we have no record as to the actual amount of success resulting. The creation on the windward sides of an orchard of smouldering smoke fires with the object of enshrouding the trees in smoke at night and thus ward off frost has been tried in a limited way in this country, and with but partial success. Two or three late spring frosts might thus be counteracted, provided there was ample material at disposal to create for a few nights dense smoke, but a week's succession of frosts may be very difficult to deal with. But any such efforts have been limited to the flowering season of fruit trees, when the frosts do not perhaps cause the temperature to fall lower than some 5° to 6°. That amount of frost it may be possible in the way described to combat, but in the winter, when we often have frosts of the severity of 20°, it is obvious that smoke clouds would not suffice to protect a football ground. Burning kerosene oil in many utensils would create an intolerably offensive smell. We are assured that what is termed kerosene is but a good quality of paraffin. Possibly this reply may lead to some further reference to the very interesting point your question has raised, especially in relation to protecting fruit orchards in bloom by smoke clouds.

**Laying out a villa garden** (*W. B.*).—The garden plan sent is one of exceeding stiffness and formality, all straight and formal lines. Is there any need for a path on the north-east side? Why not let the grass lawn run up to the flower border, and make the border somewhat serpentine rather than straight? On the south side, where a path well may be, as the warmest side in the winter, let the flower border project by a rounded bend some 3 feet just where the lawn ends and the kitchen garden begins. That will break up the long formal straight path from the house to the bottom of the garden. A division between the two gardens on a slightly-raised bank should be made of Cupressus lawsoniana or of Holly, the latter, of course, kept well pruned in. The north kitchen garden paths and flower border should be dispensed with to enable you to utilise every foot of what is after all a very limited space for vegetables. The south flower border and path could remain. The site fixed for the greenhouse is very well, but we should have preferred one nearer the house on the same side. If you dispense with the north side paths you will not require any cross path. So many paths are a waste of useful ground. Both flower borders and paths should have an average width of at least 4 feet. A greenhouse 9 feet by 6 feet is a very small one. If a span, a centre aisle takes out of it 2 feet width, so also will a path on a lean-to. A house 10 feet by 6 feet, if a lean-to, with the path at the back, or if a span house, then 12 feet by 3 feet gives stages 3 feet wide on each side and a 2-foot path down the centre. As to whether any such house is large enough for the garden, while generally amply large all depends on what you expect from it. A couple of single light frames 6 feet by 4 feet, or a double one same size as both, should suffice for your purpose. They should be stood in a sunny position close to the greenhouse. Do not expect too much from so small a garden, especially as so much depends on knowledge and management.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## HARDY WINTER FLOWERS.

It cannot be generally known that several shrubs and small trees bloom during the winter months, for they are so seldom seen. This is to be regretted, as they are not only beautiful—flowering, too, with a freedom one associates with the high summer days—but, in several cases, exceptionally fragrant. A walk round an interesting garden recently, in which winter-flowering shrubs are planted with no niggardly hand, brought to mind the importance of these kinds in the garden at this season. There, in a sunny corner, was the

TREE WITCH HAZEL (Hamamelis arborea), which is the most beautiful of its family. It may be regarded as a small tree, seldom growing more than 8 feet high, though in its native land of China it attains larger dimensions in every way. The flowers are golden yellow in colour, and consist of several curling petals with crimson calyces, which seem to shine in the winter sun. These crowd on the leafless shoots and give a fresh beauty and interest to the garden in January. The way to obtain the full value of the shrub is to plant it in a group, say, of six plants, with the little Partridge Berry (Gaultheria procumbens) as a groundwork, the latter a little evergreen shrub, crimson almost with fruits for many weeks. There are other Witch Hazels, but H. arborea should be chosen before the others. H. japonica zuccariniana flowers quite as freely, but does not produce so rich an effect; this also blooms in winter, and the pale yellow colouring is charming. The Witch Hazels are easily grown, needing no special soil, but shelter and sunshine are necessary, not from any want of hardiness, but to give the flowers as much chance as possible at this uncertain season of the year.

THE WINTER HEATH (Erica carnea).—Why this exquisite Heath is not as common in gardens as the Christmas Rose itself is a mystery. It is thick with crimson flowers for many weeks in winter, and gives a warm glow to the garden when planted in groups. A group of fifty plants—and they are not expensive—produces an effect that is in pleasant harmony with the greys and browns of the surrounding woodland. The writer planted a group consisting of this number of tufts in rough meadow land, and no feature of the garden—not even the Roses rippling over Oak fences and pergola—gave greater delight. It is mentioned in "Trees and Shrubs for English Gardens" that of all the dwarf Heaths more can be said in favour of E. carnea than of any other kind. "It is not only absolutely hardy, but it flowers with astonishing freedom at a time of year when flowers are particularly cherished. Its flowering, of course, somewhat depends upon the weather, but frequently one may see its bright rosy bells almost as soon as January comes in. By the end of February the entire plant is a mass of beautiful colour, and for

two or three months longer they retain their freshness, no matter what weather may occur. So free-flowering is this Heath that its flowers literally cover it. However freely it might be planted it would never become wearisome or out of place, for its tints, though bright and warm, are not harsh." The

WINTER-FLOWERING HONEYSUCKLES (Lonicera Standishi and L. fragrantissima) have not the rambling growth of the Honeysuckle of the hedgerow, but are usually grown against a wall. We well remember wandering in a garden one bright winter day and wondering where the rich Honeysuckle-like fragrance came from. The plant was then unknown to us, but Lonicera fragrantissima was breathing forth this sweet incense. From that moment it became one of our most cherished flower friends. The plant was growing in a sunny recess near the dining-room, so that the perfume when the window was open could float into the house.

WINTER SWEET (Chimonanthus fragrans) is very welcome at this season. In the variety grandiflorus the flowers are larger and of a clearer shade of citron yellow than the type, and though the plant is bare of leaf the blossoms make a brave show; they may be described against a well-toned brick wall for some little distance. It is just as well to bear in mind that this is one of the shrubs which bloom on the young wood, and any pruning or cutting out of useless branches that may be necessary should be done in early spring when the flowers are over, for if it is delayed there will be no flowers next year.

GARRYA ELLIPTICA we treasure for its beautiful catkins, which are in bloom in winter. Few wall shrubs are so leafy and luxuriant, and placed against a sheltered sunny aspect it bears a profusion of catkins at this season. They possess a fresh, wholesome fragrance and upon the plant have a strangely picturesque beauty. Occasionally the Garrya will cover a house front, but only in favourable situations. It is evergreen, the leaves dark in colour, oval in shape, and about 3 inches long. Male and female flowers are borne on separate plants, and the most beautiful of the two is the male or pollen-bearing form.

A CLEMATIS flowers in winter, a fact not generally known, and C. calycina is the kind. The interesting features about this Clematis are its evergreen leaves and early flowering period. Among other Clematises it is easily recognised in winter, for it is the only hardy kind to retain its leaves, and it is rarely between December and February that a plant can be found out of bloom. It was first brought to this country in 1596. In its home in the Balearic Islands it is said to grow to the tops of tall trees, and, in fact, smother them, but in this country it is seldom more than 12 feet or so in height. The leaves are deep green and glossy, the flowers drooping, greenish white, with purple marks on the inside of the sepals, and borne from the leaf-axils. They differ in size to some considerable extent, some being only 1½ inches across, others upwards of 2 inches. Like many other early-flowering shrubs, it looks more at home in some cosy corner or against a wall than it does in the open ground. About London it grows well, but is more at home in such counties as

Devon and Cornwall. In some gardens it is known as *C. balearica*.

Soon the Mezezon will be opening its purple fragrant flowers and a few early blooms appear on the Rhododendrons. *Laurustinus* is already in bloom.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

January 28.—Royal Horticultural Society's Meeting and Exhibition, and Lecture.

February 11.—Royal Horticultural Society, Committees meet, 12 noon; Annual Meeting, 3 p.m., Horticultural Hall, Vincent Square. Horticultural Club, Annual Meeting, 5 p.m.; to be followed by Annual Dinner, 6 p.m., Hotel Windsor, Victoria Street, London.

March 3.—Royal Horticultural Society, Committees meet, 12 noon.

### Royal Horticultural Society's Guild.

—With the promised support of a number of past and present students and employes in the gardens of the Royal Horticultural Society it has been decided to form a guild, with the view of keeping members in touch with one another and with the work of the society. It is proposed to issue a half-yearly magazine, comprising articles and letters contributed by members, notes on the work of the society, a list of members with their addresses and a correspondence page. Mr. Wright, the superintendent, and Mr. Chittenden, the director of the laboratory, have promised to do their best in any difficulties that may be encountered by members. It is hoped to arrange an annual dinner for the first day of Holland Park show. The fee for membership will be fixed provisionally at 5s. a year, though it is hoped that this can be reduced as soon as the guild is in full swing. Old employes or students are asked to join in making the guild a success by becoming a member, by making any suggestions that may occur as to the construction of the guild or as to its aims or their furtherance and by contributing notes, letters or articles on your work, travel, studies, &c.—Mr. R. J. WALLIS, Hon. Secretary *pro tem.*, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.

### Sending plants to the Transvaal.

It may not be generally known in this country that severe restrictions are in force regarding the introduction of certain plants to the Transvaal Colony, as we are informed that many on reaching that country have to be destroyed. Thus no person is allowed to introduce to the Transvaal from any place beyond South Africa any *Eucalyptus*, *Acacia* or coniferous plant, with the exception of seeds, any Coffee plant or portions thereof, with the exception of seed free from pulp, nor any Peach stones and Peach stocks. Plants or portions thereof of the following may be introduced under such precautionary measures as the Commissioner of Lands may deem necessary: Grape Vines or other plants of the family *Vitaceae*, Sugar Cane and plants cultivated for the production of rubber. No plant other than those mentioned above may be introduced, unless a special permit authorising any such introduction has been obtained from the Minister of Agriculture. Full particulars may be obtained by anyone interested from the Agent General for the Transvaal, 72, Victoria Street, Westminster, London, S.W.

### Agricultural statistics for 1907.

The acreage and livestock returns of Great Britain for 1907 contain much information of interest to the horticulturist. The extent of the land under cultivation, including woods, is 47,754,469 acres, or about 85 per cent. of the whole area. To this, however, must be added the various gardens, plots and allotments

that do not exceed one acre in extent. Potatoes occupied 548,920 acres, this being 17,001 acres less than in 1906, and the lowest returned since 1899. Peas, on the other hand, show an increase of 12,157 acres, bringing the total acreage up to 166,136 acres. The greater part of this increase occurred in the Eastern Counties, Suffolk recording an increase of 3,000 acres and Lincoln one of over 2,000. The area devoted to Cabbages continues to steadily increase, the total amount during 1907 being 74,896 acres. It is interesting to note that the acreage of this crop has been more than doubled during the past 25 years. Onions show an increase of 359 acres. The enormous strides that have been made during the past 10 years in the cultivation of fruit may be gathered from the fact that the returns during that period show an increase of 12,000 acres of small fruits and 25,000 acres of orchards. Thus in 1907, 82,175 acres were occupied by small fruits and 250,176 acres by orchards. The acreage of Strawberries in England was 23,623; Wales, 780; Scotland, 3,424. Raspberries: England, 6,480; Wales, 20; Scotland, 2,378. Currants and Gooseberries: England, 24,179; Wales, 177; Scotland, 1,234. Apples: England, 168,576; Wales, 3,115; Scotland, 952. Pears: England, 8,635; Wales, 93; Scotland, 183. Cherries: England, 11,952; Wales, 40; Scotland, 35. Plums: England, 14,571; Wales, 60; Scotland, 270. Of course there are other kinds of fruits included in the total acreage that are not included in the above figures. Compared with 1906, there is an increase of 1,949 acres under small fruit and of 2,489 acres under orchards.

### Beautiful new Holland plants.

—The *Revue Horticole* for January contains a splendid coloured plate of three hard-wooded plants from New Holland, namely, *Leschenaultia biloba* major, *Pimelea decussata* and *Boronia heterophylla*.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Watsonia O'Brieni.**—Referring to Mr. Fitzherbert's remarks on *Watsonia O'Brieni* in THE GARDEN of the 11th inst., I should like to say that I have proved by experiment that this plant likes plenty of moisture while in full growth and developing its flower-spikes. For two or three seasons past I have had several pots of this beautiful plant flowering profusely outside an office window in the heart of London. Bulbs arriving from the Cape in spring have been potted up in April, each one developing a robust branching flower-spike over 3 feet high. By cutting off the top spike when the flowers were fading, the buds on the lower side spikes have rapidly developed, so that the plants have been decorative for fully two months. From June onwards the pots were standing perpetually in saucers of water. The window faces south-east. Planted out of doors the same remarks apply as to moisture. Bulbs imported in spring should be potted up and started into growth in a cold frame, and afterwards carefully planted out in a sunny but damp situation. Before frost sets in the plants should be lifted and the corms allowed to go to rest, except, of course, in favoured localities, where they may be left to establish themselves. In this case, however, a covering of heather or some light material should be given during winter, so as to keep the roots fairly dry.—P. RUDOLPH BARR.

—Mr. Fitzherbert's interesting note on these plants in THE GARDEN of the 11th inst. has brought to my mind many facts in connexion with the history of the variety (*Watsonia Ardernei*) named after that enthusiastic horticulturist Mr. H. M. Arderne of Cape Town. I cannot agree with Mr. Fitzherbert that the two varieties *Ardernei* and *O'Brieni* are one and the same,

there being to my mind well-marked differences between the two plants, at least such was the case when *W. Ardernei* was first introduced. It was in the spring of 1896, in response to a request, that Mr. H. M. Arderne kindly sent me some few dozen bulbs of his *White Watsonia*, the first, I believe, to reach this country. The plants grew most freely and came into flower the beginning of August, and I exhibited them at the Chester Horticultural Show in that month. This was a new show, well organised, that came into being that year, and was visited by a deputation from the Royal Horticultural Society, who awarded the plant a first-class certificate, the popular president of the Royal Horticultural Society remarking that "it resembled a gigantic white *Freesia*." I had previously grown *W. O'Brieni*, but found this new form was far stronger and more vigorous, with branching flower spikes and flowers of greater substance and altogether a superior plant. What finally made me quite certain that Mr. Arderne's form was distinct was that shortly afterwards I was in communication with an old-established horticultural firm at the Cape, who grew a large quantity of *Watsonia O'Brieni* and did not think it was in any way different to Mr. Arderne's variety. In the course of time I received an importation from them. I might mention here that bulbs of *Ardernei* are large and deep and very uneven in shape and with deeply corrugated skins; those of *O'Brieni* are smaller, more rounded and shallow and have smoother skins. The bulbs received were of the latter type and were duly grown on. There was not the vigour about them nor were they so upright in growth and there was a decided difference in the flower; it was set more loosely on the spike, whereas in *Ardernei* the flower is held firmly and at right angles to the stem. In *O'Brieni* the flowers were more scattered and the tube was larger, giving the flower a more drooping appearance than in *Ardernei*. Two more facts in this matter I well remember: First, that had the stock been true, I could have purchased from this source *W. Ardernei* at one quarter the price I had to pay elsewhere; and, secondly, the Cape firm eventually gave up growing *O'Brieni* and took on in its place *Ardernei*, being satisfied that it was distinct and superior. Mr. Fitzherbert mentions the fact that the plant with him produces its leaves in the autumn, which fact accounts for the following. A batch of plants we had flowered in pots in the summer one season were not dried off, but kept in the house and watered. Shortly afterwards fresh leaves appeared and the plants grew on all through the winter and spring, and were finally shown in flower at the Temple Show in May, having flowered twice within less than a year. This *Watsonia* is now largely cultivated at the Cape, and owing to its rapid increase its price is much reduced, and it will be possible to obtain this spring one dozen bulbs for the price that used to be paid for one bulb. I expect for many years to come this plant will be held in esteem by all lovers of bulbous plants and will gradually establish itself all over the gardens of the South Western counties, which your able correspondent so frequently describes. In conclusion, I trust he will pardon me for not agreeing with him as to the two varieties being one and the same plant.—ROBERT W. WALLACE, Colchester.

**Roses to avoid.**—It seems very remarkable that a Rose placed at the top of the list in the Rose election as the best Hybrid Perpetual or Hybrid Tea for exhibition should incur such a storm of abuse as is meted out to the variety, but so it is with *Bessie Brown*, and one cannot deny its total unfitness for general garden cultivation. I grant it is a superb flower when shaded and brought to that perfection which the clever exhibitor is capable of doing. There are so many grand Roses now in cultivation that there is absolutely no need for anyone to cumber their gardens with worthless sorts or sorts only suitable for exhibitors to cultivate. I think the National Rose Society would do well to warn

amateurs against growing the difficult sorts. Probably it is not so well known as it should be that those superb blooms of Mildred Grant, Bessie Brown, Mrs. E. Mawley and others which take our breath away at a Rose show are mainly cut from yearling or maiden plants, and thousands of plants are destroyed or given away annually by exhibitors in order that they may be enabled to keep up their stock of maiden plants. Your correspondent W. J. Chapman asks for information as to the Roses that should be avoided by the novice. Those varieties that I would advise him to avoid are Cleopatra, Ma Capucine, Souvenir d'Elise Vardon, Bridesmaid, Mme. de Watteville, Golden Gate, Princess of Wales, Georges Schwartz, Devoniensis, Mme. Margottin, Perle des Jardins, Etoile de Lyon, Sunset, Sunrise, Luciole and E. Veyrat Hermanos. This latter, if wall space is unlimited, may profitably be grown. Robert Scott, J. B. Clark (unless prepared to treat it as a climber or pillar Rose), Alice Lindsell, David Harum, Marguerite D'ombrain, Kaiserin Augusta Victoria and its relations, Perle Von Godesberg, Duchess of Portland, Goldelse and Goldquelle are to be avoided unless one possesses a nice warm soil, and the Lady Mary Fitzwilliam group, such as Tennyson, White Lady and Corona, should not be planted where vigour of growth is desired, although for small isolated groups or beds placed well to the front they are admirable. Of Hybrid Perpetuals to be avoided I would name Gustave Piganeau, Ulster, Marchioness of Downshire, Marchioness of Londonderry, Earl of Dufferin, Horace Vernet, Salamander, Xavier Olibo, Marchioness of Dufferin and Her Majesty. It should be clearly understood I am advising the novice. Those who have grown Roses a few years and have become accustomed to their habits will be able to grow some of those I now condemn.—P.

**Dividing Daffodil bulbs.**—I was glad to see Mr. Jenkins's letter in *THE GARDEN* of the 11th inst., and I hope others will give us the benefit of their observations on this subject. My little sketch in *THE GARDEN* of the 28th ult. was made from a bulb lifted about July 20, and represents a root which wanted dividing. A certain amount of care was required in the process, since it contained the embryo rootlets referred to. The little roots shown in the sketch are the remains of the old roots of last season after being dried. I cut these as close as I can with a pair of shears when they are quite shrivelled and dry; the bulbs are then easier to handle and can more readily put out their new roots when planted. Mr. Jenkins suggests that I performed the operation too late (presumably thus accounting for the existence of the internal embryo roots), but in my observations, mostly made in the latter part of August and the beginning of September, while separating bulbs lifted in July, and again late in November, with bulbs lifted at the same time, I did not notice any difference in the state of these internal rootlets in the bulbs divided late in the season to those divided earlier. I cannot but think that they can make much growth while the bulbs are out of the ground and undivided. However, Mr. Jenkins raises the question whether it is better to divide at lifting time or to delay the operation until the bulbs have been dried. The better course to pursue with all roots which are not quite easily separated is to dry them and divide just before planting, because any internal embryo roots are laid bare by the process of division and must be injured if exposed for any length of time. If Mr. Jenkins refers to such bulbs, he is correct when he says bulbs may be injured if divided too early, but I do not follow him when he says such work "may be done too late to the detriment, i.e., the subsequent progress of the offset itself." When bulbs are easily separated without severing any of the fleshy parts of the bulbs, but by merely dividing the hard root base, I think it is immaterial at what time they are divided, for the new circle of roots is formed outside the old root base.—W. A. WATTS.

## THE FRUIT GARDEN.

### MANURING FRUIT TREES.

**W**HEN the pruning and training of fruit trees has been finished and the resultant rubbish cleared away, attention may be directed to the manuring of trees standing in need of assistance. The indiscriminate manuring of all the trees, whether in need of it or not, is an injurious as well as a wasteful practice; the individual requirements of each tree ought to be considered. An Apple tree in good bearing condition with a well-balanced growth may be given a little of the three substances for which there is the greatest demand, viz., a potash salt, phosphoric acid and a nitrate. For the tree in question a 3-inch layer of fermented farmyard manure, placed on the surface as far as the roots extend, is the most suitable mulch, this containing the above-mentioned subjects in well-balanced proportions.

If the crop of Apples is usually so large as to be detrimental to free growth, the potash and phosphoric acid must be decreased and the supply of nitrogen increased. A good manure in this case would be a dressing of basic slag at the rate of 6oz. to the square yard, and stable instead of farmyard manure. On the other hand, if growth is produced at the expense of fruit, the potash and phosphates must be increased and the nitrogenous part left out. If the tree is on a wall, root-pruning may be resorted to with advantage, but if a standard, try a dressing of 3oz. of kainit and 6oz. of superphosphate of lime to the square yard, and prune only as much as is absolutely essential. Lime is also important as a food for fruit trees, and no form is more suitable for application than lime rubble or old mortar. It will be seen that the chief point in the manuring of fruit trees is in the variation of nitrogen. I find that a dressing of nitrate of soda, 2oz. to the square yard and wood ashes (potash) 4oz. at setting time is very helpful. Pear trees require much the same treatment as Apples.

Plums and stone fruits in general object to superphosphate of lime unless on soils well supplied with lime; basic slag applied in autumn is more to their liking. They require a considerable amount of lime, and this they obtain from the basic slag. Gooseberries and Currants do well with identical treatment, farmyard manure is always acceptable, but this cannot always be given them. A good substitute can be found in the decayed vegetable matter from the rubbish-heap, from which stones and wood have been removed. A coating of this material 3 inches thick, followed for the next two or three years by artificial manure, is conducive to health and fruitfulness.

A good artificial manure for Gooseberries and Currants is 3oz. of superphosphate of lime, 2oz. of kainit and 1oz. of nitrate of soda per bushel. Apply the superphosphate and kainit in February and the nitrate at fruit-setting time. On heavy land use basic slag instead of superphosphate of lime, and sulphate of ammonia instead of nitrate of soda.

Raspberries well repay liberal treatment. Digging may be practised with advantage with the previously-mentioned fruits, but with Raspberries never. Although they are deep rooters and love a deep, cool soil, most of the fruit-producing roots are found near the surface; besides, if a root gets broken it is apt to send up a bunch of useless suckers where they are not wanted. Nothing suits Raspberries better than an annual mulch of well-rotted stable manure or leaf-mould, and in conjunction with these a good artificial manure may be composed as follows: Basic slag, 8lb.; superphosphate of lime, 6lb.; kainit, 3lb.; and sulphate of ammonia, 1½lb. Well mix and apply at the rate of 6oz. to the square yard in spring. While indicating the general method of manuring fruit trees, I would advise every grower to experiment and find out what is

most suitable to his own particular locality, as it is well known that the same manures have different effects on different soils. H. M. E.

### THE GOOSEBERRY.

This is one of the most useful and also one of the most easily grown of our hardy fruits. Although not the first to ripen its fruit, it is the first to produce fruit which can be used for cooking. Many growers begin gathering the green fruit at Whitsuntide; but in warm localities where the effects of late spring frosts are not felt it is customary to do so at an earlier date. A large quantity of fruit may be gathered from bushes which occupy little space; it is, therefore, one of the best fruits the owner of a small garden can grow with the reasonable expectation of a quick return. The Gooseberry is not fastidious as to soil, but it is not grown successfully in stiff clays.

The intending planter should prepare the land by deep digging or trenching, burying a liberal quantity of rotten manure. Bushes may be planted at a distance of 5 feet apart. Dig out a hole large enough for the roots to be spread out evenly, fill in the soil carefully and tread firmly. Do not bury the plants too deep, or numerous suckers will grow from the base of the plants.

The pruning of the Gooseberry is an important matter if high-class fruit is to be secured. Young bushes at the time of planting should have the shoots cut back to one-third of their length. Any weak or crowded shoots should be cut back to 1 inch of their base. Summer pinching, which is often neglected, is a material aid in the production of an abundance of fruit of good quality. The lateral or side shoots should be pinched back to five leaves, but the main shoots or leaders must not be pinched in the summer. These leaders should have the unripened tips cut off at the winter pruning, and the laterals are then cut back to 1 inch of their base. When the bushes are several years old, some of the best-placed and strongest shoots may be left their full length and a portion of the old worn-out branches cut away. A supply of young vigorous shoots is thus secured, which, with attention to the necessary thinning, will produce an abundance of fine fruit. The Gooseberry is surface-rooting, and deep digging must not be practised between the bushes. The soil may, however, be lightly pricked over with a fork after the winter pruning and a mulch of manure applied.

#### THE CORDON SYSTEM

of training the Gooseberry is to be highly recommended. Grown thus the plants may be trained to walls, fences, or on a trellis. Fruit for dessert is excellent from cordon Gooseberries, and another advantage is that they are easily protected from the depredations of birds. Gooseberries grown as cordons should have the laterals pinched to five leaves during the summer. The winter pruning consists of spurring the laterals back to 1 inch of their base and cutting off the weak, unripened tips of the leading shoots. The best method of

#### PROPAGATING THE GOOSEBERRY

is by cuttings. Select for this purpose vigorous, firm shoots from 1 foot to 15 inches in length. Make a clean cut through just below a joint, remove the top bud from the shoot, and rub off all the others except the four upper ones. Insert the cuttings 4 inches deep and 4 inches apart in rows 18 inches apart. Make them quite firm by treading the soil around them. There are numerous varieties of Gooseberries. The following are excellent, producing large crops of good fruit: Crown Bob, red; Early Greengage, green; Langley Gage, yellow; Eagle, white; Warrington, red; and Thumper, green, very late. The following have highly-flavoured berries, good for dessert: Champagne Red; Champagne Yellow; Ironmonger, dark red; Whitesmith, white; Leader, yellow; and Keen's Seedling, red.

Munden Gardens, Watford.

C. RUSE.

## THE GREENHOUSE.

### A BEAUTIFUL PRIMROSE.

(PRIMULA KEWENSIS.)

**T**HAT this is a welcome addition to the greenhouse at this time of the year there can be no doubt. It originated at Kew about 1900, is rapidly becoming well known, and as it is freely produced from seed everyone can easily grow it. It is a good plant for the amateur, being easily grown and very free blooming. The flowers have a strong Cowslip scent. It has scapes of bloom from 10 inches to 21 inches in length.

From a packet of seed last spring I grew about forty plants, and just now they are in full bloom. With the exception of half-a-dozen plants that resemble one of its parents, *P. floribunda*, all are vigorous and of the true *kewensis* type. Two of these also show the influence of its other parent, *P. verticillata*, having some of the foliage covered with farina. Arranged with *Coleus thrysoides* they are very pretty, also with the white Roman Hyacinths, and when used in a cut state the flowers continue to open after they are placed in water. The seed should be sown in March in well-drained pans of light soil consisting of loam and leaf-soil in equal parts, with a quarter-part of coarse sand. They should be placed in a temperature of 55° to 60° and kept moist and shady.

Seedlings appear in about two or three weeks, and should be pricked off about an inch apart as soon as they are fit to move into pans, afterwards potting them in 2½-inch pots, and shifting on as required. They should flower in 4½-inch pots or 6-inch pots, but small plants in 3-inch pots are useful for decorations. The soil should be, for pots, half loam, leaf-mould and Mushroom-bed manure, the other half with a good dash of coarse sand. They should be grown for the first six weeks in a house about 60°, afterwards removing them to a cold frame or pit during summer. In September remove them to a light and cool greenhouse. Take away the ovaries as the flowers go over to prolong the flowering season. I have a great love for this fragrant brightly-coloured Primrose, which brings such sweetness to the greenhouse in the winter months. It is very easily grown, and I do not think it is generally known; the flowers last a long time in winter.

W. L. LAVENDER.

Waltham Manor Gardens, Twyford, Berks.

### A LADY'S SLIPPER.

(CYPRIPEDIUM INSIGNE.)

A COLLECTION of this species is very serviceable at this season of the year. Grown by amateur as well as by the professional gardener, *C. insigne* is found to be one of the most useful Orchids, whether shown as specimen plants or for cut flowers in house decoration. Coming from Northern India, a cool house is naturally most suited for its cultivation.

The photograph, taken in the gardens at King's Walden Bury, illustrates what can be done by careful attention. At the end of the flowering period the plants may be repotted, giving just sufficient water to keep the foliage in good condition until growth begins. To obtain good sized plants every attention should be paid to ventilation, light, arrangement and cleanliness.

A very useful wire support has been put on the market, to raise various sized pots, which ensures a free circulation of air. When in vigorous growth, weak cow manure or soot-water may be

given. Frequent sprayings of soot-water between the pots and on the stages will impart a healthy colour to the foliage.

During the summer the day temperature should not exceed 70°, and the thermometer at night should be kept at or below 55°. As a greatly reduced temperature at night is beneficial, the sun-heat should be husbanded, the time to do this being guided by outside temperature and other conditions. If grown in a heated frame, the plants should be as near the glass as possible, and placed on a bed of coal ashes. If possible, the plants should be rearranged frequently, and the pots washed if necessary. Cleanliness in plant growing, especially Orchids, is very essential.

When the flowers begin to develop, each spike should be neatly staked out with wire supports. Those which have twisted ends with just room enough for the stem to fit in are the best. When cut the flowers last a considerable time, and are, therefore, invaluable to florists.

Highgate.

A. J. H.

### EARLY CHRYSANTHEMUM WHITEPOINT.

I HAVE been pleased with *Chrysanthemum Whitepoint* this season, and its distinctness in a

THE LADY'S SLIPPER (CYPRIPEDIUM INSIGNE).

large collection struck one as noticeable. The name is evidently derived from the white points to the florets, which are of a reddish lilac with a golden centre. The contrast between the red lilac of the greater part of the petal and the white tips is pleasing, and those who do not wish an entirely self-coloured *Chrysanthemum* may well take a note of *Whitepoint*. A consideration in its favour is that it blooms in early September. It grows about 2½ feet high.

A. M.

### ASTER GRANDIFLORUS AS A POT PLANT.

This is one of the oldest Michaelmas Daisies, but it still has few rivals with its large deep purple flowers and dwarf, compact growth. Its one defect is that in the open air it flowers too late for most districts. It is, however, an ideal conservatory plant, standing only 2 feet high, and should be potted up in rather small pieces in 6-inch pots either in autumn or early spring, using a soil similar to that for *Chrysanthemums*. The treatment subsequent to potting—stopping and disbudding excepted—should be the same as for *Chrysanthemums*. A few plants of this fine *Aster* will give a variety of colour in the conservatory during winter that can hardly be obtained otherwise.

C. C.

## TREES AND SHRUBS.

### THE BEST HEDGE PLANTS FOR VARIOUS SOILS AND SITES.

**O**FTEN the question crops up as to what are suitable subjects for forming hedges, especially when something a little out of the ordinary is required. For long, really good protective hedges the number of subjects is somewhat limited, and the planter has to fall back on one or another of the well-tried things. These are White Thorn, Holly, Yew, Oval-leaved Privet, Beech or Hornbeam, and one or another of these will be found to thrive in almost any kind of soil or position, providing the ground is not waterlogged and is properly prepared in the first instance before any planting is done.

#### PREPARING THE GROUND.

Wherever a hedge is to be formed the site should be well prepared by trenching 2 feet deep and digging up the bottom. If wet and it is impossible to plant the hedge above the natural level of the ground, advantage should be taken of the opportunity while trenching of laying a drain. If, however, it is possible to form a low bank on which the hedge can be planted, so much the better; this, of course, applies to wet ground. Should the natural soil be poor, well-decayed manure may be added during the trenching, for, although many hedge plants grow satisfactorily in poor soil, they always obtain a better start if planted in well-worked and fairly good material.

#### PLANTS FOR VARIOUS PURPOSES.

For the rougher kinds of work—field hedges and the like—it is doubtful whether there is anything to equal the White Thorn, for if planted thickly and proper attention is given to clipping it forms a hedge that is impenetrable by man and beast. When used as a garden hedge, some people prefer a mixture of Thorn and Holly in the proportion of eight to ten of the former to one of the latter. Such a mixture has some recommendation, as it makes an exceptionally strong fence, and during winter it is less naked-looking than an ordinary Thorn hedge. For positions where a high but not very dense hedge is desired, the Beech and Hornbeam form good subjects, the former being specially suited for chalky ground. Such hedges are often used for shelter in nurseries. The Holly and the Yew are both well-known and popular hedge plants, and good hedges of either always invoke enthusiasm from garden-lovers. They are plants, too, that may be grown either as high or low hedges, and they may either be kept comparatively narrow or allowed to develop to a width of from 4 feet to 8 feet.

A plant that might be used much more largely than is done at present in the southern and western counties is the common Evergreen Oak (*Quercus ilex*). It is met with in a few places, forming a high, dense hedge that is excellent for protection and shelter. It has also the advantage of being able to withstand the effect of sea air. A few years ago a fine hedge of Evergreen Oak was to be seen in the gardens at Mount Edgecumbe. It is a plant that succeeds remarkably well in sandy soil, but it should not be planted in ground of a wet, cold character. As regards clipping it stands that excellently; as well as the common Holly, in fact. Unfortunately, it is of rather slow growth during the first few years of its existence, so it would not do to use where an immediate effect is required.

If a hedge is to be formed in the shortest possible period, there is no better subject to use

A WINDING PATH IN THE ROCK GARDEN.

than the Oval-leaved Privet. This will grow almost anywhere, stands the shears well and is of rapid growth. Though it occasionally loses its leaves in winter, it is usually evergreen. The golden, variegated-leaved form of this plant is an excellent subject for a prominent position where a touch of colour is required; it is not of such rapid growth as the green-leaved Privet, so will do for a position where the other would grow too strongly. For positions where something out of the common is required, the Golden Yew might be used with advantage, while Gold and Silver Hollies, Hodgkin's Holly and *Euonymus japonicus* all form excellent subjects.

In the warmer parts of the country *Escallonia macrantha* is an effective evergreen for hedges, and it has the advantage of flowering freely; very good hedges of it existed a few years ago at Tresco Abbey. For informal hedges there are many things that can be used; the Lavender, Rosemary, Sweet Briar, Provence Roses, double-flowered Gorse, various *Cistuses* and *Berberis wallichiana* are subjects that suggest themselves, while there are many more that will doubtless occur to intending planters.

#### SELECTING THE PLANTS.

When selecting plants for hedges, it is usually advisable to choose small rather than large plants, for, as a rule, they establish themselves quicker, and it is often easier to get a well-furnished bottom from small plants than from larger specimens. When planting it is a bad plan to be sparing with the plants; it is far better to obtain a few extra than to attempt to make a small number do. By using too few plants weak places occur in hedges, and it is always difficult to get such places to thicken up. Care must be taken with the clipping for the first few years, and hedges should not be allowed to increase too rapidly in height; if too rapid growth in this direction is allowed, it will only result in weakening of the bottom, which can only be strengthened again with great difficulty. If a good bottom is obtained in the first place, height will follow. The proper distance apart to place

the sets is a question that cannot very well be answered, and must be left to the judgment of the planter. If, however, he allows the side growth of each plant to touch that of its neighbour, he will not be far wrong. With the exception of Yews, Hollies and Evergreen Oaks, the planting may be done any time from early October to March; April, May and September are the most suitable times for the other things.

W. DALLIMORE.

## THE FLOWER' GARDEN.

### ROCK GARDENING.

THOSE who have fairly spacious rock gardens and wish them to be beautiful places, and not merely the receptacles of a quantity of different plants, can only secure such a result by putting upon themselves severe restraint as to the number of kinds to be used at a time. In gardening, as in painting, no picture can be beautiful whose composition is crowded and confused. There are various considerations that influence the choice of the plants that the rock planter will put together, but we think that the following suggestions would be worthy of consideration. First, to determine which are the plants that give us the truest pleasure. Then to consider which of these will group best together and flower at the same time; for, supposing four or five favourite kinds of plants to be grouped or partly intergrouped, it is a great advantage to let them be those that will bloom together and make one complete picture, and to have the intermediate sets of groups to bloom later in their turn. This is a much more pictorial arrangement than to have the plants flowering in scattered irrelevant patches quite unrelated to each other.

Suppose, therefore, that a spur of rock garden is crowned with bushes of *Andromeda floribunda*, and that steep rocks below it are clothed with *Aubrietia* and *Arabis*, and that at their foot in cool peaty ground there is a generous planting of *Primula denticulata*. Here are four capital things of early April, all in full flower together, making one complete picture, and these four are quite enough. The colouring is of the simplest possible and delightfully harmonious, and the whole thing is so good a picture that one dwells upon it, and comes back and back to it to enjoy its beauty in a way that one never does to a more mixed planting of individual objects.

A SMALL ROCK GARDEN NEAR THE EDGE OF A WOOD.

It is, of course, more easy to do in large spaces, but even in small ones the same thing may be done in square inches instead of square feet by choosing plants of smaller dimensions.

Such an arrangement for the pictorial part of a garden by no means precludes the enjoyment of individual plants, but we think it is wiser to have these in a separate place in a series of rectangular raised beds, where each plant may occupy its own pocket, and be as easily visible and accessible as a book on a shelf or a specimen in an economic museum. Such raised beds as are in Messrs. Fröbels' delightful nursery at Zurich could hardly be improved upon. They are perhaps 6 feet wide at the bottom and 15 feet long. They are steeply rock built, and accommodate a large quantity of plants. If the beds are placed east and west as to their length it will give each a shady and sunny side; a ridge of small shrubs at the top would give more shade on the north side. Such beds also afford the best opportunity of suiting plants with special soils, for one may be built of limestone, another of granite, another of sandstone, and so

most desirable of the *Helianthus* family, but at present is not planted so largely as its merits deserve. The common name of the Willow Sunflower is appropriate, as the deep green foliage is long and narrow, resembling in some respects that of certain Sallows. As it clothes the slender stems from the base almost to the top, it is well worth growing for its ornamental leafage alone. The flowers are comparatively small, and produced in a cluster at the apex of the stem; but, being so bright in colour, they form a strong contrast to the rich green leaves. This *Helianthus* is a particularly good perennial for planting singly or in masses by the water's edge, where it grows fully 6 feet high, and at the present time makes quite a noteworthy feature in the bog or water garden. Not less valuable is it in a broad herbaceous border, where good late-flowering plants are always appreciated. A. E. THATCHER.

### THE BEAUTIFUL ORANGE LILY.

The stately Orange Lily of cottage gardens (*Lilium croceum*) is at once the commonest

A SMALL ROCK GARDEN. NOTE THE WISDOM OF MASSES OF FLOWERS AT ONE TIME.

on, so that plants from all kinds of geological formations would find themselves at home. The plants in these rock beds would be grown distinctly as samples and labelled, then those that were the best liked and that showed the most aptitude for making good combinations for the rock garden could be increased and brought into the better use.

Labels should never be seen in the beautiful rock garden; they are destructive of all pictorial effect and damping to the sentiment of the truest enjoyment of plant beauty. You want your rock plant to say to you in cheerful sympathy: "I am one of the loveliest of the plants that God has given you for purest pleasure and for your bettering in gladness and thankfulness."

### THE WILLOW SUNFLOWER.

(*HELIANTHUS ORGYALIS*.)

For giving a pleasing display of golden yellow blossoms throughout October this is one of the

and hardiest of our garden Lilies, and if planted in a suitable situation and given some small attention in the way of staking, few plants are of more striking appearance or of higher decorative value in the border. Any ordinary garden soil suits this Lily, but it has a distinct preference for deeply dug ground well enriched with decayed manure, and under these circumstances will soon form flourishing clumps, reaching from 5 feet to 7 feet in height.

The illustration shows a fine group planted behind a formal border and immediately in front of a shrubbery, and in such a position this Lily is seen at its very best, for the dark, quiet background of shrubs forms a splendid foil for its deep orange beauty. Some support is necessary for the flower-stems, as even a slight wind is likely to damage them; but whatever aid is given ought to be unobtrusive, and allow the plants their natural habit as much as possible. Too often this Lily is seen tied in an ungainly bundle to a stake. I. S. TURNBULL.

## THE ROSE GARDEN.

### NOTES ON THE WILD ROSES (SPECIES).

**R**OSA ECÆ.—This is a Rose that has never flowered with me, though I am not without hopes that one day it will do so. It flowers fairly freely in South Devon and Cornwall, and I have seen small plants of it in bloom in Mr. Prichard's nursery at Christchurch. It is very tender and the flowers are insignificant; it is only a curiosity and certainly not recommended. It comes from North Africa and Abyssinia.

*R. glutinosa*.—Another curious rather than a beautiful Rose, flowers pale pink; the flower-stalks are often quite viscid.

*R. gymnocarpa*.—A pretty and interesting Rose from North America, with small red flowers, followed by red fruit. I think this is worth growing, although my plant of it is small.

*R. humilis*.—A very pretty, free-flowering pink Rose, with a not unpleasant suggestion of magenta. These are succeeded by round red hips in autumn, that would remain all the winter if the birds would let them. Their shape is distinct and not unlike Cherries. I believe there is a white-flowered form, but I have never been able to come across it. If anyone reading these notes can inform me where it can be obtained, I shall be indebted to them. A very handsome plant first seen by me at Kew is the natural hybrid *humilis* × *rugosa*. It is well worth growing. The flowers are larger, with a long bud, and it is, I think, freer than *humilis*, the type and blooms much later; in fact, it is almost perpetual, and would, I should say, make an excellent hedge.

*R. indica*, of which there appears to be many forms. One is the parent of most of the old Monthly or China Roses; another, a large single pink that I have only seen at Messrs. Paul's Cheshunt nursery, but which might well be the parent of some of the Teas. Then a beautiful variety is the crimson sometimes known as Miss Lowe's variety or *sanguinea*; this I think is a type, and not a garden variety like the one known as Miss Willmott, which is single and of a distinct copper colour. These are all known as *Rosa indica*, and I have no doubt there are more.

Looking at the small flowers and plants, one wonders more and more that their glorious descendants of to-day can ever have had any kinship with them.

*R. lavigata*.—A native of China, but also known as the Cherokee Rose. I remember a very fine plant of it in South Devon, but, except in warm, sheltered spots, it does not flower much; a climbing Rose that has large white flowers. I believe *R. gigantea* is allied to this species.

*R. lucida*.—Best known, perhaps, by its double form (which pretty little Rose is worthy of more extended culture, quite moderate in growth), but I would also put in a word for the species which is not so frequently met with; its flowers are larger, freely produced, the foliage glossy and changes colour in the autumn to all shades of purple. The flowers though flat are clear rosy pink in colour, and borne in clusters, but only opening one at a time; they are also sweetly-scented, the fruit is brilliantly coloured (deep orange-red), as large as nuts, and last well on the plant which

is ornamental right through the year, as after the leaves have fallen the year-old wood itself changes and becomes red. It is not a rampant grower, so can easily be kept within bounds, and own-root plants can easily be raised by the suckers which well-established plants freely produce. There are other forms of the type—*alba* with white flowers, *sorbifolia*, &c., but I have only grown the type *lucida* and its double form, *lucida fl.-pl.*, both of which I can strongly recommend. It is a native of North America.

*R. macrantha*.—This, although generally known as a species, is, I believe, more correctly described as a natural hybrid of European origin. It is undoubtedly one of the most beautiful of all single Roses. It is half a climber, and a well-grown plant makes a fine pillar, with its large nearly pure white flower and glorious centre of yellow stamens. *Canina* × *Gallica* are, I believe, the parents.

*R. macrophylla*.—A single pink free-flowering Rose with good foliage, introduced, I believe, from Thibet. It is of semi-climbing habit, and is recommended, but it must not be confused with

*R. microphylla*, which has white flowers, and is also of Chinese origin, but is quite distinct in every other respect. Its wood is dark yellow or buff colour, the leaves small, and the fruit prickly.

*R. moschata* (the Musk Rose), sometimes appearing in catalogues under its synonym *Brunonis*. This and its varieties are among the most vigorous of all Roses, and its various uses are many, for pergolas where there is plenty of head room, at its best climbing up trees; some forms, notably *floribunda*, makes an excellent "lawn" plant. Introduced from the Himalayas, a good plant makes a beautiful picture. It is difficult to say which are the best form. I have *moschata alba*, *moschata nivea*, *floribunda* and *grandiflora* (the latter, perhaps, the most rampant): *nivea* I am discarding, as the stamens turn black in an unpleasant fashion before the petals fall. A large cluster of this Rose will last over a week in water and the buds will nearly all open. The fruit is very small, not much larger than dried Peas. Recommended.

*R. nipponensis*.—A free-growing climbing Rose that so far has not proved very free-flowering, but its flowers come late after most of the other species.

*R. nitida*.—I believe this to be a North American species, and it is one of my favourites. It is by no means well known and I was a long time before getting a plant of it true. It is most distinct. I came across it by accident eventually in the nursery of Mr. T. Smith of Newry. It is quite dwarf, rarely exceeding 3 feet in height, the wood closely covered with small spines that on the growth of the year are crimson in colour, with leaves a deep glossy green in spring and summer, but which in autumn take on tints that rival any *Ampelopsis*. The flowers are rosy crimson, freely produced, and are followed by bright red hips almost spherical in shape. My original plant I put on a piece of rockwork, but I have now planted an edging of it, and I think it will be an excellent Rose for the purpose. Strongly recommended and not difficult to produce from suckers.

*R. nutkana*.—A Rose calling for no special comment; flowers deep pink, followed by

small fruit. The same, however, need not be said of

*R. nuttalliana*, which I consider one of the best of the species. It forms a good bush, making long, slender shoots, on which the flowers are produced the whole length, and they are of a pleasing shade of pale rose pink, followed by coral red hips. Its native home is, I believe, North America, from which Continent we have received so many of these species.

*R. omissa*.—I doubt this being a species, although so called in most catalogues, and I think it is very closely allied to *Scabrata*. It is unquestionably, however, a very beautiful Rose of large size, deep pink in colour, of strong-growing habit and would make a good bush.

*R. pomifera* (the Apple-fruited Rose).—This has pink flowers and large fruits.

GROUP OF THE ORANGE LILY (*LILIUM CROCEUM*).

*R. pimpinellifolia*, another name for *spinossissima*.

*R. polyantha*, too well known to call for comment; a free-flowering, sweet-scented, summer climbing Rose.

*R. rubiginosa* (the native Sweet Briar), which is, I hope, in every garden.

*R. rubrifolia*.—One of the most useful of all the species. Its foliage is most ornamental for decorative purposes, and is so much sought after in my garden that I wonder the plant survives. It is not easy to describe the curious effect of the glaucous shot-silk appearance of the leaves, heightened as they are by the red stems of the plant. For association with pink Roses, such as *La France*, there is no foliage to beat it.

*R. rugosa* (Japanese Rose).—A species that is receiving, and rightly so, much attention from the hybridist. Everyone knows the type and its white form, and to mention half the varieties

that have sprung from them would take up too much space and is outside the scope of this article, but the whitest Rose that grows is *Blanc Double de Coubert* and the newer *Conrad F. Meyer*, one of the greatest acquisitions to our Rose gardens of recent years.

Purley.

H. E. MOLYNEUX.

(To be continued.)

## ROSE BEDS IN SANDY SOIL.

It is a well-known fact that Roses thrive best in a rich retentive loam. They retain their vigour longer than when in a light, sandy medium. The nature of soils varies considerably in different parts of the country, being suitable in some districts and unsuitable in others. But where amateurs have to deal with a sandy soil

they should not despair of growing very fine flowers. Numerous instances have come under my notice where splendid specimens have been grown in adverse circumstances. In a garden near Southampton that I had charge of years ago, Roses were grown in one large bed. The soil was very sandy, so it was removed to a depth of about 18 inches and good loam put in. In that district plenty of moisture was found 3 feet below the surface; being distant about a quarter of a mile from the sea—at high tide—I was informed that the sea-water permeated the soil to a considerable distance from the shore, and as the garden in question was low-lying and almost on a level with the sea, water could always be found within a few feet of the surface. The Rose trees made excellent growth for many years, and always looked in the best of health.

But the subsoil is not moist in many districts, and, where a dry rooting medium obtains, heavy mulchings should be put on to prevent undue evaporation. Furthermore, I find it best to keep the surface of the newly-formed bed rather low and not rounded. It is much better to thoroughly prepare a few beds by putting in some good loam than to rely upon a poor sandy soil. Strong-growing varieties should be planted, the following being suitable, namely:

*Dark Crimson Varieties*.—A. K. Williams, Abel Carrière, Duke of Edinburgh, Earl of Pembroke, Fisher Holmes, General Jacqueminot, Horace Vernet, Pierre Notting and Prince Camille de Rohan.

*Pale Rose and Pink*.—Abel Grand, Marchioness of Dufferin,

Mme. Eugène Verdier, Mrs. John Laing, Mrs. R. G. Sharman Crawford, Paul Neyron, Ulrich Brunner and Pride of Waltham.

*Light Crimson*.—Captain Hayward, Beauty of Waltham and Mme. Charles Wood.

*Red in Various Shades*.—Countess of Oxford, Alfred Colomb, Dupuy Jamain, Mme. Victor Verdier, M. E. Y. Teas and Senateur Vaisse.

*Rose*.—Hippolyte Jamain, Victor Verdier and John Hopper.

*White and Shades of White and Pink*.—Boule de Neige, Margaret Dickson, Merveille de Lyon, Captain Christy, Mme. Hippolyte Jamain, La France and Baroness Rothschild. These are Hybrid Perpetuals.

The following Tea-scented Roses may also be planted; Mme. Bérard, Mme. Lambard, Mme. Bravy, Anna Olivier, Duchess of Edinburgh, Marie van Houtte, Mrs. Edward Mawley and Souvenir d'un Ami.

AVON.

## GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**T**OWN GARDEN.—Not much can be done in the town garden at this season, except perhaps to make the surroundings neat and tidy. Lightly fork over the surface soil of beds and borders. Rockeries may be made now. Select a fairly shady position and form mounds or heaps of good soil, into which should

1.—A PARSLEY ROOT AS DUG FROM THE OPEN.

be dropped burrs or large stones here and there. Plant Ferns, &c., in March, by which time the soil should be in a nice workable condition. Transplant shrubs of the hardiest and most vigorous kinds. Privet hedges should be put in order and gaps filled.

**Trees and Shrubs.**—Old and decayed branches of Lilac bushes should be pruned now, taking care to cut out only the useless pieces, leaving last year's shoots until June, when growths that have borne flowers should be shortened back to about a couple of inches. Deciduous-flowering shrubs of all kinds may be treated in like fashion, and in this category the beautiful Mock Oranges are included. Hardy creepers, both flowering and foliage, may be planted now, and those that are well established should be pruned and nailed to the walls and fences against which they are growing.

**Flower Garden.**—The early-flowering Gladioli may now be planted, and for an effective display group them in colonies of half-a-dozen to a dozen in each. The corns should be planted about 4 inches deep and 6 inches or rather more apart. A fine day when the weather and soil are both suitable should be selected for this work. In cold and bleak situations, where Carnations cannot be planted until the spring, take every opportunity of stirring the quarters allocated to them, using a fork for the purpose. This should get the soil in nice working order when the planting time comes round. Sparrows are injuring the shoots of Carnations just now. To stop them insert small stakes round the plants and strain between them black thread or cotton. This is a simple and most effective remedy. Most of the hardy perennials may be divided from this time forth. It is only necessary to deal with very large overgrown clumps, and these should be broken up into nice little pieces, each with a few shoots or crowns. Lupines, Phloxes, Pyrethrums, Sunflowers, Larkspurs and Michaelmas Daisies may be treated thus.

**The Greenhouse and Conservatory.**—Keep the glass clean and ventilate more freely than formerly, but avoid giving a chill to the more tender subjects. Tea-scented and other Roses under glass may be encouraged into free growth in a temperature of from 50° to 55°. Look over the plants frequently, and if insect pests are discovered, dust with Tobacco powder. If badly infested fumigate forthwith, using any of the excellent preparations now sold. The pretty greenhouse Mosses (Selaginellas) may be increased now by propagating the ends of shoots. These should be dibbled in half an inch apart in small pots (preferably 3-inch), using a compost of loam and leaf-mould that has been sifted, to which should be added a small quantity of silver sand. Fill the pots quite full of soil, and after the cuttings are inserted place them in a small propagating frame or hand-light on the greenhouse bench in a temperature of about 65° to 75°.

**The Vegetable Garden.**—Shallots may be planted forthwith, leaving the upper part of the bulbs visible above the soil. Nine inches apart in the rows and about 1 foot between the rows is a good rule to observe. The trenching and digging of the vegetable garden that have been delayed should be pushed forward with all speed. Do not work the ground when it is very wet. In warm quarters a sowing of early Carrots may now be made. Mustard and Cress may be sown in pans and boxes. They may be raised with ease on hot-beds or in the greenhouse. Those who desire to grow big Onions and Leeks should make a sowing in boxes at the present time. Ailsa Craig is an ideal Onion for this purpose, and Prizetaker and The Lyon are good Leeks. A shallow box of light and sandy soil that is properly crooked and drained will answer well. Sow thinly, slightly covering the seed, and after watering in with a fine-rosed can, cover the box with a sheet of glass, subsequently placing it in the warmest part of the greenhouse or in the hot-bed.

**Chrysanthemums.**—Cuttings of the spidery and miniature-flowered Pompon sorts for decorative uses should be inserted in light and sandy soil without delay. Late January and February is an excellent period to propagate the decorative varieties. The early-flowering varieties may be dealt with during the same period successfully. A temperature in the glass structure of about 45° answers the purposes of these plants admirably. The cuttings need not be kept in an air-tight glass structure, as they root in about a month in any ordinary greenhouse.

## OBTAINING PARSLEY IN COLD WEATHER.

FREQUENTLY in severe weather the supply of outdoor Parsley runs short or ceases altogether, and, where there is a demand for garnishing or other purposes, it is necessary to adopt various precautions to ensure a supply. A cold frame placed over a portion of an outside bed will generally enable pickings to be made as long as the stock of leaves already in being exists. But a cold frame does not force new growth; it only preserves that already present. To obtain new growth, the greenhouse should be requisitioned and a few pots or deep boxes, according as much or little Parsley is required. The roots are dug up, as in Fig. 1, and all old and decaying foliage cut away. The tap-root and side roots are also trimmed in, as shown in Fig. 2. The roots are then ready for potting, and three of them will generally be found ample in a 5-inch pot. Fig. 3.—The plants should be well watered in,

and at first stood near the greenhouse door. In the course of a week or so they should be moved to a warm and moist corner of the house, and, if kept well watered and syringed, a quantity of fresh young growth will soon be forthcoming. Failing a greenhouse, very good Parsley can be grown in pots placed in a sunny kitchen window.

## TO GROW PARSNIPS WELL.

DEEP culture is absolutely essential if long, tapering roots of high quality are to be produced. Although it would have been better to have thoroughly trenched the quarters allocated to this and kindred subjects some time since, it is not too late to do this effectively, even at this somewhat protracted period. Soil of a light and sandy nature is undoubtedly the best, but other soils by careful working can be made quite as suitable. Quarters that were planted with Celery last season should grow Parsnips well this season, and if such are available by all means utilise them for the purpose under notice. Should the ground be trenched forthwith only very rotten manure can be used, and this must be buried right at the bottom of the trench. See that this work is done at once, and leave the surface in a rough condition. A month or six weeks exposure to wind and weather will effect a great change. Then the surface soil may be forked over, broken up, levelled and raked over and a sowing made in late February or a week or two afterwards when the weather and the condition of the soil is favourable.

## POTTING COMPOSTS OR SOILS.

Do amateurs generally take the care they ought to in making up the soil to pot their plants in? I think not. Some enthusiastic amateurs do, undoubtedly, pay special attention to this matter, and in due course reap a good reward; but the majority simply put off preparing the composts until they actually require them for use, and then, I am afraid, in their haste they use any kind of garden loam. It has been my lot to have to examine the roots of plants which amateurs have grown in greenhouses and windows, and in nine cases out of ten the loam has dropped away from the roots the moment it was turned out of the pots, most of the few roots remaining being quite dead. No amount of care in training, watering and feeding of plants will avail if the roots are growing in an unsuitable medium. Different kinds of plants require different kinds of soil, and, although it is a difficult

2.—THE ROOT TRIMMED READY FOR POTTING.

3.—THREE PARSLEY ROOTS IN A 5-INCH POT  
READY FOR THE GREENHOUSE OR WINDOW.

matter to provide them in the open garden, it is an easy one as regards plants in pots. The following table is not exhaustive, but it is sufficiently so to be a guide:

Kinds of Plants.	Soils.	Proportions.
Azaleas, Indian ..	Fibrous turf ..	One-third
	Peat .. ..	Two-thirds
	Sand .. ..	1 peck to 4 bus.
	Fibrous turf ..	Half a part
" mollis var. ..	Peat .. ..	1 peck to 5 bus.
	Sand .. ..	One part
	Fibrous turf ..	Two parts
	Peat .. ..	One part
Begonias, tuberous ..	Leaf-soil ..	1 peck to 4 bus.
	Sand .. ..	Half a part
	Rotted manure ..	Half a part
	Fibrous turf ..	Two parts
" fibrous-rooted ..	Peat or leaf-soil ..	Half a part
	Sand .. ..	One part
	Rotted manure ..	Three parts
	Fibrous turf ..	Half a part
Chrysanthemums (final and previous potting only) ..	Leaf-soil ..	1 peck to 8 bus.
	Rotted manure ..	1 peck to 3 bus.
	Bone-meal ..	Two parts
	Sand .. ..	One part
Ferns, Maidenhair ..	Fibrous turf ..	1 peck to 3 bus.
	Peat .. ..	Two parts
	Leaf-soil ..	One part
	Sand .. ..	1 peck to 3 bus.
Dracena australis ..	Same as for Ferns ..	Three parts
	Fibrous loam ..	Half a part
	Leaf-soil ..	1 peck to 4 bus.
	Rotted manure ..	Two parts
Palms (greenhouse var.) ..	Sand .. ..	One part
	Fibrous turf ..	Quarter of a part
	Peat .. ..	1 peck to 3 bus.
	Leaf-soil ..	Two parts
Liliums .. ..	Rotted manure ..	One part
	Sand .. ..	1 peck to 4 bus.
	Fibrous turf ..	Two parts
	Leaf-soil ..	One part
Zonal Geraniums ..	Rotted manure ..	1 peck to 4 bus.
	Sand .. ..	Three parts
	Loam (rather heavy) ..	Half a part
	Leaf-soil ..	1 peck to 6 bus.
Roses, Hybrid Perpetuals ..	Rotted manure ..	Two parts
	Sand .. ..	One part
	Loam (medium) ..	1 peck to 4 bus.
	Leaf-soil ..	Two parts
" Teas and Hybrid Teas ..	Rotted manure ..	One part
	Sand .. ..	1 peck to 3 bus.
	Fibrous turf ..	Two parts
	Leaf-soil ..	One part
Cinerarias .. ..	Rotted manure ..	1 peck to 3 bus.
	Sand .. ..	Two parts
	Fibrous turf ..	One part
	Leaf-soil ..	1 peck to 4 bus.
Primulas and Cyclamens ..	Old mortar rubble ..	Three parts
	Rotted manure ..	Half a part
	Sand .. ..	1 peck to 3 bus.
	Fibrous turf ..	Two parts
Fuchsias .. ..	Leaf-soil ..	One part
	Rotted manure ..	1 peck to 4 bus.
	Sand .. ..	Three parts
	Fibrous turf ..	Half a part
Annuals, tender ..	Leaf-soil ..	1 peck to 5 bus.
	Rotted manure ..	

*How to Treat the Different Ingredients.*—*Loam.*—This may be kept in the open if it be stacked in such a way as to throw off water. *Peat.*—Keep this in a dry place in a shed. *Leaf-soil.*—This is best if kept in a neat heap in the open, as the collected leaves decay better than if placed in a dry shed. *Manure (Organic).*—

Always store the manure in an open shed, but rain must be kept off. Manure exposed to the weather soon loses its goodness, as it were; all the nutriment is washed out of it or dried up. *Manure (Artificial).*—Keep all artificial manures in a dry shed, cool. *Sand.*—This, too, should be kept in a dry place, as when dry it mixes with the other ingredients better. It is a good plan to wash all sand, thus getting rid of soil particles, and afterwards thoroughly dry it. AVON.

#### A SIMPLE MEANS OF RAISING PANSIES.

PANSIES may be raised with comparative ease. Many need no more than twenty-five to fifty plants of just a few varieties. In such circumstances get a few seed pans about 12 inches in diameter and 3 inches to 4 inches deep, and, after crocking them with potsherds, fill in with a light sandy soil to the rim. This should be made fairly firm, so that cuttings or rooted sucker-like growths may be dibbled in quite easily. A good soil should be made up of loam, leaf-mould and sand in equal parts, and these ingredients should be well mixed after being passed through a sieve with a half-inch mesh. Then sprinkle a quantity of coarse silver sand over the surface soil, so that as the cuttings are inserted some of the sand may be carried to the bottom of each hole and thus ensure perfect drainage. Old Pansy plants may be lifted when the weather is not frosty, and broken up into numerous pieces. Young and supple growths should be selected, and of these one old root should provide any number between twenty-five and fifty of suitable size. Old and coarse growths are useless. Insert the shoots about 2 inches apart, and the effect will be much the same as represented in the accompanying photograph. When completed, place the pans in a cold frame or any rough structure erected in a warm aspect. By the early spring a batch of plants should be in readiness for planting outdoors. D. B. C.

#### BEAUTIFUL GRASSES TO ORDER SEEDS OF NOW.

MANY people, especially amateurs, experience a certain amount of difficulty when making out their seed lists owing to the vast quantity of names that confront them, and many very good things often get overlooked. Judging by the very few gardens in which one encounters them, the ornamental Grasses must be generally left out, a fate they by no means deserve, as they have several good points that warrant the inclusion of at least a few in every order of flower seeds that is sent to the vendor. They are comparatively easy to grow, possess a distinction and charm that is hard to surpass, and besides being of considerable use for arranging with the more showy cut flowers of the summer, they may be cut just before the heads are fully developed and dried ready for decorative purposes during the winter months, when such material is scarce. The seeds, too, can be purchased cheaply. These may be sown in preferably rather sandy soil in the open during March in the South of England, but for the Northern Counties and Scotland some find it advisable to sow in pots, pans or boxes under glass. In both instances the seedlings are transplanted in small clumps as soon as large enough, protecting them from drying winds or heavy rains for a few days to enable them to become established, when they will easily take care of themselves. Soil of a rather light nature suits most of them best.

*The Best Sorts.*—Perhaps the doyen of the whole of the annual Grasses is the Cloud Grass (*Agrostis nebulosa*). This is exceedingly graceful, and forms the most lovely garnishing for Sweet Peas that it is possible to obtain. It grows about 18 inches high and is an ornament in itself. *A. pulchella* is also very beautiful, but of dwarfer habit than the former. The small or graceful Quaking Grass (*Briza gracilis*) is another beautiful Grass that is well worthy of a place in all gardens.

It has a very light appearance, and the flower-heads are so situated that the least movement sets them trembling, hence its popular name. The Hare's-tail Grass (*Lagurus ovatus*) is of different habit to those previously mentioned, the heads being cone-shaped and covered with a thin, soft downy coat. It grows about 1 foot high, and although an annual the best way to grow it is to sow seeds in pots under glass early in September, winter the plants in a cold frame and transfer them to the open the following April. The flower-heads of *Pennisetum longistylum* are of nearly the same shape as those of the foregoing, but the long awns or hairs render them much more graceful. It is an easily-grown annual providing a little protection is given to the seedlings during wet or cold weather in the early stages of their growth. It reaches a height of 18 inches and deserves to be much more widely grown than it is at present. Other Grasses that are well worth growing and that may be raised from seeds are the Feather Grass (*Stipa pennata*)—this is a 2 feet high perennial—the Squirrel-tail Grass (*Hordeum jubatum*), the Love Grass (*Eragrostis elegans*) and the curious Job's Tears (*Coix lachryma*). The list might be extended, but the above are the pick of the ornamental Grasses that may with reasonable care be raised from seeds.

#### THE PERSIMMON.

WE are asked a question about a fruit frequently seen in London shops—the Persimmon. This is to the Japanese and Chinese what the Apple is to us. It has been cultivated by them for its fruits for many generations, and there are hundreds of named varieties recognised by the fruit growers there. More than twenty years ago a selection of varieties was introduced into the orchards of California and planted extensively in the belief that the fruits would find a ready market. But the American public would not buy Persimmons. In England it has been grown and fruited in a few gardens, chiefly as a curiosity; but where it has succeeded it has been greatly admired, as much for the rich colours assumed by its foliage in the autumn as for the beautiful rich scarlet colour of its Peach-like fruits, which are ripened in late autumn and hang for weeks after they are ripe if the weather is favourable. They are not palatable until

PANSY CUTTINGS INSERTED IN A SHALLOW PAN.

"bletted," as in the case of the Medlar, when, however, they are to some tastes delicious. In the warmer parts of these islands the Persimmon could be grown on walls outside if treated the same as the Peach, while in orchard houses their culture would be quite easy.

According to Dr. Henry, the fruit of the Persimmon has another use in China; it is cut into halves and put into water, and the oil thus obtained is used for waterproofing the common Chinese umbrellas and hats; it is known as the "Yu-shih-tzu." Even if the fruits are not considered delectable to the palate they cannot fail to please the eye.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**D**IGGING and trenching should still be the chief work. Collect leaves and mix them with long stable manure for making hot-beds.

*Forcing Vegetables* should now be in full swing, and no better method can be practised than the hot-bed system. Potatoes, Asparagus, Carrots, Lettuces and Radishes may all be sown or planted now. If the supply of salad is running short, sow Golden Gem and Paris Market Lettuce in boxes. These come on very quickly and can be cut very young. Keep up the supply of Chicory, Dandelion and Endive, as well as Asparagus, Rhubarb and Seakale, by introducing a supply to heat equal to the demand each week.

#### HARDY FRUIT.

Continue to prune, tie and nail trees as the weather permits. Look over the stock of bush fruits, and if any additions are likely to be needed prepare cuttings and plant them in a border where they will not be lost sight of. Useful trees can be grown in about three years if skilfully handled. Plant Filberts and Cob Nuts, choosing high ground for the purpose of escaping frost. Old bushes and trees may now be pruned. Cut out all suckers from the base, and by this time many of the blooms will be seen, so that this should be a guide to the pruner. Leave as many catkins as possible for pollination.

#### FLOWER GARDEN AND PLEASURE GROUNDS.

Keep the lawns neat and tidy by frequently sweeping and rolling them. Cover up tender plants to protect them from east winds or very keen frost, removing the covering after the frost has gone. Continue to plant Azaleas, Camellias, conifers and similar subjects when the ground is in good working condition. Top-dress any trees or shrubs that require it. Nothing is better for the purpose than good cow manure with soot and bone-meal added. The latter, however, should be of the very best quality. A little soot or Shigicide should be put around bulbs and plants that are just pushing through the ground.

#### FRUIT UNDER GLASS.

*The Earliest Vines* may now have another 5° of heat. Disbud as soon as the bunches can be seen, and leave only one shoot to a spur. Syringe with tepid water twice daily and see that the roots are not dry.

*Peaches*.—Do not attempt too rapid forcing in the early house till the blooms have set, when an extra 10° may at once be given, as the sun will now be getting more powerful. Finish all the work of tying and training in late houses and give all the borders a top-dressing of good loam and a sprinkling of bone-meal or Le Fruitier. Pot young Melon and Cucumber plants as soon as possible after they have made a leaf and keep them near the glass.

#### PLANT HOUSES.

Propagate now any decorative subjects, such as Pandanus, Crotons and Dracaenas. Excellent little table plants can be produced in a short time by the process known as "ringing."

*Gardenias* showing flower should have a little manure water, and as a preventive of mealy bug a spray with an insecticide every week.

*Roses* starting into growth must be kept free from aphids, maggots or grubs; these, if not detected, soon ruin a bloom.

*Begonia Gloire de Lorraine*.—Insert cuttings now for an early batch; plants of *Gloire de Sceaux* now in bloom need moving into a cooler

house. These are excellent subjects for conservatory and house decorations.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

THERE ought to be plenty of Roman Hyacinthus, Paper-white and other early Narcissi in bloom now, and if the retarded crowns of the Lily of the Valley are employed, these also will come into bloom very quickly in quite a moderate warmth, though the natural roots require special care and rather hard forcing to get them in bloom at this season. The chief points in the successful forcing of this plant are to cover up the crowns well with a good depth of Cocoanut fibre or moss and to keep the roots regularly moist throughout.

*Toxicophlea (Acokanthera) spectabilis*.—Flowering as it does in the depth of winter this stove shrub is now at its best, and a plant or two will, when in bloom, suffice to perfume a good-sized structure, so fragrant are the small white Jasmine-like blossoms that are produced in clusters from the axils of almost every leaf. Cuttings root readily during the growing season, and if potted off as soon as rooted they make rapid progress. If intended to grow in a bush form, the plants must be freely stopped during their earlier stages, as it is naturally somewhat rambling in growth, and may, if required, be treated as a roof or rafter plant.

#### FRUIT UNDER GLASS.

*Strawberries*.—In places where the earliest dishes are not looked for until the middle of March the present is a good time to commence. A well-built brick pit, in which a good lasting hot-bed of leaves can be made up, and with a single hot-water pipe round it, is a very useful aid to Strawberry forcing. For early work strong single-crowned fruits should be selected, and after cleaning the pots and removing any decayed or broken leaves, each plant should be dipped in or syringed with some insecticide. For the early batches *La Grosse Sucrée* is still an excellent variety, *Royal Sovereign* and *Sir Joseph Paxton* making a trio hard to beat.

#### HARDY FRUIT.

Push on the pruning of all the outdoor trees and bushes during open weather, so as to get this work completed before the rush of the spring work begins.

#### FLOWER GARDEN.

*Ranunculus Beds* should now be prepared by forking in well-decayed cow manure and leaf-mould. Plant Anemones, if not already done, and protect the beds with well-rotted manure. Plant also at the first opportunity any bulbs of Narcissus that may not have been got in, and where plants of Pinks and Carnations have been loosened by frost they should be tightened by carefully pressing the soil, but this should not be done while the ground is very wet.

#### KITCHEN GARDEN.

By this time most vegetable growers will have secured their catalogues of seeds for the coming season, and to a beginner the selection is somewhat difficult, owing to the quantities described; and in such cases it will be well to get such as are well known. I am aware that many think new things should be avoided, but we should remember that our old favourites themselves were new once. Vegetables that have mere size to recommend them are of little value, as, for instance, Carrots, Parsnips, or other roots.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
*Ashwellthorpe, Norwich.*

## THE KITCHEN GARDEN.

### THE BEST GARDEN PEAS FOR A LATE DISTRICT.

**F**ROM time to time we get valuable notes on all sorts of vegetables in *THE GARDEN*, but so far I have not noticed that any of the writers have made mention of varieties of Peas suitable for the later districts in Scotland and the North of England. Having to supply large quantities of Peas of the best quality for as long a season as possible, I feel that I am able to speak with some little authority on this subject. Our garden soil is a heavy one and we stand high, so that earliness is out of the question as it is understood further south. During seven seasons I have only once been able to pick Peas in June, but, as part compensation for our late start, we usually have quite decent pickings in November. For several reasons, but mainly because I require a great deal of frame accommodation for flower raising, I do not sow my first crop under glass, but just seize the first dry chance in spring to sow on a south border. After experimenting with most of the approved early sorts, I now pin my faith to the Irish-raised variety named

*The Pilot*.—It is about a week in advance of William I., and is certainly a Pea of much finer flavour. The crop, too, is excellent, and it is so hardy that I have never seen it damaged by frost. Of course, I dare not risk any of the early Marrow Peas in the ground before nearly the end of March. I then sow

*Gradus*, *Edwin Beckett* and *Boston Unrivalled*, all on the same date, and these afford a first-rate succession in an ordinary season. Last year, however, everything got out of joint somehow, and these three varieties came in together. Could I depend on the last-named coming every year as early as *Gradus*, I would grow it alone as my second early, for, without doubt, on this heavy soil it is the very best Pea in cultivation. The crop is at least three times the bulk of *Gradus*, the flavour is even better, and the pods remain usable for a longer period.

*Edwin Beckett*, here, is a better cropper than *Gradus*, and equal in flavour. To follow *Boston Unrivalled*, I find

*Alderman* usually excellent, but in 1907 it was not up to the mark.

*The Bell*, which received a first-class certificate from the Royal Horticultural Society in 1905, is the largest podded variety I have yet grown, and the quality is very good. As I have only grown it one season I will say no more about it just now, but will certainly grow it again. The next on the list is

*Glory of Devon*, a Pea of great merit, both as regards bulk of crop and excellence of flavour. I have grown it largely for four seasons and would not care to be without it. Among the later varieties

*Royal Salute*, another Irish-raised sort, stands pre-eminent. It only grows 3 feet to 4 feet high, and sets a heavy crop under all weather conditions. I have grown it during the last four seasons, and have never once had it fail. The next best late Pea here is

*The Gladstone*.—It is wonderfully productive, and stands a wet season well. The only time I have ever had to complain of this grand variety was during a year of intense drought. All the same, this Pea has given me great satisfaction during the nine years I have grown it. In good seasons

*Autocrat* is splendid, but as it does not set well in a wet season I have had to discard it.

*Michaelmas* I find very good for the latest crop if I sow during the last week in May. If I sow later it has not time to mature. I cannot close these notes without a special reference to

*Daisy*.—Here it is not only by far the finest dwarf Pea ever tried, but for bulk of crop and quality it is almost equal to many of the finest

tall sorts. So well does it succeed here that I put in several sowings, at intervals of about three weeks, and thus secure a fine succession of this one sort without taking up much space. With me it grows quite 2 feet high, and it is best when properly staked. To sum up, I would say that the best half dozen Peas for succession are The Pilot, Edwin Beckett, Daisy, Boston Unrivalled, Glory of Devon and Royal Salute.

*Preston House, Lindlithgow.*

C. BLAIR.

### RAISING EARLY VEGETABLES.

To maintain a constant supply of fresh vegetables and salads is a matter requiring careful attention on the part of all gardeners, professional and amateur. In addition to providing hot-beds as a means of producing early Carrots, Turnips, Radishes and similar subjects there are several varieties of vegetables which may be successfully grown from seed sown at this season in the greenhouse or in frames.

#### EARLY CAULIFLOWERS

are always appreciated, and by sowing seed of an approved variety in a box or pan in moderately light, firm soil nice plants may be raised for planting out in the spring. Sow the seed thinly, as this prevents damping off. When the plants have grown large enough prick them out into boxes, or if a frame is available a bed may be made therein and the plants pricked out into the bed. In raising and growing these early plants it is important that they receive the full benefit of both light and air. Draughts must be avoided. A batch of

#### EARLY CABBAGE

may be grown in the same manner, and those who experience difficulty in securing a good crop of this valuable vegetable from plants raised in the autumn should adopt this method. It is surprising how quickly a suitable variety of Cabbage will form nice tender hearts. Sutton's Earliest is a variety that is difficult to beat for this purpose.

#### LARGE ONIONS

are very popular; they are essential to the exhibitor of vegetables and are also most useful for certain culinary purposes. A small packet of seed selected from a good strain will provide a large number of plants, which, with careful culture, will in turn produce large, handsome bulbs suitable either for exhibition or kitchen use.

#### EARLY SPRING SALADS

are always welcome, and several varieties of the Lettuce may be sown under glass at this season. A Lettuce that may be grown in boxes throughout the winter and which provides a supply of delicious salad is Sutton's Forcing. This Lettuce does not form hearts, but the leaves grow very quickly and are very tender. Sow in rather light rich soil and prick out 3 inches apart. For a succession sow some approved Cabbage Lettuce, which should be gradually hardened for planting out in the spring. These early Lettuces are liable to burst after reaching

maturity, and it is therefore advisable to make a succession of sowings to maintain a supply. Plant the early Cabbage Lettuce in a warm sheltered corner of the garden.

#### BRUSSELS SPROUTS

require a long season in which to grow if a really first-rate crop of large solid buttons are to be secured. The seed may be sown now, and the plants treated as advised for the Cauliflower and Cabbage. When removing the plants from the seed-box take care not to damage the roots, and when finally planting them out in the garden dig up the plants with a ball of soil attached to the roots, and use a trowel in preparing the holes for their reception. Choose a dull showery day for this operation, and even then it is often advisable to carefully apply water to the plants to settle the soil about their roots. When carefully planted they quickly become established and make rapid growth.

C. RUSE.

### AN INTERESTING PERGOLA CLOTHED WITH FRUIT TREES.

PERGOLAS of various descriptions are to be found in gardens throughout the United Kingdom, but generally only flowering plants are used to clothe them. Where beauty with utility is desired, nothing better than Apple, Pear and Plum trees can be utilised for covering a pergola. The illustration depicts such a structure erected by the well-known firm of Messrs. Richard Smith and Co., Limited, in their nurseries at Worcester. The photograph was taken about two years after planting, and shows what rapid progress the trees have made. Such a pergola is comparatively cheap to erect, and proves a beautiful and useful addition to any good-sized garden. Although fruit trees are best planted during November, there is still time to do the work. Take care to thoroughly prepare the ground by trenching before planting, as the trees will have to remain in their positions for a number of years, when deep cultivation will not be possible.

## NEW ORCHIDS.

#### CYPRIPEDIUM SULTAN.

THIS is a lovely addition to this wonderful group of winter-flowering Orchids, and is the result of a cross between C. M. de Curte and C. Milo Westombirt variety. The flower is an exceedingly beautiful one, and is also of large size. The dorsal sepal is very large, broadly heart-shaped, with a broad white edge. The ground colour is green, heavily mottled with dull crimson. The petals are long, oar-shaped, slightly twisted, and stand out at almost right angles to each other. Their colour is a deep yet glossy crimson with a slight gold edge. The lip or pouch is of medium size, deep yet somewhat brighter crimson than the petals. This also has a narrow pale yellow edge. The foliage is rather broad. It was shown by Major G. L. Holford, C.I.E., C.V.O., Tetbury. First-class certificate.

#### CYPRIPEDIUM MINOS YOUNG.

This is a most unique-looking *Cypripedium*, and one that is sure to become a great favourite. The dorsal sepal is very large, measuring 3 inches in diameter. It is erectly held, the edges being slightly curved inwards and beautifully waved. The ground colour at the base of this sepal is green, this being heavily striated with dull crimson. Around this ground colour comes a broad band composed of small purplish blotchings, the whole being surrounded by a broad white edge. The petals are narrow, mucronate, very drooping, with crinkled edges. The colour of these is dull crimson, shading off to green at the tips. The labellum or pouch is of medium size and of a dull crimson colour, with a light gold-coloured edge. The foliage is much like that of the well-known *C. insigne*. Shown by Messrs. J. A. McBean, Cooksbridge. First-class certificate.

#### LÆLIO-CATTLEYA CORUNNA.

This is a very handsome and striking member of the *Lælio-Cattleya* group, the parentage of which is unknown. The sepals are lance-shaped, the petals being much broader and slightly

PERGOLA CLOTHED WITH FRUIT TREES.

fringed. Both sepals and petals are of a uniform bright purplish mauve. The labellum or lip is of medium size, the colour being a very rich deep velvety crimson, with slight orange markings in the throat. The plant shown was carrying one flower only. Exhibited by Major Holford. Award of merit.

#### ODONTOGLOSSUM HYERIDUM BINGELIANUM.

This is a very fine *Odontoglossum* of unique colouring. The sepals are relatively large, with a deep cream ground colour, this being very heavily mottled with brownish crimson blotches except at the tips. The petals are very similar, the markings, perhaps, being somewhat more crimson. The labellum is of medium size, white at the apex, with dull crimson and yellow markings at the base. The plant shown was carrying a raceme composed of seven fully-opened flowers and six buds. Leaves and flower-stem are characteristic of the large family of *Odontoglossums*. Shown by Baron Schröder, Egham. First-class certificate.

#### ODONTOGLOSSUM MACNABIANUM.

This a very lovely cross between *O. harryanum* and *O. wilckeanum* albens. The sepals and petals are large, with very crinkled edges, the colour being a mottling of deep brownish crimson and cream. The labellum is of medium size, purplish white at the apex, with crimson, purplish and deep yellow markings at the base. The plant exhibited was carrying a raceme consisting of twelve fully developed flowers. The leaves are broader and of a lighter green than most members of this genus. Shown by Messrs. Sander and Son, St. Albans. First-class certificate.

The Orchids described above were placed before the Orchid committee of the Royal Horticultural Society on the 14th inst., when the awards were made.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### COTONEASTER ANGUSTIFOLIA FROM DORSET.

Mr. George Manning, The Gardens, Stock Hill House, Gillingham, Dorset, writes to us as follows: "I am sending you a spray of *Cotoneaster angustifolia* for your table, which I hope will interest you. The colour is not so deep as it was last year, no doubt owing to want of sun. There has been a quantity of berries on the plant, and no doubt in a good season it will make a pretty feature in the garden as a berry-bearing plant, as it appears to be a free fruit-bearing subject. As far as I know, this is the first plant to produce berries in this country, at least that is what was told me by E. C. Buxton, Esq., of Coed Derw, Bettws-y-Coed."

#### ELEPHANT'S FOOT FROM SOUTH WALES.

The writer hopes the following may be interesting for the Editor's Table, viz., a photograph of the Elephant's Foot (proper botanical name not known to the writer). It was raised from seed some thirty years ago at this place and is now growing in a pot 1 foot 3 inches wide. The "bulb," if it can be so called, is like wood, with outside knotty squares. Strong roots go to the bottom of the pot. From the top of the bulb

the growth has gone to the top of the greenhouse (a few leaves enclosed). The foliage and stem die down about the end of June, when the stem is cut off. In about a fortnight a shoot appears, which at first grows rapidly—3 inches to 6 inches a day. Long, smooth, snake-like side shoots are thrown out, which are drawn together with a piece of tape very gently, as they snap like glass if done roughly. In a month the growth reaches

ELEPHANT'S FOOT RAISED FROM SEED.

the top of the greenhouse, then the foliage develops. — COLONEL HOWELL, *Penrheol, St. Clears, South Wales.*

[A very interesting contribution. The botanical name is *Testudinaria elephantipes*, synonymous with *Tamus elephantipes*.—ED.]

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Shrub for grass plot (H. W. H.).

The character of your soil and the fact that you intend to let the grass grow right up to the stem of the shrub makes your question a difficult one to answer, as very few shrubs would thrive treated thus. Under the circumstances you had better try *Berberis aquifolium*, which has rather a spreading habit. If something neater is required, plant an *Aucuba japonica*. Many subjects could be advised did you care to go to the

trouble of making a small bed of good soil, a course we strongly advise you to take.

**Climber for brickwork under window (H. W. H.).**—If your brickwork is white or yellowish-white you cannot do better than plant *Cotoneaster horizontalis*. This is a neat dwarf-growing subject that looks well on any wall except a red one. For the side of the front door plant the Fire Thorn (*Crataegus pyracantha*), the remarks as to the colour of the brickwork applying equally to this as to the *Cotoneaster*. If the brickwork is red plant a *Ceanothus veitchianus* at the side of the door and a Japanese golden-veined Honeysuckle (*Lonicera japonica aureo-reticulata*) under the window. You must water these well during dry weather.

**Where to obtain seeds of Verbena Miss Willmott (A. G. P.).**—We cannot tell you where seeds of this *Verbena* may be obtained. It does not usually seed in this country, although one large grower of *Verbenas* that we know states that he believes that it would seed were the flowers fertilised. Propagation is usually effected by means of cuttings. Why not secure a plant or two and try and seed them yourself?

**Tubs for Agapanthuses and other plants (Ignoramus).**—Tubs of various sorts are used for these plants. Lard pails, to be had from any provision merchants for about 4d. each, answer very well, and will last for several years providing the insides are slightly charred and the outsides painted. Holes must be burned or bored in the bottoms for drainage. Small beer or wine casks sawn in half will cost more, but they will last much longer. Char and paint them as advised for the lard pails. If you require something of a more expensive and elegant character please write again. No, it is not too late to plant *Dielytra spectabilis*, but the sooner it is done now the better. Do not, however, attempt to plant it while the ground is at all frozen.

### THE GREENHOUSE.

**What to do with frozen Crassulias (W. L.).**—As your *Crassulas* have become wilted and browned, we fear that there is little chance of saving them. However, your best course will be to cut away all the affected parts and dust the wounds with finely-powdered charcoal. Then remove the surface soil for a depth of about half an inch, and fill up the space thus made with clean silver sand. Then stand the plants in the sunniest position that you can. The object is to prevent decay; therefore be very careful indeed with water. These plants will stand the soil getting nearly dust-dry, and we advise you to let the soil in which yours are growing get in this condition before you give more water. If the roots are not killed, you may save your plants by acting on this advice.

**How to utilise a range of glass houses (Enquirer).**—This is one of those questions that a practical man on the spot could give a far more satisfactory answer to than it is possible for us to do. We presume that you wish to keep the small conservatory close to the house as gay as possible throughout the year. If so, the other structures will be none too many to grow plants necessary for the purpose. At all events, this structure, if flowers are needed in the depth of winter, must have additional hot-water pipes, sufficient, in fact, to keep up a minimum temperature, even during severe frost, of 45°. Nothing is said as to the relative positions of the other houses and frames. If they are near enough to each other to be heated from one boiler, we should advise you to certainly have pipes put in the two houses, as you can then grow various greenhouse plants therein. The frames will be valuable in the winter for bulbous plants of different kinds, and in summer for such subjects as Chinese Primulas, Cyclamens, Cinerarias, &c. For a spring display such bulbs as Hyacinths, Tulips and Narcissus, potted in the autumn and placed out of doors, being afterwards brought on gradually inside, will make a good show. In addition to these there are Indian Azaleas, Lily of the Valley, Eupatoriums, Primulas, Spiraeas, Zonal Pelargoniums, *Dielytra spectabilis* and hard-wooded plants of various kinds. Then in summer the choice of subjects is large, there being Pelargoniums of all sections, Fuchsias, Roses, Lantanas, Petunias, Cannas, *Lilium longiflorum* and many others. The bulbs of the *Lilium* just alluded to (*longiflorum*) must be potted in the autumn, and may be wintered in the frame, as well as *L. auratum* and *L. speciosum*, which flower later than it. In early autumn, apart from many summer-flowering subjects that are not then over, the Chrysanthemums figure largely, while the blue-flowered *Salvia azurea grandiflora* and the scarlet *Salvia splendens* are very useful. For late autumn and winter you have the choice of such things as Begonias of the socotrana section, including Gloire de Lorraine; Roman Hyacinths, Winter-flowering Heaths, Tree Carnations, Primula obconica, and the earliest Cyclamens, Chinese Primulas and Cinerarias.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

## GARDENERS' ROYAL BENEVOLENT INSTITUTION.

### ANNUAL MEETING.

THE annual meeting of this beneficent institution was held on Thursday, January 23, when the chair was taken by the treasurer, Mr. H. J. Veitch, and a most encouraging report submitted. We need not enter into details here, as a report is given on another page, but the warmest thanks are due to Mr. Veitch and the committee for their unselfish work in holding out a helping hand, through the subscribers, to gardeners or their widows in a time of great distress.

The utmost care is taken in selecting the candidates for election, and it is pitiable to find that out of the list of fifty-two the funds would only allow of twenty-one receiving a pension, and in two instances a year's pension was granted to the candidates through the generosity of Mr. Arthur Sutton and Mr. George Monro.

We feel that the gardeners might work more earnestly in this charitable cause; it is for them and their widows that the institution was founded, and it has been the means of making comfortable in the evening of their lives hundreds of men and women struck down by permanent sickness. Looking through the list of subscribers we find practically the same names year by year, men whose purse seems always at the command of the institution—the Rothschilds, Veitchs, Sherwoods, Suttons and other names we honour for their rich gifts in the cause of suffering gardeners and their widows.

No charitable institution we are acquainted with is more efficiently and economically managed, and this is due to a great extent to the secretary, Mr. G. J. Ingram, who loves the work for its own sake. We look forward to the time when there will be no candidates waiting for that help which is so desired, but all will be placed on the pensioners' list.

There are two funds to relieve cases of exceptional distress, the Victorian Era and the Good Samaritan, which have been of the greatest service since they were established. We hope the institution will gain in strength, but this is only possible with increased subscriptions—the gardener should work more energetically.

## FRUIT GROWERS, NURSERYMEN & RAILWAY RATES.

THE *Daily Telegraph* is, as we go to press, devoting much space to the discussion of excessive railway rates in connexion with market garden and nursery produce, a question that is of great importance, not only to the growers, but to the general public. The alleged attempt of the railway companies to form a combination for the raising of the rates for the carriage of such produce is foolish in the extreme, such a course only tending to restrict the sources of supply instead of extending them, which, we think, would be more to the companies' advantage. Such well-known men as Messrs. George Monro, Covent Garden; W. Cuthbertson (Dobbie and Co.); C. A. Pearson, hon. secretary of the Horticultural Trades' Association of Great Britain and Ireland; Edward H. Lewis and Son, Covent Garden; Jackman of Woking and many others have given their views on the subject, and all agree that something must be done to prevent any rise in railway rates and to remedy the many real grievances that already exist. Growers that have experienced any difficulty in the way of unreasonable delay, careless handling of goods, high rates, refusal of compensation for damage done and the many other points that occur in connexion with the transmission of produce by rail should send full particulars, written as concisely as possible, for publication in the *Daily Telegraph*. It is only by combined action that any real remedy can be effected, and growers now have an opportunity of putting their grievances before the public. As Mr. C. A. Pearson says, it is only by convincing the general public of the reality of these grievances that amendment will be secured.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

February 11.—Royal Horticultural Society, Committees meet, 12 noon; Annual Meeting, 3 p.m., Horticultural Hall, Vincent Square. Horticultural Club, Annual Meeting, 5 p.m.; to be followed by Annual Dinner, 6 p.m., Hotel Windsor, Victoria Street, London.

March 3.—Royal Horticultural Society, Committees meet, 12 noon.

"The Sweet Pea Annual."—The fourth issue of this official annual publication of the National Sweet Pea Society is now in the hands of the members, and, as usual, it contains a great deal that is of much use and interest to lovers of the numerous varieties of Sweet Peas. Mr. Hugh Aldersey writes the opening chapter on "Sweet Pea Enthusiasts"; Mr. S. B. Dicks contributes an exceedingly interesting illustrated article entitled "More Historical Notes"; Mr. W. Atlee Burpee sends an open letter on his impressions of the London Sweet Pea show and Sweet Peas in general in this country last year; Mr. Charles Foster deals with the "Germination of Seeds," "The Reading Trials" and

"Early-flowering Sweet Peas" in his usual interesting and concise style; Mr. G. W. Leak sets forth the merits of wire netting as a support for Sweet Peas, giving much useful information as to its cost and method of erection; Mr. G. H. Mackereth deals in a pleasant way with "The Popular vote for Sweet Pea Novelties"; and Mr. W. P. Wright, chairman of the floral committee, addresses a timely warning to the members about the "streak" disease and mixed stocks under the title of "Breakers Ahead." Other interesting contributions are "Sweet Peas in Devonshire," by Mr. R. Bathurst; "Sweet Peas in the Antipodes," by Mr. H. A. Fox, Wellington, New Zealand; and the audit of the London Sweet Pea show, 1907, by the hon. secretary, Mr. C. H. Curtis. The catalogue of Sweet Pea names and the opinions from all quarters are also exceedingly useful. Several attempts to break into poetry are also included, and these, to our mind, are the one deplorable feature about this interesting publication. Surely they do not represent the best and most poetical thoughts that this lovely annual inspires in Sweet Pea-loving bards? Copies of this annual can be obtained by non-members from the hon. secretary, Mr. Charles H. Curtis, Adelaide Road, Brentford, Middlesex; post free, 1s. 3d.

#### TO A SCHOLAR GARDENER.

O buried deep in Berkshire bowers,  
O you that left the arid town,  
By day to walk among your flowers,  
By night to take the classic down,  
And as on long-neglected land,  
With maziest overgrowth perplexed,  
With keen discriminating hand  
Repair the roughness of the text,  
And make an ancient plot more fair  
And rid from weeds of later age,  
Enclosing here, emending there,  
The garden of the Muse's page.  
There are to whom your gentle toil  
Seems to lack reason or excuse:  
For tilth that brings not corn or oil,  
Such men may say, we have no use.  
But others, wiser, when awhile  
They call a halt to wain and team,  
And glance beyond the alien pile  
Deep-shovelled from Pactolus stream,  
Will say: We envy not your bowers,  
But hail you of the saving few:  
While art is art, and flowers are flowers,  
Mankind hath need of such as you.  
"C. W. B.," in *Country Life*.

**School gardens in Essex.**—The report on the elementary school gardens in Essex for 1906-7 by H.M. Inspector is a decidedly encouraging one. The number of these gardens in the county is forty-two. Of these thirty-three are worked by the school teachers, and in nine cases visiting gardeners are employed. According to the report, "school gardening in Essex may unhesitatingly be pronounced a practical success."

#### PRIZES FOR READERS. FEBRUARY.

##### THE BEST FIFTEEN HARDY ANNUALS FOR SUMMER EFFECT.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above  
subject.

Competitors should describe briefly the colours of the flowers, height of the plants, and the best methods of raising and growing them.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Saturday, February 29. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

#### CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Apples for the new year.**—There are one or two notes under the heading of "The Fruit Garden" in THE GARDEN of the 18th ult. which I scarcely think should pass without comment. Your correspondent Mr. W. A. Cook is, I think, rather hard upon the newer varieties of Apples and Pears. Tastes differ, and one cannot lay down any rules for other people's guidance, but personally I should scarcely have chosen Blenheim Orange as one of the best dessert Apples for the new year, as it generally gets mealy before the old year is done with, and certainly for a late variety it is not comparable with Lord Hindlip, which I consider the best late Apple we have for eating. King of Tomkin's County is a very good second to this, but does not develop its full flavour in a bad season. Unfortunately, Lord Hindlip is a weak grower, but the cause of this is most decidedly not over propagation; the writer of the paragraph must have had Chrysanthemums or some such plants in his mind when he wrote about Apples "having been pushed rapidly to get a supply of scions for multiplying the stock for commercial purposes." I have never known Apples forced in heat to produce wood for either budding or grafting, and any attempt to do this would be a miserable failure; at the same time, I cannot think of any other explanation of this most mysterious sentence. As to "inbreeding" being the cause of Apples having a frail habit of growth, I do not think we have sufficient data to form any opinion upon this point, for very few raisers have paid much attention to it, and I know that many of the parentages given are purely guess work, as, for example, Newton Wonder, said to be a cross between Blenheim and Dumelow's. As a matter of fact, it is a chance seedling, with no record whatever of even the Apple the pip came from, but, on the other hand, "cross-breeding," which is also given as a cause for weak-growing seedlings, is generally looked upon as a potent factor in the production of vigour. Turning to Pears, I have nothing to say against the varieties named, except that Thompson (not Thompson's, if you please) being an October and November fruit is sadly out of place among Christmas Pears. Glou Morcean is an excellent variety, and most useful from the fact that it usually ripens at the festive season of Christmas; but out of a collection placed before the Royal Horticultural Society's fruit committee on the 14th ult., Olivier de Serres was the best, followed by Bergamotte Esperen, Glou Morcean and Easter Beurré in the order named, and none of them were anything like equal to President Barabé or Santa Claus, both of which, he it remarked, are new varieties. Passing on to the subject of Plums named in another article, I quite agree with the writer that many of the best Plums far surpass the Green Gage in point of cropping, for in most situations this is a shy bearer, and several of them are quite equal in point of

flavour. Among these I should include Reine C. de Bavay and Bryanston, but I should not include Denniston's Superb, which is, at any rate in the Midlands, of poor quality. I presume it must be good elsewhere or it would not be asked for as it is. I was very pleased to see Alger Pett's remarks upon watering trees planted on walls; dryness at the roots is a very frequent cause of non-success with trees of this class; not only does the wall keep off the rain, as the writer says, but as most of them are built without damp courses they absorb moisture from the soil, which is afterwards lost by evaporation. In the majority of cases a good soaking of water to the roots of wall trees twice a year would be most beneficial, in the early autumn to plump up the buds and in the spring to help the trees to bloom and set their fruit.—A. H. PEARSON, *Lowdham*.

**Carnation Winsor.**—There would appear a general tendency to propagate an error—quite a pardonable one, it is true—in the spelling of the name of the above Carnation. The variety is of American origin, and a novelty of 1907 so far as we in this country are concerned. Quite freely of late the name has been rendered "Windsor," and as the variety promises to be one of the most popular of recent introductions, it may be as well to set the matter right at once. The correct way to spell it is W-i-n-s-o-r.—E. J.

**Window gardens in streets.**—For the past three years about this time you have been good enough to allow me to draw the attention of your readers to the efforts of the Metropolitan Public Gardens Association to encourage the formation of outside window gardens in the poorer streets of the Metropolis. The object we have had in view is to relieve the great monotony of many of these thoroughfares, by getting the occupiers to grow plants, flowers, creepers, &c., in boxes, pots, or baskets outside some of their windows. It is astonishing what a transformation is effected by even a few such efforts on the part of the inhabitants, which change the whole aspect of a dull street and gladden the eye of every passer-by. Many of the thoroughfares are too narrow for trees, so no other form of foliage is possible; but, even where trees do exist, the window gardens are a most desirable addition. The association has therefore started prize competitions in various centres, getting the assistance of some suitable organisation in the vicinity to arrange local details. Last year there were twenty centres (chiefly situated in the central, eastern and south-eastern parts of London), 520 entries and 140 prize-winners, entailing an outlay on our part of some £25. The results are considerably in excess of those of 1906, and we are encouraged to go on. I am anxious, therefore, to let it be known that the association is again prepared, so far as its means allow, to make money grants for prizes this year to any suitable parochial or other local organisation, school, or flower show society, &c., willing to arrange as part of its summer programme outside window garden competitions in the poorer parts of the Metropolis. We were able to arrange for competitions last year in connexion with several elementary schools, whose scholars proved to be keen competitors, and I hope that their number may be increased. I should like to add that we should be extremely glad of any contribution towards our prize fund, so that we may not have to curtail the number of our competitions for lack of funds. Any who desire to take advantage of our offer should apply without delay to our secretary, 83, Lancaster Gate, W., who will supply copies of regulations, &c.—MEATH, *Chairman, Metropolitan Public Gardens Association*.

**Twelve best Apples for flavour.** There is sure to be a diversity of opinion on this subject, but as your correspondent rightly states the various opinions of growers on "Twelve of the best dessert Apples for flavour"

will prove most interesting and instructive. Some people prefer an acid Apple, a large number a sweet Apple, and others give preference to varieties possessing what is known as a Pine flavour. In dealing with this question it is most important to bear in mind the locality in which the individual varieties of Apples have proved to be of superior flavour. In the county of Hertfordshire the following twelve dessert Apples have been found difficult to beat in respect to flavour, while the majority of them are in suitable seasons good croppers, and when the necessary cultural requirements are afforded them are mostly of clean, healthy growth. These Apples are placed in their order of ripening, and it will be seen that the season extends from August to the following May. *Irish Peach*.—This is an old favourite, of medium size, possessing a delicious flavour. This Apple has often failed under severe pruning; it should be lightly pruned, as the fruits are produced chiefly on the points of the shoots. *James Grieve* is an Apple of Scottish introduction, and one that is often successfully grown where Cox's Orange Pippin fails. This is an Apple which is fast gaining favour, as it is hardy, prolific and of excellent flavour. *Ribston Pippin* comes next, and although much has been said against planting this Apple, owing to it being subject to canker, there are still many growers who, by selecting trees from a clean healthy stock and planting in warm soils and aspects, are very successful with this variety. *Cox's Orange Pippin*.—There is no better Apple for flavour, and, fortunately, this variety can be well grown in all forms, but prefers a warm, rather rich soil. It is wise to plant this variety among other Apples to ensure cross-fertilisation. The finest fruit has been gathered from bush trees growing on the Paradise stock. *Allington Pippin*.—This is an abundant bearer and the fruit possesses somewhat the flavour of Cox's Orange Pippin. The growth is vigorous and healthy. May be grown in all forms with good results. *Adam's Pearmain*.—This Apple is of a distinct sugary flavour and very juicy. In shape the fruits are conical and very pretty, having a yellowish skin, with russet spots and red streaks. Trees of moderate growth and pendulous habit. *Mannington's Pearmain* is an abundant bearer. The colour of the flesh is yellow and the flavour rich and sugary. This Apple is sometimes ready for use in November, but is often in season as late as February. *Warwickshire Pippin* or *Wyken Pippin*.—This is an Apple below medium size, is of rich aromatic flavour, a great favourite in some localities, and deserves a place in every good collection. *Scarlet Nonpareil*.—Fruit rather small, but of a refreshing crisp flavour and very handsome in colour and shape. Growth slender; makes a prolific bearer on the Paradise, but may also be grown as an orchard tree on the Crab stock. *Claygate Pearmain*.—Fruit medium in size, possessing a very rich flavour somewhat resembling Ribston Pippin. Growth of tree strong and rather spreading; succeeds both on the Crab or Paradise stock, but is, perhaps, more fertile on the latter. *Fearn's Pippin*.—Fruit medium in size, of a brisk refreshing flavour and very brilliant in colour. Growth moderate, generally good as a bush, and also successful as an orchard standard. Although most frequently classed as a late Apple, it is often fit for the table in late November and early December. *Allen's Everlasting*.—For dessert in April and May this is an Apple of excellent flavour. Size of fruit medium, and flat in shape. This variety is of rather slender growth, and forms a dwarf and compact tree when grown as a bush. Fruit must not be gathered too early or it will shrivel and become worthless.—C. RUSE, *Munden Gardens, Watford*.

—In selecting the best twelve Apples, the planter will need to have regard to those varieties best suited to his particular climate, position and soil. *Mr. Gladstone* is one of the earliest Apples we have. It is a medium-sized fruit of excellent

flavour. In colour it is red with yellow stripes. The tree is a great bearer and very adaptable to orchard culture. It is in season July and August. *Irish Peach* is a great favourite when in good condition. It requires to be eaten direct from the tree, when its flavour is fine. The tree is of medium growth and a good bearer. It makes a good orchard tree, and is also suited for the garden. It is ripe early in August. *Worcester Pearmain* is probably the most popular Apple in its season that we have. It is a splendid orchard variety, and is in great demand for market. A medium-sized fruit of splendid appearance and excellent flavour. In season August and September. *Lady Sudeley*.—This is a beautiful Apple when well grown, but, like most early sorts, should be eaten directly after gathering, when its flavour is excellent. It is a very persistent bearer, and very suitable for the garden as bush or pyramid. In season with Worcester Pearmain. *Ribston Pippin*.—This variety is too well known to need description. It is, undoubtedly, one of the best flavoured Apples we have, and succeeds best in a sheltered position on a warm soil. In season October to May. *King of the Pippins* is one of the best known Apples. It does excellently in almost any form. In season at Christmas. *Allington Pippin* is becoming a great favourite, as it is

ODONTOGLOSSUM HYBRIDUM BINGELIANUM. (FLOWER REDUCED ONE-HALF.)  
(Shown before the Royal Horticultural Society on the 14th ult. by Baron Schröder, when it was awarded a first-class certificate. See page 48.)

better known. In point of flavour it much resembles Cox's Orange Pippin, which is one of its parents, but it is not so fastidious as that variety. It is not keeping well this season, which is no doubt due to the wet, sunless season of last year. November to February. *James Grieve*.—This variety is perhaps not so well known as some of the above, but for flavour and cropping qualities it is hard to beat. It is ripe in September. *Adam's Pearmain* is an excellent flavoured Apple. The tree is an abundant bearer. Can be recommended as being specially suitable for the amateur grower. In season December to February. *Cox's Orange Pippin* is, undoubtedly, the greatest favourite of all dessert Apples. Where the conditions are suitable it should be planted largely. It succeeds well either in the garden or orchard. In season from November to end of February. *King of Tomkin's County* is one of the latest sorts we have. It is of American origin and has a splendid flavour. The fruit should be allowed to hang on the trees till late in the season, when they will keep in good condition till May. The tree is a great bearer and succeeds well in almost any form. *Duke of Devonshire* is another late variety of sterling merit. It is a medium-sized fruit of fine flavour. The tree is a good bearer of free habit, succeeding well in any form or situation.—E. H., *Frogmore*.

## THE GREENHOUSE.

### SOME OF THE NEWER CHRYSANTHEMUMS.

THE season that has just passed has not been remarkable for first-class novelties, although a few sorts are of great excellence. The Japanese blooms, as usual, have largely predominated, a few noteworthy specimens being conspicuous. Strange to relate, an impetus has been given to the incurved section by the introduction of one or two sterling novelties. The single-flowered sorts have been shown in immense numbers, and it is pleasing to note that the decorative aspect of these flowers is being better appreciated than was the case at one time. Decorative or market Chrysanthemums are now regarded with more favour. The following embrace some of the better varieties of more recent introduction:

#### JAPANESE.

*H. J. Jones* (1908).—This is a very handsome large flower of Japanese incurved form, having long, broad florets of good substance, and the colour may be described as rich golden yellow,

with a paler reverse to the florets. This variety received a first-class certificate from the National Chrysanthemum Society on October 14 last, and on the succeeding day an award of merit from the Royal Horticultural Society.

*William Petty*.—In this instance we have a very interesting novelty of Japanese reflexed form, which impressed the National Chrysanthemum Society's floral committee so much that they wished to see it again. The colour may be described as rich cream, suffused with light rose, and its attractiveness is added to by its yellowish-coloured centre.

*Mrs. L. Thorne*.—This is an excellent counterpart to the variety *H. J. Jones* above mentioned, being similar in character to that promising sort. The difference in this novelty, however, is its colour, which is best described as light canary yellow. The florets are long and broad, and build up a Japanese flower of good substance. First-class certificate, National Chrysanthemum Society, October 14 last.

*Mrs. G. F. Coster*.—This is one of the most remarkable blooms of the past season, being an ideal type of Japanese reflexed. It is an immense flower, having long, broad florets, and is ideal for exhibition. The colour is best described as amber, shaded bronze, a colour that is very pleasing under artificial light. It is of English origin, emanating from the gardens of Mr.

Martin Silsbury, Shanklin, Isle of Wight. First-class certificate, National Chrysanthemum Society, and award of merit, Royal Horticultural Society, in October last.

*Lady Smith of Trebiske.*—This variety will be best appreciated when it is stated to be a primrose-coloured sport, with light reverse to the florets, from the popular white variety Mme. Marguerite de Mons. Like the parent variety, the flowers are deep and solidly built, and are seen to great advantage when arranged in stately vases. First-class certificate, National Chrysanthemum Society, October 28.

*F. W. Lever.*—This is a Japanese novelty, having very long, broad florets that are slightly indented, curled and incurving at the ends. As an exhibition flower it should be very largely in demand. The colour is rich creamy white, with a richer cream centre. First-class certificate, National Chrysanthemum Society, and award of merit, Royal Horticultural Society, October 28 and 29 respectively.

*Miss Faith Moore.*—This is an interesting type of the Japanese incurved section, and is a flower having rather narrow florets. It is pure white, and is a distinct acquisition to this section. First-class certificate, National Chrysanthemum Society, October 28.

*Wallace Godfrey.*—Seldom are Chrysanthemums recognised for their colour alone, but in the present instance the National Chrysanthemum Society commended this beautiful flower for its colour. It may be described as a rich golden amber, tinted rose in the centre.

*Metche Beauty.*—The colour in this instance is a rich yellow, freely suffused and tinted rosy red. The flower is quite distinct in form, being a beautiful Japanese reflexed. The petals are broad and long, and are of good substance.

*Clara Venum.*—This is another distinct Japanese reflexed decorative bloom, and was certificated by the National Chrysanthemum Society as such. It is a flower of good form and useful size. The colour may be described as a deep rich crimson self. The Royal Horticultural Society also gave an award of merit in favour of this variety on October 29 last.

*George Milham (1908).*—This is an excellent English seedling from the gardens in charge of the individual in whose honour the flower is named. The date appended to the name of this variety is to distinguish it from an older one bearing the same name, but probably now out of cultivation. The flower is a Japanese incurved, having broad florets of good length and naturally incurved. The colour in this instance is canary yellow. First-class certificate, National Chrysanthemum Society, November 6.

*Freda Bedford.*—This is a market or decorative variety, and as a representative of this section is distinctly pretty. The florets are of medium width and drooping. In a good light the colour is a warm tone of deep apricot, and under artificial light it is distinctly pleasing. First-class certificate, National Chrysanthemum Society, November 6.

*Felton's Favourite.*—This is one of the prettiest Japanese sorts of the present season, but cannot be regarded as an exhibition flower. As a matter of fact it is of medium size, having somewhat stiff, crisp, reflexed florets. The colour may be described as glistening creamy white. A magnificent vase of these flowers was exhibited at the November show of the National Chrysanthemum Society, on which occasion the variety received a first-class certificate.

*Marquis of Northampton.*—This variety will be better appreciated when it is stated to be a beautiful bright bronzy yellow sport from the popular Japanese sort W. A. Etherington. As an exhibition variety it should be much in demand; the blooms staged on the occasion when the National Chrysanthemum Society gave it a first-class certificate were large and of good form. To see good blooms, a mid-August bud selection should be made. D. B. CRANE.

(To be continued.)

## HOW TO GROW THE WINTER CHERRY (SOLANUM) IN POTS.

DURING autumn and the New Year berry-bearing plants are much appreciated by amateurs for the embellishment of their conservatories, windows in the dwelling-house, and on tables in the rooms. *Solanum Hendersoni*, *S. capsicastrum* and *S. Williams's Hybrid* are the best varieties for the purpose. The plants are easily raised from seed and also from cuttings taken in spring. Some put out the plants in the open border during the summer months, and then lift and repot them early in September; but I advise the amateur to grow the plants in pots throughout the year, as there would not be the risk of giving a check to the development of the berries and of losing some of the leaves, as often happens when the plants are put out in borders and afterwards repotted.

### PLANTS FROM SEEDS.

The seeds should be sown in a shallow pan or in a flower-pot; but, as good seeds germinate freely, it is a mistake to sow them thickly, as the seedlings would be weakly. It is far more satisfactory to have a few very strong plants,

have reached the stage of growth for being put into pots singly, they may be grown in a cool frame, and they should be kept in this structure until the final potting has been done, for which purpose 6-inch and 7-inch pots will be large enough. The loam used at the final potting should be fibrous and lumpy. Directly the plants are established in their flowering pots, put them on a bed of ashes in an open, sunny position, and keep the foliage clean by frequent syringings. Straggling shoots should be pinched, and then each plant will form a nice bush. Do not feed until the large pots are getting filled with roots; then give weak doses of clear soot water once a week and similar ones of manure water twice a week. After the berries have formed, use an artificial manure according to the directions given with it. Put the plants in a warm greenhouse early in September, but admit plenty of air on all fine days; frost and fog must be kept out.

### PLANTS FROM CUTTINGS.

The best cuttings are obtained by severely pruning an old plant and then selecting the strongest of the resultant young shoots. The

FRUITS OF PURPLE GAGE PLUM.

busby and shapely, than many small, weakly ones. The soil should consist of rich loam, two parts; leaf-mould, two parts; and sufficient very coarse sand to make it porous. The drainage of the pan or pot should also be ample. Drop the seeds about 1 inch apart all over the surface of the soil, and then bury them a quarter of an inch deep. Place the seed-vessel in a greenhouse or a warm pit where a temperature of 58° or thereabout can be maintained during the day from the heating apparatus. The temperature may be a few degrees lower at night. If water is needed, immerse the pan to its rim in a vessel containing tepid water, and hold it so until the surface of the soil becomes moist.

When the seedlings are about 1 inch high they must be carefully transplanted in a similar soil in boxes 4 inches apart. Keep them near the glass; then a sturdy growth will result. The next shift must be to small pots, one plant in each. To the soil above recommended add a peck of well-rotted manure and a 6-inch potful of soot to two bushels; also put some Oak or Beech leaves on the corks and a teaspoonful of soot on the leaves. By the time the young plants

latter should be inserted in a light, sandy soil in small pots, and then kept under a bell-glass or in a propagating frame until they are rooted. Afterwards pot them and treat them as advised in the case of seedlings, but the point of each plant must be cut off when they are about 4 inches high, in order to induce a branching habit of growth. AVON.

### FIBROUS-ROOTED BEGONIAS.

CUTTINGS where increased stock and shapely plants are required must not be overlooked, as these strike readily; the present time should be seized upon to augment the existing batch. Begonias of the ornamental-leaved type, of which *B. Arthur Mallet* may be instanced, should be similarly treated; these if struck now and pushed on soon become useful sized plants, which are most serviceable on account of the rich velvety tone of colouring in the foliage. *B. M. Hardy* comes next to *B. Arthur Mallet* in point of merit, and even stands the season better. Other varieties of good habit and character are *B. Naomi Mallet*, *B. Lucy Closon*, *B. Marie Louise* and *B. Decora*.

## THE FRUIT GARDEN. THE ROSE GARDEN.

## SOME GOOD PLUMS FOR AMATEURS' GARDENS.

**A**T this, the planting season, the amateur is anxious to secure the best Plums, and I will note a few really good croppers, suitable methods of culture and their fruiting qualities. The Gages will always be general favourites, but some of the best as regards flavour are shy croppers. This is unfortunate, as it is not advisable to grow such varieties in quantity. The variety illustrated (Purple Gage, or, as it is sometimes called abroad, the Reine Claude Violette) is a splendid Plum of medium size, roundish, slightly flattened at the end, the skin purple, with yellow dots and covered with a blue bloom. The flesh is a greenish yellow, firm and sweet and the flavour is delicious. The tree is very hardy and a great bearer in any form, but well worth a wall in the northern counties.

For early supplies the useful River's Early Prolific is valuable. This makes a compact tree and is by no means a bad dessert sort when fully ripe at the end of July. Victoria, another of the cooking class, is also most useful for early September; it rarely fails to crop and is a great bearer. River's Monarch is also excellent and a heavy cropper. It is a large black Plum, and does well as a standard, but it must not be hard pruned. For later supplies the late Orange is a splendid fruit, and though a dessert variety is so free that I give it a leading position for late use.

I have referred to the Gages, and here mention must be made of Early Transparent, a splendid early variety, with yellow fruits, and excellent for wall culture. Jefferson or American Gage is a grand dessert Plum, doing well as a bush, pyramid or standard. It has a rich flavour. Late Transparent Gage is another very good variety that does well in any form; it is well worth a wall in the north. The fruit keeps well when gathered. The Gages are specially noted for their very sweet and delicious flavour.

G. W.

## GRAPE APPELLE TOWERS

AMONG the many introductions of new Grapes of recent years this variety stands out prominently as one of the best, and bids fair to replace some of the older varieties which we have had to rely on for late use. Many gardeners (especially amateurs) whose resources are limited need be very careful in the selection of varieties when planting young Vines. It is usually three or four years before he can prove for himself whether a new introduction is going to be a success or not, hence it is not wise to place too much reliance on the recommendation usually sent out by the introducers. After several years experience of the above variety I can confidently say it is one of the best late Grapes we have. It is a black Grape of medium size, round oval berry, the bunch is handsome in appearance, its quality and constitution all that could be desired of late Grapes, and its long keeping quality is one of its most prominent features.

Frogmore.

E. H.

## ROSE DUNDEE RAMBLER.

**D**UNDEE RAMBLER ROSE, shown in full flower in the illustration, is one of the old Ayrshire Roses which are happily not quite overshadowed by more recent sorts. Among the many ways of worthily using the free Ayrshire Roses, one of the best is to leave them to their own natural growth, without any staking or guiding whatever. Due space must be allowed for their full size, which will be a diameter of some 10 feet. Of these useful garden Roses none is more beautiful than The Garland, with its masses of pretty blush

ROSE DUNDEE RAMBLER ON A GARDEN ARCH.

white bloom. It is well worth getting up at 4 a.m. on a mid-June morning to see the tender loveliness of the newly-opening buds; for beautiful though they are at noon, they are better still when just awakening after the refreshing influence of the short summer night. Several others among the old Ayrshires are excellent in this way of growth, though perhaps there are none to beat The Garland and Dundee Rambler, the latter with flowers of a pleasing warm white. A grassy space where they may be seen all round, or a place where the great bush may be free at least on two sides, are most suitable, or they may be used as central or symmetrically recurving points in a Rose garden of some size. The young growths that show above the mass when the bloom is waning are the flowering branches of next year; they will arch

over and bear the clusters of flowers on short stems thrown out at each joint. The way these young main branches spring up and bend over when mature is exactly the way that best displays the bloom. Each little flower of the cluster is shown in just the most beautiful way; and it is charming to see, when light winds are about, how the ends of the sprays, slightly stirred by active air, make pretty curtsying movements arising from the weight of the crowded bloom and the elasticity of the supporting stem.

## TWO NEW ROSES.

EMPRESS ALEXANDRA OF RUSSIA.

MESSRS. WILLIAM PAUL AND SON, Waltham Cross, Herts, are the raisers of this unique Tea Rose. It was introduced in 1897, and does not seem to be as widely known and appreciated as it ought to be. Let me recommend all amateur rosarians to at least get one. The raisers describe it "as having buds of bronzy salmon and open flowers a rich lake-red, shaded orange and fiery crimson." Now this description, although perhaps as near the mark as possible, utterly fails to give one any idea of its colour. One must not use too many adjectives, but besides being original in respect to its colour, it really is a lovely shade, and most striking in the garden. I saw three very fine specimens of it at the Gloucester show last summer. Everybody was attracted by them; in fact, they were so distinct and beautiful that no one could have passed them by. I have only had one tree in my collection, and have been fairly successful with it, though I am told that in some localities it is a Rose that does not open any too well. Anyhow, last summer it did so well with me, and seeing the very perfect blooms of it at Gloucester, I ordered more for 1907-8. It is a good grower, has nice foliage and bears freely flowers of good size, full and globular, with somewhat thin petals. I may have been lucky in its culture, but it had quite ordinary treatment, and if only its sisters do as well this coming summer I shall recommend it strongly. At all events, it is most effective in the garden, and should be tried by all who have not got it.

ELIZABETH BARNES.

Some of us may think 7s. 6d. rather too much to pay for a new dwarf Rose, but my wife tells me, when discussing a new hat, "If you must be in the fashion, you've got to pay for it." Well, if any reader can screw up courage sufficient to order this new Hybrid Tea for 1908 and pay his or her 7s. 6d., they will get a lot for their money. On its arrival do not on any account unpack it till frost is out of the ground or either when the ground is wet and sodden. The best month for planting Roses is November. Now I would order for delivery early in March. The raisers are Messrs. Alex. Dickson and Son, Newtownards, County Down, Ireland. It is a Rose of the most entrancing beauty and formation, and will attract attention not only from the connoisseur, but from everyone who sees it. I saw it in the raisers' grounds at Ledbury last summer, and predict a great future for it; indeed, in a very few years it will become a most popular Rose. The raisers describe it as in

colour satiny salmon rose, with a fawn centre, suffused with yellow, the outside of the petals deep rosy red, shaded with copper and yellow. The flowers were large and extraordinarily full—a beautiful type, somewhat pointed in the centre and deliciously scented. Q.

#### DO WE MANURE OUR ROSES TOO MUCH?

WE shall soon have our thoughts directed to the matter of manuring our Roses, and it occurred to me that this subject might profitably be ventilated through the columns of THE GARDEN. We are constantly being told that the Rose is a gross feeder, and the beginner, thinking he is doing the right thing, gives his newly-planted Roses liberal doses of both animal and artificial manure, on the principle that if a little is good a quantity will be better. This pernicious practice is responsible for an enormous mortality among Rose plants, especially where chemical manures are employed. I firmly believe some of our more advanced Rose growers are finding out to their cost that there is such a thing as over-dosing with chemicals, and it would be interesting to have their experiences of successes and failures. One great disadvantage of over-feeding is the stimulus given to the production of gross unripe wood, which a severe winter would most assuredly destroy, although the grower can somewhat regulate this matter by judicious thinning out of the old wood in August and pinching out the points of the gross wood. We can do much to counteract the evil effects of over-manuring by periodically transplanting our Roses, say, once in three or four years, but when this is done a new site should be found for the plants, so that the soil in the old situation may be sweetened by exposure to the air.

My opinion is that we cannot do better than adhere to well-decayed farmyard manure, with the addition of, say, sewage, soot and steamed bone-meal. P.

#### NOTES ON THE WILD ROSES (SPECIES).

(Continued from page 43.)

*ROSA SANCTA*.—From Abyssinia. This is said to be identical with the Rose of the early Egyptians, and used by them in the wreaths that have been found with mummies. Its large, bright pink flowers are not very distinct, that is if my plant is true to name, and I have not so far been able to verify it.

*R. acubata*.—A fine vigorous bush with distinct foliage and strong spines, the flowers rather larger than usual and of a pretty shade of pink.

*R. sericea*.—One of the most distinct of species. The flowers have only four petals instead of five, and they are pure white, contrasting well with the small dark green foliage, at the base or axils of the leaves of which they are produced; the whole appearance of the plant is distinct. Some notice has perhaps been attracted to the type by the introduction during 1906 of a very striking variety sent out by Messrs. Paul and Son of Cheshunt under the name of *Sericea pteracantha*, its prominent feature, from which I take it its name is derived, is its enormously large flat spines or thorns extending often over the whole space on the stem between the leaves, sometimes 2 inches

in length. In their young stage and on the growth of the year these are bright red, and if grown so that the sun shines through them they are translucent and very beautiful. The flowers are I think slightly smaller than those of the type, but have the same characteristic four petals only and are likewise white. As it is only on the young wood that the extraordinary colour is seen this should be encouraged as much as possible, but so far the growth of my plant is not vigorous.

*R. sinica* (sometimes known as *camelliaefolia*).—A beautiful evergreen Rose, that is tender, with

THE MOON DAISY (*PYRETHRUM ULIGINOSUM*) IN THE GARDEN OF MR. A. GILL, EVERSLEY, POOLE.

large white flowers. Interesting as one of the parents of *Sinica anemone*, that most beautiful of all single Roses.

*R. setigera* (the Prairie Rose of North America). Interesting by reason of its late-flowering period; semi-climbing and fairly free.

*R. spinosissima* (the well-known Burnet Rose). A native plant and parent of all those beautiful Scotch Roses; the most interesting I have already referred to (*R. s. maxima*) under the head of *Altaica*.

*R. simplicifolia* or *berberifolia*.—I have only the variety known as *Hardy*, the peculiarity of which lies in its foliage, which is very minute, and its curious *Cistus*-like flowers. It is the only Rose that I can recall that has a spot or blotch on the petal. Its colour is yellow and the spot dark brownish maroon; a very dwarf grower.

*R. watsoniana*.—Another curiosity with its foliage reduced almost to filaments and with small insignificant pink flowers.

Purley.

H. E. MOLYNEUX.

## THE FLOWER GARDEN.

### THE MOON DAISY.

(*PYRETHRUM ULIGINOSUM*.)

ONE of the finest groups we have seen of this beautiful flower is represented in the accompanying illustration. The Moon Daisy is a great favourite of the writer's—tall, leafy and crowned with white flowers in the late year, flowers of a soft white, which seem to gain in beauty on moonlit evenings, much the same as the White-stemmed Bramble does in winter. No plant is more easily grown, if some care is taken, than the Moon Daisy; its growth is remarkably vigorous, as the illustration suggests, and it increases rapidly, replanting of the strong tufts being needful, in our experience, once in every three or four years. One thing it does appreciate and that is a moist soil. We planted a lot of it a few years ago in a damp ditch and there sprang up a little forest of stems and in autumn an abundance of flowers, which bent prettily in the wind. It is very pleasant to see the wavy flower-burdened stems on a sunny September day, when the Asters or Michaelmas Daisies are making blue clouds everywhere. The Moon Daisy may be planted whenever the weather is favourable, but only in well dug and manured soil, and watered freely during the summer if prolonged dryness is experienced. On a dry, hungry border the stems do not rise more than 18 inches. Its true beauty is only revealed when we see it as represented.

### ALPINE OR ROCK PLANTS FOR DRY PLACES.

It very frequently happens in many gardens that there is a border or corner fully exposed to the rays of the sun nearly all day, with the result that the soil becomes so parched and dry that the owner is at his or her wit's end to know what to plant in it with any hope of success. Happily, Nature has provided many plants that will thrive in such a position, and it is now intended to point out some that are especially adapted

for planting on rockeries that are notorious for their parched character during the summer months.

Perhaps the most showy subject of all is the charming dwarf-growing annual *Portulaca grandiflora*. This delights in a sunny aspect, and, providing reasonably good soil is afforded, it will grow and flower with but little attention. Seeds are sown the third week in April where the plants are to flower.

The Stonecrop or Sedum family is one from which we can select plants for our purpose with comparative freedom. The common little British plant, *Sedum acre*, is charming when draping a large boulder with its bright yellow flowers and green leaves, while for variation the golden-leaved form may be planted. *S. spectabile* is a tall-growing species that may well find a position at the back of the rockery; its pink flowers will be very welcome during September. *S. rupestre*, *S. spurium* and *S. Sieboldii* are others that are well suited for a hot, dry rockery.

The Houseleeks or *Sempervivums* also provide an abundance of sun-loving, shallow-rooting plants, the pretty rosettes of pointed succulent leaves, often surmounted by curious-looking inflorescences, rendering them objects of much interest. *S. glaucum* and *S. tectorum* are two well-known yet handsome sorts that will thrive in the hottest position during the summer months, and the lesser-known *S. montanum* and *S. californicum* will also do well in some localities. Gold Dust (*Alyssum saxatile*) is another good subject for a hot position, and the evergreen Candytuft (*Iberis sempervirens*) may also be successfully employed if a good rooting medium is provided. In the South of England some of the Prickly Pears (*Opuntias*) are used, their curiously-lobed stems, studded with clusters of spines, producing a unique effect in the rock garden. *O. camanchica albispinia*, *O. Engelmanni* and *O. Ficus-indica* are sorts that might well be tried.

The great thing during the winter is to keep them dry, and to this end they must be provided with very porous soil, one in which a quantity of crushed bricks has been incorporated being preferable. There are many other plants that could undoubtedly be used for a hot and dry rockery did the circumstances demand them, and owners of such positions would do well to experiment with any plants that are of a succulent or woolly character.

### THE MOUNTAIN CLEMATIS (*C. MONTANA*) IN NEW ZEALAND.

DR. ALEXANDER DOUGLAS writes from Reed Street, Oamaru, New Zealand: "The accompanying illustration may be of interest to your readers. The *Clematis montana* shown on the arch and pergola displays its wealth of white bloom for an extent of 60 feet in length, growing through the yellow Banksian Rose on one side and Paul's Carmine Pillar on the other. These flowering, as they all do here, at one time, make a great show of colour. In front is a native Flax and behind a native Cabbage Tree." [A similar effect might be obtained here, the *Clematis* and Paul's Carmine Pillar Rose both making a free growth; the Banksian Rose is certainly tender, but in southern counties flowers abundantly out of doors.—ED.]

## COLOURED PLATE.

PLATE 1342.

### THE ANNUAL SCABIOUS.

ONE of the most beautiful of annual flowers is the Scabious, which was so finely shown last year by Messrs. Dobbie and Co. of Rothesay, Scotland.

The flowers represented in the accompanying plate were taken from this strain, which was remarkable for its varied and exquisite colours. Nothing much can be said regarding the culture of the Scabious, as it is very simple. To obtain the best results the seed should be sown in a greenhouse during February, the seedlings transplanted into boxes or frames when large enough to handle, hardened off, and duly planted out in well-prepared enriched beds about the beginning of May. This is how the fine flowers which Messrs. Dobbie exhibited before the Royal Horticultural Society last autumn were obtained, and which caused so much comment at the time. The strain received an award of merit. Seed may also be sown out of doors in March and April, and the plants will bloom in the autumn. This old-fashioned yet beautiful annual is grown much more extensively in the North of England and Scotland than it is in the South, great interest being taken in it by cottagers and gardeners there.

## TREES AND SHRUBS.

### TWO BEAUTIFUL AND EASILY-GROWN FLOWERING SHRUBS.

IT is surprising how seldom one meets with the double-flowered Chinese Plum (*Prunus triloba flore-pleno*) outside large establishments, yet its many merits and few requirements render it a plant eminently suitable for the amateur and small grower.

It is one of the most handsome and showy hardy flowering shrubs that we have, and, providing a few simple rules are observed in its cultivation, it is a remarkably easy shrub to grow. Although quite hardy it is advisable to plant it against a south wall, owing to its flowering in April, else late frosts are very apt to seriously damage the handsome bright pink flowers. It needs a rich, well-drained soil of medium texture, and on no account must it be allowed to suffer for want of water during the summer months. It flowers entirely on wood of the previous year's growth, hence pruning will consist of cutting close back to the old wood all these growths as soon as they have flowered, which will be the end of April or early in May. If a good mulch of well-decayed manure can be given immediately afterwards, so much the better, as this will induce strong young shoots to be formed for flowering the following spring. The splendid specimen on the Duchess wall at Kew is a subject well worth looking for during the early spring months. Besides forming such an excellent shrub for south walls or beds in the open, it is splendid for forcing under glass.

to until the plants have reached the height required to fill the position in which they are planted. Almost any good garden soil suits this shrub, but, where the cutting back system is adopted, heavy feeding by means of mulching with well-decayed manure as soon as the pruning is done will be required, the idea being to encourage the formation of strong young shoots. This shrub is also suitable for gentle forcing under glass. *Forsythia viridissima* is also a good species, much like *F. suspensa*, but of more erect habit.

### OLEARIA HAASTI.

THIS pretty dwarf shrub is well adapted for growing in towns, as smoke and other fumes do not affect it, and it is especially suitable for small gardens, being dwarf in habit and possessing very free-flowering qualities. It is grown somewhat extensively in the cemetery at Blaina on an exposed situation, but it is quite at home, and the smoke and sulphury fumes from the furnaces do not seem to affect it at all. For the last three years at least the plants have flowered very profusely, being really a sheet of white blossom. I may add that this beautiful shrub is much more hardy than a great many suppose. I have seen old-established plants doing well and flowering very profusely every year at East Lothian.

J. KENNEDY.

### STAPHYLEA COLCHICA.

THIS is a very beautiful shrub, suitable alike for early forcing in the greenhouse or for outdoor planting, as it is quite hardy. But it is to call

ARCH COVERED WITH THE MOUNTAIN CLEMATIS (*C. MONTANA*) IN A NEW ZEALAND GARDEN.

*Forsythia suspensa* is another shrub whose merits demand that it should be more extensively grown. It is true that one meets with it more frequently than the *Prunus*, but it is always welcome and there is no danger of it being planted too extensively. Like the *Prunus* it is very easy to grow, and it has the additional advantage of the flowers not being injured by frost. Two systems of growing it are adopted, one being to allow the plants to grow naturally and produce long, pendent branches that are covered with bright yellow bell-shaped flowers in April; and the other is to prune the young shoots back hard to the old wood as soon as they have flowered, precisely the same as advised for the *Prunus*. This cutting back will not, of course, be resorted

to until the plants have reached the height required to fill the position in which they are planted. Just at this season many amateur and professional gardeners are procuring such plants as Azaleas, Lilacs and Rhododendrons for the beautifying in the near future of their greenhouses. May I suggest a trial to those who have not done so of a few plants of the above? Compared with the afore-mentioned plants, the sight of the *Staphylea* is rare indeed. Yet I venture to say it is equal to either of them for beauty and fragrance combined. Its flowers are pure white, are produced in large terminal trusses and are bell-like in shape. Its lasting quality is also good. Any good garden soil will suit it, but a partially-shaded position will be better than where the hot sun would play upon it. C. T.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**W**INDOW PLANTS.—The weak and elongated growths of straggly Geraniums should be cut back to within 2 inches or 3 inches of their base. This will promote fresh, vigorous growths, and ultimately make shapely plants. Shoots at the base of the plants should be detached and made into cuttings. Keep the leaves of foliage plants clean by frequent sponging. Water somewhat sparingly for a time—really until the days lengthen appreciably—such plants as Fuchsias, Geraniums, Cacti and Amaryllis. Fuchsias may with advantage be cut back at once with the object of providing cuttings and encouraging the development of sturdy shoots.

*Greenhouse and Conservatory.*—Violets in pots in the cold greenhouse should be kept near the glass and the structure freely ventilated. Cinerarias in the cool greenhouse and conservatory should now be progressing, but as they are very liable to attacks of green fly, they should be carefully overlooked. Plants affected should, just previous to coming into bloom, be dipped in some insecticide and washed free from it immediately afterwards. A solution of Sunlight soap is a simple and effective remedy. Arum Lilies are benefited by frequent applications of manure water. Eradicate green fly directly it is seen or trouble will ensue; a sponging of the leaves will save much trouble in this respect.

*Hardy Flower Garden.*—For early displays sow Sweet Peas in borders with a warm aspect where the soil is well drained. Sow thinly about 2 inches to 2½ inches deep. Plant Lilies and other bulbs; this work should not be delayed. Plant in soil that is nicely broken up and friable, afterwards mulching the bulbs with leaf-mould. In warm situations old plants of Pansies will be making splendid clumps. If an early display is desired, they should be left undisturbed; but if stock has to be increased, lift the old plants and divide them into pieces, each with a few shoots and roots adhering.

*The Fruit Garden.*—Trouble from birds may be anticipated at this period. For this reason dust the branches of Gooseberry trees with slaked lime as a protection for the fruit-buds, doing this on a showery day. Another simple remedy against their depredations is to stretch freely over the branches black cotton or thread.

2 THE SAME PLANT AFTER THE GROWTHS HAVE BEEN DETACHED.

1.—AN OLD STOCK PLANT READY FOR CUTTING BACK.

Morello Cherry trees on walls will now need attention. Securing them to the walls or fences needs to be very carefully done. Use good shreds fully 2 inches in length and half an inch or more in breadth. Place the shred in loop-like form round the shoot it is desired to control and fix it in such a way that the whole of the weight rests on the shred itself.

*Cold Frames.*—For the next month or two the cold frames should be used continuously for raising and increasing the supply of many plants. Constantly overlook the occupants and remove decaying foliage. Auriculas should be coming on. Keep the soil free from weeds and decaying foliage, and give them a light top-dressing of some rich soil. Green moss on the surface should be carefully scraped off. Sow Sweet Peas in pots for planting outdoors in April next. Five or six seeds in a pot 5 inches in diameter, or one seed in a deep 3-inch pot, will answer well.

*The Vegetable Garden.*—We are just making a new bed of Mint. The ground has been trenched and a heavy dressing of well-rotted manure incorporated. We plant the creeping-like roots in rows about 9 inches apart and about 2 inches deep. For the earliest crops of Peas, Beans, Carrots, Spinach, Lettuces and Radishes we always select a sheltered border with a warm aspect, and make sowings at this early period when the weather is free from frost. It is well to make small sowings thus early, to be supplemented by others of a larger kind later on. The first sowing of Parsley is now being made. This is sown 1 inch deep in drills about 1 foot apart.

### PROPAGATING ZONAL PELARGONIUMS OR GERANIUMS.

THESE may be increased now in very simple fashion, provided care be observed in the preparation of the cuttings and their treatment during propagation. Soil, too, is of some importance, and no pains should be spared to procure ingredients of a suitable character. The advantage of beginning propagation early in the year is that plants of a desirable variety are available the sooner.

#### HOW TO DEAL WITH THE OLD PLANTS.

At this period our stock of Geraniums is, perhaps, represented by a few old plants such as Fig. 1. The increasing length of the days has promoted growth of a suitable character, and

with such material it is possible to procure cuttings that should root readily enough. Some of these old plants will develop shoots in sufficient quantity to provide six good cuttings. Each growth should be detached with a sharp knife, leaving about two joints of the shoot removed on the old stems. Old plants treated in this way will soon emit new shoots, which will provide a free display of blooms later on in the year. Fig. 2 represents the same old stock plant after it has been cut back for the purpose of providing cuttings.

#### HOW TO MAKE THE CUTTINGS.

Fig. 3 represents a shoot detached from the old stock plant. It will be seen that the long-stalked leaves continue nearly down to the base of the cutting. To insert the cutting just as it is would be to court failure, and for this reason remove the lower leaves by simply bending back the leaf-stalk. At the same time trim off all the bracts or scales found at the bases of the leaf-stalks. Should any of the cuttings have a truss of flowers in embryonic form, they, too, must be pinched out. Fig. 4 is a good type of cutting, and aptly illustrates the points to which attention has been drawn in the above notes. In this case it will be seen the lower leaves and all bracts have been removed, and as a finish the

3.—A SHOOT SUITABLE FOR A CUTTING.

stem of the cutting has been cut through just below a joint. The prepared cutting in Fig. 4 is the actual shoot represented by Fig. 3.

#### HOW TO INSERT THE CUTTINGS.

These may be inserted singly in deep 2½-inch pots, or a number may be placed around the inside edge of pots measuring 3 inches or 5 inches in diameter. Where large plants of high culture, bearing trusses of bloom of good quality, are desired, it is better to insert the cuttings singly in small pots, but for ordinary greenhouse or conservatory decoration the other method will answer very well. With a dibber about the size of a Cedar-wood pencil make a hole about 1½ inches deep, place a pinch of silver sand in the bottom of this and insert the cutting so that it rests firmly on the bottom of the hole. A couple of sharp raps on the potting bench, followed by lightly pressing the soil with the thumb round the edge of the pot, will finish the operation. A suitable soil for this purpose is made up of equal parts of loam, leaf-mould and good silver sand, all well mixed and passed through a sieve with a half-inch mesh. Fig. 5

shows the method of inserting a number of cuttings in one pot.

#### TREATMENT OF THE CUTTINGS.

After inserting them, place the pots close together in a light and warm corner of the greenhouse, and give the cuttings a watering overhead through a fine-rosed can to settle the soil round them. Flaggings must be avoided, if possible, and watering lightly overhead on bright days is a great boon. For three to four weeks the temperature must be maintained at from 55° to 60°, and all that is then required during this

4.—THE SAME SHOOT PREPARED FOR INSERTION.

period is to supply the cuttings with water only when they need it.

#### POTTING UP THE CUTTINGS WHEN ROOTED.

When roots have formed, remove the young plants to shelves near the glass to keep them sturdy. Should any grow unduly fast, pinch out the top of the shoot. Water sparingly for a few days after this pinching process. Other plants must be carefully looked after regarding watering, as on fine, bright days the soil quickly gets dry. When the young plants give evidence of making headway they must be repotted. The larger and more robust young plants need pots 4 inches across, and those less vigorous may go into pots measuring 3 inches or 3½ inches in diameter. The soil for this repotting ought to consist of two parts good fibrous loam, half a part leaf-mould, half a part well-rotted horse manure, and one part of coarse sand, with just a dusting of bone-meal if this is easily obtainable. Break up the loam with the hands, but riddle the leaf-mould and manure through a half-inch sieve. Mix well before using. After crocking the pots, which should be washed quite clean, fill in a small quantity of the compost; then place the young plant (rooted cutting) in position, filling in all round with the prepared compost and pot firmly. Subsequently place the plants together on a nice cool bottom on the side benches of the greenhouse. Shade for a day or two should the weather be bright, and in about three days water with a fine-rosed can.

#### FINAL POTTING.

This must be done when the plants have filled their smaller pots with roots. The soil should consist of two parts good fibrous loam, half a part each of leaf-mould and well-rotted manure, and a quarter part each of crushed charcoal and silver sand. A dusting of bone-meal is highly beneficial. Pots 6 inches in diameter should be used, and the soil made very firm.

#### HINTS ON WATERING POT PLANTS.

THERE is perhaps more art in watering pot plants than in any other phase of their culture, hence it is not surprising that amateurs, and even some professionals, often go astray in this seemingly simple operation. Although hard and fast rules cannot be laid down for the watering of pot

plants, the consideration of some of the most dangerous points may perhaps be of profit. At the outset I would impress upon the cultivator the absolute necessity for knowing his plants. By this merely knowing their names is not meant: what is required is a knowledge of their rooting system, their leaf system, the kind of soil in which they are growing and also the temperature of the atmosphere that surrounds them. We must, above everything else, always keep the fact prominently before us that plants growing in pots, even under the most favourable conditions, are existing under artificial treatment. Armed with an intimate knowledge of his plants and bearing in mind that they are existing under artificial conditions the cultivator is well on the road to success in watering them.

Before the plants are put into their pots the careful grower will see that ample drainage is provided by placing broken pots or cinders over the drainage hole. This will go a long way towards the mitigation of over-watering. In applying water always give sufficient to soak the ball of soil from top to bottom, nothing being worse than serving it in dribbles. If a plant requires water at all it needs enough to thoroughly soak the whole of the soil in the pot, and to this end enough space should be left when potting to enable sufficient to be given. Many amateurs make the mistake when potting of filling the pots right to their brims with soil.

If a plant has become so dry as to cause the leaves to flag the best course to adopt is to immerse the pot in a bucket or tank of water for an hour or two, because it will be almost impossible to soak the ball of roots and soil by watering it in the usual way, owing to the soil having shrunk away from the sides of the pot. The amateur, especially during the dull days of winter, is far more likely to over than to under water his plants, and the former is the most fatal of the two, because its ill effects only reveal themselves gradually. In the winter months, therefore, only give water when there is a likelihood of the plant suffering for the want of it.

Newly-potted plants often suffer much at the hands of a careless or ignorant wielder of the water-pot. After they have had one watering to settle the soil about them great care should be taken not to apply more before it is actually required. Remember that the plant has had a check, and that roots will permeate the new soil much more readily when the latter is moderately moist than they will when it is saturated. If the leaves hang down at all this does not necessarily mean that the soil is dry, but rather that the atmosphere is arid, and a light syringing overhead under these circumstances will put matters right. The same remarks apply even more forcibly to cuttings. Keep the soil moist, not sodden, if you desire them to root, preventing evaporation of moisture from the leaves and soil by plunging the pots in Cocoanut fibre refuse and placing a glass case or frame over them.

Many amateurs have an idea that when a plant begins to assume a sickly appearance it needs water, and accordingly supply it in large quantities, never thinking that they are making matters worse. In all probability the mischief was first caused by superfluous moisture in the soil, and the proper course to take will be to examine the drainage hole and see that it is clear, then withhold water until it is quite evident that the plant will suffer if it is kept longer without it. The life of a valuable plant that has become sickly may often be saved by keeping the soil in the pot on the dry side for a time.

#### WORK TO DO DURING FROSTY AND WET WEATHER.

WE may still with almost certainty look forward to several weeks of frosty or wet weather, when the usual gardening operations must necessarily be at a standstill, and the amateur is apt to regard this time as lost, at least so far as his or her garden is concerned. This need not,

however, be the case, as there is plenty of work that can be done when the soil is frozen hard or when heavy rains prevail, and it is the object of this article to remind amateurs of the various tasks that need attention now.

Where manure has to be wheeled on to kitchen garden, fruit tree or flower plots, advantage ought to be taken of a hard frost to get it done. No damage will be done to the soil or paths, and the work can be performed with ease and comfort. Leave it in heaps until the frost departs. Although a cold task, it is often necessary to complete the pruning and nailing of fruit trees during frosty weather, as one can get about the plots or borders then without treading the soil into a concrete-like mass.

Stakes that were used last summer will need overhauling, as the bases of many of them will be decayed and therefore need resharpening. Do this at once; then paint those that require it and stand them in a box or other receptacle to dry, after which they ought to be tied into bundles according to their length. Labels, too, will need renewing, and this work ought not to be left until the spring, else a rush of other work at that time will probably mean that they will get entirely overlooked. Where the seed-list has been made out—and this ought to have been done by now—new labels may be written for the various seeds that are to be sown later on. If this is done, much anxiety and worry will be saved at sowing-time. The best way to deal with the ordinary wooden labels is to give them a very thin coat of white paint, rubbing it into the wood well with a piece of soft rag, and then write the name and any other particulars before the paint dries. Not only is it easier to write when the paint is moist, but the writing is rendered much more lasting, and it may be done with an ordinary lead pencil, preferably an HB. Labels written thus in April last year are still in the writer's garden, and the names are perfectly legible.

Where the amateur owns a glass house, or even a frame, advantage should be taken of a spell of wet weather to wash all the glass, wood or iron work, the shingle on the stages, and repair any portions of the latter that may require it. Where

5.—CUTTINGS INSERTED IN A 5-INCH POT.

the house is a lean-to against a wall the latter ought to be lime-washed, and all pots, whether empty or containing plants, should be made clean, and the empty ones stored in their respective sizes so as to be readily available when required.

Seed-boxes usually need overhauling at this season, many of them requiring new bottoms, and the same remarks apply to window-boxes. It is a good plan to remove the virgin cork from the fronts of the latter where it is employed, and give the boards under it a good scrubbing with strong soft soap water, and if time can be spared to give the cork a washing with the same solution so much the better. By this means the eggs and larvae of many insects will be destroyed.

Nets that are used for protecting fruit during the summer months often get torn, and these ought to be attended to without delay, as nothing is more irritating than to find holes in them when they are perhaps hurriedly required for use during the busy summer season. Stakes for Peas and Beans may also be trimmed ready for use, and where a difficulty is experienced in obtaining these many of those used last year will be sound enough to use again in conjunction with a percentage of new ones, taking care to ensure the latter being evenly distributed among the old ones.

If these operations, and any others of a similar nature that may crop up, are attended to at once much time and worry will be saved during the busy spring and summer months. Work well forward is a splendid motto in every calling, but in none does it apply more forcibly than in gardening.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**A**FFORD Primulas, Cyclamen and Cinerarias manure water to prolong the flowering period. These plants should now be making a fine show. Among Primulas, The Duchess and its forms are excellent. Cinerarias should have feeding stimulants every week; keep them free from aphids. They are all the better when grown on a moist bottom such as ashes or shingle. Calceolarias may now have their final potting, using good loam and leaf-soil, with a little cow manure and a small quantity of bone-meal. Prune back Fuchsias and start them in gentle heat. Sow seeds of *Asparagus plumosus*, *A. Sprengeri* and *A. decumbens*. Old plants that have done duty may be potted or top-dressed.

*Balsams* sown now make very pretty, useful and attractive plants for furnishing jardinières, &c. As soon as possible prick them out, three or four plants into a 3-inch pot, and keep near the glass. They may be flowered in these pots with skilful treatment.

*Amaryllis* seed ought to be sown now; I prefer sowing in a pan and pricking the seedlings out. See that all the stages are thoroughly cleaned and new shingle or old material thoroughly washed. At this season all houses containing plants should be put in thorough good condition.

#### FRUIT HOUSES.

*Peaches* and *Nectarines* still in bloom should be carefully dealt with. Tap the trees in the middle of the day when the pollen is ripe and dry, and gently spray with tepid soft water at closing time. Keep a chink of air on all night.

*Vines*.—Attention should be regularly paid to disbudding and regulating the growth, and, if by any chance there is any mealy bug present, a keen watch must be made in the afternoon and each pest dosed with methylated spirit. At this stage much can be done towards extermination, as they crawl out of the crevices on a fine, sunny afternoon. The first Muscat house may now be closed, as this popular Grape requires a long season to thoroughly mature.

*Cherries* and *Figs* may now be started, 45° to 50° being a suitable night temperature.

#### KITCHEN GARDEN.

Continue with the work as advised in the last calendar. Keep up the supply of forced vegetables by introducing every week, or as often as is required, a fresh supply. Make Mushroom beds and hotbeds for *Asparagus*. Make *Seakale* sets, tie up in bundles of fifty, and cover over with ashes and store in a cool house or frame. Take up Broccoli that are ready, to

preserve from frost. Examine all seed Potatoes, and, where practicable, stand them on ends, removing during the process all the weakest growths.

#### HARDY FRUIT.

Continue to clean, prune and train trees, and on wet days examine all protecting material, so that this will be ready when wanted.

#### FRUIT ROOM.

Look over the fruits regularly and eject all decaying specimens. Keep the house cool, dry and sweet. Look over Grapes in bottles regularly.

W. A. Cook.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

*Ficus elastica*.—The present is a good time for propagating this useful plant. If the tops are taken off before they begin to start into new growth they will root with little trouble. Tops about 4 inches long are best, they need not be cut off close below the joint, as they will root from any part of the stem. Some dry sand should be applied as soon as they are cut off, as this will check the loss of sap. The cuttings are best put singly into small pots and kept in the stove propagating pit until they are well rooted, and after removal they will soon be ready for potting into 5-inch pots.

#### ORCHIDS.

*Phaius grandifolius*.—The flower spikes of this fine and useful old Orchid are rapidly advancing, and I would warn cultivators against letting aphides get the upper hand before the blossoms open. These insects soon ruin the appearance of the flowers, but if the spikes are examined every few days and a damp sponge passed over them, it will keep them clean.

#### HARDY FRUITS.

*Ground Work*.—Where the site for new Strawberry beds or Raspberry or bush fruit plantations has not yet been prepared, no time should be lost in digging it. In most cases bastard trenching and heavy manuring will be the best way of treating them. Such plots may have a light crop taken off them before the bushes or Strawberries are planted, and no crop is better for this purpose than early Potatoes.

#### KITCHEN GARDEN.

*Rhubarb and Seakale*.—The crowns of this should now be covered where forced out of doors. Where earthenware pots are not at hand, old tubs, with the bottoms removed and converted into lids, will be found very useful. Place around and all over each a good thickness of material as recommended for hot-beds. All light must be excluded, and a moderate temperature must be maintained by renewing the heating material; particularly is this necessary in the case of *Seakale*, the quality of which is much impaired by an irregular temperature.

*Herbs*.—Mint and Tarragon may be brought on by lifting the roots and planting them in boxes. Cover the roots with good soil and place in a warm pit where growth will soon commence. Basil, where required, should be sown in pots, placing them in a warm vinery or heated pit. Make successional sowings every fortnight.

#### FRUIT UNDER GLASS.

*Cool Orchard House*.—Where the occupants of this are in pots and are still plunged in the open ground, they should be examined, and if the buds on any are found to be getting forward—which will probably be the case in sheltered districts—the trees should be removed under cover for safety. Many of the Apricots, Cherries and some of the early-flowering Peaches will need the protection of the orchard house long before the flowers are likely to expand, as severe frost would seriously injure them were they exposed

to its influence. Some are of opinion that frost does not harm the bloom-buds, but from careful observation I have noticed that if severely frozen, even before there are any signs of colour in the petals, there will be no fruit.

#### WINDOW PLANTS.

*Campanula isophylla alba*.—This is a great favourite as a pot plant, and in some districts it may be seen in almost every cottage window. When suspended, the drooping masses of pure white blossoms are very effective. The present is a good time for propagating this useful plant. Good cuttings may be obtained from those which were cut back after they had done flowering last autumn. About the same treatment as is required for Marguerites will suit them well. Later-struck cuttings should be grown three in a pot. A window with a northern aspect may be kept gay for at least two months; in fact, I have seen some plants in the same windows for a longer period. The blue or normal type is not so much grown, though equally pretty.

T. B. FIELD.

(Gardener to the Baroness Berners.)

*Ashwellthorpe, Norwich.*

## BEDDING PLANTS FROM SEED.

**F**EBRUARY is none too early to sow many of the flowering and foliage plants that will make the beds attractive from May until November. The gardener who has a moderately-warmed greenhouse can do wonders in the way of seed sowing, but it is when seedlings have been pricked off and require more space that he is often at a loss how to act. If he buys some inexpensive iron brackets, to hold strips of wood and thus make shelves, and nails these brackets to the wall of the greenhouse, or even to the window frames, he will find that the house will hold an extraordinary number of pots of seedlings without being overcrowded. During summer the wooden shelves can be lifted down, leaving only the brackets, which are not unsightly, or they can even be covered by creepers from below, or trailers from hanging baskets or wall-pockets above.

Verbenas should be sown at once in soil composed of two parts loam, one of leaf-mould and half a part of silver sand; this we may call the ordinary potting-shed compost that suits most plants. These lovely flowers only show at their best in gardens when they have been raised early and so attained good growth before being put out into beds.

Nicotianas are of immense service throughout the season, and either the ordinary white *N. affinis* may be chosen, or the charming rosy crimson *N. Sanderae* or one of the less known species that are equally simple to cultivate, and of which seed can be obtained without difficulty. *N. sylvestris* has fine foliage, and its long-tubed white flowers droop over most gracefully. *N. suaveolens* is of shrubby growth and only 2 feet tall, being deliciously perfumed at night. *N. acutifolia* is also remarkable for the long tubes of its flowers; its leaves are fine and it is often 3 feet high. Then *N. Tabacum virginica*, the common Tobacco plant, with red-purple blossom, attaining a height of 4 feet, is both interesting and effective.

*Phlox Drummondii* is one of the best of all carpet plants, and if sown in boxes may be pricked out an inch apart in other boxes, and can then be left for weeks undisturbed in the coolest part of the greenhouse. Some gardeners sow each seed an inch from the next in little drills an inch apart, so as to save having to transplant into other boxes, but waterings or the moving about of the box so often shifts seeds that the chances are seedlings will come up crowded after all. Any seedlings which show signs of growing

tall should have their shoots pinched out at once to encourage a dwarf, spreading habit.

Petunia seed should also be dealt with, either of double or single varieties; the dwarf varieties are only 6 inches in height and prove admirable for edgings or carpets among giant sorts. Seed should be sown on moist soils in pans and covered in with only a little silver sand; the pans must be thoroughly glass covered and the soil must never be allowed to become really dry. The seedlings are somewhat tender, so should be handled with extra delicacy when pricked out 1 inch apart in pans or boxes. At the end of March they can be given each a small 3-inch pot. Shaded from sunshine in an airy part of the greenhouse they should grow strong, but if the temperature ever exceeds 60° they had better be placed in a cold frame.

Lobelias and Pyrethrum aureum can be sown in boxes of ordinary compost; the former is a plant demanding patience, since the seedlings are very difficult to handle on account of their diminutive size. For making edgings it will be enough to prick out Lobelia seedlings in bunches of three or four 1 inch apart in boxes and allow them to form a group to be planted out later as though each were one plant. For beautiful bedding designs, however, this is not sufficiently careful, and each seedling should be pricked off separately at 1 inch intervals. The lovely double-flowering blue Lobelia makes an exquisite carpet plant.

Antirrhinums (tall, medium and dwarf), Pansies of the bedding order, Dianthus Heddergii, the Japanese Pink, Dianthus chinense, the Indian Pink, Fuchsias (double and single), single Dahlias and Marguerite Carnations can all be raised easily in the greenhouse, the temperature of which keep between 50° and 60°. E. J. D.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

FLOWER GARDEN.

Plants for north border in South Scotland (Mrs. O. C. C.).—Last season affords no criterion for flower-growing in your district, as all through the South of Scotland the soil was unusually wet, and never came into proper condition for many flowers. You appear to have gone about the preparation of the soil correctly, and with a better summer you should have more success this year. Colour schemes are frequently more difficult to work out well than they appear when in writing only, as different districts cause different conditions, which affect some plants more than others. In ordinary seasons Gaillardias and French Marigolds would do quite well in your north border, but you must not depend upon the perennial Gaillardias being hardy enough to stand your winters. Until you have a large stock of perennials worked up you should fill your borders largely with annuals, either hardy or half-hardy. Some good yellow and orange-flowered annuals, besides the French and African Marigolds, are Coreopsis or Calliopsis in variety; Chrysanthemum coronarium, of which you can

have yellow and white; Sweet Sultans; pot or Scotch Marigolds, such as Calendula Orange King; Chrysanthemum segetum Helios or Evening Star, Limnanthes Douglasii, Rudbeckia bicolor and the miniature annual Sunflowers would be useful. Good hardy perennials of similar colour are Heliopsis pitchenianus and others, although they did badly last year; Rudbeckia speciosa, Doronicum plantagineum excelsum and Inula glandulosa. Oriental Poppies bloom too early for satisfactory effects with late flowers. Try Monarda didyma, Geum coccineum and one or two of the early-flowering Tritomas. Anemone japonica alba and white Phloxes would be useful, with such hardy annuals as you can select which do not close when the sun is off them.

Soil for Watsonias (R. F. J.).—I should recommend a mixture of peat and loam, with a good proportion of grit for the Watsonias. With this I should mix a good proportion of old Mushroom-bed or hot-bed manure, as I am certain these bulbs want strong food in this country. I should plant at the end of October and keep the pots in a cold frame, when they would be likely to throw up in the early spring.—F.

How to treat Ornithogalum lacteum (Penworne).—In a garden where Ixias, Babianas and Watsonias thrive there should not be much trouble with Ornithogalum lacteum. A position and soil suitable to the Belladonna Lily would answer quite well, a deep sandy loam with cool bottom being preferred. In planting the bulbs should be kept a few inches below the surface of the soil. The plant, which is by the Kew authorities now referred to as O. narbonne, is less reliable in its flowering than some species; but in your favoured situation, when established, should give but little trouble. Endeavour to give the bulbs complete rest from the rainfall each year when the foliage has died down.

TREES AND SHRUBS.

Four creepers for a wall (Phloem). The following plants will prove satisfactory on your wall: Jasminum nudiflorum, a free-flowering shrub, which is at its best in midwinter. The main branches should be trained to the wall and the secondary branches may be spurred back after the flowers have fallen; it should be planted against the higher wall. Escallonia macrantha will form an excellent shrub as a companion to the former for the higher wall. It is quite evergreen, and bears reddish flowers freely during summer. The branches should be trained to cover the wall and the breast wood must be cut well in annually, April being a good time. For the lower wall Cotoneaster thymifolia will be found a suitable shrub. It is an evergreen with neat, tiny leaves and white flowers, followed by red fruits; very little pruning will be required to keep it in place. On the low wall, with the Cotoneaster, Euonymus radicans Silver Gem might be grown. This has silver variegated leaves of very ornamental appearance. It should be kept nailed against the wall until it has covered its allotted space, after which cut it well in annually.

Information about Clematis, Pyrus and Jasminum nudiflorum. (H. P., Leicester).—Clematis Jackmanii superba and Ville de Lyon belong to the Jackmanii section, and should be pruned at once or within the next month. Cut the branches back fairly hard; in fact, if the plants are covering their allotted space fairly well, you may cut them back to within a few eyes of the base of last year's wood. Mrs. G. Jackman belongs to the Patens group, and may be pruned now. The pruning, however, should be less vigorous than advised for the foregoing; the branches of last year may be shortened about halfway back. C. paniculata is a good species which blooms during autumn; it may be pruned moderately hard now. C. montana is a spring-flowering plant and should not be pruned until after the fall of the flowers. It may then be pruned fairly hard, if it is covering all the space that can be spared, if not the branches may be spread out and left at almost their full length. It is a distinct species. Cydonia or Pyrus japonica may be spurred back as soon as the flowers are over. If on a wall it ought to begin to flower in a few weeks' time.

It will stand hard cutting, and flowers best from spurred branches. Jasminum nudiflorum may have the branches pruned well back to within a few eyes of the base as soon as the flowers have fallen.

Shrubs and plants for woods in place of Laurels (H. P. B.).—The Foxgloves and bulbs will be excellent for filling up the bare spaces made by the removal of the Laurels. The common Bracken would also be useful if the soil is of a porous character and contains plenty of decayed organic matter such as leaves. If the trees are only thinly placed, Berberis Aquifolium, Rhododendron ponticum and even Berberis vulgaris in the most open spaces would thrive. Naturally, the choice of flowering shrubs for such a position is very limited, and before planting anything you must have the soil well dug. If you wish to destroy the Laurels, you must root them up, but do not do this simply because they are Laurels. We should think that a certain number of them would be useful in your case.

Information about Daphnes (G. F. B.).—There are two species of Daphne that will answer your description, and both are perfectly hardy. One, D. Laureola, is the common Spurge or Wood Laurel. It forms a bush 2 feet to 4 feet high, with thick, glossy leaves, and bears clusters of greenish yellow or creamish fragrant blossoms in the leaf axils from January to April. The other, D. pontica, is found in Eastern Europe, and forms a spreading bush 3 feet to 4 feet high. The flowers are very similar in colour to those of the previously-mentioned shrub, but the flowering season is not until April or May.

