INDEX OF CONTENTS.

JANUARY TO JUNE, 1909.

(FOR SPECIAL HEADINGS SEE UNDER BOOKS; CERTIFICATES; LAW NOTES; NURSERY NOTES; OBITUARY; PLANT PORTRAITS;
PLANTS, NEW; SCIENTIFIC COMMITTEE; SOCIETIES; AND ILLUSTRATIONS.)

A

APERDEEN, agriculture at, 57
Absorption of moisture by leaves, 24, 44
Abutilon, garden varieties of, 151
Acalypha hispida, the cultivation of, 51
Acanthus montanus, 200
Acetylene gas-refuse as a manure, 264, 282, 284, 299, 317, 346, 387
Acidity in soils, 412
Adiantum grossum, 51
Adonis amurensis, 179
Aeroplanes, timber for, 251
Aesculus parviflora, 123
Afforestation, a scheme of national, 56, 58, 60, 84, 92
Acaricus elvensis, reappearance of, 25
Agave attenuata, 106
Agricultural College, South-Eastern, 121
Agricultural Holdings Act, 1908, 11
Agricultural science, 73; co-operation, 57
Agriculture at Aberdeen University, 57; in the Transvaal, 297
Albinism in Orchids, 81
Almond, date of flowering of the, 249
Alpine garden, 179, 258, 309, 366
Alpine Society at St. Gallen, 90
Alternation of generations, 156
Amaryllis Belladonna in pots, 48
America, Carnations in, 163; Orchid show in, 282; notes from, 163, 359, 417
American Gooseberry - mildew in Norfolk, 233
Ampelopsis, the evergreen, 240, 253, 267
Anchusa italica, varieties of, 417
Androcymbium melanthoides, 315
Anemone blanda scythica, 278; A. patens lutea, 366; A. St. Bridgid from Gowran Castle gardens, 296; A. Traversii, 222; disease, 336
Angracum Augustum, 89; A. sesquipedale, 399
Animals, three choice, 394
Antirrhinums in America, 163, 417
Apiary, the, 23, 71, 135, 183, 231, 247, 279, 327, 395
Apple and Pear stocks, 99
Apple trees, spraying, 313; scab on, 30, 44, 123, 157, 188
Apple William Crump, 21
Apples, late dessert, 163, 187
Appointments at Kew, 121, 281
Aquilegias, 149
Araucaria imbricata, 244
Arboretum, the Dreer, U.S.A., 359
Ardisia crenata at Kew, 181

Arundinaria tessellata, 398
Ashbourne, Co. Cork, 392
Asparagus, best varieties of, 192; culture of, 99, 324
Aster grandiflorus, 36
Atmospheric nitrogen, fixation of, 73, 329, 376, 380, 390, 401

B

BACTERIA, nitrogen-fixing, 329
Bailey, Mr. J. F., 169; Mr. W. H., presentation to, 137
Bamboo, the South African, 398
Banana-culture in the South of France, 365
Bateson, Prof., on Genetics, 152
Bath, botanical gardens and park at, 415
Battersea Park, bulbs in, 316
Bayfordbury pinetum, the, 223
Bean Anthracnose or pod-spot, 91
Beans, Butter, 368; some good early dwarf, 341
Beeches, New Zealand and Tasmanian, 422
Bees, a virulent disease of, 413; swarming, to prevent, 272
Begonia x Patrie, 75
Belladonna Lily in pots, 48; the, 92
Belvoir Castle, spring flowers at, 281
Benevolent Institution, Gardeners' Royal, 28, 41, 72, 76, 92, 120, 137, 421; annual meeting, 78; concert in aid of, 265
Benthamia (see Cornus)
Bentley, Joseph, Ltd., 381
Benton, A. W., 396
Bequest to a gardener, 329
Bequest, the John Innes', 72, 105
Berlin International Exhibition, 121, 185, 201, 232, 235, 249
Big game as garden pests, 57
Birds and their food, investigations regarding, 10, 414
Birmingham, flower shows at, 329; parks, bulbous flowers in the, 314
Bishop's Stortford, new public park at, 281
Black Currant mite, the, 256
Black-rot disease of Grape, 91
Bladder Plums, 388
Blood of plants, the, 328
Board of Agriculture's leaflets, 153

Boiler incrustations softened by Eucalyptus, 249

BOOKS, NOTICES OF:— A First Book of Botany (*Elizabeth Healey*), 393; Artificial Manures and How to Use Them in the Garden, Orchard and Allotment (*Professor John Percival*), 197; Beautiful Flowers and How to Grow Them (*H. J. and W. P. Wright*), 322; Book of Nature Study (*J. Bretland Farmer*), 122, 380; Botanical Magazine, 25, 89, 169, 233, 297, 381; Chrysanthemums for Garden and Greenhouse (*D. B. Crane*), 251; Encyclopædia of Gardening (*T. W. Sanders*), 53; Familiar Wild Flowers (*F. Edward Hulme*), 282; Farm and Home Year Book, 58; Flore Alpine (*H. Corceon*), 122; Garden Annual and Almanack (*W. Robinson*), 58; Gardening Year Book and Garden Oracle (*G. Gordon*), 58; Garden Life Year Book, 298; Horticultural Directory and Year Book, 58; Journal of the Board of Agriculture, 322; Journal of the Cooper Research Laboratory, 296; Journal of the Kew Guild, 265; Lawns (*W. J. Stevens*), 169; Le Chrysanthème, 154; Les Fleurs de Pleine Terre (*M. Philippe de Vilmorin*), 201; Life Histories of Familiar Plants (*John J. Ward*), 147; Memorial Volume of the Darwin-Wallace Celebration, 164; My Garden Diary (*Sutton & Sons*), 25; Nature Study (*J. R. Ainsworth Davis*), 164; New Phytologist, 59; Orchid Stud-Book (*Robert A. Rolfe and Charles C. Hurst*), 184, 221; Paradise Retrieval (*Samuel Collins*), 115; Plants and Their Ways (*Ernest Evans*), 164; Pronunciation of Plant Names, 228; Publications received, 26, 59, 74, 91, 106, 157, 154, 169, 186, 202, 217, 251, 265, 282, 330, 346, 365, 393, 414; Report of the Woburn Experimental Fruit Farm (*Duke of Bedford and Spencer U. Pickering*), 97; Rose Annual, 1909 (*E. Mawley*), 298; School Gardening (*W. Francis Rankine*), 102; Sweet Peas and How to Grow Them (*H. H. Thomas*), 69; Synopsis of the British Basidiomycetes (*Worthington George Smith*), 131; That Rock-Garden of Ours (*F. Ed-*

ward Hulme), 147; The American Apple Orchard (*F. A. Waugh*), 196; The Book of the Cottage Garden (*Chas. Thonger*), 228; The Country Home, 382; The Handy Book of Pruning, Grafting, and Budding (*James Udall*), 217; The Insect and Other Allied Pests of Orchard, Bush, and Hothouse Fruits (*F. V. Theobald*), 357; The Life of Philibert Commerçon (*Capt. S. Pasfield Oliver*), 216; The New Flora of the Volcanic Island of Krakatau (*A. Ernst*), 8; The Small Holders' Guide (*T. W. Sanders*), 322; The Planter's Handbook (*George Bunyard*), 4; Thirty-nine Articles of Gardening (*Miss Emmeline Crocker*), 53; Trees and Shrubs of the British Isles (*C. S. Cooper and W. Percival Westell*), 322; Trees and Their Life Histories (*Percey Groom*), 375; Vine Culture Up to Date (*Alexander Kirk*), 280; Wax Craft (*T. W. Cowan*), 85; Webster's Foresters' Diary and Pocket Book (*A. D. Webster*), 53
Boshanan Castle, Cornwall, 60
Boston, U.S.A., Orchid show at, 163
Botanical Garden in Java, 265
Botanical periodical, a new German, 121
Bougainvillea Cypheri, 74
Bowling greens, Lancashire crown, 48
Brasso-Cattleya Cliftonii, 33
British Columbian shrubs, 3
British Flora, invaders of the, 248
Broccoli and frost, 195
Broccoli, Late Queen, 107; Model, 368
Brunsvigia and Amaryllis, a hybrid between, 57
Brussels, forthcoming International Exhibition at, 282
Budd, Mr. W., retirement of, 169
Budget, the, and growers, 408
Bulb exhibition at Hillegom, 152, 265
Bulbophyllum Davanum, 194; B. lemniscatoides, 68
Bulbs in Battersea Park, 316; in the Birmingham parks, 314; Bulbs, prizes offered for, at R.H.S. shows, 249
Bunyard, George (*The Planter's Handbook*), 4
Burbank Potato, the, 222
Burgess, Mr. A. E., 200
Butter Beans, 368

C

- CABBAGE, early, 275; and frost, 171
 Cactus-flowered Dahlias, 169, 292, 337
 Calceolaria, an elegant, at Sandhurst Lodge Gardens, 342; *C. Burbidgei*, 242
 Calceolarias, herbaceous, 358
 Calcium-sulphide as insecticide and fungicide, 313, 364
 Californian seed crops, the, 359
 Calvat, M. Ernest, 185
 Cambridge Botanic Garden, students at, 418
 Cambridge, Darwin centenary celebrations at, 405, 412
 Canarina campanula, 213
 Canker in Rose, 11
 Carnation Society, a French, 186
 Carnations, a tool for layering, 157; at Boston, U.S.A., 397; exhibiting, 221; perpetual-flowering, 41, 241, 267; perpetual-flowering, as bedding plants, 350; in America, 163; proposed trial of 365; the best crimson-coloured, 284
 Carnegiea gigantea (syn. *Cereus gigantea*), 162
 Carriage of fruit and vegetable produce by railway, 339, 367, 378
 Castanopsis chrysophylla, 414
 Catechism, a gardener's, 105
 Cattleya Dowiana aurea, 233; *C. labiata* cultivated on rustic blocks, 45; *C. Mendelii* His Majesty, 30; *C. Mossiae* The King Emperor, 407; *C. Trianae* var. *Courtauldiana*, 163, 187; *C. T. "Marie Feodorovna,"* 241
 Cedar, transplanting a large, at Paddockhurst, 398
 Cedar wood for cigar boxes, 217
 Cereus gigantea, 162; *C. grandiflora*, flowers of, 417
- CERTIFICATED FRUITS AND VEGETABLES:**—Apple Barnack Beauty, 142; Pear Blickling, 47; Rhubarb Challenge, 239; Strawberries Climax, 333, George Munro, 333
- CERTIFICATED PLANTS:**—Aster mesa grandiflora, 419; Auriculas Admiration, 268; Alexander Dean, 270; Bournville, 319; Bracknell, 270; Chas. Winn, 319; Claud Halcro, 268; David Copperfield, 319; Dorothy Westmacot, 319; Edith Winn, 319; Harbinger, 270; Queen of Spain, 270; Robert Bruce, 268; Salome, 319; Sweetness, 270; Ulleswater, 268; Unexpected, 319; Begonia \times Patrie, 46; B. Pink Pearl, 354; B. Saturne, 205; Bougainvillea Rosa Catelina, 268; Brasso-Cattleya Cliftonii magnifica, 174; Brasso-Cattleya Digbyano Mendelii perfecta, 206; Brass-Laelio-Cattleya Cooksonii, 174; Brassavola Martiana, 302; Bulbophyllum lemnicatoides, 348; Campanula phytidocalyx, 419; Carnations Carola, 354; Her Majesty, 419; Lady Coventry, 268; Rose Doré, 205; Cattleya Percivaliana Charlesworth's variety, 46; C. Robert de Wavrin, 269; C. Maggie Raphael Westonbirt variety, 46; C. Mossiae Countess Grey, 421; C. M. Gatton Park variety, 343; C. Schroderae Alexandra James, 239; C. S. Irene, 239; C. S. "Mrs. F. Sander," 174; C. S. The Baron, 239; C. Trianae Grand Monarch, 174; C. T. Mooreana, 141; Chrysanthemums Golden Sunset, 77; Maud Allen, 46; Cineraria stellata, 205; Crocus Sieberii versicolor, 205; Chytroglossa Marileoniae, 174; Cineraria flavescens, 300; Cynoches peruvianum Tracey's variety, 141; Cymbidium Woodhamsianum Orchidhurst variety, 141; Cypripedium Bridgei magnificum, 141; C. Curtmannii, 141; C. Earl of Tankerville, 78; C. Euryades New Hall Hey variety, 78; C. Leander Exhims variety, 109; C. Our Queen, 78; Delphinium Moerheime, 419; Dendrobium atro Brymerianum, 141; D. Lady Colman, 141; D. Schneiderianum Westonbirt variety, 206; Epidendrum densiflorum, 302; Epilaelia Lionetii, 270; Ficus australis variegata, 354; Freesia Rose Queen, 141; Gongora quinquerivis, 348; Hippeastrums Gracchus, 268; Magnificent, 238; Marcus, 238; Pinkie, 268; Hydrangea hortensis alba, 301; Iris hybrida "Sir Dighton Probyn," 355; I. h. Sir Trevor Lawrence, 354; Laelio-Cattleya Dr. R. Schiffman Westonbirt variety, 302; L.-C. Eurylochus, 348; L.-C. Felicia, 78; L.-C. Frederick Boyle var. Kerchovae, 239; L.-C. Goldcrest, 269; L.-C. Goldfinch superba, 109; L.-C. Pizarro Westonbirt variety, 141; Marguerite White Perfection, 354; Megacalinum Bufo, 239; Miltonia Bleuana Sander's variety, 270; Narcissus Queen of the West, 269; Nephrolepis lycopodioides, 301; Odontioda Bradshawiae Cookson's variety, 174; O. Ernest Henry, 239; O. Keighleyensis, 141; O. Lutetia, 141; O. Vuylstekeae Crawshayanum, 333; Odontoglossum Aglaon, 348; O. ardentissimum Norman Cookson, 46; O. Phoebe, 109; O. cariniferum, 141; O. c. Angela, 239; O. Dreadnought, 239; O. loochristiense aureo-fulvum, 269; O. mirum "Emperor of India," 348; O. percutum Cookson's variety, 239; O. Princess Victoria Alexandra, 348; O. Sylvia Westonbirt variety, 239; O. Theodora, 269; O. Wyoming, 174; Oncidium barbatum, 270; O. Charlesworthii, 348; O. Retemeyerianum, 348; Paeonia Leonora, 419; Pleurothallis Birchenallii, 270; Polystachya rhodoptera, 239; Primula Bulleyana, 352; P. Forrestii, 268; Primula \times Unique improved, 300; Pteris aquilina congesta, 205; Ptychographis Siebertiana, 354; Rhododendron Souliei, 332; Roses, American Pillar, 354; Coquina, 354; Jessie, 354; Margaret, 354; Lyon Rose, 332; Mrs. Taft, 354; Rhea Reid, 205; Saxifraga apiculata alba, 238; S. Clibranii, 300; S. decipiens Arkwrightii, 300; S. d. hybrida grandiflora, 268; S. d. Miss Willmott, 332; Sigmatastalyx Eliae, 348; Sophro-Cattleya Thwaitesii, 174; Sophro-Laelio-Cattleya Marathon var. Vesuvius, 77; S.-L.-C. Olive, 206; Sweet Peas Blanch Stevens, 419; Sterling Stent, 419; Tulip The President, 333; Vanda Watsonii, 46; Viburnum Carlesii, 300
- Ceylon, Rubber culture in, 40; Water Hyacinth, a pest in, 214
 Chemistry of heated and partially sterilised soils, 275
 Chicory as a winter vegetable, 116; blanching, out-of-doors, 355; forcing, 192, 194
 China, plant collecting in, 24
 Chiogenes serpyllifolia, 99
 Chondropetalum Fletcheri, 10
 Chrysanthemum Framfield Pink, 27, 61, 76, 106; C. Violet Lady Beaumont, 27
 Chrysanthemums for market, 16; show of in Paris, 153; single, 3; some new French, 26; French raised at the N.C.S. shows, 309; literary and artistic collections of, an exhibition of, 2
 Cigar boxes, cedar wood for, 217
 Classification of Daffodils, 42, 61, 116, 139, 156, 170
 Clay soil, to burn, 191
 Cleomes, the, 114
 Climate and the chemical composition of Wheat, 366
 Climbing Roses, notes on, 133
 Clivias at Bridge Hall Gardens, Bury, 281
 Cloches, forcing by means of, 164
 Cologynne prolifera, 241
 Coffee, a disease resisting, 153
 Coffee-leaf disease in East Africa Protectorate, 214
 Coke for keeping Potatoes, 330
 Cold, materials to keep out, 36
 Cold-weather, effects of, on green vegetables, 245
 Cole, Alfred, golden wedding of, 137
 Coleman, Sir Jeremiah, awarded the V.M.H., 11
 Colonial notes, 3, 214, 242, 258
 Colour in Irises, 391; of plants, a lecture on, 285
 Committee, jubilee of the R.H.S. Fruit and Vegetable, 381, 397
 Compensation for improvements, 272
 Concert, "Geo. Monro, Ltd.," 90, 281
 Conifers, tall, at Knepp Castle, 188
 Coniothyrium Fuckelii, a fungus causing canker in Roses, 11
 Cooper, C. S., and W. Percival Westell (*Trees and Shrubs of the British Isles*), 322
 Cornus capitata, 85
 Correvon, H. (*Flora Alpine*), 122
 Coutts, J., appointment at Kew, 186
 Cowan, T. W. (*Wax Craft*), 85
 Cowdray Park, sale of, 314
 Cranberries and Whortleberries, 49, 74, 83, 99
 Crane, D. B. (*Chrysanthemums for Garden and Greenhouse*), 251
 Crocker, Emmeline (*Thirty-nine Articles of Gardening*), 53
 Croquet ground, plan of a, 336
 Cucumbers and Vegetable Marrows, a new disease of, 314
 Cucumbers, the culture of, 193, 234, 253, 284
 Cultural memoranda, 51, 99
 Cupressus macrocarpa as a hedge plant, 196, 245, 299; C. Macnabiana, 365
 Currant-bud mite, the, 256, 272
 Currant bushes, importation of, 280
 Customs charges on plants and seeds in the Mauritius, 398
 Cyaniding a vinery, 96
 Cyclamen flowers flagging, to prevent, 92
 Cyclamens, hybrid, 107
 Cynoches maculatum, 27; C. peruvianum, 309
 Cymbidiums as conservatory plants, 308
 Cypripedium Earl of Tankerville, 101; C. T. B. Haywood, persistence of flowers of, 132
 Cytisus scoparius Andreanus, forms of, 351
- Darwin, Chas., and the *Index Kewensis*, 406
 Davidia, 321
 Deforestation in New Zealand, 225, 243
 Dendrobium hybrids, 254; D. speciosum, 219
 Dianthus Pancicii, 309
 Dickie prize at Aberdeen University, 89
 Disease, a new, of Cucumbers and Marrows, 314; of Coffee in East Africa Protectorate, 214
 Diseases, plant, a tabulated list of, 297
 Dreer arboretum, the, 359
 Droitwich experimental station, 382
 Douglas Fir, the Japanese, 307
 Dover House gardens, Roehampton, 384
 Dynevor Castle, Carmarthenshire, 165
- E**
- EDINBURGH Royal Botanic Gardens, 11
 Electricity, use of, in the manufacture of nitrate of lime, 380
 Elm, seeding of the true English, 369
 Elodea canadensis, apparent diminished vitality of, 299
 Epigaea repens, 179
 Eriophyllum caespitosum, 309
 Ernst, A. (*The New Flora of the Volcanic Island of Krakatau*), 8
 Erodium chrysanthum, 179
 Eryngium pandanifolium, 45, 76, 106
 Escallonia at Killarney House, co. Kerry, 43
 Eucalyptus, a decoction of, softens boiler incrustations, 249
 Eucumis punctata, 228
 Eulophiella Elisabethae, 407
 Euphorbia jacquiniiflora, 156; E. pulcherrima, culture of, 204
 Evergreen Ampelopsis, the, 240, 253, 267
 Evolution of the Orchidaceae, 330
 Examination of employes in public parks, 121
 Exhibition at Geneva, forthcoming, 398; Haarlem, Jubilee, 191J, 397; International, suggestion for a British, 316
 Exhibitors, professional and amateur, definition of, 372
 Experimental station at Montreal, 258
- F**
- FARMER, J. Bretland (*The Book of Nature Study*), 122, 380
 Fencing used in the London Parks, 253
 Fennel, Italian, 45, 76, 124
 Fernery, the, 34, 211, 246, 323
 Fern nomenclature, 157, 188, 203
 Ferns, hardy, spring treatment of, 211
 Fern sports, remarkable, 34
 Fern, the life-cycle of a, 246
 Fertilisers, a lecture on, 73
 Fertilising value of snow, the, 186
 Ficus parasitica, 41
 Ficus species as epiphytes, 41
 Figure-of-4 trap, 224

- Finocchio or Italian Fennel, 45, 76, 124
 Fixation of nitrogen by bacteria, 73, 329, 376, 390; by electricity and lime, 380, 401
 Floral art at the Berlin exhibition, 249
 Floral decorations at the British Embassy, Berlin, 121
 Flora of Ngamiland, the, 397; of St. Helena, 233
 Florence exhibition, 1911, 414
 Florists' flowers, 2, 26, 42, 101, 202, 277, 292, 308, 409
 Flower garden, the, 7, 23, 38, 55, 71, 85, 102, 119, 134, 151, 166, 182, 193, 214, 230, 247, 263, 279, 295, 311, 327, 342, 363, 378, 394, 411
 Flowers in December, 10
 Flowers in season, 281, 296, 314, 381, 413
 Forbes, John, Ltd., 330
 Forcing by cloches, 164
 Forcing Seakale, 176
 Foreign correspondence, 93, 393
 Forestry, 155, 195, 219
 Forest trees, cost of planting, 187
 Foster, Chas., appointment of, 121
 France, imports of garden produce from, 314; market-gardening in, 204
 Freesias, 92, 106, 139; at Christmas, 51
 French Chrysanthemums, some new, 26; French gardeners in London and President Fallières, 137
 "French" garden, the use of cloches in the, 164; notes from a, 27, 75, 132, 155, 170, 186, 210, 227, 252, 266, 294, 308, 366, 398
 Fritillaria askabadensis, 185
 Frost at Monmouth, severe, 171; effect of, on Roses, 137
 Fruit classes at the R.H.S. shows, 203
 Fruit farm experiments at Woburn, 97
 Fruit-grower's year, a market, 65, 161, 244, 305, 373
 Fruit register, 99, 163
 Fruits from Cape Colony, 153
 Fruit show, the autumn, abandoned, 30
 Fruits preserved by sulphur fumes, 314
 Fruits, stone, for amateurs, 99; the covering of ripening, 396; tropical, 29; under glass, 6, 22, 38, 54, 70, 87, 103, 119, 134, 151, 167, 183, 199, 215, 230, 246, 262, 278, 294, 310, 326, 342, 363, 378, 395, 410
 Fruit trees on walls, the training of, 149, 172, 203; spraying of, 45; under glass, need for a resting period for, 28
 Fuchsia splendens and allied species, 338, 345
 Fuchsias, 220
 Furnaces, garden, stoking, 156
- G**
 'GAME, compensation for damage by, 12
 Gardener's golden wedding, 137
 Gardener's notice to terminate employment, 144
 Garden pictures, exhibition of, 265
 Gardens of Italy, a lecture on, 74
 Gases, plant sensitiveness to, 296
 Genetics, address by Prof. Bateson on, 152
 Geneva, forthcoming exhibition at, 398
 "Geo. Monro, Ltd.," concert, 90, 281
 Geranium Traversii, 179
 Gerberas, hybrid, 273, 290, 339
 German flower bed, a, 372
- Ghent, forthcoming exhibition at, 296
 Gill, Mr. Norman, 345