Treatment of a Copper Beech (E. B. E.).—We are afraid that you could not do your tree any permanent good by watering it with manure water; the mulching as previously recommended is the best method to adopt. It will doubtless injure your turf; in fact, to do your tree any real good the turf ought to be removed, the ground forked up and the mulch left on the ground for twelve months before resowing with grass seeds. If you wish to benefit your tree to any appreciable extent you will have to sacrifice the appearance for a time. Should the mulch be disturbed by wind, as you suggest, you could spread a light covering of soil over the material to keep it in position.

Climbers for partly shaded wall (H. P. B.). Prunus triloba fl.-pl., Escallonia macrantha, Cateagrus Pyracantha, Cydonia japonica, Clematis montana and Ceanothus thyrsiflorus are all suitable shrubs for your wall. The Escallonia, Cateagrus and Ceanothus are evergreens, the others deciduous. All are of an ornamental character. The border at the foot of the wall would look very well planted with old-fashioned herbaceous plants such as Pinks, Carnations, Wallflowers, Snapdragons, Polyanthus, Primroses, Sweet Williams, Lilies, Mignonette and Pansies, with here and there a group of Roses or some dwarf shrub, such as Lavender, Rosemary, Hypericums, or summer-flowering Spiraea. The spaces made by spring-flowering plants being over could be filled with Stocks, Asters, Tobacco or other annuals.

THE GREENHOUSE.

Cigar ash for greenhouse plants (H. S. W.).—We do not know the exact constituents of cigar ash, hence cannot say definitely what its value as a food for pot plants would be. It possibly contains a certain amount of potash, and in that case it would be of some use to plants grown for their flowers or fruits. However, we do not think that sufficient benefits would accrue from its use as to justify one going to the trouble of saving it. Your other question about boiler flue-dust is one that you make difficult to answer by omitting all particulars. If it is of a sooty nature, as we may reasonably suppose, it certainly will not take the place of sand for garden purposes. Soot contains nitrate, a valuable plant food, and is usually applied to soil for the purpose of supplying food. Sand contains a very little, if any, plant food, its function being to render the soil porous.

Sowing seeds of winter-flowering Carnations (J. D.).—The present is a very suitable time to sow seeds of perpetual-flowering Carnations, as by sowing thus early the plants have a long growing season before them. With regard to hints on their culture, you will find an exhaustive illustrated article in THE GARDEN of the 18th ult. Again, being always anxious to assist the would-be cultivator of these beautiful plants, we last year offered a series of prizes for the best essays on winter-flowering Carnations. The prize essay was published in the number of THE GARDEN for March 16, 1907, and the second prize one on April 6. Previous to that a most.

instructive article on sowing Carnation seed appeared in our number for February 16, 1907. A perusal of these various articles will give you much valuable information; indeed, that in the issue of the 15th ult. alone deals far more fully with the matter than it would be possible for us to condense into the space allowed for answers to correspondents.

**Information about Tomatoes** (*J. H. S. O.*).—You do not furnish any particulars whatever about your Tomatoes, hence we cannot say the cause of your failure last year. Do you grow them in a house with other pot plants? If so this is a mistake, as Tomatoes like plenty of air of a dry character when flowering and ripening their fruit. Insects can be kept down by frequently fumigating with any of the vaporising compounds now on the market. The last query in your note we cannot decipher.

**Information about Begonia Gloire de Lorraine** (*E. C. C.*).—There is no need to throw away the Begonia Gloire de Lorraine plants after flowering, as they can be kept to bloom another year. They should, when the blossoms are passed, be kept somewhat drier than before (but by no means parched up), then in March cut them back to within 6 inches of the pot, placing them in the warmest part of the structure. They will then soon push out fresh shoots, and when these are about half an inch long the plants must be repotted. Pots a size or two larger than those they are now in form a very suitable shift. A good soil may be formed of a mixture of loam, leaf-mould and sand. In the summer, as the pots get well furnished with roots, a little weak liquid manure occasionally will be helpful. Treated in this way the plants may be flowered year after year. By a cool greenhouse we presume you mean a structure with a certain amount of fire-heat, as if not heated in any way you cannot hope to succeed in the culture of this Begonia.

**About Malmaison Carnations** (*C. S.*).—So far as we can ascertain, nothing is accurately known of the origin of the Malmaison race of Carnations, by whom raised, or first introduced. It is, however, generally held that they originated at Malmaison, in France, the favourite residence of the Empress Josephine, the first wife of Emperor Napoleon I. If that is so, then the race which seems to have begun with what is known as the Old Blush must have been in existence over 100 years. The gardener at Malmaison at that time was the famous botanist Bonpland, and he might have been the originator. From what parents the race came no one seems able to surmise, but there may have been in existence then varieties that, intercrossed, would produce such a race, but have died out, while the progeny in the form of the old Malmaison survived. To-day it would seem, although we have now numerous Malmaison varieties in commerce, that all are the product, more or less, of Malmaison parentage. Like Carnations generally, Malmaisons are subject to fungoid diseases, although these, because the plants have to be grown in pots and in greenhouses, are chiefly the product of too much moisture and imperfect ventilation. Whenever in evidence, the best way is to gently spray the plants with the sulphate of copper and lime solution, made weak, or, while they are damp, dust with sulphur, or paint the affected parts with sulphur paste. During the winter the plants need to be kept near the glass and have ample light and air. If green fly gives trouble, fumigation will clear these off, and red spider may be kept in check by syringing freely. You may obtain further information by purchasing R. P. Brotherton's "Book of the Carnation," price 2s. 9d., from the publisher, 41, Wellington Street, Strand, W.C. Generally very little seems to have been written concerning Malmaison Carnations.

**Plants for a glass structure** (*Broadgates*).—In such a structure as you purpose erecting a great many different subjects may be successfully grown. It seems to us that the space on each side of the door covered with trellis work would be particularly suitable for a Camellia, say, a red variety on one side and a white on the other; at least, if you prefer it in that way. Some of the tender Tea Roses could be trained up the roof, or other climbing and rambling plants such as *Passiflora caerulea* (blue) and *P. Stance Elliott* (white), *Plumbago capensis* (blue) and *Tacsonia Van Volxemii* (scarlet). As the structure is to be used as a lounge, we should not suggest stages of any kind, but furnish it with, for the greater part, comparatively large plants, which can be grouped on the floor. This admits of your rearranging them at any time, according to requirements or individual fancy. A few flowering plants will at different seasons of the year serve to lighten up the structure. Of foliage plants suitable for the purpose we can recommend the following Palms: *Chamaerops humilis*, *Kentia belmoreana*, *C. forsteriana*, *Latania borbonica*, *Phoenix canariensis* and *Rhapis flabelliformis*. Ferns: *Adiantum cuneatum*, *Asplenium bulbiferum*, *Cyrtomium falcatum*, *Dicksonia antarctica*, *Osmunda palustris*, *Pteris arguta*, *P. argyræa*, *P. cretica* and varieties, *P. acrostichum* and varieties, *P. tremula*, *P. Wimsettii* and *Woodwardia radicans*. Other foliage plants are *Aralia Sieboldii*, *Araucaria excelsa*, *Aspidistra lurida* and *A. l. variegata*, *Cyperus alternifolius*, *Phormium Tenax*, *Cordylina australis*, *C. Eeckhautei* and *Yucca filamentosa variegata*. Of flowering plants, large Zonal Pelargoniums, concerning which you enquire, are quite suitable, large *Fuchsias* also, while *Camellias*, *Myrtles*, Indian *Azaleas*, sweet-scented *Rhododendrons* (such as *Countess of Sefton*, *Lady Alice Fitzwilliam* and *Princess Alice*) and *Cytisus racemosus* will all form good permanent plants. In summer a few of the many flowering plants then at their best will serve to brighten up the structure. Towards the end of August *Lilium speciosum* will form a showy feature, to be succeeded later on by *Chrysanthemums*. If you can arrange it, the climbing plants will do better planted in a narrow border than in pots. The border should be 2 feet

wide and about 2½ feet deep, this allowing for 6 inches of drainage material in the bottom. As the plants are to occupy the position permanently, it is necessary that the soil of the border should be of a good lasting nature. The *Magnolia* will do better on a south wall outside than in the house.

## ROSE GARDEN.

**Climbing Roses for a fence** (*Dragoon*).—About 5 feet apart would be the right distance to plant the climbing Roses, especially as your fence is only about 5 feet high, for you would probably have to train some of the growths horizontally after a year or two. You should certainly add *Mme. Alfred Carrière* and *Mme. Hector Leuilliot*, and for a third one *François Crousse*. *Gustave Regis* is very thin, although a charming bud Rose. In planting arrange as follows: East side, commencing south end—*François Crousse*, *Bouquet d'Or*, *Cheshunt Hybrid* and *Mme. Alfred Carrière*. West side, commencing south end—*Griiss an Teplitz*, *William Allen Richardson*, *Climbing Mrs. W. J. Grant* and *Mme. H. Leuilliot*. All of these are good free bloomers. *White Maman Cochet* is not strictly a climbing Rose, but it will soon cover a 7 feet to 8 feet wall space, and is a great success when planted in such a position. We advise you to mix the cow manure with 6 inches or 8 inches of light soil beneath the fibrous loam. You must be liberal in your application of the manure.

**A hardy pink climbing Rose** (*Mrs. D.*).—There are now several pink Roses among the large-flowered perpetual sorts, and you should have no difficulty in obtaining what you desire. One of the hardiest would be *Conrad E. Meyer*. It is a delightful Rose, with large blooms of the shade of *Baroness Rothschild* and *La France*. Another excellent sort is *Pink Rover*. This is very fragrant and yields lovely blooms somewhat deeper than the old *Souvenir de la Malmaison*, its only fault being a somewhat soiled appearance of its outer petals. Then there is *Climbing Captain Christy*, always good, but scentless, and *Climbing La France*. A Rose that has rapidly come into the front rank of good climbers is *Lady Waterlow*. It has most delightful pink blooms, with *Buttercup* yellow at the base of its petals. As you prefer *Captain Christy*, we think, perhaps, the climbing form of this Rose would be the best for you to select.

**Artificial manure for Roses** (*F. A. E.*).—In the National Rose Society's annual for 1907 a good general manure for Tea Roses was given as follows: Best dissolved Peruvian guano, two parts; fine bone-meal, one part; sulphate of potash, half a part; dried blood, finely powdered, one part; and nitrate of soda, half a part. Apply in early spring at the rate of 5oz. to the square yard. The above ingredients should be well blended. Another excellent manure for all Roses is kainit, bone-meal and blood manure in equal quantities, well mixed with dry potting soil at the rate of a barrowload of soil to 1cwt. of the mixture. Keep in a dry shed, and apply a dressing to all the surface soil of the Rose beds and borders in the months of April, May and June, one dressing a month. The manure should be hoed in at the time of application. Bone-meal itself is an excellent manure if applied in the spring at the rate of 6oz. to the square yard, to be followed with waterings of manure water in May and June at the rate of 1oz. of guano to a gallon of water, applied about once a fortnight. We also refer you to our advertising columns for some excellent artificial manures.

## KITCHEN GARDEN.

**Information about Asparagus** (*T. S. K.*).—We are pleased to give you particulars of Asparagus as regards varieties, but regret being unable to recommend the one you name, as it appears to be a local sort, and not catalogued by any of the large seed or trade growers. On the other hand, the writer has had large areas of Asparagus under cultivation, and the following were the best, and we feel sure you would do well to grow one of them. There is a very fine Asparagus grown on the Continent under the name of *Giant White Head*; this may be the same as your *Snow Cap*. This we know is excellent. A very fine Asparagus is the *Early Giant Argenteuil*. This is one of the best for general culture, and a great favourite in the Paris markets. It is largely imported in a forced state to this country. Another very reliable sort is *Connover's Colossal*, and this is mostly grown in gardens in this country. We prefer the *Argenteuil* for its colour, size and earliness. During the past few years Messrs. Sutton of Reading have introduced a very distinct Asparagus called

French Giant, and it is a splendid large variety. These are the best varieties known.

**How to manage Asparagus roots** (*J. H. S. O.*).—Your query is a very vague one indeed, and we are not at all sure what it is you wish to know. If you have not already cut off the old tops produced last year, do this at once and burn them. Then remove all weeds from the surface and give a 4-inch thick dressing of partly-fermented manure or that which is of a rather strawy character if your soil is heavy and stiff. If the latter is light and porous, a similar dressing of short, well-decayed manure will be best. Rich soil of a porous or well-drained nature suits this crop best. When the shoots begin to show through the manure give the bed a dressing of common salt, 1 peck to each 5½ square yards, and at fortnightly intervals during the cutting season apply 3oz. of finely-crushed nitrate of soda to the same area. You may safely cut heads from your bed this season, but do not remove any after the third week in June.

**What to do with Seakale Beet** (*M. T. S.*).—You have grown the Seakale Beet well, and the mistake was that you did not use the leaves earlier, before frost had injured them. As you say now, they are useless. At the same time, we think there must have been a slight mistake made as regards their use after Seakale is over, as the plant is not perfectly hardy, and though we have had good leaves in March, we lifted the roots in December and placed them in a store just frost proof. This Beet may be termed a Beetroot which, by cultivation, has developed its leaves instead of the root. Sown at the same time as ordinary Beetroot, say, April, the plant at the end of the summer will have thick fleshy stalks, and these are trimmed, boiled and served with sauce in the same way that Seakale is. The other portion of the leaf is edible, being a fair dish if served like Spinach. You could also in severe weather protect the leaves with long litter or dry Bracken. You will find the plants much harder if grown on an open exposed quarter, giving plenty of room to get a firm growth.

## MISCELLANEOUS.

**Hardy Plants that retain their scent when cut and dried** (*T. H. H.*).—Besides the *Lavender* you can have *Rosemary*, *Southernwood*, *Thyme*, the red-flowering *Currant*, *Ribes sanguinea* and the *Lavender Cotton* (*Santolina Chamæcyparissus*). You will find an article dealing with ornamental Grasses on page 45 of last week's issue.

**Where to obtain a gardening pronouncing dictionary** (*A Young Reader*).—"Nicholson's Dictionary of Gardening" contains a pronouncing dictionary of plant names. This is published by Mr. L. Upcott Gill, Bazaar Building, Drury Lane, London, W.C., price 4s the complete work; but they would most likely supply you with one volume containing the pronouncing dictionary if you write to them stating what you require. This volume would cost about 4s.

**What to do with a mound of garden refuse** (*H. P. B.*).—This heap of soil would make excellent material for top-dressing trees and shrubs of all descriptions, and possibly you could utilise some of it for such a purpose. If you wish to cover it permanently you could plant it with common Ivy, *Berberis Aquifolium*, *Rhododendron ponticum* and *Eunonymus radicans*, using only one subject or a mixture of them all. *B. Aquifolium* and *R. ponticum* grow 5 feet to 6 feet high; the others are trailers. We should prefer the Ivy, as this will grow anywhere and would quickly cover the heap.

**Cost of maintaining a garden** (*Compte Rendu*).—The cost of maintaining a garden, especially one of the dimensions you refer to, with its several vineries, Peach, stove, Orchid and greenhouses, with frames and pits, so greatly depends on management and what is expected from it that no possible exact sum can be mentioned about it. Certainly we should assume that such a place cannot be worked with less than one head and three under-gardeners, and that the wages for these cannot be less than £200 per annum. We do not know what is with you so far North the cost of coke per ton; but no doubt, including cartage, it is not less than £50 a year. Seeds and bulbs, if many of the latter be grown or forced, cannot cost less than another £50, and manure, tools, barrows, mowers and other incidental expenses can hardly be less than another £50. That makes a total of £350, but it would be safer to make the estimate £400, especially that apart from seeds and bulbs, nothing has been allowed for trees, Roses, hardy or tender plants, and many things which are necessary to stock a well-kept garden. Your details are very clear and precise, but they rather leave the question of cost an open matter, for the reason we have given, that so much depends on management and on requirements. Flower-pots, stakes, Pea and Bean sticks, labels, and many other things are indispensable wants, and all help to increase the cost. It is as difficult to estimate the cost as it would be to estimate the value of produce. That no one could do, seeing that all would depend on the skill employed to create the produce, its quality when produced, and its product in the market or however sold.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE BEST POTATOES AND HOW TO GROW THEM.

(First Prize Essay.)

### INTRODUCTION.

THE Potato (*Solanum tuberosum*) is one of the most important articles of food obtained from the vegetable kingdom. It is a native of South America, chiefly Chili and Peru, and is generally believed to have been brought from Virginia to Ireland in 1585 or 1586 by Thomas Herriott (who accompanied Sir Walter Raleigh on several of his voyages) and to have been planted near Cork.

### THE SOIL AND ITS PREPARATION.

A good sandy loam, rather dry than otherwise, is that best suited for Potatoes. Crops of good quality cannot be grown on wet, heavy, undrained land, but anyone having such can greatly improve it by draining, trenching, throwing the soil up in ridges for the frost, wind and sun to pulverise and sweeten it through the winter. Partially decayed leaf soil, road grit, old potting soil, charred garden refuse, half-decayed strawy stable manure, lime, &c., are all good things for improving heavy soils. Potatoes grown in very rich soil are never of such good table quality as those from one less rich, and are also more liable to disease. Ground that has been trenched and manured with a good dressing of stable manure for the previous crop is to be preferred to heavy manuring for the Potato itself. Potatoes should not be grown on the same land two years running.

### SEED POTATOES AND THEIR TREATMENT.

Trials of Potatoes have shown that a frequent change of seed is necessary if the best possible crops are to be grown, and that Irish and Scotch grown seed is the best, the reason given for this being that the tubers are not so ripe, and the contents being in a more soluble condition are more readily available as plant food, which gives the plant a quicker and more vigorous start. The seed should be perfectly sound and properly prepared for planting. To do this (before they begin to grow) spread them out thinly in a cool, light shed, or, better still, place them on end in boxes, with the crown end up, and stand these in a frame or on a greenhouse shelf close to the glass, but if the least frost gets to them they will be useless. Seed Potatoes should weigh about 2oz., and the shoots should be reduced to the three strongest. It is not advisable to use cut seed for early varieties, but for main crop varieties Potatoes weighing about 4oz., cut so that each half has three strong shoots, yield as good a crop as, and in some cases slightly better than, whole ones.

### PLANTING.

The best time for this is from the beginning of March till the end of April. I once saw some planted the first week in June and a fair crop resulted, but this was an exceptional case. Planting should not be done if the soil is at all

wet. A good guide for this is, if it clogs the boots of the planter it is too wet and should be left till a more favourable time. For early varieties the rows should be about 20 inches apart and the sets 15 inches, for second earlies 2 feet and 1 foot 6 inches and for strong-growing main crop varieties 2 feet 6 inches and 20 inches. The dibber should not be used, except in the lightest of soils, as it cases the soil round the hole and the roots have a difficulty in breaking through it, and the sets are almost certain to be at unequal depths. The best way is to stretch a line across the ground and take out a drill from 4 inches to 6 inches deep (the heavier the soil the more shallow the drill) with a spade or a heavy hoe, give a light dusting of quick-lime, plant the sets and cover. Pick off any stones, rake out any footmarks and leave the ground tidy.

### AFTER TREATMENT.

When the tops appear through the soil if there is any fear of frost they should have a little soil drawn over them, and when they get too high for this a little dry litter, stout paper, Rhubarb leaves, hay, straw, evergreen branches or anything suitable that is to hand should be used, as the tops are very tender and if the least frost-bitten are severely checked and often ruined. If weeds appear hoe them up, and when the tops are about 6 inches high fork over the soil between the rows and mould up with a heavy draw hoe. In clay soil the ridges should be drawn up rather pointed to throw off heavy rains, but in dry soil they should be left more open to let the rain in to the roots. Moulding should be well done to keep the crop covered, as a Potato exposed to the light for a length of time is spoilt for eating or show.

### LIFTING.

For this a broad four-pronged fork is best, and great care should be exercised not to run it into the Potatoes. Choose a bright day and let the crop remain on the ground a few hours to thoroughly dry. First pick up the store size, then the planting size and store separately; the small ones should always be picked up clean, as if any are left in the ground they are a great nuisance the following summer. If there is convenience to do so store Potatoes should be kept for about three weeks before clamping. Burn the haulm and any diseased tubers.

### CLAMPING.

Choose a dry piece of ground, smooth over the surface, lay a covering of straw on it, place the Potatoes on this in ridges, cover with straw and then with 6 inches of soil taken out to form a trench on each side of the ridge. The straw should be pulled up in a tuft to protrude through the apex of soil at every 5 feet for ventilation. The clamp should run north to south, as then it is possible to open it at the south end without injury on a bright day during frosty weather if the Potatoes are wanted.

### POTATOES FOR SHOW.

Choose an open piece of well-drained ground, deeply trench it in the autumn and plant about the middle of March. The soil to be used is one-half old Mushroom-bed soil and one-half good leaf-soil passed through a half-inch sieve. Take

out a trench 1 foot wide and 1 foot deep and in this place 6 inches of the prepared soil and plant the sets down the centre. They should have been prepared as previously advised, and disbud shoots to the strongest one. Then place over them another 6 inches of the prepared soil and over this a little of that taken from the trench. If old Mushroom-bed soil is not obtainable, clean leaf-soil is nearly as good. The rows should be 3 feet 6 inches apart and the sets 2 feet. Hoe frequently, protect from frost and mould up as soon as fit with the best soil taken out of the trench. The haulm should be kept upright by driving some stakes down on both sides of each row and running some stout string along them. As soon as they are ripe they should be lifted. Have a shallow box at hand and into this place all the best tubers as they are got up, and shade from sun and air, as the less exposed they are the fresher they will look. Store in moist soil, and the day before showing wash them with soap and water, using a soft sponge. Finish off with a little new milk and wrap separately in soft white paper. Potatoes for show should be of good shape, shallow eyed, clear-skinned and all in a dish of an even size.]

#### POTATOES IN POTS AND ON HOT-BEDS.

Soil—leaf-soil or old Mushroom-bed soil one-half, good loam one-half. Properly prepared sets should be planted one in an 8-inch or two in a 10-inch pot. Disbud the shoots to two. Use clean, well-crooked pots, and warm the soil before using. Half fill the pot with soil, plant the set, just cover, and top-dress later. Keep plants close to the glass and never force hard. Water with care. In frames on hot-beds the chief thing is to get a steady lasting heat. Use the same soil as for pots, and well protect from frost. The distance should be about 15 inches between rows and 1 foot between sets.

#### VARIETIES.

Among the best forcing and early varieties are: Yellow-fleshed—Sharpe's Victor, Early Ashleaf and Duke of York; white-fleshed—May Queen, Snowdrop and Ringleader; second early varieties—Sir J. Llewelyn, Duchess of Cornwall, Windsor Castle and Centenary; main crop varieties—Up to Date, The Factor, Discovery and Syon House Prolific; show varieties—Royalty, Empress Queen, Monarch, Million-maker, Klondyke, Advancer, Eldorado, Empire, Goodfellow, Snowball, Ruby Queen and Evergood.

#### DISEASES OF THE POTATO.

*Phytophthora infestans*.—This is the worst scourge the Potato is subject to, and first came into prominent notice in 1845. Bordeaux mixture, properly applied, reduces the risk of this disease to a minimum. As the disease seldom appears before the middle of June, the first spraying should take place about then, a second about a month later, and, in bad seasons, another in August. Early varieties will only require spraying once, and in a favourable season not at all. Recipe for Bordeaux mixture: Copper sulphate (blue stone) 10oz., quick-lime 6oz., water 5 gallons. Always use wooden vessels for this mixture. Dissolve the blue stone in some boiling water, mix the lime with water, strain through some coarse sacking, and add to the blue stone solution, then add enough water to make 5 gallons. Stir well and it is ready for use. Well wet the leaves both top and under sides.

*Winter Rot*.—Flowers of sulphur sprinkled over them at the rate of 2lb per ton when storing will destroy this fungus. Land that has carried a badly diseased crop should not be planted with Potatoes again for several years.

*Wireworms, Beetles, &c.*—Fresh gas lime applied in November at the rate of 4oz. per square yard will clear off most of these.

JAMES RAWLINGS.

The Gardens, Ridgemount, Enfield, N.

## PRIZES FOR READERS.

### JANUARY COMPETITION—AWARDS.

In this competition readers were asked for essays on "The Best Potatoes and How to Grow Them." The prizes are awarded as follows:

The first prize of four guineas to Mr. James Rawlings, The Gardens, Ridgemount, Enfield, N.;

The second prize of two guineas to Mr. George Cooper, Beauvoir, St. Saviour's, Jersey;

The third prize of one guinea to Mr. A. J. Long, Wyfold Court, Reading; and

Fourth prizes of half-a-guinea each to Mr. Charles Hott, Crosses, Great Warley, Essex; and T. Scott, 20, Greenville Terrace, Bloomfield, Belfast.

This competition was the most popular that we have ever held, the number of essays sent in constituting a record. The quality of these was so high that the task of awarding the prizes was an exceedingly difficult one. We have awarded an extra fourth prize of half-a-guinea, the two essays sent in by the competitors named being of equal merit. Many otherwise excellent essays were barred from entering the prize group, owing to diseases not being even mentioned. The treatment of diseases constitutes one of the most important phases of successful Potato culture, a fact that most essayists failed to grasp.

The essays from the following were so near the prize-winning one that we very highly commend them: James Bethell, H. Tomalin, A. B. Melles, G. Bloxham, Rev. J. Bernard Hall, E. H. Caterer, W. J. Crawford, D. R. Gull, W. Hookey, F. J. Dyer, W. Crossland, J. W. Hall, J. W. Forsyth, G. H. Webster, S. W. Pettit, G. Crone, Duncan Davidson, R. W. McHardy, W. G. Holtom, S. E. D. Turner, A. Shakelton, Arthur J. Cobb, E. Jenkins, E. Platt, G. S. Jordan, A. McKinnon, J. F. Colman, J. Mackay, jun., E. Neal, F. Isted, S. T. White, W. Marchant, H. Ollington, H. Davies, C. Hobson, F. W. Gooch, Arthur Mays, R. Gibson, W. Warner, D. B. Allwork, D. Faulkner, Miss A. P. Manly, Miss M. G. Foster, D. Greenwood, T. Hayton, R. Eddersley, T. Alexander, J. Day, W. P. Wood, E. May, L. Bigg-Wither, S. G. Smallridge, A. Sutcliffe, G. H. Simmons, E. F. Hart, W. H. Morton, M. Dearden, W. L. Lavender, E. Walker, V. H. Lucas, F. Lee, T. Smith, J. C. Wadd, J. J. Thorpe, C. M. Craze, A. J. Rennie, H. Rowles and R. Steward.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS

February 11.—Royal Horticultural Society, Committees meet, 12 noon; Annual Meeting, 3 p.m., Horticultural Hall, Vincent Square. Horticultural Club, Annual Meeting, 5 p.m.; to be followed by Annual Dinner, 6 p.m., Hotel Windsor, Victoria Street, London.

February 14.—Annual Meeting of Gardeners' Orphan Fund, Simpson's Restaurant, Strand, London.

**Sweet Peas.**—In our next issue several interesting articles will appear on this popular flower, and a coloured plate will be given of the twelve leading varieties.

**Royal Gardeners' Orphan Fund.** The annual general meeting will take place at Simpson's Restaurant, 100, Strand, London, on Friday, February 14 next, at three o'clock.

**The Royal Horticultural Society's Guild.**—The first meeting will be held in No. 3 Committee Room in the Horticultural Hall, Vincent Square, after the annual general meeting on the 11th inst. The business will be the election of officers, formulation of rules, &c.

**The Gardeners' Royal Benevolent Institution.**—Lord Aldenham will

preside at the sixty-ninth anniversary festival dinner at the Whitehall Rooms, Hotel Metropole, on June 24 next.

**School gardening in Surrey.**—The first of English counties to promote evening or continuation school gardens is naturally forward in the number of elementary school gardens created since the County Education Committee became the school authority. In what may be described as the rural or administrative county area there were last year no less than eighty centres or blocks of gardens, and a total of over 1,200 boys under garden instruction. This number does not include boys' gardens in urban districts where independent education committees exists. In the borough of Kingston there are at two council schools no less than fifty-six such gardens of nearly a rod in area each, and having a capable gardener instructor. It is thus seen that in Surrey the good work begun in the evening gardens is now widely extended to the day gardens, with the great advantage that while in the evening gardens attendances were naturally irregular at lessons, in the day schools attendance is regular and assured. In some two or three years hence there will no doubt be fully 2,000 boys learning gardening, each one for two years at least. The problem to be solved is, what results are likely to follow from all this garden instruction? If it is to be all wasted, then its cost is to be lamented. If, on the other hand, it is to result in creating in years to come a literal army of cottage garden, allotment, small holding and amateur garden workers, then the results must be beneficial and the present cost of the instruction amply justified. It will be no matter for surprise if out of it all grows stronger each year that form of land hunger of which we hear so much now. If it does so, and small holdings and allotments are readily furnished, then indeed may myriads of boys now learning gardening develop into cultivators and producers of food, and become gardeners in the best sense of the term.—A. D.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Watsonia Ardernei.**—I can re-echo all that is said by Mr. Fitzherbert in praise of *Watsonia Ardernei*, which he says is identical with *Watsonia O'Brieni*. Several years ago Mr. Arderne of Claremont, Cape Town, kindly sent me several bulbs. They have grown well and increased greatly in my garden. I have now three large clumps, which bore about fifty spikes of bloom last year. Previously they had not flowered well. When they were lifted I found that the one clump I had had grown into a tangled mass of old and new bulbs. The old ones of previous years were then thrown away and three new clumps planted in good loamy soil mixed with leaf-mould and old manure. They responded well to this treatment, and last year were much admired. *Watsonia Ardernei* is really a very fine plant, possessing a distant likeness to *Gladiolus The Bride*. It differs, however, very widely in height, leaves, size and shape of bloom. The flowers are long and tubular and much smaller than those of *The Bride*. I saved some seed last year, and if it germinates it will be interesting to see whether it reverts to type or still continues to bear white flowers. The leaves of my bulbs are now (January 22) growing apace; they are now all sizes, from 6 inches to 18 inches high. I have never grown or seen *W. Ardernei* in pots. It seems to me to be a bulb better fitted to growth in the open. I should imagine that the spikes of bloom would grow up too tall under glass to be effective, and, as Dean Hole once said of standard Roses, you would require a balloon to see them properly.—(REV.) WILLIAM W. FLEMING, Coolfin, Portlaur, County Waterford.

**Twelve best Apples for flavour.**

Always a debate yet an interesting theme is the rigid selection of Apples, whether they be for cooking or dessert purposes. There is such a large selection of good Apples now available for planting that to reduce their list to a mere dozen must necessarily leave out many good varieties; besides, the tastes of electors are bound to conflict in the rigid choice of Apple varieties. *Irish Peach* I place in the front rank, as this variety is praised by everybody for its pleasant flavour, and when well developed there is handsomeness of outline and colour. This has the peculiar trait of fruiting from the tips of branches, which necessitates cautious pruning in order to secure a fullness of crop. *Kerry Pippin*, like the last named, is an old variety, and much appreciated for its piquant flavour and crispness of flesh. It is a very healthy-growing Apple, adapted to orchard standards as well as the garden bush or pyramid. It is often shelved by electors, because in size the fruit is small, but for home use this is not an important failing. *James Grieve* follows these for autumn use, and is one of the most attractive fruits we have; its flesh is soft, juicy and sweet. An Apple that has many admirers is *Gravenstein*, but is one that does not often get into an elected twelve, yet everyone partial to Apples will readily praise its flavour when this is placed under trial. We find a difficulty in preserving sound fruits for the store, because of the voracity of birds and wasps, which are attracted by its bright colour and highly aromatic perfume, which actually loads the atmosphere in its immediate neighbourhood. *Cox's Orange Pippin* scarcely needs a passing mention in flavour tests, for no other Apple competes with it unless it be the Cornish Gilliflower, which has a flavour and yellow flesh exactly identical. There is this difference, however, that while one is very handsome in well-developed samples, the other can only be defined as an ugly-shaped fruit. Cox's in suitable soil crops well, grows freely, and the fruit keeps firm and full-flavoured well into the winter. *Egremont Russet* is one of the handsomest and best flavoured in this old-fashioned but popular section. There are some ignorant in pomology who regard a russet simply as a russet, thinking erroneously they are represented by one sort only. *Blenheim Pippin* must not be omitted from the round dozen, for next to Cox's no Apple has a wider acceptance or more popular character. *The Houghlon*, one of Mr. Charles Ross's best, is a new Apple that is destined to take a very high position in Apple elections of the future. It is of the same or similar parentage as the namesake of Charles Ross, but I believe, good as this last is, *The Houghlon* has superior merits. It is of healthy character, free in growth and crop, and as handsome, if not more so, as Cox's Orange itself, which is one of its parents. *Christmas Pearmain* has been recently mentioned in THE GARDEN as a high-class fruit, and we might add that it claims every favourable characteristic in the Apple electorate. *Ribston Pippin*, the favourite of the hard, crisp-fleshed Apples, is too well known to call for exhaustive comment; special culture will produce finely-grained, high-flavoured fruit, and freedom from its vigorous enemy—canker. *Claygate Pearmain*.—In this variety there is the embodiment of a good Apple that will remain in fresh, edible condition until April or even later, and its distinctly rich flavour never fails to please even the critical connoisseur. *Mannington's Pearmain* closes the list, and in this there is a still greater richness of flavour than any of the foregoing, save Cox's Orange Pippin, but it has scarcely so vigorous a constitution as some of the more familiar sorts already described. With me it makes an extremely handsome bush and bears regularly. It is fully recognised that the critical pomologist will not find in the foregoing list all that will satisfy, but I am persuaded that for fine flavour they possess very strong claims to popular demands.—W. STRUGNELL.

**THE FRUIT GARDEN.****AMATEURS' FRUIT TREES.**

**S**HOWN in the illustration is an Apple tree in full bloom in an amateur's garden, and the variety is one of the best an amateur can grow, namely, Lane's Prince Albert; this is at its best now. It will, however, keep till the spring, and I have seen splendid examples of it staged at the Royal Horticultural Society's Temple Show at the end of May. As shown in the illustration, the tree is covered with bloom. It has been kept open in the centre, thus enabling the fruits to colour much better and keep sound longer, owing to their being well matured. This variety is a late one to flower, and on that account escapes late spring frosts. It is also a free cropper, so that it is one of the best and most profitable varieties grown for winter or spring supplies.

Some varieties of Apples are so much more suitable for amateurs than others, and those that fruit in a young state are welcome. Grown in bush form on the Paradise stock, Lane's Prince Albert soon comes into bearing. Such as Mr. Gladstone or Worcester Pearmain do well as dwarf standards, as these do not grow unwieldy, and the fruits can be gathered and eaten from the trees. For earliest use to follow these in bush form, such sorts as James Grieve (a Scotch Apple), the well-known King of the Pippins and Ribston Pippin are advised. Allington Pippin and Cox's Orange Pippin are valuable for supplies before Christmas, and after that date Christmas Pearmain, Scarlet Nonpareil, Duke of Devonshire and Sturmer Pippin come in for use. In the cooking section, Lord Grosvenor, Ecklinville Seedling, Warner's King and Bismarck are good for the autumn supply, and for later the one noted above, Lane's Prince Albert, is excellent. Newton Wonder, Bramley's Seedling, and the older but good Alfriston are also very reliable for late supplies. There are many other varieties to select from, but those named are best to fruit in a small state, and most of them rarely fail to crop. In planting bush Apples, many amateurs think they cannot be too good to their trees at the start, and therefore use large quantities of manure. This is a mistake. Feed in later years when the trees are in full bearing. Manure given at the start causes a rank, barren growth. On the other hand, the land may

require lime or other material. For instance, heavy clay soil should have a liberal amount of old fine mortar rubble or broken chalk. Garden refuse after being thoroughly burnt is excellent, also wood ashes, marl, or road scrapings from limestone roads. Light soils require more food, and spent manure and heavy loam are good. G. W.

**APPLE DUKE OF DEVONSHIRE.**

THE above variety is not so great a favourite as many others which are more showy, or larger with more colour, yet it is a splendid late dessert variety and in season from February to May, a period of the year when dessert Apples are not plentiful; the quality, too, is excellent. The fruit is under medium size, and may be described as roundish ovate, and the skin is of uniform

LANE'S PRINCE ALBERT APPLE IN A SMALL GARDEN.

lemon colour with a dull red or bronzy cheek and veined with russet. The stalk is very short, and the flesh is yellowish, juicy, rich and sweet with a fine aroma, thus making it a most desirable dessert variety. The flavour differs from many dessert Apples as it much resembles that of Cox's Orange Pippin. The tree is of stronger habit than the last-named, and it makes a handsome bush or pyramid. In the Western Counties I have seen splendid fruit from standard trees, and grown thus it makes a compact head and rarely fails to crop well. This variety was one of the best late dessert dishes in Messrs. Veitch's gold medal collection at the Royal Horticultural Society's meeting on December 31, and it should not be overlooked by amateurs who are planting dessert varieties. G. WYTHES.

## ORCHIDS.

## DENDROBIUM WARDIANUM.

**T**HOUGH most of the *Dendrobiums* are very beautiful, and many of them decidedly gorgeous in their colouring, they are certainly less popular than some other classes of Orchids. Why this is so is difficult to say, and, perhaps, some day the swing of the pendulum will again bring them into the foremost place.

Certainly one of the showiest of all is *Dendrobium wardianum*, which was first introduced from Assam about forty-five years ago, and for a long time after that was very rare. It has, however, for many years been largely imported from Burmah, and is now one of the best-known and popular of *Dendrobiums*. It is a robust-growing species that flowers very freely. The individual blooms are from 3 inches to 4 inches, or occasionally more, in diameter, the

there is time for them to perfect a well-ripened growth before winter sets in. Whether pots or baskets are used for the culture of this *Dendrobium*, care must be taken that they are not too large, and are at the same time effectually drained. Good fibrous peat mixed with a little sphagnum moss and charcoal form a very suitable compost for the roots. Whether the plants are imported or established, they should, after the flowers are past, be encouraged to make good growth by keeping them in a warm, fairly moist house, and watering them freely at the roots. This will lead to a vigorous growth, and when this is completed the plants must be removed to a cool house, fully exposed to the sun, and given less water. The result of such treatment will be that the plants lose all their leaves and the stems become almost like dried sticks, but it will lead to the formation of flower buds. As the nights get cold the plants will need the protection of a warm greenhouse, and later on a higher temperature may, with advantage, be given them. By putting batches in heat at fortnightly or longer

## TREES AND SHRUBS.

## THE LILACS (SYRINGA).

**I**T is difficult to understand how the word *Syringa*, the botanical name of the Lilac, should have become associated in the popular mind with the Mock Orange (*Philadelphus*), which by the uninitiated is nearly always spoken of as a *Syringa*. Of the Lilacs proper the best known is the common sort

*Syringa vulgaris*.—This, a native of Eastern Europe, has been grown in this country since the sixteenth century, so that is often regarded as a true native of these isles, in every part of which it forms such a charming feature during the flowering period. Another notable point is that it is one of the least fastidious of our flowering shrubs, and in park, garden, or even the town forecourt, is equally at home, and each recurring May furnishes an object of great beauty. The

popular name of Lilac is derived from the colour of the blooms of the original species, but so many varieties have been raised that the flowers now range in colour from white to deep red or purple-red through various intermediate shades of blue, lilac and pink.

With so many varieties now in cultivation a selection is essential, especially for small gardens. Among the best are: *Alba grandiflora*, white; *Cerulea* or *Delphine*, bluish; *Congo*, red; *Dr. Lindley*, rosy purple; *Mme. Kreuter*, bright rose; *Marie Legraye*, white; and *Souvenir de L. Spath*, dark red.

Double flowers are just as freely represented as the single forms, and some of the best are: *Alphonse Lavallée*, pale blue; *Charles Joly*, dark red; *La Tour d'Auvergne*, violet-purple; *Leon Simon*, bluish, very large flower; *Mme. Lemoine*, the best, pure white; *Michel Buchner*, lilac; *Senateur Volland*, reddish; and *Virginité*, bluish.

These varieties readily lend themselves to various modes of treatment in gardens. Where ample space exists, they can be grouped together in a large mass, bed or clump, while trained to a single stem I know no more beautiful object than a good specimen of Lilac in full bloom. Again, planted as a hedge or screen the

Lilac, though not of an impenetrable nature, might be far more often used than it is. H. P.

(To be continued.)

## SHRUBS THAT NEED PRUNING NOW.

**DURING** the early spring months the necessary pruning may be done to various kinds of hardy shrubs. It must not, however, be imagined that all shrubs may be pruned at this period. Pruning during early spring would mean the cutting away of flowering wood. The set of shrubs that require pruning now are those that produce their flowers on wood of the current year's growth, while as soon as the flowers are over the very early-flowering shrubs may also be pruned.

One of the most important groups requiring pruning now is formed by the late summer and autumn-flowering *Spiræas*. Some of the most prominent sorts in this set are *S. japonica* and varieties, including the pretty red form called *Anthony Waterer*; *S. salicifolia*, *S. Menziesii*, *S. Douglasii*, *S. betulifolia*, *S. pumila*, *S. Aitchisoni*, *S. lindleyana*, *S. nobleana* and a few other sorts. With the exception of *S. Aitchisoni* and *S.*

DENDROBIUM WARDIANUM.

sepals and petals being of considerable substance and usually waxy white broadly tipped with amethyst purple, the lip large, tipped with the same colour as the petals, with a broad blotch of soft yellow at the base, where there are two large eye-like spots of rich magenta-crimson. Like all Orchids, a good deal of individual variation occurs among them, but this description applies to what must be regarded as a good example of the typical form.

It flowers as a rule during the spring months, and when in quantity it forms, as may be seen in the accompanying illustration, a gorgeous display. Not only does this illustration give one a good general idea of this charming Orchid, but it also serves as an object-lesson against tying up the growths in a stiff and formal manner, as is too often done, for in this way not only is the natural beauty of the plant spoilt, but stiffer-trained plants do not flower in as satisfactory a manner as when left to assume their ordinary spreading or semi-pendulous habit.

Immense numbers of *Dendrobium wardianum* are imported every year from their Asiatic home. Those that reach here comparatively early in the year give the best results, for if potted at once

intervals, their flowering season may be spread over a lengthened period. H. P.

## CYPRIPEDIUM SULTAN.

This beautiful variety of the popular Lady's Slipper Orchid was shown by Major G. S. Holford, C.I.E., C.V.O., before the Orchid committee of the Royal Horticultural Society on the 14th ult., when it received a first-class certificate. It was described on page 47 of *THE GARDEN* for the 25th ult., its parentage being given as *C. M. de Curte* crossed with *C. Milo Westonbirt* variety. As may be seen in the illustration, which is natural size, the flower is a very large one, with brilliant and well-defined markings. It is really remarkable what a great advance has been made with these beautiful winter-flowering Orchids by hybridists and raisers during the past few years, every winter meeting of the Royal Horticultural Society witnessing the advent of one or more varieties of unusual merit. The lasting qualities of the flowers and the comparative ease with which they can be grown render them great favourites with all plant lovers.

lindleyana all require the same treatment. The pruning for these should be severe, and consist of the thinning out of old and weak shoots and the shortening of the remaining branches. It is not advisable to leave in any wood over two years old, the best results always being obtained from one year old wood. The shortening of the branches should consist of reducing them to within 9 inches or 12 inches of the base; this will allow of all the energy of the plant being thrown into the production of strong young shoots, both from dormant eyes on the branches and from the rootstock. *S. Aitchisoni* and *S. lindleyana* are different-habited plants and require somewhat different treatment. They grow naturally to a height of at least 9 feet or 10 feet, and are remarkable for their immense terminal inflorescences. On well-grown examples these inflorescences often attain a length of 1½ feet or 2 feet. To obtain such a result pruning is necessary, but the height of the plant has also to be considered. The plan to adopt is to spur back weak wood and reduce the strongest of the previous year's shoots to about half their length. Should any old branches be showing signs of deterioration, as many as possible should be removed, and suitably-placed young branches be encouraged to take their places. Shrubs of this description are gross feeders, so it is a good plan to give the ground a top-dressing of well-rotted manure after the pruning has been done.

The late-flowering *Ceanothuses*—typified by the garden varieties of the azureus group, such as *Gloire de Versailles*, *Indigo* and *Rose Perle*—require pruning now, and these should be treated in much the same manner as the last-mentioned *Spiræas*, except that the shoots of last year may be shortened rather more. *Colutea arborescens* may either be grown naturally or may have its branches spurred back now. *Hydrangea paniculata* and the variety *grandiflora* may be spurred back, and in this case a second pruning will be required when the new growth appears. Usually a mass of shoots is formed and it is necessary to reduce these in number if the best results are desired. The various members of the Blackberry and Raspberry group should have all old wood removed to allow plenty of room for the young growth of last year to perfect flowers and fruit during the coming summer.

The various species and varieties of *Clematis* should be pruned early in February with a few exceptions. The chief of the exceptions are the *C. florida* group, *C. alpina* and *C. montana*, all of which flower from last year's wood. All the *C. Jackmani* varieties may be cut well back, as also may *C. viticella* varieties. *C. patens* and *C. lanuginosa* require less vigorous treatment.

As soon as the flowers of *Jasminum nudiflorum* have fallen the shoots may be cut well back, and the same may be said of *Forsythia suspensa*. The double-flowered *Prunus triloba* is another shrub that benefits largely by an annual spurring back of the branches, and the double-flowered form of *Prunus japonica* may be treated the same.

All shrubs when grown for the sake of their bright-coloured stems, such as *Cornuses*, *Willows* and *Leycesteria formosa* should be cut hard back about the middle of March, while subjects grown for the sake of obtaining extra large foliage, such as *Paulownia imperialis*, *Ailanthus glandulosa* and *Rhus typhina* may be cut down at once.

Evergreens, such as *Laurels*, *Privets*, *Rhododendron ponticum* (when grown simply as an evergreen), *Aucubas* and various other things should be pruned in April, especially when it is thought desirable to cut them hard back; this allows of a long growing season, and they commence to grow again almost at once. Bamboos should have all old inside shoots cut away in April, and a really good thinning will be found very beneficial. In the event of any shrub having to be cut hard back it sometimes happens that it is advisable to sacrifice a season's flowers in order to obtain as long a growing season as possible; this, however, has to be left to the discretion of the owner.

W. D.

## THE GREENHOUSE.

### TREATMENT OF OLD SEED PANS AND BOXES.

EVERY year, as seed-sowing time comes round, there will be at least a few pots, pans or boxes, the contents of which have not made an appearance, although the seeds were, perhaps, sown the previous spring or summer, and as room under glass is none too plentiful during the spring months, the temptation to empty these and utilise them for other seeds is very great, it being, perhaps, considered that the seed was bad and that it is of no use keeping the contents any longer.

Those who are used to raising a very mixed collection of plants from seeds will not fall into

irregular in growing, a few perhaps of a sowing germinating quickly and others not developing for months. Primroses, Auriculas and Polyanthus may be included in this category. The awned Anemones, too, are frequently very irregular or slow, and the same may be said of the Hellebores or Christmas Roses. Where the seeds are large enough, it is a good plan to sort them out from the old soil in the spring and sow them in fresh, giving them a rather warmer temperature than usual for a few weeks. This will often induce them to germinate more quickly than they would do otherwise.

### SAINTPAULIA IONANTHA.

THIS beautiful little plant is a native of the East African mountains. Although comparatively little grown this is not from any fault of its own, but rather owing to its not having been brought

A BEAUTIFUL NEW LADY'S SLIPPER

ORCHID (CYPRIPEDIUM SULTAN).

(Natural size.)

this error, as they will be fully aware that the seeds of some subjects are exceedingly slow in germinating, but those that are not used to the vagaries of some seeds may reasonably be pardoned for throwing them away. Upon these I would impress the importance of exercising a little more patience, and will name a few subjects, the seeds of which I have found very loth to germinate. The first that comes to my mind is the *Gentianella* (*Gentiana acaulis*). Seeds of this were sown one spring, but not a seedling appeared until the next, or as nearly as possible twelve months after sowing, when a fine crop appeared. Some hybrid *Peony* seeds, again, although the tiny root or radicle had pushed its way into the soil, refused to develop their leaves for some months, despite a careful filing or chipping of the hard integument or coat. Many seeds of trees and shrubs are notoriously slow in germination, the Thorns, Apples and Plum types being among the worst. Seeds of the former have lain dormant in the soil for two years and then developed into good plants, and possibly some may have been known to need even a longer period than this to germinate. Again, there are many seeds that are most

to notice. The plant grows about 4 inches high, and is clothed with hairy fleshy leaves, from among which the flower-stems spring, each one bearing about five blooms of a dark blue colour, whose golden anthers make a pleasing contrast. Plants are mostly raised from seeds in March, but it may be propagated in various ways. Plants raised from leaves in the manner practised with *Begonias* and *Gloxinias* will give a nice supply through the winter, and will be valuable for small vases in rooms. A good-sized plant may be purchased, grown in a warm greenhouse through the winter for trial, and if approved of propagated by leaves in spring with every prospect of a good supply of plants and flowers for the coming winter. Everyone with glass accommodation should certainly give this easily-grown little plant a trial.

GEORGE W. SIZER,

Elsham Hall Gardens, Lincoln.

## A BEAUTIFUL HIBISCUS.

(H. MANIHOT.)

THE sulphur yellow flowers of this Hibiscus, with their conspicuous bronze crimson centre, are always admired. It is a plant that the amateur may enjoy in the open garden for three or four months of the year, and by sowing seed in spring it shows its full beauty the first season, while being a perennial it can be lifted in autumn and potted up to do duty another year. A native of India, it is generally given greenhouse treatment, but when grown among a collection of these plants its beauty is greatly diminished, and it often falls a prey to insect pests, from which it is absolutely free in the open garden. Seed offers the readiest means of increase, which can be obtained from most nurserymen. The seed is sown in pots about the end of February or beginning of March in light sandy soil and placed in gentle heat, shading the pots until the seedlings appear. After this a warm, airy greenhouse is best, choosing a position where the seedlings will have plenty of light. Transplant

## THE ROCK GARDEN.

## A SANDWORT (ARENARIA BALEARICA).

ONE of the prettiest of all rock plants is the Majorca Sandwort, and since its introduction into this country in 1787 it has added charm and interest to many a rock garden. Although it is a native of the warm islands of the Mediterranean—Sardinia, Corsica and the Balearic Islands—it is, curiously enough, perfectly at home with us, surviving the cold and damp of our severest and wettest winters with equanimity. It is such a rapid grower that it quickly spreads over a large area. It is more compact in growth than any Thyme, more compact, indeed, than many Mosses. It will grow almost anywhere, but is seen at its best when spreading over moist rocks, its trailing tracery of bright green clinging to the rough stone and here and there exposing its

The illustration shows this *Arenaria* growing on a low wall, about 2 feet in height, composed of large flat stones, between which a little peaty soil is inserted. The wall faces north. The *Arenaria* no longer occupies this position, having been rooted out to make way for *Ramondias*, which are now making excellent growth in the interstices of the stones. The best of the other *Arenarias* are *A. graminifolia*, which has grass-like leaves and white flowers; *A. loricifolia*, also a dwarf evergreen perennial with white flowers; *A. montana*, a handsome spreading rock plant producing large white flowers in the late spring, with its variety *A. grandiflora* and *A. verna*, which flowers in the spring. All these will thrive in the rock garden in ordinary soil. S. W. FITZHERBERT.

## THE WALL CRESS (ARABIS ALBIDA).

WHAT is possible of accomplishment by the correct placing of a commonplace subject is amply shown in the accompanying illustration, where a free-growing mass of the well-known

Wall Cress has, in the most natural manner, draped a very considerable portion of a rockery bank. Too frequently these easily-grown and beautiful subjects are overlooked, and plants less worthy and decidedly less hardy are given prominence in positions where it is not possible for them to grow or, at least, to remain long in good condition. The plant now under notice, however, is but one of many that should be seen more frequently on steep slopes or banks, such as that shown in the illustration, and where but little moisture can reach the roots in summer-time. It is not possible to select any hardy plant possessed of a growth more free or better suited to the position indicated.

There is a variety with double white flowers on taller spikes that most nearly resembles a miniature Ten-week Stock. It is a delightful plant for cutting, and as hardy as the first-named. Nor must one overlook the sheets of white blossoms produced by such plants as the perennial Candytuft (*Iberis sempervirens*) or the pure white *Arenaria grandiflora*, *Cerastium tomentosum* and the like. In the alpine Phloxes, the yellow Alyssum and *Saponaria ocymoides*, to name but a few, the amateur may provide pretty colour masses that are most effective under similar circumstances. All of these plants will succeed in quite ordinary garden soil, and may be planted at any time now during open weather.

When it is desired to increase the *Arabis*, a few of the shoots may be pulled from the sides of the plant and inserted quite firmly in the soil in a shady spot for a time. This may be done at any time when the plant is not in bloom, but, if done during the month of August, nice young specimens will be formed for planting during the autumn months or in spring. Where it is desired to quickly cover a large surface of soil—such, for example, as a stony bank—a number of the young plants just referred to should be planted at 12 inches or 18 inches apart in autumn or in spring. Thus arranged a large area may be effectively covered in a short time.

In shady places London Pride is excellent, and in positions where a deeper soil prevails the Mossy Saxifragas will be found most valuable. The *Aubrietias* in rose-pink, lilac and violet are among the most valuable of early spring flowers for banks, borderings, or edgings, and succeed in almost any position in which they are placed, the evergreen growth but a few inches high being hidden in spring with flowers. E. JENKINS.

THE MAJORCA SANDWORT (ARENARIA BALEARICA) IN MR. FITZHERBERT'S GARDEN.

into single pots as the seedlings become crowded, and as these become filled with roots move into  $\frac{1}{2}$ -inch pots, in which they remain till planting out in June. Light soil with liberal drainage when in pots, and light rich soil in a sunny position when planting out are the main features in its cultivation.

The tallest plants I have had from seed reached a height of 4 feet 6 inches, though the majority only attain 3 feet the first season. When lifted in autumn they are potted in light soil, using pots just large enough to contain the roots. Water sufficient to keep the soil moist is all the attention required till spring, when they are pushed forward for planting out again. By cutting down one year old plants to within 6 inches of the ground when lifting several shoots are produced, which form nice bushes the second year. A noticeable feature of the flowers is that they turn away from the sun, so that due allowance must be made for this trait when selecting a position for planting out. THOMAS SMITH.

Walmgate Gardens, Louth, Lincs.

surface with charming effect. It will thrive either in shade or sunshine, as long as the shade is not too dense, but it generally dies if planted in a spot where no gleam of sunshine can ever reach it. Perhaps the best position for it is where it can grow over rocks having a northern exposure, where it will enjoy full light but is not exposed to the burning rays of the sun. In the spring the tiny white starry flowers on their thread-like stalks are exceedingly pretty, and spangle the green carpet, which is not more than an inch in height, in great numbers, remaining in beauty for many weeks. Even when out of flower its close growth of vivid green is very attractive, being very rich in colour and giving beauty and cheerfulness to the rock garden. It may be established on walls, where it makes a charming companion for *Aubrietias*, *Arabis* and such-like plants. As a carpeting subject it is also useful, and extremely pretty effects can be obtained by planting hardy bulbs such as *Iris reticulata*, *Scilla sibirica* and *Narcissi* beneath a carpet of this little Sandwort.

## THE ROSE GARDEN.

### ROSES AND MANURE.

**N**EARLY all amateur rosarians read in the different catalogues, &c., "that Roses are gross feeders and require a large quantity of manure." The general result is you see all their Rose beds at the beginning of every winter with a surface-dressing 6 inches to 9 inches deep. The theory is for protection against frost throughout the winter; and then it is forked or hoed in during spring for fertilising purposes. It is quite true that Roses want a rich soil, but it is a serious mistake, especially in heavy soils, to apply these annual heavy dressings of rank stable or farmyard manure. Do these gardeners ever realise what a dressing of soot would do for a heavy soil, or, say, nitrate of soda for light soils?

Cow or pig manure is grand stuff, so also is stable manure, but do let us use them properly. Speaking generally, the best of these is, undoubtedly, farmyard manure, as it supplies almost all that is necessary for the growth of Rose trees. In soils that are not too heavy, cow or pig manure is quite the best; it is so much cooler for the roots, and also is much more lasting than stable manure. In very heavy, cold, clayey soils, the latter is the best, and a very good plan is to mix a lot of leaf-mould with it, where one wants to lighten the soil and keep it as open as possible. Now to densely coat one's Rose beds with these manures as a protection from frost is a mistake, not to mention what an ugly sight it is in one's garden. It is, in fact, not only needless, but worse than that, as it often causes the loss of the Roses. I do not mean we need no protection from frosts, far from it, in fact, not only Teas but all should have the surrounding soil of the beds, in the case of dwarfs, drawn up well over the centre of the plants several inches; for after a severe winter few sorts, if unprotected, will be found with perfectly sound wood even within a few inches of the surface of the beds. Place Bracken or light evergreen stuff among the branches of tender Roses against walls or fences and standards, or with the latter draw the shoots together and thatch with straw. So much for protection from frosts.

Roses do not like damp, it is one of their greatest enemies. Mulching with manure during winter retains moisture around their collars, their most vulnerable part, and in a wet winter or a wet spring this mass of rank manure round them is the worst possible thing. Again, the best of it hurries them on too soon in the spring, only to be cut back by the cold east winds. And further than that, when April comes all the goodness has been washed away from the roots with the rains, and it is no good away down in the subsoil.

Firstly, of course, Rose beds should be properly prepared, adding what the ground is most deficient in. What suits them best of all is a deep yellow greasy loam. Light soils should have this, if possible, added to them in addition to manure. Strong clay land should be broken

down by adding cinder or wood ashes, lime rubble, chalk, sand and long stable manure. The soil should be dug or trenched 3 feet in depth, for remember that most of our garden Roses are worked on the Dog Rose of our hedgerows, which does best in the heavy cool loams of the Midlands, so if we want success we must prepare our beds at least 30 inches in depth. In the trenching, mix the manure (according to the character of the soil) like a sandwich, i.e., alternate layers of manure and soil. Beds, of course, should be prepared a month or two previous to planting so as to allow the soil to settle down properly. As an extra fertiliser, a good thing is to work in, say, the top foot, some bone-dust or quarter-inch bones. Given beds properly prepared in such a way, all that is

with the surface soil by means of a fork, or liquid manure may be used from June onwards, once a week, by mixing three parts cow manure, one part soot and one part guano thoroughly in a tank or tub with water, only using it weak, especially the first applications. Never even then use it stronger than when the colour of pale ale, and mind in dry weather, before applying, first to water well artificially. The best time to give liquid manure is after rain. Q.

### DO WE REPOT OUR ROSES TOO OFTEN?

It has long been my opinion that the amateur's practice of repotting his Roses annually has often been the cause of many failures. The

roots, perhaps, have just begun to take hold of the new soil when they are ruthlessly turned out of their pots and seriously disturbed, many being lost, which gives the plant such a check that it rarely recovers from it. A much better plan would be to adopt that employed by many commercial growers, and that is to remove in autumn 3 inches or 4 inches of the top soil (or less if the pots are rather small), then give the plants a dressing of some good fertiliser, replacing the soil removed with other consisting of two parts fibrous loam and one part well-decomposed manure. Of course, the crocks should be examined first, and, if at all clogged with soil, let them be set free. In the spring one or two dressings of the same fertiliser, supplemented with waterings of weak liquid manure about once a week as soon as flower-buds are visible, would produce Roses of the finest quality, providing due care be taken to prune the growths to plump eyes, and that careful training is adopted so as to admit air and sunshine to the foliage. The splendid forced Rambler Roses that are now so important a feature in most establishments would benefit largely by this treatment, for their success depends so much upon having a thorough active root action. It must not be forgotten that those plants that have their pots full of roots need watering very copiously and frequently when new growth is active. P.

### ROSE MRS. E. G. HILL.

Those who enjoy the contrasting shades of colour in Grand Duc Adolphe de Luxembourg will welcome the above novelty, for it closely resembles the old sort. I should not be surprised if it surpasses this variety. It carries

its flowers more erect, the drooping character of those of Grand Duc de Luxembourg being their one defect. The coral red centre to the blooms of Mrs. E. G. Hill is, if anything, more intense than in the old favourite. I cannot say whether it is as good in growth, not having proved it outdoors, but we know it must be a good grower to surpass or even equal Grand Duc de Luxembourg. This old Rose always reminds me in growth of Viscountess Folkestone; in fact, the two would go well together. Mrs. E. G. Hill was introduced by Messrs. Soupert et Notting, and is said to be the result of a cross between Caroline Testout and Liberty. I fully expect to find it extremely popular very soon. P.

THE ROCK CRESS (ARABIS ALBIDA) FALLING OVER SIDE OF ROCKWORK.

necessary in future years is to fork in a very light top-dressing (at pruning time, say, every March or April) of short, well-rotted manure. Prune first and manure after is a sound maxim.

What I wish to particularly emphasise in these notes is that a great thing is to keep Rose trees as dry as possible throughout the winter. This is quite as important as protection from frost. With the exception of bone manure, avoid all artificial fertilisers with newly-planted Roses. The following year and afterwards a small handful of soot may be dusted round each Rose, say, in early November and early March; Clay's Fertilizer, Tonk's Manure, or any of the other artificial Rose manures, mixing the same

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**H**ARDY FLOWER GARDEN.—That the beds and borders may be in nice condition for planting a little later have those that are now vacant dug over and plenty of manure incorporated at the same time. Increase such subjects as the Periwinkle, London Pride and Creeping Jenny by dividing the plants as soon as convenient. As the frosts

Salpiglossis, Verbenas, Cockscombs, Nicotiana affinis and the newer beautiful hybrids and Balsams. Sow the seed thinly. Geraniums that were propagated last autumn should be potted up into larger pots, as they will make a comparatively early display in the conservatory.

**Vegetable Garden.**—Sow Broad Beans in rows about 3 feet apart, dropping each seed 6 inches from its neighbour; 3 inches is a good depth to sow. The earliest Peas may be sown for early supplies. Varieties such as Sherwood's Early Dwarf Prolific and The Pilot are commendable for early work. The former attains a height of about 1 foot, and the latter about 3 feet. Sow the seed thinly. Plant Myatt's Ashleaf Potato on a border facing south for early use, setting the tubers 6 inches apart in drills 6 inches deep and 15 inches asunder. Spinach may be sown at once, selecting ground that has been deeply dug and of a rich character. Sow the seed 1 inch deep and in drills 1 foot asunder. Plant Jerusalem Artichokes in rows 3 feet apart and 1 foot asunder in the rows.

**Fruit Garden.**—Complete the pruning of fruit trees as soon as possible, finishing off with Cobnuts and Filberts. When doing the latter take care not to cut away too many of the catkins; a goodly number must be retained for pollen to fertilise the female flowers. The catkins are the pollen bearers. Young Grape Vines should be planted this month. Where young canes are laid in they must be shortened back to at least half their length. This may seem a somewhat drastic operation, but it is better for their future well-being. Old Grape Vines should have already been pruned and made secure. Cut back all lateral growths on the main rods to the second or third bud. Complete the nailing and securing of all fruit trees on walls and fences.

**Trees and Shrubs.**—Ivies may be planted now, and that they may do well dig the soil deeply, incorporating at the same time plenty of well-decayed manure. Heavy soils are considerably benefited by the addition of old mortar and road grit. The Virginian Creeper may now be taken in hand, trimming the growths of superfluous and weakly shoots and training with due care those retained.

**Cold Frames.**—This valuable adjunct of the garden is becoming increasingly valuable. Give Calceolarias in frames plenty of air when the weather is fine and they will then make rapid

1.—AN OLD STOCK PLANT.

disappear Carnations, Violets and other plants that have been lifted by the frost should have the soil made firm round them. Beds and borders planted with bulbs should have the surface soil stirred where the growths are pushing through. Remove weeds at the same time. When the weather is suitable and the soil workable, transplant such subjects as Pansies, Tufted Pansies and Canterbury Bells.

**Greenhouse and Conservatory.**—In greenhouses where a temperature of from 65° to 70° can be obtained from hot-water pipes for bottom-heat, numerous plants may be raised by inserting cuttings in pots and boxes filled with light and sandy soil, and these placed in an improvised or other frames on the greenhouse bench. Plants that may be raised in this way are Verbenas, Fuchsias, Bouvardias, Geraniums, Heliotropes, Salvias, Mesembryanthemums, Coleuses, Lobelias and Petunias. Cuttings inserted now will make beautiful plants for summer and autumn flowering. In the same temperature as that already mentioned sow seeds of such half-hardy and tender annuals as Celosias, Lobelias, Petunias,

2.—THE SAME PLANT CUT BACK.

progress. Auriculas will now need attention. As they give evidence of fresh growth more water must be supplied; they will also appreciate a top-dressing of some good rich soil. Keep the frame freely ventilated, but avoid rain and drip, and, most important of all, damp. Stir the surface soil between Violets and ventilate freely on all favourable occasions. Continue to mat up the frames when the weather is frosty. Place the earliest batch of young Chrysanthemums in the cold frame to keep them growing on sturdily. Afford ample protection against frosts, however.

**Chrysanthemums.**—Young plants that were recently rooted must be kept sturdy, and to achieve this result give the plants a position on shelves near the glass in a cool greenhouse and ventilate without causing draughts. If such a position is not possible, stand the plants in cold frames, and mat up the latter in frosty weather.

When the weather is mild give a little ventilation.

### HOW TO PROPAGATE AND GROW FUCHSIAS.

This is a subject especially suitable for the beginner, as the plants are of fairly easy culture. As a plant for greenhouse or conservatory embellishment throughout the summer months it has few equals, and for massing in beds or for the centre of large mixed beds a beautiful effect is created.

**When to Propagate the Fuchsia.**—These plants are usually propagated in early autumn, say, September, and early spring, say, February and March. A September insertion of the cuttings is made when the object in view is to produce ideal specimens in the

3.—CUTTINGS PREPARED READY FOR INSERTION.

succeeding summer. A February or March propagation answers the purpose of growers who require plants of moderate size for ordinary purposes. Preparations for this latter period of propagation may commence at once, and for this purpose it is first necessary to cut back the old plants.

*How to Cut Back Old Plants.*—Fuchsias that have been kept in cool greenhouses or in warm sunny windows should by this time be in fair condition for cutting back. The first thing to do is to cut back the plants in such a way as to make use of every available piece of growth, and at the same time leave the old cut-back plants in such a condition as to encourage the development of a shapely specimen subsequently. Fig. 1 is a fair illustration of many of last season's plants at the present time. There is nothing very attractive about it, but by cutting back the plant with care we may leave it as represented by Fig. 2. If placed in a temperature of about 60°, fresh young growths will soon be formed, so that our bare-looking cut-back plant will in a comparatively short time become a thing of beauty again. As soon as the new growths are seen to be making headway, these old plants should be repotted into pots a size larger, and be flowered in these. The leading shoot is often cut back one-third to two-thirds its length to make a shapely plant subsequently.

*Making Cuttings.*—Not a single shoot should be detached from the old plants, unless use can be made of it. If properly trimmed and prepared each shoot will make a cutting that will root readily enough. The cuttings should be from 2 inches to 3 inches in length. To make a cutting the two lower leaves should be detached and the stem of the cutting severed with a sharp knife immediately below them. Fig. 3 depicts cuttings prepared for insertion.

*Soil for Rooting the Cuttings in.*—Any light and sandy soil will answer very well indeed, but an easy way of rooting cuttings is to insert them in

4.—CUTTINGS INSERTED IN A 5-INCH POT.

pans filled with sand and a sprinkling of charcoal dust, this being kept absolutely wet throughout the rooting process. If these pans are placed near to the hot-water pipes or in specially prepared propagating frames with a good bottom-heat the cuttings will root quickly.

*Methods of Inserting the Cuttings.*—Fig. 4 depicts a number of Fuchsia cuttings inserted in a 5-inch pot. In this case the soil is of a very sandy, porous nature. The cuttings are inserted to the depth of about an inch, and the soil or sand pressed to the base of each one. It is a simple operation and is easily done. Fuchsia cuttings may be rooted in warm windows by placing a bell-glass or empty jam jar over the pots containing the cuttings.

*What to do with Rooted Cuttings.*—Fresh growths will soon indicate that the cuttings are rooted, and when this is so the pots or boxes should be removed to more airy conditions forthwith. As soon as they appear established and sturdy, the rooted cuttings (young plants) should be potted up singly into deep pots 2½ inches across. Use pots that have been washed quite clean and soil made up of three parts nice fibrous loam, broken up small, one part leaf-mould and about a sixth part of the bulk of coarse silver sand. Mix these thoroughly. Fig. 5 represents a rooted cutting. Pot with moderate firmness, first of all crocking the pots carefully and covering the crocks with some of the rougher portions of the soil. In a day or two water in the young plants by the aid of a fine rose can. Maintain a temperature of from 50° to 60° at all times.

*Subsequent Treatment.*—Pot on when well rooted into 5-inch pots, and later into 8-inch pots if large plants are desired. Soil for these repottings should comprise two parts good fibrous loam, one part well-rotted manure, one part leaf-mould and a sixth part of the whole of coarse silver sand. Add a quart of bone-meal to each bushel of soil and mix well. Pot with moderate firmness throughout. To make bushy growths, the points of the more vigorous shoots should be pinched out two or three times during the growing period. In the autumn stand the plants outdoors to ripen, but place them under glass again before frost sets in.

*Good Varieties.*—Singles: Guiding Star, Cannell's Gem, Mrs. Rundle, Rose of Castile (improved), Princess May, George Gordon and Lord Beaconsfield. Doubles: Champion, Phenomenal, Miss Lizzie Vidler, Molesworth, Berliner Kind, Frau Emma Topfer and Beauty of Exeter.

#### REPOTTING AGAPANTHUSES.

THE African Lilies, as *Agapanthus umbellatus* and its varieties are popularly called, are the most accommodating and beautiful plants that we have for growing in large pots and tubs for verandah, terrace, or even hall decoration during the summer months, and it is probably due to their tolerant nature that one so often sees them neglected in the matter of potting. It is true that they flower best when the root-run is restricted and the soil is on the poor rather than the rich side, but this should not prevent us giving their root system an annual overhauling. It often happens that owing to the drainage becoming blocked through the agency of worms or other causes the soil gets into a sour and unhealthy state, and it is mainly to remedy this that an annual examination of the roots is advised.

The best time for doing this work is early in the spring, say, February, then the plants become well established in their new quarters before they are required for outdoor purposes. Turn them out of their pots or tubs without breaking the ball of soil and roots, and if the drainage and soil are in a sound and sweet condition they may be put back, some of the old surface soil and roots removed, and given a top-dressing. Where the soil has become soured as much of it as possible, together with the blocked drainage, must be removed by means of a pointed label or stick, and it will often be found possible to get them into pots or tubs of the same size that they previously occupied. Any decayed roots must be cut clean away with a sharp knife. Thorough drainage is absolutely essential, and a good soil consists of three parts fibrous loam, used rather coarse, and one part well-decayed manure, with enough rough sand to render the whole porous. Some nuts of charcoal if handy may be advantageously added, as they have a tendency to keep the soil sweet. Potting must be done moderately firm, and the plants should afterwards be stood in a warm greenhouse

and given a light syringing occasionally until established, when they are hardened off for use outside during the summer. Old lard pails, if charred slightly inside and painted outside, with a few holes bored in the bottom for drainage, answer well for growing these plants in.

#### THE AIRING OF HOUSE AND FRAMES.

##### HINTS FOR AMATEURS.

THE spring season being so near, a few words on the above will not, I think, be out of place. The method and time of giving air to plants are of greater importance than many think.

5.—A CUTTING ROOTED AND READY FOR POTTING UP.

and during the next few months the successful treatment of the lives of thousands of seedlings and other mature plants will depend a good deal on the wisdom exercised by the individual who gives it. Air can be given so as to be beneficial or detrimental to growth. When to admit air will depend altogether on the weather each day brings forth. The brighter and warmer it is the greater the amount of air that will be necessary.

Taking it for granted that a thermometer is already at hand, a fairly safe rule for general management is to give air when the temperature has risen from 5° to 10° higher than that usually maintained. For one who has not had a frame or greenhouse before, it will be necessary for such an one to enquire what the general temperature should be of the particular class of plants he wishes to go in for, and then apply the above rule. The way to admit air is by degrees, and not to give an abundance at one time as some do. That is the wrong way, especially in the beginning of the season. Another important item to bear in mind is to give air from the leeward side if possible, and not from the windward. Cold draughts and large quantities of air put on suddenly are both very dangerous to plant life. Many tender-leaved plants (such as Ferns and Vines) have been marred, if not spoilt, for the season through careless airing.

As the sun becomes hotter it will be wiser to use a little artificial shading, such as tiffany, summer cloud or whitewash, in preference to giving much air when the day is very windy or breezy.

C. T.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**SEEDS TO SOW.**—Sow Giant Windsor, Prolific Longpod and Mammoth Longpod Beans, also Green Giant and Green Longpod; these will make a good succession of all the best varieties. Sow also Peas of the second early type, such as Early Giant, Early Morn, Buttercup, Daisy and Edward VII. Give plenty of space between the rows, and do not sow the seed too thick, as this interferes with development and, subsequently, quality. Carrots and Lettuces may also be sown on a warm, protected border. On a dry day run the hoe through Cabbage and Lettuce plantations; also prick up the soil in the Parsley bed and pick off all decayed portions. Get all digging finished as soon as possible.

#### FRUIT GARDEN.

**Pruning.**—Push forward all the pruning now of bush fruits such as Gooseberries and Currants, and manure and fork over the ground; see also that all labels are intact, replacing those that are illegible. Use some good bone-meal and basic slag where the trees are poor. The weather has been much against the well-being of the

**Earliest Peaches;** a great guide should be the weather. Do not run the temperatures up in dull, foggy weather or syringe the pipes to cause vapour, as this may do much mischief. See that the roots do not suffer when near the hot-water pipes, and when watering give a thorough soaking; on closing the later houses the borders should have a good drenching.

**Vines.**—Continue to regulate the growths. Vines that have been tied down to ensure a regular break should be tied up to the wire when the growths are between 3 inches and 4 inches long, care being exercised that no shoots are broken in the process.

**Strawberries.**—Do not force these too rapidly, and if they are being accommodated in early vineries or Peach houses, move them to a dry, airy house to flower, after which, when well set, they may be taken again to a warm house and rapidly forced, when they should subsequently be taken again to a cool house to ensure perfect flavour.

#### FLOWER GARDEN AND PLEASURE GROUNDS.

Run the hoe through the beds to loosen the soil. Pick off any weeds or rubbish. Plant Lilies. Top-dress and dig or trench and rearrange herbaceous borders. Sow more Sweet Peas, also Chinese Primulas and Polyanthus in quantity and seeds of shrubs and trees. Top-dress and manure forest trees and conifers; it is surprising what the effect of a good top-dressing will do. Thin and transplant all kinds of shrubs; this may be continued up till the end of March and even later with care. In bad weather prepare soils, stakes and labels.

Oil and clean tools, machines, &c. These duties are of great importance, and should be carried out when the weather is wet or frosty and the men cannot be otherwise employed.

#### GREENHOUSE.

**Chrysanthemums.**—The first batch of these will now need attention. Pot off singly those that have been struck in pots and boxes. If the plants are not grown for exhibition, good batches of one colour are preferable than many varieties.

**Greenhouse Plants from Cuttings.**—Cut down Bouvardias and stand in a warmer temperature, in order to get cuttings for a new supply. Salvias may be given the same treatment, also Solanums. Put in cuttings of winter-flowering Geraniums, and pot on for large specimens for midsummer effect. Persian Cyclamens that have

been in boxes should now be potted up singly, using a sweet soil. Propagate in earnest now all that is necessary. Calla elliptica may now be taken out and potted; use a good rich, light compost for the first potting, and water carefully till the plants begin to make roots; they are charming when well grown. Freesias should be brought along in gentle heat in batches; they are much appreciated in the dwelling-house and conservatory. Continue to take in and

**Force Hardy Plants** such as Lilies, Azaleas, Spiræas, Laburnums, Prunus and the like. Give Arum Lilies in bloom plenty of stimulating manures. Keep Roses clean by syringing with quassia water or Mitchell's Soluble Petroleum.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**TUBEROUS-ROOTED BEGONIAS.**—The tubers must now be looked over and the double varieties started, as these take a longer time to develop flowers than the single forms. Use shallow seed boxes, with a layer of sifted leaf-mould and sand in the bottom, in which the tubers should be placed. Let the leaf-mould be fairly damp when used. No water should be given, but a temperature moderately moist is decidedly favourable.

**Lilium Harrisii.**—The stock of this should by this time be well started and a night temperature of 50° to 55°, with a rise to 65° by day, given. The syringe ought to play an important part here, the growths being liberally sprayed over several times daily. Pot up at once Lilliums of the lanceifolium type, as they are apt to shrivel if kept too long out of the soil. Plunge the pots in ashes in a cold frame and place a slight sprinkling of the plunging material over the surface of the pot. Do not give any water at present.

#### HARDY FRUIT.

**Nailing Wall Trees.**—Buds of the Apricot are beginning to swell on south walls, and nailing of these should now be brought to a close as early as possible. Where protection is given it will be well to prepare the material for placing in position. Peach and Nectarine trees, both as regards pruning and nailing, must be left as late as possible, as the longer the wood is away from the wall the better the bloom.

#### KITCHEN GARDEN.

**Broad Beans.**—These will stand bad weather much better than Peas, and as they are not so likely to be damaged by birds and other vermin, it is often advisable to plant a few rows in the autumn. Where this is not done make a sowing of Early Mazagan now in shallow boxes filled with ordinary soil for transplanting towards the end of the month, or as soon as the weather is favourable. Raising a few hundred plants in this way is of great advantage in cold, wet districts, and as they transplant readily a more even crop is ensured.

#### FLOWER GARDEN.

**Iris reticulata.**—No matter whether grown in the open border or in pots this Iris is equally effective and always admired. The flowers are equal for richness to any spring-blooming Orchids, and they are sweetly scented also. If a few bulbs are placed in fancy coloured pots and the surface of the soil covered with Selaginella, they are most useful for standing on tables in the drawing-room, or even for table decoration. Iris reticulata also lasts fairly well when cut and placed in water, but a rather cool position should if possible be given it.

**Snaptagons.**—Experience ranging over many years on a stiff soil causes one to regard Snaptagons as very doubtful biennials, at least hardy ones, and I make it a rule to sow seed very early in the year, usually in February, in

pans or shallow boxes, and in a cool house, so that plenty of stout and firm plants are furnished to dibble out in the open ground at the end of April. If some become a little drawn the tops can be pinched out.

#### ORCHIDS.

With the lengthening days a new life seems apparent in most plants, and Orchids are no exception to the general rule. Yet it would be too risky to act simply on the assumption of a permanency of open growing weather because we have been passing through a period of comparatively warm and genial weather. Watering must still be done with the greatest care and the water used in moderation.

**Miltonias.**—Miltonia vexillaria and the beautiful hybrid M. bleuana grow freely in the intermediate house, and now that the young growths are well advanced and emitting new roots from the base any potting requirements that may be necessary should be attended to. Being surface-rooting subjects shallow pans are the most suitable receptacles for them. Drain these to one-third of their depth and pot the plants moderately firm in a mixture consisting of equal proportions of fibrous peat and chopped sphagnum moss, with a portion of Oak leaves, coarse sand and small crocks added to ensure porosity. Keep the base of the plants level with the rim of the pan and leave room at the surface for a layer of chopped sphagnum moss. The plants must be placed well up to the light in the intermediate house and fresh air admitted on every favourable occasion. The newly-potted plants will not require much water for the first two or three weeks.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## THE KITCHEN GARDEN.

### ASPARAGUS FOR AMATEURS.

**F**REQUENTLY the amateur gets disheartened over the attempt to get good Asparagus, and my notes will, as far as possible, describe what may be termed simple methods, cost of production being considered. At the same time, I will note forcing and protection, and this done, the amateur who has room may have a six months' supply of this favourite vegetable. At this season the land should be prepared for the roots, and though this is the least interesting part of the work, and also the most laborious, it is an important one. The subject may be dealt with under three headings, viz., general culture, embracing the preparation of the land, sowing and planting; forcing; and the ordinary crop from the open ground.

#### GENERAL CULTURE.

It is often stated, and with a good deal of truth, that it is not necessary to go to such an outlay as regards labour and manure at the start, but so much depends upon the soil, heavy clay land costing most; but many amateurs have loamy or sandy soil, and although deep cultivation is best, when we see what good crops are grown in fields with half the labour, I think my note, as regards cost, will be understood.

Taking unsuitable land, or soil that is wet, clayey or heavy, this must be double dug now, keeping the top soil on the surface. Between now and March the amateur can greatly improve it by placing on the surface anything that will lighten it—burnt garden refuse, old Melon or Cucumber beds, wood ashes, leaf-soil, road scrapings from limestone roads, fine mortar rubble or broken plaster, and even burnt soil or marl. These forked in during March will give good results.

Another question now arises, viz., should the beds be flat or raised? I do not like raised beds at all, but in heavy land they are an advantage

as they are thereby drained, but in ordinary garden soil I advise growing on the flat, thus giving more space than can be afforded with raised beds. With heavy soil I prefer animal manure when making up the beds, and this should be applied liberally when digging, placing it between the first and second spit; later on, as the plants yield, food can be given in other ways, and this I will refer to more fully later on.

I have used the term double digging, a simple one to the ordinary gardener, but one that may require some explanation by the amateur. It means that the soil must be dug at least two spades deep. To do this begin at one end of the piece, take out a trench a spade deep and 3 feet or so in width and wheel this to the far end where the digging will finish. Then dig as deeply as possible the space cleared and on this place the next top spit, again dig the bottom, and follow on in the same way to the end. By this system the best or top soil is retained on the surface right through the work.

Light soil is easier to work, and here more manure is required; heavy loam added is also well repaid, but given ample food Asparagus does well in a sandy loam. An open position is much the best, having rows on the flat at least 2 feet apart, giving more room if it can be afforded. It will be seen that good Asparagus may be grown by ordinary means if the land is well cultivated at the start, and I have rather dwelt upon this as it is important.

#### SEED SOWING OR PLANTING.

I prefer planting to seed sowing, as time is saved; but if sowing is preferable, the same time applies, viz., late in March or early in April. Often seed is sown much too thickly in the row, with the result that a weakly growth follows. Thin sowing and severe thinning of seedlings as soon as large enough should be practised. Plants from seed will be three years before heads can be cut, and this is a long time to wait, that is why I advise plants one or two years old. I prefer the latter if planted quickly. Deep flat drills are drawn at the distance given above, the seedlings placed in, taking care to spread out the roots, and cover quickly with the fine top soil. Plants are secured at a small cost at the time named. In a dry spring it may be necessary to water, and I have in a dry summer given a mulch of litter over the surface of the beds. With good culture a few heads may be cut the next season from two year old plants.

It is important in exposed places to prevent the growths from being broken or twisted till they are quite matured, as from these the crowns for next season are being formed and supported, so that it is well to use some short bushy stakes or some twine and stakes along the rows. In my next notes I will deal with forcing, protection and the supply for the first three or four months in the year, and later on general culture, feeding and other details. As regards varieties, the amateur need not grow more than one or two at the most, I prefer Early Giant Agentuil or Connover's Colossal. G. WYTHES.

(To be continued.)

#### A USEFUL SALAD PLANT IN SPRING.

THE first three or four months in the year are the worst for maintaining the salad supply, and especially so after a succession of severe frosts which have destroyed all autumn-sown stock in the open ground. Eodive up to this date has been available, but now this is over unless given glass protection. My note concerns a good substitute for Endive and Lettuce. The plant alluded to is Carter's Endive-leaved Lettuce, a very good salad plant and most valuable on account of its rapid growth. The leaves resemble Endive, being deeply serrated, and even in a young state very good for the salad bowl. With a frame or glass I have got useful cutting material in a very short time. Sown in boxes and cut over when quite young

it may be had fit for use under a month. It is also equally valuable for sowing on a warm border for first supplies. Several sowings should be made from February to May, the April and later sowings being made on good ground in the open. G. WYTHES.

#### AN AMATEUR'S TOMATO.

VEITCH's new Dwarf Red Tomato is one which recommends itself as being specially suited for the amateur or anyone with limited convenience. Its habit is such that it needs no more than a stake 3 feet long to carry a full crop of fruit. On a well-grown plant the first truss of fruits is so near the pots as to be almost touching, and the trusses are so close to each other that the stem of the plant is covered from top to bottom. Not only is it a heavy cropper, but the fruit is handsome in appearance, solid and of splendid flavour. A batch of plants raised here in July last has been fruiting from October to the end of January, so that it has proved itself a valuable winter variety. I believe it will prove a good market sort, as the fruits will keep firm longer than any variety I know after being gathered. FROGMORE. E. HARRISS.

#### FLOWERING TREES.

(Continued from page 17.)

##### SNOWY MESPIUS (AMELANCHIER).

**M**OST of the Amelanchiers are shrubs, but *A. canadensis* attains the dimensions of a small tree, 12 feet or so high, clothed with racemes of white flowers in April, which, with the tender red of the young leaves, render it an effective subject in the garden. In the autumn the leaves change to a lovely bronze crimson tint before falling off. It is a native of North America, and is often met with under the names of *A. asiatica*, *A. Botrya-pium*, *A. sanguinea*, &c.

##### JUDAS TREE (CERCIS).

*C. Siliquastrum* (the Judas Tree) attains the dimensions of a small tree or large shrub 10 feet to 12 feet in height, and bears rose-pink, Pea-shaped flowers all over its bare stems in May. In addition to the flowers, the rounded, deep green leaves give it a distinct and handsome appearance when not in bloom.

##### THE THORN (CRATEGUS).

Most of the Thorns have a double value in the garden, as, in addition to their flowers, they bear brightly-coloured fruits in autumn. All of them flower in May or June, and a good selection is the following: *C. Azarolus* from South-East Europe, with white flowers and large fruits of a golden yellow colour; *C. Currierei*, with white flowers and Pear-shaped yellowish fruits hanging late in the year; *C. coccinea*, *C. Crus-galli* and *C. mollis* from North America, with large white flowers and bright scarlet berries; and *C. cordata* (the Washington Thorn) is a handsome tree with glossy leaves and clusters of white flowers followed by small orange red fruits. *C. orientalis* from Eastern Europe makes a handsome small tree, with white flowers followed by red fruits, and *C. pinnatifida* var. *major* (*C. Layi*) is a strong, handsome tree with large corymbs of pure white flowers and shining red fruits. The leaves of the latter turn to a striking bronze red hue in autumn. There are many varieties of the common Hawthorn, but the best are the single and double scarlets and the double white.

##### SNOWDROP TREE (HALESIA).

There are some five or six Halesias, but the best and hardiest is *H. tetraptera* (the Snowdrop Tree), which attains a height of 20 feet to 30 feet in this country, and forms a handsome sight in May when covered with its pure white, Snow-drop-like flowers. It is one of the most distinct

and handsome of flowering trees, but it is not at all common, though it was introduced into this country in 1756.

##### WYCH HAZEL (HAMAMELIS).

The best of the Wych Hazels is *H. arborea*, a native of Japan, which forms a small tree bearing deep yellow flowers studded all over the leafless stems in winter. The petals of the flowers are nearly 1 inch long, narrow and twisted, and set in small claret-coloured calyces. For winter effect there is no small tree to equal this, especially as frost does not affect the flowers to any appreciable extent.

##### LABURNUM.

The common Laburnum is a well-known and deservedly popular tree, but *L. alpinum* (the Scotch Laburnum) is not so often seen. This flowers about a fortnight later, as also does *L. a. var. grandiflorum*, *L. a. var. Parkii* and *L. a. var. Watereri*, the two latter being handsome trees bearing racemes of flowers upwards of 15 inches in length. *L. Adami* × (*L. vulgare* × *C. purpureus*) is a graft hybrid producing all yellow or all purple flowers, or the two colours intermingled on the same tree, and sometimes on the same raceme.

##### PRIVET (LIGUSTRUM).

The majority of the Privets are shrubs, but *L. lucidum* and *L. sinense*, both natives of China, form small trees or large shrubs 10 feet to 20 feet in height. The former is an upright-growing evergreen, with stout, glossy leaves upwards of 6 inches long and of proportionate width, and produce large terminal panicles of white flowers in July and August. *L. sinense* somewhat resembles the English Privet in foliage, but the growth is free and arching, and the pure white panicles of flowers are borne in such profusion in July as to almost hide the branches.

##### THE TULIP TREE (LIRIODENDRON).

This forms a large well-balanced tree, upwards of 80 feet in height, and bearing creamy white or pale yellow tulip-shaped flowers in June and July. The leaves are of a peculiar four-lobed shape, and change to a lovely golden hue in autumn.

##### MAGNOLIA.

The genus Magnolia contains some of our handsomest flowering trees, and it is a pity that some of them bloom so early in the spring, as they are liable to be cut by spring frosts. *M. conspicua* (the Yulan) forms a large spreading tree 20 feet or so high, and bears pure white cup-shaped flowers in April. *M. soulangeana* is a hybrid between *M. conspicua* and *M. obovata*, and blooms in April. The flowers are white with purple markings at the base. Other hybrids of the same parentage are *M. Alexandrina*, *M. spectabilis*, *M. rustica*, &c., all more or less resembling *M. soulangeana*. *M. Lennei* has the same parentage, but the flowers are large and deep purple in colour. *M. Fraseri*, a native of North America, bears creamy white scented flowers in May, and makes a handsome tree about 30 feet high. *M. glauca* (the Swamp Bay) is a small tree with dark green glossy leaves intensely glaucous on the undersides, and small white sweet-scented flowers opening from July to September.

##### PRUNUS (ALMONDS, PLUMS AND CHERRIES).

This family contains many beautiful trees, blooming during spring and early summer, the earliest to flower being *P. davidiana* (a Chinese Almond) which has pink flowers, and *P. d. var. alba*, a white-flowered variety of it. These bloom in February or March, and are followed by *P. Amygdalus* (the Almond) which is well known by its cloud of pink blossoms in early spring. *P. persica* (the Peach) is of little garden value, but its double pink and double white varieties are among the handsomest of our spring-flowering trees. *P. cerasifera* var. *atropurpurea* (*P. Pissardi*) is beautiful in April when covered

with its pure white flowers, its purple leaves later on giving it an added value for garden decoration. *P. pseudo-cerasus* (*Cerasus Watereri*) is a beautiful tree with double rose-pink flowers opening in May, and *P. serrulata* bearing light rose double flowers about the same time, should both have a place in every garden. *P. Mahaleb* var. *chrysocarpa* is a tree 20 feet or so in height, bearing short racemes of white Hawthorn-scented flowers; and *P. Padus* var. *fl. pl.*, is an upright-growing tree with long racemes of semi-double white flowers opening in May.

#### THE CRAB (PYRUS).

The *Malus* (Apple) section of *Pyrus* contains the most useful garden trees of the family, chief among them being *P. baccata* (the Siberian Crab), which bears rose-pink flowers in May; *P. floribunda*, a small and very popular tree with pink flowers; *P. f. var. atrosanguinea*, which is even better than the type with its deep rose-coloured blossoms; and *P. spectabilis*, with pink flowers opening in May. *P. Schiedeckeri* is of hybrid origin and comparatively new. As far as can be seen at present, it is a strong-growing *P. floribunda* with semi-double soft rose-coloured flowers borne from end to end of the branches in May.

#### FALSE ACACIA (ROBINIA).

The common *Robinia Pseudacacia* is a well-known large tree with its graceful leaves and racemes of white flowers, but there are several handsome varieties of it that are not planted so often as they deserve to be. The best of these are *aurea*, with yellow foliage and white flowers; *bella rosea* and *decaisneana*, with pretty rose-coloured racemes; *microphylla*, with small elegant foliage and white blossoms; and *semperflorens*, which blooms more or less all the summer. *R. neo-mexicana*, from the Southern United States, is a small well-shaped tree with rose-pink-coloured flowers, and *R. viscosa* (the Clammy Locust), a native of North America, bears racemes of rose-coloured flowers in July.

Bayshot, Surrey.

J. CLARK.

## NEW PLANTS.

#### NEPHROLEPIS EXALTATA AMERPOHLII.

DURING the past few years some very remarkable varieties of the above-named species have appeared, and the present plant is certainly not the least remarkable of the series, though it might claim, we think, to be the dwarfiest of those at present known to commerce. The plant is of a neat, compact habit of growth, and is possessed of a plumose density and fineness of pinnae suggestive somewhat of *Todea*. To compare it to other varieties of the same group, it would appear rather to resemble *N. e. todeoides* in miniature, the pale green colour of the fronds rendering it extremely elegant and pleasing. The fronds are about 1 foot in length, arching and tapering to a point, the exceeding dwarfness of the plant rendering it quite distinct from all its race. A most welcome addition to choice, easily-grown Ferns. It was shown before the Royal Horticultural Society by Messrs. H. B. May and Sons, Edmonton, on the 28th ult., when it received an award of merit.

#### NEW ORCHIDS.

##### CYPRIPEDIUM FAIRIEANUM COOKSON'S VARIETY No. 2.

THIS is a beautiful variety of the famous *C. fairieanum*. The plant shown was a small one in a 2½-inch pot and was carrying two flowers, one of which was not open. The flowers are more highly coloured than are those of the type, the very deep crimson markings on the dorsal sepals and petals being very pronounced. Shown by Mr. Norman Cookson, Oakwood,

Wylam-on-Tyne (gardener, Mr. H. J. Chapman). Award of merit.

##### CYMBIDIUM GATTONENSE.

THIS is a lovely plant of a fairly well-known genus, and is the result of crossing *C. lowianum* with *C. traceyanum*. The plant shown was a large healthy-looking specimen, carrying one raceme composed of six fully-developed flowers. These are of ordinary size, the sepals and petals being beautifully streaked with crimson, brown and yellow. The labellum is very conspicuous, this having a pale yellow ground colour heavily marked with bright rich crimson. The column is also noticeable, the colouring being the same as that of the labellum. Shown by Sir Jeremiah Colman, Bart., Gatton Park, Surrey (gardener, Mr. W. P. Bound). Award of merit.

##### CYPRIPEDIUM MR. F. SANDER.

ANOTHER beautiful addition to this popular genus. The plant shown was carrying one flower only, but this was very handsome indeed. The dorsal sepal is extra large, hooded, with a distinct white band running round the edge except at the base. The ground colour is green, and this is heavily dotted with good-sized circular spots of dull crimson. The petals are long, oar-shaped, hairy at the base, and of a dull crimson colour, except at the tips, where green predominates. The pouch or lip is of medium size and coloured dull crimson with a light gold edge. Shown by Mr. F. Wellesley, Westfield, Woking (gardener, Mr. W. Hopkins). Award of merit.

The above awards were made by the Orchid committee of the Royal Horticultural Society on the 28th ult.

## RIVIERA NOTES.

**MONTANOA BIPINNATIFIDA.**—This bold habited composite has been in unusual beauty lately. An old and fully-developed specimen with six or eight strong stems starting from a woody root-stock is a noble object in the December garden. The foliage is so handsome that it was grown for years as a summer foliage plant under the name of *Polymnia grandis*, and it is only in modern days that its value as a winter flower has been discovered. Its great sprays of white Daisy-like flowers, with rather irregular-shaped petals, have a grace of their own that is not excelled even by the stately *Dahlia Imperialis* in the month of November. It is a tribute to the perception of the Royal Horticultural Society's committee that they could grant a certificate of merit to necessarily small pot-grown plants, which could give but a very feeble idea of its beauty when fully developed.

**Rosa bracteata** (the double form).—Not long ago I saw in an old garden a bush of this almost-forgotten Rose with six or eight fully-expanded blooms. As this old and justly-neglected Rose has the reputation of never being able to expand its handsome buds on account of the curiously-folded petals, I shall be glad to hear if anyone else has ever seen it fully open. To my great surprise the flower is not double, but has a tuft of pale yellow stamens in the centre. The cupped petals, shaped like those of a Water Lily, incurve and nearly hide the stamens; but as the white of the petals is not pure, rather greenish white in tone, it is a curiosity rather than a beauty, and so I should not expect anybody to grow it now we have so many free-flowering winter Roses. I have no doubt that the great drought of last summer on this coast, followed by the heavy autumn rains, has caused this seldom-seen Rose to expand its flowers on the very fully-ripened growths.

**The Rev. E. Arkwright's "Telemby" Sweet Peas.**—The strain of winter-flowering Sweet Peas which Mr. Arkwright so kindly distributed last autumn is now flowering very freely and well at Bordighera in the garden at Selva Dolce,

and has given the greatest pleasure. By an accident those I have were not sown in time, and they are not yet in actual flower. They are much bolder and finer in growth than Mont Blanc and Earliest of All, which were our only winter Sweet Peas, so they are a real addition to the winter garden. The flowers are large in size and of many colours. I hope we shall hear of others who may have sown them, for they deserve all the praise Mr. Arkwright gave them. The first flowers were expanded in December before Christmas, and the succession of bloom promises to be continuous.

**Rose Noella Nabonnand** is the finest red climbing Rose for winter bloom that has yet been raised, and this season it has flowered continuously and finely for many weeks in mid-winter. As it is a comparatively new Rose it is not yet commonly grown, and needs more notices about its merits to arouse the attention it deserves.

E. H. WOODALL.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

#### Information about Violets (K. R.).

If you desire the Violets for a town garden, such as a London garden, for example, the middle or end of March would be quite early enough for setting out the young plants. At that time you should obtain well-rooted examples in pots, and plant in deeply-dug, well-manured soil. At planting time soil of a sandy nature should be made firm by treading, and in this way avoid over-luxuriance. A north-western or western exposure would be best, and with light shade overhead Violets usually succeed. For frame culture later on the above method should be first adopted, growing the plants till September, and then lift and replant into the frame. The latter for winter flowering would be best if raised a little, and the Violet plants, then full of flower-buds, should be lifted and firmly planted in good soil. It is important that during the summer the runners should be kept in check, directing by these means all the energies of the plant to the production of crowns and flower-buds. The following are the best single varieties: \*Amiral Avellan, Italia, La France, \*Luxonne and Princess of Wales. La France is the darkest in colour, and this and Princess of Wales are very large. Those marked thus \* possess the most pronounced fragrance.

**Name of and information about a plant (Suburban).**—The name of the specimen sent is *Alchemilla arvensis*. As it is only an annual it would hardly be suitable for planting between the flagstones of your path. You want something of a more permanent character, like *Sedum album*, *Thymus serpyllum*, *Arenaria balearica*, the dwarf Mossy Saxifrage or even *Campanula pusilla*. These are all low growing, and would do in such a position. If the border is shady, Lavender would hardly be a success, and it would be best to try annuals that like a little shade. Larkspurs of any sort would do, and a good show might be obtained with the numerous varieties now to be had from seedmen. Other annuals suitable would include the Night-scented Stock (*Matthiola bicornis*), Virginia Stock (*Malcolmia maritima*) dwarf Alyssum and the Forget-me-nots (*Myosotis alpestris* or *M. dissitiflora*).

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

## THE SWEET PEA.

"Here are Sweet Peas on tip-toe for a flight."—Keats.

THIS beautiful and now variable hardy annual is found wild in Italy, near Naples, and also in Sicily. It seems to have come from these shores, *via* Holland, and not from Ceylon, as has been sometimes stated. It has been a popular favourite almost from the first year of its introduction.

So far as we know the late Mr. George Glenny, of "florist's flower" fame, did not invest the Sweet Pea with any of his arbitrary rules and regulations, as to form, size, or colouring. So much the better for the Sweet Pea, which has grown, like Topsy, into a thing of elegance and beauty, beloved and admired of all. A flower is not more beautiful for being as round as a shilling; in fact, much of the characteristic beauty of the Sweet Pea absolutely depends on its being of an irregular shape.

As to habit, this is as elegant as it well can be, and we certainly deprecate the very dwarf varieties, the flowers being borne on stalks too short for cutting, while they are so near the ground as to become soiled and splashed by heavy rains.

The Sweet Pea in all its many forms really belongs to one single species—*Lathyrus odoratus*—and there is no reliable evidence that hybridism has ever been resorted to in raising new varieties. This is curious, as one might have believed hybridism possible with *L. odoratus* and its annual first cousin *L. tingitanus*, even if not with *L. grandiflorus*, *L. latifolius* and other of the perennial species.

In 1860 a white variety, having a blue edge to the standard, was sent out, and at the time was said to be a hybrid between *L. odoratus* and *L. magellanicus*, the blue perennial, or "Lord Anson's Pea." The raiser was said at the time to have been Colonel Trevor Clarke, but there seems to be no authentic record of such hybridism, and if it really did take place the probabilities are that *L. sativus*, the annual blue-flowered species, was used, and not *L. magellanicus*, which, so far as we can learn, was not existent in English gardens at the time named. Even to-day it is quite a common thing to hear the annual *L. sativus* called in error "Lord Anson's Pea."

Seeing the enormous strides in size, colour and number of flowers on a stem, made by Mr. Eckford and others in England during the past twenty years, it is certainly not easy to prophesy in what new direction improvements are likely to take place in the future.

For many years Sweet Peas have been overflowing from cottage and villa gardens, until now there is scarcely a garden large or small where they are not grown. Their value for decorations indoors, as cut rather long in the stem and loosely and naturally arranged in narrow-necked vases, is now universally recognised, and at all our best floral exhibitions there are now classes for these fragrant blossoms, and they hold their own along with Roses, Carnations and other summer exhibition flowers.

The National Sweet Pea Society's exhibitions are always beautiful and interesting, and our raisers have of late years added many lovely varieties to those already in existence. We hope their beneficent work will continue. It is a good thing to have Sweet Peas everywhere—flowers as sweetly fragrant as the Rose itself. Several articles are given in the present number upon various phases of the flower, and the coloured plate represents a few of the newer and leading varieties.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 3.—Royal Horticultural Society, Committees meet, 12 noon.

March 5 and 6.—Royal Horticultural Society's Colonial Fruit Show.

March 9.—United Horticultural Benefit and Provident Society's Annual General Meeting.

March 11.—East Anglian Horticultural Club Meeting.

**The Hampton Court Vine.**—The great Vine, so old yet so young, is perhaps a more interesting object in winter than when clothed with its many thousands of leaves and carrying its hundreds of bunches of Grapes in summer. Just now it is in a state of rest, yet of recuperation. It has been pruned, regulated, tied up to its supports and is a striking object. To how many hundreds of feet—nay, probably to thousands—do its myriad branches run? They are of all lengths, but chiefly very long, though perhaps none more so than the half-dozen that, having broken out some 4 feet up the old quaint, gnarled, picturesque stem, have been run horizontally along the great house which now shelters

the veteran, which, in spite of its Royal associations, is still regarded by the thousands of visitors to it as the people's Vine. It cannot be too readily acknowledged that, to the great interest in the old Vine's welfare taken by the King and the authorities of Frogmore, it remains under the control of so eminent a gardener as Mr. Mackellar, and that its immediate interests and culture are in the hands of the veteran custodian, Mr. Jack, who naturally regards his charge with pride and its undoubted recuperation and renewed vitality with great satisfaction. Besides providing the old Vine with a new house, its roots have received both greater room and more generous fare, and so marked is this resuscitation, especially on the part of a Vine so aged, that Vine growers anywhere need not despair of the possibility of renewing the life and vigour of any Vine, however aged or exhausted. One unquestioned good which has followed on more generous treatment is that less has been demanded from it in the form of Grapes than was formerly the case. To seek for regeneration and yet to require the old Vine to carry heavy crops of bunches would be a suicidal policy. Happily, no such policy is required. But if fewer bunches be carried, not only are those produced now much finer in both bunch and berry, but, because of the exclusion of the myriads of visitors from the floor of the vinery, no dust is created, and the berries remain as clean as if in the private vineries elsewhere. Not long ago bunches weighing half a pound gave the average. Last year numerous bunches ranged from 1lb. to 2½lb. and carried berries of the finest quality; indeed, it is doubtful whether Black Hamburgh Grapes anywhere give better flavour than do the Hampton Court bunches. Just now the vinery is being freely ventilated and kept as cool as possible. The fruit is rather wanted late than early. Aged as the Vine is, yet much of last year's wood shows thickness, solidity and maturity of which any gardener might be proud to have on young Vines.—A. D.

**"Bottled torture."**—Some importance has been attributed during the past week to what has been described in the daily press as an epidemic of "bottled torture," which it was said London had narrowly escaped by the energetic action of the Medical Officer of Health for the City. "The attention of the doctor," says the *Daily Telegraph*, "was recently called by the Assistant Medical Officer of the General Post Office to the serious results which followed the use of the material known by the above terrible name, which it was discovered was sold by a novelty dealer in the City for the purpose of practical joking. In one case the victim suffered from extreme irritation of the skin, which almost amounted to cellulitis, as the result of the application of this substance. Dr. Collingridge, in his last report, states that 'bottled torture' consists of the stinging hairs of the pod of a tropical plant, *Mucuna pruriens*. The pods are 4 inches or 5 inches long, shaped like the letter 'S,' and clothed with a thick coating of short, stiff bristles of a bright brown colour, the points of which are notched or finely serrated, and easily penetrate the skin, causing unbearable itching. The City dealer was at once informed of the danger of the use of the material, and immediately destroyed it; and the wholesale firm of novelty dealers who supplied it to him, and had no idea as to the purpose for which it was bought, at once discontinued its sale. Four retail dealers in other parts of London also destroyed their stores." The principal details of this story are ancient history. At the time when the stinging hairs of *Mucuna pruriens* were used in medicine as an anthelmintic, it used to be said that one of the first practical jokes played on the new medical or pharmaceutical student by those "in the know" was to let loose some of these stinging hairs, which are so fine as to be scarcely visible in their individual character, some of which, however, would never fail to penetrate the skin, usually on the back of the hands or between the fingers. Intolerable itching

resulted, the intensity of which was increased by rubbing, facts which I can verify from my own experience while handling the pods in the Kew Museum. As a drug the Cowhage or Cowitch, as it is sometimes called, has been known in European medicine since 1640. In Britain it was first introduced into the Edinburgh Pharmacopoeia in 1783, and into the London Pharmacopoeia in 1809, as an anthelmintic or vermifuge. The hairs with which the pods are densely clothed act mechanically on the intestinal worms, and were administered mixed with honey or treacle. At the present time they are very little used. The plant is a lofty annual climber, bearing dark purple papilionaceous flowers and golden brown pods somewhat like those of the Sweet Pea, and belonging to the same Natural Order. In India it is found all over the plains, and it also grows in the tropical regions of America and Africa.—JOHN R. JACKSON, *Claremont, Lympstone, Devon*.

**"Eighth Report of the Woburn Experimental Fruit Farm."**—This report, prepared by His Grace the Duke of Bedford, K.G., and Spencer W. Pickering, F.R.S., deals entirely with insecticides and fungicides, and many important facts are brought to light through its agency. Some of the most important experiments carried out were in connexion with mussel-scale, moss and lichen, and the Apple sucker (*Psylla mali*). In treating the mussel-scale, the emulsion soda wash, containing 6 per cent. solar distillate, 2 per cent. caustic soda, and ½ per cent. soft soap (for which is now substituted copper or iron sulphate with lime) proved most satisfactory. For the removal of moss and lichen from trees, a 10 per cent. solution of lime was not found an efficient substitute for a 2 per cent. solution of caustic soda. For the treatment of the Apple sucker, a 2 per cent. decoction of tobacco, sprayed on after the eggs are hatched out and before the blossoms expand, appears to be the most effective. The report is published by the Amalgamated Press, Limited, Carmelite House, London, E.C.

**Black scab or warty disease of Potatoes.**—In an interesting and instructive leaflet published by the Wye Agricultural College, Mr. E. Salmon, F.L.S., deals with this Potato disease fungus, known botanically as *Chrysophyctis endobiotica* (Schilb.). It was introduced into England from the Continent in 1895 and is now known to occur in nine counties in England, Scotland and Wales. The disease may be readily identified by means of the gnarled, warty-like excrescences that are formed on the affected tubers. According to reports received by the author white varieties are more susceptible to the disease than the coloured sorts. The counties in which the disease has been noticed and recorded are Cheshire, Merionethshire, Nottinghamshire, Lancashire, Westmoreland, Cumberland, Stirlingshire, Clackmannan and Perthshire. The opinions quoted of such men as Professor M. C. Potter, Armstrong College, Newcastle; Mr. J. W. Eastham, College of Agriculture, Holmes Chapel; Dr. Borthwick of Edinburgh Botanic Gardens; and Mr. George Massee of Kew all tend to prove that the disease is a most insidious one, and point to the necessity of immediate steps being taken for its extermination. All who have had any experience with fungoid diseases of Potatoes will know only too well the rapidity with which they spread, hence it is with surprise and alarm that we read Mr. Salmon's statement that "although the Board (of Agriculture) knew of outbreaks of this disease in 1901, they have taken no steps to stamp it out or to prevent it spreading through the country." The disease is at present in its infancy, and all that is possible should be done to eradicate it ere it is too late. Potato growers already have enough diseases to combat without being saddled with another, which Mr. Salmon warningly states is likely to cause the same trouble and loss to Potato growers as the Finger-and-Toe disease does at present to growers of Turnips.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**The Vine weevil.**—Cultivators of the Vine will be well advised to examine their borders and to keep a sharp look-out for the presence of this pest during the coming season. Information has reached me from various sources of the ravages caused by the larvae of this weevil. Cyclamen, Begonias, and various other plants are also attacked by them. The larvae feed principally on the roots, while the perfect insect seldom attacks other than the foliage.—M.

**Gilla coronopifolia.**—Mr. Fitzherbert is very interesting, as he always is, in his recent remarks upon this beautiful plant. I first got the seed in July, 1903, from an old garden in Rheims, and sowed it, by the gardener's instructions, at once. The seedlings bloomed well in 1904, and generally have done so since; but my own experience, and that of many friends to whom I have given seeds or plants, is that the earlier stages of growth are very slow and satisfactory and blooming a little uncertain. Devonshire has a magic climate, and in the experienced hands of Mr. Fitzherbert the plant is evidently mending its manners. Last year my plants, which had all been pinched, were magnificent, each having from a dozen to fourteen spikes of bloom about 4 feet high. Last year, in North-east Kent, we had no rain to speak of from May till the end of September, and with cold, sunless days there has been little or no bloom.—CHARLES PRENTIS, *Borden, Sittingbourne*.

**Carnation cuttings.**—In the paragraph on "How to Make Carnation Cuttings" (page 32) it is stated that "the proper length of a cutting is about 3 inches, though half an inch less is quite long enough." My experience of cuttings of 2½ inches or 3 inches long is that a large number are quite devoid of the essential firmness and stability that go to promote complete success. Anyone who will put a 2½-inch long cutting on a tape measure will find that he has but a very small one indeed, and when a cutting of that size is inserted an inch deep in the pot of soil but very little remains. Moreover, I am very sure that these small cuttings, however possible to the professional, are a source of much disappointment, and not a few failures, in the case of the amateur, who, to be on the safe side, as he imagines, follows such advice to the letter. I have seen such cuttings in the hands of capable propagators damp off wholesale, and the chances for so doing are distinctly favourable under ordinary systems of propagating. The advocates of small cuttings appear to quite overlook the fact that but a very small plant exists when this tiny cutting is rooted, and that a proportionately longer period of time is required by such to make a really good plant. As a matter of fact, a made cutting of not less than 4 inches, and far better if 5 inches, of many varieties is decidedly to be preferred, the measure to be taken from the tips of the heart leaves to the base. I would like to add a word of warning about inserting the cuttings singly in small pots, as recommended on page 33, paragraph 1. Very few amateurs are possessed of a superfluity of bottom-heat to be able to do this, and to not a few the simple expedient of two boxes—one deep and one shallow, the former 7 inches or 8 inches, the latter less than 2 inches—placed over the hot-water pipes and covered by a plain sheet of glass will make a perfect propagating box and one always at command. A little Cocoanut fibre in the bottom of the larger box for retaining moisture should be provided and kept moist. For the rest, fill the shallow box with pure clean washed river or pit sand and make firm. No mixture nor admixture of soils can compare with it, while its preparation is almost *nil*.—E. JENKINS.

**Slugs on Maidenhair Ferns.**—I should like to thank your correspondent F. Perkins for his kind information in your issue of the 11th ult. about the Maidenhair fronds. At his suggestion I placed pieces of Orange peel about my Ferns and have caught quantities of tiny white transparent slugs, who were evidently causing the trouble. No doubt many amateurs will value this useful hint.—L. F. T.

**Cotoneaster angustifolia.**—Two years ago I enquired from various amateurs and nurserymen in the South whether the above had produced berries. Mr. Manning's plant was the only one I could hear of as producing berries. A gentleman near Bath told me he had a few flowers, but no berries. In January, 1905, I planted several specimens here on a warm rocky slope, and at the same time in a garden on the Menai Straits. One of these, being planted against a warm south wall, could hardly have had a more favourable situation, but no flowers have ever formed. Is it possible that there are male and female plants? At Christmas a plant of *Cotoneaster thymæfolia* flowered freely here.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

**Dividing Daffodil bulbs.**—Mr. Watts (see THE GARDEN, page 39) says he does not follow me when I say the work of dividing Daffodil bulbs "may be done too late," &c. If your correspondent will again read my opening remarks on page 15, having reference to the root-fibres shown on the bulb in the sketch, in conjunction with the following paragraph, the meaning will be at once obvious. Such root-fibres as those shown were taken to be the new roots, inasmuch as in a large number of varieties the old roots perish and dry up naturally when the bulbs are out of the soil and for a time exposed to the air. In others, as some poeticus sorts, *incomparabilis*, &c., where a more viry or fleshy semi-persistent character of root-fibre obtains, these root-fibres remain good for a much longer period—how long, however, will depend upon the manner of storing, the place of storage and other things. In a similar degree would these things influence the early or late issue of the young root-fibres from the bulb. Bulbs kept perfectly dry and in an airy place may go for months and display no great inclination to put forth new roots; indeed, I have at this moment, January 23, a few bulbs amply demonstrating this fact, while others of the same variety in a quite dry place, but in their thousands, gave signs at the end of September last of a desire to be in the soil again. It is all a question of environment. So far as the division of any bulb is concerned, much depends upon the variety. Such a bulb as that illustrated, however, with a little downward pressure of the thumb, would be instantly in three perfect parts, and far greater care would need to be exercised were it desired to retain it as shown in the sketch; the offsets would easily fall away if such bulbs were handled a few times. In mother bulbs of the Emperor or Empress type the outermost offsets, when the bulbs are a little dried, may be broken away with a slight hand pressure with perfect ease and absolute impunity, while an inner series of divisions erectly disposed may require (or not) the touch of a pointed knife on the underside of the connecting basal plate to bring about their separation. In such a case no possible harm could ensue to the young oncoming roots at that time, not only within the bulb, but protected in the most perfect manner possible by the gently receding base of the bulb itself. That both the embryo root-fibres, together with the germ of flowering and the leafage, do develop materially within the bulb during what is known by cultivators as the "dormant" period is beyond question, and to the writer this internal progress has been a source of unflinching interest during many years. In early July the germ of flowering may be just visible to the eye, while in October an inch-long flower-bud and green-tipped leaves are all disclosed if the bulb be cut in halves.—E. H. JENKINS, *Hampton Hill.*

## THE FRUIT GARDEN.

### GOOSEBERRY WHINHAM'S INDUSTRY.

IT is very doubtful whether, for general purposes, this well-known Gooseberry can be beaten. It has several points that tell largely in its favour, and if one were limited to growing only one variety of Gooseberry the choice would probably lay with Whinham's Industry. It belongs to the large fruited section, the berries being of good size, dull red, almost round, and slightly hairy. The flavour, too, is good, and as the fruit possesses a rather thick and tough skin, it travels well when ripe, thus rendering it an almost ideal variety for market purposes.

The hush has an upright habit, is very prickly and is a vigorous grower. It is, however, more shallow rooting than many varieties, and consequently is liable to suffer during extended

absolutely cleared of the enemy. To this opinion, however, we hold contrary views, gained not from hearsay but from actual experience. Gas-tar toned down with clay and water was the favourite prescription in bygone days, and we well remember the warm welcome that was accorded its inception as a positive remedy for bug on Vines many years ago. Many other compositions were prepared for coating the rods of Vines, all in turn giving more or less hope at the time of application and a corresponding disappointment as the season advanced. The application of tar paint was, to say the least of it, a most disagreeable task; but our hopes of success and our disgust of the presence of the insect was so strong that the offensiveness of the composition was not regarded as a serious impediment. Even the tar coatings were not proof against attack, for stray insects would invariably locate themselves in more or less obscure prominence and demand individual treatment. We prefer methylated spirit and petroleum as being equally destructive of insect life

GOOSEBERRY WHINHAM'S INDUSTRY.

periods of drought, when some other sorts would not be so affected. This may, however, be avoided by giving the soil over the roots a good mulching of well-decayed manure or any other material that would be likely to check excessive evaporation. The variety is a very heavy cropper in most districts in the South of England, and the fruits are excellent both for preserves and dessert. As cuttings root very easily a stock can soon be secured, and anyone who is contemplating planting Gooseberries now or next season should certainly include a bush or two of this good all-round variety.

### MEALY BUG ON VINES.

THE note dealing with this most loathsome of garden pests in THE GARDEN recently affords effective prescriptions if carried out with a determined spirit and continued, not in one season only, but as long as one stray bug remains in possession. The persistency of these creatures is proverbial; indeed, some gardeners are heard to say that an infested vine can rarely be

and less so to the Vine leaves. The merest touch of either suffices; indeed, sufficient ought not to be used to moisten the leaf, for death is assured by the smallest drop of spirit.

We employed gas-tar in the proportion of half a pint to a gallon of the prepared clay and water, all being reduced to the consistency of thin cream and kept well stirred to ensure of it being of equal strength. It is, of course, necessary that not only should the Vines be dealt with on drastic lines, but the roof, floor, walls, wires, &c., also should have scrupulous attention in detail, otherwise there will be much further trouble given. The wires, strainers, and eyelets are best painted with petroleum in a neat state, making sure that none falls on the Vine bark during the course of the work. It is often in such places that the bugs are found in hiding, even after the washing down of the roof has been completed.

Prior to the painting with the tar mixture loose bark which separates readily from the rod should be pulled off, laying a cloth or double mat beneath to catch any that fall with this residue, making sure that this is taken out promptly.

## THE FLOWER GARDEN.

### COLUMBINES AND THEIR CULTURE.

**M**ODERN hybrid Columbines or Aquilegias are among the most graceful and attractive of all the flowers of the outdoor garden. Columbines of a sort we have always had, our forbears grew the quaintly named

and quaintly-shaped flowers, every cottager in the country does so even now. But the difference in the flowers! If the old-time Aquilegia was worthy of the name of Columbine, then are the modern representatives of the race entitled to claim the whole harlequinade; the grace of Columbine herself, the shimmering changes of colour of harlequin, even the merriment of the clown are all suggested by the modern Aquilegia in the heyday of its flowering.

The florist, for once in a while, has here permitted Nature to lead him instead of attempting to shape her efforts with mathematical primness, and for this we are glad. True, he never could have conventionalised such an unconventional flower as the Columbine, but he might have clipped her elegant spurs, he might have encouraged doubling of the flowers and so much of what we now most prize would have been lost to us. The illustration shows how well his work has been done as regards the form of the flowers, of their delicate and marvellously beautiful colours mere black and white reproductions can convey no hint.

Fortunately for those to whom new varieties of plants have prohibitive prices, the Columbine in its improved forms can be readily raised from seed. A greenhouse is not necessary for the raising, although some cultivators sow seed in heat and thus forward the flowering period a little. This latter method is generally adopted when seed is saved from home-grown plants, as this is not ready until summer is well advanced. It should be sown as soon as ripe, and if the grower does not mind waiting a while for flowers he may well sow in light and sandy soil outdoors. This is Nature's own method, and although it is the gardener's boast that he "doth mend Nature," it is extremely doubtful if he can mend her in the matter of raising hardy perennials from seed. Certainly many of them will grow if sown as soon as ripe in the open, whereas they fail to germinate in a cold frame in spring. But the latter is the more general way of sowing the Aquilegia, largely because nurserymen do not make a practice of offering seeds as they are harvested. March is the usual time for making a start, and a shallow, well-drained seed pan should be used. Soil composed of equal parts of loam, leaf-mould and coarse sand suits admirably, and the seed may also be mixed with a little sand to ensure its even distribution. Thin sowing is imperative, as is early pricking out, for the seedlings make far-reaching roots, and these are easily broken if allowed to ramify too much. A fairly deep box should be used for pricking out the seedlings; they should be set 3 inches apart and shaded

for a few days from bright sun. Planting in the open garden may be done at any time after May is out, but as the plants will not flower until the following year it is well to put them in a reserve bed and plant in their flowering quarters either in October or at the end of February. Site and situation are not very important matters, as the Aquilegia is by no means fastidious: I have found it form good clumps and make a pretty effect on an Ivy-covered bank facing north. It flourishes singularly well in heavy soil on the chalk, thousands of self-sown

being sent to Kew, it was decided by the authorities that its correct name was *Salvia dichroa*.

Nicholson's description of the plant is very misleading, for it gives its height as from 2 feet to 3 feet, whereas my plant, last year, attained a height of considerably over 9 feet, with a spread of 6 feet at the base. A large specimen, such as this, bearing many hundreds of long flower-spikes, is a beautiful sight when in full bloom, and is quite the glory of the garden in the month of July. The leaves are rather over

1 foot in length and are deeply cut, being roughly corrugated on the upper side and covered with hairs on the reverse. The largest bloom-spikes are fully 3 feet in length, and a length of about 9 inches of the blossoms is expanded at the same time.

The flowers at the base of the spike open first, and as these fade the upper ones expand, the blooms eventually enclosing to the extreme top of the spike, so that its flowering period is an extended one. The individual blossoms are lavender-purple in colour, the middle lobe of the lip being white. On cutting one of the longest flower-spikes, forty-eight expanded or partially-expanded blooms were found on it, while in all there were almost 180 flowers and buds.

This *Salvia* being a native of the Atlas Mountains, in North Africa, cannot be considered absolutely hardy; indeed, even here in Devon it is usually cut by the winter frost, but has never been killed although entirely unprotected. Towards the close of August the plant generally dies down to the ground level, sending up fresh growth in the late autumn.

This year, however, it did not die down quite to the ground, but threw up new growth from the bases of the old stems a few inches above the ground. These new growths have, however, been badly cut by the frost, of which we have up to the present experienced 7°. It is a very shy seed-bearer, the long flower-spikes with considerably over a hundred blooms, rarely perfecting more than half-a-dozen seeds in their capsules. This plant deserves to be more widely known than it is at present, its free-flowering and

stately habit making it an object worthy of inclusion in the foremost gardens in the country.

South Devon.

S. W. FITZHERBERT.

### THE WINTER ACONITE.

THIS charming little plant is flowering rather late this season, owing to the severe weather we have experienced. Each spring as I watch its furled yellow buds rising from the damp, and often frozen, earth I wonder why it is not always found in gardens. Even the smallest plot of ground should have a few clumps of this pretty little plant. How delightful it is to see a broad mass of its golden yellow blooms glistening in the February sunshine. Because of its earliness the Winter Aconite is worthy of a place in the garden among other spring bulbs, but it produces the finest effect when naturalised in the turf under deciduous trees or in wild corners. In such situations it seeds itself freely, especially if the soil is not too cold. E. TESCHEMACHER.

THE SPURRED COLUMBINE: ONE OF THE MOST BEAUTIFUL FLOWERS FOR DECORATION.

seedlings being annually produced in my garden. At the same time it will grow very well in almost pure sand, also in the shade of a wood or in the open.

Should it be desired to increase any particular variety the plant should be dug up, carefully pulled to pieces with the hands and replanted in well-worked, sandy soil. This may be done in early spring or as soon as flowering is over. C.

### SALVIA DICHROA.

THIS splendid *Salvia* is practically unknown in England, though in "Nicholson's Dictionary of Gardening" it is said to have been introduced into this country in 1871. Its rarity is proved by the fact that during the past thirty years there has not been a single mention of it in the volumes of *THE GARDEN*. My plant was originally given to me by Lord Walsingham as *Salvia tingitana*, but, upon a flower-spike and foliage

## COLOURED PLATE.

PLATE 1343.

## SOME GOOD SWEET PEAS.

**A**S Sweet Peas are so rapidly increasing in popularity, articles will, as occasion permits, appear in the pages of *THE GARDEN*. For the benefit of new readers, or any that may have missed them, we direct attention to the article on "The New Sweet Peas," by Mr. A. Malcolm of Duns, N.B., which appeared in the issue for November 2, 1907, and that on "How to Grow Sweet Peas," by Mr. Horace J. Wright, in the issue for January 4 last.

Owing to the rapid rate at which Sweet Pea novelties are introduced nowadays, it requires more than a casual effort on the part of the everyday cultivator to keep in touch with even the best of them; the worst he may well keep at a distance, provided some kind friend who has tried them will point them out. Most growers like to know what are the best dozen varieties, both for the garden and the show tent, and many experts will not hesitate to select a dozen for both purposes.

*Evelyn Byatt.*—This is probably the best standard orange-coloured variety on the market with the exception of St. George. It was, I believe, first exhibited in 1905, when it received the distinction of an award of merit, an award that it has since proved to be well placed. It has frequently been described as an improved Gorgeous, the colour being a much brighter orange than that of the last-named variety. The standard is very rich orange, the wings a sort of rosy salmon with a lighter keel. A point in its favour is that it does not burn in the sun so badly as most other varieties of this colour, hence it is a favourite with many for garden decoration. The flowers are rather small and it is not often that it produces four on a stem.

*Henry Eckford.*—But for its unfortunate habit of burning in anything like strong sunshine, this might easily be termed the prettiest Sweet Pea yet raised, the colour being peculiarly soft and pleasing. However, so delicate is its texture that it is almost worthless for the decoration of a sunny garden. By planting in the shade, or by protecting the plants during the sunniest part of the day, flowers of the most exquisite colour may be obtained, and they are well worth the trouble involved. Without some precaution of this sort the flowers are often scorched by a hot sun to a biscuit colour, or streaked with light whitish patches. As an exhibition flower Henry Eckford was unfortunate in encountering

and it cannot, at least at present, be left out of the best twelve or even the best six sorts. It does not burn in the sun as badly as does Henry Eckford; in fact, it has been grown in the full sun in light soil, and also in heavier soil on a hillside, without scorching. The thing to avoid with all these delicate orange shades is a low-lying situation, where the morning dew is retained until the sun gets enough power to injure them.

*Miss Willmott.*—This is a much older variety than either of the preceding, but, though eclipsed by them on the show-board, it is by no means done with as a garden Sweet Pea. As a matter of fact, it is still the market growers' standby in its colour, and is still one of the most popular varieties in commerce. With good culture it will produce four large flowers on a stem, and none of its rivals are credited with doing more. In some strains of seed a giant form is produced, and this is capable of holding its own with any Sweet Pea yet raised. Probably this variety burns less than any of the orange shades, and it may still be considered the best of its colour for the garden.

*Audrey Crier.*—In the opinion of many this is the finest Spencer Sweet Pea yet raised, and the fact that it gained the silver medal of the National Sweet Pea Society as the best variety of its year speaks volumes in its favour. It has, however, an unfortunate reputation for fixity, or rather for the want of fixity, and anyone who tries it for the first time this year would be well advised to prepare for disappointments. At its best it is a variety that commands instant attention, and when it can be guaranteed to come true from seed it will take its place in the very front rank of exhibition varieties. In the garden it is very showy, but has a slight tendency to scorch in the full sun. Though in the hands of many cultivators during the past two years, it may really be looked upon as a 1908 variety, since it has only been offered in quantity for the first time this year.

*Enchantress.*—This charming variety came under the ban of the National Sweet Pea Society last year as being too much like Countess Spencer and one or two other varieties, and the strong family likeness must be admitted. But while Enchantress is quite the equal of Countess Spencer in everything that has made that variety so popular, it occasionally gives flowers far superior to anything that the Countess is capable of; they are very large and several shades deeper in colour than those of Countess Spencer, and could their production be depended upon Enchantress would occupy a much higher position than it does at present. The sporting proclivities of Countess Spencer are notorious, and unless a strain guaranteed to come true can be obtained far better grow Enchantress. It is a splendid garden variety, as well as being eminently suitable for exhibition, and most of the long, strong stems carry four large flowers.

*Frank Dolby.*—This grand Sweet Pea was a novelty of last year and proved to be one of the best fixed new varieties on the market. The colour may be described as a lovely pale lavender, much the same as that of Lady Griseld Hamilton, but the flowers are much larger and possess a fine waved standard. This waviness is not shown at all well in the coloured plate. The plants are very vigorous and the flowers come in most instances four on a stem, the latter being very long and stout. It is a grand variety, both

SWEET PEAS. (Reproduced from a photograph sent by a reader.)

Such selection must, however, be a purely arbitrary one, and only an index of personal opinion, for probably no two experts could be found who would agree as to all the varieties which should make up the dozen. The twelve varieties depicted on the accompanying coloured plate are not, therefore, put forward as the best dozen, either for the garden or for exhibition; but every one is in the very front rank in its colour, and it would be difficult to find another twelve to beat them. With the exception of St. George most are comparative veterans—that is as Sweet Peas go—so that the bulk of them are inexpensive.

such a rival as Helen Lewis on its *début*, for the latter has undoubtedly kept it off many show-boards.

*Helen Lewis.*—Since its somewhat sensational introduction this has reigned as queen among the orange shades, and an interesting fight for supremacy may be looked to between it and St. George. Originally known as Orange Countess, Helen Lewis has also been unfortunate in its treatment by some of the trade growers, at least three distinct stocks, two of them very inferior, having been placed on the market. Despite this, the variety occupies the highest possible position among exhibition Sweet Peas,

for exhibition and garden decoration, its colour and graceful outline appealing to most people. Some seem to think that Mrs. Charles Foster will supersede it, but this will not happen until the latter has become more fixed.

*Dorothy Eckford.*—Ever since its introduction this variety has reigned supreme as queen of the whites, and though its supremacy is at last threatened Dorothy is still far from being deposed. Its opponents' chief claims to favour are based upon the possession of a waved standard instead of the plain one that Dorothy sports, but neither Nora Unwin nor Etta Dyke has yet beaten it for purity and density of colour—if such a term be allowable in speaking of a white flower—and it is doubtful if the new white Spencer from America will be more successful. With extra good culture Dorothy Eckford will yield a proportion of four flowered sprays, and nothing better than these need be desired. As a garden variety it is probably the most generally useful of all Sweet Peas.

*John Ingman or George Herbert.* These two varieties are already bracketed by the National Sweet Pea Society as being too much alike, and there is not the least doubt in the minds of many good judges that they are absolutely synonymous. Certain it is that either has been shown as the other at some of the leading exhibitions in the land, and that without being detected; in fact, one may place the two in the hands of an expert and defy him to tell one from the other. John Ingman has become somewhat more notorious than George Herbert, simply because it has shown a greater tendency to sport, but the purchaser can buy either in the assurance that he is getting the same thing, that is, if he buys of a reputable dealer. By buying from a Mushroom firm it is possible to get a variety with a quite plain standard, whereas that of the real Simon Pure is delightfully waved.

*Mrs. Collier.*—This variety is the best representative of a little fable with which Sweet Pea growers amuse and deceive themselves. They fain would have a yellow Sweet Pea, therefore they call a cream a yellow, and put forward Mrs. Collier as the best realisation of their dreams. That it is the best of the so-called yellows that have been tried by the general public is not gainsaid, but that it is very far indeed from being a true yellow a glance at the illustration will show. There are several strains of it on the market, some of which have a tendency to produce an altogether unfair percentage of two-flowered sprays; but there are other strains which will give a fair proportion of fours, and thus it is again a case of the best market being also the cheapest. At least three varieties are put forward as superior yellows this year, viz., Clara Curtis, Devonshire Cream and James Grieve, to say nothing of the American primrose Spencer, so that it looks as if the reign of Mrs. Collier is likely soon to end.

*Black Knight.*—This is an exhibitor's variety, pure and simple, for it produces quite a negligible effect in the garden, and finds little favour as a cut flower. It, however, makes a

decided change in the colour scheme of the Sweet Pea, and for that reason is worth growing. It is king in its class, having kept that position in spite of the challenge that the newer Black Michael threw out, and it scarcely seems likely that any of this year's novelties will supplant it, though at least one is expected to do so; Black Knight should still be included in every good-sized collection.

*Queen Alexandra.*—Last on the list here, but foremost in both the garden and the

A RARE SAGE (SALVIA DICHROA) IN DEVONSHIRE. (See page 76.)

show tent, is the variety that bears the name of our revered Queen. Judging from the extreme brilliancy of its colour it is just the flower that one would expect to burn in the sun, but it has an unblemished sunny weather reputation, and is one of the brightest of all garden decorative Sweet Peas. This year sees the advent of two new scarlets—and there are others in reserve—but whether they will oust the present favourite from pride of place time alone can tell; they will have to be extra good to do so, that much is certain.

E. J. CASTLE.

## THE NATIONAL SWEET PEA SOCIETY'S TRIALS AT READING.

THERE is no gainsaying the fact that the trials of standard varieties and novelties of Sweet Peas conducted by Mr. Charles W. Foster at the University College Gardens, Reading, last summer for the National Sweet Pea Society constituted the very best work that this popular and go-ahead society has ever done, and every true lover of this fragrant and beautiful annual will hail with satisfaction the statement that similar trials are to be conducted at the same place and under the same supervision again this year.

The thing that struck one most on the occasion of the visit of the members of the society was the uniform stage of development and the complete absence of disease. To get 310 groups of Sweet Peas practically all in their best flowering stage on a given date is a feat worthy of the supervisor, but to get them all to this stage without a trace of any fungoid disease in a wet season like that of last summer is still more wonderful, and proved beyond doubt that the society had secured the right man to conduct these trials.

Of the 310 groups a few were duplicates, i.e., there were two or more groups of a variety, and some of them were unnamed seedlings. Of these eighty-three were badly mixed, fifty-seven being named varieties and the remainder seedlings, some of them being so much mixed as to render it exceedingly difficult to determine which was supposed to be the variety. Some very good things were noticed among these mixtures, and providing they are fixed many of them will provide welcome additions to existing stocks. As one would naturally expect, the waved standard varieties were the worst so far as unfixedity was concerned, the majority of the mixed groups being of this type. Many of the pink varieties of this section were also too much alike, and it is satisfactory to note that the society has now published a list of too-much-alike varieties.

The groups of named varieties that were noted as being quite true numbered 126, some of these, however, being duplicates. In the unnamed seedlings some of the groups were true, but only one of these could be considered of exceptional merit, and this was very near an existing named variety. St. George, the silver medal variety, was in grand condition, and undoubtedly fully deserves the honour bestowed upon it. Eckford's strain of Helen Pierce was the only variety considered worthy of a first-class certificate, and this beautiful Sweet Pea is beyond doubt the best received from America.

The fact that the greater part of the expenses entailed in conducting these experiments were provided by voluntary contributions indicates fairly clearly a determination on the part of raisers and introducers of novelties to do all that is humanely possible to prevent these getting on the market until at least a very large percentage of a variety can be relied upon to come true.

F. W. H.

## ORCHIDS.

### A GOOD WINTER-FLOWERING ORCHID.

(*LÆLIA ANCEPS*.)

**L**ÆLIA ANCEPS and its varieties are very beautiful winter-flowering Orchids, and the white varieties, namely, *L. a. alba*, *Stella*, *Dawsoni*, *sanderiana*, *Hilli*, *Williamsii* and *Schröderæ* are most useful for decorative purposes during the dull period of the year. They are comparatively easy plants to cultivate, and flower satisfactorily every year when once their requirements are thoroughly understood and met. In most cases they will now have finished flowering for the season, and it is advisable to clean each plant thoroughly, as during this period they are often attacked with a soft white scale which will do serious injury to the resting buds unless exterminated. The proper time to repot or top-dress them is when new roots are being emitted from the last made pseudo-bulb. This usually takes place during the month of February.

#### SOIL AND POTTING.

The most suitable soil in which to grow them is probably *Osmunda* fibre cut into pieces about the size of an hen's egg, with some sphagnum moss worked in the surface during the process of potting. It is not necessary to pot up all the old back bulbs, if two or three are left behind the bud that will be quite sufficient. These back bulbs, if stock is required, should be potted firmly in well-drained pots, with a surfacing of sphagnum moss, and placed in a warm house and kept in a moist condition. They will soon commence to make new growth, and as soon as these appear they should be potted in the compost that is used for the old plants. Use pans without side holes for the plants that require repotting, press the soil firmly between and around the roots, and work in some bunches of living sphagnum on the surface, which should be just below the level of the rim of the pan. Do not disturb the old plants unless it is quite necessary; simply pick out some of the old material with a pointed stick from between the roots and replace it with fresh compost.

#### TREATMENT AFTER POTTING.

When the plants are newly potted much discretion is needed in watering the plants. If the soil is kept too wet the young roots, instead of penetrating the compost, will turn black at the tips, and the growth of the plants will be checked in consequence. All that is needed until the plants become established is sufficient root moisture to prevent shrivelling. When the young growths are making headway the supply of water should be gradually increased, and when the plants are in full growth a copious supply must be given. A night temperature of 55° to 60° is suitable, and they should be grown in full sun with abundance of atmospheric moisture and a free circulation of air.

W. H. PAGE.

### SWEET PEA "STREAK" DISEASE.

**W**HAT is this fell disease that has made its appearance among this beautiful annual during the last two or three seasons? A great deal of doubt seems to exist as to what it really is; but something must be done to check its ravages if Sweet Peas are to be cultivated as extensively as their many merits demand. I first noticed it two years ago, and last summer lost a row some 25 yards long through its agency. Portions of the plants examined microscopically revealed no

tangible traces of disease, and all efforts to check it were unavailing. The plants were exceedingly healthy until about a fortnight after flowering commenced, when the disease, or whatever it is, made its appearance. There can be no mistaking it when it does come, the first indications being a distortion of the top portion of the plant and the flowers coming streaked. After a few days the blooms refuse to more than partly open, and, finally, the buds drop off and the whole plant becomes more or less distorted and covered with brown streaks along the main stems.

Preventive and repressive measures taken were spraying with sulphide of potassium, Bordeaux mixture, dusting with flowers of sulphur and lime, and watering with nitrate of soda solution, the last named being resorted to as a stimulant to help, if possible, the plants to grow out of the attack. But, as previously stated, these efforts were quite useless, the plants sickening and dying off at the rate of several a day. I ought to have stated that cutting back

## THE ROSE GARDEN.

### TRELLISES FOR PROTECTION OF TENDER ROSES.

**I**N gardens that are not naturally sheltered it becomes necessary, if we would grow some Tea Roses of the choice but tender varieties, to protect them in some way against the cruel east and north winds, and it is quite possible to do this now without much artificial aid. The charming *wichuraiana* Roses adapt themselves so readily to any sort of training that we may quickly form natural screens with these Roses alone. A slight framework of stakes or Bamboo canes is all that would be required, because in two or three years the plants could be made almost to support themselves. A few Oak posts let into the ground at intervals of 8 feet or 10 feet and about two strands of stout wire stretched between would be another simple arrangement.

A BEAUTIFUL ORCHID (*LÆLIA ANCEPS*).

the plants as soon as the distorted tops were noticed was also done, but without any benefit resulting.

Twenty-five sorts, a yard of each, were lost in this way in about four weeks, standard varieties and novelties alike succumbing. I have heard it suggested that eelworm is responsible, and the disease has been described as *Peronospora vicie*. There may be some truth in the former, but the disease is quite distinct from *Peronospora*. Reports received from widely apart localities as to the ravages caused by this disease last summer prove that it is spreading rapidly, and at present growers seem quite unable to fight it with success. Most likely the National Sweet Pea Society will take it in hand during the coming season if it presents itself, which undoubtedly it will do; but whatever is done must be done promptly if we are to save this lovely flower from destruction. Possibly some reader has discovered a remedy; if so, a description will be welcomed by many lovers of the Sweet Pea.

F. W. HARVEY.

Now as to planting. Procure two year old own root plants if possible of such sorts as *Jersey Beauty*, *Gardenia*, *Alberic Barbier*, *Elisa Robichon*, *Edmund Proust*, *Lady Gay*, *Hiawatha*, *Dorothy Perkins* and *René André*, and plant them about 5 feet apart. The plants would have growths of about 4 feet to 5 feet long. These should not be cut back, but just trained horizontally or nearly so on to the sticks or wires.

If a taller screen is desired, train the Roses upright and allow them to reach the top and then fall over. For this purpose *Dorothy Perkins* would be splendid, and *Sweetheart* is another excellent sort especially for its foliage. Perhaps choicer Roses would be preferred from the Tea and Hybrid Tea sections; if so, a close-fitting trellis would be best, one that a basket-maker would provide. Such a trellis could be covered with Roses of semi-climbing growth, such as *Grüss an Teplitz*, *Gustave Regis*, *Gloire des Rosomanes*, *Frau Karl Druschki*, *Corallina* and the like.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**HARDY FRUIT.**—Although the period for planting is getting late, I have just prepared quarters for making the last planting of Raspberries. The youngest canes, *i.e.*, those of last season's development, are those that should be selected and planted in soil that has been deeply dug and well manured. Cut back the canes after planting to within a few inches of the soil, as this promotes strong growths subsequently. Gooseberry and Currant trees should have their pruning completed without delay. As a protection from injury by birds I have always found that a solution of lime and soot is an excellent expedient. My fruit tree borders are now receiving a top-dressing with decayed manure and good soil.

**Hardy Flower Garden.**—Herbaceous perennials may be divided. I prefer the late winter and early spring for this work better than any other time. Do not divide the old clumps carelessly, but take infinite pains to avoid damage to the plants. Many subjects will break up quite easily. A strong, sharp knife is very useful for this work, although I have seen plants chopped up into pieces of various sizes by the aid of a spade, but this method is not commendable. Early Sweet Peas may be assured by making a sowing forthwith. I always select a warm quarter of the garden where protection from north and east winds can be provided; these plants invariably do well then. Plant Anemones and roots of

Geraniums may be cut back at this season. From past experience I find that both these subjects do not object to being cut back hard; they invariably break away strongly afterwards. The beautiful *Agapanthus umbellatus* should be dealt with now. My rule is to repot well-rooted plants, using soil composed of two parts loam and one part leaf-mould, with sand in sufficient quantity to keep the soil open. Decayed manure may be used in place of leaf-mould if the latter is difficult to obtain. Young shoots forming at the base of flower-buds of Azaleas should be picked off; if allowed to remain they draw upon the resources of the buds and prevent them from fully developing. I am just potting up a batch of Tuberose (The Pearl), and am placing three tubers in each pot 6 inches in diameter. In adjusting them in position, the crown of each should be just above the soil, the latter comprising loam of a light and sandy character and leaf-mould in equal proportions.

**Chrysanthemums.**—This should be a busy period with these plants. I am now lifting and dividing the old plants of the outdoor border sorts; these in many instances break up quite easily. The divided pieces may be planted forthwith where they are to flower next autumn. Plant firmly, observing a distance between the plants of from 2 feet to 3 feet. Insert cuttings of the decorative *Chrysanthemums* as they can be acquired. Use light and sandy soil, and insert the cuttings around the inside edge of pots or in shallow boxes. Place these in the greenhouse, where they should root within a month. Young plants should be stood in frames to keep them sturdy, taking care, however, to afford protection against severe frosts.

**Roses.**—When the weather is favourable plant Roses without delay. The sooner planting is completed the better. A few new varieties and other interesting sorts I am planting in specially-prepared quarters. I never attempt to plant Roses unless the ground is free from frost. Do not be unduly anxious to prune Rosea, this work being best left another week or two. A few plants that I am growing in pots in the cool greenhouse are beginning to grow away nicely; these I am now watering more freely, and also syringing with tepid water on fine days. This I shall continue to do until the blooms expand.

**Window Gardening.**—The pretty white and blue *Campanulas*, so useful for basket-work, may be increased by means of cuttings. Young growths should be selected, and these inserted in soil of a light and sandy nature. Use pots of a convenient size. I make a small propagating frame by using a box 6 inches to 8 inches deep, covering this with sheets of glass and placing the box in a sunny window. *Genistae* and other spring-flowering plants may be stimulated by occasional waterings with manure water or weak doses of sulphate of ammonia. The Chinese *Primulae* as they go out of flower should be thrown away, as they are useless afterwards. *Hyacinths*, *Tulips*, *Narcissus* and other bulbous subjects that are making free growth should be brought to the light of the window without delay. See that the soil is kept moist.

**The Vegetable Garden.**—Plant early Potatoes forthwith. For this early planting I select the warmest border in the vegetable garden and plant when free from frost. Shallots may be still planted 6 inches to 9 inches apart in the rows, and in rows about 1 foot or rather more apart. Early Peas may be sown as soon as opportunity affords. Rhubarb is now giving

evidence of growth. That in the open may be forced by placing tubs, boxes, or any similar contrivance in an inverted position over the crowns, and the boxes covered in turn with long

2.—THE SAME PLANT AFTER FLOWERING.

stable litter. Other plants for later supplies should be mulched with decayed manure. I am just making a planting of Seakale and preparing quarters for Horseradish, which I am proceeding to plant forthwith.—D. B. C.

### INCREASING THE ARUM LILY.

THE Arum Lily, better known to botanists as *Richardia africana*, is one of the most popular of our greenhouse plants. This plant is also known as the Lily of the Nile, having been introduced into Europe from South Africa so long ago as 1687. It is a plant of comparatively easy culture when proper conditions are provided for it under glass. There are other species of this attractive plant, notably *R. elliotiana*, a plant producing lovely yellow flowers and having spotted leaves; *R. Pentlandi*, another yellow sort with green leaves; *R. albo-maculata*, white; and *R. hastata*, yellow and green. *R. africana* has given us one or two dwarf forms, each of which has smaller white flowers and dwarfer growth than that of the original. The plant figured here is a comparatively new dwarf white distributed by Mr. W. J. Godfrey of Exmouth a few years ago, and is regarded by many as an improvement on the original form. Fig. 1 represents a plant just coming into flower, with the flower-spathe partially developed, and as soon as the display is finished, in order to increase the number of plants, they will be divided in the manner described below.

### DIVIDING THE PLANTS.

The treatment of plants of the different species varies somewhat. For instance, the African sort, *R. africana*, and its smaller allies, generally speaking, are not divided until May, while those of the other species are better when divided and potted up in February. The variety illustrated here has been grown in a cool greenhouse all along, but, when accommodation in this glass

1.—PLANT OF DWARF ARUM LILY.

*Ranunculus* at this period; they do well in good open soil that has been enriched with well-decayed stable manure. Fork into the surface soil of the hardy flower border a good top-dressing of decayed manure.

**The Greenhouse.**—Tuberous-rooted *Begonias* should now be started into growth. I find that good and distinct colours of these plants give much satisfaction. The tubers may be encouraged into growth by placing them half their depth in a light and sandy compost in shallow boxes. Keep the soil just nicely moist. *Fuchsias* and

structure is inconvenient, the plants may be placed in a hot frame, or ordinary cold frame when all danger of frost is past. Assuming there is plenty of room in the cool greenhouse subsequent to the flowering period, we prefer to keep the plants there. Fig. 2 represents a plant turned out of its pot ready for division. It will be observed that it is well rooted, and will derive considerable benefit either by being transferred to a pot of larger size or by division of the roots for increasing the supply of plants. If growers prefer to repot the plants intact, it will be better to place those now growing in 6-inch pots into others 8 inches in diameter. Larger plants that are in 8-inch pots may be transferred to 10-inch pots, in which case they should ultimately make really noble specimens. Division is very easily done, and is achieved by simply using pressure with the thumbs and fingers, inserting the tips of the former well down into the crown of the plant. Each individual growth may be separated in this way. The character of the growths will be found to vary, some being much stronger than others.

Fig. 3 will serve to illustrate the character of the divided pieces. The plant in Fig. 2 has given us two strong pieces similar to the centre one in Fig. 3, as well as the two smaller pieces. These should be potted up singly into pots of a convenient size, this being determined by the quantity of roots adhering. In this instance the largest divided portion needed a 6-inch pot, the next a 5-inch pot, and the two smaller pieces

3.—A PLANT DIVIDED.

lift the plants and place them in pots, using soil of the kind already described. Subsequently place the plants in a cool greenhouse for a few weeks, later on giving them rather warmer quarters. Never let the plants suffer for want of water, and as the flower-spines are developed apply liquid manure repeatedly.

For early supplies of bloom plants should be grown entirely in pots. After gradually hardening them off in the early summer they should be transferred to pots of larger size, subsequently plunging these in the open garden where they are to remain during the summer months.

#### HOW TO PRUNE GOOSEBERRIES.

ALMOST every beginner in gardening will have a few bushes of this fine summer fruit in his or her garden, and with the advent of March comes the time for pruning, the work being left until then so that the operator may ascertain to what extent the birds have taken the buds and prune accordingly, first of all removing those shoots that have been rendered budless by these pests. At one time it was usual to prune for spurs, much the same as is now done with Red and White Currants, but this system has now fallen almost entirely into desuetude, the plan now adopted being to cut out all old worn-out shoots and prune back those formed last year to a plump bud situated on well-ripened wood.

Of course enough of the inner growths must be removed to render the centre of the bush open, and every shoot that is left should be far enough away from its neighbour to allow of the clenched fist being passed freely between them. Possibly the term "well-ripened" wood may need some explanation to beginners. If we examine a last year's shoot of a Gooseberry bush it is almost certain that we shall find at least several inches of wood at the top that is, to some extent, soft and pithy, and this is the portion that is not well ripened and must therefore be removed. Some varieties of Gooseberry, such as Warrington, have a pendulous habit, the ends of the growths reaching to the ground and even rooting there. In pruning these cut the shoots so that the portions remaining are clear of the soil by at least 6 inches, and always cut to a bud that is pointing in an upward direction. This may seem a waste of good material, but soiled Gooseberries, even when green, are of little use, and when ripe they are quite worthless. If cuttings are required, some of the best shoots may be utilised for this purpose, making them 12 inches long and taking out all the buds, except four or five at the top.

Insert them firmly, half their depth, in moderately light soil. This work is, however, much more successful if done during November. Collect and burn all prunings as soon as the work is finished, as the spines, if left lying about, render summer work among the bushes dangerous.

#### HOW TO GROW SINGLE DAHLIAS FROM SEED.

IN one season plants may be raised from seeds, which will bear flowers in great abundance. Not only are the plants of great value as border subjects, but the flowers are much prized for cutting for the filling of vases in the dwelling rooms. About twenty years ago I had a great deal to do with the raising and growing of single-flowered Dahlias, mainly for the supply of cut blooms for table decoration in the autumn. This work was carried out most extensively, and very few other kinds of flowers at that part of the year were as valuable. But since that period a wonderful advance has been made by hybridists in the raising of new and improved varieties, the colours of which are exquisite. The single Cactus Dahlia has now come to the front, and is a decided acquisition. From a single packet of seeds many and various are the colours of the flowers on the resultant plants. Every amateur who possesses ordinarily good garden soil can grow these Dahlias. He should

*Sow the Seeds at Once.*—Pots are better than boxes for raising the seedlings in. Procure some 6-inch pots and fill them three parts with good sandy loam and leaf-soil in equal proportions, and sow the seeds 1 inch apart, covering them a quarter of an inch deep. Place the seed vessels near hot-water pipes in a glass structure, or plunge them to their rims in a mild hot-bed. The seeds quickly germinate under these circumstances, and the seedlings must be judiciously exposed to the full light in order to obtain a sturdy stock. Put the young plants separately into small pots as soon as they have developed a pair of rough leaves, and harden them in a cool frame prior to planting in the open.

*Plants in the Open Border.*—Any open, sunny position in the garden will be suitable; but as the plants will continue to bear blooms late in the year it would be advisable to select a place near a sheltering wall or fence, or put out the plants in a block in a border where a temporary shelter may be erected over them when frosts come. All that is necessary to be done during the summer-time is to supply the roots with water in dry weather, and to stake and tie up the branches. AVON.

4.—STRONG DIVISIONS POTTED UP.

pots 3 inches in diameter. Fig. 4 and Fig. 5 represent the divided pieces potted up. The two larger pieces should make fine strong plants at an early date, but the smaller pieces will take much longer to evolve growths that will flower satisfactorily. For the repotting above referred to, use a compost made up of three parts good loam, one of well-rotted manure or good leaf-mould, and a fair quantity of coarse silver sand or road grit, all well mixed together. Always use clean pots and crocks, and see that the drainage is well arranged before filling in the soil.

#### PLANTING IN THE OPEN.

The original form of *R. africana*, as we have already suggested, should be divided in the middle of May and planted forthwith in the open garden. Give the divided portions a space 1 foot apart in rows about 2 feet asunder. In light soil deeply dig the ground, take out a trench as for Celery, and plant in this. The plant is a great lover of moisture, and needs the quarters prepared so that full advantage may be taken of the copious applications of water that must be applied during the summer months. In the late summer or early autumn, preferably September,

5.—WEAK DIVISIONS POTTED UP.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**MALMAISON CARNATIONS.**—Pot up now into the pots in which they are to bloom all the young stock; use good fibrous loam, leaf-soil, sharp silver sand and some Velthra at the same strength as the makers recommend. See that the pots are clean and well drained, and press the soil fairly firm. Give very little water till the roots have got hold of the new soil. Keep in a cool and airy house. Top-dress larger or older plants with some well-approved manure. Wood's is an excellent preparation, and, as the plants attain growth, a little feeding will be beneficial every week; little and often should be the rule. Stake and tie those throwing up flowers.

**Border Carnations.**—These should now be placed into the pots in which they are to flower; three plants in a 6-inch pot are advisable. These may be placed in a cool house or in airy frames. There are some excellent varieties among these, and colours which are much admired and prized after the majority of the Malmaisons are over.

**Winter-flowering Carnations.**—Those struck last month should now be potted singly and kept in a growing temperature, and those potted up singly in December will soon require to go into a 4½-inch size. Keep the growth free from aphids and thrip by syringing with weak insecticides occasionally. There are numerous varieties of these to select from.

**Bedding Plants** of the Geranium (*Pelargonium*) section should now be potted up singly and the points pinched out, so that they will make good bushy plants. Place them in a growing temperature and close to the glass. Put *Lobelias*, double and single, into heat and propagate as soon as sufficient growth has been made to get cuttings. They will strike very well in sand, when they should be put in boxes in some light soil, keeping them near the glass to prevent a drawn growth.

**Dahlias and Begonias** may be started if cuttings are required. Do not put them in strong heat to weaken; rather start early and keep just warm enough to induce growth, when some very strong cuttings will soon be obtainable. These will give more satisfaction than weak puny plants, and, as a word of caution, do not get forward more plants than can be accommodated properly. *Hippeastrums* will now be throwing up their flowers and should be given a little more warmth and be top-dressed. Soot water should also be given every now and again; this improves the foliage.

#### CONSERVATORY.

This should be gay at the present time. Keep the climbers well regulated and tied in such a way that they look as though they have not been tied. *Cobæa scandens* and *Taxonias* require a good deal of thinning, otherwise they will exclude the light to the detriment of other plants and also from the windows of the dwelling-rooms. Many climbers will now want top-dressing. *Camellias* should have copious supplies of manure water.

#### KITCHEN GARDEN.

**General Work.**—Early-sown Lettuce should be thinned out, and if necessary place the thinnings in other boxes for a succession. Plant more Potatoes in frames, also French Beans and Asparagus. All these little dainties are required and are expected. Keep up a good supply of Rhubarb, Chicory, Dandelion and Seakale. Sow Mustard and Cress twice weekly. Look over the autumn-sown Lettuce and repair

gaps if any, so that the spare seed-beds may be dug up. The same remark applies to Cabbage. More Mint and Tarragon should be placed in pots or boxes and in heat. Look over the stock of Cauliflower, and if there are many blanks sow at once in boxes or frames, with just sufficient heat in cold weather to keep frost away.

#### FRUIT HOUSES.

**Peaches and Nectarines.**—The process of disbudding will now require daily attention. Do not resort to too drastic methods. Good disbudding is the making of the trees, and also future crops. There is generally too many growths left, and these ultimately have to be cut away.

**Figs.**—These should now be tied, stopped and trained. Stop strong leads unless any vacant spaces require filling. Do not leave the shoots too close together. Well-exposed, short-jointed wood always bears the best fruits. Give plenty of moisture to large plants in small pots, and when the fruits are swelling give a top-dressing of cow manure and now and again some Le Fruitier.

**Vines.**—Continue to disbud and tie down as advised in last calendar, and take care that no plants interfere with the well-being of the Vines. See that the Muscat house border is moist now that the house is closed, and on fine days syringe the rods left and right with tepid water.

#### STOVE PLANTS AND PALMS.

Plants that require shifting into larger pots may be treated during the next week or two. Use good sweet soil, and if a plant is potted to stay in the pot a considerable time, good soil and good drainage are essential. Propagate anything useful—*Panicum*, *Isolepis*, *Gardenia*, *Ixoras*, *Crotons*, *Dracænas*, *Nepenthes*, &c. If propagated now good plants can be had for use in summer. Any small Palms that want potting on may be done now. Do not give too much root-room, only what is absolutely necessary: 3-inch, 4½-inch, 6-inch and 9½-inch pots are those more useful for house decorations. Palms if well managed can be kept in small pots a long time by the aid of stimulants skilfully administered.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**PITCHER PLANTS.**—Few plants are more interesting in a warm stove than *Nepenthes* or *Pitcher Plants*, and they are easily grown. Of course, they require attention to get perfect *Pitchers*, but in a warm stove they thrive well with the treatment given other fine foliage plants. At one time these plants were costly, but they are now very reasonable, and are readily increased. Now is the best time to make a start, and the best way is to grow them in baskets, as then they get the copious syringing so necessary in their culture. If grown in pots, which I do not advise, there must be ample drainage and the collar of the plant be raised well above the rim. I prefer shifting the plants every year to get healthy foliage. The soil for these plants cannot be too open. Turfy peat with the soil shaken out and some lumps of charcoal with potsherds are the principal materials, adding fresh sphagnum moss free from slugs to the upper portion. After potting they should be kept close and syringed three or four times a day, according to the weather. The temperature should not be allowed to fall below 65° at night, with 10° higher by day, with ample shade.

#### FRUITS UNDER GLASS.

**Strawberries in Pots.**—The earliest plants of such varieties as *La Grosse Sucrée* or *Vicomtesse Héricart de Thury* will now be swelling their fruits. Give liberal treatment as regards both the temperature and watering. It is always

important to gain as many days as one can, hence a few of the most forward ones can possibly be given a position upon a shelf in a vinery, early Melon pit or plant stove. Upon the first appearance of colouring guard against over-feeding, so as not to deteriorate the flavour. Continue to introduce into a growing temperature, steadily at first, fresh relays of plants, bearing in mind that a medium number at more frequent intervals is better than a larger quantity with a long time between the supplies.

#### HARDY FRUIT.

**Raspberries.**—Where these have not already received attention they should be taken in hand when all danger of severe frost is past. If grown in clumps, five canes will be sufficient to reserve for each, and these should be the best-ripened ones. Examine the stakes to see if they are sound; they are very liable to snap off close to the ground.

#### KITCHEN GARDEN.

**Rhubarb.**—It is now time to see about making fresh plantations, as the crowns of unprotected stools show signs of moving. The plant is a gross feeder, and does not suffer in any way from the roots being brought into direct contact with manure, provided this is not in too raw a state, so a rich pasture should be given both by digging in a good quantity of manure and by mulching after planting is finished. Three crowns will be sufficient to form a good stool, and these should be taken from the old plants with as many roots as possible. All growth must be allowed to remain on the plant for the first year at least, as this will tend to produce strong crowns.

#### FLOWER GARDEN.

**Bedding Pelargoniums.**—Where the staging arrangements of the houses available for working on a stock of bedding plants are good, the system of potting off the latter singly in small pots is the most satisfactory. This should now be carried out, dealing first with the strong-growing, green-leaved forms and then the weaker variegated ones. In some cases, however, pots are not so satisfactory as boxes. This is especially the case where the only houses at disposal are vineries and fruit houses without staging. Give the plants, after boxing or potting, a little extra warmth, such as may be found in a vinery recently started.