 School gardens in Surrey, 209, 226, 252; in Staffordshire, 121

SCIENTIFIC COMMITTEE:—Asbestos, vegetable, 188; albinos amongst British flowers, 13; albinism in Orchids, 142; Algæ on sewage sludge, 94; Anthurium, a fasciated, 94; Apple-pip germinating in the fruit, 158; Aquilegias, double-flowered, 401; Asparagus, a species of, from the Punjab, 254; Auricula, a double-flowered, 284; beetle in Vanda teres, 188; bulb-mite, the, affecting Cineraria, 158; bulb on inflorescence of Lachenalia tricolor, 188; Carnations diseased, 62, 94; Carrots, colour changes in, 157; Cineraria killed by bulb-mite, 158; Cyclamen, a malformed, 15; variation in foliage of, 94; proliferation in, 142; Cypripedium with a double lip, 188; Dendrobium hybrids, 254; Dianthus, hybrid, 401; Eucrosia bicolor, 222; Euonymus japonicus, fasciation in, 188; fasciation in Anthurium, 94; Fatsia injured by gnawing animals, 284; Gleditschia Delavayi, 317; grease bands for fruit trees, 14, 222; gummosis in Lemon, 222, 253; Hippeastrum hybrid, 254; H. pardinum, 142; Impatiens × comoricoma, 369, 401; inheritance of characters in Pea seeds, 253; Lachenalia tricolor with bulbs on inflorescence, 188; Larix americana, 369; L. Griffithii, 369; Laurel, a variegated-leaved, 401; Lemon, gummosis in, 222, 253; library, presentation to the, 284; Lonicera Standishii, fruits of, 401; malformed Orchids, 157, 222; Mendelism and Orchids, 157; Narcissus, hybrid, 317; nomenclature of multigeneric Orchid hybrids, 62; Notonia Grantii, 142; Orchids, albinism in, 142; interesting hybrids, 188, 317, 369; malformed, 62, 94, 142, 157, 222, 401; Parsnips, diseased, 157; from wild stock, 222; Peas, damaged by frost, 369; inheritance of characters in seeds of, 253; Pisum species from Palestine, 369; Plagiospermum sinense, 317; Plasmopara nivea, a disease of Parsnips, 157; Polystichum species, 254; Potato affected with Stemphylium atrovirens, 157; Primrose from Shetland, the season of flowering of a, 401; Primroses, variations in, 317; Primula hybrids, 369; P. sinensis, variation in, 158; proliferation in Cyclamen, 142; Ranunculus auricomus, depauperate form of, 369, 401, 418; Rhubarb, a species of, from the Punjab, 254; Richardia diseased, 62; Rose canker, 62; Rose with foliar sepals, 369; Salices, hybrid, 317; Salix herbacea from Ben Lawers, 401; S. pentandra, 369; Scilla hæmorrhodalis, 94; sewage

sludge, algæ on, 94; Stemphylium atrovirens, a disease of Potato, 157; Sweet Peas, decay in roots of, 222; Trachycarpus excelsus, monœcious character of, 401; Tulipa Fosteriana, 284; Tulips, malformed, 369; branched, 317; Urceolina miniata, 284; vegetable asbestos, 188; Viola lutea and V. lutea amæna, 369; Willows, hybrid, 317
 Scolopendrium vulgare, a much-prized variety of, 416
 Scotland, introduction of the Potato in, 13, 62; notes from, 342; prospects of the Lily season in, 377
 Sea Buckthorn, large specimens of, at Regent's Park, London, 384
 Seakale as a green vegetable, 369; forcing, 176
 Seed crops in California, 359
 Seed firm's employes at dinner, 25
 Seeds, enormous number of, produced by an Orchid, 314; packed for the Tropics, 137
 Selborne Society, the, 25
 Sheffield, gift of a public park to, 314
 Shrewsbury flower show, prizes at, 120; vegetable competitions at, 123, 139, 156
 Shrubs of British Columbia, 3
 Shrubs, the pruning of town, 400
 Simpson, Mr. W. J., 169
 Sinningia "Dr. Maxwell T. Masters," 73
 Slade, Mr. T. H., 41, 137
 Small holdings, prizes for, 105
 Smith, Worthington G. (*Synopsis of the British Basidiomycetes*), 131
 Snow, destruction in a nursery by, 171, 202, 217, 314; the fertilising value of, 186

SOCIETIES:—Aberdeen Chrysanthemum, 110; Bath and District Gard., 159, 191, 223; Bath and W. and Southern Counties, 345; Bickley and District Gard., 191; Birmingham Botanical and Hort., 401; Birmingham Gard., 63, 128; Bournemouth and District Gard., 223; Brighton and Sussex Hort., 63; Bristol and District Gardeners', 63, 128, 159, 224, 255, 369; British Gardeners' Association, 223, 233, 255, 370, 387, 421; (London Branch), 125, 191, 223, 334; Caledonian Hort., 63; Cardiff Gard., 47, 80, 143, 223, 255; Chesterfield and District Chrys., 78; Chester Paxton, 47, 63, 159; Colchester Rose and Hort., 285; Commons and Footpath Preservation, 125; Cornwall Daffodil and Spring Flower, 270; Coventry Chrysanthemum, 63; Croydon and District Hort., 63, 80, 160, 175, 223; Debating, 47, 63, 128, 143, 175, 191, 223, 369, 421; Derbyshire Gard., 128; Devon and Exeter Gard., 223; Devon Daffodil and Spring Flower, 271; Dorchester Gardeners', 160; Dumfriesshire and Galloway Hort., 158; Dutch Bulb Growers', 334; Esher Cottage Gard., 63; (Kent Hort., 62, 142, 334, 404; Gloucestershire Root, Fruit and Grain, 387; Gloucestershire Rose and Sweet Pea, 189; Guildford and District Gard., 421; Hemel Hempstead Hort., 110; Horticultural Club, 62, 189, 285; (Annual Dinner), 125; Huntingdonshire Spring Flower, 287; Ipswich and District Gard., 175; Ipswich and E. of England Hort., 285; Kent, Surrey and Sussex Daffodil, 318; Kingstown Gard., 224; L'Association Française des Amateurs et Jardiniers Chrysanthemistes, 334; Leeds Professional Gardeners', 110, 225; Linnean, 14,

Hort., 14; Salisbury and District Gardeners' 143; Scottish Hort., 62, 110, 175, 254; Selborne, 281; Société Française d'Horticulture de Londres (annual dinner), 79; Spilsby Daffodil, 317; Stirling and District Hort., 421; Torquay and District Gard., 191, 223; Union of French Horticultural Traders, 175; United Hort. Benefit and Provident, 110, 175, 254, 319, 404; Wargrave and District Gardeners', 160, 175, 225, 255; Yorkshire Gala, 402
 Soil, acidity in, 412; chemistry of heated and partially sterilised, 275; fertility and soil exhaustion, 364; inoculation, lecture on, by Prof. Bottomley, 189; sterilising, 224
 Solanum nigrum in Uganda, 393
 South-eastern Agricultural College, Wye, 121
 South-west, spring flowers in the, 389
 Spot disease of Odontoglossum Uro-Skinneri, 145
 Spraying Apple trees, advice on, 313; fruit trees, 45; to destroy weeds, 365
 Spring flowers in the south-west, 389; in the Maritime Alps, 257, 277
 Stachys tuberosa, 192
 Stackpole Court, Pembrokeshire, 218
 Staffordshire, school-gardens in, 121
 Stapf, Dr. Otto, 25
 Stepping-stones, plants for placing between, 240
 Sterilising soil, 224, 275
 Stocks for Apple and Pear, 99
 Stoking garden furnaces, 156
 Strawberries at Pitt House Gardens, Chadleigh, 253
 Street trees, care of, 90, 400
 Sulphate of ammonia, the yearly output of, 91
 Sulphur fumes for preserving fresh fruits, 314
 Summer flowers, a border of, 212
 Surrey, a school-garden in, 209, 226; school-gardening appointment in, 200; by-law to protect wild plants in, 329
 Swanley Horticultural College, 216
 Sweet Peas, early, 401; in tubs, 202; some of the newer, 177; trials of, 10; Têlemly, for winter flowering, 156
 Sweet Peas, Henry Eckford, 202; Mrs. Wilcox, 92; Masterpiece, 416; Mrs. B. Gilbert, 93
 Syon House, Brentford, 364

T

TABLE decorations, floral, 28
 Tap-union, Shipwright's patent adjustable, 265
 Têlemly Sweet Peas for winter-flowering, 156
 Temperature of respiring plants, the, 200, 221
 Temple flower show, the, 344, 347; and refreshment tents, 330; Lilies at the, 399
 Tennis lawn, to set out a, 238
 Thalictrum dipterocarpum, 216
 Theobald, F. V., (*The Insect and other Allied Pests of Orchard, Bush, and Hot-house Fruits*), 357
 The Warren House, Stanmore, 323
 Thomas, H. H. (*Sweet Peas and How to Grow Them*), 69
 Thonger, Chas. (*The Book of the Cottage Garden*), 228
 Thrips in greenhouses, 329
 Thuja Lobbii as a hedge plant, 284
 Thunderstorm, damage by, 368, 393
 Tiflis, proposed research stations at, 396
 Timber for aeroplanes, 251; for forcing houses, 80, 112; for home use, 219; planting in Great Britain, 219
 Town planting, 220, 262, 400
 Tradescant's tomb at Lambeth, 281
 Training of fruit trees on walls, the, 149, 172, 203
 Transplanting a Cedar at Paddockhurst, Sussex, 398; trees and shrubs, preparations for, 61
 Transvaal, the, agriculture in, 297; phylloxera in, 382
 Trap, figure-of-4, 224; a novel mouse, 365
 Trees and shrubs, 41, 61, 196, 220, 228, 245, 275, 361, 414; for winter effect, 131.
 Trees, forest, cost of planting, 187; grubbed by steam engine, 329; street, care and preservation of, 90, 400
 Tregothnan, Cornwall, 289
 Trenching, 61, 76, 107, 201, 203
 Trials of Dahlias, 169; of Sweet Peas, 10
 Triteleia uniflora, culture of, 179
 Tropical fruits, 29
 Tulips at Lowdham Nursery, 368
 Turf-cutting machine, a, 202

U

UDAIPUR, India, destructive hail-storm at, 398
 Udale, James (*The Handy Book of Pruning, Grafting, and Budding*), 217
 Uganda Protectorate, an unsatisfactory report from, 298

V

VACANT lands, a society for the cultivation of, 267, 312
 Vaccinium, the species of, 49, 74, 83
 Vanda cœrulea, 194; at Brougham Hall gardens, Penrith, 264
 Vanilla cultivation in Hawaii, 293
 Vegetable competitions at Shrewsbury show, 123, 139, 156
 Vegetable society, a national, 329, 345, 382

- Vegetables, 43, 116, 194, 217, 245, 275, 324, 341, 368; carriage of, by railway, 373; effects of cold weather on green, 245; novelties in, 4; scarcity of good winter, 154
- Veitch, Harry, portrait fund, 329, 382
- Veitch Memorial Medallists, new, 91
- Veronica Bidwillii, 309
- Versailles and Petit Trianon, 177

NEW ZEALAND PLANTS.

IN 1907 a party of New Zealand scientists, with the assistance of the New Zealand Government, visited the several groups of islands south of New Zealand, of which the Aucklands are by far the largest. The object of the expedition was magnetic observation, botany, zoology, and geology. Captain A. Dorrien Smith, who was a member of the party, and whose account of some of the things he saw was recently published in the *Kew Bulletin*, collected numerous plants and seeds, not only in the various islands visited, but also in New Zealand proper. These he brought home last May, the plants being conveyed in 12 Wardian cases to his father's famous garden at Tresco, where already many New Zealand plants are established and happy. The following list of plants he has collected has been prepared by Captain Dorrien Smith, those marked with an asterisk being, so far as can be ascertained, new to cultivation in this country. In addition to the living plants, he also collected and brought home a great variety of seeds, many of them being of plants not known in gardens, and these were generously distributed among botanical and other establishments.

Kew has been largely enriched with New Zealand plants in consequence of this expedition, and if someone can only discover the right treatment for some of them, either at Tresco or in other gardens in which they are being tried, British horticulture will be considerably the gainer as the result of the enterprise and zeal of Captain Dorrien Smith.

The New Zealand climate is temperate and very healthy; the temperature is more equable than in the British Isles, the summers being cooler and the winters warmer; the annual rainfall varies from 25 inches to 112 inches, and the soil in many parts is "a rich leaf-mould." It might have been expected that both plants and animals would have developed along lines more favourable to man than has proved to be the case, for, with the exception of a few good timber trees and the Flax Lily, there are no plants of any particular economic account. All the fruits, vegetables, and cereals, on the production of which in that country important industries have been built up, are recent introductions from western

Meanwhile, as it is not unlikely that many of the plants will soon have become extinct from such causes as cultivation, animals, fires and introduced weeds, we need to secure all we can get from New Zealand that is likely to make our gardens richer. It is unfortunately true that scarcely any New Zealand plant has proved hardy in this country except in such favoured districts as the West of Scotland and Ireland, the southern coast of Cornwall and Devon, and the Scilly Islands. Some of them will grow fairly well in inland gardens when afforded shelter, but they are never certain, a frost of average severity proving too much for them. Fortunately, however, there are many gardens in the more favoured districts where the New Zealand plants thrive perfectly. There may also be many plants in the alpine regions of New Zealand which only require to be introduced into British gardens to prove quite hardy here. Generally the plants sent home are those that are easily obtained in low-lying, warm districts; it has been too much trouble to go up into the mountains for specimens, and even when this is

[Photograph by Captain Dorrien Smith.]

FIG. 1.—CELMISIA SPECTABILIS GROWING WILD IN NEW ZEALAND.

countries. It would appear that, whilst Nature endowed New Zealand with all the conditions favourable to the development of plants and animals, she omitted to provide an industrious, enterprising race of men until, in 1769, Captain Cook discovered the islands, and even then nothing was done towards making the most of their resources until 1840. Since that time, however, New Zealand has gradually grown until it is now a veritable Land of Promise. Naturally rich and sufficiently isolated to be outside the influence of politics, fortunate also in being peopled with a race which is almost exclusively British, foreigners and Maories counting for very little, the founders of New Zealand have set out to work the country on democratic lines, "unhampered by climate, slavery, vested rights and vested ruts, immigration, or the enervating seductions of power over subject races." From what is known of the country, enterprising young men with a knowledge of soil cultivation need not hesitate to go to New Zealand, where the people are determined to make the millionaire and the pauper equally impossible.

done, such plants either perish on the way or sicken so much as to never recover under the changed conditions of an English garden and climate. Seeds, therefore, should be largely relied upon, and although we have not been fortunate with some of the seeds brought home by Captain Dorrien Smith, still seeds are more likely to enable us to get many of the plants established than are imported living plants.

According to the Kew records there were 83 species of flowering plants and 54 species of Ferns from New Zealand in cultivation at Kew in 1864. There are many more now, including 40 species of Veronica and 10 species of Olearia. Thanks to Captain Dorrien Smith, no fewer than 10 species of Celmisia have recently been added, but these plants have so far proved as difficult to manage at Kew as the beautiful Ranunculus Lyallii and Myosotidium nobile, which in some gardens are fairly easy. It is more than probable that Celmisias are killed by coddling, and if we only had the courage to leave them to fight it out with the weather they would do better. The genus is almost peculiar to New Zealand, where it forms "one of the chief ornaments of

the mountain and alpine flora of the colony, the various species usually composing a large proportion of the vegetation, especially in the South Island, where the mountain slopes and valleys are often whitened for miles from the abundance of their large Daisy-like flowers."

Pleurophyllum speciosum, an ally of *Celmisia*, is one of the noblest of New Zealand plants, but so far no one has grown it in this country. Compositæ are very numerous in New Zealand, constituting about one-seventh of the total number of flowering plants, and many of them are worth growing in gardens. Some of the species of *Ranunculus*, too, are exceptionally handsome. (Such genera as *Gentiana* (16 species), *Myosotis* (22 species), *Dracophyllum* (18 species), and *Veronica* (84 species) are specially interesting horticulturally, some of the species being described as really handsome. *Veronica*, the largest genus of flowering plants in New Zealand, is a conspicuous feature of the vegetation of the higher regions. There are six species of *Fagus* (Beech), the only northern genus of forest trees represented in the southern hemisphere. Whilst Ferns are largely represented in New Zealand, some of the best of those grown in gardens being from that country, there are no Orchids of any account. Iridaceæ are represented by one genus only, *Libertia*; Amaryllidaceæ by one, *Hypoxis*; and Liliaceæ by 10, including *Cordylina*, *Astelia*, *Dianella*, *Phormium*, and *Arthropodium*. It is remarkable that whilst *C. australis* is one of the easiest plants to grow, *C. indivisa*, which grows in the mountains and is by far the finest species of the genus, proves difficult. *Bulbinella Rossii* is another magnificent Lily, which no one has yet managed to grow in this country, although many attempts have been made. Perhaps Captain Dorrien Smith, who saw the plant growing abundantly in the Aucklands, will be able to hit upon the right treatment for it at Tresco. There are only two Palms in New Zealand, both of them being well known in gardens here as *Areca Baueri* and *A. sapida*. Captain Dorrien Smith states that *A. Baueri* occurs in Norfolk and Chatham Islands, not on the mainland, and it is probably scarce in Chatham Islands.

The best book on New Zealand plants is the *Manual of the New Zealand Flora*, by T. F. Cheeseman, published in 1906, under the authority of the Government. It is based on the *Handbook of the New Zealand Flora*, published 40 years ago by Sir Joseph Hooker. The descriptions, which are in English, are excellent for their clearness and thoroughness, and they are often accompanied by observations on the habits, &c., of the plants which are likely to be helpful to cultivators.

FLORISTS' FLOWERS.

THE RETROSPECTIVE CHRYSANTHEMUM SHOW IN PARIS.

FIRST and foremost in the literary and artistic retrospective show held in connection with the recent Chrysanthemum exhibition was the original portrait in oils of Capt. Blancard, the introducer of the Chrysanthemum into Europe in 1789. Beneath the portrait was a coloured plate of the flower introduced by him and figured for the first time in the *Botanical Magazine*, pl. 327.

On the walls right and left of this was a remarkable series of curiosities of all kinds. These included a portrait of Louis Pelé, lent by M. Lemaire, and an oil painting of some Chrysanthemums raised by Pelé in 1846, and a number of photographs of famous growers and raisers, together with many coloured pictures of old varieties long since discarded by growers.

The most interesting and extensive collection came from M. René Momméja, an amateur and collector, well known for the many valuable and artistic curios he possesses relating to the Chrysanthemum. In a series of closed glass cases he showed Japanese silks, pottery, porcelain of the 17th and 18th centuries, lacquerware, &c., all bearing upon them figures or designs of Chrysanthemums. He had a large collection of Japanese books containing pictures of individual flowers, and also other Chinese and Japanese plates and drawings of views of Chrysanthemum gardens and exhibitions. An extensive collection of cultural and other treatises published in Europe also formed a part of this exhibit.

Mr. Harman Payne is another well-known collector, and he, too, made a substantial display. A collection of 299 coloured engravings of Chrysanthemums from all the old botanical and horticultural publications during the past century was staged by him. We also noted a series of large photographs of varieties now no longer in cultivation, some rare old catalogues of Salter and Forsyth, and other literary curiosities. The most curious object in Mr. Payne's collection was a card of invitation to visit the annual Chrysanthemum show held by the Emperor of Japan in the Royal Gardens at Tokio.

The Librarian of the National Horticultural Society staged some rare books and pamphlets from the society's library. We noticed some old volumes of the *Bon Jardinier* containing early references to the flower, also references to John Salter's book, and several others. Especially rare are *Les Chrysanthèmes dans l'Est de la France*, par E. Moreau fils; and *Notice sur les Chrysanthèmes de la Chine*, par M. le Chevalier Soulange-Bodin. There were also kindly lent by the family a bulky volume, of which Capt. Blancard was the author, entitled *Manuel du Commerce des Indes*, and several autograph letters of his. He made several voyages to China and India before the date of his introduction of the Chrysanthemum. In several other glass cases were some rare old catalogues and pamphlets, kindly lent by M. Nonin, M. Philippe de Vilmorin, M. E. Rosette, M. Loizeau, M. Le Colier, and others.

FIG. 2.—MERYTA SINCLAIRI IN MR. CHEESEMAN'S GARDEN, AT AUCKLAND. (The figure is that of Mr. Cheeseman.)

- **Ligusticum* Haastii.

- " " Gilliesiana.
- " " Lewisii.
- " " linifolia.

M. Charles Baltet sent a few framed pictures and engravings of flowers of the Chrysanthemum, and of Japanese Chrysanthemum shows. High above the walls around the show were panels commemorating the four principal epochs in the history of the flower. They were as follows:—

Blancard, 1789, importation of Chrysanthemum.

Bernet, 1826, first seedings.

Fortune, 1846 and 1863, Pompons and Japanese introduced to Europe.

Calvat, 1891, distribution of the modern race of large-flowered varieties.

The society has every reason to be pleased with the result of its efforts. Never before has there been displayed to the public view, either in France or elsewhere, such an exhibition of literary and artistic curiosities relating to the Chrysanthemum. Much interest was excited in the contents of the numerous glass cases containing exhibits, and it was undoubtedly owing to the provision of these cases that so large and valuable a collection was gathered together. The idea originated with M. George Gibault, the society's librarian, and he is to be warmly congratulated on the outcome of his efforts.

The other section of the retrospective exhibition, namely exhibits of old plants and flowers grown anterior to 1895, was scarcely so satisfactory. The growers sent an indifferent collection, and the varieties were not cultivated to the best advantage. A large number of the old Anemone varieties were shown, a good many Pompons, but very few of the old incurved and Japanese.

SINGLE CHRYSANTHEMUMS.

If the value of single Chrysanthemums be estimated by the novelties which were offered for sale last spring—I counted between 90 and 100—it would appear to be very great. But such an overwhelming number of new kinds is of no advantage, for what grower would entail the labour of cultivating so many new kinds unless he had great expectations that they would prove superior to those already in cultivation? It is obvious that size of bloom is being pushed to a detrimental extent, many of the new flowers being too large in proportion to their rather flimsy florets. At the same time, some of the large-flowered varieties are of great value alike for furnishing vases, and for growing in small pots for room decoration. A good-sized, perfectly-furnished plant can be produced in a 6-inch pot, suitable for placing in an ordinary vase, and that alone is a desirable quality. But if the plants are to furnish flowers for cutting, 9-inch to 11-inch pots are to be preferred. A plant of the one size exacts no more labour to cultivate than that of the other, and the bigger plant gives a much larger return of equally fine blooms. The flowers are also suitable for table decorations. There are several pink varieties, but all are a little flimsy, if Miss Rose is excepted. Yellow varieties appear too white by artificial light to be effective, but in the crushed strawberry Mary Richardson we have a very fine flower. *Physalis Franchetii* and this *Chrysanthemum* mixed together are a lovely combination. But the variety that I prefer to all others is Earlswood Terra-cotta when not disbudded. The flowers remain fresh and unaltered in tint for many weeks, and, by artificial light, the colour is much softened. Browned pieces of the Royal Fern form an ideal setting. There is no reason why single varieties of suitable colours should not be mixed with each other, but, on the whole, the most charming arrangements are those which are not mixed. At the Edinburgh Chrysanthemum exhibition there were a few decorated tables of great beauty, but, undoubtedly, the most pleasing and artistic exhibit was that in which only yellow flowers were employed. B.

THE BULB GARDEN.

IRIS HIMALAICA.

MAY I suggest the above as a name for a species of Iris, hitherto, I believe, undescribed, which was sent to me from a locality within sight of Darjeeling in February, 1907? In the case of these plants the colour of the flower was a deep violet blue, and I find that Mr. T. Smith, of Newry, grows a sky-blue form under the name of *I. Clarkei* and a purple variety under that of *I. decora*, both having been raised from seed received from the Himalayas. The true *I. Clarkei* and *decora* are, of course, quite distinct.

This Iris has been thought by some to be a form of *I. sibirica orientalis*, but in reality it is far more closely related to the Chinese *I. Delavayi* than to any form of *I. sibirica* with which I am acquainted. Its falls are always blotched like those of *I. Delavayi* and not veined as in the case of *I. sibirica*, and the capsule and seeds closely resemble those of the

ing; sheaths splitting into fine fibres. Leaves linear, moderately firm at first, but drooping when full grown, upper surface smooth and polished, under surface finely ribbed and slightly glaucous, 2 to 3 feet long, $\frac{3}{4}$ inch broad. Stem slender, lozenge-shaped rather than round in section, solid, 2 feet high, overtopping the leaves, branched, bearing three heads of flowers. Spathes two-flowered, valves yellowish green 3 inches long; pedicels 3 inches long. Perianth tube triangular, $\frac{1}{2}$ inch long; standards spreading, lanceolate, with deeply-channelled limb, $1\frac{1}{2}$ inch long and $\frac{3}{4}$ inch broad, violet-blue veined with a deeper shade; falls 2 inches long by 1 inch broad, obovate-cuneate, violet-blue blotched with white and yellow at the throat. Style branches very broad, keeled and conspicuous, $1\frac{1}{2}$ inches long; crests small, overlapping. Capsule 2 inches long, oblong, trigonous; seeds flat, circular, with dark centre and pale margin. *W. R. Dykes, Charterhouse, Godalming.*

COLONIAL NOTES.

NOTES ON BRITISH COLUMBIAN SHRUBS.

BRITISH Columbia is a country of flowering shrubs. Wherever the giant conifers have been cleared shrubs spring up rapidly, one of the first to appear being *Sambucus pubens*, which is common around Vancouver, growing to a height of 15 feet. The creamy spikes of blossom are by no means the most showy parts, as in July their place is taken by the scarlet fruits which make a fine show in contrast to the abundant foliage. This is, I think, the most effective subject around here, the berries hanging until at length they are eaten off by little birds.

Spiraea Douglasii is a weed here, spreading quickly on the edges of swamps in company with *Ledum latifolium*, *Kalmia glauca*, and other similar shrubs. It flowers abundantly and continuously from July to October, the later flowers being of a much deeper colour, as they are seedling plants.

Another noteworthy subject which attracts attention when in flower is *Cornus florida*, which very often attains the proportions of a tree. When burnt over by a bush fire, it is one of the first to spring up again, clumps of suckers coming from the old roots. The colour of the leaves in the autumn is very distinct, being a mixture of yellow and pink. The fruits when ripe are eagerly eaten by the native grouse.

Amelanchier canadensis is a pretty shrub to be found here, although not very common. It is not vigorous in growth, but flowers freely along the whole length of the branch; the purple pome and autumn colour of the leaves also enhance its decorative value for the garden.

Acer rubrum is one of the most ornamental and common shrubs. It is ornamental the whole year round, with ever-changing attire. In winter the young shoots are crimson, in spring they are hidden by the delicate tints of the young leaves, which in summer are green, but in autumn turn to brilliant scarlet in the open and yellow in the shade, rivalling *Liquidambar styraciflua* for colour effect.

High up the mountain side, never below 3,000 feet, grows *Rhododendron albiflorum* in the shade of *Abies balsamea* and other conifers. Towards the end of July its freshly-opened, creamy flowers and shining green leaves are like a drink of cold water to the hot, tired climber. It is a lovely shrub this, living for six months among the snows. When the spring flowers are over down on the lowlands, the little humming birds come up the mountains where spring has just awaked, to sip the honey from the wide-open flowers.

All of these shrubs are worthy of a place in British gardens, as are many others which grow in nature's garden here. *R. Glendenning, Vancouver.*

[Photograph by Captain Dorrien Smith.]

FIG. 3.—OLEARIA INSIGNIS GROWING IN NEW ZEALAND.

former. It differs, however, from *I. Delavayi* and *I. sibirica* in having a solid stem at all stages of its growth, while the drooping leaves are also very characteristic, having a curiously smooth and polished upper surface, which contrasts strongly with the slightly glaucous under-surface.

My plants came into flower this year about the middle of June, having grown well under fairly moist conditions in a soil rich in humus. The blooms have the drooping appearance so characteristic of the Himalayan Irises, such as *Duthiei*, *Kumaonensis*, &c., and the style branches rise above the tips of the spreading standards. The markings of the falls consist of white blotches on a violet-blue ground, and the throat is tinged with yellow. There is no trace of either crest or beard, so that the plant belongs to the *Apogon* section and has nothing to do with *I. Clarkei*, the name under which it was sent from Darjeeling.

The following is a more detailed description: *I. himalaica*.—Rhizome slender, wide-creep-

VEGETABLES.

NOVELTIES IN VEGETABLES.

THE French gardeners are cultivating for early forcing a Carrot named Paris Egg, a very rapid grower. This may be followed by Early Nantes, a Carrot that has become a great favourite with English gardeners, the roots being of nice form and a bright-red colour. Another variety-resembling Early Nantes is Lobberich, a stump-rooted variety, and late in coming into use; very sweet and good, and deserving to be better known.

heavy croppers. The stalks of these varieties sometimes weigh 4 lbs. each. They are tender when properly cooked, and pleasant to eat. The plants are not to be despised as decorative objects in the pleasure grounds or the mixed flower border.

The Australian brown-skinned Kangaroo differs from most Onions raised in warm countries in being a long-keeping bulb. The skin is amber-coloured, the bulb in shape almost globular, of middle size, firm of flesh, and weighty for its size. The variety should have a good future, it is an excellent market Onion.

be sown weekly—the earliest in mild hot-beds—from the end of the month of March onwards. In the open ground this Radish makes quick growth, and the flesh remains tender for a long period of time, and free from woolliness. The netted Sedan Radish is the equal of Salvator; the root long, pear-shaped, smooth as to skin, and netted black on white. Seeds may be sown at frequent intervals from March onwards.

Of Runner Beans the variety Ohne Gleichen (Peerless) was introduced in 1907; and, judged by the crops of that year, it is a thoroughly valuable variety, which will take a higher rank than the July Runner, from which it was raised. The pods are about 7 inches long, and very freely produced; as good a Bean for the private garden as for marketing.

Among Dwarf Kidney Beans, Thuringia is a fine late-cropping variety, with long and broad pods. The plant is well adapted for cultivation in a cool climate. White Paris Flageolet resembles the variety Thuringia, excepting that the pods are of greater breadth.

The white-flowering, white-podded, conserving variety of Broad Bean that originated in Holland is certainly worth cultivation. The plant has great vigour, it crops heavily, and the pods are well filled and of great length. The seeds may be conserved in the green as well as ripe state. The colour, yellowish-white, is appreciated in a preserved vegetable. *F. M.*

FIG. 4.—A SNOW-SCENE IN THE ROYAL BOTANICAL GARDENS, EDINBURGH.
(See page 11.)

In Celeriac, the variety *Délicatesse* (Delicacy), introduced into commerce several years ago, has maintained its good reputation. The plant has fine foliage, the root is oval-globular and smooth, and it possesses but few fibres. It is peculiarly white in the flesh, and tender in eating. The short-leaved Apple-shaped Celeriac is a highly-esteemed variety.

Among Rhubarbs, a vegetable which in culinary uses is treated as a fruit, the novelties Cyclops and Monarch are valuable as being

Amongst the earliest short-topped and bright-coloured varieties of forcing Radishes are First Crop and Non Plus Ultra, adding to these Drie Brunnen, a famous Erfurt variety. Würzburg Giant is unexcelled as a variety for cultivating in cold frames. The seeds should be sown thinly, or the plants liberally thinned, in order to get fine-sized roots with tender flesh. The Salvator white Radish has been some years in commerce. It is a summer variety, and is becoming a favourite with the public. Seeds may

NOTICES OF BOOKS.

* "THE PLANTER'S HANDBOOK."

MR. BUNYARD has produced a useful handbook, which conveys in plain language much information of a practical nature, easy of reference, well illustrated by line drawings, and handy in form. Directions are briefly given as to the manner of employing trees and shrubs in gardens and parks, the kinds of soils in which they succeed best, proper seasons for planting, and the treatment afterwards necessary. Mention is made of most of the species and varieties of trees and shrubs of recent introduction which are hardy in these islands, the number of which is very large; yet it is regrettable to note how few are those which the ordinary planter and gardener puts to any useful purpose. In this regard we may take as examples Maples (*Acers*), which, if more freely planted, would impart a distinct and pleasing character to the garden and park. How seldom do we note such varieties of the Norway Maple (*Acer platanoides*) employed as *A. p. Reitenbachii*, and *A. p. Schwedleri*, with claret-coloured leaves, or *A. californicum texanum*, a grand, hardy tree, succeeding on dry as on wet land; *Acer dasycarpum*, a species with striking foliage, and capable of growing in any ordinary soil; *Acer Negundo*, of which there are several variegated varieties, *Acer colchicum rubrum*, *A. c. aureum*, and *A. tataricum Ginnala*, all of which Mr. Bunyard includes in his list of desirable trees. We think that he has made his list of *Quercus* too brief, although mention is made of the finer American species. We take it that by *Quercus macrophylla* is intended *Q. macrocarpa*—an Oak with very striking foliage. Flowering shrubs come in for plentiful notice, for which planters should be thankful, and there are useful lists of trees and shrubs with silvery and golden leaves, and of coniferous trees suitable for a variety of purposes. This last list might have been extended with advantage to many readers.

* *The Planter's Handbook*, by George Bunyard, V.M.H. Published by George Bunyard & Co., Ltd., Maidstone. 1908. Price 3s. 6d. net.

NOVELTIES OF 1908.

AGAIN the season has come when it is customary to pass in review the garden acquisitions of the past year. Although many are engaged in the search for new plants, and in the work of raising hybrids, it is the few who, having secured the lead, are able to keep it, therefore most of the better novelties have been shown by the well-known amateurs or nurserymen.

THE ORCHIDS.

In the matter of showy Orchids, the hybridist seems to have it all his own way, for but few new species have been imported. It is pleasant to note that what are known as botanical species of Orchids, having interesting but small flowers, have met with the recognition they merit.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. H. Balfantine), secured five First-class Certificates for plants exhibited from his famous collection, viz., for the handsome *Odontoglossum Bingleianum*, *O. Wilckeanum Schröderianum*, *O. crispum Princess of Wales*, a charming flower of perfect form; *O. Phœbe*, and the new and pretty *Miltonia St. Andre*.

Lieut.-Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), as in former years, takes the lead in the number and quality of the many fine home-raised hybrids which he has shown. First-class Certificates were obtained by *Cypripedium Sultan*, C. Helen II. Westonbirt variety, and *C. Actæus Bianca* (three noble flowers); *Brasso-Cattleya heatonensis* Westonbirt variety, *Lælio-Cattleya Elva* Westonbirt variety, *L.-C. Clive magnifica*, and the famous *Cattleya Schröderæ* "The Baron," a superb variety imported by Messrs. Sander & Sons. Awards of Merit were given to *Lælio-Cattleya Corunna*, *L.-C. Pizarro*, *L.-C. Cornelia* Westonbirt variety, *L.-C. Lustre gigantea*, *L.-C. Ortrude*, *L.-C. luminosa* Westonbirt variety, *Cattleya Enid magnifica*, *Cypripedium Arethusa*, *C. Dante magnificum*, *C. Rossettii*, one of the best of yellow *Cypripediums*; *Sophracattleya Saxa* Westonbirt variety, *Sophracattleya Danæ superba*, *S.-L.-C. Medea* vinicolor, *Brasso-Cattleya Madame Hye* superba, *Odontoglossum Eleanor* Westonbirt variety. At the last show of the season the handsome *Cypripedium Antinous* secured a First-class Certificate.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), who combines modern Orchid growing of the showy class with his favourite culture of rare, pretty and curious botanical species, has the longest list of certificated plants, visitors to the Royal Horticultural Society having to thank him for the opportunity of seeing some thirty charming and rare species for which he has been voted Botanical Certificates in addition to a good number of showier floral novelties. These latter include *Cattleya Mossiæ Goossensiana* and *Odontoglossum Wiganianum superbum*, which secured First-class Certificates; and *Cattleya Maronii aurea*, *Catasetum Russellianum*, *Cirrhopetalum Wendlandianum*, *Angræcum angustum*, *A. Germinyanum*, *Dendrobium Jerdonianum*, *Odontoglossum platycheilum superbum*, and *Epidendrum virens*, which obtained Awards of Merit. The thirty Botanical Certificates were awarded to a remarkable and varied collection of rare species, many of which will be found in the appended reference to illustrations in the *Gardeners' Chronicle* during 1908.

Sir JEREMIAH COLMAN, Bart. (gr. Mr. Collier), in the first half of 1908 secured Awards for a number of handsome Orchids chiefly raised in his fine collection at Gatton Park. These were *Cymbidium Gattouense* (*Tracyanum* × *Lowianum*), *C. Lady Colman* (*eburneo-Lowianum* × *Tracyanum*), both elegant hybrids; the pure white *Diacattleya Colmanæ*, *Dendrobium Cybele* Gatton Park variety, *D. Thwaitesiae Bound's* variety, *D. Chessingtonense* Gatton Park variety, and among species the yellow *D. Brymerianum* Gatton Park variety, *Cirrhopetalum pulchrum*, and the singular *Bulbophyllum mirum*, which attracted so much attention in the handsome group staged at the last Temple Show. Sir JEREMIAH COLMAN also flowered for the first time the remarkable *Bulbophyllum lemniscatoides*.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), had one of the finest novelties of the year in the rich scarlet

Sophracattleya Doris, which obtained a First-class Certificate on November 10; his other best exhibits being *Odontoglossum perculatum* J. R. Roberts, *O. Ossulstonii* Glebelands variety, *Cypripedium Ernest Read* and *Catasetum maculatum*.

NORMAN C. COOKSON, Esq. (gr. Mr. Chapman), in *Odontoglossum crispum* Leonard Perfect, which secured a First-class Certificate and Medal, showed the finest "crispum" of the year; his *O. crispum* Kenneth being also good. In *Calanthe Angela* (F.-C.C.) and *C. Norman* (A.M.) Mr. COOKSON beat his own record for brilliant ruby-crimson *Calanthes*. Phaius Clive secured a First-class Certificate; *Cattleya Fabia* Cooksoniæ is a showy white flower with purple blotch on the lip, and *Cypripedium Fairrieanum* Cookson's variety, one of the darkest yet shown.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), has shown some distinct hybrids during the year, and at the Temple Show staged one of the finest of *Cattleyas*, viz., *Cattleya Mendelii* His Majesty the King, which secured a First-class Certificate, and whose picture it is said was accepted by her Majesty Queen Alexandra.

H. S. GOODSON, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day), received First-class Certificates for *Odontoglossum cœruleum* "King of England," with violet and white flowers; the scarlet *Odontioda Charlesworthii* Goodson's variety; *Lælio-Cattleya St. Gothard*, and *Cattleya Venus*; and Awards of Merit for *Cymbidium eburneum Goodsonianum*, *Lælio-Cattleya Elva* var. *St. Vincent*, and *L.-C. Golden Oriole* Goodson's variety.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks, produced the fine *Odontoglossum crispum* "Queen of the Earth" (F.-C.C.), the rosy-purple *O. illustre* Theodora; also *O. Queen Alexandra* Crawshayanum, one of the finest coloured hybrid *Odontoglossums*, *O. Zenobia* (Hallii × Edwardii), and several other hybrid *Odontoglossums* of merit.

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Black), showed the distinct novelty *Odontioda Thwaitesii* (*vulcanica* × *Harryanum*), the richly-coloured *Sophracattleya Warhamiensis* "J. M. Black," and the pretty white-petalled *Cattleya Maggie Raphael* delicatissima.

GURNEY WILSON, Esq., Haywards Heath, showed the fine pure white *Brasso-Cattleya Queen Alexandra* Glenthorpe variety, and several interesting species of Orchids.

HUBERT GROGAN, Esq., Slaney Park, Baiting-glass, exhibited the dark violet *Odontoglossum Groganæ* (*Edwardii* × *Uro-Skinneri*).

LEOPOLD DE ROTHSCHILD, Esq. (gr. Mr. Jas. Hudson), showed the deep magenta-rose *Cattleya Clarkiæ intensa*; J. S. MOSS, Esq., sent the white *Odontoglossum nebulosum* Mossiæ; W. THOMPSON, Esq., Walton Grange (gr. Mr. Stevens), the floriferous *Miltonia Bleuana Stevensii*; J. FORSTER ALCOCK, Esq., Northchurch, the dark-coloured *Cypripedium bellatum* Exhibis variety, and *C. Berkleyanum* Exhibis variety.

NURSERYMEN.

MESSRS. SANDER & SONS, St. Albans and Bruges, have obtained First-class Certificates for the showy *Cymbidium Sanderi* (*insigne*) *superbum*, *C. Sanderi splendens*, the violet-blue *Vanda cœrulea* "R. Chollet," *Brasso-Cattleya Madame Chas. Maron* Sander's variety, *Cypripedium Dreadnought*, *Odontoglossum MacNabianum* and *O. Magali* Sander, the last-named being one of the largest and most remarkable *Odontoglossums* yet raised. The Award of Merit plants were *Cattleya Schröderæ* "Queen Alexandra," the unique blotched *Odontoglossum Pescatorei* Sanderæ, *O. Lord Ossulston* Sander's variety, *Vanda amœna* Sanderæ, *Cypripedium Troilus* Lord Nelson, and *Oncidium bicallosum* Sander's variety. Messrs. SANDER & SONS also received Botanical Certificates for *Cymbidium Dayanum* and *Megaclidium colubrinum*.

MESSRS. CHARLESWORTH & Co., Haywards Heath, have exhibited many excellent hybrids, including the handsome *Brasso-Cattleya Cliftonii* and the pure white *Vanda cœrulea* Charlesworthii, both of which secured First-class Certificates; *Sophracattleya Antiochus rubra*, *Sophracattleya Felicia*, *Sophracattleya*

Marathon, *Cattleya Rhoda* (*Iris* × *Hardyana*) in several fine and distinct forms; the deep red *Odontioda Charlesworthii* (F.-C.C.), one of the finest novelties of the year; *Odontoglossum Clytie*, *O. Gladys*, *O. hibernicum*, *Lælio-Cattleya Elinor*, *Trichopilia nobilis alba*, *Bifrenaria tetragona* and *Phalænopsis Lindenii*.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, the pioneers of the Orchid-raising industry, are beginning to show the good results of secondary crosses of some of their earlier productions, the very handsome *Cypripedium Elatior* (*Leeanum* × *Baron Schröder*) far surpassing *C. Baron Schröder* at all points while retaining its rich, deep claret-purple, white colouring and fine substance, and *C. San Actæus Etoniense* being the result of transferring the size and shape of *C. insigne* Ilarefield Hall to the good habit and white dorsal sepal of *C. Actæus Langleyense*.

Orchid novelties were also shown during the year by Messrs. ARMSTRONG & BROWN, Tunbridge Wells, Messrs. HUGH LOW & Co., Messrs. STANLEY & Co., Messrs. J. & A. A. McBEAN, Cooksbridge; Messrs. MOORE, LTD., Rawdon, Leeds, and others.

CONTINENTAL EXHIBITS.

Mons. CHAS. VUYLSTEKE, Loochristi, Ghent, whose hybrid *Odontoglossums* are the envy of all Orchidists, showed a selection of varieties at the Temple Show, those of violet-blue colour being specially novel and attractive. First-class Certificates were awarded for *O. illustre* luxurians and *O. eximium* Queen Alexandra, and an Award of Merit for *O. laudatum*.

At the same exhibition Mons. GRAIRE, of Amiens, showed *Odontioda St. Fuscien*, a pretty scarlet-mottled flower.

Earlier in the year Mons. JULES HYE DE CROM, Ghent, secured First-class Certificates for his white *Cattleya Suzanne Hye* de Crom and for the variety *Jungfrau*. Mons. MERTENS, Ghent, has been a frequent exhibitor of good *Odontoglossums* at the Royal Horticultural Society's meetings. Mons. CHAS. MARON, Bruoy, France, received Awards for *Cattleya Rutilant* (F.-C.C.) and *Brasso-Cattleya Helene Maron* (A.M.).

The following new and rare Orchids are among those illustrated in the *Gardeners' Chronicle* during 1908.

- Bulbophyllum mirum*, May 30, p. 348.
- Bulbophyllum orthoglossum*, June 20, p. 406.
- Catasetum Claesianum*, Sep. 19, p. 211.
- Cattleya Mendelii* Holford's variety, May 2, p. 278.
- Cattleya Venus*, Oct. 10, p. 258.
- Cypripedium Actæus*, Oct. 10, p. 261.
- Cypripedium Charlesworthii* Bromilowianum, Oct. 31, p. 210.
- Cypripedium Dreadnought*, Dec. 5, p. 389.
- Cypripedium Minos* Young's variety, Feb. 1, p. 74.
- Cypripedium San-Actæus Etoniense*, Dec. 12, p. 425.
- Cypripedium ventricosum* album, June 27, p. 414.
- Dendrobium Brymerianum* Gatton Park variety, Suppl., Aug. 8.
- Dendrobium criniferum*, Mar. 28, p. 194.
- Dendrobium Madonnenæ*, Mar. 14, p. 162.
- Diacattleya Colmanæ*, Feb. 22, p. 114.
- Epidendrum costatum*, Dec. 19, p. 425.
- Epidendrum falcatum*, Suppl., Nov. 28.
- Epidendrum Lambeauianum*, Sep. 26, p. 228.
- Lælio-Cattleya Elva* Westonbirt variety, May 30, p. 349.
- Maxillaria luteo-alba*, Mar. 14, p. 165.
- Miltonia vexillaria virginalis*, May 30, p. 351.
- Miltonia vexillaria* Westonbirt variety, May, 30, p. 352.
- Odontioda Charlesworthii*, May 30, p. 353.
- Odontioda St. Fuscien*, May 30, p. 353.
- Odontoglossum ardentissimum* Madame Vuylsteke, June 6, p. 363.
- Odontoglossum crispum* Leonard Perfect, May 16, p. 321.
- Odontoglossum crispum* Memoria Waterloo, June 11, p. 18.
- Odontoglossum crispum* Perfect Gem, April 11, p. 239.
- Odontoglossum egregium* Madame Jules Hye de Crom, June 6, p. 362.
- Odontoglossum Lalressei*, May 23, p. 328.
- Odontoglossum Macnabianum*, Jan. 18, p. 45.
- Odontoglossum maculatisimum*, June 6, p. 362.
- Odontoglossum perculatum* J. R. Roberts, June 20, p. 395.
- Odontoglossum Pescatorei* Westonbirt variety, Suppl., Oct. 3.
- Odontoglossum Phœbe*, June 27, p. 421.
- Odontoglossum Queco* Alexandra var. *Crawshayanum*, July 18, p. 42.
- Odontoglossum Wilckeanum imperiale*, May 2, p. 287.
- Odontonia Lalresseeæ*, May 23, p. 329.
- Orchis latifolia* × *maculata*, Sep. 12, p. 194.
- Polystachya flexuosa*, Oct. 17, p. 276.
- Sophracattleya Doris*, Nov. 21, p. 356.
- Vanda cœrulea* Charlesworthii, Nov. 28, p. 374.
- Vanda pumila*, July 18, p. 43.
- Vanda Watsonii*, Feb. 29, p. 131.

(To be continued.)

The Week's Work.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Preparations for forcing.—In every establishment where large quantities of soft fruit are required, it is imperative that a programme should be drawn up at the beginning of the season, thus systematising the procedure in regard to the forcing operations. In most cases it

is not only necessary to cultivate fruit of the highest excellence, but it is of equal importance that the crops shall ripen at the proper time. More especially do these remarks apply to crops of a temporary character. The gardener should obtain information as far as it is possible as to the approximate dates

when any special demand for fruit is likely to be made upon him. In the case of permanent crops such as Grapes, Peaches and Figs, it is a help to have neat boards hanging in each house, recording on these boards the dates of the stages in the new development of the season, from closing the house before growth has commenced to the gathering of the fruit. Such records have a great value in the following season.

Fruit trees at rest.—Fruit trees under glass need a period of absolute rest. When the pruning has been done, the house should be cleared of any pot plants it formerly contained and the ventilators opened widely at all times unless there is danger of the water in the pipes becoming frozen. If this can be done for several weeks before the house has to be closed for forcing so much the better. The presence of pot plants on fruit-tree borders during the resting season has a very prejudicial effect upon the roots, often causing shanking and bud dropping.

Melons.—If ripe fruits are desired at the end of April or early in May, no time must now be lost before sowing seeds of some trustworthy sort. Fill, therefore, some 2½-inch pots with loamy soil containing a little finely-broken mortar rubble, and warmed to the temperature of the house. Insert two seeds in each pot, and if both germinate, remove the weaker plant as soon as this can be determined upon. Plunge the pots in a moderately warm hot-bed until the seedlings are well through the soil, afterwards placing them on a shelf near to the glass. Although the earliest Melons may be grown successfully in pots, we find that the plants cultivated in beds are most satisfactory. The earliest crops need the advantages of a hot-bed, and the material for forming this should be prepared at once using partially decomposed leaves and stable litter in equal parts. In our case we have the benefit of hot water pipes under the fermenting materials, and it is therefore only necessary to have a small hot-bed, the top of which is raised to within a foot of the trellis. On this hot-bed is placed a bed of soil 18 inches wide by 9 inches deep. The soil is made quite firm, this point being essential. If the loam is of a retentive nature, the inclusion of some old mortar rubble will improve it, and poor soil may be enriched by the addition of finely-crushed bones.

Cucumbers.—Young plants must be raised without delay to fruit in succession to the old plants now showing signs of exhaustion. Sow the seeds singly in 2½-inch pots containing a compost of loam and leaf-mould in equal parts. The soil should be warm when used, and in a sufficiently moist condition that no water will be required until the seeds have germinated. Plunge the pots in a similar hot-bed as advised

for Melons. A hot-bed will afterwards be needed, as in the case of Melons, for forming the beds upon, and if a covering a few inches deep of half-rotten Oak leaves is placed over the bed it will be of great benefit. An atmospheric temperature at night of 65° to 70°, and an increase of about 10° during the day will alike be suitable for the Melons and Cucumbers.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Failures.—Every gardener is bound to meet with failures sooner or later, some owing to unavoidable circumstances, but others are due to improper methods and other adverse conditions which experience will in the future enable him to overcome. It will be well at this season to look

back over the old year and note as far as possible the reason why such and such a crop was not the success it might have been, and take steps to rectify this during the New Year.