**Roses.**—Where protection has been lavishly applied the bulk of it had better be removed now. It is one thing to protect during weather of exceptional severity, and quite another to still afford the same when only normal cold exists. In the latter case we encourage premature growth, and this is almost certain to suffer later on. Even if the young growths do not exhibit signs of frost, the resulting blooms generally receive sufficient check to cause them to open into any but perfect specimens. T. B. FIELD.

(Gardener to Baroness Berners.)

*Ashwellthorpe, Norwich.*

## SWEET PEAS FOR TABLE DECORATIONS.

OF the numerous hardy flowers it is doubtful whether there is any subject that will compare with Sweet Peas for all forms of the floral decorator's art. What other hardy flower is there that has the combined good qualities of sweet fragrance and infinite variety of colour that is now represented in Sweet Peas of an up-to-date collection? Added to the foregoing charms, there is the pleasing character of the newer forms as represented in the waved or crinkled standards of Countess Spencer and its large and interesting progeny. So pleasingly diverse is this subject as a whole that only one conclusion regarding its

merits can be arrived at, and that is, that it is incomparable for decorative uses in a cut state. There may be other hardy subjects of a more showy character, such as the Shirley Poppies for instance; but extremely beautiful though they may be, they lose considerably in consequence of their want of fragrance and their comparatively short-lived experience.

When generously treated the Sweet Pea invariably responds most liberally with blossoms of good quality for several months. Although there are persons who are disposed to decry the demand for blooms of high quality for decorative uses, there can surely be but one opinion as to the relative value of good blooms and those of poor quality. Sweet Peas of high quality should be used for the adornment of our homes whenever possible, and those who desire to excel in this department should make a careful selection of varieties, so that the best and most distinct may always be available, and these in a wide range of colours. While we appreciate the indispensable character of self-coloured sorts, it should not be forgotten that there are several good bicolors and many beautifully shaded and tinted varieties that must be regarded as invaluable where these flowers are used pretty freely and where constant change in the character of the decorations is desired.

It should be remembered that there are Sweet Peas of certain distinct and pleasing tones of colour that are ideal for displays in the daytime, when the natural light enables them to charm us with the beauty of their character and grace. These same colours under artificial light are useless, and for decorations in the evening should be avoided. For this reason Sweet Peas of mauve and lavender colours and those of kindred shades should be used exclusively for decorations in the daylight. The richer colours, such as crimson, orange, salmon, scarlet, magenta, rose and carmine are ideal for decorations under artificial light, and they may, of course, be used for displays during the daytime also.

Generally speaking, the best effects are obtained by grouping flowers of one colour together. In this way we may have constant change in our colour schemes. Vases, bowls and table decorations arranged with Sweet Peas invariably make a beautiful display when confined to blooms of one colour. Seldom do we meet with pleasing contrasts or really interesting harmonies of colour in Sweet Peas. We have seen cream-coloured flowers contrasted with those of an orange or scarlet colour and the effect was fairly good. We have also seen the cream-coloured flowers associated with those of some of the mauve and lavender tones of colour somewhat effectively. Also some of the colours that are closely allied have been used in conjunction most effectively, and in this connexion it is a good rule to associate three or four tones of colour in proper sequence in order to make a really pretty display.

There is a tendency in most indoor decorations to crowd the Sweet Peas somewhat unduly, and in this way the beauty of the arrangement is spoiled. Each individual flower should be disposed in such a way that its stateliness and the beauty of its form may be truly exhibited, and this is only possible when the Sweet Peas are lightly arranged so that each spray of blossoms speaks for itself.

Foliage of the Sweet Pea is the best embellishment for all arrangements of Sweet Peas, flowers and little of this is really needed. There is a weakness with many exhibitors at our shows to use in association with the Sweet Peas Gypsophila (both annual and perennial sorts) somewhat freely. We have seen fairly good displays of this kind, but we much prefer to see the Sweet Peas alone when blooms of good quality can be obtained. Maidenhair and other Ferns are sometimes interspersed among the Sweet Pea blooms, but seldom is the effect pleasing or artistic, and the trailing fronds and growths of the different forms of the Asparagus are used for creating a so-called finish, but not always with satisfactory

results. If foliage other than the Sweet Pea be used, we prefer that of a hardy kind, using such material as the Hornbeam, the Thorns and similar subjects, which may be gathered in abundance from our hedgerows, and always with pleasing tones of buff and coppery colours, to say nothing of the dainty greenery seen in such material. Grasses may be employed most effectively if not used too freely. To simplify this matter of arranging the flowers pleasingly follow the very simple rules suggested above, and by avoiding the elaborate creations so often met with at the shows bring into effect something simple, bright and artistic.

D. B. CRANE.

## HARDY LADY'S SLIPPERS

(CYPRIPEDIUMS.)

(Continued from page 29.)

CYPRIPEDIUM MACRANTHON is a rare plant from the East. The flowers resemble those of *C. spectabile* in outline. The leaves and stems are comparatively slender and about a foot high. The flowers are generally borne in twos, and the petals, which are unusually broad, are somewhat hooded, having the appearance of being attached to the lip, which is spherical, less than an inch in diameter, and the expanded flower spans 4 inches across. The petals are purplish, variously marbled a darker shade, and the slipper varies from pale pink with crimson veining to a rich deep purple. It succeeds under conditions recommended for *C. californicum*.

*C. montanum*, known also as *C. occidentale*, is a pretty plant, quite easy to grow, and as effective as any of its group. Its stems are about a foot high and bear several flowers, the petals of which are twisted, purplish, and occasionally marbled at their bases. The slipper is white, shaped like that of *C. pubescens*, veined with pink externally and lined internally, about an inch in extreme length, but narrower than any others in proportion to its length. The flowers are pleasingly fragrant and very lasting, while the plants succeed in any ordinary loam. I have grown it well in places where Lily of the Valley thrives, and it is charming associated with Ferns in the cooler parts of rockeries. *C. montanum* does not appreciate peat, leaf-soil or much moisture, requiring nothing but the treatment one would give to *C. calceolus*. This species makes huge clumps in a wild state, and I have had specimens with thirty to forty flowering crowns on one plant.

*C. parviflorum* is a moisture-loving plant, preferring the cool banks of waterways and a root-run of peat and leaf-soil. It does not thrive in loam. The stems are about a foot high and they bear several flowers of dainty shape and bright colouring, the sepals and petals being of a ruddy brown and elegantly twisted; the slippers are golden yellow, spotted rosy carmine on the inside and elegantly poised so that the interior may be seen from above. The flowers are 4 inches to 5 inches across, but they do not appear so large, as the petals are narrow and drooping, and the slipper is contracted at the top, narrowing gradually to a sharp tip. The plant is not difficult to grow in the right place, but it is hopeless attempting its cultivation in dry, wind-swept gardens.

*C. pubescens* is a stately plant quite 2 feet high, bearing broad sheathing leaves of considerable substance and hairiness. The flowers are thrown high above the foliage and are somewhat nodding, the petals and sepals drooping, much twisted, coloured brown with yellowish veining and mottling. The slipper is yellow and very large, measuring more than 2 inches in length in some cases and quite half as broad, the petals falling on either side. One may regard this as the finest of the yellow-slippered group. The plant may be well grown in peat and leaf-soil on the banks of waterways in cool and sheltered places. The roots are very long, and the prolonged

growing point indicates association with sphagnum moss or similar growth in a wild state, and it is remarkable that plants partially submerged thrive best.

*C. spectabile* (the Moccasin Flower) is a vigorous plant with stout stems, hairy leaves and rounded flowers in twos, the petals of which are pale rose, the upper one hooded, the "wing" petals narrow and widely divergent. The lip is a rounded pouch coloured pale pink, rose or deep purple in various specimens and quite an inch across. It succeeds under treatment advised for *C. parviflorum* and *pubescens*. This plant is becoming very scarce in its native habitats, hence every effort should be put forth to keep existing plants in good condition. An annual mulch of leaf-soil or manure and peat is of use in winter, the plant's direction of growth being towards the surface.

M.

## THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### A BEAUTIFUL VARIETY OF BEGONIA GLOIRE DE LORRAINE.

We have received from Mr. H. Dudderidge, the Dorset Nurseries, Blandford, a handful of blooms of a splendid form of *Begonia Gloire de Lorraine*. Concerning it, our correspondent writes: "This sported from the old variety about three years since. I worked up a stock of it and sent it out last year under the name of The King. The flowers are double the size of the old variety, and of a deeper and richer shade of pink." These remarks are fully borne out by the specimens sent, and such a superior form as this should ere long quite supersede the type. At the same time, we have seen other sports showing a great improvement on *Gloire de Lorraine* itself, but their relative merits could only be determined by actual comparison. Still, the great beauty of the flowers sent made a considerable impression on us, and we anticipate a great future for it.

### AN APPLE GROWN IN 1906.

Mr. J. Everard, The Mount Gardens, Wadhurst, Sussex, writes as follows: "I am sending for your table an Apple grown in 1906, and gathered in October of that year. The same fruit you made a note of in THE GARDEN for July 20, 1907, 'Editor's Table.' The other Apples are known locally as Wadhurst Pippin. The trees of this variety bore a fair crop last year, when all the others were practically failures."

[A remarkable Apple, named by our correspondent Easter Crab. Although somewhat shrivelled, it is quite sound, and looks like keeping for some time yet.—ED.]

### NARCISSUS GOLDEN SPUR.

An anonymous correspondent sends us flowers of this old but beautiful Daffodil. Their letter reads as follows: "I am sending you a few flowers of *Narcissus Golden Spur* for your table, and I hope they will be acceptable. They have been grown in a 5-inch pot and have had rather warm treatment during the past three weeks, as they were required in a hurry for a special purpose. I consider this to be still the best of the trumpet section for early pot work. As you will see the flowers are of excellent size and substance."

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Growing Sweet Peas on a border facing north (J. M.).**—You omit to state the width of your border, which is important. Providing it is 4 feet wide and that the Ivy on the paled fence is thin enough to allow some light to filter through we think you could successfully grow Sweet Peas on the border, especially if the summer is a very hot and sunny one. You must, of course, cut the roots of the Ivy within 1 foot of the fence, else they will take the food from the soil that is intended for the Sweet Peas. Plants raised in pots would be best; failing these do not sow seeds in such a position until the end of the third week in March.

**About planting Lilies (Rus in Urbe).** We advise you to plant your Lilies in clumps, placing three bulbs 1 foot apart, so as to form a triangle. *L. tigrinum splendens* would do well in an open space among shrubs, providing the latter were not more than 3 feet 6 inches high. The slight shade provided by the shrubs would prove beneficial. *L. speciosum rubrum* is a comparatively dwarf-growing variety and would do well in your border. When planting dig out a hole 6 inches deep, place an inch thick layer of sand in the bottom and stand the bulbs on this. Then place more sand round and over the bulbs and fill up with soil. Any manure used should not come into actual contact with the bulbs. We have seen both these Lilies doing well in London gardens.

**Probable cause of Sweet Pea buds dropping (Pan).**—As your plants were growing strongly and were quite healthy it is evident that disease was not the cause of the buds dropping. This trouble was very prevalent last season and was almost certainly a result of the very dull and wet weather. The fact that your soil is of a heavy retentive nature would make matters worse. It may be, too, that you fed the plants too frequently and heavily, but on this point you give no particulars. You have done quite right in draining the site, and if you well trench it and mix with the upper 12 inches any material such as road scrapings, burnt soil, wood ashes, old mortar rubbish and old hot-bed manure this will greatly improve it. Given more favourable weather this summer and provided you do not overfeed your plants you should have better results.

**Plants for border (Captain E. F. O.).**—We think the following perennials will be suitable: *Adonis vernalis*, *A. amurensis*, *Achillea alpina*, *Megasea cordifolia purpurea*, *Polemonium Richardsonii*, *Onosma taurica*, *Lychnis Viscaria rubra* pl., *Hepaticas* in variety, *Primula Sieboldi* in variety, *Inula glandulosa*, *Incarvillea Delavayi*, *Geum Heldreichii*, *G. minimum*, *Gypsophila paniculata* fl. pl., *Helenium pumilum*, *H. cupreum*, *Pyrethrum Pericles*, *P. Hamlet*, *P. James Kelway*, *P. Mrs. Bateman Brown*, *Dodecatheon Meadia*, *D. Jeffreyanum*, *Scabiosa caucasica* and *c. alba*, *Rudbeckia Newmanii*, *Eryngium olivarianum*, *Aster amellus Riverslea*, *A. a. Perry's Favourite*, *Campanula muralis*, *C. G. P. Wilson*, *C. carpatia Riverslea*, *C. Hendersonii*, *Aster subcaeruleus*, *Hybrid Columbianus*, *Erigeron speciosus*, *Achillea mongolica*, *Aster aeris*, *Stokesia Cynacea piceox*, *Heuchera sanguinea*, *H. Rosamunda*, *Heuchera cordifolia*, *Delphinium Escholtziana*,

*Thalictrum aquilegifolium* and *T. a. purpureum*. Annuals: *Godetias*, *Antirrhinums*, *Linum grandiflorum*, *Chrysanthemum coronarium*, *C. carinatum* vars., *Dianthus Heddewigii*, *Nemophila insignis*, *Eschscholtzia* in variety and *Candytuft*.

**Improving the soil in a herbaceous border (B. M., Farringdon).**—The soil in your border can be improved by mixing with it old hot-bed or other well-decayed manure, road scrapings, wood ashes, burnt earth or sand. Spread each or all on the surface and fork them in between the plants. Leaf-soil, too, if available, would greatly assist in rendering the soil more workable.

**Sweet Williams gone wrong (Lady H.).**—Your Sweet William plants seem to have suffered from the attack of a fungus, a species of *Septoria*, and from frost. There is no cure for the former, but spraying with sulphide of potassium, a quarter of an ounce to a gallon of water, will prevent it from spreading. I should destroy all the most diseased plants and spray the others three times, with intervals of a week.—G. S. S.

### TREES AND SHRUBS.

**Plants in shade under trees (Liberty).**—Very few plants will prove satisfactory under the shade of trees, and none that belong to what must be regarded as the summer-flowering class are likely to succeed. Both the major and minor Periwinkles are extremely useful for furnishing the ground underneath trees, and the Ivy, in its different varieties, as well as *Eutonymus radicans variegata* are among the best of plants for the purpose. Other subjects that do fairly well if the shade is not too dense are *Berberis Aquifolium*, *Aucubas*, *St. John's Wort* (*Hypericum calycinum*), *Gaultheria Shallon*, *Butcher's Broom* and *Cotoneaster microphylla*.

**A pleached alley (A. M. B.).**—As the Hornbeam trees are young there should be no difficulty in bending over the tops to the required height. This must be done as soon as possible, certainly before the young leaves appear. The trees opposite one another should be bent over at the same time, and tied in such a manner that they will eventually form a perfect canopy. Occasional attention in the matter is needed throughout the year, as a few shoots are always apt to get out of bounds. We do not know of any book dealing with this special subject.

**Trees and shrubs for a wood (W. B.).**—The number of trees and shrubs likely to thrive under the conditions named are decidedly limited in number, but we think the following will suit your purpose: *Berberis Aquifolium* and *B. vulgaris*, *Cotoneasters* of sorts, especially *C. microphylla*, *Butcher's Broom*, *Bladder Senna* (*Colutea arborescens*), *Hawthorn* (*Crataegus Oxyacantha*), *Ivies*, *St. John's Wort* (*Hypericum calycinum*), *Periwinkles*, *Blackthorn* or *Sloe*, *Brooms*, *Rosa rugosa*, *Symphoricarpos racemosus* (Snowberry), *Caragana arborescens*, *Cornus alba* (Dogwood), *Lycium europaeum*, *Rhus Cotinus*, *Robinia Pseud-acacia* in variety and the double-flowered *Furze*. Of flowering plants to take the place of those named by you, we know places where the Bluebell flourishes in dry woods, and think you would find that satisfactory as well as the *Winter Aconite*. The *Solomon's Seal* also does well in shade. In fairly sunny glades the *Marigolds* and *Eschscholtzias* will supply a welcome bit of colour, and will flower all the better if the soil is dry. The *British Woodruff* is another subject likely to give satisfaction.

### THE GREENHOUSE.

**Raising perpetual-flowering Carnations from seed (J. D.).**—The present is an excellent time for sowing the seeds. Use clean  $\frac{1}{4}$ -inch pots, thoroughly draining them, and use soil composed of two parts good loam, half part sand and half part burnt garden refuse or soil. Sift the mixture through a fine-meshed sieve, then half fill the pots with the rough material and finish off to within three-quarters of an inch of the brim with the fine portion, making the whole reasonably firm. Scatter the seeds on this thinly and then cover them with about a quarter of an inch of fine soil, pressing this slightly down, giving a watering with a fine rosed can. Cover each pot with a pane of glass, or place a sheet of brown paper over several, and stand them in a temperature of 48° to 55°. When the seedlings appear, remove the glass or paper promptly and place the pots near the glass. As soon as they are large enough to handle pot each seedling into a  $\frac{1}{2}$ -inch pot and then treat as you would rooted cuttings. The main point to note is to avoid coddling; plenty of fresh air is what all Carnations delight in.

**Ivy-leaved Geraniums gone wrong (T. H.).**—There is no sign of any fungus on your Ivy-leaved Geraniums. From the appearance of the leaves I should imagine that they have been kept in too damp and close an atmosphere.—G. S. S.

**Greenhouse plants attacked by caterpillars (E. R. H. W.).**—From your description I imagine that your plants are attacked in the summer by the caterpillars of the small white butterfly (*Pieris rapae*); but there are so many green caterpillars that it is impossible to name them accurately without seeing them. Please send a few specimens next summer, and I will gladly name them.—G. S. S.

**Lilies in fibre for church work (W.).**—If, as we surmise, the scarlet-flowered forms would be required for the great festivals of Whitsun and Christmas, we may say at once that we fear there is no Lily to answer your purpose. The scarlet colour most freely employed at Christmas-time is the *Poinsettia*, and the scarlet double-flowered *Pelargonium* at Whitsuntide. It would not be practicable to grow either of these in the fibre. There are reddish-flowered forms—shades between crimson and carmine with purple-red in minor degree—in the varieties of *Lilium speciosum*, but these would hardly meet the case. A good scarlet-flowered Lily is *L. pomponium verum*, which would require forcing for the earlier-named festival, but it is not one we can recommend for the purpose. Your ideal variety, the white *Madonna*, is unique, and the only other white varieties suitable are the well-known *Easter Bermuda Lily*, *L. longiflorum* variety and *L. speciosum Kratzeri*. Either of these would be valuable for your purpose, but the taller growth of the latter, 3 feet or more, would hardly find sufficient support in the fibre to bring it to perfection. The other Lily is about 2 feet in height, and, forced in a moist, warm temperature, may respond fairly well to the suggested treatment. The time of planting would depend upon the amount of artificial heat at your disposal and when the plants were required for use. For Easter work the bulbs would need planting in September, and from Christmas onwards forced along rather sharply. For the harvest festival season, say, September, dormant bulbs planted in March and April would answer if grown on naturally. In those instances where the plants require a long season of growth, a good soil mixture is the best. The *Madonna Lily*, flowering naturally in July, would need growing in a brisk forcing temperature to flower it at Whitsuntide, and the bulbs should be planted in autumn. For Easter, with little or no forcing, tall scarlet Tulips would be available, and these could be well grown in the fibre. With an earlier start, the red-flowered varieties of the *Darwin Tulip* would bloom, but these are not of the true scarlet shade of colour.

### FRUIT GARDEN.

**Pruning newly-planted young bush Apple trees (Rustic).**—We advise you to prune these at once. First remove any very thin inside shoots, then cut the laterals back to within two or three buds of their bases, taking care, of course, to leave any that are required to form main branches or leaders to fill up blank spaces. Any such shoots, and also the existing leaders, should be pruned back two-thirds of their present length, so that one-third only is left. This will induce them to break away strongly in the spring. In pruning these, take care to cut to a plump wood bud that is pointing as near as possible in the direction the future shoot is required.

**Pruning Gooseberry bushes (Redlands).**—If you have not had your Gooseberry bushes pruned this winter, and we hope not, then all you have to do is to shorten back their long shoots of last season just one-third their length, that is, leaving 20 inches of shoots in each case, also cutting back to two buds all inner or weaker shoots breaking from the main branches. Your pruner of last spring seems not to have known that Gooseberry bushes bear most of their fruit on the shoots made the previous year. If the long shoots on yours be well ripened or hard, and you leave two-thirds of their length on each, you should have a fine crop of berries next summer. Their hard pruning last spring naturally forced them to make strong shoots, not, in consequence, producing fruit.

### KITCHEN GARDEN.

**Applying salt to Asparagus beds (H. T.).**—We presume that each bed is 18 yards by 2 yards, and for each a good dressing would be 18 lb. of common salt or  $\frac{1}{2}$  lb. per square yard. The time to apply this is April, but we do not advise it unless the soil is of a fairly porous nature. On heavy, retentive ground, which in itself is unsuitable for Asparagus, salt would probably do more harm than good. Salt is one of the easiest things to procure, and any grocer worthy of his salt would supply you with as much as you require.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

## BEAUTIFUL ANNUALS FOR BEDS & BORDERS.

### HOW TO GROW THEM.

RECENT years have seen a great advance in the popularity of annual flowers of all sorts, and this is largely due to the attention that they have received from the nurserymen or raisers ; but they are still very far from having their merits properly recognised, excepting that queen of annuals, the Sweet Pea. That all are as beautiful and adaptable as the Sweet Pea cannot be truthfully urged, but it can be certainly said that a garden may be made extremely attractive for many months of the year by the use of annuals alone.

Nor is this wealth of floral beauty confined to the individual who possesses a greenhouse, for there is a wide choice of quite hardy annuals, while all of those which are called half-hardy or semi-tender can be raised in the open garden quite easily. It is true that it is necessary to wait for comparatively warm weather before sowing of the latter can be safely undertaken outdoors, and this delay in sowing means a delay in flowering, but not by any means a delay that will prevent the plants from blooming well the first season. With the fine and mild autumns which we now get so regularly, this very lateness of flowering is an advantage, for plants last much longer in the comparatively cool conditions of autumn, and one must not overlook the fact that one of the chief legitimate grievances against annuals is their rather brief flowering season.

The shortness of the flowering season is, however, grossly exaggerated in many cases, for there are, at least, some annuals which last in bloom as long as any flower found in the garden. If any one doubts the accuracy of this statement let him carefully raise and put out plants of the dwarf Alyssum called Thorburn's Bouquet, and they will be found to be covered with bloom from the time that they are about as large as a crown piece until a really severe frost puts an end to them. In sheltered places it is not unusual to find this plant in flower at Christmas. Cultural matters have far more to do with the longevity of annuals than many folks suppose, and the capabilities of a well tended bed or border will often surprise even the expert gardener.

### HOW TO RAISE HALF-HARDY ANNUALS.

Shallow pans are best for raising these. They should be washed clean and dried before using, a dirty or wet pan often being responsible for disasters at pricking out time. After arranging a layer of drainage material in the bottom of each pan, it should be filled to within an inch of

the brim with light, sandy soil ; loam and leaf-mould in equal parts, and half a part of coarse sand make a good mixture for raising seedlings. All the fine seeds should be mixed with silver sand before sowing, as this enables an equal distribution to be made ; such seeds will need no further covering, but they may be pressed into the soil with the bottom of another pan. When large enough to handle, the seed should always be placed in position in the pans, giving each seed from half an inch to 1 inch of space, according to its size and also the size of its seed leaves. A layer of half sand and half soil should be scattered over all large seeds to a depth of not more than half an inch.

Sowing finished, cover each pan with a pane of glass to check evaporation, or stand the pans on top of each other, first, however, gently immersing the pans in a tub of tepid water. Stand them in a warm, moist corner of the greenhouse, and examine them daily after they have been sown a week to see if any of the seeds are showing signs of life. As soon as the first few green shoots break through the soil remove the upper pans from off those below ; if glass is used, it should be removed almost as early, as it is not wise to weaken the young plants by keeping them too confined. Gradually accustom them to the full light and plenty of air, and before they commence to crowd each other, prick them off into other pans or boxes. A light soil should still be used, and a layer of sand on the surface of the soil given to the more tender sorts, such as the Ten-week Stock, Portulacas, Petunias and others which have a tendency to rot off at the soil line. As a general rule, 2 inches between the young plants should be allowed at the pricking-off stage.

Shading must follow pricking off, and the syringe will be found useful in assisting re-establishment, but it must be used very gently and so that its spray falls in a fine shower. When the plants are able to hold up their heads without shading, gradually inure them to cooler quarters, and eventually place them in a cold frame, where they should receive more and more air until they are planted out at the end of May.

### TWELVE BEAUTIFUL HALF-HARDY ANNUALS.

Arctotis grandis, white with blue disc, 2 feet ; Asters Ostrich Plume and Ray ; Brachycome iberidifolia (Swan River Daisy), various colours, 12 inches ; Martynia fragrans, purple, as handsome as a Gloxinia, 18 inches ; Nemesis Strumosa Suttonii, the large-flowered strain, various colours 15 inches ; Nicotiana Sanderae, various colours, 3 feet ; Hibiscus Manihot, sulphur with a large dark eye, a beauty, 18 inches ; Layia

elegans, yellow and white, 12 inches; *Portulaca grandiflora Thellusonii*, orange scarlet, a plant for a hot dry place where nothing else will grow; *Phlox Drummondii*, many colours, 9 inches to 18 inches; *Salpiglossis grandiflora*, various colours, very attractive, 2 feet; and *Venidium calendulaceum*, orange and yellow, one of the very best, 1 foot. The above only give a brief idea of the numbers of these lovely flowers.

## FORCED DAFFODILS.

AMONG the large number of beautiful and varied exhibits before the Royal Horticultural Society on the 11th inst. there was a small group of some eleven varieties of Daffodils at the end of Messrs. Barr and Sons' stage. They were interesting in many ways.

Naturally, first to the specialist, who is only human after all, and is always glad to welcome the return of his favourites to the floral world. Certainly a great enthusiast did say to me, "Quite out of character," and rather held up his head in disdain. He was in a measure right, because they were not up to what they would have been had they been grown under natural conditions in the open; but it is a gain to a vast number of flower-lovers to be able to get them so early in the year. Hence, secondly, the general public must have been interested, because it showed them what it was possible to produce under good conditions of forcing. The little collection was a varied one. They were able to see not only Golden Spur, but others of quite a different type, notably: *Artemis*, a medium-sized incomparabilis, with a white, well-formed perianth and spreading yellow cup, after the style of Princess Mary; *Magpie*, a butterfly-looking Leedsii, with a reflexed white perianth of good substance and a yellow cup; *Outpost*, a fine early big trumpet with Emperor colouring, but more like *Glory of Leiden* in shape; and *Gold Cup*, a very beautiful yellow self of quite a Tenby shape, but altogether a larger flower. These two last are undoubtedly fine things, and some day, if they show themselves to be of good growth and increase well, may come into the market; at present, I believe, the stocks are not for sale.

Thirdly, the flower-growers had an object-lesson as to the direction in which they might grow something to give the flower-buyers a little variety. The shows of the Royal Horticultural Society have rightly a distinctly financial side. Without the stimulus of acquiring money much that is accomplished would be left undone. If this little collection did nothing more, it must have made those who force early Daffodils think.

The following is a list of the varieties exhibited: *Outpost* (described above); *Magpie* (described above); *Coronatus*, an all yellow *Outpost*, trumpet shortish, perianth broad and spreading; *Princess Ida*, forced it comes practically white; *Santa Maria*, a large yellow trumpet self, distinguished by its narrow twisted perianth; *Golden Spur*, large yellow self; *Gold Cup* (described above); *Excelsior*, a yellow self, with a very deep shade in the trumpet; *Cabeceiras*, a sort of bicolor, the narrow perianth is so very light in colour; *Maximus*, a deep yellow self; and *Artemis* (described above).

JOSEPH JACOB.

## FORTHCOMING EVENTS.

March 3.—Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster, 1 p.m. to 6 p.m. Lecture at three o'clock on "Bulbous Plants in New Zealand," by Mr. E. White.

March 5 and 6.—Royal Horticultural Society's Colonial Fruit Show.

March 9.—United Horticultural Benefit and Provident Society's Annual General Meeting.

March 11.—East Anglian Horticultural Club Meeting.

## NOTES OF THE WEEK.

### Royal Horticultural Society's Book of Arrangements for 1908.

This publication is issued annually by the society, and proves exceedingly useful, as it contains particulars of the various meetings and exhibitions to be held by the society during the year. On March 31 the Royal Dutch Bulb Growers' Society of Haarlem offer cash prizes for forced Hyacinths, to be shown at the society's meeting. April 14 will be Daffodil day, a 7-guinea silver vase being offered by Messrs. Barr and Sons. May 26, 27 and 28 are the dates of the Temple Show, which is to be held as usual in the Inner Temple Gardens, Thames Embankment. Fellows only will be admitted on the second day from 7 a.m. till noon, this being a new rule made so that Fellows may enjoy a "private" view of the show. The public will be admitted by purchased tickets on May 26, from 12 noon to 7 p.m.; on May 27 from 12 noon to 7 p.m.; and on May 28 from 9 a.m. to 6 p.m. The Veitchian Cup is again offered to amateurs. The great summer show is to be held as usual in the beautiful grounds of Holland House, Kensington, on July 7 and 8. The Sherwood Cup is offered at this show for twenty-four bunches of Roses, with their own foliage, shown in vases by amateurs. The exhibition of British-grown fruits is to be held at Westminster on October 15 and 16, and at noon on the second day Miss Edith Bradley will give a demonstration in fruit bottling.

**Commercial botany.**—The busy centres of commerce, such as the great docks of London, Liverpool and Bristol, or the commercial salerooms in the City of London, would appear to be scarcely the places where a gardener or any lover of plants would find much to interest them in their own particular line; but that there is a closer connexion between a garden and a commercial saleroom than one at first imagines is fully realised when we remember the intimate relations and co-operation that exists between the Royal Gardens at Kew and the centres of British and Colonial commerce. It often occurs that some product unknown to the commercial man finds its way to the produce broker, and is put upon the market for the purpose of testing its value; but a knowledge of its botanical source and relationship with other well-known plant products considerably helps to determine its properties and value, and for the botanical determination of the plant producing the new product the aid of Kew is frequently requisitioned. Quite recently, at one of the drug auctions in Mincing Lane, one bag of about 11lb. weight of seeds, quite unknown to many frequenters, were offered for sale; they proved to be those of the Cedron tree (*Simaba Cedron*), belonging to the Natural Order Simarubaceæ and native of New Granada. The genus *Simaba* is comprised of about fourteen species, all of them trees or shrubs of South America. Very few of them have been introduced, but the species in question was sent to Kew so long ago as 1846, and is probably the only one in cultivation. It is a small tree about 15 feet to 20 feet high, bearing racemes of flowers from 3 feet to 4 feet long and fruits about the size of a swan's egg. One seed alone is developed, having the appearance of a very large Almond. The interest in the plant lies in the seeds, to which remarkable properties have been attributed, both for the cure of snake-bites by the natives and as a remedy in fevers, owing to its intensely bitter taste, which, as is well known, is the distinguishing character of the Order, the Quassia being the most familiar example among gardeners. In 1850 the Cedron was first brought to notice in this country as a medicine, and in 1884 it was again recommended as a febrifuge and for the cure of toothache. As a remedy for the bites of snakes, scorpions, centipedes, &c., its use by the Indians dates from time immemorial, and for this purpose a small portion of the seed mixed with water is

applied to the wound, and about two grains scraped into brandy is given internally. It was not stated whether the seeds offered for sale on January 16 were quite dried, or whether they retained any vitality so that they might be utilised for raising plants.—JOHN R. JACKSON, *Claremont, Lympstone, Devon.*

**The protection of flowers.**—A Bill to be brought before Parliament shortly provides that any person stealing, destroying, or damaging with intent to steal any plant, root, fruit, flower, or vegetable product having a market value and growing in any cultivated or enclosed land or in the hedge or bank bounding any such land shall be guilty of larceny. Hitherto only gardens and such places have been protected from the plant-stealer. A clause is included in the Bill to protect persons from prosecution for plucking wild fruits and flowers growing by the roadside.

**A new Potato.**—As all vegetable growers know, the Potato weakens, and new varieties are necessary at times. Wythes' Bountiful, sent out by Messrs. Cutbush, Highgate, may with advantage be given a trial by those who esteem Potatoes of the best quality. This was raised with other seedlings some years ago by Mr. Wythes and was considered of such good quality that it was kept for stock. It has a rough-skinned flattish or pebble-shaped tuber, and when cooked is white and floury. It is early and a free grower. In the trials by the Royal Horticultural Society it was given three crosses for crop and quality. Last season the tubers were free from disease.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Variegated Kales.**—While the variations in form of leaf as well as colour found in curled Kales are to the plant physiologist interesting, the various variegated forms, though when seen under favourable conditions are pretty, have no edible value, and if employed in flower garden decoration seem to be sadly out of place. There have been in curled Kales marked and very excellent improvements during the past twenty years, as the trial on a large scale at Wisley in 1906 evidenced. Then both of tall and dwarf, green and purple tinted, the forms seen were of great excellence and many of considerable massiveness, enhancing their value for ordinary edible purposes materially. There were in that trial a few of the variegated or fancy coloured strains, but even in so open and comparatively smokeless district as Wisley is, when the breadth was seen by the vegetable committee of the Royal Horticultural Society these forms obtained no admiration; indeed, they seemed to be very much out of place. Of what may be regarded as members of ordinary garden vegetables, efforts in the past to utilise them in flower gardens for so-called decorative purposes have been limited to Beets and Kales. These efforts, however, have had little success. Certainly, were these products seen in any flower garden now, they would cause smiles of contemptuous derision to rise on the faces of critics. When the late venerated Dean Hole once declared that passing from a florid parterre flower garden to the vegetable garden he gladly rested his eyes on the cool leafage of Parsley, he was but emphasising his dislike of crude burning colouration as once seen and still may be seen in flower gardens where such crude arrangements prevail. But such gaudy tints were not obtained from ordinary variegated vegetables. Still less is the far more subdued yet much more pleasing flower garden decoration of to-day.—A. D.

**Manuring Roses.**—In THE GARDEN of the 8th inst. I see that your contributor "Q." states that "6 inches or 9 inches of manure" forces Roses on only to have them nipped by late

frosts. If he dresses two beds, one with 6 inches or 9 inches of manure (wish I could give mine as much), the other bed lightly dressed, I think he will find that the lightly-dressed bed starts into growth first.—SYDNEY MARTIN.

**Dessert Apples for the Cotswolds.**—To those who have not already included Allington Pippin in their collection, I can very strongly recommend them to do so. I planted maidens of this Apple the year it was first offered to the public. The second year after planting these trees bore heavily and have continued to do so ever since. When I first tasted this grand Apple I must confess that I was rather disappointed with its flavour. This, however, has greatly improved as the trees have become older and have cropped so freely. I cannot honestly say that it is as good as one of its parents, viz., Cox's Orange Pippin, but to-day those we have in the fruit-room are quite the best-flavoured Apples left; in fact, it is delicious, and in my opinion should not be eaten before this date. It will keep for another two months, and even longer than this, in a proper fruit store. I think this variety should be worked on the seedling Apple stock in order to give it vigour. There will be no question about its cropping freely and regularly. Thinning the Apples will well repay the trouble; in fact, it is a necessity if good-sized fruit is desired. "H. R." also mentions James Grieve as a good early sort, which it certainly is. I do not know a better, and such a prolific bearer too.—T. A.

**Scab in Potatoes.**—In the issue of THE GARDEN of the 25th ult., there appears an article respecting scab in Potatoes. As I used to be troubled in that way, perhaps a few remarks on how I dealt with the disease may not come amiss, more especially as my remedy comes under the category of those substances mentioned in the article as being likely to be the cause. I always give a good dressing of lime in the drills immediately before placing the sets. If this remedy does not prevent scab, I am absolutely convinced that it does not cause it. I have used quick-lime in the drills, and on taking up the tubers found them completely covered with lime with no ill results. I have recommended lime to my neighbours, who, without exception, have found it a most safe cure. I may be wrong in my remedy, but here is the result since using the same: Thirteen first prizes and one second in fifteen entries, no other classes being open to me. A representative of a well-known Scotch firm, referring to my exhibits last year, said: "I would not have believed that such Potatoes could be grown in England; I have never seen better staged and very few as good."—S. G. S.

**Promise of spring.**—I have a Hyacinth in an open bed in my garden that came into bloom on the 28th ult. It is not very tall yet, but the flower (single) is quite perfect and as large as when flowering in April. As the thermometer, a few feet from where it grows, registered 18° of frost for two nights not three weeks ago, and the flower-bed has no protection, the flower-stalk must have progressed rapidly. The bulb was planted early in October.—G. R. EGERTON, *Sussex*.

**Grape Appley Towers.**—With regard to this fine Grape, though I quite endorse all that your correspondent "E. H." writes in its favour, yet writing from my own experience of nearly ten years with this variety, I should hesitate to recommend it to an amateur, for two

main reasons—first, being such a vigorous grower, it requires much more room than any Grape I know; second, the laterals are the most brittle I have ever handled, the very greatest care and patience being required when tying them down. Even at midday on a bright sunny day, when Vine laterals are usually the most pliable, I have always found those of Appley Towers very stubborn. These are two points which I think every amateur has to give attention to when considering the question of Grape growing.—J. J., *Bryanston*.

**Introduction of the Malmalson Carnation.**—In answer to the query in THE GARDEN of the 1st inst. respecting the introduction into this country of the Malmalson Carnation, I write to say that in the year 1877 it was only to be found in the houses of the Bentinck family or their immediate friends, and I was always told by members of that family that some of them (I do not remember which) had brought it from Holland here. They thoroughly understood the art of growing it to perfection. They said that it required a cool greenhouse, and their

## THE FRUIT GARDEN.

### PLUM PONDS SEEDLING.

**T**HIS is one of the largest Plums grown, and on that account it is a favourite with both market growers and amateurs. In the southern parts of the country I have often seen it growing under the name of Fonthill Plum, and bearing remarkable crops; it is also known in some places as Pond's Purple. It is a cooking variety, is in season during September, and is much liked in the kitchen for its brisk flavour and good cooking qualities, for preserving and compotes. The fruits are oval, very large, with yellowish green flesh which adheres to the stone. When carefully gathered they keep good for some time if not too ripe. The tree is a good bearer and of rather spreading growth. Grown as a standard in a well drained or warm soil the fruits colour beautifully.

There are other varieties, such as Magnum Bonum, that are nearly as large, but I do not

A GOOD KEEPING PLUM: POND'S SEEDLING.

habit was to cut the blooms before they were quite out, bring them into the house and put them in water in a warm room. Then after a day or two the blooms would expand into an enormous size. Of late years I have never seen them so fine.—R. W.

**Carnation Winsor.**—Your correspondent "E. J.," on page 50, raises a question as to the correct spelling of the name of this Carnation; but perhaps he will tell us whether it is named after a man or woman, or after a town or district. In the former case it is quite probable that it is correct to spell it without the letter d; but if it is named after a town, village or district, which itself would in all probability be named after our own royal town of Windsor, then surely we are justified in spelling it thus. This mutilation of the English language by Americans reminds one of the schoolboy who proceeded to show his father how to plough, although the latter had been at ploughing more or less for well nigh half a century.—ANGLIAN.

think they equal Pond's Seedling in cropping, and the variety illustrated is one of the very best croppers we have. Some of the larger Plums are somewhat shy bearers, so that this variety is more valuable when grown for market. In Scotland I have seen some splendid crops of Pond's Seedling grown on south-west and west walls, and the fruits were enormous and of splendid colour. In most parts of the kingdom this variety makes a good standard, but should not be too much crowded. At the same time, if grown in a very exposed or windy place the fruits, owing to their size, suffer. I have grown it as a cordon, but do not advise it grown thus, as the hard stopping to keep the trees in shape checks the growth too much. Dwarf bushes give splendid results. G. WYTHES.

### THE OLD GREEN GAGE PLUM.

THE writer of the article on page 30 of THE GARDEN appears to have formed a very bad opinion of the cropping qualities of this Plum.

Standards and large bushes are more prolific in market gardens than in private ones. The soil contains less humus, consequently the growth is not so gross and more fruitful. Again, bullfinches and other bud-eating birds are all but exterminated where fruit is grown largely. I would also add that it is only rarely that a perfectly ripened fruit can be gathered from a standard or bush tree even in these southern counties. Before they reach that stage they are usually cracked and wasp eaten. Cracking is not so common when the crop is heavy, but the fruit lacks flavour.

Good crops of dessert fruit can be obtained with almost certainty if trees are trained against a wall facing to any point but north and pruned and trained in a certain manner. Spur-pruning as usually followed is useless. The wall space must be sufficient to allow the tree to extend 9 feet in each direction, and this is none too much. Trees that are more restricted need constant-root pruning and are never so satisfactory.

Drainage is usually provided when a garden is made, but if the ground is wet and heavy it may be supplemented by digging a trench 2 feet deep from the site of the tree to the nearest pipe drain, and if 6 inches of broken brick is placed in the bottom of the trench the water will percolate through it to the drain. The soil should be at least 18 inches deep, and if it grows ordinary vegetables well no other preparation is needed than digging it to its full depth in dry weather and mixing a barrowload of wood ashes and the same of mortar rubble (a bushel of lime may be substituted if the rubble is unobtainable) to every 4 square yards. Plant the trees rather high, and if growth is too gross lift every three years, adding more lime to the soil. It is, however, in

#### PRUNING AND TRAINING

that the greatest mistakes are commonly made. Gage Plums, and especially the Green Gage, will all flower profusely when spur-pruned, but seldom swell their fruits, which drop off at an early stage. Trees covered with blossom each spring, but bearing little or no fruit, are to be seen in many of the best gardens where spur-pruning is rigidly practised. I have for many years adopted a different method. In July all coarse shoots are cut out and a number of short, thin, wiry growths laid in. When pruning in winter these are retained as nearly as possible at their full length. All three year old wood not needed as main branches is cut out. The following summer the wiry shoots form numerous short fruiting spurs. If well ripened these invariably produce flowers which set freely, and the crop requires to be thinned. Thus the growths laid in 1906 would have formed spurs in 1907, and would fruit this summer and be cut out in the winter following. They are never "spur-pruned," the spurs referred to being merely clusters of buds on short stems.

To transform an ordinary "spur-pruned" tree to this system is difficult, but well worth doing; they can be made to carry good crops sooner than newly-planted trees. Begin by cutting off about half the spurs in winter and laying in the young growths next summer as advised above, removing the older spurs, especially at the top of the tree, as these require light and air in July. Some of the trees in my charge were treated in this manner in 1896 and have borne good crops each season since. It is generally rather awkward work, as the best growths are produced almost at right angles from the face of the tree, and if not carefully trained make ugly bends or snap off.

As soon as ripening commences the fruit must be protected from rain or it will crack. This we do by the use of long lights sloped against the wall, or by securing a narrow sheet of tarpaulin to the top of the wall and fastening the other selvage to a wire stretched about halfway down on 5-inch stakes 2 inches from the wall. Under such protection perfect dessert fruit may be picked for a considerable period.

## THE FLOWER GARDEN

### A GLADIOLUS MYSTERY.

SINCE the day when I first saw the splendid collection of Gladioli owned by Mr. W. C. Bull of Ramsgate I have been an ardent admirer of these magnificent flowers, and have grown a selection of named sorts with great success from year to year. Last spring, however, destruction threatened several of the choicest and gave me a very uneasy time. The corms

GLADIOLUS STEM ATTACKED BY A CATERPILLAR.

were started indoors and planted out at the end of March when in strong growth, a plan I have always found to answer admirably. Last spring, however, soon after planting out, I noticed immense, almost semi-circular portions were disappearing from the more tender part of the plant near the ground. The illustration shows an attacked plant with portions eaten out at the side and near the apex. At first I thought the damage must be credited to a particularly voracious slug or snail, but the absence of slime on the plants, the peculiar shape of the wounds and condition of their edges soon convinced me that I had another foe. Ordinary search availed nothing, so I had recourse to a small hand-fork, and on the first plant unearthed I found the unwelcome visitor shown in the illustration. It was lying full length on the corm of the Gladiolus, but curled itself into a circle when disturbed.

As far as my entomological knowledge allows I made this out to be the caterpillar of the great yellow underwing moth. It was fully 1½ inches long, brown in colour, with reddish markings along its side and back. These caterpillars are in the ground all the winter, but do not seem to feed until spring brings new and succulent growth into being. When fully fed they bury

themselves in the soil, turn to reddish chrysalids, and finally emerge as moths about July. The moths are very conspicuous by reason of their orange yellow hind wings, contrasting so vividly with the brown fore wings. They are very fond of docks, and may be frequently caught feeding on them. With regard to the caterpillars, there is nothing to be done but hunting them near their food plants, of which they have many. At the first sign of attack the soil near the affected plant should be stirred with a hand-fork, which will expose the pest. Its despatch may be left to the discretion of the finder. C. J.

### AN OLD-FASHIONED BORDER PLANT (HONESTY).

THE honesty of which we hear the most is that which some misguided individual—who evidently never had tried "both ways"—stated, once on a time, to be the best policy. Now, although this sort thrives amazingly in gardens, it is not the one shown in the accompanying illustration, and therefore not to be dealt with now. The Honesty illustrated is just as popular as the other sort, and may also be found in several shades. Of these the purple or rose colour is the oldest and most common, the white the newer and most generally useful. Together they make a very happy combination, and are ideal plants for the spring decoration of the waste spot or wild garden. They grow a good 3 feet high, flower freely and over a long period, and are even more beautiful in death than in life, as most people who have seen the bright silver seed vessels in winter decorations will admit.

The possession of these silvery seed vessels—or rather the central integument which divides the seed vessel into two—gives the plant several of its names. Two of the most popular of these are Money Plant and Money-in-both-pockets, while the scientific name of *Lunaria* is given because of the resemblance of the silvery pods to the full moon. The possession of these silvery discs may even account for the name of Honesty; they somewhat suggest shillings, and the plant may have been regarded as the emblem of honesty in keeping so much good cash in reserve for its owner.

To leave the problematical and come to the practical. The Honesty is an annual or biennial—according to what sort of a botanist one is—and needs to be renewed from seeds every year. These should be sown outdoors in June or July, in a reserve border, and given the treatment usually accorded to other biennials, such as Canterbury Bells and Foxgloves. They may be planted in autumn or spring, but the earlier the better, as they flower in April and onwards. They do very well in damp shade, but are far from being particular as to either soil or situation.

### TWO FINE GLADIOLI.

Or all the bulbous family the Gladiolus is, perhaps, second only to the Lily, and usually remarkably cheap in comparison with the position it holds. Therefore, those who are disciples of this most handsome race will not grudge the few extra pence necessary to the purchase of the two named below. Those who are accustomed only to the ordinary varieties in cultivation, beautiful though even these are, have no conception of the majestic beauty thirty or forty corms of *Princeps* or *America* can bestow on any suitable spot in the garden. In common with all the family, it pays to well enrich the soil before planting and also to start the corms in 5-inch pots in a codd frame prior to planting out. Transfer them to their positions in April. When growing strongly, and before the weather gets hot, mulch them heavily with half-decayed manure, and in due course they will paint for you a picture such as few plants can equal and more than compensate the few details of culture. They also force readily provided heat be spared till the flower-spikes can be felt. GEORGE AITKENS.

## THE ROSE GARDEN.

## NOTES ON THE WILD ROSES (SPECIES).

**ROSA LUTEA.**—Under this heading are grouped the four or five Roses that are generally known as the Austrian Briars. The Austrian Briar proper is a single yellow Rose, a native of Germany and Austria, that was introduced by Gerard into England so long ago as 1596. Its counterpart, the Austrian Copper, seems to have reached us somewhat later, but undoubtedly they were among the first of the wild Roses not indigenous to the soil to be cultivated in England. The double form of the yellow Austrian Briar, known as *Harrisonii*, was raised by a Mr. Harrison in 1830. Then we have the semi-double yellow Persian Rose that reached Europe in 1838 by the aid of Sir G. Willock. That is a native Persian Rose, but whether the native Rose is really a single or semi-double (which latter I should think most unlikely) I have never been able to discover.

Some of the varieties of *Rosa spinosissima* always seem to me to have a good deal of affinity to *lutea*, yet *spinosissima* and *lutea* have always been treated as distinct species—*Altaica* and *Nan-thina*, for instance, varieties of the former and so classed by most authorities, especially the latter, is so much like the Austrian Briar that in the winter season it is not easy to distinguish between them; but to return to *Rosa lutea*. If one's Rose garden is outside the radius of the smoke of a big city so that there is plenty of fresh air, all these varieties of *lutea* are easy to grow. Here on my light chalky subsoil they flourish exceedingly—they are evidently lime lovers—left severely alone, except occasionally bending over a long shoot, they are quite free-flowering, and few Roses are more welcome. They are early flowering and there are no other Roses like them. A well-flowered bush of the Copper Briar that has not suffered from frost, at its best, is one of the most beautiful sights of a June garden. Is there a purer yellow Rose than *Harrisonii*? The single yellow Austrian is beautiful, but do not attempt to smell it or you will regret it. Hardy, but susceptible to the late April and May frosts, the species and its varieties should be in every garden. The hybridist is turning his attention to *Rosa lutea* at last with success. No doubt many of the old rosarians tried less successfully in the past, but we are now beginning to find out the secret, and we may look forward not without hope to yellow Carolines, *La Frances* (the indirect product of *Rosa lutea*), *Soleil d'Or*, *Gottfried Keller*, *Parkfeuer* and the *Lyon Rose*. So we progress; slowly, it is true, but none the less surely.

**Rosa wichuraiana.**—A species of Japanese origin—of quite recent introduction, 1887, I think, is the date generally given—but no doubt a native of China—that great birthplace of the world's flora. I doubt much if any single species has in so short a time created such a change in the Rose world as *wichuraiana*. The type, with

its delicately scented pure white flowers that blooms when all other species are over (I cut several flowering sprays of this Rose last Christmas morning), with its beautiful foliage that lasts through frost and snow till the spring comes to renew it, is distinct from all other Roses in its method of growth, and is seen at its best hanging down over a flint wall or creeping over rockwork, but so rapid is its growth that but a short time elapses before it completely covers the ground all round it. It is the Rose substitute for Ivy. It is not more than ten years ago since we received the first *wichuraiana* hybrid, and although they must run to nearly hundreds now, I think only the fringe of the possibilities of this cross has been touched. And if this is so with regard to *wichuraiana*, why may it not be so with regard to the other species that await the skilled hand of the hybridist? It seems to me that most of our Roses have come to us through four or five distinct channels. Are we going to avail ourselves of the others? It is a

AN OLD-FASHIONED BORDER PLANT: HONESTY.

big subject, and a most interesting one. If these notes on such of the species as have come under my ken in my garden should be the means of inducing others to grow them, I shall be more than satisfied, and shall always be willing to give any information in my power respecting them. Such rapid progress has been made among Roses during the past ten or fifteen years that the many beautiful colours and exquisite shapes now appeal to all classes.

Purley.

HERBERT E. MOLYNEUX.

## TREES AND SHRUBS.

## A BEAUTIFUL PLANT IN WINTER.

(CELASTRUS ARTICULATUS, THUNB.)

**A** SPECIAL value attaches to any plant capable of supplying colour or contrast in the outdoor garden during the winter months, when nearly all vegetable life is dormant and but few flowers are to be seen. In this connexion plants having brightly-coloured fruit are particularly valuable, but as these in many instances are inconspicuous when in bloom, they are often overlooked in favour of those having showy flowers produced during the spring and summer months.

The subject of the present note is one of the showiest plants in the arboretum at Kew during winter, and deserves to be more widely known and planted than it is at present. A hardy deciduous twining shrub, *Celastrus articulatus* is widely distributed through Northern and Central China and Northern Japan. It grows rapidly, in cultivation attaining a height of some 10 feet to 15 feet, producing long, straggling growths several feet in length during one season. The bark of the young wood is light brown or ashy grey, covered with prominent lenticels. The leaves are somewhat variable in shape, usually obovate, but sometimes orbicular or oval; they are narrowed at the base to a short, broad petiole, and the margin is coarsely serrate. The small greenish yellow flowers, produced in axillary three-flowered clusters, appear when the leaves are about half grown. They are followed by globose fruits, greenish yellow in colour, becoming bright yellow when mature. After ripening the fruit splits into three shell-like portions with crisped margins, which reflex, forming a three-lobed cup, in the centre of which is a bright red aril, which encloses the seeds. A similarly constructed fruit is that of the common Spindle Tree (*Euonymus europæus*), to which *Celastrus* is closely related.

The fruit is produced in great quantity along the short lateral growths of the current season, and remain on the plant well into the winter. Little cultivation is needed beyond thinning out the old growths and encouraging the production of fruit-bearing wood. The plant should be placed near some rough poles, roots of trees or an unsightly fence and allowed to grow with unrestricted freedom to obtain the best effect.

H. SPOONER.

## THE LILACS.

(Continued from page 64.)

ONE caution to purchasers of Lilacs is to always stipulate that the plants are on their own roots,

otherwise suckers from the stock are always a nuisance, and unless carefully attended to they will often overpower the scion. Even on its own roots there is a natural tendency for the Lilac to produce suckers, and if the plants are intended to flower well, these suckers must be rigidly cut away, as if this is not done they will grow in a particularly rank fashion. Should any of the bushes run up too tall for the position occupied by them, they may be cut back hard immediately after flowering. By so doing the display of

flowers may, the first season after this drastic treatment, be lessened, but afterwards the plant will be much improved.

One more purpose for which the Lilac in its several varieties is particularly adapted is for forcing into bloom, and thus playing a part in the embellishment of the greenhouse long before their brethren out of doors are in flower.

*S. persica* (the Persian Lilac).—This, the smallest and most graceful of all the Lilacs, is an exceedingly beautiful flowering shrub. It is seen to great advantage as a single specimen, under which conditions it forms a rounded bush from 4 feet to 8 feet in height, with slender gracefully-disposed branches clothed with leaves, varying in length from three-quarters of an inch to 1½ inches, while they are usually less than half an inch wide. The flowers are in the type of a lilac-purple colour, but in the variety *alba* they are almost white. A singular form is that known as *laciniata* and *pinnata*, in which the leaves are cut into several narrow lobes. In flower it is a counterpart of the type. The Persian Lilac would appear to have been cultivated in this country soon after the common sort, and, like that, to have quickly become a favourite.

*S. chinensis* (Rouen Lilac).—An unsatisfactory name for a most beautiful Lilac, as it has never been proved to be a native of China. It has also been called *Syringa dubia* and *S. rothomagensis* and the various popular names of Rouen Lilac, Siberian Lilac and Lilac Varin. The generally accepted idea of its origin is that it is a hybrid between the common and Persian forms, and certainly its general habit would suggest that such was the case. It had its origin in the Botanic Garden, Rouen, in 1795, when M. Varin was director, hence the last mentioned popular name. It combines in a valuable manner the prominent characteristics of the two species mentioned previously, having the graceful habit of the Persian and the vigour, though in a lesser degree, of the common sort. It will reach a height of 10 feet to 12 feet or more, and in May the flower panicles, which exceed in size those of *S. vulgaris*, are at their best. There is a form of this known as *rubra*, in which the blossoms are a good deal richer in colour than those of the type. The above are the sorts that would be, even by the uninitiated, recognised as Lilacs, but there are in addition several other species of *Syringa*, some of which in general appearance show a considerable leaning towards the Privet family.

*S. japonica* is the best of this section, and when in bloom it is certainly a striking shrub. In Japan it is said to attain the stature of a tree, but in this country it is more the size of the common Lilac. The flowers are individually small, but borne in large branching panicles, so that they make a goodly show. They are in colour white, or nearly so, and being at their best in June and July, when all their brethren are past, greatly enhances their value. The other members of this Privet-like group are

*S. amurensis*, a native of Mandshuria, and *S. pekinensis* from China.

*S. Emodi* (Himalayan Lilac).—This is altogether of sturdier growth than the common form,

and has large leaves and terminal panicles of white or pale purple flowers. Even at its best it is not equal to the better-known species, but it is valuable from the fact of its late flowering. A very fine variety of this is *rosea*, raised from seeds sent from Northern China. In this the leaves, flower-panicles and individual blooms are all larger than those of the type. Wherever possible, it should certainly be grown in preference to the ordinary form. This is sometimes met with, particularly in French nurseries, as *S. Bretschneideri*, so named in honour of its discoverer.

*S. Josikua* (Hungarian Lilac).—Somewhat of the growth and general appearance of *S. Emodi*, but less showy, while it blooms in May when we have such a wealth of flowers among shrubs in general. A fine variety of the Hungarian Lilac

SEEDLING ERINUS ON ROCK GARDEN STEPS.

was given an award of merit by the Royal Horticultural Society on June 11 last. The panicles of flowers are large and pyramidal shaped, while the individual blooms are of a rich reddish rose colour. This variety was, I believe, raised by M. Victor Lemoine of Nancy, but it is not yet readily obtainable from nurseries. Though much more might be written concerning Lilacs in general, this should serve to direct renewed attention to their merits, and many will, no doubt, be planted during the present winter. They are comparatively easy to grow, and at all times the shrubs present at least a tidy appearance. When in flower the graceful inflorescences render them objects of great beauty, and the delightful fragrance of many of them finds favour with most people.

## THE ROCK GARDEN.

### ALPINE FLOWERS FROM SEED.

**M**ANY interesting and beautiful alpine plants are readily raised from seeds, and as these can generally be procured in spring from seedsmen and others, a few suggestions on their cultivation may prove of service to those attempting this work for the first time. Generally speaking, home-grown seeds give the least trouble, for this reason, that alpine plants are difficult to germinate if held over till spring, do so readily if we have seed collected as soon as ripe and sown in autumn. If, however, we

procure seed of those varieties characterised by having a hard outer seed-coat and find them slow and irregular in germinating, then it is well to retain the seed-pots until the following year, as it not infrequently happens that some vegetate the second year.

**THE BEST TIME TO SOW ALPINES** is early autumn and early spring, or, to be more exact, the middle of August and the beginning of March. In the former case it is rarely advisable to prick out from the seed-pots that year; far better to grow cool in a frost-proof house and shift whenever there is some appreciable growth in spring, as these hardy plants bear standing in the seed-pots far better than the majority of hand-raised seedlings; those sown in spring will transplant as soon as they are strong enough.

#### SOIL.

As already indicated, some alpine plants may take two years to germinate, consequently we must guard against the soil turning sour during this period. The pots used must be clean and drained one-third of their depth: those measuring 3½ inches and 4½ inches diameter are useful sizes, the smaller being employed for rare seeds. A suitable compost consists of two parts loam, one part leaf-soil and one part sharp silver sand. Pass through a half-inch riddle for filling the pots and through a fine sieve for finishing the seed-bed and also for covering the seed. Having prepared the desired quantity of pots ready for sowing, my practice for all rare seeds, and which may be extended with advantage for all alpine plants, is to stand the pots in a tub or tank and flood with boiling water, sufficient to come within half-an-inch of the top of the pots. By this means all

insect and vegetable life is destroyed, and one has the assurance when the seed germinates that it is only such as was sown. Having stood the pots in the water for an hour they are then withdrawn and allowed to drain and cool, after which the seed is sown.

#### A GOOD POSITION FOR THE SEED-POTS

is a greenhouse or frame, where frost is excluded. On no account should they be subjected to any appreciable degree of artificial heat, and, provided the pots are standing on a coal-ash bottom or cool stage and covered tight with small glass squares, no further watering will be required until germination takes place. For those species marked thus (\*) in the appended list, as soon as the seedlings are visible, tilt the cover glass of

the pot a quarter of an inch to admit air, and gradually increase the ventilation by removing the cover glass as the seed-leaves expand, and affording air to the structure in which the pots are placed. At this stage a suitable position for the seed-pots will be an unheated frame well exposed to the sun; fill the frame to within 9 inches of the lights with ashes or similar material. Plunge the seed-pots to the rim and cover at night with the lights, but air freely on all favourable occasions throughout the day.

Water is best given by standing the pots to the rim in a tank or tub until saturated. On no account must the seedlings be flooded, and the pots may be well on the dry side before repeating the operation. Unless sown too thickly (which should always be avoided) it is not advisable to transplant alpinines too early; those already indicated and which are generally employed in quantity may conveniently be transplanted to well-drained boxes, using a light potting soil similar to that for bedding Verbenas and Lobelias. Water should be withheld for a day, then give sufficient to thoroughly moisten the soil. Grown on in a cold frame, under which treatment they are healthy and strong, they are then ready for transplanting into any light sunny position in the open garden during the month of June.

Those plants marked by a dagger (†) in the list include some alpinines which are of extremely slow growth, consequently pots are recommended for these at all stages until large enough for permanent planting. The soil varies for several; the majority succeed in that having chalk or limestone as an ingredient (old mortar rubble is an excellent substitute), the exceptions being *Pterocallis*, *Ramondia*, *Aquilegia glandulosa* and *Dianthus glacialis*. The soil should be slightly rougher, to which some crushed sandstone or limestone, as advised, should be added. What is known as "thimble" pots are large enough for single plants at this stage, and after potting these are returned and plunged in the frame as before. By the middle of June no covering is required for either the seed-pots or transplanted seedlings, except to ward off heavy rains, and from this date an east or west aspect meets the requirements of the plants.

By the first autumn those marked by an asterisk are carefully lifted and planted in their permanent quarters, and as all of these flower the first year following that in which they are sown, and continue to increase in strength and beauty each succeeding year, there is scarcely another class of plant which yields so rich a return for the initial labour and expenditure. A few of the others named will be large enough for permanent planting, and will flower sparingly the first season; but these are best planted during spring, about the month of March, care and attention being given them until well established. All of those mentioned should be ready for the final planting when two years old. Alpinines raised from seed are suitable for filling vacancies on the rock garden, and can scarcely be excelled for the purpose of planting new or existing wall gardens.

#### ALPINES READILY INCREASED FROM SEED.

\**Aubrietia*, \**Alyssum*, \**Arenaria montana* and *A. balearica*, †*Androsace sarmentosa* and *A. Chumbyi*, †*Anemone Pulsatilla* and others, †*Ethionema grandiflorum*, †*Aquilegia glandulosa*, \**Campanulas* (dwarf sorts), \**Dianthus cæsia*, *fragrans*, *plumarius*, &c., †*D. neglectus* and *glacialis*, \**Draba Aizoon*, \**Edelweiss*, \**Eri-geron*, \**Erinus*, \**Erysimum*, \**Gypsophila*, \**Helianthemum*, \**Hypericum reptans* and *kalmiana*, †*H. repens* and *coris*, †*Iberis*, \**Linaria*, †*Linum narbonense*, †*Lithospermum graminifolium*, †*Ononis*, †*Onosma alba roseum*, †*Phyteuma*, †*Pterocallis pyrenaica* (not *P. comosum*), \**Papaver*, \**Pentstemon heterophylla*, \**Saponaria splendens*, \**Sedums*, \**Silene alpestris* and *Schafta*, †*Ramondia* and †*Saxifraga longifolia*. *Cyclamen*, *Cytisus*, *Genista*, *Gentians*, *Primulas* and *Smilacina* will often take a full year to germinate.

Walsgate Gardens, Louth.

T. SMITH.

## THE GREENHOUSE.

### HOW TO GROW THE TRUMPET FLOWER.

**M**ANY gardeners and nearly all amateurs fail to produce good flowering specimens of the Trumpet Flower (*Tecoma Smithii*), yet if a few well-defined rules are adhered to its culture is simple enough, and good flowering plants of it should be the rule rather than the exception. Flowering as it does in the late autumn and early winter months, the orange-coloured flowers and ornamental foliage provide a welcome change at this period.

It is time now to prune the old plants fairly hard and place them in a warm house so as to induce them to make shoots for cuttings. A slight syringing once or twice daily will considerably help the formation of these. When about 3 inches long detach the young shoots with a very slight heel of young wood, and insert them into well-drained pots filled with sandy soil, either one into a thumb pot or several round the edge of a 3-inch pot. Stand these, or, better

whenever it is required, and liquid manure of a weak character may be given at intervals. Over-feeding must, however, be strictly guarded against, as gross growth is not desired.

At the end of the summer the plants are taken into a cool airy greenhouse to flower, giving them a position where plenty of light can reach them. After flowering gradually withhold water, and so induce the plants to rest for the winter. During the resting period very little water is required, and the plants may be stood closely together in a corner out of the way. A variant of the above system is to turn the old plants out of their pots now, remove some of the old soil, and repot them into pots of a similar size. Cut the main shoot or shoots well back, and then when they break leave four or five of the best placed shoots to grow on. Treat in the same way as advised for young plants, taking care to remove side shoots as promptly as possible. Young plants, however, are usually the most satisfactory.

#### SERICOGRAPHIS GHIESBREGHTIANA.

This old favourite was extensively grown some years ago, but it is now rarely seen. Though coming from Mexico and usually treated as a

THE WELSH ALPINE POPPIES IN ROUGH STEPS.

still, plunge them in Cocoanut fibre, in a close propagating case with a bottom temperature of about 65° to 70°, where the cuttings will soon emit roots. When rooted, remove the pots from the case and gradually harden off the young plants, keeping them near the glass so that sturdy growth may result. After the young plants have been subjected to cooler conditions for a week or two they must be potted off singly into well-drained 3-inch pots, using soil composed of three parts good fibrous loam, one part well-rotted manure, and one part sand. Stand these close to the glass in a temperature of about 50°, and allow them to grow on until the pots are filled with roots, when the final potting must be given.

For this use pots 6 inches or 8 inches in diameter, using the same mixture as advised above, with the addition of a 6-inch potful of bone-meal to each bushel of soil. Good drainage must be provided and the soil must be made firm, much the same as it is for *Chrysanthemums*. At the end of June, providing the plants have become well established, they ought to be stood outdoors to enable the wood to become well ripened. All side shoots must be removed as soon as seen, this and the ripening of the wood being two very important factors in the flowering of this plant. Give water

stove plant it succeeds best when fully exposed during summer and autumn, but should be taken indoors before the nights get cold. It may be readily propagated from cuttings taken from the strongest shoots early in the year. The cuttings will root freely in any light sandy soil. Three or four may be put into each pot, and when ready potted on without dividing them. The early struck plants may be stopped once, and those put in later grown on without any stopping. A rather light sandy soil should be used for potting, and during the early stages grow the plants on in heat, but after they have made a good growth they will do better in a cold pit, the lights of which should be taken off during favourable weather. Towards the end of August or early in September take them indoors under shade and warmth. They will make excellent growth, but will fail to flower. Warmth should be given as soon as the nights begin to get cold; they should begin to flower about October, and will continue to do so until Christmas or perhaps later. The bright crimson flowers are produced from the axils of the leaves. Even when not in flower the fresh green foliage is attractive. I may add that this useful plant is now included with the *Jacobinias*.

A. H.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**W**INDOW GARDENING. — My old Fuchsia plants have just been cut back in order to induce them to break away again strongly. The Fern-case, too, has just been gone over, removing old leaves and replanting where the plants are past their best. The surface soil

1.—AN OLD PLANT POTTED UP FROM THE BED LAST AUTUMN.

has been stirred and a top-dressing of good soil added. I have watered Cacti for the first time this season, knowing the plants will derive considerable benefit therefrom. The flowering plants are already making the windows gay. To improve their appearance and to give them a much-needed stimulus I have just watered them with weak liquid manure.

**Cold Frames.** — Overlooking the subjects in cold frames is our constant care. The close condition in which they have been kept for a long time past has caused the leaves and plants to damp off. These should be removed promptly, otherwise they may contaminate others. I make a rule to give each individual subject personal attention, and on every mild day air is now admitted freely by slightly tilting the frame-light. Wipe the glass free from sooty and other dirty matter, as this contributes much to the well-being of the plants. Carnations in frames are beginning to give evidence of new growth. I am removing decaying foliage and stirring the surface soil. Plants in small pots that are well rooted I am placing in larger pots, giving them good soil and potting firmly. Bulbous-rooted subjects, such as Hyacinths, Tulips and Narcissi, should be removed from the plunging material, where they have been developing their roots for some time past.

**Vegetable Garden.** — This is a busy period, and much in the way of seed sowing and planting must be done forthwith. The second early Potatoes must be planted for succession where they may have fairly warm, sheltered quarters. I have just made a sowing of Parsnips, choosing quarters that were well trenched and where Celery was planted last season. Sow the seed 1 inch deep in drills 15 inches asunder. In warm situations, where protection from cold winds can be provided, I am now making my first sowing of Radishes and Lettuces. It is quite an easy matter to make quarters for these by building artificial screens. Seakale may be planted now with the sure prospect of success. My method is to dibble the sets in the prepared quarters in rows 2 feet apart, allowing a space between each set of about 1 foot. Cover these with about an inch of soil, and when growth commences remove all shoots but the strongest.

**Hardy Flower Garden.** — When the weather is open and the garden soil nice and friable, the conditions are ideal for planting operations. I am now dealing with most hardy plants, and in this category I include such subjects as Phloxes, Delphiniums, Pansies, Sweet Williams, Canterbury Bells, Pinks, Carnations, Hollyhocks, Peonies and quite a host of similar hardy plants. No garden should be without a good border of these useful, easily-grown plants. I always give each subject plenty of room, so that as the ample growths develop there shall be space for it to do itself justice. Plant the taller-growing subjects at the back of the border. Sweet Peas may be sown at this time. Sow the seed thinly; some friends of mine prefer to set their Sweet Pea seeds individually, 6 inches apart, and the results amply justify the extra trouble taken. Sow in clumps 3 feet to 4 feet apart, and, if many clumps are to be grown, in one part of the garden. The rows of clumps must be at least 4 feet asunder. Cover the seed with about 2 inches of soil.

**Greenhouse and Conservatory.** — In warm greenhouses where bottom-heat can be obtained, seeds of the more tender-flowering subjects should be sown forthwith. I make a sowing at this time of Verbenas, Petunias, Celosias, Torenias and the pretty Rhodanthe, using a light and sandy compost, and with a bottom-heat of from 65° to 70° these subjects may be raised quite easily. Pots, seed-pans and shallow boxes may be used at the will or convenience of the raiser, each with equal success.

**Roses.** — Complete the planting of Roses without delay. I prefer to finish this work before this period, if possible, as the plants will soon be called upon to make growth from which the blooms are to be obtained. For the best effect in the garden I have planted many of the better ramblers and Penzance Briars, to say nothing of the pretty Polyantha Roses. — D. B.

## PROPAGATING FIBROUS-ROOTED BEGONIAS.

This class of Begonias is perhaps not so well known as the tuberous-rooted type. For summer bedding and greenhouse decoration they are equally beautiful. Individually the flowers look quite small by the side of the best tuberous varieties, but this is more than recompensed by there being twelve to twenty times the number of flowers on a plant. As they possess no bulb or tuber they require a little water during the winter months. At present the plants require a fair amount of water, as they are making new growth, from which we must obtain cuttings.

**Taking and Inserting Cuttings.** — On the plants lifted and potted up last autumn from the beds, or those retained which flowered in the greenhouse last summer, plenty of cuttings should now be available. The plant illustrated is an example. From this a number of cuttings can be obtained, after which, if kept moderately dry for a week or two, the plant as shown at Fig. 2 will make fresh growths, and be available as a pot plant or for bedding. The making of the cuttings requires a little explanation in addition to the knowledge afforded by Fig. 3. The base of the cutting must be a node (the point from which the leaves grow on the stem) or it may have a slight heel by cutting off a very small portion of the older stem from which it is growing. Sand is a suitable medium for rooting the cuttings, or light sandy soil may be used. Pots that will hold four or five cuttings, similar to the one illustrated, or shallow wooden boxes may be used. The cuttings root readily in a frame or hand-light at the warm end of the greenhouse.

**Potting up the Rooted Cuttings.** — In about a month from the time of inserting the cuttings they will be ready for potting off singly in small pots, or if large potfuls are desired three cuttings may be placed together in a 4-inch (large sixty size) pot. Use soil composed of equal parts loam and leaf-mould; adding plenty of sand. Peat is not essential for fibrous-rooted Begonias, but if available it will be beneficial to use a little

2.—THE SAME PLANT WITH CUTTINGS REMOVED.

with the potting soil. Return the newly-potted plants to the frame or hand-light for a week, leaving a little air on, which may be increased each day. A slight spraying with a syringe or fine rose water-pot will be helpful, and shading from bright sunlight can be afforded by means of tissue paper. When removed from the frame a light shelf in the greenhouse will suit the plants.

**Potting on the Plants.** — Select a few of the best plants of each variety for growing in the greenhouse during the summer. Those that were potted up singly into small pots may be shifted

into 5-inch (forty-eight size) pots, and those three in a pot will be better in 6-inch (thirty-two) pots. The previous soil recommended will suit the plants for this potting if a little well-decayed manure is added. Plants to be grown in beds and borders can be potted into a size larger pots than they are in at present, that is, single plants from 2½-inch pots into 4-inch pots, three plants from 4-inch pots into 5-inch pots. Previous to planting them outside they should be grown in a frame for a few weeks, the lights being left off altogether for the last ten days or a fortnight.

*Varieties.*—Three of the best and most free-flowering varieties are *semperflorens alba*, white under glass, outside tinted with pink; *rosea*, rose-pink; and *Mrs. Bertram Currie*, red flowers and

remove the paper and place the boxes near the glass, a sturdy growth being what we now require. Henceforth watering must be very carefully done, giving it when required early in the morning, so that the leaves of the young seedlings quickly dry. Pans or pots may also be used for sowing the seeds in.

*Treatment of the Plants.*—When the seedlings possess two or three true leaves they must be pricked off into other 4-inch deep boxes, draining them and

using soil as advised for seed sowing, except that the leaf-soil

or manure should be used in a more flaky condition. Before pricking out the seedlings, make the soil moderately firm, and give it a quarter-inch thick surfacing of clean sand. Place each plant 3 inches from its neighbour, taking care to press the soil well round the roots. Water in with a rosed can and place in a warm, rather close greenhouse or frame for a week or so until they have taken to the new soil, when commence to gradually inure them to more airy conditions. Water with caution;

excessive watering and bad ventilation are frequently the cause of young plants going off with a black ring round the stem just below the leaves. By the end of April the plants ought to have been gradually hardened so that they occupy cold frames, taking the lights off during fine days, and simply protect from frosts at night. At the end of the third week in May the plants can, in most localities, go into their permanent quarters,

4.—CUTTINGS INSERTED IN A POT AND ONE ROOTED READYFOR POTTING INTO A 2-INCH POT.

3.—ON THE LEFT IS THE CUTTING AS TAKEN FROM THE PLANT; ON THE RIGHT, ONE PREPARED FOR INSERTION.

rich bronze red foliage. Among double varieties one of the best is *Triumph of Lorraine*, with rosy red flowers and deep bronze-coloured foliage.

#### RAISING ASTERS FROM SEEDS.

It is exceedingly doubtful whether any half-hardy annual is so popular as the varieties of the so-called Aster that is known to the botanist as *Callistephus*. Although many attempts have been made to detract from their merits by possibly interested persons, there is no disputing the fact that, when well grown, the many beautiful varieties now on the market take a lot of beating, considered either from a garden or house decorative point of view. As with every other plant that we grow, good cultivation must exist from the beginning, and for the first batch of plants a sowing must soon be made.

*Sowing the Seeds.*—This first sowing must be made under glass, and where a hot-bed exists this is the best place to raise the seedlings. Secure some 3-inch deep boxes, bore or burn some holes in the bottom, and cover these with pieces of broken pots. The soil for sowing the seeds in must be of a rather light nature, one consisting of two parts good loam, one part leaf soil or thoroughly decayed manure, and one part sand suiting admirably. Pass this through a quarter-inch mesh sieve, then place a layer of the rough material over the crocks in the bottom of the box and fill up with the fine soil. This, when pressed moderately firmly, should come to within three-quarters of an inch of the top of the box. All is now ready for the reception of the seeds, and these must be scattered thinly, half an inch apart being none too much. Cover with a quarter of an inch layer of fine soil, give a light finishing with clean sand, and press just tight enough to fix it with the bottom of a clean pot or pan. If these directions are properly carried out, it will be seen that the soil is roughly half an inch below the top of the box, this space being left for watering. Give a good soaking through a fine-roset can, cover each box with a sheet of brown paper, and stand in the greenhouse or hot-bed frame. As soon as the seedlings appear promptly

5.—THE RESULT OF POTTING ON THE ABOVE ROOTED CUTTING.

planting the large sorts 15 inches apart each way, and the dwarf varieties 12 inches apart. The beds should be well dug and manured before planting. If the seedlings have been treated as advised they will be fine sturdy plants, each possessing a mass of roots, and can be planted out without any serious check occurring. Sowings may be made under glass at intervals of three weeks from the end of February until the middle of April, and from then until the middle of May seed may be sown in the open where the plants are to flower, taking care to thin the seedlings early. The plants from the outdoor sowings will flower well late in the season when the others are over.

*Asters in Pots.*—It frequently happens that during the late summer and autumn months the beginner's greenhouse presents a bare appearance, and flowering plants of any sort would be welcome to brighten it up. This is where the Aster, especially the dwarf, bushy branching strain, comes in useful. When the flowers are just beginning to open tread the soil down firmly round a desired number of the best shaped plants, and then give it a thorough watering if at all dry. Leave it for twenty-four hours, then with a spade cut round each plant a few inches from the stem, lift and transfer to a pot of suitable size. Make the soil firm, water well, and then stand the plants in a shady, rather close corner of the greenhouse for a week or so when the plants can go on the stage, shading them from bright sunshine. Some cultivators prefer to grow on the young plants entirely in pots, and where time and space abound this method is to be commended. In this case, instead of pricking the seedlings out into boxes, each would be potted into a thimble pot, and eventually potted on in other sizes until pots 4½ inches or 6 inches in diameter were reached, these being large enough for the plants to flower in.

*Some Good Varieties or Types.*—Perhaps the most general favourite is the *Ostrich Plume* Aster, a beautiful double or semi-double type, 18 inches high, the feathery petals and branching habit rendering it one of the most useful Asters we have. It may be had in several colours. *Comet* is another graceful type, the reflexed petals reminding one of Japanese *Chrysanthemums*, 18 inches. *Victoria* is a well-known 18-inch high type, the petals of which curve outwards. The *French Peony-flowered* type is beautiful and distinct, the petals curving inwards similar to an incurved *Chrysanthemum*. The original strain reaches a height of 2 feet, but a dwarf type may now be obtained that only grows half as high. *Sutton's Little Gem* is a charming dwarf type, specially suitable for pots. It, like the others mentioned, can be had in several colours. Single Asters are also charming, especially those that have twisted petals. The *Ray* type finds favour with some people, as they stand dry weather well. The flowers are semi-double, the long, straight petals radiating from a bright yellow centre or disc.

## THE TOWN GARDEN.

**INTRODUCTORY.**—Man is a 'gregarious animal, and he flocks to the towns as naturally as the wasps to the treacle jar; he is also a gardening animal, and wherever he is and whenever he is there the innate, inherent love of gardening must assert itself. Recognising these two facts, and being desirous of pleasing every section of his readers, the Editor has commissioned the writer—as one who has done it and knows how it is done—to give a few brief hints every week to enable every reader to have a garden which shall blossom like the Rose.

**The Soil.**—At the very outset, and, indeed, all through the chapter, I would emphatically assert that the soil is at the bottom of all good gardening. There are various ways of looking at this statement. Some may treat it as a joke; some may regard it as a truism; some as a sound, common-sense dictum. The latter is the sense in which it is now put forward, and it is incontrovertibly true, to the last spade-ful of mould, the last clod of earth, the last grain of sand in the garden. With good soil and plenty of it, you can grow everything; with poor soil and plenty of it you can grow a lot; with poor soil and little of it you can grow weeds and weary—and precious little besides.

But here, at the very start, we unlucky town gardeners get our first set-back in the handicap; it may be to scratch; it may be a few inches nearer to the limit man, according as our soil is poor and plentiful or poor and scarce. However, there is this beautiful thought underlying the question of town garden soil, and it is worth dwelling upon, viz., there is always room for improvement. There is no need for the town gardener to stand, Alexander-like, and sigh for fresh worlds to conquer; they are here, literally and absolutely at his feet, and my advice to him is to go in and win. A healthy spirit of enquiry is good to foster at the outset, and a spade and fork should be called in to help. Armed with these, proceed as far in the direction of Australia as the land will allow; it may be 6 inches; it may be 2 feet; if it is only 6 inches, make it 2 feet; if it is 2 feet make it 3 feet—always strive for a little more than you have got. Remove all empty tins, broken glass, stones and brick-bats encountered by the way, and put them in a heap; they may come in very useful later on for paths, &c.

In digging down 2 feet or 3 feet at this season, keep the bottom soil always at the bottom, but break it up with the fork. On this place a 6-inch layer of the best manure the nearest mews can supply; this should be rather old manure at this season, but not so old as to have become hoary, as is common with many manures that have lain long in heap. This layer of manure should have a 6-inch layer of the adjoining soil thrown on to it, followed by an intimate mixing of the two with the fork. Six inches more manure, 6 inches more of soil admixed, and the top 6 inches of soil is returned to cover all, unmanured and unbroken, simply inverted or turned over as it leaves the spade or fork. This deep trenching will open up store-houses of plant food that have previously been locked, and the difference, especially during a dry summer, between plants grown on soil that has only been dug 9 inches deep and those on other that has been trenched 24 inches deep will be very marked. The roots of most plants will penetrate the soil to a much greater depth than is generally supposed, providing the substratum is broken up sufficiently to enable them to do so. That is all for now; but it leaves a bed of soil which by late spring or early summer will grow anything or everything—that is, with a skilful grower to lend a hand at times.

Next week I hope to say something about the lawn, with special reference to cats, chickens and earthworms. E. J. CASTLE.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**F**ORCING ROSES.—Continue to force these and keep the plants free from aphids by syringing with some suitable insecticide. Remove the plants from a warm to a cooler house as the buds show prominently; they become a better colour and last longer. Place under cover some more of the rambler section; these force slowly very well, and are useful for the conservatory and house decoration. Keep the plants well supplied with stimulants if the pots are well filled with roots. Put in to force also *Deutzias*, *Lilacs*, *Azaleas* and *Rhododendrons*; syringe them well twice a day.

*Ferns* should now be inspected, and those that have been resting may be potted up and started afresh. The *Nephrolepis* may go into strong baskets. Most of these, being strong growers, must be given good substantial soil and when well rooted copious supplies of water and liquid manure, also an occasional dose of soot water. Large plants should be top-dressed, and also see that the drainage is clear, otherwise the soil would soon become waterlogged and sour. I have found that *Adiantum farleyense* succeeds best in good fibrous loam and dry cow manure, with plenty of sharp sand. A stove temperature is also required, and shade must be given when the sun is very bright. Pull the blinds down immediately the sun is likely to reach them to prevent the young fronds getting scalded.

#### FRUIT INDOORS.

**Cucumbers and Melons.**—Old Cucumber plants should be pulled up as soon as the new ones are ready; the new ones are so much better. Sow seed for a succession frequently all through the season. Plant out Melons as soon as they are ready, and allow 18 inches from plant to plant and grow in the cordou system. Secure a good set before allowing any to swell.

#### KITCHEN GARDEN.

**Prepare the Ground** and plant out autumn-sown Onions. Carter's Record, Ailsa Craig and Reading all respond to this treatment, as well as the Tripolis. Give a good dusting of soot over the plot, which should be heavily manured. Good Onions cannot be grown without rich culture. In raising the plants place a fork under them so that they can be drawn out without injuring the roots, and finish planting by making the plants firm.

**Shallots, Garlic and Artichokes** should be planted now. Rhubarb plantations may now be made and large pans or tubs placed over some roots and then hot manure. Make a sowing of Brussels Sprouts seeds in a cold frame; these will make an early plantation. Further sowings of Broad Beans and Peas should be made, and a sowing of Spinach.

#### PLEASURE GROUNDS AND FLOWER GARDEN.

Get on with planting as fast as possible in suitable weather, and do not allow plants to remain uncovered when transplanting, otherwise the little fibrous roots soon feel the effects. In all cases where necessary stake and tie. If this is neglected much injury may be done in a short time. Examine all old ties and labels, and where necessary replace them.

**Conifers** may be planted and removed. Make the soil firm about the roots by ramming, and it is well to afford a little fine rich soil to extra choice plants at the time of planting, as the small roots catch hold of this very quickly and soon make progress.

**Herbaceous Borders** that require renovating should be seen to at once. Where plants have

outgrown the space allotted they should be restricted by taking up the whole clump and replanting. Select the outside pieces which are the most vigorous, and secure fresh labels if necessary. New ones can be painted or written or printed when wet or frosty days occur.

**Lawns.**—Keep these neat and tidy by sweeping and rolling. A top-dressing may be afforded if the grass is poor or mossy. Wood ashes, soot and bone-meal make a very good stimulant. Any turf-laying should be done now.

#### HARDY FRUIT.

Push forward the pruning and tying and training of all fruit trees, and on frosty mornings wheel manure on to the borders. To cordon trees on the Quince give a top-dressing of bone-meal, kainit and basic slag. Keep a sharp look out for small birds; it is best to put black cotton on the bushes and nets on the walls.

**American Blight.**—This should be kept at bay by going over all the affected branches with a hard paint-brush and some methylated spirit or petroleum emulsion. Well brush the insecticide in to thoroughly exterminate the pest. This should be done several times during the growing season.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**TUBEROSES.**—Many fail in growing the Tuberose successfully, and this may be traced to two causes. One is supplying water to the roots before growth begins, and the second to the attempt to grow the plants in too cool a temperature without the help of bottom-heat. The soil should be moderately moist when potting, and then water will not be needed. To start them into growth a genial bottom-heat is required, with a top temperature of 65°. When they begin to grow begin watering, and by the time the flower-spikes appear they will take it freely, and may also have occasional doses of liquid manure. Before potting, break off all offsets from the tubers, pot firmly and place them well down in the soil, leaving about 1 inch of the neck showing above the surface. One tuber is sufficient for a 5-inch pot, two for a 6-inch and three for a 7-inch pot. The first-named size I find the most useful.

**Euphorbia jacquiniiflora.**—This useful plant often gives some trouble to the propagator. The earliest opportunity should be taken to secure the first batch of cuttings. Plants from which the bloom was cut at Christmas will now be starting into growth, provided they have been kept in the store. The young shoots should be cut off close to the old wood, and a little dry sand applied to stop the bleeding; they may be put in singly into small pots or three together into a 3-inch size. Peat, loam and sand in equal parts may be used. The cuttings should not get withered during the process of making, and they should have the warmest part of the propagating pot. If kept quite close, with a moist atmosphere, they will not require any watering for the first three or four days. Too much moisture at the base of the cuttings before they have properly callused is sure to cause them to rot off.

#### ORCHIDS.

**Dendrobiums.**—Continue to bring on successional plants of Dendrobiums, and if any insects are suspected sponge the plants before being placed in heat. Any that finished up their growth late and are consequently not very well ripened must be brought on slowly at first, for if introduced at once to heat and moisture greatly in excess of what they have been resting in, the stems will frequently grow at the nodes instead of flowering.

#### KITCHEN GARDEN.

**Seeds to be Sown.**—We have come to the season when the seed of several vegetables should

be put in; among them will be Brussels Sprouts. To have these early and in the best condition the plants require a long season of growth, therefore one or two of the best varieties should be sown early. As it will not be possible to do so out of doors yet with success, the first batch of plants should be raised under glass on a gentle hot-bed. As soon as the seedlings appear, allow plenty of air and prick them off into cold frames as soon as they are ready to handle, making the soil firm, which will promote sturdy growth. In the meantime an open position should be selected and prepared for them, and to ensure the plants growing freely through a season of drought, a good deep tilth should be provided with the addition of a good dressing of decayed manure.

#### FRUIT UNDER GLASS.

*Early Peach House.*—Here the fruit will be swelling apace, and if the crop is heavy, rub off some of the badly placed fruits and those on the under side of the branches. Syringing with tepid water twice daily will hasten the swelling of the fruit and also assist to keep the foliage clean. Ascertain the condition of the border, and if water is needed give a thorough soaking at a temperature of 85°. Old and established trees may have liquid or an artificial manure each time water is required, but younger trees that are full of vigour will be best without it until the Peaches have stoned.

#### FLOWER GARDEN.

*Hardy Plants in Pots.*—These will now be on the move, and will require attention in the way of seeing that the pots are on a good bed of ashes to keep the worms away. The bottoms of pots and sides of frames can be also examined for slugs. Although there may be nothing that cannot claim in its way to be hardy, some things will probably be all the better for a little protection in the event of frost, notably *Monstretias*, the young leaves of which are apt to be crippled, and it is as well to avoid this if early flowers are required.

*Daffodils.*—In looking through the many varieties of Daffodils now in flower, one is struck by the excellent display, too, that is furnished by a trifling outlay, and requiring very little labour. As in the case of many other flowers, the purchase of new and rare varieties is expensive, but it is not necessary to go in for them if a fine bank of colour in a little variety is all that is required.

*Polyanthuses in Pots* are coming fast in flower. Like the Daffodils, they are capital plants for the present season where the supply of glass is limited, and they last in flower a long time.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## NEW ORCHIDS.

#### CYNBIDIUM LADY COLMAN.

This handsome addition to the Cymbidiums is stated to be the result of a cross between *C. eburneo-lowianum* and *C. traceyanum*. The plant shown was carrying two racemes of flowers composed of four and five blooms respectively. These are large, the sepals and petals being of a uniform primrose ground colour, with dull crimson narrow streakings. The labellum is of medium size, finely recurved, the colour being deep bright crimson blotches on a white ground. The column, which is rather conspicuous, is dull carmine, with short deeper carmine or crimson streaks. Shown by Sir J. Colman, Bart., Gattton Park, Surrey. Award of merit.

#### DIA-CATTLEYA COLMANÆ.

This is a new bi-generic hybrid between *Diaerium bicornatum* and *Cattleya intermedia nivea*. The habit of the plant and the shape of the flower are those of both parents. The latter is pure white, with the exception of a faint primrose marking on the labellum. The plant shown was

carrying one raceme composed of one fully opened flower and three buds. Shown by Sir Jeremiah Colman, Bart., Gattton Park. Award of merit.

#### LYCASTE SKINNERI ORION.

This is a lovely variety of the well-known *Lycaste Skinneri*. The plant shown possessed only one flower, this being of large size. The sepals are large, ovate and of a light old rose colour. The petals are medium in size, the colour being pale carmine except at the tips, which are white. The ground colour is also faintly streaked with white. The labellum is creamy white, with a yellow cushion at the base. Shown by J. Bradshaw, Esq., The Grange, Southgate. Award of merit.

#### SOPHRO-CATTLEYA ANTIOCHUS RUBRA.

A lovely addition to this already beautiful bi-generic race of Orchids. The plant shown had only one flower, but this was a lovely specimen. The sepals are lance-shaped and rather long, the colour being rich crimson-purple. The petals are of the same colour, but much broader, the edges being slightly crenated. The labellum is long, rather narrow, with beautifully crenated margins. The colour is very rich velvety crimson, with clear, narrow, golden markings at the base. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

## ANSWERS TO CORRESPONDENTS.

#### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

#### FLOWER GARDEN.

**Information about Dahlia tubers** (Ed. R. Dahlia).—As you do not wish to increase your stock, the simplest plan will be to leave the old roots as they are for the present. It is not necessary to cut away the old tubers; indeed, it would be very unwise to remove them all. If you have a greenhouse, or even a cold frame, we advise you to pot each clump into a large pot at the end of March, using soil composed of two parts loam and one part leaf-soil or well-decayed manure, and then place them in the greenhouse or frame, taking care that frost does not reach them. When the shoots appear remove all except the two strongest. Keep near the glass and plant outdoors at the end of May or early in June. If the tubers are very large you may cut some away so that you can get them into pots that are not too cumbersome. If you have no glass at your disposal, you may plant the clumps in the open early in May, removing the shoots as advised for those in pots and protecting those left should late frosts threaten.

**Carrying out a bedding design in Stocks and Asters** (Milfield).—The design is bold and excellent, but your scheme of planting is scarcely satisfactory. You already have far too many colours, and colours, too, which do not blend at all well. In these circumstances it would be wise to keep blue *Lobelia* out of the design entirely; neither is your suggestion of mixing the colours in Nos. 2, 3, 4, 5, 10, 11, 12 and 13 commendable. You would

obtain a far more satisfactory effect by leaving out all the blue, purple, rose and carmine Stocks, and keeping the whole design to pink, white and yellow Stocks; the *Nemesias* would not clash with this arrangement. Here is an alternative planting: 1, white Stocks; 2, 3, 4, 5, pink Stocks; 10, 11, 12, 13, yellow Stocks; 6, 7, 8, 9, carmine-pink Stocks; these latter are added to give brilliancy. In this arrangement use *Nemesias* to edge all the beds, excepting 10, 11, 12 and 13, which edge with dwarf white *Alyssum* *Thornburn's Bouquet*; this can be raised out of doors. Either leave out the *Asters* entirely or use a bright pink one for filling 6, 7, 8 and 9; do not use them in the same beds as Stocks, as the flowers do not associate at all nicely.

**Twelve early - flowering Chrysanthemums for a London garden** (*Rus in Urbe*).—You may grow the early-flowering Chrysanthemums in your London garden quite easily, with the sure prospect of obtaining a bright and cheerful display from the plants during the autumn months. Your chief aim should be to procure sturdy plants at the end of April or beginning of May. If possible, give the plants a nice warm, sunny position, as in these quarters they do well. A dozen Japanese varieties that will make a small garden bright and gay are the following: Nina Bliak, scarlet-bronze; Goacher's Crimson, rich crimson; Roi des Blancs, pure white; Polly, bronze; Fée Japonais, creamy primrose; Claret, bright claret; Rosie, terra-cotta-bronze; Horace Martin, yellow; White Massé, white; Improved Massé, rosy mauve; Harrie, bronze, tinted crimson; and Pride of Keston, reddish rose. Pompons are beautiful for the garden, having small compact flowers, which are borne in profusion on dwarf, branching plants. We recommend the three following sorts: Orange Pet, bronze; Mr. Selly, pale rose pink; and Reggie, cream.

**Campanula pyramidalis roots growing** (*E. H.*).—The fact that *Campanula pyramidalis* (as well as many other species) can be increased by means of root-cuttings has been known to professional propagators for many years, but it is little used, as these *Campanulas* are so readily raised from seeds, and seedlings grow more vigorously than plants obtained from root-cuttings.

**Treatment of Box edging** (*Beaconsfield*).—The only thing you can do to the Box edging is to take it up, pull it to pieces, and replant during the showery weather next April. Before replanting, take care that the ground is well dug, and, if necessary, some manure should be incorporated with it. The plant you send a portion of is the Winter Sweet (*Chimonanthus fragrans*). For information about Mistletoe please see reply to "H. N. H." in this issue.

**Six single-flowered Chrysanthemums for decorative uses** (*Strathmore*).—We recommend the following single-flowered varieties as suitable for November and December displays: Edith Pagram, rich pink; Irene Cragg, pure white, with yellow disc; Bronze Edith Pagram, bright reddish bronze; Mary Richardson, reddish salmon; Miss Mary Anderson, white, suffused rose; and Mrs. Fergusson, a pink sport from the last-named.

**Snowdrops attacked by mould** (*H. W. F.*). Your Snowdrops are attacked by the Snowdrop white mould or mildew (*Botrytis galanthina*). It belongs to the same genus as the fungus which attacks the common White Lily. I am afraid that there is no remedy, and that the best preventive as regards the disease spreading is to at once take up and burn every diseased bulb, and do not plant other bulbs in the same position for two years.—G. S. S.

**The cultivation of January-flowering Chrysanthemums** (*Amateur*).—To ensure the development of Chrysanthemum blooms in January a late propagation is important, and a late period of stopping is also an essential factor. Nor must we forget that the selection of varieties is all important. Propagate by cuttings at any time between the present and May; the earlier the cuttings are inserted the bigger the plants will be. After being rooted the young plants should be potted up, and when 6 inches high the point of each plant should be pinched out. Other shoots will evolve as a consequence of this treatment, and these in turn, when 6 inches long, should be pinched or stopped as before, and each succeeding 6 inches of growth treated in like fashion. The last pinching should take place during the third week in July, from which point the plants should be grown on to the terminal buds. The plants do well when finally potted into 8-inch or 9-inch pots. House the plants as late in October as possible, being guided in this matter by the weather at the time. The plants must be kept cool and abundance of air given for quite a long time, gradually reducing the ventilation, so that by the time the buds are nicely set sufficient fire-heat may be given to dispel frost

and damp and to assist in the opening of the blooms. Good sorts are Nagoya, yellow; Winter Cheer, bright rose; Heston White, pure white; Allman's Yellow, rich yellow; Winter Kouigen, white; Tuxa o, bronze; S. T. Wright, crimson; and Mme. L. Charvet, pink.

**Flowers for a town garden** (E. M. P.).—Most of the cheap plants to be bought from barrows and stalls shortly, Pinks, Carnations, Auriculas, Sweet Williams, Hollyhocks, Pansies, Arabis, Polyanthuses, Violas, early-flowering Chrysanthemums, Foxgloves, Giant Daisies, Michaelmas Daisies, also many hardy annuals raised from seed, and such tender ones as Asters, Stocks and Zinnias, also Soapdragons and Pentstemons, may do very well for your town garden if it be not too enclosed and gets some sun and air. All the plants named may be planted at once if ordered, and hardy annuals raised from seeds sown in April thinly in clumps and protected from slugs. Stocks and Asters, unless you have a frame or greenhouse to raise them in, had best be purchased as strong plants in May next. But while it is easy to advise, all the same, lack of light, or much smoke, a close atmosphere and no virgin soil may do much to interfere with success.

**Chrysanthemums with semi-double flowers** (W. S. M.).—Unless the plants of Horace Martin are propagated by cuttings each year and subsequently grown well, they invariably develop semi-double blooms. It is, therefore, necessary to adopt means to ensure the bloom evolving in double form. By all means propagate cuttings taken from your old plants at once, and when rooted grow them on strongly. Later on, say, at the end of April or early May, set outdoors the young plants that have been hardened off. Give them quarters that have been deeply dug and well manured, and give each plant a space fully 3 feet square. Plant firmly and insert stakes for their support in good time. Keep the hoe busy between the plants during the growing period, and when the buds are well set apply manure water pretty frequently. We should be disposed to slightly thin out the more crowded buds from among the clusters that are so freely developed, and then we have little doubt the results will equal your expectations.

**About decorative Chrysanthemums** (Strathmore).—These plants may be grown with little trouble. All that is necessary is to get the cuttings rooted in good time and grow the plants on to the terminal buds. The only stopping that it is well to carry out is to stop the plants when they are 6 inches high, repeating the operation at each succeeding 6 inches of growth, giving the last stopping or pinch at the end of June. By these means capital bushy plants are brought into being. We advise you to thin out the more crowded buds in the clusters of terminal buds, otherwise the resulting flowers may be unduly crowded. A dozen good sorts to flower during November and December are: White, Ivory or White Star and Heston White; yellow, Mrs. Greenfield, Nagoya and Allman's Yellow; pink, Pink Star or Pink Ivory, Mme. Paolo Radaelli and Mme. Louis Charvet; bronze, Bronze Soleil d'Octobre and Mme. G. Rivol; red or crimson, Dazzler and Kathleen Thompson. There are many others, but we think these will suit your requirements.

## TREES AND SHRUBS.

**Shrub for bed in grass plot** (H. W. H.).—Under the circumstances we do not think you can do better than plant *Berberis Darwini*. This is a neat-growing evergreen shrub that bears a profusion of bright orange yellow flowers in late spring, when it is an object of great beauty. *B. stenophylla* would also do well in such a position, but this has a rather pendulous and loose habit. It is, however, a beautiful object for a bed in grass. The last-named grows more quickly than the former, and so would make a screen in a shorter time.

**Information about soil for Rhododendrons** (M. J.).—We reply to your queries seriatim. A simple method of testing soil for the presence of lime is to take samples from various parts of the garden, mix them together, place a small quantity in a glass jar or tumbler and pour on this a wineglassful of muriatic acid. If the liquid fizzes freely a good amount of lime will be present, but if it only bubbles a little or not at all lime will not be present in sufficient quantity to harm Rhododendrons. You can please yourself about taking out holes 4 feet wide now and making them larger later on; the only objection to it is the extra expense incurred in making two operations of the work. In the event of your making the beds 6 feet wide now you could plant round each Rhododendron such plants as the hardy Heaths, *Pernettya mucronata*, or some of the dwarf Lilies. The plants you mention would not thrive in peat. Camellias like best a mixture of turfy loam and peat, used in a rather rough state for beds. It is difficult to say what your black soil is. Certainly it is

not leaf-soil. It has what gardeners call a sour or unkind look about it, and we do not think it would suit Rhododendrons. Still, it might be worth while to try it with one or two common sorts if you possess any.

**Book on grafting** (Reader).—The best book on grafting trees and shrubs that we are acquainted with is the English translation of "The Art of Grafting and Budding," by Charles Baltet. It was published at THE GARDEN office many years ago, and we do not think it is now in print, but a copy might be obtained from a dealer in second-hand books.

**Lilac not flowering** (Reynardson).—We are surprised that this Lilac has not flowered as the treatment detailed by you is in every way satisfactory. We advise you to shift your plant into a larger pot, using some good soil. This will encourage vigorous growth and probable formation of flower buds. To induce flowers, a very necessary item is to keep away all suckers.

**Information about grafting Abies** (Reader). The different Abies are usually grafted on to seedling stocks of a species as nearly related as possible to the scion. The stocks should be young, vigorous, and established in pots. The method employed is what is known as veneer or side grafting, and the point of union should be as near the ground as possible. The grafted plants must be kept in a close propagating case under glass until a union is complete. This operation is usually carried out in early spring before growth recommences, and late in the summer and in autumn when growth is completed.

**Wistarias not flowering** (G. C. C.).—Your Wistarias may possibly flower this year, but if they do not do so we recommend the following treatment: About midsummer or soon afterwards pinch back all the vigorous shoots on the main or leading stems to within 1 foot of the main stem in order to check the very strong growth. These shoots will again break into growth from the buds just below where the shoot was stopped, and after these have grown a few inches they should be again stopped. The result will be the formation of flower-spurs at the foot of the shoot first shortened. Early in the spring cut back the second shoots to within five or six eyes of the main stem, and the young growths from these eyes are then to be treated in the same way as those of the previous year. Any very weak shoots had better be cut away entirely. By following this course of treatment an ample show of flowers will be produced.

## THE GREENHOUSE.

**Information about Hedychium gardenianum** (Reynardson).—This plant is a liberal feeder, and under such treatment it will soon form a large mass and flower profusely. It needs an ordinary greenhouse temperature, say, a minimum of 45°, and thrives admirably if planted out in a prepared bed. A mixture of three parts turfy loam to one part each of leaf-mould, cow manure and sand will suit it well. Copious supplies of water, too, during the growing season are very helpful. Failing a prepared bed in which to plant it, a large pot or tub may be used. It may, if preferred, be stood out of doors during the summer months.

**Destroying worms in plant pots** (H. G. P., New Brighton).—Lime water is the best thing we know of for ridding the soil in pots of worms. It is a safe remedy with practically all ordinary greenhouse plants, with the exception of those that require peat, such as Heaths, Azaleas and Boronias. We cannot make out what your plant is; the word looks like *Aspidistra*, and, if this is correct, you may safely use the lime water. Place a lump of fresh lime the size of the clenched fist into 2 gallons of water, stir well and then allow the mixture to stand until the water becomes clear, when it is ready for use. Be careful, when using, not to disturb the lime at the bottom of the vessel. Give the soil in the pot a good soaking with the clear lime water, but only do this when the soil is already moist.

**Plants for a greenhouse** (H. A. S.).—In such a structure as you suggest many flowers might be grown and flowered in a perfectly satisfactory manner. In the first place, bulbous plants, concerning which you enquire, will do well therein. Of course, the subjects chosen must be perfectly hardy, but you have the choice of such things as Hyacinths, Tulips, Narcissi, Scillas, Snowdrops, Glory of the Snow (*Chionodoxa*), Grape Hyacinths (*Muscari*), Croci and similar subjects. Many alpinas, too, are likely to prove satisfactory. Among them may be especially named several of the Primulas, Campanulas, Saxifrages, Forget-me-nots, hardy Cyclamen, Hepaticas, Spring Navelwort (*Omphalodes verna*) and Hellebores. Several of these, however, would be effective only throughout a

limited period of the year, and we think you would derive great pleasure from growing a collection of the best hardy Ferns, which would associate well with the different subjects named and prove very beautiful after the spring-flowering plants are over. Though many of the hardy Ferns are deciduous, the charming tints of their developing fronds render them extremely interesting and attractive.

**Carnation leaves diseased** (Slough).—The Carnation leaves sent were so badly infested with rust, spot and red spider that it is quite useless to ever expect satisfactory returns from them. Every scrap should be burned, and their places occupied with healthy plants.

**Laelia not developing its flowers** (Lewia). We showed your letter to a well-known cultivator of Orchids within the London district, and he at once gave London fogs as the cause of the trouble. They have this year been unusually prevalent, and have destroyed thousands of blooms of different kinds. A suggestion which some consider helpful is, when the flowers are clear of the sheath, to keep the roots drier than usual in the event of foggy weather.

**Heating a small greenhouse** (Subscriber).—We should say that a large oil-stove would suit your purpose, for, though many fail with them, we have seen several instances where they have proved perfectly satisfactory. The main point is that the stove be kept scrupulously clean, for if it is not attended to carefully in this respect failure is certain. Next, the ventilating of the house is also a very important item. As the house is in rather a damp position, you will find it a great advantage in winter, even if the weather is mild but damp and close, to keep the lamp burning and give plenty of ventilation, as by this means it is quite possible to get rid of the superabundant moisture.

## FRUIT GARDEN.

**Peach tree Early Alexandra dropping its buds** (A. F. J.).—Unfortunately, this variety is noted for dropping its buds, and nothing we know of can be done this spring to prevent those buds from dropping which are more or less in condition to do so. It has generally happened in our experience that enough sound buds have been left to produce a fair crop. We presume that you are satisfied that the tree is not suffering from the want of water. If it is, that fact alone would, undoubtedly, account for the dropping. In any case, whether you think it is dry or not, we should give the tree an extra soaking of clear water at a temperature of 55° Fahr., on a fine morning, with plenty of air in the house. To prevent the buds from dropping another year, we would advise you to train the summer shoots a little wider apart, thereby exposing the branches and leaves to more air and sunshine, and, as a consequence, resulting in stronger and plumper buds.

**Using caustic wash on fruit bushes** (T. S.). Yea, in winter, when the bushes are at complete rest, but not when the slightest appearance of growth has taken place, and as fruit bushes usually start into growth earlier than Apple or Pear trees, it would be safer we think to defer the application until next winter. It all depends on the condition of your bushes at the present moment. The wash is fatal to young growth.

**How to grow Mistletoe on Apple trees** (H. N. H.).—The way to grow Mistletoe on Apple trees is to select one or more of the strong branches of the tree on which it is desired to grow the plant, and cut a notch in the bark of the branch on the under side, deep enough and long enough to enable you to prise it up sufficiently high to insert the seed of the Mistletoe in the aperture (each berry contains one seed), pressing it down afterwards to secure the seed in position, taking care, however, not to bruise the seed or the operation will turn out a failure. The seed should be protected against birds by tying a piece of tiffany over the cut bark and leaving it on until growth takes place. Now is a good time to carry out the work.

**Apple Roundway Magnum Bonum** (Pomona).—Those who value an Apple for its high quality, rich flavour and pleasant aroma should not fail to include this in their collection, even if the collection is a limited one. It is in season from March to May, and at that late time of the year, for Apples, is invaluable either for dessert or cooking. The variety does not crop so freely or so heavily as do many sorts, but this defect is balanced by the size and weight of the fruit as well as by its excellence. For bush or pyramid culture in the garden it should be worked on the Paradise stock, but for orchard culture (for which it is also suited) it should be worked on the free or Crab stock. The fruit should be allowed to hang on the tree as long as possible. To anyone purposing planting Apple trees for market we do not recommend this variety. Both Newton Wonder and Bramley's Seedling are splendid Apples, and a great recent acquisition to the list of first-class cooking Apples. Of the two we prefer the former, Newton Wonder. This variety is very prolific, and the quality as good as Wellington. It is of large size and splendid colouring.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W. C.

## PRUNING ROSES.

THE time for pruning Roses is approaching, and a few notes on the subject will doubtless be useful to our readers. For the majority of Roses the second week in March is a good time, but slightly earlier in early districts and slightly later in late ones. Tea Roses are best left until April. If these have begun to shoot out, retain some of the young growths.

In the following instructions it should be remembered that Rose-growers prune the last year's growth, so that if it is directed to prune back to 2 inches or 3 inches, that measurement is reckoned from where the growth starts from, frequently from the previous year's shoot.

Another fact is worth remembering, and that is to look over the plants in September and free the centres from small, useless wood and much of the old wood; the young wood is then enabled to ripen well. If quality of blossom is desired, the number of growths retained in September will be reduced to three or four of the best and ripest of the current year's production. All soft, rank growths are best pinched or stopped in September.

### CLIMBING AND RAMBLING ROSES

should receive their principal thinning out and pruning soon after flowering, the plants being released from their supports for this to be done; their growths are subsequently retied and spread out.

### STANDARD ROSES

are pruned on the same lines as dwarfs or bushes, except that they will sometimes make rather shorter growths. These are retained a little longer than dwarfs of the same sorts. The centre of the heads of the standards should be well thinned. In all pruning cut back to an outward eye or bud where possible.

### PRUNING ROSES FIRST TIME AFTER PLANTING.

This should be done rather severely. Many are in a dilemma how to treat climbing and rambling Roses the first season. We have proved that the best results were obtained in the future when the plants were cut back to within about 2 feet of the ground the first season. A ripe growth or two may

be left somewhat longer if desired. Where these Roses are grown as free bushes in beds they may be left almost unpruned the first year, but when planted in the spring they should be pruned hard at the time of planting. Next week we shall deal with individual hybrids and varieties.

## "STREAK" DISEASE IN SWEET PEAS.

THE article on "Sweet Pea 'Streak' Disease," by Mr. F. W. Harvey, in THE GARDEN of the 15th inst. describes exactly the way in which my Sweet Peas were affected when the disease first appeared four years ago, but since then the disease has each year attacked the plants in an earlier period of their growth. In 1905 I brought a diseased plant to the National Sweet Pea Society's show; it had stopped growing when about 3 feet high, before any blooms had opened; the tops shrivelled up and the buds refused to move. It was on view at the show, but the disease seemed to be new to all the experts there. In the late autumn of that year, at Mr. Horace Wright's suggestion, I sent a plant to Mr. Massee, who discovered some traces of Peronospora on it; but it was a very poor specimen, the growth being quite over, as it was very late in the year. In 1906 the disease appeared quite early, when the plants were about 1 foot high. Believing it to be Peronospora, they were frequently sprayed with Bordeaux mixture, and later with sulphide of potassium, all to no purpose; the disease spread from plant to plant until nearly all were affected. In October the plants were all lifted and burned, and the supports, wire netting, walls and surface of the stations were sprayed with formalin (a 2 per cent. solution) with the idea of destroying all resting spores. In the spring of 1907, when preparing the stations no animal manure was used, as they had been heavily manured the three previous years; the second spit was replaced with fibrous loam from old pasture land, and this was dressed with Vaporite some wireworms being present. A dressing of superphosphate (about 4oz. to the square yard) was given to the top spit along with a small quantity of sulphate of potash and some burnt clay, all being forked in a month before planting out. The seeds were sown singly in 3-inch pots in a compost of fibrous loam, with some leaf-mould and sharp sand, and were grown in a cold frame until 3 inches high, being planted out about the middle of April.

The disease appeared in some plants very soon after planting out, and attacked others at different periods of their growth. An eminent bacteriologist and expert in fungoid diseases very kindly undertook to examine the plants; he had them under observation as they were attacked all during the growing season, but could not find any trace of Peronospora, no internal fungus mycelium in the tissues, and when grown on under warm, moist conditions no sign of Peronospora appeared on the surface. Later in the autumn I saw it suggested in a gardening

newspaper that the trouble might be caused by eelworms. I accordingly sent some roots of diseased plants for examination and they were found to be swarming with eelworms, apparently two distinct species, one of which was recognised as *Tylenchus minimus*. Some time afterwards, before destroying all the plants, I had the roots examined of some plants that had not shown any appearance of disease and some eelworms were found in them also, but these plants were quite withered at the time and the eelworms might have attacked them after their growth was over. It is quite possible that the eelworms may have been merely an effect and not the cause of the disease. It was noticed that there was a great absence of nodules and rootlets on the roots of all the diseased plants that were examined last year. The disease seemed to spread from plant to plant in the row until all were affected; some isolated stations escaped and diseased plants did not communicate the trouble to my neighbour's plants on the other side of the wall, although almost touching them.

These particulars may be useful in helping to determine during the ensuing growing season what this dire disease is and how it may be combated; it is to be hoped that the National Sweet Pea Society will take the matter in hand, keep under observation some gardens where the disease appears this year, and collect experiences from any of the members who may be so unfortunate as to have their plants attacked. Mr. Walter P. Wright has sounded the alarm "Breakers Ahead!" and the members of the National Sweet Pea Society must wake up to the danger, for the very existence of *Lathyrus odoratus* is in jeopardy.

HENRY J. R. DIGGES.

Dunkerron, Donnybrook.

MY attention has been called to Mr. F. W. Harvey's note in your issue of the 15th inst. on "Sweet Pea 'Streak' Disease." It may interest your readers to know that we are also troubled with this in Ireland. I examined microscopically during the course of last summer a considerable number of specimens, but invariably with the result that no trace of fungus mycelium could be found in the tissues of the affected parts, nor on the surface of them; the cause is certainly NOT *Peronospora vicia*. On placing the affected plants in an atmosphere thoroughly saturated with moisture a copious development of a *Botrytis* invariably took place after some time; but this, I am inclined to think, was a case of saprophytism occurring when the parts were already dead. Later in the year the roots were investigated and found to contain eelworms in plenty, but there were no galls or similar malformations such as are usually caused by the destructive members of this group. These worms were identified by my colleague, Professor Carpenter, and were found to belong to a species hitherto not recorded as being parasitic. Professor Carpenter found them also apparently equally abundantly in the roots of apparently healthy plants, so that it would not appear that these worms were the cause of the trouble. We hope to make further enquiries into the matter next year. It is possible that the disease may be of bacterial origin. Spraying and other preventive measures taken have so far proved of no value whatever.

GEO. H. PETHYBRIDGE.

Royal College of Science, Dublin.

THE note by Mr. F. W. Harvey on page 79 is very opportune and interesting, and if it leads, as I hope it will, to the bringing forward of some remedy, it will have served a valuable purpose. Up till last year I had never had a plant attacked and then only two plants were affected. Curiously enough, these were in the very centre of a semi-circle of eight pink varieties, and the plants attacked were of a very vigorous variety and a novelty at that, to wit, Agnes Eckford

However, I knew the "streak" of old, and immediately I saw the first trace of its appearance I pulled up the affected plants and burnt them, root and branch. But what caused the "streak" or whether it is a disease I have not the faintest idea. At present I throw in my verdict with that of the old gardener in a Berkshire vicarage garden. Last year his employer said to him, "Charles, what is this streak disease in Sweet Peas that the gardening papers are bewailing?" "Streak disease, sir," was the answer, "streak disease! Well, sir, streak disease is a mystery." That it is fungoid mystery is my own opinion; I certainly should not credit it to eelworm. I have had a deal of experience of the latter pest, and have never known it to give trouble after the plants had reached the flowering stage. Collapse generally takes place when the plants are anything from 6 inches to 18 inches high.

F. J. CASTLE.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 3.—Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster, 1 p.m. to 6 p.m. Lecture at three o'clock on "Bulbous Plants in New Zealand," by Mr. E. White; Horticultural Club Monthly Dinner; Lantern Lecture by Mr. C. E. Pearson, 6 p.m., Hotel Windsor, Victoria Street.

March 5 and 6.—Royal Horticultural Society's Colonial Fruit Show.

March 9.—United Horticultural Benefit and Provident Society's Annual General Meeting, 8 p.m., Royal Horticultural Hall.

March 11.—East Anglian Horticultural Club Meeting.

### Examination in horticulture.

An examination in elementary horticulture, for lads and young men under nineteen years of age, will be held under the auspices of the Royal Horticultural Society on Wednesday, March 25, in as many different centres in Great Britain and Ireland as circumstances may demand. The general conduct of this examination will be on similar lines to that of the more general examination. Intending candidates should write at once for a copy of the syllabus to the secretary, Royal Horticultural Society, Vincent Square, London, S.W.

**Colonial Fruit Show.**—On March 5 and 6 the Royal Horticultural Society will hold an exhibition of Colonial-grown fruit and vegetables, both fresh and preserved. Fellows will be admitted at 1 p.m. on the 5th and at 10 a.m. on the 6th. The exhibition will be open to the public on payment of 2s. 6d. from 2 p.m. to 6 p.m. on the 5th, and on payment of 1s. from 10 a.m. to 6 p.m. on the 6th. The band of the King's Colonials will perform each day.

**Note from Baden-Baden.**—To those lovers of early spring-flowering plants unacquainted with it, *Crocus atticus* well deserves to be recommended. It has been in flower here since the 6th inst., and was at its best on the 15th inst. The flowers are not large, but exquisite in shape and lovely in their shining pink colour. It is easy to cultivate, and received no protection this season at all; *Eranthis hymenalis* is just beginning to appear.—MAX LEICHTLIN.

**Potato trials in Surrey.**—With the co-operation of Mr. Charles Moon of Chessington Court the Surrey Education Committee during 1907 conducted trials of Potatoes (change of seed) on similar lines to those previously conducted at Merton in 1905 and Farnham in 1906. Ten varieties were chosen, namely, Up-to-Date, Duchess of Cornwall, Factor, Peckover, Dalmeny Beauty, British Queen, Superlative, Royal Kidney, Sir John Llewelyn and Table Talk, and all were grown under exactly similar conditions.

The results fully confirmed those obtained in 1905 and 1906, and forcibly demonstrate the superiority of Irish and Scotch sets for planting in the South over those saved in Surrey. We give the results of Up-to-Date as being indicative of the general results. Surrey seed, 14lb.; Hants, 49lb.; Spalding, 46lb.; Scotch, 73lb.; Irish, 84lb. Twenty-six tubers of each were planted. In Royal Kidney, Sir John Llewelyn and Table Talk the Scotch seed gave slightly better returns than that obtained from Ireland. As Mr. Alex. Dean, V.M.H., who personally superintended the trials, reports, the above facts are "of supreme importance, and should have the fullest consideration by Potato merchants."

**Dwarf flowering shrubs in a London park.**—On entering the Broad Walk from the south entrance of Regent's Park, a little to the left is a very interesting bed to all lovers of flowering shrubs. The centre of the bed contains *Rhododendron dahuricum* in full flower at the time of writing (February 17). Also may be seen the tree *Wych Hazel* (*Hamamelis arborea*), just going over, to my mind a most interesting plant, with its branches covered with the yellow and brown blooms. The white *Mezereon* (*Daphne Mezereum album*) is also in flower, but the purple flower is not so forward. Other plants yet to flower in this bed are *Rhododendron Early Gem* and *præcox*, also *Daphne neapolitana*. As the days lengthen the latter will no doubt be wreathed in bloom. The little Winter Aconite springing up here and there over the bed, make all who love a garden pause at this particular corner of one of the best of our London parks. It should induce all who have a sheltered corner in their London houses to plant a few of the above-named, especially for the pleasure they impart at this dull time of the year in the open garden.—G. S. JORDAN.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Sweet Pea nomenclature.**—One thing in connexion with the beautiful coloured plate of Sweet Peas issued with THE GARDEN last week, which I noted was that of twelve varieties, ten had personal names and only two had non-personal appellations. Looking over a list of sixty-five selected varieties of these flowers published in the National Sweet Pea Society's schedule of classes for the coming exhibitions, I found that only twelve had non-personal names, all the rest having personal ones. Apart from the fact that individuals are paid but poor compliments when their names are attached to varieties that, such is the growth of variety in Sweet Peas, may be out of cultivation in two or three years, is there among raisers of Sweet Peas so poor imaginative power that names that are non-personal and short concise ones also cannot be found? I cannot conceive that there can be any special craving for the fugitive immortality associated with Sweet Pea naming. Would that the National Sweet Pea Society would offer prizes for best names, as for best flowers.—D.

**Cotoneaster angustifolia.**—This has fruited well with me against a south wall in Kent.—CRANBROOK, Hemsted Park.

**Buchu plants of South Africa.**—Referring to a recent note on the relations of plants and commerce it may be of further interest to record the appearance in the London drug market at the beginning of February of the leaves of a rutaceous plant, which were offered under the name of "Aniseed Buchu." It may perhaps not be generally known among the readers of THE GARDEN that the term Buchu is given in medicine to certain species of *Barosma*, of which

*Barosma betulina*, or Birch-leaved Buchu, is acknowledged in the British Pharmacopoeia as the true source of the drug, which is given medicinally as a tonic and diuretic. The plant furnishing these leaves is a small shrub, a native of Cape Colony, where the leaves are collected during the flowering and fruiting season. The leaves of *Barosma crenulata* and *B. serratifolia* are also known as Buchu by the natives and sometimes find their way into the English drug market. But those of the so-called Aniseed Buchu are said to be furnished by *Agathosma villosa*, a plant belonging to the same natural order (Rutaceae), but not known to possess any economic value, though *A. virgata*, a native of the mountain slopes of Cape Colony, is known as "Bok Buchu" by the people, among whom it is used in pulmonary complaints. All these plants belong to the same natural order as the well-known perfume plant of Australia (*Boronia megastigma*). From the fact that many plant products that appear in commerce spasmodically are gathered during the fruiting or seeding season, and that their botanical identification is

## THE FRUIT GARDEN.

### PLUM COE'S GOLDEN DROP.

**T**HIS excellent dessert Plum is grown under various names, and in the Eastern Counties I have frequently seen it grown and sold under the names of Bury Seedling and Coe's Imperial. It was raised by a Mr. Coe at Bury St. Edmunds 100 years or more ago, and is still one of our best late dessert Plums. In many gardens it is not robust enough for a standard, though on the South Coast in a warm soil I have seen it bearing splendid crops grown on a short stem. The fruits hang on the trees when other kinds are past. However, such a splendid fruit is well deserving of a wall, and, given ample room, it gives a good return. This Plum is not ripe, even in the South, till well on in September, and in the North it is an easy matter, by gathering late and storing in a cool place, each fruit being placed singly in tissue paper and laid in

vinery is provided there is no reason why the amateur should not plant Vines with the most satisfactory results. One occasionally meets with a Vine planted in a border under the greenhouse staging, with no care taken as to the soil in which it is planted, nor to the drainage of the same. This treatment cannot be successful in producing good quality fruit.

#### PREPARING THE BORDER.

The thorough preparation of a Vine border is most essential, and entails a fair amount of labour; however, by a careful estimation of the material required for this purpose, and arranging for this to be at hand before commencing operations, the necessary preparations for planting Vines is not the difficult task that many suppose it to be. In the majority of cases it is wise to have a hard and impenetrable bottom to the Vine border, which should slope from the house to the front of the border. Place a few rows of 3-inch drain pipes across the prepared surface, connecting these with a drain carried in front of the border. This drain should consist of 4-inch pipes. Place between the pipes a layer of limestone or broken bricks, covering them with about 2 inches of the same material.

The next question is the preparation of the soil in which the Vines are to grow. Turf cut from an old pasture is best for this purpose. This may be used quite fresh, although it is frequently advised that turf for this purpose should be kept in stack for a year. This fresh turf is very likely to contain wireworms, but these are not injurious to the Vine roots, or in fact any tree or shrub, although so destructive to many other plants, such as Carnations and Carrots. Taking these facts into consideration, it will be found that the quantity required for planting a medium sized vinery is moderate, especially when it is remembered that only a portion of the border is completed the first year, a portion of the remainder being added annually until finished. This system is far better than filling in the whole bulk of soil in the first instance, as, by adding fresh soil, food is supplied to the Vines, and the border becomes evenly filled with healthy roots. Place a layer of the turf, grass side downwards, over the drainage, building up the outer walls with the same material and filling in between these walls soil prepared by mixing ten barrow-loads of roughly-chopped turf, one barrowload of old mortar rubbish and 1 cwt. of Vine Border Compound as supplied by the leading firms dealing in artificial manures. The turf should be light rather than heavy, what is termed a sandy loam being the best for this purpose. Make the border moderately firm by treading the soil as the work of filling in proceeds.

#### PLANTING THE VINES.

Do not undertake this until the plants commence to swell their buds. Turn them out of the pots and carefully remove the soil from their roots. This may be done by placing the ball in a vessel containing tepid water and removing the soil with the hands. If several Vines are being planted deal with one at a time, so that the roots are not exposed for a longer period than is absolutely necessary. Prepare a shallow bed for the reception of the roots, spreading these out carefully and covering them with 3 inches or 4 inches of soil. The Vines must be allowed to grow at least 1 foot before any artificial heat is applied. If any attempt is made to force them into growth before they have made fresh roots total failure will be the result. If there is no inside border and the Vines are taken through the front wall into the house the exposed portion of the rod should be protected during the winter. Single rods should be planted from 3 feet 6 inches to 4 feet apart.

#### THE PLANTING OF GROWING VINES.

This may be undertaken from May to July, and in some cases these prove more satisfactory than the dormant plants. Disturb the roots as little as possible.

Munden Gardens, Watford.

C. RUSE.

A SPLENDID DESSERT PLUM: COE'S GOLDEN DROP.

often greatly assisted by the presence of seeds or fragments of fruit, it often happens that the seeds are in a condition for germinating, and plants new to cultivation may thus be raised.—

JOHN R. JACKSON, *Claremont, Lympstone, Devon.*

**Snowdrops flowering in three weeks from planting.**—While clearing out my seed and bulb chest towards the end of January, I happened upon six home-saved Snowdrop bulbs which had been overlooked at the October planting. They had made such a brave effort to grow in the box, having made shoots an inch long, that I thought they were worthy of encouragement. Accordingly, the next day, January 28, I put them in on a sunny south border, about 1½ inches deep. To my astonishment when potting about the border a fortnight later I saw two or three tiny white flower-buds where the patch of Snowdrops were planted. At first I could scarcely believe my eyes, but to-day, St. Valentine's Day, there are two fully expanded flowers daintily dancing in the sunshine. And what valentine could be more welcome?—E. J. C.

single layers in a drawer, to keep them good to the new year.

Of late years this variety has found much favour when grown as a pot tree, and grown thus it does grandly; the tree fruits in a very small state, and the crops hang well. I grew this variety on the back wall of a cold house and got a splendid return, as with glass protection it never failed us, and the tree was not a rank grower by any means. In a warm garden it makes a nice pyramid when grown in this way. The trees at times suffer when in blossom, so that, if possible, a sheltered position should be chosen, the soil well drained and the roots not too deeply planted, so that rich surface food may be given.

G. WYTHES.

### THE PLANTING OF YOUNG VINES.

JUDGING by the various queries dealing with this subject which appear from time to time in THE GARDEN, it appears to be an important matter with many readers. When a suitable

## THE FLOWER GARDEN.

### A PRETTY AND USEFUL ANNUAL.

(*COLLINSIA BICOLOR*.)

**A**LTHOUGH so long an inmate, and a favourite inmate, of our gardens, the pretty little *Collinsia bicolor* does not appear to have received any generally recognised popular name. It is well worthy of one, but the generic name of *Collinsia* comes so readily to English tongues that no other seems really necessary. As a dwarf edging plant for beds or borders this *Collinsia* is deserving of more attention, for if the soil is well firmed after planting the specimens rarely exceed 9 inches in height, and bear a profusion of pretty little delicately-coloured flowers. As may be seen by the illustration these somewhat resemble a *Salvia* or *Snapdragon* in shape, so that they make a welcome change from the general run of summer garden flowers. They are generally white, tipped with blue or bluish lilac, though there is a pure white form called *candidissima*. The *Collinsia* is a native of California, but is classed as a hardy annual in this country, and is really so in all but cold and wet districts.

The culture usually accorded to hardy annuals should be given to it, but in view of its possessing a modicum of tenderness sowing should be deferred till the weather gives promise of being fairly warm and sunny, say the end of March or the beginning of April. On light soils and in warm districts autumn sowing will be found to give the best results, the plants forming sturdy and good-sized patches before the heat of the sun urges them into flower. In wet and cold districts autumn sowings generally perish in the winter.

### HOW TO PREPARE AND SOW A LAWN.

THE one feature about our gardens and public parks that immediately appeals to visitors from tropical or subtropical countries is the velvety closeness and verdant hue of the lawns which abound, a feature that has been characteristic of British gardens from the earliest times. Certainly there is nothing more restful and refreshing for tired eyes than a well-kept grass plot, no matter what its size may be, and nothing provides a better setting for the highly-coloured flowers of many kinds that abound in most gardens. There are two methods of preparing or making a lawn, viz., by laying down turves or by sowing seeds. As the former, to be successful, should be done in early autumn or winter it will be useless to deal with it now, but seeds are best sown in the spring, say early in April, although they can be sown in the autumn with a fair prospect of success.

#### PREPARING THE SOIL.

As in every other gardening operation, a good beginning is absolutely essential if success is to crown our efforts, and it is quite useless to sow grass seeds on soil that has only been prepared in a haphazard manner. Although the ground, especially where it is of a heavy or retentive character, is best prepared in the autumn, there is still time to do the work, but it must be carried

out at once. Artificial draining is not often required, but if it is needed it must be done before anything else is seen to. Levelling will be the next task, and this needs a certain amount of care so as to ensure as nearly as possible an equal depth of good soil over the surface. This good soil ought not to be less than 9 inches in depth all over the plot; twice as much is better. If the soil is very heavy or sticky it will be necessary to add such substances as road scrapings, leaf-soil, burnt earth or garden refuse, or even well-decayed old hot-bed manure, so as to render it more friable.

After levelling thoroughly, dig the soil, taking care to remove the roots of any perennial weeds such as Docks, Thistles and Nettles that may be present. Many opinions exist as to the wisdom

levelling, tread the whole of the bed so as to make it firm but not hard. When this is finished the surface in general should be quite level, and a raking with a coarse-toothed rake is all that will be needed before sowing.

#### SOWING THE SEEDS.

The quantity of seed needed will be the first consideration. To ensure a good thick crop 1lb. per square rod is not too much; less may be used, but this is not advisable. Practically all seedsmen of repute supply excellent mixtures of grass seeds, varying the kinds according to the soil, so that it is needless to name the grasses here. A still day must be selected for sowing, and it is imperative to scatter the seeds evenly over the surface. Some sowers prefer to go over the plot twice, using half the quantity of seed each time, working across the first course taken.

After sowing, give the bed a raking over to cover the seeds and then roll it with a light roller, doing this in two directions so as to ensure every portion being rolled. Birds are very fond of many grass seeds, and where the plot is only of medium or small size it is wise to protect the seeds with fish netting or strands of black cotton secured to sticks a few inches from the surface.

#### AFTER TREATMENT.

The young plants will usually present themselves in three or four weeks, and growth will subsequently be fairly rapid. If the weather is dry copious waterings will be needed or the young plants will quickly perish. The first mowing should be given when the young grass is about 3 inches high, and this operation needs a good amount of care. A sharp scythe is usually better than a mowing machine, but the latter may be successfully employed providing the knives and blades are perfectly adjusted so that the cutting is clean. Close cutting must not be performed, it only being necessary to remove the tops of the plants. Throughout the summer light rollings and mowings will be necessary, and watering must be attended to if the weather is dry. This is most important.

A USEFUL ANNUAL (*COLLINSIA BICOLOR*).

of manuring soil for lawns, but, as in most other things, this will be ruled by local circumstances. It is certainly preferable to secure a site that was manured well for some other crop the previous year, but where this is impossible and the ground needs manure, this may be incorporated when digging, taking care to use short material only and see that it is evenly distributed.

Digging finished, the ground must be allowed to settle for a few weeks, or until sowing time, which is, preferably, early in April. By this time, if much levelling was needed at the outset, some parts of the plot will have settled down more than others and some additional levelling will be necessary. Select a day when the soil will not cling to the boots for this work, and after

thinks his own particular pet sorts are the best. So, although I have grown Potatoes in about six counties of Great Britain with success, under varying conditions of soil and climate, I look upon the task of selecting the best Potatoes as a subject open to much criticism. Still, from proper criticism springs knowledge, so I welcome it. We depend on the Potato as a source of food supply to a large extent, and we require the supply to last for as long a period as possible during the year. Therefore, to get best results, careful attention must be given to certain points, from the selection of the sets till final earthing up.

#### SELECTION AND PREPARATION OF SETS.

These should be carefully selected tubers, free from disease, of medium size, and from 2oz. to

## THE KITCHEN GARDEN.

### THE BEST POTATOES AND HOW TO GROW THEM.

(Second Prize Essay.)

**E**VERY grower of this useful and necessary tuber (like our friends the raisers of Sweet Peas)

3oz. in weight, with robust sprouts at the time of planting. To ensure this, all sets should be selected (or, if bought, procured) early in the autumn, and stored in an airy, light, yet frost-proof place in special boxes.

The system practised here in Jersey is the best I have yet met with, and is universal. Even the poorest labourer has his Potato boxes, constructed from quarter-inch deal boards, 24 inches long, 12 inches wide and 2½ inches deep, provided with stout cross handles 1 inch thick, and standing 4 inches clear above the top of the box. The seed size tubers are picked up in these boxes straight from the ground, taken to the storeroom and stacked up in tiers. During the slack winter months they are carefully looked over and all diseased tubers removed. About three or four months before planting time, and before growth commences, they are graded according to size, and set up on end in their boxes to sprout, free circulation of air being given at all times, except during actual frost, and growth is confined to one or two strong sprouts.

The following advantages result from the above method. A sprouted tuber given favourable weather comes up at once, and an earlier crop results. Should the weather be unfavourable, planting can be delayed until the soil is in a suitable state, when, once in the ground, the sets go on without a check. At planting time the boxes are taken out as they are, the sets are put direct from them into the trenches, and the result is a perfect set with sprouts undamaged. I have dwelt on this at length, as upon the proper selection and treatment of the sets the crop to a great extent depends.

#### SOIL AND PREPARATION OF THE SAME.

The quality and quantity of ground to be set aside for Potato culture must, of course, be determined by the cultivator. Potatoes may be and are grown excellently in nearly every class of soil, although the best results may be expected from sandy loam. It is just here, however, that a little judicious experimenting, together with an intelligent observation of your neighbour's crop, may come in useful. Take notice of those sorts which do well in your immediate neighbourhood on soil similar to your own, test their keeping and cooking qualities where possible, and make your selection of varieties accordingly. Should you desire to grow for the show table, the appearance of the tuber must also be studied. I have no hesitation in saying that tubers quite suitable for both purposes may be obtained by observant selection.

As regards preparation of the soil, for my own part, whenever possible, I practise and strongly recommend autumn digging and manuring, then leaving the ground rough to get the benefits accruing from frost and snow. Give a liberal manuring with half-rotted stable manure, trenching the same in at least 1 foot. By this process there will be a friable, mellow top crust at planting time, which will work easily and evenly. I am

well aware that on the point of autumn digging and manuring expert opinion differs; however, I contend that ground so prepared in nine cases out of ten is in a far more suitable condition to receive the sets and gives better results than when prepared and planted straight away in spring. Where good natural manures cannot be obtained, artificial must be used. There are at the present time many excellent sorts of Potato manure on the market; but for those who like to prepare their own, the under-mentioned is an excellent mixture: Three parts superphosphate, two parts kainit and two parts sulphate of ammonia. Sow it broadcast over the ground before commencing to plant at the rate of 8lb. to 10lb. per square rod. This mode of application encourages root formation and the tender rootlets run less risk of damage by contact with the strong chemicals than when the manure is sown in the trenches in quantity.

#### PLANTING.

The principle to guide us here must be to see that sufficient space is given to every plant to mature and absorb sun and air, according to the character of the variety and the state of the soil. There is no doubt that close planting is a source of disease, resulting as it does in a drawn weakly haulm, which when saturated with moisture and without sufficient space for air and sun to penetrate and dry it falls a prey to disease and the crop is worthless. With care in planting the opposite result would probably have been obtained.

The following are safe distances to plant: Early varieties—1 foot from set to set, 18 inches to 2 feet between the rows; second earlies and small top varieties—12 inches to 16 inches from set to set, 2 feet to 2½ feet between the rows; main crop—15 inches to 18 inches from set to set, 3 feet to 4 feet between the rows.

#### TIME OF PLANTING.

This depends in a great measure on the locality and season. If a warm sheltered south border with light good soil is available a late February planting of a good early variety would probably have good results. But for all ordinary purposes, and especially if the soil is of a cold nature and exposed, March and April are the most suitable months, and even May is not too late. The advantages of early planting are always counter-balanced by the risk of late frosts and inclement weather, and cannot be generally recommended.

#### CULTIVATION.

If good results are desired this must be carefully attended to. As soon as the growth shows above ground lightly fork or hoe carefully between the rows, thus keeping down weeds and making the soil more suitable for earthing up. Should frost threaten have litter handy, or even Pea sticks, which can be laid along the rows for protection and easily removed when not required. Careful attention must be given to earthing up as growth progresses, and when it is apparent that the haulms will be bruised by further working among them the final earthing should be given, taking care to draw the soil well up around the stems and not to leave a hollow for the reception of moisture around them.

#### DISEASE.

The old saying, "Prevention is better than cure," is very applicable to Potato culture, and those who wish to raise a crop of good, clean, sound tubers, free from disease, should spray their crop occasionally during the growing period with "Vermorite" or some other good preparation of Bordeaux mixture. The result will more than repay for the trouble taken. The first spraying should be performed at the end of June or early in July. Earthing up will prevent spores of the Potato disease being washed from the haulm to the tubers in the event of the former being attacked. The list of the best varieties will be given next week.

## THE GREENHOUSE.

### SCENTED-LEAVED PELARGONIUMS.

**I**N the history of gardening there was a time when the scented-leaved Pelargoniums were more extensively cultivated than they are at the present day. The passion for novelties and the enormous number of plants now at the command of the gardener probably accounts for the change in taste, but, where possible, a selection of the Cape species should certainly be cultivated, for though the flowers are small they are often beautifully and delicately marked, and the fragrant foliage possessed by many is compensation for lack of more showy qualities.

One frequently sees scented-leaved "Geraniums," as they are popularly called, in cottage windows, turning their leaves and flowers towards the light, but in more pretentious places the showy fancy, zonal and Ivy-leaved varieties have displaced them. Exception, however, must be made in the case of Gunnersbury House, where there are some remarkable specimens trained in the form of fans over trellis work, forming portable fragrant screens capable of being used in a variety of schemes of indoor and outdoor decoration. Our principal nurserymen also stock a collection of the best varieties, and from this fact it is safe to assume that there is still a demand for them.

Nearly all the species of Pelargonium, of which some 170 are known, are natives of the Cape of Good Hope, and were probably introduced to Europe by the early Dutch and English settlers during the end of the seventeenth and the beginning of the eighteenth century. As early as 1690 Pelargonium cucullatum, one of the parents of the florists' Pelargoniums, was known in England, and *P. zonale* and *P. inquinans*, the two original parents of the race of zonals, were introduced in the years 1710 and 1714 respectively. Linnæus knew about twenty-five species, which he described under the name Geranium. In his celebrated work "Geraniologia," published in Paris in 1787 to 1788, L'Héritier first applied the name of Pelargonium, and included Linnæus's species. Early in the nineteenth century they were much cultivated in England, and probably

reached the culminating point of their popularity on the appearance of Sweet's "Geraniaceæ," a handsome work in five volumes, containing 500 coloured plates of plants of the Geranium family. It was published in London during the years 1820-30.

Some species are worth growing as foliage plants alone for the sake of the form of the leaves, which is often as elegant and varied as are the fronds of some of the most beautiful Ferns. These, when well grown, make excellent subjects for table or window decoration, and harmonise in almost any group of flowering plants. A selection of the best varieties most suitable for cultivating as foliage plants is as follows:

*P. crispum*.—A slender, much branched species from South Africa, with small fan-shaped leaves crisped at the margins and arranged on the stems in two ranks; sweetly Citron scented. The purple flowers are produced in September in two-flowered to three-flowered clusters. The variety

majus has larger flowers, and variegatum has leaves beautifully blotched with white.

*P. denticulatum*.—A species with finely-cut leaves of medium size, very sweetly scented. The flowers are lilac or rosy purple, the upper petals being two-lobed. The variety majus is usually cultivated, and odoratum is more fragrant than the type.

*P. filicifolium odoratum* is probably a form of the preceding species with finely divided leaves, suggesting, as its name implies, the fronds of a Fern. It is a very fragrant variety.

*P. Radula*.—The leaves of this species are cut into many lobes, which have revolute margins; they are rough to the touch on the upper surface, soft and velvety beneath. The flowers are small, pale purple with dark streaks. The plant has a balsamic fragrance, and is cultivated for its essential oil. The many varieties under this name are probably hybrids between *P. Radula* and *P. graveolens*, the latter having larger and less divided leaves.

*Lady Mary*.—Leaves of medium size with undulating notched margins; Citron scented.

*Lady Plymouth*.—A very attractive variety with deeply cut fragrant leaves, beautifully variegated with white on a green ground. It is one of the best of the cut-leaved varieties.

*Little Gem*.—Leaves deeply lobed with toothed margins; Peppermint scented. Flowers bright rose coloured.

*Stag's Horn*.—As indicated by its name, this variety has leaves beautifully cut and lobed in a variety of ways, with the margins finely toothed and crisped; a very attractive foliage plant.

R. SPOONER.

(To be continued.)

## THE EDITOR'S TABLE.

### MESSRS. BULL'S PRIMULAS.

We have received from Messrs. W. Bull and Sons, King's Road, Chelsea, London, S.W., some flowers of their Chinese Primulas which are very fine indeed. Varieties that specially appealed to us on account of their large size and exquisite colours were Duke of York, deep crimson; Giant White, large single white with yellow eye; Countess, delicate blush pink; Imperial Blue, beautiful lilac-blue; Pink Beauty, blush pink; Ruby Queen, rich crimson-magenta, small yellow eye; The Duchess, pure white with a zone of crimson surrounding a clear yellow eye; Vulcan, deep bright crimson, extra fine; and Blushing Beauty, a very large variety.

*Denticulatum.*

*Little Gem* & *Lady Mary.*

*Crispum variegatum.*

TYPES OF SCENTED-LEAVED PELARGONIUMS.

*Filicifolium odoratum.* *Radula major.* *Lady Plymouth.* *Stag's Horn.* *Filicifolium odoratum.*

TYPES OF SCENTED-LEAVED PELARGONIUMS.

## COLOURED PLATE.

PLATE 1344.

## EXTRA FRILLED SINGLE BEGONIAS.

**T**HE advent of this charming break in the single Begonia marks an epoch in the advancement of this useful family similar to that obtained by the raisers of the fimbriated Primulas, and will, when known, find as many admirers.

There are many people who consider the smooth-flowered single Begonia to be a comparatively stiff and gross-growing plant, and not without some reason, but the frilled varieties when well grown possess a charm and beauty that can in no sense be termed stiff, and as the foliage is much smaller than in the ordinary singles, the plants being also much more branching in habit, they are graceful in appearance and of great utility for decorative work in the conservatory, while for bedding they will be found quite equal, if not superior, to the ordinary single Begonias.

Up to the present the finest frilling is to be found in the salmon and pink shades of colour, but doubtless in the near future the other colours will be brought to the same level of quality. This section also produces shades and combinations of colours that are not found in other Begonias; the lovely salmons and pinks, combined with yellow, buff, or orange, can only be compared to the shades to be found in a glorious sunset. The flowers figured in the coloured plate were from plants raised from seed by Messrs. Blackmore and Langdon, the well-known Begonia experts of Twer-ton-on-Avon, Bath, in 1906, and these plants flowered profusely during the whole summer of 1907, some of them lasting well for four months. They are quite easily raised, and good plants can be obtained from seed in six months from the time of sowing. Seedlings, like all Begonias, are variable in character, but this extra frilled strain will be found a great advance on any previously offered of this type.

## NEW PLANT.

CYCLAMEN LOW'S SALMON KING.

THIS is certainly one of the most delightful of the deep salmon rose shades of colour that we have seen in this popular group of winter-flowering plants, and as such it merits the attention of all gardeners and amateurs. The very high percentage of 95 per cent. to 97 per cent. of the seedlings, we are informed, come quite true to colour, the latter being especially valuable when seen under artificial light. The individual blossoms are large, and borne upon strong stems 9 inches or so above the ample marbled leafage, which forms a perfect setting to the flowers. Shown before the Royal Horticultural Society by Messrs. Hugh Low and Co., Enfield, on February 11. Award of merit for the strain.

## TREES AND SHRUBS.

## THE TWELVE BEST WALL PLANTS.

**F**REQUENTLY the question arises as to what are the most suitable climbers for covering walls. In the first place, the word "climbers" is given a great deal of latitude by some people, for they refer to any plant growing against a wall as a climber. For the present I propose to discard the word, for some of the best plants mentioned below are not climbers at all, but quite strong bushy shrubs when allowed to grow naturally. The reason for placing such plants against a support is that a little extra protection is necessary for them than is obtainable in the open ground, or that they prove such excellent

with good soil. It is not advisable to procure large plants to begin with, for small ones become established quicker, and eventually outgrow older specimens.

## AFTER TREATMENT.

Until the available space is covered it will be necessary, in the case of plants that do not cling naturally to the wall, to go over them occasionally and nail up the leading branches, pruning away all those that are not required. When, however, all the space has been covered, the owner has to decide as to whether his plants are to be kept neatly cut back to the wall or whether they are to hang naturally. The latter way has much to commend it. On the other hand, they take up a lot of room grown in this manner, harbour dirt, attract sparrows, and are often damaged by wind.

A CREEPER-COVERED COTTAGE.

subjects for covering walls that it is out of the question to neglect them. In the selection of the best plants it is necessary to settle on the height of the wall to be dealt with, for if a wall is only 10 feet or 12 feet high the planter has a far wider range of subjects to deal with than if the wall is double that height. Consideration is also needed as to the particular part of the country in which the wall is situated, for if in the milder places, such as Devonshire and Cornwall, many plants may be grown which have to be included among the occupants of the warm greenhouse further north. With these objects in view I have based the following selection on the material required for a wall 20 feet or 25 feet high, situated in any but the coldest part of the country.

## THE PLANTING OF WALL SHRUBS.

When about to plant shrubs at the base of a wall care should be taken to excavate holes at least 3 feet across and 2 feet deep, filling them

## SELECTION OF SORTS.

*Ivy*.—Although Ivy is so common everywhere, it must be admitted that it is the most useful of all wall plants. As an evergreen it has the advantage of keeping an otherwise ugly object sightly throughout the year, while it grows rapidly, thrives in both town and country, and gives a good account of itself in positions where other plants would fail. It also gives little trouble when once established, except a good hard cutting back in April each year. In addition to the common Ivy and the stronger growing variety called *canariensis*, the following sorts are of use: *Algeriensis*, *amurensis* and *dentata*, notable for their very large leaves; *digitata*, *Emerald Green*, *caenwoodiana*, *deltoides*, *donerailensis*, *himalaica* and *nigra*, with comparatively small leaves; *marginata major*, and *Crippsii*, with silver variegated leaves; and *chrysophylla*, *chrysomela* and *palmata aurea*, with golden variegated foliage. W. D.

(To be continued.)

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

#### HARDY FLOWER GARDEN.—

When the weather is suitable and the soil fairly workable, I make a rule to plant perennials quite freely. The present is an excellent time for this work, such subjects as Pinks, Delphiniums, Pansies, Sweet Williams and Canterbury Bells answering well from an early spring planting. Old and worn-out clumps of perennials should be lifted and divided; any of the outer pieces, if broken off with care, make useful plants in the flowering period. They should be planted firmly in deeply-dug soil. For immediate results I often make a planting of the free-flowering Aubrietia, Arabis alba (both single and double forms), alpine Auriculas and similar subjects in sunny positions. Rambler and other climbing Roses may still be planted, as may other climbers such as the Clematises, Passion Flowers, Hops, Ivies and Virginian Creeper. For covering up unsightly quarters and to climb over arbours, trellises and stumps of old trees, these climbing plants are most suitable.

*Chrysanthemums.*—By the aid of a cold frame I raise a nice batch of young plants from cuttings inserted at this period. The cuttings are made about 3 inches long, and are inserted round the edge of pots of any size available; when space is limited I prefer to use shallow boxes. Light, sandy soil will answer the purpose of propagation very well. Always press the soil firmly at the base of each cutting and water in after the box or pot is full, using a fine-rosed can. Place in the cold frame forthwith, and, if possible, make up a bed of leaves beforehand. I find there is just a little bottom-heat gained in this way, and, provided the frame is matted up when frosts prevail, root-formation will be speedy at this season.

*The Vegetable Garden.*—During the month of March my time is much occupied with preparing the ground for planting and sowing. My second early Potatoes are now planted to maintain the supply of this vegetable when the first becomes exhausted. In spare corners of the garden I usually make a sowing of herbs at this season. Peas, Broad Beans and stump-rooted Carrots do exceedingly well when sown at the present time, often gaining on those sown earlier. Parsnips should be sown in ground that has been deeply dug and well broken up. Sow the seed in drills 1 inch deep and the drills 15 inches asunder.

*Frames.*—The frames are invaluable at this period. For raising seedlings of all kinds, and for hardening off tender subjects that have been raised in the greenhouse or hot-bed, the cold frame is indispensable. Lilies that have to be potted up should be dealt with

1.—AN OLD PLANT AFTER BEING STORED FOR THE WINTER.

without further delay; it is already quite late enough to do this work. The satisfactory condition of the occupants of the cold frame may be promoted by carefully ventilating the same on mild days. Avoid draughts at all times. Hardy border Chrysanthemums, Pansies and Violas, and many other such plants I made a rule to lift and break up into numerous pieces at this season; individual pieces of each kind are then dibbled into some light sandy soil, and in such circumstances they soon make beautiful plants for summer and autumn flowering.

*The Fruit Garden.*—Even at this period old Filbert trees that are overgrown may be pruned, cutting away the old branches. Raspberries may still be planted. Shorten the long, thick roots, retaining those of a fibrous nature. The canes should be cut down to within 1 foot of the ground; they then break away strongly and do

well the next year. I find it a good plan to give the roots a mulching of manure by spreading it round about the base of the plants. Complete the pruning and nailing of Apricots and Peaches on walls. Cut out dead wood and weak growths; cut others back to spurs. D. B.

### INCREASING DAHLIAS.

THERE are several methods of increasing Dahlias from stocks that are already in our possession. We have to assume that the old roots that were lifted last autumn have been stored in some dry, cool, dark quarters during the past winter, and are now quite dormant. See that the label of each tuber is securely tied to a portion of the roots before placing them together in the basket or box for removal to the propagating quarters, and in this way avoid what is sometimes considerable inconvenience and disappointment when the labels are missing. The most popular and also the most satisfactory way of increasing stocks is that of propagation by cuttings. Provided the grower can command quarters where bottom-heat can be obtained or where genial quarters in a heated glass structure are available, no difficulty whatever will be experienced in procuring cuttings and rooting them quite easily. The present is an ideal period to commence operations.

*Treatment of the Old Tubers.*—These should be embedded in some light and sandy soil in boxes, pots or any similar receptacle, and stood on the greenhouse or conservatory bench for the fresh young growths to develop. Make the soil just moist to encourage the tubers to grow, and if the receptacle containing them can be arranged near to the hot-water pipes so much the better. A better plan, however, is that of making up a bed for the roots on the side benches of the greenhouse, where a gentle bottom-heat can be obtained from the hot-water pipes immediately underneath them. The old roots as represented by Fig. 1 should be arranged in regular order

from the back to the front of the greenhouse bench. Should the side benches be made of wood, cover these with slates, boards or anything answering the same purpose. Subsequently place a layer of light and sandy soil over the slates, &c., and proceed to arrange the tubers in the manner above suggested. The tubers will be found to vary considerably in their character, but the one illustrated here is a fair representative of the majority. As soon as the collection as a whole is arranged in position, fill in the spaces between them with some light soil, and keep the same moist. Water from a fine-rosed can is the better method of making the soil just nicely moist. If the temperature can be maintained at from 55° to 65°, growths of a very satisfactory kind

2.—METHOD OF PLACING THE OLD TUBERS ON A GREENHOUSE STAGE.

will quickly evolve, and the quarters allocated to the old plants (roots) will be represented as seen in Fig. 2.

*Inserting the Cuttings.*—Have the necessary pots and soil ready for the insertion of the cuttings, so that as soon as they are ready to be detached they may be inserted forthwith. Fig. 3 represents an old tuber lifted from the bed and depicting the roots recently emitted and the strong and sturdy shoots that have developed. Generally speaking, cuttings should be from 3 inches to 4 inches in length, although they are

3.—PLANT LIFTED FROM BED ON GREENHOUSE STAGE.

often much longer. We prefer the shorter cuttings, as it is then possible to detach with each individual cutting a small piece of the tuber, which will help to support it until it is rooted. Those who wish to raise a goodly number of plants will not be disposed to cut back the shoots so hard. Fig. 4 represents an ideal cutting of the kind just referred to. It will be observed that the lower leaves are removed and the stem of the cutting cut through immediately below a joint; it is then ready for insertion. We prefer to insert the cuttings singly in what are known as thumb pots, although, where accommodation is limited, a number of cuttings may be inserted round the inside edge of a 3-inch pot. The soil for the cuttings should be made up of two parts good fibrous loam and one part of leaf-mould, or, failing the latter, Coconut fibre refuse and plenty of coarse silver sand. A bottom-heat of from 65° to 70° will enable the grower to ensure root-formation within a period of about ten days. Fig. 5 represents a cutting inserted in a 2½-inch pot. Keep the cuttings syringed, using water that is slightly tepid. Constant syringing is necessary in order to maintain moist conditions during root-formation. Our chief concern from now onwards is to keep the young plants from getting drawn. They must be gradually inured to harder conditions by carefully ventilating the glass structure, so that by the middle of May the plants may be placed in cold frames. Again reverting to the propagating period, any rough propagating frame may be made up on the greenhouse bench. A box

covered with sheets of glass is an admirable arrangement for the purpose, or a bell-glass may be used by those who need only a few plants of each sort. A high temperature is not really necessary, except for hurrying on an early batch of plants. Cuttings rooted in cooler conditions are more likely to give good results, especially where there is a deal of uncertainty how to control the plants subsequently. Before the planting out in June the young plants must be repotted into 5-inch pots, otherwise the roots will get pot-bound and the plants suffer in consequence.

#### HOW TO GROW SNAPDRAGONS.

NOTWITHSTANDING the fact that *Antirrhinums*, or Snapdragons as they are popularly called, are hardy perennials, there is a rapidly growing tendency to treat them as annuals, a system that is quite satisfactory where flowers for late summer and autumn are required. The many beautiful varieties now on the market render them one of the most useful subjects that we have for bed or border work, while their continual flowering propensity makes them most valuable where a show of flowers is needed over a lengthened period. Roughly, the varieties may be divided into two sections, viz., the Tom Thumb or dwarf sorts and the tall-growing varieties. The culture of both types is the same.

To secure good plants from seeds to flower this summer and autumn, a sowing must be made under glass at once, using well-drained pots, pans or boxes for the purpose. A good soil for sowing the seeds in is one composed of two parts loam, one part sand, and one part flaky leaf-soil or well-decayed manure. This must be sifted through a quarter of an inch mesh sieve, taking care of the rough portions as well as the fine. After placing the crocks in for drainage, half fill the pots or pans with the rough soil, and then fill to the brims with the finer. When pressed moderately firm with the bottom of a clean pot the soil should be about half an inch below the brim of the pot or pan. Scatter the seeds thinly on the surface, give a light sprinkling of sand, and lightly press the whole with the bottom of a pot. Give a watering with a fine rosed can. cover with a pane of glass or a sheet of brown paper, and stand in a warm greenhouse or on a hot-bed in a frame.

The soil in the pots or boxes must not be allowed to become dry, but any watering that is needed must be carefully done so as not to wash the seeds out of the soil. As soon as the seedlings appear, remove the coverings of glass or paper and stand the pots near

5.—CUTTING INSERTED IN A "THUMB" POT.

4.—CUTTING PREPARED FOR INSERTION.

the glass, a sturdy growth from the first being imperative. When an inch high the seedlings must be pricked off into other pans or boxes, using the same soil as advised for the seedlings, but leaving the leaf-soil or decayed manure in a rougher or more flaky condition. Place each seedling 3 inches from its neighbour. As soon as the young plants are thoroughly established in these receptacles, a hardening off process must be commenced, gradually inuring them to cooler conditions, so that they are ready for planting in the open by the third week in May.

To obtain the best results from these plants very rich soil is not advisable, the tendency in such being to make gross growth at the expense of flowers. Soil that was well manured for a crop last year is best, and if a quantity of old mortar can be incorporated with it so much the better. The Snapdragon, however, is not at all fastidious as to soil. One foot apart is a good distance to plant, taking care to retain the ball of soil and roots as intact as possible. The Tom Thumb varieties, owing to their compact habit, are not so extensively grown now as they were some years ago, the more graceful taller varieties being most favoured.

Seeds may be sown in drills in the open during June and July for flowering the following summer, thinning the seedlings early and transferring them to their permanent quarters in the open. Beds of one colour in each are very effective, hence it may be well to name a few of the best varieties. Dobbie's Crimson King is one of the best. As its name implies, the flowers are of a brilliant velvety crimson, the leaves being deep green on the upper surfaces and dull crimson beneath. White Queen, a pure white variety, and Yellow Queen, a clear yellow, are two other splendid varieties supplied by Messrs. Dobbie and Co. The habit of the three named above is very similar. Cottage Maid is a new variety of high merit. The colour of the flowers is a mixture of pale rose and white. It is of a rather strong habit, and the flowers are of very large size. This variety was universally admired when shown before the Royal Horticultural Society by Messrs. Dobbie a year or two ago. Sutton's Golden Chamois and Carmine Pink are also excellent varieties in the tall section, the colours being explained by their names.

## THE TOWN GARDEN.

**THE LAWN.**—The town gardener has many things in his garden on sufferance only, but it is not so with the lawn, for with a due amount of attention the finest lawn imaginable may be had. The noxious weeds which blow in and root from waste land in the country are unknown in the town, for there is no waste land. The constantly falling deposit of soot which the town gardener is so apt to bemoan gives to his grass a colour, and imparts to it a vigour for which country grass often sighs in vain. Soot also ranks high as an insecticide, so that earthworms and leather jackets—most awful nuisances in the country—rarely trouble a lawn in town.

Cats, of course, abide in towns, and their penchant for giving evening entertainments on the lawn is an unfortunate feature of town life. I speak feelingly on this point, for I slept for three years in a room which overlooked the only lawn in a long row of town villas, and I am convinced that I should have had more hair now had things been different. There are three ways of dealing with this cat nuisance; one is to keep the cats out of the garden, two is to persuade all the neighbours to grow a lawn, three is to do without a lawn one's self. The third will be found the easiest; but, then, what true gardener ever let difficulties worry him?

Chickens are almost on a par with cats; they do not sing so much o' nights, but they take it out of the lawn in the daytime. As one is supposed to fence securely against chickens, there is no compensation for damage done. Personally, I have had little trouble with chickens, as my little black and tan terrier has strong views of his own concerning them, and the sight of a few piles of feathers about the garden and on the lawn has convinced my neighbours that it is wisest to keep their chickens shut up, or clip their wings. A friend once told me of a sure cure for chickens on the lawn, but I have never tried it. It is simple in the extreme. Purchase a Pea-shooter and a box of Beecham's pills, hide in the bedroom, and as the chickens arrive aim a pill at them through the shooter. They pick it up, and, I am told, do not return for more.

If it is decided to defy cats and chickens and have a lawn, I strongly advise that it may be raised from seeds. As before stated, weeds quite rarely find their way into town lawns, but they are always present in turf, therefore avoid turf and rely upon seeds. Instead of making elaborate calculations as to how many seeds will be required at a thousand or so per square yard, place the matter in the hands of a good nurseryman. Tell him the nature of your soil, the aspect of the lawn, and its approximate size in square yards.

Meanwhile, prepare the ground. If poor, dig in some well-rotted stable manure, or give it a good dressing of one of the advertised fertilisers. In any case dig it 1 foot deep, and leave it in rough lumps for a week or two. By the middle of March it should break down fairly fine. After the fork use the rake to make it finally level, and remove all hard clods and stones. It is now ready for sowing, and if the wind should be blowing it is wise to mix the seed with a good bulk of fine, dry soil. Scatter this evenly all over the prospective lawn and at once pull the roller over it, using in lengthwise and crosswise of the plot. If no roller is handy, pat every square inch of the lawn down well with the back of a spade, or the seeds will not germinate.

Drive in a few stout pegs round the outside of the plot and stretch stout green twine across and across the lawn to them. The twine used should be dark to keep off the sparrows, and it should be strong to keep cats and chickens at bay. Nothing more need be done until the blades of grass show, when the twine should be removed and the roller run over the grass if worms have disturbed the soil. Cutting will be the next operation—but "that's another story."

E. J. CASTLE.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANT HOUSES.

**G**ARDENIAS now require plenty of feeding to help the buds. They are not much if the flowers are small and weak. Pot any small, autumn-struck plants into 4½-inch pots, using loam, leaf-soil and peat, with a good amount of sharp sand to keep the soil open, as these plants require copious supplies of liquid. Keep the plants syringed several times a day, especially on the under side of the foliage.

*Ixoras*.—Pot any now that require it, using two parts good fibrous loam and one part best peat; make the soil very firm in the pots. Top-dress large plants that do not require potting. These are also gross feeders, and are easy to keep clean if syringed regularly, as recommended for Gardenias.

*Achimenes* and *Caladiums*, and, in fact, all bulbous plants may be shaken out of the old soil and repotted now. *Hippeastrums* (*Amaryllis*) that are now showing their spikes may have manure water occasionally; keep a little warmer or cooler as occasion may demand.

#### FRUIT HOUSES.

*Peaches* and *Nectarines*.—Disbud these as early as possible after the growths are large enough; always leave a good growth to train up to take the place of the present fruiting, and leave one on the top to draw the sap. Keep the tree clean by fumigation and syringing. In succession houses give plenty of air to trees in flower and distribute the pollen every day when it is thoroughly dry. Give good supplies of water to the trees that need it, so that it may reach the deepest roots.

#### VINERIES.

Continue to tie down and regulate the growths. Do not tie in more than will conveniently cover the roof, or it will be at the expense of quality. Stop the shoot when it has made about two leaves beyond the bunch. The house should now be kept at 65° by day and 60° by night. Muscats and second vineries closed at the beginning of the month may now have a little more heat, and if at all dry give a thorough watering with water at no less a temperature than the house; 5° to 10° warmer will be an advantage.

#### KITCHEN GARDEN.

Now is the time to be busy on land and plots that have been well tilled. If the weather is fine and dry a sowing of Parsnips should be made. Carter's Holborn Marrow, Maltese and The Student are good and sweet varieties. Further sowings of Peas and Beans should be made according to requirements. Shallots and Garlic must be planted at once, if not already done. Herbs may be sown, the existing plants divided, if necessary, and the ground cleaned and dug. It is a good plan to have a small patch of young plants coming on each season, especially with Thyme and Sage. Continue to force Seakale, Asparagus, French Beans, Lettuce, Chicory and Endive, putting in quantities sufficient to meet the demand.

#### HARDY FRUIT.

Persevere with the pruning and training of all trees. Get out the protecting material for covering Apricots. A double thickness of netting acts as a good screen and protector; for absolute safety blinds are the best.

*Peaches* and *Nectarines*.—Nail and tie these in very neatly, and let the operator have in his eye a straight shoot from the base. Very few objects look better in the fruit garden than a well trained tree. If there is the least suspicion of any insects

being present, syringe with some good insecticide or petroleum and soft soap; if this is done before and after blooming very few attacks of aphid need be feared.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**ARUMS** OR **CALLAS** now being in full growth and throwing up spathes require frequent feeding with liquid manure in a diluted form, and to be kept constantly moist at the roots. A temperature of 50° at night suits them best, but if it is necessary to bring them forward quickly they will bear more heat, though the spathes will then be less lasting. *Callas* of the *elliottiana* type which may be wanted to flower in April and May should now be potted. If the corms have been well ripened they will be found totally devoid of living roots. In potting use good fibrous loam, with a liberal mixture of dry and finely-pulverised cow manure, using also a good quantity of silver sand, a handful or less of which, according to the size of the corms, should be placed round each one. Keep the crowns well below the surface to encourage the principal feeding roots, which spring from the base of the new growth. Place the plants in a house with a moist temperature of from 60° to 65°.

#### HARDY FRUIT.

*Apples* and *Pears*.—Push on with pruning of standard Apple and Pear trees and bring the work to a close as quickly as possible. Trees that are to be regrafted should be headed back. When cutting off the branches leave a foot or so more of wood than will be actually required for drawing up the sap, and this can be cut away when the time arrives for grafting. Look over young, also newly-planted, trees and see that the ties are secure.

#### FLOWER GARDEN.

*Rose Clumps*.—Although the time for pruning individual Rose bushes has hardly yet arrived, attention may be given to big clumps that have found a home on old trees, blocks or wire arches placed over beds. Once established, such clumps are sometimes left entirely alone, but this is a mistake. It is always advisable to remove superfluous wood, weak stuff that is of no use, and to cut back the soft tops.

#### KITCHEN GARDEN.

*Sowing Parsley in Heat*.—Many ignore sowing Parsley in heat, pricking it off into boxes, or, better still, a pit or frame, and finally planting it out on a warm border in April, as being a too tedious operation. But from experience I know of no kitchen garden crop that pays better for a little extra trouble, especially if thereby a blank can be avoided. Some nice useful sprays may be secured by lifting old stools and placing them in rather deep boxes in a brisk heat.

#### ORCHIDS.

*Cattleya citrina*.—Though this species can hardly be termed a really difficult Orchid to grow, the fact remains that in a very large number of instances it does not thrive satisfactorily. It requires probably less heat than any other *Cattleya*, being found growing naturally high up on the hills in Mexico. Its peculiar habit—that of growing with its head downwards—seems to show that the foliage should not be wetted. Still, I like to dew the plant over lightly when growing. The temperature for *Cattleya citrina* should be kept as steady as possible, and will only vary a little all the year round. The minimum during the winter should not fall below 50°; in summer it need not rise above 55°.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashtwellthorpe, Norwich.

ANSWERS  
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

FLOWER GARDEN.

**Moss on a lawn (Carnation).**—You are acting correctly in raking out the moss, but we do not like the idea of covering the grass afterwards with sand. A much better plan would be to procure some finely-sifted soil and give the lawn a quarter-inch thick dressing with this, supplementing it with a mixture of superphosphate of lime, 6lb.; Peruvian guano, 3lb.; and bone-dust, 3lb., this quantity being evenly spread over five square rods or poles. The work must be done at once.

**Stocks and Phlox Drummondii (D. C.).**—As a general rule the middle of March is quite early enough to sow Stocks; but you probably have some valid reason for sowing at the middle of February. The Phlox should be sown on an open border in the first week of May, a site facing east being preferable. Thin and transplant before crowding takes place, pinch out the points when 3 inches high to make the plants bushy, and again transplant to 6 inches apart. If for any reason the Stocks do not thickly fill the beds you could plant the Phlox among them as soon as the Stocks are in flower. Then, when the Stocks have finished flowering, place the hand flat on the soil with the stem of a Stock between the fingers and gently but firmly uproot it. Stocks make but few roots, so that if the removal is carefully done the Phlox need be scarcely disturbed. Water them well afterwards with a rosed can. If this plan does not commend itself to you give the Phlox in the nursery bed a thorough soaking of water one night, and the next morning pull up the Stocks and level the beds. When the sun has left the beds in the evening, dig up the Phlox with a trowel, lay them on a board for carrying to the beds, and then plant them firmly, with as much soil adhering to their roots as possible. Well water them in and they should go on growing and flowering without a check. If the weather is showery such care is not required, but it should be remembered that the Phlox will then be large plants, and that the sun has great power in July. You may peg down the growths or not at discretion. The plants should flower until frosts stop them. With regard to the ditch mould, if your soil is heavy use half mould and half garden soil; if your soil is light use one-third of ditch mould. Too much ditch mould would grow leaves instead of flowers.

**Treatment of "cankered" Carnations (E. E. F.).**—Many theories have been put forward to account for border Carnations going off as those sent, but no satisfactory solution seems to have been arrived at. The majority of cultivators put it down to the effects of frost, either acting on the pith of the plant or just where the stem enters its soil (the vulnerable point). One very important matter is in planting to see that the stem is made secure in the soil and does not sway about with the wind. To save the layers plant them in a spot that has not previously been occupied by Carnations.

**Burning Pampas Grass (E. C. Crichton).**—We cannot recommend the burning of the old or withered tufts of leaves of these plants, and the practice might easily be carried too far. The firing of the tufts merely does away with the rubbish and dead material, even when judiciously applied, and there is the danger of destroying the heart growths of the plant. At the best such drastic measures afford little or no assistance in the direction of

resuscitation, which is what is most needed at such a time. The probabilities are that the plant has quite exhausted the soil of the position it now occupies, and could be best restored to vigour and health by lifting, dividing and replanting in a well-prepared position next April. If this were done the clearing out of the tuft would be a simple matter. You do not say whether the plant continues to flower or not, but if not, there is need for attention, as above suggested.

TREES AND SHRUBS.

**Distance apart to plant Pyrus floribunda (G. C. C.).**—When ten or twelve years old the plants will cover a diameter of 15 feet, so that due allowance must be given at planting for ultimate development. Close planting might be practised if provision is made for removing alternate plants in a few years' time; still, much the best method is to plant 18 feet apart and carpet the ground with varieties of Erica vagans, thereby obtaining a bright effect in autumn when the Pyrus-flowering season is past. Although most frequently met as a small standard with a large mop head and grafted upon another stock, there are many positions, such as banks and undulating ground, where dwarf bushes planted 6 feet to 8 feet apart would soon become an effective group, while upon large rock gardens there are usually positions in which its utility can be clearly demonstrated.

**Where to procure Azalea peat (M. L. W.).** The best Azalea peat that we know of can be obtained from Messrs. Epps and Co., nurserymen, Ringwood, Hants. The firm supply several kinds of peat. It would be advisable to obtain samples, then you could select the most likely. We are afraid that you will not find any peat very cheap by the time you get it, as cost of transit adds considerably to cost of material.

**Evergreen climbers for north-east end of cottage (E. G.).**—As you desire as far as possible to avoid nailing, there is nothing so good as Ivies for the purpose named. You may plant either one variety or a mixture. We can recommend Emerald Green, with rich green leaves; angularis aurea, whose leaves are mottled with gold; and Cavendishii, in which they are margined with white. With these three a pretty combination might be formed.

ROSE GARDEN.

**Pruning newly-planted hedge of Roses (G. L. K.).**—As you have only recently planted the Roses it will be best to defer any pruning of the same till the end of March. As the desire is doubtless to have the plants reach the 5 feet height as quickly as possible, we advise you to retain the hardest growths almost their entire length, unless they exceed the height; but all soft, pithy, unripe shoots must be cut back to within a few inches of the base. The next and succeeding years you should have one or two of the oldest growths of each plant cut down to the ground, which will thus keep the base of the hedge from becoming bare. The wichuraiana Roses, producing as they do such long trails of growth, sometimes 12 feet in a season, may be utilised to droop over in a pendulous fashion, and then when they have blossomed cut them away. These would be succeeded another year by the young growths which are constantly appearing. If it be practicable to allow a growth or two to trail along the ground or over some rockwork close by, this will be far better than crowding the growths in the hedge.

**Planting Roses on a fence (Dragoon).**—When we referred to the "west side" we meant the western aspect of the fence. This aspect would be most suitable for both Gustave Regis and White Maman Cochet. Therefore, in the rearrangement we advise you to plant upon the eastern aspect of the fence Griss and Teplitz, Bouquet d'Or, Cheshunt Hybrid and Mme. Alfred Carrière. On the western aspect White Maman Cochet, William Allen Richardson, Climbing Mrs. W. J. Grant and Gustave Regis; in both aspects plant in the order as given.

**Pruning various Roses (Mrs. S.).**—The Briar Roses, such as Harrisonii and the Penzance hybrids, need only to have their extreme ends just tipped this season. After they become established they should have some of the old wood removed each year immediately after flowering and all young growths retained their full length. The plant of Conrad F. Meyer planted last November should be pruned back to within 2 feet of the ground, and Gottfried Keller to about 18 inches. Another season

both of these varieties should be very sparingly pruned, treating them rather as free bushes or pillar Roses. We do not recommend the application of Tonke's manure to Roses planted in November. Such plants would be benefited by weak applications of liquid manure about once a week during May and June. A very safe liquid manure is made from cow or sheep manure and soot.

**Trailing Roses for tubs (Ignoramus).**—The best Roses for your purpose are such sorts as have flexible growths. These could be selected mainly from the wichuraiana group. You could plant, say, two plants in each tub, and as they would possess growths some 3 feet to 5 feet in length, they could be brought over the sides of the tubs and partly up the bank this season. In course of time these plants will produce several growths from their base, which could be utilised to droop over the front part of the tub. Such growths could either be curtailed when they have reached any desired limit, or allowed to run upon the ground. Early-flowering sorts are: Jersey Beauty, Gardania, Alberic Barbier, Griss and Zabern, Ruby Queen and Aglaia. Late-flowering: Dorothy Perkins, Hiawatha, Mandus Triumph, René André, wichuraiana (type), François Foucard, Paul Transon, Bennet's Seedling and Félicité Perpetue. Some of these flower early and late. You could plant alternately the early and late-flowering sorts, so as to prolong the blooming period.

THE GREENHOUSE.

**Information about Asparagus Sprengeri (Wexford).**—This is an exceedingly difficult matter to advise on without seeing the plants, for some plants of Asparagus Sprengeri form several crowns and readily lend themselves to division, while others produce all, or nearly all, of their shoots from one central crown. If division can be carried out, we certainly advise you to do so. Better wait till the middle of March, then turn out of the baskets and cut off any old fronds that are no longer fresh. Next, with a pointed stick, untwine the roots as far as possible without injuring them; then, either by using a pail of water or by holding under a tap, wash all the soil away from the roots. This will enable you to see exactly where the division can be performed without any risk. We presume you intend to again furnish your baskets from the divided plants, in which case the best rooted and most shapely ones should be chosen for the purpose; the others, if you wish it, may be potted. This division will necessarily inflict a considerable check on the plants; therefore even the baskets must not be hung up until the plants become established, as in a hanging position they are naturally more exposed than if they were standing on a snug, shaded portion of the stage. A month should suffice for them to become sufficiently established to allow of their being hung up again. After division, frequent damping with the syringe will assist greatly in keeping the shoots fresh till the roots are again active.

**Liliums to flower in August (Veronica).**—In order to have Lilium auratum in flower by the middle of August the bulbs should be obtained and potted without delay. Care should be taken to have bulbs that are in a good plump state, as if they have been exposed and dried satisfactory results cannot be expected from them. In the first place, if you desire one plant to be at its best on August 15 it will be necessary to pot half-a-dozen bulbs, for Nature draws no hard and fast line, and it is quite impossible for anyone, even with the experience of a lifetime, to induce one to flower on a specified day. The weather plays a very important part in the matter, and no one can foresee the kind of weather we shall experience between this time and the middle of August. A suitable sized pot for a single bulb of Lilium auratum is one 6 inches to 7 inches in diameter. This must be clean and effectually drained with a few pieces of broken crocks in the bottom. A mixture of two parts loam to one part peat and about half a part of sand forms a suitable compost. In this the bulb must be potted at such a depth that there is about 2 inches of soil above the topmost portion of the bulb. Then place in a good light position in the greenhouse, giving enough water to keep the soil moderately moist, but care must be taken not to overwater, especially till growth recommences. As the plants develop a sharp look out must be kept that they

are not attacked by aphides or green fly. As the season advances you must exercise your own discretion whether you think they will be in flower by the required time, and if they are likely to be late keep them somewhat warmer. If too early they can be kept back by placing in a shaded spot out of doors. No manure will be needed.

**Spraying Marguerites to prevent attack by leaf-mining maggot** (*Benrhya*).—In the "Pests of the Flower Garden," Dr. M. C. Cooke recommends for spraying purposes 1 lb. of sulphate of copper to 25 gallons of water, the copper to be thoroughly dissolved in a gallon or so of hot water, and then made up to the necessary amount. We, however, have had no experience of its efficacy in the case of the Marguerite fly.

**Daffodil leaf gone wrong** (*W. J. P.*).—It is very probable that the fibre has been allowed to get too dry, for it is simply a medium to maintain a regular state of moisture around the roots. Again, you do not say where the bulbs were placed first, and any marked change of temperature is decidedly harmful. In the case of Narcissus flowered indoors, a light position and a free circulation of air is very necessary, as in a close atmosphere both flowers and foliage are very apt to turn yellow. We have mentioned the several possible causes of failure, and leave it to you to decide which is likely to apply to your particular case.

### KITCHEN GARDEN.

**How to plant Cucumbers and Melons** (*G. W.*).—By all means place them on mounds. Both Melons and Cucumbers are best if only given small heaps of soil at the start, and this is added to frequently, in the case of Cucumbers every two or three weeks, in the shape of rich surface dressings. The small, white, tender roots soon take hold of the new material, and the plants benefit greatly. By doing this work piecemeal the plants get the food at the time there is a greater demand on the roots. Melons are somewhat different at the start. About a bushel of soil would suffice; then more as soon as the fruits have set; a good dressing this made as firm as possible. Soil should not be given Melons at the start; food then causes a rank growth and the fruits do not set freely. Once the fruits are secured, help as advised is beneficial. When the Melons are planted, firm the soil to secure a dwarf growth.

**About Potato crops** (*D. C.*).—Your crop of Duchess of Cornwall was a moderately good one, much better than many growers secure. The examples that you quote would be grown under very special conditions, cuttings being taken from plants started early and grown under glass, so as to secure as many plants as possible.

### MISCELLANEOUS.

**Mistletoe on old Apple trees** (*W. R. H.*).—A few bunches on each tree we do not think would do any harm. The way to make it grow is to cut a notch under the bark of the branch on which you wish it to grow, and push the seed in rather tightly, taking care, however, not to bruise the seed or the operation will be a failure. Each berry contains a seed, and the present is a good time to plant it. The firm of Messrs. Richard Smith and Co. of Worcester make a speciality of growing and selling young Apple trees with Mistletoe growing on them.

**Pear trees with scaly bark** (*B. A. F.*).—Judging by the prunings sent, the cause of the injury to your trees (the scaly bark) is the poverty of the soil in which they are growing. It takes many years to bring land which has been under trees to a fertile condition, all the elements which go to furnish the fibre and tissue of trees having been exhausted. It would have been better had vegetables been grown on the land for a few years before planting the trees (manuring the land heavily for this crop in the meantime). The best thing to do now will be to replant the trees in new loam of rather a heavy texture, adding half a bushel of road grit to a barrowful of loam, also a gallon of bone-dust and the same of lime, in order to induce a more vigorous and healthy growth. When this has been accomplished the diseased and weak growths may be cut away and the healthy growth made to take its place.

**Names of plants.**—*E. M. M.*—*Begonia haagseana*.—*J. Price*.—*Thuya plicata* (large fruits); *Juniperus* (*Juniper*) *chinensis* (small fruits).—*C. G.*—*Diedalscanthus nervosus*.—*G. A.*—1, *Picea nigra*; 2, *Abies amabilis*; 3, *webbiana*; 4, *Cornus capitata*; 5, *Osmaethus lilifolius*.—*No Name, Dunkeld, N.B.*—The leaf you send is of *Moschosma riparia*.—*P. S.*, *Dulverton*.—Hybrid *Hippeastrums* or *Amaryllis*.

### QUESTION.

**Wattled hurdles.**—Can any of your correspondents kindly inform me where I can obtain closely-made wattled hurdles suitable for protecting shrubs from the winds.—*R. G.*

## SOCIETIES.

### ROYAL GARDENERS' ORPHAN FUND.

The twenty-first annual meeting of the above fund was held at Simpson's, Strand, on the 14th inst., Mr. H. B. May presiding. The adoption of the report was moved by the chairman, seconded by Mr. W. Marshall and unanimously adopted. A cordial vote of thanks was proposed and seconded to Sir William Treloar for his kind assistance in presiding at last year's annual dinner. Mr. E. Sherwood was re-elected treasurer, thanks being accorded him for his past services, and Mr. M. Rowan was re-elected auditor. Messrs. W. R. Alderson, G. H. Barr, G. H. Cuthbert, W. Howe, J. Lyne, W. Poupard, T. W. Sanders and W. P. Thompson were re-elected on the committee and thanked for their past services. Mr. E. Parsons of Covent Garden was elected on the committee in place of the late Mr. Assbee. Mr. Wynne was re-elected secretary and cordially thanked for his services.

At the end of 1907 the number of children in receipt of the full allowance, granted after election, was 95, while 19 others were receiving much-needed financial assistance while waiting for advancement to the full pay list, the total amount distributed during the year being £1,511 10s., or £100 more than the previous year's total.

The accounts of the past year show an increase in receipts over 1906 amounting to £69 18s. 10d., an increase of £100 in the children's allowances, an addition of £120 16s. 11d. to the amount invested in Consols, an addition of £50 to the deposit account and a large sum carried forward. The annual festival dinner is this year fixed for Tuesday, May 12, at the Hotel Cecil, when the president, the Duke of Bedford, K.G., has consented to preside. The committee earnestly appeal for more support in the form of annual subscriptions, and we trust that our readers will not let them appeal in vain. The secretary, to whom subscriptions should be sent, is Mr. Brian Wynne, 30, Wellington Street, Strand, London, W.C. The result of the election was as follows:

ELECTED.			
Votes.		Votes.	
Percy E. S. Warwick ..	377	Hilda A. E. Tickner ..	257
Lucy M. Claxton ..	367	Bessie Seaman ..	221
Alice Arnold ..	361	Thomas H. Thomas ..	182
Herbert E. Smithers ..	358	Ethel M. Blackmore ..	133
Jeanie M. Lamond ..	353	Dorothy Wiggins ..	130
John H. McCullum ..	322	William H. N. Mullens ..	127
Edward John Ward ..	294		

NON-ELECTED.			
Votes.		Votes.	
Violet G. Randall ..	102	Alice R. Gascoigne ..	71
Reginald G. Grist ..	84	Ellen Ashton ..	60

Mr. H. J. Veitch appealed to the committee to put the four unsuccessful candidates on the funds and Mr. T. W. Sanders supported the notion. This resolution was carried.

### WANSTEAD AND LEYTONSTONE HORTICULTURAL SOCIETY.

At the annual meeting held recently re-elections took place as follows: President, Mr. W. P. Forbes, J.P.; lady president, Mrs. Ashbridge; and Mr. Carleton Roberts as hon. secretary and treasurer. Sir John Bethell, M.P., has placed his grounds, Park House, Blake Hall Road, Wanstead, at the disposal of the society for their annual show.

### SEVEN KINGS AND GOODMAYES HORTICULTURAL SOCIETY.

UNDER the auspices of this society the Rev. Joseph H. Pemberton recently delivered a most instructive and appreciated lecture on "Growing Roses for Exhibition." The Ilford Urban Council have granted the society the use of the Seven Kings Recreation Ground for the annual summer show, which is fixed for July 18.

### NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening, the 17th inst., there was a meeting of the executive committee of the above society at Carr's Restaurant, Strand, when Mr. T. Bevan occupied the chair. The newly-appointed president, Sir Albert Rolitt, was present, and, in returning thanks for his election, remarked upon the present condition of the society as compared with that when he was president a few years ago. He commented on the budget, on the decreased membership, and on the question of affiliated societies, interspersing his remarks with several practical suggestions for the consideration of the committee. The question of the *locale* of the society was touched upon, and the possibility of an accession of members and exhibitors being obtained if there were good grounds for holding the shows in London, as was formerly the case. Sir Albert suggested that later in the year, when arrangements were being considered for 1909, the committee might well give attention to some of the suggestions made, and which were much appreciated and attentively listened to by the members present.

Mr. C. E. Shea wrote thanking the society for having elected him a vice-president, which he accepted. A letter was also read from the Crystal Palace Company confirming dates and conditions upon which the 1908 shows are to be held.

In view of the interest that is being taken in the forthcoming Franco-British Exhibition at Shepherd's Bush, Mr. Harman Payne enquired whether the committee had

arranged in their series of shows for a Chrysanthemum exhibition, as enquiries from abroad were sure to be addressed to him on the subject. Mr. Witty replied that he would enquire.

The members retiring by rotation from the floral committee were replaced by the election of Messrs. Curtis, Higgs, Oliver, Erickett, Springthorpe, Felton and Newton. The finance committee, consisting of Messrs. Cragg, Ingamells and Moorman, was elected as well as the new schedule and publication committees. Upon the report of the schedule sub-committee, the various classes at the October, November and December shows and the prizes recommended were passed. The date of the annual outing was fixed for July 27 next. The Barry Chrysanthemum and the Newcastle and District societies were admitted in affiliation. Five new members were elected.

### EAST ANGLIAN HORTICULTURAL CLUB.

AT the February meeting of this club Mr. W. Messenger of The Gardens, Woolverston Park, Ipswich, gave a most instructive and practical paper upon "Wall Fruit." His arguments proved him to be a thorough master of every detail, and the able manner in which he handled the subject made it very interesting. A good discussion followed, Mr. L. Smith, Shotesham, speaking at length and very much to the point. Mr. H. Goude, Catton, also made one or two most practical suggestions. Mr. T. B. Field, Mr. E. Peake, Mr. J. Powley and others also took part in the debate. There was a capital collection of exhibits upon the tables.

### WARGRAVE GARDENERS' ASSOCIATION.

AT the last ordinary meeting of the association Mr. G. Stanton, F.R.H.S., of Park Place, read a most interesting paper on "The Beauty of a Garden in Winter." Besides giving a description of the many trees, shrubs and plants used to give a cheering aspect at the dull period of the year, there were many small points referred to, which would escape the eye of any but experienced students of Nature, such as the shape, colour, coverings of leaf-buds, the bark of trees, the effect of rain drops and frost on the leaves, branches, &c. A discussion followed, and a vote of thanks was accorded Mr. Stanton at the close. Mr. Botley obtained the cultural certificate for an exhibit of Cyclamen, and Mr. Glen for three fine Arums.

### ILFORD HORTICULTURAL SOCIETY.

A solid silver Rose bowl has been presented to the society by Mr. A. Coveney to be competed for at the flower show in July next.

### United Horticultural Benefit and Provident Society.

The annual meeting of the above society will be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Monday, March 9, at 8 p.m. Mr. W. Collins, 9, Martindale Road, Balham, S.W., is the hon. secretary.

"Country Life" for February 29 contains, among other articles: "Country Home: Keele Hall" (illustrated); "New College, Oxford" (illustrated); "An Island Flora.—II." by John Vaughan; "Well-broken Retrievers in the Field" (illustrated); "Sport in Norway.—II." by Sir H. Seton-Karr; "In the Garden" (illustrated); "Wild Country Life."

### TRADE NOTES.

#### WALLACE'S BULBS FOR SPRING PLANTING.

AUTUMN is the season usually associated with bulb planting, but all good gardeners know that there are some bulbous plants such as *Lilium* and *Gladolli* that are best planted in the spring. We are reminded of these by the receipt of Messrs. R. Wallace and Co.'s catalogue, describing bulbous and other plants for spring planting. Copies can be obtained post free by writing to the firm at Kilmahid Gardens, Colchester.

#### "ALL ABOUT SWEET PEAS."

IT is with pleasure that we have perused the fourth edition of Mr. W. Sydnham's little book bearing the above title. In reality it is an A B C of Sweet Peas, and it is very evident that the author has been to a considerable amount of trouble to make its contents as reliable and up-to-date as possible. As a book of reference it has long been of the greatest use to Sweet Pea growers, and we heartily commend it to all our readers. Descriptions of all varieties known to the end of 1907 are given, those of the older sorts having been revised according to modern knowledge. We need not say more about it than to mention that for several years we have kept a copy by us for almost daily reference.

#### PUBLICATIONS RECEIVED.

"The Case for the Goat," by "Home Counties." Price 3s. 6d. Messrs. George Routledge and Sons, Limited, Broadway House, Ludgate Hill, London, E.C.  
"Villa Gardens," by W. S. Rogers. Price 6s. net. Messrs. Greening and Co., Limited, 91, St. Martin's Lane London, W.C.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## WASPS AND DESTRUCTION OF QUEEN WASPS.

**A**MONG the most familiar insects in our gardens we may fairly place the wasps, though in many ways they may be considered an unmitigated nuisance, particularly when they attack ripe fruit or enter our dwelling-houses, which they are very fond of doing at meal times, when they are certainly unwelcome guests. Yet they have their good points, for, unlike bees, which only collect honey and pollen, with which they form the bee bread on which their young are fed, they feed their grubs with a considerable amount of animal food, consisting of grubs, small caterpillars, flies, aphides and other insects. They are most hardworking insects. Lord Avebury, when he was conducting some experiments in reference to their intelligence, found that they worked from early morning until dusk. One morning he found a wasp which he had purposely left in his study so that it could have access to it at work at a few minutes after four, and it made 116 visits to the honey during the day, the last being made at 7.46 p.m. In the course of these journeys rather more than sixty-four grains weight of honey were carried to the nest.

Our British wasps, six in number, belong to the genus *Vespa*, which also includes the hornet (*V. crabro*). Two species, *V. vulgaris* and *V. germanica*, are equally common and often resemble one another so closely that careful examination is required to distinguish to which species a specimen may belong. *V. norvegica*, a not uncommon species, often builds its nest in bushes. The hornet may easily be distinguished from any of the wasps, by its much larger size and by its browner colour. But queen wasps, which are much larger than the males, or workers, are often mistaken for them. When cold weather sets in in the autumn and food is becoming scarce the wasps drag the remaining grubs out of their cells and kill them. The young queens leave the nest and search for convenient winter quarters, and the males and workers gradually die off as food fails and the cold increases. The queens often make their way under the tiles or slates of a roof and remain under shelter during the winter.

One day in the autumn some years ago I noticed a number of wasps flying and crawling about the tiled roof of a house, evidently searching for some aperture through which they could creep inside. And on one occasion, going up into the roof of a house in which I was living, I found several queen wasps on each window

(there was a window in each gable) trying to make their way to the open air; I need hardly say that they were not successful in their laudable efforts. These wasps had evidently made their way into the roof, and when aroused by the warmth of a fine spring day naturally flew to the light of the windows and were baulked by the glass in their endeavour to get out. The females which survive the winter and are able to leave their winter quarters at once begin to search for suitable positions in which to make their nests, more often than not choosing some hole in a bank in which to commence operations. Having made a few cells the queen protects them with an umbrella-like covering, which forms the top of the nest. In each cell she lays an egg, which in due course hatches, and she then has to feed the grubs, as well as continue to build the nest. The grubs soon undergo their transformations, and the young wasps at once begin to assist their mother in feeding the grubs and constructing the nest, which soon grows apace as fresh wasps are reared. The material of which the nest is composed is fibres of wood, which the wasps gnaw off old palings, posts, or any available woodwork. These fibres, mixed with a secretion from the mouths of the insects, are formed into a grey paper-like substance; instances are known of wasps having used paper in the construction of their nests.

A large nest when completed will measure from 16 inches to 18 inches in height and from 12 inches to 13 inches in diameter; it is usually rounded or oval in form, the outer walls are about half an inch thick, composed of several layers of the paper-like material, which are so arranged that there are air spaces between them. This no doubt renders the nest both warmer and drier than if the walls were solid. The rows of cells or combs, unlike those of bees which are vertical with the cells horizontal, are horizontal with single rows of vertical cells, the latter having their mouths downwards. There may be from ten to fifteen tiers of these cells, which are about half an inch apart and attached to one another by small pillars, which give strength and solidity to the whole structure. The number of cells in a nest have been computed by various persons at from 8,000 to 16,000, but probably the higher figure is far in excess of the number that any nest ever contained. It is said that each cell is used three times, and that towards the end of the season the nest may contain from 10,000 to 12,000 inhabitants. Until the beginning of September all the inmates have been workers (with the exception of the queen), then the lower tiers of cells are filled with grubs, which eventually become male or female wasps. It might be thought that the cells being vertical

with their openings downwards they would be useless for rearing the grubs in, as the latter would naturally fall out, but this is not the case. The female wasp when she lays an egg attaches it to the top of the cell by means of some viscid fluid and the young grub remains attached by the same means. As it grows, the front joints of its body become sufficiently enlarged to prevent it from falling out. At first the grubs are fed with the juices of fruits or the nectar of flowers, and afterwards on insects. The transformations of wasps occupy about a month, the eggs hatch in about a week, the grubs become chrysalides in a fortnight, and the wasps emerge in the course of another week. Wasps are too well known to render it necessary for me to describe them, but I may call attention to the fact that they have really four wings, though they appear to have only two, the lower wings have a series of fine hooks on their upper edge by which they can be attached to the others; the upper pair are folded lengthwise when not in use.

The sting of these insects is really the same instrument with which the females deposit their eggs, therefore the male wasps have no sting, but the workers have, as is too well known. The workers are really undeveloped females, which accounts for their stings.

#### THE BEST WAY OF DESTROYING WASPS

is no doubt killing the queens in the spring, but it is not by any means certain that they will be met with; however, offering a reward for everyone caught is often very useful, and a few shillings expended in this way is money well spent. Of course, the sooner a nest is destroyed after it is found the better; it is a good way if the nest is in a position which renders it difficult to find in the dark to place a mark which can be easily recognised at the entrance to the nest while there is still light. There are many means of killing the wasps in the nest. Rags dipped in melted brimstone, or tar pushed well into the mouth of the nest and then lighted, a squib, formed of a strong brown paper cover and filled with equal parts of brimstone, gunpowder, charcoal and saltpetre, may be pushed well into the nest. As soon as it is well alight place a turf over the entrance to the nest to keep in the fumes. Cotton wool dipped into a strong solution of cyanide of potassium (just enough boiling water should be used to dissolve the cyanide), pushed well into the nest, or 2oz. of the cyanide dissolved in a pint of water, poured into the nest are very effective. It is better to place a turf or some earth over the nest to prevent the fumes escaping. When anyone has the misfortune to be stung by a wasp the best thing that they can do, if they can reach the part, is to at once suck it well, and, if possible, make the place bleed with a view of getting rid of the poison before it has mixed with the blood. Then rub in hartshorn or ammonia in some form, washing soda or sweet oil, and keep as quiet and cool as possible so as not to increase the circulation of the blood.

In a letter sent to me by the Editor the correspondent asks "the best way to get rid of queen wasps when they first come out from their winter hiding-places in April? We are anxious to kill them before nesting time." The answer to this is: "There is no special means of killing queen wasps; but if found flying about, a syringeful of soapy water, properly applied, would no doubt bring them down and render them helpless for a few moments." G. S. S.

## THE EDITOR'S TABLE.

#### SPLENDID APPLES FROM LINCOLNSHIRE.

Mr. Thomas Smith of Walmsgate Gardens, Louth, Lincs. sends beautiful specimens of Apples, which fully bear out what he says about them in the following letter: "In view of the frequent reference made in the pages of THE GARDEN about the comparative merits of Apples

suitable for amateurs who have only limited ground, I have sent you a small sample of five varieties of Apples generally classed as culinary sorts, although some of them are quite acceptable upon the table at this season. Considered only as cooking Apples, their long season, combined with the useful size to which the fruits attain, should, I think, give them a distinct preference in planting to those early season Apples which are only in use for a few weeks. Emperor Alexander, Bramley's Seedling and Newton Wonder are the produce of open ground trees; Lane's Prince Albert and Bismarck are from two year old pot trees. The two last-named varieties fruit in a younger state than the others; in fact, the propensity of Lane's Prince Albert to produce fruit-buds in a young state is its only merit, and unless the fruit is rigidly thinned in its early years, a dwarf and stunted tree will generally result. All the fruits were gathered during late October, with the exception of Bramley's, which was picked in November."

## NOTES OF THE WEEK.

#### FORTHCOMING EVENTS.

March 9.—United Horticultural Benefit and Provident Society's Annual General Meeting, 8 p.m., Royal Horticultural Hall.

March 11.—East Anglian Horticultural Club Meeting.

**Lent Roses.**—That section of winter-blooming Hellebores generally known under this quaint designation are in large variety at Long Ditton, Messrs. Barr and Sons having secured a very representative collection. But the gems of the group are found in a selection of seedlings placed in the firm's hands for distribution by a well-known veteran amateur hardy plantsman of Devonshire, who has devoted his energies to the crossing and improvement of these Hellebores, and certainly the strain thus created may well be described as *H. orientalis grandiflorus*, so very fine are the flowers and so strong the general growth of the plants. While colouration is varied in the flowers, one of a charming rosy pink hue, the colours being shaded, forms a real gem, and is known as *rosea*. Without doubt all admirers of these exceptionally fine Lenten Roses will presently seek to secure plants and thus enrich their gardens with these novelties.—D.

**Brighton and Sussex Horticultural Society.**—This South of England society has this year, the seventeenth of its existence, arranged for three shows to be held respectively on April 7 and 8, August 18 and 19, and November 3 and 4. Jeremiah Colman, Esq., is the president, Mr. J. Thorpe, 53, Ship Street, Brighton, is secretary. The schedules include some very good classes, many of which are open, substantial prizes being offered in most cases. The committee is a strong one, and it is hoped that the shows this summer will be an advance even on the splendid exhibitions held last year. As usual, they are to be held in the Dome and Corn Exchange, Royal Pavilion, Brighton. All exhibitors of plants, flowers, fruits and vegetables would do well to secure copies of the schedules.

**Preparing museum botanical specimens.**—The *Kew Bulletin* for February contains some interesting information in an article by Mr. J. W. H. Trail on "Museum Preparations." Anyone that has attempted the preserving of botanical specimens in spirit will know how difficult it is to retain, in very many instances, the natural colour of the specimens being dealt with. This difficulty has been overcome by Mr. Trail by boiling the specimens in a solution of acetate of copper, washing the plants after boiling them and then placing them in the preservative. One or two minutes' boiling suffices for green seaweeds and submerged parts of vascular plants, but the leaves and young stems of most plants

need over five minutes' boiling, while those with thick cuticles may require from fifteen to twenty minutes. Plants thus boiled may also be pressed and dried between sheets of paper with good results. The colours of flowers and fruits are, however, variously affected by this process, the colours of some only being retained.

**Croydon Horticultural Society.**—The schedule of prizes offered for competition at the forty-first summer show, to be held near Haling Park, Brighton Road, Croydon, on Wednesday, July 18, is now ready, and a perusal of the classes is well worth while. There are many open classes for Roses, table decorations, collections of plants, cut flowers, fruits and vegetables, in all of which the prizes are of a substantial character. Amateurs and cottagers are also well provided for, and, of course, some classes are reserved for local residents. We are pleased to see this splendid provincial society making good headway, due, no doubt, to the energies of the secretary and committee. The secretary is Mr. A. C. Roffey, 55, Church Road, Croydon, to whom all enquiries should be addressed.

## PRIZES FOR READERS. MARCH.

#### SCHOOL GARDENS.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above subject.

Competitors should describe briefly the laying out and size of the plots, crops to grow, tools required, and the best methods of teaching the scholars.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Tuesday, March 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Daffodils in pots.**—Reading in THE GARDEN of February 22 about forced Daffodils quite out of character, if we take it for granted that this is correct where do our Roses, Carnations, Lily of the Valley, Solomon's Seal, Lilies and lots of other things come in? For my part I think the Daffodils grown in jam pots or vases surpass most things in spring. Perhaps February 11 is rather early, but from the end of February through March it is possible to get grand blooms of a lot of varieties quite up to those outside, and in some cases better, should the season be rough. I have grown such varieties as Mme. de Graaff, Glory of Leiden, Mme. Plomp, Victoria, Emperor, Golden Spur, Horsfieldii, Barri conspicuus, Frank Miles, Duchess of Westminster, Sir Watkin, Stella superba, and have had some really fine blooms three weeks to a month earlier than from the same varieties outside.—H. H.

# Manuring and repotting Roses.

In recent issues two very important questions have been asked by "P.," who evidently wants to hear the experience of growers. This has induced me to answer these questions from my own experience and observation. I am convinced that very many do manure their Roses too much. It is not uncommon to see these with a thick coat of animal manure on their roots sufficient for two plants. This excludes the air from the soil and roots, charging the soil with stimulants far beyond the needs of the roots, thus causing it to become sour. Another point to remember is that it is the weak-growing varieties that suffer most. I am convinced that the major portion of weak-growing varieties are ruined by over-feeding, and if these were lifted and replanted in fresh, open, sweet soil this would give them a new life. I consider more evils attend the use of artificials than other kinds, especially in the hands of the inexperienced, although they are most useful when used in right proportions and at the proper time. On page 67 "P." asks if we report our Roses too often. My experience induces me to say that in the majority of private gardens we do. During my experience (which extends over many years and many gardens) I have observed that those who only report once in two or three years get the best results. When serving as a young man in large gardens I found those gardeners that treated their plants on the method advocated on page 67 always had good results. In one place in West Norfolk, where the soil was poor and good loam difficult to obtain, we used to report only when the soil was packed with roots, and when these were disentangled giving larger pots.—J. C. F.

**Black scab in Potatoes.**—In THE GARDEN for February 15 there is a note on an article by Mr. E. Salmon, F.L.S., dealing with Potato disease fungus. Is it a fungus? I do not think it is, because it is in certain soils that Potatoes go this way. The cause of it is grit or sand in the soil. When the Potatoes are swelling the irritation of the soil causes warts, and a sure preventive is leaf-soil. Another thing that causes warts on Potatoes is fresh manure, this being put in with the Potatoes. Farmyard manure should never be put in the ground the same year as the Potatoes. It is better to use artificial manure, which will give far better results. I am in Perthshire and the garden where I am employed used to cause Potatoes to come warty, but when I plant my Potatoes with plenty of leaves round them they turn out free from warts. I hope you will bring this to the notice of Mr. Salmon.—JAMES T. M. ROBSON, *The Gardens, Kincardine Castle, Auchterarder.* [It is quite evident that our correspondent has not had any experience with the black scab or warty disease of Potatoes (*Chrysophyctis endobiotica*) or he would not question its being a fungus. The disease or scabbing that he refers to is doubtless the old *Sorosporium scabies*, a totally different thing, but also a fungus. Many growers, however, believe that scabbing is caused by caustic or irritating substances in the soil, and that the fungus (*Sorosporium scabies*) is only a result of the scabbing. Grit or sand is present in variable quantities in all cultivated soil, and we have seen Potatoes lifted from very sandy soil that possessed very clear skins.—ED.]

**Introduction of the Malmaison Carnation.**—Your correspondent "R. W." (page 87) must be somewhat wrong in his dates, for in the catalogue of Messrs. Downie Laird and Laing for the year 1874 plants of this Carnation are priced at 2s. 6d. each. It is also in Messrs. Henderson's catalogue for 1875. I have no older catalogues to refer to.—H. P.

**Book on grafting.**—"Reader" will find "Grafting and Budding" (C. Baltet) catalogued by Morgan and Co., S. St. Mary-at-Hill, E.C. He might get one at a railway bookstall, as I obtained one at such a place a few years ago.—J. B.

# THE GREENHOUSE.

## PRIMULA KEWENSIS.

AS a natural hybrid, of whose origin nothing is known save the abundant external evidence of the plant itself, this plant, which a few years ago appeared at Kew, is certainly among the most remarkable natural hybrids of the present day. It is obviously a natural hybrid between *Primula floribunda* and *P. verticillata*, and, as a matter of fact, appeared as a solitary example in a sowing of the seeds of the first-named species. The authorities at Kew were quick to note the great difference of growth, and kept a watch over the plant in question. The growth and leafage generally was that of a giant *P. floribunda*, the leaf blades alone being five or six times as large as the original. Later on, when the plant was showing for flower, the unmistakable evidences of hybridity became apparent, and the mealy leaf character of *P. verticillata* was noticed. Since that time this same characteristic has been amply evidenced in the hybrid, and later to a larger extent in some of its seedlings.

The plant itself has much improved under cultivation, and its whorls of yellow, fragrant blossoms often reach 18 inches or more in height. Quite as remarkable as the plant itself is the fact that prior to its appearance, and frequently since that time, efforts have been made to

A NEW FERN: NEPHROLEPIS EXALTATA AMERPOHLII.  
(A description of this plant appeared on page 72.)

reproduce it, the former at least without any good result. More than once has the present writer attempted to cross the species named, and in making the cross each way obtained nothing more than what existed before. Not a few others (the late Mr. Burbidge to my personal knowledge among them) did the same with no better results. And there is this remarkable fact remaining, that whether by wind, insect or other agency, but one solitary ovule, in an ovary containing many of the embryo seeds or ovules, was influenced apparently to produce the original plant, a sort of indication, one may presume, that but one tiny grain of pollen, or at least one pollen tube, if that be a correct description, was effectively transmitted to the ovary. Obviously, "Great things from small beginnings spring," and in this remarkable plant we have now a winter-flowering subject of great merit and attractiveness.

I believe that Messrs. Veitch, who put into commerce the original plant, have raised a variety with a more pronounced farinose leaf character, which should form an interesting companion. Seeds sown now make very fine examples for flowering next autumn and winter.

E. JENKINS.

## LIBONIA (JACOBINIA) FLORIBUNDA.

This useful winter-flowering plant is not met with in gardens so often as it should be. The flowers, which are covered with a fine pubescence, are produced on short axillary racemes and are tubular, the tube being scarlet and the mouth

and terminal lobes yellow. While the flowers are not large, their profuseness and bright colours make a very effective display, especially as well-grown plants are of neat, bushy habit, and almost as leafy as the common Box.

This plant can be increased with the greatest ease by means of cuttings put in about February or early March. The young plants should be grown on in a moist, warm greenhouse under conditions similar to those given to *Epacris*, &c., after they are cut back in spring, potting them on as they require it and frequently pinching out the tips of the shoots. During the hot summer months they can be stood in a cool frame, and care should be taken that they do not suffer from want of water, either at the roots or overhead. They are free rooting plants, and a rich soil composed of turfy loam, silver sand and cow manure will suit them, with occasional supplies of manure water when the pots are full of roots. In October they should be placed in an intermediate temperature, which is necessary for them throughout the flowering season. T. B. FIELD.

## A NEGLECTED GREENHOUSE FLOWER.

(THE EPACRIS.)

UNFORTUNATELY, the general cultivation of this and various other groups of what were once termed "hard-wooded greenhouse plants," has fallen into abeyance since the introduction of many of the popular greenhouse plants of to-day, the improvement of many of the old existing things, such as *Cinerarias*, *Carnations*, &c., and the comparative cheapness and convenience of heating arrangements for glass structures of the present day compared with those of fifty years ago. For many reasons this is to be deplored, for our forefathers loved the *Epacris*, *Acacias*, *Aphelexises*, *Phenocomas*, *Grevilleas*, *Boronias*, *Ericas* and so on, the successful cultivation of which was considered to be the best test of a gardener's skill. These are now rarely met with, and too often, instead of being grown year after year in the same garden, they are purchased annually from one or other of the few firms of nurserymen who still make a speciality of these plants.

The *Epacris* are Australian shrubs and essentially peat-loving plants. They may, of course, be increased by seeds, except in the case of garden varieties: but this is rarely attempted, growers finding that more favourable results are obtained by means of cuttings of young shoots, which may either be inserted in April or August; for many reasons the former month is preferable. They are inserted in a soil of fine peat and silver sand, the component parts being almost in equal proportions. Pots 5 inches or 6 inches across may be used, and these should be three parts filled with clean crocks. On this a handful of rough peat may be placed and the remainder filled to within a third of an inch of the top with compost; on the compost a thin layer of sand may be placed after the whole has been made thoroughly firm. The cuttings, which may be from 1 inch to 1½ inches long, must be inserted firmly, about one-third of their depth being placed in the soil. Water with a fine rosed can, plunge in a propagating case in gentle bottom-heat, cover each pot with a bell-glass and roots will be formed, with proper care to watering, &c., in a few weeks. When rooted stand near the glass in the open house for a week or two, then pot the tiny plants singly into 2½-inch pots, using a compost of two parts peat and one part sand. As soon as they are established pinch the point out of each plant, and repeat this when young shoots are 1 inch or 1½ inches long; this repeated on several occasions will ensure a good stocky foundation for the future plant.

Repotting must not be done very frequently, and the smallest shifts possible must be given when it is necessary, as *Epacris* strongly object to over-potting. The roots are very fine, and

unless all the old material is well filled with roots before new is given they are unable to take advantage of the cultivator's generosity and the result is that continual watering causes the surplus soil to become sour.

No flowers should be allowed to be produced during the first year, as flowering will seriously weaken young plants. By the second April from the time the cuttings were inserted nice stocky plants will have been formed, which may be in 5-inch or 6-inch pots. About the end of the month they may be finally stopped, placed near the glass in a warm greenhouse and growth encouraged in every way. The aim from this period onwards must be to obtain long, strong, well-ripened wood. With this end in view growth must be assisted as much as possible, and about the middle of June the plants must be plunged out of doors in a sunny position, or be given a place in a light and sunny greenhouse with no fire-heat and a free circulation of air. If the pots are well filled with roots gentle stimulants may be provided in the form of weak cow manure water or weak guano water.

Early in September all plants should be housed in a cool greenhouse, to which no artificial heat is admitted until the temperature falls below 35°. Great care must be taken with watering, as either over or under watering is harmful. Early in December a batch of the most forward plants may be placed in a warmer house to develop their flowers, other batches being brought in at intervals of three or four weeks. As soon as the flowers fade cut the shoots well back and place the plants in a warm and moist house to encourage new growths; the further cultivation will be similar to that already noted.

The plant illustrated is a white-flowered variety known as The Bride. Other good sorts to grow are longiflora, a species with long red and white flowers; miniata and m. splendens, with long red flowers; alba odorata, white; Exquisite, pink; Fireball, bright red; alba and candidissima, white; Eclipse, crimson and white; Vesuvius, crimson; carminata, deep pink; Sunset, red; and Mont Blanc, white. When growing on old plants it should have been mentioned that it is advisable to thin out the shoots and only allow comparatively few to develop, as the object is to obtain as long and as strong shoots as possible, which will bloom from end to end. K.

### THE LION'S TAIL (LEONOTIS LEONURUS).

THE well-flowered plants which have been shown by Messrs. Veitch and Sons on several occasions should bring it into more general cultivation. It is certainly one of the most attractive winter-flowering greenhouse plants we have, and is almost hardy. In sheltered nooks it will flower out of doors, and is one of the plants which will not succeed if grown under shade and too much warmth. The plants should be grown out in the open during the summer. Propagated from the strong terminal shoots early in the spring, the cuttings may be treated similarly to the Salvias. If put in singly in small pots and placed in the propagating pit where there is a good bottom-heat they will soon root, and should be removed before they begin to run up. It potted on as they require, using a good rich loamy compost and potted firmly, they will make sturdy growth.

After the plants are well established they should be well exposed to the air and light and later on placed out in the open. Careful attention to watering is all that will be necessary until they are removed to the greenhouse in September. Light and air, with full exposure to sunshine, is necessary, and only sufficient fire-heat to keep out frost and the atmosphere dry in wet weather. I believe that there are many old introductions which if more fully exposed to the sun would flower more satisfactorily. The above is also known as Phlomis Leonurus, and comes from South Africa. A. H.

## THE ROSE GARDEN.

### PRUNING ROSES.

(Continued from page 97.)

THE instructions given herewith are mainly for those who grow for garden decoration. If wanted for exhibition, prune rather more severely. In pruning old plants transplanted this season or in the autumn, wait until the eyes appear to be bursting into growth at the base of the plants, and then prune them back rather hard. For instructions as to varieties not found in these lists, we would refer our readers to our issues of February 23 and March 2 of last year.

#### HYBRID PERPETUALS.

*Very vigorous.*—Most of these may be used as pillar Roses, and in that case their annual growths are left almost full length. Cut away dead and soft wood, also any more than two or three years old. When used as bushes leave growths from 15 inches to 24 inches long, and if wanted for pegging down the long annual growths may be bent over their full length.

Barbarossa	Glory of Waltham
Boule de Neige	Mme. I. Pereire
Climbing Captain Hayward	Maharajah
" Frau Karl Druschki	Margaret Dickson
" Mme. E. Verdier	Paul Neyron
" S. M. Rodocanachi	Thomas Mills
" V. Verdier	Ulrich Brunner

*Vigorous growing.*—Remove all soft, pithy wood and cut back the longest of last year's ripened growths to within 6 inches or 8 inches of their base, lateral and weaker shoots to 2 inches to 4 inches. If any sort has proved to be a shy bloomer prune it very little, and in April bend over the growths or tie them upright to form low pillars. Many in this group make splendid pillars to dot among bush Roses, such an one being Frau Karl Druschki. The majority make fine standards.

Abel Carrière	H. Schultheis
Ami Martin	Her Majesty
Ards Rover	Hugh Dickson
Baron de Bonstetten	John Hopper
Charles Lefebvre	Jules Margottin
Commandant F. Faure	Lord Bacon
Crimson Queen	Mme. G. Luizet
Duke of Edinburgh	Mme. J. Bonnaire
Duke of Teck	Mlle. Renee Denis
Dupuy Jamain	Marchioness of Lorne
Earl of Dufferin	Mrs. F. W. Sandford
Ella Gordon	Mrs. J. Laing
Eugene Fürst	Prince C. de Rohan
François Michelon	Rev. A. Cheales
Frau Karl Druschki	Sultan of Zanzibar
Gloire de Margottin	

*Medium growth.*—Prune back last year's strongest shoots to within 2 inches to 4 inches of their base, small laterals prune back to 1 inch or 2 inches. In most cases 1 inch will be ample to retain. Remove all soft, pithy wood, also weakly wood, from the centre of the plants.

Alfred Colomb	Mme. Eugene Verdier
Alfred K. Williams	Mme. Victor Verdier
American Beauty	Mlle. Annie Wood
Beauty of Waltham	Mlle. Eugénie Verdier
Black Prince	Marchioness of Londonderry
Bob Davison	Marie Corelli
Camille Bernardin	Marie Finger
Captain Hayward	Marie Baumann
Caroline d'Arden	Mrs. A. M. Kirker
Charles Lamb	Mrs. Cocker
Comte de Raimbaud	Mrs. G. Dickson
Countess of Oxford	Mrs. R. G. Sharman Crawford
Crown Prince	Mrs. Stewart Clark
David R. Williamson	Oberhofgartner A. Singer
Dr. Andry	Oscar Cordel
Dr. William Gordon	Pierre Notting
Duchess of Bedford	Pride of Waltham
Duke of Connaught	Prince Arthur
Eclair	Reynolds Hole
Exposition de Brie	Rosslyn
General Jacquemhot	Salamander
Grand Mogul	Senateur Vaisse
Jeannie Dickson	Star of Waltham
Jubilee	Suzanne M. Rodocanachi
Lady H. Stewart	Tom Wood
Laurence Allen	Victor Verdier
Louis Ricard	Violette Bouyer
Mme. Bois	Waltham Standard

*Moderate growers.*—First cut away all soft, pithy shoots, then prune the hard growths made last year to within 1 inch to 2 inches of their base. Prune to a good plump "eye" or bud, even if so doing it is necessary to leave shoots a greater length than stated. With many sorts in this group there will remain only one or two really good growths to prune back, but even one growth will yield two or three fine shoots, which should each bear a bloom.

Baroness Rothschild	Louis van Houtte
Duke of Albany	Mabel Morrison
Duke of Fife	Marie Verdier
Duke of Wellington	Marquise de Castellan
Earl of Pembroke	Merveille de Lyon
Etienne Levat	Mme. C. Wood
E. Y. Teas	Spenser
Fisher Holmes	Uster
Gustave Piganeau	Victor Hugo
Helen Keller	White Baroness
Horace Vernet	Xavier Olibo
Lady Overton	

#### HYBRID TEAS.

*Moderate or weak growing.*—Prune away soft wood, last year's growths retain 1 inch to 2 inches in length and thin twiggy shoots if wanted may be cut back to one eye. Unless required for exhibition the sorts from this list should be avoided as standards, but they make splendid dwarf standards.

Annie Marie Soupert	Mrs. W. J. Grant
Charlotte Gillemot	Nadia
Corona	Oberhofgartner Terks
David Harum	Papa Lambert
Elizabeth Kitto	Paul Lede
F. Deegen	Professor F. Roeber

Liberty	Souvenir de Mme. E. Oudin
Mme. Cadeau-Ramey	Tennyson
Marie L. Poiret	Violoniste E. Lévêque
Marjorie	W. F. Bennett
Marquette Liitta	White Lady
Mildred Grant	

*Medium growth.*—Cut away all soft growth and thin out the small shoots. Prune the strongest hard growths made last season to within 2 inches to 3 inches of their base; the small shoot cut back to one or two eyes. Where large bushes are desired many sorts in this group may be very sparsely pruned if uninjured by frost. La France is such an one. Frequently this sort succeeds best thus treated.

Alice Grahame	Killarney
Alice Lindsell	Konigin Carola
Amateur Teyssier	La France
Augustine Guinoisseau	La Vendemoise
Aurora	Lady Battersea
Baron Van Pallandt	Lady Clanmorris
Baronin A. Von Biel	Lady Faire

Irish Harmony	Souvenir de Mme. E. Verdier
Jeanne Barrioz	Souvenir d'Helene
Joseph Hill	Souvenir du Pres. Carnot
Kaiserin A. Victoria	Souvenir de S. Gray

*Vigorous growing.*—Cut out soft and weakly wood, also one or more of the oldest growths each year. To obtain quantity of blossom prune back last year's growths to 3 inches or 4 inches of their

base, but for garden decoration the growths may be retained even from 8 inches to 10 inches in length. Many of the sorts may be partially pegged down, selecting a long ripened growth and bending it over, with the result that blossom will appear all over the bent growth.

Admiral Dewey	Lady Rossmore
Aimée Cochet	Lady Wenlock
Avoca	Lohengrin
Bardon Job	Lyon Rose
Bellegneur	Ma Tulipe
Betty	Mme. Abel Chatenay
Caroline Testout	Mme. Alfred Sabatier
Celia	Mme. J. W. Budde
Charles J. Grahame	Mme. L. Moissy
Colonel Chaverendier	Mme. M. de Luze

John Ruskin	Warrior
La Tosca	W. F. Lippiatt
Lady H. Yiucent	William Askew
Lady Moyra Beauchere	William Shean
Lady Q. Ewart	Yvonne Vacherot

*Very vigorous.*—Many of these may be used as climbers or pillar Roses; they also make good free bushes, grown singly or in groups, and splendid standards. Retain last season's best growths almost their entire length when used as climbers, pillars or free bushes, and laterals cut back to 2 inches or 3 inches. If used as bushes or standards, prune back to within 15 inches or 2 feet of their base, and lateral shoots 2 inches or 3 inches. All soft, pithy wood should be removed entirely and any worn-out growths. J. B. Clark should be grown as a pillar Rose; this and F. Crousse and others of this group make fine hedge plants.

(To be continued.)

## ROSE REINE CAROLA DE SAXE.

THIS Rose as exhibited at one of the autumn shows gave promise of being a very useful sort. It is one of those varieties that possess very stout petals and a very compact sort of flower, with a beautiful conical form. It reminded me somewhat of Oberhöfgartner Terks, although perhaps not so pointed as that very distinct Rose. The colour is a beautiful blush, paling to French white at the extreme edges of the petals. I think it is a Rose to be looked after. It was raised by Gamon and introduced in 1903. As present-day raisers are giving us so many novelties with semi-double flowers, we naturally value the semi-double sorts when they possess the merits of distinctness and good lasting qualities.

## THE KITCHEN GARDEN.

### ASPARAGUS FOR AMATEURS.

(Continued from page 71.)

**I** PREVIOUSLY referred to soils, sowing and planting, and will now briefly note an easy method of obtaining early supplies. Under this heading comes forcing and protection, and of course before the beds can be forced there must be a strong plant, and to get this so much depends upon the room at disposal and means to force. Many amateurs buy roots for forcing early in the year, but this is rather costly, as the roots when lifted and forced are useless, and this is a point that many cannot overlook. At the same time, I have no wish to condemn this system, as during the past few years the growers of forcing roots have paid much attention to them, and now very fine material may be purchased ready for forcing. On the other hand, there is a more natural system, that is, of forcing the permanent beds. Here there is no waste, the beds last many years, and each year force more readily if given ample attention during the growing season, so that good crowns are formed for the purpose. The culture, too, is so simple that it is admirably adapted for amateurs.

#### FORCING AND PROTECTION.

Earlier I referred to the age when the plants are strong enough to cut, and this also applies to forcing. They must not be forced till at least three years old, or have been in the permanent beds at least three years. For many years, for a Christmas supply, we always made it a point of lifting our oldest bed and placing the roots in frames on a bed of warm leaves, this being done early in November, new beds being planted every spring. I refer to this not to advise it to my readers, but to show that old plants force more readily. For instance, if the amateur has a patchy bed, or a bed where the ground may be required for other purposes, here the plants treated as above are made good use of, and it is much better to plant or sow a new quarter occasionally than waste ground on a poor plant. Lifted plants placed in heat or over manure force very quickly in two or three weeks, and there will be heads with a genial bottom-heat; but avoid too much warmth, as this causes a weak, thin growth. I advise less heat and slower forcing and that is why I always prefer fresh leaves in the late autumn, as these heat slowly, retain the heat

longer, and are moist, whereas in large bodies of stable manure the heat is too violent and forces too quickly. If the latter is used let it, if possible, be incorporated with leaves; if not, it should before using be placed in bulk in the open and frequently turned over thoroughly to sweeten.

We now come to the beds, and for early supplies there must be space between the beds of at least 2 feet, allow 3 feet if possible, and this space is filled in in November and December with fresh leaves. I have secured the best results from beds with two rows of plants, these being 18 inches apart in the centre and 1 foot at the outside on 3 feet 6 inch beds. Here the warmth readily permeates through, and the depth of both the bed and the alleys are equal, 2 feet to 3 feet, or

EPACRIS 'THE BRIDE'. (See page 111.)

the latter may be more if there is plenty of heating material. Of course, this applies to new beds made specially for forcing, and the beds at the sides may be made with any material at hand, such as slates, tiles, or bricks, the latter being pigeon-holed. I admit that here is a little expense, but once made it lasts for many years, and soon repays the cost of lifting or forcing under glass. In a stiff soil we have done without walls, merely using a few stakes and boards to keep the soil in position, and if the heating materials are well firmed or trodden when placed in the alleys and left till next forcing season the beds will keep in shape. When a good body of leaves is trodden in, the top portion may be covered with warm stable litter, and a good

depth of this also should be placed over the surface of the beds, and the long strawy material on the top to throw off rain. It may be necessary to add to this at times. The Asparagus will appear in from four to six weeks, but the beds must be well drained in heavy land. Raised beds are best, and I have seen the same forced for over twenty years.

An amateur may not want to go to the expense detailed above, and may wish to force at a less cost. Here the process is simple, providing there is room between the beds. By digging out the soil to a depth of 2 feet, and filling in, say, with 3 feet of warm or prepared manure, and covering the surface of the bed with a good thickness of the same material, good heads may be secured in about six weeks, and the manure next season may be taken out and used as a surface dressing.

A word as regards premature forcing; by this I mean too early or too rapid. It is far better to collect the leaves or material and place in a heap till required than to put it in the alleys or trenches too early, as the plants must have sufficient rest. Too much heat causes a few weak shoots to push through, and the strong crowns damp off. November or December is quite early enough to start with beds, and better results are obtained even later when manure is the heating agency, say, January or early February.

#### PROTECTING THE BEDS.

It is a good plan to protect permanent beds to get heads in advance. By this I mean that any amateur who has a strawy litter at command may with advantage cover a bed at night, removing the litter early in the day. In my next article, which will probably be the most important to amateurs, I will go into the culture of the open ground supply.

G. WYTHES.

#### BEST POTATOES.

(Continued from p. 101.)

ANY selection, however good, will fail to please all, but from actual tests of the varieties named, all well tried sorts, both as croppers and disease-resisters, and taking the Potato as a food product first, and for show purposes afterwards, the cultivator who fails to find in the following lists the sorts suitable for his purpose must be hard to please indeed. Those marked with an asterisk are suitable for exhibition. Six first early varieties: \*Sutton's Al, \*Midlothian Early, \*Sir John Llewelyn, Duke of York, \*Sharpe's Victor (forcing) and Sharpe's Express (forcing). Six second early varieties: \*Dalmeny Radium, \*Dickson's New Century, \*Sutton's Reliance, \*White Beauty of Hebron, \*Maid of Coil and British Queen. Twelve main crop varieties: \*Sutton's Superlative, \*Snowdrop (Perkins), \*Up-to-date, \*King Edward VII., \*Edgecote Purple, \*Dickson's Eastern Planet, \*The Factor (Dobbie's), \*The Crofter (Dobbie's), \*Rob Roy (Massey's), \*Discovery (Sutton's), \*Duchess of Cornwall and \*Daniels' Special.

In conclusion, it should always be borne in mind that the Potato, if grown year after year on the same soil without a change of seed, seriously deteriorates, therefore seed should be exchanged, say, every two years. Varieties with strong and healthy constitutions are what is required, and we should aim at preserving the really good sorts we already have, and at once discard any variety which is a poor cropper under good cultivation or has the least tendency to disease.

GEORGE COOPER.

## THE FLOWER GARDEN.

### ANNUAL FLOWERS FOR DRY WALLS AND STARVED POSITIONS.

**A**MONG hardy annuals which grace our gardens during summer are some which find a place on account of their vivid colouring, while not a few win their way by reason of their dainty form, or it may be having features of other interest. Such a plant is the pretty annual Violet Cress (*Ionopsidium acaule*). The whole plant is exceedingly small; the leaves are arranged in the form of a rosette, above which, early in the season, appear the dainty cross-formed flowers of a delicate soft lilac colour. When grown like the ordinary run of annuals in beds or borders its merits are easily overlooked, for to enjoy it one must grow it in half-shady spots on raised ground, such as may readily occur on the rock garden, or, better still, to meet it a little below eye level ensconced in the crevices and courses of a shaded dry wall or nestling in the joints of rough steps in the informal part of the garden.

It sows itself freely after the first year, and each succeeding season will the seedlings appear

and in such positions they are the admiration of everyone. It is the plant for starved ground, and where the courses of dry walls are sown with this annual during February they present a striking feature in the garden right through summer and autumn. In rich soil it will grow 3 feet high, but in such positions the vegetative growth is always produced at the expense of flowers; grown as indicated above the average height is 9 inches to 12 inches and the flowers are produced freely in sunny positions.

*Saxifraga Cymbalaria* is also an annual and a fitting companion for similar positions and aspects named for *Calceolaria mexicana*. The growth of this plant is quite in accordance with the commoner members of the same great family, so that it is unnecessary to describe it in detail. The colour of the flowers is a soft citron yellow, and it is one of the best plants for the rock garden in summer.

THOMAS SMITH.

Walmgate Gardens, Louth.

### ANEMONE BLANDA.

THIS, in many of its seedling forms, is now most beautiful, especially in those positions where, by reason of a little natural shelter, the foliage was not harmed by the recent cold, searching winds. No more valuable plant exists, while its infinite

variety from seed renders it still more beautiful for grouping freely in the garden. The scarlet Windflower, as well as the Apennine kind, is also gay with blossom.

### THE TWO-LEAVED SQUILL.

(*SCILLA BIFOLIA*.)

THIS, I think, is one of the most valuable of the Squills. It flowers much earlier than *S. sibirica*, and even in my upland garden I am generally able to pick many of its exquisite deep blue blooms during the first days of February. It is strange that this precious bulb is not more widely cultivated, since it can be purchased nearly as cheaply as *S.*

*sibirica*. *S. bifolia* grows freely in any light sandy soil, and does best in a sunny, sheltered situation. It delights in leaf-mould. An established colony makes a most delightful picture early in the year. During severe or wet weather I find it helpful to place a sheet of glass over a few of the finest clumps.

E. TESCHEMACHER.

### TOP-DRESSING PRIMULA SIKKIMENSIS.

AMONG the *Primula* species which require some care to retain them in the garden for several years is the beautiful *Primula sikkimensis*, whose pale yellow, sweetly-scented flowers dangling from the tallish stems are so much enjoyed in their season. It is not, as a rule, of very long duration, often, indeed, failing after its third year in gardens where it has done well. Its life may, however, be prolonged if it is well watered in dry weather, and, more important still, kept top-dressed in spring, summer and autumn.

The waterings it should have in dry weather increase the necessity for this, as they wash the soil from about the crowns and bring the roots, which naturally lie near the surface, closer to it. The winter's frost has also a tendency to lift the crowns, so that they not only require

A PRETTY WINDFLOWER (ANEMONE BLANDA) IN MR. BLICKHAM'S GARDEN AT LEDBURY.

in autumn and the little rosettes cover the ground with a carpet of green throughout the winter.

*Sedum ceruleum*.—Quite one of the prettiest blue-flowered annuals is *Sedum ceruleum*, which is also suited for the position indicated to the Violet Cress, except that it requires sun. The leaves of the seedlings are succulent, as in most Sedums, and arranged in the form of small rosettes, which gradually elongate into the flowering head. The colour of the flowers is the summer sky reflected—a bewitching shade of azure blue. The plant attains to a height of 6 inches when in flower, and as it appears in the same position year after year from self-sown seed, there is consequently no difficulty about raising new plants. The appearance of the plant when in flower is light and airy, and it is distinctly beautiful when seen in a fair-sized patch.

*Calceolaria mexicana* is one of the easiest annuals to naturalise in any garden; a single plant will in the following year give rise to thousands, the seedlings appearing in the most unaccountable positions. Medium or rich soil produces plants quite out of character, while spontaneous seedlings, which not infrequently occur between stone joints in pavement, wall or step, produce plants which literally cover themselves with delicate lemon-coloured blossoms,

pressing gently into the soil in spring, but are also all the better for some fresh material about them, even if the roots themselves do not show on the surface. I have found nothing better than some fine loam, with a little peat and sand added, or, failing the peat, a small proportion of leaf-soil. Many years of experience with this beautiful *Primula* induces one to write this short note. S. ARNOTT.

### PLANTING BORDER CARNATIONS.

ALTHOUGH these Carnations are fairly hardy, it is not advisable to leave the best varieties exposed in the open borders throughout the winter, as severe frosts and excessive moisture damage the plants more or less. The wise amateur will have stored many valuable rooted layers in a cool frame, from which position they will be taken early in the spring. It is not necessary to wait until the end of April before the plants are put out. But duly prepare the border for their reception early in March, and on the first favourable opportunity do the planting.

#### PREPARING THE BORDER.

Merely digging the soil and putting in manure will not do. It should be trenched at least 20 inches to 2 feet deep, and the manure so placed that the roots of the Carnations will not come into contact with it until they have commenced to grow after planting. This means that the manure, which should be well rotted, not strawy, must be mixed with the soil about 9 inches below the surface. All the lower or subsoil must be well broken up, and the digging done, if possible, while the ground is fairly dry.

Carnations thrive best in firm ground, so that it is advisable to make the soil firm by judicious treading while it is moderately dry and before any plants are put out.

#### PLANTING.

When Carnations are layered every care is taken to induce the formation of many roots. Now, at planting time, those precious roots should be preserved. Lift the plants with the aid of a hand-fork and place them in boxes for conveyance to the border. Then plant them in rows about 16 inches apart and the same distance from each other in the rows. Make the soil firm around them with the hands, and afterwards loosen the surface of the soil with a Dutch hoe, and finally rake off any large stones. The plants will then so on become established in their new quarters. AVON.

### THE WHITE SWEET SULTAN.

THE Sweet Sultan belongs to a family (the *Centaureas*) which has furnished our gardens with many good plants, both annual and perennial. All are useful alike as decorative subjects in the border and as cut flowers in the house, from the giant *C. macrocephala* to the baby forms of *C. Cyanus*, the popular Cornflower. Probably the latter in its various colours is the greatest favourite of them all, but now that the improvement of the Sweet Sultan—which is scientifically called *C. moschata*—has been seriously taken in hand it should make a bold bid for supremacy.

For many years we have had more or less dingy purple Sweet Sultans, dirty white Sweet

Sultans and a very passable pale yellow form; but at last we find the improvement in the race is seriously undertaken, and the fine new varieties already obtainable give a splendid earnest of what we may expect in the near future. The illustration shows one of the newer white forms, and those readers who only know the flowers as produced by the ordinary seedsmen's packet will at once note the improvement exhibited—improvement in the purity of the colour and improvement in the size, for the modern white Sweet Sultan is twice as big as many of its forbears. For cutting these white Sweet Sultans are most admirable. Highly artistic in appearance, possessed of long and strong stems, delicately perfumed and lasting long in water, they approach very nearly the ideal cut flower.

A PRETTY ANNUAL: WHITE SWEET SULTAN.

As to culture, they grow themselves. They are hardy annuals, fairly vigorous in constitution, grow 18 inches to 2 feet high and battle bravely for themselves in the ordinary border of mixed flowers. The newer varieties are, however, worthy of a better fate than this. They may even be entrusted with the filling of a prominent flower-bed or formal parterre, and will acquit themselves nobly. For this purpose, and for all others where it is desired to get the best possible out of the plant, seeds should be sown on a reserve border about the middle of March. Use a light, sandy compost, sow in shallow drills 3 inches apart, prick out the seedlings early and transplant them to their flowering quarters soon after the middle of May and the Sweet Sultan will be far from being the least attractive plant in the garden.

## INTERESTING PLANTS AT KEW.

**P**OLYPODIUM AMERICANUM. — This, a native of the Andes of Ecuador, is one of the rarer Polypodiums, and, although it cannot be called a handsome plant, it is not devoid of interest. The specimens at

Kew were raised from spores secured from a dried frond sent to the Herbarium some years ago for naming. Formerly it was grown in the Tropical House, but the plants have now been transferred to the Temperate Fern House, with the result that the fronds are more stunted in their growth. They are lance-shaped, with rather blunt apices, and when young each is covered with an almost white, dense coating of woolly matter, thus leading one to suspect that it likes a rather dry atmosphere.

It has a creeping, rather slender rhizome, by the division of which it is readily propagated. It is also easily raised from spores, and delights in a peaty soil.

*Selaginella watsoniana*. — This pretty *Selaginella* is of garden origin, a piece being casually secured some few years ago. Although regarded by the Kew authorities as a species, it is possible that it may be a variety of *S. Martensii*, the species that it most nearly resembles in habit. It does well in a temperate house, the foliage coming a better white than when given a tropical temperature. At the bases of the plants the small leaves are greyish white, then comes a sort of broad band of clear green, the tops of the plants being a clear creamy white. When the plants are grown rather closely together in a pan they produce a fine effect.

*Jasminum primulinum*. — This beautiful Chinese species is now flowering in House No. 4, its large, bright yellow flowers proving a welcome addition at this time of the year. It is a pity that this plant has not proved hardy at Kew, the specimen planted against the bulb border wall having succumbed. It has practically the same habit as *J. nudiflorum*, but the flowers are much larger, some of them coming semi-double. The leaves are trifoliate, and young shoots are produced in abundance. The plants noticed were growing in a large pot, and appeared to be quite at home. The specimens planted out in the Himalayan House, although making an abundance of new growth, show no signs of flowering. This may possibly indicate that it flowers best when the roots are confined to a pot.

*The Cornelian Cherry*. — This hardy-flowering shrub, known botanically as *Cornus Mas*, ought to be grown far more extensively than it is at present. At the first glance one may easily mistake it for the Witch Hazel (*Hamamelis arborea*), the deciduous branches being very freely besprinkled with the small bright yellow flowers. It makes a large shrub of erect habit. The variety *Xanthocarpa* has a semi-pendulous habit, and the flowers are of a paler colour. Both are in flower in the beds near the Temperate House, and prove excellent subjects for following the Witch Hazels. The spring-like beauty of the Cornelian Cherry is very welcome at this season of the year; it is so fresh and winsome,

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**LAWNS.**—At this period I make it a rule to rid the lawn of Plantains, Daisies and Dandelions, as they become very troublesome later on. With material that is known as "lawn sand" I sprinkle the offending weeds, and in this way remove the trouble. My seedsman supplies the "lawn sand" at a low cost. I am just now making good all bare and patchy quarters by laying down new turf and making a sowing of reliable lawn Grass seed on less-worn patches. Top-dressing is an excellent stimulus for grass at this period; wood ashes and charred earth should be evenly distributed on the surface. In a little while worm-casts will be much in evidence, and should be dealt with before they become really troublesome. With a good Birch broom I go over the whole of the surface, sweeping it frequently. Subsequently the lawn is well rolled, and in this way the turf is again made firm and even.

**Chrysanthemums.**—I am lifting the old plants that flowered in the outdoor garden last autumn, and these are being divided into numerous pieces. The sucker-like growths in almost every instance have roots adhering, so that strong plants are soon developed. Those who have a cold frame may dibble in these divided pieces and thus hurry on their root formation. Cuttings of the varieties to flower in pots under glass next autumn are now nicely rooted, and these should be potted up singly into "sixties" (pots measuring 3 inches in diameter). Use clean pots and crocks, and prepare soil made up of two parts loam, one part leaf-mould and one part well-rotted horse manure. Pass these ingredients through a coarse sieve, and add coarse silver sand or road-grit in sufficient quantity to make the whole porous. Repot the young plants moderately firm, afterwards standing them in the cold frame or on shelves in the cold greenhouse.

**Hardy Flower Garden.**—Gladioli are planted at this period. I prefer to group this flower, arranging half-a-dozen to a dozen corms in each

group, and the corms about 1 foot, more or less, apart. The warmer quarters should be planted at this early season. Our patch of Lily of the Valley is just now being dressed with a thin layer of well-rotted manure, the old hot-bed material being used for this purpose.

**Roses.**—I have only just received a number of Roses ordered last season, and, although I would rather have planted them in November last, I do not fear the results of present planting. We spread out the roots when planting, and, that this may be done satisfactorily, we do not hesitate to take out a good hole in each instance. In the near future I propose to prune trees that are on warm walls; in other cases the pruning must be deferred for a while.

**The Greenhouse.**—I am preparing for raising a number of annuals under glass just now. With a little propagating frame arranged on the side bench of the greenhouse, just over the hot-water pipes, I can obtain the requisite bottom-heat to cause the seeds to germinate quite readily. A temperature above 40° will germinate seeds, but I prefer it to be quite 15° to 20° warmer for most subjects. Half-hardy annuals may be raised by the foregoing method quite easily. Cuttings of Fuchsias, fibrous-rooted Begonias, Bouvardias, Salvias, Geraniums, Hydrangeas, Lobelias, Marguerites, Petunias, Dahlias and Heliotropes, besides many other similar subjects, may be inserted now. Pots or boxes filled with light sandy soil should be used for inserting the cuttings in, and these placed in the propagating frame forthwith. Water in with clean water from a very fine-rosed can.

**Vegetable Garden.**—My Onion bed is now in beautiful working order, the surface soil having just been forked over and made friable. The first sowing is to be made at once. I am drawing the soil round Cabbages planted in warm quarters last autumn; this is a much appreciated attention. Vacant ground that it is intended to crop in the near future should be trenched or deeply dug without further delay. Autumn-sown Onions should be planted at once. I obtain handsome bulbs in July from these Onions planted at the present time on ground previously occupied by Celery. D. B.

## THE HELIOTROPE AND ITS PROPAGATION.

THERE is not a lover of flowers who does not recall the familiar Cherry Pie, by which name the Heliotrope is popularly known. Its distinct and sweet fragrance has always been a fact, and one gladly welcomes the prospect of dealing with the plants in practical fashion forthwith. The Heliotrope is a native of Peru, and was introduced so long ago as 1757. There is only one species, but of this there are several beautiful varieties.

**Treatment of Old Plants in Pots.**—The glass structures of many amateurs possess a few old plants in pots, such as are represented in Fig. 1. Specimens of this kind look anything but attractive, and if left to take a natural course would very likely give weak and sickly shoots that would never produce the beautiful sprays of blossoms for which the Heliotrope is famous. For this reason these old plants are pruned in the early spring, preferably in late February. The pruning must be somewhat severe, but should be determined by the character of each individual plant. Cut well back is the safer course to follow, as this induces new shoots to form.

**What to do with Cut-back Plants.**—The result of the cutting back of the old plants will be seen in the illustration in Fig. 2. In the present instance the old plant has been cut back moderately, but sufficiently hard to induce it to

2.—THE SAME PLANT MODERATELY CUT BACK.

break away freely into useful growths. The shoots that were removed are not thrown away, but are preserved for the purpose of making cuttings. The plants, after being cut back, should be partially shaken out and repotted, using pots of the next size to those they previously occupied, and soil made up of loam, leaf-mould and manure from an old hot-bed, and plenty of sand, all well mixed together. See that the drainage is well arranged and this covered with some of the rougher portions of the soil to prevent the smaller particles from working down into and between the potsherds forming the drainage. Pot firmly. Subsequently place the old plants in a glass structure where a temperature of about 60° can be maintained, and in such circumstances, by a frequent syringing overhead, new shoots will soon develop and the foundation of bushy plants be laid.

**Cuttings and How to Make Them.**—Cuttings should be some 2 inches to 3 inches in length, and should, if possible, be of comparatively recent growth. The series of cuttings as seen in Fig. 3 gives a fair indication of the character they should represent when trimmed and ready for insertion. The lower leaves have been removed and the stem of the cutting cut through immediately below a joint.

**Inserting the Cuttings.**—These may be inserted in pots, pans or shallow boxes, in each of which they root very readily, provided soil of a suitable kind is used. A suitable soil may be made up of loam, leaf-mould and silver sand, the two former ingredients being passed through a sieve with a quarter-inch mesh and the whole mixed well together. When inserting the cuttings always see that the soil is pressed firmly at the base of each one, otherwise they may fail. Water in with clean water from a fine-rosed can as soon as the box or pot is filled with cuttings, placing them subsequently in a warm corner of the

1.—AN OLD PLANT PREVIOUS TO BEING CUT BACK.

greenhouse, where a little bottom-heat from hot-water pipes can be obtained. The cuttings root much quicker when placed in a temperature of from 65° to 70°, and this may be effected by standing the pots, &c., in a small propagating frame on the greenhouse bench, arranged over the hot-water pipes, or by using a bell-glass placed in the same position.

*Cuttings after Rooting.*—As soon as the cuttings are nicely rooted, as represented in Fig. 4, they should be potted up singly into 3-inch pots. These pots are known also as "sixties." Loam and leaf-mould in equal quantity and the liberal addition of coarse silver sand makes an ideal compost for the first potting up. Well mix the soil and pot fairly firm. To induce a bushy style of growth it is well to pinch out the point of the growth. Pot up into larger pots from time to time as the pots get full of roots, and in the end give them sunny quarters in the greenhouse or conservatory, or harden off preparatory to planting outdoors in June.

*Heliotropes from Seed.*—These are raised quite easily from seed, and in late February and throughout March, with a brisk bottom-heat, either from hot-water pipes or hot-bed, they may be dealt with most successfully. Sow the

4.—ROOTED CUTTING READY FOR POTTING UP.

seed a sixteenth of an inch deep in light sandy soil, using pots, pans or shallow boxes that are well drained. If a temperature of from 65° to 75° can be provided, the seed germinates freely and young plants are soon brought into being.

*Varieties.*—Lord Roberts, deep blue, white eye; Bouquet Blanche, white, very sweet; Mrs. J. G. Day, white, shading to lavender; Swanley Giant, bright blue; Mme. de Bussy, blue, with white centre; F. W. Harry Gulliver, deep mauve, shaded rose; Mme. Nelson, violet-mauve, compact; Chameleon, violet-purple, spreading trusses; The Queen, nearly white; Paul Arosa, deep blue, white eye; Madge Arthur, deep purple-blue; and Dr. Jenlin, deep violet-blue, one of the finest dark varieties.

#### HOW TO PRUNE EVERGREENS.

IN many gardens throughout the country one frequently encounters some quick-growing evergreen that has either been allowed to outgrow its allotted space and so present an untidy or

3.—CUTTINGS READY FOR INSERTION.

uncared-for condition, or else the branches have been cut back with a pair of shears, or even a hedge-trimmer, so as to give it a close, rusted appearance, that is far from being a pleasure to behold. Many amateurs, too, make the mistake of cutting back their evergreens in the autumn, so that the plant is more or less bare all the winter.

Generally speaking, the end of February or early in March is the best time for pruning evergreens; new growth is then quickly made and the plants soon regain a cheerful appearance. A sharp pruning knife or a pair of sécateurs are the best implements to use, and if large specimens of Laurels or similar shrubs are to be dealt with, a sharp, narrow-bladed saw may also be necessary. The first operation will consist in removing any dead branches that may be present, cutting back into living wood. If the branch is a large one and has to be removed by means of the saw, pare the cut over with the knife and then paint it over with ordinary coal tar.

This done we must next see about the removal of branches that are crossing or chafing each other, and also give the specimen a general thinning out. The idea seems to be general that if a shrub is of an evergreen character overcrowding of the branches does not matter, but this is a mistake. True, it is desirable to have the branches closer together than are those of a fruit tree, but this is more often than not overdone to the detriment of the shrub or climber. Assuming that the plant under notice has filled its allotted space, we must next proceed to prune back adventuresome shoots, and this is where the hedge shears are often wrongly brought into use. Certainly it is quicker and easier to clip round a shrub or over a wall of Ivy than it is to remove each shoot separately, but the results in each case are such as to justify the slower method. An evergreen properly pruned should scarcely show a cut leaf, each shoot being removed separately by means of the knife or sécateurs. This is not such a tedious process as it may at first appear, and it is eminently more satisfactory. Ivies, Euonymuses, Laurels and Aucubas are evergreens that may be treated as advised above.

Such conifers as the Pines and Spruces require but little pruning, but where any shortening is needed the lateral should be removed entirely, taking care that a shorter one is left to take its place.

#### A USEFUL AMATEUR'S PLANT.

(CYPERUS ALTERNIFOLIUS.)

THIS evergreen native of Australia is not nearly so extensively cultivated in our greenhouses and windows as its merits demand. It is a most useful subject for providing greenery in almost any floral arrangements, and for rough usage, such as standing in draughty halls, stuffy rooms and other places where plants are required for decoration it will beat even an Aspidistra. The character of its foliage is at once unique and graceful, and its culture does not make any excessive demands on one's intelligence and time. Propagation is a simple operation. It can be performed by means of seeds, divisions or

cuttings, the two last-named methods being almost universally adopted. March is the best time to perform either, and personally I prefer cuttings to divisions. The divisions have, however, the advantage over the cuttings in that they make large specimens more quickly. In dividing a plant care must, of course, be taken to secure each portion with good roots and crowns, using a sharp knife to separate the portions. These are potted up at once into well-drained pots of a suitable size, a compost of equal parts of good loam, sand and peat being most suitable. Give a watering-in and then plunge the pots if possible to their rims in Cocoanut fibre refuse, allowing them a temperature ranging from 60° to 65° until they are established.

Cuttings require rather more care than divisions, but if they are rooted in March and grown on all the summer, they provide excellent material for embellishment the following winter. Mature heads of leaves must be selected, and they ought to have about 1 inch of stem retained. It will be found convenient to trim in the leaves to within 1½ inches of the stem before inserting the cuttings. Thumb pots, well drained, are the best to use, one cutting being placed in each, the portion of stem retained being the part to insert, so that the ring of leaves lies flat on the surface. Over the centre of this place a mixture of finely-sifted sand and peat, water with a rosed can and then plunge the pots to their rims in Cocoanut fibre refuse and afford a warm moist temperature. It will not be long before young shoots will push up from the leaves, and when they are about 3 inches high give the young plants a move on into 3-inch pots, using a mixture of loam, peat and sand. Keep them warm still, but the atmosphere less moist, until they have filled the pots with roots, when another move, this time into 4½-inch pots, should be given. As soon as they are established in these pots remove them to the cool greenhouse, and in a fortnight they will be ready for use in almost any position. In warm localities the pots may even be plunged in the open with success, providing the plants are not allowed to suffer for the want of water. At all times the latter must be freely applied, as the plant is a great lover of moisture. Almost any nurseryman will supply plants, or they may frequently be purchased in markets under various names, the most popular of which is the Umbrella Grass. The present is a good time to procure plants for stock purposes, and it is usually advisable to give them a rather warm house for a week or two after purchasing.

5.—YOUNG PLANT ESTABLISHED IN A 3-INCH POT.

## THE TOWN GARDEN.

**A RESERVE BORDER.**—By a reserve border is meant a spare strip of ground wherein seeds can be raised, cuttings struck, or plants nursed back to health whose constitutions have become in any way debilitated; not that I approve, as a broad, general principle, of nursing sickly plants back to health; it is usually far better to buy or raise new ones. This reserve border should be in the sunniest part of the garden, a spot facing south-east or east being preferable. It need not be in the most conspicuous part of the garden, for, though there is nothing objectionable but much that is commendable in it, it must not be forgotten that plants are not expected to bloom within its precincts. Still, I would far rather give up the very best part of a garden than go without a reserve border, for it is indispensable if really good gardening is to be done.

In making such a border, let it slope gently from a wall or fence, if possible, and, above all things, do not have it more than 3 feet wide. One should always be able to reach across such a border without setting a foot on it, and over-reaching is a practice that every true man should set his face against! Seedlings, cuttings and weakling plants in general do their best in a light and sandy soil, and as the soil is not likely to be all that is desired in this respect it should be made so. Sweepings from the sides of the road after a heavy rain are excellent for making soils porous and open, while leaf-mould is the best ingredient for lightening heavy soils. A 3 inch layer of leaf-mould and a 1 inch layer of road grit or coarse sand, well mixed with the top 6 inches of the soil proper, will make a border that will spur on the most recalcitrant plant to do its best. After mixing in the sand and leaf-mould, leave the border rough until seed-sowing.

**SEEDS FOR EARLY SOWING.**—I do not propose to give lists of vegetable seeds, as I do not believe in growing vegetables in a town garden. It is all very well for people in the country—who, of course, cannot get vegetables—to try and grow them; but in towns the things are brought to one's very door, and are, moreover, sold at such knock-down prices that it does not pay to even think of growing them, so much better may the thoughts be employed in other directions. Besides, there are many reasons, upon which I need not dilate, why a town garden is not an ideal place for growing vegetables. Fruit, too, should not be attempted; not that one can raise much fruit from seed, even in the country. This leaves us flowers, and of them we will have abundance. There is still plenty of time for the planting of hardy herbaceous or perennial plants, and also for the sowing of what are known as half-hardy annuals, so that for the present I will confine my remarks to what are known as hardy annuals. These, I may inform the uninitiated, are plants which are raised from seeds sown outdoors, and which flower and die in the same year that they are sown. An exception to this rule occurs when the seeds are sown in the autumn, as then the plants flower and die early the following year. From these vast fields of experience I have garnered a few tussocks of knowledge, and they are given for the benefit of the reader in the following list of hardy annuals for towns: Virginian Stocks, Cornflowers, Sweet Alyssum, Candytuft; Godetias Duchess of Albany, Lady Albemarle and Duke of York; Sunflowers, dwarf and tall; Sweet Peas Dorothy Eckford, Gladys Unwin, Miss Willmott, Mrs. Walter Wright, Triumph and Paradise; Night-scented Stock, Mignonette, Shirley Poppies; Nasturtiums, dwarf and tall; Salvia Hornum Blue Beard, Saponaria calabrica and Linum grandiflorum rubrum. All, or almost all, of these will grow in a true town garden, and there are many half-hardy annuals—a list to be given later—which will bear them company. The above list of seeds should be ordered at once, as a first sowing should be in mid-March.

E. J. CASTLE.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### HARDY FRUIT GARDEN.

**PRUNING AND TYING** ought to be finished by this time; any arrears must be speedily dealt with. When the finishing touch has been given prick up all the surface soil with a fork and leave the borders all trim and tidy. The ground around walls should not be cropped nearer than 4 feet, and this only leaves just sufficient room to walk round and examine the tree and room for the step ladders which have to be used for tying and disbudding during the growing season.

**Figs** grown outside that have been protected may now have the covering taken away and the trees pruned and trained where long shoots of fruitless wood exist. These should be cut out to make room for prolific growths. The branches of the Fig should not be too close together, or there is not proper room for leaf development, and if the pruning of the Fig can be done in the growing season so much the better. There is no reason why really good Figs cannot be grown outside.

**Strawberries.**—Where spring planting is done, now is a good time to plant. Royal Sovereign does well when planted annually, either in the autumn or the spring, and invariably the largest fruits are obtained from these plants. Those planted in the autumn should be looked over, and if any are lifted by the influence of frost press them down in the soil and make as firm as possible. The Loganberry and its varieties should be pruned and tied similar to Raspberries. They do well tied to poles or over arches or on strained wire.

#### FLOWER GARDEN.

**Edgings.**—Where such as Box, Arabis and Thrift are employed all blank spaces should now be filled, and any new designs in edging forthwith carried out. Beds containing Wallflowers, bulbs and similar plants should be pricked over, and if the soil is poor a little artificial manure will work miracles in a short time. Where Tea Roses have been covered the protective material must be removed. The planting of shrubs and trees should be got on with now as fast as possible, choosing fine weather (dry) for the operation. Bamboos, Camellias and Azaleas should have some manure forked in lightly; a little bone-meal of the best quality, with some soot, suits these plants to a nicety.

**Rhododendrons** will be benefited by a mulching of cow manure. Any choice plants in bad health should be taken up and placed in hospital, where they should receive a supply of new sweet soil, being divested of all the old sour material. This is the best system of dealing with plants so affected.

#### ALPINES.

These are now growing rapidly. A top-dressing should now be given, and after the necessary cleaning off has been done any bare spots must be made good from the reserve; the more tender plants may have the covering removed. Continue to put a little soot or slugicide around the plants and bulbs that are likely to be devoured by slugs or birds. Plant out now seedling Saxifragas, especially var. longifolia, planting these in vertical interstices and making the soil firm. All the Primulas should have a top-dressing at this season. They derive much benefit by being helped as they are pushing up their flower-spikes.

#### KITCHEN GARDEN.

March is a busy month in this department, and the sowing of seeds will demand much attention. Small sowings of Cauliflower Autumn

Giant, early varieties of Broccoli, Turnip Early Milan, Nimble Six Weeks and Early Snowball may be made. Of course, another sowing will be necessary towards the end of the month. Vegetable Marrows for an early supply should be sown in pots in a warm frame. Early Bush is a good one for early work, and it does not take up much room in a frame. Peas may be sown in quantity now of all the best Marrow varieties. Give plenty of room between the rows.

#### EARLY VINERY.

Increase the day and night temperature to 60° and 65°, running it up with sunshine at closing time. Give a little air on all favourable opportunities, especially in the morning. Continue to stop and tie down, regulating the shoots so that all the space is covered. Thin the berries as soon as possible after they are set. When the Vines are in bloom it is a good plan to give them a sharp tap about midday, as this will effectually distribute the pollen. Shy-setting varieties may have the pollen distributed by means of a rabbit's tail tied on a stick or Bamboo cane; damp down several times daily and syringe twice daily, thoroughly wetting every part.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**PALMS.**—These should now have attention. They are among the easiest plants to cultivate, their chief requirements being good drainage and an abundant supply of water both to the roots and foliage. In the latter case, however, be sure it is clean. Perhaps the greatest error it is possible to fall into in growing Palms is to keep them dry at any period of the year. In regard to repotting plants, it is of the utmost importance to preserve intact the large, fleshy roots which are sure to be found coiled among the drainage. Sometimes these are ruthlessly destroyed; but it is a fatal error, for they are the feeders and real life-supporters of the plant. For soil use one part loam, one part peat, and one part good vegetable mould, well decomposed, with a good portion of sand added.

**Sowing Seeds.**—This is the time when many seeds require to be sown. Among others are Acacia lophantha, Grevilleas, Fuchsias, Celosias, Coleus, Myrsiphyllum and Cyclamen, the latter only if we cannot afford to wait until August for plants raised then, which will certainly be best, though a season is lost in flowering them. Avoid the mistake of sowing all seeds in strong heat; this has the effect of checking rather than forwarding the vegetation of seeds of those plants which require cool treatment when growing, and only seeds of warm house plants should be sown in a high temperature.

#### FRUIT UNDER GLASS.

**Figs in Borders.**—Where these show indications of making too much growth, it will be found a good plan to modify the treatment in a measure by lessening the atmospheric moisture and withholding, but not beyond the safety point, water at the roots.

**Newly-planted Trees.**—If this work is contemplated, now is a good time to do it, perhaps as suitable a time as can be chosen, provided in removal there is not too great a check given to the roots. Arrange, if it can possibly be done, to limit the border. In making a new border, guard against using anything of an exciting character in the soil. Good turfy loam and lime rubble will supply all that is needed, taking care to have the soil on the dry side so that it can be thoroughly rammed.

#### KITCHEN GARDEN.

**Early Carrots.**—With the soil in a nice condition there need be no longer any delay in sowing the first bed of Carrots in the open.

Carrots, like Turnips, need a warm border; indeed, more shelter at the start, as the seed is longer in germinating. Much may be done to assist germination by placing litter over the beds at night and during frosty weather. For this sowing Early Nantes is one of the best, and though a few days later than Parisian Forcing, it is of better quality.

#### FLOWER GARDEN.

**Double Violets in Frames.**—I find nothing answers so well as striking the cuttings in shallow boxes in March, placing them in cold frames till rooted, then grow them on deeply-worked, rich soil in an open position during the summer and lift them with good balls in September.

**Carnations.**—The winter on the whole has been favourable to plants in the open ground, and where autumn planting has not been done the layers should be severed from the old plants and put into their permanent quarters early in the present month.

**Auriculas.**—The plants will soon be in full growth, the flower-trusses showing, and a few early varieties will be in blossom by the end of the month. Sufficient water may be given to keep the soil quite moist, but never in excess. Air must be given on all safe occasions. The early morning sun will benefit the plants, but in this treacherous month some trying weather may be experienced. Any extremes of temperature will prevent many pips from properly expanding, therefore every precaution must be taken to avoid this evil.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

bays for the dwarfier *Helianthemums*. Good *Helianthemums* are: *Vulgaris*, *croceum*, c. fl.-pl., *Yellow Standard*, *venustum*, *Fireball*, *rhodanthum*, r. fl.-pl., *mutabile*, *polifolium* and *formosum*. The latter is a species with yellow-brown spotted flowers, which grows 1½ feet to 2 feet in height.

#### Planting an autumn border

(W. F.).—For the purpose you mention it will be better if you adopt a modification of the plan referred to, and the taller sets of groups in the back lines could be omitted. The plan to which you refer is, for convenience, rendered in a straight line, but may be followed or adopted with equal advantage in a crescent or undulated outline. It is not quite the same thing when you desire to make three borders, and in the plan cited the climax gathers intentionally to the centre, and this could only be imitated in your case assuming that on the right and left hand you take up the two ends of the plan, and, starting from the house end of the plot, with your face to the garden, work the present centre of the plan into your cross border position. The objection to this is that in coming into the garden you would see the strong tones of scarlet in the front and possibly little besides. You understand that the chief object of the plan in question was for an autumn display, while the introduction of Sweet Peas would take it into the early summer. Still, you might employ these in self colours quite well, and by working masses of pure white and scarlet *Phloxes* in front of these and in lieu of the Dahlias, a good result should be secured. *Godetia* might replace *Megasea*, while *Pentstemons* and white and yellow *Chrysanthemums* could also be employed.

**Hardiness of *Incarvillea Delavayi*** (*Batnacarron*).—Although hardy in the ordinary acceptance of the term, *Incarvillea Delavayi* is not usually a long liver in the North, as its tuberous roots are liable to decay after a year or two, and you should trust to young roots rather than to large and old ones. It is always worth while to raise new plants from seeds, and these are produced and ripen freely in your climate. They can either be sown when ripe or kept until spring, and should be sown in sandy soil and in pots placed under glass. The seedlings should flower in the second and third years from seeds, and will probably remain in perfection for two or three years more, but their term of life is an indefinite quantity.

***Gypsophila paniculata*** (O. N. F. K.).—We think you had better be guided by the fact and experience at hand. Frequently a large, spreading head of the above has but a comparatively small-sized rootstock, and the *Gypsophila* is not, perhaps, one of the most tractable of garden plants when unskillfully divided. It would be better, we think, when you have lifted the plant, to ascertain the size of its rootstock, and the reduction of the shoots springing from the crown will then be an easy matter. In reducing these shoots, if this is deemed necessary, remove only those towards the inner portion of the crown-tuft, as these rarely have room for full development. As you have previously, with satisfactory results, removed large examples of the above-named subject, we cannot advise you to depart from the method you then adopted. The season of returning growth is, however, the best for transplanting it.

**Information about Irises** (L. M. T. M.).—From your letter it is not quite clear whether the Beeches are really trees as ordinarily regarded or merely forming a hedgerow or wind-break. If the trees are of large size we fear you will not succeed with the Irises, at any rate not within 20 feet or so of the bole of the tree. The Beech is both deep and superficial in its rooting, and the latter, coupled with the density of the shade, precludes successful planting near. There would not be much fear of success were you to plant near the path on the hedge side, and by adding old mortar rubbish for such as belong to *I. stylosa*, of which *speciosa* is a variety, the soil conditions would be made more favourable. Where thin tree shade exists, or where it is desired to plant in the foreground of trees, some of the Irises may do well. In other circumstances, and where the finer examples of tree-life are seen on rising ground or gentle slope, let them alone. There is a grandeur all too rare in the gnarled and wattled roots as they lift their large limbs above the surface, and a majesty in trunk and stem, telling of mature years that should not be hidden from view. Snowdrops and Winter Aconites may perchance spangle the sward at their feet while these giants are taking their repose, but nothing more than this should be tolerated to mar the greatness and the beauty of the scene. The most appropriate things for the verandah pillars would be *Clematis Jackmani*, *wichuraiana* *Roses*, *Rose Alister Stella Gray*, *Rose Lady Gay*, *Honeysuckle*, *Jasminum nudiflorum* and *Clematis montana*. By taking out a 3 feet wide and deep hole at each position, making good the soil, and planting two each of the *Clematises* and one each of the others a good display would result. If you merely wish for annual

effect you might try the Sweet Pea in separate shades of colour, or in white and pink you might add the two varieties of *petenolia* Pea to the first set, and these would flower profusely for a long period in early summer. If these replies do not quite meet your case write us again with reference to this reply. If Ferns could be planted at the side of the verandah walk, you could not select anything better than *Scolopendrium*, *Polystichum* in variety, *Lastreas* and *Athyriums*. In their company you could also plant the *Hepaticas* and the Christmas Rose.

**Plants for a sloping bank** (*Rockbank*).—You appear to possess a good opening for planting the more showy hardy alpines and similar plants, provided the bank soil is of fairly good quality and an assured depth. Here and there you might plant a group of the *wichuraiana* *Roses*, as, for example, near the central steps, and with fairly good plants of *Yucca recurva* near the summit of the steps a good effect would result. The following are among the more suitable subjects: *Achillea tomentosa*, *A. umbellata*, *Saxifraga apiculata*, *S. sancta*, *S. cordifolia* *purpurea*, *S. Wallacii*, any of the *Setacea* group of *Phloxes*, *Aubrietia* in variety, *Arabis alpina* fl.-pl., *Saponaria ocymoides*, *Alyssum* in variety, *Saxifraga Hostii*, *S. Cotyledon pyramidalis*, *Anemone sylvestris*, *Gypsophila cerastioides*, *Iberis* in variety, *Cyclamen latifolium* and *Alyssum saxatile*. In this way you will get a display for several weeks together.

**Information about a *Tritoma* bed** (A. A. G.). From a bed of 16 feet in diameter you should, with good culture, get each year some two or three hundred spikes of bloom, and a sight worth a long journey to see. With the soil in the condition you describe it is small wonder there is so little bloom and so poor a display. You really appear to possess material sufficient for three times the soil area, and we strongly advise you to replant a large proportion elsewhere. The remedy is simple, and is as follows: During the latter half of March lift all the plants and place them aside for a day or two. Then thoroughly trench and manure the soil. The above plants grow and flower most freely in rather light soils, and the bed should be dug fully 2½ feet deep, adding well-decayed horse manure or hot-bed manure quite freely and working it in among the soil at varying depths. It will also be an advantage if you can get a couple of cartloads of sand, or, indeed, any rough grit, and good leaf-mould might be added. By freely incorporating these latter with the staple a much more open rooting medium will result to the general well-being of the plants. Divide these latter into tufts, the crown stock of which is about 8 inches through, and replant the divisions at 18 inches apart over the entire bed.

#### THE GREENHOUSE.

##### Arum Lilies failing to bloom

(A. J. M.).—You should have given fuller particulars about the *Arum Lilies*, and particularly whether the failure to bloom is temporary or permanent. You leave us quite in the dark as to how the plants have been grown, and as a result we can only surmise the cause of the failure. Frequently during the winter season, and especially during times of severe fog or even a long period of sunless days, the spathe, which you refer to as the flower spike, fail to develop. In that case the exterior of the spathe becomes greenish and presently shrivels, some time elapsing ere a new flower spike is formed or produced. If the failing is temporary it is due probably to climatic conditions, and if it is permanent it is due most probably to cultural errors incidental to or aggravated by weakness and other causes. In any case the temperatures named, 75° to 80°, are altogether excessive for these plants, and can only end in weakness and subsequent general failure. A temperature of from 55° to 60° is ample. Healthy examples can scarcely receive too much moisture, and the early flowering of such things depends wholly upon the treatment meted out to them.

**Information about Lilies in pots** (*Mrs. Cl. D.*).—The plant of *Lilium speciosum rubrum* must be repotted at once; indeed, it would have been better had this been done three months ago. In the first place, give the plant immediately a good watering, and when sufficiently drained, say, the next day, it will be ready for repotting. The new pot should be sufficiently large to allow of an inch of fresh soil all around the old ball of earth, for as the shoots are now being pushed up the new roots will be active, and consequently you will not be able to remove much if any of the old soil. A suitable potting compost for this Lily is two parts loam to one part each of peat or leaf-mould and silver sand. Such a mixture can readily be obtained from any local nurseryman. In carrying out the operation of potting the pot should be quite clean, and effectually drained by means of a few broken crocks in the bottom. The old ball of earth should be put somewhat deeper in the soil than it was before, as the new shoots of which you speak push out roots just at their base, and they are greatly benefited by some new soil in which to run. The plant should from now be kept regularly watered, increasing the supply as the new roots

## ANSWERS

### TO CORRESPONDENTS.

#### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

#### FLOWER GARDEN.

**Plants for a bank** (*Ignorant*).—Rock *Roses* or *Helianthemums*, or *Sun Roses* or *Cistuses* would be very effective in the position you mention, or you might form a mixture of the two. The *Rock Roses* are, of course, dwarf plants, rarely, except in one or two instances, attaining a greater height than 6 inches or 9 inches; the *Sun Roses*, on the other hand, may be had from 1 foot to 8 feet in height. Very nice informal groups can be formed by a judicious grouping of the two families, as by this an undulating mass is produced with a great variety of colour. The *Rock Roses* or *Helianthemums* may be obtained in variety with yellow, white, pink, red, orange or brownish flowers, and they should be planted in groups of six or eight of each colour together. The *Cistuses* are usually white or pink, but are sometimes white blotched with reddish brown. The tallest growing one is *C. laurifolius*, and this forms a strong growing bush, which bears white flowers 2 inches to 3 inches across. Other good sorts are *recognitus*, *ladaniferus*, *cyprinus*, *villosus*, *undulatus*, *canescens* and *monspessulanus*. When planting, the *Cistuses* may be placed towards the back of the border, advancing here and there to the front, and so forming

take possession of the soil. From this time give the plant a good light position in the greenhouse, where it will gradually develop and ultimately flower. Even during the resting period the soil of any Lily should not be allowed to become very dry.

**Information about Tree Carnations** (*J. H. W.*).—The Carnations may be stopped in order to develop a bushy habit, and if shifted on into larger pots when necessary they will form flowering plants for next autumn and winter. Some varieties are more liable than others to have the foliage distorted in the way complained of, but in a light structure with a free circulation of air it is less troublesome than in a closer atmosphere.

**Tulips going wrong** (*L. C. W., O. C.*).—After a careful examination of the specimens sent we have come to the conclusion that the trouble has arisen from the bulbs having been insufficiently ripened. The wet, cold weather experienced last summer would readily account for this, and the fact that the bulbs of Red Duc Van Thol were satisfactory might be explained by their having been grown in a more favourable position. The bulbs are certainly not old ones left over from the previous year.

**Freeseias going wrong** (*Wexford*).—There is certainly a fungus on some of the leaves of Freeseias which were enclosed, but we think it is the consequence, not the cause of the trouble. The leaves appear to be unusually thin in texture, which points to insufficient ventilation. Freeseias require a free circulation of air. The sudden attack may be accounted for in this way. As the leaves grew throughout the winter they would from some cause or other become gradually thinner in texture, and consequently unable to bear any special strain put upon them. This would happen directly the sun commenced to gain power, so that an unusually bright day might burn the leaves as yours are. If the roots were in poor condition, the foliage would suffer even more when the extra strain came than if the roots were healthy.

## ROSE GARDEN.

**Suggestions for Rose garden** (*Britannia*).—The plan which you have sent is a very excellent one, and we have pleasure in offering suggestions for the planting of what cannot fail to be a very pretty Rose garden. In the centre bed, No. 1, we should recommend a garden seat with a light wirework frame over it, upon which you could train such beautiful ramblers as Dorothy Perkins and Hiawatha, or a number including early-flowering varieties such as *Gardenia* and *Alberic Barbier*. This seat would form a welcome retreat upon a hot day, and it would enable you to enjoy the view of your Rose garden. For the four triangular beds we would suggest standard Roses, planted as follows: Nos. 10, *Billiard et Barré*; 11, *Hugh Dickson*; 12, *Gustave Regis*; 13, *Grüss an Teplitz*. In the parallelogram beds you could plant half-standards, as follows: Nos. 6, *Mme. Abel Chateau*; 7, *Antoine Rivoire*; 8, *Caroline Testout*; 9, *Frau Karl Druschki*. In beds Nos. 2, 3, 4 and 5 plant dwarfs of *Mme. Philippe Rivoire*, *Grüss an Sangerhausen*, *Le Progrès* and *Richmond* respectively. In beds Nos. 14, 15, 16 and 17 we would suggest *La Tosca*, *Lady Ashtown*, *Liberty* and *Mme. Edmée Metz* respectively. Then in the remaining beds, Nos. 18, 19, 20, 21, 22, 23, 24 and 25, we advise the following: *Paul Ledé*, *General Macarthur*, *Earl of Warwick*, *Pharisæer*, *Mme. Leon Pain*, *Melanie Souper*, *Lady Battersea* and *Betty* respectively. You might prefer to have more than one sort in a bed, especially of the standards and half-standards; if so, the variety of sorts is very abundant. Moreover, you might not be able to procure the sorts named at this late season; but we much prefer a bed of one sort when practicable. In bed No. 1, should you not approve of an arbour or Rose temple, you could have one tall weeping Rose in the centre, surrounded by short pillars of the many lovely sorts now available, and in this case you could employ such grand things as *Lady Waterlow*, *François Crousse*, *Mme. Jules Gravereaux*, *Mme. Hector Lenilliot*, &c. We think your suggestion of a bordering of dwarf *Polyantha* Roses for the outer borders a very good one. Around this border, at intervals of about 10 feet, you could plant a free-headed standard Rose such as *Mme. Alfred Carrière*, *Longworth Rambler* and *Lady Gay*, or some pillar Roses of a similar variety, then blocks of some of the sorts named in our previous answer, which would consist of many of the best Hybrid Teas, with some Hybrid Perpetual to give the

richness of colour wanting in the Hybrid Teas. Plant them in blocks of about eight of a sort, thus: . . . These would consist of such fine things . . . as *Killarney*, *Joseph Hill*, *Mrs. David McKee*, *Marquise de Sinety* and *Countess of Annesley*, and, if you cared to introduce them, a few blocks could be selected from the China Roses such as *Comtesse du Cayla* and *Queen Mab*, or some of the true Teas of the *Marie van Houtte*, *Lady Roberts*, *Mrs. E. Mawley* and *Boadicea* type. If you planted pillar Roses around the outside border, as suggested, these could in time be linked together by chains or rope, but for this purpose they need to be fast growers with long, flexible growths, such as we obtain from the lovely *wichuraiana* and *Ayrshire* groups.

**Pruning standard Roses** (*Amateur*).—We are publishing several lengthy articles on the pruning of Roses. You will find in our issue of March 10, 1908, an illustration of a standard Rose pruned. It is advisable to bear in mind when pruning standards that their growths have a somewhat pendulous tendency, and if large heads are desired it is not wise to prune them too severely. But always aim at removing the old wood as much as possible if quality of bloom be desired. Where a good big head is wanted then one must prune more on the extension system, retaining the old wood where it continues to produce healthy young growths. Keep the centre of the heads free from small twiggy shoots, for it is important to allow sunlight and air to enter freely among the foliage, and, moreover, there is no safe hiding place afforded for caterpillars. Speaking generally, vigorous-growing Roses, such as *Caroline Testout* and *Frau Karl Druschki*, should have the last year's growths shortened back to within 5 inches or 6 inches of the wood produced the year before. Very small shoots no larger than straws may be cut back to one or two eyes or buds. Tea Roses, if the growth has escaped injury by frost, should be very sparingly pruned. Roses of *Gloire de Dijon* and *William Allen Richardson* type will make enormous heads if not pruned too much. It is a good plan to form a sort of horizontal framework, so as to induce the long growths to spread outward in all directions, then from these flower-buds appear all over them. When pruning such the second year the small growths are spurred back just as one would a fruit tree, and the following year some of the horizontal growths are cut clean away to make room for younger and more vigorous growths. The lovely drooping Roses of the *Dorothy Perkins* type should be encouraged to droop, and in this case do not curtail their growths, but merely spur back laterals and remove one or two long growths if too crowded.

**Forming a Rose garden** (*Britannia*).—We think you could not do better than form your proposed Rose garden on the plan given by our esteemed correspondent, Mr. Goodwin, in our issue of November 10, 1906. Of course, all bush Roses were planted in this garden; but as you propose to plant standards, we recommend you to plant the sorts catalogued as being vigorous. If you adopt our suggestion, we advise a centre bed of about 6 feet diameter of standards, then about seven beds around the centre one of half-standards. These beds will be of a parallelogram form, say, 4 feet by 6 feet. The remaining space could be taken up with circular beds of dwarf Roses. The reason we advocate these latter is because you would find a difficulty in procuring standards or half-standards of some of the most beautiful and newer sorts. A few pillar Roses or weeping Roses of the *Dorothy Perkins* and *Hiawatha* type would have a beautiful effect in the angles where space is not sufficient for a bed. We take it that although you desire to plant beds of one colour, yet you would prefer a variety of sorts in a bed. The whole list of forty-seven varieties enumerated by Mr. Goodwin is excellent. They could very well be grouped in beds of a colour, making a bed of, say, cream, yellow and orange shades, with *Mme. Ravary*, *Le Progrès*, *Mme. Eugene Bouillet*, *Paul Ledé*, *Senateur Belle* and *Prince de Bulgarie*. The centre bed of, say, pinks should consist of such fine sorts as *Caroline Testout*, *Mme. Abel Chateau* and *La France*. As you desire us to name some good Hybrid Perpetuals, we can recommend, in addition to the sorts mentioned by Mr. Goodwin, the following: *Mrs. John Laing*, *La France de '89*, *Mrs. R. G. Sharnan Crawford*, *Clio*, *Ulrich Brunner*, *Charles Lefebvre*, *Gloire Lyonnaise*, *Dr. Andry*, *Jeanne Dickson*, *Duke of Edinburgh*, *Rev. Alan Cheales*, *Admiral Dewey* and *Eugene Furst*. In addition to Mr. Goodwin's list of Hybrid Teas, we name at your suggestion some recent novelties of merit. These are *Betty*, *Countess of Annesley*, *Countess of Gosford*, *General McArthur*, *Lucien Lemos*, *Marquise de Sinety*, *Wm. Shean*, *Reine Marguerite d'Italie*, *Melanie Souper*, *Mme. Philippe Rivoire*, *Grüss an Sangerhausen*, *Lady Wenlock*, *\*Billiard et Barré*, *\*Lady Waterlow*, *\*François Crousse*, *\*Mme. Hector Lenilliot*, *\*Countess Cairns*, *Dr. J. Campbell Hall* and *\*Florence Pemberton*. Those marked with an asterisk would make fine standards. As regards the hedge, you would do well to provide some supports, such as Oak posts and wire stretched between. Good sorts of perpetual-flowering habit for this hedge would be the following, planted about 2 feet apart and arranged in order as given: *François Crousse*, *Gustave Regis*, *Climbing Mrs. W. J. Grant*, *Gloire de Dijon*, *Longworth Rambler*, *Climbing La France*, *Frau Karl Druschki*, *Mme. Hector Lenilliot*, *Lady Waterlow*, *Ards*

*Pillar*, *Lina Schmidt Michel*, *Mme. Jules Gravereaux*, *M. Desir*, *Pink Rover*, *Mme. Charles Monnier*, *Mme. Isaac Periere*, *Clio*, *Ulrich Brunner*, *Alister Stella Gray*, *Grüss an Teplitz*, *Wm. Allen Richardson* and *Sarah Bernhardt*. *Polyantha* Roses to border each side of the hedge should be planted about 18 inches apart. We advise several plants of a sort, say, six of each, and the following are the best: *Perle d'Or*, *Aschenbrodel*, *Mme. N. Levavasseur*, *Aeunchen Müller*, *Eugenie Lamesch*, *Katherine Zeimet*, *Leonie Lamesch*, *Marie Pavic*, *Mme. G. Pernet*, *Cecile Brunner*, *Gloire de Polyantha*, *Petite Constant* and *Philippine Lambert*. For the three borders plant bushes in blocks of a sort, say, in eights thus: . . . These could consist of such varieties not included in the other beds, if you desire variety, otherwise plant the best, such as *Caroline Testout*, *Mme. Abel Chateau*, *Frau Karl Druschki*, *Lady Battersea*, &c. Roses may safely be planted up till the middle of April, but we should advise you to procure your plants at once and heel them in on a north border. Evergreens may be planted up till May.

## KITCHEN GARDEN.

**Artificial manures for Lettuces and Carrots** (*Norfolk*).—For Lettuces you cannot beat nitrate of soda. This is given when the plants are thoroughly established in their permanent quarters and are growing, sprinkling a small teaspoonful round each plant during showery weather. Applications may be given at intervals of three weeks. The nitrate should be finely crushed. For Carrots we do not advise the use of artificial manures, as these often have an injurious effect on the roots. It is far better to select a site that was heavily manured for a crop last year, an old Celery or Onion bed being ideal. This, if thoroughly dug and pulverised, will give excellent roots without the addition of any manure this season.

**Sowing vegetable seeds for exhibition** (*J. C. J.*).—It is difficult to obtain really good Turnips at the hot season of the year (August 26). Your best way will be to make three small sowings in positions in the garden where it is not too hot and in well-enriched land. (Giving one lot six weeks' time, another seven and another eight, you will then have three barrels to your gun, and have a good chance to carry off the prize. Canadian Wonder French Bean also should be planted in rich soil and in a position where it is not too hot, and at three different times, allowing ten weeks, eleven and twelve. It is later for Broad Beans, and you will find it difficult to obtain good pods at that time. However, by planting in rich heavy land in a cool position no doubt you will succeed. In sowing allow thirteen, fourteen and fifteen weeks.

**How to grow Salsify** (*G. W.*).—Salsify is a vegetable, and frequently notes as to its value as a winter vegetable have appeared in THE GARDEN. The following practice should be adopted. Ground should be selected that has been deeply dug, double dug for preference, and the ground must not be manured with fresh stable manure, as this causes the roots to fork badly, and, though the land should be rich to get good results, we advise soil that was well manured for the previous crop, such as Celery or Onions. There are only a few varieties, such as *Sutton's Giant*, the *Mammoth* and the ordinary variety. The seed should be sown in April or May. In your district an early May sowing would be quite soon enough. Sow in drills 18 inches apart, just cover the seed, and thin in the row to 9 inches between each plant. Hoe between as required during growth, and lift the roots carefully in November. They bleed if broken. Store in a shed just frost-proof in sand, soil or fine ashes. Clean and cook the roots with a little vinegar in boiling water. Serve with white sauce.

**Grafting Tomato on to Potato** (*J. P.*).—There is between the Tomato and the Potato plants sufficient affinity to enable one to be successfully worked on to the other by grafting, but not the least benefit to either results. The only person we have any knowledge of who did very successfully graft the Tomato on to the Potato and *vice versa* was the late Mr. James Martin, at one time nursery foreman to Messrs. Sutton and Sons, Reading, and a great expert in such matters. He took young plants of Tomatoes when a few inches in height and cutting off their tips slantingly grafted them on to young Potato plants in pots, treating Potato tips on Tomato plants in the same way. In the end the Tomato plants on Potatoes bore small fruits and the Potato root bore small Potatoes at the same time, but in the other case the Tomato roots on which Potato tops were grafted did not produce either Tomatoes or Potatoes, except that the Potato tops did produce green air tubers or swollen buds at the axils of the leaves. It was an interesting experiment, but had no cultural value.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE BEST FIFTEEN HARDY ANNUALS FOR SUMMER EFFECT.

(First Prize Essay.)

**H**ARDY annuals which brave all the rigours of winter in the open ground, as distinguished from half-hardy species sown and raised in heat, are so cheap nowadays (most of them can be bought in penny packets), so simple to cultivate, and so brilliant and effective when in bloom, that, paradoxical as it may seem, they are, with the exception of the Sweet Pea, the most despised, yet the most useful, plants of the flower garden. Despised for their cheapness, useful for their adaptability to all soils and situations, and yet it is, perhaps, on account of this cheapness that they are grown in a careless way and left to shift for themselves; sown in an uncongenial position, and, in many cases, left unthinned. To obtain the best results, the first thing to be considered is the

### PREPARATION OF THE GROUND.

The soil should be deeply dug and well manured with half-decayed remains of a Mushroom bed or Cucumber frame worked in 6 inches or thereabouts below the surface. A little leaf-mould is an excellent rooting medium and sufficient to afford nourishment to the young seedlings and give them a good start in life. If not already done, beds or borders, as fancy suggests, should be marked out, and a convenient width left for paths.

### SOWING THE SEEDS.

As the seed of most hardy annuals is very minute, the soil cannot be worked too finely nor the covering be too thin, in fact the dust-like seeds of such as Shirley Poppies are best sown by simply scattering them over the surface without being covered or raked over. Thin sowing is most important, and, in the case of very small seeds, somewhat difficult, but an even distribution can be managed by mixing them with dry sand and sowing both together. For blooming in April and May the seed may be sown in August and September. Personally, except in a few instances, I prefer to sow in March. It is true an earlier bloom is secured by sowing in the autumn, provided the young plants escape slugs and are not weather-beaten; but against this, the thinning after a spring sowing can be better performed, and there are seldom any gaps to fill. Broad-cast sowing is not advised, the seedlings being more difficult to thin than those in drills.

### THINNING.

In this operation no hard-and-fast rule can be laid down. Due allowance must be made for vigour of growth and difference in height. In the process of thinning out, therefore, let it be done not too rigorously, but so generously that the plants may derive to the utmost extent the

benefits of fresh air and genial sun. This operation will be lessened if the seed is sown thinly, as advised; besides, it requires a philosophical temperament to root up fine, healthy plants like so many common weeds.

### AFTER CULTURE.

After being thinned the ground should be kept free from weeds and occasionally stirred, and a dusting of soot applied in showery weather to protect the plants from slugs. If the weather is very dry, copious waterings should be given between sunset and sunrise, tepid rain water being preferable. With the exception of Sweet Peas, insect pests seldom attack these plants. Green fly, perhaps, is the most common foe, and may be syringed or sprayed with insecticide. If dead blooms are regularly removed and seed-pods prevented from forming, the blooming period will be considerably prolonged, in many plants until cut down by the first sharp frost. Inattention to this important item is doubtless the cause of hardy annuals being generally looked upon as a short-blooming race, often greatly exaggerated. Coming now to the selection of

### THE BEST FIFTEEN HARDY ANNUALS

for summer effect, it must be remembered that many plants have been introduced during the last few years and sent out as hardy annuals, but which at the most could only be regarded as half-hardy, such as Asters and Nemesis, which require heat and protection in their early stages of growth. But the species which I venture to write down as the best—or, at least, what I consider the best—are hardy in the truest sense, and not only are they effective, but they last in flower over a very long period. I give them alphabetically:

*Barbionia aurea*.—A most beautiful decorative plant, with fine foliage and large golden yellow flowers, 18 inches. Sow in autumn or spring, and thin out and stake 2 feet apart.

*Candytuft*.—Varieties: Little Prince, white, 6 inches; White Spiral, 12 inches; Carmine, 12 inches. Sow in autumn or spring in drills 1 foot apart; thin out same distance. No stakes required.

*Centaurea Cyanus* (Cornflower).—Various colours. King of Blue Bottles, 12 inches; Victoria, blue and rose, 9 inches. Culture, same as Candytuft.

*Chrysanthemum*.—Striking varieties in many beautiful colours are found in *C. carinatum* and *C. coronarium*, both single and double forms. 1 foot to 3 feet; Dunnettii, dwarf double, yellow, crimson and purple, 12 inches; Morning Star, primrose; Evening Star, yellow, 18 inches. Sow in autumn or spring, and thin out at a distance apart equal to the height. No stakes.

*Coreopsis*.—Varieties: Tinctoria, yellow and brown, 3 feet; Drummondii, 18 inches; Dwarf crimson, 9 inches. Culture, same as last.

*Eschscholtzia*.—Brilliant Poppy-like flowers. Varieties: Golden West, golden yellow; Mandarin, orange, shaded crimson; Rose Cardinal, rose; all 12 inches. Culture, same as Candytuft.

*Godetia* (E. Enothera).—Brilliant silver-shaped flowers. Whitneyi, carmine; Duke of York,

crimson-carmine; Duchess of Albany, pure white; 12 inches. Culture, same as last.

*Gypsophila elegans*.—Mauve; *graciliflora* alba, white; 18 inches. A combination of elegance and grace. Culture, same as last.

*Larkspur* (Annual Delphinium).—Producing fine spikes of flowers in shades of pink, blue, mauve, purple and white; these are admirable subjects for beds or borders. Stock-flowered, 3 feet; Rocket-flowered, 12 inches. Culture, same as *Chrysanthemum*.

*Lavatera*.—Magnificent profuse blooming plants, with flowers like single Hollyhocks; *rosea* splendens, rose; *alba* splendens, white; 3 feet. Thin out 3 feet apart. No stakes.

*Nemophila insignis*.—Bright blue, 6 inches. Invaluable for edgings, ribbon borders, and carpeting beds. Thin out 6 inches apart.

*Phacelia campanularia*.—Without a doubt the most brilliant blue-flowered annual. One of the earliest and longest in bloom; 9 inches. Sow in spring and thin out 12 inches apart.

*Poppy*.—The Shirley Poppies are almost endless in variety of shade and colouring; 2 feet. Sow in autumn or spring 2 feet apart, and thin out a like distance.

*Sweet Pea*.—The "Queen of Annual Flowers." Varieties: Dorothy Eckford, white; Romolo Piazzani, blue; Countess Spencer, pink; John Ingman, rose; Coccinea, cerise; King Edward, crimson; Queen Alexandra, scarlet; Frank Dolby, light blue; Lady G. Hamilton, mauve; Black Knight, nirroon. So much has been written concerning the culture of the Sweet Pea that it would be superfluous to mention more than that autumn or spring sowing may be practised in deeply trenched and well-manured ground. Thin out 4 inches to 6 inches apart, stake when 2 inches high with tall stakes, 6 feet or 8 feet.

*Viscaria cardinalis*.—Brilliant crimson flowers, surpassing even *Linum rubrum*; 12 inches. Sow in autumn or spring and thin out 12 inches apart.

#### SOWING FOR EFFECT.

Whether contrast or harmony be the desired end, the arrangement of the beds and borders should be tastefully carried out. Colours should not clash; that is, rose-coloured or red flowers should not follow scarlet or orange, nor orange next yellow, nor violet next blue or rose. White should not follow yellow, but is a relief to other colours. Light blue will harmonise with orange, violet with yellow, dark blue with orange yellow, and scarlet with yellow and light blue. Beds composed entirely of one colour are sometimes effective, such as the yellow *Bartonia*, blue *Phacelia* and earmine *Candytuft*. *Godetia Whitneyi* in a central bed edged with *G. Duchess of Albany* and *Nemophila insignis* can scarcely be improved upon. For a background a row of Sweet Peas, formed in crescent shape, is by no means difficult to arrange when sown in mixed colours. Colour-fancy will always predominate, but I can conceive nothing better than to start with Dorothy Eckford (white) and lead up gradually to scarlet with Countess Spencer, John Ingman, Coccinea, King Edward and Queen Alexandra; then a break of Dorothy Eckford, leading up to dark blue and maroon with Frank Dolby, Lady G. Hamilton, Romolo Piazzani and Black Knight. *Lavatera* (rose and white) also form an elegant background, especially in association and gradation with *Larkspurs*, annual *Chrysanthemums* and *Coreopsis*.

#### AS CUT FLOWERS.

Whatever arrangement may be adopted in the garden, most of the beautiful flowers I have attempted to describe are suitable for decoration in a cut state, either in *epergnes* or vases. To spare the scissors will assuredly shorten the period of blooming; but, on the other hand, when the seed-vessels are not allowed to form they last in flower longer than many perennials.

W. H. MORTON.

Ellamcote, India Road, Gloucester.

## A MIXED BORDER FOR AUTUMN.

(This subject is of such general interest that we publish the Second Prize Essay.)

IT is a delightful task to plan a border to be in full beauty during the autumn. It should be a mass of bloom in September and October, with a very fair display in November until frosts become serious.

The beautiful autumn flowers often do not receive justice, simply because in many gardens they are crowded out for lack of space or merely used as individual items in mixed beds which are expected to show more or less bloom throughout the year. How worthily some beautiful families of plants might be grown if gardens were arranged so that each part should appear in fullest beauty at some particular time! It would be far more interesting than a general mixture throughout, and the pictures seen would be more harmonious.

Let us imagine, then, that a space 100 yds. by 4 yds. is to be planted as an autumn garden. The colour scheme might be worked out thus: Begin with purples, mauves, greys and whites, leading into rose colour, more white, and then take the colour right up through all shades of yellow to rich red, scarlet and orange, toning down again through palest yellows and white to salmon pink, ending finally in blues, contrasted with pale yellows. The most useful family by far in this border would be the perennial *Asters* or *Michaelmas Daisies*, many of which have such tender and delicate cloud-like colourings that they would blend the whole scheme harmoniously together and present a spring-like freshness even in the dying months of the year. They are particularly useful as white flowers, their growth being such that they never form too heavy a mass of white. I should use *Dahlias* somewhat sparingly, for though the flowers are beautiful in many shades of colour and in some of their forms, yet their stout foliage tends to be rather coarse and unpleasing. *Snappedragons* would be most useful. An early outdoor sowing would produce strong young plants just coming into bloom when required, and both tall and dwarf sorts could be used in the same colour, so that the mass would run back to a good depth in the border. In the centre display the yellow *Helianthemums* would be invaluable, with *Cannas*, *Kniphofias*, *Gladioli*, *Nasturtiums* and *Gaillardias*, all of which would harmonise sumptuously together. I would have the latest hardy *Chrysanthemums* throughout the border; their fresh smell and healthy green make them rank very high among late flowers, and their colourings could be easily adapted to tone or contrast anywhere. There would also be the latest-flowering *Phloxes* in their best shades, and a few annuals, including *Mignonette*. These would be the main incidents, but of course many other plants could be used just where they seemed to be required.

In the mildest climates there would be a less restricted choice of subjects, but for the scope of this paper we will suppose that our garden possesses average climatic conditions. *Begonias* are good where there is much moisture, but on hot dry soils *Geraniums*, less showy, would replace them. The beautiful *Belladonna Lilies* could be used in the South of England. In planting, a much better effect is obtained by having good-sized groups of one plant rather than by dotting single specimens at intervals along the border. This leads to repetition, which is dull, whereas the grouping method gives a series of pictures, which are all the more beautiful if the colour effects are restrained and plenty of foliage plants are used. Of course these groups should not be stiff, and though every plant must show to good advantage, it is well to avoid monotony of height by allowing some of the taller plants to come forward, and vice versa.

#### THE BORDER.

Beginning at one end of the border the *Asters* *Andromeda*, *pulchellus* and *W. Bowman* would be seen growing with white *Dahlias*, *Shasta Daisy*, purple *Salpiglossis*, *Heliotrope*, mauve *Toy Geranium*, grey *Phlox* and white *Chrysanthemum*, and for foliage plants *Maize* and the late *Eryngium Yabali*. Then there would be a good drift of white *Snappedragon*, the *Asters* *Mrs. Earle*, *Novelty*, *White Spray* and *grandiflorus*, with the cream *Chrysanthemum* *Mme. Desgrange*, the yellow *Leonard Peto* and the white *Fair Maid*; pale yellow *Nasturtiums*, which cover the ground well if the tall varieties are used, and towards the front late-sown *Mignonette*, *Achillea* and *Stachys lanata* for grey foliage. The rose colours come next, in different shades of red and pink—*Aster* *Mrs. Rayner*, tall *Phlox*, *Snappedragons*, *Pentstemons*, *Mallow*, Japanese *Anemones*, *Helehyssum*, *Nicotiana Sanderae*, *Chrysanthemums* *Bijou Rose*, *Marie Massé* and *Mme. Hubert*, and as foliage *Tree Lupin* and *Megasea cordifolia*. Now come more *Asters*—*Proserpine*, *Janus* and *lanceolatus*, with white *Mallow* and *Nicotiana sylvestris*, bronze *Chrysanthemum* *Le Pactole* and white *Césarine*. The yellow colourings follow—tall *Helianthus* *Rev. W. Dodd* and *hirsutus*, *Helioopsis* *Soleil d'Or* and *Solidago sempervirens* make a background for African *Marigolds*, *Nasturtiums* and French *Marigolds*, yellow *Cannas*, *Gaillardias*, *Funkia* foliage and double *Gypsophila*.

Next are the reds and scarlets—*Cannas* *Italia* and the gorgeous giant *Alphonse Bouvier*, *Kniphofias* *Clotho* and *Leda*, *Fuchsias* *Riccartoni* and *globosa*, scarlet *Dahlias* and *Gladioli*, crimson *Snappedragons* and *Chrysanthemums* *Radium*, *Kuroki* and red *Marie Massé*, *Lobelia fulgens* and crimson *Begonias* and *Geraniums*, toned down by *Eulalia japonica* and more *Mignonette*. Again comes yellow—*Harpallium rigidum*, *Helenium autumnale*, *Helianthus orgyalum* and *pubescens*, *Inula macrocephala*, with *Montbretia*, yellow *Chrysanthemum* *Flora*, dark *Nasturtiums*, *Cannas* *Gold Bedder* and *Menelek*, with foliage of *Rheum officinale* and scented *Geraniums*.

Now appears a white stretch of *Chrysanthemum uliginosum*, *Aster vimineus*, single *Gypsophila*, *Nicotianas* *sylyvestris* and *affinis* and white *Phlox*, followed by and growing among the salmon pink shades of *Gladioli*, *Phlox*, *Verbena* *Miss Willmott* and *Pentstemons*. With these grow scented *Verbena* and *Mignonette*. The border is finished in blue tones with contrasts of pale yellow. Blue *Asters* *Margaret*, *Ariadne*, *Daphne*, *floribundus*, *acris*, *Amellus*, *Councillor Waters* and *E. J. Lowe*; white *corymbosus* *Persens* and *gracilliums* with yellow *Chrysanthemums*, *Helichrysum* and *Snappedragons*; cream and sulphur *Dahlias* set off the glorious blues of *Salvia patens*, double *Lobelia* and *Nigella*. A good planting of the orange *Lily tigrinum* is also here, backed by *Southernwood* and *Tree Lupin*.

A smaller border could be arranged in the same way, with less extensive groups of plants or a more restricted use of kinds. It must be remembered that summary laws cannot be laid down for the planting of such a border. It must be done as it appeals to individual taste, and the choice of flowers would, therefore, somewhat vary. It would be very charming to plant the whole as a *Michelsmas Daisy* garden, grown with some of the *China Roses*, Japanese *Anemones* and *Phloxes*. The *Daisies* would flower from August to December, so it would be truly an autumn garden, and the tender pinks of the *Roses* would harmonise well with the other flowers.

Perhaps, however, where unlimited space is not to be had, the greater choice of plants first indicated would be more generally satisfactory. Experience will always teach fresh arrangements of colours and plants, and new happy unpremeditated effects will constantly reveal themselves.

MISS HOPKINSON.

Sutton Grange, Wansford, Northamptonshire.

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

March 17.—Royal Horticultural Society's Exhibition of Flowers and Fruit, Vincent Square, Westminster; Lecture on "Beautiful Flowering Trees and Shrubs" by Mr. G. Gordon, V.M.H., 3 p.m.; British Gardeners' Association Meeting, Horticultural Hall, Westminster, 4 p.m.

March 25.—Royal Botanic Society's Show, Regent's Park, N.W.

March 31.—Royal Horticultural Society's Hyacinth Exhibition, Vincent Square, Westminster.

**Horticultural show for readers of "The Garden."**—We particularly draw our readers attention to an important announcement respecting a horticultural exhibition that appears on another page. It has been suggested that such an exhibition for our readers only would prove interesting, and we are, therefore, offering approximately £100 in prizes and medals for flowers, fruits and vegetables. We know that our readers include some of the best cultivators in the country, both professional and amateur, and we hope that all will make an effort to exhibit and win the prizes. The schedule of classes, which has been carefully compiled by a number of experts, is published among our advertisement pages, and it will be published from time to time until the date of the show, which we hope to announce shortly. Our readers will then have an opportunity of letting us see the results of their labours, which, we anticipate, will be very interesting. Readers, of course, will be admitted free to the exhibition and there are no entrance fees.

**Presentation to Mr. P. Murray Thomson.**—On a recent afternoon a few of the subscribers met in the Royal British Hotel, Edinburgh, and presented Mr. P. Murray Thomson, the late energetic secretary and treasurer of the Royal Caledonian Horticultural Society, with a cheque for a handsome amount and a framed address of farewell and appreciation. No notice of the presentation was sent to the subscribers, or the company would have been a larger one, but it was representative and large enough to show the esteem of the horticulturists of Scotland for Mr. Thomson. The presentation was made by Mr. W. H. Massie in well-chosen words, and Mr. Murray Thomson made a feeling reply. On the motion of Mr. David W. Thomson, Mr. J. W. M'Hattie was warmly thanked for his services as secretary and treasurer to the fund.

**Destruction of blight on Beech trees.**—Recently some interesting experiments were made with the Beech trees on the estate of Archibald Grove, Esq., M.P., Pollard's Park, Chalfont St. Giles, for the extermination of *Cryptococcus fagi* by Messrs. Merryweather and Sons of London, in conjunction with the Board of Agriculture. The gentlemen representing the above body were Dr. Stewart McDougall of the Edinburgh University; Mr. Newstead of the Liverpool Practical School of Medicine; and Mr. Lees, Inspector of the Board. Messrs. Merryweather were represented by their engineer, Mr. A. T. Maryon. After the trees had been carefully examined by Dr. McDougall and his colleagues, it was decided to treat them with a compound consisting of a paraffin emulsion and caustic soda. This liquid was distributed through a series of portable flexible pipes by means of a high-pressure Merryweather spray-pump, operated by a small petrol motor, discharging the liquid at the spraying nozzle at a pressure of 100lb. to the square inch. By the help of specially-constructed scaling ladders supplied by the engineers it was found possible to get at close quarters with the fungus, which mostly infests the trunk of the tree, and to spray the affected parts quite successfully.

There is every reason to believe that this treatment, if persevered with by the owners of Beech forests, will soon entirely stamp out the disease which is making such ravages in the district.

## PRIZES FOR READERS.

## FEBRUARY COMPETITION—AWARDS.

In this competition readers were asked to name the best fifteen hardy annuals and describe the best way to grow them. The prizes are awarded as follows:

The first prize of four guineas to Mr. W. H. Morton, Ellamcote, India Road, Gloucester.

The second prize of two guineas to G. Cope, Holly Bank, Oakfield Road, Selby Park, Birmingham.

The third prize of one guinea to Mr. George Aitkens, The Gardens, Erddig Park, Wrexham, Denbighshire.

The fourth prize of half-a-guinea to Mr. J. R. Sissons, The Gardens, West Bank, Mansfield, Notts.

This competition was a most popular one, the number of essays sent in being very large. Generally speaking, the lists were rather weak, and it would appear that the term "hardy" as applied to annuals is not well understood.

The essays from the following, which we highly commend, were very good indeed: Miss Mabel Thomas, E. C. Howell, D. B. Allwork, A. E. Speer, W. West, Miss S. M. Laurie, Miss E. M. Kent, W. Latter, Miss A. Cecil Bull, W. G. Holton, Miss H. M. Cockburn, A. W. Podger, W. Rawlings, D. E. Elder, Charles Turner, Godfrey Upton, J. Sargent, Leo. Allen, John Broadhurst, Thomas Crowe, C. W. Caulfield, E. M. Gunnell, F. W. Tooch, M. L. Dearden, A. O. Spence, Miss E. M. Keep, J. W. Canning Wright, Georgina J. Waterston, Miss E. K. Franklin, John Parr, Hugh McMullan, jun., R. E. Williams, Mrs. E. Anderson, A. J. Long, H. J. Lees, T. W. Herbert, Thomas Stevenson, E. C. Pooley, Charles H. Maskell, J. M. Callum, George Sewell and E. J. Lloyd Edwards.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Dividing Daffodil bulbs.**—It is the latter part of the following sentence in Mr. Jenkins's letter on this subject in THE GARDEN of January 11 that I do not think is quite clear: "Daffodils may be divided too early, to the detriment of the offset, and the same operation may also be done too late, to the detriment, i.e., the subsequent progress of the offset itself." If Mr. Jenkins means by this that Daffodil roots may be lifted too early or too late or kept out of the ground too long I can, of course, understand, for in either of these cases they must suffer, but presuming that they have been lifted at the right time and not kept out of the ground too long, I think the later they are divided the better. The root selected for my sketch was one which ought to be divided; it would necessitate many sketches to illustrate every sort of root that might be divided. I chose that particular root as best illustrating my remarks on the subject, and, as I said before, the roots shown are the remains of the old ones of the last season; the new ones would not issue from underneath the bulb but from the fleshy circle outside the circle of these old roots. I think the sketch makes this clear. It is, of course, well known that the old roots shrivel up when the bulb is lifted and properly stored, but they do not disappear, and it is not wise to pull them out entirely. As I divided the root in question myself after making the sketch I may be allowed to say what sort of care was necessary. It was one which should, in my opinion, be divided immediately before planting,

since it contained the embryo rootlets referred to, and it was not one that could be safely divided in the rough and ready way Mr. Jenkins suggests, because the root base was tough and could not be severed without the aid of a knife. An attempt to pull the bulbs apart would almost certainly have resulted in the root base of one or both of the offsets being stripped off. The result of my observations is that when bulbs are held together by the root base alone it is immaterial when they are divided; great care is, however, necessary in dividing these when the root base is at all inclined to be tough. When the bulbs are joined together by the fleshy parts as well as the base these fleshy parts should never be severed with a knife, for the reason explained in my note on page 624, and the best time to divide these bulbs, in my opinion, is immediately before planting.—W. A. WATTS.

**Fasciation of the Apple.**—Last year was a remarkable one for fasciation of various

plants, shrubs, &c., but in no instance has such behaviour on the part of the Apple been recorded. That this noble fruit was not wanting in producing such peculiar growth is shown in the accompanying diagram, which is a true representation of a shoot taken quite recently from a tree. The growing points had been removed, probably when summer pruning or later. There is, however, sufficient evidence left to show that towards the point it again endeavoured to assume its normal form by breaking away into three separate growths. No doubt the day will come when we shall be able to definitely describe why such occurs, and it will not be surprising to find periodic seasons have a particular influence in causing such productions.—M.

**Wattled hurdles.**—FASCIATED GROWTH OF APPLE.

Your correspondent "R. G." can get wattled hurdles from Messrs. Coe and Son, Holt, Norfolk.

**Introduction of the pink Malmaison.**—With reference to the introduction of the old pink Souvenir de Malmaison Carnation into this country, you may be interested to know that my father, Mr. J. H. Martin, first saw, and subsequently grew it, at Hersham Lodge, Walton-on-Thames, Surrey (the then residence of B. F. Barton, Esq.) in the year 1872. They were year-old plants then. It was probably introduced after the conclusion of the peace caused by the fall of Napoleon and the restoration of the Bourbon Kings of France by England and the allied powers.—SYDNEY MARTIN, *The Lodge, Clarewood, Bickley, Kent.*

## THE ROSE GARDEN.

### ROSE PLANTING IN MARCH.

**A**LTHOUGH November is, perhaps, the best month in which to plant Roses in the open ground, if the work is carefully carried out in March or even in the beginning of April good results will follow, providing the plants are fresh and vigorous and have not suffered by exposure. Roses which are procured through salesmen in the open markets are often exposed for a considerable time to the evil effects of drying winds, which considerably reduce their vitality, and when dealing with these plants extreme care is often necessary to ensure success. Plants, however, which have not suffered in this way may be relied upon, and will, in many cases, produce flowers this season which are almost, if not quite, equal to those produced on plants which were put in in November. These remarks apply to the Hybrid Perpetuals, Hybrid Teas and Tea Roses. Other classes may, however, be planted at this season with equally good results, but in the case of Ramblers, &c., many flowers cannot be expected the first season, unless extra strong pot plants are procured, and little or no pruning afforded them at the time of planting. The beds or borders having been prepared in the manner which has been fully described in the pages of *THE GARDEN*, planting should begin as soon as the plants are selected and procured. If the roots are the least dry, place them in a vessel containing water, removing them as required when the holes are prepared for their reception. Pruning is also a matter of importance, and hard pruning is followed by shortening long coarse roots, using a sharp knife for this purpose. Do not cut the fine fibrous roots. The holes must be large enough to allow the roots to be spread out horizontally. Place some of the finest soil about the roots, and press the same firmly with the hands, then add more soil and tread all round the plants, levelling the surface with the spade as the work proceeds. Finally, provide a mulch of manure to the beds. This is not intended to act as a manurial aid, but is applied for the purpose of checking a too rapid evaporation, thereby producing a condition of the soil suitable for the emission and growth of young healthy roots. Standard Roses must be provided with stakes at the time of planting. The chief points to remember when Roses are being planted in the spring months are—to secure good plants, moist roots at the time of planting, and prune hard. C. R.

### ROSE CAROLINE TESTOUT AS A STANDARD.

THE Rose is generally associated with the garden as being especially suitable for planting in a mass, but grown as a standard or half-standard budded on the common Brier it succeeds admirably, the stiff, erect growth natural to this Rose just suits for this form of training. I would advise those who have not tried it to do so at once. E. M.

### PRUNING ROSES.

(Continued from page 113.)

#### TEA-SCENTED AND NOISSETTES.

IN most places the pruning of Tea Roses should be deferred until April, but, of course, in early districts towards the end of March would be a suitable time.

*Moderate growers.*—Most of these are very tender; they would repay the trouble if planted at the foot of a south wall or on a south border sheltered by a wall. Cut out soft wood and small shoots that overcrowd each other. Probably much of the wood has been injured by frost. If the pith is brown, cut back the shoots until

white sound pith is found. Cut the ripened wood back to 2 inches or 3 inches; the small shoots to one or two eyes.

Cleopatra	M. Ada Carmody
Corinna	Mme. René Gerard
Devoniensis	Narcisse
Georges Schwartz	Princess of Wales
Goldquelle	Souv. d'Elise Vardon
Luciole	Sunrise
Ma Capucine	

*Medium growth.*—Prune well the ripened wood of last year to within 2 inches to 4 inches. One growth on each plant should be retained a little longer than this. It is well to do this with all Tea Roses unless they are very badly injured by frost. Remove small wood and discourage basal growths.

Albert Durand	Mme. Charles

Lady M. Corry	Sunset
Lady Roberts	Sylph
Lena	The Bride
Lina Curtis	Yvonne Gravier
Mme. A. Mari	

*Vigorous sorts.*—These should be pruned sparingly; cut back the hard shoots to within 6 inches or 8 inches of their base. With all Tea Roses some one or two shoots may with advantage be cut down right to the ground each year. With varieties that produce heavy blooms such as Maman Cochet, the growths should be supported by a stick.

Mme. E. Verdier	Zephyr
Mme. Jean Dupuy	

Most of this group are excellent to plant against south or west walls, and they will soon attain a height of 6 feet to 8 feet by as much in width.

*Very Vigorous.*—Most of the following are known as climbing Roses. They are well adapted for covering house fronts quickly, with south or west aspect. Many of them make beautiful standards; they are also first-rate for pillars in sheltered gardens, also for roof or walls of conservatories. If used as free bushes the growths should be cut back to within 2 feet or 3 feet of the base, and with some sorts, notably Mme. Jules Gravereaux, it is a good plan to just raise

the plants each year, replanting them in the same position. This induces blossom and checks the vigorous growth. Upon walls the annual growths are retained full length. To retard the new shoots bring the growths slightly away from walls. If early flowers be desired the tender growths should be protected by hanging up mats or netting each night.

	W. A. Richardson

*Other Groups.*—As to pruning the various other groups I may say briefly that Moss Roses, R. damascena, R. alba and R. gallica should be pruned as advised for vigorous-growing Hybrid Perpetuals. After flowering old wood should be freely discarded. The Hybrid Chinese represented by Blairii No. 2 prune very sparingly; Miniature Provence Hybrid Polyantha, as advised for medium Hybrid Tea Roses; the China or Monthly Rose, as advised for medium Tea-scented; Bourbon and Rugosa Roses, as recommended for vigorous Hybrid Teas; Penzance Briars, Austrian Briars, Scotch Roses and the numerous species of Roses, merely tip the shoots, and frequently not so much as that, but encourage new wood by cutting out an old growth or two each year.

*The Rambler Race*, including multiflora Ayrshire and R. sempervirens, should be severely thinned of old wood after flowering time, and the annual growths retained almost their full length. Shorten laterals back to 1 inch or 2 inches if weak, if strong to 6 inches to 12 inches. This year the old wood of such as Crimson Rambler has suffered badly from the frost, where it was not removed after flowering.

*Wichuraiana Roses* should be well spread out, otherwise they become an entangled, unmanageable mass of growth. Laterals should be freely cut back, but the long growths are best retained in their natural pendulous manner. When necessary some old growths should be cut down to the base. These Roses will soon recoup themselves from the base, but wherever practicable open them out well for they are capable of covering an enormous area.

*Weeping Roses* on tall stems are pruned but little the first season after planting. The second year cut some of the old shoots back hard, but retain the young wood. Where necessary to train into position this should be done by bending growths and tying to the stem, but as a rule the wichuraianas, which make the best weepers, will droop gracefully unaided. P.

### ROSE CONRAD F. MEYER.

IT is difficult to understand why this Hybrid Rugosa Rose is not more popular. Grown as a hedge it made a splendid picture in my garden last June. The great silvery rose, very sweet-scented flowers are produced in wonderful profusion. This Rose can be trained on a pillar or over an arch, but is seen at its best when allowed to form a free bush. If planted as a hedge it must be given plenty of room; to try and keep it within bounds by interfering with its great prickly shoots would take away half its charm. A few old growths should be removed each year; beyond this little pruning is needed. When visiting a nursery eighteen months ago I saw a row of Conrad F. Meyer twenty yards long in full bloom. The plants had been growing in an unpruned state for two years, and the effect of their long shoots bent to the ground by the weight of countless flowers was extremely fine. E. TESCHEMACHER.

## THE FLOWER GARDEN.

### SOME OF THE NEWER CHRYSANTHEMUMS.

(Continued from page 52.)

**V**ARIETIES mentioned in the earlier contribution were chiefly the large-flowered exhibition sorts, but in the present instance there is a goodly sprinkling of single-flowered varieties of considerable promise.

*Splendour*.—This striking Japanese bloom is regarded with much favour by many. It is a noble-looking flower, having broad, loosely-incurving florets that build beautiful exhibition specimen blooms. Colour, Indian red with buff reverse. Award of merit, Royal Horticultural Society.

*Amarantha*.—A large Japanese with broad reflexing florets of good length. Colour, rosy amaranth with silvery reverse.

*Rose Pockett*.—In this instance we have a very promising Japanese flower of large proportions. The colour, as defined by the National Chrysanthemum Society's floral committee, is buff yellow. The committee expressed a wish to see this variety again.

*Marjorie Gouldsmith*.—This is an ivory white flower of promise that the National Chrysanthemum Society's committee also wish to see again. It is a good Japanese incurved bloom, having broad petals that build a deep flower.

*Maurice J. Cole*.—A sport from the popular W. A. Etherington, and is regarded by some experts as identical with another sport from the same variety named Marquis of Northampton, and fully described on page 52. The colour is a bronzy yellow. The National Chrysanthemum Society also wish to see this variety again.

*Bessie Evans*.—This is a Japanese reflexed flower of solid build, having long, evenly reflexing florets that build a flower of good form. Colour, creamy white centre shaded bluish pink on the lower half of the flower. First-class certificate, National Chrysanthemum Society, November 18, 1907.

*Henry Prior*.—A pretty buff yellow sport from the popular decorative Japanese variety Mme. Gabrielle Debie. The National Chrysanthemum Society's floral committee commended this variety, November 18, 1907.

*Beacham Keeling*.—This is a pretty Japanese incurved variety that the National Chrysanthemum Society's committee wish to see again. The flower is one of neat and even form, having fairly long florets of good breadth. Colour, rich buff, the inside of the florets being light chestnut.

*Mab Ellis*.—In this instance the flowers are of medium size and are classified by the National Chrysanthemum Society as being suitable for market purposes. The colour may be described as bright yellow. For late November displays this is a variety of promise. Commended by the National Chrysanthemum Society's floral committee, November 18, 1907.

*Foxhunter*.—As shown before the National Chrysanthemum Society this is a rather flat Japanese flower, but its rich bright chestnut colour, with old gold reverse, makes it a very attractive variety. The florets are of medium width and incurve slightly at the ends. First-class certificate by the National Chrysanthemum Society as a market variety, November 18, 1907.

*Romance*.—A very useful incurved variety that evolves large and attractive exhibition blooms of good form without the need of "dressing." Florets of good breadth and substance that build a somewhat deep flower. Colour, rich canary yellow. First-class certificate, National Chrysanthemum Society, November 6, 1907.

*Clara Wells*.—This is a distinct acquisition to the incurved section. The blooms are large and

of beautifully even form, having florets of good length and medium width. Colour, buff yellow, paling somewhat at its apex. First-class certificate, National Chrysanthemum Society, and award of merit, Royal Horticultural Society.

*Mrs. J. Hygate*.—This may be regarded as the incurved novelty of the past season, notwithstanding the fact that it was first distributed as a Japanese variety. As submitted to the National Chrysanthemum Society's floral committee, it fulfilled, in every particular, the points of a true incurved flower, as defined and accepted by that committee since its inception. It is a very large flower, having long florets of good breadth, building a deep specimen for exhibition purposes. It is of massive character, though refined, and is a chaste white bloom. First-class certificate, National Chrysanthemum Society.

#### SINGLE-FLOWERED VARIETIES.

*White Edith*.—This belongs to the large-flowered single type, and is suitable either as a freely-flowered sort for decoration or disbudded for exhibition. Pure white, with yellow disc. First-class certificate, National Chrysanthemum Society, November 6, 1907.

A BEAUTIFUL HARDY ANNUAL: NIGELLA MISS JEKYLL.

*C. Rolijant*.—A charming addition to the large-flowered singles. The form is good and the colour a pleasing shade of rosy carmine, with a yellow disc. First-class certificate, National Chrysanthemum Society, November 6, 1907.

*Crown Jewel Improved*.—This is an excellent addition to the large-flowered singles, the blooms being typical specimens of the type and the florets rather broad and somewhat pointed. Colour, terra-cotta, tipped gold. First-class certificate, National Chrysanthemum Society, November 6, 1907.

*E. Nottell*.—A free-flowering representative of the large-flowered section. The sprays are beautiful, and these, when disbudded, evolve handsome individual blossoms. Colour, a pleasing tone of primrose yellow. First-class certificate, National Chrysanthemum Society, November 6, 1907.

*Mrs. Harris*.—A promising large-flowered single that the National Chrysanthemum Society's floral committee wish to see again. The colour is rich yellow, with bronzy yellow reverse.

*A. Howard*.—This is another large-flowered single that the National Chrysanthemum Society

commended on November 6, 1907. The florets are of medium width and of good length, and the colour is deep rose, with a yellow disc.

*Elsie Matthews*.—A useful large-flowered single suited alike for exhibition or for decorative uses. The colour in this instance is pale chestnut, with a yellow disc. First-class certificate, National Chrysanthemum Society, November 6, 1907.

*Lillie Godfrey*.—A charming flesh pink-coloured variety. The blossoms are of medium size and are borne in beautiful sprays, so useful for decorative purposes. First-class certificate, National Chrysanthemum Society, October 28, 1907.

*Mrs. Chamberlain*.—Another beautiful October-flowering single of rather larger size than the last-mentioned. Colour, bluish pink. Florets of medium width, neatly arranged around a well-formed disc. First-class certificate, National Chrysanthemum Society, October 28, 1907.

*Exmouth Yellow*.—This is a beautiful single of exquisite form, and valued because the plants come into flower in October, when there are few singles available. Colour, a distinctly pretty shade of bright yellow. Awarded a first-class

certificate by the National Chrysanthemum Society, October 28, 1907. D. B. CRANE.

#### LOVE-IN-A-MIST.

(NIGELLA MISS JEKYLL.)

This is one of the most beautiful of annual flowers, and should be sown between now and mid-April very thinly in the border. The flower is larger and deeper than that of the ordinary Love-in-a-Mist; the colour a rich blue, veiled over with bright green bracts. It is very easily grown, and just a simple annual flower. P.

#### A BEAUTIFUL NEW ANNUAL FLOWER.

(DIMORPHOTHECA AURANTIACA.)

I HAVE been expecting an article from one of your contributors on the subject of this very beautiful annual, catalogued by Messrs. Barr and Sons this last spring as a new introduction; it seems very little known. This state of things will not, I venture to think, be long the case,

for a more effective plant for a brilliant mass of colour I do not know. The flowers, as large as those of the Gazania and much the same colour, are produced in the greatest profusion, and by keeping the faded blooms cut off a constant succession is produced up to late autumn. It comes very freely from seed, and the habit is neat and bushy; it is about 12 inches to 15 inches high.

Borden, Sittingbourne. CHARLES PRENTIS.

## SWEET PEAS.

### VARIETIES TO GROW THIS YEAR.

THE selection of Sweet Peas given in THE GARDEN of the 15th ult., is an excellent one, like the coloured plate; but, though the latter endeavours to show the true "wave" of the latest development (not with folds like a serviette, as numerous coloured abortions have shown), the list of sorts given reminds one of the show-boards of last summer, and not of what to exhibit at this year's shows. To be explicit, there are other and better sorts—at least, in the opinion of the writer; and now invidious comparisons shall be made, solely—let it be clearly understood—in order that the best of a colour shall be grown.

Evelyn Byatt.—This does burn, and burned badly last summer; while

St. George hardly burns at all, and is a finer and larger flower.