Hot-beds.—It will be necessary in many gardens to augment these considerably during the present month as there are very many choice vegetable

ables which can be brought forward with the aid of hot-beds and portable frames. We should hear much less of the French system of gardening if, as I have long advocated, gardeners were provided with a greater number of these portable frames and learned to put them to the best use. They are invaluable to the gardener who has to supply large quantities of forced vegetables, and not only are these of use during the spring months, but they can be utilised with advantage every day in the year, and with the aid of freshly-fallen leaves much less expense incurred in providing the requisite heat. The chief danger in hot-beds lies in the engendering of too much, rather than too little heat, and before adding the soil one should make absolutely certain that the heat is well on the decline, for if once the soil becomes baked, as it most assuredly will if the heat is excessive, no crops will grow in it satisfactorily. Asparagus, Carrots, Turnips, Potatoes, Radishes and such crops are all suitable to this kind of treatment. Cucumbers, Marrows and Melons can also be successfully grown by this method later in the year.

Carrots.—Late sowings made either in heated pits or on hot-beds for supplying young roots early in the year should now be thinned just sufficient to prevent the young plants from becoming drawn. The soil should be stirred between the rows, and air admitted to the frame cautiously whenever the weather is sufficiently mild, on bright days syringing the plants and closing the ventilators at 1 p.m.

Peas.—Those which were sown last month in pots will now have germinated. These should be kept as near the glass as is possible in a cool house or even a cold frame, avoiding the use of fire heat at all times. Make another good sowing of some of the early large-podded varieties in 10-inch pots, and raise the plants in cold frames.

Broad Beans.—These require similar treatment, and provided they are not unduly forced, will produce splendid crops long before one can expect them in the open.

Spinach.—If from any cause the autumn-sown crops prove to be a failure, it will be found a capital plan to sow one or other of the very large-leaved varieties thinly in cold frames. It is surprising what large quantities may be picked from an ordinary-sized three-light frame.

I have found the "Carter" a very reliable variety for this kind of treatment.

Lettuce.—Make small sowings of this in a gentle heat for cultivation under glass. Choose those varieties best adapted to forcing.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Open spaces in London.—During the past two years much interesting and valuable information has been published in the *Gardeners' Chronicle* on park management by the superintendents in the great provincial cities of Cardiff and Glasgow. My own efforts, I fear, will be less successful than theirs have been, and I have some difficulty, from the fact that the parks and other open spaces of London are not under one authority. It has therefore appeared to me desirable in my first article to convey an accurate idea of London's open spaces, and of the divided responsibility that exists for their maintenance and control. The increase in the number and extent of the public parks, gardens, and open spaces within the county of London has been most remarkable during the past 20 years. They are controlled either by the Government, the London

County Council, the City of London Corporation, or the Metropolitan borough councils, of which there are 28 separate governing authorities.

The Royal parks.—The Government have the control of about 1,460 acres, which includes, among others, the important spaces of Green Park, Greenwich Park, Hyde Park, St.

James's Park, Kensington Gardens, Regent's Park, and Primrose Hill. These are all situated within the county, and in close proximity to thickly-populated districts. They are under the management of H.M. Office of Works, and their maintenance is defrayed from the Imperial Exchequer.

The L.C.C. parks.—The London County Council's area of parks, gardens, churchyards, and open spaces comprise about 5,000 acres, and number 112 places, extending from Hampstead and Highgate in the north-west to Tooting and Streatham in the south-west, and from Hackney Marshes and Hainault in the north-east sections to Sydenham and Eltham in the south-east.

The City Corporation.—The City of London Corporation has only a few small places within the county, but outside they have the charge of nearly 6,500 acres, which includes Epping Forest, Burnham Beeches, and Coulsdon Common.

The borough councils.—The 28 metropolitan boroughs have the management of 160 small enclosures, principally small squares, greens, and churchyards, bearing a total acreage of 266 acres. These are controlled and maintained by the borough council in whose area these small but useful enclosures are situated. A large number of them are admirably kept, and all fully justify their cost in procuring and adapting them for the use of the public as an aid to healthful recreation.

Open spaces as playing grounds.—When one considers that within the small area of the London county there are nearly 7,000 acres of park land and open spaces already secured for the use of its inhabitants and visitors, the fact is a very gratifying one. The admirable provision of land for sports and games causes one to wonder how Londoners existed prior to the development of these open spaces. Encouragement is given to basket ball, bathing, boating, bowling, croquet, cricket, football, golf,

gymnasium, hockey, hurley and shinty, lacrosse, lawn tennis, quoits, roller skating, skating on ice, and spiro pole, and a large sum of money is annually expended on bands and other forms of music.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

The forcing house.—Place successional batches of bulbous and other plants in this structure. Tulips will bear harder forcing than most bulbs, but Narcissi and Hyacinths must be brought on gradually or the results will be disappointing. It is essential that all bulbs for forcing should be well rooted before their introduction to heat. Among shrubs suitable for the forcing house at the present time are Acer, Laburnum, Lilac, Prunus triloba, Staphylea colchica, and Azaleas of all kinds (see article on this subject in *Gardeners' Chronicle*, December 12, 19,

26, 1908). Solomon's Seal (*Polygonatum multiflorum*) forces well, and if properly hardened afterwards may be used even in draughty corridors and similar places where most forced plants are not capable of remaining in a good condition. From the present date home-grown Lily of the Valley crowns may be forced successfully, and the flowers from these are usually much more fragrant than those obtained from crowns retarded last season. The moss that is laid over the Lily crowns should be kept in a moist condition, and it must not be allowed to become so matted together that the flower-spikes can only penetrate it with difficulty.

Hippeastrums.—In gardens where there is a considerable stock of *Hippeastrum* bulbs, a batch may now be started into growth, selecting for the purpose firm bulbs that do not require repotting. Carefully remove a little of the surface soil with a pointed stick and afterwards apply a light top-dressing. These plants should be labelled so that they may not be selected for early forcing next season. They will need to be repotted then and will flower later.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Fruit trees on walls.—The pruning and training of hardy fruit trees should be pushed forward in favourable weather. After one of the best autumns on record, the weather broke in December, and caused this work to be delayed. With the aid of planks, however, to walk upon,

training can be carried out when ground-work must of necessity be postponed. On no account permit the ground to be trampled upon when it is in a wet and pasty condition. If any trees have suffered neglect it will be well to cut out a considerable amount of the old wood, even if this involves the sacrifice of a little fruit for a season.

Morello Cherries.—The season of Morello

Cherries may be lengthened by planting a few trees in different aspects, though trees for supplying the main crop should be planted on the north side of a wall. The Morello is not fastidious either as to soil or situation, and if they are planted in a position where fruit trees have not been grown previously, but the soil is in a fair condition, it is not necessary to provide new soil for them. In such a case, spread a coating of wood ashes and lime rubble over the top of the soil and let this be thoroughly incorporated with the staple as the work proceeds. On the contrary, if fruit trees have formerly occupied the site, then apply a compost of good loam, lime rubble and wood ashes. Good drainage is of the first importance, and if this does not exist naturally it must be provided. If fresh drainage is required, place a quantity of brickbats, clinkers or stones in the bottom of the hole, adding slightly smaller material, then placing some turves with the grass downwards, this keeping the fine soil from clogging the drainage. After the turves, put in sufficient soil to bring the trees to the desired height, carefully spreading out the roots to their full length. Fill in between the roots with fine soil, then make the whole quite firm, this latter point being important, as trees planted loosely in rich soil are apt to make unfruitful growth. When finished, the soil should be slightly higher than the surrounding ground to allow for sinking, and till this has taken place, the trees should not be permanently tied. If the trees are young, very little pruning will be necessary the first season, beyond shortening any extra strong shoots. Mulch with some light protective material, but not with heavy manure.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Alterations.—The commencement of the year is a favourable time for altering beds, borders, or shrubberies, either in regard to their outline or in the rearrangement of the plants. The fashions in flower gardening change from time to time, and in very recent years there has been

decided reaction from the formal system of planting. Whatever style is favoured, the flower garden should not be limited to a set of beds of geometrical character collected around the dwelling-house, but should be spread over the entire area of the pleasure grounds.

Every gardener should think out some different mode of planting for particular beds each season. *Bulbs.*—If there are still some bulbs that have not been planted, they should be put into the ground at once. There is something to be said for keeping Anemones over until January before planting them, and in such cases where the soil is of a stiff nature some leaf-mould and sand had better be mixed with the staple before planting, placing a little sharp sand under the base of each tuber. It is rather late to plant Narcissi, but if any are still left over they may yet be capable of giving good returns. Shoots that are appearing now above the soil may need to be guarded from insects and birds.

Protection from frost.—Certain plants are apt to suffer injury from cold reaching their roots, and in such cases a thick covering of fine ashes or some other suitable material will afford them useful protection. Dracenas and Palms may require to have their tops protected, and whilst not neglecting to do this, be careful to avoid placing an excessive amount of covering on them

before it is really necessary. Heather and Bracken are suitable materials for protecting such plants, provided they were cut and dried for the purpose some months ago.

General work.—Present work may include the making or renovating of old paths that have become green. Flower-beds may be dug or trenched, if the ground is not very wet. Fresh turf may be laid on parts of the lawn that have become shabby in appearance.

THE ORCHID HOUSES.

By W. H. WHITE, Gardener to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Platyclinis.—One of the most attractive plants now flowering in the Orchid houses at Burford is *P. uncatata*; although the individual flowers are very small, they are produced on elegant thread-like racemes. The inflorescences arise from half-grown shoots, and the plant having to support so many flowers, and also continue growing, abundance of water must be given to the roots. *P. Cobbiana* has just passed out of bloom, and should also be kept well supplied with water. Plants of the spring-flowering *P. glumacea* have already commenced to grow, and from the present time

until the new pseudo-bulbs are thoroughly matured the plants will need plenty of water at the roots. The summer-flowering *P. filiformis* is now at rest, but the roots must at all times be kept moist. Either of these plants, if they require it, may be repotted immediately they commence to grow, or within a very short time after flowering. To enable the plants to show off to the best advantage when in bloom, shallow Orchid pans are the most suitable receptacles. By using these pans very little drainage is required, thus lessening the weight which would inevitably occur with the well-drained ordinary flower-pot. For many years the plants at Burford have grown exceedingly well when potted firmly in a compost of fibrous peat and Sphagnum-moss in equal parts, both materials being chopped up finely and mixed well together; a moderate quantity of finely-broken crocks is added. An intermediate temperature where such plants as *Miltonia*, *Sobralia*, *Cymbidium*, and *Celogynes* are grown, will suit *Platyclinis* the whole year round. Suspend them near to the roof glass in a light but not sunny position, and on very bright mornings syringe the underparts of the leaves with tepid rainwater.

Cattleya house.—Such plants as *Vanda tricolor*, *V. suavis*, and *Aerides crispum* are now producing quantities of aerial roots. It is advisable to tie in each of these, at intervals, and without unduly cracking them, towards the stem of the plant, and afterwards to gradually guide the young points down into the potting material. The roots will then afford more support to the plant, and be less likely to suffer injury at their points. Afford these Vandas sufficient moisture to preserve the Sphagnum-moss in a fresh-growing condition, and the surface of the stage upon which they stand should be kept moist. *Oncidium cheiroporum*, which has been growing in this house is prominently showing its flower-buds, and the flowers will open better if the plants are now placed in a light position in the East Indian house. While the plants are in bloom, keep the compost rather on the dry side. After flowering, return the plant to its former quarters, and when growth recommences it may be repotted as advised for the *Platyclinis*, with the addition of an equal proportion of leaf-soil. This *Oncidium* will also thrive when suspended or elevated upon suitable stands near to the roof of the intermediate house.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous and Border Plants, Bulbs, Liliacs, Azaleas, &c., at 12; 1,000 Roses, at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Hardy Border and Herbaceous Plants, Liliacs, Ferns, Bulbs, &c., at 12; 4,000 Roses and Fruit Trees, at 1.30; Palms, Azaleas, Rhododendrons, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Choice Burmese Dendrobes, Established Orchids, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39.3°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, December 30 (6 P.M.): Max. 25°; Min. 18°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, December 31 (10 A.M.): Bar. 30.3; Temp. 40°; Weather—Slight rain.

PROVINCES.—Wednesday, December 30 (6 P.M.): Max. 53° Sligo; Min. 21° Colchester.

A Volcanic Island and its Flora.

The process of the colonisation of a new land by the vegetation that will ultimately cover it, has formed an attractive subject for investigation ever since attention was directed to the new islands, coral and otherwise, that from time to time emerge from the sea. The wholesale destruction of vegetation produced by violent volcanic activity is followed by the recovery of their temporarily lost territory by the adjacent survivors, or by those which are reintroduced through human agency. But it can only happen at infrequent intervals that it is possible to study on a large scale the solution of problems of distribution involved in the re-establishment of the flora upon an island, somewhat remote from the nearest land, which has had its covering of plants entirely removed by a catastrophe such as that which devastated the island of Krakatau (or Krakatoa, as it is sometimes spelt) in the great eruption of 1883. The island, which lies about 22 to 28 miles to the north-west of Java, experienced an outburst of volcanic activity before which even the eruption of Mt. Pelée, in Martinique, appears almost commonplace. The dust that was ejected from the crater passed into the upper atmosphere, and is believed to have been concerned in the production of the marvellous sunsets that formed the subject of so much comment in Europe for many months afterwards. It is estimated that something like four cubic miles of solid matter was shot out of the volcano, and the adjacent islands were covered to a depth of over 100 feet with pumice and ashes. The roof of the cavernous space below the craters then fell in, and the whole of the northern part of the island was submerged. The water which thus poured into and surged out of the depression formed great waves, which

rose to a height of about 130 feet and washed the coasts of Java and Sumatra, whilst the effect of the disturbance even extended into the North Atlantic.

The remaining part of Krakatau was sterilised, so far as all things living were concerned, by the rain of hot stones and pumice which fell over its whole surface.

The island to-day, a quarter of a century after the event, is once again clothed with vegetation, and though it has been as yet imperfectly explored, the results of several botanical visits made for the special purpose of investigations of this nature have yielded results of great interest. The first visit after the eruption was made in 1886 by Dr. Treub, the Director of the Botanic Garden at Buitenzorg, in Java, and 11 years afterwards, in 1897, he again visited its shores. After a further interval of nine years another expedition was made to Krakatau and the nearest islands, and a very interesting account of the results of the discoveries thus made has been given by Prof. Ernst, of Zurich*.

It might have been expected that the process of colonisation would have followed the same general lines as have prevailed in coral islands, but this is not the case, doubtless owing to the existence of the high land formed by the volcanic mountain Rakata, which rises abruptly to about 2,728 feet above the sea level.

Dr. Treub, in the earliest visit, found that vegetation was not confined, as he had expected, to the coast, nor were the immigrants derived from ocean-borne seeds and fruits. The winds had clearly formed the means of introduction of the earlier plants, consisting as they did mainly of the lower types of the vegetable kingdom. Algæ, especially the gelatinous "blue-green" forms, and the Ferns were the first to arrive, and although a few flowering plants had established themselves round the coast, they formed but a small proportion of the whole vegetation. In other words, the ocean currents were not the immediately effective agents of transportation, as seems to be generally the case with the low-lying coral islands. When Treub paid his second visit to the island the strand flora had markedly increased, and the characteristic dominant plants of the eastern tropical coasts were establishing themselves. The creeping *Ipomea Pes-capræ*, and other plants along with it, had already begun to form a characteristic association on the beach. Further inland a sort of grass steppe constituted almost a jungle of grasses, which in many places attained to a height of 5 or 6 feet. Shrubs were still scarce, and trees were conspicuous by their absence.

To-day the picture is largely changed. Many flowering plants, including trees, have reached the island, and the photographs of the coast show that in some districts there is an arborescent vegetation which is invading the coastal as well as the inland zones. *Casuarina equisetifolia* and the splendid *Barringtonia*, together with other trees, such as *Calophyllum*, and *Terminalia*, have established themselves, whilst the Screw Pines (*Pandanus*) and Coco Palms are also spread-

ing over the littoral regions. The remarkable discovery was made of a fine *Cycas circinalis*, with fertile leaves arising from a stem over 5 feet in height. The ovules were not fertilised, and no male plants were seen, a circumstance which accounts for the isolation of the specimen. It was unfortunate that, owing to the expedition being imperfectly provided with the means of travelling in a land offering considerable obstacles to exploration, it proved to be impossible to investigate the vegetation of the peak. The lowland flora was already so dense that a way had to be cut through it, whilst, as might be anticipated, the heavy rains had ploughed out gorges and ravines in the soft, volcanic ash and pumice, and thus rendered rapid progress impossible.

The analysis of the soil showed that it was remarkably poor in phosphorus and nitrogen. It was of importance, therefore, to ascertain how the plants obtain these indispensable elements. As to the former, we know nothing positively as yet, but it is interesting to find that the leguminous species have already the bacteria associated with them which are responsible for the well-known leguminous tubercles on the roots of these plants. A new bacillus was also isolated from the soil which, like some others already known to science, has the power of fixing free nitrogen from the atmosphere, thus rendering it available for other forms of plant life.

The existing vegetation, taken as a whole, and so far as it is at present known, has reached the island by three principal agencies. The wind, by which the earliest immigrants were imported, accounts for about 37 per cent. of the vascular plants, and this includes about 25 flowering plants and 16 Ferns, but leaves out of account the lowest organisms to which we have already referred. Sea currents and birds are mainly responsible for the remainder, and as time goes on it is likely that the proportion of those thus introduced will be increased.

But, of course, as the land becomes occupied, the chances in favour of additional immigrants succeeding in gaining a permanent footing in the land will become diminished, inasmuch as the newcomers will have to compete for growing space with individuals that have already established themselves.

The vegetation as it now exists is already beginning clearly to show that sub-division into plant associations which, in all places where free competition can occur, result from what we might term the political differentiation of the vegetable world. The strand flora is an easily recognised type. The grass steppe is another, as is also the *Barringtonia-Calophyllum* belt. As time goes on we may expect the forest to invade the grass land, and each of these larger complexes will undergo further sub-division on lines which will be mainly determined by physical and biological factors working independently of human interference. For it seems improbable, with so much fertile country still open to settlers, both in Java and Sumatra, that man will find it worth his while, at any rate for the present, to spoil the progress of this large-scale experiment. We venture to express the hope that so great an opportunity for study will not be neglected, and that observations will in the future be made at intervals considerably shorter than decades.

* *The New Flora of the Volcanic Island of Krakatau*, by A. Ernst, Ph.D.; translated by Prof. Seward, F.R.S. Cambridge: University Press, 1908.

FIG. 12.—CHONDROPETALUM FLETCHERI, A DIGENERIC HYBRID (ZYGOPETALUM MACKAYI X CHONDROKORHYNCHA CHESTERTONII). SEPALS AND PETALS BRIGHT EMERALD GREEN WITH PURPLE MARKINGS; LIP WHITE, TINGED WITH SULPHUR YELLOW; CREST, A SHADE OF ROSY-LILAC.

CHONDROPETALUM FLETCHERI.—Our illustration (fig. 12) represents this singular bigeneric hybrid, raised in the nurseries of Messrs. SANDER & SONS, St. Albans, by crossing *Zygopetalum Mackayi* with the totally dissimilar *Chondrorhyncha Chestertonii*, whose deeply-fringed labellum was expected to appear in some degree in the hybrid. But the strong individuality of *Zygopetalum Mackayi* has been proved before by crosses made between it and various widely-separated genera, the result of which has been false hybrids, the progeny still remaining *Z. Mackayi* in effect. In this case, although the expected result was not arrived at, a decided step has been made in securing a very beautiful hybrid of neat habit and quite distinct from *Zygopetalum Mackayi*, although a botanist, without knowledge of the manner in which the plant has been obtained, would not find any botanical feature to separate it from *Zygopetalum*. The plants, which are very floriferous, have conical pseudo-bulbs furnished with bright-green leaves. The inflorescence is about 18 inches in height, the handsome flowers, having the sepals and petals nearly equal, bright emerald green with short lines and spots of purplish-chocolate colour. The broad lip is white, tinged with sulphur yellow, and bears no trace of the blue veining of the seed-bearing parent, although the crest, which is of true *Zygopetalum* form, has a delicate rosy-lilac fringe in front of it. The plant was exhibited by Messrs. SANDER & SONS at the Royal Horticultural Society's meeting on November 10 last.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Committees in 1909 will take place on Tuesday, January 12, in the Society's Hall, Vincent Square, when there will be competitive classes for late Grapes.

ROYAL GARDENERS' ORPHAN FUND.—We are informed that the Duke of PORTLAND will preside at the annual festival of this fund, which will take place at the Hotel Cecil on Thursday, May 6.

BEFORE THE SNOW.—The weather up to Christmas was as remarkable for its mild character as the present weather is for its severity. Now that most gardens have been so recently buried in snow, it is difficult to realise that last week many were gay with a host of flowers, including not a few tender species. In last week's issue, on page 451, we published a list of 88 species in flower in the gardens of Lord MOUNT EDGEMORE, at Tre-widden, Cornwall, on December 8, and we have received further communications respecting similar abnormal flowering. An interesting list is sent from Abbotsbury, near Dorchester, the residence of Lady MARY LECHESTER, by the gardener, Mr. KEMPSTALL, of plants in bloom on Christmas Day. There are 119 species enumerated, including such tender genera as *Nicotiana*, *Fuchsia*, *Hydrangea* and *Dahlia*. Mr. KEMPSTALL informs us that nearly all these flowers were destroyed on December 27, when 2 inches of snow fell, followed by 8th of frost. Another list has been forwarded by Mr. HENRY D. McLAREN, Bodnant, Tal-y-Cafn, North Wales, of the plants in flower in his garden at Christmas. Mr. McLAREN states that he can usually find between 50 and 60 species in bloom at the end of the year, but this season the number at Christmas was 80. Sir ARCHIBALD BUCHAN-HEPPEN sends a list including about 40 species, and the range of subjects is a very wide one. Sir ARCHIBALD BUCHAN-HEPPEN's garden at Prestonkirk is situated on the south-east coast of Scotland, 100 feet above sea level and 23 miles from the sea.

SWEET PEA TRIALS FOR 1909. We are informed that the Committee of the National Sweet Pea Society will continue its series of trials at the gardens of the University College, Reading, in 1909, and will test novelties, and grant Awards and Certificates according to merit. For these trials the varieties will be accepted only from the raiser or introducer; a charge of 2s. 6d. for each variety will be made. At the request of numerous seedsmen, the Committee will conduct another trial solely for the purpose of testing correctness and purity of stocks of Sweet Peas. A charge of 5s. per variety or stock sent for trial will be made. Sweet Peas for these trials should be sent to Mr. C. FOSTER, University College Gardens, Reading, not later than January 25. For the Novelty Trials not fewer than 15 seeds should be sent, and for the Purity Trials not fewer than two dozen seeds of each variety or stock. At the same time, a list of the varieties, together with the amount due for trial charges, should be sent to the hon. sec., Mr. C. H. CURTIS, Adelaide Road, Brentford, Middlesex. Novelties will be received under number, although names are much preferred. Any variety meriting an award must, if under number, be named before such award can be granted. The proceedings of the Floral Committee will be printed in the autumn of 1909, and a copy will be sent to every person or firm sending seeds to either or both of the sets of trials.

CULTIVATION OF LEONOTIS LEONURUS AT THE CAPE.—The Lion's Tail (*Leonotis Leonurus*) has recently been referred to in some of our contemporaries as a plant that should be more extensively grown for autumn and winter flowering. Besides the attractive character of the plant, it may be interesting to those who grow it or intend to do so, to know that it possesses narcotic properties (notwithstanding that it belongs to the usually considered harmless Order Labiatae), and that its cultivation at the Cape of Good Hope, where it is a native, is a subject that recently occupied the attention of the Legislative Council, which brought in a Bill to prohibit the cultivation of this plant as well as *L. ovata* and the common Hemp (*Cannabis sativa*), the same narcotic property being contained in all three plants. It is a well-known fact that in tropical countries the Hemp plant develops a narcotic resinous coating on the leaves, stem, and flowering tops, which is used either for smoking or for infusing in water in the preparation of an intoxicating beverage. In India the gum resin is known as Churrus or Charas, and is said to be collected by men clothed in leather garments brushing about amongst the plants, and thus bruising them, so that the resin exudes and becomes attached to the clothing of the collectors. The dried flowering tops, called Gunja, are smoked, and they are sometimes to be seen in the London market, where the article is generally known as Guaza. The intoxicating effects of all these preparations of Hemp are well known, and a similar principle seems to be contained in the plants of *Leonotis*, hence the action of the Cape Legislative Council, whose Bill provided that it should not be lawful for any person to sell or grow and cultivate either of the three plants before-mentioned under a fine of £25. Provision, however, is made that nothing should hinder a registered chemist and druggist from using any of these plants for medicinal purposes under the directions of a medical practitioner. It is provided also that licenses should be obtainable from a minister by anyone intending to cultivate the plants for purely medicinal purposes. The reasons for the necessity of legislative restrictions were stated to be that the habit of smoking the plants by the natives

caused them to become indolent and stupid, resulting in insanity and consequent confinement in lunatic asylums and prisons. In India similar effects are produced by the continued use of Hemp—exhilaration at first, followed by great depression but often with "wild reveries and causeless laughter." Long continued use is said to be a prominent cause of insanity. In some parts of India an Excise license is required to cultivate the plant.