Henry Eckford.—Almost every flower burned, and it is too small for exhibition. "Dobbie's" assert that their selection is sun-proof, and it is to be hoped so, for the colour is quite unique at present.

Helen Lewis is good, the best last year, but this year St. George will be grown in much larger quantity.

Audrey Crier, Enchantress and Miss Willmott are condemned for various reasons, and rightly so, for

Countess Spencer is by at least one grower of excellent trade reputation guaranteed as having come true for the last three seasons; and this for two seasons I can vouch for.

Audrey Crier, when shaded, is magnificent.

Frank Dolby, grown side by side with Lady G. Hamilton and Mrs. Walter Wright, does not convince one of superiority. Fours were very scarce, three being the rule.

Dorothy Eckford is the best known white here in England, but one of the greatest authorities in the Sweet Pea world has said that Burpee's White Spencer is the best white he has seen. He, therefore, who wishes the best should try both.

John Ingman is the largest and possibly the finest in its colour yet seen; of the varieties sold under this title Bolton's is the finest form.

Mrs. Collier is a splendid cream, and is not classed as a yellow. Who would dream of bracketing it with the Hon. Mrs. Kenyon, Dora Breadmore or the Primrose Spencer? Of course we all laugh at the description yellow as applied to Sweet Peas.

Black Knight, small and three flowers on a stem. In

Hannah Dale it meets its victor, for this is a large maroon. Even

Horace Wright, a violet-blue of not at all too clear a complexion and rendering twos chiefly and rather shyly, would eclipse it.

Queen Alexandra is undoubtedly the finest scarlet so far as can be seen, but it does burn occasionally, and instead of this colour

King Edward VII., quite as fine a flower, although crimson, should be grown for showing. Of course one may grow both and shade the former.

But where are the others necessary to complete the colour scheme? Have we no blues?

Lord Nelson is the best of the deep shades, and Romolo Piazzani of the lighter; large flowers and trusses. The latter appear of the palest blue, but when left to expand for a few days the colour

deepens to a lovely shade—at least the ladies so term it.

Dora Breadmore is a splendid buff, strong grower, free bloomer and produces three or four flowers on a stem, and lastly

The Marquis, the finest mauve of all.

But what to grow for the best six or twelve levies toll on my judgment and also time during the preceding year, visiting shows and, better still, growers' gardens. Mine own twelve (and more) are expected to excel all and sundry, but will they? Here they are, with their supporters, which are grown in smaller quantity, shown in parentheses: White, White Spencer (Etta Dyke, Dorothy Eckford); cerise, John Ingman; scarlet and orange, St. George (Helen Lewis); cream, Mrs. Collier (Clara Curtis); yellow, Primrose Spencer (James Grieve); buff, Dora Breadmore; maroon, Hannah Dale; blue, Lord Nelson (Romolo Piazzani); purple, Duke of Westminster; mauve, The Marquis (Lorna Doone); edged, Dainty (Evelyn Hemus); striped, Marbled Blue; marbled or watered, Helen Pierce; crimson, King Edward VII.; violet, Horace Wright (this gives twos usually); and pink, Countess Spencer (Mrs. Hardcastle Sykes).

In all things "a good big 'un will beat a good little 'un," and Sweet Peas, unlike Roses, have no class of exhibition varieties useless, or almost so, for all other purposes. One word more. Take care that the best seed is obtained. Three seeds for 3d., or twelve for a 1s., good and true, are better than an ounce of doubtful ones for the same money.

St. Albans.

W. B.

## TULIP LA MERVEILLE.

LA MERVEILLE is one of the beautiful May-flowering Tulips that have come to us from France. It was first shown at the May show of the Paris International Exhibition in 1900 by MM. Vilmorin-Andrieux et Cie. In the following issue of the *Revue Horticole* it was mentioned as one of the best novelties there. There is no doubt that the future has borne out the favourable opinion of the flower which was then formed. By sheer merit it has slowly made its way in the gardening world, until to-day it is regarded as one of the best of all May-flowering Tulips. It is a "Parisienne" in every sense of the word. No Tulips in that graceful and pretty group have properties which are more in accordance with the *raison d'être* of their characteristic name than La Merveille. They are as a class tall-growing flowers of a longish and mostly reflexed shape, with pretty colouring. Jaune pur (Parisian Yellow) and La Vierge (Picotee) are two well-known flowers that belong to this same group. La Merveille has many points in its favour; it is sweet scented and has a beautiful orange red colour with a clear yellow zone at the base of the petals. In shape it is what is often called in English lists "pitcher-shaped," that is, the flower narrows about two-thirds of the distance from the bottom, and then arches out again at the top. It is very hardy and stands both wind, rain and sun remarkably well. Except when the latter is very hot it generally retains its graceful appearance, and, although it looks somewhat delicate and fragile, it remains in perfection for a considerable time. I find in taking people round my garden that it invariably attracts their attention, and I can quite believe Mr. Hartland's description of it in his Tulip list as "quite the lady's fancy at Ard Cairn." I need hardly add that it is splendid as a cut flower. Its long, wiry stems and pretty reflexed petals lend themselves to artistic arrangements in vases. Some three or four years ago La Merveille "broke" in certain gardens, that is, its uniform self colour became changed into stripes of orange red and yellow. I have not seen it in its new dress yet, but I have bought some bulbs of La Merveille panachée (broken), and one of my excitements of the coming season is to see how it will suit its graceful wearer.

JOSEPH JACOB.

## TREES AND SHRUBS.

### THE GORSE.

PROBABLY no indigenous plant is more neglected than the common Furze or Gorse (*Ulex europæus*), and yet there is nothing more beautiful or useful in certain positions. Where the ground is so poor and stony that it will hardly grow anything else, the Gorse will thrive and produce a wonderful display of golden yellow flowers for practically half the year. It is a common plant among the Heather in this district, and I have seen it more or less in bloom all the year round, except during very severe weather. It is a difficult subject to transplant, and should be obtained in pots if plants are desired, or a better plan is to dig the ground over roughly and sow it with seeds. Two year old seedlings are fairly successful if planted out during showery weather in April. They are usually from 6 inches to 1 foot in height at that age, and should be cut back to within 3 inches of the ground when planted. By doing this they are not so exposed to drying winds, and if care is taken to plant them well, 60 per cent. or 70 per cent. of them will live. When once established growth is very rapid, and they soon make a good show. Old Gorse that has become ragged and weak can be improved by cutting it back to the ground and inducing a fresh growth entirely from the bottom. If Gorse or common Broom were more freely used in rough places, many a spot would be beautified that is otherwise unsightly. The double Gorse (*M. europæus* var. *flore-pleno*) is a dwarfer and bushier plant than the type, and bears double flowers of the brightest golden yellow colour. This is raised from cuttings of half-ripened wood struck in cold frames in August, or of fully-ripened wood outdoors in October, and is always transplanted from pots, as it is quite as impatient of removal as the type. A bed of this plant is quite as effective as some of the subjects used for bedding, and much more easily grown. At Kew it is now being used very extensively for filling up spaces where the soil is none too good, large quantities of plants being propagated a few years ago. The Irish Furze (*U. europæus* var. *strictus*) is an upright-growing form with single flowers. It is no improvement on the type, and is also more tender.

Hedges of Gorse are very effective and also ornamental, and it is rather a pity that we do not see it more often used in this direction. In some country districts the Gorse is cut during the winter and wattled into thick hurdles to be used as wind breaks for various purposes, its dense bushy habit rendering it especially suitable for this work, the only drawback being the number of spines that are produced on the branches.

Bagshot, Surrey.

J. CLARK.

## THE TWELVE BEST WALL PLANTS.

(Continued from page 103.)

THE VIRGINIAN CREEPER (*Vitis inconstans* syn. *Ampelopsis Veitchii*).—As a deciduous shrub the same may be said of this as of the Ivy as an evergreen, for it thrives in almost any position, is ornamental throughout the summer, and during autumn is gorgeous by reason of the bright colours affected by the foliage. It climbs without assistance, is held firmly to the wall by its tendrils, and gives no more trouble than an annual cutting back.

The Fire Thorn (*Cratægus Pyracantha*).—This is known better, perhaps, under the simple specific name of *Pyracantha*. It is a first-rate wall plant though strictly a bushy shrub. When kept cut fairly close back to a wall its dark evergreen leaves are effective, while it is of neat appearance. In addition to its general green effect it has two periods of extra beauty, one in May, when covered with its large flat heads of white flowers, and again in autumn and winter,

when laden with its profusion of rich orange scarlet fruits.

*Wistaria*.—For the front of a house, either alone or in conjunction with Ivy, the *Wistaria* is excellent; in fact, it is one of the most ornamental climbing plants we possess. If given good soil when first planted, it grows rapidly, and may be depended upon to bloom freely each year. Until the branches have covered their allotted space they should be trained up two or three times a year, cutting away the weak points of the shoots in spring; after a good foundation of branches has been laid, however, vigorous pruning in July and again during winter may be resorted to, with the end in view of obtaining short, well-budded spurs, from which an abundance of the lovely racemes of fragrant lilac flowers will be produced during May and June.

*Escallonia macrantha*.—Should a site be available on a south or west wall, this lovely flowering shrub might well be introduced. Although quite hardy in many counties, it is not to be depended on in the open ground everywhere; with the extra protection, however, afforded by a wall it becomes quite safe. As an evergreen it has much to commend it, but its most pleasing period is during late summer and early autumn, when laden with its short racemes of pretty rose-coloured flowers. By pruning the breast wood fairly close back in April the plant is readily kept within bounds.

*Clematis montana*.—Although most of the decorative sorts of *Clematis* are valuable for clothing walls, there is nothing more beautiful than the Himalayan Mountain *Clematis* when covered with its glittering, starry white flowers in May. A strong and vigorous grower, it thrives under a variety of conditions and is not subject to the distressing disease that so often proves fatal to the garden *Clematises*. It quickly covers a large area, forming long shoots annually, from almost every bud of which flowers are produced. To keep it within bounds it is necessary to cut the young wood hard back as soon as the flowers have fallen. Should variety be required, a form called *rubens*, with reddish flowers, has recently been introduced from China.

*Hydrangea petiolaris*.—It is curious that this Japanese *Hydrangea* has not been made more use of in the past for covering walls, for it is of rapid and compact growth, and a self-clinger, fastening itself to its support by means of aerial roots after the manner of the Ivy. The leaves are deciduous, but after their fall a rather bright effect is produced by the brown bark. The flowers are in large flat cymes in July and August, a goodly number of fertile and a few larger and more conspicuous sterile ones composing each head. Pruning consists of trimming back breast wood in spring.

*The Winter-flowered Jasmine* (*Jasminum nudiflorum*).—A charming effect is produced by this plant when covered with its pretty golden flowers from December to February. It may be planted in any aspect, and always blooms well. The branches should be cut well back as soon as the flowers have fallen.

*The Jasmine*.—This is the summer-flowering *Jasmine*, and admired by all on account of the fragrance of its pure white flowers, which are produced over a period of two or three months.

It thrives best in a sunny position, and should be well thinned out each spring, taking care to retain a fair amount of young wood yearly. Left to grow naturally it forms a picturesque tangle.

*Cydonia japonica*.—In some parts of the country this is essentially the cottager's wall plant, and is generally spoken of as "*Japonica*." Trained against a wall it readily attains a height of 20 feet, and by being kept well spurred back during summer it rarely fails to produce an abundance of scarlet flowers in spring. The variety *cardinalis* is exceptionally rich coloured.

*Garrya elliptica*.—This evergreen shrub does not require very severe pruning to be had in its best condition. It is well suited for planting in the angle of a wall, where it can be allowed a certain amount of freedom. Apart from its

TULIP LA MERVEILLE.

evergreen leaves the long, pendulous catkins of yellowish green flowers are very conspicuous in March.

*Cotoneaster microphylla*.—Though it is not usual to plant this against a high wall, it will under favourable circumstances surmount one 20 feet high. It forms a compact green surface, and is very effective in May when covered with white flowers, and again in autumn when laden with vermilion fruits.

This completes the list of twelve of the best subjects for walls. Of course, many first-rate plants have had to be omitted which would be in every way desirable. Roses, for example, are not mentioned, but for general purposes those referred to will hold their own anywhere.

W. DALLIMORE.

## THE GREENHOUSE.

### POTTING YOUNG PLANTS FOR BEDDING.

**Y**OUNG plants of *Geraniums*, *Marguerites*, *Heliotrope*, &c., which have been wintered in pots, pans or boxes should now be potted off singly into 3-inch pots. Although these plants do not need a very rich compost at this stage, care should be taken to give them a suitable soil, moderately light, and, above all, made porous by a free admixture of sand. The soil when used should be neither too wet nor too dry; also see that it is of a suitable temperature. A cold, wet soil must never be used for potting. When

potting off carefully preserve all the young roots and remove dead leaves and flowers. The pots should be perfectly clean and dry before they are used. Pot rather firmly. Arrange the plants in the greenhouse or heated frame, where they must remain until they have made new roots. For the first few days they must be kept close, and in some instances it may be advisable to provide a slight shade during bright sunshine until the plants become established. Spray overhead frequently should the weather be bright, and apply water to the roots by means of a fine-rosed watering pot when the soil in the pots shows signs of getting dry. When the plants have recovered and are beginning to root into the fresh soil, admit air gradually at first, but increase the amount as the season advances. In many gardens all the glass structures are crowded at this season, and the individual plants are apt to suffer somewhat from this cause unless they are frequently rearranged and all dead leaves, &c., removed. This rearrangement will also prevent the roots pushing through the drainage hole into the bed of ashes beneath. C. R.

### SCENTED-LEAVED PELARGONIUMS.

(Continued from page 102.)

As stated in a previous article, the Cape species of *Pelargoniums* are commonly known as *Geraniums*, and one is often asked how the two genera are distinguished. There are several technical differences, the most essential being in *Pelargoniums* a somewhat woody stem, petals of unequal size, and the presence of a tube containing nectar running down and attached to the flower-stalk. This nectary

is not noticeable to the ordinary observer, but can be clearly seen by cutting across the flower-stalk just below the bloom. The stamens are ten in number, but usually three or more are abortive, and are not furnished with anthers. In *Geraniums* the corolla is regular, that is, the flowers have five petals of equal size, the nectariferous tube is absent, and the ten stamens are all fertile. At Kew there are about fifty species of *Pelargoniums* in cultivation, all natives of South Africa, with the exception of *Pelargonium Drummondii* from Australia, and *P. Cotyledonis*, a native of St. Helena.

### CULTIVATION.

The plants may be propagated by means of cuttings, taken from tolerably firm wood, inserting

*Quercifolium minor.**Tomentosum.**Ordinary variety.*

## FORMS OF SCENTED-LEAVED PELARGONIUMS.

them in light sandy soil at almost any season of the year, but probably spring or late summer are the more suitable seasons. The cuttings, from 2 inches to 3 inches long, should be cut off at a joint and have the lower pair of leaves removed; they are then firmly inserted in the soil, and will quickly root in a temperature of about 60°. Little water will be needed until new leaves begin to appear. For their subsequent culture a mixture of turfy loam with a little leaf-mould and decayed manure is suitable. Pots of too large dimensions should be avoided; specimen plants of fair size may be grown in pots of 5 inches or 6 inches diameter. In spring the plants should be placed in a little warmth to encourage new growth, and afterwards transferred to a cool house or frame to flower. When flowering is over it is advisable to expose them to sun and air so as to get the wood hardened before the winter. They may be stored in a cool house or frame during winter months, when little water need be given them. The following sorts have leaves resembling those of the common Pelargonium, but in most cases are delightfully fragrant, and the flowers of not a few are bright and attractive.

*P. capitatum* (the rose-leaf Geranium).—This and other species are largely cultivated in the South of France, Algeria, and South of Spain for the sake of their fragrant oil which is distilled from the leaves. The oil is the basis of many favourite perfumes, and is said to be used as a substitute for Otto of Roses. The plant has weak and trailing stems furnished with long white hair, the heart-shaped leaves are three to five-lobed, the lobes rounded and toothed. The rose-purple flowers are borne in dense clusters on stalks longer than the leaves. The whole plant is Rose scented.

*P. odoratissimum* (the Nutmeg Geranium).—This also is cultivated for the sake of its essential oil. The plant has a short stem which produces many weak branches from its base. The leaves, provided with long stalks, are heart-shaped at the base and three to five-lobed with rounded toothed margins. The flower-stalk originates opposite a leaf, and bears from five to ten small white flowers in an umbel. The plant sometimes met with as *P. fragrans* is probably a form of this species.

*P. quercifolium* (the Oak-leaved Geranium).—This species or forms of it are frequently seen in cottages. The leaves, broadly heart-shaped in outline, are furnished with two to three pairs of oblong side lobes, and often have a back spot in the centre. The red or purplish flowers are

produced, several in an umbel, on rather short stalks. The variety minor is smaller than the type.

*Fair Helen* is a large Oak-leaved variety with rose-coloured flowers.

*P. tomentosum*.—A thick plant covered all over with white soft velvety hairs. The long-stalked leaves are broadly heart-shaped in outline, with three, five or seven lobes, the margins of which are toothed and notched. The flowers, produced in a loose panicle, are white, with red near the centre. The whole plant is strongly Peppermint scented. The variety lobatum has its leaves more deeply cut than the type.

*Dale Park Beauty*.—A very fragrant variety.

*Duchess of Devonshire*.—Flowers bluish white with a maroon blotch.

*Prince of Orange*.—Leaves orange scented.

*Rollison's Unique*.—A handsome free-flowering sort with purplish crimson flowers.

*Scarlet Unique*.—Flowers dull crimson with a maroon blotch; very free.

*Shottesham Pet.*—Rosy purple flowers; delicately perfumed leaves.

*Mrs. Douglas*.—A variety with rich mauve-coloured flowers, the upper petals blotched with maroon.

## COLOURED PLATE.

PLATE 1344.

## GOOD PEAS FOR SUMMER AND LATE SUPPLIES.

EARLY in the year I noted some of the best early Peas, and will now briefly deal with the value of later varieties, at the same time mentioning a few of the best sorts for exhibition, as a correspondent asks for some information on this point. Fortunately, there are a great number of splendid varieties to select from. Soils greatly influence the summer and autumn crops, and many fail to get the best results. For instance, we are asked what would be a reliable Pea for exhibition the last week in August; and that could readily be answered if it was a mere question of variety, but the cultural conditions are even more important, and no grower who exhibits would rely upon a single sowing for a certain date, as the plant is so much influenced by the weather and the nature of the soil.

## SOIL AND SITUATION.

Peas often do fairly well with only ordinary culture, and therefore, when there are failures, the right cause is not considered. The seed is blamed, whereas the soil or cultural conditions are probably at fault. For instance, in a dry summer, with a shallow soil resting on gravel, there are often failures. Here the soil must be made good by digging out trenches and replacing the poor soil with good and a liberal supply of food. Our best exhibitors prepare the land some considerable time in advance of sowing, and rely upon deep cultivation and liberal supplies of food. They also sow thinly and in an open position, and if pods are required for a certain date one sowing is not relied upon. If good dishes are required at the end of August from light soil, instead of one sowing, say, the early part of June, we advise two or three, one ten days earlier and another as much later. There will not be a waste of seed, as a longer succession of good pods will result. In heavy land with a good depth of soil, well enriched with manure, two sowings would suffice, say, the first at the end of May or early in June, and the second a fortnight later. One of these would give the crop at the time required if the land was in good condition, the position open, and a good plant secured at the start.

## LATE CROPS.

I have touched upon the season asked by our correspondent, but pods are often required later.

Much of the advice given above is applicable as regards soil and culture, and in gardens with a good depth of soil Peas may be had very late in the northern part of the country. I have had regular supplies well into November, but the rows, to do them well, must be a good distance apart to allow all the light possible to reach the plants, and they must be situated on a good sunny, open border. Some varieties are what are termed continuous croppers, and better adapted for late supplies than others, as they continue to form flowers and set pods at the upper portion of the plant. For late supplies in a poor soil trenches are most valuable, as plants growing in these can easily get the moisture required.

#### EXHIBITION VARIETIES.

This is a point I am asked to refer to, and there are some splendid things to select from.

*For July and August.*—Last season, at the great Shrewsbury show, on August 24, the first prize for Peas in a very strong competition went to Sutton's Centenary, a splendid marrowfat variety averaging ten to twelve Peas in a pod. Another very fine Pea is Sutton's Peerless Marrowfat, and Sutton's Magnum Bonum is also good. These are splendid for exhibition and of grand quality, size and reliable in every way. The newer Carter's Quite Content, one of the longest podded marrowfat Peas in cultivation, is a superb variety for exhibition; it may be termed a giant, and was one of the leading prize-winners last season. This variety was raised by Mr. E. Beckett, and distributed by Messrs. Carter and Co., High Holborn. The coloured plate given with this issue will enable readers to gain a good idea of the size of the pods. Carter's Exhibition is also splendid, it being a 5-foot Pea of the Telephone type. A later marrowfat of fine size and shape is Carter's Dreadnought; this is of dwarf growth, usually reaching 3 feet in height. No list would be complete that omitted that fine Pea Edwin Beckett, sent out by Messrs. Cutbush. It is a grand Pea, having nine to eleven Peas in a pod, and it does well with ordinary garden culture. A very reliable exhibition variety is Veitch's Prodigy, a 5-foot high Pea having a robust growth and large handsome pods, each containing nine to eleven Peas, and these of splendid quality. Veitch's Prestige is also a remarkably handsome Pea of medium height for July and August.

#### LATE VARIETIES.

These are different in some respects from the exhibition varieties, and find more favour with growers who have a fair depth of soil. Veitch's Autocrat is a splendid late 4-foot Pea of the Ne Plus Ultra type, and it has a splendid constitution. Chelsonian may also with advantage be included in this list, as it is one of the best for late supplies. Carter's Michaelmas is an excellent late Pea, and I have had it good till the end of November; it is remarkably free from mildew, is 2½ feet high, and is very prolific and of splendid quality. Other late varieties of special merit are Sutton's Windsor Castle, a robust grower of splendid quality, and Sutton's Continuity, a late Pea of rich marrow flavour and a continuous cropper. Sutton's Late Queen and Latest of All complete the list; both are grand autumn varieties. G. WYTHES.

## THE FRUIT GARDEN.

### FIG TREES IN POTS.

**W**HEN grown in pots, the Fig is one of the best fruits we have. Naturally the tree is inclined to make a too strong growth, but having the roots restricted it is brought into bearing when very young. In later years it can be fed liberally, and produces fruit freely from the short growths made yearly. The tree illustrated shows how fruitful it is under pot culture.

*Varieties.*—Brown Turkey and Negro Largo are excellent, and of the newer ones, St. John's, a fair-sized green fruit with white flesh, very sweet

POT FIG TREE BEARING A GOOD CROP.

and juicy and remarkably early, and Pingo de Mel, which is another of the early kinds and very similar to the St. John's in growth and earliness. This variety has yellowish flesh and large green fruits of good quality when its earliness is considered. Nubian is a fine black fruit, late and remarkably rich, and the Bourjassote Grise has rich dark red fruit. Osborn's Prolife and Brunswick are good pot varieties, the last two being mid-season or earlier than the Nubian and Bourjassote Grise.

Doubtless the best all-round pot Fig is the Brown Turkey, a large brownish purple fruit of excellent flavour and earlier than the Negro Largo. I have always found the large dark red varieties, like the last-named, are longer maturing their fruits, which thus makes them more suitable for late supplies. I have, by retarding

the trees in the spring, that is, placing them in a cool place or under a north wall, had the fruits well into December. It will be seen how useful these fruits are, as it is not easy to force the early green varieties named above, and get good fruits in March or even earlier. The Brown Turkey is valuable for a succession. This may be had in splendid condition from May to October, and it is one of the best for its free cropping; it bears a good second crop. Negro Largo is much shyer, but it may be had some months later.

Some of my readers may like the small sweet Figs grown in Spain, such as the Early Violet. These bear large crops in pots, and force readily with little trouble. The White Ischia is another delicious smallish white fruit, an enormous bearer; when quite ripe the flesh is pale yellow and of delicious flavour. This bears two or three crops in a year, and requires severe thinning. The

Brown Ischia also is excellent, and somewhat similar to the others named. The Angelique, or Madeline as it is also named, is an early good fruit of peculiar shape, and forces well. The

#### CULTURE OF THE VARIETIES NAMED,

to give a long succession of fruit, say, from March to December, is by no means difficult; but in a small state the grower must be careful not to have too much root space at the start. I also prefer the plants grown on a single stem, as then it is easier to keep down sucker growths. The Fig should have some good loam, with a liberal addition of fine old mortar rubble or wood ashes mixed in the soil. Firm potting is essential, and as what are called yearling trees can be got at such a small cost at the start from the growers, these potted on will fruit the second season; but they make good plants the following year, and fruit for many years.

At the start 7-inch or 8-inch pots are large enough—I mean for the first fruiting season—and later on, when a shift is required, the smallest possible size should be given, as a liberal portion of the old surface soil and lower roots may be removed as the plants attain age. I like to repot early in the autumn, some time before the leaf drops. It is not necessary to repot yearly when a good-sized plant is obtained, say, every other year, giving a rich top-dressing and using bone-meal and good manure freely for the purpose. After the crop is over it is a good plan, say, from July to October, to place the trees in the open, but those forced the earliest must be kept growing under glass to

get well-matured wood till the wood is ripened.

To get ripe Figs in March start the trees in November, and the early sorts named are valuable for hard forcing; 50° to 55° in mild weather is ample, and if a mild bottom-heat can be given the plants soon respond. Close stopping of the shoots is important, as these shoots are the fruit-bearers another season. With pot trees it is a good plan to remove weakly spray growths and not crowd the leading shoots. As the fruit swells more warmth can be given, also food in the shape of liquid manure. At all times the grower must be careful in watering, as with a good number of fruits liberal supplies are required. If the roots get dry the trees cast their fruits badly. Trees to fruit in the early summer months should be started in March, and later for a succession. G. W.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**W**INDOW GARDENING. — As the plants indoors are growing more vigorously, I am watering more freely than formerly. Ferns in pots, if they are root-bound, need pots of larger size to do well. Old Geranium and Fuchsia plants are now ready for repotting; I propose therefore to do this at once. India-rubber Plants, Aralias, Palms and Aspidistras (Parlour Palms), &c., all so valuable for window decoration, should be repotted at this season. When repotting see

1.—SET WITH BAD SPROUTS; THE RESULT OF KEEPING TUBER AWAY FROM LIGHT.

that the old soil and roots are thoroughly watered some time beforehand, so that the whole ball of soil and roots get well moistened. Plants that are very dry stand in a pail of tepid water for some time. The surface soil in Fern cases in the window should be renewed. I find it better just to remove the loose soil, replacing this with a mixture of loam, leaf-mould and peat in equal parts and plenty of silver sand, all well mixed.

**Cold Frames.**—Some of the earliest Lilies are starting into growth, and for this reason should be removed from the plunging material and placed either in the cool greenhouse or cold frame; the latter should be much in demand at this season. For hardening off Chrysanthemums and numerous seedlings raised during the past month frames are indispensable. Take care, however, not to allow draughts to prevail, otherwise the occupants will suffer. For some time to come protection must be afforded the frame-lights at night; in fact, at all times when there is a prospect of frost. By carefully manipulating the frame-lights and making the occupants of the cold frame comfortable I invariably raise a fine lot of sturdy plants. Top-dress Auriculas that are in pots; a good soil for this purpose is equal parts of decayed cow manure and loam, rubbed through a sieve to break it up. This top-dressing gives a much-needed stimulus to the flower-spikes that are now fast developing.

**The Greenhouse.**—Cuttings of Fuchsias, Geraniums, Heliotropes and Petunias may be inserted. I always put in a batch of cuttings in March, as they make charming plants by mid-summer. Any light sandy soil may be used for propagating purposes, and the cuttings should be inserted around the edge of some of the smaller-sized pots or in shallow boxes. Take care to press the soil to the base of each cutting. I am making another sowing of the better half-hardy annuals. All that is needed is a gentle bottom-heat; a hot-bed is also useful for the same purpose. Cannas may be sown now. I find it better to soak the seeds for twenty-four hours before sowing, also taking the precaution to make a notch in the shell; a file or knife will do this. Sow the seeds singly in  $2\frac{1}{2}$ -inch pots or those a trifle larger, using soil composed of two parts loam and one part leaf-mould. To germinate the Canna seeds a bottom-heat of something like  $70^{\circ}$  is necessary. Seedling Petunias, Heliotropes, Perilla, Nicotiana and similar subjects should be pricked off forthwith. Light sandy soil that has been passed through a quarter-inch sieve is suitable for the seedlings. Pans, boxes or pots may be used, and after being filled with the seedlings should be given a warm corner of the greenhouse to get established.

**The Hardy Flower Garden.**—This should be a very busy period. Hardy Ferns may be planted forthwith, and among the numerous hardy flowering plants that need to be planted without the least delay I am taking in hand the following: Carnations, Sweet Williams, Pansies and Violas, Delphiniums, Hybrid Pyrethrums, Solomon's Seal, Lilies of the Valley, London Pride and quite a host of beautiful hardy plants that are indispensable in all gardens. Continue to plant Gladioli in beds and borders, arranging them in groups for effect and planting 4 inches deep and about 4 inches apart from one another. The better hardy climbing plants may still be planted. I have made good use of the Clematis, Honeysuckle, Roses, Jasmine and similar subjects for covering arches, pillars and arbours.

**The Vegetable Garden.**—I am making sowings of different vegetables for succession—Broad Beans in drills 3 inches deep and 2 feet to 3 feet asunder, Main Crop Onions, Parsnips, Carrots, Early Milan Turnips and Cabbage. Second Early Peas should be sown now. Main Crop Potatoes should have the sets placed 7 inches deep and 15 inches to 18 inches asunder in the rows, the rows being  $2\frac{1}{2}$  inches to 3 inches apart.—D. B. C.

### SPROUTING MAIN-CROP POTATOES.

THE sprouting of main-crop Potatoes is a practice generally more honoured in the breach than in the observance. Earlies and second earlies are sprouted by the careful cultivator as a matter of course, but the main-crops are often deprived of their shoots as they form, simply because planting time is still some way ahead; or if left on they are left severely alone, so that they often present the appearance of that shown in Fig. 1. Such shoots are worthless, and one had better be without than with them; weak and drawn to start, they give weak and drawn leafy shoots, and the crop of tubers is a poor one. Instead of leaving maincrops to their own resources, cultivators would do well to give them just as much attention as is now deemed to be the rightful prerogative of the first and second earlies, for they will repay the trouble expended tenfold. It is a fact but little realised that the character and number of the sprouts on a Potato set largely determine the character and number of

the tubers yielded as crop; yet such is the case, and the cultivator can have—within reasonable bounds—either large or small tubers for his crop, according to the manner in which he manipulates the sprouts on his sets.

The first step to this is to set the selected seed tubers on end in a shallow box, as shown in Fig. 2. The illustration shows a box of Up-to-Date, still one of our very best main-crops, though a little more liable to disease than some of the newer sorts. As may be seen, the tubers are rather large, and the selection of good-sized sets is always advisable with varieties that naturally run large. Thus, 2oz. tubers should be regarded as the minimum size for Up-to-Date, the range extending from that weight to 3oz. To prevent the tubers from making the kind of sprout shown in Fig. 1 they should be stood on end as soon as possible, always keeping the large, or rose, end uppermost, as it is from thence that the best sprouts are produced. The box should be stood in a light but frost-proof place, and should not be covered up at all, excepting in very severe weather. If covered, the sprouts become drawn and weakened, whereas the aim should be to keep them sturdy and semi-tuber-like.

In a very short time the tubers, if well exposed, should resemble that shown in Fig. 3, sprouts of varying strength being produced from all the bold eyes. In practice it is found that a tuber planted with all its sprouts retained gives a mixed crop, in which small tubers preponderate. The sprouts nearest the surface in planting commence growing first, so that the tubers coming from them have a start of those from other shoots which have to travel farther in order to get to the light, and this gives inequality of size; the fact of many sprouts being retained causes a weakening of the whole, and this accounts for the tubers being small. With fewer sprouts, and those on the top of the tuber or set, growth commences much more evenly, and as the strength of the tuber is concentrated on a minimum number of shoots, the shoots become much stronger, and the tubers are consequently larger. Many shoots, many but small tubers;

2.—BOX OF TUBERS SET UP TO SPROUT.

few shoots, fewer but larger tubers may be taken as a Potato-growing truism.

Taking it for granted that a crop of good-sized tubers is most generally desirable, all the sprouts on Fig. 3 are rubbed off, with the exception of two, or perhaps three, at the top end. Fig. 4 shows a tuber so dis-sprouted, and it also shows clearly the correct—i.e., the large—end at which the sprouts should be retained. Only two sprouts are retained in the example illustrated, and that number is generally sufficient. It may, however, be found that other sprouts will push at the side of the two retained—from the same eye or basin—and these must be rubbed out as they show, leaving the two sturdy central sprouts

3.—TUBER SPROUTED NEAR THE GLASS, BUT CARRYING SUPERFLUOUS SHOOTS.

in sole possession. Such shoots will be anything from half an inch to 1 inch long by planting time, which should be the early part of April. If the shoots show a tendency to become drawn and weakly before the ground is ready for their reception, the box should be stood in a shed having a northern exposure to retard growth a little.

#### SOWING ANNUALS IN THE OPEN.

Not a few amateurs are apt, when reading instructions about sowing and raising annuals under glass, to imagine that they cannot be successfully sown and raised in the open garden, and consequently those that have no glass at their disposal refrain from growing these beautiful subjects, or, if they do grow them, deem it necessary to purchase the plants. While glass culture in their early stages has much to commend it in connexion with annuals, practically all can be sown and raised in the open with good results, providing a little care is exercised when carrying out the work.

In the first place we must determine for what purpose the plants are required, and then plan our operations accordingly. Generally speaking, annuals are used for two purposes, namely, the filling of beds and the filling of blank spaces in borders. Taking the last-named purpose first, it is usually advisable to sow the seeds where the plants are to flower, thinning the seedlings as soon as they are large enough to handle. Now the seeds of the majority of annual flowers are very small indeed, and to sow them in the open border with only ordinary preparations is, in most cases, a sure road to failure. In the majority of flower borders, especially where the soil is heavy, the ground is none too friable, and the following method should be adopted to ensure success.

Mix up a barrowful of good soil similar to that used for filling seed boxes, two parts good loam and one part sand, with a good sprinkling of leaf-soil if the latter is procurable, forming a good mixture. Pass this through a half-inch meshed sieve. Then with a spade scoop out the original soil of the border where it is desired to sow the annuals to a depth of 2 inches, and fill in the depression thus made with the prepared soil. Make this fairly firm and sow the seeds thinly on the surface, covering them very slightly in the case of tiny seeds and deeper in the case of comparatively large ones. Water with a fine-

rosed can, and then stretch strands of black cotton across the patch rather thickly a few inches from the surface, fixing them to sticks to keep birds at bay. Should dry weather prevail afterwards, water each patch as often as may be deemed necessary, never allowing the soil to become very dry and using a fine-rosed can for the purpose. It is when the seeds have just sprouted, and before the tiny root has grown enough to penetrate the soil, that the most damage from drought results. If the above precautions are taken, the majority of annuals can be raised satisfactorily in the open border.

Where beds are to be filled with annuals the above plan has its drawbacks. It will frequently happen that at the time when the annuals need to be sown the beds in question will be occupied by other plants, and the cultivator cannot therefore sow the seeds where the plants are desired to flower. This is where a reserve bed or two in some open yet inconspicuous part of the garden will come in useful. Place on this reserve bed a 2-inch or 3-inch thick layer of the soil mixture advised above, and in this sow the seeds, treating them exactly as advised for those sown in the border.

It is when the seedlings appear that we must vary our border system. Instead of thinning them out early, lift them carefully with a fork as soon as they have made a few true leaves, watering them well one evening and lifting them the next. Then into another bed of prepared soil prick out the seedlings 2 inches to 3 inches apart in the row, and allow a distance of 6 inches between each row. Water in well with a fine-rosed can, and if the weather is sunny shade for a few days with brown paper, leafy branches stuck in the bed, or any other material that may be handy. By adopting this system the plants will soon make a mass of fibrous roots and will prove most useful for filling beds and making good any blanks in the border. Of course, they will be later than those sown and raised under glass, but in many gardens this is an advantage rather than otherwise.

#### ANNUAL NASTURTIUMS.

The annual *Nasturtium*, or *Tropæolum majus* as the botanists call it, is regarded by many as a common subject to be relegated to some obscure portion of the garden, or not worthy of a place at all. Why this should be so is hard to conceive, unless it is that its easy culture makes but little demand on the intelligence of the cultivator. With a little care in the selection of varieties and site for the plants there is hardly another annual that will give such a brilliant display of flowers for so little outlay of money and time.

The plants are represented by two distinct sections, viz., the Tom Thumb or dwarf and the climbing. The former are excellent for filling beds and blank spaces towards the fronts of borders, while the latter are admirably adapted for climbing over trellis work, wire netting, unsightly hedges, over clumps of Pea sticks in the border, or as a trailing or climbing subject for window boxes. The culture of both types is the same. For all ordinary purposes the seeds are best sown where the plants are to flower, and as the latter are very susceptible to frost, the end of April or the beginning of May will be soon enough to sow.

As regards soil, the one thing to specially avoid is heavy manuring. If this is resorted to, enormous stems and leaves will be produced at the expense of flowers; also very light and dry soil should be avoided. The plants will grow in such soil, but their flowering period is considerably curtailed. With these two exceptions, the plants will thrive in any soil that is likely to be encountered in gardens. For filling beds sow the Tom Thumb varieties 9 inches apart each way, placing two seeds in each hole and allowing the two seedlings to remain and grow together. The reason for this is that when the plants flower there may be one or two not true to colour, and

these can then be removed without making a gap in the bed. Two inches is a good depth to sow; the climbing varieties should be sown 1 foot each way.

After culture will consist in keeping down all weeds, supplying abundance of water during dry weather, and, above everything else, picking off the seeds as soon as the flowers have fallen. The seeds make an excellent substitute for Capsicums if placed in vinegar as gathered. If the above instructions are persistently carried out, these plants will provide a glorious display of flowers until frost kills them. The following are excellent varieties in the dwarf section: Carter's Cloth of Gold, yellow foliage, bright scarlet flowers; Empress of India, deep slate-blue foliage, rich crimson-scarlet flowers; and Ruby King, green shaded foliage, bright ruby-coloured flowers. Besides the foregoing and many others, there is a variety now in commerce with handsomely variegated foliage. The climbing varieties are usually grown in mixture, but crimson, scarlet and yellow varieties can be obtained.

#### RAISING ST. BRIGID ANEMONES FROM SEED.

This lovely Anemone should be grown in every garden. The flowers are large, semi-double, very freely produced, and of various colours. The foliage is also extremely pretty, setting off the flowers to perfection while they are growing, and is well suited for mixing with them in vases in place of Fern fronds or other foliage.

If seeds are sown in a prepared border in April the resultant plants will bloom the same year. If the soil is naturally light and sandy it will suit the Anemone very well; but if it is of a heavy, retentive nature, then it will be advisable to mix plenty of leaf-mould, sand and light soil from the potting shed with the ordinary surface-soil wherein the seeds are to be sown. Open out drills 18 inches apart on deeply-trenched and well-manured ground. As the seeds adhere together, they must be mixed with dry sand and then be gently rubbed in the hands to separate them. Sow the seeds thinly about 4 inches apart in the drills, and cover them with fine soil half an inch deep. An open, sunny border is the most suitable for these plants. All that is needed during the summer is to keep the surface-soil loose and free from weeds by hoeing, and also to give water freely in very dry periods. AVON.

4.—TUBER PROPERLY SPROUTED, WITH ALL BUT THE TWO TOP SHOOTS REMOVED.

## THE TOWN GARDEN.

**PERENNIAL PLANTS.**—These are the mainstay or backbone of any garden, whether it be in town or country. In their ranks are numbered all the hosts of Roses, Chrysanthemums, Carnations, Dahlias, Pansies, Violas, Michaelmas Daisies, Irises, Pyrethrums and scores of others which do so much to beautify the garden year after year once they are properly planted. It is obvious, then, that a garden, to be worthy of the name, must contain a good proportion of perennial plants, or, as they are frequently called, hardy herbaceous plants. As herbaceous is a somewhat puzzling word, I will just mention that it strictly means herb-like, and is applied to plants whose stems or top growth die to the ground each winter, but whose roots remain alive and send up new stems each succeeding spring.

Fortunately for the town gardener, the majority of these hardy herbaceous plants are of a very obliging disposition, and will thrive almost anywhere if they receive a little encouragement. Mind, there are some real tantalisers in the family—plants that require as much coaxing to persuade them to grow as a New Cut canary does to sing—but if these are avoided and only a few stereotyped favourites taken in hand, there need be hardly any failures.

**A SELECTION OF PLANTS.**—To anyone who does not care about variety, or whose garden is in the very heart of a crowded bricks and mortar area, I can unhesitatingly recommend German Irises in various colours, London Pride, Creeping Jenny, Violas, Periwinkles and the perennial Sunflower called *Helianthus rigidus* as being of the grow-and-flower-anywhere class. A little water in dry weather will assist them in their good work, but they will do more even without this than many other plants will do with it. In districts where the proportion of bricks and mortar to gardens is not so great, the following may be expected to either thrive or do fairly well, according to circumstances: *Achillea Ptarmica* The Pearl, white, long-lived and worth growing in quantity; *A. millefolium* roseum, pink, not so good, but useful in a dry spot; *Anemone japonica*, pink and white varieties, likes moisture; *Armeria maritima* (Thrift), pink, a neat foliaged little edging plant; *Calystegia pubescens*, pink, a beautiful climber, which soon gets out of bounds; *Chelone barbata* (or *Pentstemon*), coral red flowers in elegant spikes; *Delphiniums*, blue, in various shades, beloved by slugs when young; *Erigeron speciosus*, mauve, Daisy-like flowers; *Gypsophila paniculata*, white, finely called the Gause Flower and Fern Saver; *Helenium grandicephalum striatum*, chocolate yellow and crimson, a very fine cut flower; *Heuchera sanguinea*, graceful spikes of red flowers for cutting; *Lupinus polyphyllus*, blue and white spikes and elegant foliage; *L. arboreus* (the Tree Lupin), yellow; *Lychnis Chalcedonica*, a glorious scarlet; *Papaver Orientale* (the flaming perennial Poppy); *Polyanthuses* and *Primroses*; *Pinks* (the old white and Mrs. Sinkins); *Pyrethrums*, single and double and in a variety of colours; *Chrysanthemum (Pyrethrum) uliginosum*, white, one of the very best autumn flowers for towns; *C. maximum* King Edward VII., a giant white Marguerite; the Shasta Daisy, something like the preceding; *Solidago* (Golden Rod) in variety, yellow; and *Thalictrum aquilegifolium*, fine foliage for cutting. From the above list readers should be able to select twelve or twenty-four plants to almost fill every requirement. The plants should be ordered without delay, as planting may be done at any time between now and the middle of April—the sooner the better. Meanwhile, the soil should be enriched with manure and deeply dug, for replanting will not be required for several years, and the plants should have a deep and rich root-run if they are to do their best under adverse circumstances. E. J. CASTLE.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANT HOUSES AND FRAMES.

**CHRYSANTHEMUMS.**—The earliest batch will now be ready for a shift into 4½-inch pots, and this should be done before they get pot-bound. Provide good substantial soil at this potting, stand on a cool bottom and grow them sturdy in order to make robust plants. A batch of cuttings may now be put in for very late work. In the warm stove all the plants that require potting should now be done. *Ixoras*, *Crotons*, *Gardenias*, *Dracænas*, *Allamandas* and *Clerodendrons* will probably need this attention. Any large plants of the two last named that are in tubs or planted out should have the top soil removed and the plants pruned and cleaned, finishing off with a top-dressing of some good fibrous loam, with some peat and a handful of bone-meal and sand added.

#### FRUIT HOUSES.

**Grapes.**—Continue to thin the berries of early varieties as they become large enough. When done at one thinning—and this should be the aim of every Grape thinner when a quantity is to be thinned—put down mats or a canvas cover to collect the berries as they fall. This saves much time in cleaning up. As soon as the house is finished apply a good sprinkling of guano or Le Fruitier and water in thoroughly at a temperature 10° above that of the house. Maintain a steady temperature of about 65° to 70°.

**Peaches and Nectarines.**—Continue to thin the fruits at an early stage, as the sooner these are off the better for the crop. Continue disbudding, doing this in the early house as soon as possible now. Successional houses in flower must have plenty of air and the trees a sharp tap every day at noon to distribute pollen.

**Cherries** should now have a little more warmth and be fumigated before coming into flower.

#### FLOWER GARDEN.

**Hardy Annuals** may now be sown in spots where they are to flower. Sow thinly in drills or broadcast. Cover the seeds with some fine soil but very slightly, though the larger the seeds the deeper should they be sown.

**Half-hardy Annuals**, such as Stocks, Asters and Zinnias, should be sown in boxes or frames in gentle heat. A good place is on a mild hot-bed where Asparagus or similar crops have been forced. Sow thinly and water with a fine rose, after which do not water until the seedlings are coming through, or the seeds may perish by being too wet. On the other hand, they must not be allowed to become dust-dry. As soon as the seedlings are large enough they should be pricked out into other boxes and all carefully labelled, so that no mistake occurs in the colours or varieties at planting time.

**Border Carnations.**—These may have a sprinkling of soot or Carnation manure, this being lightly pricked in. A good dressing once or twice in the spring also prevents the sparrows eating the tips of the plants. Put out any spare plants that are in pots to fill up blanks.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**GLOXINIAS FROM SEED.**—The advantage in growing seedlings is that they are not so liable to be troubled with insect pests. For flowering the same season the seed should not be sown later than the second week in March. I have

sown early in January, but find there is little gain, for the seed germinates quickly, and if we get dull, dark weather the young plants will be liable to damp off, or if they survive they will not be so vigorous as those raised later. The seed being very small, care should be taken not to sow too thickly, and if the soil is left loose on the surface before sowing and then gently pressed no further covering is necessary. I always place the seed-pots in a light and thus avoid shading. If the surface soil is not allowed to get dry, the seed will germinate well and there will be far less trouble with damping.

#### ORCHIDS.

**Calanthes Veitchi.**—Now is a good time to repot this *Calanthe*. Fresh roots will by this time be forming at the base of the old pseudo-bulbs, the soil having been kept quite dry since flowering. Carefully shake all the old soil from among the roots, and sort the pseudo-bulbs into sizes, as it is not advisable to mix large and small together. The pots should be quite clean and half filled with crocks. As much moisture at the roots is required during the growing season, it is essential that abundant drainage be provided. The soil is important, and it is on the preparation of this that success largely depends. The soil that gives satisfactory results is one largely composed of fibrous loam—three parts of this to one of partly-dried cow manure, but not much decayed. A free addition of sharp silver sand and charcoal will keep the whole porous when the loam is of a heavy character.

#### KITCHEN GARDEN.

**Outdoor Tomatoes.**—The middle of March will, as a rule, be found the best time for sowing Tomatoes for open-air work. When sown earlier the plants frequently suffer through being pot-bound, as they cannot be turned out till the weather is settled and fairly warm. If the seed is sown now in small pots and the young plants brought forward in a temperature of 60° until the first rough leaves are formed, that of a warm, sunny greenhouse will then suit them best until hardening off in frames takes place about the middle of May.

#### HARDY FRUITS.

**Open-air Peaches.**—All Peach trees on walls must now be pruned and either tied to the wires or nailed to the wall, as the case may be. Wherever possible prune to a triple bud, reducing the growths so that those remaining will be about 4 inches from one another after tying is completed.

#### THE ROSE GARDEN.

Wherever possible let decayed leaves and manure be mixed up together and used freely as a mulch between established plants. By mulching now there is a good prospect of the feeding properties being washed down to the roots at a seasonable time. Let there be no delay in filling up any gaps in old or new plantations of Roses. It is not yet too late to plant from the open ground.

#### FLOWER GARDEN.

**Sweet Peas for Pots.**—These are much more amenable to pot culture than might generally be supposed, and give very little trouble, while they keep up a bright display for a considerable period, and may be grown in pots by those who have little or no convenience for growing them in the garden. The seeds should be sown now, about seven or eight in a 5-inch pot. Good loam, with aliberal addition of manure, may be used, and it should be pressed moderately firm. The seeds should be well covered with soil. After sowing the pots may be placed in any light, open position in a frame or cool greenhouse. Care must be taken that there are no mice about. After the seeds begin to germinate light and air, with a moderate supply of water, is all that is needed until the seedlings require some support.

Ashwellthorpe, Norwich.

## BOOKS.

## "ROSES: THEIR HISTORY, DEVELOPMENT AND CULTIVATION."\*

A NEW book on the national flower, with a title that promises something removed from the ordinary, by such an acknowledged authority as Mr. Pemberton, is assured of creating that necessary amount of curiosity that prompts desire to sample its contents, which a cynical publisher laid down as the one thing needful to make a successful book. In his preface, Mr. Pemberton notes the change that has taken place in recent years with regard to the cultivation of the Rose, from being "primarily an exhibitor's flower, it is now extensively grown for garden and house decoration"; in other words, it has become the flower of the home, and keen exhibitor though he is (and one hardly knows where to find a keener), yet he has successfully managed to sink what has been his own preference, and has written a book with the avowed intention and hope of affording assistance (in the cultivation of the many and varied classes of the Rose that are now grown) to the Rose gardener rather than to the Rose exhibitor.

A short introduction served the purpose of recording a few modest personal reminiscences, which might well have been extended at far greater length. One who exhibited at the first show of the National Rose Society, and who has never missed exhibiting at a single Metropolitan show of the society since, must have stored away a fund of recollections that could not fail to be of interest, at any rate to exhibitors. But that is one of the unexpected features of the book. The exhibitors and exhibition side of Rose culture occupy only the thirty odd pages out of the 330 that complete the book, a bare 10 per cent.

I am inclined to think that the first of the subsidiary titles is not quite made good by the subject-matter; at any rate, the historical aspect is not the strong point of the book. There is no single chapter dealing with the question, unless the first can be said to do so, and that is headed "The Rose, the Flower of England," and the mention of the date of the introduction of any particular species or variety to cultivation, which is done throughout the book, can hardly be said to constitute a history of the Rose.

The arrangement and scheme of the book otherwise is excellent. Briefly it is as follows: Starting with as clear a statement as is possible perhaps, dealing with such a thorny question as the botany of the Rose, the book proceeds with the foundations of the subject, namely, the species, taking first the British wild Roses, then treating such of the wild Roses of other countries as have come under the writer's observation, from thence to the first of the Hybrids (the summer-flowering varieties), on to the first of the Perpetuals (summer and autumn-flowering varieties). Part II. is devoted solely to the cultivation of the Rose, and begins *ab initio*, with the soil, manures (here placed in their proper place, namely, before), the plants and the planting, after which follow pruning, budding, other means of propagation and hybridisation, then three chapters on exhibiting, a chapter on growing Roses under glass, followed by one on pests, the whole closing with an appendix consisting of a short descriptive list of Roses recommended for cultivation. The chapter on the botany of the Rose is as unbotanical as is possible, and the veriest tyro can have no difficulty in following or appreciating it. The family of the Rose is divided into sixteen sections, on the lines laid down by the late M. Crépin, each briefly described, is accompanied by a most interesting analysis of the species, and which, as if anticipating his critics, the author describes as "an attempt to indicate, however

imperfectly, the sections, species and sub-species from which the hybrids have originated." Whether or not his printer has played him false I cannot say, but the analysis contains more errors of commission and omission than the whole of the remainder of the book. The analysis is set out in four columns. Column one, the sixteen sections before referred to. Column two, the species, each of which belongs to one or other of the sixteen sections. Column three, the sub-species, presumably derived or related to the species. Column four, a hybrid, typical of those derived from the species or sub-species.

I do not believe in taking out *en bloc* any portion of a book that one is criticising and reprinting it. I will, therefore, forbear from going into further details, but the line between the species and sub-species has not been kept distinct. Why is *setigera* a species and *rubrifolia* (spelt *rubrifolia*) a sub-species? *Hibernica* is said to be a native species in the letterpress, but is called a sub-species in the analysis. *Macrantha* is also down as a sub-species, but it is, I believe, a natural hybrid between *canina* and *gallica*, and should, therefore, be in column four, not three; *Xanthina* is not a species, and its proper column is certainly not two, but three, if not four; and Austrian Yellow is *Rosa lutea*, yet one is in column three and the other in column two. *Soleil d'Or* might well have been mentioned as a hybrid of *lutea*. Then *Rosa sinica* is not a hybrid of *berberifolia*, with which it has no concern, but is an allied form, or sub-species (if preferred) of *lævigata*, and *Marie Leonidas* is in column four as a hybrid of the Banksian, but the only Rose I know of that name is the double form of the Macartney Rose or *Bracteata*. In the letterpress *Rosa stylosa* is referred to as a sub-species of *arvensis*, but *Rosa stylosa* is one of the sixteen primary families or sections. Then there are some curious omissions. Mr. Pemberton asks for an examination of the table, and draws attention to two facts, "(1) the distance the Hybrid Teas are removed from the original species, and (2) that there are many species from which little, if any, advance has been made." "They remain as they have come from the hand of Nature, they have no progeny," and then he very truly says: "Does not this fact indicate the wide field still open to the hybridist for the production of new Roses; how much remains to be done in directions other than crossing and interbreeding Hybrid Teas? And, further, does it not suggest the probability that great as the progress of the Rose has been in the nineteenth century, it will be greater still in the twentieth, and that some of the most beautiful varieties of the genus *Rosa* are yet to come." That is undoubtedly true, but he need not have omitted to give descendants to at least six of his species or sub-species. *Rubiginosa* can boast of the Hybrid Sweet Briars of Lord Penzance; *alpina* is commonly thought to be the parent of the Boursaults; *lucida* has many varieties beside *lucida plena*, *lucida alba*, *sorbifolia*, &c.; *canina* is reputed to be one of the parents of *Macrantha*; *lævigata* or *sinica* is the parent of that beautiful hybrid *sinica anemone*; and *spinosissima* is surely the parent of all the dwarf Scotch Roses, not to mention Stanwell Perpetual, &c.

Is it to be wondered at that I found Mr. Pemberton's analysis of the species one of the most interesting pages of the book? But apart from this all Rose lovers will, I am sure, welcome the fact that so large a portion of his book (approximately one-fifth) is devoted to the species; they are far too much neglected in Rose gardens, and the letterpress, apart from the analysis, gives most interesting descriptions of each. They are deserving of far wider culture, and no doubt this book will materially help towards that end. Mr. Pemberton gives *Rosa moschata* as the source of that most precious of scent Attar of Roses; I have always understood that a variety of *Rosa damascena* called *Kazanlik* was cultivated for that purpose. Printers' errors perhaps are responsible for the date of *Rosa lutea* introduction as

1586, most authorities put it ten years later (1596). Messrs. Loddiges' name, the famous nurserymen of Hackney—some of whose Roses were still in existence on the site of their old nursery twenty-five years back, although they flourished in the early part of the nineteenth century—is spelt Loddings. And why is General Jacqueminot throughout the book given the two accents over the two first "e's" and an additional "e" (as if he had not enough "e's" already) tacked on to the final "l," so that one hardly recognises an old friend? I cannot find any authority for this pedantic spelling. The accents one can forgive, they are perhaps correct, although dropped by general consent years ago, but the final "e," where did it come from? One turns quickly from these small points (pin pricks, I believe they are called) to the essence of the book. There is a charm about the unexpected, altogether apart from its privilege of "always happening," that is pleasant, and I have found this portion, or Part I., of Mr. Pemberton's book particularly pleasant reading, and I can thoroughly commend it to all garden lovers. Part II., on "Cultivation," appeals more particularly perhaps to Rose lovers, but the initial chapter on "Soils" contains many truths that must be learnt by all cultivators of the soil, be they vegetable or flower growers, and one notes in passing that the writer is not a believer in the heavy autumn mulch, to be afterwards "forked in" in the spring, that is so commonly but erroneously recommended. He pins his faith to the hoe *properly* used as the garden tool.

The following chapter on "Manures" is of equal interest. He reminds us of two facts that are often lost sight of—(1) that plant life derives its food from two sources, the atmosphere and the soil, in the proportion of three-fourths from the atmosphere and one-fourth from the soil; (2) the importance of some knowledge of the composition of the soil in which the Rose is growing; for if a soil is deficient in but one of the five essential ingredients necessary for the plant, although rich in the other four, it may become more or less barren; that is to say, the fertility of the soil depends upon the small proportion of the one, not on the abundance of the four. Just as the strength of a chain lies in its weakest link, so the minimum of any one essential ingredient, not the maximum of the others, is the measure of the soil's fertility. This is the principle in scientific husbandry known as the "law of minimum." The moral is easy to draw. The whole subject is exhaustively treated, and the chapter on "Manures" is one of the best I have read on the subject.

Planting in all its aspects is treated with the fulness that its importance deserves. Carelessness or indifference at this stage is fatal. A lack of knowledge of the necessary details is at the bottom of half the budding rosarian's disappointments. A careful following out of the directions will, I have no doubt, save the life of many a plant yet to be planted, and that is one of the strong points of this book. It is not a book written only for experts by an expert; it is that and more, for it is written by an expert for novices in such a way that they can readily grasp all the essentials. Take the stumbling-block of pruning—not quite such a big block as it used to be perhaps before the issue of that most successful of all the National Rose Society's pamphlets, that on pruning, but still a stumbling-block to many—a perusal of the chapter shows the matter put in a simple way, with such reasonable explanations that complications vanish—the difficulties too.

Mr. Pemberton has the courage to recommend the secateur in place of the old pruning-knife. I have long used the pattern with a double cutting edge. A bad cut on the thumb, which rendered that useful member useless for weeks, was the cause of my adopting the "ladies' tool," as most of my Rose friends call it, and I quite agree with his remarks thereon.

Nothing but praise can be written of the chapter on budding (with its excellent illustrations

\* "Roses: Their History, Development and Cultivation." By the Rev. J. H. Pemberton. Published by Messrs. Longman and Co. Price 10s. 6d. net.

by Miss Pemberton), and the other methods of propagation by means of cuttings, grafting and layering. I should have liked to have referred at length to the chapter on hybridisation, but space will not permit. It has had the advantage of revision by Messrs. Alexander Dickson and Sons of Newtownards, Ireland; it is therefore unnecessary to say more respecting it.

Into the next three chapters Mr. Pemberton endeavours to condense all he knows about exhibition Roses—how to grow them, exhibit them and judge them. There is not a word about his personal triumphs, or that he was the first to tie Roses on the plants—a universal and necessary practice now. Nothing but what is essential, helpful and necessary for the novice to know, is here set down, and many an expert will turn to these pages and find something he had not thought of before!

No book on Roses would be complete without a chapter on growing them under glass, so one finds it there. It is a subject that I am very ignorant of. I have never grown a Rose under glass, but I have no doubt this chapter is equally deserving of the praise that I have tried to give all these chapters dealing with the cultivation of the Rose.

In his final chapter, on "Pests," Mr. Pemberton goes to the root of the matter. He says: "If the plants are in good health, there will be little or no disease; but, on the other hand, from whatever cause—from cold or wet, heat or drought, defective root-action, resulting in a lowering of the constitution and a retardation of growth, there the disease seizes its prey (and therefore we should do all we can to maintain the plant in a healthy condition)." The various insect and other pests and enemies of the Rose are dealt with and a remedy given. The book closes with an appendix, which is a descriptive list of selected Roses recommended for cultivation. It contains some 200 names, all of them, it goes without saying, good Roses. The list is subsequently divided up into best Roses for particular purposes, which will be found specially useful for reference.

This critique is a long one, but the subject deserves exhaustive treatment. The few errors, if errors they are, will be remedied when the next edition is called for, which, unless I am much mistaken, will be very soon. I can thoroughly recommend the book to all those who are Rose lovers, and still more strongly to those who are not Rose lovers, but only gardeners. It will occupy a distinct place among garden literature; it is unlike any other Rose book, in its matter, its treatment and its scope, and, I may add, its thoroughness; its illustrations reproduce for us for the most part the "old" Roses of the days when the Rose was young, but are none the less welcome on that account. Coming from the source it does, I hope I shall not be misunderstood when I say that to me its striking feature is the unexpected character of its contents; but one realises on calm consideration how much wiser is the course the author has adopted from the Rose point of view than would have been the one that might have been, nay, was, expected of him. H. E. MOLYNEUX.

## NEW ORCHIDS.

### LÆLIO-CATTLEYA DAFFODIL.

This is quite a unique and beautiful addition to this bi-generic race of Orchids. As its name implies, it reminds one of a Daffodil—at least, so far as its colour is concerned. The sepals are lanceolate, dull cream in colour, the two lower ones having a midrib of dull, rather pale yellow. The petals are also cream-coloured, ovate with crinkled margins, and just a flush of yellow in the centre. The labellum, which is of medium size, is deep rich yellow, with a beautifully fringed apex. The plant shown was carrying one flower on a very erect stem, the bloom being

about 2½ inches in diameter. Shown by Messrs. Armstrong and Brown, Tunbridge Wells. Award of merit.

### LÆLIO-CATTLEYA HELENE MARON.

A very large-flowered species, the result of crossing L. C. Impératrice de Russie with some other species not named. The enormous flowers are of a uniform pale lilac colour, with the exception of the labellum, which has almost purple markings, with a deep yellow flush in the throat. It is also very heavily fringed and crested, this giving the flower a beautiful appearance. The plant shown possessed two flowers, these being produced from a medium-sized sheath. Shown by MM. Ch. Maron and Sons, Brunoy, France. Award of merit.

### MAXILLARIA LUTEO-ALBA.

This magnificent plant attracted a considerable amount of attention, chiefly on account of the enormous quantity of flowers it was carrying and the symmetry of the plant. The flowers are very curious, the sepals being a dull brownish orange, with white bases. The petals are pale yellow, with a slight blotch of dull carmine at the base. The labellum is small and white, with a deep rich yellow mark in the centre. A very fine specimen indeed. Shown by Mr. Walter Cobb, Normanhurst, Rusper (gardener, Mr. C. J. Salter). Award of merit and cultural commendation.

### DENDROBIUM CHESSINGTONENSE GATTON PARK VARIETY.

A very lovely variety or form of a beautiful Orchid. It is larger than the type, the colour being rather deeper and the handsome labellum being more conspicuous. The deep crimson blotch on the latter is very fine indeed. Shown by Sir Jeremiah Colman, Bart., Gatton Park, Surrey (gardener, Mr. W. P. Bound). Award of merit.

### DENDROBIUM CYBELE GATTON PARK VARIETY.

Here, again, we have a splendid improvement on a good Orchid. The flowers of this variety are large and of excellent colour, the labellum being very handsome indeed. At the base is a very rich and well-defined blotch of dull crimson, surrounded by a clean band of deep yellow. Then comes a broad band of creamy white, and finally an edging of deep lilac. Shown by Sir Jeremiah Colman, Bart. First-class certificate.

### CYMBIDIUM SANDERI SUPERBUM.

A superb variety of a grand Orchid. The raceme on the plant shown was a large one, and was carrying nine fully opened flowers and two well-developed buds. The flowers are rather deeper coloured and larger than those of the type, the sepals and petals being of a uniform delicate pink and white hue. The labellum is of medium size, reflexed, the pinkish white ground colour being freely dotted over with well-defined deep crimson lines and dots. Shown by Messrs. Sander and Sons, St. Albans. First-class certificate.

### CYMBIDIUM SANDERI VAR. SPLENDENS.

This, again, is a good improvement on the type, the flowers being very handsome indeed. Eight fully opened flowers and one bud made up a very stiff-stemmed raceme. The sepals and petals are very pale pink, these forming a striking contrast to the dull magenta-red labellum. Shown by Messrs. Sander and Sons, St. Albans. First-class certificate.

### ODONTOGLOSSUM CLYTIE.

This is a very pretty and unique-looking Odontoglossum, the result of a cross between O. Edwardii and O. Pescatorei. The compound raceme is large, carrying a number of rather small flowers in a loose manner. The ground colour is very deep lilac or almost mauve, with large blotches of dull magenta-crimson freely placed thereon. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

All the above were shown before the Orchid committee of the Royal Horticultural Society on the 3rd inst.

## RIVIERA NOTES.

**IMPATIENS OLIVIERI AT LA MORTOLA.**—It was a pleasant surprise the other day to see in the well-known gardens at La Mortola bold bushes of *Impatiens Olivieri* flowering freely in semi-shade at the end of the month of January, showing that this fine Balsam is much hardier and more robust than any other species known on this coast. As a plant for sheltered entrances or cool rooms it is likely to prove of much value. Its fine habit and handsome foliage would always be attractive even if the flowers failed to open freely in the house. It does not bear full exposure to the sun on this coast, so it should not be planted in the open; but with this reservation it is a valuable addition to Riviera gardens.

**TREE WITCH HAZEL** (*Hamamelis arborea*).—There must be, I think, considerable variation in the flowers of this excellent winter-flowering shrub. As in the case of *Chimonanthus fragrans*, seedlings vary very greatly, and some forms are much brighter than others. Speaking for myself, I had never seen anything half so bright before as a plant now in flower here sent out from England, while a well-grown bush which is covered each winter with its wiry blossoms has produced a much paler and duller flower that is only of moderate interest, comparatively speaking. It is a welcome shrub for any cool and out-of-the-way place where it is not exposed to much sun in summer, and is really beautiful when the lilac-flowered *Erica mediterranea hybrida* is planted near it, as they flower together in mid-winter—a season which this year has been entirely left out of our calendar.

**ALOE ARBORESCENS VAR. NATALENSIS.**—For those whose garden is on sunny rocky slopes this fine form of early winter-flowering Aloe is indispensable; it is both so much finer in the flower-spike as well as more truly winter flowering. To most gardeners "one flowering Aloe is the same as another," but to those who know their plants this form is much the best for general planting. It is longer and finer in its flower-spike, and brighter in colour than the type, which is called popularly by the French *Corne de Bélier*, and by the English generally confounded with the *Tritoma* or Red Hot Poker, which it so closely resembles at a little distance. In dry and windy situations near the sea such succulent plants are highly desirable, and with the increasing craze here and hereabouts for "sticking in a Palm" just because it is green in winter, these valuable flowering shrubs are being forgotten.

**THE DOUBLE PINK DAISIES** so much used for winter bedding are planted nowadays in graceful "arabesques" on the grass—never in beds of any size or regular shape—and it is a decidedly pretty fashion. These thin and prettily waving lines of Daisies or Pansies look much better than a solid mass, while bold groups of Stocks, Carnations, *Ranunculus* and similar-habited, taller-growing flowering plants break up the surface very happily. It is worth adapting to English gardens and surroundings, where often twice the number of flowering bulbs is used with less satisfactory and less lasting effect. As grass here is clipped and not mown, this plan is, perhaps, easier in France than it would be in England; at any rate, it greatly reduces the quantity of bulbs for spring gardening and introduces a fresh feature, which relieves the stiffness of bulb-bedding. Two fine old shrubs,

**LOCHROMA COCCINEA** AND **L. TUBULOSA**, are in fine flower this winter, and are well worth a place among other shrubs. *L. coccinea* is much less hardy and less vigorous than *L. tubulosa*, but as it is not so rampant, and is a very free-flowerer in autumn and spring, it should be given a somewhat sheltered place where its clusters of brick-red, bell-shaped flowers can expand freely.

**L. TUBULOSA** is an excessively vigorous and rampant grower, handsome in foliage, which

is not often injured in ordinary seasons. Its bunches of violet-blue flowers of considerable size are really very handsome, but they are apt to be hidden by the abundant foliage, unless a little thinning of the shoots is practised. There are so few shrubs of so bold a habit that flower freely in winter, so it should not be forgotten by those who plant on these shores. Although these shrubs belong to the great *Solanum* family, the flowers are tubular or bell-shaped, and pendant rather than nodding or erect. Few shrubs this season have been more ornamental than the

**ABUTILONS.**—The finer hybrids, though beautiful as pot plants, are of comparatively little use in the garden. It is the old *A. striatum* and its seedlings that make an effect in the shrub garden, and this fine season they have flowered continuously without any check. Their growth is so vigorous, the foliage so gay and fresh, the abundance of vari-coloured flowers so great that no garden on this coast should be without a good batch of seedlings, which may be weeded out as they flower if inferior in any way. It is not known, I think, how necessary it is to cut them back severely in March or April; without this they are apt to get too straggling and lose much of their beauty. When grown in the open the flowering branches may be cut freely for decorative purposes, as they are particularly lasting in water. There is a large-growing

**SIDA ARBOREA** that is closely allied to the Abutilon, which also deserves notice, as its deep red flowers are upright or horizontal, and form large branching flower-heads that are effective among the solid and rather deep green foliage. The quantity of ripe heads of seed spoils the beauty of some of the old and largest bushes, but judicious pruning will keep this handsome shrub in order. It loves a dry and sunny situation where more tender plants refuse to grow.

Nicc.

EDWARD H. WOODALL.

## THE EDITOR'S TABLE.

**W**E invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

### TULIPS, SPIRÆAS AND LINUM.

I am sending three specimens of flowers, with notes, as I was reading in your paper that such things are desired for your table. Tulip Standard Silver is among the newer sorts of Tulip; the colour, which is silver, feathered crimson, is very pretty, and the variety is useful for growing in pots. *Spiræa confusa* is a useful white-flowering shrub. Established plants in pots easily come into flower if put in a warm greenhouse early in the year from outdoors. *Linum trigynum*.—This old yellow-flowering greenhouse plant is not often seen. It flowers in February, and is useful for walls or pillars. It will do well in a vinery. —A. J. LONG, Head Gardener, *Myfold Court, Reading*.

### HEATHER AND VIOLETS FROM GLOUCESTER.

Mr. H. Prentice of The Gardens, Hartpury House, Gloucester, sends an interesting and well-grown collection of winter-flowering subjects, about which he writes as follows: "I send you a few bits of plants which I hope will assist to brighten your table up until you are able to get the lovely spring flowers. To-day has been

warmer than many days last summer, and the outside garden is very interesting, for each day there is always something coming in flower, and it is so welcome. The Anemone (yellow) and Crocus (also yellow) were full out in to-day's sun, also two blooms on a very small plant of *Saxifraga burseriana* Gloria. The coloured Heath is a grand sight edging a bed of Rhododendrons (alpine varieties) and growing in all peat. The white form is next to it (kindly name them, as I am not certain). *Cotoneaster Simonsii* is growing on the north front of the above house, and a grand sight. It is spurred in each year, and is always well berried. Needless to say, it is very much admired, and only needs a lighter-coloured wall to show it off better. *Mahonia Aquifolium* colours best here on the clay; it is used largely for undergrowth, and makes dull and bare places interesting and cheerful. *Jasminum nudiflorum* is also very pretty on the north-west wall of the stable. Violets (Marie Louise) have done well again this winter, but Mrs. J. J. Astor is only now beginning to flower freely."

[The *Ericas* are *E. mediterranea hybrida* and *E. mediterranea alba*.—Ed.]

### A BEAUTIFUL VIOLET.

Mr. J. Heath, the Violet specialist of Kingskerswell, South Devon, sends a plant of the Parma Violet called Perfection. Its freedom of flowering is remarkable and the growth vigorous; it is a most commendable variety. Mr. Heath writes: "I am sending for your table a plant of Violet Parma Perfection. This variety rarely produces a runner, and the plant sent is naturally grown, never having had a runner removed. It is not so early to bloom as Marie Louise, but keeps on later, and good flowers are to be had in May. Of course the plant sent has been under glass since last October, but the frost has been so severe this winter that it has been frozen hard several times."

### STRELITZIA REGINA (BIRD OF PARADISE FLOWER).

Mr. Dale, Talbley House, Cheshire, sends flowers of this remarkable plant with the following note: "The *Strelitzia* is one of the most beautiful and distinct stove plants, with yellow and bright blue flowers borne on long stems issuing from a boat-shaped sheath. It should be potted in peat three parts, loam one part and a little rough sand. It is a good plan to pot the plant in 10-inch or 12-inch pots without drainage, and if possible to let the root go through the hole in the bottom of the pots into the bed or border. I have two plants treated this way and they are rarely without flowers in winter or summer. The flowers do not quite attain the beautiful colours during the winter months as in the summer. The most troublesome pest is the white scale, which should be sponged off when seen. Remove the old flower spikes as soon as they are over. The *Strelitzia* should have plenty of liquid manure water. The best time to pot is the end of February or early in March, and a little care should be exercised in watering until the plants are established."

### BEAUTIFUL HARDY HEATHS.

Miss E. A. Perkins of The Limes, Stratford-on-Avon, sends sprays of two beautiful hardy *Ericas*. The letter reads as follows: "A very interesting bed and uncommon colour for winter and spring is formed by *Erica mediterranea* edged with *Erica mediterranea alba*. These have been flowering all the winter, as you will see by the flowers enclosed, which were uninjured by the sharp frosts we have had several times during the winter. A nice lot of double Daffodils coming into flower make a pleasing bed for some time, and these are followed by *Lilium tigrinum*, which is still one of the hardiest, best growing and most luxuriant in open situations in light loamy soil."

## PRIZES FOR READERS. MARCH.

### SCHOOL GARDENS.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above subject.

Competitors should describe briefly the laying out and size of the plots, crops to grow, tools required, and the best methods of teaching the scholars.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Tuesday, March 31. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Testing Dahlia tubers** (*G. R. P., Rugby*).—If your Dahlia tubers have been frozen they will now be soft and rotten. If the tubers are sound at present and have a whitish hue when cut through, you may retain them with good results. You are probably aware that the buds, and subsequently shoots, are produced at the base of the old stem or just at the junction where the tubers are joined to it. This is the part to be taken most care of.

**Using fowl manure and leaves for flowers** (*Amateur*).—You can use the mixture of fowl manure and leaves for any flowers, fruits or vegetables, and we think it would be even better than farmyard manure, especially if your soil is of a rather heavy character. Of course its real manurial value will be determined largely by the amount of fowl manure that it contains. By what you say, we presume that you have kept the manure dry, and this was quite correct.

**Treatment of Pampas Grass** (*Oakwood*).—It would have been helpful had you given us an idea of the size of the plant; and not a little depends upon this and the actual growth made each year. Plants that are much cut by frost or cold winds would be most uncertain in their flowering, and in your district should be planted in the most warm and sheltered position available. Preferring a deep bed of rich sandy loam, with good drainage, the plant should receive copious watering during dry weather, and liquid manure if the growth is at all spare or thin. Lacking the fuller details of the past season's

growth, we can only advise you to persevere in the above-named manner, provided you are persuaded that the soil conditions are ample. If the plant was but a small one when transplanted four years ago, it may still be minus that strength and vigour necessary for good flowering.

**Information about Violets** (*B. T. F.*).—Any good farmyard manure if well decayed may be used, and quite fresh cow manure where the soil is of a very light or sandy nature, burying the manure a few inches below the plants. Violets, where the plants stand but one year, do not root very deeply, and 12 inches may be regarded as the safe distance for the manure. It is rather late now to start with cuttings. These should be well rooted at this time; but if you cannot obtain from the open-ground plants a sufficient number of rooted runners, take the youngest portions of the plants when divided. The better way is to take in October or November the unfowered runners, and root them during winter in a frame. These make fine plants for putting out early in April. The kinds most freely used in the London and other markets are *La Parma* (double), and *La France* and *Princess of Wales* (single).

**Climbing flowering plants to cover trees** (*H. Hampshire*).—Our reply would have been more to the point and useful had you given the age and size of your trees. If they are old and have occupied the ground for a long time it would be useless to plant any climbers among the roots of such trees, as they would have no chance whatever of permanently succeeding, or if the tops of such trees are large and of dense growth in summer it would be equally as futile. But if there is a fair amount of light among the branches in summer, where the climbers could have the benefit of light and air, then you may plant such subjects with fair prospects of success, provided that a border of new soil is placed round the stem of such trees, say, 4 feet wide and at least 1 foot deep. This system is practised with much success in the South of France, the old Olive trees being covered with Roses and other climbers. The following would be likely to succeed: Early and late Dutch Honey-suckle, Clematises montana, Jackmanii, Vitalba and Flammula (very strong growing).

## TREES AND SHRUBS.

**Clematis and Cotoneaster** (*Alford*). We greatly fear such a combination would not result successfully, inasmuch as the varieties of Clematis Jackmanii are usually of so dense a growth that any under plant would be more or less obliterated. Moreover, the horizontally-disposed branches of the Cotoneaster would require much training to keep them in position, and thus much of its beauty would be lost. The Ceanothus would be even in worse case, for here the flowering and the colours would clash. Your better plan, we think, will be to adopt a close-growing and close-clinging climber, such as Ampelopsis Veitchii, over which, with annual pruning, the Clematises could be trained; or, as the wall is a high one, you might plant in panel fashion Crataegus Pyracantha and the Clematises already in mind. Or, again, you might try some of the climbing Roses in conjunction with the Clematis and allow the two to ramble away together. If you are still bent on an evergreen background, we think you might find the Crataegus the most serviceable, and by annual autumn pruning hard back of the Clematis, with a comparatively thin training during growth and flowering, secure a fair measure of success from both.

**Clematises for a pergola** (*Mrs. E. V. N. P.*). There is a large number that are suitable to plant in conjunction with Roses upon a pergola, the best being found among the Jackmanii and lanuginosa sections. A few good varieties are: Jackmanii, Henryi, Lady C. Neville, Star of India, lanuginosa, l. candida, Gipsy Queen, Mme. E. Andre, Nelly Moser, Marcel Moser, William Kennett, Sensation, Mrs. G. Jackman, Mme. van Houtte, Princess of Wales, Blue Gem, purpurea elegans, Ville de Lyon, Jackmanii rubra and Mrs. Hope. Of the small-flowered section, Clematis Flammula, C. F. rubra marginata, C. graveolens, C. paniculata and C. grata are very beautiful. Good turfy loam is the best soil for them. The ground should be well dug and some spent hot-bed manure added.

## THE GREENHOUSE.

**To propagate Crotons** (*C. E. R.*).—The best way to propagate Crotons is by means of cuttings. These should be obtained from the leading shoots of old plants, and they may be struck by placing singly in small pots in a mixture of loam with plenty of sand and covering with bell-glasses in strong moist heat. If well attended to in the matter of syringing to keep them moist they soon emit roots, without losing

any of the leaves attached at the time they were inserted. When rooted the cuttings should receive a little air by tilting the glass, gradually giving more till they bear full exposure in the propagating pit. If a propagating pit is not available select the warmest and closest house that you have, put the cuttings under bell-glasses in it and keep it as warm and moist as possible. When potted off the rooted cuttings will need to be grown in a similar warm and moist atmosphere.

**Azalea producing red and white flowers** (*C. H. L.*).—There is nothing extraordinary in the fact that a branch of your Azalea has produced crimson flowers; such a thing often occurs in the case of Indian Azaleas. You can perpetuate the sport by means of cuttings taken from young shoots any time during spring or summer. Make the cuttings 3 inches or 4 inches long, and insert them firmly in sandy peat and place in a close and warm propagating case until rooted. It is unlikely that the sport will be of any special value, as such things occur so often and there already exists a very great number of varieties.

**Treatment of seedling Oranges** (*Vannetia*). Your informant is quite incorrect in stating that Oranges raised from pips will not bloom unless they are grafted on to something else. The facts of the case are that Oranges (in common with many other trees) take years to attain the flowering size. This may be noticed in the case of Apples, Pears, Plums, &c. For this reason they are generally used as stocks for grafting, not as grafts themselves. The grafts or scions are taken from a mature plant that has reached flowering size, and consequently, when a union is complete and growth recommences, flowers are produced. It is exactly in the same way that grafting is adopted in the case of fruit trees. The grafting of Oranges needs considerable care in carrying it out in a satisfactory manner. The method employed is veneer or side grafting, and it should be carried out during the spring or summer months. The head of the stock may be shortened, but not cut away altogether. After being grafted the plants must be placed in a close propagating case in a gentle heat till a union is complete.

**How to grow Crinum longifolium** (*R. J. D.*).—Crinum longifolium, a South African species which is also known as C. capense, is quite hardy in the southern portion of the country, including the London districts. The leaves are long and brittle, hence it should not be planted in wind-swept spots, and, as it needs full exposure to the sun, it is best at the foot of a south wall. Being a fairly liberal feeder it must not be planted too near the wall, where it is liable to get somewhat starved, but in a south border. The bulbs are club-like, 1 foot or more in length, and they should be planted at such a depth that the upper part is just level with the surface of the soil. The upper portion generally consists of sheaths of old leaves, so that if the tops of these are level with the soil the apex of the bulb is somewhat below the surface. In preparing for planting, the soil should be taken out to a depth of 2 feet, and, if necessary a little drainage should be put in the bottom, but unless the soil is stagnant this is not required. Some good turfy loam, a little well-decayed manure and some sand should be mixed together, and the bulbs firmly planted in this mixture. No further care will be needed unless the weather is very dry, when this Crinum may be freely watered, for it enjoys a liberal amount of moisture during the growing season. It may also be grown in pots, in which case it will not be possible to bury the bulbs as deeply as in the open ground; but, still, they should be put as low as they conveniently can. In pots the bulbs should be just protected from the winter's frost.

## KITCHEN GARDEN.

**Dusting Peas and Beans with soot and lime** (*E. M. L. B.*).—If slugs are very prevalent it will be advisable to sprinkle soot or lime round your Peas and Beans at intervals until the plants are several inches high. We do not advise you to dust the plants themselves with these substances, because in some instances they burn the plants. Birds will not harm the Beans; to prevent them eating the young Peas you must place wire or old fish netting over the latter, or else attach strands of black cotton to sticks a few inches from the soil. These must be placed over the rows before the seedlings appear, as it is when the latter are just pushing through the soil that birds attack them.

**Application of salt to mixed crops of vegetables and fruit trees** (*R. W. R.*).—Salt on some land, when used sparingly and with knowledge, is a useful manure, especially for vegetables, but not for fruit trees. On land in close proximity to the sea it has been found to have an injurious effect upon any crop to which it has been applied. The clouds formed by evaporation from the sea always contain more or less salt, and those passing inland condense and the salt is brought down with the rain, supplying the soil with quite as much salt as it can do with. Urine must never be applied to fruit trees. It is excellent when mixed with plenty of soil and then added to the vegetable quarters. A mulch of fowl manure mixed with its bulk of soil is an excellent manure to apply

to any crop, and may be applied with great advantage to fruit trees.

**Spring Cabbage bed** (*A. J. M.*).—We are not sure whether the Cabbage plants you refer to are still in the seed-bed or in the open quarter. If the former, it is most likely that clubbing in one or another of its forms is the cause of the trouble, and this you can determine by pulling up a few plants. If affected by this disease or malady, the stems below ground and about the roots will be covered with large warts or swellings, and their only chance lies in the plants being lifted and these warts cut away and burnt. If the Cabbage tribe is subject to this failing in your soil the best remedy is a dressing of gas-lime, or you might try a dressing of Vaporite, obtainable from any sundriesman. Had you sent a few of the plants for inspection we might have given you better advice.

**Information about Seakale Beet** (*M. T. S.*). We think, as you suggest, the writer of the note on Seakale Beet must have either protected the Beet in some way or the season was unusually mild, as this Beet is not hardy. There is a form of Beet called the Spiach Beet, which is quite hardy, the leaves of which are thrown up in profusion from the base and cut like ordinary Spinach. To get a large fleshy midrib Seakale Beet must be sown early to secure a good growth, severely thinned, and protected in winter by placing long litter round the plant. Some growers also earth it up in November, but in some cases we have found it spoils the flavour, and if this happens, by putting a few drops of Lemon juice at the cooking in the water it is removed. Do not use soda; this spoils the stalks and discolours them.

## FRUIT GARDEN.

**Black Currant shoots for inspection** (*M. P. R.*).—The shoots that you send are, undoubtedly, attacked by the Black Currant mite, the swollen rounded buds being the ones affected. As only one bush out of a large number is affected we strongly advise you to root it out and burn it at once. As a preventive we advise the following: From late March to the middle of May dust the bushes at fortnightly intervals with a mixture of fresh air-slaked lime and flowers of sulphur, 2lb. of the former to 1lb. of the latter. Use it when the bushes are damp.

**Blood manure for Vines** (*S. W. J.*).—Blood is rich in nitrogen, and therefore an excellent manure to apply as a summer surface-dressing for Vines. It is best applied in a dry state, mixing with it before it is applied to the border four times its bulk of soil, and then scattering it thinly over the border, afterwards covering it over with a thin layer of good loam. It is best applied after the Grapes have been thinned the first time, and again at the last swelling.

**Warty growth on Apple trees** (*H. E. G.*).—Your Apple tree is suffering from a disease common to some varieties of Apples, especially when the trees are growing in heavy, cold soil. It is named canker, and, as far as we know, there is no absolute cure for it, but trees suffering from it often live for a long time and bear fair crops of fruit. As your tree seems badly affected, and has not borne fruit for some years, we advise you to root it up and burn it, then plant a strong healthy young tree in its place, first trenching the ground and manuring the same liberally.

**Pruning recently-planted trained trees on a wall** (*Benrhod*).—Cut back the leading upright shoot of last year's growth, leaving it a little more than half its length. From this cut shoot will emerge next year one at the top, forming another main branch or leader, and one on either side, adding two side shoots—three in all. The side shoots of last year's growth must be served the same way, and they will also produce two side shoots and a leader the same as the top shoot. This process will have to be continued every year until the trees have filled their allotted space.

## MISCELLANEOUS.

**Information about Walnut leaves** (*Broad-gates*).—We reply to your queries seriatim. We have not heard of Walnut leaves being injurious when used as leaf-soil. We have seen them used in conjunction with other leaves for this purpose without any harm accruing. If you have only Walnut leaves it might be as well to use them experimentally and see what happens. Damping off is a fungoid disease that attacks seedlings, generally near the surface of the soil. It is caused by the seedlings standing or growing too close together, this encouraging moisture to remain on the stems at the point mentioned, and so enabling the fungus to attack them. Thin sowing, careful watering, and adequate ventilation are preventives. Certainly, Roses that were planted three years ago and hard potted then will need pruning this year; if you send us full particulars as to varieties and the treatment as to pruning since they were planted, advice will be given. You may safely mulch the border you mention with Cocoanut fibre refuse. You will have seen the illustrated article on fibrous-rooted Begonias in our issue of the 22nd ult., which answers your query about these plants. When writing again kindly use a separate sheet of paper for questions on one subject; this facilitates the work of replying.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## TOMATOES OUTDOORS.

THIS is a garden crop which is becoming more important every year as the supposed difficulties concerning its successful growth in the open air becomes dissipated by experience and practice. Last year taught us a useful lesson in this respect. It has been stated by many writers, and generally acknowledged by growers, that the crop proves a failure when the summer happens to be dull and cold, the same as it was last year. I certainly shared this belief until I was convinced to the contrary by some splendid crops which I saw last autumn in many parts round London. This fact, I think, ought to go far to inspire confidence in the possibility of securing splendid crops in warm summers, and moderately good even in bad ones, of this popular and profitable fruit. To the inexperienced there will always remain certain points of difficulty attached to the successful growth of this crop out of doors until he has learned by experience how to provide the conditions necessary, and by the help of which alone success is possible.

I scarcely think it would prove to be a lucrative crop on the north side of the Trent, but undoubtedly would be so in our Home and Southern Counties. It should be planted in warm, well-drained and generously-manured land of a light rather than of a heavy texture, facing south if possible, and if sheltered from north and east winds so much the better. In my opinion the greatest factor in bringing about the success of this crop is to have strong healthy plants when the time for planting in the quarters comes round; another important factor is the frequent application of the hoe among the plants during the season of growth. It is impossible to exaggerate the value of this work in aerating and increasing the fertility of the soil. Having selected the land on which the Tomatoes are to be planted, it should at once be bastard trenched and well enriched with farmyard manure if this has not already been done, the ground afterwards being left rough until planting time comes round. Having prepared the land, our next object must be to produce the plants.

March 20 is a good time to sow the seeds. These should be sown thinly in pans or shallow boxes in finely-sifted mould, the seeds being covered by rather less than a quarter of an inch of the mould. Place the pans or boxes on a shelf near the glass on the sunny side of a greenhouse or in a frame on a hot-bed with a slight heat. After watering through a fine rose, place a piece of glass over the pans or boxes, and let them remain on until the seedlings are up. As soon as they are about 2 inches long they

should be pricked out into shallow boxes (any old boxes will do) filled with mould of a similar description to that in which the seeds have been sown, and which should consist of loam and leaf-mould in equal quantities. Pricking out is a technical garden term, and means making a hole with a pointed stick in the soil large enough to receive the roots of the young plants, and deep enough to allow of its being pressed into the soil to half the depth of its stem, from which new roots will soon emit. They should be planted 3 inches apart, or they may be potted singly into small pots, but boxing takes less time and is least expensive. The young plants after transplanting should be returned to the positions occupied by them before. To grow the Tomato successfully, the grower must have constantly in his mind the fact that the young plants must be grown hardily and sturdily (attenuated and weakly plants are of no use), therefore the air of the house or frame in which they are grown must never be stuffy or overheated, but must, at the same time, be artificially warmed, especially at night during this cold time of the year, to ensure steady growth and to admit of a current of air at all times, excepting in very cold weather.

In the course of three weeks after transplanting the foliage of the plants will meet in the boxes, and the time has come for them to be potted, each into a 5-inch pot, using three parts of loam and one of leaf-soil unsifted. In potting, sink the young plant again in the pot to nearly half the length of its stem, filling the pot with soil into which new roots will soon emerge. The young plants must again be placed under glass as soon as potted, in a fairly warm and airy position facing the sun. By the first week in May, if all has gone well, they will have made healthy, sturdy plants from 12 inches to 18 inches high, many of them no doubt showing a few flowers, which should be encouraged to set fruit by distributing the pollen grains by brushing with a rabbit's tail. The Tomato is a tender plant, therefore it should not be exposed to frost at any time. However, the time has now come for placing the young plants out of doors in a sheltered position on a bed of ashes (about May 15). In order to protect the plants from frost at night, a temporary covering should be erected over them in the way of a skeleton frame-work of wood, over the sides and tops of which mats or some other covering could be placed at night until danger from frost had passed, leaving them exposed in the daytime.

This hardening process will have prepared the plants for planting out in their summer quarters by about June 7. They should by then be strong, well-rooted plants, many of them bearing from one to two bunches of fruit, which should be ripe by the end of July or beginning of August.

We will now return to the land in which they are to be planted, and which we left in a rough state after manuring and trenching in March. The first thing to do will be to scarify the surface either by a harrow or fork, and then draw shallow drills to mark where the rows are to be. The first two drills should be 1 foot apart, the next 18 inches, and the next 1 foot and the next 18 inches again, and so on through the piece. By thus planting in rows only 12 inches apart it is possible to fasten the two rows of plants to one support, thereby considerably reducing the expense. The 18-inch space between the rows affords adequate room for walking and working among the plants and for gathering the fruit; 15 inches should be allowed between plant and plant in the row.

#### PLANTING.

The holes should be dug out with a spade and made deep enough for at least 4 inches of the base of the stem of the plant to be buried in the soil, from which new roots will soon shoot forth. Plant when the soil is comparatively dry, tread firmly round the plants, and give a good watering immediately afterwards. On no account must it be forgotten to thoroughly water the plants the day before they are planted.

#### AFTER MANAGEMENT.

An important matter which must receive timely attention is the cutting away of the side shoots or laterals as fast as they form, or the growth will become so dense as to prevent light, air and heat circulating among the plants, to the injury of the fruit. Yet another important matter I would notice is the necessity of cutting off the top of the plant, three joints above the top bunch of fruit, as soon as four bunches of fruit are secured to each plant. This will hasten the swelling and maturity of the fruit enormously. Many growers I know, in the hope of securing a heavier crop, defer this operation until more bunches are secured. It is a fatal mistake to make. The summer is too short to ripen such late-formed fruit.

**Supports for the Plants.**—Many use Bamboo canes, one to each plant. This is an effective way, no doubt, but an expensive one, entailing much time to carry out and a considerable outlay for canes. The simplest and cheapest way, I think, is to fix pieces of fairly strong wood between every two rows at a distance of 20 yards apart, and to stretch one or two thin wires the length of the rows, tying the plants of both rows to this. I saw a large quarter last year, the plants on which had been allowed to lie on the ground, the grower thinking they would come to no good owing to the bad season. So far as I could see they ripened up nearly as well as those which were supported by sticks.

**Watering.**—The plants should be watered at least once a week for about three weeks after planting. By that time the roots will have taken hold of the soil, and no further watering will be needed.

**Mulching.**—A thin mulch of rotten manure placed about 2 inches deep on the surface of the soil round the plants as soon as the tops are cut off, as advised before, works wonders in helping to swell up and increase the weight of the crop.

**Gathering the Fruit.**—This should be done before it is ripe—that is to say, as soon as it has taken on a decided colour over, say, half its surface. It should be placed on boards or in shallow boxes, two layers deep, on a greenhouse shelf, or inside a frame under glass where there is a genial (but not too much) heat and a current of warm air passing over them. In about ten days the fruit will put on as brilliant a colour as is to be found on most grown under glass.

**Varieties.**—The heaviest cropping outdoor variety I know is Sutton's Open Air, but it is somewhat corrugated in outline, and this militates against its market value. Sutton's Abundance and Earliest of All are excellent, so is Carter's Sunrise and Veitch's Frogmore Selected.

OWEN THOMAS.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 25.—Royal Botanic Society's Show, Regent's Park, N.W.

March 31.—Royal Horticultural Society's Hyacinth Exhibition, Vincent Square, Westminster.

**"The Garden" Horticultural Show.**—Our announcement last week to the effect that we intend holding a horticultural exhibition for our readers only some time during July next has created much interest, which augurs well for its success. In case any of our readers overlooked the schedule last week, we draw their attention to the fact that it is published again this week among our advertisement pages.

**New varieties of Japanese Quince (*Cydonia japonica*).**—M. V. Lemoine et fils of Nancy announce for distribution three new varieties of this beautiful and well-known shrub. They are Abricot, a dwarf form with semi-double flowers of a beautiful bright kind of golden hue; Grenade, large, globular, almost double flowers of a deep scarlet; Orange, semi-double flowers of a clear orange red.—H. P.

**New Hydrangeas.**—The name of Lemoine of Nancy is known to everyone as a most successful hybridist, and the successes that have emanated from that establishment form a very long list. Of late years attention has been devoted to Hydrangeas, and three new varieties are announced in the February catalogue just issued. They are said to be a selection from several thousand seedlings, the result of artificially crossing *H. Otaksa monstrosa*, *H. Mariesii*, *H. Souvenir de Claire* and *H. rosea*. From these a good number of plants were selected for further observation, and the three varieties were ultimately chosen therefrom. They are *Avalanche*, described as the whitest of the Hydrangeas; *Fraicheur*, enormous clusters, flowers medium, round, white, shaded rose, tips greenish, eye mauve; *La Lorraine*, large corymbs and flowers, these last having the edges slightly toothed, in colour soft rose, turning to bright rose.—H. P.

**Winter-flowering Carnation Society.**—The next exhibition in connexion with this society will be held in the Royal Horticultural Society's Hall, Westminster, on Wednesday, April 1. The schedule is a most comprehensive one, the section devoted to amateurs being of special interest. Good prizes are offered, and all lovers of these charming winter flowers should make a point of attending the exhibition. Full particulars can be obtained by writing to the hon. secretary, Mr. Hayward Mathias, Lucerne, Stubbington, Fareham, Hants.

**Huntingdonshire Daffodil and Spring Flower Society.**—The annual exhibition in connexion with the above society will be held in the Corn Exchange, Huntingdon, on Tuesday, April 21. The classes are open to all England, and some good prizes are offered. Copies of the schedule can be obtained from the hon. secretary, Miss L. L. Linton, Stirtloe House, Buckden, Huntingdon.

**Compounds (poisonous) for horticultural and agricultural purposes.**—It is satisfactory to find that the Poisons and Pharmacy Bill successfully passed its second reading in the House of Lords on Thursday last, and was referred to a joint committee of both Houses of Parliament. The horticultural trade is materially interested in this Bill, as by Clause 2 power is given to persons, other than chemists, such as nurserymen, seedsmen and agricultural agents, to stock and sell (under provisions to be made by the Privy Council) weed killers, insecticides, sheep

dips, &c. It will be remembered that the Traders in Poisonous Compounds for Trade Purposes Protection Society has for years past been working to this end, and it is due to the efforts of the society that this clause has been inserted in the Bill. All those interested in the sale of these compounds should assist the society in its efforts to get Members of Parliament to support Clause 2 of the Bill, so that the same may become law this Session.—G. H. RICHARDS.

**"Journal of the Kew Guild."**—This is an annual publication that is eagerly looked forward to by Kew men all over the world, and no doubt many will be wondering why the present number is so late in appearing. An excellent portrait of Mr. Irwin Lynch, M.A., V.M.H., Curator of the Cambridge Botanic Gardens, forms the frontispiece, a most interesting memoir accompanying it. A full page illustration of Cambridge Cottage, formerly the residence of the late Duke of Cambridge, is also given, this building having been converted into a public museum. The letters from old Kewites, chiefly from abroad, are, as usual, a most interesting feature. Death, we are sorry to say, has visited several members during the past year, portraits of five deceased members being given.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Iris luteo-alba.**—This little plant is now in flower with me, and I think that if I had been able to include it in my group at the Royal Horticultural Society's meeting on the 3rd inst. it would have caused much interest. Roughly speaking, it is a white reticulata, so slightly shaded with cream and pale blue as for these colours to be scarcely noticeable, except on close inspection. It is smaller and dwarfer, too, than the reticulata type, and altogether a somewhat insignificant flower; but the unique colour makes it of great interest to lovers of this section.—F. HERBERT CHAPMAN, Rye.

**A hint on Rose pruning.**—There is no harm done by allowing a few buds to push into growth at the top of the shoots before pruning is commenced. This is often an advantage. When the top growth commences the roots are also active, and owing to this after the pruning is done the dormant buds quickly develop into strong vigorous shoots. The end of March is quite early enough to commence pruning the Hybrid Perpetuals, to be followed by the Hybrid Teas, leaving the Teas to be dealt with in April.—C. RUSE, Munden Gardens, Watford.

**Autumn Snowdrops and the seasons.**—The dull and wet weather which generally prevailed here during 1907 had the effect of either hindering or delaying the flowering of the autumnal-blooming Snowdrops. *Galanthus coreyensis* did not bloom with me at all, and *G. octobrensis*, *G. Elsäe* and *G. Rachelæ* did not come into flower until well into January, and some of these are still in bloom in the last days of February. *G. cilicicus* opened in the beginning of January.—S. ARNOTT, Dumfries, February 27.

**Destroying wasps.**—Re the article on wasps (pages 109 and 110), I have found the following very effective in destroying them: Plant batches of *Centaurea montana carnea* and *C. m. rubra*; then, when they first begin flowering, look over them every day when it is fine enough for wasps to fly. The queens are attracted to these in numbers, and with a pair of strong leather gloves they may be taken and killed. Another plan is to place jars or bottles of beer, sweetened, into which they crawl and get either intoxicated or drowned. Our firm grow large quantities of these *Centaureas*, and it was quite by chance I noticed the wasps feeding on them last spring.—GEORGE GIBSON, Leeming-Bar.

**The sorrows of the seedsman.**—

It may not be generally known, yet such is the fact, that the seedsman often has to work a great many hours of overtime during his busiest seasons, and has to crowd as much into those hours as he is physically able to accomplish. In a busy seed and bulb business there are two calls for this strenuous exertion, viz., when the bulbs are dispatched and when the seeds are sent out. The bulb season begins in earnest early in August and continues until well into November. Out of this time there will probably be some eight weeks in which the staff will have to work until 9.30 p.m., or, in exceptional cases, until nearly midnight for six days in the week. In my own case I have worked until 11 and 11.30 for some time in order to cope with orders, and this not owing to any bad management, but to a bad season and late delivery of bulbs. The seed season opens early in January and runs on to the end of March; this will generally give from one to two months of overtime, the assistants often working thirteen and fourteen hours a day. And not only are the hours long, but everyone is working at full pressure. Now, I am not grumbling at this state of things, it is what is expected by all who enter into the seed trade, whether he hold the post of office boy or manager; but what I do plead for is this, that those who send their orders to the seedsman shall endeavour to make his work as light as possible. I will first give a few instances of how work is often complicated and increased. Nearly all seedsman send out order sheets on which to write out the order, or in many cases the names of seeds or bulbs are printed with spaces for the quantities to be filled in by the customer. Now if these sheets were always used in the way intended, they would make the execution of an order very simple. Unfortunately, many people lose these order sheets almost as soon as they get them; then when making out their orders they collect a few odd sheets of notepaper, sit down and begin to jot down "impressions" for the coming season's gardening. They order a few items, totally ignoring the sequence of subjects in the catalogue from which they are working. Then follow a few interjectory remarks on cultivation or the crops of the previous year, then a few more items and so on. It is no exaggeration to say that these "mixtures" often have to be entirely rewritten before the order can be executed, and this when every minute is precious and the staff is working at highest pressure. Even when the order sheet is used it is often so carelessly filled in that it is almost impossible to say what is required. In some cases marks will be placed just halfway between two varieties, so that it is guesswork to say which to send. In other cases marks are so faint that a magnifying glass is required to decide whether an ounce or half an ounce is wanted. Then, again, marks are made and partly obliterated, so that doubts are raised as to whether the item is wanted or not. Again, when seeds are offered by the ounce, some people will persist in ordering by the packet. Or others, when they get to choice flower seeds worth anything from 2s. 6d. to £8 per oz., placidly put 1oz. before everything they fancy. Of course, in these cases the seedsman will at once make the corrections without much loss of time, but a little thought would have prevented even this little extra work. Another class of purchaser sends off his order early in the season, but forgets to put any name or address on it, and at the end of a week or so—according to his patience—writes indignantly to know when he may expect his goods. Some persons persist in asking questions about bulbs or seeds which have been anticipated and are fully answered in his seed or bulb list. Of course, this is want of thought. Of late years all the leading authorities among bulb growers, or rather users of bulbs, have advocated early planting. This is very good advice, but has added another trouble to the bulb merchant; for some of his clients having got this idea of early planting

firmly into their heads, they give the nurseryman no peace until their orders are executed. Having shown a few of the trials of a seedsman (a number more could be cited if space allowed), I ask that those whom he serves will do their best to make his task as light as possible. (1) By using order sheets, &c., provided for the purpose. (2) By abstaining from asking questions answers to which may be found in the catalogue of the seedsman or bulb merchant. (3) By writing or marking the orders distinctly so that there can be no doubt as to what is required and how much of it. (4) By making out the orders in proper sequence from seed or bulb list, and writing questions or other remarks on a separate paper. (5) By exercising as much patience as in you lies, believing that the seedsman will attend to your wants as soon as he possibly can, if for no higher motive than to make room for other work which is needing his attention.—A SUFFERER.

### A VISIT TO MR. F. HERBERT CHAPMAN'S GARDEN.

WE recently had the pleasure of visiting the garden of Mr. F. Herbert Chapman of Guldeford Lodge, Rye, who is, perhaps, best known to the horticultural world as the raiser of the beautiful yellow Freesia named Chapmani. The garden in question is situated immediately beneath a very steep and high cliff that breaks all north and east winds, so that it is most favourably placed for plant life of all kinds. Horticulture, it should be mentioned, is really a hobby of Mr. Chapman's, bulbous plants, and particularly Freesias, being his pet subjects, the crossing of these and Narcissi being extensively carried out by him.

Freesia Chapmani was naturally largely in evidence, and it certainly is a charming plant, the deep rich yellow flowers possessing almost as much fragrance as the well-known *F. refracta*, while in size they also compare favourably with the last-named species. Much has been written and said as to how Mr. Chapman secured such a splendid novelty, but, needless to say, a greater part of this has been merely surmised, hence it may be of interest to record the exact crosses made. At the outset, *Freesia refracta alba* was used as the seed parent, the flowers of this being fertilised by pollen from *F. aurea*, a little-known species that possesses dirty yellow flowers. The result of this cross was plants with flowers of varying shades of yellow, none of which satisfied the hybridist, hence the deepest yellow blooms were selected and the pollen from these used on *F. refracta alba* again, *F. Chapmani* being the result. It will, therefore, be seen that a double cross was necessary for the production of the handsome yellow Freesia that is already a general favourite.

Among other forms of Freesia that we noticed was one named Lemon Drop, a pale lemon-coloured form of *F. refracta*, and an improved form of *F. refracta alba*, the flowers being pure white instead of cream, with the usual yellow markings. A new break in colour is provided by a plant or two with a rich apricot tint suffusing the flowers.

A box of seedlings that were flowering was most interesting, the whole of the plants being the result of one cross. Among them were deep yellow, white, apricot and pale yellow hues, thus proving that the Freesia, like many other plants, is most variable when crossing is resorted to. Seed is sown during June in shallow boxes and the bulbs are allowed to flower in these before they are transplanted. The age that the seedlings attain before they flower varies considerably, some producing blooms the first year and others needing a period of four years to reach the flowering stage. The deep lilac Freesia Tubergeni, of course, finds a home here, and

Amethystine, a pale lilac form of it, is also grown. When we remember that the crossing of Freesias, at least in this country, is at present only in its infancy, we may safely predict that many other beautiful forms will be produced ere many years elapse.

Narcissi seedlings abounded everywhere, and no less than fifty distinct crosses were made by Mr. Chapman last year, records of all being carefully preserved so that the parentage of any prizes that may result will be known. Some seedlings of *N. calathinus*, only about an inch high, had the characteristic twisted leaves of this species, even in this early state. Seeds of Narcissi are sown as soon as ripe in shallow boxes and given cool treatment from the first, the young bulbs being transferred to beds in the open after the second year's growth has been completed.

Irises of the reticulata section were just in flower, and some very charming things were among them. We particularly noticed some substantial improvements on *I. Krelagei* and *I. melusine*, the first-named being especially variable, a form of it named *grandiflora intensa* being, as its name implies, larger and deeper in colour than the type. Considering the hardness of these plants, and the early period of the year in which they flower, it is surprising that they are not more widely grown.

Some Cyclamen seedlings, resulting from a cross between *C. ibericum* and a variety of *C. persicum*, were rather disappointing, little improvement on the first-named being noticed among them at present. However, a further cross has been made, the results of which may, perhaps, prove more satisfactory.

Besides hybridising, Mr. Chapman is a very capable cultivator of Narcissi, and visitors to the Midland Daffodil Society's show held at Birmingham last year, will no doubt remember the excellent group of fifty varieties that won for him the first prize and gold medal of the society. A silver-gilt Banksian medal was also awarded him last April by the Royal Horticultural Society for a splendid group of Daffodils shown at Vincent Square. Undoubtedly, Mr. Chapman is a coming man in the horticultural world; certainly he is an enthusiastic hybridist, in which he is greatly assisted by Mrs. Chapman, who apparently has a natural gift for colour selection.

### VIOLET PLANTS IN POTS.

USUALLY Violets are grown in frames throughout the winter when an early supply of flowers is required. There are few persons who do not love Violets, and I suggest that a few nice clumps be lifted and placed carefully in flower-pots for the decoration of the conservatory and dwelling-rooms. I have grown many pots of Violets for this purpose, and they have always been much appreciated. Procure a number of 7-inch and 8-inch pots, put in good drainage, and then pot the lifted clumps much in the same way as you would an ordinary Zonal Pelargonium.

Do not bruise the roots, but press the soil—which should be of a light nature and in a medium condition as regards moisture—gently around the roots. Then place the newly-potted plants in a cool, airy frame for about ten days. New roots will quickly take possession of the fresh soil, and when the flower-buds commence opening take the plants to the conservatory. It is only necessary to have the plants in the dwelling-rooms while the flowers are fully open. Careful watering must be the rule, and manure water is not necessary. Dead and fading leaves should be regularly removed, because they would, if left on the plants, not only mar their beauty, but cause the loss of many flowers. Princess of Wales and La France (single-flowered) and Mrs. J. J. Astor and Marie Louise (double-flowered) are good, reliable sorts to grow. AVON.

## THE KITCHEN GARDEN.

### SOME VALUABLE CLIMBING FRENCH BEANS.

**F**REQUENTLY it happens that the amateur can devote some space to climbing Beans, but the best results are not always obtained from the old Scarlet Runner. These at times are late in bearing, and require more room than often can be given them. My note concerns a very different type of Bean, which should greatly interest amateurs, and not only be more valuable on account of the compact growth, but more so for their excellent quality. The variety July is a very distinct sort as the pods are stringless. This is a great gain in the cooking; but this I will refer to later. They bear so freely that quite forty pods have been seen on a single stalk. Another important point is their earliness. Last season—by no means an early one—July gave pods the second week in July from seed sown the last week in April, whereas the runners of the older type were quite a month later. The plants do not need tall stakes—3 feet to 4 feet—and the pods are long, thin and straight, averaging about 6 inches in length, and produced in pairs or clusters. The seeds are

require little preparation. If cooked when quite young, then served with butter, they are delicious.

Another way of serving this Bean when cold is to mix it, whole, with salad. Served thus the good quality of the pod is not lost. The July Climbing also has other good points: it keeps longer when fit for use than others. Doubtless its small seeds and fleshy pods are in its favour in this respect.

Successor is an excellent Bean to follow the July; it has larger pods and is of excellent table quality. Though not so early as the first-named, it is valuable for its long cropping and the large quantity of fine pods produced. This, in my opinion, is one of the best of the climbing French varieties, a superior form to those first introduced, and a reliable Bean for amateurs who have none too much space for the Scarlet Runner group. It should be sown late in May for a succession; indeed, last year I made two sowings, one in May and another a month later. By so doing I got good pods well into October, and in quantity. It variety also sets very freely and does well against a fence or wall. Grown thus it does not require sticks and gives a good return. Feeding in dry seasons should not be overlooked. It is an easy matter to feed with any good food and well water it in afterwards.

Those who have liquid manure would find this one of the best foods for the purpose. Another point worth attention is to avoid crowding the plants. It is well to give plenty of room. If the seed is sown too thickly, thin out when a good plant is secured. Amateurs may also forward a crop by sowing in boxes in frames and planting out early in May. This done, I have had July fit for table in June. Both these varieties were raised by Messrs. Carter and Co. of High Holborn.

G. WYTHES.

### SOWING MISTLETOE

JUDGING by the vast quantities that are sent to the London markets every Christmas, chiefly from France, the Mistletoe (*Viscum album*) is as popular as ever in this country. Although generally regarded as a parasite it is not strictly so because, owing to its possessing green leaves, it is capable of absorbing carbonic acid gas from the air, and

forming from this, in conjunction with the moisture and minerals derived from its host, starch, which is the principal of plant foods. Another erroneous idea entertained by many is that Mistletoe will only grow on Apple trees or those closely related to Apples. Undoubtedly it is most frequently met with on these trees, but it will also grow on the Ash, Lime, Poplar, Whitethorn and occasionally on the Oak.

Generally speaking a moist locality suits it best, but it may sometimes be induced to grow under more arid and dry conditions. The seeds, which are ripe early in March, may be sown at once, choosing the under side of a branch where the bark is smooth and living. The berries may simply be squashed on the bark so that the seeds are held there by the sticky substance contained in the berries, or slight cuts can be made and the seeds inserted therein. Whichever system is adopted means must be taken to prevent birds stealing the seeds, this being most effectively accomplished by hanging pieces of fish or wire netting over the spots where the seeds are sown. No further care is necessary. Very little growth will be made the first summer, and even when fully established the plants are of slow growth. As the male and female flowers are produced on separate plants one of each at least is necessary to secure a crop of berries. The illustration portrays a fine bunch of this semi-parasite that has affixed itself to an Apple tree. Although its presence cannot be beneficial to the tree it is doubtful whether any appreciable harm is done; at least, trees that have large bunches growing on them seem little the worse for it.

## THE GREENHOUSE.

### WATERING AND VENTILATING GREENHOUSE PLANTS IN SPRING.

**I**T is a very easy matter for the amateur to err in the watering and ventilating of his plants during the spring months. At no other season of the year is it so necessary to pay close attention to both points in the cultivation of plants under glass. In the autumn the foliage and wood are both fairly well matured and will withstand the changes in the weather, in the summer it is possible to ventilate and give water freely without causing any serious injury to the contents of the house, but in spring we have cold east winds, alternating spells of bright sunshine and cloud, and as the new growths of the plants are very tender any neglect in regard to airing and watering may cause irreparable damage.

In the depth of winter there is usually quite enough moisture in the greenhouse without sprinkling water on the floor; indeed, we try, or ought to try, to keep the interior of the structure dry for the benefit of the plants. But as the sun gains in power and new shoots grow on the plants more moisture is required. Our aim should be to produce a temperature and an atmosphere which will induce the healthiest growth of the plants. If the interior of the greenhouse be very dry in the afternoon when it is closed, and the hot-water pipes are heated in the usual way, the plants will suffer and insect pests be favoured. It is the wisest plan to slightly damp the floor at closing time, especially if the sun shines at the time; then if you enter the house an hour afterwards the temperature will be higher but the perceptible moisture in the atmosphere will feel agreeable. Open the ventilators slightly early enough in the morning to prevent the temperature rising unduly, but do not cause a chill to the plants through excessive ventilation. As a rule on clear days the ventilators should be gradually opened wider—according to the strength of the sun's rays—till noon, then it should be the rule to gradually close them. Furthermore, damp the floor at noon on bright days, as well as when the house is closed. If you find the temperature too high, and at the same time a cold east wind is blowing, it would be wiser to syringe more water on the floor and walls of the house than to open wide the ventilators at once.

The watering of plants, especially newly-potted ones, requires to be carefully done at this season. If the soil be moist a syringing of the foliage will be more beneficial than watering the soil, but all leaves should be dry by sunset. AVON.

MISTLETOE GROWING ON AN APPLE TREE. (Now is the time to sow the seed.)

small; the pod fleshy and stringless. It is certainly the earliest climbing French Bean I have grown, and adheres well to the sticks. The quality of the pods when cooked is not unlike that of the Butter Beans; they are delicious. Here I would ask amateurs to adopt a different way of cooking to that usually followed; that is, to gather before the pods have become old. Cook them whole, and, being stringless, they

## THE FLOWER GARDEN.

### MISTAKES MADE IN SOWING SEEDS.

**A**MATEURS will now be busily engaged in sowing seeds in the open borders, and, although they will probably cover the seeds properly, they will make the surface of the soil very smooth with the back of the spade or rake down the lumps of earth to a fine powder. At this season cold east winds are prevalent, and when the tender seedlings are fully exposed to such winds a serious check is the result. Instead of making the surface of the border quite smooth, leave it somewhat lumpy; these lumps of soil, averaging the size of Walnuts, act as a natural shelter to the tiny seedlings, breaking the force of the wind. Some finer soil may be scattered on the seeds, so as to secure proper germination; but the surface itself should not be beaten down flat. There is another mistake very generally made, and that is neglect in the treatment of the subsoil, or that portion immediately below the surface. When ground is dug in the autumn and winter, clayey soils especially are left in a rather lumpy condition, and the mere breaking up of the top crust for the reception of the seeds is not sufficient. Make good use of the garden fork and thoroughly break up the subsoil before putting in the seeds. Especially is this necessary where seeds are sown in quarters where the resultant plants are to remain to come to maturity. AVON.

### HELLEBORUS PETER BARR.

THIS is, perhaps, the darkest-flowered variety of *Helleborus colchicus* yet seen, and will doubtless find favour with those who appreciate at their full worth this interesting section of the Lenten Rose. The plant possesses all the good attributes of the species from which it springs, and, apart from that deeper tone of purplish plum colour characteristic of these plants, the blossoms are larger and the sepals more widely separated, thus giving a less cupped character to the flower than is seen in some forms. The vigour and freedom of growth and flowering are all that could be desired, and for the rest the accompanying illustration will afford our readers a good idea of its bearing. It was exhibited before the floral committee of the Royal Horticultural Society on the 3rd inst. by Messrs. Barr and Sons, Covent Garden, when it received an award of merit. E. J.

### MUSCARI (GRAPE HYACINTHS).

THE Muscari, Starch Hyacinths or Grape Hyacinths, are familiar bulbs hailing from Eastern Europe, where they inhabit mountain slopes in the drier regions. They vary little from one another, and the group has proved a puzzling one to systematic botanists, and still more puzzling to the cultivator who has no herbaria at hand to help him in determining his specimens. There are, however, two distinct groups; one, of which the Musk Hyacinth is an example, has closed flowers with flattened tips, and which are mainly of grey or brown colouring with blue tops; the other group are mainly of blue colouring, the flowers being nearly spherical and closely aggregated in dense spikes. The members of the first group may be dismissed from consideration (with the exception of the Musk Hyacinth) as being of no garden value; the second group contains many useful garden plants.

The characters which separate the species are so minute (or wanting altogether, being lost in a host of geographical forms and seedling variations) that it is impossible for a monographer to accurately describe each plant's superficial details so that it may be readily determined, and as these details contain no cultural lesson, and the plants have no garden value as units, it will perhaps be more helpful to describe the prevailing colour of

masses and to remark such features that appear constant and easily recognised when they occur.

Muscari require no special treatment; all are hardy in the strict sense of the term, and they possess considerable hardihood in that they are able to live and thrive under harsh conditions, holding their own with grasses when naturalised, enduring droughts unharmed, surviving prolonged floods so long as they can maintain root-hold, and they appear to do just as well on a wind-swept hillside growing in hungry soils of limestone formation as in the richer soils of moist valleys and well-tilled gardens. Their increase is rapid, seedlings crop up by the thousand

purpose they are intended. In the Dahlia, as in *Chrysanthemums* and other subjects, it is not always the finest exhibition varieties that are the most popular when it comes to rough treatment. At the same time, it does not follow that a Cactus Dahlia should be condemned as a failure simply because it fails to give a good return when treated merely as a shrubby plant, when perhaps it is one of the most telling varieties on the show bench if properly cultivated. As each succeeding year there are a good number of new varieties added, and as old ones deteriorate, it is necessary, if the grower would keep his collection up to date, that he should add and discard accordingly.

HELLEBORUS PETER BARR.

(Natural size.)

around parent clumps and offsets are equally numerous, and so tenacious of life are they that one may hoe seedlings down several times a year and yet the plants manage to make growth in ungarded moments sufficient to build up a flowering bulb in its appointed time.

*M. alpinum*.—This has loose spikes of flowers which are abruptly closed at the throat; the lower bells are yellowish grey, as in *moschatum*, the upper ones blue, and a few buds at the tip of the spike are generally monstrous, i.e., are prolonged coloured pedicels which never bear open flowers.

*M. armeniacum* has small spikes bearing a small inflorescence of dark blue colouring, the outline of which is bluntly cone-shaped. The flowers are quite round, and they appear like the "pips" of well-formed Blackberries.

*M. atlanticum* has slender spikes of sky blue flowers, pretty in the mass and delicately fragrant.

*M. botryoides*.—A familiar blue Grape Hyacinth, the flowers of which are arranged in a loose spike, becoming widely separated from each other as the spike attains its full length. A pretty species for massing and a very prolific plant.

*Var. album*.—The dainty Starch Hyacinth. A neat-growing, white-flowered form whose leaves are pale green and whose stems are also whitish near the summit.

*Var. pallidum*.—A lilac-tinted azure blue form or selection, very refined in colouring and a capital rockery plant. Grandiflorum is a new form with larger flowers on spikes 6 inches to 8 inches long coloured a deeper azure blue. G. B. MALLETT.

(To be continued.)

### THE BEST DAHLIAS.

To grow suitable varieties is half the battle in exhibiting, and in a lesser degree success in any other branch of horticultural work is dependent on using those varieties most suitable for the

In the following notes I will endeavour to briefly describe a few of the finest varieties in all sections, commencing with the best exhibition Cactus sorts, which of all the family are the most changeable. Among the varieties introduced last spring are twelve really useful additions as follows:

*Lustre*.—Deep brick red, somewhat darker near the centre, florets quilled and slightly incurved, the blooms being of large size and borne on strong robust plants.

*Mrs. W. H. Ruby*.—A very free-flowering Cactus Dahlia, the plants being of dwarf and healthy growth.

The blooms are of average size but unusually deep. Colour, creamy white in the centre shading to white at the tips. Probably the best all-round white to date.

*Caradoc*.—A pure yellow possessing extra strong, erect flower-stems. Yellows being still very scarce this is well worth a trial, although possibly not seen quite up to expectation last autumn.

*Ruby Grinstead*.—One of the loveliest colours, i.e., a soft salmon fawn. The flowers are large and almost globular, but of the finest form, and although sparingly produced they last well and have very stout stems. To ensure getting a good bunch of this for exhibition several plants should be grown.

*Hyacinth*.—This variety flowers very much in batches, but is a beautiful flower and a telling one in competition. The form is very incurved and the florets narrow. The colour is yellow at the base but quickly shading to a mauvy pink. The plants are tall and of fairly good habit.

*Kathleen Bryant*.—Deep crimson and a dwarf, free-flowering variety of good form. It is very useful, and greatly needed on account of its colour.

*Rev. Arthur Hall*.—This variety was very disappointing, as it did not flower until quite late in the season; still, it is doubtless a good

thing. It is one of the narrowest-petalled Dahlias, and when good is difficult to beat. The colour is bright ruby crimson.

*Flag of Truce.*—Here we have a good white, but an uncertain one as regards flowering. Several excellent bunches were exhibited last autumn which possessed grand form and petals. The plants are very sturdy and have very stiff flower-stems. Like many other sorts, the cold, backward season may have been particularly detrimental to this variety.

*Eureka.*—This is a very large flower of most distinct colour, perhaps best described as a purplish plum colour, somewhat lighter at the tips of the petals. The blooms are very deep and they are freely produced on long stems.

*Daisy Staples.*—Mauve-pink, flowers freely, and has good stems; medium size.

*T. A. Havemeyer.*—A large-flowering variety; colour, yellow at base, shading to deep red, the tips of the petals being lighter.

*Clincher* produces huge flowers, but on pendent stems; colour, a beautiful shade of heliotrope on the outer florets, shading to almost white in the centre.

Coming to older varieties, I can but briefly describe them. The best of these are:

*Nelson.*—A grand flower when in form, but very uncertain as to depth; colour, purplish crimson.

*Mrs. Macmillan.*—One of the most reliable Dahlias; form neat, stems good; white in the centre, quickly deepening to pink.

*Wm. Marshall* is another very reliable exhibition variety, and one of the largest. The plants are of very strong growth; colour is orange to yellow in the centre. It is best shown not too large, when it is much more refined in the florets.

*Mrs. Geo. Sterenson.*—Pure yellow, a variety of very upright growth, with stiff flower-stems. The blooms are star-shaped.

*Mrs. F. Grimsted.*—A very dwarf variety, making very little wood, yet flowering freely and producing large blooms of good form; colour, deep rich crimson, with purplish shading.

*Star.*—Yellow to light orange, a striking colour; form star-like, habit of the best, and an easy variety to grow.

*The Pilot.*—Colour, bright yellow, shading to bright terracotta. The flowers are carried on stiff stems; a reliable Dahlia.

*Faunus.*—A variety above the average in size, with long narrow florets. Useful and constant.

*Oscar.*—The plants are dwarf and sturdy, and the blooms are carried perfectly erect. They are of medium size and neatly formed. The colour is bright crimson scarlet.

*H. Shoemith.*—Deep crimson, very narrow florets indeed. Plants very dwarf, free and of erect habit.

Regarding the plants only as suitable for cutting and garden decoration, the following are the best new sorts not mentioned above:

*E. Cadman.*—Deep red, florets straight and evenly arranged, the flowers being deep. A good Cactus.

*Countess of Malmesbury.*—A lovely light pink, the flowers being well away from the plants on stiff stems.

*Thomas Challis* has an erect habit, producing neatly made flowers on good stems. Colour salmon.

*Acrobat.*—A sturdy strong-stemmed bi-coloured Cactus. Not very free but a striking variety.

Of older sorts and sorts already mentioned, Caradoc, Daisy Staples, Lustre, Mrs. W. H. Raby, Mrs. Macmillan, Primrose, Star, The Pilot, Delight, Thomas Parkin, W. Jowett, Sirius, Mrs. H. L. Brousson, Floradora, Eva, General French, Spotless Queen and Britannia.

Almost every year witnesses the introduction of another new section, and thus the Fancy Cactus, since they have a class devoted to them at the National Dahlia Society's shows, must be recognised here. The best six of these are:

*Meteor.*—Pinkish white ground, speckled and striped with crimson and purple. Form very incurving, almost ball shaped.

with white. A bouquet composed entirely of this at the National Dahlia Society's show was a perfect picture.

*Nain.*—Dark chestnut, a free-flowering variety, the blooms keeping good in the centre.

*Mignon.*—Although not really small enough to be classed as a Pompon Cactus, this is a useful and beautiful Dahlia, being a strong healthy grower and producing quantities of perfect blooms. The colour is deep pink with lighter centre.

*Coronation.*—Crimson-scarlet, one of the best.

*Peace.*—White, a sturdy grower and just the type needed.

*Tomtit.*—One of the smallest, not over free-flowering, very fine petalled and neatly formed.

*Little Dolly.*—Another pink, somewhat smaller than Mignon, which it otherwise resembles.

P. P.

(To be continued.)

## THE QUEEN OF SAXIFRAGES FROM SEED.

*SAXIFRAGA LONGIFOLIA* is not inappropriately named the Queen of Saxifrages, inasmuch as the individual rosettes are the largest of all the encrusted section, which give it a singularly ornamental appearance when not in flower.

From the seedling stage it slowly gains strength and increases in size and beauty throughout the years till eventually the accumulated vigour of the plant finds expression in a pyramidal head of blossom composed of hundreds of flowers; this crowning event, when it occurs, terminates the life of the individual. Unlike the majority of encrusted Rockfoils, *S. longifolia* never produces offsets, so that it can only be raised from seed, which ripens readily in the open air, but owing to insect agency in cross-fertilising the flowers, the progeny will often exhibit a multitude of forms; to ensure the type coming true, the flowers must be fertilised by their own pollen, which can be best secured by enclosing a part of the flower-spike in a fine muslin bag.

The seed may either be sown in autumn or in spring, as it germinates readily at any of these seasons; the soil should consist of sharp grit and loam, to which is added a small quantity of old mortar rubble, unless the loam is natural limestone soil. Germination may be accelerated in mild warmth, but as soon as the seedlings are evident a cool treatment is much safer owing to the risk of damping off, and as soon as the little seedlings are large enough

to handle they are pricked off into pots or boxes, allowing a distance of 1½ inches between them and using a compost similar to that named already.

The following summer the plants are large enough for potting singly, which is the most convenient system to adopt; the pots require liberal drainage at all times, and from this time forward a small quantity of peat in the compost imparts a degree of coolness which the roots particularly delight in, though no amount of sunshine ever comes amiss to the vegetative parts.

When large enough for permanent planting, a vertical position, such as illustrated, should be given, as then superfluous moisture rapidly drains away, while a cool root run should be the

THE QUEEN OF SAXIFRAGES (*SAXIFRAGA LONGIFOLIA*) THREE YEARS FROM SEED.

*Mrs. Caselton.*—A tipped variety, being reddish salmon at the base with white tips. The plants are not very free, but the flowers are neat and pretty.

*Victorian.*—Probably the best all-round Fancy Cactus. White ground thickly striped and speckled crimson.

*Cockatoo.*—Unique colour, yellow tipped with white; pendent habit.

*Columbia.*—Red, tipped white; very reliable.

*Sirius.*—Yellow ground, striped crimson. An old but very reliable fancy.

In the Pompon Cactus we have a section which, as it becomes better known, will be a very popular one. The best of these are

*Gracie.*—A most lovely little flower, the base of the florets being bronzy yellow, then tipped

cultivator's aim at all times, selecting a sunny exposure, for in such positions the lime incrustation upon the leaves is fullest developed.

THOMAS SMITH.

Walmgate Gardens, Louth, Lincolnshire.

### TULIP PRINCE OF AUSTRIA.

I AM led to write these lines from finding that a friend who is well up in gardening matters, and who every year grows a nice collection of spring bulbs both indoors and out, does not know Tulip Prince of Austria. One has read of a devotee of Sir Walter Scott who said that he wished he had never read any of his novels, so that the pleasure of reading them for the first time might be something which he had yet to enjoy. Just so with this Tulip. I almost wish I did not know it, for I can hardly imagine a more pleasant surprise than to come across it for the first time. Jenny, Princess Helen, Proserpine, Duchess of Parma, Vermilion Brilliant and Couleur Cardinal are each in their way lovely flowers and special favourites of mine; but not one of them has so many good points, all as it were combined in one single plant. It has a splendid habit, a good constitution, a peculiarly taking colour and a most delightful perfume. As a catalogue now before me says: "Prince of Austria may be called 'the forcing Tulip' *par excellence*." The same almost might be said of it as a "bedder." This last spring I had a large bed in front of my dining-room window. Not far away was one of Duchess of Parma, and there were good-sized clumps of Arlis, Cottage Maid, Chrysolora and several others. I thus had a good opportunity of making comparisons. Two things were most noticeable—first, Prince of Austria retained its petals for a longer time than any other; and, secondly, owing to this characteristic, and also because the warm orange red of its first opening gradually passed with advancing days to a real orange, it practically made two beds. Its thin, wiry stems carry the long, sweet flowers without any support even under glass, and the particular shade that they then assume is just as pleasing, if not more so, than when it flowers in the open border. I have some pots and boxes in my greenhouse now (February 3), which will be in full glory before many days are over. On second thoughts I

begin to wonder, would the surprise of seeing them for the first time be more than the pleasure of anticipation with which I now look forward to seeing again well-tried and too-long-absent old friends.

JOSEPH JACOB.

### TWO OF THE BELL-FLOWERS.

(*CAMPANULA PUSILLA ALBA* AND *C. ALPINA*.)

IN "Nicholson's Dictionary of Gardening" *Campanula caespitosa* and *C. pusilla* are given as two distinct plants; but in practice it is impossible to distinguish any difference between them. Their dissimilarities, if any, are so minute as to have no importance in horticulture. The plant is the commonest as well as one of the loveliest of all the little *Campanulas*, thriving in sunny or shady places among rocks or on level ground. Its culture involves no difficulties, it being one of the easiest of plants to grow, in this respect differing greatly from the majority of alpine plants, many of which are exceedingly capricious plants. It flowers from June until October, and may be used indiscriminately for edgings, carpets, or the rock garden. It is very close and erect in growth, rarely forming flower-stems over 5 inches in height. The lanceolate leaves are light green, and are carried on thin, wiry stems, with small, drooping, pale blue flowers. The pure white variety is even more charming, and has a freer habit than the type. Of this there are two forms, one almost entirely disappearing in the winter, while the other is evergreen, keeping the ground carpeted during the dark days of the year with emerald foliage. It is easily increased by division or seed and rejoices in a calcareous soil, so that limestone chips should be added in quantity to the loam in which it is grown.

*C. alpina* is a rare plant in cultivation, but a very beautiful one and closely allied to *C. barbata*. It forms a small, dense tuft of narrow, grey, downy leaves, and sends up a flower-spike rather over 6 inches in height bearing drooping bells of a deep purple-blue tint. It flowers in May and June. It appreciates rich soil, and should be given a compost of leaf-mould and loam in equal proportions mixed with an abundance of limestone chips. It often proves a difficult subject to grow, in some gardens dying out after flowering.

S. W. FITZHERBERT.

## THE ROSE GARDEN.

### MULCHING FOR ROSES UNDER GLASS.

ROSES, like Vines, revel in a good mulching, not of cold and wet manure, but a good reliable mixture, something that will attract the young fibrous roots to the surface. It frequently happens that a border of Roses will flourish admirably for a year or two under glass and then show signs of exhaustion. The skilled cultivator will anticipate this state of things and provide his plants, be they pot grown or planted out, with some nourishing food. An excellent mixture is as follows: Two parts pulverised sheep's manure, three-fourths of a part of wood ashes, a fourth of a part of fine bone-meal and four parts good soil. Give a liberal application of this now before the plants become too far advanced.

Where possible let this take the form of a top-dressing rather than remove existing soil, but where the pots will not allow of this some pieces of slate stuck around the pots will give additional space. In a week or two it will be found that the fine roots have not been slow to find out the food. Such a mulching as this would be most beneficial to outdoor Roses that seem to need help in the growing season, say, about May.

P.

### WICHURAIANA ROSE DEBUTANTE.

ALTHOUGH not profusely produced, there is something charming about the late sprays of bloom which this Rose yields. Even as late as the first week in December pretty little flowers could be cut, and they are particularly welcome when upon most of the pillars there are few, if any, Roses to be seen. There can be no question that raisers will soon be giving us a group of late-flowering rambler Roses of the *wichuraiana* tribe, and considering the readiness that this tribe can be mingled with other groups by crossing, we are hopeful that such lovely gems as René André and Alberic Barbier will be produced as autumnal bloomers.

P.

TWO OF THE BELL-FLOWERS (*CAMPANULA PUSILLA ALBA* AND *C. ALPINA*).

## GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**H**ARDY FLOWER GARDEN.—Although it is getting late, hardy creepers may still be planted. I am just finishing planting the Clematises, Passion Flowers and Honeysuckles. The beautiful *Crocsmia aurea* and *C. imperialis* may be planted now; when the bulbs are planted about 4 inches deep and from 4 inches to 6 inches apart I find they invariably do well. This subject should have a nice warm border with a sunny aspect. The different forms of the Pansies should be planted forthwith; for a free and interesting display, however, I plant the Tufted Pansies. These plants revel in soil that has been deeply dug and enriched with a heavy dressing of good, partially rotted manure. Hardy Ferns succeed well when planted at the present time. I find it a good plan to plant them in both shaded and partially shaded positions.

*The Window Garden.*—My window plants are responding generously to the extra attention they have received of late. The rule is to periodically sponge the leaves of foliage plants to cleanse them from accumulations of dust, their appearance being much enhanced by using tepid milk and water occasionally. Old Geraniums and Fuchsias may be repotted with advantage just now. Fresh, sweet soil and clean, well-drained pots are important factors in successfully treating

Milan Turnips, Carrots, Onions, Radishes and Lettuces. I am taking advantage of fine days when the soil is friable to make any sowings of

1.—OLD PANSY PLANT LIFTED FOR DIVISION.

second early Peas. Peerless Marrowfat, Duke of Albany, Telephone, Daisy and Telegraph should be sown forthwith; these should come into bearing just as the earlier varieties have finished.

*The Greenhouse.*—Glass houses, in which Azaleas and other spring-flowering plants are blooming freely, should be shaded from bright sunshine or their display will not last very long. I find that by tacking a breadth of tiffany to the inside of the roof an effective shade can be provided. This must be done where there is no roller blind, and I do not care to make use of a permanent shading of the nature of a wash.

*Roses.*—Pruning is the all-important work at this period. I commence with what are known as Hybrid Perpetual varieties. Prune these Roses back moderately and well thin the branches, retaining shoots having a firm, hardened appearance, each of which has conspicuous "eyes," from which the subsequent growths are to be obtained. By these means I procure many very handsome flowers in late June and early July. Where a quantity of blooms are desired rather than a limited number of those of good quality, the trees must be pruned less hard. Varieties differ, making it necessary to cut away extra grossness of growths that spoil the even formation of a tree. The less vigorous shoots should be cut back to within about 9 inches. Roses of medium growth, such as, say, Charles Lefebvre, should be shortened to about 6 inches. The Tea-scented Roses must not be pruned for a week or two yet. The present is a good time to top-dress the beds and borders, using well-decayed manure and forking this in. D. B.

## INCREASING PANSIES IN THE SPRING.

The orthodox method of raising new plants of the named Pansies is by cuttings in the late summer or during the autumn months. The summer insertion of the cuttings is carried out with the object of planting the resulting plants in the succeeding autumn, usually during the earlier half of October; and this for producing a free display of blossoms in the spring and early summer is, without a doubt, a most satisfactory rule to follow. However, it is not always possible to deal with them in the autumn; but Pansies may be easily increased in the manner described below.

*Lifting the Old Plants for Division.*—Anyone who possesses a garden frame, or who can make a temporary structure that will answer the same purpose, may lift and divide Pansies with the greatest ease. Four small planks or boards, 6 inches to 8 inches in width and of a length to suit the requirements of the grower, may be nailed together in the form of a frame, and this covered with a spare frame-light or old window-sash. Throughout March and April the old plants that were cut back late in the autumn should be represented by plants of tuft-like form, and each with a large number of sturdy little shoots that divide up into useful pieces very readily. In some gardens this cutting back of the Pansies may have been neglected, and the old plants may even now have the old coarse, elongated growths still adhering. Should this be so, cut back these old, useless shoots forthwith, and after leaving the old plants for a time, say, a week or a fortnight, lift and treat them as we now prescribe for plants that were cut back last autumn. Fig. 1 represents an old plant lifted from the hardy border. The plants vary in character considerably, some being more tufted in form than others. If the old clumps are lifted with care, many of the roots may be preserved intact, and quite a large number of pieces may be obtained with a quantity of roots adhering.

*Dividing the Old Plants.*—If the old plant is firmly gripped with both hands in the first instance, and the thumbs and fingers pressed well into the base of the growths, they will divide quite easily. See that the division takes place among the roots rather than among the growths. A few of the shoots will be useless for perpetuating the stocks, and for the guidance of the inexperienced such pieces are illustrated in Fig. 2. It will be noticed that these growths are coarse, and, although some of them may root, they cannot be regarded as desirable, as they would ultimately lack the vigour that younger growths with roots adhering almost invariably evolve.

*The Best Divided Portions.*—Fig. 3 represents the varying character of Pansy growths. The biggest piece in the centre may be planted intact, or each of the young growths may be detached

2.—SOME OF THE OLD AND USELESS GROWTHS.

these plants in the spring. In a little while new and vigorous shoots will develop, and these will make the window gay throughout the summer. Bulbous subjects, such as Hyacinths, Tulips, Daffodils and Crocuses, as they go out of flower should be removed to a cool shed or spare room, and the soil kept just moist only until the foliage becomes seared, then they may be shaken out and stored away until next autumn. In this way I make use of the bulbs a second time, planting them in spare corners outside another season.

*Vegetable Garden.*—There is plenty of work to do here just now. Many seeds have still to be sown for both summer and winter vegetable supplies. Sow the following seeds without further delay: Broad Beans in drills 3 inches deep and from 2 feet to 3 feet asunder; Parsnips, in deeply-dug quarters, in drills 15 inches apart and about 1 inch deep; main-crop Potatoes about 7 inches deep and in drills rather less than 3 feet asunder. The "sets" should be placed about 15 inches apart in the rows; vigorous growing sorts require rather more space between them. Available quarters I am now sowing with Early

3.—GOOD GROWTHS THAT SHOULD BE RETAINED: NOTE THAT EACH HAS SOME ROOTS.

and these inserted with the others in some light sandy soil. Shoots without roots should not be discarded, as they will, at this period, root in a comparatively short time. Some of the cuttings will need to be trimmed of seared or decaying foliage. This treatment will enhance the success of root formation, and enable the grower to raise a large number of plants.

4.—AN EXCELLENT PANSY OR VIOLA FRAME.

*Suitable Soil for Propagating Purposes.*—Light sandy soil is suitable for the cuttings. We make up a mixture of loam, leaf-mould and sand in equal quantities, and pass this through a sieve with a half-inch mesh. Subsequently, the heap is given a thorough mixing and then it is ready for use. The quarter in the garden allocated to the frame is then dealt with, being dug over and levelled, if this has not been done already. A warm aspect should be selected if possible.

*A Good Type of Viola Frame.*—The shallow, span-roof frame represented in Fig. 4 is an ideal one. For all hardy plants and for bringing on other less tender subjects it is almost indispensable. We prefer it to the ordinary cold frame, because ventilation is so easily carried out, and the plants derive so much benefit from light all round. It is 10 inches at the sides and 20 inches at its apex; because of this the plants are always kept so stocky, and are always so very easily controlled. The frame-lights are hinged and can be opened on either side as a protection or otherwise, whichever way the wind may be blowing. Fill in to the depth of from 4 inches to 6 inches with the prepared soil, level, and make firm. Insert the pieces in rows, starting first with a label bearing the name of the variety being dealt with, and following on with each variety in similar fashion. The rows should be about 3 inches asunder. Dibble in carefully and see that the soil is firmly pressed at the base of each one. Water in with clean water from a fine rosed can when the work is done, and keep the frame rather close for a time, i.e., until root formation is denoted by growth at the apex of each shoot. Fig. 5 shows a frame filled with divided pieces that are doing well. When rooted, give the plants abundance of air.

#### REPOTTING ROOM AND WINDOW PLANTS.

POSSIBLY more mistakes are made in the repotting of these plants than in any other phase of their culture, with the exception, perhaps, of watering, and much harm may easily be done in this direction by those who are not conversant with a plant's likes and dislikes and its period of growth. The best time of all to repot practically all plants is just when new growth is commencing after a period of rest, and this especially applies to those now under notice. It may be taken as a good general rule that plants grown in rooms and windows rest more or less during the winter months, new growth commencing with the advent of spring; hence it will be seen that the best time of the year for repotting these is in April.

The first question that will arise is that of suitable soil, and although different plants may prefer different soil mixtures, practically all those grown in rooms and windows will thrive in the following: Good fibrous turf that has been stacked for at least six months two parts, leaf-mould or well-decayed and flaky manure one part and sand one part, with a quart of bone-meal added to every barrowful of soil. The loam or turf is best pulled to pieces with the hands, lumps about the size of Walnuts being preferable.

The leaf-mould must have any sticks or other rubbish removed, and it or the manure may with benefit be passed through a three-quarter-inch meshed sieve. Mix the whole well together and use when it is moist, not wet. A good test is to take a handful of the mixture, squeeze it tightly and then let it fall a distance of 2 feet to the ground. If it breaks up it will not be too wet, but should it remain in a ball it will need some drying. Very dry soil must also be avoided.

The size of pots must next be considered, and, generally speaking, those 2 inches more in diameter than those in which the plants are at present growing will suffice. In some instances pots of the same size or even smaller may be advisable. All must be scrubbed quite clean, both inside and outside, and on no account use them until they are dry. New pots must be soaked in water for about ten minutes, and the inner and outer surfaces allowed to dry before using. If this is not done, and the new pots are very dry, they will absorb the moisture from the soil to the detriment of the plants. Place a good-sized piece of broken pot, concave side downwards, over the hole in the bottom of the pot; then over and around it place some smaller pieces so as to get nearly an inch of drainage. Over this place a little rough soil, and the pot is then ready for the plant.

Turn the latter carefully out of its pot by placing the fingers across the surface of the soil and turning it upside down, giving the rim of the pot a smart tap on the edge of the bench. If the plant is healthy and needs repotting it should be a mass of roots, and care must be taken not to injure these. With a pointed stick carefully unwind the roots that are among the old drainage material and remove the latter. Then loosen some of the most healthy-looking roots round the sides, remove any loose soil from the surface, and place the ball of roots and soil in the new pot, taking care to get the plant in the centre. The depth to pot is a point where many beginners go astray; a good rule is to pot not more than a quarter of an inch lower than the plant was in its old pot. A potting-stick or rammer will be necessary, and this may be made from a 1-inch or 1½-inch wide lath, making it level at the end. Place some soil round the old ball of soil and roots and ram it with the potting-stick, keeping the latter close to the side of the pot so as not to injure the roots. Moderately firm ramming only will be required for most plants. Make the surface level and tidy, leaving half an inch space for watering. Give one good watering with a rosed can, and for the next two or three weeks water very carefully indeed, keeping the plants away from bright sunshine until established.

Where sickly plants are being dealt with, the above procedure must be varied. It will usually be found that when a plant is sick its root system is in a bad condition, and to repot it as advised above would only make matters worse. Turn the plant out of the pot, carefully shake or pick away as much of the old soil as possible, and then wash the roots quite clean under a running tap. Most likely many of them will be dead and decaying, and these must be cut away, retaining only those that are alive. This is a

case where a smaller pot will most likely be best, and instead of 1 inch of drainage provide 2 inches or even 3 inches for good sized pots. Also leave out the bone-meal and manure from the soil, making up a mixture of two parts decayed turf, two parts sand, and one part leaf-mould. Use only the fibrous lumps of the loam or turf. In repotting these sickly plants a potting stick is not usually required, the soil being best tugged moderately firm round the roots with the fingers. The watering must be very carefully carried out for a considerable time, so as to encourage new roots to penetrate the fresh, sweet soil. A light syringing overhead daily, the plants being taken to the kitchen sink for the purpose, will prove of great benefit.

#### EARLY LETTUCES WITHOUT GLASS.

It often happens that the owner of a garden where no glass structure exists would like an early crop of Lettuces from a spring sowing; and his or her wishes may be gratified with little trouble or expense. Select the warmest position available in the garden, and, if the soil is heavy or composed chiefly of clay, add a liberal amount of road scrapings, leaf-soil, or well-decayed manure, so as to lighten it up somewhat. Then draw a few shallow drills 1 foot apart and sow seeds of a quick-growing Cos variety, such as Giant White Cos, scattering them thickly in the drill. Cover with half an inch of fine soil, and no more attention will be needed. When the seedlings appear growth will be comparatively rapid, owing to the plants standing close together. When from 2 inches to 3 inches high they may be cut the same as we cut Mustard and Cress, and a very tender and welcome salad will be provided. A sowing may be made for this purpose at once.

#### THINNING ANNUALS.

ALTHOUGH writers in the horticultural press have for years been trying to impress upon their readers the absolute necessity for thinning the seedlings of annuals as soon as the work can possibly be done, one still encounters patches of these plants, especially in amateurs' gardens, that look as though the owner desired a mass of greenery instead of the beautiful flowers that many annuals, under proper treatment, are capable of producing. It is of little use to allow the seedlings to remain crowded until they attain a height of several inches, because the mischief is then accomplished. Early thinning must be resorted to, giving each seedling plenty of room so that it may develop into a sturdy plant that will be a pleasure to behold. Should any sceptics read this note, perhaps they will try both ways this summer and note the results.

5.—FRAME FILLED WITH DIVISIONS: NOTE HOW EASY IT IS TO VENTILATE SUCH A STRUCTURE.

## THE TOWN GARDEN.

**SINGLE DAHLIAS FROM SEEDS.**—Those who desire to have an abundance of blooms of single Dahlias for the adornment of their rooms and who do not want the trouble, or have not the convenience, for winter storage of the clumps are not debarred entirely of their fancy, for they can grow any quantity from seeds. Strong plants raised in the spring will flower the same season if planted out on deep, thoroughly worked ground early in June, and though they may not yield flowers good enough for exhibition, they will prove invaluable for decoration. The seeds can be purchased quite cheaply, and should be sown at once in boxes or pans of light soil—such, for example, as a mixture of equal parts of loam and leaf-mould, with enough sharp sand to keep it open. Put this in the receptacle, make the surface firm and level, thoroughly soak with water and after the lapse of an hour or two sow the seeds very thinly. Either a greenhouse or a warm frame will serve admirably to start with, and as soon as the seedlings are through and large enough to handle, let them be pricked off into rather stronger soil singly in small pots. From this stage a frame where they will be perfectly safe from frost is preferable to a greenhouse, as there is not the same liability to drawing up and consequent weakness. Except for watering, which must be done with the greatest care after moving, the plants will not make much demand upon the time of the grower, and the returns in flowers will most generously compensate him for the trouble taken.

**THE GRASS PLOT.**—The town garden without its lawn or grass plot is scarcely worthy the name of a garden at all. At this season of the year it is possible to give such help as will prove beneficial to the grass right through the summer, and the satisfaction derivable from the lawn will be proportionately greater. If there are any bare patches, scratch them over with an iron-toothed rake and sow seeds rather thickly. This done, spread over the entire surface the siftings from old potting compost—it is, of course, imperative that all corks or stones shall be removed—and this will cover the seeds and at the same time make the grass somewhat unsightly. This condition will, however, be only temporary, for the succeeding growth will be stronger, greener, healthier and brighter as a result. If it is not possible to use the material named, quite as much good will be done by dressing on the refuse from an old hot-bed. Most amateurs make up a little bed for raising seedlings in the spring, and the old material that has done service for this purpose should never be wasted. In either of these cases the rains will soon wash the material away and the lawn will become clean again. Failing these things we may have recourse to concentrated plant foods, and for March and April application there is nothing to excel nitrate of soda or sulphate of ammonia, according to convenience, provided that care is used not to apply more than 1oz. to the square yard. The soda may cause a little browning, but this will soon pass off and leave a beautiful sward. Whenever the weather is favourable the grass should be thoroughly rolled with a machine of medium weight, while cutting must be done as soon as necessary, setting the knives rather high for the first and second cuttings, which may be left on the surface.

**SURFACE SOIL.**—Now that practically all the plants are pushing their growths through the surface of the ground it will be safe and markedly advantageous to loosen the top soil so as to allow of the free admission of warm air, as this will encourage growth. In many cases it may not yet be quite safe to use the hoe; but a planting fork attached to a long handle will do the work splendidly. This should be one of the routine operations, as it can never do harm.

H. J. WRIGHT.

## GARDENING OF THE WEEK.

## FOR THE SOUTH AND SOUTH MIDLANDS.

## PLANTS UNDER GLASS.

**P**LANTS raised from seed during the past month should receive attention as soon as they are large enough to handle, pricking them out into pots or pans which have been prepared with some rich fine soil, this being carefully looked over for grubs and worms. When pricked out shade from bright sunshine for a few days, but keep them in a light position, and now that the days are getting longer the house or pits where these are grown should be damped down several times daily.

*Caladiums* that have filled the pots with roots must have a shift into a larger pot, and at this potting use coarser material with plenty of sharp sand. The little variety known as *Argyræ* should now be potted up into small pots, as it is very useful for decorative purposes, but must not be overpotted.

*Cucumbers.*—Top-dress these plants as soon as the roots are discovered coming through; little and often is the best method to ensure success. Keep the vines nicely tied in and cut the fruits as soon as large enough. Stop the plants at the next joint to the fruit.

## FRUITS UNDER GLASS.

*Melons.*—Allow the plants to run up the roof its entire length before stopping, and get a good set before allowing any to swell. Sow for succession. There are endless varieties now, but growers should rely for the main-crop on some approved variety. As regards flavour, green-fleshed varieties seem to be the most popular with our employers.

*Figs.*—Trees, whether planted out or in pots, when swelling their fruits must have abundance of water at the roots, or the fruits will probably drop. Trees in pots should have manure every week. Tie in enough young growths, but do not overcrowd them. Any barren or misplaced shoots must be cut out and replaced with new ones. Pinch the leading shoots at about the fifth leaf, as this will mean the production of the second crop. Keep plenty of moisture in the house, syringe twice daily, and shut up with a good solar temperature.

*Vineries.*—Continue to thin and tie as recommended in the last calendar. A little more heat may now be given the Muscat house. All Vines ought to be started now, as the latest Grapes require a long season to ripen well, especially for late keeping.

## KITCHEN GARDEN.

*Asparagus Beds.*—The manure that was put on in the autumn has now done its duty, and the roughest portion may be raked off. Then give a dressing of some artificial manure, and with a fork prick it all over and make tidy. In about a fortnight an application of common salt will be found beneficial, both as a manure and a weed killer.

*Seakale* may be sown or planted at any time if the ground is ready. I prefer planting sets, those prepared from long, straight roots or thongs, as advised in a former calendar, being the best, as extra good crowns can be got in six months under skilful treatment.

## LAWNS.

Prepare ground for the reception of grass seeds, as these must be sown during the next fortnight. Lawns of cricket or golf grounds must also be kept swept and rolled frequently with a heavy roller.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardlee, Horsham, Sussex.

## FOR THE NORTH AND NORTH MIDLANDS.

## PLANTS UNDER GLASS.

**CALADIUMS.**—These are not difficult plants to cultivate. Heat and moisture are the two chief essentials to success, and given these the rest of their treatment is easy enough. If not already done, no time should now be lost in starting the corms into growth. In regard to soil, I find that the best of leaf-soil, with a little good loam and road scrapings, are as good a choice as can be made, two-thirds of leaf-soil to one of loam being a good proportion. Failing good loam, I have added old Mushroom-bed manure with excellent results. Firm potting is not needed. All the work may be done with the hands, unless it is a large plant to which a shift is being given during its growth, then a potting-stick may be useful, but it should be used sparingly.

*Begonia Gloire de Lorraine.*—When shoots can be obtained about 3 inches or 4 inches long they should be inserted singly in small pots filled with loam and leaf-mould in equal proportions, with plenty of silver sand, care being taken that the soil is made firm round the cuttings. Water and place them in a propagating frame with bottom-heat of about 80°, plunging the pots to the rims in Cocoanut fibre and shade from sunshine.

## FRUIT UNDER GLASS.

*Melons.*—The earliest Melons are sufficiently advanced for planting out, and it must now be determined whether they are to occupy ordinary mounds on beds or to fruit in pots. Where time is a consideration, the pot system is to be preferred, as the roots, being confined to a narrow limit, are more under the control of the cultivator. In potting use a good sound calcareous loam, adding a portion of old mortar rubble as a corrective. Let the collar of the plant stand well above the soil and ram firmly. When the holes are made, and before plunging, place a piece of slate in the bottom of each for the pots to stand on.

## KITCHEN GARDEN.

*Tripoli Onions.*—The first favourable opportunity should be taken to transplant these, it being better to get them established in the ground while the latter is in a moist condition and before the sun has too much power. The plants may be put out about 6 inches apart, and the rows should not be closer than 1 foot. Each plant should be made quite firm in the soil.

## FLOWER GARDEN.

*Tufted Pansies.*—Apart from their value on the border, these make charming pot plants, and as such may be recommended to the notice of those whose space is limited for planting them out. Cuttings inserted early in August and wintered in cold frames should now be potted into 4-inch or 5-inch pots, using a compost of nice sandy loam with which a small portion of spent Mushroom soil, well rubbed to pieces, has been incorporated. The plants will bloom early and continue to flower all through the summer if seed-pods are promptly removed and they get the help of a little weak manure water when the pots are full of roots.

## ORCHIDS.

*Lycaste Skinneri* is still one of the best and most easily-grown Orchids for cutting, and what makes it more useful is the long time its large fleshy blooms remain good on the plants and in a fresh state in water. Grown cool it is surprising what a lot of bloom a strong plant will produce. I find good turfy loam mixed with peat gives stronger flowers, but if loam is used more drainage is required, adding a few lumps of charcoal to keep the compost sweet.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Position for *Lychnis Haageana*** (*Subscriber*).—This plant prefers a sunny position and a moderately light well-drained soil. If to the soil of the bed of which you speak you could add a good proportion of leaf-mould, grit and very short manure, we think the plants would be quite a success therein. In planting keep the semi-tuberous rootstock not less than 3 inches below the surface. In some soils and localities the slug is a most troublesome pest during winter, eating both crowns and rootstock. In winter time you might mulch the bed with fine ashes to keep the pest at bay.

**To grow large Sweet Peas** (*S. P. Oxted*).—You cannot do better than follow out the instructions given in Mr. Horace J. Wright's article that appeared in THE GARDEN for January 4. It is rather late to commence operations now, but if you trench and manure your soil well it should give you good results. Whether you will be able to secure flowers as large as those depicted in the coloured plate is very doubtful, as light soil is not ideal for these plants. But you should have no trouble in getting stems at least 9 inches long. On really good soil and under first-class cultivation we have seen stems 30 inches long.

**Blue-flowered Hydrangeas** (*Spero*).—Blue flowers may be produced on the Hydrangea by means of sulphate of iron. It may be mixed with the soil before potting or it may be applied in solution afterwards at intervals while the flowers are being formed. The exact proportion necessary depends to a great extent on the nature of the soil used, for if there is a certain quantity of iron in the soil less is needed than if it is almost absent. It is only by experiment that the correct proportion is arrived at, but in mixing soil for potting a tablespoonful may be added for each peck of soil. For watering the plants afterwards about twice a week a pinch may be added for every two gallons of water.

**Plants for pond** (*Ashdown*).—The old pond with its rich mud soil and damp bottom should afford ideal conditions for the lovely group of *Kämpfer* Irises, also *Iris sibirica* in variety, *I. ochroleuca* and many others of the flag and allied sections. The Willow herbs would also be good, and you might with advantage add such *Spiræas* as *Aruncus*, *giganteus*, *venusta*, *palmata*, *p. alba*, the taller *Thalictrums*, *Acanthus latifolius* and *Telekia speciosa*. By the addition of peat soil here and there mingling with the present soil, such Lilies as *canadensis*, *pardalinum*, *superbum*, and others, as *L. Henryi*, *L. auratum* *platyphyllum* could be grown. For autumn effect the herbaceous *Lobelias*, and particularly *L. fulgens*, *L. syphillicia*, *L. cardinalis* and their following, should be seen, while in spring free plantings of such *Narcissus* as *Emperor*, *Incomparabilis* in variety, *Poeticus fl.-pl.* *princeps* and others would be delightful. By a little arrangement an ideal spot could be

created. The Daffodils could not be planted before September; all else could be planted at any time now.

**Moving Winter Aconites** (*E. M. L. B.*).—It will be better to wait until the growth is well matured before you remove them, and at that time it will be to their advantage and future success if you divide the plants quite freely. When replanting make allowance for the future development of the tufts.

**Exhibiting alpine** (*Amateur*).—"Three alpine in pots, distinct genera," is by far the more finished and explicit term in this case, and cannot in any sense be misconstrued. "Three alpine in pots, genera" is an incomplete and unfinished phrase, and the addition of the word "only" is necessary to an intelligible rendering. Brevity and clearness are the points to be aimed at by flower show committees and schedule-makers, and this cannot be improved upon in the present case so far as it goes. Its weak point, assuming you have given us the full and complete wording of the class, is that the plants may be shown in or out of flower, and, though flowering plants may be inferred, it is not so stated. A more complete rendering, therefore, would be: "Three alpine in pots, in flower, distinct genera." The last word has not our fullest sympathy, because in spring some genera—e.g., *Saxifraga*—are strongly represented, and greater latitude to exhibitors, and a wider sphere of usefulness generally, should follow if the word "genera" were deleted, the class then reading: "Three alpine in pots, in flower, distinct."

**Plants for bank and stream** (*Furness*).—It were better to avoid the stone and plant the more picturesque of the moisture-loving plants to be in keeping with the pretty scene. You do not give the height or the extent of the bank, and these would have enabled us to decide as to the better plants for the purpose. The following, however, are all moisture-loving and would be suitable: *Acauthus latifolia*, *Tritoma uvaria*, *Camassias*, *Spiræa palmata*, *S. p. alba*, *S. venusta*, *S. Aruncus*, *S. giganteus*, *Monarda didyma*, *Hemerocallis* or Day Lily in variety, *Bocconia cordata*, *Iris abricica*, *I. Kämpferi*, *Telekia speciosa*, *Flag Iriæa*, *Primula japonica* (so that its roots may reach moisture), *P. denticulata* *cashmiriana*, *P. Sieboldii* in variety, *P. rosea*, &c. *Galtha palustris fl.-pl.* and *Picaria grandiflora* may be placed against the stones in the stream, and such things as *Lent Lilies* (*Narcissus Pseudo-narcissus*), *Narcissus poeticus ornatus*, *N. p. fl.-pl.*, *N. Emperor*, *N. obvallaris*, *N. princeps*, with many others, may be finely grown in the bank. The finest *Narcissus pallidus præcox* and *N. Queen of Spain* we have seen were just in such a cool spot as the picture portrays. Do not omit the common Primrose, the Wood Anemone, and the English Bluebell (*Scilla nutans*) for thin carpets or fringes to other plants. There is nothing so fine in woodland scenery or suchlike places as this delightful trio. All but the bulbs could be planted at once.