BIRDS AND THEIR FOOD. The recently-published Supplement to the *Journal of the Board of Agriculture* (December) is devoted to the consideration of the food of British birds from the economic standpoint, as affecting the farmer and gardener. Mr. NEWSTRAD is to be congratulated on this first instalment of the results of an investigation that has long been greatly needed, and the booklet ought to be in the hands of everyone who is interested in this important subject. It should serve as the means of cutting the ground from under the ignorant statements so often made as to the utility or injury done by this or that native bird. For example, it is stated on p. 28 that the stomach of a blue titmouse which had been shot as "red-headed at the Peas," was found not to contain a single Pea, but to have been filled with American blight insects. We note earwigs are said to be not eaten apparently in large numbers, but amongst its destroyers the Robin is mentioned. We recall an instance that came under our own notice, in which a partly tame robin would always fly down when earwig traps were examined, and greedily devour every individual that it could catch. We have also known of a case in which rooks have saved a large field of Wheat from wireworm. A specimen was shot and examined, and its stomach was filled with the larvæ, and only contained a few grains of the sprouted Corn. It is pointed out that many hard-billed birds feed their young on caterpillars and other pests, and thus a bird which, in its adult state, may ordinarily be a great source of damage, may, in the breeding season, do much good. The work should do much to stimulate further research, and the directions given for collecting useful and accurate observations add greatly to its value.

MASTERS' MEMORIAL LECTURES.—The Royal Horticultural Society has arranged with Professor HUGO DE VRIES to deliver two lectures during 1909 in connection with the fund raised as a memorial to the late Dr. MAXWELL TYLDES MASTERS. The first lecture will be delivered on June 22, the subject being "Masters' Vegetable Teratology." The second lecture, on "The Production of Varieties," will be given by Prof. DE VRIES on September 28. Both the dates are those of ordinary fortnightly meetings, and the lectures will be delivered at 3 p.m. in the lecture-room.

THE YELLOW STRIPE DISEASE OF DAFFODILS.—The current number of the *Journal of the Royal Horticultural Society* contains an account of "Yellow-stripe" in Daffodils, contributed by Mr. H. R. DARLINGTON. This malady, which appears to be on the increase, has been ascribed to various causes. Some have regarded it as being due to over-manuring; others to the presence of *Bacterium hyacinthi*, a microbe which is known to cause disease in the stored bulbs of Hyacinths. Mr. DARLINGTON believes that Yellow-stripe is due, in some cases, to cold, in others, to the consequences of the destruction of the roots by the caterpillar of the Swift moth. He concludes that the malady is not infectious, and that, therefore, there is no need to destroy infected plants.

BRITISH GARDENERS' ASSOCIATION.—The next meeting of the London branch will be held on January 9, at Carr's Restaurant, Strand, at 7.30 p.m., when Mr. CYRIL HARDING, of the Parks Department, Cardiff, will deliver an address upon "Garden Cities: What they are and what they might be."

THE VICTORIA MEDAL OF HONOUR.—We understand that the President and Council of the Royal Horticultural Society have filled the two vacancies caused in the roll of the Victoria Medal of Honour in Horticulture caused by the death of Mr. MARTIN SMITH, V.M.H., and Mr. GEORGE NICHOLSON, V.M.H., by appointing to this honour Sir JEREMIAH COLMAN, Bart., and Mr. CHARLES ROSS. Sir JEREMIAH COLMAN has done much service for horticulture by a long series, extending over many years, of experiments in Orchid breeding and by the instructive exhibits which he has sent to the Society's shows. Mr. CHARLES ROSS is one of our veteran gardeners and fruit growers, and has raised a larger number of seedling Apples than any man living—more probably than any one ever has done before him—and many excellent ones amongst them, such as "Encore," "Charles Ross," and "The Houblon." We are very glad to find that his persevering work has at last been recognised by the bestowal of the highest honour the Society has it in its power to confer. An appreciative notice and portrait of Mr. Ross appeared in our issue for October 24, 1908, p. 299.

ROSE CANKER.—Rose growers will read Mr. H. T. Güssow's account in the *Journal of the Royal Horticultural Society* of a new parasitic Rose canker with mingled feelings. Whilst they cannot but admire the admirable account which he gives of the disease, they will regret that they have a new enemy with which to contend. The disease, which the author shows to be due to a fungus, *Coniothyrium Fuckelii*, starts on the one-year-old wood, but is not readily recognised till its attack is well advanced. The first indication of the presence of the parasite consists in red-brown or purplish spots on the young wood. Mr. Güssow considers that *Coniothyrium* is a wound-parasite, and suggests that a careful watch should be kept for the disease in its early stages, and that, when it makes its appearance, the affected shoots should either be removed altogether or the diseased spots cut out and the wound dressed with creosoted wood tar.

THE ROYAL BOTANIC GARDENS, EDINBURGH.

WHEN the experimental garden of the Caledonian Horticultural Society was added to the Royal Botanic Gardens, Edinburgh, in the sixties of the last century, part of the area was devoted to the cultivation of Conifers, and many new kinds were being introduced from America at about that time. The ground was laid out by James McNab, whose artistic feelings found expression in the admirable curves of the pathways through the newly-formed Pinetum. The illustration at fig. 4 shows one of the paths in winter, bounded on the left by a belt of *Abies* and *Picea*, and on the right by *Cupressinæ*. Conifers do not thrive luxuriantly in the Edinburgh garden. As young plants they succeed well, but the expectations formed 40 years ago upon the aspect of the young specimens in the collection have been by no means realised. The appearance of the taller trees, *Abies grandis*, *A. Lowiana*, *A. firma*, and *Pseudotsuga Douglasii*, on the left of the illustration, were planted by McNab, and their condition at the present time is not satisfactory.

It has been the practice in these gardens for some years past to cultivate, as far as possible,

the plants under glass in borders, rather than in pots. The illustrations at figs. 13 and 14 show the new fernery which was planted late in the spring of 1908. This house replaces one of the old houses which had fallen into disrepair—the very house in which William McNab cultivated his wonderful specimen Heaths. Large blocks of red sandstone have been used for the rock-work, with here and there a tree stump for the epiphytic Ferns, Mosses, and Hepaticæ. Although the Ferns were only planted in May, their growth has been marvellous. Fine examples of many species are seen, amongst which may be noted *Lindsaya retusa*, *Acrostichum viscosum*, *Davallia tenuifolia Veitchii*, *Platy-*

THE AGRICULTURAL HOLDINGS ACT, 1908.

REMARKABLE INNOVATIONS.

THOSE who, for some years past, have been agitating for codification of the law relating to Agricultural Holdings and Market Gardens by combining into one statute the principal Acts of Parliament relating thereto, will have good reason to congratulate themselves on the advent of the New Year, as on January 1, 1909, the Agricultural Holdings Act, 1908, which effects this reform, came into force. This Act (which, for the sake of brevity, we will term the new Act) repeals not only the Market Gardeners' Compensation Act, 1895, but also the

FIG. 13.—A CORNER IN THE NEW FERNERY AT EDINBURGH ROYAL BOTANIC GARDENS.

cerium grande, *P. angolense*, *P. æthiopicum*, *Polypodium quercifolium*, as conspicuous examples. The *Lygodium*s form graceful plants for the pillars of the central dome. In one respect cultivation of this kind is very easy in Edinburgh. The low intensity of insolation renders elaborate shading unnecessary. The shading furnished by the growth of climbing plants is sufficient even during the short period of hot summer days. The Fernhouse was erected by Messrs. Mackenzie & Moncur, of Edinburgh, and it is an admirable example of their work. R. L. Harrow.

Agricultural Holdings Acts of 1883, 1900 and 1906, together with certain sections of other Acts and embodies their provisions in a single new statute.

The benefit conferred upon agriculturists and market gardeners by this partial codification of the law should be considerable, as, although the new Act does not purport to embrace in addition the numerous decisions given in the courts on the effect of various words and phrases so as to bring to light the numerous traps which lie in the path of the unwary, yet it at least enables those affected to obtain a rough idea of their

rights, and will induce many to weigh with more care than hitherto the effect of tenancy agreements to which they are invited to bind themselves. It is, unfortunately, true, however, that although the new Act is of vast importance to the market grower, it does not yet interest the nurseryman, inasmuch as the Government has not yet found leisure to make the promised enquiry into the possibility of extending to nurserymen the benefit of the Agricultural Laws.

In proceeding to explain the effect of the new Act, it may be useful to point out that many of its provisions will be familiar to those who watched the stormy passage through Parliament of what was once known as the Land Tenure Bill; on its becoming law, this Bill was legally termed the Agricultural Holdings Act, 1906, and was due to come into force on January 1, 1909. For the sake of convenience, however, it now stands repealed, and its provisions, with those of the other statutes referred to above, are together incorporated in the new Act.

COMPENSATION FOR IMPROVEMENTS.

Those who perused certain articles on the subject of agricultural law which appeared in these columns on November 3 and 10, 1906, may recollect that the question of compensation for improvements was explained at some length, and it was then pointed out that, as regards improvements to which the Market Gardeners' Compensation Act, 1895, applied, the Act was not retrospective; that is to say, compensation could not be claimed thereunder in respect of improvements made before January 1, 1896. As a matter of fact, those who framed that Act did not intend to make any distinction between improvements carried out before the date in question and those carried out afterwards; but the section which dealt with this point was not worked quite so clearly as could have been desired, and in a case which was taken to the House of Lords, it was decided that the Act of 1895 only applied to improvements effected after it came into force. It was felt at the time that this decision involved a hardship which was not intended by the legislature, and the matter has now been put right in the new Act, with the result that after January 1, 1909, a considerable benefit is conferred upon market gardeners whose holding was, on January 1, 1896, in use or cultivation as a market garden with the knowledge of their landlord. In future they will be entitled to claim compensation for improvements which they carried out before January 1, 1896, provided they had not received written notice from their landlord that he objected to such improvements before they effected them.

Such remaining sections of the new Act as create new law apply equally to farmers and market gardeners, and in connection with improvements there is a further enactment of considerable importance. It was pointed out in the previous articles referred to above that when a tenant, on quitting his holding, claimed compensation from his landlord for improvements, he must not seek to take credit for that part of the increased value of the land which was really attributable to the special character of the soil; that is to say, the inherent capabilities of the landlord's property, as distinguished from works carried out by the tenant. This is no longer the law, as the outgoing tenant now becomes entitled to claim, in respect of various improvements mentioned in the new Act, such a sum by way of compensation as fairly represents the amount of increased value to an incoming tenant, even though part of such increased value is clearly attributable to the inherent capabilities of the soil itself. The improvements to which this provision refers cover the items Nos. 1 to 16 in the previous articles referred to above, and include such matters as the reclaiming of waste land, planting orchards, laying down land to pasture, draining, etc.

ARBITRATION.

The new Act provides that all disputes are to be referred to a single arbitrator, and any agreement between the parties to refer the matter to more than one arbitrator is absolutely void. This provision applies irrespective of whether the dispute arose either before or after the passing of the new Act. Furthermore, the arbitrator is bound, if desired by either party, to specify the amount awarded in respect of not only any particular improvement but also of any other

special matter dealt with by his award. If, as is highly probable, the parties cannot agree on the person who is to act as sole arbitrator, then either party can call upon the Board of Agriculture to nominate someone to act in that capacity.

DAMAGE BY GAME.

In country districts the damage caused to crops by the depredations of game leads to many disputes between landlords and their tenants. The latter already have statutory protection in the case of hares and rabbits, but a different question arises when the damage is caused by what is legally regarded as "game" for this purpose; that is to say, deer, pheasants, partridges, grouse and black game. The new Act provides that the tenant is to be entitled to compensation from his landlord for damage caused by such game (in cases where the tenant has not the right to take and kill the game) where the damage caused amounts to more than a shilling per acre. Any agreement to the contrary between landlord and tenant is void, and any agreement made beforehand to limit the amount of compensation is also void. If, after the damage is caused, the landlord and tenant cannot agree on what would be reasonable compensation, the matter has to be referred to arbitration, but before seeking to recover compensation the tenant has to take several important steps, viz. :—

1. He must give notice in writing to the landlord as soon as he observes the damage.

2. He must give the landlord a reasonable opportunity of inspecting the injured crop; that is to say (a) in the case of a growing crop he must do this before the crop has begun to be reaped, raised or consumed; or (b) if the damaged crop is already reaped or raised he must give the landlord a similar opportunity for inspection before beginning to remove the crop from the land.

3. He must claim the compensation by notice in writing given to his landlord within one month after the expiration of the calendar year (or such other period of 12 months as the parties may have agreed to substitute for the calendar year) in respect of which the claim is made.

At first sight these provisions may appear a little contradictory, but on closer scrutiny it will be observed that the effect of them is that the tenant need only give notice of the damage to his landlord immediately, and is not obliged to give notice of his actual claim until a period which may be much later.

Landlords reading the Act may perhaps be excused for feeling a considerable amount of anxiety with regard to amounts which they may have to pay by way of compensation for damage thus caused by game, but they may possibly feel some slight measure of relief when they reach a further clause which provides that in the case of tenancy agreements made before January 1, 1909, the arbitrator, in fixing the amount of compensation for damage of this kind, must give the landlord due credit in those cases where he has already made allowance for the anticipated depredations of game by accepting a lower rent than he would otherwise have demanded. Further, relief is also afforded to the landlord by a provision to the effect that if the right to kill and take game belongs to some person other than the landlord (e.g., a person holding the sporting rights), then such other person is bound to make good to the landlord any compensation which the latter has to pay to the tenant. *H. M. V.*

(To be continued.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

GRAPES.—There can be no doubt as to the variety named "Canon Hall" Muscat being distinct; but whether it is a sport or seedling from Muscat of Alexandria is a question of some uncertainty. I am inclined to think it is a seedling, the result of a cross between Muscat of Alexandria and some European variety. With a view to raising new varieties, numberless attempts have been made to cross "Asiatic" and

European kinds of Grapes. As an instance of this, I may mention Melville's Muscat Champion, Thomson's Duke of Buccleuch, and Thomson's Golden Champion. These are all said to be crosses between the Asiatic Muscat of Alexandria and the European Hamburgs, and, like "Canon Hall," not one of these can be said to be satisfactory, although all of them are remarkable for their large, handsome bunches and berries of excellent flavour. Like "Canon Hall," they are gross and robust growers, but, except in young vines that are grown in light, airy vineries, there is a great deficiency of firm pith in the wood. In consequence of this, the buds rarely produce compact, shapely bunches, and the spurs often fail altogether after a few years, showing clearly that something is wrong in the constitution of these hybrids. At this season, horticultural societies usually revise their schedules of prizes, and in cases where Muscat of Alexandria classes are provided, it would be well if the word "Alexandria" were omitted, making it to read "White Muscat," and thereby prevent those unpleasant differences between judges and exhibitors that have been frequent in the past. I note in the columns of the *Gardeners' Chronicle* that the Council of the Royal Horticultural Society has decided to hold fortnightly exhibitions of fruit during the forthcoming year. This is a step in the right direction, and it is to be hoped that Grape growers will come forward with the best varieties in their proper season. It would be instructive as well as interesting if a special effort were made to bring as many as possible of these so-called varieties of Muscats together, say, at one of the autumn shows. *J. McIndoe.*

MELONS.—Seeds of an approved variety should be now sown. Take a number of carefully-drained 2½-inch pots, and fill them with moderately-moist, fine compost consisting of loam and leaf-mould. Plant a seed ½ inch deep in each pot, and cover with shaded pieces of glass. Plunge the pot in a hot-bed of 80°, and maintain an atmospheric temperature at night of 70°. No water will be required until the plants appear, when they should be placed near the glass in a house having a night temperature of 70°. Keep the plants carefully watered, and in bright weather syringe them, in each case using tepid water. The plants may be fruited in 10 or 12-inch pots, or be planted out at 2 feet apart upon a ridge or hillock of compost, placed well up to the glass, upon a hot-bed. The bed should be composed of carefully-prepared stable litter and tree leaves, or, as in our case, hot-water pipes may be used for affording the necessary bottom heat. *Thomas Coomber.*

MANURING OF LAND.—The weather having been unusually dry and mild, ground operations have been carried out under most favourable conditions. A general survey should now be made to ascertain which fruit trees need manure, as by so doing matters will be greatly facilitated later, when on frosty mornings manure may be wheeled to the different trees. No hard-and-fast rule can be laid down, as some soil requires much more manure than others, and trees that annually carry good crops of fruit need most assistance. Where farmyard manure is procurable, this should form the staple, using as auxiliaries wood ashes, lime, and such chemical manures as kainit and super-phosphate. Unless well manured every year or two, Apples and Pears grown on the dwarfing stock soon become exhausted, a frequent error with regard to these trees being to apply too much manure when planted and too little afterwards. On heavy soils inclined to hold water, it may be better to defer mulching with manure until the growing season. Old-established Apple and Pear trees in orchards will be greatly benefited by a surface mulch of manure, as the winter rains will then wash the manurial properties down to the roots. All bush fruit quarters are also considerably improved by a good dressing of manure annually, which should be lightly pointed over afterwards, as digging too deep injures the roots of these trees. *F. Jordan.*

ESCALLONIA.—Mr. Divers (p. 438, vol. xlv.) remarks on the probability of these lovely shrubs doing well in the climate of south-west Ireland. He is quite right, and it would doubtless surprise many if they were to see how remarkably vigorous most of the Escallonias are here. *E. macrantha* is almost as vigorous as the Laurel, and a variety with rather smaller leaves is a more continuous flowerer, but equally as strong in growth. *E. montividensis* attains to a height of 7 or 8 feet, and is about the same in diameter, flowering for fully three months (October to January); it has some fine paniced corymbs open now (December 22). *E. Philippiana* is a wonderful sight in June and July, with its dense panicles of small, white flowers. What I take to be *E. pterocladon* is a shrub about 12 feet high, and, at the present time, has quite a number of

viding there be an eye at each piece, are planted in March, 5 rows in the bed, plant not deep, neither in wet or stiff ground; spend them with Parsneeps, and in housing spread only through a board floor." Lawson, in *Scottish Agricultural Products*, says: "To Thomas Prentice, a common day labourer, who lived near Kilsyth, is the honour due of bringing this useful esculent into general culture in Scotland in 1728." He adds there was long a prejudice against it, because it was not one of the food roots mentioned in the Bible. The first book on the Potato is that by John Forster, in 1664, entitled, *England's Happiness Increased, etc., by a Plantation of Roots called Potatoes*. This work is also exceedingly scarce, and I wonder if it is in the Earl of Haddington's famous library at Tynninghame? *Donald McDonald*.

the ordinarily blue *Gentiana campestris*, remarking that he had found it occupying an area of several square yards at an elevation of about 1,000 feet in the Scottish Highlands, while all the plants at a lower elevation were of the usual blue colour. The plant had evidently come true from seed, and this, he thought, was probably true of the majority of albinos when self-fertilised. There are numerous examples of albino varieties of British wild plants occurring naturally, and Mr. FRASER produced a list which, supplemented by other members, is here reproduced, but it is by no means exhaustive.

Papaver Rhœas
Matthiola incana
Viola odorata
" *hirta lactiflora*

Centaurea nigra
Carduus nutans
Cnicus palustris
" *arvensis*

(See p. 11.)

its pretty whitish panicles in flower. *E. langleyensis*, although occupying a somewhat poor position, does equally well. The Escallonias make magnificent hedges here, the refreshing gloss of the foliage is ever attractive, and they bear close clipping quite as well as the Yew. *A. J. Elgar, Killarney House Gardens, Co. Kerry*.

THE POTATO IN SCOTLAND.—With regard to Mr. R. P. Brotherton's note on p. 451, vol. xlv. although James Donaldson's little book, published in 1697, may contain matter of no value, the book itself is very scarce. I saw £4 given for a copy last year in a London auction-room, and my own copy cost me 50s. John Reid, who wrote *The Scots Gardener*, and produced it in 1683, gave us the first book on gardening in Scotland. He states, on page 107: "Potatoes being cut in as many pieces as you please, pro-

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

DECEMBER 22.—*Present*: Mr. E. A. Bowles, F.L.S. (in the chair), Messrs. A. W. Sutton, G. S. Saunders, J. T. Bennett-Poë, E. M. Holmes, H. J. Chapman, L. Crawshay, A. Worsley, F. J. Baker, J. Fraser, and F. J. Chittenden (secretary).

Malformed Cyclamen.—Mr. CRAWSHAY showed an interesting, though not very uncommon, malformation of the Cyclamen, where two flowers had been produced in the axils of two of the sepals of an otherwise quite normal flower. All the flowers on the plant, which was a seedling, were similarly malformed.

Albinos among British wild flowers.—Mr. J. FRASER showed specimens of an albino form of

Viola lutea amœna
Polygala vulgaris
" *serpyllacea*
" *calcareæ*
Silene acaulis
Malva moschata
Geranium Robertianum
Ononis spinosa
Trifolium incarnatum
Rubus rusticanus
Rosa canina dumalis
" *succulosa*
Rosa dumetorum
Epilobium hirsutum
Scabiosa succisa

Campanula rotundifolia
Calluna vulgaris
Erica tetralix
" *cinerea*
Centaurium umbellatum
Gentiana campestris
Verbascum nigrum
Bartsia Odontites
Ballota nigra
Thymus Chamædryas
Galeopsis Tetrahit
Ajuga reptans
Polygonum Bistorta
Orchis muscicola
" *maculata*
Scilla nonscripta

Plants in bloom.—Mr. BOWLES showed specimens of *Felicia petiolaris* gathered from the open in a Wimbledon garden, where the plant had flowered up to the present since the autumn. He also showed specimens of the following species of Crocus, which were flowering out-of-doors considerably before their normal period

of bloom:—*Crocus Imperati* (monophyllus) and a depauperate form of the same species; *C. Selberi* and *C. chrysanthus*. *C. Imperati* was also shown from Wisley.

Grease bands.—Mr. J. WATKINS, orchard foreman to Sir Edmund Loder, Bt., Maplehurst, Sussex, sent a grease band from an Apple tree with an enormous number of winter moths (*Cheimatobia brumata* and *Hybernia aurantiانا*), both male and female, adhering to it. Mr. WATKINS wrote that when he took the band off nearly 400 male and female moths were upon it, and that there were many bands on which 200 and upwards have been caught. The trees had never been banded before; but now some 10,000 had been done. The mottled umber moth was the first to be caught, but later the small winter moth was entrapped in much greater quantities. Birds appear to take a great number of the moths from the bands and devour them, particularly the blue tits. Few moths were caught when the bands were first put on (in the first week in October). The larger proportion of females was caught from the middle to the end of November, and a few are still attempting to ascend the tree stems. Males were most abundant earlier.

LINNEAN SOCIETY.

DECEMBER 17.—Mr. W. C. Worsdell exhibited living specimens of various forms of *Selaginella*, and remarked that in *Selaginella inequalifolia*, Spring, *S. Willdenovii*, Baker, *S. canaliculata*, Baker, *S. serpens*, Spring, *S. Mettenii*, A. Br., he observed rhizophores which had grown out spontaneously into leafy shoots. The mode in which this takes place shows that the rhizophore has the morphological character of a shoot, as there is clearly but a single organ here concerned, and there is no question of the shoot developing out of an organ of a different nature represented by the extreme base of the whole structure. The exogenous origin of the normal rhizophores, the fact that the two (upper and lower) at the base of each dichotomy of the stem form therewith a tetrachotomy, two arms of which are in a plane at right angles to the other two, and their constant, definite place of origin, are all in favour of their shoot-nature. Transitions occur between the normal rhizophore and the extreme leafy form. The rhizophore is probably homologous with the "protocorm" of *Lycopodium* and *Phylloglossum*, and with the organ known as *Stigmara*; if so, it follows that both the "protocorm" and *Stigmara* are also of shoot-nature. It is very unlikely that organs intermediate between shoot and root can exist in Nature.