### THE GREENHOUSE.

**Plants for a greenhouse** (*A. B. Belfast*).—You may grow *Gloxinias*, *Primulas*, *Cyclamen* and *Begonias* in the structure named by you, as well as many other plants. None of the above require much heat; in fact, no artificial heat is needed throughout the summer months, when a free circulation of air is necessary. Such being the case, it is not well adapted for Orchids, though that well-known *Lady's Slipper* (*Cypripedium insigne*) would prove satisfactory therein. Other greenhouse flowering subjects that you might grow are *Clivia* (*Imantophyllum*) *miniata*, *Lantanas* of sorts, *Cannas*, *Streptocarpus*, *Fuchsias*, *Javanese Rhododendrons*, *Epiphyllums*, *Kalanchoe flammea* and *Achimenes*. There is also a considerable choice of foliage plants that would do well in such a structure, particularly *Araucaria excelsa*, *Aspidistra lurida variegata*, *Eurya latifolia variegata*, *Grevillea robusta*, *Ophiopogon japonicum variegatum* and the following Palms: *Chamærops excelsa*, *C. humilis*, *Corypha australis*, *Kentia belmoreana*, *K. forsteriana*, *Latania borbonica*, *Phoenix canariensis* and *Rhapis flabelliformis*. Ferns, too, must not be omitted, among the best being *Adiantum cuneatum*, *A. decorum*, *A. elegantissimum*, *Asplenium bulbiferum*, *A. dimorphum*, *Cyrtomium falcatum*, *Davallia bullata*, *D. Mariesii*, *Lastrea aristata variegata*, *L. varia*, *Neprolepis exaltata*, *Onychium japonicum*, *Pteris arguta*, *P. cretica* and varieties, *P. serrulata* and varieties and *P. Winsettii*. The plants above enumerated will thrive in a structure with a minimum winter temperature of 45° to 50°, rising 10° or so during the day. As the season advances the temperature will, of course, rise. During summer no fire-heat will be needed.

**Carnation leaves diseased** (*R. W. York*).—The leaves that you send are affected by a fungus commonly

known as rust. Spray the plants with methylated spirits and water, one part of the former 100 parts of the latter, using a very fine nozzle for the purpose.

**Hyacinths and Tulips in pots failing** (*A. G. H.*).—We have met with several instances of comparative failure this season in the case of bulbs that have been forced, and have come to the conclusion that most, if not all, of the trouble arises from the drill, cold summer experienced last year. In some districts it was also very wet, and these various adverse conditions would account for the bulbs being insufficiently ripened. This theory is also further borne out by the fact that the bulbs were so slow in rooting.

**Cleaning a Palm of scale** (*S. B.*).—We have never seen a Palm leaf in such a state from scale, and you have certainly plenty of work before you to clean it. Perhaps the most satisfactory way would be to put it on the fire; but, still, you may try to remove the scale without injury to the leaves. The better way will be to make a very strong lather of soft soap, and thoroughly paint the leaves on both surfaces with it. Then, after three or four hours, sponge the leaves well, a fair amount of pressure being necessary. Should any insects be left after this, repeat the painting and sponging. Another method may, perhaps, suit you better, and that is to paint over the leaves with methylated spirit, taking care that no part is untouched. Then, after two or three hours, sponge the leaves with soft soap. We have found methylated spirit very helpful in many cases, but have never had the opportunity of practising on anything so bad as the leaf you sent. The small black scale with which it is practically covered is the most difficult of all to dislodge.

**House for Orchids** (*Orchis, Manchester*).—We think such a house as you have built a very good one for an amateur. Your better way will be to grow what are usually termed Mexican or intermediate house Orchids; that is to say, those which can be successfully cultivated in a house with a minimum winter temperature of 50°, rising 10° to 15° during the day. As spring advances it will, of course, be kept somewhat warmer, but in very hot weather in the summer fire-heat may be discontinued. Even at that period, should the weather be cold and wet a little heat in the pipes is helpful. From this it will be understood that the temperature maintained is a fairly comfortable one at all seasons. The following is a selection of easily-grown kinds suitable for an amateur: *Cattleya labiata*, *C. Loddigesii*, *C. Mendelii*, *C. Mossii*, *C. Trianae*, *Celogyne cristata*, *Cypripedium insigne*, *C. leucum*, *C. apicarianum*, *Dendrobium nobile*, *D. Pierardii*, *D. wardianum*, *Leelia anceps*, *L. purpurata*, *Lycaste Skinnerii*, *Oncidium marshallianum*, *O. varicosum* and *Zygopetalum Mackayi*.

**Information about boiler pipes** (*Miss Jones*).—There would certainly be considerable danger to the plants by reason of the near proximity of the pipes, were the latter heated to any extent, for then the arid conditions generally, or the excess of steam when watering was being done, might do much harm. In such instances a close stage is best. Slates over the ordinary lath staging, and with sand or ashes thereon, or corrugated iron sheets also covered in the same way, would afford at once a cool and far more natural base for the plants, while dispensing with much watering and the usual host of insect pests delighting in, and inseparable from, great dryness. Even though the pipes be not unduly heated, there is ever present that greater aridity and lack of moist atmospheric conditions that play a great part in the successful cultivation of the plants themselves. By all means cover the staging over without delay with finely-sifted ashes or sand, or fine shell shingle if procurable. Thus arranged a spray now and again from the syringe will materially assist in the diffusing of those more genial conditions to plant life within the house.

### ROSE GARDEN.

**Pruning Rose Conrad F. Meyer** (*F. W. D.*).—Sometimes this very vigorous Rose is grown more as a shrub than as a bush plant, and in this case the plants would attain a larger size more quickly if not pruned the first year after planting. Should you desire to grow it as a strong bush or pillar, we recommend cutting back most of the growths about the middle of March to within about 2 feet of their base, but retain two or three growths from 3 feet to 4 feet long. It is evidently a clerical error on the part of the National Rose Society in describing Paul Neyron in their official catalogue as a Hybrid Tea. It is quite as much a Hybrid Perpetual as Victor Verdier one of the reputed parents of the variety. We believe we are correct in saying Paul Neyron was the result of a cross between Victor Verdier and Anna de Diesbach. Root action does not commence with the growing out of the eyes or buds, as you may see if you examine one or two. Many varieties exhibit signs of great vitality until the spring, when they die off. If you could select good ripe wood and endeavour to induce them to callus before final planting, you would have greater success in rooting the cutting. This callus is a secretion

formed at the base of the cutting, and from this the roots appear. Some growers put the cuttings in pure sand in the autumn and then, when callused in the spring, they are finally planted, and those not callused are discarded. Sand for the cuttings to rest upon is an excellent aid to free rooting.

**Climbing Roses with weakly growths** (*H. J. C.*).—Your plants will produce vigorous growths, although somewhat severely pruned last spring. Providing the roots were healthy and planted in good soil well prepared, there should be this summer some fine long growths produced from the base of the plants. Doubtless, last season there was more activity going on at the roots, which, of course, was not visible, and it is no unusual thing for these vigorous climbers to apparently stand still the first year. We advise you to do but little to them; just shorten back the laterals to two or three eyes and mulch the plants with some short well-decayed manure. If weather is dry during May and June, help the plants by an application of water now and then. This would apply more if they are planted against a wall.

**Utilising Rose prunings as cuttings** (*J. G. K.*).—We fear you would have very little, if any, success with the growths pruned away at this season of the year. It seems contrary to Nature for such cuttings to form a "callus," from which the roots are produced, as they do this much more readily when the sap descends in the autumn. We have ourselves experimented with these growths and the result has not warranted us in recommending it. Of course in the autumn the hard summer growths made into cuttings will root readily of most varieties, especially if some Cocoanut fibre or road sand be placed about and beneath the cuttings. Such cuttings examined a few days ago had formed nice little roots. An excellent mode of rooting Rose cuttings is to make them in the autumn, tie in small bunches and immerse them in moist sand until the spring. On examination only plant those that are "callused" over at the base, and such are almost sure to send out roots. Of course many may have small roots upon them, but if carefully planted in gritty soil they will soon become established. This plan is much better than planting out a lot in the open ground in the autumn, because we are more sure of a crop of plants. If the weather happens to be very severe during winter, and the cuttings are raised up, this seems to have a deleterious effect on them, whereas if they are kept in sand away from the frost they escape this.

**Rose garden alterations** (*Britannia*).—As you have now rearranged the beds there will be only two beds less than before. We would suggest the centre bed as previously advised, and the other beds as follows: Standards—2, Billiard et Barré; 3, Hugh Dickson; 4, Griss an Teplitz; 5, Gustave Regis. Half-standards—6, Caroline Testout; 7, Mme. Abel Chateau. Dwarfs—8, Frau Karl Druschki; 9, Le Progrès; 10, Antoine Rivoire; 11, Griss an Sangerhausen; 12, Paul Ledé; 13, Lady Ashtown; 14, Liberty; 15, Mme. E. Metz; 16, La Tosca; 17, Richmond; 18, Pharisier; 19, Melanie Souper; 20, Mme. Leon Pain; 21, Lady Battersea; 22, Earl of Warwick; 23, Betty. Six good varieties for the arches would be Carmine Pillar, Blush Rambler, Félicité Perpétue, Flora, Tea Rambler and Electra.

**Penzance Briars on a fence** (*P. M. D.*).—Three feet is a very low height to restrict these charming Briars to, but you may safely prune them so that the hedge is made tidy without fear of losing their blooms. We should advise you to tie in as much of the growth as you can without overcrowding, and cut the other away. If some of the growths are trained horizontally they will bloom all along the growth. Where they enter your neighbour's garden they may be cut away, and it would certainly be best if you keep the growths all on your side. A few uprights with wire stretched between, and the growths tied to them, would give you a more effective partition and, at the same time, provide you with more blooms. It does not matter how the growths are bent, providing they do not break; in fact, the more they are tied down the more bloom is obtained. In making any ties see that they are not very tight. You could plant a single row of the dwarf Polyantha Roses along the border, and they would give you their pretty little blooms nearly all the summer and autumn, such sorts as Perle d'Or, Oloire des Polyantha, Perle des Rouges, Aschenbroedel, Eugénie Lamesch, Petite Constant, K. Zeimet and Mme. N. Levasseur being among the best.

**Sulphate of ammonia for Roses** (*Rose*).—In order that the greatest good may be obtained from this chemical there should be a sufficiency of lime in the soil. It is a good practice to apply about half a pound of lime per square yard in November, then in the spring give a dressing as follows: Sulphate of ammonia, 2lb. to 3lb.; superphosphate, 5lb.; both well mixed together and applied at the rate of about a quarter of a pound to a square yard. If you are uncertain as to whether your soil needs lime, we advise an application of bone-meal instead of the sulphate this season, allowing about a good handful for each plant, but well distributing it over the surface. The following is also an excellent compound for Roses: Superphosphate of lime, twelve parts; nitrate of potash, ten parts; sulphate of magnesia, two parts; sulphate of iron, one part; and sulphate of lime, eight parts, applied in February and March at the rate of a quarter of a pound to a square yard. The ordinary dressing of good farmyard manure is also given, and liquid manure during May and June.

## FRUIT GARDEN.

**Covering for fruit trees as a protection from birds and spring frosts** (*H. Hampshire*).—You do not give the size of your bushes or pyramids, and therefore we cannot very well give even an approximate idea of the cost. The most effective and cheapest way we know of to protect the buds of such trees from birds is to fix some rough rather strong poles (four or five, according to the size of the trees) round the trees a little distance from them and one in the middle, all slightly taller than the tree, placing over these poles 1-inch mesh repaired herring nets, double thickness. These are to be bought very cheap. They may be left on the trees day and night until the buds are safe. These nets placed double thickness will be found to be an effective protection against birds, as they will also be against ordinary frost, say, from 5° to 7°, but should harder frost be anticipated, it is easy to throw over the nets some further protection in the way of cheap tiffany, mats, or any other covering available.

**Fruit trees and Roses for new garden** (*F. A.*).—1. Apples, dessert: James Grieve, ripe September; Cox's Orange Pippin, October to Christmas; King of Tomkin's County, December and January. Pears, dessert: William's Bon Chrétien, ripe September; Doyenné du Comice, November; President Barabé, February and March. Plums, dessert (Gages): Dennison's Superb, ripe August; Golden Drop, October. 2. Apples, dessert: Irish Peach, ripe August; Allington Pippin, November and December; Duke of Devonshire, February and March. Pears, dessert: Beurré Giffard, ripe August; Marie Louise, October and November; Le Lectier, January. Plums: Oullin's Golden Gage and Green Gage. 3. Apples, dessert: Worcester Pearmain, September and October; Ben's Red, July and August; Cox's Orange Pippin, October to Christmas; Christmas Pearmain, December and January; Rosemary Russet, February to May. Apples, kitchen: Early Victoria, August and September; Grenadier, October and November; Blenheim Orange, November and December; Lord Derby, December; Lane's Prince Albert, January and February. Pears, dessert: Jargonelle, August; Louise Bonne de Jersey, October; Fondante d'Automne, September and October; Doyenné du Comice, November and December; Beurré de Jonghe, January; Josephine de Malines, February and March. Pears, stewing: Vicar of Wakefield, Christmas and January. Plums: Rivers' Early Prolific, The Czar, Belgian Purple, Green Gage, Victoria and Reine Claude de Bavay. Cherries: Elton Whiteheart, early; May Duke, early; Black Eagle, midseason; Frogmore Bigarreau; The Noble, late; Waterloo Heart, late. 4. Currants: The best Red Currants are Fay's Prolific, Scotch and Victoria regina. The best White Currants are Dutch and Transparent. The best Black Currants are Baldwin and Boskoop Giant. Gooseberries: The best green Gooseberries are Green Gage and Langley Green. The best reds are Crown Job, Lancashire Lad, Red Champagne, Warrington and Winham's Industry. The best white Gooseberries are Cheshire Lass, Bright Venus and Whitesmith. The best yellow Gooseberries are Keep-sake, Golden Lion, Champagne Yellow and Golden Gem. They should be planted in rows across the east end of the kitchen garden. 5. Climbing Roses for rustic fence A: Bennett's Seedling, Dorothy Perkins, Crimson Rambler, William Allen Richardson, Aimée Vibert, Alistair Stella Gray, Gloire de Dijon, Carmine Pillar, Electra, Reine Olga de Wurtemberg, Reine Marie Henriette, Lamarque, Ards Pillar and Climbing Caroline Testout. For planting against the house we recommend the following: Gloire de Dijon, William Allen Richardson, Mme. Lambert, Reine Marie Henriette, and in a warm position with slight protection in winter, Marmalade Niel. 6. Standard Roses for B B B as for plan—Hybrid Perpetuals: Alfred Colomb, Ben Cant, Boissac, Captain Hayward, Charles LeFebvre, Clio, Duke of Edinburgh, Dupuy Jamin, Etienne Levet, Fisher Holmes, Frau Karl Druschki, Hugh Dickson, Margaret Dickson, Mme. Eugene Verdier, Mme. Gabriel Luizet, Marchioness of Londonderry, Marie Baumann,

Mr. Cocker, Mrs. R. G. Sharman Crawford, Reynolds Hole, Suzanne Marie Rodocanachi, Ulrich Brunner and Mrs. J. Laing. Hybrid Teas: Augustine Guinoisseau, Caroline Testout, Charles Graham, Dean Hole, Earl of Warwick, Florence Pemberton, Griss an Teplitz, J. B. Clark, Kaiserin Augusta Victoria, Killarney, Lady Battersea, La France, Liberty, Mme. Ravary, W. J. Grant, Richmond, Souvenir de Mme. Eugene Verdier and Viscountess Folkestone. The above are among the cream of the varieties, and are all of vigorous growth. The colours will be found in any good Rose catalogue. 7. Bush Roses for C C in plan—Hybrid Perpetuals: A. K. Williams, François Michelon, Annie Laxton, Baroness Rothschild, Countess of Oxford, Countess of Rosebery, Crown Prince, Duchesse de Morny, Duke of Teck, General Jacqueminot, Helen Keller, Her Majesty, Jules Margottin, Mme. Victor Verdier, Marchioness of Downshire, Marie Baumann, Marie Verdier, Maurice Bernardin, Merveille de Lyon, Mrs. John Laing, Mrs. R. G. Sharman Crawford, Paul Neyron, Rev. Alan Cheales and Senateur Vaise. Hybrid Teas: Antoine Rivoire, Captain Christy, Caroline Testout, Countess of Caledon, Countess of Derby, Dean Hole, Dorothy, Exquisite, George Laing Paul, Gladys Harkness, John Ruskin, Killarney, Lady Moyra Beaulerc, Liberty, Mildred Grant, Mme. Abel Chateau, Papa Gontier and Rainbow.

**Apple twigs with red eggs** (*J. Wilson*).—The red eggs on the twigs of your Apple tree are those of one of the beetle mites belonging to the family Oribatida. These mites are very common on trees, and, I believe, are perfectly harmless. They are said by those who have studied them to feed on the minute vegetable growths found on the bark of all trees. The black eggs are, I believe, those of one of the aphides, but I am not certain. Most of the winter washes will not kill the eggs of insects, but one lately devised and known as V.I. is said to. I believe it can now be obtained from the vendors of such things, or from Messrs. Cooper and Nephew's chemical works, Berkhamsted.—G. S. S.

**Pruning young Pear trees** (*A. B.*).—From your description we take it that your young Pear trees are horizontally trained. The leading shoot in this case must be cut back in the same way as that recommended for the Peach in order to secure another layer of side shoots, as well as a new leader for next year. In the case of the side shoots, if the leading growths of last year are only of moderate length, they need not be shortened at all; but should they be from 15 inches to 18 inches long, then they had better be shortened to 10 inches. If the wood-buds on these shoots break freely, they should be disbudded and left 5 inches apart. The shoots emanating from these buds should be stopped during the summer (about the middle of July), cutting them back to within seven buds of their base, and in winter pruning to two buds of their base, when in due course fruiting spurs will form at the base of these cut-back shoots.

**Pruning young Peach trees** (*A. B.*).—We presume your young Peach trees are fan-trained and are growing against a wall. Last year's growth on the centre or leading shoot should be shortened by one-third its length. This will result in the wood-buds below breaking strongly. Three of the best of these must be retained to grow into shoots during the coming summer, one to form the leading upright shoot, and the two others to form side shoots, one on either side to be trained obliquely. All the remaining wood-buds on these shoots must be rubbed off. Each leading side shoot of the tree must be served in the same way as the leading shoots. By doing this you will be adding two branches to each existing shoot, thereby helping to make your young trees well furnished at their base, or more bushy as you term it. If there are more of these than can be got in at 6 inches apart, they must be cut back to within two buds of their base, when they will form fruit-spurs and produce fruit the following season.

## MISCELLANEOUS.

**Plants for mound beneath Pine trees** (*Fetis*).—You will not be able to get many plants to thrive beneath Pine trees, especially in such a position as you describe. You cannot do better than plant the mound with common British Ferns, and among them place Snowdrops, Daffodils, Anemones and similar plants. You might, of course, experiment with likely shrubs, such as Gaultheria Shallon, G. procumbens, Berberis Aquifolium and Butcher's Broom. Many plants that thrive well beneath the shade of deciduous trees refuse to grow beneath Pine trees, and it is rarely that grass thrives satisfactorily in such a position. We think, however, that you will find the Ferns, Snowdrops, &c., a success, and the combination is a very pretty one, especially when the dead Fern fronds are left on the plants and the Snowdrops come through among them.

**Gravel for garden paths** (*L. Earle*).—The best material for paths such as you speak of is good clayey gravel. This should be spread while in a damp state and be well rolled before it has a chance to dry. Before being wheeled on it should be allowed to set on the surface, and after each heavy rain a good rolling should be given. The worst period for gravel paths is a light rain after a dry period and a thaw after a frost. In each case the effect is the same—the lower part is hard and the upper soft, consequently the upper part lifts. The only thing to do in such a case is to use the paths as little as possible for a few days. It is quite probable that some local nurseryman will be able to tell you of the nearest place where you can obtain suitable gravel, or if you write to the Park's Superintendent at Liverpool he will probably give you the desired information.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## AN ENEMY TO SWEET PEAS.

AN enemy to Sweet Peas, to some extent common, and yet very rarely saddled with its crime because of its cunning, is the Pea or Bean weevil (*Sitona lineatus*). It was my misfortune last season to receive a visit from these destructive pests, and it was more by accident than good management that I discovered the identity of the invaders. The first indication I had that the plants were attacked was on April 4, when they were about 3 inches high, and I noticed that tiny notches were being nibbled in the leaves. The conclusion came to was that slugs had been at work, and I therefore dusted all the rows well with soot. It was not, however, until a month later that matters really became serious. During the first week in May I found that the leaves of a number of young plants had been eaten away so that nothing but the midribs remained, and although the lead had not been interfered with, I was considerably exercised in mind as to what was the cause and how to remedy it. A visit to the gardens of two of my friends showed the same state of affairs in a somewhat lesser degree, and in each case the slug or sparrow was named as the culprit.

From the frequent dustings of soot I had given with no apparent check on the depredations, it was evident that some other measures would have to be taken, and I therefore, on the evening of May 7, went out armed with a lantern to hand-pick, as I expected, the slugs. There was not, however, a slug to be found anywhere; but I discovered a small brown beetle with a very hard skin or shield which I subsequently ascertained was the Pea weevil, and it was evident that these were the invaders. Having discovered their identity I was, I am thankful to say, able to effectively check their depredations.

In appearance the weevil is a tiny striped beetle from one-fourth to one-fifth of an inch in length. It is of a dark colour, the body being covered with grey or greenish grey scales. The antennæ are of a dull red colour, very slender, and with club-like terminations. Its legs are ferruginous. The under surface of the beetle is clay coloured, so that when it falls on its back to the earth it can scarcely be detected. Its plan of attack is to eat small notches in the leaves of young plants, and so interfere with their growth; in severe infestations the leaves may be eaten to the midribs, such being the case last year with two of my rows, viz., King Edward and Dorothy Eckford. The notches are semi-circular and very similar to the nibble

of a slug or peck of a sparrow, and for this reason these are often innocently accused where the weevil is to blame. The weevil feeds after nightfall, and when alarmed readily falls to the ground, feigning death until the danger is past. Its eggs are laid either upon or just beneath the soil, close to the roots of the plants. These hatch into small white, footless, wrinkled grubs, with brown heads and biting jaws. The larva bores a channel along the main roots of the plants and also appears to feed on the nodular growths found on the roots of Sweet Peas and other leguminous plants. When full grown it is about one-fourth of an inch in length and pupates in an earthen cell at a depth of about 2 inches below the surface of the soil. At first the pupa is pale creamy white, later its eyes become black and the proboscis-sheath darkens. The adult weevil hibernates in the hedgerows, Barley stubble, &c. It appears early in spring and attacks the young Peas as soon as they are above ground, laying its eggs on or near the roots. From these eggs we get a summer brood of the weevil, which appears about the middle of June. This in turn lays eggs, which hatch into larva in the autumn and feed all winter on leguminous roots. The winter larva matures in May and appears as an adult weevil in June. In some cases it has been known to come from the pupal condition as early as March. Thus the weevil may live in one or two ways during winter, either by hibernating in adult form or by feeding in the larva stage on leguminous roots.

The method I adopted to check its ravages was to dust the ground and plants with fresh slaked lime and soot mixed, after dew or rain, repeating the process at intervals of four or five days. I also had the surface soil finely broken up and tightly pressed round the plants to prevent the weevil coming up. This was found to be an effective check, and although the rows of King Edward and Dorothy Eckford had suffered so severely they ultimately made a good show. The check they had received, however, made them somewhat late. During the winter, in the hope of finally exterminating the pests, I have given all my garden a good dressing of ground lime, and left it rough so that the frost may have full play, but whether this will prove effective remains to be seen. Other remedies which are recommended are as follows: Finely powdered guano dusted over the plants after rain, spraying the rows with arsenical washes, and the application of a weak mixture of paraffin water and a little soft soap, which makes the leaves of the plants distasteful to the weevil; with the last-named, however, there is some

danger of injuring the growth of the plants, as paraffin is inimical to vegetable life and must be very sparingly employed.

Much useful information on the subject is to be obtained from a pamphlet (Leaflet No. 19) issued by the Board of Agriculture, to which I am indebted for many of the data here given which relates of the life history of *Sitones lineatus*.

J. STAVELEY HARPER.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

March 31.—Royal Horticultural Society's Hyacinth Exhibition, Vincent Square, Westminster; Lecture at 3 p.m. on "The History of the Cabbage Tribe," by the Rev. Professor G. Henslow, V.M.H. Horticultural Club, Hotel Windsor, 6 p.m., the Rev. Joseph Jacob on "Tulips."

April 1.—Winter-flowering Carnation Society's Exhibition, Royal Horticultural Society's Hall, Vincent Square, Westminster.

April 7.—Bournemouth Horticultural Society's Show; Brighton and Sussex Horticultural Society's Show; Cornwall Daffodil Society's Exhibition.

**Gardeners at cricket.**—Mr. and Mrs. Harry J. Veitch have again invited the various committees of the Royal Horticultural Society to Burnham Beeches during the coming summer for the purpose of playing a cricket match.

**Royal Botanic Gardens, Edinburgh.**—The conversion of the old glass houses in the Royal Botanic Gardens, Edinburgh, which were for long quite out of date, has been in progress for some years, and they have generally been replaced by others of larger size and of the most improved types. An important addition has just been effected by the completion, so far as the structure itself is concerned, of a new Fern house, with a couple of annexes, this occupying the east end of the main range and entering from the main pathway. The structures are most convenient and commodious, and will afford space and conditions suitable for the cultivation of the choicest Ferns. The main building, which is about 70 feet long and terminates in a domed part higher than the remainder, is being furnished with sandstone blocks in the form of rockwork, among which the Ferns will be planted so as to give it a natural appearance. The annexes are about 60 feet in length and are at right angles to the main house. The contractors for the building were Messrs. Mackenzie and Moncur, Limited, and Professor Bayley Balfour and the contractors are to be congratulated on the design and execution of this important addition to the gardens. Some outdoor alterations, which will add greatly to the amenity of the gardens, have also been in progress for some time.

**An uncommon Marsh Marigold (*Caltha polypetal*).**—In a recent ramble through the glass houses of Veitch's Royal Nurseries at Exeter I came across a fine example in flower of *Caltha polypetal*. My attention was drawn at the same time to an account of the plant as given by Mr. Reginald Farrer in his recently-written book "My Rock Garden," which, as it will probably commend itself more or less to most plant collectors, but some of whom, however, may not see it, I copy it in its entirety. He says, "The Marsh Marigold or Kingcup of our bogs has a double form that you may admit if you like; but a very different person is *Caltha polypetal*, newly introduced, and now selling for about a guinea a plant. This, to describe it briefly, is the ordinary Marsh Marigold, multiplied by three—in all its parts, leaf, flower, stem—a tropical-looking aquatic of unequalled glory. The plant has a curious history, which may or may not be legendary.

Report says that an Italian peasant found it in some unknown corner of the country, and, in consideration of its marvellous size, brought it to Rome and laid it at the feet of Pope Leo. The old Pope benignly accepted the offering, and *C. polypetal* established itself in one of the fountains in the Vatican Garden. But the Pope would never let anyone else possess bud or seed or baby of it, and there year after year it wasted its sweetness on the desert air, being seen by nobody except an aged gentleman, who, presumably, had other things to think about. This policy survived Pope Leo, and continued until the English gardener (all honour to his name; he is a male Antigone, daring a formal sin to secure the Higher Holiness) resolved that such a scandal should no longer endure. So he took with him into the Vatican Gardens a covey of his sisters and his cousins and his aunts, and while they engaged the custodian in a conversation on Renaissance Art, our hero hooked out a root or two of *Caltha* with his umbrella. And now Pope Pius is none the poorer, and the whole world is the richer. I cannot but think or dimly hope that horticulture has a code of ethics to itself. Why should a friend's seed-pod fall neglected, or a prey to slugs, when one has a pocket ready to receive it? However, I hasten to reassure all my acquaintances; my own spirit is far too meek for such adventures, I merely admire the law-breaker from afar. I cannot steal, though to beg I am by no means ashamed." This is a pretty and well-told little story, and may be taken as an example of Mr. Farrer's style throughout an interesting and readable book. —JOHN R. JACKSON, *Claremont, Lympstone, Devon.*

**The Veitch Memorial Trustees** offer the following prizes for competition at the shows of the Royal Horticultural Society. On October 15 and 16 next a first prize of £10 and a silver medal, a second prize of £5 and a bronze medal, and a third prize of a bronze medal for the best collections of five distinct varieties of Grapes, three bunches of each, to include two distinct white varieties, grown by the exhibitors only. On December 8 next and at the first meeting in April, 1909, one medal and £5 on each occasion for the best group of winter and spring-flowering Carnations, either in pots or as cut flowers, or a combination of both, to occupy a space of 100 square feet, and grown by the exhibitors only. All these prizes are open for competition by amateurs only.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**"The Garden" Flower Show.**—As an old reader of THE GARDEN I feel I must write and congratulate you on the good news which appears in your latest issue. I, like many others, have read THE GARDEN for many years, and its arrival by post week after week, year in and year out, has been very eagerly looked for. Having benefited so largely from what I have read and having put into practice the excellent precepts laid down from time to time by your much appreciated contributors, my garden has become most interesting to me. It is particularly gratifying, therefore, to read that we readers are to have a horticultural show all to ourselves. This surely is quite a unique event, and cannot fail to stimulate us all to make a great effort to excel during the ensuing summer season. There is nothing like friendly rivalry to stimulate interest and whet one's appetite for higher achievements, and a flower show in which lovers of flowers, &c., can exhibit the products of their garden in competition with others who have culled their knowledge from the same source cannot fail to be an event of more than ordinary interest. I hope you will be able to publish the

actual date of the show soon, and trust you may also be able to secure a well-known building in London for the purpose. You are very generous in the number of competitions provided, and, most important of all, you have made classes to suit readers having either large or small gardens. Whether I shall be a fortunate winner of a silver medal I know not, but I shall try my best to win one. I am glad you are providing a series of classes exclusively for amateurs. Wishing you every success in this interesting venture.—AN OLD READER.

**Winter Salads.**—A few weeks ago there was an article in THE GARDEN on "Winter Salads." It may interest amateur readers to hear how I have a constant supply of delicious salads all through the winter. About the end of July I sow in the open curled and round-leaved *Batavian Endive*. Nice plants are formed by the middle of October. I then take them up and plant them in close "packets" with good balls of earth in a well-dug piece of open ground, pressing them firmly in. I then place over them empty boxes as large as possible and not more than a foot high, and press them down closely so that no light can get in. In about six weeks I find the *Endive* is beginning to bleach and is fit to eat. I keep reserve plants pricked out ready to go under the boxes when required, and until well into February I get nice salads. I also sow *Lamb's Lettuce* in long lines in July for winter use. The little wild *Cress* makes a very nice addition to a salad; it grows in most gardens as a weed and in damp lanes.—J. G. A.

**Destroying queen wasps.**—This question is one of great importance to all fruit growers. As "G. S. S." points out, queen wasps can often be caught in late autumn when they are looking for a place in which to pass the winter. A good trap for them at that season can be made by shredding up old Russian mats and placing loose-wards of this material in the roofs of outhouses. On wet days the wads may be taken down and the wasps, usually in a drowsy state, killed. "G. S. S." states that the queen wasp or mother feeds her young in spring for a short period, and also that the grubs are fed at first on the juice of fruits and the nectar of flowers. As fruits are not plentiful in spring, we may take it for granted that the first brood is fed on the latter food. This is probably the reason that queen wasps are often to be found hovering around Gooseberry bushes when the latter are in flower, though I have never observed them collecting honey from the flowers. Has the practice of placing bottles of syrup in likely places at that time had a fair trial? I intend to test it this season, and if the Editor thinks it likely to be of general interest, will communicate the result. [Yes, do please.—ED.] As to destroying the nests, cyanide of potassium, though most effective, is one of the most deadly poisons. Coal tar is very generally used for the purpose, but there is not the slightest need to light it. We use a water-can having a long spout and pour in about half a pint of tar and close up the hole. The fumes from the coal tar are quite sufficient to kill all wasps in a few days and the grubs as they emerge from their cells.—J. COMBER, *Nymans Gardens, Crawley, Sussex.*

—I was very interested by the article on wasps by "G. S. S." and the destruction of the same by killing the queens and destroying the nests. A most simple and effective method of destroying the nests, I have found from long practical experience, is by procuring an ordinary wine or spirit bottle and filling the same with paraffin. After dark proceed to the nest, and with a light discover the entrance hole, then pour the contents of the bottle into the hole and push the neck of the bottle in to make a plug, and I can assure readers that there will not be a wasp alive in two days, the fumes of the oil having destroyed them. It would be wise to inspect the nest during daylight, as sometimes there are two entrance holes, but this is not often the case.

Occasionally, too, the hole takes an upward course.—H. H., *Box Road Nurseries, Bathford, Bath.*

—In connexion with the article on wasps in *THE GARDEN* for the 7th inst., I should like to mention that last year I caught thirty-two queen wasps in April and May. The method employed was very simple. I hung in various parts of the garden American glass fly-traps filled with cider or beer and treacle. Whether the wasps were attracted by the flies caught or by the smell of the contents of the glasses I do not know; but the fact remains that they came readily to their doom. As far as I remember we had not one wasp in the house all through the summer, and very few in the grounds; but as there was a scarcity of wasps in the neighbourhood, our immunity may not have been entirely due to the spring destruction. I must also join issue with the writer of the article as to the advice given about destroying nests by cyanide of potassium. No turf should be put over the nest for at least twenty-four hours. The mixture, if strong enough, retains its deadly qualities for quite that length of time, and as there are always a certain number of wasps away from the nests it should be left open for them to return to it, when they will die with the others. In a couple of days the nest should be dug up or turfed, to prevent any chrysalids coming to life. For the past twenty years I have been in the habit of destroying all the nests found in our grounds by a strong solution of cyanide of potassium poured into the nest from a watering-pot with a long spout. It has always been effectual. The wasps die instantly, and I have never been stung.—M. WILLIAMS.

—May I bring to the notice of readers of *THE GARDEN* a method of destroying queen wasps, as advocated by Sir George Kekewich in a letter to the *Field* last summer, in which he details his experience. He says: "I have been in the habit of hanging on the walls of my garden, under the eaves and in sheds or summer-houses, or any other protected place, a number (say a dozen) of wide-mouthed glass jam jars half filled with well-sugared beer, each year during March, April and May. I killed in the first year seventy-five queens and two queen hornets, in the second fifty-six and in the third twenty-five. I then moved to another locality, and this year I have killed seventy-one." As this is such a simple method compared with chasing them with a syringe or other weapon, and has the merit of being very effectual, we are giving it a trial in the gardens here this spring in the hope of reducing the wasp plague, which has been very virulent of late years.—R. W. DEAN, *The Gardens, Audleys Wood, Basingstoke.*

—There is a very simple way of destroying wasps' nests which is not mentioned in the interesting article on wasps in *THE GARDEN* for the 7th inst. If you think it of interest to your readers, it is as follows: Having located the wasps' nest, go to it after dark armed with an old wine-bottle into which about a tablespoonful of turpentine has been put. Thrust it neck downwards into the mouth of the nest, ramming it round with bits of turf or wads of grass to keep it firm and exclude the air. By the next morning you may take the bottle away, as the fumes of the turpentine will have killed all the wasps. If the hole is too small for a wine-bottle, an old Harvey sauce bottle is as effectual, only do not leave the cork in, as one clever person I knew did, and was much astonished at finding the nest as strong as ever the next day. Everybody has, or can get, turpentine (spirits of), while many people do not like to have as dangerous a poison as cyanide of potassium about.—MILDRED E. DOBBS.

**White Water Lilies.**—This picture of the wild Water Lily, from a photograph kindly sent by a reader in Ireland, is interesting as showing the beauty of the Water Lily on our lakes and rivers. We hope to publish soon some advice about planting the hybrid *Nymphaeas*, those raised by M. Latour-Marliac and others.

**Hardiness of *Incarvillea Delavayi*.**—In your "Answers to Correspondents" recently I saw a reply to "Balmacarron" on the hardiness of *Incarvillea Delavayi* and its not being a long liver. I wish to state that if they are taken up in the autumn, washed quite clean, dried, and then put in dry Coconut fibre or dry soil and stored away in a cool place till spring, they will keep healthy and right for any length of time. It is being left in the cold, wet ground that kills them through the autumn and winter. By taking them up they can be retarded, if desired, for several weeks, keeping them dry and planting any time in spring. I have no doubt that a lot of our fleshy-rooted herbaceous plants would be better treated this way.—E. SMITH, *Cheshire.*

**Forcing *Incarvillea Delavayi*.**—We cannot hear sufficient of that valuable introduction *Incarvillea Delavayi*. Its long-flowering period, the elegant outlines of its blossoms and their dainty colouring, its hardiness (it endures here Arctic temperatures without any protection), the wonderful ease with which it is raised from seed and flowers the second season, are

from the dry state into which the roots had got from the rough treatment they had received. Why, by retarding and forcing it would seem one could have these lovely blooms all the year round!—E. HEINRICH, *Plönegg, near Munich (Bavaria).*

## THE HOE IN THE GARDEN.

**H**UMBLE though it may be, it is very doubtful whether any tool, excepting the spade, is as useful in the garden as a good steel hoe, at least one being absolutely necessary even in the smallest garden. It is equally doubtful whether many wielders of this tool get the utmost amount of good that it is possible to obtain by a proper and intelligent system of using it. Hoes, like many other things, vary considerably in shape and size, many of the so-called improvements that are on the market being almost useless for the purpose they are intended for. One, however, that is not met with nearly so frequently as its merits demand is the sprout-hoe, invented, I believe, by the Rev. Foster-Melliard, and if I were limited to one only this would be my choice. It can be worked either by pushing or drawing, while the sharp lance-like point is most useful for digging out weeds of a deep-rooting nature, such as Docks and Nettles.

In most gardens, however, several hoes at least will be allowed, and where this is the case the Dutch hoe and the swan-necked draw hoe must be included. The former is a most valuable tool for destroying small weeds in beds and borders without disturbing the surface to any great extent, and the latter is most useful for heavier work in the kitchen garden, where it is frequently desirable to stir the soil to a good depth. The best type of this hoe that I have ever seen was the ordinary swan neck fixed to a handle, a thread and nut being provided at the extreme end of the neck. Steel blades of varying sizes were made to fit this neck, so that the user had half-a-dozen different sizes at his command, which, when not in use, took up but very little room.

But it is the benefits to be derived by the constant use of the hoe in the garden during the greater part of the year that we are most concerned, and the one that stands out from among the many others is the preserving of moisture in the soil. There is no gainsaying

the fact that where soil is frequently hoed during hot weather the moisture is retained therein to a much greater extent than it is in soil that is left untouched, simply because the natural tubes or ducts in the soil are broken and the ends protected by a layer or mulch of fine soil. Were the hoe used more frequently and the hose or water-can less better results in many instances would be obtained than have been hitherto. This is a point that many otherwise good gardeners are apt to overlook. Then, again, air is admitted freely to the soil, and as pure air is of the greatest benefit to the roots of plants, the good done in this direction will be very great indeed. Grubs, too, of many kinds are exposed and placed at the mercy of birds that are ever on the look out for them. Cultivators, generally, are too often apt to regard the hoe as a tool for destroying weeds only, and, although this was probably its primary mission, we should not be backward in availing ourselves of its services for the purposes named above. Of course, there are many other uses to which forms of this humble tool may, with advantage, be put, such as earthing up Potatoes and other plants, and one can only hope that its value will in future be recognised to the full. H.

A BEAUTIFUL GROUP OF WHITE WATER LILIES.

surely enough to make it dear to one's heart. To all this, however, by an accident comes to me the revelation that it can be forced as easily and as quickly as Rhubarb, and with proper treatment may be had in bloom at Christmas. On February 20 I was startled by loving hands bringing a cut flower and leaf of *I. Delavayi*; it was brought to my bedside, where I was stricken down with influenza. Never in my life had anything in the way of cut flowers given me so much pleasure before. Catching first sight of the colour I thought it was a *Cattleya*. To look out of the window and see the fields covered, as at present, with 12 inches of snow, and then look back on this bright *Incarvillea* is a pure delight. In the autumn of last year I cleared a bed upon which I was in the habit of throwing any spare seeds, and with other things came up three thick roots of *Incarvillea*. Having plenty elsewhere, they were left in a basket in a shed, quite dry, till winter came. Then they were taken to the cellar of the dwelling-house, where until Christmas they still remained in the dry, hot air of the boiler-room of the house central heating apparatus. When at last pity was taken upon them, they were potted and put into the greenhouse, where within seven weeks they produced their lovely flowers

## TREES AND SHRUBS.

### ACCLIMATISATION OF FOREIGN SHRUBS.

SOME experiences, extending over a number of years, in the acclimatisation of foreign shrubs and trees may perhaps be of service to persons living, like ourselves, in the South-West of England. Our garden, though situated as described, stands in a rather exposed position at the top of one of the low chalk hills of the Dorset downs, some 320 feet above sea level. In spite of this, and of the fact that as many as 20° of frost have been registered during the present winter, we have several kinds of delicate foreign shrubs and trees doing very well out of doors.

The first secret of successful acclimatisation appears to be the thorough seasoning of the woody stem before trusting the plant outside during the winter. Many years ago the seed of a beautiful New Zealand shrub, locally known as Matipo (*Pittosporum undulatum*), was sent to me from that country. Having reared a number of young plants and grown them to a height of about 18 inches, I, one winter, allowed ten of these to remain on an outdoor shelf behind the greenhouse, facing south. One frosty night I lost every one. Supposing this shrub to be too delicate to bear our climate I kept the remainder under glass for

the next few years; but as they grew larger increasing difficulties in the way of housing put me to the necessity of trying to harden them. With this end in view I began planting the shrubs out during the summer in the beds, lifting and potting them late in the autumn and storing them in a cold house or in a fireless room within doors. After a year or two of this treatment they acquired firm, woody stems with a more robust habit of growth. Two years ago I determined on the experiment of leaving them out for the winter, and the result has been entirely satisfactory, as they have safely endured two of the coldest spells that we have experienced since 1894. This shrub is well worth trying by anyone living in the South or West of England. It has black stems, which contrast charmingly with its shiny, prettily waved, Holly-like leaves, the young shoots displaying a most delicate shade of malachite green in the spring. It is evergreen, and I find it most useful for cutting in winter. The flowers are dark red with yellow stamens, inconspicuous but very sweet scented. A hedge of this shrub is to be seen at Falmouth, in Cornwall, growing luxuriantly.

Cabbage-tree Palms from New Zealand have been successfully hardened with us by the same process as the Matipos, and have borne the severe frost of this January without hurt. I am now putting a Loquat from Rio Janeiro through the same course of training, and hope to plant it out for good this summer. The second point in

acclimatisation is the choice of situation, and this is not quite so simple as it seems, owing to the fact that dangerous draughts or currents of cold wind are sometimes directed by surrounding objects into apparently sheltered nooks. Such a current exists in our own garden, and its path may be easily traced across the bed of Wall-flowers and through the Forget-me-nots. The south-east wind, kept off in the main by a belt of shrubs, enters through a narrow opening, strikes against the wall of the house, and swirls back into an otherwise well-protected corner. A Myrtle placed there was absolutely shrivelled during the frost-wind of January, while another which had never stood a winter out of doors before, but whose position was carefully chosen last autumn, is quite unharmed. Everyone can by observation discover these dangerous currents in his own garden, and must avoid them in planting delicate shrubs. A position facing due south is often trying to plants, owing to the great variation between the night and day temperatures,

and I prefer one looking west or south-west if possible. I once lost a number of Cabbage-tree Palms in an open shed facing south, notwithstanding a partial screen of hurdles and straw, and I doubt the advantage of open sheds in general, as I think the slight movement in the free, unroofed air often saves plants from frost-bite, and that therefore a carefully-chosen position in the open is preferable. It must be said that we have very little snow in this part of England, and practically none has fallen during these last two winters. As a final word, I may add that delicate plants are very much safer with their roots in the open soil rather than in pots or tubs, and, of course, a mulching round them in autumn is an advantage.

Blandford, Dorset.

E. H. G.

### THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### LILAC AND CINERARIAS.

Mr. H. Henderson, head gardener at Brookhams Park, Hatfield, Herts, sends very fine sprays of Lilac and good Cineraria flowers. He writes as follows: "I enclose a few sprays of Lilac, which may be interesting. About six plants were lifted on January 1 of the present year with good balls of soil attached to them and placed in a cool greenhouse close together. The soil was placed round them just to cover the roots. A good watering was then given and the plants syringed twice a day till the flower-spikes appeared. During the last fortnight they have been beautiful for decorating the drawing-room and also the dining-room table. I also enclose a few Cineraria blooms which have been very good. The strain is that of Messrs. Cutbush's, Barnet."

#### SPRING-FLOWERING IRISES.

Mr. Perry, Hardy Plant Farm, Enfield, Middlesex, sends several spring-flowering Irises, comprising *Iris Tauri*, a sweet smelling sort of a wonderful satiny purple colour with a yellow line down the fall, and at the apex very deep purple variegated with white; *Iris galatica*, which is of strange beauty, blue, purple and yellow in subdued shades, making this flower one of the most interesting of its section. Mr. Perry also sends *Iris Heldreichi*, *I. histrioides*, *I. Vartani* (which are now becoming more known) and the richly-coloured form of *I. reticulata* or the netted Iris, called *purpurea*.

#### STREPTOSOLEN JAMESONI.

Mr. W. Bee sends us splendidly-grown sprays of this grand old greenhouse climber. He writes: "This is an excellent plant for flowering in the winter, and one that is often grown to cover a pillar or some unsightly corner, for which it answers very well; but it is seen to far better advantage when grown as a pot plant. Early in March is a good time to insert the cuttings, which root readily, and when struck should be potted on as required, never allowing the plants to get pot-bound. It should be grown near the glass, and frequently turned in order to get a well-balanced plant. Loam, leaf-mould and sand make a good potting soil, and for the final potting 8-inch pots are quite large enough. A warm greenhouse suits it best. If kept to a single stem and tied up it is quite easy to grow

A TENDER PLANT ACCLIMATISED: *PITTOSPORUM UNDULATUM* IN BLOOM IN A POT.

the plants 7 feet or more in height, and when clothed with graceful sprays of orange-coloured blossoms they are very effective for the greenhouse or grouping in the conservatory. The sprays are also very useful when cut. The plants require plenty of syringing to keep red spider in check, and should never be allowed to get dry or the leaves soon turn yellow and drop off. As soon as the pots are well filled with roots after the final potting they require liberal treatment in the way of manure and soot water."

## THE KITCHEN GARDEN.

### A USEFUL SEED-SOWING TABLE FOR AMATEURS.

A REGULAR supply of vegetables throughout the summer months is always much appreciated. When a person knows how long it will take for certain kinds of vegetables to come to maturity from the date of sowing the seeds or planting the tubers, he also has a very good idea as to the quantity of seeds he ought to sow each time in order to obtain a supply of produce sufficient for his requirements. Furthermore, the following table will prove a good guide when it is the intention of the owner of the garden to exhibit the produce from it. In the southern counties the respective crops will come to maturity about a week or ten days earlier than in the northern, so that due allowance must be made, as the table of sowing refers to the southern part of the country. Maturity means the condition of the particular kind when it is fit to use—at its best for the table.

Name of Vegetable.	Date of Sowing.	Date of Maturity.
Beans, Broad .. ..	March 1 .. ..	June 25
" Runner .. ..	April 20 .. ..	July 25
" Dwarf .. ..	April 20 .. ..	July 25
Beetroot .. ..	April 10 .. ..	August 20
Cabbage, early .. ..	March 10 .. ..	July 10
" late .. ..	March 1 .. ..	July 25
Cauliflowers, early .. ..	March 1 .. ..	July 1
" autumn or late .. ..	March 20 .. ..	September 1
Carrots, Horn .. ..	March 1 .. ..	June 20
" Intermediate .. ..	April 1 .. ..	August 25
Cucumbers .. ..	April 1 .. ..	July 1
Celery .. ..	March 1 .. ..	August 15
Leeks .. ..	March 1 .. ..	November 1
Lettuces, early Cabbage .. ..	April 1 .. ..	June 10
" Cos .. ..	April 20 .. ..	June 20
Onions, spring-sown .. ..	March 1 .. ..	August 10
Parsnips .. ..	February 20 .. ..	October 20
Peas, early varieties .. ..	February 20 .. ..	May 10
" late .. ..	March 1 .. ..	June 15
Potatoes, early varieties .. ..	February 20 .. ..	June 1
" medium .. ..	March 1 .. ..	July 10
" late .. ..	March 1 .. ..	August 10
Radishes .. ..	March 20 .. ..	May 1
Turnips, early varieties .. ..	March 20 .. ..	May 10
" main-crop .. ..	April 10 .. ..	June 10
Tomatoes, outside grown .. ..	March 1 .. ..	August 10
Vegetable Marrows .. ..	April 1 .. ..	August 1

Of course, seeds of vegetables which are sown in boxes in frames, and the resultant plants put out later in open borders, are Celery, Tomatoes, Cucumbers (in frames entirely) and Vegetable Marrows. The other kinds named in this list are raised entirely outdoors.

AVON.

### LÆLIO-CATTLEYA PIZARRO.

THIS beautiful new hybrid is the result of a cross between *Lælia joughiana* and *Cattleya dowiana aurea*. The flower on the plant exhibited was a very large and handsome one, the petals and sepals being of a uniform rosy carmine colour. As may be seen in the illustration, the petals are broader than the sepals and the edges are prettily crimped. The labellum or lip, however, is the most beautiful portion of the flower, the colour of this being deep orange streaked with the richest purple. It was shown before the Orchid committee of the Royal Horticultural Society by Major G. L. Holford, C.I.E., C.V.O., Westonbirt, Tetbury, Gloucester (gardener, Mr. Alexander), on March 3, when it received an award of merit.

## THE FLOWER GARDEN.

### MUSCARI (GRAPE HYACINTHS).

(Continued from page 141.)

**M**USCARI BOURGAEI.—A blue-black species. The spikes are dense and rounded, and they appear early in the season. It is more fitted for rockeries than for grass planting.

*M. comosum* (the Tassel Hyacinth) bears loose spikes of dull blue flowers; the upper buds are attenuated, forming a kind of

flowers are abruptly contracted at the mouth and they are a dirty yellow in colour, borne in loose spikes. Var. *flavum* is a more refined plant, coloured clear yellow, and the spikes are as large as the var. major, an improved and giant *moschatum*.

*M. neglectum*.—A familiar plant with large bells arranged in short spikes. Those at the summit of the spikes are blue, those at the base black, and the small throat is faintly lined white. The var. major of gardens is *M. racemosum*.

*M. pallens*.—A delicately beautiful Muscari, long known to cultivation but now quite neglected. Its flowers are small, arranged in

LÆLIO-CATTLEYA PIZARRO. (About two-thirds natural size.)

tassel. It is grown by many, but it is scarcely so interesting as the

Var. *monstrosus* (the Feathered Hyacinth).—A curious and beautiful monstrosity. The stems support a feathery mass of prolonged pedicels and flowers, which are transformed in curled, twisted and tasselled wiry processes, forming a mass of pale purple, rosy lilac or sometimes pink filaments.

*M. commutatum*.—An old-time plant with long spikes of purplish blue fragrant flowers in attenuated cones, very variable in colouring and size.

*M. conicum*.—A strong-growing species, with stems nearly 1 foot high bearing large cones of flowers of a beautiful shade of cerulean blue. This is quite the best Muscari for naturalising and border planting. Its rich colouring has earned for it the popular name "Heavenly Blue."

*M. Heldreichii* is a dainty plant, coloured a pale shade of blue, the spikes are short and the inflorescence compact, forming an abrupt cone. More suitable for planting in the rock garden than for naturalising; early.

*M. latifolium*.—A splendid Muscari with dark violet flowers arranged in a well-furnished spike 5 inches to 6 inches long; rare.

*M. moschatum* (the Musk Hyacinth).—A dull-coloured plant valued only for its fragrance. The

dainty cones, and they are the palest blue in colour. A choice rockery plant.

*M. paradoxum*.—A giant Grape Hyacinth with large bulbs, strong glaucous leafage, and black-purple flowers in dense cones nearly a foot high, known as the "Black Hyacinth." A striking plant of novel colouring; it can hardly be called beautiful.

*M. polyanthum*.—A rare and beautiful Muscari. The spikes are 8 inches to 10 inches long, and the flowers are arranged in a graceful raceme of considerable length, the whole coloured rich azure. It lasts a long time before the flowers wither and the spikes do not "spindle," as is the case with *M. conicum*. A splendid rockery plant; it will rival *M. conicum* for purposes of naturalising when available in sufficient quantity for that purpose.

*M. racemosum* (the common Starch Hyacinth). An old-time species of variable colouring, whose flowers are in compact spikes, generally true blue; but there are various colour forms that are made to do duty for other species, and from which they can hardly be distinguished even when grown side by side.

*M. szovitsianum* is a very dainty little plant, and distinct from most of its kind in its late season of flowering and very pale blue, slender spikes of small flowers. The shade of colour is

that peculiar to *Hyacinthus azureus*. A refined Muscari and one of the prettiest bulbous plants, fully deserving the best place the rockery affords.

Most of the Muscaris make exceedingly pretty pans for the alpine house, and they are charming when associated with other bulbs in pots and pans for the decoration of apartments in their season.

GEORGE B. MALLETT.

### THE BEST DAHLIAS.

(Continued from page 142.)

DOUBLE fancy Dahlias alter so little from year to year that it is almost needless to name the best, as some of them have been leading varieties for many years. I will, however, just give the names of a few, say, twenty-four, which are second to none, although by no means the only useful sorts: W. Powell, light yellow; R. P. Rawlings, yellow; Mrs. Gladstone, soft pink; Mrs. Slack, blush, edged purple; Chieftain, light purple; William Rawlings, deep purple; J. T. West, yellow, edged purple; Dr. Keynes, buff, tinged red; T. J. Saltmarsh, yellow, suffused red; Prince of Denmark, maroon; Colonist, dark fawn; Gracchus, orange buff; Warrior, scarlet; Shirley Hibberd, dark crimson; George Rawlings, very dark; Mand Fellows, pink, tinted purple; Goldfinder, yellow, edged red; John Hickling, deep yellow; Duke of Fife, cardinal; Henry Walton, yellow, heavily edged; Harry Keith, purple; John Walker, white; and Mrs. Langtry, cream, edged crimson.

Pompons show a decided inclination to increase in popularity, and they richly deserve to, as few flowers give a better return for the work expended on them. A few of the best are as follows: Thalia, rosy pink; Tommy Keith, red, tipped white; Nerissa, soft silvery pink; Rosebud, white, edged pink; Bacchus, bright crimson; San Toy, white, edged carmine; Sunny Daybreak, pale yellow, edged red; Ideal, deep yellow; Emily Hopper, yellow; Adelaide, blush; Daisy, amber; Darkest of All, very dark; Lilian, primrose, edged peach; Ganymede, amber, tinted lilac; Jessica, yellow, edged red; Censor, soft plum; George Brinkman, pure white; Queen of Whites, white; Kitty Barrett, yellow, tipped red; and Neatness, pale salmon. Nearly all of the Pompons and doubles are good varieties for all purposes, so it is hardly necessary to give separate lists as in the case of the Cactus varieties. Practically all those named above are good exhibition varieties, and they are equally valuable for decoration. P. P.

### THE ROSE GARDEN.

#### A FINE NEW POLYANTHA ROSE.

OF the novelties of the year 1907, Aennchen Müller will certainly prove to be one of the most distinct and, I may say, useful. It is a break; and that is what we want. There are scores of good Roses put into commerce each year; but their resemblance to existing sorts is so very close as to make one doubt whether they should have been introduced. Therefore, when one

obtains a distinct variety, naturally it is made much of. In growth I believe this Rose will prove to be about equal to Leonie Lamesch. The clusters of bloom constituting individual sprays are really enormous, frequently numbering from twenty to twenty-five individual flowers, and each flower has three rows of petals, which are curiously twisted something like a Cactus Dahlia. The colour is a lovely cherry pink or almost coral red, with a distinct white centre to the flowers. When grown outdoors the colour is a richer pink than when grown as a pot plant. It has rather a bad tendency to mildew, which may hinder its culture for pot work, but outdoors this tendency seems to vanish. I think there must be a close relationship between Aennchen

ROSE AGLAIA OVER ARCHES.

Müller and that lovely semi-rambler Tausendschön, for they both came from one raiser, J. C. Schmitt, in the same year. Reputedly, Aennchen Müller is the result of a cross between Crimson Rambler and Georges Pernet. P.

#### ROSE AGLAIA.

This is a free-growing climbing Polyantha Rose, which, when well established, produces masses of small canary yellow flowers. It is a charming companion to the better-known white Rose Thalia—its counterpart, except in colour—both being distributed in 1896. Trained on an arch, pergola, or tree stump it is at its best. Against a wall and in dry positions it is liable to mildew and red spider. J. COMBER.

### COLOURED PLATE.

PLATE 1344.

#### PERPETUAL-FLOWERING CARNATIONS.

A VISIT TO MESSRS. HUGH LOW AND CO.'S NURSERIES.

THE winter or perpetual flowering Carnations are a comparatively recent introduction to this country, that is, so far as the newer types are concerned, but there is no doubt whatever that they have come to stay, the splendid exhibits that are staged at the Royal Horticultural and other exhibitions during the winter months doing much to popularise them. Hitherto these Carnations have been regarded by the ordinary grower with some awe, the erroneous idea having been circulated that special glass houses were needed for their culture, and that the plants were of a tender nature. We recently paid a visit to the extensive nurseries of Messrs. Hugh Low and Co. at Bush Hill Park, Enfield, for the purpose of inspecting their stock of these beautiful and exceedingly useful winter-flowering Carnations; and although we anticipated a grand sight, we were not prepared for the magnificent spectacle that confronted us. Out of the ten acres or so of glass structures situated in this wonderful nursery nearly one acre is devoted to these plants. In one house, at the time of our visit, were no less than 70,000 cuttings inserted in sand, and in another house we observed some 65,000 rooted cuttings potted off into 2½-inch pots. To give our readers some idea of the extent to which these plants are propagated here we made a rough calculation of the number of cuttings that are rooted during the propagating season, i.e., from October to May inclusive, and the number was not far short of 500,000. The cuttings are made from sturdy side-shoots, and these are inserted in beds of pure sand, these being formed on raised stages within 3 feet or 4 feet of the glass, the bottom temperature ranging from 50° to 55° and the atmosphere from 45° to 50°. We particularly noticed, in all the houses, the abundance of fresh air afforded the cuttings and plants, no coddling being the maxim.

#### THE HARDINESS OF THE PLANTS.

We mentioned at the outset that an idea seems to have become general among many growers that these plants need warmth and special houses, hence it may do much to explode this theory if we mention an experiment that Messrs. Low have conducted at their nursery. In some fully-exposed beds plants of border Carnations and others of the perpetual-flowering type were planted side by side last September. Notwithstanding the fact that these plants were exposed to 23° of frost early in January, they came through it quite unharmed, and at the time of our visit the perpetual-flowering sorts could have given the border varieties several points as far as appearance was concerned. Even the owner of a cold greenhouse can successfully grow these plants, or they may be grown entirely in the open. Thus young plants ought to be set out in

open beds in May to flower all the summer. If it is desired to leave them out all the winter, cut them back in the autumn when flowering is finished. If, however, a slightly heated or cold greenhouse is available, lift the plants during August or September, pot them up, and transfer them to the greenhouse, where they will continue to flower during the winter. This is a phase of culture that is at present in its infancy, but one that we venture to predict will become exceedingly popular in the near future.

A mistake that is often made in growing these Carnations is in the cutting back of the plants at the end of the flowering season or late spring. They should be cut back hard, so as to induce the formation of sturdy shoots during the summer months for flowering the following winter.

#### GROWING FLOWERS FOR CUTTING.

Although Messrs. Low do such an enormous amount of business in young plants, their energies are by no means confined to these, large quantities of plants being grown for providing flowers for cutting. In one house measuring 250 feet by 35 feet, and about 14 feet from floor to ridge, are fixed two large wooden tray-like benches about 1 foot from the ground, these running the entire length of the house. Each is about 8 feet wide, and these are filled entirely with flowering plants. These plants were set here in June last in about a 3-inch layer of soil, each plant standing, roughly, 1 foot from its neighbour. The soil used for this purpose is good loam, with a fair percentage of burnt garden refuse incorporated. To do away with staking, wires are stretched tightly the entire length of the house about 1 foot from the surface and the same distance apart, and then string is threaded across these so as to form squares of about 1 foot each. Through these the flowers are pushed and held almost erect.

Some of the varieties that we noticed doing particularly well here were *Britannia*, a magnificent scarlet, raised in this country; the old but still useful white *Lady Bountiful*; *Mrs. Burnett*, the new salmon pink that created such a stir last year; *White Perfection*, a superb white variety that will take a lot of beating, the stems being remarkably long and the calyces non-splitting; *Enchantress*, the superb pink variety that is a universal favourite; *Robert Craig*, a good scarlet of vigorous habit; *Winsor*, the new deep pink variety, the stems of which are scarcely so long as some, but the habit is good; *Victory*, a deep or dull scarlet that is a great favourite in America; and *Harlowarden*, the well-known deep crimson variety.

We also noticed in this house a two year old plant in a pot of the unique buff-coloured, flaked with scarlet variety, *Oriflamme*, that was carrying no less than fifty buds. Enormous quantities of plants are also grown in pots for providing cut flowers, and we noticed a large number in 5-inch pots that are for sale, these being the size most recommended by the firm. Messrs. Low advise giving the plants plenty of pot room, and warn growers against potting the young plants too deeply. An ideal soil mixture for the general potting is one composed of rather stiff yellow loam, one-sixth part well-decayed (preferably cow) manure, one-twelfth part wood ashes, a good sprinkling of sand, and a 5-inch potful of bone-meal to each barrow-load of the foregoing.

#### RAISING NEW VARIETIES.

This is usually done by means of crossing the best varieties and then sowing the seeds. A

maxim of the firm is that nothing new shall be sent out unless it is an improvement on existing varieties, and to give our readers some idea of how rigorously this is carried out, we may say that out of 7,000 seedlings raised last year only about forty plants in all were retained for further testing; from these only six or seven new improved varieties are expected, and these are the only result of a year's work in handling 7,000 plants.

The general cleanliness of the plants was particularly noticeable. Should any rust appear Messrs. Low find it easily checked by spraying the plants with methylated spirits and water, one part of the former to one hundred parts of water.

#### MALMAISON CARNATIONS.

These are also cultivated here extensively, no less than 50,000 plants being layered last summer. Contrary to general ideas, Messrs. Low find that there is a rapidly increasing demand for the best varieties of this type. Large quantities of seedlings are raised annually for the purpose of securing something new, but, like the perpetual-

## PLANTING ROCK FLOWERS.

EARLY spring is a most suitable time for planting alpine and rock plants generally, as at this season root-growth is slightly in advance of the top, so that they readily take to the soil and become established before the extreme of summer drought. When stones of a considerable size are used in building rock gardens, ideal conditions are offered by planting behind; the roots come in contact with the cool surface in the soil, while the vegetative growth rests upon the exposed surface of the stone. New works will, of course, require careful supervision for a season, as extreme shrinkage and subsidence generally follow where soil has been recently moved. There is often some difficulty in selecting plants for new rock gardens, and the temptation to overdo variety requires careful guidance. The best rock gardens sustain interest not in variety alone, but in masses also. *Saxifragas* offer a ready example. A single specimen of *S. longifolia*, will give a clear idea of the beauty and utility of these large forms, but it is scarcely possible to

SOUTH-EAST PORTION OF ROCK GARDEN IN THE WALMSGATE GARDENS, LOUTH, Lincs.

flowering varieties, they have to undergo very severe tests before they are even exhibited. We noticed a large number of stock plants in 8-inch and 10-inch pots, each possessing from eleven to thirteen fine shoots, for flowering next summer.

In concluding it may be well to emphasise a few points in connexion with the perpetual-flowering type. Thus we have seen that the plants are quite hardy and may be grown in the open or in a cold greenhouse; plenty of air is needed at all times; cuttings root easily in pure sand; plants for flowering may be either planted out in the house or grown in pots; rust may be held in check by spraying with methylated spirits and water; and after flowering the plants should be pruned hard back. Orchids, hard-wooded plants, *Cyclamen*, *Roses* and fruit trees are also extensively and well grown at these nurseries, the stock in every instance being remarkably clean and vigorous. Visitors to the Royal Horticultural Society's fortnightly meetings will be familiar with the fine exhibits of hard-wooded plants, *Cyclamen*, *Carnations* and *Orchids* that are exhibited by this firm.

conceive the beauty of the small species unless we grow a good colony of them.

From the illustration, which shows the south-eastern portion of the rock garden here, some idea may be gathered of the general effect produced by the more vigorous rock plants in the month of June. On the right hand side of the path *Erinus alpinus alba* freely intermingles with the *Winter Heath* (*Erica carnea*), and skirts a patch of the *Sandwort* (*Arenaria balearica*), and finally joins hands on the summit with *Saxifraga Cotyledon pyramidalis*. Immediately below the *Sandwort* is seen the *Erinus* crossing the path under the shelter of a rock step. The crevice at which it terminates is occupied with the *Wall Bellflower* (*Campanula muralis*), while alternate crevices are planted with *Achillea umbellata*, *Draba aizoon*, *Antirrhinum glutinosum*, *Acæna Buchananii* and *Dianthus neglectus*. Higher up occur *Rock Roses*, double *Dyers Greenweed*, &c., while prominent in the foreground are *Hypericum reptans*, *Onosma alba rosea* and a flowering plant of *Saxifraga Cotyledon pyramidalis*.

THOMAS SMITH.

Walmsgate Gardens, Louth.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**VEGETABLE GARDEN.**—I am now making up new beds of various kinds of herbs, as this may be done very successfully at this period. These subjects are increased by seed sowing and by either dividing the old roots or by the insertion of cuttings. In the case of Mint, I prefer to detach pieces of sucker-like growths about 4 inches in length with roots adhering, planting these 4 inches apart in prepared beds. From these pieces I invariably gather a supply during the summer. Second early Potatoes are still being planted, but I am leaving the main-crop sorts for another fortnight. Radishes do well at this period when a sowing is made on warm sheltered borders outdoors. I am now making a sowing of winter greens for next autumn and winter supplies. Brussels Sprouts, Kale in variety, Broccoli, Cabbages and Savoyes should be grown in all gardens. Select a warm situation if possible and sow thinly.

**Fruit Garden.**—A newly-planted bed of Raspberries is now having attention. I am cutting back the canes to within 6 inches of their base, as by these means they will get well established and make capital fruiting canes for the succeeding year. My established canes I usually shorten back slightly; most of them are 4 feet or thereabouts. Keep the surface soil between Strawberries loose, thus aerating it and at the same time keeping the weeds under. Use a Dutch hoe for this stirring of the soil.

**Hardy Flower Garden.**—There is much to be done at this season. Hardy perennials that have not yet been planted should be seen to without delay, as it is getting rather late to plant them in the hope of obtaining good results this year. Seeds of the popular hardy annuals may be sown forthwith, and at any time during the next few weeks. Of the better hardy annuals I sow the Sweet Pea, Cornflower, Candytuft, Clarkia, Godetia, Gypsophila elegans, Sunflower, Larkspur, Lupin, Shirley and other Poppies, Mignonette and the Eschscholtzia, besides several other most interesting subjects. It is well to remember to have the quarters well prepared before sowing and to sow the seeds thinly.

**Chrysanthemums.**—Plants that are to produce large flowers next autumn should be well hardened off by this time. My plants are standing in the cold frame with the top of each plant near to the glass to prevent them getting drawn and weakly. On fine days and in the absence of frost at night, I am ventilating the frames quite freely. On sunny days, when the wind is not in

1.—PART OF A FROND OF ASPLENIUM BULBIFERUM SHOWING NUMEROUS BULBILS THAT HAVE FORMED UPON IT. BELOW ARE SHOWN A FEW OF THESE BULBILS DETACHED.

the cold and cutting quarters, I am pulling down the framelights so that the plants get an abundance of air. In this way they are kept sturdy and short jointed. Pot up singly into pots 3 inches in diameter rooted cuttings of the decorative Chrysanthemums. Use soil of a lasting kind, such as loam, two parts, and half a part each of rotten manure and leaf-mould, with plenty of coarse silver sand. Mix well.

**The Greenhouse.**—For the next month or two the greenhouse should be used for the purpose of bringing on backward plants, and for raising numerous plants for conservatory embellishment and for flowering outdoors in the summer. Half-hardy annuals may be sown at this time, using pots, pans and shallow boxes, filling them with carefully-prepared light sandy soil. I always wash the pots and pans scrupulously clean, and make the drainage perfect. This is covered with some of the rougher siftings of the prepared soil, and the latter is then filled in and made perfectly level before sowing the seeds. Balsams, Nemesia, Nicotiana, Phlox Drummondii, Salpiglossis, Marigold, Schizanthus and the Zinnia are among the more popular of the half-hardy annuals. The soil should be rich and fine, and the seed sown thinly and covered but very slightly. When watering is necessary stand the pans or boxes in a vessel of slightly tepid water, never allowing this to over-run the surface of the soil.

**Orchids.**—My small collection of Orchids is being overhauled just now. Those that are making new growths I am about to repot. My Odontoglossums are now very interesting. I am taking the trouble to shade the plants from bright sun, at the same time ventilating very judiciously. Draughts are always a source of trouble, I therefore avoid them if possible, at the same time circulating air freely between them.

D. B. C.

### FERNS FOR AMATEURS' GREENHOUSES AND ROOMS.

AMONG the very large family of Ferns there are a few which rival Palms and Aspidistras as serviceable plants for room decoration, also for growing in greenhouses where little or no heat is provided. In a room they should not be stood near a fire or in any position where the atmosphere is hot and dry. During the summer they require a fair amount of water, in winter much less will be necessary as growth is not very active; anything approaching a parched condition must, however, be avoided. As a rule Ferns succeed best in moderately small pots.

#### PROPAGATION.

There are several methods of propagating Ferns—by spores, the counterpart of seeds, being the most general. Davallias, Polypodiums and others with creeping rhizomes are propagated by division. Asplenium bulbiferum is increased rapidly by means of the young plants on the fronds. Pteris and Maidenhair Ferns are propagated by division of the rootstocks.

#### SOIL.

Most of the Ferns mentioned below can be grown in soil consisting of two parts fibrous loam and one part leaf-mould, adding plenty of coarse sand. For Davallias peat and leaf-mould should be used. In the following notes, when speaking of several Ferns, the word "hardy" is used. This does not refer to its standing outside unharmed in this country, but to its being fitted to survive the varying and trying conditions usually prevailing in rooms and passages.

#### VARIETIES.

**Hare's-foot Fern.**—This Fern, Davallia canariensis, is found wild in the warmer parts of Europe. The plants require very little heat to cultivate them successfully. I have seen the Hare's-foot Fern grown for a number of years in a fairly light position in a room. The rhizomes as they hang over the side of a pot are very suggestive of the name Hare's-foot Fern. A smaller-growing plant from Japan named D. Mariesii, to which the name of the Squirrel's-foot Fern is sometimes applied, is almost or quite as hardy. This is the plant which the Japanese

2.—BULBILS OF ASPLENIUM PRICKED OFF INTO SANDY SOIL ON THE LEFT; ON THE RIGHT IS SHOWN A YOUNG PLANT POTTED OFF.

3.—A GOOD SPECIMEN OF ASPLENIUM BULBIFERUM.

twist and grow into all manner of queer shapes, quantities of which are imported into this country.

*Maidenhair Ferns.*—These include some of the most popular Ferns, the fronds of *Adiantum cuneatum*, the best-known sort, being especially valuable for cutting and arranging with cut flowers. Some ladies are very successful with this Fern in the window of a warm room where no gas is burned. Our British Maidenhair, *Adiantum Capillus-veneris* and its varieties, are very suitable for the cold greenhouse one often finds attached to the suburban house. Another position for this plant is the window of a cool room, one facing north for instance. Maidenhair

4.—A PLANT OF POLYPODIUM AUREUM, ONE OF THE BEST GREENHOUSE FERNS, DIVIDED.

Ferns are readily propagated by division of the roots, preferably in spring. March is a good month. They may also be easily grown from spores, but it is not often necessary to sow any, sufficient young plants being found in the crevices of the bricks, under the stages, or on the surface of the pots of other plants growing in the house.

*The Holly Fern.*—This is a very distinct Fern and one of the best for a room or cold greenhouse. The dark, shining green fronds being somewhat leathery in texture, the plants stand the varying conditions of a room better than most Ferns. *Aspidium* or *Cyrtomium falcatum* is the Latin name of this Fern. It is a native of South Africa and some parts of Asia, being especially abundant in Japan. Young plants are readily raised from spores, but it is seldom necessary to do this, sporlings coming up under the stage or elsewhere in the greenhouse.

*Polypodiums.*—These Ferns are very widely distributed throughout the world, several being natives of Britain. For greenhouse and room decoration the Golden Polypody (*Polypodium aureum*) is the most largely grown. The plant obtains the name from the creeping rhizomes, which are covered with golden yellow scales. The arching fronds are bluish green in colour, 2 feet or more in height. During winter the plants may lose one or two of the older fronds, but plenty of young ones will be produced in spring to replace them. A native of America and Australia, it was one of the first Ferns introduced into this country. Propagation in a small way can be most readily carried out by division

of the rhizomes, as illustrated. Spores germinate freely when large quantities are required. In addition to being grown as pot plants, they are highly ornamental when cultivated in baskets and suspended from the roof of the greenhouse. The variety *Mayii*, which occurred as a chance seedling in the nursery of Messrs. H. B. May and Sons of Edmonton, has crested fronds.

*Ribbon Ferns.*—Thousands of these Ferns are grown annually in the large market nurseries and sold in Covent Garden. These are mostly grown from spores, this method, with one or two exceptions, being more satisfactory than propagation by division. The two species most largely grown are *Pteris cretica* and *P. serrulata*; both plants have numerous varieties, *P. Wimsetti* being perhaps the best of the crested sorts. A variegated form named *albo-lineata*, with green fronds freely margined with creamy white, is a desirable and fairly hardy plant. An Australian *Pteris*, *P. tremula*, is very distinct from the foregoing and taller in growth, being often 3 feet in height. In the matter of soil, *Pterises* are perhaps the least fastidious of all Ferns, as they thrive in ordinary potting soil such as that used for *Geraniums*.

*Spleenworts.*—There are quite a number of *Aspleniums* or *Spleenworts* suitable for the town or suburban greenhouse, of which *A. bulbiferum* and its varieties are the best known. These are natives of Australia and New Zealand. The illustration plainly shows the young plants developing from the bulbils produced on the fronds. These, if severed from the parent plant and pegged on pans of sandy soil, soon make sturdy little plants.

*Ladder Ferns.*—During the last few years the *Nephrolepis* or *Ladder Ferns* have developed a large number of interesting crested and tasselled varieties. Most of them are very suitable for hanging baskets suspended from the roof of the greenhouse or in the bay window. Another suitable position for them is the top of a Bamboo stand, where the long, slender fronds will hang down and show to advantage. Large plants of *Nephrolepis* can be grown in comparatively small pots, provided they receive plenty of moisture. They are readily propagated by division of the crowns, by buds produced on the wiry stolons or runners, which develop into young plants, and by spores. *Nephrolepis* should be potted in a lumpy fibrous soil in preference to a fine compost. Useful plants for the amateur are *N. cordifolia* and *N. c. compacta*, *N. exaltata*, *N. Fosteri* and *N. Piersoni*.—A. N.

HOW TO GROW GOOD CARROTS.

To grow good-sized Carrots of excellent shape is, or ought to be, the aim of every beginner, because there are very few households indeed where the roots are not required, and the growing of shapely solid roots is a moderate test of an amateur's proficiency in vegetable culture. As the time is now past for sowing for early crops, we must devote ourselves to the more important main crop, and even this will depend, to a great extent, on work that has been previously performed. The ideal soil for Carrots is one that contains a preponderance of sand; but good roots can be grown in almost any soil providing it is well cultivated and the proper types are selected.

As stated above, very much will depend on work previously done, and this work consists in digging the soil 2 feet deep and working, if the ground is poor, some well-decayed manure in the bottom spit. A better system is to select a site that was well trenched and manured for a crop last season, and, where this exists, all that will be necessary now is to fork it over a good spit deep and allow it to remain a week or two to settle. The best Carrots the writer has ever seen were grown on an old Celery bed without any additional manure whatever.

About the second week in April will be the time to sow the seeds, and the beds will need some preparation before this operation is performed.

The surface must be well firmed, preferably by treading, doing this, however, when the soil is so dry as not to adhere to the boots. Then rake the surface level, and remove stones and any other rubbish that may be present. For this crop, as for most others, the most convenient method is to sow in drills, as weeds can then be easily kept down by means of the hoe. As a general rule, 12 inches from row to row is none too much for the long-rooted types, but 9 inches will suffice for the stump-rooted varieties. These drills should be made 3 inches wide and flat at the bottom, 1 inch deep being sufficient. Many beginners make the mistake of drawing the drills wedge-shaped, so that when the seed is sown only a very narrow line is made, the result being a crowded mass of seedlings. With the flat-bottomed drill this is avoided, the seeds being scattered thinly all over the bottom and covered in with nearly 1 inch of fine soil. Lightly rake the surface level, and finally tread the whole firm. Carrots delight in soil that has been moderately compressed.

With the seedlings, which are rather slow in appearing, will also come weeds, and these must be removed as soon as possible, else, being of quicker growth, they will smother the young Carrots. Hoe well between the rows, and when the plants are large enough to handle, thin them so that each stands 2 inches from its neighbour. When large enough for cooking alternate roots must be drawn out so that each of those remaining stands 4 inches from the next. In thinning, care must be taken to promptly fill up all holes that are made, firming the soil at the same time, else the Carrot fly will be almost certain to find the exposed crowns of those that remain and lay her eggs therein, the roots thus attacked being spoiled by the larvæ that hatch out. Useless thinnings, too, should be removed and burned, instead of being thrown down on the bed as is frequently done.

Where wireworms are suspected, a dressing of Vaporite or Kilogrub should be given according to directions before digging over the bed, these substances giving off fumes that are fatal to wireworms and other grubs but not injurious to plant life. Where the soil is very heavy the

5.—A GOOD PLANT OF POLYPODIUM AUREUM.

addition of burnt earth, road scrapings, leaf-mould or similar substances will be of great assistance. On heavy soil the long-rooted sorts ought not to be grown, stump-rooted varieties giving much better results. Where the soil is very sticky or clayey good roots can be grown by making deep holes, 4 inches apart in the rows, with a crowbar, filling these in with good lighter soil and sowing the seeds therein. When the seedlings appear, thin so as to leave one at each station. The long-rooted varieties do best in rather sandy soil that has been deeply cultivated. Some good varieties are: Stump-rooted—Early Nantes and Sutton's Favourite; long-rooted—Sutton's New Red Intermediate, Long Red Surrey and James's Intermediate. H.

## THE TOWN GARDEN.

**HALF-HARDY ANNUALS.**—The amateur gardener who has a frame or a greenhouse can find among the half-hardy annuals plants of superb beauty that will flower profusely from July until well into September, and all of them can be raised from seeds with the utmost ease, provided that reasonable care be taken at all times. When strong plants are brought steadily forward with a view to planting towards the end of May they will thrive satisfactorily in any fertile soil, and succeed almost as well in town gardens as they do in the purer air of the country. While there is not the smallest doubt as to the desirability of sowing either at the end of March or during the first half of April, it is not imperative, for capital results may be secured by sowing the seeds thinly in the positions in which the plants are to bloom some time from the middle to the end of May, but, of course, the display will be much later than that from earlier-raised plants.

**SOWING THE SEEDS.**—This is a far more important operation than many cultivators appear to suppose, if one may judge by the careless manner in which it is often carried out. As a matter of fact, the success of the plants depends largely upon the manner in which the seeds are sown and how they and the subsequent seedlings are treated. The first essential is a compost consisting of about equal proportions of flaky leaf-mould and light loam, and to these ingredients may be added a little sharp road-grit or coarse sand, so as to keep the soil open and porous. This should be thoroughly mixed a few days in advance of use. Next we must prepare some shallow boxes, pans or pots, according to convenience, but in most cases the first-named are best. Some little provision for ventilation is desirable, and the receptacles should then be filled to within an inch or so of the top with soil, the surface of which must be made moderately firm and quite level; if the soil is dry soak it and the seeds can be sown an hour or two later. In distributing the seeds strive for evenness and thinness, as these things encourage better progress and relieve the necessity of much thinning out. The box should be placed in a frame or a greenhouse until the seeds have germinated.

**TREATMENT OF THE SEEDLINGS.**—As soon as the seedlings are large enough to handle thinning out must commence, for it is in the best interests of ultimate success that the young plants shall never touch each other. When the plants are grown thus from the earliest stages they keep stocky and strong and develop their full, and in some instances remarkable, powers of branching. As soon as necessary they must go into other boxes, and gradually they should be accustomed to more and more air, until at last the lights can always be kept open, except during torrential rains; or, if it is desired to have especially fine plants, each one can be placed in a 2½-inch pot until the time arrives for planting out in the garden.

**SOME OF THE BEST KINDS.**—In making selections it is always well if each grower can be persuaded to choose for himself, as tastes vary so widely that what may be most pleasing to one will be the reverse to another. At the same time it may be well to make one or two suggestions as to those that are generally accepted as the most useful kinds of all. A start may be made with Asters, and while no one would desire to deprecate the charms of the older types, it can scarcely be disputed that the modern Comets and Ostrich Plumes are superior; they can be procured in distinct colours if required. Of the older forms Victoria and Chrysanthemum flowered are splendid. Ten Week Stocks either mixed or in separate colours are superb, and in addition to being beautiful are delightfully perfumed. Then, too, there are Zinnias, Phlox Drummondii, African and French Marigolds, Nemesis, Salpiglossis and others worthy of attention, and all responding to the treatment outlined above.

H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**VIOLITS IN FRAMES.**—The propagation of these should now be done. If some fine leaf-soil is placed around the plants, the runners will soon take hold of this mixture and quickly form sufficient roots, when they should be separated from the parent plant. In some cases it is well to take cuttings a little earlier and strike them in boxes, but for a quantity I have found the former the best method. The ground on which these are to be ultimately planted should have plenty of manure and leaf-soil and a dressing of soot, and be got ready at once so that time is not wasted when the runners are ready. The most popular varieties are: Amiral Avellan, reddish crimson, comes rather late, but is very useful for house decoration; Comte de Brazza, white; La France; Marie Louise, lavender-blue; Lady Hume Campbell, blue; Mrs. J. J. Astor, heliotrope; Princess of Wales; and wellsiana, purple.

**Rhododendrons, Azaleas, Conifers and Camelias** may be propagated by seed, and this should be sown at once in seed trays or boxes. Provide ample drainage and good substantial soil that will last a year in condition if necessary. Sow thinly and cover with moss till germination takes place. Stand the boxes in a warm frame of about 55°.

**Lobelias** and other bedding plants raised from seed should be boxed off as soon as the plants are large enough; grow them on in warm frames or low span houses where they will be near the glass. Shade the seedlings for a few days after disturbance. Grevilleas, Torenia, Saintpaulia and the like should be pricked off into small pots as soon as large enough, and place them on shelves in the stove or other warm house near the glass.

#### KITCHEN GARDEN.

**Onions.**—The main crop should now be sown. Rich soil is necessary, and this should have been well prepared and exposed. Choose a fine morning for seed-sowing, rake the ground down fine, and give a good sprinkling of soot all over. Sow in drills about half an inch deep, label correctly, and make the ground as firm as possible. In addition to exhibition varieties sow Brown Globe, James's Keeping and Bedfordshire Champion; these will be found of good quality when many others have passed their best.

**Turnips.**—Good sowings of these should now be made, and Broccoli, Brussels Sprouts and Cauliflowers must also be sown in quantity.

#### HARDY FRUIT GARDEN.

See that Apricots, Nectarines and Peaches have sufficient protection from frost. Draw down the blinds the last thing at night and remove early in the morning if frost is not present. Prepare stocks of Apples and Pears for grafting. Sow alpine Strawberries in boxes and prick out as soon as large enough; these fruits are better raised from seed than layers. Sutton's Large Red is an excellent variety. Look over and examine the fruits of Apples and Pears in the fruit-room and eject those that are unsound.

#### FLOWER GARDEN AND ROCKERY.

Keep the beds that are filled with spring-flowering plants and bulbs clean and tidy. Stake any that require support before they fall over. Sow seeds of alpine and plant out from the reserve. Clean and top-dress all those plants that have been dormant, using good open soil. Prune Hybrid Perpetual Roses, and in doing this cut out all the small weak growths; strong growers should be cut back to two or three eyes.

See that the stakes of standard and half-standard varieties are good; if not, replace them.

#### FRUITS UNDER GLASS.

**Vineries.**—Continue to tie down and regulate the shoots. Thin the berries as they become large enough. Muscats starting should now have a temperature of 55° to 60°. Later vineries should be damped down on all bright mornings and afternoons, with just the smallest amount of fire-heat at night.

**Peaches and Nectarines** swelling their fruits must have ample supplies of liquid and be sharply eyringed twice daily.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CROTONS.**—These are far more generally used in a small state for table decoration and for filling bowls and other receptacles. For this purpose the plants, of course, soon get too large, and annual propagation has to be made according to the demand. Old stock plants are kept in some places, and the present is a good time to commence operations with these, as the top buds are still dormant, but yet just on the point of bursting. It is better to propagate now than later, when the leaves from these buds have commenced to unfold. If left until these start, the leaves in many cases are checked and never attain to their proper size.

**Bougardias.**—Plants that were cut back should now be starting into growth and producing shoots that will form cuttings. When about 2 inches long these should be placed in 5-inch pots in a mixture of loam, leaf-mould and sand in equal parts, care being taken that the soil is made quite firm round the cuttings. Water and place them in a propagating frame with a bottom-heat of about 80°, plunging the pots to their rims in Coconut fibre and shading from sunshine.

#### HARDY FRUIT.

**Fig Trees in the Open.**—These have in many gardens been closely covered, and it is well now to gradually uncover them. The trees should now be pruned, lightly cutting out dead wood and naked branches. By this means the centre of the tree is kept well furnished with young fruiting wood and there is less loss in severe seasons. I do not advise laying in much sucker growth, but hard, firm shoots, which spring from the leading branches. In training keep the trees close up to the walls. It is well to restrict the leaders to a certain space, as they bear little fruit when not kept in check.

#### KITCHEN GARDEN.

**Cucumbers.**—Early-sown plants will now be coming on apace and will soon supplement the winter crop. If any extra early fruit is formed on the main stem or on the first laterals, it will be wise to remove it. If there is ample room for the plants, do not pinch too rigidly, but allow the growths to extend somewhat, reducing their numbers if too crowded. This will encourage the foundation for free and continuous cropping. A night temperature of 70° when mild weather prevails will be suitable, closing early and damping the foliage over with tepid water. The floors also must be kept moist by sprinkling two or three times daily.

#### FRUIT HOUSES.

**Peaches and Nectarines.**—At this season great care is necessary with late houses, for untold mischief is annually wrought in late Peach houses by the common practice of throwing open both top and bottom ventilators while the trees are expanding their blooms and onwards till the fruit is set. In sheltered situations and on calm

sunny days little or no harm may result from the practice, but to expose the delicate petals of Peaches and Nectarines to the force of cutting winds and draughts is simply to court disaster. Assist at midday in the usual way all shy setting varieties, and damp down moderately when the air is reduced in the afternoon.

#### ROSE CUTTINGS.

Where plants are required for indoor use they may now be produced in plenty by dibbling the cuttings in rather thickly into 5-inch pots and plunging in bottom-heat. The roots soon form and top growth is also quickly made. The cuttings must be about 6 inches in length from dormant wood from indoors. As soon as the cuttings are rooted the pots must be lifted out of the plunging material and the plants potted singly a few days afterwards, shading them until the young roots are getting well into the compost, when they may be gradually inured to less heat and moisture.

T. B. FIELD.

(Gardener to the Baroness Berners.)

Ashwellthorpe, Norwich.

### NEW ORCHIDS.

#### CATTLEYA SUZANNE HYE DE CROM.

THIS is rather a unique-looking Cattleya of hybrid origin. The good-sized flower is pure white, with the exception of the labellum, which is lightly marked in the throat with rich yellow. The petals and labellum are prettily crenated at the edges. Shown by Mr. Jules Hye De Crom, Ghent, Belgium. First-class certificate.

#### ODONTOGLOSSUM GLADYS.

This is a pretty addition to the Odontoglossums, and is the result of a cross between *O. cirrhosum* and *O. harrayanum*. It resembles the latter in colour, but the flowers are larger and more star-shaped. The sepals and petals are of equal size and even lanceolate shape, the edges being beautifully crenated and the apices acute. The cream ground colour is almost obscured by the numerous large brownish crimson blotches. The labellum is rather elongated, deep primrose yellow at the apex and heavily mottled with dull crimson at the base. The plant exhibited had one inflorescence composed of four fully-opened flowers. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

#### LELIO-CATTLEYA ELINOR.

Here we have a perfectly self-coloured member of this bi-generic family, the medium-sized flowers being of a very rich golden yellow hue. The throat of the labellum is tinted lightly with orange, but this is not very noticeable. A very rich-looking specimen. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. Award of merit.

#### CATTLEYA ENID WESTONBIKT VARIETY.

This is an exceedingly large-flowered Cattleya, and the specimen exhibited was a very fine one indeed, an enormous inflorescence being composed of five fully-opened flowers. The sepals are lanceolate and the petals are almost ovate, the colour in each instance being bright lilac. The fimbriated and somewhat broad labellum is heavily streaked with rich carmine, with yellowish markings at the base. Shown by Major G. L. Holford, C.I.E., C.V.O., Westonbirt, Tetbury, Gloucestershire. Award of merit.

#### LELIO-CATTLEYA LUMINOSA WESTONBIKT VARIETY.

Here we have a marked improvement on a very fine Orchid. This variety has larger and much richer-coloured flowers than the type. The large sepals and petals are of a deep orange, apricot and yellow hue, the petals having very deeply-crenated margins. The large labellum is very deep rich carmine, thus providing a very striking contrast to the colour of the sepals and petals. Shown by Major Holford, C.I.E., C.V.O. Award of merit.

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

### FLOWER GARDEN.

**Campanula Allioni from seed** (E. J. L. E.).—We have found no special difficulty in raising plants of this from seeds when these were sown in thoroughly drained pots of soil composed of loam, leaf-soil and sharp sand, very thinly covered with fine earth of the same character and the pots covered with a sheet of glass and brown paper until the young plants appeared, when light and air were gradually given. From your letter, however, we consider that you have taken every care with your seeds, and that it is these which are at fault. It is possible that the original plants you raised were hybrids which gave and continue to give unfertile seeds, a thing which sometimes happens with hybrids. From what you say about the appearance of your plants they are probably such. Although we fear they will never give you fertile seeds now, you might try the effect of brushing the flowers gently with a camel's-hair brush when the plants come into bloom so as to convey the pollen from one flower to another. We compliment you on your clear letter.

**Sweet Peas for exhibition** (X. Y. Z.).—The first essential to success in the cultivation of Sweet Peas for exhibition lies in the thorough preparation of the soil. It is necessary that you decide for yourself whether you will grow the plants in clumps or rows, equally gratifying results accruing from either system provided that all other conditions are favourable. In working the soil go to a depth of 2 feet or more, thoroughly digging the entire depth and working into the second spit a generous dressing of horse manure if the land is heavy, and of cow manure if it is light. In the surface soil, after the initial preparatory work is completed, prick a mixture of five parts of superphosphate of lime and three parts of sulphate of potash, at the rate of 2oz. to the square yard. This should be done immediately, so as to allow the ground to settle down before the seeds are sown at the end of the present month or during the first week of April. In sowing, set the seeds about 1½ inches down on a firm, level base; they should be placed about 3 inches asunder, and subsequently will need to be thinned gradually until the plants stand from 15 inches to 18 inches apart for flowering. The number of stems on each plant should be restricted to three, the superfluous ones being removed one or two at a time, so as not to give a shock to the plants. Before the seedlings are 3 inches in height, twiggy sticks rising 12 inches above the surface should be put to them, and just before they reach the tops of these the permanent stakes must be put into position. Do not water until it is absolutely necessary, and, when you do, give a thorough soaking, and follow a few hours later with weak liquid manure if you think that the plants want assistance, but never give this until they are in bud. If you want to exhibit a set of twelve you ought to grow eighteen varieties, and they might include Audrey Crier, Etta Dyke, Primrose Spencer, Lord Nelson, Sybil Eckford, Black Knight, Duke

of Westminster, Helen Lewis, Helen Pierce, King Edward VII., Queen Alexandra, George Gordon, Lady Grizel Hamilton, Jeannie Gordon, Phenomenal, Countess Spencer, George Herbert and Dorothy Eckford.

**Six kinds of annuals for a show in August** (F. R. R.).—The following are suitable: Sweet Peas, Asters, Stocks, Godetias, Salpiglossis and Calliopsis bicolor nana. All except the Sweet Peas and Godetias should be raised by sowing seeds in boxes at once. The Sweet Peas should be sown in deeply-dug ground early in April, and the Godetias at the end of that month.

**Lawn mower for one man** (M. A. P.).—A mower with blades 10 inches wide is the most suitable size for one man to use. Many gardeners have to push machines with 12-inch blades, but, unless the lawns are kept in first-class condition, this is very hard work, and nothing is gained by using such a machine. Ransome's, Green's and Shanks' machines are all excellent and thoroughly reliable, and you can with safety purchase either of these makes.

**Incarvillea Delavayi** (G. T. S.).—Plant the Incarvillea in a rather sheltered though sunny position in the open and in deep rich soil. The plant is quite hardy, and the crowns may be buried some 3 inches below the soil. It not infrequently happens that where the roots are much dried or belong to an importation that a long time elapses before growth appears. In an ordinary way the plant starts quite late into growth, so that there need not be any fear on that score.

**Stopping Pentstemon cuttings** (H. H.).—Unless the Pentstemon cuttings are weak and drawn there is no need to stop them, as, if planted out under favourable conditions, they will grow freely and branch out of their own accord. You do not state the condition they are now in, and whether they are still in their stove pots or otherwise. If they were originally put into stove pots and still remain therein, no time should be lost in potting them singly, for they should be planted out as soon as it is safe to do so.

**Twelve kinds of herbaceous flowers for exhibition** (F. R. R.).—We presume you mean kinds and not varieties. It is always advisable to carefully read the rules in the schedule and so make sure of facts. Here are twelve kinds which you should have no difficulty in obtaining by the date named: Gaillardias, Pyrethrums (double or single-flowered), Aster amellus, Phlox (herbaceous), Campanula pyramidalis, Coreopsis grandiflora, Helenium grandiflorum, Veronica spicata, Helianthus Hookeri, Delphiniums, Tritomas and Scabiosa caucasica.

**Narcissus bulbs failing** (J. H. W. S.).—Every root on the bulbs sent was quite rotten, and in most cases the bulbs also, which circumstance would point to some very unsuitable treatment. What that has been is, of course, impossible for us to definitely say, but we think they have been kept too wet. Again, if they are stood in a close room, these Narcissi are far more likely to go off than if they have a free circulation of air around them. There is no trace of disease or insects on the bulbs, except that they are absolutely rotten. Plenty of light is also very necessary to the development of Narcissi when they are grown indoors. We thank you for your kind remarks.

**Herbaceous Phloxes** (Nemo).—Only three of the varieties mentioned are known to us, and we could not say that you have these true to name. If they are, Jeanne d'Arc is white; John Lee, crimson; and Pantheon, soft rosy salmon. The colours of all the sorts named should have been obtainable from the person or firm who sold them to you. Whether Phloxes are good for exhibition depends not a little upon the cultivation meted out to them, but there are many finer white varieties than the first-named. A distinct set of Phloxes for the purpose indicated should include Flambeau, fiery red and orange; Sylphide, pure white; Pantheon, soft rosy salmon; Embasement, salmon scarlet, purple eye; Iris, mauve-violet; and Eugene Danzanvilliers, rosy lilac, white eye.

**Carnations for exhibition in August** (F. R. R.).—Mrs. Keen, scarlet flake; Master Fred, crimson bizarre; Princess Beatrice, pink and purple; and James Maguire, rose flake, are good varieties. If the plants be grown under glass in a cool structure and plenty of air admitted to them, the blooms will be clean and of first-class quality. The best soil is one composed of fibrous loam two parts, leaf-soil one part and well-rotted stable manure one part. A 5-inch potful of ground oyster-shells should be added to two bushels of soil. The same quantity, or a little more, of old mortar rubbish will do instead of the oyster-shells if you cannot procure the latter. When the pots are full of roots you may feed with artificials. Sulphate of ammonia, nitrate of potash and phosphate of potash are useful. A teaspoonful in one gallon of water is a strong enough dose.

**Sweet Peas and Violets for market** (M. B.).—In the case of Sweet Peas, you will find that the most profitable to grow for market are those with clear decided colours, the more washy tints being but little sought after. The following are good: Dorothy Eckford, white; John Ingman, rose and carmine; Countess Spencer, pink; Helen Lewis, orange; George Gordon, magenta; King Edward VII., crimson; Queen Alexandra, scarlet; Gladys Unwin, rose-pink and Miss Willmott, salmon pink. The dark coloured varieties, such as Navy Blue, Duke of Westminster and Black Michael, do not, except occasionally, sell well. The best Violets are: Amiral Avellan, La France, Luxonne and Princess of Wales, all single; and Comte Brazza, De Parme, Marie Louise, Mrs. J. J. Astor and Neapolitan, double. We are sorry that we do not know of any book dealing with these two subjects, but "Sweet

Violets," can be obtained from THE GARDEN office, and "Sweet Peas" from Messrs. Collingridge of Aldersgate Street, London.

### TREES AND SHRUBS.

**Elm tree suckers in a plot** (*F. T. E.*).—We answer your questions *seriatim*. We think that many of the roots and suckers are those of the Elm that is cut down, and also from those near the corners of the plot parallel with A. The two at the other end of the plot and 20 feet away will also contribute their share. The roots of the Elm cut down are most likely alive. Undoubtedly the soil is impoverished by the roots and suckers, and as it is would be unsuitable for Roses. But if you dig a trench, say, 18 inches wide and 2 feet deep all round the plot and cut all the roots encountered, the plot can be made suitable for Roses. If possible such a trench should be left open. Of course, you must, besides digging this trench, remove all roots and suckers that are in the plot, else they will remain alive for a long time and give you a lot of trouble.

**Pruning Gorse bushes** (*E. M. L. B.*).—You may cut your Gorse bushes down at once or you may leave them until flowering is over. If you do the work at once you gain two extra months for growth and lose the flowers. Personally we advise sacrificing the bloom for one year, so that advantage can be taken of the longer growing season. While you are at it, cut the plants well down, as new growth will appear from near the ground as readily as from branches left 2 feet or 3 feet in length.

**Climbers for a choice position** (*L. J.*).—Of the plants you mention *Azara microphylla* is the most suitable subject for your wall; a still better plant, however, would be *Escallonia macrantha* or *Ceanothus thyrsiflorus*. It is more than likely that the plant you refer to as *Schizophragma hydrangeoides* is *Hydrangea petiolaris*. The former shrub is extremely rare, and the latter is often met with under the former name. It is a good wall plant and thrives in almost any aspect. *Aristolochia altissima* and *Decumaria barbara* will thrive in either a west, east or south aspect.

**How to treat seedling Laburnums** (*Mid-Norfolk*).—The seedling Laburnums you mention will not be of use for forcing for several years yet, and you will obtain better results by planting them out in the open ground for three or four years. Turn them out of the pots and shake all the soil away from the roots, then spread the latter out to their fullest extent and shorten very long ones. Leave the plants in the same position for eighteen months, then transplant them and shorten back the strongest roots. During summer, if very rank growth is made, shorten the branches a little; what you want to aim at is short sturdy growth producing strong buds. In about four years your plants ought to be in good condition for forcing. If by *Acacia* you mean the hardy False *Acacia* (*Robinia Pseud-acacia*), it is of no use for forcing. The Australian *Acacias* are, however, first-rate greenhouse plants. They succeed best by being well cut back after flowering.

**Pruning of various flowering trees** (*Rebecca*).—*Prunus Mume*, *P. Pissardi* and *Pyrus Malus floribunda*, when grown as small trees or bushes in the open ground, rarely require pruning, all that is necessary being to thin out a few inside branches when they appear to be getting too crowded. All naturally form shapely trees, which are always of better appearance if not cut back. When thinning is necessary, the branches may be removed as soon as the flowers have fallen. *Prunus triloba* may have the branches spurred back as soon as the flowers fade, the object in this instance being to get good strong young shoots which will flower from end to end. Trees cut back in this manner should be well fed, and, as the method of culture is a very exhaustive one, they require renewing earlier than trees that are grown naturally. The Siberian Crab (*Pyrus baccata*) may be treated as recommended for *P. floribunda*. It is not usual, neither is it necessary, to plant *Pyrus floribunda*, *Prunus Mume* or *P. Pissardi* against a wall. *P. triloba*, however, is a great success when grown in such a position; it is, though, perfectly hardy and forms a fine feature in the open.

### THE GREENHOUSE.

**Climbing plants for greenhouse** (*Miss S. H. T.*).—It is impossible to recommend any climbing plants for the greenhouse which are not liable to become infested with mealy bug, for the simple reason that no such plants exist. As your *Tacsonias* were so badly attacked there is little doubt that the pests have taken possession of the house and are hidden in any available crevice. This being the case they will at once take possession of any new climber and spread rapidly. It is, therefore, evident that nothing

can be planted with any measure of success till the house has been thoroughly cleaned. How difficult this is can only be realised by those who have undertaken the work. All the woodwork should be scrubbed down with a strong lather of soft soap and water, working it well into every crevice. Then the walls should be whitewashed with hot lime and the structure repainted. Even with all this it is very possible that some of the pests will make an appearance when a new plant is put into position. It will, therefore, be necessary to keep a sharp look out and attack the enemy as soon as ever it puts in an appearance. The old adage of a stitch in time saves nine is well exemplified in the case of a greenhouse in which mealy bug has appeared, for if only half a dozen are allowed to remain undisturbed they quickly increase in a wholesale manner. Where an isolated bug or two are liable to occur a very good plan is to keep a bottle of methylated spirit with a small brush close at hand. A drop of the spirit will dissolve the woolly matter and kill the insect, as well as any eggs it may touch. *Passiflora Imperatrice Eugenie* or a *Tacsonia* are among the best of climbers.

**Aspidistra flowering** (*N. H.*).—The flowers of this plant are stiff, wax-like creations of a dirty chocolate and cream colour. They are produced close to the soil in the pot. They do the plant no appreciable harm and there is not any need to remove them, unless, which is very unlikely, the plant is in an unhealthy condition.

**Growing Tulip *Lucretia* in pots** (*Florist*).—We have never grown *Lucretia* in pots, but if you can manage other double Tulips, such as *Murillo*, successfully for market purposes and always fail with *Lucretia*, the fault is probably inherent in the variety, and we advise you to try another sort, say, *Premier Gladstone*. For example, *Rose Blanche* would be a perfect double white were it not for its weak stem. As to the stems of the Tulips getting soft and "knackling over," if this happens when they are cut, there is nothing better than splitting the ends of all the stems in the form of a cross for about three-quarters of an inch up them, and keeping the vases in a fairly warm temperature.

**Stephanotis with seed-pods** (*J. F. B., Ditchingham*).—It is not at all uncommon for the *Stephanotis* to bear a few seed-pods, but they are seldom allowed to develop, as they tend to weaken the plant, and if allowed to ripen and young plants are raised therefrom, they are, as a rule, very shy flowering compared with those obtained from cuttings. These strike root readily enough if put into a close propagating frame kept at a stove temperature. We therefore advise you to remove the seed-pod from your plant. It is not usual for the *Calla* to produce two fully-developed spathe on one stem. At the same time it is by no means rare, and in THE GARDEN for July 8, 1905, we published an illustration of the golden-flowered *Calla* (*Richardia*) *elliottiana* that had behaved in a similar manner.

**Repotting tree Carnations and other plants** (*Notice*).—You may now without delay repot the different subjects concerning which you enquire. In repotting, particularly in the case of the *Fuchsias* and *Geraniums*, take off as much of the soil as you can from the old ball of earth without disturbing the roots to any great extent. It is very necessary that the pots be quite clean, both inside and out, and they should never be used while wet. Effective drainage, too, is very necessary. It need not be excessive, say, one large crock or oyster shell over the hole in the bottom of the pot and a few smaller pieces above this. Suitable potting soil may be obtained from any local nurseryman, stating, when ordering, the purpose for which you require it. In potting take care that the soil is in a moderate state of moisture, as if too wet or too dry it is equally injurious. It must be worked down regularly all round the old ball and pressed firmly, but not excessively so.

**Erecting a greenhouse** (*Miss P.*).—For the purposes you name the greenhouse might well be of the "sunk" or "pit pattern," a 2-feet wide pathway excavation running through the centre, with brick or concrete side walls to keep up the soil bed. The level of the standing bed internally should be at least 6 inches above the outside surrounding level of ground, and with a 3-inch-deep bed of ashes and clinkers for standing plants upon, a good drainage would be secured and the plants kept free from worms. The outside walls of brick should not be less than 2 feet out of the ground, and upon this the wall plate should be set. We must leave it to your own knowledge of the facts as to whether water or much damp would ensue by adopting the above course, and if so the remedy is to start nearer the ground level. A sunk house is of necessity cheaper and requires no internal staging. The soil from the pathway excavation could be thrown on to the side beds to raise them. As you are connecting the new house up to an existing heating arrangement, your first thought should be that of levelling the ground to ascertain at what height the flow-pipe could be introduced to the new arrangement. A very slight rise from the old to the new will suffice, the turn of the level, for example, in every 9-feet run. For keeping out frost 2-inch pipes will be amply large.

**Treatment of *Salvias* (*Mid-Norfolk*)**.—You will succeed far better with your scarlet *Salvia* if you take and root cuttings of young shoots now, and throw away your old plants. By commencing with young plants each year more vigour is obtained and better flowers are the result. As soon as the cuttings are rooted pot them off singly into rich loamy soil and grow them on in a light greenhouse until the end of June, pinching out the points several times to obtain a good stocky foundation. Then pot into 8-inch pots and place the plants out of doors in full sun. By pinching out the points of the shoots you can regulate the flowering season, but do not stop them after July.

**Plants for an unheated greenhouse** (*Cymro*).—Cucumbers would be even less likely to succeed in your unheated greenhouse than Tomatoes, so you may give up all idea of growing them successfully. During the summer months *Fuchsias*, tuberous-rooted *Begonias*, double-flowered Ivy-leaved *Pelargoniums* and similar subjects should grow and flower in a satisfactory manner therein, but they will in all probability be killed if left there during winter. In the case of such a small structure, with no provision for heating, we think you would derive the greatest amount of pleasure from growing a collection of the choicer kinds of hardy Ferns, which are extremely beautiful throughout the summer months, and in winter give but little trouble and no risk of their being injured by frost. A few of them, too, are evergreen, and therefore effective at all seasons. You could, of course, have hardy bulbs, such as *Daffodils*, *Tulips* and *Hyacinths*, during the spring months.

***Acacias* not flowering** (*L. E., Musselburgh*).—The *Acacia* (*Mimosa*) with Fern-like foliage is *Acacia dealbata* and that with needle-like leaves is *Acacia Riciana*. With regard to their non-flowering, we are considerably handicapped by the fact that the only information you give is that they grow on the roof of a cool greenhouse. The first-named (*Acacia dealbata*) is naturally a fair-sized tree of 20 feet to 30 feet in height, or even more, and it is very probable that its non-flowering is due to a want of space for its development. The large flowering sprays of it that one meets with in the florists' shops are sent to this country from the Riviera, where this *Acacia* is a popular tree. If cramped and confined within the limits of a greenhouse its non-flowering is thus readily accounted for. The second species (*A. Riciana*), judging by the specimens sent, produces its buds freely enough, as one would naturally expect it to do, and their falling is undoubtedly the result of some check. Are the roots allowed to get too dry, or does the structure get too cold at times?

### FRUIT GARDEN.

**Pruning newly-planted Raspberry canes** (*O. S. M.*).—You must cut down your Raspberry canes to within 4 inches or 6 inches of the soil at once. This, of course, will mean that you will not get any fruit this year, but you will secure strong young suckers for fruiting next season. If your soil is of a rather light and dry nature, we strongly advise you to mulch over the roots with well-decayed manure before very hot weather is experienced. This will keep the roots moist and help the plants a great deal.

**Wire netting to protect fruit from birds** (*R.C.*).—Wire netting, having a mesh from 1 inch to 1½ inches, suffices to keep out all birds, but 2-inch mesh will, as a rule, keep out blackbirds and thrushes. While it is these latter birds which prey so largely on bush fruit when ripe, it is the small birds, tits and finches, which prey so severely on the buds of the bushes in the winter and early spring; they do great damage also to Pear and Plum buds in cold weather. For that reason it is best to have the smaller mesh wire to protect your bushes, as if not now being injured in the winter by small birds, they may be so at any time later. We prefer to have bush fruit in a wired-in enclosure with wired door for admission, the sides being from 5 feet to 6 feet in height, and having round rods or bearers fixed across the enclosure from side to side, over which, during three months of the winter and for six weeks in the ripe fruit season, the whole can be covered with small mesh fish netting.

**Melons in frames** (*M. S. W.*).—You may rest assured that the seeds were not at fault. We scarcely understand whether you sowed the seeds in a box or placed them in small pots and the latter in a box. Small pots are much the best, as it is then a simple matter to transplant into the frames without breaking the roots. You do not say if the frame retained the bottom-heat. This is a strong point with frame culture, as, if the plants received a check, the fruits would cease to swell. With frame Melons grown only with manure as the heating agency, it is not well to sow the seed too early, as so much depends on the weather. We advise you to sow quite a month later in future, and by so doing secure a more rapid growth and get more sun-heat. With seed sown so early in the year it is necessary to keep a good relay of fresh manure round the frame to retain the warmth. It is not right to gather the fruits before they are ripe; if you do this the flavour is greatly impaired. You must also, when the fruits begin to colour, maintain drier conditions. It is an easy matter to ascertain when ready to cut, as the stalk cracks at the fruit, and you may then place on a warm, dry shelf to flush. As regards the splitting, your plants had too much moisture.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## WATER PLANTS IN TUBS.

IT often happens that the owner of a small garden desires to cultivate a few at least of the many beautiful water-loving plants that are now on the market, and although his or her garden may not be suitable for the construction of a pond, much may be done by the judicious use of tubs, or even zinc buckets may be successfully employed for the smaller plants. The best tubs for the purpose are empty paraffin or colza oil casks sawn in two, each cask thus forming two good-sized tubs at a cost of 4s. 6d. or 5s. the two. These must be freed from oil, and this can readily be done by lighting some straw or paper in them and rolling them along a path or roadway for a few minutes, taking care, however, that the wood is not severely burned. This done, see that any bung-holes are stopped with hard and lasting wooden plugs and the tubs are then ready for use.

Undoubtedly the best system is to sink the tubs to within an inch or two of their rims in the soil, as a more natural effect is then usually gained. Sometimes, however, this system is not practicable and the tubs may then be stood on the surface. Where this is done a charming effect may be produced by building a small rockery around the tubs, forming plenty of good-sized pockets for the reception of trailing and other plants. Into the bottom of each tub place a 2-inch thick layer of gravel, then procure some very fibrous loam, pull it into pieces the size of hens' eggs, adding a little well-decayed yet flaky manure, half filling the tubs with the mixture. Fill up with water and in a few days the plants may be inserted, providing the period is May or early June. Practically all water-loving plants may be grown thus, and the following can be specially recommended: The Reedmace, Typha latifolia, Water Lilies of the Laydekeri and pygmaea sections, the Cape Pond Weed or Water Hawthorn, Aponogeton distachyon, and the pretty little Limnanthemum peltatum.

If the soil is of a heavy or clayey nature a much better effect can be obtained by taking out the soil for a distance of 18 inches or so round each tub and to a similar depth, well puddling the bottom and sides with a 4-inch layer of stiff clay and then filling in with a good soil mixture that contains some peat. This soil can be kept wet with a little trouble, and in it may be grown various bog plants, such as Calthas, Arrowheads, Alismas, Bog-bean and the Water Forget-me-not, that do not like their roots entirely submerged.

## THE ROSE ANALYSIS, 1900-1907.

BY the courteous permission of Mr. Mawley and the Editor of the *Journal of Horticulture* I am permitted to again place before your readers the accompanying analysis, which has already appeared in the columns of your contemporary:

"In order that the following table of Hybrid Perpetuals and Hybrid Teas, and also that of Teas and Noisettes, may be clearly understood, it may be advisable at the outset to once more explain the system upon which they have been compiled. For the last twenty-one years the name of every Rose in the first, second and third prize stands has been taken down at the leading Rose show of the season—that held annually in London in July by the National Rose Society. The results thus obtained have been tabulated, and the varieties arranged in the published tables according to the average number of times each Rose was staged at the last eight of those exhibitions. This applies to nearly two-thirds of the Roses which find places in those tables. For the sorts of more recent introduction the longest trustworthy averages are given instead, while the still newer kinds are given positions according to their records for the last exhibition alone."

The last exhibition, held on July 4, 1907, in the Royal Botanic Gardens, Regent's Park, was the largest in point of number of exhibition blooms exhibited that the society has yet held, and the inclement weather that preceded the show only prevented it from being at the same the finest, from the point of view of quality as well as quantity.

It is interesting to note that such an authority on all matters connected with the weather as Mr. Mawley is, is of opinion that long and severe frosts in the winter and keen frosts in the spring are not to be dreaded so much by the exhibiting rosarian as unseasonable weather in June, the exhibition flower requiring conditions that allow of a gradual and unretarded progress from the time that the bud is fairly well developed until the flower expands its petals.

Last season we had an excellent start, I mean the sunny autumn produced plenty of well-ripened wood, which passed well through the—on the whole—mild winter. I do not remember Roses pruning better than they did in March and April of last year, and writing on the prospect of the Rose season early in June, I thought I was justified in predicting a record year. The result only partly bore me out, wind, rain and cold played havoc with the early flowers, and it was a matter of surprise to see so many good flowers as were exhibited on July 4th. It is too early to say much of the prospects for 1908, and although we have had several severe frosts, not

much harm has been done; but I am afraid we shall have to prune much harder than was the case last year to get down to that absolutely sound wood that must be found to secure healthy growth.

The good Roses, therefore, of the year were not produced, as they usually are, from the first crop, and better quality flowers were more plentiful a week later. It will be gathered from the explanatory paragraphs above that Mr. Mawley's analysis does not touch on the quality of the individual flower, but only on its presence at the exhibition, and therefore it would be well to emphasise the importance of the second column, which sets out the average number of times shown spread over eight years, rather than column three, which gives the number of times shown at the 1907 show (in the winning boxes only), as we get the early season corrected by the later one, and a fair mean is arrived at.

H. E. MOLYNEUX.

(To be continued.)

### HYBRID PERPETUALS AND HYBRID TEAS.

Position in Present Analysis.	Average No. of Times Shown.	Times Shown in 1907 in Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

April 7.—Bournemouth Horticultural Society's Show; Brighton and Sussex Horticultural Society's Show; Cornwall Daffodil Society's Exhibition.

**Metropolitan Public Gardens Association.**—The many public gardens and open spaces that exist in the metropolis have rightly been called the lungs of London, yet it is doubtful whether the majority of those who use them and receive benefit thereby know to whom they are indebted for the laying out and upkeep of these gardens and spaces. The above voluntary association, founded twenty-five years ago, is responsible for a very great number of them, and it is with pleasure that we have perused a copy of the annual report for 1907. From 1884 to the end of 1906 no less than 106 open spaces and gardens have been laid out by the association at a total cost of £42,663. Besides this, the association has contributed a total

sum of £7,198 5s. towards the acquisition or the formation of thirty-four other open spaces. It is satisfactory to note that the list of subscribers to this most deserving association is steadily on the increase, and all who have an interest in the betterment of London should become subscribers. Besides gardens and open spaces, the association keeps a kindly eye on street trees, and has also a sub-committee for the promotion of window gardens in the poorer districts, an object that is worthy of the highest praise. The Earl of Meath is the chairman and hon. treasurer of the association, and Mr. Basil Holmes is the secretary. Copies of the report, price 6d. each, and full particulars can be obtained by writing to Mr. Holmes at 83, Lancaster Gate, London, W.

**Essex County Technical Laboratories, Chelmsford.**—The School of Horticulture, County Laboratories, Chelmsford, is just completing its year's work with an advanced four weeks' course, with the view to the students on April 8 taking the Royal Horticultural Society's examination. The County Dairy School has just completed a six weeks' course of instruction, thirteen students attending. An eight weeks' course commenced at the school on March 30, the students at the end sitting for the British Dairy Farmers' Association's diplomas and certificates for butter and cheese-making.

## PRIZES FOR READERS. APRIL.

### HOW TO MAKE A SMALL ROCK GARDEN—LIST OF SUITABLE PLANTS ALSO TO BE GIVEN.

**A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA**  
are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Thursday, April 30. Both amateur and professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Rose General Jacqueminot.**—I observe that in his very interesting review of the Rev. J. H. Pemberton's valuable book on Roses Mr. H. E. Molyneux calls attention to the retention by the author of the accents in the word "Général," and remarks that they have been dropped by common consent for many years. If Mr. Molyneux will refer to page 7 of "The Official Catalogue of the National Rose Society" (a body with which he is associated, to its great advantage) he will see that Général Jacqueminot appears in full accent accents. Mr. Pemberton's use of the third "e" is not so well supported.—WALTER P. WRIGHT.

**The best fifteen hardy annuals.** I read with pleasure the excellent essay on "The Best Fifteen Hardy Annuals for Summer Effect," published on page 121. In the list there

given by Mr. Morton I notice the absence of *Nigella*. The old Love-in-a-Mist is a pretty pale blue or white. The new variety Miss Jekyll is larger and the blue colour more decided; it is one of the prettiest and most graceful annuals in cultivation, hardly surpassed by any for cutting or garden effect. The graceful stems and curious seed-pods are still ornamental on last year's plants. The plant grows about 1 foot high, is easily accommodated in the matter of soil, but the seeds must be sown very thinly. I very much prefer it to *Centaurea Cyanus*, whose place in the list I should give it. To those who have not yet grown this lovely plant I commend the excellent coloured plate opposite page 8 of Vol. LXIX. of THE GARDEN and the illustration on page 125 of the present volume. No garden ought to be without "The delicate odour of *Mignonette*." I know of no other plant which adds so much fragrance to the garden air, and for its scent alone I would give it the place accorded by Mr. Morton to *Gypsophila elegans*. —H. P. BRIDGE, JUN.

**Forced Daffodils.**—Seeing the article in THE GARDEN for the 22nd ult. on "Forced Daffodils," I beg to add our experience, which may be useful to some of your readers. This year we gathered our first blooms on January 26, a full week later than usual, on account of the late arrival of the bulbs. Our flowers are always finer than outside ones, the white sorts being specially lovely, as they are so clean and free from stain and blemish, and none of the sorts come the least out of character. We obtain an early result by potting as soon as bulbs are procurable, usually the first week in September for the first batch, afterwards potting up at intervals of fourteen days till the middle or end of October, or even later if a late batch is desired for a long succession. The pots or boxes are put in a cold frame, carefully covered with mats and left till the bulbs are well rooted, then brought into a light, low greenhouse only slightly heated, i.e., 45° to 55° Fahr. Soil: Turfy loam, jadoo and ordinary garden soil. I am convinced that the least amount of bottom heat is fatal to Daffodils, and the cooler they are kept the better, giving plenty of tepid water when they are showing buds. The varieties we grow are: *Mme. Plémp*, *Emperor*, *Empress*, *Horsfieldii*, *Vesuvius*, *Cabeciras*, *Henry Irving*, *Ardh Righ*, *Van Zion*, *Sir Watkin*, *Gloria Mundi*, *Titan Beauty*, *Autocrat*, *William Goldring*, *Mme. de Graaff*, *Mrs. Langtry*, *Cernuus*, *Albicans*, *Moschatus* of *Haworth*, *tortuosus*, *Queen Bess*, *Barrii* *Conspicuous*, *Nelsoni*, *minimus*, *Queen of Spain*, *Mary of Cambridge*, *Ariadne*, *Salmonetta* and *Lulworth*. I may say I have seventeen blooms from twelve bulbs of *Mme. de Graaff*. After flowering harden off and plant the bulbs out in the garden, where they flourish and multiply, and bloom the second if not the first year. —LILIAN E. SAGE.

**Anemone coronaria.**—I am very anxious to hear the experience of others in growing the above. Some years ago they grew to perfection in my garden, and for about five years the flowers were enormous and the admiration of everyone who saw them. It did not matter how we treated them; we left some in the ground, lifted and dried others, and any particularly beautiful colour I could increase indefinitely by breaking up the root. They were invaluable as cut flowers in the spring, and the foliage also was so strong and long-stemmed and easy to arrange. The blooms were at least 4 inches across and sometimes more. Then one spring the young growths came up looking weak, brown and withered, and I thought they had been touched by frost and east wind and would recover; but they never did. I got fresh seed and tried over and over again, but never succeeded with them after they were planted out of the seed-boxes. Then I got some apparently

healthy roots from a firm who make a speciality of them. Very few came up; those which did had, as usual, the few burnt-looking leaves and no flowers. I have tried them all over the garden in parts in which they had not been grown before, and for the last few years I have reluctantly given up attempting to grow them. I shall be most grateful if anyone can tell me how to make them succeed again, as I have been given a lot of seed from specially fine ones. There is one curious fact. At the time when the *Anemones* would grow anywhere in the garden—more than ten years ago—a few were planted in a dry rockery bank. The flowers here were only about 2 inches across, but these continue to come up every year, though they have never been divided or moved, and they look healthy, but the flowers are small and they do not increase. The soil is exceedingly poor, and the stones are limestone. I put a little manure and soil round things unmethodically in early spring. The aspect is south-east. The borders where the others used to flourish are only a few yards away; yet, if what destroyed them was disease, it was not communicated to the plants on the rockery bank. —E. T. LLOYD EDWARDS, *Bryn Oerog*, near *Llangollen*.

**Rose Gloire Lyonnaise.**—Noticing a very vigorous young shoot springing from the base of a plant of this Rose, which is growing on a wall, a measurement was taken, with the result that the shoot was found to be 14 feet 6 inches in length. Is this an exceptional growth for this

THE COCKCHAFER AND ITS LARVA.

Rose to make in one season? I think this shows that *Gloire Lyonnaise* is suitable for growing as a pillar or climbing Rose. The wall on which our plant is trained is about 16 feet high, and some of the best flowers have been produced near the top. The plant received no special attention other than a thinning of the shoots, removing the old and exhausted wood and retaining the young, vigorous shoots. No manure water has been applied during the past summer, nor has any fertiliser been applied to the roots of the plant. Although this Rose was introduced by Guillot in 1884, and is a general favourite in gardens, it is seldom seen treated as a climber, but experience teaches that it is peculiarly adapted for growing on high walls. —C. R.

## INSECT PESTS.

### THE COMMON COCKCHAFER.

(*MELOLONTA VULGARIS*.)

THE cockchafer or, as it is sometimes called, the May bug is one of our most familiar insects, and at the same time one of the most destructive, for the beetles feed on the foliage of various trees and their grubs on the roots of most plants; in fact, the grubs are much more injurious than the cockchafers. Fortunately this insect is not nearly so abundant in this country as on the Continent, where they sometimes entirely strip trees of their leaves, but they are seldom in such numbers as to seriously injure the

foliage of our trees. It is by no means an easy insect to destroy, as when the cockchafers are feeding on the leaves of large trees they are very difficult to reach, but they may be shaken or beaten off into rick cloths or tarpaulins and killed before they have time to recover from the shock of their fall. Poultry and pigs will eat them with great relish.

The grubs are very tenacious of life, neither moisture nor drought seems to have any ill effect on them. They have been known to survive a fortnight's immersion in water with apparently no ill effects, and have endured a month's confinement in dry earth without injury. No insecticide has any effect on them when in the soil, unless Vaporite or bisulphide of carbon has. The best way of getting rid of them, if there be any reason for suspecting the presence of these grubs, is to turn up the soil and search for them. Fortunately rooks, seagulls, plovers and other insectivorous birds are very fond of them, and they are so large and conspicuous that they are easily seen when ground is being dug over or trenched. Night-jars kill large numbers of the cockchafers.

The grubs, as may be seen from the illustration, are about 2 inches in length, fat and much wrinkled, and are of a dirty white colour with darker heads and legs, the end of their bodies being somewhat swollen and of a bluish grey colour caused by their contents. They usually lie in a bent attitude, as shown in the illustration. They are often known by the names of white worms or Connaught worms. That they are capable of doing an enormous amount of mischief can easily be understood when it is known that they do not attain their full size until they are three years old. Then, in the autumn, they each form a rough kind of cell in the ground, about 2 feet from the surface, in which they become chrysalides. They remain in this condition until the following summer, when, in May or June, the cockchafers emerge from the soil, their transformations having taken about four years altogether. The favourite food of the cockchafers consists of the leaves of the Beech, Elm, Sycamore, Oak, Willow, Apple and Pear. The grubs chiefly favour the roots of the *Rhododendrons*, *Azaleas*, *Asparagus*, *Strawberries*, grass and the roots of most trees. They may easily be mistaken for the grubs of the Rose chafer (*Cetonia aurata*), that beautiful shining metallic green beetle often found in the blossoms of Roses and Strawberries, and which is nearly related to the cockchafer, but among other slight differences the Rose chafer grub has a brown horny patch on either side of the first part of the body.

### THE FELTED BEECH COCCUS.

(*CRYPTOCOCCUS FAGI*.)

THIS insect, which is very injurious to Beech trees, is, unfortunately, much more common now than it was a few years ago. At one time it was a comparatively local insect, now it is to be found in most parts of England. Unfortunately, it has only lately been recognised as a dangerous pest to Beech trees, and at present the majority of owners of trees which are infested by this coccus seem quite ignorant of their real condition, and take no steps to destroy the pest. It is injurious to the trees in two ways, by drawing off their sap and by smothering the bark with a white felt-like substance, under the protection of which the insects live and breed. The presence of this insect, unlike that of many others, can be recognised at once by the white patches of the cotton-like exudations which proceed from their bodies, and when this insect has been allowed to remain unmolested for some time the stems of the trees look as if they had been whitewashed, and they no doubt are then rapidly becoming unhealthy and the pest will be

very much more difficult to exterminate than it would have been some months earlier.

The insects themselves are very small, and look like small oval eggs about one-sixteenth of an inch in length and of a yellowish or pinkish white colour, their limbs being somewhat rudimentary, as they do not move about much. Each is, however, provided with a long proboscis with which they are able to pierce the bark and to suck the sap of the tree. Being wingless they are no doubt carried from one tree to another by birds or the wind. The best way of destroying this pest is by laying sacks or canvas on the ground round the trunk of the tree so as to catch anything that may fall from it, then wet the affected parts with soap and water and scrape off as much as possible of the felt-like material, and afterwards scrub the tree with a stiff brush dipped in strong paraffin emulsion or in a new winter wash known as Voss No. 1. Either of these insecticides may also be syringed or sprayed on, but unless the felt matter is scraped off first it is very difficult to make the insecticide break it up so that the insects are reached. When applied with the brush it should be well worked into any irregularities there may be in the bark. This operation may have to be repeated, for it may be found that some of the eggs have not been killed and that white patches again make an appearance. In case suddenly denuding a tree of its unusual covering should be any detriment to it, it might be useful to fasten canvas over the parts or paint them with a mixture of clay and cow manure, which would gradually disappear under the influence of the weather.

The Felted Beech Coccus belongs to the same family (the Coccidæ) as the mealy bug and scale insects. Fortunately, it is only known to attack Beech trees; but as the Beech is one of our finest and handsomest forest trees, and also one of the most useful, it is most desirable that means should be taken to destroy this pest as soon as it is noticed. Every owner of a Beech tree should be on the watch for this pest.

G. S. SAUNDERS.

## THE ROSE GARDEN.

### THE PRESENT TREATMENT OF ROSES UNDER GLASS.

THE last few days of bright sunshine have been most welcome to the Roses grown under glass, and one may trace its influence in the more healthy colour of the foliage. Plants pruned early that are now showing bud should receive a sprinkling of some good fertiliser, and it should just be pointed into the surface soil with a label. A deep stirring of the surface is to be avoided because numerous little feeding roots lie just beneath and they must not be injured. Plants more advanced, with buds the size of marbles, will benefit now by an application once a week of liquid manure. That made from cow manure and soot is as serviceable and as safe as any. About a bushel of the former and a peck of the latter put into porous bags and dropped into a tank or cask holding about 40 gallons of water, will make an excellent stimulant, and may be given at about the rate of 1 gallon of the liquid to 10 gallons or 12 gallons of water. Later on, as it becomes necessary to fill up the cask, the liquid being weaker, may be given about half-and-half. A change of food is very beneficial, so that anyone having an opportunity of collecting sheep manure would find it serviceable to have another cask containing some of this excellent stimulant.

Roses planted out in borders under glass can be considerably helped by a mulching of fresh cow manure. The ammonia arising from the manure will feed the foliage, and the small feeding roots will soon come to the surface for the mulching. Where these natural manures are difficult to procure, waterings with guano water are to be commended. Good reliable guano, at the rate of 1oz. to 2oz. per gallon, is a first rate stimulant. Pot plants just starting into growth should receive a sprinkling of bone-meal, this

being just pointed into the soil. There is no doubt about the value of bone for Roses, and one may see how the roots welcome it by the way they fasten on to the small particles.

If mildew proves at all troublesome, a dusting of green sulphur applied with a fine dredger will keep it in check. This sulphur is much superior to all other forms. A syringing with a solution of Lifebuoy carbolic soap is also an excellent remedy, and it also tends to keep the green fly in abeyance. A half bar to 3 gallons of warm soft water is about the right proportion, and it should be syringed on before 9 a.m. on a fine morning. Green fly, as soon as they appear, should be checked. McDougall's Tobacco sheets are very efficacious and easy of manipulation. One sheet is sufficient for 1,000 cubic feet, so that they are very handy for the amateur.

Where necessary the plants should be tied out to sticks in order that every leaf may be exposed to the sunlight. Sometimes it is necessary to bend the shoots in different ways in order to obtain a well balanced plant, but the foliage will soon right itself if the work is done in good time.

Rambler Roses in pots are now showing their sprays, and they will need a sprinkling of some good artificial manure if this was not applied earlier. These Roses are very gross feeders and they require plenty of water, sometimes on bright days it being necessary to water three or four times owing to the somewhat small pots being full of roots.

Now is a good time to strike some cuttings under glass. The growths that have borne a blossom are just in the right condition for rooting. Make them with two joints and retain the top leaflets, and cut the shoot level near the bottom joint or eye. Dibble them round the side of 3-inch pots of sandy soil, and place in a frame where bottom heat can be given. A box placed on the hot water pipes, if in full light makes an excellent propagator, a pane of glass being laid on the top and removed and wiped over each morning. The pots should stand in an inch or two of sand or Cocoanut fibre, and the foliage of the cuttings be just sprinkled on fine mornings. A sheet of newspaper laid on the glass is necessary during bright sunshine. When roots are formed and are about half an inch in length the cuttings should be potted off into 3-inch pots and given a temperature of about 60° by day. By careful potting on and gradual hardening off the little plants may be planted out during the summer. If sudden cold draughts are permitted to reach these rooted cuttings, mildew is almost certain to appear, and prompt measures must be taken for exterminating it as advised above. Plenty of air without draughts is what is needed.

P.

### POLYANTHUS NARCISSUS MONT CENIS.

SHOWN in the accompanying illustration, from a photograph taken by Messrs. Vandyk, is a very fair example of the so-called "sitting-room gardening" grown by the writer. These bulbs were planted about the middle of November, 1907, in boxes specially made, Cocoanut fibre taking the place of soil. They were standing out of doors all through the severe weather, and were at one time completely frozen over. Rain, snow, frost, cold winds, thick London fogs and very little sunshine have been their lot up till the beginning of March, 1908, when they were carefully lifted and transplanted into the wooden flower-stand shown in the photograph and brought into the drawing-room, the latter taking the place of the greenhouse. In less than a week the writer was rewarded with a grand show. No support of any kind was given to keep the flowers together. "His fact points to the excellence and fine quality of the bulbs.

J. A. E. DRURY-LOWE.

POLYANTHUS NARCISSUS MONT CENIS GROWN IN A SITTING-ROOM.

## THE FLOWER GARDEN.

### THE AFRICAN OR CAPE LILY.

(AGAPANTHUS UMBELLATUS.)

**M**OST valuable in the garden when grown in large pots or tubs, and arranged at intervals on broad walks or terraces in front of noble mansions, where its tall blue umbels, carried on lofty stems, have a very ornamental effect in the late summer, towering above the pendent, strap-shaped leafage, is this handsome South African plant, sometimes known as the Cape Lily. For conservatory decoration the Agapanthus is particularly useful, since, at the time of its blooming, there are not many blue flowers available for culture under glass. In the southern counties, however, it succeeds admirably if planted permanently in the open, and in the course of twenty years or so will form huge clumps 5 feet or more in diameter, which in the early autumn will bear dozens of splendid flower-heads. In this locality—South Devon, close to the mouth of the river Dart—it flourishes to perfection. It is sometimes stated that the Agapanthus requires abundant moisture during its period of growth, but this is evidently a misconception, as the plants growing at Kingswear are in very light and shaly soil, which becomes dust-dry in the summer, and they never receive a drop of water other than rain, yet they flower magnificently. They are entirely protected on the north and east, and are open to the south-west. They are never harmed by the severest winters that are experienced, beyond having 1 inch or 2 inches at the ends of the leaves browned in exceptionally hard frosts, but this rarely happens.

The most generally known form is the blue type, but there is another, deciduous white, sort which is evidently a distinct species, though it is not recognised by Nicholson, who only gives *A. umbellatus* and its variety *albus*, which is, naturally, also evergreen. This white variety I have lately obtained from Tregothnan. The deciduous white is quite distinct from *A. umbellatus*, its foliage being less than half the width of the leaves of that species. It flowers a trifle earlier than *A. umbellatus*, and its blossoms are rather more sparsely disposed in the umbel. In the autumn its leaves turn yellow and eventually die completely away, the new leaves starting from the crown in March.

In the accompanying illustration the deciduous white species and the blue *A. umbellatus*, evergreen, are both shown. The plant in the front with the, apparently, larger flower-heads is the white one; and that in the background, with the blossoms in many cases unexpanded, is the common blue-flowered plant. The subject in the immediate foreground is the white variety of *Commelina cœlestis*. It requires a very severe frost to kill the blue Agapanthus, for where 20° or more were registered every winter and the foliage was destroyed the plants never failed to make fresh growth in the spring.

South Devon.

S. W. FITZHERBERT.

### WORK AMONG THE SWEET PEAS.

The middle of April and onwards is a good time for setting out those plants that have been raised in pots in the southern counties, but, perhaps, in the north of England and Scotland it may be as well to defer the work a week or two. Of course the plants will have been raised under perfectly cool and airy conditions, keeping the lights quite off the frames during every fine day. Whether the plants are to be put out in clumps or rows will, of course, rest with the cultivator, but whichever system is adopted it is wise to make a sort of basin 2 inches or 3 inches deep for the clumps, and a trench of a similar depth for the rows. Then scatter on the surface some approved artificial manure at the rate advised by the vendor, or a dressing of superphosphate, 6oz.

to each 3 feet run of the row may be given, turning the soil over and mixing it and the manure well together before planting.

There is not so much danger of overcrowding when plants are put out of pots as there is when seeds are sown in the open, but 6 inches is none too much space between each two plants. The basin or shallow trench will afford a slight protection from cold winds, and will facilitate watering and feeding when the plants are in flower. Small twiggy eticks must be put to the plants at once or else boisterous winds will do a great amount of harm.

Where seeds were sown in the open at the usual time, i.e., the middle of March, the tender seedlings may soon be expected, and with their advent comes a certain amount of anxiety. Sparrows are exceedingly fond of them, and these pests must be baffled by means of wire guards, fish netting or strands of black cotton. The two last must be supported by sticks a few inches from the ground. Black cotton is the most

effective of all, and it is not much more trouble to fix than is the netting. Commence at one end of the row by tying an end to a corner stick, then hold the reel in the palm of the hand so that the cotton plays out between the fingers, keeping it taut and giving it two twists around each stick as they are reached. It will, of course, be necessary to go backwards and forwards over the same ground several times to get a sufficient number of strands over the row, but no ties need be made until the row is completed or the cotton on the reel is exhausted.

Slugs, too, have a liking for the seedlings, but these can be effectively checked by using Kilogrub. This is scattered down each side of the row, not on the seedlings, and just scratched in with a hand fork, trowel, or even a pointed stick. If wireworm is suspected, dig in Kilogrub 6 inches deep along each side of the row or round the clump, taking care not to disturb the young plants. Where the seed is not yet sown, this substance may be dug into the soil before sowing, wireworms, leather jackets, eelworms and other ground pests quickly succumbing to its deadly fumes. It is also wise to incorporate this substance before setting out pot plants, i.e., where ground pests are present.

Last year germination was very irregular, many seeds remaining in the soil quite hard and sound after some of the plants were up. The writer searched for these seeds, and, when they were discovered, each had a slight notch filed or cut into its hard outer covering, after which they were returned to the soil, with the result that

THE AFRICAN LILY (AGAPANTHUS UMBELLATUS), BLUE AND WHITE FORMS, IN MR. FITZHERBERT'S GARDEN.

germination was soon effected. Owing to the wet and sunless weather experienced last summer home-grown seeds are not likely to give much trouble in this respect this season, but some of the American-grown seeds may behave in a similar manner.

As the seedlings are growing much good will be done by stirring the soil between them twice a week with a stout pointed stick, this allowing air to freely enter and permeate the soil and at the same time destroying young weeds that are sure to appear. Thinning must be attended to early, leaving the plants 3 inches apart at first, and when they get 3 inches high pull out every other one so that they finally stand 6 inches apart. For exhibition purposes twice this distance is none too much. As soon as tendrils appear twiggy sticks 12 inches or 15 inches high must be afforded the plants, leaving the main sticks until the plants have nearly reached the tops of the smaller ones. This may seem double labour, but it is quite justified by results. If the tall sticks are placed in position at the outset the plants frequently become attenuated and weak, but by using the smaller sticks first a sturdy, healthy foundation is secured. The future treatment of the plants will be dealt with when the time for staking arrives. H.

### HARDENING OFF BEDDING PLANTS.

At this season of the year the hardening off of bedding plants constitutes one of the most

important operations in the flower garden, and with all the frames and glass houses full the amateur is often at a loss to know how to carry out the work. Providing a wall or fence facing south or west is available, the frames may soon be emptied of many of their contents, thus making room for other plants that are less hardy. In the case of a wall or a close boarded fence, all that will be necessary is to fix up some stout stakes, leaning one end on the wall and allowing the other to rest on the border several feet away from the wall or fence, the stakes, of course, standing in a sloping direction. Along the tops of the stakes and on the wall or fence nail securely one edge of a mat or other protective material, and at the bottom edge a roller may be fixed. During the daytime the mats can be rolled up and fixed by strings to the wall, thus

### EARLY - FLOWERING HARDY PRIMULAS.

THERE is no flower which brings deeper pleasure to the true gardener than the little "Bird's een" of the Craven Highlands. *Primula farinosa* is widely distributed, being found in mountain marshes in temperate regions, including our Yorkshire fells. It bears delicate lilac blossoms on stems of varying height, but usually about 9 inches or 12 inches. Individually the flowers are small and produced in crowded heads, supported by slender stems which sway in the lightest breeze. The popular name of "Bird's een" is attributed to the conspicuous marking which surrounds the centre of the corolla tube, giving the effect of an eye. Plants of this *Primula* can always be procured at reasonable

during summer. It flowers in April and May, being probably the earliest-flowering hardy species. The colour is a pure, intense bright pink, with a small golden eye. The plant is a native of the Himalayas, and occurs right up to the snow-line. It is a deciduous species and soon makes large masses, throwing up sheaves of blossom from established clumps. The flowers are borne on stems 9 inches to 12 inches in height or more, and always appear before the leaves.

*Walmgate Gardens, Louth.* THOMAS SMITH.

### LILY OF THE VALLEY (FORTIN'S VARIETY).

ALTHOUGH autumn is, perhaps, the best time for making fresh plantations of Lily of the Valley, circumstances often render it necessary to defer the operation until spring. To those making plantations I would strongly recommend the above variety. It has the same sweet scent as the old variety, while the individual flowers and the trusses are both much larger than those of the older forms. The foliage is correspondingly large and, as may be supposed, it is quite as vigorous. C. C.

[A coloured plate has been given of it in THE GARDEN.—ED.]

### THE HARDY PRIMROSES IN POTS.

ONE of the most charming ways of growing the hardy Primroses is in pots, and two beautiful kinds for the purpose, from photographs taken in the alpine house in the Royal Gardens, Kew, are *Primula frondosa* and *P. pedemontana*. The former is, although it is illustrated as growing in a pot, quite hardy in this country, growing well in a half-shady place when planted in moist sandy peat and loam. It is a true perennial and may be increased readily by dividing the crowns as soon as the plant has done flowering. It is one of the most useful early-flowering Primulas for growing in pans for the alpine house and one of the easiest to grow. And what is an "alpine house" some may ask? It is a little house, unheated, except in severe frosts and damp weather, where the early flowers of the year may be enjoyed under glass. It is a sort of unheated greenhouse, and should be more evident in our gardens. One may enjoy spring flowers in comfort when outside, perhaps, cold winds are blowing and snow falling. *P. pedemontana* is a native of the Alps in Piedmont, its bright crimson flowers appearing in April.

### HOW TO GROW THE HARDY PRIMULAS IN POTS.

Several of the Primulas are especially adapted for this purpose, notably, *P. marginata*, which is very free-flowering and lasts in perfection for some time. Even when not in flower the singular beauty of the margined leaves make this plant very attractive. When grown in pans Primulas should be potted in rich porous soil, thoroughly well drained, as stagnant moisture of any kind is fatal to them. They require plenty of water in the growing season, and when possible rain water should be used. The best time for repotting is just after they have finished flowering, so that they will have time to make good growth as early as possible in the year. A frame with a northern aspect is most suitable in which to grow Primulas, and the pans should be plunged to the rim in ashes. The lights should be left off all through the summer months, but should be used to keep off excessive rain in autumn and winter. Plenty of air should always be admitted during the winter. Primulas are readily raised by means of seed, which should be sown as soon as ripe. The seedlings should be potted off as soon as they are large enough to handle and should be grown on in a shady frame. Some are very slow growing and require careful watching in order that they are not smothered by such things as Liverwort and other weeds. If the facts given above are too meagre we shall be very pleased to answer any questions on growing these beautiful flowers in pots.

THE PIEDMONT PRIMROSE (*PRIMULA PEDEMONTANA*).

affording the plants stood on the border an abundance of sunshine and fresh air. The mats will, of course, be let down at night.

Where the fence is an open one, snug temporary quarters can be provided for many bedding subjects by nailing or tying thick mats along the face of the fence, thus preventing north or easterly winds from reaching the plants. In each case mats must, of course, be provided at each end of the border to prevent cold winds blowing on to the plants from either end, and in many instances it will be wise to allow these end mats to remain down during the daytime as well as at night, especially when cold winds prevail. Of course, it must be distinctly understood that half-hardy plants must not be stood direct out of warm houses or frames into these temporary shelters; such a course would be disastrous. It is plants that have been submitted to cold frame treatment for a fortnight or so that may be thus stood out, and, where such a course has been adopted, these temporary shelters will provide sufficient protection from the second week in April until bedding-out time for such plants as Asters, Stocks, Zinnias, Verbenas, Pelargoniums, Lobelias and, indeed, almost any of the subjects that are used for summer bedding. A 2-inch thick layer of ashes should be placed on the border before standing the plants thereon, else worms will prove troublesome. Gradual hardening off is the key to beds full of sturdy flowering plants during the summer months,

rates, but it is readily raised from seed, and the seedlings flower in the second year. The plant is deciduous, the leaves dying down in autumn, leaving scarcely any trace of its presence during winter. It is only upon careful examination of the position that the plump buds are revealed which indicate the rich harvest to follow. It succeeds in cool, well-drained positions on the rock garden, associating admirably with *Ramondias* and dwarf Ferns.

*P. nivalis* is another exquisite gem for amateurs. The plant is really the creation of the gardener, or rather the name is, for the plant itself belongs to the *viscosa* section, and is placed as a variety of *P. pubescens* by the Kew authorities. At any rate, *P. nivalis* is a most charming albino. I have seen it the admiration and envy of gardeners years ago, where it flourished in a cottage garden in a mining district, thereby proving that expert culture is uncalled for. It flowers with prodigal freedom in spring, and the large snowy trusses are borne on 3-inch to 6-inch stems. With age the plants assume a sprawling character, and when this occurs they must be broken to pieces and replanted, crowns with a piece of old stem attached rooting easily. It will succeed in good loam freely mixed with stone chippings, and is not averse to a sunny position, provided always that the roots be cool.

*P. rosea* is the jewel of the Bog Primulas. Growing freely in rich, moist soil, it luxuriates in positions where the roots are actually in water

## THE KITCHEN GARDEN.

### ASPARAGUS FOR AMATEURS.

(Continued from page 114.)

**T**HIS last note on the above is doubtless the most important to the amateur, as many who are unable to protect or force in any way can grow good crops in the open. Even here the amateur does not always get the best results, and I have endeavoured to avoid all costly details and make the cultural work as simple as possible. I must also refer to failures, and advise, as far as possible, the remedy. Only recently I saw some beds sown with Radishes and Lettuces, and although the injury would not be noticeable at the time, such a system is detrimental to the plant. To grow Asparagus well the surface of the beds should be kept free of all growths, weeds and otherwise, from the start. On page 70 I referred to the formation of the beds, soil and sowing or planting, and advised the latter. Any time from the end of March and through April is a good time for planting if the growths are not far advanced.

It is well to plant quickly, as exposure will do much mischief. If seed is sown, do not sow thickly all along the row, but at intervals of 6 inches apart, dropping a few seeds at each place. These later on are easily thinned. I advise the Giant French or the Early Giant Argenteuil for sowing; the latter is a great favourite in the Paris market, and is largely forced and imported into this country. There is also a very fine variety of recent introduction called Palmetto that is well worth attention. The variety which is best known in this country is Connover's Colossal.

#### OPEN GROUND CULTURE.

At the early stages of growth the amateur must not cut the plants too hard, and cutting, which usually begins early in April, must cease at midsummer, as the plant must have time to form new crown growths for the next season. Another point that often arises is whether all the growths that appear should be cut or the thin weakly ones left. I prefer to cut all, as the small spray can be used for soups or other purposes, and during the growing season it is then an easy matter to feed. In this country we often get late spring frosts, and the early growths are much influenced in consequence, and to help the growth or ward off severe cold it is a good plan to cover the surface of the beds with dry short litter at nights, this being placed in the alleys early in the day. By the end of May the cutting must not be so severe, the small spray being left and also a few larger growths if the shoots are at all weak.

*Feeding and Manuring.*—Asparagus is often fed at the wrong season. I think it is almost useless to place, as is often done, large masses of rank manure on the surface of the beds in the early autumn months, as with a heavy wet soil the manure frequently rots the crowns. I am aware it is a difficult matter to feed with liquid manure from July to October, but if food can be given in a liquid state at that season it is of far greater value than later in the year. There is, however, no difficulty in giving a quick-acting fertiliser in the shape of nitrates or guano, and if this is given in showery weather or well washed in, it is of great value. For many years I had a light soil resting on gravel to deal with, and we required large quantities of Asparagus early in July. We gave the beds a mulch of well-decayed manure, and often, say, some three or four times during the season, a top-dressing of a good fertiliser, well watering it in. Such aids as fish manure, Peruvian guano and other quick-acting fertilisers are of great value, as these are easily applied and the plant soon takes hold of the foods, with the result that it assists in building up a strong crown growth for

future requirements. Of course, new beds, I mean beds just coming into bearing, will not for a time require large quantities of food; but here some of the aids noted above, if the growths are good, will be valuable. We often overlook the value of water for this plant; if it can be liberally given when in active growth, the labour is well repaid. Liquid manure is one of the best foods we have whenever it can be obtained; failing this, give the other foods advised above. I do not contend that Asparagus beds should not be given food in the autumn when top growth ceases, as so much depends upon the soil. Very light dressing is beneficial, as it is washed down to the roots by the winter rains and by the early spring is incorporated with the soil; but I do not advise the heavy solid manure in quantities often given.

Soot is a most valuable winter food if mixed with slaked lime and rich soil in equal proportions, as this clears the land of pests, which are often harboured by other manures. It may be given at any time, say from October to April. Salt is often given at the wrong season, and does more harm than good. The plant, though a native of our shores, is greatly benefited by salt dressings, but these should be given in spring or during active growth. Lime as advised is most helpful on heavy land, and may be used freely at the season named, but salt should be omitted when lime and soot are given as a surface dressing. For many years, with difficult land to deal with, we found night soil a splendid fertiliser; it was laid up for some months and liberal quantities of

## THE FRUIT GARDEN.

### THE TREATMENT OF YOUNG VINES.

**A**LTHOUGH the work of planting Vines is an important matter, future success will greatly depend upon their treatment during the first season. Young Vines recently planted will be commencing to grow, and this is a critical period for them. Do not cut them back or they will bleed and die. Select a strong "break" near the eaves of the house to form the leading shoot and rub out all above it, but preserve all the shoots below the leader. Allow the leader to grow without stopping, but the side shoots should be stopped at the eighth leaf. It will be found necessary to place some sticks in the border to which the shoots growing beneath the wires can be secured. By encouraging the growth of auxiliary shoots the stem of the Vine is strengthened. An abundance of healthy foliage well exposed to the light induces a free root action, and the result is a strong, healthy Vine. As the season advances admit, during fine weather, plenty of air. All bunches of fruit must be removed as soon as seen. During warm weather syringe the Vines and close the house about 4.30 p.m.; this will ensure the necessary damp atmosphere during the night.

Some varieties, such as Muscat of Alexandria and Lady Downe's Seedling, require a slight

PRIMULA FRONDOSA IN A PAN AT KEW, IN FLOWER NOW.

lime used when in bulk, and with it wood ashes or burnt garden refuse and any spent soil added. It was a valuable food, either for new beds or as a surface dressing. Another point that should not be overlooked, especially in light soils, is to have a good depth of surface soil to blanch the growth. It also prevents the beds drying in the summer months. Many good growers at that season, just as the growth begins, give a good mulch of rich soil or manure and do not feed again unless with liquid manure or fertilisers. I have gone into detail over food supplies, but if these are given as advised and at the season named, they are not at all costly, as many of the substances named above are at hand and are readily applied.

G. WYTHES.

shade during the bright summer months, otherwise their foliage is frequently scorched, even when an abundance of air is admitted. A suitable shade may be procured by placing a piece of fish netting over the roof of the vinery. Do not allow the roots to become dry. When all the leaves have fallen cut back the side shoots close to the stem. The main rod, if strong and well ripened, may be left some 6 feet or 8 feet in length, but if it is weak cut it back to a good plump bud. When the pruning is completed tie down the rods in a horizontal position and allow them to remain until the spring. If mealy bug has been noticed during the growing season, steps must be taken for its eradication.

Munden Gardens, Watford.

C. RUSE.

# GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**WINDOW PLANTS.**—My window-boxes are now making a brave show. Crocuses are over, but Daffodils and Hyacinths are looking well in windows with a warm aspect.

Small shrubs are making windows in cooler aspects look very interesting, and window-boxes planted with Wallflowers are distinctly promising. As soon as the bulbs have finished flowering I propose to plant some of the window-boxes with Tufted Pansies (Violas). These plants are seldom used for this purpose, but they make a beautiful display for several months. Window plants indoors should be repotted without delay; many plants will need this attention. Well-known foliage plants, such as the Aspidistras, Aralias, Dracenas, Palms and Indiarubber Plants do not want repotting annually. When the plants are growing satisfactorily I repot them about once in three years, varying this rule only occasionally.

**Roses**—A few days ago I pruned my Hybrid Perpetual Roses; this was done rather later than usual owing to the cold weather in the latter half of March. Just now I am pruning my Hybrid Tea-scented Roses, as I invariably find they succeed very well when taken in hand at this time. The Tea-scented Roses I prefer to complete the pruning of before the middle of April, as they are somewhat tender, and I would rather defer this important work till well on in the month in consequence. For exhibition purposes and in all cases where large blooms of good form are wanted, I find it a good plan to cut back rather hard. For ordinary garden decoration and where blooms are wanted in abundance, it is better to prune the plants moderately. I never prune the Teas and Noisettes so severely as I do the more vigorous-growing Roses. Always use a sharp knife, and prune close to, and in the same direction as, the bud.

**Hardy Fruit.**—There are indications that my Morello Cherries will soon be in blossom. I have frequently noted a tendency for the trees against walls and fences to become infested with black fly. When this pest is in evidence I prepare a solution of soft soap and water, dissolving 2oz. of the former in a gallon of the latter, and after frequently stirring the insecticide apply it to the flowers before they open by the aid of a syringe. This invariably rids the plants of the pest. Should one application be not sufficient, a second will doubtless effect the remedy. Take means to protect the blossom from injury by birds by netting them forthwith. Fish-netting,

which is now sold very cheaply, may, if doubled, be used as a slight and sufficient protection against late frosts. This material should be hung over Peach, Cherry, Apricot, and Nectarine trees. The netting should be secure, so that it does not blow against the trees.

**The Vegetable Garden.**—Potato planting should be continued, giving attention to the first batch of the main-crop varieties. At this period I make a sowing of main-crop Carrots, selecting quarters where the ground is open and friable and where manure has not been recently applied. Lettuce and Cabbage plants that have wintered in the seed-beds should be planted out forthwith; with the approach of more genial weather they make rapid progress. For succession a sowing of Lettuce seed should be made in a warm border at once. Brussels Sprouts, autumn Cabbage, Kale, Broccoli and Savoys should be sown at this period. Sow the seeds 1 inch deep in drills 6 inches asunder, and, most important of all, sow thinly. My first Celery seedlings are now being transplanted. I have selected a sheltered quarter in a warm aspect, and have made up a bed of good soil. The seedlings are transplanted about 4 inches apart.

**The Greenhouse.**—The Japanese Azaleas (*A. mollis*) and the beautiful Ghent Azaleas will soon be making the greenhouse and conservatory gay, and, together with the floriferous Indian Azaleas (*A. indicum*), will reward one for their careful nurturing of months past. I am taking the precaution of erecting a light shading of tiffany to run on brass rings, stretched on wires running across the glass house, to shade the plants from bright sunshine, otherwise their display will be brought to a premature conclusion. As the Azaleas go out of flower I propose to repot the more rooting plants.

**Hardy Flower Garden.**—For blooming in the middle of July next and later I am now sowing outdoors some of the newer Sweet Peas. The ground has been deeply dug and a trench taken out similar to that required for Celery, and this filled in to within 6 inches of the surface with well-rotted manure. The latter has been trodden in and the soil returned to the surface. This has been levelled previous to the planting. By the aid of a dibber holes have been made 2 inches deep and 3 inches apart in two rows throughout the length of the quarter allocated to them. One seed is dropped into each hole and the soil raked over as a finish. After labelling, two rows of black cotton are strained over the rows, and this I am convinced from past experience will prevent any harm coming to either seeds or seedlings from birds. When the seedlings are 4 inches high the plants will be thinned out to 6 inches apart. By these means good results are almost sure to follow.—D. B. C.

## METHODS OF INCREASING THE HERBACEOUS PHLOXES.

THERE are few plants that add more to the attractiveness of our gardens in the late summer and early autumn than the beautiful herbaceous Phloxes. They are divided up into two groups, one section being known as the summer-flowering and the other the late or autumn-flowering. The summer-flowering sorts are obtained from *Phlox suffruticosa* and the late varieties belong to the *decussata* section. In the present instance we propose to confine our remarks exclusively to the latter section, as this is undoubtedly the more popular of the two. Phloxes are increased in several ways. They are easily raised from seeds,

2.—REPRESENTATIVE PIECES OF DIVIDED PLANT.

although this is a method seldom practised. More often the old plants are lifted and divided, or sucker-like shoots are propagated in the spring or cuttings are inserted in late spring or early summer, and the issue in such instances is highly satisfactory.

**Lifting and Dividing Old Plants.**—During late March and April the old plants should be bristling with numerous shoots of recent development. This is the time to lift and divide them. They take most kindly to division, many of the older plants breaking up into quite a large number of useful little pieces. Old plants that have been left in one position for some years do not divide so easily as do those that are two years or three years old at the most. The older the plant is the harder and more unsatisfactory is it in the centre. In such cases it is better to break off the outer pieces, leaving the hard unsatisfactory pieces alone. Fig. 1 represents an old plant just lifted. It will be noticed that this is a fine large clump, capable of being broken up into several pieces of fairly large proportions, or a number of smaller ones for the same purpose. Fig. 2 gives a very good indication of the size of the pieces into which to divide the old plants. It will be observed that each piece has several shoots on it, thus ensuring the development of a useful clump before the summer is over. The divided portions should be planted in the specially prepared flowering quarters, first breaking up the surface with a fork to make the soil friable; it is so much easier to deal with the plants then. Plant the pieces 18 inches to 2 feet apart; we prefer the latter distance. Better effects are obtained in the flowering period when the plants are grouped in colonies. Half-a-dozen, more or less, pieces in each group will suffice, and they should be planted firmly. In some gardens it is more convenient to plant the Phloxes in rows in special quarters. Where this is so give each plant 2 feet of space in the rows and about 2½ feet or rather more space between the rows, then they will do well. Fig. 3 is a good representation of the smaller divided pieces. We have a preference for material of this kind, because by its use it is a comparatively easy matter to grow stately spikes of blossoms of vigorous growth and high quality flowers in consequence. These same pieces if planted 18 inches apart and the planting carried out carefully will give a splendid account of themselves before the flowering is over.

**Raising Phloxes from Cuttings.**—Very few persons are aware of the fact that Phloxes may be raised from cuttings quite successfully and with ease. Plants resulting from cuttings inserted during March, April and even May make handsome exhibition spikes of blossom. This is a method seldom practised by southern growers, yet by its recognition it is possible to make a large number of plants from one old stool. The cuttings should be from 3 inches to 4 inches in

1.—AN OLD PLANT OF PHLOX MRS. JENKINS LIFTED FOR DIVISION.

length, and to make them ready for insertion they should be cut through just below a joint; the latter is denoted by the junction of a leaf-stalk with the stem of the cutting. Fig. 4 serves to illustrate what a cutting should look like when ready for propagation. The cuttings may be propagated in 5-inch or other pots, using soil comprising loam and leaf-mould in equal parts and plenty of coarse silver sand, all well mixed and sifted through a sieve with a half-inch mesh. Fig. 5 shows several cuttings inserted in a 5-inch pot. The pots may be placed in a cool greenhouse or cold frame until rooted, subsequent to which period they must be carefully hardened off and planted in their flowering quarters when nicely rooted and well established. Fine cuttings, rooted in a pot as above described, may be transferred as whole to the flowering quarters, giving fully 2 feet space (we prefer more) between each clump of plants. Grand plants may be created in this way.

*Raising Phloxes from Seed.*—Seed sown at the present time should produce excellent results. Procure the seed from a firm of good repute and sow in light soil in shallow boxes or pans. Cover the seeds lightly and make the soil moist by holding it in a vessel of water, keeping the surface soil above the water level. In gentle heat the seeds will germinate satisfactorily. When the seedlings can be handled prick them off individually, using shallow boxes and light soil. Subsequently harden off and plant outdoors in late May. This is a very fascinating occupation, as it is possible something really good and new may be brought into existence.

#### HOW TO GROW GOOD BEETROOTS.

By a good Beetroot large size is not meant, but rather a shapely, firm, medium-sized root of good colour. The best soil for this crop is a rather light but well worked one, two spits deep being none too much to loosen the soil. On no account must manure be incorporated, as this tends to coarseness and forking in the roots, features that the merest novice will realise are most undesirable. If a site that was manured well and cropped with some other vegetable last season can be selected, this will suit splendidly, and, providing it is not very stony, good shaped roots may confidently be expected. The best time of all for sowing the seeds is the end of April or early in May; some cultivators sow earlier, but there is a risk of the seedlings being damaged by frosts, and in a hot season early sown plants have a tendency to run to seed.