Mr. George Massee exhibited preserved specimens and lantern-slides of the "Black Scab" of Potatoes. During the past few years this disease, caused by a parasitic fungus, has assumed the proportions of an epidemic in various parts of this country. The tuber is the part most frequently attacked, but very young leaves are sometimes infected. In tubers the young "sprouts" are attacked, and, owing to the stimulation induced by the parasite, the infected sprouts rapidly increase in size and form large coralloid masses or warts, which frequently cover the greater portion of the surface of the tuber (see fig. in *Gardeners' Chronicle*, August 22, 1908, p. 146). These masses eventually become blackish-brown in colour, due to the presence of myriads of dark-coloured resting-spores. Infection always takes place from without, consequently the epidermal or peripheral cells alone are infected. The presence of mature resting-spores imbedded deeply in the tissue of the host, at first sight appears to contradict this statement, but this appearance is due to the rapid growth and division of uninfected epidermal cells, which soon forms a tissue superposed on what was previously the periphery. A point of interest in connection with this disease is the absence of periderm, which in other diseases of Potato tubers is so readily formed. On germination, the inner, thin hyaline wall is extruded in the form of a sphere, through a crack in the thick-coloured outer wall of the resting-spore. The thin wall of the extruded inner membrane soon deliquesces, and liberates myriads of elliptical, 1-ciliate zoospores. The facts that the host is infected through the epidermal or peripheral cells, and the extrusion of the inner wall of the resting-spore as a sphere,

from which the zoospores escape in an active condition, indicate that the parasite belongs to the old and well-known genus *Synchytrium*. What happens to the zoospores after their liberation into the ground remains to be discovered, but experiments conducted at Kew prove that soil once infected produced a diseased crop even after a period of five years.

Messrs. H. and J. Groves exhibited specimens of *Luzula pallescens*, Besser, collected in Woodwalton Fen, Hants., by Mr. J. Groves in company with Mr. E. W. Hunnybun, who discovered the plant there last year.

Dr. Otto Stapf, F.R.S., Sec.L.S., exhibited, for comparison, specimens of *L. pallescens* from Central Europe.

Mr. G. Claridge Druce, M.A., exhibited as a probable new British plant, *Montia lamprosperma*, Chamisso; the characters by which it is distinguished from *M. fontana* being, it was stated, the larger, Chestnut-brown, shining seeds, reticulate rather than tubercular. In *M. fontana* they are small, dull-black, and strongly tubercular. The plant has a distinctly northern range, and from its being the only form found in the Faroes, and from its occurrence in Scandinavia, Russia, and North Germany, it might be expected to grow in Scotland. Mr. Druce has specimens which he found in Ross-shire in 1881 in Glen Spean, and on Loch na Gar, the latter at an altitude of 3,400 feet.

Mr. Clement Reid believed he had met with the seeds of both species in his researches in British leaf-beds.

A paper, by Mr. R. P. Gregory, M.A., was communicated by Prof. A. C. Seward, F.R.S. The author stated that in 1877 Hermann Müller described four forms of *Valeriana dioica*, distinguished from one another by the size of the flower and by the relative development of the male and female reproductive organs. The phenomenon appears to be very similar to that which was described by Darwin in *Rhamnus catharticus*. It has been found that the individuals of *Valeriana dioica* may be conveniently arranged in four groups, which are distinguished as, respectively, "Female," "Hermaphrodite," "Long-styled Male," and "Short-styled Male." But while the central types of each group are readily distinguishable, it must be distinctly recognised that they are connected by a series of intermediate forms, and that there is no discontinuity between successive groups.

ROYAL HORTICULTURAL OF IRELAND.

DECEMBER 17.—The 79th annual meeting of this Society was held at 33, Dawson Street, Dublin, on this date.

The following is an extract from the report of the Council:—"The Council's arrangements with the National Sweet Pea Society to hold its provincial show in Dublin was a prominent feature. Public patronage, nevertheless, fell short of expectation, and this in spite of judicious advertising. The spring show, extending over two days, came out somewhat better, yet, in hopes of obtaining more satisfactory results in the near future, the Council have considered the possibility of holding the next spring show in conjunction with the Royal Dublin Society's spring show at Ballsbridge. Sixty-two new members joined during the year, while losses by resignation and death totalled 16. The membership includes three honorary members, 45 life members, 268 annual members, and 63 practical members, or 377 in all. Seven members of the Council retire by triennial rotation, viz., Messrs. G. Watson, J. McDonough, J. W. Henderson, Rev. Canon Hayes, E. D'Olier, Hamilton Drummond, and H. Crawford. Mr. Hamilton Drummond does not seek re-election, leaving two vacancies to be filled."

The Chairman, Sir John Nutting, Bart., said the Royal Horticultural Society had 10,000 members, and the Irish Society ought to have 1,000. The holding of their spring show in connection with the spring show of the Dublin Society was a step in the right direction. Agriculture and horticulture were very closely allied. He wished that something could be done to induce the artisan classes to take an interest in the Society's shows.

The report was unanimously adopted.

The Secretary stated that the Society would

hold three shows next year, namely, one at the spring show of the Dublin Society, a Rose show in July, and a third show later on.

The following were then elected to replace the outgoing members of the Council:—Mr. George Warren, Mr. James M'Donough, Mr. Wylie Henderson, Mr. Edmond D'Olier, the Rev. Canon Hayes, Lady Alhreda Bourke, and Mrs. Grier. Mr. Knowlden was appointed secretary.

ST. IVES (HUNTS.) HORTICULTURAL.

DECEMBER 21.—The 10th annual show of the above society was held on this date in a large marquee in the centre of a wide street known as the Broadway, and consisted of garden, farm, and dairy produce. Being market day, the tent was at times crowded with visitors. Amongst the principal classes in the garden section were those for Apples and Pears. Of three dishes of cooking Apples there were 12 exhibits. The 1st and 2nd prizes were won by the Earl of SANDWICH, Hinchinbrooke, Huntingdon (gr. Mr. J. Barson), with large and richly-coloured fruit; 3rd, Mr. C. COUSINS, Croxton Park, near St. Ives. Of three dishes of dessert Apples there were 12 exhibits. Mr. C. COUSINS won the 1st prize splendidly with Cox's Orange Pippin, Ribston Pippin, and King of the Pippins; 2nd, R. M. COPLEY, Esq.; 3rd, The Earl of SANDWICH.

For three dishes of dessert Pears, of which there were six exhibits, the 1st prize was well won by Sir A. W. MARSHALL, Buckden Towers, with Josephine des Malines, Glou Morceau, and an unnamed variety; R. M. COPLEY, Esq., followed closely with Josephine des Malines, Winter Nelis, and Glou Morceau. For one dish of dessert Pears there were 10 exhibits, and in every case these were of a high quality. Mr. T. LONGLOD was 1st with a magnificent dish of Doyenné du Comice. For one dish of Apple Cox's Orange Pippin, there were 16 entries. R. M. COPLEY, Esq., easily won the 1st prize with perfect specimens. For one dish of any other dessert variety, R. M. COPLEY, Esq., again led amongst 11 entrants, staging very fine and well-preserved fruits of Ribston Pippin.

The Earl of SANDWICH showed the best cooking Apples. Prizes were also awarded for Onions, Carrots, and Potatoes, and in each case these vegetables were well shown. E. B.

NATIONAL DAHLIA.

DECEMBER 29.—The first meeting of the Executive Committee of the above society was held on this date at the Hotel Windsor, Victoria Street, W., under the presidency of Mr. George Gordon.

It was decided to hold one exhibition on Thursday and Friday, September 2 and 3, 1909, at the Crystal Palace, and another on Tuesday and Wednesday, September 21 and 22, at the Royal Botanic Gardens, Regent's Park. The schedule was passed for both shows, and in addition to providing competitive classes for decorative and garden Cactus Dahlias, Certificate of Merit will be awarded for seedling varieties suitable for this purpose.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending December 30.

The coldest night for nearly 14 years.—After six weeks of unseasonably warm weather a change took place on December 23, since which date some very low readings have been recorded. On two days the highest reading in the thermometer screen rose only to respectively 24° and 25°, while on the last three nights the exposed thermometer has registered from 23° to 31° of frost. The latter is the lowest reading recorded here since February 7, 1895, or for nearly 14 years. The ground temperatures have fallen considerably during the week, the reading at 2 feet deep being now only of about seasonable warmth, and at 1 foot deep 2° colder than the average. Snow has fallen on each of the last three days, and on the evening of the 29th covered the ground to the depth of 5½ inches. The sun shone on an average for 26 minutes a day, or for about 50 minutes a day short of a seasonable duration at the end of December. During the nine days ending the 27th no sunshine at all was recorded. Light airs alone prevailed during the week, the direction being almost exclusively some easterly point of the compass. There was about a reasonable amount of moisture in the air at 3 o'clock in the afternoon. E. M., Eerhamsted, December 30, 1908.

MARKETS.

COVENT GARDEN, December 30.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Acacia (Mimosa), Azalea, Bouvardia, Calla, Camellias, Carnations, and others.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and plants, including Adiantum, Asparagus, Berberis, and others.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants and their prices, including Aмпelopsis, Aralia, Araucaria, and others.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples, Grapes, Lemons, and others.

Potatos.

Table listing various potato varieties and their prices, including Kents, Lincolns, and others.

REMARKS.—Prices are about the same, but trade is not so good. Very small consignments are arriving on account of the severe weather. Edward J. Newborn, Covent Garden and St. Pancras, December 30, 1908.

COVENT GARDEN FLOWER MARKET.

The Christmas trade finished satisfactorily, though no exceptional prices prevailed. In some few instances, chiefly for best quality produce, things were a little dearer. The sudden change in the weather may make a considerable difference in the value of all things, and if the conditions remain severe the supplies from France will fall off.

CUT FLOWERS.

Good Chrysanthemums are becoming scarce, but ordinary blooms are plentiful, although dearer. Supplies of Roses have fallen off considerably, and their value is sure to advance.

POT PLANTS.

There was the usual activity caused by the Christmas trade, but since then there has been practically no demand for plants. Azaleas are a leading feature; these plants are well flowered this season.

CATALOGUES RECEIVED.

SEEDS.

Table listing various seed catalogues and their publishers, including HARRISON & SONS, LEICESTER, and others.

MISCELLANEOUS.

Table listing various miscellaneous items and their suppliers, including ISAAC GODBER, STANCLIFFE ESTATES CO., LTD., and others.

REMARKS.—All vegetables are very dear owing to the wintry weather. The Christmas trade generally was good, Apples especially maintaining good prices. The supply of Pineapples was greater than the demand, and consequently, these fruits did not realise the high prices anticipated by the brokers.

Obituary.

ALEXANDER WHYTE.—We regret to announce the death of Mr. Alexander Whyte, F.L.S., F.Z.S., the well-known explorer and authority on economic botany. Mr. Whyte was a son of the parish minister of Fettercairn, Kincardineshire. As a young man he went out to Ceylon; Coffee-planting was then in its heyday. His interests were markedly scientific. He studied tropical botany, particularly in its economic and trade aspects. When he left Ceylon Mr. Whyte became attached to Sir Harry Johnston's expedition to Central Africa in the official capacity of naturalist, and in the course of these journeys in Nyassaland and Uganda, he laid the foundations of a knowledge of the plant and animal life of the continent possessed by few, if any, men of the time. Some 500 new species were discovered by Mr. Whyte in these journeys. In 1898 his services were secured by the British Administration in Uganda. His headquarters were at Mengo, the native capital of Uganda, and there he started experimental gardens and commenced other branches of research work. On his return from Mombasa to Uganda, Mr. Whyte had passed through British East Africa, and in 1902 the Government selected him as Director of Agriculture in that Protectorate. Here he made many and important discoveries in the botany and natural resources of the Protectorate. He retired in 1903 from the Government service, but in the two succeeding years he made visits to Liberia to investigate the rubber resources of that country in the interests of a London company, which held important concessions from the Liberian Government. He travelled widely through Liberia, and made many discoveries of scientific and commercial importance. He brought home with him a large collection of herbarium specimens. These were classified at Kew, between 60 and 70 of the plants proving to belong to genera and species new to science. These plants have been described and named by Dr. Stapf in the *Journal of the Linnean Society*. Among them are many new rubber-yielding vines of genera closely allied to *Landolphia*, the well-known rubber vine of the Congo. These rubber vines are distinct from the Brazil rubber tree, which was introduced some years ago in Ceylon and the Malay Peninsula. Mr. Whyte was never married, and is survived by a sister.

JOHN LEWIS.—The death of Mr. John Lewis occurred recently in Canterbury, New Zealand, where he had built up a most successful florist's business. Mr. Lewis was born in Herefordshire in 1842. He began his career in England with the late James Cranston in 1852, and, after serving for a few years, he went to Messrs. R. Smith & Son's nursery at Worcester. Later, he worked in turn at the nurseries of Mr. C. Turner, Slough, and Messrs. Lee Bros., of Hammersmith, being manager of a branch for the latter firm. After this, he left for New Zealand. He proceeded to Lyttelton in the ship "Blue Jacket" in 1866, and a few months afterwards settled in Timaru. Having taken out an assortment of seeds, he commenced nursery work on some land near the Smithfield Freezing Works. About three years later he established himself at Maori Hill, where he bought several acres of land for nursery work, and erected six glasshouses—three being devoted to Grape growing and three to flowers. These houses, it may be mentioned, contain 4,000 square feet of glass. Mr. Lewis was one of the originators of the Timaru Floral and Horticultural Society over 30 years ago, and he has been one of its most enthusiastic supporters. The deceased leaves a widow and two children.

GEORGE WALPOLE.—The news of the death of Mr. George Walpole, of Mount Usher, Rathnew, Co. Wicklow, will be received with regret by the many garden lovers who have visited the famous gardens at Mount Usher, and more especially by those who had the privilege of Mr. Walpole's personal friendship. Mount Usher was jointly owned by the late Mr. Walpole and his brothers, and the gardens have developed to their present dimensions from a comparatively small beginning. Those who have seen Mount Usher can never forget it with its sparkling streams, shady trees, and wonderful store of horticultural trea-

tures. There is no other such garden in Ireland, and the writer has never met anyone who was disappointed with it. The brothers Walpole retired to this beautiful spot every Saturday morning, and there they worked, and planned, and enjoyed the company of their plants until Monday morning, welcoming any of their friends who came to see them. Each individual opinion and prospective change was carefully considered on these occasions, and altered or modified, as required, until unanimity prevailed. The late Mr. George Walpole was one of the kindest, most hospitable, and generous of men, and was universally loved and esteemed. It is a regrettable coincidence that Mr. Acton, the Earl of Annesley, and Mr. Walpole, all of whom were connected with important gardens in Ireland, should have died within a short period. *F. W. M.*

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. JAMES A. COOK, for 2½ years Assistant Gardener at Kingsgate Asylum, Newmachar, Aberdeenshire, as Gardener to Colonel JOHN LEITH, J.P., Arnage Castle by Ellon, Aberdeenshire, in succession to Mr. WILLIAM EUHART, who has been appointed Gardener at Kingsgate Asylum.

Mr. L. PERFECT, for the last 8 years Orchid grower to R. BROOMAN WHITE, Esq., Arddarroch, Garelochhead, as Gardener to JAMES WATSON, Esq., Caldwell, Irvine. (Thanks for 2s. which has been put into R.G.O.F. box.)

Mr. R. LICKMAN, for the past 9 years Foreman in the Gardens, Coombe House, Kingston-on-Thames, Surrey, as Gardener to J. E. GREAVES, Esq., Bron Eifion, Criccieth, North Wales.

Mr. JAMES A. PAICE, as Gardener to Rear Admiral Sir JOHN JELlicoe, "Thornton," Harrow Weald, Middlesex.

APPLE SHOOTS DECAYING: *C. H.* The twigs are attacked by Brown Rot. All dead branches should be cut off, and the bushes sprayed next spring with the Bordeaux mixture at half strength just when the leaves are unfolding.

APPLES: *C. W., British Columbia.* Cox's Pomona is said to have been raised by Mr. Cox, of Colnbrook Lawn, who also raised Cox's Orange Pippin.

CHRYSANTHEMUMS FOR MARKET: *S. G. R.* It is difficult to give a definite answer to your questions, for some of the early varieties may also be flowered later. Take *Mme. Paolo Radaelli* for an instance. This was shown in the first week in October and also in December. Yet it may be classed as a mid-season variety. The following varieties may be recommended:—*Early flowering:* *Roi des Blanches*, *Boule de Neige*, *Carrie*, *Lady Mary Fitzwigram*, *Miss B. Millar*, *Horace Martin*, *Goacher's Pink*, *Harvest Home*, *Goacher's Crimson*, *Nina Blick*, *Le Pactole*, *Polly*, *Nellie Blake* and *Black Prince*. *Mid-season:* *Alice Byron*, *Mme. Paolo Radaelli*, *Mme. G. Rivol*, *W. Holmes*, *Mrs. Millar*, *Moneymaker*, *J. Shrimpton*, *Mrs. Wingfield*, *W. Duckman*, *Mrs. W. J. Scott*, *Cullingfordii*, *F. S. Vallis* and *Western King*. *Later flowering:* *Negoya*, *W. H. Lincoln*, *Mrs. Thompson*, *Golden Ball (new)*, *Violet Lady Beaumont*, *Snowdrift*, *Mme. R. Oberthur*, *Mathew Hodgson*, *Winter Cheer*, *Mme. Pankoucke*, *Mme. L. Charvat*, *Lord Brooke*, *Framfield Pink* and *Tuxedo*. Many others might reasonably be added to the above list, and it must be borne in mind that considerable variation occurs in the same varieties when grown under different conditions. Some varieties which flower early may also be flowered late. Of new varieties we may mention *Felton's Favourite*, which flowers early, and continues to bloom on the secondary growths. *December Gold* and *R. F. Felton* are two good yellow varieties. These should be tried, but do not cultivate them in large quantities until you have proved their value. Varieties which succeed with one grower sometimes fail with another. The

incurved varieties are favourites in the market, and such old sorts as Mr. G. Glenney, Mrs. G. Rundle and Mrs. Dixon are of better form than some of the more recent additions.

CINERARIAS FAILING: *G. W.* The plants appear to have suffered from the effects of frost before they were removed to the greenhouse.

CUCUMBERS FAILING: *A. E. P.* We have submitted the fruits to our fungus expert, who states that no disease is present. The trouble must, therefore, be due to some cultural error, or to something that has caused a check to the plants.

FIG TREES: *F. S.* The pruning should be done first and the prunings removed to the fire for burning, but it is more convenient to paint the trees before they are trained, always, of course, drawing the brush in the direction in which the buds are growing. It is not a good practice to smear the buds themselves over with this kind of insecticide, and where harm results from the painting, it is generally traceable to carelessness in its application.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: *Expectans.* Mannington's Pearmain.—*C. L., Colburg House.* Striped Beefing.

PLANTS: *W. A. B.* A very pretty form of *Cypripedium Leeanum*, but we know of no distinguishing name for it. So many varietal names have been given that there seems to be no room for others. Many thanks for the postal order for the Gardeners' Royal Benevolent Institution.—*R. A.* *Epidendrum O'Brienianum*.—*P. M. 1.* *Calanthe rosea*; 2, *Oncidium flexuosum*; 3, *O. sphacelatum*.—*J. M. 1.* *Cassinia fulvida* (syn. *Diplopappus chrysophyllus*); 2, *Cupressus pisifera variegata*; 3, *Pinus Strobus*; 4, *Cupressus Lawsoniana stricta*; 5, *Pernettya mucronata*; 6, *Cupressus Lawsoniana*; 7, *Phillyrea media*; 8, *Ilex aquifolium* var. *crispa*; 9, *Cupressus sempervirens*; 10, *Berberis stenophylla*; 11, *Thuja borealis*; 12, *Cupressus Lawsoniana erecta viridis*.

PURCHASE OF GOODS: *Holt.* Judging from the facts as related in your letter, you are entitled to reject the whole of the goods, but if you prefer it you may accept such as are in accordance with the contract and reject the rest. In either case, you are not bound to return the rejected goods to the seller; it is sufficient to intimate to him your refusal to accept them. But you might send them back to him, leaving him to pay the carriage. It would be desirable to have the goods examined by an expert, so as to have an independent witness in case of further trouble.

ROMAN HYACINTHS: *G. W.* The bulbs, though of fair size, do not appear to have developed an inflorescence, due probably to improper ripening last autumn. In cutting them through, there is no appearance of a flower-spike.

VIOLETS DISEASED: *F. A.* The plants are infested with *Botrytis*. Spray them with sulphide of potassium at the rate of one ounce in three gallons of water twice a week. Decaying wood harbours the fungus, and any dead shoots of trees should therefore be removed.

THE COMMON MYRTLE.

OF the 100 or so species of Myrtus, the best known is Myrtus communis, which was first described by the great botanist Linnæus. The "Common" Myrtle, as it is called, is very widely distributed, being found as far west as the Azores and as far east as Afghanistan and Beluchistan. Forms of it—there are, apparently, many—are found on both shores of the Mediterranean, and also for some miles inland, the chief habitat ranging between the 30th and 40th degree of northern latitude. In looking over the specimens in the herbarium at Kew I noticed one fine, large-leaved form, almost identical in appearance with that illustrated at fig. 15, with a Geneva label attached to it. As Geneva is slightly above the 46th degree of latitude, and probably too cold for the Myrtle in winter, it is possible the specimen may have been taken from a cultivated plant accustomed to have protection of some kind during the coldest period of the year.

One is apt to think that there is only one

form of the Common Myrtle, but an examination of specimens from different parts of the geographical area mentioned shows that there are considerable differences between the plants from various regions—geographical forms, no doubt, modified by soil, climate, altitude and general environment. This accounts in a measure for such names as Dutch, Italian, Roman, Box-leaved, &c., which have been applied to certain forms.

Myrtus communis is a beautiful evergreen shrub varying from 3 to 10 or 12 feet in height, and, in the Holy Land and Afghanistan, even forming a small tree. The leaves vary much in size, some being large and ovate lance-shaped, tapering to a sharp point; others are smaller, but similar in shape; while others, again, are even smaller, not exceeding half an inch in length and not more than a quarter of an inch in width. Some forms appear to be stunted and "scrubby" in appearance, owing to the fact that, the internodes being shorter, the leaves are much closer together. Others have a more luxuriant appearance, with larger leaves and longer internodes.

Speaking broadly, the Common Myrtle may be said to have three distinct forms, namely, the large or broad-leaved (as shown in the sketch), the medium-sized, and the small or narrow-leaved, with intermediate variations.

The flowers, which appear during the summer months, are pure white, with numerous conspicuous stamens. They are, in all cases that I have seen, borne singly in the axils of the almost opposite leaves and on the young wood only. The flowers are, as a rule, freely produced, even on plants two or three years old raised from cuttings, slips or layers. It is not often, however, that one sees a Myrtle not only flowering freely, but also producing its fruits abundantly in the open air in such a fickle climate as that of Middlesex. The spray illustrated is from a plant about 10 years old and nearly 4 feet high grown in a 14-inch pot. Each year it is exceedingly effective when clothed in its white blossoms, but until this season I have never noticed it in fruit before. The shape of the fruits is as drawn, each being three-celled and containing several kidney-shaped seeds, as shown in the illustration.

Just as the leaves of the Common Myrtle vary considerably in shape and size, so do the fruits. In some cases they are smallish, globular berries, but in the herbarium specimens examined none was quite so large or so long as those shown in the illustration. At first they are green, but assume a dark or blackish-purple colour when ripe. There seems, however, to be a white-fruited form (baccis albis) of the Italian Myrtle, but it is exceedingly rare. Another form, cultivated at Kew in 1885 and 1886 under the name of M. mucronatus, has yellowish-white fruits. This is apparently identical with another form called "tarentina," the leaves of which are about half an inch long, narrow, lance-shaped, acute, and about a quarter of an inch in width.

So far as cultivation is concerned, plants flourish in a compost of loamy soil and leaf-mould, which should be firmly rammed round the roots when pots are used. The plant from which the illustration at fig. 15 was prepared receives practically no attention during the year beyond the usual watering. From

April or May to October or November it stands outside the house, facing westwards. This year, however, it was still outside until Christmas Day, but the fall of snow and the frost necessitated its removal to a greenhouse on the morning of December 28. The plant itself was raised from a shoot placed in a bottle of water. This seems to be an easy method of propagation, as roots are soon produced even in an ordinary dwelling room if the atmosphere is not too hot and dry. Cuttings of the half-ripened shoots inserted in moist, sandy soil during July and August also root freely.

Of the other species of Myrtle, perhaps the best known is the more tender Chilean plant, Myrtus Ugnii, known formerly under the name of Eugenia Ugnii. This species produces, under greenhouse culture, roundish, red or black fruits of an agreeable taste. Other species of Myrtle are distributed over Peru, India, the Falkland Islands, and other parts of the world, but from a garden point of view they do not possess the importance of the Common Myrtle, which, in the most favoured parts of the kingdom, can be grown out-of-doors against walls or in other sheltered positions. J. Heathcote.

ORCHID NOTES AND GLEANINGS.