The surface of the bed should be trodden moderately firm and then raked over, removing stones, sticks or any other rubbish that may be present. Then draw out broad-bottomed drills

4.—CUTTINGS READY FOR INSERTION.

$1\frac{1}{2}$  inches deep and 1 foot apart, and sow the seeds thinly therein, covering them with soil and making the surface of the bed level and tidy by slightly raking it. A mistake that many amateurs make is to sow the seeds too deeply; it should be remembered that the so-called seeds are really dried fruits, containing, perhaps, two or

3.—SUCKERS WITH ROOTS.

three seeds, which are in reality small, hence  $1\frac{1}{2}$  inches is quite deep enough to sow them.

When the seedlings appear thin them early so that they stand 9 inches apart, and if the variety is a dark-leaved one remove the greenest leaved seedlings. Birds are very fond of the tiny plants, and during dry weather often do much damage by eating them, hence steps must be taken to prevent attacks by these pests, the most effective being to place old fish netting or strands of black cotton over the beds, attaching these to short sticks a few inches from the surface. Work during the summer will consist of hoeing frequently between the rows, this fulfilling the two-fold purpose of keeping down weeds and preventing moisture escaping from the soil.

As soon as frost is experienced the plants must be carefully lifted, the leaves twisted off, and the roots stored for the winter in clean ashes, soil or sand. Care must, of course, be taken not to bruise or injure the roots in any way, else the colour when the Beets are cooked will be pale. The long-rooted varieties are usually cultivated for the main crop where a good deep, rather light soil is available; for early crops and for shallow or heavy soils, the Turnip-rooted sorts are best. In lifting and preparing Beetroots for exhibition during the summer, select those of even size and good shape, and carefully sponge away all the soil without injuring the skin. Any very fine roots that are present may be removed without any harm accruing, but judgment must be used in this operation. Good varieties are—Long-rooted: Dell's Crimson and Sutton's Blood Red; Turnip-rooted: Sutton's Globe and Egyptian Turnip-rooted.

#### HANGING BASKETS FOR THE GREENHOUSE.

A GREENHOUSE without a few hanging baskets filled with plants always presents a somewhat bare and unfurnished appearance, no matter how well the stages are filled, and as the present is an excellent time for transferring many plants from pots to baskets some hints as to the way to proceed may be of use to the novice. The first thing to consider is the baskets, and these are preferably made with stout galvanised wire or Teak-wood. They should be provided with three rigid wires, 1 foot or more in length and terminating in a stout hook at the top for hanging up the basket. Chains are frequently employed instead of the rigid wires advised, but these are a nuisance when it is desired to take down or hang up a heavy basket, as a little practice will quickly prove. The baskets may be of almost any shape desired, but for general purposes the simpler the design the better. Wire baskets are generally made bowl-shaped and wooden ones square. Small boxes with virgin cork nailed on the front and some holes bored in the bottom for drainage make excellent receptacles for hanging on walls, these, of course, being drained and filled with soil the same as pots.

Having decided on our baskets, we must now proceed to line them. Moss is frequently employed for this purpose, but, as it forms an excellent refuge for slugs and other pests, its use

is not advised. Good fibrous peat is decidedly better, and should be used where it can be obtained. Cut it into slices 1 inch thick with a sharp knife or an old saw, and place these slices evenly round the sides of the basket so that the soil placed inside will not get washed out. Where peat is not available, good fibrous turves make an excellent substitute, these being used when the grass is just dead or in a partially decayed state. The general soil must next be considered, and, although a few special plants may need a particular mixture, the ordinary run of greenhouse subjects will thrive in the following: Very fibrous loam two parts, peat or flaky leat-soil one part, well-decayed flaky manure half a part, and sand half a part. Pull the loam and peat to pieces with the hands, leaving many pieces as large as hens' eggs and making none smaller than Walnuts. If some small pieces of charcoal can be incorporated so much the better, and the whole must be thoroughly mixed before using.

We now proceed to fill the basket with the plant or plants to be used. Generally speaking, one kind of plant to a basket is preferable, mixed baskets seldom presenting a pleasing appearance. If it is desired to clothe the sides of the basket as well as the top, small plants may have their roots pushed through the wires or wood at the sides, but this is not needed with creeping or naturally pendent plants; it is also a nuisance when one wishes to turn the plant out of the basket. However, this is a point that must be decided by individual taste. Having selected our plant for the basket, it must be turned out of

5.—CUTTINGS INSERTED AROUND THE EDGE OF A 5-INCH POT.

its pot, all drainage and sour soil removed from the base and top of the ball of soil and roots, and some of the side roots gently loosened with a pointed stick. This done place it in the centre of the basket if one plant only is to be used, taking care that the top of the ball is at least 1 inch below the top of the basket. Then work the soil well round it with the fingers, making the whole moderately firm as the work proceeds.

During hot weather an abundance of water will be needed, and at least twice a week the baskets should be taken down and thoroughly soaked in a tub of water to which a little Clay's or other approved fertiliser has been added. The work of filling the baskets, especially where a pendulous plant is being used, will be greatly facilitated if the basket is hung up at a convenient height; for smaller and more erect plants stand the wire baskets in a large pot or pan and the flat-bottomed wooden ones on the bench. The following plants, besides many others, are suitable for baskets in a cool greenhouse: Fuchsias (almost any), Oxalis floribunda, Asparagus Sprengeri, Begonia glaucophylla, Achimenes, Tradescantia zebrina, Campanula isophylla, Ivy-leaved Geraniums (these go well with Fuchsias), Glory Pea (Climanthus Damperi), Nephrolepis cordifolia pectinata, Davallia Maresii, Maidenhair Ferns—such as Adiantum cuneatum, A. capillus-veneris and A. gracillimum—and the Golden Polypody (Polypodium aureum).

## THE TOWN GARDEN.

**HARDY ANNUALS.**—There are no flowers grown in British gardens that come in for as much unjustifiable abuse as those that are included in the comprehensive category of "Hardy Annuals." The seeds are sown somewhat thicker than Mustard and Cress, anything from four to a dozen seedlings are thinned out and then, because the plants do not branch out and flower profusely, the grower writes them down as absolutely useless. There was never a greater mistake made. The beauties of Clarkias, Godetias, Coreopses and others are not seen by those who do their gardening, if such it may by courtesy be called, in that manner, but if the seeds are sown thinly and the superfluous plants removed early so as to allow an abundance of space, hardy annuals will be found especially beautiful and pleasing in the garden.

**HOW TO SOW THE SEEDS.**—It is permissible to sow either in lines or clumps, and personally I much prefer the latter system, although in long, narrow beds delightful effects may be created by line sowing. For clumps the easiest way is to take an 8-inch pot, invert it, grasp it firmly and press the rim into the ground; then give the wrist a half turn, bring it back to the normal position again and lift. If this is done when the soil is in a pleasant state for moisture the operation will leave a ring with a drill of any depth that the cultivator desires—for large seeds like Nasturtiums it may be  $1\frac{1}{2}$  inches deep, while for small seeds like Godetias, Clarkias and others it may be about a quarter of an inch. In these circles the seeds should be set very thinly, and as soon as the seedlings show through the surface thinning must commence, and it should be carried out so efficiently that the plants of practically all stand 5 inches or 6 inches apart, and for many kinds this will not be sufficient. If desired, tallies recording the name and date of sowing can be put in the middle, or sticks may be used to indicate occupied ground, and the latter is the system I prefer, as I do not think that numbers of labels add to the attractiveness of a garden. However, this is purely a matter of taste.

**SOIL PREPARATION.**—This is a matter of importance if the finest results are to be achieved. Deep digging is the first thing, and there must be the incorporation of manure according to the state of fertility. All the annuals appreciate a good soil, but to make it excessively rich is an error, as it will lead to such gross and luxuriant growth that flowers will be conspicuous merely by their absence. When the digging has been completed the surface should be made moderately smooth, and the base of the drills must always be firm and level. It is immaterial whether the soil is enriched with natural or concentrated fertilisers, providing the former is perfectly sweet.

**TIME OF SOWING.**—Herein the cultivator of hardy annuals has plenty of latitude, for he can commence at once, and if he so desire can make successive sowings onwards to the end of May. As a general rule it may be said that the most suitable time is from the second week of April to the end of the month. This is another case in which it is imperative that each grower must exercise his own judgment, and to arrive at a decision he will have to take into consideration the nature of the soil and the weather.

**A SELECTION OF ANNUALS.**—Some excellent kinds include *Bartonia aurea*, which is rather straggling in habit and must be allowed 12 inches from plant to plant; *Candytufts*, *Clarkias*, *Godetias*, *Mignonette*, *Larkspurs*, *Comflowers*, *Convolvulus*, *Nasturtiums*, *Linum grandiflorum*, *Nemophila*, *Saponarias*, *Silenes*, *Poppies*, *Eschscholtzias* and *Virginian Stocks*. It will be observed that Sweet Peas are not embodied in this selection; this must not be taken as a sign of unworthiness, but that they are of too much importance for inclusion in a list and are always treated of on their own merits in special articles.

H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANTS UNDER GLASS.

**C**ROTONS that were ringed a time back will now be ready to come away from the parent plant. Have some good potting material at hand, so that when severed the plant is at once put into a very small pot; it will then scarcely feel the shift.

**Winter-flowering Carnations.**—These will now be ready for placing in 3-inch or  $4\frac{1}{2}$ -inch pots. Give them good loam, sand, leaf-soil, a small quantity of spent Mushroom manure, and a little artificial as recommended by the vendors. Drain the pots thoroughly and make the soil firm. Place the plants in a position near the glass where they will not get drawn. Border Carnations of the newer types should be potted into the flowering pots and placed on a cool ash bottom. These make a beautiful show after the principal batch of Malmaisons are over.

**Amaryllises** that have flowered should be grown on in a warm house or pit, syringing the foliage twice daily till thoroughly developed, when they may be allowed cooler treatment. Prick out seedlings raised this spring into small pots or pans and keep them somewhat close.

#### HARDY FRUIT GARDEN.

Trees in this department are very backward, owing to prolonged frost during March. Keep the protecting material over tender trees for some time yet, and draw the blinds down every night so as not to be caught unawares, as the frost often comes on in the morning, though it may not appear frosty at night. Keep a sharp look-out for aphids on the Peach trees, and syringe with extract of quassia or XL All as soon as the flowers are over, choosing a fine morning for the operation, as the foliage will then get dry before nightfall.

#### KITCHEN GARDEN.

Sowing seeds will demand a great deal of time now. All arrears of main-crop sowing should be made up as quickly as possible, and the main sowing of Carrots should now be made. Carter's Improved Horn, Carter's Golden Ball, Nantes and Long Surrey are excellent varieties.

**Potatoes.**—More should now be planted, choosing good, reliable cookers. Make another sowing of early Beet, Turnips and Celery for main and late crops. Finish planting Seakale sets, and give not less than 18 inches by 2 feet 6 inches between the rows. Give abundance of air to all early crops growing in frames, and gradually harden off all young plants that have been forwarded by such means.

#### FLOWER GARDEN.

Plant out new subjects in vacant places and in spots which have been well prepared. Manure sites that are intended for Dahlias. Plant out Pansies and Violas where they are intended to flower. Uncover plants that have been protected, such as Gerberas, Dracenas, Fatsias and Frementias, and give a little top-dressing. Prune Roses of the more tender varieties, and fork over the beds or borders. Shift Bamboos and Arundinarias, choosing, if possible, dull days for the operation, and quickly convey them from place to place. Encourage growth on Belladonna Lilies; the stronger these can be grown the better will be the flowers. A little artificial manure helps them, as does a top-dressing of spent Mushroom bed manure.

#### ALPINE GARDEN.

Sow seeds and prick out those already sown. Make good all vacant spaces from the reserve nursery. Keep every plant neatly labelled, as

it is most interesting to employers to be able to walk around and see the names of the plants.

#### CONSERVATORY.

This should be kept very bright and gay now. Tie climbers loosely, and when an opportunity occurs thoroughly clean every portion. Keep all dead and decaying flowers picked off, and take away all plants when they are over, as one bad plant in a collection will spoil the whole effect.

#### FRUIT HOUSES.

Continue to pay such attention as recommended in the last calendar. Sow more Melons for succession. Strawberries ripe and ripening should be removed to cool houses.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**SALVIAS.**—There are but few plants which brighten up the conservatory or greenhouse during the autumn and onward to Christmas better than these, and if fine specimens are required by the autumn, no time should be lost in getting in the cuttings. The first thing is to get good strong cuttings. Sometimes the old plants, from which the first cuttings must be taken, are not in the best condition, but the cuttings grow away very quickly and the tops may be taken again. Salvias may be grown in any ordinary soil, but they succeed best in good loam, with manure added. During the summer they should be grown in a pit, giving plenty of air, or the lights may be taken off altogether in favourable weather. *S. splendens grandiflora* is certainly the finest scarlet variety grown.

#### FRUIT UNDER GLASS.

**Peaches and Nectarines.**—Early Peaches that have finished stoning may have the temperature raised several degrees without any further fear of fruit dropping. If the final thinning has not yet taken place no time should be lost in doing it, as this final swelling requires all the resources of the tree. Syringe freely and deal promptly with any insect pests that may appear. Keep the borders well watered and give weak manure water at each watering. In later houses a little time should be spent daily in disbudding, thinning the fruit, &c. In this way the work comes lighter than if done all at once, and it is far better for the trees that disbudding should be done a little at a time.

#### HARDY FRUITS.

**Strawberry Planting.**—Autumn planting is undoubtedly the most satisfactory way of making a Strawberry plantation, providing good plants that will fruit the first year can be obtained, but this is not always the case, especially on light soils and bad seasons for getting runners. In this case I much prefer to have the runners planted thickly in the autumn, making the final planting in the spring, the present being a good time for the work. This allows time for the soil to become well settled after being trenched. A fine day should be chosen for treading and raking down the plot, so that it may be ready for planting when the weather appears to have set in mild, and if planting just precedes a nice rain this will settle the soil well round the roots and give the plants a good start. Be careful not to bury the crowns when planting and to make the soil firm about the roots.

#### KITCHEN GARDEN.

**Seakale Planting.**—In the more favoured districts, where a supply of forced Seakale is expected early in November, a limited batch of early made, strong cuttings may now be planted, choosing a sunny border. Planting for the production of the main forcing batches will be best done about the middle or end of the month.

The roots are then more likely to escape injury from frosts, which often catches extra early plantings.

**Main Crop Celery.**—I am no advocate for sowing the principal crop of Celery in heat. Nothing beats a frame in a warm sheltered position. About the middle of the month is a good time for sowing. Let the seed bed consist of a light loamy leaf-soil passed through a coarse sieve. Firm it well, sow thinly, and well water with a fine rosed pot. Keep the lights shut down till germination occurs, and cover with mats at night. When growth commences air should be increased until the lights are entirely removed.

#### FLOWER GARDEN.

**Everlasting Pea.**—All the varieties of Everlasting Peas are useful, but the pure white variety is especially so for supplying cut flowers during the hottest summer months. These may be readily increased at this time of the year by taking off the young growths as soon as they have pushed about 6 inches through the soil. Take a sharp knife and run down so as to sever them about 2 inches or 3 inches below the ground level; insert these cuttings round the edges of pots or pans and treat like any other soft wooded cuttings at this time of the year. A very large percentage of them will soon root, and may be potted off singly and hardened off preparatory to planting out.

**Dog's-tooth Violets in Grass.**—One great advantage in planting these in grass is that they present us with their flowers unsullied by the splashings of heavy rains. The Dog's-tooth Violets are delightful at the present time in leaf and blossom. On a sunny day the effect is unique. We cannot get such fine effects by growing the Dog's-tooth Violets in beds and borders. The usual practice is to drill these little bulbs into lines for edgings; but every garden that has grass about it, which it is not necessary to mow till summer, should certainly have a large colony of Dog's-tooth Violets.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

## THE EDITOR'S TABLE.

#### A SEEDLING VIOLET FROM DEVON.

Mr. J. Heath of Kingskerswell, Devon, sends flowers of a seedling Violet, with others of the variety *Souv. de J. Josse* for comparison. The flowers of both are the same colour, but those of the seedling have much firmer petals, which are also waved, thus giving the flowers a very attractive appearance. He writes as follows: "I am sending for your table a small bunch of a seedling Violet that I have raised, and with it, by way of comparison, a few blooms of *Souv. de J. Josse*. The latter is the finest of its colour on the market at present, but, unfortunately, it has the thin pointed petal after the manner of California. The seedling has more substance altogether, and in waviness of petal somewhat resembles a good *Spencer Sweet Pea*. Although I have raised many thousands of seedlings in my time, this is the only one I am retaining as being distinct enough to keep. Cross-fertilisation with Violets is practically impossible, which accounts for so very few new varieties; but by following the lines by which I obtained this seedling, I hope in the spring of 1909 to send you something worth seeing."

#### AN UNUSUAL CYCLAMEN FLOWER.

Mr. Edward Wormald, 15, Berkeley Square, W., sends us a rather unusual form of fasciation in the Cyclamen. The flower sent was quite normal, but about half an inch below it a rather small yet perfect leaf was produced, this leaf having about half an inch of stem so that it was on a level with the flower. Undoubtedly the petiole of the leaf and the flower-stem had grown

together and thus formed one, branching occurring near the apex, thus proving the close affinity between flowers and leaves.

#### A REMARKABLE DAFFODIL.

Mr. H. Harland, gardener to the Rev. G. Rogerson, Milton House, Newton Abbot, sends us a very remarkable example of *Narcissus Empress*, four good-sized flowers being produced on one stem. It is, of course, an example of fasciation or the growing together of two or more stems. The stem in question was very much flattened and deeply ridged, but the fusion was perfect. Three of the flowers were quite normal, but one, the largest, had seven perianth segments and also a malformed segment situated on the outside of the trumpet, a short distance from the base and growing in the same direction as the trumpet. Fasciated examples with two flowers are fairly common among the trumpet Daffodils, but we have not previously seen four on a stem.

## ANSWERS TO CORRESPONDENTS

#### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

#### FLOWER GARDEN.

##### Violet leaves diseased (T. H. D.).

The state of the leaves is certainly not due to red spider, but corresponds with the fungus named *Aecidium violæ*. Comte de Brazza is a weak-growing variety, and this, coupled with bad ventilation, is probably the cause of the disease. It is almost hopeless to try and effect a cure, the best course being to root up the plants and burn them, taking care to thoroughly clean out the frames and scrub them well before using them for Violets again. If you do not care to adopt such drastic measures, try the following: Cut off all the affected leaves and burn them, and then thoroughly spray the plants and surrounding soil with a solution of sulphide of potassium, 1oz. to three gallons of water. Afford free ventilation at all times when the weather is open.

##### Raising *Linnea borealis* from seeds (L. B. W.).

The charming little *Linnea borealis* is rather difficult to raise from seeds, which are often unripe when saved. They should be sown in a pot or pan, well drained in the usual way with broken crocks for about a fourth of its depth, with some turfy loam above, the remainder being filled up to within 1 inch of the top with fine soil composed of loam, with about a third of peat or leaf-soil and a good proportion of sharp silver sand. Press this carefully down, but do not make too solid, and sow the seeds, pressing them gently into the soil with a flat piece of wood, but not covering them when doing so. Just cover them over with some fine soil of the same kind, and water carefully so as not to dislodge the seeds. Cover the pot with a sheet of glass, and over this put a piece of brown paper. Should the soil become dry before germination the seeds will probably be useless, and the best way to water is to dip the pot to the rim in water, allowing this just to rise through

the surface and replacing the glass and brown paper. When the seeds germinate give air and light gradually, always, however, keeping the seedlings in partial shade. Prick out into similar soil about 1 inch apart before planting out. The *Linnea* is a shade lover, and grows freely in woods. A soil of peat or leaf-mould, loam and sand in about equal proportions will grow it satisfactorily if the plants are shaded from sun. We grow it behind a hedge, which shades it from the south, west and south-west, and where it only receives the minimum of sun in the early morning. A few stones are placed about the plants, and these conserve the moisture. It is rather difficult to establish, but when once established does well. It should have plenty of water in dry seasons.

##### Crocuses diseased (H. C. C.).

The Crocuses are affected by *Botrytis parasitica* (Cavaca). We add Cavaca's verbatim report: "The disease attacks primarily the shoot growing from the corm, and the leaves are destroyed in portions." In the Crocuses under notice the corms were all quite healthy, only the shoots had suffered. In damp atmosphere an epiphytic mycelium appears, which forms small, velvety, whitish sclerotia. These sclerotia were also present in the Crocuses. The sclerotia when ripe become hardened and black. The diseased portions of the plant rapidly decay and, of course, fall to the ground, and the soil thus becomes infested and the disease is propagated by means of conidia. You must carefully watch the plants this year, and cut off and burn all diseased parts. This will most likely prevent the spread of the disease to the corms. Should the disease appear next year, it would be better to dig up the corms, select those which are quite healthy, and transplant them in a special bed in the nursery, not in the garden. It is most likely that a good many will then recover.

##### Raising Asters, Stocks, &c., without a glass house (Stirling).

You may raise seedlings of *Schizanthus*, Asters and Stocks quite easily without the aid of a propagator of the kind you mention in your letter. If we understand you correctly, you may sow the seeds in pots, pans or boxes and stand these in your cold frame, where they will germinate quite satisfactorily. As a matter of fact, these seeds may be sown outdoors where they are to grow in April, but rather later in the month so far North as your garden is situated. The seeds would germinate even in a room with a northern aspect, but the process would be distinctly slow. We prefer the window in a southern aspect, however, to the other position, but do not begin too early. The only advantage that raising these plants in heat is, that you can ensure an earlier display by these means. We do not advocate the purchase of the propagator you mention.

##### Pæony damaged when renovating border (Stirling).

We should not move the two pieces into which your Pæony got broken unless you very much wish to remove them to some other quarters. The Pæony may be planted at any time between September and April, but the latter date is somewhat late for the planting to be performed. As a rule the plants seldom flower the first year after planting, appearing to suffer by the removal. The second and third year, however, they may be relied upon to do well. These remarks apply especially to plants with undamaged roots. It is very difficult for us to advise you with regard to your broken plant without seeing it first, and this, of course, is out of the question. As you have already planted the broken pieces, we should not again interfere with them, unless it is your intention to find new quarters next autumn; in that case we should be disposed to lift and replant at once rather than wait until then.

##### Summer bedding (E. J. W.).

As you appear to desire a display as late as possible, we think you have erred in too great a variety of early or mid-summer subjects generally, and we note that you have omitted entirely the most valuable family of Asters, also *Celosias*, garden *Marigolds*, *Verbenas* and *Mignonette*. These are of much service for late flowering, and you might with advantage make a freer use of *Zinnias*, which are invaluable for late work. The *Nemesia* group would appear better in the forefront of the Argemone, an arrangement that would remove it from *Erysimum*. The *Celosias* and *Marigolds* should be freely used, and *Mignonette* would be valuable always. The beds on the grass, if these are to be cleared in early June, would do well for late-raised *Zinnias* or Asters, *Celosias*, *Verbenas*, &c. It is quite possible that some of the *Godetias* would give you a far greater return at flowering time than Argemone, which, compared to many other things, is unduly tall. If you have a reserve plot of ground, your better plan will be to make successional sowings of the seeds, while such later-flowering things as *Celosia*, *Snapdragon* and *Aster* will be better raised in the ordinary way

and transplanted. We thank you for your remarks as to the helpfulness of THE GARDEN.

**Information about Violets** (A. R. W.).—The two varieties named by you are among the finest of the family Mrs. Arthur being probably the finest double yet introduced. In the singles Kaiser Wilhelm is a great advance upon the older sorts. Taken together, we think they cannot be beaten.

**Annals** (E. T. L. E.).—It is not at all an easy thing to define what is an annual from a certain point of view, because so many so-called annuals but need the protection of a frame or glass house, or a little warmth, to render them perfectly perennial. The fact, however, that you can root cuttings of certain plants which are regarded as annuals, and by these means make of them a plant of perennial character, does not quite fit the situation, and a large number could be cited of which this much is quite true. The terms "annual," "biennial," or "half-hardy annual" are rather terms of convenience and usage, and are only approximately correct. At the same time, the true annual is that which springs from seed, and dies root and branch the same year after flowering. What may be done by special means is quite another matter. In the true annual the root and branch system perishes as a result of maturity after perfecting seeds to perpetuate its kind. The Virginian Stock is one of these. On the other hand, certain annuals may be made biennial by sowing the seed at too late a period for flowering. A self-sown annual will grow, flower and perish the same year, but the so-called "annual," which for three years grew and flowered, has no real claim thereto.

**Plants for border** (Britannia).—If your desire is for the plants to bloom, as you say, in "late summer and autumn," we fear the Delphiniums and Aquilegias will not be quite suitable, and, so far as the Campanula is concerned, this will depend upon the species you have in mind. In such a case, too, seeing that you apparently wish for long, massed lines of things, the idea of planting varieties of one colour would not be good, and a much more decided display could be obtained by planting those subjects that flower together. For example, such plants as *Helianthus multiflorus* major, yellow, for the back; *Kalmia* (Tritoma) *Uvaria*, scarlet, next; *Phlox* Mrs. E. H. Jenkins, pure white, next; and *Aster Amellus*, mauve, or *Rudbeckia Newmanii* for front. These would all bloom together. If, however, you require a display at an earlier date, you could plant other things in conjunction with the above-named. Perhaps you will let us know as to this, and we can then definitely advise you. We think the Clematis alone will be best on the trellis, and by planting such as *Jackmani*, *J. alba*, *Lord Wolseley*, mauve-blue; *Henryi*, white; *Miss Bateman*, white; *Lady Lonsborough*, pale mauve; *Viticella rubra*; and *Ellen Moser*, white, barred with red, you will have a good set. We thank you for kindly mentioning THE GARDEN.

## THE GREENHOUSE.

**Treatment of Arum Lilies** (A. J.). Both the Arum Lilies (*Richardia*) concerning which you enquire behave quite differently from the common Arum Lily (*Richardia aethiopica*). This forms an elongated root-stock and retains its foliage throughout the winter, whereas the underground portion of the two named by you is a kind of flattened tuber, which passes the winter in a state of absolute rest. During this period they should be kept dry, and early in the year, when they commence to start into growth, they must be repotted. By this you will see that you have given yours the correct treatment, and a temperature of 50° by night, rising to 60° or even 70° by daytime, will not be too hot, at least for *R. Pentlandii*, which, being a native of the northern portion of the Transvaal, requires more heat than *R. albo maculata* (not *immaculata*), which comes from the southern part of Natal. When once growth recommences the foliage is rapidly pushed up and, if the plants intend to bloom, the flower-stem also. As the pots get full of roots a little liquid manure occasionally will be beneficial. After the flowers are over the plant makes its growth for another year, when it must be treated the same as during the growing period. By the end of the summer the leaves will turn yellow and ultimately die down when the soil should be kept dry till the new year is a month or two old.

**Arum leaves brown at the edges** (Gertrude). This is a very common trouble with Arums, which has at one time or other aroused a good deal of controversy. Several theories as to its cause have been put forward, but the generally accepted idea is that it is produced by a too liberal use of stimulants and by too close and moisture-laden an atmosphere. This theory is borne out by the fact that plants subjected to a hardy mode of treatment and a free circulation of air are seldom attacked in this way. These are the points to bear in mind in combating the evil. As the Arum is quite hardy in the favoured parts of this country, one can perfectly understand that it resents too close an atmosphere. At the same time, we beg to point

out that our efforts to oblige are, in many cases, greatly handicapped by the absence of any information as to the conditions under which the plants are grown.

**Cyclamen buds going off** (A. W., Surrey).—No objection can be taken to the cultural details given by you, and the leaves and flowers that you sent show that the plants are in a flourishing state. The cause of the buds going off is, doubtless, too close an atmosphere, for, though the temperature given by you is quite correct, a free circulation of air is necessary. If stood rather closely together the buds are liable to damp, for which reason some cultivators elevate the plants on inverted pots. The leaves sent show that the plants have had a liberal amount of liquid manure, and highly-fed one are always more liable to damp than those which have been less liberally treated.

## FRUIT GARDEN.

**Fig tree casting its first crop** (R. T. S.).—To enable you to secure a good first crop on your Fig tree it is essential that you give the tree a period of complete rest in a cool atmosphere for at least three months before starting it into growth. Unless you can do this, we can see no prospect of your ever securing a satisfactory first crop; and from what you say of the position in which the tree is planted and the condition under which it is grown, it seems to us impossible for you to give the tree this needful rest. Therefore we think that the best thing for you to do will be to dismiss the idea of a first crop, and to do your best by stopping the young shoots at the sixth leaf, by preventing the overcrowding of foliage, and by feeding with manure water to secure an extra heavy second crop. If it is important that you should have an early crop of Figs, why not grow a few trees in pots, introducing them into heat in November from a cold shelter? You would then obtain ripe fruit early in April. The variety St. John is the best for this purpose.

**Peach tree buds dropping** (R. K., Paerlowsk, near St. Petersburg).—Our correspondent writes: "I am quite desolate about the exceedingly strong buds dropping off *Violette Hative* and *Dymond* Peach trees, and I am very anxious to learn its cause and how to prevent it. Beyond the two varieties in the same house are *Crimson Galande* and *Humboldt Nectarines*. They also drop buds, as, I think, all Peaches do more or less, every year, and one does not care about this as long as there are enough buds left for a full crop. I have observed it for several years on these two varieties, happening as well on the strong growth as on the weak. When the buds are cut through then one sees that they are black in the centre. Are these two kinds especially subject to bud dropping? I must add that the trees are about ten years old, a picture of health and are never neglected. They are forced very slowly and the shoots were not overcrowded last year. I think I dare say that they never suffered from dryness at the roots; plenty of lime in the soil. They are planted in a raised border, as all Peach trees are with us. Have good soil and drainage. Last year they bore a full crop of first-class fruit. This year they cannot bear a good crop, because too many buds have dropped." We are anxious to be of service to our Russian correspondent, and thank him for the plain and clear way in which he has placed the case of Peach bud dropping before us. The ample provision he has made for the successful growth of his trees and the precautions he seems to have taken against failure makes it difficult to suggest the cause or to propose a means of preventing such failures in the future. The question is an old and perplexing one. We scarcely remember the time when it did not cause serious anxiety and loss to many gardeners in this country. For this reason we draw special attention to the subject by publishing our correspondent's letter at length in the hope that some of our readers, who are experts in fruit culture, may be able to throw some new light on the subject. The buds sent with the letter are so discoloured and withered that they do not help us in any way to elucidate the matter. We may say that we have not found the variety mentioned especially liable to this weakness. Our greatest trouble in this country in this respect has been with the early American varieties, and this only refers to their culture under glass. When grown out of doors they do not drop their buds. We refer more especially to the varieties *Alexandra* and *Waterloo*. Of late years this has been overcome, even in these varieties, to a great extent by not applying any fire-heat at all until after the fruit has stoned, when it is quite safe to apply fire-heat to expedite forcing. It is much colder in Russia in spring than it is with us, and we suggest that the extra heat required to sustain the heat in your case has had something to do with the trouble. Try what covering up with protecting materials at night will do next spring, and use as little fire-heat as possible. *Peregrine Peach* was sent out in 1904 (Rivers), and those who have grown it speak of it in the very highest terms. It is something like *Crimson Galande* as far as growth and cropping qualities are concerned, but it is much better in flower and is larger and handsomer. Both *Nectarines* are grand. There is nothing to choose between them, but

Early Rivers is a fortnight earlier grown under the same conditions. If the leading Vine shoot is strong, do not stop it until it reaches within 2 feet of the top of the house. If, on the other hand, it is weak, stop it when it has made a growth of 4 feet; this will strengthen the shoot for fruit bearing next year. The laterals of these shoots may be stopped in the first instance at the third leaf, and the subsequent laterals, which will grow from the first laterals, at the second leaf, and so on from succeeding ones until the end of the growing season.

## ROSE GARDEN.

**Roses and mildew** (A. D. Z.).—The Rose you name, *Reine Marie Henriette*, is notoriously addicted to mildew, even when planted in the best of positions, namely, in the open garden upon an arch, but when planted against a wall the consequent liability to drought at the root is a sure incentive to trouble from this fungus. We advise that all soft wood be removed at once and burnt, as this probably contains more mildew spores than the old wood, then give the plant a good syringing (preferably with a fine-spray syringe, such as the "Abol") of a solution of Lifebuoy carbolic soap. A half bar to three gallons of soft water is an effectual solution. Keep the plants syringed at intervals and well in advance of any appearance of the fungus, then we think you will not be troubled so much as last season. This solution is quite harmless to young growths. Climbing Roses against walls should be well watered twice a week in a dry season, and even in such a season as last it sometimes happens that the plants against some walls are very dry at the roots.

**Using green bones for Roses** (Woodpecker). We do not think you would gain much by buying green bones and breaking them up for your Roses, especially as you have not got a machine for doing the work. Bones are so very slow in dissolving that it would be a long time before the plants derived any benefit from them. If you had a machine that would grind them up into fine meal it would be worth your time to purchase them at the rate you name, but we do not advise you to buy them for use in the manner you suggest.

## KITCHEN GARDEN.

**Manure for kitchen garden** (A. G. G.).—By what you say we have little doubt that your garden needs a good application of lime. Soil that has been well worked and heavily manured for forty years will certainly be very rich in humus or organic remains, and we advise you to apply lime at the rate of 8oz. to the square yard. This dressing should be given when the ground is vacant, securing fresh lime and placing it in heaps until it is slaked, then spreading it evenly over the surface and digging it in.

**Securing a supply of vegetables** (E. H.).—In reply to your question as to a good handbook, we think you would find the "Book of Vegetables," by G. Wythes (Lane, Vigo Street, W., 2s. 9d.), of great help during the coming season. We are glad to advise on the points you mention. Of Peas we gather that you wish a supply as long as possible and not too many at one time. If you have a fair depth of good loamy soil in the favoured district you reside in, you should have a good succession of Peas from May to October. We have recently in THE GARDEN given copious notes on early, mid-season and late Peas, so will not repeat varieties. The lists given are most reliable, and contain the cream of the Peas in cultivation. For an earliest supply you would sow on a warm sheltered border early in February; again, three or four weeks later, these also on a somewhat sheltered border; after that we would advise sowing every three weeks on an open quarter till the end of July. Of Beans, we presume you mean Dwarf French. If Broad Beans are meant, these should be sown in February, March, April and May for a succession and they like a heavy soil. The Dwarf French Beans may be sown from April till August, every four weeks in good land well enriched with manure, sowing an early variety in April and May; later sorts such as *Veitch's Progress* or *Canadian Wonder*, for later supplies. Of course, the Runner Beans will give a longer supply; these you would sow early in May and a month or six weeks later. As regards quantity to sow, here again so much depends upon the requirements of the house at a certain date, and for eight persons, if you sow a couple of rows thinly, say, half a pint of seed, this should suffice. As regards Peas, you would require double that quantity at each sowing or even more for the earlier sowings. For Spinach we would advise sowing in February and monthly till September, but sow as thickly as possible. A quart of seed should give you enough for the year. The August sowing must be larger, as this is for the winter supply.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock St. et, Covent Garden, W.C.

## OUR COMING FLOWER SHOW.

AS it is most probable that many of the intending exhibitors or competitors at our coming flower show may be new to such exhibiting, it may be well to point out a few things that may be interesting and useful. Taking the classes as published, Roses claim first notice. These may be shown in ordinary boxes filled with water-tubes, or in boxes filled with green moss, into which are set small bottles or vases, each one to hold one flower in water; or boxes may be dispensed with, and small, neat vases, each one holding one flower, stood in proper order and in limited space on the show tables. In such cases the stems should not be too long, so that the flowers stand erect, thus showing their good points. Not to utensils or boxes, but to flowers, are prizes given; still, it is well to stage flowers as neatly as possible in all cases.

Bunches of garden flowers need not be tied, but should be just a comfortable handful in each case and be neatly arranged in each bunch. These should be set up singly in vases of from 6 inches in front to 9 inches in height at the back, and not be crowded. Sweet Peas should be loosely placed in the vases, not bunched or compressed. About eighteen to twenty spikes of bloom in each vase, neatly or lightly arranged, will be most favoured. Of course, fine form and fresh colouring will tell materially. Bunches of garden annuals should be set up as advised for other garden flowers, although annuals may be included with garden flowers. Perennial or biennial flowers cannot be included with annuals. Those, however, may comprise both hardy and tender kinds. Carnations should be shown in vases and have fairly long stems, so that the flowers stand well above the vase, and not be crowded.

In exhibiting fruits from bushes, these are best staged on neat plates that have been dressed with Vine or other large, soft leaves. A fair quantity of each fruit—say, a pint for instance—would represent a dish. Quality of fruit, especially size, colour and freshness, would have more weight than quantity.

Vegetables should be thoroughly cleaned and neatly trimmed of all superfluous leaves

before staging. Collections look best when arranged on a carpet of fresh green Parsley. Failing that, have a groundwork of clean white paper, setting up the taller or larger kinds of vegetables at the back, and keeping the smaller things, such as Tomatoes, Peas, Beans or Potatoes, for the front. All single dishes should be shown on plates, which will be specially provided.

All these things, including flowers, fruits and vegetables, must be placed by the exhibitor, if present, in the proper position for each class, according to its number as shown on the tables. If all exhibitors will look for those numbers and place their exhibits properly, also see that their entry cards are carefully and correctly placed on each exhibit, they will render the work of the managers and judges very simple. With regard to ladies' special classes, although they may compete as amateurs, if such, or in any open classes also, in arranging table decorations, baskets or bouquets, effort should be made as far as possible in having the flowers in water or otherwise spraying them occasionally to keep them fresh. Last but not least, the greatest care must be taken to cut out, preserve and, finally, in due course send in with the entries all the coupons. Those who cannot bring their exhibits will be at no disadvantage with those who can; they will be carefully staged by competent men.

"A GRATEFUL READER" writes: "As one who has in more recent years enjoyed reading THE GARDEN from week to week, and having gained considerable information by these means, I am delighted with the prospect in view of competing with other readers in friendly rivalry in the different classes so generously provided for us. I am conscious of my own shortcomings and want of practical knowledge of some of the subjects for which there is to be a competition, but am hopeful that, having the knowledge of what is to take place so well ahead, and by reference to the columns of THE GARDEN each week, as well as to my earlier copies, I may do justice to your paper and to myself. Permit me if you will please to make a suggestion. Why do not you print the schedule of prizes on a separate sheet and publish this with each successive weekly issue? Were you to do this, I and other readers would be pleased to pass this on to some of our enthusiastic amateur gardening friends, and by these means bring this excellent idea, of a show open exclusively to readers of THE GARDEN, before others who would be interested." [We intend to have a separate sheet.—Ed.]

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

April 11.—Seascale and Lake District Horticultural Society's Spring Show.

April 14.—Royal Horticultural Society. Exhibition of flowers, plants, &c. Special Daffodil prizes, 1 p.m. to 6 p.m. Lecture at 3 p.m. by Mr. E. A. Bowles, on "Hardy Cacti and other Succulents." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

April 15.—Royal Caledonian Horticultural Society's Spring Show.

**Journal of the Royal Horticultural Society.**—Part I. of Vol. XXXIII. of this journal is now in our hands, and, as usual, its contents are most varied, interesting and useful. The Rev. Professor G. Henslow, M.A., V.M.H., deals with "The True Darwinism" and "Phyllotaxis, or the Arrangement of Leaves," and Mr. H. Morgan Veitch contributes an interesting article on the "Amateur and Horticultural Law." Other useful and interesting articles are "The Relation of Meteorology to Horticulture," by R. H. Curtis; "Arches, Pillars and Pergolas," by W. P. Wright; "Japanese Dwarf Trees," by A. Maunérne; "Mistletoe," by W. Smyth; "Gesneraceae," by Colonel R. H. Beddome, F.L.S.; and "A Bundle of Herbs," by Miss H. C. Philbrick. The reports of the trials of perennial Asters, Cannas, Dahlias, Tulips, Melons, Strawberries, French Beans, Kales, spring-sown Onions, Potatoes and outdoor Tomatoes held at Wisley, and the reports on manures, appliances, &c., are also most useful. We should like to see these parts of the Journal bound into more lasting covers than the paper ones at present used. The contents are certainly worth it, and the books would then become most valuable for reference. The price to non-Fellows is 7s. 6d.

**Beans, Peas and Potatoes in 1907.**—The returns of produce of crops in Great Britain for 1907, published by the Board of Agriculture and Fisheries, price 4d., provide most interesting reading. Beans were a good crop generally, the yield for Great Britain being 34.5 bushels per acre, or 5 bushels over the average. In England the crop was 34.5 bushels, Wales 28.7 and Scotland 36.4 bushels per acre, these results being 5.2, 2.8 and 2.2 bushels respectively above the mean of the previous ten years. The yield per acre of Peas, though not so high as in 1906, was 2.3 bushels in excess of the average. It is interesting to note that the culture of Peas is almost wholly confined to England, the acreage in Wales and Scotland representing less than 1 per cent. of the total for Great Britain. In England the best results were secured in the Eastern, North-Eastern and South-Eastern Counties. The Potato crop was a very poor one. The yield for Great Britain was 5.4 tons per acre, nearly two-thirds of a ton less than in 1906 and one-third of a ton less than the average. England had the best results compared with the average, the deficiency being only a quarter of a ton; but in Wales the crop was 1 ton per acre below the average, and in Scotland half a ton. The shorter crop, combined with a smaller acreage, reduced the total yield by 450,000 tons as compared with 1906. In England the Eastern, North-Eastern and East Midland groups of counties gave an over-average yield; but in every county, with the exception of Worcester, in the West Midland, South-Western, Northern and North-Western groups the yield was below the mean. The principal over-average yields were obtained in Cambridgeshire, Essex, Middlesex and Buckinghamshire. Westmorland, Wiltshire, Cumberland, Devonshire, Derbyshire, Lancashire, the North Riding and Hertfordshire gave the poorest returns. Fife had a decline of three-quarters of a ton an acre, but Perth had a third of a ton over the average.

**The Midland Daffodil Society.**

The dates originally arranged for the annual exhibition in connexion with the above society—April 23 and 24—are now confirmed, and the exhibition will be held in the Edgbaston Botanic Gardens. The committee anticipate a most interesting display of seedlings from the foremost raisers in the country, so that the exhibition will be one of unusual interest. A handsome silver challenge bowl, as a memorial to the late Rev. S. E. Bourne, as well as ten other silver bowls and vases, is being offered, so that exhibitors have plenty to attract them. Mr. Herbert Smith, the hon. secretary, will be pleased to furnish full particulars: his address is Tenby Street, Birmingham.

**Swanley Horticultural College.**

This college exists chiefly for the purpose of training young women in the various branches of horticulture and allied subjects, and it is pleasing to note that steady progress is being well maintained. The annual report for 1907 is of a favourable character. The chief feature of the year was the establishment of the course in natural history, which has for its object the training of third-year students who have passed the ordinary gardening course and wish to increase their knowledge of natural history subjects in order to qualify as teachers of gardening and Nature study. The silver salver, which is held for the year by the student gaining the highest aggregate number of marks in the midsummer examinations, was gained by Miss Margaret Legg. The syllabus of work is a most interesting one and is well illustrated. Full particulars of the various courses may be obtained by writing to the Principal.

**Horticultural Instruction in Essex.**

The Essex County Council was one of the first to include horticulture among the subjects suitable for secondary education, and it is gratifying to find that the work is still proceeding on well-defined and comprehensive lines. The report and handbook of the education committee contains some interesting information regarding the teaching of horticulture in the county. Mr. C. Wakely, the staff instructor, draws attention to the practical results of the early work constantly being met with, many former students now holding good positions in the country. During the year three demonstrations were given to gardeners and amateurs in the county gardens at Chelmsford, a teachers' holiday course was held during the third and fourth weeks in August, many school gardens were laid out and those already established were visited, two gardeners' associations visited the county gardens and lectures were given at no less than thirty-six centres in the county, so that residents have had ample opportunities of securing knowledge on this subject.

PRIZES FOR READERS.  
APRIL.

## HOW TO MAKE A SMALL ROCK GARDEN—LIST OF SUITABLE PLANTS ALSO TO BE GIVEN.

A First Prize of FOUR GUINEAS,  
A Second Prize of TWO GUINEAS,  
A Third Prize of ONE GUINEA,  
And a Fourth Prize of HALF-A-GUINEA  
are offered for the best essays on the above subject.

The notes (restricted to 1,500 words) must be written on one side of the paper only, and be enclosed in an envelope marked "Competition," addressed to "The Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, W.C." The answers must reach this office not later than Thursday, April 30. Both amateur and

professional gardeners may compete, but it is hoped that those who contribute regularly to the pages of THE GARDEN will not do so. The name and address of the competitor must be written upon the MS., and not upon a separate piece of paper. The Editor accepts no responsibility for and cannot undertake to return the MSS. of unsuccessful competitors. The Editor's decision is final.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**"The Garden" Flower Show.**

There is a special reason for rejoicing over the coming flower show for readers of THE GARDEN, that is, assuming it be held in the Horticultural Hall or some other similar central building, and it is that for once a real competitive miscellaneous flower show will be held in the heart of London. This is a class of show plentiful all over the kingdom outside of London, and always constitutes the most popular forms of flower shows, because, not only inclusive of almost everything found in gardens at the time of year in which the show is held, but has the charm or excitement of being competitive, and that enhances interest so much to visitors. Grand as are the Temple and Holland Park shows of the Royal Horticultural Society, there is no competitive element in them, hence there is nothing which specially arouses the interest of visitors. How different at great provincial shows, where the greatest anxiety is manifested to find the leading exhibits in the respective classes. I venture to hope that, seeing how plentiful are trade or honorary exhibits at the usual shows, none other than those competing will be included in the exhibition.—D.

**Late Peas.**—I was very much surprised to find no mention of Gladstone in the list of varieties recommended for late supplies by Mr. G. Wythes in his article on page 128. It is one of the very best late Peas on the market, and is seldom attacked by mildew. Added to this good point we have medium-sized well-filled pods and a flavour that is not surpassed by any other standard variety. A list of late varieties is certainly not complete without it.—PISUM.

**Sweet Pea nomenclature.**—"D.'s" protest under the above heading in a recent number of THE GARDEN has come none too soon. I have often wondered why raisers of novelties should follow one another like a flock of sheep, by giving new Sweet Peas, with very few exceptions, personal names; but to prove that all raisers of Sweet Peas are not possessed of such poor imaginative power as "D." thinks, and are capable of striking out a line for themselves, I give a list of a small collection of novelties which I sent to the Shrewsbury show last year: Mother o' Pearl, Opal, Pearl, Amethyst, Ruby, Moonstone, Coral, Scotch Pearl, Jarjoon, Topaz, Seashell, Cowrie, Red Admiral, Romani Rani, Sycra Lee and Helen Grosvenor. Exception may be taken to the last two names on the ground of their being personal, though Sycra Lee is really a dromesky nav (Gypsy road-name), and the last name on the list was chosen because the flower is, in the opinion of several experts who have seen the plants growing, a great improvement on Helen Lewis, and came from the same cross as that which produced Romani Rani (Gypsy lady) and Sycra Lee.—HUGH ALDERSEY, Aldersey Hall.

**Mistakes made in sowing seeds.** The caution of your correspondent "Avon," page 141, not to pat down the surface of the soil after sowing the seed, might be applied to seed sown in pots or pans as well as in the open ground, to which he refers. It is a common practice to use comparatively fine soil in seed-

sowing and pat it down firm and level before scattering the seed on it, then, after covering with some more fine soil, the surface is patted down quite smooth and solid. As the seed germinates the smooth surface on which it lies is not at all adapted for the insertion of the tiny rootlets, and the soil above, even though it may not be too deep, is pressed into one unbroken surface, through which the young and succulent plants have much difficulty in making their way, and many perish in the attempt.—H. P.

**Introduction of the pink Malmaison.**—With reference to the paragraph in a recent issue as to the introduction into England of the pink Malmaison this must have been some years at least before 1872, as there was in 1869 in the greenhouse of my father's house a very large plant of this Carnation. The stem was as thick as my thumb, and it grew on a wire trellis to a height of about 4 feet and about the same width, carrying a splendid crop of very large flowers for many months. I have never since seen such a fine plant, and it must have been several years old in 1869.—J., *County Kerry*.

**Destroying wasps.**—In a recent number of THE GARDEN I noticed an article on wasps and a cure for their sting. Do other readers know of the use of garden mould for the latter purpose? I have found it infallible, rapid and it is certainly cheap. If you moisten a little mould, put it on the wound, and tie a handkerchief over it, all pain will have ceased in from twenty to thirty minutes. One summer I was stung three times at short intervals, once on the arm (wasp up my sleeve), once in the neck (wasp down back of collar) and the third time at a garden party on the lip (biting a cake with a wasp on it). In each case the cure was perfect. By "garden mould" I mean common garden earth.—Colonel R. DE VILLAMIL.

**Irises in flower at Godalming.** There are in flower here to-day (March 23) two plants of the somewhat uncommon *Iris fosteriana*, a Juno Iris remarkable for its colouring. The falls are of a rich shade of yellow, while the drooping standards are of a deep purple, the two colours forming a strange contrast. Another Juno Iris, a recent importation from Central Asia, is flowering here for the first time. In form and growth it resembles a small *I. rosenbachiana*, but the colouring is quite distinct, the prevailing tone being a pale primrose. A ridge of a deeper yellow runs down the falls, flanked at first by four, and lower down by six, lines of a brownish purple, which spread into a patch of this colour on the blade of the falls. Perhaps the most striking of all the early Junos is a hybrid of *sindjarensis* × *persica*. This plant has produced four large flowers of a wonderful combination of turquoise and purplish blue, set off by a bright orange ridge on the blade of the fall. It was raised by Mr. C. G. van Tubergen of Haarlem, and deserves to be more generally known.—W. RICKATSON DYKES, *Charterhouse, Godalming*.

**Saxifraga longifolia.**—It is not absolutely correct to say (see page 142) that this plant "never produces offsets"; but it is true in the main, and particularly so if the remark be directed to the narrowest-leaved varieties so frequently regarded as typical of the great Pyrenean Rockfoil. The more linear-leaved forms rarely, if ever, produce an offset; but the broader-leaved forms, in which the rosettes are of a more blunt character, do sometimes reproduce their kind in this way. In the wild state, however, the species varies considerably as the obvious outcome of seeding for generations. At the present time I have one or two offsets of a distinct form of *S. longifolia*, and these, growing alongside some seedlings of a good form of the type, are making far better progress than the latter. When the rosettes flower there is not much trouble to get seeds, and, as pointed out by Mr. Smith, the seedlings, if well cared for, soon make fine plants.—E. H. JENKINS.

## NEW PLANTS.

### CYPRIPEDIUM BERKLEYANUM.

This plant is the result of a cross between *C. Boxalli* and *C. bellatulum*. Two flowers were borne on a rather short erect stem, the latter being covered with fine hairs. The dorsal sepal is of medium size, curved forward, the white ground being densely spotted with dull crimson dots except at the edges, which are white. The petals and labellum are of a dull magenta crimson. The leaves are broad and slightly mottled with dark green on a light green ground colour. Shown by Mr. J. Forster Alcock, Northchurch. Award of merit.

### PHAIUS CLIVE.

This is a very handsome member of this comparatively little-known family. The plant exhibited had one very erect stout-stemmed raceme composed of ten fully-opened flowers and fine buds. The sepals and petals are ovate lanceolate in shape, the colour being a mixture of deep lilac, cream and gold. The labellum is the most conspicuous part, this being large, well opened and of a deep brownish crimson at the base, the top portion being a mixture of white, cream and purple. A yellow and orange bar runs down the centre, thus giving the flower a most striking appearance. Shown by Norman C. Cookson, Esq., Oakwood, Wylam (gardener, Mr. H. J. Chapman). First-class certificate.

### ODONTOGLOSSUM CRISPUM SEEDLING.

This very unique seedling of a well-known Orchid was raised by Messrs. W. Bull and Sons, King's Road, Chelsea, and was exhibited by them. As a result of crossing two plants of *O. crispum* this is most interesting on account of the colour. The plant was a very small one and only had one flower, the seed from which it was raised not being sown until March, 1905. The white ground of the flower is very heavily marked with large brownish crimson blotches, with traces of purple surrounding them, the labellum having a bright yellow blotch on the centre.

### CATLEYA SCHRODERÆ QUEEN ALEXANDRA.

This is a lovely variety and will prove a valuable addition to this already large family. The large flowers are of a beautiful pale lilac hue except the large labellum, which has a bright purple ring about halfway down, this being followed by a broad band of rich golden yellow in the throat. Shown by Messrs. Sander and Son, St. Albans. Award of merit.

### CATLEYA SUZANNE HYE DE CROM, JUNGFAU VARIETY.

A very fine variety indeed of a new Orchid. The flowers are larger than those of the type and of a uniform pure white with the exception of rich yellow in the throat of the beautifully fringed labellum. Shown by M. Jules Hye de Crom, Ghent. First-class certificate.

### CYPRIPEDIUM HELEN II. WESTONBIRT VARIETY.

Here we have a very beautiful variety of the Lady's Slipper Orchid. The dorsal sepal is large, the yellow ground colour being fairly thickly sprinkled with good-sized dull crimson blotches, except at the edge, which is white. The petals are dull brownish purple, with small dull crimson dots placed rather thickly thereon. The pouch or lip is of medium size, stands well forward and is of a pale brownish hue. Shown by Major Holford, C.V.O., C.I.E. First-class certificate.

### BRASSO-CATLEYA SCHRODERÆ DIGBYANA SUPERBA.

This is one of the heavily-fringed forms of this bi-generic family. The sepals are lanceolate, recurved and pure white. The petals, too, are of the purest white, but much broader than the sepals. The labellum, which is very heavily fimbriated, is large, well opened and pure white, except for a rich deep yellow marking in the

throat. Shown by Messrs. Charlesworth and Co., Heaton, Bradford. First-class certificate.

### RHODODENDRON PURITY.

This is probably one of the most shapely-flowered varieties of the hybrid set so frequently referred to as Himalayan. The flowers are large, very pure white, campanulately inclined, and produced with a good deal of freedom on quite dwarf and fairly compact-growing plants. Exhibited by Mr. Charles Turner, Slough. Award of merit.

### IRIS SIND-PERS AMETHYST.

A very beautiful and showy Hybrid Iris, having *I. sindjarensis* and *I. persica purpurea* as its parents, the new comer partaking very largely of the species first named. The chief colour tone is violet-blue, deepest in the centre of the flower, while the blade of the fall is whitened with the exception of the margin, which is deep blue. Raised and exhibited by M. C. G. Tubergen, Haarlem, Holland. Award of merit.

All the above were exhibited at the Royal Horticultural Society's meeting on the 31st ult.

## THE ALPINE HOUSE AT KEW.

**D**URING the spring months there is not a more interesting spot in the whole of the famous gardens at Kew than the little alpine house that is situated at the northern end of the herbaceous ground, a position that is overlooked by the majority of visitors. Within this little house are flowered the choicest of the alpine or rock plants that are grown at Kew, the idea being to simply provide a protection from boisterous winds and heavy rains, perfectly cool treatment and an abundance of fresh air being demanded by these plants.

Perhaps the most interesting specimens now flowering in this house are some fine plants of *Heloniopsis japonica*, a new and rare hardy plant from Japan. The rose-purple flowers are borne in rather dense globular clusters on stout erect stems about 6 inches long. Each flower measures about three quarters of an inch in diameter, the perianth segments being narrow and lance-shaped and placed in the form of a star. Added to these we have long stamens regularly arranged, with a long pistil surmounting the whole, thus giving the flowers and the inflorescence the appearance of miniature *Nerines*. The leaves are lanceolate, about 4 inches long, and are produced in very dense clusters.

*Shortia uniflora* will be better known, and here it is doing well, the dainty pale pink frilled flowers being held well above the handsomely-tinted foliage. The variety *grandiflora* has rather larger flowers of a deep shell pink colour and very beautiful foliage, but the flower-stems are too short for it to be of much service. The old *Primula marginata*, with its handsome pale lilac flowers and serrated leaves, appeared quite at home, the flowers in the different plants showing considerable variation in shape.

Tulips naturally find a place here, and we specially noticed some grand specimens of the handsome *Tulipa kaufmanniana*, eight bulbs being grown in a 7-inch pan. This varies somewhat in colour, some of the outer segments having the characteristic rosy red marking down the outside and others being quite a uniform deep cream colour. The general colour of the flowers is deep cream, with a deep yellow zone in the centre, and when they are fully open one can realise what a gem this plant is. A variety named *aurea* that we saw in the open border is even more handsome, the colour being rich yellow with a deeper yellow zone in the centre, and the red markings on the outsides of the outer segments. A few red spots are also placed inside the petals, just above the deep yellow zone. *Tulipa pulchella* is a dainty little species from Cilicia, and is worthy of a place in the best Tulip

collections. The flowers are rather small and flimsy, the colour being deep bright rose-pink, with slaty blue blotches forming a zone at the base inside the cup. The erect foliage is rather narrow and grooved. *Tulipa præstans* is a branching species, *i.e.*, several flowers are produced on one stem. These are most gorgeous creations, the colour being a vivid orange scarlet. A curious feature about this Tulip is that the broad leaves are thickly covered with fine minute hairs on their inner surfaces.

Among the Saxifrages none is more imposing than the handsome *S. Grisebachii*, a native of Macedonia and a member of the encrusted section. The leaves form neat rosettes, and from the centre of each spring a unique and handsome inflorescence. The small rosy red flowers form a rather dense tuft at the top of an erect stem. This stem, too, is of a reddish colour, and situated upon it in a regular manner are good-sized leaves of a uniform reddish colour except at the tips, which are deep green, thus adding to the charms of this beautiful Rockfoil. The plants at Kew are growing in pans between pieces of sandstone and look quite at home. *Saxifraga apiculata* Alberti is a fine variety of this well-known species, the flowers being much larger and brighter in colour than those of the type. *S. Scardica*, a native of Macedonia, was producing its good-sized pure white flowers in profusion, the dense tufts of foliage providing a pleasing foil of green. Some small plants of *S. Boydii* were also flowering well.

## A BEAUTIFUL HEATH.

(ERICA CARNEA.)

It is to be regretted that the hardy Heaths (*Ericas*) are so little seen in our gardens, flourishing as they do in any ordinary sweet soil, for the

## THE ROSE GARDEN.

### VARIETY WANTED IN FORCING ROSES.

AT the Chicago Florists' Club in December last the subject was discussed relative to the need of greater variety in our forcing Roses. Perhaps this matter affects our American neighbours more than it does us, seeing that they depend so largely for the enjoyment of the Rose from specimens grown under glass. But the thought must have occurred to all who handle large quantities of forced Roses that there is room for a greater variety. It seems almost absurd to suggest it when we remember our multifarious collection, which has attained to almost a prodigious size. But so few have the desired qualities of a forcing Rose, which is, briefly, self colour, full and deep flowers, perfect shape, brilliance and clearness of colour, long stems, erect growing, good lasting properties, sturdy growth and fragrance. This latter quality I must admit is almost ignored by the florist.

We could do with a real good white. I know some will say at once that we have Frau Karl Druschki. Of course we have, and a good Rose it is; but it does not come up to my ideal of a white forcing Rose. We want a snowy white Catherine Mermet, with all its sublime shape, finish and fulness. The greenish whiteness of The Bride is against the advance of this Rose. Kaiserin Augusta Victoria also has a yellowish tinge, so also has White Maman Cochet, and a weak stem also. L'Innocence is not at all bad, but its petals are terribly impatient of damp.

Have we a good red? I say no; not the ideal red. Liberty and Richmond are good, and until

no. Perle des Jardins and Mme. Hoste are extensively cultivated under glass; but they are not the ideal yellow, although it is doubtful whether we shall ever improve on them. In Lena we have a glorious colour, but a very thin flower. Harry Kirk may possibly prove a good thing, so also may Mme. Paul Varin Bernier, although this latter is rather undersized. I imagine Mrs. Aaron Ward will be a gain to this section, and perhaps the Lyon Rose will be an acquisition to the salmon yellows. I rather fancy the best improvements we are likely to obtain in the yellows and orange shades will come either through the Hybrid Teas or that advancing group *Rosa pernettiana*.

Shall we ever improve upon Bridesmaid for a pink? It seems to me very doubtful. Great things are expected of Mrs. Jardine, an Irish Rose that has found its way first to the United States; but it will have to be a good Rose to surpass Bridesmaid. As a salmon pink Mme. Abel Chatenay will probably never be beaten for late spring flowering; but I am told the new Joseph Lowe is a very prolific bloomer in winter, and it has a great resemblance to Mme. A. Chatenay, although a sport from Mrs. W. J. Grant. P.

### THE ROSE ANALYSIS.

(Continued from page 162.)

MR. MAWLEY's comments on this table are as follows:

"It is interesting to try and gauge from time to time by these tables the advances that the Rose is making in one direction or another. In other words, the trend of public opinion, at all events from an exhibitor's point of view. For instance, taking the table of Hybrid Perpetuals and Hybrid Teas, one cannot but notice from year to year the unchecked advance of the Hybrid

THE WINTER HEATH (*ERICA CARNEA*) IN MESSRS. BAKERS' WOLVERHAMPTON NURSERIES.

general idea that they must be planted in peaty soil is quite erroneous. One of the prettiest is *E. carnea* (the Winter Heath), and the accompanying photograph shows a lovely patch of it growing on the rockery at Messrs. Baker's nurseries at Codsall, Wolverhampton. Its beautiful rose-pink flowers are most acceptable and pleasing to the eye, as it comes into bloom while all other early spring flowers are still practically dormant. It first commences to show a little colour during the dull days of January, and by the end of February and throughout March it is a perfect blaze of colour. The variety *E. carnea alba* is also well worth growing. G. W. K.

we get something better they will be largely grown; but already there are murmurings against Richmond, owing to a weakness or flaw in its flower-stalk, which hinders it lasting any length of time when cut. Is the new Rhea Reid likely to replace either of these? It comes from the raiser of Richmond, and he says its blooms are as large as American Beauty (from which it is a seedling crossed with a seedling Hybrid Tea), as double as Bridesmaid, as sweet as La France, as red as Richmond in winter, and resists mildew. Should all this prove true, then Rhea Reid is the red forcing Rose we are looking for. Have we a good yellow? Again I must say

Tea, together with the gradual decline of the Hybrid Perpetual. This year there are no fewer than thirty-two Hybrid Teas on the list, last year there were twenty-six and five years ago only fourteen. And yet at present we cannot afford to dispense with the Hybrid Perpetuals altogether, or our gardens would lose much of their beauty. On the side of the Hybrid Tea we have a daily increasing army of large continuous flowering and mostly pink Roses with, as a rule, little fragrance. On the other side we see a diminishing array of so-called Perpetuals which flower bravely enough during the summer, but only moderately during the rest of the season. They are somewhat

smaller in size, and generally some shade of crimson in colour, and in many cases have a most delicious perfume. Our hybridists having so successfully obtained increased size and freedom of flowering in the Hybrid Teas are, no doubt, now turning their attention to the further improvements most needed in that section, namely, more crimsons and some good yellows of lasting colour, like *Maréchal Niel*, and, above all things, greater perfume.

"At the last exhibition few varieties were exceptionally well represented, in fact, only Captain Hayward and Gladys Harkness have never before, and Mrs. W. J. Grant and Marquise Litta have only once before, been as frequently staged. Whereas K. A. Victoria, Her Majesty, H. Vernet, Ulster, M. Baumann, C. Lefebvre, Fisher Holmes, Tom Wood, Earl of Dufferin, Victor Hugo, Beauty of Waltham, Xavier Olibo, Duke of Teck and Louis Van Houtte, all but one, be it noticed, Hybrid Perpetuals, have never before been as sparingly exhibited.

"Turning now to the newer Roses, by which is here meant those varieties on the list which are five or fewer years old. Of those sent out in 1902 Alice Lindsell, No. 13 (creamy white with pink centre), and Florence Pemberton, at No. 16 (creamy white, shaded pink), virtually retain their former positions, while Aimée Cochet, No. 67 (flesh pink), which did not appear in the last analysis, secures a place at the bottom of the present one. Of the two 1903 varieties, both of which are new to the analysis, Gustave Grunerwald (carmine pink) on its first appearance takes up a very creditable position at No. 30, while Mrs. T. Roosevelt (light pink) will be found at No. 50. I have not grown Mrs. T. Roosevelt, but can strongly recommend Gustave Grunerwald for general garden cultivation on account of its distinct shade of pink and its good and dainty habit of growth. To 1904 we are indebted for three fine acquisitions, both for exhibition and garden purposes, viz., Dean Hole, Hugh Dickson and Lady Ashtown. Little need be said of Dean Hole (pale carmine, shaded salmon) considering that, although only three years old, it has already risen to the third place on the table, and is a far better garden Rose than either of the varieties which occupy the leading places above it. Hugh Dickson (bright crimson) may be said to have leapt into favour, having at one bound risen from No. 61 to No. 8. Lady Ashtown (deep pink), one of the best all-round Roses of recent introduction, has risen from No. 20 to No. 15. Mrs. David McKee (creamy yellow), on the other hand, has since last year fallen from No. 45 to No. 50. Dr. J. Campbell Hall, No. 63 (coral rose), has also lost a few places, but is, nevertheless, a very pretty garden Rose. We now come to five varieties which were sent out in 1905. J. B. Clark (crimson, shaded plum), the sensational flower of the National Rose Society's exhibition in 1905, has risen from No. 32 to No. 21. Countess of Derby (flesh peach), which is new to the table, takes up a position at No. 42. The deep-petalled Betty (coppery rose, shaded yellow), also new to the list, will be found at No. 56. Richmond (bright crimson), likewise new to the analysis, secures a place at No. 63. The remaining variety, C. J. Grahame, No. 63 (bright crimson), has not improved on its previous position of last year. The only Rose distributed in 1906 which was shown a sufficient number of times at the last exhibition to obtain a place in the table is William Shean (pink), which secures a place at No. 56.

Greatly to the honour of our British raisers be it said that as many as twelve of the above sixteen new Roses were raised in the north of Ireland, and ten of them by a single firm. As regards the other four Roses, we are indebted for two of them to America, for one of them to France, and for the remaining variety to Germany. Of the sixteen Roses all but one are Hybrid Teas, while nine, or more than half, are some shade of pink."

H. E. MOLYNEUX.

## THE ROCK GARDEN.

### SAXIFRAGA BOYDII ALBA.

**N**EXT to the true major forms of *Saxifraga burseriana* the above-named plant is certainly, when well grown, the finest of the early white-flowered *Saxifragas*. How well this plant may be grown and flowered, and how pronounced its fine encrusted character is when seen under the best treatment, were abundantly

BOYD'S WHITE-FLOWERED ROCKFOIL (*SAXIFRAGA BOYDII ALBA*). (About two-thirds natural size.)

demonstrated by the splendid examples seen at the Royal Horticultural Hall recently when Mr. E. A. Hambro of Hayes Park, Kent, exhibited the plant so finely. The plant in question was the best we have ever seen, and was simply covered with its handsome opaque pure white blossoms, and the effect of these latter above the spreading leaf-tuft was very fine. We regard this plant as a hybrid between *S. coriophylla* and *S. burseriana*, and it is not, as might reasonably be assumed from its name, merely a white-flowered form of the well-known, if rare, *S. boydii*. Grown in very sandy loam with crushed sandstone, and pieces of the same interspersed with the soil, the plant was perfectly happy, and reflected the highest credit on the intelligent care and cultivation bestowed upon it by Mr. Grandfield, the gardener. The illustration depicts but a portion of what we believe to be the finest example of its kind seen at any London exhibition, a large pan of 8 inches across being studded with the purest of white blossoms an inch or so removed from the grey leaf-tuft.

E. JENKINS.

### ERINUS ALPINUS ON A WALL.

THE lovely little *Erinus alpinus* is nowhere so beautiful as on a wall, and a long stretch almost covered with its purplish flowers is charming in the extreme, whether the wall be an old red sandstone one, one of whin or limestone or old discoloured bricks. Even when out of flower the green cushions formed by the leaves are great ornaments to a garden or other wall. I know of one long stretch of wall some 12 feet or 14 feet high, screening from the sea breezes an old Scottish garden, and on the outside of this, fully exposed to the sea winds, and with the spray borne by the wind being carried against it occasionally, this little *Erinus* flourishes, and there must be thousands of plants in this wall.

The *Erinus* should be established from seeds sown in the crevices with a mere modicum of soil over them. If the wall is kept fairly moist for a time they will soon germinate, and the most crucial stage will be over. An old wall with crumbling mortar offers the best medium for the *Erinus*, and in a few years the vacant crevices will be filled with young self-sown plants. On a wall either *E. alpinus* or *E. hirsutus* is better than the white variety of *alpinus*, which is not so effective, although very beautiful also. There are many gardens in wet districts where the *Erinus* will not thrive on the level, but dies out

in winter, and there the system of wall cultivation will prove a boon.

S. ARNOTT.

## COLOURED PLATE.

PLATE 1845.

### ROSE HUGO ROLLER.

**T**HE Rose of which we give a coloured plate cannot fail to become a general favourite, for in the exquisite combination of colour we have a blending that is almost unique, even in the very extensive collection of Roses now in cultivation. In the garden it is one of the first to catch the eye, and the brighter the sun the more vivid is the crimson tint brought out. It would seem to be a real hybrid between a Tea Rose and a Hybrid Tea, as the erect stems give evidence of the Hybrid Tea character, while in refinement of bloom and in delicacy of colouring the Tea Rose predominates. The blooms, which are produced sometimes in small clusters and sometimes singly, are borne erect, a quality that will commend it to all who appreciate this excellent trait in a Rose. Exhibitors will find this variety a useful addition to the most select box of Teas, for the blooms will come quite a good size with the aid of free disbudding, both of the buds and side shoots, and, although the crimson colour is intense, it will be more helpful to a box of Teas than the self-coloured crimsons, which many think tend to mar the more delicate-coloured Teas which always predominate.

Hugo Roller received an unanimous award of merit when exhibited before the Royal Horticultural Society last summer. It was raised by Messrs. William Paul and Son, Waltham Cross, to whom we are indebted for the blooms from which our coloured plate was prepared.

## THE FLOWER GARDEN.

### RAISING HEPATICAS FROM SEED.

**H**EPATICAS, the varieties of Anemone Hepatica or Hepatica triloba, the old name of the plant, are such beautiful spring flowers that an extended appreciation of their worth is devoutly to be desired.

In order that this may be realised, it is highly necessary that only such varieties as are most easily cultivated should be encouraged, as there are but few who can succeed with some of the weaker and more delicate sorts, beautiful though these are. Thus the double blue Hepatica, which is such a charming flower, is successful in only a few gardens, and the double white, enfeebled possibly by over-propagation, bids fair to rival it in delicacy under common conditions in the garden. It is, therefore, most desirable that the raising of Hepaticas from seeds should be encouraged, so that free-growing, vigorous varieties may be secured; while by this means there is every probability that seedlings will appear

been collected they may remain on the paper, well spread out, for some days until they are apparently hard on the exterior, when they should be sown without further delay, so as to secure seedlings the following spring.

Although sowing may be done in the open ground in small drills and covered with about a quarter of an inch of fine soil, there is considerable loss in doing this, as the seedlings will be liable to injury from the changes of weather, and many may be thus destroyed when in a miniature stage. It is much safer to sow the seeds in boxes or pans, and much care is necessary to prevent the soil from becoming dry on the surface and to keep the seeds in a uniform condition of moisture. The soil ought to be of a sandy character, with some leaf-soil and sand added to good loam. It must not be too light and open, however, or the little roots of the seedlings will be liable to dry up, especially if the method recommended in the following paragraph is not followed. This is simple, and consists in sowing the seeds round and just beneath the edges of pieces of slate pressed slightly into the soil. I have raised many Hepaticas in this

the seeds are fresh, but if kept until the spring after ripening they will be longer germinating. Although some trouble and patience are required, the results are excellent and well reward one for the trouble taken.

### THE WOOD CRANE'S-BILL.

(GERANIUM SYLVATICUM.)

WE hear but little at the present time of the value of the Wood Crane's-bill (*Geranium sylvaticum*) and its varieties as border or wild garden flowers, although many plants of lesser worth than these are sought after and prized. Like others of the extensive genus to which it belongs, this Crane's-bill is one which has not only much true beauty, but is also a plant which is so accommodating in its ways that it may be cultivated in places where few other flowers would grow. It is a rare native of woods and thickets in the north of Great Britain, as well as of various parts of Europe, Siberia and West Asia, so that its natural preference for shelter from sun points it out as a valuable plant for growing under trees and in shade, although it can be successfully cultivated in full sunshine. It comes into bloom in June and lasts for a considerable time in beauty, frequently continuing through both June and July, and forming a handsome plant some 2 feet or a little more in height, having erect stems and leaves with from five to seven lobes, each lobe deeply toothed.

While the colour of the typical form of *Geranium sylvaticum* is purple or blue, it is rather variable, and this tendency has given rise to some beautiful and welcome varieties, of which that shown in the illustration, *G. sylvaticum album*, is one of the most desirable. In this variety the pure white flowers are produced as freely as those of the purple or blue varieties, and the appearance of a good plant in the border, the wild garden, or the large rock garden is acceptable to all in its season. A very pretty rose-coloured variety, *G. s. roseum*, is also in cultivation, and one of the most pleasing of all is one of a silvery blue. The cultivation of the Wood Crane's-bill is simple in the extreme, as, although preferring a free and rather open soil, it will grow in any ranging from a poor and sandy one to a stiff loam approaching to clay. It is readily increased by division in spring or immediately after flowering, and plants of the type can be raised from seeds sown either when ripe, or in spring in little drills in the open, or in pots or boxes under glass. Seeds germinate readily, and, if the young plants are given proper treatment in the way of timely pricking out, they will bloom the year after.

*Sunnymead, Dumfries.*

S. ARNOTT.

THE WHITE-FLOWERED WOOD CRANE'S-BILL (*GERANIUM SYLVATICUM ALBUM*).

which will yield blooms of different shades of colour from the parent plants. The process is a little tedious, but the results will amply compensate for the time and trouble necessitated.

The raising of Hepaticas from seeds has long been practised, but, as a rule, only upon a very limited scale, partly owing, no doubt, to the fact that seeds of these lovely flowers are seldom, if ever, offered by the seedsman. It is thus necessary to save seeds from one's own plants, and in this case it is desirable to have a small collection of the different colours in one's own garden, so as to endeavour to cross-fertilise the plants, although this is not absolutely necessary, as there is some variation in a natural way. This cross-fertilisation may be effected with a small camel's-hair pencil, transferring the pollen from one flower to another. When the seeds begin to ripen, which is when they will part readily from the stalk, the plants must be gone over daily, removing the seeds which can be detached without pulling them off, and placing these on a piece of paper in a dry, but not too warm, room until the whole are collected. If the plants are not visited daily at this time, many of the seeds will fall to the ground and be lost. When all have

way, and have first pressed the pieces of slate slightly down into the soil, so as to leave a mark. Round the edges of this, and about a quarter to an eighth of an inch from the margin, the seeds were sown very thinly and just covered with fine earth, the pieces of slate being then pressed down upon them rather firmly. The seedlings will appear the spring after sowing, as a rule, but some will not germinate until the following year. It is as well to allow them to remain in the boxes for a year after they appear, standing them outside in a shady position during summer and until late autumn, when they must be again put into a cold frame or a cold greenhouse, giving them a little top-dressing at the same time. The following March they can be planted out about 6 inches apart if in a place where they are to bloom, but about 3 inches apart if they are afterwards to be removed again. They will require little after-care, except an occasional top-dressing to keep the crowns about the level of the soil.

From seeds of a varied collection many charmingly-coloured seedlings will result, including various shades of blue, rose, pink, red and purple. Seedlings will bloom at intervals, but the general time is the third and fourth year after sowing if

MANY years ago Verbenas were grown largely for bedding and pots, and well-filled beds of the old Purple King, Lord Raglan, Lady Cowley, &c. were much admired. These varieties were raised chiefly from cuttings of young tender tips about 2 inches in length inserted in 6-inch pots or pans and filled with a sandy compost and placed in frames kept very close, such as that of an old Cucumber frame, and in this way, along with many other useful plants to be grown for bedding, were rooted quickly in spring in heat from the tips of the autumn cuttings; but many of these old varieties seem to have gone out of cultivation and the stock raised nowadays is more from seed. We have excellent varieties as to colour, &c., which are kept separate, and if sown in February or March and forwarded in a slight warmth make capital plants for putting out at the end of May. Given a good soil these seedlings grow strongly and probably resist mildew better than some raised from cuttings. Be that as it may, the plants make a very useful show during the summer months, and from a few packets of seed of different suitable colours a good batch of plants may be raised without much trouble.

H. MARKHAM.

## WATER AND BOG GARDENS.

APART from the interest and pleasure derived from the cultivation of moisture-loving plants, there is a distinct charm associated with these subjects when carefully employed in the embellishment of a water garden; nor is this all, for without water in some form or other it is impossible to do adequate justice to the many beautiful forms of plant life which by nature are aquatics. To name but one group we have the Water Lilies old and new. The formation of ponds is a simple enough matter, and with a little management they can be introduced into small gardens. There is, of course, the question of space, which frequently hampers operations at the beginning, and probably some slight misapprehension regarding the initial cost; yet if one considers the relative freedom wherewith these plants flourish under the conditions indicated and the modicum of labour and material required for their future

well-being, it becomes obvious that all subsequent outlay is reduced to the lowest possible limit.

It need scarcely be remarked that where the conditions favour natural treatment such should invariably be followed, as not only is it pleasing in itself, but it accords with Nature's method of informal grouping, while it also admits of greater variety being employed, even where the ground treated is of moderate dimensions. Where the position does not lend itself to such treatment, no other style of water garden can excel the formal tank. In shape this should be fairly rectangular, this being the easiest and cheapest to construct.

The salient features of the sketch may be briefly summarised as follows: 1. The outline of tank and bottom are uniform in construction, being made of cement concrete. 2. All projected parts are 6 inches below water level, and may either be constructed of concrete or brickwork built in cement; these are beds formed to retain the soil, the means for supplying water being shown in section. 3. Grass or stone pavement covers concealing the outside margin of the tank. 4. The bottom is concave, giving at least 3 feet of water in the centre. The four prominent circles indicate the positions of the four colour forms of *Nymphaea Marliacea*—*alba*, *carnea*, *rosea* and *chromatella*.

I offer below suggestions for suitable plants for the various beds, employing those which are distinct in leaf or refined in flower, and which furnish a succession of delightful interest during summer and autumn. 1, *Iris Kempferi*, duplex white; 2, *Ligularia macrophylla*; 3, *Iris gigantea*; 4, *Senecio Wilsoni*; S 5,

*Sagittaria japonica plena*; 6, *Lobelia Queen Victoria*, *Aster Hon. E. Gibbs* and *Primula sikimensis*; 7, *Astilbe chinensis*; 8, *Solidago nemoralis*, *Phlox Coquelicot* and *Caltha palustris plena*; S 9, *Pontederia cordata*; 10, *Rodgersia pinnata* or *podophylla*; 1a, *Primula rosea*; 3a, *Primula Sieboldi* (*cortusoides*); S X, *Hottonia palustris*; (S) Y, *Aponogeton distachyon*; S Z, *Herpestis reflexa*. All the plants named must be planted above water level, except those marked "S," which are aquatics. *Nymphaeas* for eight positions, marked by small dots: *Atropurpurea*, deep wine-coloured flowers; *clisiana*, red to crimson; *gladstoniana*, cream white; *Laydeckeri* lilacina, rose lilac; *L. rosea*, light to deep rose; *odorata*

PLAN OF A WATER GARDEN (SCALE 16 FEET TO 1 INCH).

*exquisita*, soft rose, deeper centre; o. *sulphurea grandiflora*, sulphur yellow.

There is such a wealth of moisture-loving plants that I have made this selection with diffidence. When one remembers the White Willow Herb, the great Water Buttercup, the Globe Flowers and Swamp Lilies, to mention but a few of the subjects which revel in swampy ground and in no way inferior to those favoured, one is inevitably forced to make a choice even where none are indifferent, and nearly all are worthy of admiration. After all a very great deal depends upon individual taste, but, as mentioned above, the material to select from is so extensive that there is no difficulty in obtaining what one most desires.

THOMAS SMITH.

Walmsgate Gardens, Louth, Lincs.

A SMALL WATER AND ROCK GARDEN.

## THE KITCHEN GARDEN.

## PEA GRADUS GROWN UNDER GLASS.

RECENTLY I saw some very fine plants of the above Pea grown in boxes and pots, and they were remarkable for their sturdy growth and fine leafage. *Gradus* may be termed a dwarf marrowfat of the early type, and it is even earlier than some of the green round early Peas, which are often of inferior flavour. It was sent out some years ago by Messrs. Laxton of Bedford, and each year it has proved of great service on account of its earliness. It is a 3-feet high variety, and even when grown in pots or boxes it does not exceed that height. Last season I saw a large quantity of this variety sown in frames for late supplies, and

grown thus it gave a splendid crop. It was quite free from mildew, and the pods set freely and filled well, there being no gaps. It has other claims on those who like a late supply, as when sown last July it gave splendid dishes in October, and the crop was equal to a July one.

## EARLY CAULIFLOWERS UNDER CLOCHES.

WHEN visiting Gunnersbury House Gardens a week or two ago I was much interested in the vegetable department, and specially noted a splendid lot of early Cauliflowers. The plants were remarkable for their size and fine leafage, considering the season, and will give very early heads, being all grown under cloches, or bell-glasses as they are known in this country. It is somewhat uncommon to see such a good array of these glasses in this country, but it shows at a glance what splendid assistance they are. Mr. Hudson informed me that they are by no means costly

and they are so much lighter than our hand-glasses; at the same time they are not only useful for the purpose named but for so many others. Some are used for early Lettuces, and for this they are excellent, as several plants can be grown under one cloche. These retain the sun-heat so well that the growth is most rapid. It is scarcely necessary to add that on the Continent the cloche is very common, and at this season of the year immense numbers are used for early vegetables. I am sure the amateur would find them of great value to raise early plants and protect others, and also for rooting cuttings of shrubs and other hardy plants.

G. W.

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**H**ARDY FLOWER GARDEN.—I am planting Pansies and Violas just now. The ground has been well dug and heavily manured, and the surface soil is also friable and in capital working order owing to a forking over of the quarters a few days ago. For ordinary garden embellishment I allow a space of from 6 inches to 9 inches between the plants, giving the greater space to the stronger-growing varieties. Although late, the planting of perennials may be done still. For a sunless border many of my friends are often in doubt as to what to plant. I find that Lilies of the Valley, Solomon's Seal, the Japanese Wind-flower (*Anemone japonica*), Foxgloves, Primroses and Polyanthus, *Solidago canadensis*, London Pride and the Periwinkle, besides many kindred subjects, do well in this position. Old plants of the early-flowering outdoor Chrysanthemums may be lifted and divided at this time; each year I make a division of the plants in early April with considerable success. Seeds of the Sunflower may be sown where they are to flower. When the seedlings are through the soil protect from slugs.

**Cold Frame.**—This valuable adjunct of the garden is becoming more in demand each day as the spring advances. For hardening off the more tender subjects raised in heat, either from seeds or cuttings, the cold frame is indispensable. I use it for boxes, pans and pots containing seedling Snapdragons, *Mimulus*, *Lobelia* and numerous other things raised in heat, where, by gradually inuring them to hardier conditions, the young plants become fitted to be transferred in a week or two to their flowering quarters outdoors. It is absolute folly to take plants from the greenhouse and plant them outdoors; they must be hardened off preparatory to planting them in the beds and borders. Still continue to cover the frame-lights at night, as late frosts are sure to visit us when we least expect them.

**Roses.**—All kinds of Roses may be pruned now. I pruned my Hybrid Perpetual Roses at the end of March, the Hybrid Teas during the first week of April and now I am finishing the pruning by dealing with the Tea-scented Roses. I hope to complete this work before the 20th inst. Roses in pots are doing well in the greenhouse; the buds are opening kindly and are free from

1.—OLD PLANT OF IVY-LEAVED GERANIUM.

green fly. Weak doses of liquid manure I find help the buds at this time very considerably. Standard Roses planted last autumn and during the present early spring have each been staked; this is a matter that must not be delayed if it has not already received attention. Briars that I intend to bud later on are now receiving attention. I rub out all except about three of the most promising eyes at a point nearest to the height I wish the future head to be.

**The Vegetable Garden.**—Mushroom beds for summer supplies may be made up now outdoors. The material for this purpose should be used in sufficient quantity to ensure a steady warmth till the spawn has thoroughly penetrated through the whole heap. These outside beds should be covered with tarpaulins or anything of a similar nature, or straw-thatched hurdles. Either of these protective agencies will throw off heavy rains, which is an important factor in successful culture. I am still making new beds of herbs, both by cuttings and by seeds. Main-crop Potatoes should be planted without delay; it is a good plan to get the planting done before the warm weather comes along. Early Peas I am now earthing up, at the same time inserting sticks for their support. Main-crop Peas I am sowing at the present time, as they will be wanted to succeed earlier sorts in July next. Spinach may be sown between other subjects as a catch crop just now.

**The Greenhouse.**—Pelargoniums of the show, fancy and regal types are coming into flower already, promising to make a bright display in the near future. These plants should not be coddled, but should receive abundant ventilation, otherwise they will speedily be infested with green fly. The Zonal and Ivy-leaved types are also doing well, some of the more forward plants already developing stout and sturdy flower-spikes. Keep the plants rather dry at the roots, and when water is given, follow the same with a weak application of manure water. Auriculas coming into flower should be placed in a cold

greenhouse and shaded from the sun. A greenhouse with an east or northern aspect appears to suit them very well.

**Trees and Shrubs.**—I am busy planting trees and shrubs that have been unavoidably delayed. It is not too late, if care be observed in the planting, to do this thoroughly. The Ivy is a much-neglected subject in many gardens, and it is difficult to account for this seeming want of interest. I am still planting a few of the better and more interesting sorts. Evergreen shrubs that have made free growth may now be pruned. In this connexion we include the Laurels, Aucubas and kindred subjects. The growths must not be cut back with the shears, but individual shoots trimmed back with the pruning knife.

D. B. C.

### IVY-LEAVED PELARGONIUMS AND THEIR PROPAGATION.

THESE plants are more popularly known as Ivy-leaved Geraniums, and as such we will refer to them in these notes. Old plants, of course, vary in their character, so much so in fact that it is almost impossible to illustrate what may be described as a typical plant. It is largely a question of age.

**Cutting Back Old Plants.**—The plant in Fig. 1 represents one that was struck last year and that is now making two or three vigorous growths, which for many purposes would soon become somewhat tall and spare in their character. With a specimen of this kind it is possible to achieve much. A beginner would possibly

3.—ONE OF THE GROWTHS SUITABLE FOR MAKING INTO A CUTTING.

hesitate to cut back the plant at all, fearing to irretrievably damage the prospect of the ensuing season's display. Old plants of the Ivy-leaved Geraniums should not be cut back so hard as is the case with the Zonal Geraniums, which were dealt with some few weeks back. The plants now under notice are longer jointed than the Zonal types, and the joints are altogether different in their character, as a comparison will reveal. These are reasons, apart from other considerations, why the plants are not cut back so hard. Fig. 2 illustrates how the cutting back should be done. It will be observed that the growths have been removed at a point in the stem about three-quarters of an inch above a joint; when these ends heal up they will be so shrivelled that no unsightly appendix will be noticeable. Growth will soon evolve in the axils of the leaves immediately below the place where the cuts were made, and a bushy plant guaranteed as a consequence.

**Detached Growths and what to do with them.**—Shoots of varied character are acquired when the old plants are cut back, and these should be used

2.—THE SAME PLANT CUT BACK: NOTE HOW THE CUTTING BACK HAS BEEN DONE.

for the purpose of perpetuating the different varieties. The growth, as represented in Fig. 3, is quite typical of the majority of those that are detached from the old plant. As a matter of fact, this is one of the growths resulting from the cutting back of the plant in Fig. 1. It is an ideal shoot and should make a very excellent cutting. To make this growth into a cutting it will be necessary to remove the lower leaf, cutting this off close to the stem of the cutting and removing all the bracts at the same time. To complete the making of the cutting, the stem should be cut through immediately below the joint where the leaf-stalk adheres to the stem of the cutting. Some growers would perhaps prefer to make the cutting rather shorter, by removing

a temperature of about 55°, and in these conditions they will root very speedily. Pot up singly into small pots as soon as rooted.

*Reliable Varieties.*—Ryecroft Surprise, salmon pink; Souvenir de Charles Turner, deep rose-pink; Corden's Glory, scarlet; Ryecroft Scarlet, bright scarlet; Galilee, soft pink; Phrosa, bluish lavender; Miss Clara Walker, salmon cerise; H. Cannell, rosy scarlet; Leopard, lilac-pink, blotched crimson; Mrs. Banks, white; Mme. Crousse, silvery pink; and Hon. Mrs. Boyle, rosy pink.

#### POLYANTHUSES AND PRIMROSES AS POT PLANTS.

THE man with the unheated greenhouse is frequently at his wits' end to find suitable subjects to place therein, quite ignorant of the fact that many beautiful yet commonplace subjects are quite suitable for the purpose. One class of plants eminently adapted for such work consists of the choice Polyanthuses and Primroses, and where plants of these are growing in the open they may be lifted and potted at once with the greatest success, providing reasonable care is observed in the operation. Select some of the healthiest looking plants that possess plenty of flower-buds and tread the soil firmly around them. Then crouch some good-sized pots and proceed to lift the plants, cutting right round each one several inches away from the centre of the plant with a good sharp spade. Lift with as much soil and roots adhering as possible and transfer the plant promptly to the pot, pressing the soil moderately firmly around the ball of roots. If the natural soil is of an open or light nature this will answer admirably for the pots, but where it is heavy and sticky an ordinary potting mixture, in which loam predominates, must be used. After potting give the plants a watering in and place them in a cold frame, if possible for a week or ten days, keeping the lights nearly closed so that the plants become established in their new quarters. After this they may be transferred to the greenhouse to open their flowers, and a brilliant display will be the result. Where a cold frame is not available they may be placed direct into the greenhouse, standing them in a shaded position and ventilating carefully for a few days.

#### AURICULAS AND POLYANTHUSES.

THE amateur beginner in gardening finds the possession of a small greenhouse or frame very often a sort of white elephant, because he imagines only tender plants can be grown in such places during the winter months, and he has no heating apparatus to enable that to be done. Yet without heat in a house or frame how many charming plants may be grown such as will withstand frost and come through the winter unharmed. Foremost among these hardy plants come Auriculas and Polyanthuses, plants that will even do well through the winter outdoors; but if in a house or frame in pots, are then so much better protected, and will flower as a rule fully a month earlier in the spring. The beginner, when reading of Auriculas, is apt to think reference is made only to the fine and rather dear show varieties, whether of the old florists' section or the still more beautiful alpinas. Any of these a real amateur cultivator may grow under glass, once he has mastered their cultivation, with great success. But the beginner should be content to start with the cheap border varieties, such as can be purchased now from florists in pots at from 2s. 6d. to 3s. per dozen, getting them at once shifted from 3½-inch pots into 5-inch pots, using for compost turfy loam two-thirds, the other third consisting of old hot-bed manure, leaf-soil and sharp white sand, the whole being well mixed. In repotting remove the drainage and one-third of the soil from the roots of each plant, then repot, doing so firmly and keeping the stems well buried. New roots

will later form from close beneath the leaves. At some future potting a year later the portions of root-stems below the younger roots should be cut away, or otherwise they may harmfully decay. The plants need no heat, and will not care for exposure to strong sunshine. Being alpine plants, shade and coolness suit them best.

After flowering is over, should none be required to produce seed, the flower-stems should be pinched or twisted off just beneath the flower-truss, then allowed to die away. Unless some one variety or more seems exceptionally good, it is best to save no seed, or rather not to wait for flowering, but get a packet of good alpine border Auricula seed at once, sowing it in a shallow pan on good fine sandy soil, just pressing it in, well damping it and covering with glass, then shading with paper, as the germination will be better in darkness than in light. Plenty of patience is needed with Auricula seed, as it grows irregularly. Still, the paper shading must be removed when some plants appear. All the same, keep the pan all the summer in a shady, cool place. By August many of the seedlings will be fit to prick off into other pans or into shallow boxes thinly, and be large enough to pot up singly in November. It is thus possible through seed-sowing to create a stock of scores, or even hundreds, where the simple trouble described is taken.

If Auricula plants become infested with aphids, wash the leaves with a tiny brush and a decoction of tobacco and quassia chips. Polyanthus plants even now showing bloom may be purchased from barrows or florists even more cheaply than Auriculas, and simply need similar treatment in potting, the plants being kept in full light and air so that bloom does not become drawn or colourless. All these can be planted out into the open ground on a shady border as soon as flowering is over. If desired and plants do well, they may be lifted into fresh pots in November. A packet of seed of a fine strain should be obtained at once and sown as advised for Auricula seed, also it should be similarly treated; but as the seedlings will grow much faster, these had best be dibbled out into the open ground 6 inches apart for the summer and kept well watered; then so many as desired may

4.—CUTTING ON THE LEFT PREPARED FOR INSERTION; ON THE RIGHT A ROOTED CUTTING READY FOR POTTING UP.

the two lower leaves and cutting through the stem immediately below the second leaf; this is quite a matter of opinion and is of little moment.

*Cuttings and Rooted Cuttings.*—For the guidance of the inexperienced, Fig. 4 is given to illustrate a cutting prepared for insertion, and also to show a cutting rooted and ready for being potted up. This cutting has been made from the smallest of the three growths represented on the plant in Fig. 1.

*Potting Up Rooted Cuttings.*—Rooted cuttings, as represented in Fig. 4, should be potted up when they are fairly well rooted. It is better to do the potting up before the roots get matted together, as they will when a number of cuttings are inserted in one pot. Fig. 5 represents the same plant as shown in Fig. 4 potted up and established with great possibilities before it. Pots 3 inches in diameter, of deep build, should be used for the first repotting, and the compost should be made up of the following ingredients: Four parts good fibrous loam, one part leaf-mould and one part well-rotted manure, the whole of these soils being passed through a sieve with a half-inch mesh. Add sufficient coarse silver sand or clean road-grit to make the compost porous, giving the heap a good mixing before using. Pot firmly, taking care to crouch the pots properly so that good drainage may be provided.

*How to Root the Cuttings.*—The rooting of the cuttings is a comparatively simple matter, provided proper conditions are observed. The soil for propagation purposes should consist of four parts loam, one part leaf-mould and one part coarse silver sand or river sand, all passed through a half-inch mesh sieve and well mixed. For autumn propagation we prefer inserting a number of cuttings around the edge of 5-inch pots, but for spring and early summer work insert cuttings individually in 2-inch pots. Embed the cuttings about 2 inches deep, pressing the soil firmly at the base of each one, otherwise they will be likely to fail. One watering in should suffice for a long time. Place the cuttings in a warm corner of the greenhouse, maintaining

5.—ROOTED CUTTING POTTED UP INTO A 3-INCH POT.

be lifted into 6-inch pots in November, and thus help to fill the greenhouse or frame. D.

#### A CATCH CROP OF RADISHES.

BEGINNERS in gardening are not infrequently hampered by lack of space in which to grow the various crops of salads and other small things. Where such is the case a nice batch of Radishes may be obtained as follows: In the centre of the space between each two rows of late Potatoes draw a 1 inch deep flat-bottomed drill and sow therein seeds of a quick-growing Radish, such as French Breakfast. The Radishes resulting from this sowing will be ready for use before the Potatoes are high enough to do them any harm, and the latter will not suffer in the least.

## THE TOWN GARDEN.

**BEDDING PLANTS IN FRAMES.**—At the present time there are, doubtless, many thousands of bedding plants in frames that are destined to brighten the summer flower garden, and if the grower is to get the full value of them later on it is essential that they shall have regular attention. It is necessary that they have all the air that is possible, while light is equally beneficial. In towns the cultivator suffers seriously from the poorness of the light, but he commonly makes matters worse by neglect on his own part. If he would keep the glass in his frames, and in his houses too, for that matter, scrupulously clean, the plants would thrive far more satisfactorily, and, as a consequence, bloom much more profusely in due course. Watering will demand the grower's attention, and in this respect care must be exercised not to be too generous in the supplies, or just about as much harm as good will result. Further, all dead and decaying leaves ought to be removed as soon as they are seen, as any trouble of this sort on one plant will soon spread to others that are growing in the same structure. Flowers should be pinched out as soon as they are seen. If it is possible to plant out the yellow *Calceolarias* before the end of the month, it will be found that they will grow better and the irritating summer losses will be fewer in numbers.

**CATS IN GARDENS.**—One is always hearing walls at the damage done by cats in town gardens, and questions are constantly being asked as to how these active and determined felines can be circumvented. Speaking from my own experience I can say that I have not had half-a-dozen cats in my garden during the past thirteen years, and I have kept them out by the aid of wire netting. In the period named above I have had two sets, and it was in the interval between taking down the old and putting up the new that the few cats that have honoured my garden by their presence paid their visits. The netting is 3 feet wide and of 2-inch mesh, and it is carried its full height above the fence on supports 2½ feet high; it will thus be seen that above the wire there is a full 9 inches of swaying netting, and it is precisely that part which the cats do not appreciate. Although the supports are flimsy a venturesome animal will occasionally travel up them, but when that additional storey is reached and it commences to swing it at once decides that the soil in my neighbours' gardens is just as good as that in mine and it descends. Far be it from me to swear to the elegance of the arrangement, for there is nothing of that sort about it, but for its efficacy I can safely vouch. The secret of success lies in bad workmanship, for the wire is so slack that except at the posts no cat will tackle it. One of my friends who knew of my good fortune decided that he would enclose his garden, but he wanted the wire to look nice. With this end in view, he procured 1-inch mesh, 2½ feet high and had a support to the top of every 3 feet (I should have mentioned that my supports are 7 feet asunder), and from these he stretched the netting as tightly as he could. When the work was completed it looked neat and smart, but as for keeping out the cats—well, it was useless, for they tested it carefully, found it firm, told their friends, and those who wanted to see the garden simply walked over the wire in the most convenient spot.

**CLIPPING IVY.**—Notwithstanding the sombre appearance of some Ivy, it is one of the best wall and fence plants that can be grown in towns, and my collection of about twenty varieties, all small-leaved, from *Cheals*, is a pleasure to me and my visitors. I mention the plant now as the time is opportune for the annual trimming. If this work is done much earlier there is an interval of bareness, but done now new growths are soon produced and the attractiveness of the garden is scarcely marred. H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### KITCHEN GARDEN.

**CUCUMBERS AND MELONS.**—Top-dress Cucumbers that are fruiting, using a little often. A box of soil should be put into the house at night, and by the morning it will be warm, and the work may then be done. Keep the plants well syringed twice daily, and stop at every joint next the fruit, allowing only one fruit to develop at a joint. Sow for succession Carter's Model and Sutton's Peerless, two good varieties for table and exhibition use. Sow more Melons for succession and frame work. A variety called Carter's Frame is an admirable one for cool frame treatment. Hero of Lockinge is also a fine variety for growing in frames after the bedding plants have been cleared out.

**Tomatoes.**—Pot singly now varieties for outside culture. Carter's Outdoor and Sunrise are both excellent for the purpose. Grow in a warm house or frame for a week or two, after which they should be placed in cool frames. They will then make strong sturdy plants for putting out into their summer quarters. It is very often the cause of failure that plants in too weak a condition are planted outside; they take a long time to recover, and when they do half the summer is gone.

#### FRUIT HOUSES.

**Grapes** that are swelling rapidly should be given plenty of liquid manure, also an occasional dressing of Le Fruitier or guano, which should be well watered in. Keep the laterals pinched. This operation should be done frequently, so that the Vines do not miss the flow of sap. Shut the house up early in the afternoon, damping down every crevice thoroughly. Succession houses should be brought along slowly or according to requirements. Where there is plenty of space between the wires and the glass the shoots ought not to be pulled down to the wire too quickly or they may snap and cause a gap. Keep the roots in a fairly moist position, especially near the pipes, or red spider may gain a footing and be difficult to dislodge.

**Peach Houses.**—Where fruits are reaching the stoning period the temperature may be slightly lowered for a week or two. Keep the growths regularly tied; cut away any that is not required when the stoning period is over. Give the trees a thorough watering with farmyard manure into which some soot has been mixed; this will keep the foliage nice and green and healthy.

#### PLANTS UNDER GLASS.

**Himalayan and other Rhododendrons** coming into flower should be kept in a cool, dry and airy house; at the same time the paths and stages must be damped down daily and twice on bright days. Top-dress and tie in growths of *Lapagerias*; these plants require cool treatment to be a success.

**Bougardias** that were recently started will now supply cuttings which may be put in at once to increase the stock. Old or large plants may be shaken out and repotted.

**Fuchsias** must go into the flowering pots and keep the points pinched till they are required for flowering. Pot early-struck cuttings on as may be necessary. Shift on small plants of *Grevillias*, *Cordylines*, *Bambusa gracilis*, *B. fuleata*, *Boronia*, &c. Keep up the supply of forced shrubs and bulbs for the conservatory and mansion and for the supply of cut flowers.

#### LAWNS AND FLOWER GARDEN.

Keep the lawns in trim condition by rolling and sweeping, the grass verges neatly cut, and

the gravel paths neat and free from weeds. Stake any plants that need it. Continue to plant out alpine from the reserve and sow seeds. Keep the various portions free from objectionable weeds.

**Hardy Ferns** should have a top-dressing, or if the soil is very poor and worn out replace it with new. Evergreen and deciduous Ferns in the rock garden are always nice, and an endeavour should be made to keep them in good condition. The Parsley Fern (*Allosorus crispus*) is always refreshing and the Holly Fern (*Polystichum setosum*) is a fine one for the window. Ferns delight in a nice fresh open and sweet mixture, and a good collection is always interesting. W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
*Leonardslee, Horsham, Sussex.*

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**POTTING ORCHIDS.**—A great many Orchids require repotting just now, and when potting them it is necessary to get away entirely from the method followed in treating ordinary greenhouse plants. The reason is that in the majority of instances the compost is more in the nature of a mechanical support than a manurial one, although Orchids doubtless derive some little sustenance from various materials used; but this is principally in the way of moisture, and could this element be continuously provided, there is no doubt that many of our best-known species would thrive for an indefinite time on bare blocks of wood, provided also that the roots had good hold.

**Herbaceous Calceolarias.**—A glance at healthy *Calceolarias* in any stage of growth is sufficient to convince one that they are gross feeders. Let this but be fully recognised and acted upon by affording abundance of stimulants, keeping the plants clean and free from aphides and thrips, with plenty of air and light on all sides.

#### KITCHEN GARDEN.

**Sowing Vegetable Seeds.**—Why sow seeds early when the plants are not needed to plant out till June or July? In some gardens the quarters are not available till the early crops, such as Spring Cabbage, Potatoes and Peas, are cleared. Many sow early in March on a sloping border at always the same spot, or as nearly as possible. What is the result? In some seasons there is a fair supply of vegetables, often a scarcity, and in others a total failure. I am aware some will say it is an easy matter to transplant them or prick out, but how few persons can do this with the commoner vegetables, such as the Brassicas. My advice is sow thinly and make three sowings instead of one, if there be the least doubt that the crop cannot be planted when the plants are ready.

#### FRUIT UNDER GLASS.

**Melons.**—In the earliest house the plants are swelling their fruits and require supports. Remove all surplus fruits and all flowers, also superfluous growths, stopping and tying as necessary. Afford efficient supplies of water, giving liquid manure as necessary for the maintenance of free growth. Genial atmospheric moisture must be maintained by damping early in the morning and afternoon and syringing the plants lightly about 3 p.m. on bright afternoons. Later plants showing fruit blossoms should, unless abundant and the plants vigorous, have the first flowers removed. Secure a somewhat higher temperature and drier atmosphere during the setting, only affording as much moisture as will prevent flagging. Stop the shoots at one joint beyond the fruit, but employ the knife as little as possible during the setting period.

#### HARDY FRUIT.

**Strawberries.**—Where old plantations have not yet been looked over this ought to be done at

once, removing all decayed leaves and weeds. The soil round the plants should be made firm and any slugs found harbouring beneath the foliage destroyed. When this is done give a dusting of soot or lime among the plants. The ground between the rows may be hoed to free it from any weeds that may be making their appearance.

#### FLOWER GARDEN.

*Hardy Cyripediums.*—Where it is intended to grow them in the open ground—and in no other place do they flourish so well and continue healthy so long—a suitable position for them is one sheltered from the north and east winds, with a little shade overhead. The soil should be taken out about 18 inches deep, or if the soil be light and well drained, 12 inches deep will be sufficient. In the case of clayey soils a few inches of rough crocks or clinkers will be necessary to form a drainage, and then fill in the hole with roughly chopped peat and half-decayed leaf-soil in about equal parts, with the addition of some rough charcoal nnts and sphagnum moss. In this mixture the plants invariably do well, provided a sufficient supply of moisture is forthcoming in the growing season.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

### THE EDITOR'S TABLE.

WE invite our readers to send us anything of special beauty and interest for our table, as by this means many rare and interesting plants become more widely known. We hope, too, that a short cultural note will accompany the flower, so as to make a notice of it more instructive to those who may wish to grow it. We welcome anything from the garden, whether fruit, tree, shrub, Orchid, or hardy flower, and they should be addressed to The Editor, 20, Tavistock Street, Covent Garden, London, W.C.

#### DAFFODILS FROM MR. PETER BARR.

Mr. Peter Barr, V.M.H., whom we are pleased to know is living among the Daffodils in Scotland, sends us, as he so kindly did last year, several interesting Daffodils in flower. In the collection were the following, accompanied by Mr. Barr's notes dated March 25. They are as follows: "I send you a few Daffodils at present in flower, some of them just open, others in flower some time ago. *Narcissus Corbularia* from Ovar Marshes, Portugal. Of this section it is the first to flower. During winter sportsmen from punts shoot snipe over where this form grows. In the centre of the marshes is an island covered with conifers. On this island the flowers of *Corbularia* are extremely small, the soil being pure dry sand; in the marshes the plants have large flowers, nearly double the size of the specimens sent, the leaves long and twisting, and like the figure in Sweet's "British Flower Garden," Vol. VII., t. 164. Haworth calls it *serotina*, Salisbury's name is *turgida*, said to flower in May, and abundant at Tarbes in the French Pyrenees. I have searched this locality and consulted botanists, but there is no such plant. *C. citrinum* does grow there. To my mind, Haworth, Salisbury and Herbert, I feel sure, were mistaken. In no single instance did I find a yellow and sulphur Daffodil growing in the same sort of soil. I take it that Mr. Bourne, in his book on Daffodils, took it for granted that this Ovar plant was *C. conspieua*. At the present time *C. conspieua* is unknown as a wild plant, and can only be had true from bulbs grown in Guernsey, and from which island the trade have been supplied for a long series of years. The best bulbs are those raised from seed. *C. conspieua* might be found about Tangiers. When there I did not chance to see any *Corbularias*, but Mr.

and Mrs. Brookes (both dead) assured me a Hoop-Petticoat *Narcissus* did grow about Tangiers, and promised to get me bulbs, but did not keep their promise. I am now trying another source. Now that many people spend the winter there, some one or other may read this paragraph. I shall be indebted if they will send me a few bulbs. To prevent further trouble over this plant I propose to name it Ovar Hoop-Petticoat, unless one of your readers will give it a botanical name. I am writing to Mr. J. G. Baker and suggesting that he will give it a name. Ajax Mrs. Buchanan, raised by Baron de Soutellinho, ont some weeks and terribly battered with north-west winds. A. Queen of Portugal, hybrid between Oporto yellow and triandrus albus. It is smaller, flowered earlier than Queen of Spain and is paler in colour. A. cyclamineus, A. minimus, A. pallidus *præcox*. Hybrid between Ajax and cyclamineus, Mrs. Alfred Tait. *Moschatus*, true."

#### RHODODENDRONS AND SAXIFRAGAS FROM HOWTH.

Mr. R. Farrer sends a collection of interesting spring flowers from Howth. He writes as follows: "I enclose a few flowers for your table. *Rhododendron ciliatum*, which is perfectly hardy here, is, as usual, smothered with flowers. The only special treatment it asks for is to have the seed vessels nipped off soon after flowering. *Daphne blagayana* requires no particular care except to be top-dressed with large stones from time to time. I also enclose a small scrap of *Erica codonodes*, with its brightly-coloured buds, and some *Saxifraga* flowers, including two spikes of *S. Grisebachii*, which seems to have made itself at home; a spike of *Faldonside*, certainly an improvement on *Boydii*; and two flower-heads of *S. sancta*, the most effective of all at this time. Its golden yellow entitles it to pre-eminence."

#### THE TELEMV SWEET PEAS.

Mr. Adcock, The Gardens, Litcham Park, Petersfield, Hants, kindly sends flowers of this interesting strain of Sweet Peas, which are similar in colour and quite as sweetly scented as those which we associate with summer days. Our correspondent writes: "I am sending you a few Sweet Peas—Telemv strain—which I am growing here. They are very good, I think, in colour, and when better known will, I am sure, be largely grown. The colours are very distinct, namely rose and cream, red bicolor, violet, red and white stripes, lavender and lilac, purple and maroon, pale primrose, blue and red. The seed was sown on September 15. I am also flowering some in pots, but have cut some of these down to about 4 inches from the rim. I intend to plant them out early in April, and hope to have them in flower in May. My advice for this part of England is to sow about the middle of October to flower early in May."

#### A CURIOUS CŒLOGYNE.

Mr. C. Burtenshaw of St. Helens House Gardens, Norwich, sends an unusual flowering portion of the well-known Orchid *Cœlogyne cristata*. Two rather small well-formed inflorescences were produced from one pseudo-bulb. His letter reads as follows: "I am sending you a piece of *Cœlogyne cristata* for your table; you will see it has two flower-spikes from one pseudo-bulb. I should like to know if it is unusual for *C. cristata* to do this. The plant has five pseudo-bulbs with pairs of inflorescences, but the flowers are not so fine as in the single spikes. It appears that what is usually the growth has developed into a flower-spike. It behaved in the same way last year and made the new growth from the base of both flower-spikes about an inch from the bulb. The plant is in a 10-inch pan and is very robust; last year it had thirty-one spikes of bloom and this year it has forty. I have had it photographed recently and would send you one, but I am afraid if I waited until they are developed the flowers would be too far gone to send, as they have been out some considerable time now."

## ANSWERS TO CORRESPONDENTS.

### RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

#### FLOWER GARDEN.

##### Manuring Sweet Peas (A. Roy).—

It will be quite safe to use the Sweet Pea manure every ten days at the rate you suggest. Regarding the watering with some other guano, we advise you to be careful with this. If you use it very weak it may do good; but without knowing exactly what it is we cannot advise you definitely on this point. However, use it weak and often, and so err on the right side. Do not commence feeding until the first flower-buds are discernible.

##### Treatment of Dahlia tubers after cuttings are taken (Ignoramus).—

If you have rooted sufficient cuttings to produce the required number of plants, the old stools may well be thrown away. If you desire to keep them they may remain in the boxes, cutting off all weak growths to their bases and leaving only the two most sturdy shoots to each stool. Give them very cold treatment—a cold frame will do—and keep them near the glass. It will not be safe to plant them in the open until the end of May, when they should be put out the same as the young plants now in pots.

**Pruning a Polygonum (F. W. H.).**—You may prune *Polygonum baldschuanicum* at once, spurting back the young wood to within a few inches of the base if your plant is outgrowing its position. If, however, it has lots of room for development, it will do very well without any pruning. In fact, examples left to grow naturally over some old tree or rustic support and left untouched for several years give an excellent account of themselves. Should a number of the inside branches die they may be removed if the work can be done without injury to living branches.

**"Broken" Prince of Austria Tulip (A. S.).**—The Tulip sent is a "broken" form of Prince of Austria. This means that the peculiar change, which florists call a break, has taken place. Every Tulip, with certain exceptions, begins life as a self-coloured flower, and then suddenly, after the lapse of a few or many years, the colour changes and becomes striped. Until last year I do not remember having seen any "broken" Prince of Austria; then I had one in a bed of about 150. This form has no special value, but if you or your employer like it, I advise you to mark the fifteen and carefully ripen them off. They will end their days in their new dress.—J. JACOB.

**Raising ornamental Gourds (A. E. S.).**—If you know how to raise Vegetable Marrow plants under glass, you cannot do better than treat the Gourds the same. Sow the seeds in 2½-inch or 3-inch pots, one in each pot, the second or third week in April, and place them in a temperature of 60° to 65°. When the seedlings appear move them to a house where the temperature is 10° lower, keeping them near the glass. If they become pot-bound move into 4½-inch pots, gradually inuring them to cooler conditions ready for planting out early in June. Under the circumstances we think it would be wise to cut back the *Daphne* after it has finished flowering, and thus induce it to push up new growths from near the base.

**Diseased Tulip (E. T. E.).**—The *Tulipa fosteriana* bulbs sent are badly affected with the fungus *Botrytis parasitica*, and there are also mites, though in all probability it is the presence of the fungus that causes this trouble. It is impossible to say if the germs were present when the bulbs were bought. It may have been so. We find, however, that this fungus appears when decayed or decaying organic matter is in the soil, and when the conditions of the environment have been favourable to its growth. These are warmth, damp and want of air. These three factors combined are only too ready to promote its development. The fungus probably grows for a time unnoticed in the soil, and then attacks the plant just about the soil level or a little below. It then rapidly extends down the stem into the bulb, which in turn begins to decay. If nothing was added to the virgin loam when

potting, and nothing used to cover the pots that would set up decay, it points to the germ being present in the bulbs when bought.—J. JACOB.

### TREES AND SHRUBS.

**Fir tree in bad condition (M. M. W.).**—The specimen of *Abies nordmanniana* you send is badly attacked by a species of *Chermes*, probably *C. abietis*. It often infests this particular Fir, and, curiously, selects this particular species from among numerous other sorts. The fact may frequently be noticed of every example of *A. nordmanniana* being attacked by the insect while all the other Firs growing in the vicinity are left alone. This insect, or an allied species, however, attacks other conifers, and *Pinus Strobus* may often be seen infested with it. In the event of your specimens being badly infested cut them down and burn them and water the ground where they stand with boiling water. If the attack is not bad you can cure it by syringing the trees once every nine days for the next two months with the following mixture: Take from a quarter to half a pound of soft soap and one pint of paraffin and mix together into an emulsion. To this add five gallons of soft or warm water, mix well together and keep the mixture stirred while applying it to the trees.

**Planting a Wistaria (K. B.).**—You may plant a Wistaria at once, or, if you obtain an example established in a pot, the planting may be done any time within the next two months. The most suitable soil for it is rich loam, not too heavy. You will not require to do any pruning, other than removing the ends of the shoots which are not well ripened, until the plant has covered the allotted space, unless a lot of breast-wood is formed. When this is the case, keep the main branches nailed up and spur the breast-wood in to within a few buds of the base. This may want doing twice a year—July and February.

**Pruning Pyracantha and Ceanothus (A. B.).**—You may prune your *Pyracantha* at once. If it has grown out a long way from the wall cut it well back. This will result in a loss of flowers and fruit for one year, but you will get a good supply the next. If it is not far from the wall, less vigorous pruning will be required, and you will save some of the flowers and fruit for this year. It is very often, however, found to be advantageous to give a *Pyracantha* a hard pruning now and then. You do not say whether your *Ceanothus* flowers in spring or autumn. If it is a spring-flowering sort, prune it as soon as the flowers have fallen; if an autumn-blooming variety, prune at once, spurring the wood back to within a few buds of the base of last year's wood.

### THE GREENHOUSE.

**Potting Zonal Pelargoniums (Rev. E. B. P.).**—As your plants are two years old we presume that you have some special reason for retaining them. In the ordinary way young plants would have been secured from cuttings inserted in the autumn, and, if cuttings were inserted now, nice young plants for flowering during the autumn and winter would result. If you decide to retain your plants as they are, turn them out of their pots, remove the old drainage and any sour, loose soil that may be present at the bottom and top of the ball of soil and roots, and then loosen a few of the side roots with a pointed stick. Pots 2 inches more in diameter than those they now occupy will be large enough, and these will need one large crock or small oyster-shell over the drainage hole, and a few smaller pieces around and over the large pieces. The best soil is good fibrous loam three parts, and sand one part. If the loam is not very fibrous, add a small proportion of leaf-soil or Cocoanut fibre. To each bushel of soil add a 5-inch potful of fine bone-meal. Pot moderately firmly and water carefully until the plants are established.

**Malmaleons and Roses (J. P.).**—The association of these is not a good plan, and the mildew is most probably caused by the coldness and the incessant draughts, coupled with the moisture and the syringing. As the Roses are planted out, your only course is to move the Carnations and give the Roses more congenial treatment. Old plants of Malmaleons not infrequently exhibit in winter time the paleness of leaf seen in the specimens sent, and a little soot water or weak liquid manure at the root, in conjunction with a more active root condition, will be of much assistance to the plants.

**Making the most of a greenhouse (E. H. T.).**—You do not say a word as to the structure and its position, or whether it is heated, but we should say a good plan will be to fill it with Tomatoes during the summer, and in the winter it can be used for the storing of bedding plants to be sold next spring. We do not know of any book dealing with the subject.

**Moving a greenhouse (Leanto).**—It will be quite possible to convert your lean-to greenhouse into a span-roofed structure, and the roof, as per sketch, will not be too flat. With regard to the last part of your question as to the plants that would thrive in it, we are in the first place handicapped by the fact that you give no idea of its size other than its width, there being no mention of the length. We see there is a boiler marked on the plan, so if you purpose to devote your attention to flowering plants, there is nothing to prevent your growing the usual series of greenhouse plants that are of simple cultural requirements. Such things as *Fuchsias*, *Pelargoniums* of different sections, *Begonias*, *Lantanas*, *Cannas*, *Lilium longiflorum* and similar subjects will keep the house gay during the summer, and in the autumn there are *Bouvardias*, *Lilium speciosum*, *Salvia splendens*, *S. azurea grandiflora* and *Chrysanthemums*. For the early months of the year, different bulbous plants such as *Tulips*, *Hyacinths*, *Narcissus*, *Crocus*, and *Scillas* may be potted in the autumn and taken into the house soon after Christmas. These will furnish a bright display, and in addition you may grow Chinese *Primulas*, *Cinerarias*, *Cyclamen* and *Lily of the Valley*, all of which will flower before the summer occupants of the structure display their floral charms.

### ROSE GARDEN.

**Rosa wichuralana and its history (G. O.).**—The word "*wichuraiana*" is derived from the discoverer's name, Herr Wichur, who was a German botanist. He accompanied the Prussian expedition to China in 1859-61, and during that expedition the species was discovered. This botanist was suffocated in the year 1866. In the "*Index Kewensis*" *R. wichuraiana* is mentioned there as *R. Luciae*. It was not until about the year 1895 that an American, Mr. Manda, took the species in hand and hybridised it with other Roses, which produced such sorts as *Manda's Triumph*, *Pink Roamer* and, later on, *Gardenia* and *Jersey Beauty*. Evergreen Gem came to us from the United States. The well-known Dorothy Perkins originated also in America, its parents being the species and the Hybrid Perpetual Rose *Mme. G. Luizet*. The species is a very low, trailing plant, with bright glossy foliage and large clusters of pure white single blooms, blooming in August. It is very readily hybridised, and is capable of vast improvement in the hands of the skilful hybridist.

**Climbing Devonensis with injured growths (J. A. D.).**—You were quite right in your surmise that the growths are suffering from the effects of the winter. In the case of the above-named Rose, the rank growths it will so freely produce are so seldom really well ripened that they fall an easy prey to the ravages of the frost. Good sound, hard wood rarely suffers so much as the soft pithy wood. Your best plan will be to cut these growths away another year. You should protect the shoots in some way, for it is a very tender Rose. As regards *Caroline Pillar*, the old wood which is blackened is the result of injury by frost, and *Crimson Rambler* has suffered the same in many places. It is very strange that the old wood suffers like this while the new wood escapes; but the fact is that the energies of the plant seem to be centred in the young growths; and this teaches us a lesson—that is, to discard the old. Had this been done in August or September last, the plant would have been all the better for it. It is, however, not too late to remove them now, as we fear you cannot expect good trusses of bloom from frost-injured wood. We do not believe that the plants have been injured by the sewers, and do not hesitate to attribute the trouble to the frost.

### KITCHEN GARDEN.

**French vegetable gardening (A. S. W.).**—The writer of the article in the *Daily Mail* on French gardening at Thatcham in Berkshire has wisely omitted, as you say, reference to cost of this style of gardening, nor does he furnish his readers with any balance sheet. He states, for instance, that the temperature in the frames was up to 80° while it was snowing outside, yet says not a word as to how such heat was obtained. Certainly in such cold weather no manure bed would give that heat for a week, and only a powerful heating hot-water apparatus could do so continuously. This one fact alone

suffices to throw doubt on the entire story. Admittedly French cultivators do beat our home growers in methods and in enterprise and labour. With them "*la petite culture*" is a species of slavery almost—but, at least, it is all for themselves. Only where both ordinary manure and liquid manure or sewage is plentiful can the description of culture under cloches, handlights and frames as described in the newspaper article be carried out, as the soil has to be made a sort of perpetual manure bed. The suggestion that Melons are being grown in frames throughout the dead of winter is absurd, and shows that the writer of the account you sent was both ignorant and gullible. We cannot give you any idea as to the cost of providing an acre of ground with frames, cloches and handlights. It is really a matter for some trader who deals in these things. But you might get some local carpenter or builder to give you a price for a long series of stout rough wooden frames some 6 feet wide and long enough to take some ten or twelve lights, each 6 feet by 4 feet. In such a series of frames you could no doubt grow during the winter Cauliflowers, Lettuces, Carrots, early Potatoes and dwarf Peas, and get such crops much earlier than from the open ground; but once you had such crops, whether few or plenty, you would have to find a good market for them, and one as near home as possible, as long carriage by rail soon eats up profits. We have no wish to discourage you, but begin, if you do, in a small way at first, and thus see how far such a business may grow into success.

**Information about Asparagus (J. S. B.).**—Have you not seen the articles that have recently appeared on "*Asparagus for Amateurs*"? They practically answer all your queries, and for the preparation of the bed kindly refer to them. The best time for planting is the end of March or early in April. Plants two years old are best where early returns are desired. We cannot say what the variety is that you mention, but *Connover's Colossal* and *Giant Argenteuil* are splendid sorts.

### MISCELLANEOUS.

**Size of a bowling green (G. A. K.).**—A full-sized bowling green should measure 42 yards square, i.e., the green should measure 42 yards along each boundary.

**Secretary of the Royal Horticultural Society (An Old Reader).**—Address your letter to the Secretary, Royal Horticultural Society, Vincent Square, Westminster.

**Black growths from a well (Mrs. M. C.).**—The black string-like growths are the spawn or mycelium of a wood-destroying fungus. This spawn is named *Rhizomorpha subterranea*, and is not uncommon under the bark of diseased Elms. On Elms it frequently gives rise to a large fungus named *Polyporus squamosus*. The white growths belong to the black, and are an abortive attempt on the part of the mycelium to produce the perfect fungus. This the spawn cannot do owing to its unfavourable surroundings. Both growths are common on wooden shoring in mines. It is often phosphorescent. It has nothing to do with the dry-rot fungus.

**Bones as manure (H. J. C.).**—Bones to be of use as manure may be prepared in various ways. The simplest in your case, having no proper chemical appliances, is to have them broken up quite small, even into dust if possible. The dust particles would become soluble in the soil in the course of a season or a few months, the larger pieces, ranging from the size of a Hazel Nut to that of a Walnut, some two or three years. These latter are best for Vines or fruit trees. Chemists who manufacture manures crush or grind bones into a dust or meal; they also steam them and make a soft quickly soluble phosphatic manure. They also soak them in a bath of sulphuric acid, and thus manufacture what is known as superphosphate, a brown-coloured compound that is also quickly soluble. We fear you could not raise steam to sufficiently great heat to soften the bones. Best smash them with a heavy hammer on an iron floor.

**Manure samples (A. Roy).**—Short of analysing the two manure samples sent, which would be a very costly process, we subjected the samples to soaking in water for eighteen hours, with the result that the white dust No. 1 is, without doubt, good bone-dust or meal, that is, very finely ground bones, making an excellent phosphatic manure, but because not steamed is slow in dissolving. A pint in a bushel of potting soil for plants would do good. It is also good for Vine or fruit tree borders or Asparagus beds, where crops are of a permanent nature. The other, No. 2, is evidently superphosphate, produced by bones dissolved in sulphuric acid. It dissolves quickly, and gives off more ammonia than the other does. This superphosphate, with one-third in bulk of sulphate of ammonia mixed, should make excellent Sweet Pea manure. You might add, to make a complete manure, one-third of the whole of well-crushed kainit or potash; this mixture should be used sparingly.

TEA ROSE HUGO ROLLER.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## OUR FLOWER SHOW.

OWING to the great demand for THE GARDEN since we published the schedule of prizes in connexion with our show in July several numbers are almost out of print. As some of our readers may, later on in the season, wish for certain back numbers, we would impress upon them the importance of carefully collecting all the coupons. We have received many letters expressing entire approval of our coming show, which will simply be a friendly rivalry between those of our readers who wish to compete. The date of the show is Wednesday, July 29, and it will be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, London, S.W.

## SCHOOL GARDENS.

(First Prize Essay.)

INSTRUCTION in gardening is undoubtedly of great value to the scholars of our village schools. The interest which is taken in their allotments by the boys is proof of the suitability of this instruction, and the fact that every rural boy hopes to have a garden of his own some day is an inducement to him to acquire a knowledge of the art. The patience and perseverance inculcated at this early period of their lives is of incalculable benefit to the boys; moreover, they look upon the gardening lesson as a recreation, and, I am informed by the schoolmaster here (who is an expert gardener), that the combined theoretical and practical instruction which he imparts has had most happy results. The boys take great delight in their work, and it is found that it makes them better scholars, encourages such excellent habits as observation, method, tidiness, economy and interest in the garden of the home.

One is glad that gardening is now included by the Board of Education in the curriculum of schools. The subject, however, not being compulsory, is, I am afraid, only taught, as a rule, where the head teacher has the inclination and ability; but it is pleasing to note that many of our county councils have taken up this important matter seriously and have appointed county instructors to organise and teach classes in cottage gardening.

### LAYING OUT AND SIZE OF PLOTS.

Given a piece of land 24 yards by 20 yards and fourteen pupils (i.e., the Board of Education's regulation number), I would divide the land into nine plots, each 5 yards long by 5 yards wide with a path 1 yard wide all round, dividing the plots from the flower borders (each 1 yard wide) on the east and west sides, and from the fruit break (3½ yards wide) on the north side, and

from the necessary tool-house, etc., on the south side. The southern portion of the ground should be arranged for, 1, a look-up house for tools; 2, a covered shed for keeping wheelbarrow, Pea and Bean sticks, Bamboos, &c.; 3, a manure heap, which is, perhaps, one of the chief means of bringing about the best returns from the garden; 4, frame, where the boys should be taught how to prepare a hot-bed; 5, Rhubarb bed; and 6, herbal break.

Dividing the ground into allotments is far better than having a general garden. Two boys cultivate each plot, which leaves two vacant allotments. One is to be used by the instructor as his demonstration plot and the remaining one as a seed or nursery bed. The arrangement of the boys is an important matter, and the following plan, which has worked very successfully for a number of years, may be recommended:

Let the numbers (1 to 14) represent the boys, placed according to size and ability:

1 2 3 4 5 6 7 8 9 10 11 12 13 14

No. 1 (the best) takes No. 14 (the weakest) as a partner, No. 2 takes No. 13 as a partner, and so on.

### CROPS TO GROW.

*Fruit.*—With regard to the fruit trees and bushes, and indeed the seeds, it should be remembered that a good thing takes up no more room than an inferior one, and, further, no more attention is required; therefore, it will be advantageous to start only with good, well-tried sorts. Apple trees, good varieties and suited to the locality, should be planted at the back of the Gooseberries and Currants. Gooseberries and Currants should be of the "one leg" type; they are easier to clean, and produce better results. The following Apples, Gooseberries and Currants are reliable: Apples (cooking): Lane's Prince Albert, Warner's King and Keswick Codlin. Apples (dessert): Cox's Orange Pippin, Peasgood's Non-such and King of the Pippins. Gooseberries: Whinham's Industry, red; Whitesmith, white; and Early Sulphur, yellow. Black Currants: Lee's Prolific and Black Naples. Red Currants: Red Dutch and Raby Castle.

*Vegetables.*—The drills to run from north to south, 9 inches to 10 inches apart. Take one season for example: Shallots, one row; autumn-sown Onions, one row; spring-sown Onions, two rows; Parsnips, two rows; Carrots, long and short (one row of each), two rows; Spring Cabbage (to be succeeded by Leeks in trench), one row; Potatoes, one row; Runner Beans, one row. All these 2 yards of each. Winter Greens (Broccoli, Kale, Brussels Sprouts or Savoys), two rows; 1 yard. Alter the list of vegetables slightly year by year, e.g., let Celery take the place of Leeks and late Peas take the place of Runner Beans, and, of course, change the ground for the crops annually.

*Flowers.*—Sweet Peas and hardy annuals should form the east border. The following list of hardy annuals, which should be sown out of doors early in April, may be selected from: Mignonette, Larkspur, Malope, Shirley Poppy, Godetia, Candytuft, Sunflower and Nemophila. The following perennials have not the pernicious

spreading habit of so many of their class, and can all be raised from seed sown in the open seed-bed in June to flower the following season: Pentstemon, Antirrhinum, Hollyhock, Pansy, Delphinium, Polyanthus, Forget-me-not, Wall-flower, Lupin and perennial Phlox.

#### TOOLS REQUIRED.

The tools required for each pupil are spade, garden fork, rake, draw hoe and Dutch hoe. There must also be a serviceable wheelbarrow, a brush and three garden lines.

#### METHODS OF TEACHING.

All practical work should as far as possible be preceded by demonstration lessons in school, illustrations to be given on the blackboard. These should afterwards be reproduced by the boys in their note-books or diaries, *e.g.* (a), the sowing of seeds, as Parsnips, long Carrots and Beet, should be shown on blackboard thus: . . . 4 inches to 6 inches, . . . 4 inches to 6 inches, . . . 4 inches to 6 inches, . . . drill. This method saves labour and seeds. There is no need to sow thickly all along the drill for such vegetables as mentioned. (b) Pruning and grafting operations may be easily illustrated on the blackboard, and form very interesting and instructive work at the subsequent drawing lessons. The demonstration plot (No. 5) should be the ground where the practical teaching is given. The teacher should prepare the ground, open drills or trenches, sow seeds and shut drills, the boys standing round as a class. The pupils should do similar work on their own plots, and here it must be mentioned that no measurements between rows should be permitted, the object being to train the eye of the young gardener.

A diary should be kept by each scholar and dates of preparing the ground, sowing, cropping, &c. should be recorded. These diaries must be a special feature of the work; they should be carefully inspected, marks awarded periodically, and the books finally given to the scholars at the end of their school life for future reference. Autumn is, of course, the best time to start laying out the school garden. Lessons should be given in school on trenching (bastard and real), drainage, manures, soils and the uses of the various tools.

The month of July should see the gardens at their best, and this is the time for the annual inspection. No difficulty should be found in securing a judge. The head-gardener from some neighbouring gentleman's place can be relied on to come and pass judgment on the different plots. Prizes should be provided, ranging from a spade (the coveted first prize) to the useful weeding fork, a most excellent type of which, with flat steel prongs at a cost of a few pence, is to be had to-day.

In conclusion, may I say a word for the girls? Let the flowers be their care. Experience shows that as gardeners girls are at least the equals of their brothers, and among the upper classes women as gardeners have achieved name and fame. I should also like to add that in my humble opinion there are few more pleasant sights than well-cultivated and kept allotments. There is no more pleasant, healthful, refining and profitable way of spending a man's leisure hours than in the cultivation of a plot of ground, either as an ornament to his surroundings or as a means of supplementing his earnings by the vegetable produce which he obtains, and it is the proud boast of a Briton to be able to say that the "Cottage Homes of England" are distinguished in this respect from those of almost every other nation. If this country is to keep up her distinguished name in this respect, we must train up the rising generation with a thorough knowledge of horticulture, and since THE GARDEN has given such prominence to school gardens it would be a decided acquisition to add such a useful paper to the ordinary school literature and magazines. G. M. WALDRON.

*Bluetts, Peterston-super-Ely, Glamorgan, South Wales.*

## PRIZES FOR READERS.

### MARCH COMPETITION—AWARDS.

In this competition essays on "School Gardens" were invited. The prizes are awarded as follows: The first prize of four guineas to G. M. Waldron, Bluetts, Peterston-super-Ely, Glamorgan, South Wales.

The second prize of two guineas to Mr. Henry J. Orchard, Helmingham, Stowmarket, Suffolk.

The third prize of one guinea to Mr. A. E. Burgess, 16, Briscoe Road, Hoddesdon, Herts.

The fourth prize of half-a-guinea to F. W. Mosedale, 263, Edward Street, Nuneaton.

Although the number of essays sent in was not so great as in some former competitions, the quality was very high. The following is a summary of the views most generally expressed in the essays: Single or dual plots, with demonstration and reserve plots, is a better system than one large plot. The schoolmaster, if qualified, makes the best teacher; gardeners, generally speaking, do not make good teachers. All work done should be entered in a note-book, to be presented to the scholar when leaving school, thus providing him with a mass of useful information for reference. The children should, in addition to being shown how to do a thing, be told why it is necessary to do it. We very highly commend the essays from the following, all of which were of exceptional merit: M. E. Dishusall, S. E. Hymans de Liel, Thomas Down, Dorothea B. Allwork, James Colville, G. H. Webster, George W. Naish, William Lucas, W. H. Morton, Winifred S. Baker, M. Dearden, Henry J. Neal, T. O. Jones, Thomas Alexander, R. Findlay, Victor H. Lucas, Edna M. Gunnell, Ruth L. Hopkins, "A. N. T.," Arthur J. Cobb, John Botley, John Rhodes, Fred Hudson, S. W. Grimble, Rev. A. A. Kerridge, H. Tomalin and "Northants." One well-thought-out and written essay was sent without name or address.

## NOTES OF THE WEEK.

### FORTHCOMING EVENTS.

April 21.—Devon Daffodil and Spring Flower Show.

April 22.—Royal Botanic Society's Show, Regent's Park, N.W.

July 29.—Flower Show for Readers of THE GARDEN at the Royal Horticultural Society's Hall, Vincent Square, Westminster.

**Shropshire Horticultural Society.**—The annual report and statement of accounts of this remarkable provincial society for 1907 are of a most gratifying character, and the committee are to be congratulated on securing such good returns during the unpropitious weather experienced last summer. The total receipts from all sources amounted to £5,922 12s. 8d., this being £283 17s. 5d. in excess of 1906. The number of annual subscribers steadily increases, and the takings at the gate on the two days of the show also give a substantial increase over those of 1906. The balance in hand after the expenses of the year had been met was £786 11s.

**The Nurserymen, Market Gardeners' and General Hailstorm Insurance Corporation, Limited.**—The thirteenth annual general meeting of this company was held at 41 and 42, King Street, Covent Garden, on Friday, the 3rd inst. The accounts showed an increase in the year both as regards premium income and interest. The year had been peculiarly free from hailstorms, but two further claims had been settled since the accounts were closed. During the thirteen years the premium income had increased from £681 1s. 9d. to £2,476 13s. 10d., which showed

that the company was meeting a distinct need and becoming better known. A dividend of 7½ per cent. and a bonus of 2½ per cent., making £1,000 in all, was declared, and £1,500 added to the reserve fund, making the reserve £13,500. The invested funds at the end of the year amounted to £23,969 0s. 7d. The company were not paying big dividends, but were building up their reserve fund against heavy claims which might come in at any moment. The area insured now amounted to over 35,500,000 square feet of glass.

**Weather in North Wales—a bad outlook.**—The weather since the New Year has been very wet. Cold winds and hail showers have prevailed, and the outlook in this part of the country is serious, not only for gardeners, but farmers alike. Many fields are too sodden for tillage, seed-sowing up to the present is out of the question, and everything points to a very late season owing to the condition of the land. I append the total amount of rain for the three months ending March 31, 1908, viz., 11·48 inches, against 6·69 inches for the three months ending March 31, 1907, which gives 4·79 inches in excess of 1907.—J. S. HIGGINS, *Râp Gardens, Corwen, North Wales.*

**Mr. Robert Sydenham's Business.** Our readers will doubtless learn with interest that from May 12 next the extensive seed and bulb business established and built up by Mr. Robert Sydenham, Tenby Street, Birmingham, will be carried on under the title of Robert Sydenham, Limited. In converting this business into a private limited company it has not been done with a view to raising more capital, but with the idea of giving a direct interest in the business to those members of the staff who have worked hard with Mr. Sydenham in the past. We are sure that all our readers who know him will be pleased to learn that Mr. Robert Sydenham will still retain full control as governing director, and will be quite as interested and active in the business as before, so that orders will still receive the same courteous and prompt attention.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

**Cotoneaster angustifolia in Victoria, B.C.**—A few years ago I was much interested in this shrub, when I saw it first mentioned in THE GARDEN. As soon as it was put on the market I obtained a plant from France and the following year I secured ten more. They all grew well, except one, which died; in fact, it never made a start. A year ago this winter we had 22° of frost and they got frozen badly, being in an exposed place, but they broke out fine in the spring, and last summer the first plant I imported had a fine lot of yellow berries on it. The other nine never had a flower on them. I have sold them all now, but have young stock raised from cuttings and some grafted on the Hawthorn.—G. A. KNIGHT, *Mount Tolmie Nursery, Victoria, B.C.*

**Rabbits and wire netting.**—May I add something to your answer to "Eaten Up" in a recent issue? Rabbits will burrow under wire 6 inches deep in one night. If, however, the wire is buried 6 inches and another 6 inches at the bottom turned outwards, the rabbits will never get under it. A rabbit, when he wants to burrow under anything, begins close up to it, and when he comes down to the horizontal piece of wire he gives it up as a bad job. Also 2-inch wire will let through young rabbits, and it is only a case of two or three days before they will be too big to get out; 1½ inch mesh is the only safe one. I have had wire down for ten years as above. At first the rabbits tried to get through, but in all the ten years no rabbit has ever burrowed under.—FRED STREET.

**Borecole or Kale.**—At no time does the value of this, the hardiest of all green crops, come home to us with such force as in late winter and early spring, when the severity of the winter will have cleared the kitchen garden quarters of most green crops except the hardy Kale. The great improvement in the quality of vegetables (notably Potatoes and Peas) of late years has not been so marked in relation to the Brassica tribe, and yet the very useful trial of Borecoles (Kale) carried out by the Royal Horticultural Society at their Wisley Gardens in 1907, and which were inspected by members of the fruit and vegetable committee in the spring of that year, disclosed the fact that considerable attention had been given to the improvement of this, what may well be termed the poor man's most useful winter and spring vegetable. It was found that, growing side by side with old types and strains, the following, in the estimation of the judges, were distinctly in advance of the older ones, and to each of which an award of merit was recommended: Chou de Russia (Carter), Dwarf Moss Curled (Carter), Cottagers' (Barr), Cottagers' (Carter), Cottagers' (Veitch), Selected Dwarf Curled (Kent and Brydon) and Tall Green Curled (Veitch). At the following meeting of the fruit and vegetable committee Kale Chou de Russia (an old Russian stock) was thought so highly of, especially for its great hardiness, as to be deserving of a higher award, and a first-class certificate was recommended.—OWEN THOMAS.

**Hyacinths at Vincent Square.** It was a matter for surprise to learn that the Dutch growers of bulbs who were over here to represent the donors of the liberal cash prizes offered at the recent meeting of the Royal Horticultural Society for Hyacinths in pots were disappointed with the examples exhibited for those prizes. Surely they of all persons should know that bulbs of such fine spike-producing form are not now grown by them, or, if so, they are not put on the British market. The best of the spikes seen in the recent competition were small compared with the very fine ones that used to be seen in the old days at South Kensington when some famous home growers used to compete. If Dutch growers continue their prizes, they must furnish competitors with bulbs that have gone through the process of spike-creation before sending them over here. But, after all, from either a home decorative aspect or for competitions, is the game worth the candle? No growth or culture can make the Hyacinth other than a dense, formal, tubular spike, that has in respect to its stiffness no equal among flowering bulbs. On the other hand, we have now a marvellous selection of graceful Daffodils, of beautiful cup-shaped Tulips, of lovely Irises, and many others, all cheap, easily grown, and productive of great variation in form and of exceeding beauty. None of these emit that strong perfume which so often in a greenhouse or room renders the Hyacinth a trying plant. Nothing more wretchedly stiff and formal, as well as bizarre, has, perhaps, ever been seen at the Horticultural Hall than the huge collection of Hyacinths in pots staged at one end, the product of bulbs such as are commonly classed as bedders. Why so many should have been thus grown it is hard to say, but it was inconceivable that such an exhibit assisted to popularise Hyacinths. If it be really desired to encourage bulb culture in pots, let us have classes for six kinds and four kinds, distinct, to be shown plunged in moss, thus bringing in Hyacinths, Tulips, Daffodils, Scillas, Crocuses, Muscaris, Irises, or any others to furnish good variety.—A. D.

**The acclimatisation of foreign shrubs.**—Your correspondent "E. H. G." in THE GARDEN for the 28th ult. may be interested in learning that for several years past the Matipo or Pittosporum undulatum has grown with me on a heavy, wet, clay soil without any protection during the winter, and that it flowers freely. It is now a standard tree about 6 feet high. I collected the seeds from a large tree, in

which the laughing jackasses were playing, in the Zoological Gardens in Sydney in the year 1887. The Loquats also grow here without any protection: these were from seeds obtained in Japan in 1895.—ARTHUR SHILLITOE, *Sydenham Hill, S.E.*

—"E. H. G." may be interested to hear that Pittosporum tenuifolium, a New Zealand shrub, has been doing well in the open ground without any protection for eight or nine years here in Norfolk. There are several specimens growing in various parts of the garden, all more or less exposed, some 6 feet or 7 feet high already. Two small ones reared in a Cornish garden died the first winter, as transplanted shrubs when sent from the South-west of England to the East are so apt to do; those now doing so well here were reared from seed gathered from the same Cornish garden, raised under glass, potted separately when big enough, and kept under slight protection for the first two or three winters. Specimen sprays are enclosed. Is P. undulatum the same or a larger-leaved variety? In Gauntlett's catalogue Pittosporum undulatum is called Australian Daphne.—M. A. P., *Harleston, Norfolk*. [Pittosporum tenuifolium and P. undulatum are two distinct plants; the former comes from New Zealand, and the latter is native of Australia. P. undulatum has much larger leaves and heads of fragrant white flowers. The specimen sent was that of P. tenuifolium.—ED.]

**A beautiful white Orchid.**—I see that you welcome photographs of interesting

A GOOD PLANT OF THE WHITE-FLOWERED  
CELOGYNE CRISTATA ALBA GROWN BY  
MR. P. FLETCHER, BACUP.

plants, so I enclose one of Celogyne cristata alba. It occurred to me when I had cut half-a-dozen spikes that it would make a good photograph for THE GARDEN—that accounts for the gaps.—P. FLETCHER, *Holmes Villa Gardens, Bacup*. [We thank our correspondent very much for the interesting photograph.—ED.]

**The Megasea-leaved Primrose.** It would, I think, be useful to compare some experiences with this bold and pleasing Primrose (*Primula megaseeifolia*), which is so handsome and distinct that no one who knows it will be disposed to question the justice of the award of a first-class certificate given for it by the floral committee of the Royal Horticultural Society. This is a sufficient commendation for those who know it not, but it is when we come to the actual cultivation of the plant in the open air that some comparative experience will be useful. If I recollect aright, it was first distributed by Mr. Sprenger of Vomero, Naples, although I am subject to correction on this point. I know that I had it from him at the time of its introduction, and that I was one of the first to grow it in the open air in Great Britain. At that time I was in hope that it would prove a hardy perennial with me, and it is its subsequent behaviour with me and with others with whom I have been in correspondence and communication that induces me to pen these notes upon the plant, and to ask for the results of the trials of others. Its native habitats lie, I am informed, in shady and moist

ravines, and it certainly appears to do best in shady or half-shady places, planted with its roots within touch of water, although the crowns are well above it. There it will thrive fairly well, if the climatic conditions are favourable. Here, however, the trouble lies. It is a winter bloomer, and however desirous we are of having hardy flowers at that season, we must admit that there are few which will long retain their beauty in a severe time. This severe weather, after a year or two of successive mildness, proved the weak point with *Primula megaseeifolia*, for a hard winter came on, the flowers that were open were destroyed, and the most advanced buds crippled, while the leaves themselves were injured. In order, then, to maintain the plant in health and beauty, it had to be covered with a hand-light in winter, so that I have reluctantly come to the conclusion that with us it is more properly a Primrose for the mild district or for cultivation in the greenhouse or conservatory.—S. ARNOTT, *Dumfries*.

## THE WARREN GARDENS, LISMORE, IRELAND.

ON the 25th ult. I paid an exceedingly pleasant visit to Miss Currey's extensive Daffodil grounds at Lismore. Warm rain had fallen almost the whole of the previous day. It had been the first real growing day of the year, and accordingly Miss Currey, who, I believe, had actually seen the leaves and stems of her favourites grow, was in the very best of spirits and full of hope for a good season, although the damp autumn and winter had been so trying. Coming straight from the Northern Midlands of England the earliness of Southern Ireland was a revelation. I had not a single Daffodil out at home, but here Henry Irving and Golden Spur were over and glorious Maximus in full perfection, Sir Watkin about half out and numerous dear old-fashioned flowers of the early historic age of Daffodils in bright patches, scattered here and there within the large walled garden, which, from its precious contents, she appropriately names "The Holy of Holies." These survivals of the past (Regina Margherita, Her Majesty, Mrs. H. J. Elwes, Oporto Yellow, Lismore, Leda, Bishop Mann, Humes Giant, Lobularis, Nanus and many another now almost forgotten and probably unknown to the younger generation of Daffodil lovers) have a warm corner in their owner's heart. They remind her of her early struggles and her early friends. Did not King Barr himself pick out Lismore from a little clump of *Cernuus* seedlings, and were not some of the others the very varieties with which she first started on her now well-known and prosperous business?

To-day none of these would gain an award from the Daffodil committee. They do not come up to the florist flower standard, and varieties which do not do this, although they may have a great decorative or highly-paying market value, have to go through the world as plain "Mr.," without any mystical letters after their name to give them distinction. We badly want a new "Order of Merit" to separate and to mark such as these. But I am digressing. The whole of the grounds were a picture of order and neatness. Deep trenches divided the beds and work was in full swing. Here were some women roguing, and there some boys weeding, a few were picking flowers, and directly after I left Miss Currey herself was going to gather in preparation for an exhibit in London the following Tuesday. It must not be thought that these old stagers are all that are grown. They are a mere drop in the ocean. On a field where in the distant past had stood a leper "hospital," and immediately opposite Monalaur (Hill of the Leper) were large breadths of the best standard varieties, while the greater part of the "Holy of Holies" had, in patches of varying size, many

of the best of the newer ones. Plenipo was fine; King Alfred, sturdily and strong; Sirius, just showing his brilliant trumpet; Artemis, a real fine incomparabilis, almost ready for market; others (the vast majority of course) still keeping themselves warm in their nice green coats, waiting patiently for the wand of spring to touch them with its liberating warmth and moisture, when they would suddenly appear among their sisters at the ball and take part in the Daffodil dance, the gayest of the gay. Mrs. Robert Sydenham (Magni) all in pure white, with her elegantly frilled trumpet and firm broad perianth, excellently proportioned; Atalanta, another white beauty, with a long shapely trumpet of the palest ivory; Duke of Leinster of the incomparabilis,

in his gay uniform of brilliant orange scarlet and creamy white; The Geraldine, in brilliant scarlet and white; and Warrior, the brightest of them all, with his rich yellow perianth and deep scarlet cup, will all be there to give grace and beauty to the brilliant company.

I think it will be gathered from what I have said that Miss Currey caters for two distinct classes of customers—the fancier, who wants the florist's type, and the gardener, who wants something decorative, something, say, that can be cut for the house or brighten the border. The soil of Lismore and the methods of culture adopted at the Warren Gardens are such as ensure firm, hard, well-ripened bulbs. I wish everyone could see as I did photographs of Lismore bulbs, cut open and placed side by side with others from richer and more highly-manured land. They would then see why Miss Currey's American customers write so often to congratulate her on the way her bulbs travel. It is irritating to buy firm specimens that have been highly fed and find soft bulbs and poor results when they flower. One custom that obtains at Lismore is giving certain varieties a sort of "Jubilee" rest. A proportion of the bulbs are planted by themselves and allowed to remain for two or three years undisturbed; by this means Miss Currey considers the stock is kept strong, and certainly with her "it works," for the foliage of all her bulbs looked the picture of health. I noticed among the Daffodils a few heads of Darwin and May-flowering Tulips, all in splendid condition. Mrs. Moon was being grown for an English dealer in considerable quantity. Gesneriana was also largely cultivated. I do not wonder at Miss Currey saying, "No Tulip sells so well." A look at the packing and drying sheds concluded my visit, and I hurried away just in time to catch my train to Waterford. JOSEPH JACOB

## ORCHIDS.

### BEAUTIFUL WINTER-FLOWERING ORCHIDS.

CALANTHES.

**A**MONG the many beautiful and useful winter-flowering plants of fairly easy culture where reasonable accommodation is to be had, *Calanthe vestita* and *C. Veitchii* should find a place. Though Orchids, their successful culture should in no way strike terror into the heart of anyone. *C. vestita*, which is a natural species, was introduced into European gardens about the year 1848 from the East Indies, while *C. Veitchii* is a hybrid between *C. rosea* and *C. vestita*, and is one of the earliest of the late John Dominy's many successes at hybridisation among Orchids. It flowered for the first time in 1859. *C. vestita* produces a spike carrying numerous milk-white blooms nearly 2 inches across, with a yellow blotch in the centre of the flower; in the subvar. *rubro-oculata*—the blotch is reddish purple, and has a very beautiful effect. *C. Veitchii* produces a spike carrying frequently thirty-six to forty deep rosy pink flowers, the spike itself being from 3½ feet to 4 feet in length when well grown. Though the culture of the two varieties is practically identical, as a rule

A NEW ORCHID: VANDA SUAVIS PALLIDA.  
(Single flower, natural size.)

*C. vestita* is the earlier-flowering variety. When the flowers are past the pseudo-bulbs should be stored in a dry intermediate temperature, entirely withholding water. About the month of April signs of fresh growth will be noticed from buds situated at the base of the pseudo-bulbs. When this occurs the pots should be removed to a moister atmosphere, and where the syringe can be used between the pots no water should be given until after the potting, which is generally done as soon as young roots appear.

For potting quite clean pots of various sizes should be prepared. Pots of 4½ inches to 5 inches diameter are large enough for single bulbs of *C. vestita*, but for *C. Veitchii* larger sizes should be used; 6-inch pots for single bulbs and still larger ones if three or four bulbs are to be grown in one pot. The sizes named are large enough for the flowering pots, into which the bulbs

must be placed, as a shift is not to be recommended. The soil I prefer consists of one-third each of good fibrous peat, loam and dried cow manure rubbed through a three-quarter-inch mesh sieve, in addition to which chopped sphagnum and also broken charcoal and sand (enough to give the whole a gritty touch to the hand) should be added. Turn out the pseudo-bulbs, shake away all the old soil, remove any two year old bulbs and nearly all the old roots—which perish as the flower-spikes pass away—leaving just enough to help as a support in keeping the bulbs in position in the new pots. The latter should be filled to one-third with clean crocks, filling the pot up to the rim with the prepared compost. Place the bulb on the top and make firm, finishing off so that the base of the bulb is level with the top of the pot.

The pots should then be returned to a good growing temperature varying from 70° to 75° in the day and from 65° to 68° at night. A little ventilation may be given when the higher temperature is reached in the day-time. Syringe between the pots two or three times a day, but give water sparingly until the new roots are running freely through the soil.

If the house in which the *Calanthes* are grown is naturally a dry one, a very fine misty spray over the foliage once a day at closing time may be given, but not otherwise, and even then not sufficient to cause any water to run down into the centres of the young growths. As the leaves develop a little shade from the sun should be given during the brightest part of the day, but as the pseudo-bulbs finish growth the shading can be dispensed with. When the bulbs begin to form plentiful supplies of water will be needed, and diluted cow or sheep manure water two or three times a week. The flower-spikes appear generally about the end of the month of September, when a neat stake should be placed in the pot to tie the spikes to as they increase in length. If this is not done the spikes grow in all directions, sometimes very awkwardly. As the spikes develop the foliage will begin to turn yellow and die away. Less water will then be necessary, but not withholding it entirely until the spikes are cut. Keep a sharp look out for a flat soft scale, which is the chief enemy to the *Calanthe*. If its appearance is noted, the leaves must be immediately sponged with tepid water and soft soap.

The pseudo-bulbs of *C. Veitchii*, which are often from 9 inches to 12 inches in length, have a depression or neck about halfway, and great care must be exercised in working among plants of this variety, as they soon snap.

Bryanston Gardens, Blandford. J. JAKES.

### VANDA SUAVIS PALLIDA.

This is a beautiful specimen of a comparatively little-known genus. The plant shown was a large one, and was carrying a very fine inflorescence composed of twelve fully opened flowers. These are creamy white with numerous yellowish green spots over the sepals and petals. The leaves are lanceolate, opposite and of a rich deep green colour. It was shown by Theodore Pauwels, Esq., Orchid Villa Nursery, Meiselsbeke Station, Belgium, at the Royal Horticultural Society's meeting on the 17th ult., when it received a first-class certificate.

### ODONTOGLOSSUM PULCHELLUM.

This pretty plant is still in flower, and it is one of the easiest to grow in the genus. The flowers occur on erect spikes and are pure white, excepting a little yellow centre. A plant I noted in flower during the week was carrying twenty-five of these pretty spikes, making a very nice show. *O. pulchellum* thrives well in any cool, moist and well-ventilated house, and may be freely watered as long as root and top growth are active. No regular resting season is required, but a diminution of the water supply is advisable in late autumn. H.

## THE ROSE GARDEN.

MR. EDWARD MAWLEY'S  
ANALYSIS, 1900—1907.

(Continued from page 177.)

**T**URNING to the table, Bessie Brown again heads the list, and will continue to do so until we get a very wet season. The surprise to most people will, I think, be to find Dean Hole third in the analysis; and the season was by no means favourable either. I find on referring back to last year's article I predicted that both Dean Hole and Hugh Dickson would soon be found higher; the one jumps to third on the list, and the other to eighth (from being No. 61). Lady Ashtown also rises. Other Roses that make their appearance for the first time are Gustave Grunerwald (a garden Rose first and an exhibition Rose afterwards), Countess of Derby, Mrs. T. Roosevelt, destined to take a higher position, as likewise will Betty and William Shean. The latter will probably be found in the first twelve before we are much older. Which are the best twelve Hybrid Perpetuals or Hybrid Teas? That is a question that I am more often asked I suppose than any other by the budding exhibitor; and it is not easy to answer, as there are so many things to take into consideration. The analysis does not answer it, although it helps one considerably in arriving at a solution. An ideal exhibition box of twelve Hybrid Perpetuals or Hybrid Teas should, I think, contain at least four crimson or dark Roses—and there are only two in the first twelve, or three if you count Ulrich Brunner—three white or flesh, and the remaining five should be some shade of pink or yellow. New varieties must also be taken into consideration if you are to keep up-to-date.

The list supposes that a certain number at any rate of maidens will be cultivated, and I suggest that a small exhibitor would do well to grow a fair number of each variety of the following. The three whites or flesh-coloured varieties are easy to pick out—Bessie Brown, Mildred Grant and Frau Karl Druschki; the four reds are Ulrich Brunner, Hugh Dickson, A. K. Williams and Marquise Litta; the five pinks, Dean Hole, Mrs. John Laing, Caroline Testout, Lady Ashtown and William Shean. All these varieties are fairly generous with exhibition flowers; in other words, their flowers are more likely to be perfect. For instance, plant for plant, Hugh Dickson will give you twice as many exhibition flowers as J. B. Clark, and where your number of plants is strictly limited one must grow those sorts that are likely to give you most opportunities of showing. Given a perfect flower of each, probably J. B. Clark is the finer form; but you so seldom get it, and so we shall find Hugh Dickson and similar kinds being grown more and more every year. I was interested to see that the Nickerson Roses (as they have come to be called) each figure well up in the tables, the Hybrid Tea being third, the Hybrid Perpetual fourth and the Tea fourth, although all of them were necessarily of recent introduction. In the new Nickerson competition this last qualification is done away with, and the result will give us the best red, pink, white and yellow Rose (irrespective of date of introduction) in cultivation, not from the exhibitor's standpoint, but as an all-round Rose. Before leaving the Hybrid Perpetuals and Hybrid Teas one notices that Messrs. Alex. Dickson and Sons of Ireland are the raisers of the first three Roses on the list. I hardly anticipated Dean Hole would so soon take the place of Frau Karl Druschki. I do not think anything short of a magnificent red Rose will cause the white to take a lower place. Is Avoca going to be good enough, or are we to wait for an Alexander Dickson?

HERBERT E. MOLYNEUX.

## AMONG THE ROSES.

WHAT a lot there is to do now if you are a lover of Roses and are determined to "do well"! How delightful it is, too, to see the evenings lengthening out and giving us longer working days. Rise early now and get to work among your Roses if you want real success. There are so many things to think of. Most readers will have finished their pruning by the time these notes are in print. This is a very late spring. I did not begin to prune my Hybrid Perpetuals till the 23rd ult. Remember after pruning to look out for buds going to break in places not wanted—i.e., where the growths from them would crowd too much, grow inwards or cross one another. Scratch all these off neatly with the thumb-nail.

Use the hoe constantly after every fall of rain now. Constant hoeing is far better than summer mulching. If you want a really good tool let me recommend you to write to Messrs. H. G. Norton and Co., High Street, Cheltenham, and order a "Gayton rake." It is really a three-pronged rake designed by the writer many years ago and now made by this firm. It beats anything ever made for this work, will go anywhere and get over the ground thoroughly, quicker and better than any hoe. I find a 6-foot handle to it the most useful, though I have all sizes.

Keep a sharp look out for green fly in odd sheltered spots. They may be found if carefully searched for. Every one of these destroyed now means a lot of trouble saved later. Early in March I carefully dusted round all my plants with old soot as a preventive against mildew. Certainly if we want to fight this terrible pest successfully we must keep up the constitution and hardness as much as possible. I have been spraying during the last few weeks all the sorts that were attacked with this awful fungus last year with Mr. George Bunyard's "Medela." Q.

## ROSE INSTITUTEUR SIRDEY.

This is a deep golden yellow Rose of exquisite beauty of colouring, and destined, I think, to take a foremost position. The glowing colour reminds one of that beautiful Trollius Orange Globe, and, compared with William Allen Richardson, the variety named above is of a much more fiery golden in the centre. Under glass it is especially good, and the growth is as vigorous almost as Mme. Ravary, a variety it surpasses in colour and in fulness, but I am rather afraid outdoors it will not equal it in vigour. If we could but impart this colour into a Rose of the type of Mme. Ravary, we should be going a long way towards reaching our ideal of a golden bedder. P.

## THE GREENHOUSE.

## THE CINERARIA.

**S**INCE the introduction of the stellata or "star" Cineraria, Cinerarias have held a high place in public favour. They are delightful plants for use in rooms or the conservatory, and their cultivation is not difficult. The old florist's type of Cineraria was formerly largely increased from the offshoots springing from the base of the plants. This method of propagation is now seldom practised, as it is possible to procure good seed which has been saved from the best of the individual strains in cultivation.