LÆLIO-CATTELEYA COUNTESS TORBY. (L.-C. HIPPOLYTA VAR PHOEBE × L.-C. EXIMIA.)

THIS is a pretty new hybrid raised by Messrs. Moore, Ltd., Rawdon, Leeds, and flowered by J. Talbot Clifton, Esq., Lytham Hall, Lytham. In size and colour it approaches L.-C. eximia (L. purpurata × C. Warneri), the orange-yellow colour of L.-C. Hippolyta (L. cinnabarina × C. Mossiæ) being entirely eliminated, as we have seen in other instances where varieties with deep shades of yellow have been crossed with rose-tinted flowers. The sepals are lanceolate, nearly 3 inches long; the ovate-acuminate petals 1½ inches wide; both silver-white, delicately tinged and veined with pale lilac. The base of the lip is white, with a yellow flush extending to the chrome yellow disc, the front being deep rose-purple. It is a very attractive winter flower.

ODONTIODA GATTONENSIS.

(ODONTOGLOSSUM KEGELJANII (SYN. POLYXANTHUM) × CODILIODA NOEZLIANA.)

THIS hybrid has flowered in the collection of Sir Jeremiah Colman, Bart., Gatton Park (gr. Mr. Collier), from a cross made and raised by Mr. W. P. Bound, until recently gardener at Gatton Park. It may be compared with O. Bradshawii, illustrated in the *Gardeners' Chronicle*, January 19, 1907, p. 36, but it has a yellow ground colour and firmer texture, inherited from O. Kegeljani. The sepals are lanceolate, the upper the broadest; the ground colour lemon-yellow, showing on the reverse side in a broad band up the middle, the face being reddish-orange, with the lemon-yellow ground showing at the base and tips. The petals are broader than the sepals, and similarly coloured, except that on the lower halves a few lemon-yellow markings appear. The lip has the expanded side lobes striped with reddish-brown, the front lobe having a large reddish blotch surrounded by a narrow primrose-tinted band, the toothed margin being deep orange colour. The callus has four strongly-developed teeth of a yellowish tint, and an imperfectly-developed ridge on each side. The column is reddish-purple, darkest on the wings. It is a charming flower; the nearly scarlet surface colour is on a substantial lemon-yellow ground.

NEW OR NOTEWORTHY PLANTS.

*WEDELIA OBLONGA.

THE species here described is a pretty novelty which has been grown by Messrs. J. Veitch & Sons from seed collected in British East Africa by Mr. Diespecker. The flower-heads measure from $1\frac{1}{2}$ to 2 inches in diameter, and are of a pleasing lemon-yellow colour, whilst the ray-florets are somewhat conspicuous by reason of the deeply-trifid corolla limb. From the absence of a pappus in this species, one would expect it to have a very restricted distribution. As we have no information, however, as to the exact locality in which the seeds were collected, a correct idea cannot be obtained until additional material is forthcoming.

The genus *Wedelia* consists of about 90 species, the greater portion of which are American. It is very difficult to distinguish it from *Aspilia*, which differs merely in having neutral ray-florets, the latter being fruitful in *Wedelia*. Indeed, Bentham considered that *Wedelia*, *Aspilia*, and *Blainvillea* might be regarded as one large genus, the whole group scarcely distinct from several other purely American genera. He, however, kept them apart, chiefly for practical purposes. *Wedelia* belongs to the sub-tribe *Verbesineæ*, which, as defined by Bentham and Hooker in the *Genera Plantarum*, comprises about 700 species, contained in 71 genera. The great majority of these are American, and they are very difficult to separate into groups, except into very artificial series. Bentham was of the opinion that the tribe *Helianthoideæ* was probably the most ancient of the order *Compositæ*. The species referred to it are usually rather coarse herbs or shrubs, with more or less scabrid or hirsute indumentum, and leaves, or, at any rate, the lower ones, mostly opposite.

The following description was drawn up from a living plant sent to Kew by Messrs. Veitch & Sons:—A subprocumbent plant, attaining a height of almost 3 feet. Branches grooved or somewhat angular, more or less densely covered with white, glandular hairs. Internodes $2\frac{1}{2}$ to 3 inches long. Leaves oblong or oblong-lanceolate, acute, mucronulate, auriculate at the base, 3 to $3\frac{1}{2}$ inches long, $\frac{3}{4}$ to 1 inch broad, with glandular hairs on both surfaces; lateral nerves seven to ten on each side of the midrib, immersed above, prominent below. Heads pedunculate, $1\frac{1}{2}$ to 2 inches in diameter; peduncles $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long. Outer bracts of the involucre foliaceous, ovate-lanceolate, about $\frac{1}{2}$ inch long, glandular-hairy, ciliate; inner bracts somewhat scarious. Palea of the receptacle lanceolate, ciliate towards the apex, subacute. Ray flowers about 12, tridentate; achenes somewhat four-angled, glabrous; pappus absent; tube densely pilose; limb oblong connate, deeply trilobed. Disk flowers about 30; achenes subterete, glabrous; tube densely pilose on the lower portion; style branches apiculate, acute, pilose. *J. Hutchinson, Kew.*

* *WEDELIA OBLONGA* (*Hutchinson*), *sp. nov.*—*Planta subprocumbens, circiter 1 m. alta, ramis sulcatis vel subangulatis plus minus dense glanduloso-pubescentibus, internodiis 6-7 cm. longis. Folia oblonga vel oblongo-lanceolata, acuta, mucronulata, basi-auriculata, 7-9 cm. longa, 1.5-2 cm. lata, utrinque glanduloso-pilosa, nervis lateralibus 7-10 supra immersis subtus prominentibus, venis arcte anastomosantibus. Capitula pedunculata, 3-4 cm. diametro; pedunculi 4-6 cm. longi. Involucri bracteæ externae foliaceæ, ovato-lanceolatae, 8-10 mm. longæ, 3.5 mm. latæ, utrinque glanduloso-pilosæ, ciliatæ; internæ subscariosæ. Receptaculi palea lanceolatae, versus apicem ciliatæ, subacutæ. Flores radii tridentati, circiter 12; achænia subquadrangularia, 2 mm. longa, glabra; pappus 0; tubus 2 mm. longus, dense pilosus; lamina oblongo-cuneata, 1.5 cm. longa, 7 mm. lata, dentibus 3 mm. longis, 2 mm. latis obtusis. Flores disci circiter 30; achænia 1.5 mm. longa, subteretia, glabra; tubus 4 mm. longus, inferne dense pilosus. Antheræ 2 mm. longæ. Stylis ramis apiculatis, acuti, pilosi.*

British East Africa: from seeds collected by *Diespecker* 1 Eldoma Ravine, *Whyte* 1

FIG. 15.—FRUITING SPRAY OF THE COMMON MYRTLE (*MYRTUS COMMUNIS*).

(See p. 17.)

NOVELTIES OF 1908.

(Concluded from page 5.)

IN its application to garden plants, the term novelty admits of very broad interpretation, for it is usual to describe as novelties plants long known to science, but only recently introduced to cultivation, and also plants already known in gardens, but whose uses for decorative purposes have only recently been fully recognised. Then we have the florists' varieties obtained by hybridisation and selection—an ever-productive and remunerative field of operation which is, perhaps, the most interesting of garden pursuits.

The seedsmen may be said to produce the largest number of sterling novelties, which are all the more to be held in esteem in that they are within the reach of all lovers of pretty flowers, from the cottager to the millionaire. Yet it is this class which is the most difficult to deal with in the matter of recording novelties, for such novelties are seldom exhibited at public exhibitions, and, even in the gardens which they beautify, their names are often not recorded. Yet, if we take, for instance, Stocks, Wallflowers, Dianthus, Primulas, and other showy flowers, usually obtained from the seedsmen, and compare these now sent out by Messrs. Sutton & Sons, Messrs. Jas. Veitch & Sons, Messrs. Carter & Co., Messrs. Webb & Sons, Messrs. Cannell, Messrs. Dobbie & Co., and other of our seedsmen, with those we knew even a few years ago, the improvements wrought will be evident. Would it not be possible for the Royal Horticultural Society to arrange for periodical displays of annuals and biennials?

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. Bain), has flowered many pretty and rare shrubs during the year, and received awards at the Royal Horticultural Society for Viburnum Carlesii, Philadelphus Lemoinei rosacea, Asparagus filicinus, and Zephyranthes aurea, the last-named a pretty, yellow, Vallota-like flower.

MESSRS. JAS. VEITCH & SONS, Chelsea, continue to exhibit desirable novelties, chiefly new Chinese species, plants from this firm certificated during the past year including Deutzia Wilsonii, Rosa Moyesii, Eremurus Bungei magnificus, Thalictrum dipterocarpum, Sarcococca ruscifolia, the compact-growing Ilex Pernyi, Populus lasiocarpa, Stock (Matthiola) Veitch's Magenta, Begonia Col. Laussedat (good yellow bedder), B. Kewensis (a cream-white variety, excellent for baskets), Acanthus montanus, the elegant Dracæna Doucettii var. de Grootii, and Nepenthes Dr. John McFarlane, which secured a First-class Certificate, and which Messrs. VEITCH consider one of the best they have shown.

MESSRS. SANDER & SONS, St. Albans and Bruges, exhibited a remarkable selection of new Palms and foliage plants at the Ghent Quinquennial Show, and at the last Temple Show, a number of which will be found in the appended list of novelties illustrated in the *Gardeners' Chronicle*. One of the most generally useful, Pereskia Godseffiana, with beautifully-coloured leaves tinted with gold, green, and purple, may be grown for all decorative purposes and also as a bedding plant. Caladium Centenaire is a robust and strong-growing variety with beautifully-coloured leaves.

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr. Mr. J. Hudson), grows with his fine-coloured Nymphæas, a selection of the best Nelumbiums, and secured a First-class Certificate for the crimson *N. speciosum* Osiris. On September 29 he showed 18 varieties of hardy Heaths from his novel Heath-garden at Gunnersbury, many of them new varieties.

HIPPEASTRUMS have made good progress, as shown by the exhibits of Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Chapman), ALFRED DE ROTHSCHILD, Esq. (gr. Mr. Sander), MESSRS. KERR & SONS, and Mrs. BURNS, Hatfield (gr. Mr.

Fielder), the last-named of whom obtained a First-class Certificate for Purity, the best pure white Hippeastrum yet raised.

MESSRS. BLACKMORE & LANGDON, Bath, secured awards for tuberous Begonias Empress Marie, Duchess of Cornwall, and Frilled Queen.

Begonia Clibran's Pink, shown by Messrs. W. CLIBRAN & SON, is also a pretty novelty, and one of the very best of the winter-blooming section, obtained by crossing *B. socotrana* with a tuberous-rooted variety.

FERNS appear to be returning to favour, and deservedly so, if we call to mind the varied and beautiful collections shown by Messrs. HILL & SONS, of Edmonton, who received a First-class Certificate for *Nephrolepis rufescens* amabile; and Messrs. H. B. MAY & SONS, Edmonton, whose best new exhibits were *Aspidium falcatum* Mayi, *Pteris aquilina* Nicholsonii, and *Nephrolepis rufescens* Mayi ornata. Mr. C. T. DRUERY obtained a First-class Certificate for the elegant *Polystichum aculeatum gracillimum* Drueryi.

ROSES.—While the large double Hybrid Perpetual and Tea-scented sections have been strengthened with new seedling varieties, the elegant Ramblers and Wichuraiana hybrids have increased in favour, especially the Wichuraianas whose glossy leaves, graceful climbing habit and profusion of flowers render them among the best of garden subjects for cultivation on pillars, arches, and rockeries. The gold-medal novelties of the year are Mrs. J. Campbell Hall, shown by Dr. J. C. HALL, Monaghan; Mita Weldon, Alex. Hill Gray, and Dr. O'Donnell Brown, by Messrs. ALEX. DICKSON & SONS, Newtownards; Lady Alice Stanley and His Majesty, shown by Messrs. MCGREEDY & SONS, Portadown. Others, which have received awards and attracted attention, are Florence Edith Coulthwaite, Geo. C. Waud, Mrs. David Jardine, and Molly Sharman Crawford, all from Messrs. ALEX. DICKSON & SONS; Rosa Wichuraiana Lady Godiva, Messrs. GEO. PAUL & SONS; Tausendschön, HOBBIES, Dereham, and WM. PAUL; Elaine, Refulgence, White Dorothy Perkins, B. CANT; Mrs. E. J. Holland, Mrs. Alfred Tate, and Mrs. Christie Miller, the last three from Messrs. MCGREEDY & SONS, Portadown.

CARNATIONS have been shown at the meetings of the Royal Horticultural Society, and it is noteworthy that the method of showing the flowers with a proportionate length of their own stems and foliage is preferable to the old-time method. The groups of these beautiful florists' flowers shown by LEOPOLD DE ROTHSCHILD, Esq., from his gardens at Ascott, Leighton Buzzard (gr. Mr. Jennings), by Messrs. HUGH LOW & CO., CUTBUSH & SONS, MORTIMER, BURNETT, and DOUGLAS were most artistic. Mr. JAS. DOUGLAS, Edenside, Great Bookham, received awards for Cardinal, Hercules, and Splendour. With Auriculas, Mr. DOUGLAS stands almost alone in the novelty list, having secured awards for Vanguard, Harrison Weir, Mrs. Jas. Douglas, and Phyllis, at the National Primula and Auricula Society, on April 29, and with Coronet, Mayday, and Mildred Jay, on May 12.

CHRYSANTHEMUMS AND DAHLIAS have received great augmentation by novelties, which have been regularly reported in the *Gardeners' Chronicle*, and some of the best of them illustrated.

MISCELLANEOUS.—Gladioli, Delphiniums, Pyrethrum, and other showy specialities of Messrs. KELWAY & SONS, Langport, have been much in evidence, Gladiolus Golden Measure and G. White Cloud gaining Awards of Merit on September 1. At the same meeting, Messrs. WALLACE & CO., Colchester, secured similar awards for a new and beautiful strain of Gladiolus raised between *G. primulinus* and varieties of *G. gandavensis*; also for Kniphofia R. Wilson Ker, K. Goldelse, and Delphinium Progression. Narcissus novelties have also been evolved during 1908, but the recognition of distinct new

kinds becomes difficult. Messrs. BARR & SONS, Covent Garden, showed many good novelties, and secured awards for *Dimorphotheca aurantiaca* and the dark-coloured *Helleborus* "Peter Barr." Mr. G. REUTHE, Keston, continually shows rare Alpines, Himalayan *Rhododendrons*, and other rare flowering shrubs, his awards being for *Rhodothamnus kamschaticum*, *Campanula Raddeana*, *Erica cinerea pygmaea*, and *Tunica Saxifraga flore pleno*. Other exhibitors have brought to notice novelties of varying degree of value.

The following new or specially noteworthy plants and fruits have been illustrated in the *Gardeners' Chronicle* during 1908:—

- Acacia podalyriifolia, Jan. 4, p. 11.
- Acantholimon venustum, Oct. 11, p. 259.
- Acleris obesa, April 11, p. 226.
- Androsace imbricata, May 30, p. 344.
- Anthurium Laucheanum, April 25, p. 258.
- Anthurium Sanderi, Supp., May 7.
- Apples Feltham Beauty, Sep. 5, p. 178; Red Victoria, Oct. 24, p. 297; Renown, Oct. 24, p. 292.
- Arctostaphylos manzanita, Aug. 29, p. 163.
- Asparagus filicinus, Aug. 15, p. 122.
- Asparagus filicinus Giraldui, Aug. 15, p. 123.
- Aster Climax, Oct. 21, p. 308.
- Auricula Phyllis, May 16, p. 320.
- Begonia Clibran's Pink, Nov. 21, p. 357.
- Brachyglottis repanda, July 18, pp. 52-53.
- Bromelia tricolor, April 25, p. 261.
- Caladium Centenaire, Supp., April 25.
- Campanula Raddeana, Aug. 22, p. 139.
- Carnation Enchantress, Aug. 8, p. 107.
- Carpenteria californica, Aug. 8, p. 112.
- Celastrus articulatus, April 18, p. 242.
- Cocos nucifera aurea, May 2, p. 279.
- Codium Fred. Sander, May 2, p. 275.
- Columnnea magnifica, Feb. 1, p. 66.
- Cyclamen Mont Blanc, April 18, p. 253.
- Cytisus kewensis, Nov. 7, p. 323.
- Dahlia Snowdon, Sep. 19, p. 220.
- Darwinia Hookeriana, April 18, p. 243.
- Dianthus arboreus, Jan. 25, p. 52.
- Dimorphotheca aurantiaca, June 6, p. 364.
- Dipelta verticosa, Aug. 8, p. 102.
- Encephalartos Woodii, Supp., May 2.
- Erythronium, species of, April 4, pp. 212, 213 and 215.
- Eucryphia cordifolia, Aug. 15, p. 129.
- Euphorbia, species of, Nov. 28, p. 372.
- Grape Prince of Wales, Oct. 24, p. 301.
- Greya Sutherlandii, Feb. 29, p. 138.
- Helianthemum roseum, June 27, p. 419.
- Hillebrandia sandwicensis, Supp., Dec. 12.
- Huernia brevirostris, Sep. 12, p. 198.
- Iris Amethyst, June 13, p. 356.
- Iris gracilipes, Aug. 15, p. 125.
- Iris tectorum and var. album, Aug. 22, pp. 142-3.
- Juliania (new genus) adstringens, Feb. 15, p. 99.
- Leonotis Leonurus, Feb. 29, p. 139.
- Lewisia Cotyledon, May 30, p. 342.
- Libertia grandiflora at Kew, Jan. 4, p. 2.
- Lopezia lineata, May 9, p. 294.
- Lupinus arboreus Snow Queen, Nov. 7, p. 324.
- Malvastrum hypomadarum, June 20, p. 394.
- Meconopsis sinuata, Sep. 12, p. 202.
- Melon Eminence, Nov. 14, p. 343.
- Mesembryanthemum pyropeum, Jan. 18, p. 42.
- Montanoa mollissima, Supp., Jan. 18.
- Moræa iridioides, Supp., Feb. 8.
- Narcissus Evangeline, April 11, p. 227.
- Nephrolepis rufescens Mayi ornata, Dec. 5, p. 391.
- Nigella integrifolia, Sep. 26, p. 227.
- Nuttallia cerasiformis, with flowers and fruit, April 25, pp. 266-267.
- Oliveranthus elegans, Oct. 17, p. 275.
- Ozothamnus rosmarinifolius, Aug. 1, pp. 82-83.
- Pæonia lutea superba, Supp., July 18.
- Pæonia Mlokosewitschii, Supp., July 25.
- Peach Albatross, Oct. 24, p. 294.
- Pear Blickeing, Feb. 22, p. 122.
- Pereskia Godseffiana, April 25, p. 260.
- Philadelphus grandiflorus laxus, Feb. 8, p. 82.
- Philodendron Ilsemanii, May 2, p. 289.
- Pinanga Micholitzii, April 25, p. 259.
- Platytheca galioides, Oct. 24, p. 290.
- Polystichum angustifolium densum, June 13, p. 381.
- Polystichum falcatum Mayi, May 16, p. 312.
- Primula malacoides, Dec. 5, pp. 396-397.
- Prunus tomentosus and fruits, May 9, pp. 296-297.
- Ptychoraphis Siebertiana, Supp., April 25.
- Rhododendron Countess of Haddington, Mar. 28, p. 197.
- Rhododendron Pink Pearl, July 18, p. 48.
- Rhodothamnus kamschaticum, Aug. 15, p. 128.
- Robinia Kelseyi, Dec. 19, p. 427.
- Rodgersia tabularis, Sep. 19, p. 210.
- Roses Albatross and Lyon-Rose, Supp., Dec. 5; Alex. Hill Gray, Sep. 26, p. 236; Blush Rambler, July 11, p. 39; Elaine, July 11, p. 29; Lady Alice Stanley, Sep. 26, p. 237; Lady Godiva, July 11, p. 25; Madame Plantier at Frogmore, Nov. 21, p. 361; Mrs. Ed. J. Holland, Mrs. Alfred Tate, Supp., Dec. 12; Tausendschön, Supp., July 11; The Garland, July 4, p. 14; White Dorothy Perkins, July 11, p. 27.
- Sempervivum holochrysum, July 25, p. 62.
- Stapelia Bayfieldii, Aug. 29, p. 168; S. bella, Aug. 29, p. 168; S. flavirostris, Sep. 5, p. 188; S. gigantea, Sep. 5, p. 182; S. glabriflora, Sep. 5, p. 186; S. Hanburyana, Aug. 29, p. 167; S. hirsuta var. depressa, Aug. 29, p. 170; S. hirsuta unguiculata, Aug. 29, p. 169; S. longidens, Sep. 12, p. 166; S. olivacea, Sep. 12, p. 197; S. Pillansii, Sep. 5, p. 187.
- Stachyurus præcox, Mar. 28, p. 196.
- Tropæolum double-flowered, May 16, p. 311.
- Viburnum Carlesii, May 30, p. 346.
- Zephyranthes aurea, June 20, p. 405.

—James O'Brien.

SAXIFRAGA FORTUNEI.

WHILE the great majority of Saxifragas flower in spring and early summer, there is a small group, consisting of some three or four species, which do not open their flowers until autumn. Perhaps the best-known species belonging to this group is *S. sarmentosa*, more often grown for its foliage than for its flowers. Of the others, the best is *Saxifraga Fortunei* (*Botanical Magazine*, t. 5377), which is illustrated in fig. 16 from a photograph taken in the Kew rock-garden at about the beginning of November. It was introduced to cultivation from Japan by the traveller after whom it is named nearly 50 years ago, and is hardy when planted in sheltered positions. The reniform cordate leaves are lobed, lacinatedly toothed, and form a rosette, from which arise the stout stems bearing panicles of pure white flowers. These flowers are remarkable for the unequal petals, of which one or more may be twice or thrice as long as the others. The petals, which vary in length from $\frac{1}{4}$ to 1 inch, are unequally serrated. Although hardy, and capable of flowering outside in favourable seasons, *Saxifraga Fortunei* succeeds best when grown in a pot and kept under

[Photograph by W. Irving.]

FIG. 16.—SAXIFRAGA FORTUNEI AS IT FLOWERED AT KEW IN NOVEMBER LAST.

the cover of a cold frame, where it is protected from any frosts that occur about the time when it is in flower. Closely resembling this species, but with a less hairy stem, is *S. cortusifolia* (*Botanical Magazine*, t. 6680), which flowers about the same time. The chief difference lies in the petals, which, in this species, are entire. It is a later introduction than *S. Fortunei*, having been sent home by Mariès in 1883 from the central mountains of Japan, where it is found at a high elevation. Another species, closely resembling *S. Fortunei*, is *S. madida*, seeds of which were received from Tokio in 1907. This species also has entire petals, but the leaves are more deeply, 8-9 lobed. Broadly speaking, these three plants may be considered as distinct forms of one variable species, for they are all of the same habit, and flourish under similar conditions. Owing to their lateness in flowering, they do not produce seed in the open, but may be readily propagated by division of the crowns in the spring. The other species belonging to the group is *S. cuscutæformis*, which may be described as a miniature *S. sarmentosa*. W. I.

EXPERIMENTS ON THE VALUE OF NITRO-BACTERINE.

As all horticulturists know, Nitro-Bacterine is the name given to the preparation of the nodule-organism *Pseudomonas radiculicola*, which we owe to Professor Bottomley, and for which it is claimed that, when applied to the seed of leguminous plants, or to the soil in which such plants are grown, it increases the yield of the crop. Mr. Chittenden, the director of the research station of the Royal Horticultural Society, has published recently (*J. R. H. S.*, xxxiv., November, 1908) the results of an extensive series of experiments made at Wisley on the value of this preparation. Mr. Chittenden's paper is prefaced by an excellent review of the history of the progress of our knowledge concerning the nitrogen-fixing powers of leguminous plants.

Since the history of this subject has already been dealt with in these pages (*Gardeners' Chronicle*, Dec., 7, 14, 21, 1907) we need not now recapitulate the whole story. Nevertheless, it is essential to make clear, with respect to this subject, what is known with certainty and what is doubtful or conjectural.

Ind., 26, 304, 1907) has shown that, when cultivated, apart from the leguminous plant, in an alkaline medium containing saccharine substances, the micro-organism produces a nitrogenous slime. This substance, gum-like in nature, he considers to be that which, when produced by the bacterium in the nodules of the root, is taken up by the cells surrounding the nodules, and so serves as the source of nitrogen to the leguminous plant. That some such series of events occurs in the plant is undoubted, though the exact nature of the nitrogenous substance produced by *Pseudomonas* and laid hold of by the plant is not yet known. Further, there appears to be no doubt that Nitro-Bacterine, like its commercial forerunners, is capable of inducing nodule-formation.