## SEED OF THE CINERARIA

may be sown in May and June, and, as a rule, the plants raised in May will give the best results; but plants raised from a sowing made in June provide late flowers during the following April and early May. If an early display is required, plants may be raised in April which will flower during November and December. The seed may be sown in well-drained pans or pots filled with finely-sifted soil. A suitable soil consists of loam one part, leaf-mould two parts and silver sand one part; this should be thoroughly mixed. Fill the seed-pots to within an inch of the top, making the surface soil moderately firm and perfectly even. This can easily be accomplished by the use of an empty 3-inch pot, or, better still, a small, perfectly smooth piece of wood (circle-shaped) to which a short handle is attached. Sow thinly and cover with a slight covering of fine soil. As the term "fine soil" is so often used and may lead to some

A TYPE OF THE WHITE-FLOWERED CINERARIA IN MESSRS. JAMES AND SON'S NURSERY.

A RED OF THE FINE TULIPA KAUFMANNIANA.

confusion, it may be as well to state clearly here that the bulk of the soil used in the pots should be passed through a quarter-inch mesh sieve. A thin layer of soil which has passed through a finer sieve should be prepared, on which the seed is sown, afterwards covering the seed lightly with a sprinkling of the soil passed through the finest sieve. A sieve for preparing this fine soil for seed-sowing can be easily made by procuring a piece of perforated zinc about 9 inches square, and tacking this to a small wooden frame. Failure in raising choice seedlings is often brought about by covering the seed with coarse, unsuitable soil. After sowing, give water through a fine-rosed watering-pot, and place in a frame or house which can be kept fairly close until the seeds have germinated. Cover the seed-pots with a piece of glass and a little moss, taking care to remove this as soon as the seedlings appear.

CINERARIAS GROW VERY FREELY, and should not be allowed at any stage to suffer through becoming pot-bound. It is not necessary to prick off the seedlings, but as soon as they begin making their second leaf they may be potted singly into 3-inch pots. The soil used should consist of the best loam at hand, leaf-mould and sand, passing this through a half-inch mesh sieve. Care must be taken not to cover the hearts of the plants. Place the plants in a cold frame, which must be kept close and shaded, sprinkling them both morning and evening with soft water during the first week after potting. After this time air may be admitted gradually at first, increasing the amount as the season advances. The plants should be grown as hardy as possible, night air being admitted when the weather permits. Never allow the plants to become crowded, or the result will be weak growth, which renders them liable to attacks from aphid and disease.

#### REPOTTING IS NECESSARY

as soon as the pots are full of roots. Some growers shift the plants at once into the pots in which they are intended to flower, but, as soon as it is advisable to give them an intermediate shift into  $4\frac{1}{2}$ -inch pots. The best position for the frame in which the plants are growing during the summer months is under the north wall of some building. Slugs are very fond of the young tender leaves of the Cineraria, and will, if not prevented, destroy the plants in a very short time. It is always advisable to place a sprinkling of soot on the ashes on which the plants are arranged; this should be renewed from time to time, also the base of the pots examined, as it is here that the slugs frequently hide during the day. When the foliage of the plants suffers from any cause their beauty is greatly impaired, therefore every care should be taken to maintain the same in a clean, healthy condition. Give the plants their final shift when they are ready, using rather more loam of a coarser texture than at the previous potting, and see that the roots

are not dry before they are turned from the pots. Where there is plenty of room a few of the strongest plants may be potted into 9 $\frac{1}{2}$ -inch pots, and these will form very fine specimens, but for general purposes 6-inch and 8 $\frac{1}{2}$ -inch pots are large enough. From the first appearance of the flower-buds well-diluted manure water may be given twice weekly.

#### ROBUST PLANTS MUST BE ENCOURAGED

from the first, and then the culture of the Cineraria is not difficult, but weakly plants are liable to fall a prey to numerous enemies. Mildew is sometimes troublesome, and as soon as it is noticed dust the foliage and soil with sulphur. Fumigation with Tobacco paper was often attended by serious risks to the plants, but now the destruction of aphid can be safely accomplished by using Richard's XL All Vaporising Compound. When the routine treatment is carefully carried out the Cinerarias amply repay for all the care bestowed upon them, and they range among the best of our greenhouse plants for producing a bright display of flowers.

Munden Gardens, Watford. C. RUSE.

[Our illustration is of one of the white-flowered Cinerarias now in their full beauty in Messrs.

James and Son's nursery at Farnham Common, near Slough. We have frequently described this beautiful race in *THE GARDEN*, but never have we seen them in greater perfection than this year. The many houses filled with the flowers are a wonderful picture of intense and refined colour, whites as pure as a snowdrift, deep purple, crimson and blue, either self or with a white centre, an attractive and welcome variation from those which are of one shade. Such a dazzling display we have never seen. The star or stellata Cinerarias are represented by beautiful colours, one, a self crimson, having the brightness of a summer flower.—Ed.]

#### TWO INTERESTING NOVELTIES.

I ENCLOSE two photographs which may interest you. One is a double Cyclamen which turned up in a batch I had last year; the other, and perhaps more interesting photograph, is a drooping form of *Primula obconica*. The flower-stems at first are erect, then, just as the buds begin to open, they bend over until they hang quite down below the pot, and when the stem reaches its full length it bends again close to the flower-head, this time in an upward direction, thus showing the flowers to full advantage. The plant, I imagine, will be a beautiful subject for hanging basket work.

Brahan Gardens, Perth. E. A. STENNING.

#### OVER-FORCED TUBEROSES

ONE of the principal causes of failure with Tuberoses is giving the plants too much heat at the start. It matters little how good the bulbs are; if more than an intermediate heat is given previous to the flower-spikes showing, failure will occur. My first proof I had of this was with a batch of extra large, firm bulbs which were potted early and placed in a stove. Growth was rapid and vigorous, which led me to expect great things; but not more than one in a dozen threw up a flower-spike. My experience is that a bottom-heat of, say, 70°, with a top-heat of 55°, is a safe one till the flowers appear. After this an increase may be given, and the plants assisted at each alternate watering with liquid manure. It is best to subject the bloom-spikes to a cooler house for a few days before cutting them. J.

A PENDULOUS-FLOWERED PRIMULA OBCONICA GROWN BY MR. STENNING.

## THE FLOWER GARDEN.

## THE WATER LILY TULIP.

(TULIPA KAUFMANNIANA.)

ONE of the newer species of Tulips that come from Central Asia is *T. kaufmanniana*. It was found in 1876 or 1877 in Turkestan by Dr. Albert Regel. The illustration gives a good idea of the general effect of a bed of this lovely flower. It resembles nothing so much as a mass of white Water Lilies, and an appropriate English name for it would be "The Water Lily Tulip." It flowers with me from the middle to the end of March, and, if the situation suits it, will come up year after year; in fact, owing to its habit of forming "droppers," it is a little difficult to eradicate when once it has occupied a certain spot. I often see it in gardens grown singly or in twos or threes, but this gives nothing like such an effect as a bold mass. Seen then on a bright sunny day, with every bloom wide open, it is a fine sight. The perianth varies from yellow, through primrose to white, while the three exterior segments have very often a brilliant splash of red on the outside. It grows about a foot high, and the individual flowers are 2 inches to 2½ inches long. Ordinary good garden soil suits it very well. It seeds freely, but I have been told that plants raised from English-ripened seed are not as strong and vigorous as those from abroad.

JOSEPH JACOB.

## A BEAUTIFUL HARDY FLOWER.

(GAURA LINDHEIMERI.)

THIS pretty slender branching species makes a very useful plant for massing in large beds, and it may be grown in the herbaceous border with good effect. Although introduced some fifty to sixty years ago from Texas I do not think, for the above purposes it is grown as much as its merits deserve. From a packet of seed sown at the present time in pans, clean, well drained and filled to within half an inch of the rim with a sweet sandy soil and stood in a gentle warmth to hasten germination, the young seedlings will soon appear, and when large enough prick them off into shallow boxes at about 3 inches apart. Shade them from the sun and encourage the plants to make headway, after which the boxes may be placed in a cold frame until they can be stood out in a sheltered position. The plants should be of nice size for planting out by the end of May. The individual blooms are not much in themselves, but the light feathery stems so abundantly produced form a great relief to the more flat-growing subjects.

## PHLOX DRUMMONDI.

OF late years these have been greatly improved, and the different colours may be used for various purposes with excellent effect. Beds filled with the soft delicate pinks or the richer scarlets as a

groundwork, relieved with other suitable tall-growing subjects, make a very pleasing show. If sown in March and forwarded in heat, the separate colours being kept correctly named, fine plants for bedding out will be ready by the first of June.

Wrotham Park.

H. MARKHAM.

## A BEAUTIFUL ROCK GARDEN PLANT.

(ADONIS AMURENSIS.)

ONE of the earliest rock garden plants to bloom is *Adonis amurensis*, the most recently introduced and probably the least-known member of the family to which it belongs. A native of the Far East, it occurs in Asiatic Russia, on the banks of the lower Amur, in the Islands of Saghalin, Tezo and Northern Nippon, the central island of Japan. A few years ago it was introduced from Japan to our gardens, and where successfully cultivated is much appreciated for its beautiful golden yellow flowers, which appear during the dull month of February. In Japan, *Adonis*

A DOUBLE-FLOWERED CYCLAMEN GROWN BY MR. STENNING.

*amurensis* is largely cultivated, and the flowers enter into the composition of many of the tasteful floral arrangements for which the Japanese are so justly famed. To the Japanese it is known as "Fuku Juso" or "The New Year's Day Plant," and is usually employed in combination with Plum blossom as a decoration for New Year's Day, a date which in the old calendar corresponds to our February 1.

In a horticultural work published in Japan, some twenty-one varieties of this plant are described, the flowers of which vary in colour from white through various shades of yellow to red; some forms are double, and others have petals cut after the manner of *Dianthus laciniatus*. At present only two forms are in cultivation in this country—the type and the one with double flowers, both of which are yellow, and it would appear desirable to introduce some of the other varieties with flowers of a different colour. *Adonis amurensis* is a perennial plant about a foot in height, with finely-divided Fern-like foliage and large flowers of a golden yellow colour.

H. SPOONER.

## TREES AND SHRUBS.

## STACHYURUS PRÆCOX.

AS is the case with many of our deciduous spring-flowering shrubs, *Stachyurus præcox* hails from the Land of the Rising Sun. Two other species are also known, one of which occurs in Central China and the other in the Himalayas, but these have not yet been introduced to general cultivation. *Stachyurus* belongs to the family of which *Actinidia*, *Stuartia* and *Camellia* are other members frequently seen in gardens.

In Japan, *Stachyurus præcox* is very common in mountain forests and at sea level in Yezo, appearing as a graceful spreading shrub some 10 feet high, with flexible semi-scandent branches clothed with thin, oval, lance-shaped, pointed leaves 4 inches to 6 inches long and toothed at the margins. In the axils of the leaves of the young wood spikes of flower-buds form in summer and early autumn, and in very early spring, before the new leaves appear, these develop into drooping racemes 2 inches to 3 inches long, crowded with many bell-shaped yellow blossoms. Although small individually, being not more than one-third of an inch across, these flowers appear in such profusion and so early in the year that they render the shrub decidedly attractive and ornamental. A somewhat sheltered spot should be chosen in which to plant it, as, although it can withstand the cold of our winters, the rains and rough winds of spring often destroy the flowers in exposed situations. H. SPOONER.

## AN UNCOMMON SHRUB.

(EUPTELEA POLYANDRA.)

AT the present time this shrub is almost unknown in England, though it is to be found

in Continental catalogues, and, strange to say, it does not appear in the Kew Hand List of Trees and Shrubs. When better known, however, it is sure to find a place in all good collections of shrubs, especially where those with brilliant autumnal colouring are sought after. From our experience with this *Euptelea*, which extends over several years, it can claim to be quite hardy and is not injured by spring frost, as one would expect it to be from the tender appearance of its young leafage. It is a moderate grower, and would in time apparently make a well-formed shrub neat and refined in growth, with little or no necessity for pruning. I am unable to say whether the flowers are ornamental, as it does not appear to produce these in a young state, but the foliage when mature much resembles some of the smaller-growing entire-leaved Vines, and in the autumn puts on very attractive red and yellow tints. It is a pity more thought is not given to the shrubs which have brightly-coloured foliage in the autumn; there are many of them, and they add greatly to the beauty of the garden. A. E. THATCHER.

## GARDENING FOR BEGINNERS.

## GARDEN WORK WEEK BY WEEK.

**WINDOW GARDEN.**—For immediate displays window-boxes should be planted with Wall-flowers and Forget-me-nots. The Golden Wallflower makes the better contrast. Window-boxes in shady or rather sunless positions should be planted with the Creeping Jenny and some of the better hardy Ferns. In a little while the effect will be most interesting, and throughout the summer they will present a nice green appearance. The Tufted Pansies may still be planted in window-boxes in a fairly sunny position. They must have good rich soil and be planted firmly; their display should commence within a few weeks and continue till the autumn.

**Chrysanthemums.**—Plants of the early-flowering varieties that are well rooted and have been carefully hardened off in a cold frame may be planted in sheltered beds and borders outdoors. These plants should make the garden gay from August onwards. The decorative varieties that are to be grown and flowered in pots should be kept sturdy by admitting air freely to the cold frame. On fine days the frame-lights may be drawn off altogether. Plants in pots measuring 3 inches in diameter, if well rooted—and this can be determined by turning out the more forward plants—should be repotted into others 5 inches in diameter. Make up a compost consisting of three parts fibrous loam, one part leaf-mould, half a part decayed horse manure, a dusting of wood ashes and a good quantity of coarse sand. Well mix the heap of soil, and afterwards repot the plants that are ready, doing this firmly.

1.—OLD WINDOW GERANIUM AFTER WINTERING AND NOW READY FOR CUTTING BACK.

Subsequently return the plants to the cold frame to get established.

**The Vegetable Garden.**—Plant Potatoes now for main-crop supplies. These should be ready for lifting in the late summer or early autumn. Onions for pickling purposes should be sown without delay. A good open, sunny quarter of the garden answers well for this crop. In this case it is better to sow the seeds broadcast,

raking them in carefully. Good soil is not desirable, and beyond keeping the bed free from weeds nothing further need be done. Sow Short Horn or Intermediate Carrots forthwith for successional supplies. These Carrots should be ready in late July. Sow the seeds about half an inch deep and in rows 9 inches asunder. Soil that has been well worked and not recently manured should be selected for Carrots.

**The Fruit Garden.**—At this period early Peach trees on walls outdoors should be disbudded. Thin out the side shoots and rub off those that are developing at right angles to the wall. When the blossoms fade and fall it is a good plan to examine the trees, and, should there be the slightest suspicion of insect pests, dust the affected parts with tobacco powder. Autumn-planted fruit trees may have their prospects improved by pinching back the unripe ends of the shoots. By these means it is possible to make a good foundation for the trees. The young shoots of Grape Vines should be disbudded now. Retain the strongest and most promising of those with fruit in embryo where three or more shoots have developed together.

**Hardy Flower Garden.**—This is a busy period. Annuals of all kinds if not already sown outdoors should be sown at once. If the seeds be distributed thinly where the plants are to flower, the results in July and August will be quite satisfactory. Among the better annuals may be mentioned the Larkspurs, Lupines, Malope grandiflorum, Candytufts, Shirley and other Poppies, Nasturtiums, Sweet Peas, Nigella hispanica, Nemophila insignis, Eschscholtzias, Saponaria calabrica, Clarkias, Cornflowers and Linum grandiflorum. Sweet Peas that were raised in pots may be planted in their flowering quarters if the plants have been properly hardened off. A pot with five to six seedlings will suffice for one clump. The clumps should be about 3 feet apart in rows, and the rows about 4 feet asunder. Take out the soil 18 inches deep and fill in two-thirds with well-rotted manure. Return the garden soil, level and then plant each potful of Sweet Peas in the centre of the clump. Insert small stakes for their support when they are planted. Those who prefer the Sweet Peas in rows should take out a trench as for Celery, filling this in in the same way as advised for the clumps, plant a double row of the Sweet Peas so that the plants are arranged alternately near the sides of the trench and observe a distance of at least 6 inches, or preferably 9 inches, between each plant. By these means beautiful Sweet Peas may be grown and the plants come into flower in late June or early July.

**The Greenhouse.**—Those who desire an early display of Primulas should sow seeds of the Chinese varieties at this time. The resulting plants should be in flower in the midwinter. For successional displays sow in May and June to flower in January and February next year. Loam and leaf-mould in equal parts, and these passed through a fine sieve, and the free addition of coarse silver sand will make a suitable compost if well mixed. Fill this in in nice clean seed-pans and make fairly firm. Make the soil moist by allowing water to percolate through the hole in the bottom of the seed-pan. Sow the seeds thinly and cover with a fine layer of dry soil. Cover with a square of glass and place in a temperature of from 55° to 65°. D. B. C.

## STANDARD TRAINED WINDOW GERANIUMS.

Though the Zonal Geranium is the greatest of all favourites of the window gardener, it is rarely

that one sees it trained in what is known as standard form, viz., the form shown in the illustrations. And yet it is eminently adapted to this mode of training; it forms a somewhat unique window ornament when so trained, and, moreover, makes a capital screen. The plant illustrated made such a screen for several years in a Berkshire cottage window, which it almost filled with leaf and blossom for several months in the year. One point in favour of these standard

2.—STANDARD GERANIUM 2½ FEET HIGH IN WINDOW: RESULT OF PRUNING FIG. 1.

Geraniums for windows should not be overlooked, and that is that they fill the upper part of the window—a part which is generally left somewhat bare.

To grow one of these plants, one of the strongest of the cuttings struck last autumn should be selected now, and grown on well all the summer, or until it is as high as the cultivator desires. Meanwhile, no side shoots should be allowed to develop, all buds on the stem being rubbed out as fast as they show signs of coming to life. When the desired height is reached, the end of the main and only stem should be pinched out with the thumb and finger, which will leave the plant in possession of several good leaves. From each of these leaf axils a side branch will, or should, issue, and as many of these as are required to form the head of the standard should be retained. Four is a good number. These four shoots may be trained in any way that the owner may fancy, but the best form for a window is, undoubtedly, the fan-shaped, shown in the illustration. After the plant has flowered each year it should be allowed to rest for the winter, keeping its soil then decidedly on the dry side. Early in spring it should appear somewhat like that in Fig. 1, and should then be pruned by cutting back all the shoots made in the previous year to within an inch or so of the point of origination. If this is done each year the plant can be kept in a comparatively small pot, and it will not soon overgrow the window space. A cut-back plant breaking with new growth is shown in Fig. 2, at the stage when it should be tied out, as in Fig. 1. (The late) E. J. CASTLE.

## PROPAGATING CHOICE GLADIOLI.

It is, of course, well known that most, if not all, of the florist's varieties of *Gladiolus* may be propagated by means of spawn, as the tiny cormlets that are produced on the larger corms are called, and, although this system answers very well for ordinary purposes, it has the drawback of several years having to elapse before the plants resulting from these cormlets reach a flowering size. It is also fairly well known that corms possessing two or more eyes can be cut while dormant into as many pieces as there are eyes, with a fair hope of success. Here, again, the cultivator has a difficulty to contend with, some of the dormant pieces refusing to start into growth when planted, or, if they do, the growth made is so weak and unsatisfactory that nothing is gained by the operation. This cutting of the corms will, of course, only be resorted to where it is desired to make the very most of a variety for some particular purpose, as, however successfully it is performed, the flowers for the ensuing season must be forfeited, because, even should any appear, it will be wise to remove the buds as soon as they are seen.

Having a few choice varieties last year that I particularly wished to propagate, I varied the above plan somewhat, with most satisfactory results. Instead of cutting the corms while they were dormant, they were planted whole in a deep box, as shown in Fig. 1, soil containing a good proportion of leaf-mould and Cocoanut fibre refuse being used. The box was placed in a warm greenhouse (45° to 50°) near the glass until the plants had reached the stage shown in the illustration. Some of them had two strong shoots, as shown in Fig. 2, and these I decided to cut, the operation being performed with a clean, sharp knife from top to base, as shown in Fig. 3, taking care to secure one shoot and a number of roots to each portion. The cut surfaces were then dusted with powdered charcoal in the orthodox manner, and the sections potted separately into 3-inch pots, using soil containing one-third leaf-mould and a good sprinkling of sand for the purpose. The plants were kept rather close in the greenhouse for a fortnight, receiving a light syringing overhead daily, and at the end of that

1.—SPROUTING GLADIOLI BEFORE PLANTING.

time they were placed in a cold frame, the pots being plunged in ashes and the plants gradually inured to the open air. After a fortnight or so in the cold frame they were planted in open quarters, and at the end of the season each cut portion had produced a flowering size corm and a number of cormlets.

The corms that only produced one shoot were allowed to remain in the box until thoroughly hardened, this being accomplished gradually to prevent any check to the plants, and then transferred to the open, disturbing the roots as little as possible. Even where propagation is not desired it is a good plan to start choice varieties into growth under glass, blindness being thus usually obviated. The plants take to the treatment very kindly and grow away and flower without any check whatever. It is, of course, absolutely necessary to avoid coddling them at any period of their growth.

This procedure may be regarded by some as very elaborate, but one only devises it for special purposes, the results, as compared with those obtained from cutting the corms when dormant, fully justifying the extra trouble taken. H. E.

## TREATMENT OF ROSES UNDER GLASS.

UNLESS it is the intention of the grower to really force the Roses, care should be taken not to subject the plants, especially those that are in the structure permanently and trained under the roof-glass, to too much artificial heat. Rose trees do not require much artificial heat in spring, and not any in the summer time; they receive sufficient from the sun's rays.

## VENTILATION AND CLEANLINESS

are very important points in the successful cultivation of Roses under glass, and must receive very careful attention. The ventilators should be opened fully except when cold east winds are blowing; then certain ventilators should be opened to admit air without causing a direct draught on to the foliage. From Teas and Hybrid Teas three crops of flowers may be secured every year, so that a number of young shoots will grow more or less in profusion throughout the spring and summer months. If these young shoots become badly infested with aphids, they will get a check and the flower-buds will be malformed. Fumigation on two successive evenings when the weather is calm will clear the foliage of the pests, and, following the fumigation, syringe the trees thoroughly and wash off the dead aphides and their excrecence. It is wonderful how luxuriantly the trees will grow after such treatment. If mildew appears on the leaves, syringe them with soapy water. Gently boil 4oz. of soft soap for twenty minutes in one gallon of water, and then add 2oz. of flowers of sulphur and boil all together for ten minutes longer. Half a pint of this mixture to one gallon of rain

water will be a sufficiently strong dose to use. AVON.

## AUTUMN-PLANTED ONIONS.

A BED of autumn-sown Onions is an important crop in all gardens, and beginners may take them in hand and succeed with this subject, provided they can give them suitable quarters and rich soil of good depth. These Onions are generally sown in late August, although there appears to be a feverish anxiety with some people to begin earlier; but this is quite unnecessary. We will not go into the question of raising the plants just now, but confine our attention to the spring planting of the best plants in the seed-bed. As we have already remarked, the quarters must be deeply dug—it is better to trench the ground—and plenty of good lasting manure worked in. A dressing of soot dug in when the ground is prepared is very beneficial. Before planting the ground, which should be left rough on the surface for a time to become sweet and friable, must be broken up with a fork and then raked over and levelled. Plant these autumn-sown Onions in beds in rows. The rows should be about a foot apart, and the Onions about 9 inches from each other in the rows. If possible, lift each plant with a trowel, so that the roots are not disturbed more than can be helped. Take special pains to plant firmly and evenly, and within a week or two of the planting the periodical hoeing between them must begin. The hoeing must not be continued for more than about a month, as it will then be necessary to give the Onion bed a good mulching with thoroughly rotten manure that has been passed through a coarse sieve. Spent Mushroom bed manure is excellent material for this purpose; that obtained from an old hot-bed will answer equally well. Keep the ground moist all through the growing period, using manure water during their most vigorous-rooting season. Lift the bulbs as soon as the leaves turn yellow or become seared. These Onions do not keep very well, but will last until the later supplies come in. Ailsa Craig, Giant Rocca, Globe and White Leviathan are good sorts to grow.

Autumn-sown Onions may be purchased in the spring from several sources, many of the leading Scotch firms making special provision for supplying the needs of those who do not care to raise them from seed.

2.—GLADIOLUS WITH TWO SHOOTS: A SUITABLE CORM FOR DIVIDING.

3.—THE SAME CORM DIVIDED READY FOR POTTING UP.

## THE TOWN GARDEN.

**GROWING SALADS.**—It is always a matter of surprise to me that more town dwellers do not produce a portion at least of their own salads. I venture to affirm that no matter where the produce is purchased it will not taste as crisp and sweet as that which has been produced in our gardens, and is cut perhaps half-an-hour, or even less, before it is required for use. Assuming that the garden is kept quite free from cats, we can produce our own Lettuces, Radishes, Mustard and Cress, Tomatoes and Water-cress, and a neighbour of my own even went as far as to attempt the culture of Beet and Celery, but I should hesitate to recommend others to follow this example, for the results were hopelessly bad. Except in the case of Tomatoes, all the kinds mentioned can be readily grown without the use of frames, and if these are not at command it is always easy to procure the necessary Tomato plants at comparatively small expense.

**LETTUCES.**—To grow these satisfactorily, the seeds should be thinly sown in seed beds specially prepared for the purpose by incorporating with the top 3 inches or 4 inches of soil an equal bulk of flaky leaf mould or failing that flaky manure. Directly the seedlings are large enough, thinning out should commence, and when the young plants are of suitable size they should be transplanted at about 1 foot asunder or less, according to the variety. Plants left in the seed bed after the position assigned to the transplanted ones is fully occupied will, of course, develop and prove useful. Two splendid Cabbage Lettuces for this purpose are Continuity and Tom Thumb, while of Cos varieties Sutton's White Heart and Paris Green will take some beating. It may be mentioned that if a glut comes and the plants cannot be used rapidly enough as salad, they can always be boiled for use as a vegetable even after they have bolted, but to obviate this care should be taken to make small sowings at fairly frequent intervals.

**RADISHES.**—These are excellent town plants, provided that the soil is in thoroughly good condition, but on poor, badly worked ground they grow so slowly that they are never as crisp and tender as they ought to be. Therefore, let the soil be deeply dug and manured according to judgment prior to being made moderately firm for the reception of the seeds which should be thinly sown. The sowings should be small and made at frequent intervals, and water must be given to keep the plants in constant progress. It will be wise in the majority of gardens to thread the beds with strong black cotton or tanned netting to keep the birds at bay, as I have found that the town sparrow is apt to carry the thinning out beyond a reasonable degree. French Breakfast is an excellent variety.

**MUSTARD AND CRESS.**—These plants are so popular and so largely grown that it is not necessary to give more than a word or two to them in passing. Both grow splendidly either in the border or in boxes, and it is easy to have a supply of young fresh produce throughout the year if it is required. Cress is slower in germinating than Mustard, and the seeds should be sown about three days earlier for the two kinds to be ready for cutting at the same time. In neither case should the seeds be covered.

**WATER-CRESS.**—That this can be easily grown without running water and in any shady corner of the town garden may occasion some surprise, but nevertheless it is a fact. The essentials are good soil that will hold moisture either in boxes or in the open garden, some seeds, plenty of water and a determination that the soil shall never be allowed to approach within measurable distance of dryness. It is due simply to the latter point that failures occur. Seeds are sown in soil that is favourable and the seedlings and plants are watered in the ordinary course in precisely the same manner as other things, but this will not do.

H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### PLANT HOUSES.

**D**ENDROBIUMS that have been kept cooler during the flowering stages will now be making growth and emitting roots around the base. They should be either top-dressed or placed in larger pots and stood in warmer quarters in order to complete their growth. The shading of all houses that require attention should be seen to without delay, as the sun now is daily increasing in power.

**Winter-blooming Plants**, such as Salvias, Eupatorium and Coleus thrysoides, placed in warmth a week or two since, will now have grown enough to take cuttings: a few old plants of Coleus are very useful if grown on the second year, as they make fine heads of bloom. Cuttings taken now will probably do better than if taken sooner, as they get away quicker. Pelargoniums should be kept syringed and those showing flower assisted weekly with weak manure. Pinch later varieties and pot for the last time.

#### PITS AND FRAMES.

Continue to prick out annuals, doing this before they become crowded, or they weaken very considerably. Calceolarias should be kept free from aphids, and pay strict attention to watering, dewing them overhead with a fine spray of soft water and give a weekly watering of soot water.

**Chrysanthemums.**—Continue to pot on those that are ready and stand on a cool bottom.

#### KITCHEN GARDEN.

**Asparagus Beds** should have a dressing of salt, as this will benefit the plants and check weed growth.

**Beet.**—Sow main-crops the end of the week and also Beans and Peas for succession. Sow, where possible, in isolated rows, as these crop much better and the produce is much finer. Scarlet Runners may be sown in pots or boxes for planting out next month. Carter's Emperor is a marvel, both in quality of produce and quantity. Sutton's A1 and Prize Winner are also most reliable varieties.

#### FRUIT HOUSES.

**Vineries.**—Keep the earliest house well supplied with moisture and give a thorough watering with Le Fruitier or Vine manure. Keep all the laterals well pinched back so that the leaves get the full benefit of sun and air. Look over the bunches and see that each berry has enough room to develop. Muscats coming into flower must be kept warmer, and when actually in flower a temperature of 75° by day will not be too much. When Muscats are in good and vigorous health there is no difficulty in getting a good set at this season, though it is just as well to go over the rods and give them a sharp tap about midday.

**Tomatoes in fruit** must have occasional supplies of liquid manure. Successional batches in flower should have artificial setting and be kept somewhat drier; later in the season this does not matter, as the plants get more air and set quite readily. Cut Cucumbers as soon as they are ready, as they weaken the plants if left on later. Keep smaller or younger plants well watered and close to the glass so that these make sturdy growth.

#### HARDY FRUITS.

Sweet Cherries have an abundance of bloom showing. It is a good plan before they actually open to give the trees a good spraying with quassia water so as to prevent aphids attacking them, and a search should be made for these pests frequently so that they can be attacked before

they get a footing, otherwise they are difficult and troublesome to dislodge.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)  
Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

**CLERODENDRON BALFOURII.**—Few stove climbers are more beautiful or showy than this when growing at all naturally. The blossoms are too well known to need describing, and they are very freely produced when the plants are healthy and strongly grown. Various modes of propagation have been tried; taking cuttings of young shoots 6 inches long or less with a heel, and placing them in strong bottom-heat, is a favourite plan with some growers.

**Campanula persicifolia grandiflora.**—How well suited are the varieties of the Peach-leaved Campanulas for pot culture and gentle forcing! For the latter purpose, however, those plants are best where the potting was done early in the autumn and the plants in some degree established and ready for the purpose. I find it a good plan to pot up some sturdy pieces into 7-inch pots now and plunge them outside for a full season. If hard forcing is to be successfully accomplished, then without disturbance and given plenty of liquid manure when growth begins such plants will yield several beautiful spikes of their snow-white flowers.

#### FRUIT UNDER GLASS.

**Figs.**—Trees in active growth will now require more water, and those carrying heavy crops of fruit will need more than usual care. Trees in pots in the earliest house should be liberally treated to manure water every other time of watering. In the case of bush trees, stop and tie out as they require it, while with those trained either on walls or under the roof-glass the young growths should be regulated so that they may not touch each other.

#### HARDY FRUITS.

**Mulching Fruit Quarters.**—The value of annual mulching of all quarters devoted to fruit is not fully appreciated. Good stable or farmyard manure is the best possible dressing for fruit plots, and where lime is deficient in the soil a little of this may be added; but in many soils this element is already quite enough in evidence. Useful as it is, used in due ratio with other substances, it is easy enough to get too much lime in many soils. For stone fruits of all kinds it is especially valuable, and if Peach borders and the soil around Plum and Apricot trees had a little more of it and less humus there would be often more fruitful growth and less fruit dropping at stoning-time.

#### KITCHEN GARDEN.

**Onions** sown in boxes in January will now be ready for planting out, and though they will put up with some little inconvenience in the matter of room, they must not remain much longer in boxes or they will be starved once the roots are so entangled as to cause a bad start. Any that are potted on singly may remain in their pots for another week or two, as they are in no danger and are best planted after the roots have well grasped the soil.

#### FLOWER GARDEN.

**Outdoor Chrysanthemums.**—If an increased number of plants are required, the roots should now be divided and planted in boxes in sandy soil. Every single shoot with a root attached will quickly develop into a stocky little plant if it is to be kept close for a time. The more robust the plants are the greater is the prospect of a good crop of bloom. Plants growing at the foot of south walls will need renovation after the long damp winter we have had.

T. B. FIELD.

(Gardener to Baroness Berners.)

Ashwellthorpe, Norwich.

DAFFODILS AT VINCENT SQUARE.

THERE is no doubt 1908 is a late season for Daffodils. The display on Tuesday, the 31st ult., was small in quantity and rather poor in quality. But as last summer was so sunless and dark, I fear we shall see "want of character" (as the experts generally put it) all through the season. If a bulb has not been properly ripened it cannot do itself justice when the flowering time comes, any more than a runner in a race for which he starts untrained. Again, there was next to nothing before the committee. Four flowers were shown for an award of merit, but none received the coveted honour. These were: Mervyn, a small shapely Emperor; Felicity, an early canary yellow Magni; William Baylor Hartland, a fine, very large and early bicolor; and the tiny, but extremely interesting, White minor (a counterpart of minor, only pure white). The most interesting group was that put up by Mr. Dawson of Penzance. It contained, as his exhibits always do, a number of absolutely new flowers. Judging from the space mapped out for him, he must have expected to stage a great many more than he actually did. The late season and unpropitious weather baffled him. Still, there were some nice flowers. Estelle, a handsome artistic-looking bloom, with a large pale yellow perianth and wide red-edged cup, the whole hung from the stalk, like a spider, supported by its single thread; Althea, a large graceful incomparabilis, with Almond-shaped divisions of the perianth, which was pure white, and a large spreading cup with a broad edge of a taking shade of dull red; Chough, a flower that I saw Mr. Felton looking at very hard, it has a big red cup of curious irregular outline, but the perianth is a little "rough"; Orchard Yellow, one of those flowers betwixt and between the Magnis and Medios, striking on account of its deep yellow colour; Fusee, a large, red flat-cupped bloom, with a yellow perianth; Doreen, very neat, with its Engleheartii type of red-edged cup and a pale primrose reflexed perianth; Nora, a giant Leedsii, with a nice frilled centre; Northern Light, one of my favourite incomparabilis type; and Leonard, a magnificent white Magni, were among those on this stand that took my fancy. The last-mentioned (Leonard) is most distinct, and this is something in these days when we are getting so many nearly alike. It has a very flat "double triangle"-shaped perianth, and a fine, bold trumpet, ivory white, with very little fluting or frilling. Some connoisseurs might think it a little large, and on that account condemn the flower; but to me it seems just right. Miss Currey from Lismore sent over a very pretty exhibit. The individual flowers were nothing very particular, but the whole had a glorious golden effect, which was heightened by the introduction of a few fiery cups, such as Sirius, Flambeau, C. J. Backhouse, Coral, Torch and Topaz. Messrs. Barr and Sons' flowers did not come up to their previous exhibit of the 17th ult., but a big firm like them must have awkward seasons "between times," when good flowers are scarce. Peter Barr was, however, conspicuous, and, though small, in good form.

The collection staged by Messrs. Cartwright and Goodwin was noticeable for two reasons, first, because they are a "brand-new" firm, and, if I mistake not, this was their maiden appearance in public; and, secondly, because they had nearly twenty pots of different varieties as well as a beautiful little lot of cut blooms. It was an excellent start and richly deserved the silver Banksian medal which the committee awarded it. It is evident they have got hold of some exceptionally good things. Mervyn (mentioned before) is a real "show table" flower, and it will be interesting to see it when cut from the open ground; it is a cross between Emperor and Tenby, and early.

Évangeline in the centre was a flower worthy of the place of honour. It was a white Home-spun, but it had a pale yellow cup. This is Irish, but I think it describes what I mean. Felicity, White Lady, Citron, Alton Locke, Glitter and Glory of Nordwijk were some of the others in this fresh-looking group. I must congratulate the new firm on their start.

JOSEPH JACOB.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

FLOWER GARDEN.

**Tulip bulbs (C. C.).**—There is no reason why your Tulips should not bloom next year, providing you have planted them in good soil this season, and give them good culture until the leaves naturally turn yellow. When only one leaf is formed it generally indicates that the bulbs are too weak to flower. We advise you to give the beds a mulching with well-decayed manure, keep all weeds down between the plants and allow the leaves to obtain all the light possible. There is no such thing as male plants in Tulips; the male and female organs are produced in the same flower. Certainly growers can distinguish bulbs that are too weak to flower from those that are strong enough to do so.

**Saxifragas pyramidalis and S. longifolia (E. C. C.).**—The small Saxifragas which surround the parent ones can either be left where they are, seeing, however, that they have some soil put about them in which to root, or taken off and planted separately, either in the rock garden or in pots, now or as soon as the parent plant flowers. If the latter is not going to bloom this season they can be removed at once. If you allow them to remain in a clump together they do not form such handsome rosettes or give such good plumes of flowers, and, as both are perfectly hardy, they can be put on the rock garden quite well. Your large ones not looking healthy is probably due to their being about to flower. The rosettes which bloom are exhausted by the flowering and die afterwards. We may add that you cannot have the true S. longifolia, well named the Queen of Saxifragas, which does not produce offsets, and can only be raised from seeds.

**Moving Crocus corms (E. M. L. B.).** As you have to remove your Crocuses this spring it will be much the best to at once replant them, disturbing them as little as possible. The thing to aim at is to get them to ripen off as naturally as possible. If you put them away in silver sand until the autumn they would probably be too weak to flower next year. We are assuming, of course, that you must for some reason lift them before the leaves naturally turn yellow. Regarding your Daffodil bulbs we are not quite sure what you mean by them being blind. If you mean that they are not going to flower this year this may be because the bulbs are too weak, and we do not advise you to throw them away. Give them good treatment, affording the foliage plenty of sunshine and fresh air, and, above all, do not disturb them until the leaves naturally die down.

They may then be lifted, and providing they are not diseased should be strong enough to flower next spring.

**Treatment of Omphalodes (E. C. B.).**—Sow the seeds in a warm position either in the open or in pots to be transferred bodily to the border when large enough. If the soil of your district is light and warm there will not be much difficulty in growing the plant.

**Planting Iris stylosa (Ard Coille).**—This charming Iris should be planted now if it has done flowering with you, but it may also be planted in August. It should have the sunniest and most sheltered position you can give it, and be among stones if in the open.

**Fungus on Sweet Pea plot (G. E. J.).**—You give us no indication whatever as to what the fungus is like, but assuming that it originates from the manure, we do not think it is likely to harm the Sweet Peas. We advise you, however, as a precautionary measure, to pull or hoe it up as soon as possible.

**Seeds of alpine (Enquirer).**—If you write to Messrs. Thompson and Morgan, Ipswich, for their seed list, you will find many of the free-growing alpine plants enumerated and seeds offered for sale. It is not clear from your letter for what purpose the plants are desired, but doubtless by request the above-named firm would mark their list to suit your requirements. Many good alpine seeds are easily raised from seeds, others require every care. If you care to send fuller particulars, we might be able to give you more definite assistance.

**Planting Hepaticas (Ard Coille).**—These are roots, not bulbs, and they are best planted as soon after flowering as possible. They may be planted later, but do best when planted early. Hepaticas form a section of the genus Anemone, and are sometimes called simply Hepaticas. Correctly, however, they should be called Anemones, and Anemone Hepatica is the true name of the common Hepatica, the large-flowered one from Transylvania, frequently called Hepatica angulosa in gardens, being correctly A. angulosa. An American form is A. acutiloba.

**Information about bulbs (A. E.).**—The various bulbs enumerated by you, in fact, bulbs in general, make their growth after the flowering season is past. We advise you not to disturb your border of bulbs in any way, especially as you have such a miscellaneous assortment therein. If the border has been well dug and the soil is fairly good, it would be, perhaps, the better way to leave it altogether untouched and not lift any of them even when dormant. Treated in this manner there would probably be a few losses, but on the other hand some would be more vigorous than newly-planted ones. In your opinion the soil is rather poor, a thorough watering with weak liquid manure may be given at once and repeated in about a month's time. One effect of leaving bulbs untouched for a second season is that they flower a little earlier than newly-planted ones.

**Diseased Carnations (C. C.).**—The Carnations are attacked by a small nematoid worm named Tylenchus or eelworm of gardeners. They attack the collar of the plant, causing it to swell. There is really no cure. Only a few of the plants sent were attacked. Destroy all affected plants and replant the sound ones elsewhere. The worm in question is microscopic. The millipedes sent merely feed on the decaying tissues of the Carnations, and are not the cause of the decay. Give the ground a good dressing of quicklime after the Carnations have been removed; this will destroy any of the pests left in the soil. If any plants are again attacked, destroy them at once.

**Treatment of Iris reticulata (S. P. B., Birmingham).**—Iris reticulata is not everywhere a success, but it thrives under so many and varied conditions that we advise you to leave yours in the ground to see if they will become permanently established. No glass will be needed over the bulbs, as after the flowering season is past the plants make their growth and perfect their bulbs for another year. In time the foliage dies down, and the bulbs may then be lifted if required. They should not be left out of the ground for any great length of time, and if they cannot be planted within a week or two a very good plan is to lay them in a box and cover with sand. A light sandy loam that is at the same time effectually drained and a warm, sunny position suits this Iris best. Even when established it is often preferable to lift the bulbs every second year and replant them, as it can then be seen if there is any trace of disease about them. As yours were planted only last September, if the conditions are much as above indicated, we advise leaving them undisturbed for another year. The Magnolia would succeed perfectly well under the conditions named by you.

THE GREENHOUSE.

**Bulbils on Aspleniums (Ard Coille).** It is not quite correct to say that when the bulbils form on the fronds of Asplenium bulbiferum the fronds gradually wither and die. We have seen fronds remain quite green for many months after the bulbils appeared. The latter do, however, make the fronds look rather old and dejected, and if one can spare the time, and the bulbils are not wanted, there is little doubt but what the life of the frond would be prolonged were the bulbils picked off as early as possible.

We have no doubt that the Cinerarias you enquire about have been grown in a poorly lighted structure and some distance from the glass. This, together with inadequate nourishment, would make the plants tall and weak looking, and the flowers small and of poor colour.

**Pelargonium leaves diseased (A. C.).**—The Pelargonium leaves are attacked by a fungus which often gives trouble, especially in the case of highly-fed plants or those that have been kept rather close and warm. We should not be surprised if, in the first place, the mischief originated from the attacks of aphides or green fly, as apparently there were traces of them on the younger leaves enclosed. Spraying with a solution of permanganate of potash for the fungus and vaporising for the aphides, with a free circulation of air, will bring about a cure.

**How to grow Caladiums (Enquirer).**—In advising as to the culture of Caladiums we will commence with the present time, when the corms or tubers are either quite dormant or just starting into growth. If they have been wintered in sand, they must be taken therefrom and carefully examined, cutting away any sign of decay that may be visible. A mixture of loam, peat or leaf-mould and silver sand—that is to say, the same sort of soil employed for many stove plants—is very suitable for Caladiums. As these plants require the temperature of a stove, it is very necessary that the soil be taken into the house some hours before using, as a check set up by cold soil is very injurious. Pots from 3 inches to 5 inches in diameter, according to the size of the corms, are very suitable for the first potting, as it is better to shift them when the roots are active than to put them into full-sized pots at once. In potting place a little sand just at the base of the corm, and then press the soil down moderately firm; beware, however, of making it too hard. After being potted, little water will be required at first. The supply must, however, be increased as growth takes place, and when the foliage develops and the roots are active a fairly liberal amount of water may be given. After potting, Caladiums need a structure in which a minimum night temperature of 60° is maintained. This may be 10° or 15° higher during the day with advantage. If the pots can be plunged in a gentle bottom-heat, so much the better. Shading must not be overdone, though from about the middle of April a slight shade during the hottest part of the day will be beneficial. Apart from the water at the roots, a fair amount of atmospheric moisture is very helpful, but particular care must be taken in the use of the syringe, as the young leaves are exceedingly brittle. As the pots get well furnished with roots, a little weak liquid manure should be occasionally given. Caladiums can be brought into a room for three or four days occasionally without injury, provided the leaves are mature and the plants have been gradually hardened a little. During the summer less fire-heat will, of course, be needed, but enough should be given to ensure that the lowest night temperature is not at any time below 60°. Of course, it will generally be higher. In the case of the varieties with massive leaves, it may be necessary to support each leaf with a neat stick. Aphides sometimes attack the young leaves, but they can be destroyed by vaporising with the XL All Vaporiser.

## FRUIT GARDEN.

**Peach tree foliage injured (C. J. N.).**—The injury to the foliage bears a close resemblance to that caused by what is known as Peach blister, but it is unaccompanied by any trace of the usual fungus which is the cause of blister, and therefore we are forced to the conclusion that the injury is the result of sunburn or scald. This is not an uncommon complaint, especially at this early season of the year when the foliage of the Peach is so very tender. The burn is caused by the sun striking on the tree while the foliage is damp and before air is admitted in the morning. The way to prevent a recurrence is to ventilate earlier in the morning; indeed, the safest and best way is to leave a small amount of air on the back ventilators all night, excepting, of course, when the weather is rough and cold.

**Colour for back wall of vinery (J. R.).**—We do not think any material advantage would be derived from having the wall a dark colour. It is true that the wall would absorb more heat coloured thus than it would if white, but the temperature would not be so likely to remain steady. In our opinion there is little to be said for or against your suggestion.

**Shoots of outdoor Peach tree injured (W. D.).**—We think with you that the injury to your Peach tree shoots has been caused by frost acting on gross and immature wood of the previous year's growth. We notice a rather deep wound on the thicker branch, as if caused by rubbing against some hard substance. This has been known to cause a similar injury, especially where the hard substance has happened to be galvanised wire. We should lift and replant the tree early in the autumn. This will have the effect of preventing such strong growth in future.

**Seedling Apple for inspection (A. P.).**—Unless you can improve the flavour of your seedling Apple by grafting it on another stock and by good cultivation, we do not think it good enough to keep. We already have better flavoured varieties.

## MISCELLANEOUS.

**Information about Laurustinuses and Lilacs (Moor Hen).**—To succeed with Laurustinuses and Lilacs you should have your ground well trenched, and in the case of the Lilacs enriched by the addition of manure and good loam. For Laurustinuses you might add a little peat or leaf-mould during the planting operations. You may obtain plants at once, if possible; but, if you are unable to do so before the end of April, leave it until the autumn. When you plant the Laurustinuses, stake each plant carefully, as they are rather bad subjects to establish if allowed to be blown about by wind.

**Insect of the beetle family for inspection (Vinea).**—The insect that you sent is the common cockroach (*Stylophaga orientalis*), and, as you say, it is most destructive to all kinds of vegetation under glass. They delight in dry and warm situations, where they hide during the day, coming out and commencing to feed as soon as darkness falls. At Kew they are a great plague, very fine specimens abounding in the Palm house. The most effective means of destroying them are as follows: Procure some glass jam jars, quarter fill them with sweet oil, and then place them in a slanting position among the plants that the pests attack. The cockroaches will commit suicide in the oil. Or take some pieces of brown paper 2 inches square and place a dab of phosphorus paste about the size of a large Pea in the centre of each. Lay these among the plants in the evening and collect them next morning. A curious thing about this poison is that some nights the cockroaches will eat nearly all of it and on others they will scarcely touch it.

**Loam and sand (Novice).**—True, fibrous loam can be obtained only from an old pasture, because it is the roots of the grasses which furnish the fibre. Where the soil is of a good medium or firm loam, the turf and spit of soil may be from 5 inches to 6 inches thick; where of a rather light or sandy loam, or of a stiff clayey nature, the thickness of the turves should not exceed 4 inches. Any such loam turves should be stacked, grass downwards, for from six months to nine months, if possible, to enable the grass to decay and the soil to be sweetened before using. The sand employed should be sharp, clean, white, quite free from clay, and be used with the loam just as the latter may be stiff or sandy. A stiff loam needs an admixture of one-tenth part sand; a light sandy loam will need one-half that quantity. For seeds and cuttings the proportion of sand has to be greatly increased. The proportions given are for strong potted plants. Certainly fibrous-rooted Begonias need rather more sand than would Fuchsias or Geraniums. Soil thrown up by moles is quite unfit for potting purposes, as it lacks fibre, and, being subsoil, lacks also fertility and sweetness. It is fit only to spread about thinly on grass or other soil. We should prefer using old garden soil to mole-hills, especially if, after being rough screened, there is mixed with it well-decayed leaf-soil, sharp white sand, and a small proportion of stable manure, well beaten up to give fibre. Without fibre soil in pots runs together and bakes so hard that air is excluded and roots cannot run. What you describe as red soil is no doubt what is commonly termed yellow virgin loam. That is the best of all loams for potting. A black soil usually is either peaty or boggy or contains too much sand. Still, you have to make the best use of such soils or loams as may be had in your locality. It is not possible for us to determine whether common pot plants will do best in your native loam or in old garden soil. Why not try them in both mixtures and note the result?

## SOCIETIES.

### THE HORTICULTURAL CLUB. THE TULIP.

AFTER the usual monthly dinner of this club, held at the Hotel Windsor on Tuesday, the 31st ult., under the chairmanship of Mr. W. A. Bilney, the Rev. Joseph Jacob gave an extremely interesting lecture on "The Tulip and its History." The cult, as he pointed out, was one of considerable antiquity, since even as far back as 1554 their beauty was appreciated and recorded by noted botanists of the time, and both Clusius and Gerard refer to them in 1573 and 1597. By 1634, indeed, the Tulip had attracted so much attention and had produced so many varieties in evidence of its peculiar sportive character that the Tulip mania commenced, new forms fetching fabulous prices far and away exceeding even those realised by the rarest Orchids of to-day, one bulb of an unnamed form actually being sold for £5,000. Speculation, indeed, reached the verge of insanity, and it is recorded that two bulbs only of a rarity existing, the owner of one paid a small fortune for the other, which he at once destroyed to render the remaining one "unique." Madness could hardly go further, and it is therefore not a matter for surprise that a reaction followed, so that in 1637 Tulip fanciers of the speculating kind tried to realise, with the result that a "slump" followed, the States General of Holland stepped in and instituted regulations, and by 1638 common-sense had reasserted itself. Eventually, in 1730 to 1740, popular taste turned to American plants and Tulip cultivation fell into the background, but the varieties by this time ran into thousands.

The first double Tulip (*T. Intea centifolia*) is recorded in 1665, and Parrot Tulips came to the fore in 1690. The origin of these appears to be somewhat mysterious, since they agree when in form with no known species. France appears to be the locality where they are first recorded. The curious fact was stated by the lecturer that in a catalogue issued at the end of the eighteenth century the quoted varieties of *Ranunculus* far exceeded those of the Tulip, two bulbs of each of 500 kinds being offered for £30. In 1820 to 1840 there was waged the war between the florist Tulip connoisseurs of the North and South, the former considering the character of the marking to be the first essential and the latter the purity of the flower. The precise shape of the flower was also a vexed question, Glenn fixing it as a cup embracing one-third of a sphere; Groom, another authority, at one-half; and Slater, a third expert, at nine-sixteenths. In 1849 the National Tulip Society was founded and Tulip cultivation was greatly in favour. In tracing the history of the flower up to the present date the lecturer interpolated with the data above cited a number of very interesting facts relating to the introduction of new varieties and species. There is no doubt that we owe the majority to the East, but it appears to be somewhat an open question how far the native Tulips of Italy, France and elsewhere may not have played their part, while curiously enough the wonderfully distinct section of the May-flowering Tulips appears to be due to survivals in old cottage gardens from an unrecorded source. The subsequent discussion was rendered more interesting by the presence of Mr. Krelage of Haarlem and Messrs. Barr, Ware, Wallace and Jenkins, all experts in this particular line. Mr. Drury mentioned a colony of *T. undulatifolia*, a fine scarlet form which he met with in the vicinity of Smyrna, the bulbs being massed in hard, bare, stony ground, the heat of which at midday was so great that the hand could hardly bear it, a point indicating the need of bright sunshine for perfecting the bulbs. Some interesting remarks were made concerning that unique peculiarity of the Tulip, namely, the "breaking," as it is called, of the flower into coloured forms, which are preceded in the seedling, for, it may be, six or seven years, by altogether different and uniform tints so that the breeder's patience is often sorely taxed before he can know what is the result of his sowing. The address was so full of the results of research that it is to be hoped it may eventually take such form as to permit of its publication in the Royal Horticultural Society's Journal. A hearty vote of thanks was accorded to the lecturer and also to Mr. Krelage and the other experts who had contributed to the subsequent discussion.

### MANCHESTER ORCHID SOCIETY.

This society made an earnest effort for extended support and patronage by the ample proportions of their exhibition held in St. James's Hall on the 1st and 2nd inst. The display of Orchids was generally considered the finest ever staged in Manchester, both in bulk and quality, and during the brighter part of the weather the various exhibits were seen to great advantage.

Messrs. Armstrong and Brown, Tunbridge Wells, set up the finest display yet seen in the North, and this fully deserved the society's gold medal and an illuminated vote of thanks awarded. The display was arranged in three half-circles, with a large Palm as a centre for each. The central group contained *Odontoglossums* carrying strong spikes and *Dendrobiums* in variety, and the side groups were chiefly composed of *Dendrobium nobile virgiale*, these being supported by other well-known kinds in quantity. Messrs. Cypher, Cheltenham, also secured a gold medal for a meritorious display, in which *Dendrobiums*, *Odontoglossums* and *Oncidiums* were utilised to great advantage. Messrs. Charlesworth, Bradford, were also awarded a gold medal for a collection of high merit, in which *Miltonia bleiana grandiflora*, *Brassia Cattleya Bradshawe superba*, *Odontoglossum His Majesty* and many others were prominent. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, also received leading honours for a large display of the best kinds, with the addition of a charming display of Carnations, pot Roses and Palms. Messrs. Cuthbush, Highgate, were also deservedly awarded a gold medal for an extensive display of hardy forced plants, in which Lilacs, Azaleas, Rhododendrons, Laburnums, &c., were effectively staged.

The following exhibitors were awarded silver-gilt medals: The Liverpool Orchid Company, Gateacre, for an extensive display, including masses of *Dendrobiums*, *Cattleyas*, *Odontoglossums*, and other kinds; Messrs. Sander and Son, St. Albans, for a small but effective display of *Lidia Cattleya* Empress of Russia, excellent plants *L.-C. Lucia* and many fine types of *Athuriums*; Mr. J. Robson, Altrincham, exhibited a stand in which *Dendrobiums*, *Odontoglossums*, *Cypripediums* and cut Roses were prominent; Mr. W. Thompson, Stone, staged a valuable and interesting collection; Mr. F. A. Ward, Northenden, was well to the fore, chiefly with varieties of *Odontoglossums*; Messrs. McBean, Cooksbridge, had a large display in which *Odontoglossums* were in strong form.

Silver medals were awarded to Mr. E. Ashworth, for choice *Cypripediums* and *Odontoglossums*; Messrs. Frank Dicks and Co., Manchester, for Cinerarias and cut flowers; Mr. J. McCartney, Bolton (two medals) for the competition in the Thompson's cup and Low's cup; Messrs. Moore and Co., Leeds, for Orchids; Messrs. A. J. Keeling and Sons, Bradford, for a collection of Orchids; Mr. R. Ashworth, Newchurch, for *Odontoglossums*; Mr. J. E. Williamson, Stretford, for a small but choice lot of Orchids; Mr. J. Bromlow, Rainhill, for a pleasing lot of *Cypripediums*; and Messrs. Dickson, Brown and Tait, Manchester, for a collection of *Dafodils* and *Primula Kewensis*.

Crown medals were awarded to Messrs. A. Warburton, A. Jensen, Hayward's Heath; and Mr. J. Edwards, Sherwood, for table decoration.

## EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" column a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR OF THE GARDEN, accompanied by name and address of the sender.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## COLOUR IN BEDDING OUT.

It is only by the skilful juxtaposition of colours that flower-beds are made beautiful, for a combination done without care or taste will displease, no matter how fine the varieties of plants. No gardener of to-day would dream of mingling scarlet and magenta, but there are smaller mistakes still made; for example, all flowers described as pink are grouped together, though salmon pink is, in reality, pale or diluted scarlet, and rose pink is of the magenta or carmine family.

### A FEW SIMPLE RULES

may be borne in mind when planning or planting beds. One is that rose pink be accompanied only with crimson, purple, lemon, cream, white, lavender or mauve, except when the pink is exceedingly pale, in which case it looks well with royal blue and blue-violet. Salmon combines excellently with terra-cotta brown, such as the tint of crimson Coreopsis; with indigo blue, such as deep blue Salpiglossis; with lemon, orange, grey-blue, like the tint of the Ageratum or "blue" Asters; and also with maroon-purple, as well as cream and white. Scarlet is gaudy, yet admissible with orange or yellow; indeed, a bed leading up from white through cream, lemon, amber, orange, vermilion, to a deep scarlet centre proves a charming one. Bright blue or blue-violet or blue-lavender look their best with cream or lemon or blush pink or apricot, but can be used with orange, scarlet or rose-pink for very gay effects. Red, purple, mauve and lemon are very pretty together; magenta is made softer in hue by being mingled with cream.

### THE ARRANGEMENT OF COLOUR

is nearly as important as its choice, for too large a preponderance of one tint will spoil the beauty of a bed, while another may be injured by too slight an admixture of colour. For example, a white bed never pleases if there are just a few spots or a thin line of a bright hue, such as scarlet or royal blue in it; this gives a mean appearance, an all-white filling would be far preferable. A bed of royal blue Phacelia campanularia with a narrow edge of a rose-pink flower would not attract much admiration, for the eye would, unconsciously, look for more of the pink. Phacelia plants alternated with rose-pink

Asters will, however, produce a satisfying display. It is interesting to make a close study of all these matters.

Take, for instance, a bed in which is a large centre portion of scarlet, then a wide outer portion of snow white, finally a narrow edge of amber; the colour combination is not faulty, yet it will not actually delight the eye. Take, instead, a bed with scarlet centre mass, encircle this with a broad ring of amber and let the edging belt—not too narrow—be of the white—or, better still, cream—and the display will prove one of the best in the garden. The colours melt softly one into the other, while a ring of orange between the amber and scarlet and one of lemon between cream and amber would yet more improve it.

### THE JUXTAPOSITION OF BEDS

is fully as important as the juxtaposition of colours in any given bed or border. When we survey a lawn we see all the bedding out that is upon it probably; certainly when we walk over the turf we get the effect of several of these beds that lie near together, and if their colours clash we shall not be charmed. A bed of magenta Petunias close by one of scarlet Verbenas will disgust instead of charming the artist's eye. To manage to have beds of many different coloured plants yet keep the garden landscape artistic is not so difficult, however. We can use beds of all-white flowers to separate those of gay ones, or groups of silver, gold or ruddy brown foliage plants. It has been said that a bed of Chilean Beet, Coleuses, Alternanthera and Iresine placed between two typical beds of magenta Petunias and scarlet Geraniums will make them bearable occupants of the same 12 feet of turf.

### FOLIAGE PLANTS IN FLOWER-BEDS

are serviceable for dividing gay tints that would otherwise clash; gold leaves, perhaps, do this best of all, but bright green foliage is as useful as crimson or bronze, and the silver tint of Pinks and Cerastiums has many uses. Carpet-bedding designs invariably contain numerous foliage subjects, and this is the reason they give so subdued and beautiful an effect when seen from a short distance. It is the fashion to object to geometrical patterns, but it may be doubtful whether the present style of filling all beds with blazes of colour has as much to recommend it.

## NOTES OF THE WEEK.

## FORTHCOMING EVENTS.

April 28.—Royal Horticultural Society. Exhibition of flowers, plants, &c. Special show of Auriculas and Primulas, 1 p.m. to 6 p.m. Lecture at 3 p.m. by Mr. Edward White on the "Profession of Landscape Gardening." Admission, 2s. 6d. Royal Horticultural Hall, Vincent Square, Westminster.

April 29.—Royal Horticultural Society. School teachers', &c. examination, 6.30 p.m. to 10 p.m. Royal Horticultural Hall, Vincent Square, Westminster.

## Our Coming Flower Show.—

Several readers have written suggesting that vases should be provided for the bunches of cut flowers, Sweet Peas, &c. at our forthcoming show to be held on July 29. We have pleasure in stating that vases, tabling and dishes will all be provided. Of course, where exhibitors desire to show Roses or other flowers usually shown in boxes these must be provided by the exhibitor, as also must fancy vases required for table decorations.

## Prizes for Agricultural Students.

The Board of Agriculture and Fisheries have received from Mr. Martin Suttén and Sir George Barham, on behalf of the Dr. Fream Memorial Committee, of which the Earl of Jersey was the president, the sum of £200, the income from which will be applied to provide a prize of books to be competed for each year by students in the science of agriculture. So long as an examination is held by the National Agricultural Examination Board for the National Diploma in Agriculture the prize will be awarded to the person who obtains the highest marks in that examination. Owing to the generosity of an individual donor the Board will be in a position to award a sum of £5 as a Fream Memorial prize at the next examination for the diploma.

## American Gooseberry mildew.—

On the 8th inst. Lord Carrington received at the Board of Agriculture a deputation composed of the following delegates from farmers' clubs in Kent: Mr. J. D. Maxted (chairman), Messrs. G. Mount, W. W. Berry and E. S. Salmon (mycologist to the South-Eastern Agricultural College, Wye) of the Canterbury Farmers' Club; Messrs. G. E. Champion, B. Champion and T. Edmunds of the Maidstone Farmers' Club; and Messrs. H. Chapman and S. Lee of the West Kent Farmers' Club. Mr. Maxted, in introducing the deputation, remarked on the seriousness of the possible introduction of the American Gooseberry mildew into Kent, and on the large financial interests at stake in the county. Mr. E. S. Salmon said that since the appearance in England of the American Gooseberry mildew the outlook for owners of Gooseberry plantations in Kent has been one of considerable anxiety. The pest had, to quote the Board of Agriculture's own words, "rendered the cultivation of Gooseberries unprofitable wherever it has appeared, and in some cases impossible." At the last meeting of the Kent County Council a resolution was passed unanimously that an application should be made to the Board of Agriculture for an order (to be issued now) to empower the council, in the event of any outbreak, to order the grower to destroy immediately the diseased bushes, and not to allow the grower the alternative of pruning as at present permitted by the Board's orders issued to affected counties. The Kent County Council passed a further resolution that in all cases of compulsory destruction of diseased bushes, the grower shall receive some compensation; this compensation to be paid out of the rates only, if it cannot be obtained from the Board of Agriculture. Mr. W. W. Berry laid stress on the importance of the matter from the labour aspect. Taking the acreage of Gooseberries in Kent as 6,000 acres,

he pointed out that the wages bill would be not less than £60,000 annually; and asked whether it was not worth while to spend a little in compensation in order to preserve so important a crop to the county. Lord Carrington received the deputation sympathetically, and expressed the desire to do all he could to keep Kent free from the disease. The payment of compensation from Treasury funds was not at present possible, but the whole matter was under consideration. If the means adopted should prove during the course of the summer to have been ineffectual to stop the disease from spreading in the various affected counties, the Board would be prepared to take more drastic steps.

## South-Eastern Agricultural College, Wye.—

A meeting of the governors of the South-Eastern Agricultural College was held at Wye on the 13th inst., Lord Ashcombe presiding. The resignation of the vice-chairman, Mr. George Marsham, was accepted with sincere regret, and Mr. F. S. W. Cornwallis was appointed in his stead. The principal, Mr. M. J. R. Dunstan, reported an attendance of 122 students for the spring term, and that 123 had already entered for the summer term, commencing on June 1. The establishment of professorships of agriculture and agricultural zoology in connexion with London University is under consideration. Members of the college staff are actively engaged in research work in mycology, soil bacteriology, animal digestion, frost protection of orchards and other problems of agricultural and horticultural importance. A troop of the East Kent Yeomanry has been formed of the college students, who will go into camp with the regiment at Aldershot.

## The Western New York Horticultural Society.—

The proceedings of the fifty-third annual meeting of the above important American society, held at Rochester, New York, on January 22 and 23 last, are now published in book form, and include some interesting papers and discussions. An experiment, mentioned by F. C. Stewart, botanist at the New York agricultural experimental station, respecting the gumming or gummosis of stone fruit trees is worth a trial. He stated that Van Hecke, an European investigator, had found that trees that received 3lb. of common salt about the roots were free from the disease, while untreated trees were nearly ruined. This experiment, of course, needs confirming before the treatment can be regarded as an absolute cure, but it is so simple that all who have trees affected should give it a trial. A unique feature of this society are those prizes known as the Ellwanger prizes. They are offered yearly to members of the society for the best maintained private place with regard to ornamental and fruit trees, and for the best private collection of large and small fruits. The whole of the essays are of a practical nature and cannot fail to be of great value to the numerous members of the society. The secretary is Mr. John Hall, Granite Buildings, Rochester, New York.

## CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

## Garden soil, wasps and tetanus.

I observe that a correspondent in your issue of the 11th inst. recommends the application of garden mould as a cure for the sting of a wasp. Though the intention of the writer is doubtless of the best possible, and his advice may seem to him to be fully justified by his experience, may I be permitted to point out the risk and danger of applying garden earth to the punctured skin, for it is well known that soil is the favourite habitat of the tetanus bacillus. Only within the past month the coroner for North-east London (Dr. Wynn Westcott) has held two inquiries on infants dying from tetanus (lockjaw) produced

by the application of Fuller's Earth (which is a real soil); and he informs us he has on an average four such cases every year. The *British Medical Journal* (the 11th inst.) has a paragraph on this important subject, and I think the fact to which I am referring cannot be too widely known.—M. D.

**Destroying wasps.**—I was much interested in your article on wasps a few weeks since, and write to call attention to a remedy for their sting (as also of bees) not generally known. Cut an Onion in two and rub it gently for 10min. or 15min. on the affected part, and the pain is almost entirely relieved. I have tried it after being stung on the lip and on the neck. If stung in the throat, I believe sucking an Onion would be the best remedy that could be used in this dangerous position.—B. ADDY, M.D.

**Naming Sweet Peas.**—I fear I cannot congratulate Mr. Aldersey on his "imaginative powers" re the naming of Sweet Peas, judging by the list of sample names he has given on page 174. Out of the sixteen names three are "Pearls," although two have diverse prefixes. On such a basis he might have had the whole sixteen as "Pearls," giving fifteen out of the number some diverse prefix. But with some others why adopt such odd appellations as Jarjoon, Sycra Lee and Romani Rani, unless Mr. Aldersey is a follower of George Borrow and an admirer of the Romany language? While naming of new varieties will go on I trust those names will be at once simple and pleasing. Few, indeed, will care to adopt a gipsy jargon, but Gipsy, Fairy, Columbine, Coquette, Charmer or Cinderella would all be pretty names and specially suited to such graceful flowers as Sweet Peas.—D.

**Peach tree buds dropping.**—Your correspondent "R. K." (page 172) omits stating whether the trees have been infested with scale or aphid, also whether they have been sprayed with any of the many preparations that are on the market for the destruction of these and other pests. After carefully reading his letter, it appears to me that the roots of the trees are in a healthy condition, and therefore the cause of the disaster must be sought for in the treatment which would externally affect the buds. Spraying the trees during their resting period with a strong solution of caustic alkali may cause the trouble, especially if the operation is delayed until the buds are ready to open. Many experienced fruit-growers are cautious when applying this preparation to their fruit trees, especially to stone fruit, experience having proved that the annual spraying of these trees with caustic alkali may be injurious. Spraying with petroleum emulsion also requires care. The petroleum is a sure incentive to trouble if not thoroughly mixed with the water before being applied to the trees. Both these preparations are excellent when used with discretion for the destruction of the various pests which affect fruit trees, but if used too frequently or too strong the results will prove disastrous. Trees growing under glass are sometimes injured by fumigation. It frequently happens that other plants are cultivated in the same structure as the Peaches; these plants become attacked by aphid, and fumigation is resorted to to clear the pest at a time when the buds on the trees are in a critical condition. This has sometimes been the cause of the trees casting their buds. The two varieties mentioned as being the chief sufferers, viz., *Violette Hâtive* and *Dymond*, are, as a rule, prolific, and possess a hardy constitution when grown in this country. The former has proved to be a suitable variety for forcing, while the latter, owing to its hardiness, is generally recommended as a suitable Peach for outdoor cultivation, although it may also be successfully grown under glass. It is most essential that the wood of Peach trees be thoroughly ripened during the autumn.—C. RUSE, *Munden Gardens, Watford.*

**The cat nuisance.**—Your correspondent "S. G. G." asks for a means of preserving his plants from the ravages of cats. If he procures some short pieces of Holly with about two or three dry or withered leaves on and sticks them between his plants about 8 inches or 9 inches apart, the cats will soon leave him in peace. This is an old remedy and usually proves effectual when all else fails.—S. MARTIN, *Clarewood Lodge, Bickley, Kent.*

**Sowing annuals.**—I read with interest the remarks on page 141 on sowing annuals in borders. After preparing soil in the way there mentioned I have found it a good plan, instead of sowing broadcast, to mark off stations with small sticks about 18 inches long, and sow a few seeds round each stick, cover up with the prepared soil, and the sticks may then be used for carrying the strands of black cotton as a protection against birds. It is surprising the number of clumps one can sow in this way from a small packet of seed. The germination can be watched more closely, which is in itself a pleasure to the enthusiast, and should heavy rains cause the soil to cake a small Canterbury hoe may be used between the stations with safety, the seedlings being finally thinned to one at each stick.—G. NICHOLLS, *Bletchworth.*

**Sowing Mistletoe seeds.**—May I point out a little error your contributor of "Sowing Mistletoe," in the issue for the 21st ult., makes re "As the male and female flowers are produced on separate plants, one of each at least is necessary to secure a crop of berries." According to George Nicholson, "the flowers are dioecious or monoecious," and this is forcibly illustrated here at York, where one may at any time see a nice piece on an Apple, worked from berries originally placed in an incision in the bark and at present carrying berries, although quite alone and a great distance from any other plant, the nearest one also carrying berries. This is growing among other trees half a mile away—proof, I think, that male and female flowers are carried on one plant.—T. C. [It is true that Nicholson refers to the whole genus as being dioecious or monoecious, but he makes no special reference to the common Mistletoe (*Viscum album*), which is generally considered to be dioecious, that is, female flowers are produced on one plant and male on another, hence our correspondent's letter is most interesting. Perhaps he will kindly send flowers when the plant is flowering.—ED.]

**Daffodils for early work.**—At the close of some remarks upon the early Daffodils at Vincent Square on March 17th, the Rev. Joseph Jacob observes: "I could not help thinking how much we have to learn about which are the best sorts for early work in the end of January and February." If this passage applies rather to recent introductions, there is not only much truth in it, but for the amateur who has a large assortment of varieties at his command, a very wide field for experiment, and not a few surprises to boot. Such surprises will ever be of a two-fold nature, and there will be, doubtless, as many prizes awaiting discovery as there are blanks to record. The latter term may require a little explanation, as the "blanks" do not of necessity represent the absolute failures, but rather those varieties which, not expanding kindly, obviously impress the experimenter with the fact that the artificial heat has in their case been misapplied, and, in reality, is irksome in the extreme. What is required in a forced flower of a Daffodil is a characteristic bloom, not an undersized or miserable representative, around which even well-informed men will either speculate rashly or hesitate as to its identity. With good bulbs and rational treatment, the variety that will force at all is often enough a superior thing to its fellow in the open air, and points of interest of beauty and refinement are revealed of which the ordinary observer previously had little or no knowledge. Quite

apart from the early start, which is essential always, and the season of preparation for rooting under ordinary conditions in the open air, there is a further need for care and discretion when bringing in the pots to the greenhouse and the immediate treatment bestowed. Fresh from the plunging bed not a few err in subjecting the pots of bulbs to over-dry conditions, and these, if long continued, are sure to militate against success. Then, again, inadequate supplies of moisture are responsible for many indifferent results in forcing all bulbous-rooted things, and there are other items of culture of equal import. The period of flowering in the open air is by no means a reliable guide as to their behaviour when being forced. Some, indeed, as the common Lent Lily (*N. pseudo Narcissus*), *N. biflorus* and the May-flowering *N. poeticus*, refuse to appear above the soil even after weeks of forcing treatment, and will appear at their usual time after the pots are again turned into the open air. *N. poeticus ornatus* is most impatient of heat, and if too early applied the variety is distinctly sulky, and a later introduced batch will often precede the first in flowering. Few would expect that Horsfieldi, Empress and grandis, flowering in the order given, in the open, would come altogether when being forced, and not infrequently the latter is the first to expand. *Maximus* forces well, too, but its shyness is proverbial. *Albicans*, *cernuus* and *C. pulcher* are easily forced, and in this state are more chaste and beautiful than ever. *Barrii conspicuus* is far more beautiful when grown under glass and comes well and early. Chaste and elegant are terms easily applicable to the typical *Leedsii* and *L. superba*, and if not suited to market work, they are very dainty and graceful when seen in the sitting-room. Other forms of *Leedsii* also respond very readily.—E. JENKINS.

**Sweet Pea streak.**—What is this disease commonly called streak in Sweet Peas? I am of opinion that various causes of failure are, and will be, put down to this rather remote and insidious disease until a definite diagnosis can be given. The writer of this note noticed a rather peculiar circumstance in connexion with a row of Sweet Peas in a garden in which he was serving several years ago. This particular row was intended for supplying cut flowers late in the season and the seed was not sown until the end of April. An ordinary drill was prepared and the seed sown in the usual manner, perhaps rather thicker than is now customary. The seed quickly germinated and the plants grew apace. Supports were afforded in the shape of pea-sticks. The plants still grew and remained perfectly healthy until they were about 3 feet in height. At this their growth stopped, although to all appearances they remained healthy for some time. Every effort was made to induce the plants to grow, but without success. After remaining in this condition for a few weeks, a cream-coloured stripe was discernible running the entire length of the stems, otherwise the plants were quite green, and a stranger would not notice anything wrong with them. In this condition they remained throughout the season until cut down by frost. Was this the streak disease? I have not seen this peculiarity since, but I have frequently seen flowers striped during a spell of cold, wet weather, and have heard of this being caused by "stripe disease." Cold, heavy soil requires an abundance of leaf-mould, road-scrappings, &c., incorporated, if Sweet Peas are to be grown really well. I am inclined to think that wet, heavy soils, with the addition of grubs that attack the roots, are often the cause of disease.—C. RUSE.

**Birds plucking Primula and Polyantha blooms.**—Can you or any reader suggest any way of preventing chaffinches and greenfinches from picking off the flowers of *Primulas* and *Polyanthus*? Black thread will deter sparrows, but other birds seem to care nothing for it.—FESTINA LENTE.

## TREES AND SHRUBS.

### THE HEATH GARDEN.

OUR native Heaths may be classed among the most beautiful members of the British flora, and they and one or two allied plants are responsible for some of the most gorgeous natural effects imaginable. Everyone can call to mind the showy nature of wide expanses of Heather and Ling spreading over hundreds of acres of hill-sides and moorlands, while equally lovely sights are produced when these two subjects are seen growing in companionship with the autumn-flowering Gorse (*Ulex Galli*). Although it is impossible to reproduce these effects on Nature's extravagant scale in the garden, it is possible to have very charming pictures by the judicious use of the various Heaths. If the cultivator is unable to copy Nature in the production of broad effects, he scores in the case of variety, for not only is he enabled to collect for his use the several hardy sorts which are found growing wild in our isles, but he has the advantage of a number of exotic ones, the majority of which are extremely beautiful and different in habit and flowers from the British species.

Not only are the hardy Heaths an extremely beautiful group of plants, but they are exceedingly useful, for one and all bloom with the greatest freedom, the flowering period extending over a considerable length of time. Some sorts, in fact, may be found in bloom for four or five months of the year, while with a collection of the various hardy sorts flowers may be gathered at all times of the year. With such a beautiful and free-flowering group, it goes without saying that they are extremely popular, and representatives are rarely seen in gardens where peat loving plants thrive. Some idea may be gleaned of the usefulness of this particular group of shrubs by the fact of several firms of nurserymen making Heaths the principal feature of their trade, while in some large establishments they are propagated extensively for private use. In the Royal Gardens, Kew, during late years considerable use has been made of Heaths, numerous large tracts of ground being covered with the various spring, summer, or autumn flowering sorts.

It is an excellent plan when beginning their culture to form a garden for them and kindred plants, keeping out coarse or strong-growing things which would be likely to rob them of food and moisture. At Kew the custom prevails of planting large masses of Heaths; then, as "dot" plants here and there, rare shrubs are introduced which require light soil and special attention. It is found to be an excellent plan, and several shrubs that are somewhat tender while young have been enticed to grow out of their delicate stage by the protection afforded to the roots and lower parts of the stems by the close-growing Heaths.

If space is no object, when the Heath garden is being laid out it will be found a good plan to form large masses of each section; if, however, space is limited a more enjoyable feature can be produced by planting a large number of sorts rather than a larger mass of one or two varieties. A particularly pleasing group can be formed of the Mediterranean Heath (*Erica mediterranea*) in several varieties. This, when mature, attains a height of 12 feet or 15 feet, but it takes a long while to grow to those dimensions. About eight years of age it may usually be found 3 feet or 4 feet high, and from the age of two years it will have produced its reddish flowers freely. In addition to the type there is a compact dwarf variety called *compacta*, a variety with white flowers and another with glaucous leaves. The tall and short varieties planted in patches are effective, as they give the group an undulated appearance.

The two white-flowered tree Heaths, *Erica arborea* and *E. lusitanica*, are an excellent pair of ornamental shrubs, which collectively, singly or

intermixed with the Mediterranean Heath form very showy groups. The former grows into a very large bush with dark green foliage and innumerable fragrant white flowers, which are at their best during April and May. *E. lusitanica* is distinguishable from the last named by its upright, plumed habit, brighter green leaves and longer, unscented flowers. A good companion for the last-mentioned pair is *E. australis*, a rather straggling plant with large red flowers. It blooms during March and April.

Two excellent dwarf spring-flowering plants are *E. carnea* and *E. mediterranea hybrida*. The former grows into a dense carpet-like mass with red flowers, which begin to open in February and last until May, while the latter grows somewhat taller and has a longer flowering period. It is not uncommon to find flowers open in November, while by February they are in first-rate condition, and continue so until May. It is freer than the ordinary Mediterranean Heath and has a longer flowering period, the flowers of the latter not opening until early March and being all over by the end of May. After the spring-flowering set is over we have a blaze of colour from *E. cinerea*, one of our native species. This is sometimes found but a few inches high and at others upwards of a foot. It always blooms well, the flowers being reddish purple. There are, however, forms with white, red, rose, deep purple and various intermediate shades of coloured flowers. Other Heaths which bloom about the same time are the Cross-leaved Heath (*E. Tetralix*) and *E. ciliaris*. The former may be met with, having red, pink or white flowers, while the blooms of *E. ciliaris* are red in colour. The autumn-flowering section begin to bloom in August, and some of them continue in flower until December if the weather is mild.

One of the most beautiful of this set is the Cornish Heath (*E. vagans*). This grows from 18 inches to 2½ feet high, and bears innumerable pink or light red flowers. Closely-related sorts are multiflora and grandiflora. *E. maweania* is a dwarf autumn flowerer related to *ciliaris*; it is extremely ornamental and bears large quantities of deep red flowers. Possibly the tallest of the autumn-blooming section is *E. stricta*; this is of upright growth and bears reddish flowers. Should space permit, the Ling (*Calluna vulgaris*) could be appropriately admitted into the Heath garden. Of this there are varieties with white, pink and red flowers, while some have golden leaves. In stature some grow but a few inches high, and others 2 feet to 3 feet. The best possible

#### POSITION FOR A HEATH GARDEN

is a hillside on peaty ground, for, although it is not really essential that peat should be present in the soil for their successful cultivation, the best results are usually obtained from ground naturally of a peaty nature. Providing the soil is free from lime or contains it in minute quantities only, it is quite possible to grow first-rate specimens in loamy soil, and anywhere where a *Rhododendron* will grow Heaths may be expected to do the same. Next to peaty ground, light loam or sandy ground will be found the best rooting medium, and this will be greatly improved if it is trenched 1½ feet in depth and a few inches of peat and decayed leaves forked into the upper layer. It is inadvisable to excavate beds to a depth of 18 inches or 2 feet and fill them up with peat. Far and away better results are obtainable if a few inches of peat is forked into the surface soil of the natural ground. Even when lime is prevalent in the natural soil and this has to be removed, it is better to partly fill the bed with sandy soil free from lime than with peat.

The time to plant is not of great moment, any time between August and March being suitable, providing the weather is not very dry or frosty. The plants should be trod firmly into the ground, and as soon as they are planted a good watering should be given, followed by a top-dressing of decayed leaves. One point in the cultivation which is worthy of attention is the cutting back of the shoots after flowering is over. This cutting

back of the branches removes the seeds, and the plants are not impoverished as they would be were seeds perfected. It also has the result of keeping the plants compact.

#### PROPAGATION

is usually effected in two ways—by cuttings or by layering. The former is the most satisfactory method and is productive of the best plants. Cuttings of tiny shoots are made during late summer and early autumn, and are inserted in pots of sandy peat and stood in a close propagating case until rooted. As soon as roots are formed they are hardened off and placed in a cold frame for the winter. About May they are transferred to nursery beds. By frequent attention to stopping, nice bushy plants may be obtained in two years from the time the cuttings were inserted.

Layering may be done at any time, and consists in weighting down branches with pieces of stone into loose soil. The branches should be left undisturbed for twelve months, then be planted in nursery borders for a year previous to being placed in their permanent positions.

While enumerating the spring-flowering Heaths mention ought to have been made of *E. Veitchii*, a tall-growing white flowering plant. Its chief peculiarity is its floriferous nature. It was introduced by Messrs. Veitch of Exeter a few years ago.

#### THE OSOBERY (NUTTALLIA CERASIFORMIS).

The genus *Nuttallia* was so named to perpetuate the memory of Thomas Nuttall, professor of natural history at Philadelphia and author of several works on American botany. There are two species in the genus, one of which, the Osoberry, is cultivated in our gardens. A native of North-west America, *Nuttallia cerasiformis* was discovered by Douglas on the banks of the Columbia River, where it forms a small forest tree about the size of *Amelanchier Botryapium*, which it suggests in appearance. It is also common in moist places in California. Under cultivation it forms a shrub or small tree from 2 feet to 12 feet high, with numerous shoots developed from the base. In early spring, before the leaves appear, it produces large quantities of greenish white flowers in small drooping racemes after the manner of the white variety of *Ribes sanguineum* (the Flowering Currant). It is, however, a member of the Rose family, and closer akin to the Almonds and *Spireas* than to *Ribes*.

The flowers terminate the young growths, which arise from buds on the previous year's wood. They are dioecious, that is to say, the male and female blooms are produced on different plants. The male plant flowers the most freely, but a casual observer will detect little difference in the appearance of the flowers in the two sexes. A critical examination, however, will reveal fifteen stamens with very short stalks arranged inside the calyx tube in the male flowers, while in those of the opposite sex the stamens are rudimentary and the centre of the flower is occupied by five green carpels. The whole plant has a faint Almond-like perfume when in bloom. The Osoberry seldom sets fruit in this country, although its bluish black berries are freely produced in its native habitat. This may probably be due to the fact that the sexes are often isolated under cultivation, or, considering the severity of the weather which is often experienced in early spring, the flowers may be injured by frosts. In its native country the berries, or, more correctly, drupes, are eaten by robins and other fruit-eating birds, though they are most bitter to the taste and have a heavy odour of bitter Almonds. As an ornamental shrub the value of *Nuttallia cerasiformis* lies in its earliness and the freedom with which its flowers are produced. It succeeds in almost any garden soil, and needs little pruning beyond thinning when the branches become too crowded. H. SPOONER.

## THE ROSE GARDEN.

### AMONG THE ROSES.

**A** FEW hints now may be useful to our rosarian readers. Remember only plodding perseverance with patience will overcome all difficulties! Examine now every plant carefully at least once a day till July. See that no dead wood is left anywhere. Be careful how you walk about the Rose beds when the ground is sodden; and every time you trample on the soil for spraying or anything use the hoe afterwards as soon as possible. I always have a "Gayton" rake with me and wherever I have to tread I rake before moving on. In dry weather, where dormant buds do not seem to start into growth, nothing helps them better than a spraying of soft water, only just enough to wet the plants. Do this after the sun is off them in the evenings. It is wonderful how it softens the wood, and so helps the buds to push out. Those varieties which produce a number of flowers at the ends of their shoots want disbudding; remove the buds not required as soon as possible, being careful not to injure those that are retained. The plants receive less check to their root-action if this is done by degrees. Carefully and gradually thin the buds, as by suddenly removing all but one small bud the flowers are never so perfect. It is no good disbudding small decorative sorts such as Dwarf Polyanthas, as it does not make the blooms of these any larger. Never allow too many shoots, as spindling growths never give good blooms, and if the plants become too crowded they have no chance of ripening their wood properly; in fact, it is fatal in many ways, so remember it always pays to remove superfluous shoots. When one sees that the buds are going to send out triple shoots, scratch off or neatly cut away two, always leaving the best one. When hoeing or raking look out for cockchafer grubs, as they will often go for the roots of Roses and damage them. Always be on the look-out for pests of all kinds. Finger and thumb from the first beats anything, even for keeping down aphids; in fact, for maggots or any pests. For example, later on when the cuckoo-spit or spittle fly appears, if you spray or syringe only the froth is washed away, which means the little beasts simply require a lot more sap from the plant to replace it, and if an insecticide is strong enough to destroy this pest, it is most likely strong enough to injure the foliage. The only way is to remove the spittle with the finger and thumb, and then find the insect and kill it. One or two of these sap suckers just a very few days on a shoot means, at any rate, no exhibition bloom on that shoot. Look over all foliage most carefully. If you find any eaten or rolled, hunt for the grub, pinch the rolled leaves and so kill it. Do not try to pick them out, or they will drop to the ground and be lost. If you dislike staining your fingers, wear gloves; but search diligently for all caterpillars in the early stages, so as to kill them when just hatched out. Search for them on the shoots, the foliage, and in the bud. Beanstalks laid about are good earwig traps. Whenever I find an ant's nest I get a dredger of Keating's powder, turn over the nest with a spade or trowel, and smother them with a heavy dusting; this is most efficacious. Look out for suckers; when they do not pull clean out they must be cut right out. Leave any part of them and they will soon grow up again. Q.

#### ROSES WITH EXTRA TALL STEMS.

LOOKING through "London's Encyclopædia" the other day I came across a note of his referring to a tall Briar stock some 15 feet in height and which carried seven different varieties of Roses. This was in a Paris garden. He also found some of similar height at Malmaison and the Grand Trianon. Why cannot we have some of this

description in this country? It would not be impossible, because we sometimes meet with very tall Briars in our woods. There can be no question but that a very tall Briar, budded with, say, Dorothy Perkins or Hiawatha, would be a most glorious feature of any garden when the tree was fully developed and well supported against gales. These wichuraiana Roses might readily be trained to a single stem by using their own growths, and when the desired height was attained allow them to droop over in shower-like profusion of growth, but they would be very slender for some years, whereas a real good Briar would have more staying power. If there are any very tall weeping Roses in the country it would be interesting to hear of them from readers of THE GARDEN. P.

#### PENZANCE BRIARS ON ARCHES.

The delicious fragrance of the foliage of these Roses makes them welcome at all times, and it may not be generally known that they make fine displays when grown upon arches, although such display is very fleeting. They might well be associated with a late-flowering sort if the arches are fairly wide, because one may always restrict these Roses to two or three long growths if it be desired. If only one sort of Briar can be planted I would advise Anne of Geierstein if real vigour is needed. It is one of the most vivid-coloured of the lot, and has a most lusty habit, with rich deep green foliage and reddish spines. For a more moderate growth Lady Penzance is the best, and its charming coppery yellow blossoms always please. Some of the finest specimens of these Briars grown as single bushes or columns that I have ever seen I met with in the garden of that ardent rosarian the late Sir Alexander Arbuthnot. They were truly noble examples of what these Briars are capable of developing into if allowed to grow unrestricted. To keep them together hoops were placed at intervals around the stalwart growths, and I am sure some of these specimens were fully 12 feet in height.

I am persuaded we have not exhausted the possibilities of *Rosa canina* in the matter of yielding some novelties. What a good thing it would be if some more varieties of the type of Una were raised. I consider this one of the loveliest of our early-blooming garden Roses, and no one could dispute this if they saw the fine bed of it at Kew Gardens.

We want some amateur to come forward possessed with the same zeal as Lord Penzance to take hybridising in hand of some of our grand hardy species. The late Mr. Girdlestone had tendencies this way; but, alas! he was taken from us all too soon. I think if one raiser would specialise upon one species, and another raiser on another, and so on, we should obtain more striking results that would enrich our gardens with many excellent novelties. P.

#### ROSE PHILADELPHIA RAMBLER.

I do not know whether last season was exceptional, but the above variety developed a curious trait in the production of green centres to its blooms, which decidedly marred its beauty. Probably this was attributable to the spring frosts, for under glass I do not remember seeing a flower so deformed. It is really a splendid sort for pot culture, although not nearly so free in the production of clusters of bloom as Crimson Rambler, but in richness of colour and exquisite formation of its blooms it is far superior. The crossing of Crimson Rambler with Victor Hugo is said to have given us this Rose; if so, may we not hope for some really fine improvements upon the old Crimson Rambler when crossed with other varieties? There is certainly room for a good brilliant-coloured dwarf sort to supersede Mme. Norman Levasseur, although under artificial light this fine Rose is a great success. We are likely to see this spring forced plants of it in standard form, and they cannot fail to be most useful to the decorator. P.

## THE FLOWER GARDEN.

### THE FLAME NASTURTIUM.

(*TROPEOLUM SPECIOSUM*.)

THERE is no doubt that many people in the South of England experience some difficulty in establishing this handsome Chilean climber. In Scotland and the North of England it may often be seen growing freely without apparent care, wreathing shrubs and small trees with festoons of its elegant, soft green foliage and dainty vermilion flowers. Like many other Chilean plants, it delights in humid surroundings, though not in stagnant moisture at the root.

#### WHERE TO PLANT.

Our Southern climate is too dry and scorching, unless special positions are chosen. Good places, not exposed to drying winds or the direct rays of the sun, are often to be found on the north side of buildings, walls, or hedges. Unfortunately, the latter usually require clipping just when the *Tropeolum* is at its best, and for this

cover them 4 inches deep with the compost. Good roots will soon form two or three shoots each, and as they are of a dark colour and inconspicuous at first, it is well to place a few Birch twigs against them as a protection from disturbance. Watering in dry weather is well repaid by the increased vigour of the plants.

#### SUPPORTS AND TRAINING.

The plant will not cling to the bare wall as Ivy does, but it needs no tying, its leaf-stalks always seem waiting for an opportunity to coil around any available support. We have tried wires strained vertically, wire netting and Hazel boughs fastened to the walls. The strongest and best growth is invariably on the upright wires, but the plant looks far more natural on the boughs or netting, only that the growths become confused and often choke each other. A little attention to training given daily will prevent this. The *Tropeolum* also succeeds well if planted with a commoner creeper and allowed to ramble through it.

#### SUBSEQUENT TREATMENT.

The thicker stems, where slightly protected, will often survive the winter and grow away

A HARDY ANNUAL (*GILIA NIVALIS*): SEED TO BE SOWN NOW.

reason a wall is to be preferred; the soil, too, is moister, and not so likely to be exhausted by hungry roots. It sometimes grows freely on the north side of Hollies and other evergreen shrubs, especially when the boughs extend for some distance close to the ground. A fine Yew hedge at Paddockhurst had, and perhaps still has, its north side beautified by this climber. The clipping of this hedge was deferred until the *Tropeolum* had finished flowering.

#### PREPARING THE SITE.

In both heavy and light soils it is generally necessary to dig a hole about 2 feet deep, the larger the better, and place at least 12 inches of garden refuse or decayed manure at the bottom and tread it in firmly; this gives the long white tuberous roots a cool, moist run in summer.

#### HOW AND WHEN TO PLANT.

Plant in March or April just before growth begins, using a compost of turfy loam and sandy leaf-mould, or, better still, the remains of an old Cucumber bed mixed together. Fill in the hole with the above to within 4 inches of the ground level, lay the roots 1 foot apart each way and

vigorously on the return of warmer weather. An annual mulch of decayed manure is much appreciated and will sustain the plants in good health for several seasons. If they show signs of exhaustion after three or four years take up the tubers, placing them in damp moss to prevent drying, and replant as soon as possible, preparing the ground as advised above. J. COMBER.

*Nymans Gardens, Handcross, Sussex.*

#### A HARDY ANNUAL FOR THE BEES.

(*GILIA NIVALIS*).

This charming hardy annual is not met with nearly so frequently as its merits demand, possibly because it is not very well known. In common with the other *Gilias* it likes a rather light soil with an open position, and given these it will make a most handsome plant, as may be seen by the illustration. It attains a height of about 18 inches, the elegant growths being thickly bespangled with the white flowers, which have an orange marking in the throat. Besides this they are most delicately scented and are great favourites with the bees. Other

VIOLA GRACILIS.

(Shown by Messrs. Wallace and Co. at a recent meeting of the Royal Horticultural Society. Natural size.)

good members of this genus are dichotoma, a dwarf-growing plant with pearly white flowers, thus rendering it valuable for edging; tricolor, with flowers of various hues; and coronopifolia, a little-known plant of Larkspur-like habit, but bearing scarlet flowers.

### SHORTIA UNIFLORA.

This is a Japanese species of much merit, and with much of the floral character of the North Carolina *S. galacifolia*. The whitish pink-tinged blossoms are of large size, and spring rather freely from a miniature, nearly prostrate tuft of small, leathery, entire, cordate, dentate leaves of a ruddy tint, above which the blossoms rise to a height of 3 inches or more. The plant may for cultural purposes be regarded in the same light as the better-known species, while a brief description of it would be a large-flowered *S. galacifolia* of miniature habit of growth. It was shown by Messrs. R. W. Wallace and Co., Colchester, before the Royal Horticultural Society on March 31, when it received an award of merit.

### VIOLA GRACILIS.

UNDER this name Messrs. R. W. Wallace and Co., Colchester, exhibited before the Royal Horticultural Society, on March 31, a delightful Grecian species of *Viola*, with lanceolate, slightly crenate leaves  $1\frac{1}{2}$  inches in length. The plant is singularly free-flowering, and the flowers, of an intense royal purple or violet, have a conspicuous white eye, which renders them decidedly attractive. Whether this is an improved form of the

species first described or not we cannot say; certainly the "dull purplish blue" colour cited as belonging to the original plant could hardly be said to adequately portray that of the delightful plant under notice. We think very highly of Messrs. Wallace's plant, and recall the fact that at the last Temple Show a fine mass of it was among the attractions of this firm's exhibits. The plant illustrated received an award of merit.

### HELONIOPSIS JAPONICA.

THIS is an interesting and beautiful Japanese plant belonging to the Lily family. In habit it is something like the North American bog plant (*Helonias bullata*), but the individual flowers are larger and not so closely set on the stem. The genus *Heloniopsis* is a small one, consisting nominally of four species, spread over Japan, Formosa and Corea. These are all very similar in habit and appearance and might well be all forms of one species. Only two are at present in cultivation, *H. japonica* and *H. breviscarpa*, both from Japan. *H. japonica* has a wide range on the central mountains of Japan at an elevation of from 2,000 feet to 7,000 feet, and was first introduced into this country by Messrs. Veitch through their collector, Mr. Maries. It, however, was a very scarce plant till recently, when fresh importations were received from Yokohama, and it will soon become more plentiful in gardens on account of its early-flowering qualities. As may be seen in the accompanying illustration of a plant growing in a pan in the Alpine House at Kew, the leaves are produced in a dense rosette, quite close to the ground, and are each 4 inches to 5 inches long and about 1 inch wide at the broadest part. When young they

are green, but gradually become tinged with a bronzy shade. The large Scilla-like flowers are produced six to ten together, in a short raceme, at the top of a stem reaching a height of 8 inches to 10 inches. The colour is delicate rose-purple.

### CULTIVATION.

When grown in pans for use in a cold house the plants should be potted up in a mixture of peat and fibrous loam, and grown during the summer months in a shady frame with the pots plunged to the rim in ashes or Cocoanut fibre. Plenty of water is required during the growing season, and the plants should never be allowed to get dry. In the rock garden a shady, sheltered place should be chosen for this plant, such a position that would suit the *Cypripedium*. When suitably placed it is quite hardy, and as the flowers are of good substance they last for a long time in full beauty. The other member of this genus (*H. breviscarpa*) is a smaller-growing plant with white flowers and violet stamens, and was exhibited at a meeting of the Royal Horticultural Society by Messrs. Barr and Sons in March, 1905. A coloured plate of it appeared in THE GARDEN, July 22, 1905. W. IRVING.

## COLOURED PLATE. PLATE 1346.

### HOW TO GROW GLOXINIAS.

AS with many other classes of plants, there has been a considerable amount of improvement effected in the garden varieties of *Gloxinia* within the last few years, and a visit to the summer show of the Royal Horticultural Society held at Holland House will serve to show the great beauty and the wide difference in flower to be found among them. One notable feature is that the strains of the present day are for the greater part characterised by more compact habit and much neater foliage than was at one time the case. The merits of the *Gloxinias* as decorative plants, as cut flowers for the embellishment of the table and other purposes are now so generally recognised that many nurserymen make a special feature of their culture. Among them are Messrs. Peed of the Roupel Park Nurseries, Streatham, from the flowers in whose collection the accompanying coloured plate was prepared.

While *Gloxinias* are, as above stated, largely grown at the present day, there is one item connected with their culture which is very generally overlooked, and that is their value to the amateur with but a single greenhouse in which a miscellaneous collection of plants is grown. There is a widespread idea that a fairly warm house is necessary for the successful cultivation of *Gloxinias*, which is perfectly correct if it is intended to raise seedlings that are required to flower the same year, but given second season's tubers (which can be purchased at a cheap rate when dormant), they can be flowered in a perfectly satisfactory manner if given the same treatment as the tuberous *Begonias*, whose value to the amateur for the embellishment of the greenhouse is now so fully recognised. These tubers will be about the diameter of a halfpenny to a penny, and if potted in the spring into 3-inch or 4-inch pots, shifting them into 5-inch ones when the roots have made a thorough start, they will flower beautifully in the summer. Of course, they will naturally be later than those which have been grown in a warmer structure. With regard to the cool treatment of *Gloxinias* I may mention that for some years we have had a fine late summer display from tubers wintered in boxes

ONE OF THE MOST CHARMING OF SPRING FLOWERS: *SHORTIA UNIFLORA*. (Natural size.)

of dry sand in an ordinary greenhouse, where the temperature in winter frequently went down to 42° to 45°, then in spring they were potted into small pots, being afterwards, when all danger from frosts was over, shifted into their flowering pots and stood in a cold frame. The glass was lightly shaded when necessary and the frame shut up early in order to husband the sun-heat. When grown in this way the plants are naturally of a hardy nature (that is compared with those from a warm structure) and consequently they are valuable for the decoration of the dwelling-house, wherein a few days will do them no harm, as well as for the greenhouse itself.

#### PROPAGATION AND CULTURE.

Gloxinias are, generally speaking, increased by seeds of which superior strains can be obtained from the better-class dealers. The seed, which is exceedingly minute, should be sown in February. A suitable compost is a mixture of loam, leaf-mould and sand, well incorporated together and passed through a sieve with a quarter of an inch mesh. Whether pots or pans are employed, they must be quite clean and effectually drained, and then filled to within half an inch of the rim with the prepared compost. This must be pressed down moderately firm and made quite level, but on no account should it be patted down hard and smooth, as the tender rootlets have a difficulty to make their way therein. Before sowing the seed the soil should have a good watering through a fine rose, and then, while the surface is still wet, sprinkle the seed very thinly. Then lay a square of glass over the pot or pan, and place in a structure with a minimum night temperature of 55°, rising 10° to 15° during the day. No sun should be allowed to shine on the glass, as, if this happens just as the seeds are germinating, the heat generated thereby is apt to kill many of them. When the seed is sown, some cultivators prefer to give it a slight covering of the finest soil, while others use no covering but the glass.

When the young seedlings are above ground the glass must, of course, be removed, and as soon as the tiny plants are sufficiently advanced to handle they must be pricked off into pots or pans. The next shift will be putting them singly into small pots, from which they may be put into pots  $\frac{1}{2}$  inches to 5 inches in diameter. For these later pottings much the same kind of soil may be used, viz., equal parts of loam and leaf-mould with a good sprinkling of sand. It must not, however, be sifted at all but simply pulled to pieces with the hand. As the pots get furnished with roots the plants may be grown cooler, but, as above-mentioned, for growing in an ordinary greenhouse one year old tubers are necessary. After the plants have done flowering and they show signs of going to rest, water must be gradually withheld, and when they are absolutely dormant the tubers may be turned out of their pots, shaken clear of the old soil, and stored in shallow boxes of dry sand.

Propagation other than by seed is carried out by means of leaf cuttings. This is particularly useful for the increase of a plant showing any marked peculiarity, or one that is greatly superior to its fellows. All that is necessary is to take off the fully grown leaves with the leaf-stalk attached to them. Then dibble these upright

into pots of sandy soil, burying the leaf-stalk at such a depth that the blade of the leaf is just level with the surface of the soil. If put in early in the summer and potted off singly when they are well rooted, these leaf cuttings will make nice little tubers the first season.

When Gloxinias are grown in quantity many peculiarities may be noted, one of them being that, as a rule, the purple or purple and white flowers are more vigorous in growth than the spotted ones.

## THE EDITOR'S TABLE.

MORE DAFFODILS FROM MR. PETER BARR.

Mr. Peter Barr, V.M.H., sends us another interesting collection of Daffodil species and

a sweet-scented flower supposed to be of hybrid origin; minor plenius, a small double-flowered variety, the history of which is unknown; the rare little triandria concolor; corbularia, from Obar marshes; and corbularia tenuifolia, a smaller-flowered variety from the Geroz Mountains.

#### AN UNUSUAL CYCLAMEN FLOWER.

Mr. E. Heinrich sends from Planegg, near Munich (Bavaria), a dried flower of a double Cyclamen, purple in colour, with the following note: "With reference to the note under the heading of 'An Unusual Cyclamen Flower' in 'The Editor's Table,' the 4th inst., I send you the flower and leaf of a similar Cyclamen monstrosity which I cut off and preserved last year. As an additional curiosity a second flower-bud is pushing from the axil formed by the leaf and flower." We thank our correspondent very much for sending this curiosity.

## KITCHEN GARDEN

### DWARF BEANS.

VARIETIES of this useful vegetable are very largely grown by amateurs, and when the amount of delicious Beans that can be grown in a comparatively short time and the limited space required for the development of the plants are considered, it will be found a most profitable crop for the owner of a small garden to grow. It is not wise to sow the seed outside until the last week in April, as the young plants are very tender and so liable to be cut down by frost. Even when sown at this time it is often necessary to have some protection at hand to place over the young plants during cold frosty nights, such as are often experienced during May. If the ground has been dug during the winter and is in a fair condition, all that is required to prepare the bed for sowing is to lightly fork over the surface, breaking up the lumps, and then draw out the drills with a hoe, or in the case of a very light sandy soil holes may be made with a dibble and one seed dropped in each hole. The distance of the rows may be from 1½ feet to 2 feet apart, according to the variety, some sorts being more vigorous than others. The distance between the plants in the rows should be from 6 inches to 10 inches. Place the seeds from 3 inches to 4 inches apart and thin out as soon as the rough leaf appears. Cover the seeds with about 1½ inches of soil.

After treatment consists in keeping the ground free from weeds and applying occasional heavy waterings during dry weather. Successional crops may be sown up to the middle of June. If the ground is very dry when late sowings are made, water the drills before sowing, also allow the Beans to soak for about six hours in water; this will greatly assist germination. Late crops are much benefited by a mulching of rotten manure.

Gathering the crop is an important matter. The only way to keep the plants bearing is to gather all the Beans as soon as they are of a suitable size. Two varieties which have been proved excellent in various soils and climates are the well-known Canadian Wonder and the new variety of moderate growth but a prolific cropper called Sutton's Evergreen.

C. RUSE.

THE RARE HELONIOPSIS. (From a photograph taken in the Alpine House at Kew.)

hybrids from his Scottish home. Pallida præcox, from France and Spain, is the largest among them, the trumpet being exceedingly long. Queen of Portugal, a small-flowered canary yellow Magni, is interesting as being a natural hybrid found in Portugal. Spurius is another Magni of medium size, with deep canary yellow perianth and golden trumpet, that is semi-wild in Holland. Golden Spur, too, as found in a semi-wild state in Holland, is very rich in colour, and the flower sent by Mr. Barr had a rather longer trumpet than usual. Henry Irving very nearly resembles the flower of Spurius, except that the perianth is rather paler. Bicolor of Tuscany and Scotica appear to be synonymous, although the first named had a rather longer trumpet. Other interesting sorts were the charming little white-flowered Moschatus, a native of Spanish mountains; odoros rugulosus,

## GARDENING FOR BEGINNERS.

### GARDEN WORK WEEK BY WEEK.

**C**OLD FRAME.—At this period I am constantly taking the more tender subjects from the cool greenhouse and transferring them to the cold frame to harden off. In this connexion Geraniums, Fuchsias, Heliotropes, Begonias and other equally tender plants are arranged with a proper consideration for their height and proportions, so that they are easily overlooked and controlled. By these means I hope to plant outdoors in the vacant beds and borders plants that have been carefully hardened off at the end of May or in the early days of June. Bulbous subjects that have ceased flowering I am transferring from the greenhouse to the cold frame—at least, those that are worth keeping. Violets that have finished their display in cold frames I am now lifting and dividing. By these means it is easy to increase one's supply of plants for next season's display of blossoms.

*The Flower Garden.*—Sweet Peas that were sown in pots quite early in the year are now ready for planting in their flowering quarters, that is, assuming they have been already hardened off in cold frames. If planted in clumps 3 feet to 4 feet apart in rich soil or in holes that have been filled with good well-rotted manure, they should produce blooms in abundance at the end of June or early in July. Should rows be preferred, plant the Sweet Peas 6 inches apart. Hardy annuals of all kinds may be sown now: the resulting plants should bloom in mid-July and later. In some cases the flowering may begin earlier. At this period I am thinking of raising perennials from seed for flowering next year. This is an easy and inexpensive way of obtaining a large number of plants. A bed of soil that has been well worked, in a sunny aspect, will be chosen for the purpose.

*The Greenhouse and Conservatory.*—Glass structures in which there are plants in flower need to be carefully ventilated, as the temperature rises so suddenly at this season. At this period I make a rule to water the plants in the morning and very strong-growing subjects again in the afternoon if they require it. Well-known greenhouse plants, such as Heliotropes, Geraniums, Fuchsias, tuberous-rooted Begonias, Petunias and kindred subjects should receive their final potting for the present season without delay, if they have not already received this attention. From this timely work the plants

invariably come into flower in really good form in June or July and continue in flower for quite a long period. Carnations that I grow under glass I am just now placing in their flowering pots. The border sorts treated in this fashion yield very handsome flowers. I usually put three plants in a 7-inch or 8-inch pot.

*The Vegetable Garden.*—The final planting of Potatoes for this year I am about to complete. Many of the earliest Potatoes need attention in the way of hoeing. Keep the hoe busy between the rows of plants, by these means stirring the surface soil and keeping weeds under; draw the soil round about the most forward plants as a protection against late frosts. Beds of early Onions I am thinning already, and by using the Dutch hoe between the rows find that growth is being promoted. The same remarks apply equally well to Parsnips. For July supplies I am making a sowing of French or Kidney Beans, placing the seeds in pots and boxes and utilising the hot-bed and warm greenhouse for the purpose. Asparagus beds should be made up at once if this work has not been done before. What are known as crowns, and these vary from one to three year old, should be planted in specially-prepared quarters and the work done with the greatest care. Never permit the roots to get dry. Plant 15 inches apart in rows and let the rows be 18 inches asunder.

*The Window Garden.*—Overlook the plants frequently, and, should there be any trace of green fly, sponge with soapy water; this will speedily remove this pest. Dutch bulbs that have finished flowering should be taken outside and planted in spare portions of the hardy border for flowering there next year. As spring-flowering subjects cease blooming the window-boxes should be emptied and got ready with some good soil for summer-flowering plants. It is important that good drainage be provided. Musks and Myrtles should be repotted forthwith, as their growth will soon be very vigorous. Cacti, Aloes and other succulent plants I am now giving more water. D. B. C.

### METHODS OF INCREASING MICHAELMAS DAISIES.

THE perennial Asters that are better known under the common name of Starworts or Michaelmas Daisies are becoming increasingly popular, and deservedly so. Not many years since this subject was generally regarded with a certain amount of disfavour, chiefly because of the rampant growth that characterised most of the then known sorts and also because of the dull flowers the plants produced. All this is now changed. During the last ten to fifteen years great advance has been made; types have been improved upon, and numerous beautiful and fascinating varieties are now to be seen in any fairly up-to-date collection of Starworts. As plants for the hardy border in late summer and throughout the autumn they are invaluable.

*Lifting of Plants for Division.*—There are several methods by which the Michaelmas Daisies may be increased, and the most simple means of doing this is by division. These plants need to be lifted and divided every second or third year at least. Some of the more vigorous sorts make huge roots, and for this reason we would rather divide them annually, or at least every other year. Fig. 1 represents a one year old plant of Aster vimineus Freedom, a variety that is not by any means vigorous, yet the dense, tuft-like growth proves that immense numbers of shoots

will be produced. Assuming the grower desires to increase his stock of plants of this variety, he may, by the aid of a stout knife or other sharp instrument, insert the same well into the crown of the plant, and, with considerable pressure, the old stool will divide up into three or four fairly large pieces, similar to those represented in Fig. 2. The merest novice could deal with a plant in this fashion most successfully, and from such divided pieces grand specimen plants would be developed in the course of the succeeding season. Now, this old plant represents just one species of the Starworts, of which there are

2.—THE SAME PLANT DIVIDED INTO LARGE PIECES.

numerous other popular species, but they may, in almost every instance, be treated similarly.

*Other Methods of Dividing the Old Plants.*—The simple method of division advocated above would hardly be observed in the case of the choicer sorts. Each little piece is too valuable, and for this reason the most has to be made of the smallest pieces. A plant similar to that represented in Fig. 1 could be divided quite easily into thirty or forty, and possibly fifty pieces, if care be observed in carrying out the division. In order to make this quite clear and that other types may be represented, three smaller divided pieces, each representing a different type of Michaelmas Daisy, are shown in Fig. 3. Each of these small pieces will make handsome plants in the flowering season.

*What to do with the Divided Pieces.*—There are several ways of dealing with the pieces into which an old plant has been divided. The larger pieces, as shown in Fig. 2, may be planted at once into their flowering quarters. They should be planted quite 3 feet apart, and the vigorous-growing sorts even 4 feet asunder. The smaller pieces may also be planted direct in their flowering quarters, although it is better to first of all plant them in cold frames to make nice sturdy pieces before placing them in their permanent quarters. Plant them in any fairly light, sandy soil and they will then do well. The choicer varieties we prefer to pot up into 3-inch or 3½-inch pots, as they may then be placed in the cool or cold greenhouse, or be arranged in the cold frames. Fig. 4 indicates how the plants look when potted up. Loam and leaf-mould in equal parts and a dash of coarse silver sand is soil that answers well at this time.

*Increasing the Plants by Suckers and Cuttings.* To produce large and handsome sprays of the Starworts, and to represent them in ideal condition, there is no better method than that of raising plants from sucker-like growths or from cuttings. Any old plant will provide an abundant supply of suckers, as are represented in Fig. 5. These suckers may be inserted in light soil of the kind above described, using boxes, pots, or, what is much better, making up a bed of soil in the cold frame and dibbling in the suckers in

1.—OLD PLANT OF MICHAELMAS DAISY LIFTED FOR DIVISION.

rows firmly. Within a short period these suckers make splendid pieces for transferring to their flowering quarters. The spring and early summer should be chosen for taking cuttings. At this period the old plants are producing numerous shoots, any of which, if detached and made into cuttings, will soon develop into plants that will make the garden beautiful with their display in the early autumn. We prefer to insert the cuttings in shallow boxes or pots, using light, sandy soil, and placing these in the cool greenhouse during the rooting process. A cold frame kept close also answers well.

Good varieties are: *Amellus Stella*, *A. Distinction*, *A. Riverslea* and *A. bessarabicus*. Others are: *Acris*, *cordifolius elegans*, *Novi-Belgii* *D. B. Crane*, *N.-B. Cottage Maid*, *N.-B. F. W. Burbidge*, *N.-B. laevigatus*, *N.-B. densus*, *Ericoides* *Hon. Edith Gibbs*, *E. Enchantress*, *E. Sensation* and the type, *diffusus*, *Coombe-fishacre*, *laevis* *Chapmani*, *l. Calliope*, *Novae-Angliae*, *Lil Fardell*, *Mrs. S. T. Wright*, *puniceus pulcherrimus*, *vimineus* *Cassiope* and *v. nanus*. It is impossible in this note to mention more than just a few of the best.

#### TREATMENT OF POT BULBS AFTER FLOWERING.

MANY amateurs are at a loss to know what to do with the bulbs of *Narcissi*, *Hyacinths* and *Tulips* that have been grown in pots after the flowering is over, and many even throw them away under the erroneous impression that they are worthless. It is true that the bulbs are considerably weakened when grown under these, to some extent, artificial conditions, and it is equally true that they will not be suitable for pot work the following year, yet with careful attention to a few details in their subsequent management very good results may be obtained from such bulbs the following spring.

We must first of all bear ever in mind the fact that whatever flowers are to be produced next spring are formed in the bulb during the present summer, hence it is obvious that to get good flowers then the bulbs must have good treatment after flowering this spring. Many seem to think that a bulb, once it has flowered, may well be left to look after itself; but in reality this is just the period when it needs the most care, that is when a future crop of flowers is desired. In the production of this embryonic flower the

4.—TWO OF THE SMALLER PIECES POTTED UP INTO SMALL POTS TO GET ESTABLISHED BEFORE PLANTING OUTDOORS.

leaves play a very important part, hence to cut off leaves from bulbs, pot ones especially, is to weaken the plant to a considerable extent.

The one thing to aim at is to get the bulbs well ripened, which really means that the tissues are fully packed with food for the use of the roots, leaves and flowers the following spring, and to ensure this the bulbs should be treated as follows: As soon as flowering is over remove the old flower-stem and commence to give the bulbs cooler treatment, a two or three weeks' sojourn in a cold frame being the best course to adopt. After this the plants may go into the open

3.—SOME OF THE SMALLER PORTIONS.

ground, either turning the ball out whole into an out-of-the-way border that is quite open or else laying the bulbs in trenches in a nursery bed. Take care of the leaves, and do not disturb the roots any more than is absolutely necessary. Should the weather prove at all dry afterwards, give good soakings with water at frequent intervals, the object being to enable the leaves to die off as slowly and as naturally as possible. When the leaves have quite disappeared the bulbs may either be lifted and stored in the usual way or else left where they are to flower the following season.

Whichever course is adopted, the ground in which they are to flower should be given a good sprinkling with finely-ground bone-meal in October, digging it into the ground before planting in the case of lifted bulbs and carefully pricking it into the soil between those left where planted out this spring. *Narcissi* treated thus may be used for pots the second year; but *Tulips* and *Hyacinths* usually take longer to regain their vigour. Much will, of course, depend upon how early the bulbs were forced into flower; the earlier they are made to flower the weaker they will be. Bulbs grown in fibre are seldom worth retaining, especially those of *Hyacinths* and *Tulips*.

#### HOW TO GROW SCARLET RUNNERS.

POSSIBLY there is not a vegetable grown that is a more general favourite among amateurs than the climbing Bean known as *Scarlet Runner*, yet, owing probably to its tolerant nature, it often has little good culture or attention given to it. Apart from its value as a vegetable, it is a most useful plant for decorative purposes during the summer months. Planted against an ugly fence, trellis, or in front of any eyesore that may be present in the garden, it will quickly transform it into a thing of beauty, the large green leaves and scarlet or white flowers being freely produced. The plant delights in a deeply-worked soil of a rather cool nature, with a liberal addition of well-rotted manure. Given these, it is not particular as to position. Some of the best crops the writer ever saw were grown under large standard Apple trees, and it will flourish equally well in the open.

Providing the soil was well trenched and manured in the winter, as it should have been, all that will be needed now is to lightly fork it over where the rows are to go. Take out a shallow trench some 4 inches deep and 12 inches wide, and in the bottom drop the seeds 3 inches apart. It is not safe to sow until the second week in May, or even later in Northern counties, as the plants are very tender. Some growers favour a double row, and, where this is desired, the trench should be 18 inches wide, having the two rows 9 inches apart. Where two or more rows are grown, they should be at least 5 feet asunder. After sowing cover the seeds with 2 inches of soil, and then look out for slugs. These pests seem to have a special liking for *Scarlet Runner* seedlings, and in one night they will almost ruin a row. A sprinkling of Kilogrub along each

side of the row, according to the directions supplied with it, will usually prove an unsurmountable barrier; dusting freely with sharp coal ashes will also prove effectual in preventing slugs doing much damage.

As soon as the plants are well up supports ought to be provided for them to climb upon. Poles are undoubtedly the best, and where they can be obtained should be used in preference to anything else. Failing these, stout strings fixed in an upright manner will answer very well. They should be fixed tightly about 6 inches apart, a good plan being to fasten a stout wire or cord to stakes driven into the ground firmly 6 feet apart. These stakes should be at least 5 feet out of the ground, so that other wires or strings can be fastened tautly to them at the top, then the upright strings may easily be tied to the bottom wires and stretched and fastened to the top ones. Market growers never allow *Scarlet Runners* to climb; the tops are kept pinched out as they form, and although good crops are thus obtained the pods are frequently of poor quality, owing to contact with the soil. During dry weather a mulch of well-decayed manure along either side of the row, with copious waterings, will be of great benefit.

5.—SUCKER-LIKE GROWTHS READY FOR INSERTION IN POTS, BOXES OR PREPARED BEDS IN COLD FRAMES.

Good varieties are *Carter's Scarlet Emperor*, *Sutton's Prizewinner* and *Webb's Exhibition*.

#### GOOD POTTING SOILS.

Now that the repotting of greenhouse plants will be in full swing, some consideration of the soil to be used may be of assistance to many who are perplexed over this question. It is the custom of many to advise a different soil mixture for almost every kind of plant, and while this is most likely sound advice, there are very few amateurs who are able to benefit by it owing to the great trouble experienced in getting the different constituents advised. Practically all plants usually grown in greenhouses may be successfully cultivated in one or the other of three mixtures and the majority of them in one. Thus if soil is made up of good loam or decayed turf three parts, leaf-soil or Coconut fibre one part, and sand one part, nearly all ordinary plants such as *Geraniums*, *Fuchsias*, *Carnations*, *Palms*, *Dracaenas* and *Aspidistras* will thrive in it. The Coconut fibre is advised as a substitute for leaf-soil where the latter is difficult to obtain.

Ferns and other plants that like a proportion of peat in the soil will flourish in loam two parts, peat two parts, sand one part. *Heaths*, *Rhododendrons* and allied subjects will need loam one part, peat three parts, and silver sand two parts, with thorough drainage of the pots. Given these three mixtures, the ingredients of which are comparatively easy to obtain, the amateur can undertake to grow any greenhouse plant that is likely to fall into his hands. Feeding, of course, can be resorted to in the case of those plants that need more generous diet, a good general proprietary manure being the safest and most generally useful substance to use.

## THE TOWN GARDEN.

**GROWING TOMATOES.**—There is satisfaction in producing any plants in the restricted area of the town garden, but the man who is clever (or fortunate) enough to grow a fine crop of Tomatoes preens his feathers and speaks with full pride to his friends of the wonderful results which he has achieved. And after all there is comparatively little in it, for given moderately good weather and a modicum of common-sense there are few plants that can be more easily grown on the walls and fences of urban gardens. Provide a south or a west aspect, raise or purchase some sturdy, healthy plants, and one has travelled three parts of the way along the road to success, unless wet weather steps in and is prolonged, as this is a condition of affairs that is the reverse of conducive to success in outdoor Tomato culture either in town or country.

Those who determined to raise their own plants in frames will now have them in 2½-inch pots, and they must be kept sturdy by having them well up to the glass and admitting as much fresh air as possible. As soon as the plants have filled these pots with roots they must be moved on into those 5 inches in diameter, in which they can remain until the end of May or early in June, when they will be planted out. At all periods close attention must be paid to the removal of the shoots that come in the axils of the leaves, as a true cordon is the best form for outdoor culture; no efforts must be spared to keep the plants stocky, so that when they do go out to their fruiting quarters they will carry one truss of fruit and be promising another in the form of flowers. Such stuff as this is certain to bring the utmost satisfaction to its growers.

**PURCHASING PLANTS.**—As it is now too late to raise plants from seeds for outdoor culture those who did not commence earlier must procure their stock of plants by purchase, and I would urge earliness if there is a frame in which they can be kept for about a month. When the purchase is postponed until the day before planting is to be done the plants are often so "proud" through having been grown constantly in a close, warm temperature that they suffer a severe check, and do not thrive nearly as satisfactory as those that have been managed on more rational lines. Buy the plants at once, pot them moderately firmly in a mixture of three parts of loam and one part of leaf-mould, with a little coarse sand, exercise the greatest care not to over water until the roots are working freely in the new soil, admit plenty of fresh air as soon as the plants have got over the shift and excellent material will be at command by the time planting has to be done in about five weeks from now.

**THE BEST VARIETIES.**—A vast amount of importance is attached by some growers to securing certain varieties, but I have come to the conclusion that it is not so much the particular variety as to the manner in which the plants are managed that goes towards success. There cannot, of course, be the slightest doubt that some sorts are superior setters to others, and if they are procurable I should give the preference in the order named to the following: Carter's Sunrise (this variety did grandly even in such a bad season as last year, but the plants were exceptionally good to start with), Comet, Early Ruby and Supreme. All these are, it will be noted, small fruited, but have big clusters.

It may be well to remind readers that it is common for the first truss of fruit to come with the central bloom large and malformed, and when this is the case it should be at once picked out, as it takes far more energy from the plants than it is worth. When planting out the soil of the stations should be deeply and thoroughly worked, and, if the medium is very poor, some sweet manure should be worked into the second spit sufficiently far down that it will not come in contact with the roots in the early stages. H. J. WRIGHT.

## GARDENING OF THE WEEK.

### FOR THE SOUTH AND SOUTH MIDLANDS.

#### FRUIT HOUSES.

**V**INERIES in which early Grapes are swelling fast should be kept well supplied with moisture and liquid manure, at the same time looking over the bunches and noting if any of the berries need removing before the final swelling takes place. Give a little air on the top ventilators early in the morning, and gradually increase according to outside conditions. In bright and warm weather the fires should be shut off quite early, as too much fire-heat may cause an attack of red spider. Should this pest make its appearance, sponge the affected parts at once with soap and warm water. Keep the laterals in check by stopping at every joint. Vines in succession houses should be finally disbudded and tied down gradually.

*Peaches* swelling rapidly should have plenty of water and liquid manure occasionally. Keep the shoots tied in, and do not allow any more to remain than is absolutely necessary. Close the house with a good heat and with a copious syringing. Guard against pests, and should any appear well mix half a pound of sulphur in hot water, and before cold—say, at a milk temperature—well syringe the trees with it, and repeat for several days in succession.

*Strawberries.*—The last batches will now require to be housed, cool treatment being the best. Those plants that have finished fruiting, if wanted for planting purposes, should be placed in cool frames. Strawberries now require water in sunny weather twice daily, and up till the fruit commences to colour should be syringed morning and afternoon.

#### PLANT HOUSES.

*Poinsettia pulcherrima.*—Propagate this by cuttings, choosing good strong shoots about 5 inches or 6 inches long, and if possible take off with a heel to each. The pots should be ready to put the cuttings in before the latter flag. They make roots in a few weeks, when they should be afforded cool treatment.

*Euphorbia jacquiniæflora* should be afforded similar treatment. Both these are charming and most useful winter-flowering plants, and no pains should be spared to bring about the best results.

*Winter-flowering Begonias.*—Rooted cuttings of these should be placed in small pots and another batch put in for succession. Continue to pot *Chysanthemums* as they require it, and more may now be propagated for small decorative work.

*Winter-flowering Carnations* may be potted and afforded cooler treatment. The first batch should now be ready for 4½-inch pots. *Celosias*, *Cockscombs* and *Fuchsias* must be afforded larger pots as they become ready. Keep the occupants of the stove well syringed and sponged as necessary. Large plants that are growing rapidly should have an occasional watering of soot water or manure, but do not feed plants till they have a pot full of roots and really require assistance.

#### KITCHEN GARDEN.

*Beetroot* may be sown now. Carter's Blood Red is a fine main crop. Carter's Perfection, Sutton's Black and Sutton's Perfection are all of the very best quality. A few more rows of the Globe Beet may be sown for early supplies.

*Sow Marrows* in quantity now for main crop, and plant out in frames or under hand-lights the varieties of Bush Marrow; these fruit very early. More Broccoli, Cauliflower, Savoys and Kales may also be sown in an open spot and protected from birds. Sow Lettuces, Radishes

and other salads frequently in order to keep up a good succession. Hoe Cabbages and give a sprinkling of nitrate of soda.

#### FLOWER GARDEN.

Keep all beds and borders free from weeds. Stake any plants that require it before they become disfigured. Sow seeds of Wallflowers, *Myosotis*, *Delphiniums*, *Canterbury Bells* and *Pansies*. Prepare a border quite in the open, and when the seeds are sown sprinkle a little fine soil over them. Examine early Roses on walls, and syringe with quassia extract if the least sign of aphid is seen. Put long stakes to early Sweet Peas and sow again for succession.

W. A. COOK.

(Gardener to Sir Edmund G. Loder, Bart.)

Leonardslee, Horsham, Sussex.

### FOR THE NORTH AND NORTH MIDLANDS.

#### PLANTS UNDER GLASS.

THE sun will now generally afford sufficient heat for plants under glass, and sometimes even shading will be necessary. Abundance of air must be given, and, in proportion to its heat and dryness, an increased supply of water will be necessary, but this must not be given indiscriminately, for plants that are making but little growth will require a much less supply than those that are vigorous.

*Training Plants.*—This will embrace tying and pinching, for they are aids that we employ to ensure the plants assuming and maintaining some clearly defined form. The earlier the several details in connexion with training are put in hand the better, and the results of careful intelligent work are so marked that the work becomes of great interest. The details, of course, vary with practically every kind of plant that is grown.

*Bedding Plants.*—These should now be all cleared out of fruit houses, as the latter will be well on the move and the temperature too high and moist for plants that are likely to be planted out of doors in the course of a few weeks; exception may be made in the case of very lately boxed or potted stuff that can have an extra week inside so as to give it a start.

#### FRUIT HOUSES.

*Strawberries.*—Plants in pots that have the fruit colouring should be placed in cooler quarters. The flavour of fruit from plants thus treated is usually improved, and they carry better when sent by rail or post. Feed plants that are swelling fruit, placing supports where necessary. Thin out the small weak blooms on plants in blossom. Should mildew become troublesome dust the plants over with flowers of sulphur.

#### KITCHEN GARDEN.

*Tomatoes.*—Get all the plants intended for planting outside into 5-inch or 6-inch pots, so that they may be growing on into strong sturdy plants. Place in cold frames, and after repotting keep rather close for a few days, afterwards well hardening them without injury.

*Vegetable Marrows.*—For raising early plants a few seeds may now be sown singly in small pots; plants thus raised must be carefully hardened.

#### HARDY FRUIT.

Attend to newly-grafted trees and replace the clay if it has dropped off; see that young or newly-planted trees are breaking where wanted, and if too many shoots grow, rub away those that are not likely to be required.

*Peaches and Nectarines.*—Most of these will now have passed beyond the flowering stage and will require careful attention with regard to insect pests. If any aphid be seen choose a nice morning and at once set to work with a sprayer or syringe, using some such mixture as a good quassia extract.

T. B. FIELD.

(Gardener to the Baroness Berners.)  
Ashwellthorpe, Norwich.

## NEW ORCHIDS.

**CYPRIPIEDUM BELLATULUM, EXHUMES VARIETY.** This is a very fine form of a comparatively well-known Lady's Slipper Orchid. The plant exhibited was small and only had one flower. This had a rather small dorsal sepal, very broad shell-like petals and a small labellum or pouch. The white ground of the sepal and petals was thickly studded with large circular dots of deep magenta crimson, those on the labellum being much smaller. The foliage is prettily mottled as in the type. Shown by Mr. J. Forster Alcock, Northchurch, Herts. First-class certificate.

**CATTLEYA SCHRODERÆ THE BARON.**

In this plant we have a very fine variety of a good Orchid. The sepals are lance-shaped and pure white, the petals also being white. These are, however, very broad, almost forming a circle, with a sort of crest at the apex. The labellum is rich orange in the throat, then comes a band of deep lilac, and finally a fimbriated edge of white. Shown by Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Tetbury, Gloucester. First-class certificate.

**DENDROBIUM BRYNERIANUM, GATTON PARK VARIETY.**

A most distinct-looking member of this popular family can be claimed for this variety. The plant shown was carrying nine fully opened flowers, as well as a number of buds. The blooms are of medium size and of a very rich uniform yellow, with the exception of a rich orange marking in the throat. The labellum is the most conspicuous part, this being very large, and fimbriated so as to form a sort of network with the segments. Exhibited by Sir Jeremiah Colman, Bart., Gatton Park, Surrey (gardener, Mr. W. P. Bound). Award of merit.

**CYMBIDIUM EBURNEUM GOODSONIANUM.**

New Cymbidiums are not so frequently seen as many other Orchids, hence it is pleasing to find an honoured variety. This plant had numerous long narrow leaves and one flower. The latter was of medium size and white with the exception of the prominent labellum and column. These were heavily tinged with magenta-purple. Shown by Mr. H. S. Goodson, Fairlawn, Putney (gardener, Mr. G. E. Day). Award of merit.

All the above were exhibited at the fortnightly meeting of the Royal Horticultural Society on the 14th inst., when the awards were made.

ANSWERS  
TO CORRESPONDENTS.

## RULES FOR CORRESPONDENTS.

**Questions and Answers.**—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.

## FLOWER GARDEN.

**Primroses and Iris stylosa for inspection** (K. C.).—We have carefully examined your plants, and cannot find any traces of disease. In the case of the Primrose there is a hard, gnarled mass from which a few roots are produced, thus proving that the plant, though small, is very old. We think that the fact of the plants being in your possession for some years, and that you have always increased them by division, is the cause of the trouble, and

advise you to procure an entirely fresh stock. It is quite natural for the Iris to look shabby as yours does, but this ought not to have prevented it flowering. It is quite possible that it has been much too dry at the roots. Plants growing under a south wall often suffer in this respect, even when the soil in an open position is saturated, hence we advise you to very carefully watch it during the coming season. Your treatment otherwise seems to have been correct.

**White form of Soldanella** (T. R. B.).—We have no recollection of a white form of *Soldanella alpina*, while we have a dim recollection of a whitish-dowered variety of *S. pusilla* of years ago. If your plant has flowers of a good white colour it is by no means common; it is a great rarity, and we congratulate you on your find. We hope you may succeed in raising a good stock of it.

**Information about Violets** (W. S. C.).—The frame to which you refer would do quite well, or any ordinary single or double light frame you have to spare would do equally well. These plants require to be first well grown in the open and lifted carefully for planting into frames in September, placing the frame in a sunny position for the winter. Double Violets do not produce seeds so freely as the single varieties, and frequently the large-petaled flowers produce no seed at all, the seed-bearing flowers being either small petaled or devoid of petals, and they usually appear later than the better-formed flowers. This apetalous character would cause them to be overlooked by you perhaps, but they are usually found under the leaves of the tuft. It is doubtful, however, if in your district you would secure much success in this direction.

## TREES AND SHRUBS.

**Dead branches on Monkey Puzzle tree** (Mrs. R. D.).—There is nothing to be gained by leaving the dead branches at the base of an otherwise healthy *Araucaria imbricata*, and you may remove them at once. Have them cut off close to the trunk with a saw, then the cut surfaces smoothed over with a sharp knife and finally coat over the cut with coal tar.

**Cutting back Aucubas** (Co. Cork).—It is quite correct to cut back bare and straggling shoots of Aucubas, but you must do the work at once, then new growth will quickly be formed. You can cut them to almost any height you like, as they readily break and make compact shrubs. You omit to furnish any particulars about your plants, so that we can only give general advice.

**How to prune a Magnolia grandiflora** (Kington).—You may prune your *Magnolia* any time from the middle to the end of April. It is not advisable to prune it hard; simply remove dead wood and any branches that have become overgrown. The cause of the ends of the shoots dying is probably due to late growth last year and insufficient ripening; the wood of many trees last year was not so well ripened as usual, and some trees, more especially evergreens, have been injured this year more than is usual by winter weather and cold winds.

**Treatment of a Clematis** (C. A.).—It is probable that your Clematis will start again from the root-stock. Very often dormant buds are found just above the roots, particularly if plants have been increased by means of cuttings. It is extremely doubtful whether the broken piece will root; you would have stood a better chance with it if you had cut it up into pieces of two joints each and inserted these pieces in pots of sandy soil placed in a warm propagating case. By keeping the soil moist in the pot containing the roots, and by keeping it in your greenhouse, you will stand a good chance of new growth starting, which will doubtless produce flowers during late summer or autumn.

## THE GREENHOUSE.

**Hydrangeas producing blue flowers** (A Reader).—The question of Hydrangeas producing blue flowers has been before now freely discussed in THE GARDEN as well as in other horticultural journals. Some soils will quickly cause the flowers to turn blue, and this is generally put down to the presence of iron in the soil; but, at the same time, the whole matter is still a subject for conjecture. When grown in pots, one of the most successful methods of treatment is in potting to thoroughly mix about a tablespoonful of sulphate of iron with each peck of soil. Then in addition, as the pots get furnished with roots, put a pinch in the water about twice a week. Another way is to mix iron refuse from the blacksmith's shop with the potting soil; but this does not always lead to the desired change of colour. Alum water is

highly recommended by some in order to turn the flowers blue. The alum should be given at a strength of 1oz. to each gallon of water. To prepare the alum it should be crushed and dissolved in a little hot water. This mixture must be given just as the flower-trusses show, watering the plants with it at intervals of eight or ten days, and discontinuing it when the flowers begin to open. If the roots are very dry the plants must be at first watered with clear water, as the alum would at that time prove injurious.

**Crickets in a greenhouse** (A. L. L.).—These creatures generally infest warm, dry places; they dislike damp very much. We have found damping well round the pipes and other places in the house that are likely to become very dry and warm effective in keeping them at bay. They may also be trapped by placing some dry hay or other rubbish in a flower-pot and laying the latter on its side in a dry, warm place. Shake the hay over some boiling water every morning.

## MISCELLANEOUS.

**Grubs in soil** (K. R. Inage).—The grubs you forwarded are those of a fly belonging to the family Bibionidae, and probably to the genus Bibio. The flies may often be found in gardens settling on shrubs and plants; they do not fly well and have narrow black or reddish bodies and rather smoky-coloured wings. At times they appear in large numbers for a few days, usually about the end of this month or the beginning of May. One of the common species belonging to this genus is often called the St. Mark's fly, on account of it generally making its appearance about St. Mark's Day (April 25). They will soon cease to do any injury, as they will become chrysalides. The pests can be killed by making holes rather deeper than where the grubs are working near the plants, say, four to each plant, and placing 1oz. of Vaporite at the bottom of each hole, which should be at once filled in to prevent the gases which are given forth escaping.—G. S. S.

**Weedy tennis lawn** (M. B.).—It is fortunate that the coarse weeds now plentiful on the ground you have had prepared to sow with grass seeds to form a tennis lawn have come up so early; had they not appeared until the grass was sown they would have choked the grass, and one could not have been destroyed without serving the other the same. Now your work should be to have every portion of the weedy ground lightly forked over, to extract and pick off every piece or plant of the Celandine or other weeds; then at once, when the whole is made quite fine and level, sow the grass seed, well rolling it in. Failing to fork over the ground, then use a push or Dutch hoe to cut under all the weeds fully an inch in depth, then have them drawn off with a coarse iron rake, and so leave a fine surface, quite clean and perfectly levelled, ready to sow the grass seed on. If you have not had the ground well trodden over to make it equally firm and level after lifting the Potatoes, that should be done, or later it may settle down into hollows and lumps.

**Books on gardening and agriculture** (Student).—It is, perhaps, hardly in our province as an horticultural paper to recommend books on practical farming and livestock. Still you may find elementary knowledge in agriculture in Tanner's "First Principles of Agriculture," price 1s., and in Muir's "Manual of Dairy Work," price 1s., published by Macmillan and Co., London; also in small books on livestock, horses, cows, pigs and others, each about 1s., published by Upcott Gill and Co., Bazaar office, Drury Lane, London. These cheap books should be mastered before obtaining more expensive ones. "The Book of Vegetables," by G. Wythes, price 2s. 9d.; and T. W. Sanders's "Vegetables and their Cultivation," price 5s. 4d., the former published by John Lane, Vigo Street, and the latter by Messrs. Collingridge, Aldersgate Street, London, should help you so far as vegetables are concerned, and in more general gardening you can hardly do better than obtain "Gardening for Beginners" from the office of this paper. After all, the knowledge acquired by practice and work is indispensable to success.

**"Intensive" gardening** (Mrs. K.).—The term "intensive," as applied to gardening, simply means thorough or high class. Intensive culture is found as well represented in our best gardens as in French gardens. As to any book on the subject in English, we know of none under that appellation, but if you obtained "Vegetables and Flowers: Their Culture from Seeds and Roots," price 5s. 5d., from Sutton and Sons, seedsmen, Reading, you would obtain in that way the best possible instruction in what may be termed high-class culture of vegetables to be had in any book. So far as the French method is concerned, without doubt what is in such case described as "intensive" applies to their system of cultivating salads through the winter under glass cloches, hand-lights and frames, but that is a costly method. That sort of culture is chiefly done in the neighbourhood of Paris or other great towns, where there is a good market and manure is cheap and abundant. The French people are great salad consumers. So much cannot be said of the British people. Necessarily with the French cultivator, because his plots are small, he trenches deeply, works into the ground plenty of manure, uses liquid sewage freely, also irrigates with canals where practicable and crups every foot of his ground to the utmost of his ability. Systems that with very hard work indeed and long hours of labour may give a profit in France, may be unacceptable to our own people.

**Books on various subjects (Enquirer).**—Your query apparently reads carnivorous plants and trees, but from the association of the two we conclude that you mean coniferous plants and trees. If so, by far the best work is the second edition of "Veitch's Manual of Conifers." As a botanical work the "Treasury of Botany" will be a great help to you, and on soils "The Soil," by A. D. Hall, M.A., is a good work. You omitted to stamp your envelope.

**Names of plants.**—H. Fry.—The Violets you send appear to be good flowers of Neapolitan.—J. C. D.—*Saxifraga ligulata*.—D. Edwards.—The Mezeron (*Daphne Mezereum*).—J. A. P., Glastonbury.—*Spiraea coofusa*.—A. K. M.—*Primula denticulata* var. *cashmiriana*. We do not know where you can obtain seeds.—Y. G. Hadden.—1, *Primula denticulata* var. *cashmiriana*; 2, *P. denticulata*; 3, *Matthiola* sp.; 4, apparently *M. sinuata*; 5, *Quercus Ilex* var.; 6, *Primula marginata*. It is most difficult to name such poor specimens.

## SOCIETIES.

### ROYAL HORTICULTURAL SOCIETY.

THE exhibition held on the occasion of the fortnightly meeting, which took place on the 14th inst., was a most comprehensive and interesting one. Daffodils, Roses, and forced flowering shrubs were the most prominent features, and these were exhibited in splendid form by many of our leading growers. Orchids were comparatively scarce, probably owing to the close proximity of the Ghent exhibition. Rock and alpine plants were well staged, and the perpetual flowering Carnation was very largely in evidence.

#### ORCHID COMMITTEE.

Present: Mr. J. Gurney Fowler (chairman), Messrs. James O'Brien, Harry J. Veitch, H. Little, Stuart H. Low, W. Boxall, J. T. Acock, A. A. McBean, John J. Cypher, F. Mentieth Ogilvie, J. Charlesworth, Walter Cobb, H. G. Alexander, W. P. Bound, H. A. Tracey, Gurney Wilson, R. Brooman White, W. Bolton, Frederick J. Hanbury, W. H. White, F. Sander and de B. Crawshaw.

Messrs. James Veitch and Sons, Limited, Chelsea, staged a very pretty little group containing fine plants of *Odontoglossum triumphans*, *O. ardentissimum* lamus, good forms of *O. crispum*, *O. Pescatorei*, two fine plants of the curious *Zygopetalum crinitum*, and a splendid specimen of the well-known *Ada aurantiaca*. All the plants were well grown, and the exhibit was tastefully arranged. Silver Banksian medal.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, staged a nice group containing some well-grown specimens. *Dendrobium barbatulum*, a white-flowered species, the blooms of which are small and densely packed in an arching raceme, *Odontoglossum Pescatorei*, *O. triumphans*, *O. odoratum*, *Dendrobium Niobe* and some choice *Cypripediums* were some that we noted as being specially noteworthy. All were neatly arranged with Maidenhair Ferns. Silver Banksian medal.

From H. D. Goodson, Esq., Fairlawn, Putney, S.W. (gardener, Mr. George E. Day), came an interesting group of well-cultivated plants, including such as *Odontoglossum luteo-purpureum*, *O. crispum* varieties, *O. loochistiense* tracyanum, *O. Adriane*, *Oncidium cuculatum*, *Brassocattleya digbyana-mossie* Wagneri, *Miltonia phalaenopsis* and *Masdevallia ignea*. These were well-grown plants. Silver Flora medal.

Mr. A. W. Jensen, Lindfield, Sussex, staged a well-cultivated group of Orchids, some choice unnamed specimens being among them. We specially noticed a very handsome form of *Odontoglossum crispum*, also some good *Cattleyas*. Silver Banksian medal.

Messrs. James Cypher and Sons, Cheltenham, had a very choice little group of Orchids in the annex. This contained magnificent plants of *Miltonia vexillarium*, a plant of *M. v. virginialis*, the lower petal of which is white; *Dendrobium Apollo-alba*, *Laelio-Cattleya dominianum*, *Masdevallia macrura* and other rare subjects. Silver Banksian medal.

Sir Trevor Lawrence, Bart., K.C.V.O., Burford, Dorset, was awarded a cultural commendation for a magnificent plant of *Dendrobium fimbriatum oculatum*. This plant was about 4 feet high and was covered with its rich yellow fimbriated flowers.

Messrs. J. and A. A. McBean, Cooksbridge, Sussex, had a pretty little group of rare plants, mostly unnamed forms of *Odontoglossum* and *Cattleya*. All were splendidly cultivated. Silver Banksian medal.

#### FRUIT AND VEGETABLE COMMITTEE.

Present: Mr. George Bunyard (chairman), Messrs. J. Cheal, Alex. Dean, H. Parr, A. R. Allan, J. Davis, G. Reynolds, J. Jacques, Charles Foster, W. Barnes, J. Vert, J. McIndoe, George Wythes, W. H. Divers, C. G. A. Nix, W. Poupard and E. Beckett.

Sir E. G. Loder, Bart., Leonardlee, Horsham (gardener, Mr. W. A. Cook), exhibited fifteen dishes of Apples and Pears in a good state of preservation considering the time of year. Of Apples, Scarlet Pearmain, Profit, Mère de Venise (small), Calville Malingre and Winter Pearmain were in the best condition. Pears were represented by two fine dishes of Catillac and Duchess de Nemour.

Davies's Challenge Rhubarb is a new variety raised by Mr. T. E. Davies, The Nurseries, Syderstone, Norfolk. Two plants were exhibited, as well as a number of bunches. One of the plants weighed  $\frac{1}{2}$  stone and the other possessed ninety-two sticks. The stems were very long, solid and of a very bright scarlet hue outside. It is a most attractive variety, and is the result of a cross between Victoria and Mitchell's Prince Albert. Cultural commendation.

#### FLORAL COMMITTEE.

Present: Mr. William Marshall (chairman), Messrs. C. T. Drury, W. A. Biley, R. C. Notcutt, J. Green, T. W. Turner, C. R. Fielder, J. F. McLeod, William Howe, J. Jennings, W. Bain, Charles Dixon, G. Gordon, A. Turner, H. J. Cuthbush, Charles E. Pearson, William Cuthbertson, W. J. James, Charles E. Shea, E. Mawley, R. C. R. Nevill, George Paul and E. H. Jenkins.

Messrs. H. B. May and Sons, Edmonton, filled a long table with flowering plants, such as *Salvia* *Pride of Zurich*, *Roses* *White Pet*, *Mme. Levassieur*, *Princess Ena*, a single pink-flowered *Polyantha* that is very free and charming, the new climbing *Rose Liberty* and other plants. *Cinerarias* of a choice and beautiful strain were also shown. In *Cyrtanum falcatum* Mayi we have a good new form of a very hardy type that should possess much value. Silver Flora medal.

Messrs. J. Cheal and Sons, Crawley, displayed alpine plants with choice shrubs. The hardy things included *Primroses*, *Anemones*, *Aubrietias*, *Saxifrages* and others.

Miss F. W. Currey, The Warren Gardens, Lismore, Ireland, had a rich and beautiful display of *Narcissus*, in which *Apricot*, *King Alfred*, *Lucifer*, *Ariadne*, *Atalanta*, *Lady Margaret Boscawen*, *White Slave*, *Chancellor*, *Firebrand* and others were distinct and good. Silver-gilt Flora medal.

Messrs. R. H. Bath, The Floral Farms, Wisbech, had a display of early-flowering Tulips and Daffodils. In the Tulips, *Hector* (bronzé and white) and *Joost van Vondel* (pure white) were very fine. *Ophir d'Or* (a rich yellow) was also excellent. In the Daffodils, *White Queen* and *Duke of Bedford* were conspicuous. A charming lot of *Chionodoxa* was also noted in the group.

Mr. C. F. Waters, Balcombe, Sussex, showed the American Carnation very finely in company with a few *Malmans* and the new and showy *Marmion*. Bronze Flora medal.

Messrs. William Cuthbush and Sons, Highgate, had a rocky and alpine exhibit, in which many choice spring flowers were seen to advantage. In this way *Puschkinias*, *Primulas*, *Aubrietias*, *Phlox canadense*, *Daphne Cneorum*, *Cypripedium acaule*, *C. pubescens*, *Trilliums* and *Mertensia virginica*, with blue flowers, were all good; while flowering shrubs, such as *Rhododendrons*, *Viburnus*, *Pyrus*, &c., were in good bloom. The same firm also set up a table of Tree Carnations in excellent condition, Robert Craig, Mrs. Lawson, The President and White Perfection being superbly shown. Messrs. Cuthbush also arranged a table of such flowering shrubs as *Azaleas*, *Ericas*, *Boronias*, *Lilacs*, *Roses*, &c. *Rhododendron Smithi aurea* was also noted in good bloom. Silver-gilt Flora medal.

Messrs. Hogg and Robertson, St. Mary Street, Dublin, had an arrangement of Tulips and Daffodils, the latter in choice and good sorts, such as *Lady Boscawen*, *Incognita*, *Countess Cadogan* and *Santa Maria*. Silver Flora medal.

Rose White Dorothy Perkins came again from Messrs. E. R. Cant and Sons, The Old Rose Gardens, Colchester. This new-come is likely to be much in demand in the near future.

The yellow trumpet Daffodil *King Alfred* was superbly shown by Messrs. Carter and Co., Holborn. A bank of flowers staged in solitary examples, with foliage in mass representing a perfectly-natural bed of these things. The flowers and the colour were superb. There must have been several hundreds of flowers in the group.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, brought a most interesting lot of plants, flowering shrubs, &c. *Ribes speciosa*, *Lonicera Maackii*, with white flowers, *Deutzia discolor grandiflora*, *Lilacs*, *Polyantha* *Roses*, *Vitis henryana*, *Viburnum tomentosum* *Mariesii* and *Berberis wallichiana hyperoleuca*, with yellow flowers, were among the things noted. Silver Banksian medal.

A small exhibit of *Rhododendrons* came from Mr. W. G. Vivien, Clyne Park, Blackpool, R.S.O., South Wales.

Mr. Robert Sydenham, Birmingham, exhibited *Lily of the Valley* in moss fibre, also an assortment of Daffodils in the cut state. A most interesting exhibit.

Mr. F. Herbert Chapman, Rye, Sussex, had a few choice Daffodils, of which *King Alfred*, *Duke of Bedford*, *M. J. Berkeley*, *Horace*, *White Queen*, *Will Scarlett* and a pot of triandrus pulchellus were noticeable.

The Guildford Hardy Plant Nursery brought a small exhibit of alpine and early flowers in variety, including *Primulas*, *Fritillaries*, *Saxifrages*, *Doronicum Columnae*, *Drabas*, *Aubrietia* *Dr. Mules* and *Viola munbyana*.

Mr. H. C. Pulham, Elsenham, Essex, had a small rocky exhibit arranged with early flowers and shrubs, *Primulas*, *Anemone vernalis* and *Hepaticas*.

The table of *Roses* from Mr. George Mount, Canterbury, was a great success and one of the features of a fine show.

Mrs. J. Laing, Richmond, Joseph Lowe, Mme. Pernet Ducher, Mme. Abel Chatenay, Mme. C. Ramey, Anna Olivier, La France, Prince de Bulgarie, Mrs. W. J. Grant, *Perle des Jardins* and *Caroline Testout* were among the best in a really superb lot. Gold medal.

Mr. J. Crook, Camberley, Surrey, showed a fine strain of *Polyanthus* in many shades of colour.

Hardy spring flowers from Messrs. Jackman and Sons, Woking, were very pleasing, *Primulas*, *Mertensia virginica*, *Lilacs* and others being very good.

A grand display of *Hippeastrums* came from Mr. Alfred de Rothschild, Ilalton, Bucks, an entire table near the entrance being filled with excellent material. The crimson shades predominated, and the flowers of these were of fine proportions, the plants being well grown and flowered. Silver-gilt Flora medal.

Miss Alice M. Smith, Barnham, Bognor, Sussex, had an exhibit of early flowers, including *Primroses*, *Daisies*, *Anemones*, *Hepaticas* and other plants. The giant white *Daisy* is of large size and said to be excellent for bedding.

Messrs. Barr and Sons, Covent Garden, in addition to a ample display of *Narcissus*, in which many choice sorts, such

as *Bedouin*, *King Alfred*, *Fireflake* and *Peter Barr* were seen, had quite a display of *Darwin Tulips*, *Lenten Roses* and early spring flowers generally, which were much admired. Silver Flora medal.

The Misses Hopkiss, Shepperton-on-Thames, had a pretty exhibit of *Primroses*, *Anemones*, *Trilliums* and other plants.

Messrs. Pope and Son, King's Norton, Birmingham, had a choice lot of Daffodils, among which *King's Norton* was the giant of yellow kinds.

The Pelargoniums from Messrs. Cannell and Sons were particularly fine and in great variety, the bunches being also fine. Silver Flora medal.

The *Narcissus* from Mr. C. Dawson, Rosemoran, Gulval, Penzance, were very charming, and there were many new sorts displayed. *Buttercup*, the result of *Emperor* x *odorus* variety, is a fine self yellow, *Hypatica*, *Bedouin*, *Geoff*, *Pearl*, *Diver* (a white flower), *Glion* (a rich cupped sort), *Bernardin* (a glorious flower with pale orange crown) were among a choice lot. Gold medal.

Messrs. G. A. Clark, Limited, Dover, displayed to advantage a variety of hardy spring flowers, *Primroses* being very fine.

Choice flowering shrubs, such as *Hydrangea*, *Streptosolen*, *Boronias*, *Crowea angustifolia*, *Rhododendron veitchianum*, *Erica propendens* and other plants were well shown by Messrs. James Veitch and Sons, Limited, Chelsea. *Xanthoceras sorbifolia* and a grand specimen of *Medinilla magnifica* were also shown by Messrs. Veitch. Silver-gilt Banksian medal.

Messrs. K. W. Wallace and Co., Colchester, displayed a fine variety of hardy plants, including *Anemones*, *Fritillarias*, *Hepaticas*, *Irises*, *Tulips* and *Primulas*. Bronze Banksian medal.

Messrs. Hugh Low and Co., Enfield, had a rich and varied display of *Carnations*, *Acacias*, *Polyantha* *Roses*, *Heaths* and other plants, not least being that fine trailing plant *Lotus peltorhynchus*, whose scarlet blooms are very striking. The *Carnations* were a grand lot. Silver-gilt Banksian medal.

Messrs. Cartwright and Goodwin, Blakebrook, Kidderminster, had a beautiful display of choice Daffodils, such as *Rising Sun* (yellow Ajax), *Scarlet Eye*, *Marigold* and *Gloria Mundi* being very fine; *Aureole* (an early yellow incomparable with a much laced corona), *Yellowhammer*, *Alice Knight* and *Duke of Bedford*. Silver-gilt Banksian medal.

Messrs. Peed and Sons, West Norwood, S.E., had a large assortment of alpine and rock plants, with *Pansies* and *Daffodils*.

*Carnations* and *Lilies* from Mr. W. H. Page, Hampton, made a superb show, the former being of the finest possible description. Over a setting of *Maidenhair Ferns* the flowers in their many and brilliant shades were seen to perfection. Silver-gilt Banksian medal.

*Rhododendron Aucklandi hybridum* and *fosteriana* were in fine form from Sir E. Loder, Bart., Horsham (gardener, Mr. Cook), the plants being a mass of blossoms. Silver Banksian medal.

Messrs. R. and G. Cuthbert, Southgate, had a small display of Tulips.

Mr. A. F. Dutton showed *Carnations* in his usually fine form. Bronze Flora medal.

The collection of hardy plants from Mr. G. Reuthe, Keston, Kent, was most interesting, and contained a great variety of choice alpine and hardy shrubs in flower. Bronze Flora medal.

Messrs. Bull and Sons, Chelsea, exhibited stove plants and Daffodils in variety.

The Misses Kipping, Hutton, Essex, had a nice arrangement of hardy plants.

*Calceolarias* of a good strain were well shown by Mr. H. D. Broughton, Birch Hurst, Andover.

Messrs. W. Paul and Son, Waltham Cross, showed some very fine *Roses*, including *Laurant Carle*, a satin rose flower of great charm; Mrs. Aaron Ward, a chaste flower of white and apricot; *Renée Wilmart Urban*, soft flesh pink; and *Frau Ernst Borsig*, rose peach. Silver Flora medal.

Messrs. Carter and Co., Holborn, had a fine bank of *Cinerarias* in variety, obviously of choice strains.

Messrs. James Veitch and Sons, Limited, Chelsea, had a sumptuous group of well-flowered shrubs, in which were *Hydrangea hortensis*, blue; H. H. Thomas Hogg, white; H. H. rosea, blue, &c. *Rhododendron Handsworth Early Red* and *Clematis montana rubens* were also noted in fine condition.

Mr. L. R. Russell, Richmond, staged a fine bank of such forced shrubs as *Lilacs*, *Azaleas* and *Prunus*, together with *Clematis* and other plants in variety; a really fine display. Silver Flora medal.

Very pleasing were the *Acers*, *Grasses* and *Ivies* from Messrs. Thomas Cripps and Son, Tunbridge Wells, and in addition to the natural grace and beauty of the plants the group was well arranged. Bronze Flora medal.

Mr. Charles Turner, Slough, staged a pretty group of *Caladiums* in many choice and beautiful varieties, the colours being in some instances very fine. Bronze Flora medal.

Messrs. Carter Page and Co., London Wall, had a choice lot of *Violas* in great variety and of much beauty.

From Lissadell, Sir Josslyn Gore Booth, Bart., brought a fine collection of cut *Narcissus*, in which *Incognita*, *Firebrand*, *Mrs. R. Sydenham*, *Ariadne*, *Cresset* and others were seen. Silver-gilt Banksian medal.

Mr. Maurice Prichard, Christchurch, Hants, brought many fine alpine plants in bright effective masses, the *Aubrietias* and *Primroses* being particularly good. Silver Banksian medal.

Messrs. T. S. Ware, Limited, Feltham, also displayed hardy and alpine plants in infinite variety, together with species of *Primulas* and many other plants of interest. Bronze Flora medal.

## EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object he wishes to make the "Answers to Correspondents" columns a conspicuous feature, and, when queries are printed, he hopes readers will kindly give enquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITOR of **THE GARDEN**, accompanied by name and address of the sender.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and, where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

## THE GHENT EXHIBITION.

**T**HE centenary exhibition of the Royal Agricultural and Botanical Society of Belgium now being held in the Casino, Ghent, was opened by His Majesty King Leopold on Saturday, the 25th ult. As one would naturally expect, the exhibition is an exceedingly good one, the best growers of horticultural produce in Belgium, France, and some from Britain contesting the various classes in a friendly international spirit. Such international exhibitions as this, we think, must do a great deal towards the promotion of good feelings between the people of the various countries concerned, as well as providing opportunities for the advancement of horticultural knowledge. In one respect only was the exhibition disappointing, and this was the lack of really good novelties. Orchids certainly provided plenty of new varieties, but apart from these there were very few striking specimens. Messrs. Sander and Son had the best novelties, other than Orchids, in the show, their various foliage plants, enumerated on another page, being of considerable interest. Messrs. Ker and Son, the well-known Hippeastrum raisers of Liverpool, scored numerous successes with these handsome plants, some very good forms being among their group. Mr. C. Engelmann of Saffron Walden had a beautiful new Carnation of the perpetual-flowering race, the colour and scent of which reminded us very much of the Old Crimson Clove. A decided break in the colours of the Cinerarias was furnished by three plants of the large-flowered section exhibited by Messrs. Vilmorin and Co. of Paris. In colour the flowers of these plants are a glowing scarlet, and the only name given them at present is Scarlet Hybrid.

Fruits were naturally not forthcoming at such an early season, although forced Strawberries might, of course, have been shown. A few groups of Oranges in pots were the sole representatives of fruit in the exhibition. Generally speaking the arrangement was good, but not better than we see at home, although a better effect was obtained owing to the abundance of space at disposal. Floral arrangements for table and room decorations were carried out on a more elaborate and extensive scale than we see in this country,

but in this case also plenty of space proves a valuable asset. Fine as were the numerous exhibits of Orchids it is a pleasure to record that none were quite equal, both from an artistic and interesting standpoint, to the magnificent bank staged by Major Holford, Westonbirt, Tetbury, Gloucester. After the show had been open a short time it was impossible to get near this group owing to the dense throng of admiring visitors.

Perhaps the most interesting feature of the whole exhibition was, as nearly as possible, a replica of the first exhibition held in "Frascati" 100 years ago. The room was portrayed as faithfully as possible, even to a painted canvas representing the view as seen from the window of the inn at that time. Similar kinds and species of plants were shown within to those displayed at the first exhibition, and nothing could portray more lucidly the enormous advances that have been made in horticulture during the past century. Will similar advances be made during the next? is a question we may well ask ourselves. Although some kinds of plants seem to have reached their zenith others appear to be but still in their infancy so far as development is concerned, and time alone can prove what they are capable of producing.

## THE MEANING OF TULIP TERMS.

**T**HE Tulip is, I think, the oldest flower to which the term "florist" has been and still is applied. Immediately it was introduced into Western and Central Europe it seems to have "caught on" and absolutely fascinated everyone by its gorgeous and brilliant colouring. Indeed, in the first treatise on Tulips ever written the author tells us that it is "le chef d'œuvre de Dieu," and that it was the chief ornament of Paradise. This was, roughly speaking, just 100 years after its first appearance from Constantinople and the East. It shows the hold it took upon the flower-loving public of those days and the estimation in which it was held. What, then, more natural than that this flower, which has always been extremely varied in its markings and colouring, should create a need of technical words to convey these differences to the initiated! It is terrible to see (say, in the Florilegium of Sweetius) the many-worded names that are applied to his pictures of Tulips, but which are only, as it were, samples of the labels that we should have to put to all to-day if we did not make

use of such terms as "breeder," "feathered," "flamed," "bizarre" and so on.