So much for the undisputed facts; now we turn to the consideration of what is not certain. It is not certain whether nodule-formation, without which nitrogen-fixation is impossible, necessarily and always means nitrogen-fixation. Greig Smith states, for example, in contradiction to earlier investigations, that *Pseudomonas* occurs not only in the roots but in the stems of leguminous plants, and points out that, in the stem, nitrogen-fixation does not occur, owing to the unfavourable (acid) medium in which the bacterium finds itself. In such situations then, *Pseudomonas* must not only not be yielding up combined nitrogen to the plant, but must, in some measure, be actually robbing the plant of its nitrogen compounds.

This conclusion is supported by the facts that under certain conditions *Pseudomonas* in pure cultures loses its powers of nitrogen-fixation.

In the light of these facts, *Pseudomonas* appears in a very different character from that commonly ascribed to it. Instead of being an inevitable nitrogen-benefactor, disinterestedly handing over its nitrogen-wealth to its host, the leguminous plant, we see it as an invader which may at one time, and under one set of circumstances, succeed in plundering the scanty store of nitrogen in the plant, and at another time and in other circumstances, may be subdued by the plant and, domesticated within its tissues, serve as a source of nitrogen to the plant.

Just as disease-producing organisms may, under certain conditions, become attenuated and so fail to exert their characteristic effects, just as the fungus responsible for the germination of various Orchids may, in certain circumstances, lose this power (*Gardeners' Chronicle*, November 14, p. 344), so *Pseudomonas* may lose its virulence of nitrogen-fixation and, though in the plant, it may cease to play the part of a paying guest. It is of no use to point to the success of leguminous plants on poor, uncultivated land in support of the argument that the nodule-organism does supply the plant with nitrogen compounds. The fields of nature's battles are broad and cover many failures. It is not enough to be able to say in favour of Nitro-Bacterine that it may do good. It must be proved that it must do good or at least it must be known that, under such and such precise conditions, it does good.

The horticulturist is not practically interested in sterile soils. Those which he labours may not always be ideally rich, but it is doubtful whether they are ever without their own home-made brand of Nitro-Bacterine.

It is, therefore, incumbent on any one who advocates the use of artificial cultures of Nitro-Bacterine for horticultural purposes to demonstrate that the bacteria which constitute the essential part of such preparations are more potent agents of nitrogen-fixation than are the races which, as there is every reason to believe, are universally present in ordinary cultivated land.

Again, it is not known whether very early inoculation of leguminous seedlings is beneficial or not. It does not follow that, because seedling Peas develop nodules at a very early stage, they will grow into more vigorous plants than they would have done had inoculation followed its normal, more tardy course.

As to known facts: It is certain that most leguminous plants avail themselves of atmospheric nitrogen. Unlike the generality of plants, which soon perish unless provided with suitable supplies of coloured nitrogen, leguminous plants may flourish in the absence of such supplies.

It is also known that the power of nitrogen-fixation does not reside in the green plant itself, but in a colourless micro-organism, the bacterium known under the name of *Pseudomonas radiculicola* of Beijerinck. This bacterium is a member of the large community of micro-organisms which inhabit the soil. *Pseudomonas* gains access to the leguminous plant through its roots, multiplies therein and sets up the abnormal growth of the tissues of the root which results in the formation of nodules or tubercles.

It has been isolated, cultivated in the laboratory on suitable artificial media, and has been shown under these conditions to bring the free nitrogen of the air into combination with other elements, and so, ultimately, to construct the protein—substances on which its life and growth depend.

Quite recently Greig Smith (*J. Soc. Chem.*

If these arguments are admitted, and they could be reinforced by many other considerations, it will be recognised that the application of Nitro-Bacterine to horticultural practice cannot as yet be based on scientific knowledge, but only on empiricism.

We must either relegate the problem to the laboratory and wait with what patience we may till more is discovered as to the detailed behaviour of *Pseudomonas* under rigidly controlled conditions, or we must submit Nitro-Bacterine to the test of experiment and be guided by the results.

It must, of course, be admitted that if the horticulturist had to wait, before consenting to try new methods, till they had received the imprimatur of the scientist, his advance would indeed be slow. For the scientist has to adopt the laborious practice of unravelling, thread by thread, the intricately tangled skein of Nature. Therefore, it is well that the readier though rougher empirical method—that of giving the thing a trial—should proceed in pioneer fashion in advance of the slow-moving scientific body. But the method of large-scale experiment has its own difficulties, and must be tested by such trials as those carried out by Mr. Chittenden at Wisley. *Frederick Keeble, Sc.D. D.M. Cayley.*

(To be continued.)

THE ROSARY.

CULTURAL NOTES FOR JANUARY.

MATERIAL used for protection, whether straw, Fern or litter, should be as loose and as dry as possible when applied, as it will then resist the action of severe frost much better. This applies also to drawing up the soil about tender dwarf varieties—if planted against a wall they will require the protection of a mat.

As I have before stated, October is the best month to plant most classes of Roses, for the ground is then warm and favours root action long before the top growth is active. In spring-planted Roses the reverse is often the case, the wood breaking into growth first. But in town gardens, where the atmosphere is heavily laden with impurities, the trees do better if planted in the spring as they will thus escape much of the dirt and smoke, and the new growths will suffer less injury. The success of spring-planting will be more assured if the land to be planted has been well trenched and manured during the autumn, since this affords the ground time to settle. Moreover, the soil will not be liable to shrink as in the case of planting on freshly-dug ground.

Dwarf-budded Roses should be planted 2 inches below the union of stock and scion, but previous to this operation all suckers and bottom growths should be removed. There is much to be said in favour of employing budded plants rather than those on their own roots, for one year's growth on worked plants will equal that of two years' or more made by varieties grown from cuttings. Of course, if these latter plants can be had of equal strength to worked plants there will be no objectionable suckers, for all the shoots will be of the proper variety. Hardy climbing and pillar Roses may be thinned out where the growths are much crowded, removing the unripened and weakly shoots. This will permit increased light and air to reach the shoots which are left. The following Roses can be recommended for spring planting and growers can depend on their distinctive character.

Hybrid Teas.—Caroline Testout (satin pink), Liberty (bright crimson), Madame Ravary (golden yellow), Madame Abel Chatenay (pink and salmon), Countess Gosforth (pink, suffused yellow), Grace Darling (creamy white), Gros an Teplitz (bright crimson), Florence Pemberton (creamy white), and Frau Carl Druschki (snow white). *Hybrid Perpetuals.*—Ulrich Brunner (bright red), Mrs. R. G. Sharman Crawford (soft pink), Margaret Dickson (white and

pink), Hugh Dickson (brilliant crimson), Prince Camille de Rohan (velvety crimson), Mrs. John Laing (brilliant soft pink), Duke of Edinburgh (bright crimson) and Marchioness of Londonderry (ivory white). *Tea-scented varieties.*—Madame Hoeste (pale lemon), Madame Lambard (salmon), Madame Cochet (rose), Marie van Houtte (yellow), Mrs. E. Mawley (carmine), Perle des Jardines (rich yellow), Souvenir de S. A. Prince (white), Madame Falcot (apricot), Devoniensis (white), and Papa Gontier (rosy-crimson).

Forced pot Roses may, at the beginning of the New Year, be given a few more degrees of heat up to and not exceeding 50°, except when caused by the sun, when the temperature may be allowed to reach 60°, provided that a free circulation of air is maintained and that the syringe is freely used during the day. Should red spider or aphid be troublesome, fumigate

forced Roses that have been cut down should be placed in a cool house or frame. This will furnish room for the newly-grafted plants as they are taken from the frames.

Another batch of Roses can now be pruned and brought into the cool end of the forcing house for furnishing a succession of flowers. These plants, having plenty of root action, will bear a considerable rise of temperature with abundance of ventilation, but the house should be closed early, leaving the ventilators open a little during the night.

Planted-out Roses under glass which have made much progress may be given gentle warmth during the day, with a good circulation of air. A small quantity of fresh air may be admitted at night time also. One good syringing during the day, with a slight damping late in the day, will suffice for the present. *J. G. D.*

FIG. 17.—NEW DESSERT APPLE WILLIAM CRUMP.

APPLE WILLIAM CRUMP.

or vaporise the house towards evening, when the foliage is dry. If mildew appears use "sulphur-vivum" and soft soap. These should be well dissolved and applied to the hot-water pipes when they are fairly warm. One or two applications will generally suffice to kill the fungus. Towards the end of the month, when the flowers and buds are ready to cut from the earliest batch of plants, there will be a plentiful and continuous supply of green wood for herbaceous and soft-grafting, which can be used after the flowers are gathered. The dormant grafting under glass will now soon cease, and as the earliest-worked plants are taken from the frames their places can be filled by stocks grafted with green shoots until all the stocks, Briar, Manetti, and De la Griffieræ are dealt with. The early

This new variety of dessert Apple was exhibited at the last meeting of the Royal Horticultural Society, when it received an Award of Merit from the Fruit and Vegetable Committee. It was shown by Mr. W. Crump, of Madresfield Court Gardens, Malvern. It is the result of a cross between Cox's Orange Pippin and Worcester Pearmain. The fruits, as shown, vary a little in form, for, whilst some of them bore a considerable likeness to Cox's Orange Pippin, one fruit in particular had the upper portion cone-shaped, as in Worcester Pearmain. The fruits have much of the high colouring of Worcester Pearmain. In the illustration the fruits are shown of the natural size.

The Week's Work.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Early vines in pots.—If the vines were started at the beginning of November, the buds should now be breaking freely. Until the vines have safely passed through the flowering stage, be careful not to employ high temperatures at night, especially during cold weather. Should it be necessary to resort to hard forcing in order that the crop may ripen at the earliest possible time, such forcing may be more safely employed when the days become longer and the roots of the vines are more active than at present. Examine the hot-bed, and if it is found that the plunging materials are declining in heat, remove part of the bed, and afterwards add some fresh stable litter and leaves, mixing the whole together. These materials should have been previously prepared for this purpose, and if this has been done they may be used with greater safety. Extra care is necessary in watering until the weather becomes more favourable to growth. At the same time, when a plant is receiving water, fill up the pot twice, that the whole of the soil in the pot may be moistened. Diluted liquid manure and an occasional watering with weak soot-water will provide sufficient stimulants until the fruits are set. On fine days the vines may be syringed in the morning and again at noon. The atmosphere should be kept moist by damping the paths and other ground surfaces in the house at frequent intervals. When it is necessary to commence disbudding, remove the weakest growths first, and afterwards, when it can be seen which shoots are required to furnish the trellis, the surplus may be also removed. At the disbudding stage, the atmospheric temperature at night may be increased to 60° or 65°, according to the weather, but full advantage should be taken of the sun's rays, admitting air only on the most favourable occasions.

Early permanent vines.—Do not be in too great a hurry to remove growths from these vines. Although useless shoots may be rubbed off at once, the general disbudding should be deferred until it can be determined which shoots are likely to develop the best bunches of fruits. In the case of these vines, I always defer the removal of surplus shoots to a later stage than is usual with crops that are not forced so early. If the borders were thoroughly watered before the house was closed, they should need no more until the vines have passed out of flower; but they must be examined, and, if water is necessary, let it be applied in a clear, tepid state. When there are both inside and outside borders, it is sometimes necessary to place coverings on those outside to carry off excessive rain or snow; but, except in very cold districts, it is not wise to cover the borders with fermenting materials, which are apt to sour the soil.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Planting an orchard.—Autumn is undoubtedly the best time for planting fruit trees, but circumstances sometimes arise which compel the work to be postponed until the spring. In cases where this has occurred, there is no reason why complete success should not be obtained, provided the work is now taken in hand, and a little extra care is extended to the trees in the event of a period of dry weather coming before they have become established. When a new orchard has to be planted, it frequently happens that the gardener is not able to choose the most suitable site for fruit culture, but has to select a piece of ground convenient to the existing garden, and make the best of it. The best site is one sheltered on the north and east sides, lying pretty high, having a gentle slope to the south or south-west, and where the natural drainage is more or less perfect. The soil should be of a deep loam, but if it is not exactly what is required, its condition may be improved by adding various materials. Having selected a site, it has to be decided whether the orchard shall be cultivated for crops or laid down in grass. It is much better to cultivate the ground, cropping it with vegetables or small fruits between the rows of trees. This culture will bring

in a return the first season for the capital invested, and the trees will afterwards succeed better than if the surface is covered with grass. Supposing the former plan is adopted, the land should be bastard trenched, and, as the work proceeds, thoroughly cleaned of all the perennial weeds. When this is finished and the ground has settled, any addition of wood ashes or lime rubble which may be thought necessary may be made. The ground may afterwards be marked out in rows according to the style of tree to be planted. Half standards, such as trees with stems 3 to 4 feet high, are suitable for this class of plantation; but if it is intended to graze calves or other animals in the orchard, trees with 6-foot stems will be better. On the exposed and colder side of the orchard, Damson trees may be planted somewhat thickly, following next with Apples and Plums, thus reserving the warmest positions for Pears, in localities where these will succeed. The distance allowed between the trees may vary from 12 to 20 feet, according to the variety and style of tree chosen. The intervening spaces in the rows should be filled with bush fruits, leaving the open breaks to be planted with Potatoes and other vegetables, or with small fruits. Strong stakes should be in readiness to secure the trees from damage by winds, immediately after planting. Planting should be carried out as soon as the ground is in a workable condition; but it is better to delay it for a few days if the soil is wet or pasty. Before planting a tree, shorten any damaged or excessively strong roots in order to encourage the formation of fibres. Plant the trees firmly, and apply a light mulching when the work is completed. I always prune newly-planted trees, but not excessively, merely shortening the shoots until they are 12 to 18 inches long, removing all weak wood, especially any in the centre of the trees. Do not allow such trees to ripen fruits the first season after planting.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Trenching.—I do not advise this work to be practised, in the case of heavy lands, before the New Year; but where a large area of ground has to be trenched, no time should be lost in pushing forward with the work. I advocate deep cultivation and the working of the soil, wherever possible, to a depth of at least 3 feet. Moreover, it is of the utmost importance that the bottom layer of the soil should be brought to the surface and exposed to the influence of the weather, whatever its condition or nature may be. By such treatment, a considerable depth of soil can be quickly converted into a suitable medium for the growing of all kinds of vegetables. There is probably no land more difficult to work in anything but the most favourable weather than stiff, retentive clay, having, perhaps, only 2 or 3 inches of surface soil. In order to convert such a soil into good garden mould, considerable perseverance must be exercised. But, assuming that the garden has been well drained to the depth of 3 feet 6 inches, the conversion can be brought about in a very few years by deeply working the soil and adding to it various ingredients for making it more porous and less adhesive. Such a soil is frequently lacking in lime. A liberal surface dressing of this material will therefore be very beneficial if applied every alternate year. Wood ashes, or ashes from the refuse heap, leaf-mould, road-scrapings, soot, and especially old mortar rubble, are other valuable ingredients to mix with such a soil. Burnt ballast, which is generally known as burnt or charred clay, is frequently used for lightening and assisting in draining stiff land; but I am not persuaded of its good results and consequently am unable to recommend it.

Leeks.—In order to obtain the finest specimens of Leeks, it is necessary to sow seeds at once in a gentle heat. Much the same treatment is required as that previously recommended in the case of Onions. Seeds may either be sown in boxes and the seedlings pricked out into other boxes when quite young, or they may be sown in 3-inch pots and potted on as required. For the purpose of getting extra fine specimens during August and September, the latter method is to be preferred.

Potatoes.—The earliest crop of Potatoes in pots should not be unduly forced, but the growths

should be kept in an upright position by supporting them with neat, bushy sticks. At this season the plants require all the light possible, but not much water. Potatoes growing in heated pits should be moulded up directly the shoots are from 3 to 4 inches in length, using a light compost, which has been previously warmed to the same temperature as the atmosphere in the pit, and choosing the warmest part of the day for the operation. A little fresh air should be admitted to these pits each day when the weather is favourable. Plant successive batches of tubers, and see that sufficient stock for succession is laid out to form sprouts in a light position where frost cannot enter.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Dendrobium Wardianum.—Plants of this species that have been rested in a cool house, and on which the flower-buds are well advanced, may now be placed in a slightly warmer house. The cool part of the intermediate house will be warm enough for these plants for a week or two, after which time they will require the lightest position available in the Cattleya house. Notwithstanding that the plants are pushing forth new growths simultaneously with the flower-buds, the cultivator must not be tempted to afford them much water at the roots, or the new pseudo-bulbs will grow too rapidly and prevent the proper development of the flower-buds. If the plants are removed from their resting quarters and placed in a high temperature, the flower-buds are liable to turn yellow and fall off. Until the inflorescences open, water must be given at comparatively long intervals of time and then not in sufficient quantity to saturate the compost.

Dangers of excessive warmth in early stage of flowering.—Beginners in Orchid culture will probably have noticed that for several weeks past some of these plants have been pushing their flower-buds at the extreme nodes of the pseudo-bulbs only, and that the blooms on the back nodes are gradually developing. If these plants had been removed into the warmer house when the first flower-buds appeared, the later would never have developed. These remarks apply to nearly all of the *D. Wardianum* hybrids, including *D. Aspasia*, *D. micans*, *D. Wardiano-japonicum*, *D. Juno*, *D. Clio*, and *D. Euterpe*. Very large numbers of Burmese *Dendrobiums*, including *D. Wardianum*, *D. thrysiflorum*, *D. crassinode*, *D. primulinum giganteum*, *D. Devonianum*, *D. Falconeri*, and *D. Pierardii*, are, at this season, being imported into this country, therefore a few notes on their cultivation may prove useful.

Treatment of newly-imported plants.—The plants, when received, should be placed in a moderately cool and dry atmosphere. After a few days, they may be potted in pots or pans just large enough to accommodate them for one season. With the exception of *D. thrysiflorum*, the other species mentioned are all of pendulous habit. For these, shallow pans, or ordinary flower pots, with suitable wire handles attached, should be used in order that they may be easily suspended from the roof of the house. *D. thrysiflorum* succeeds best in pots. The plants, on being placed in the pots or pans, should be made quite firm by placing broken crocks around them up to the rim of the receptacle, and also by tying a few of the pseudo-bulbs to the wires or to neat sticks. The crocks in which the plants are fixed should be well watered two or three times each week, and as soon as root and top growth have started freely, the potting materials may be added. In doing this, take out the crocks to about one-half of the depth of the pot, and refill with a compost of *Osmunda* fibre and *Polypodium* fibre in equal parts, cutting the substances up moderately fine, and adding plenty of small crocks to assist proper drainage. Some growers prefer to add *Sphagnum* moss to the compost, but I find it is immaterial whether moss is used or not. After potting, place the plants in a warm atmosphere, such as is maintained in a Cattleya house, and afford light waterings at first, being careful not to over-water them. As the new growths gain in strength and roots become plentiful, water may be more frequently and liberally given.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Salvia.—As *Salvias* pass out of flower most of the plants should be destroyed, retaining scarcely more than are sufficient to supply cuttings for propagating purposes later on. Plants thus kept for stock purposes should be pruned to induce them to make strong, clean growths. When the plants have again started into growth, a few specimens of *S. splendens* and its varieties may be potted on to furnish extra large plants.

Plants in frames.—As the weather may become colder, provision should be made for protecting plants in frames by means of outside coverings. Field mice are sometimes driven into frames by stress of weather and if they are not detected and trapped will quickly do irreparable damage. Ventilate the frames freely in favourable weather and exercise great care in watering. Encourage the plants growing in these comparatively cool conditions to become of sturdy habit, and therefore the better able to withstand low temperatures.

The conservatory.—Now that most of the late-flowering *Chrysanthemums* have been removed from the show house, there may be a deficiency of bright-flowering plants of fair size. For placing at the front of the groups, or on the side stages, scarlet Tulips are obtainable in abundance; but amongst the taller, forced plants, the paler shades of colours largely predominate. This lack of brightness may be remedied in some degree by the use of tall plants of some of the perpetual-flowering *Begonias*, such as *B. fuchsoides*, *B. coccinea*, and *B. gracilis*, which flower very freely. During the winter months such *Begonias* may be exposed to all the light available; but later, as the sun gains power, they require partial shade. Careful consideration must be given to the ventilation of the house and the watering of the plants, for on most days at the present season the out-of-doors atmosphere is heavily charged with moisture and moisture of this kind is apt to prevent the flowers lasting so long as they would otherwise. At the same time, it is necessary to admit some air to the conservatory each day, and, in the matter of watering, it must be remembered that, whilst it is better to keep most plants on the dry side at this season, yet extremes of dryness must be avoided. Any water that may drain, or be spilt, on the slate or stone pathways must be mopped up at once, for cleanliness in every particular should be rigidly insisted upon in the house where the preservation of flowers is a matter of the greatest importance.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Plants in flower.—Christmas Roses are now gay, and should be afforded some protection from slugs and worms. If soot and lime be mixed in equal quantities and spread around the plants it will answer the purpose.

Erica lusitanica is perhaps one of the best of the Heather family, on account of its early and free-flowering character. It grows 6 to 8 feet high in a short time. *Chimonanthus fragrans grandiflora* is beautiful. Against a wall, the plants in the open are only now in bud. *Jasminum nudiflorum* is well adapted for walls or pergolas or for training up the stems of trees or on fences. *Rhododendron Nobleanum*, flowering during mild weather, affords a touch of colour which is much appreciated from the present time until March.

Bamboos.—These are a fine feature in the dull winter months. They may be planted at the present time if the weather is of a suitable character. *Arundinaria anceps* is one of the first to feel the effects of a shift, and therefore should be moved some day when the weather is moist.

Protection of tender plants.—It should be remembered that, although certain plants need protection from frost, the protective material should not be applied until the last possible moment, nor should the covering be so dense as to exclude light and air; for otherwise it would have the effect of making the plants even more tender. It is important also that the material should not be allowed to remain upon the plants for a longer time than is absolutely necessary. The

material employed should be of a light character, such as dry Bracken leaves or Heather. Heather may be entwined amongst the branches in such a manner that it will not cause a great weight upon the plants in the event of heavy snowstorms. As the roots of many plants are liable to suffer considerable injury from frosts, these also should be protected with dry peat, leaves, or ashes, applying the material in sufficient quantities to repel frosts. *Gunnera manicata* should have its crowns wrapped up in dry bracken, or even dry hay and over the protective material may be tied an old leaf belonging to the same plant. This will serve as a sort of waterproof, keeping the crown dry, and therefore less liable to injury. *Rhododendron Thomsonii* should have some dry material placed around its base and similar treatment is required by many tender species of *Rhododendron*, such as *R. Aucklandii*, *R. Edgworthii*, or any hybrids of these species. *Crinum*s should have their tops protected. *Draecenas* need to have their stems bound up. *Romneya Coulteri* requires protection for its roots. *Phormium*s not only need to be tied up, but some slight protection should be afforded to the roots also. In some districts it is necessary to protect the choicer Tea and Hybrid Tea Roses. *Choisya ternata* should have some long branches placed over it, fixing the branches in the ground. *Carpenteria californica* should be

well, Peckham, Finsbury, Dulwich, Southwark, Golder's Hill, Avery Hill, Ravenscourt, Springfield, Waterlow, Ruskin, Kennington, and Myatt's Fields. Each park is in the care of a superintendent who is responsible to the chief officer of the L.C.C. Parks Department. The largest of these parks is Victoria, consisting of 217 acres, and Myatt's Fields is the smallest, being only 14½ acres. They are classified according to size as first, second, third, and fourth class parks.

The staff.—Employment is found in the L.C.C. parks for nearly 900 persons, some for the maintenance of order, but the greater number for the carrying out of park work. It is open to anyone in the gardening department to qualify for promotion to the position of a first-class superintendent; but, before promotion can be gained by one of the lower ranks, it is necessary to pass an examination in horticulture. These examinations are undertaken every year by the Royal Horticultural Society. The object of the test is to stimulate observation and interest in all the details of park work, and all those who pass in the first and second classes are given a weekly increase in salary of 2s. or 1s. respectively. Upwards of 100 young men sat for this examination in January, 1908, and it is probable that there will be more candidates at a similar examination to be held in the course of a few days.

The removal of snow.—The recent heavy fall of snow caused considerable work in the parks: snow being so great a hindrance to locution that it is the superintendent's duty to remove it from the paths as quickly as possible. Carriage drives are best cleared by snow ploughs drawn by horses. Every effort has to be made to clear the snow from all thoroughfares before a thaw takes place, or the paths would remain in a most unsatisfactory condition for a long time.

Skating on ice.—For a few days it appeared as if there would be skating on some of the park waters—a recreation eagerly sought after by the public. Everything should be done for the purpose of meeting any emergency that may arise; fortunately the regulations require the ice to be 3 inches thick before the public is allowed to use it. There are about 24 places under the control of the L.C.C. where skating is permitted. Everything is done to render the pastime available to the greatest number of persons possible, and also to prevent accidents. When skating can be carried on safely the parks remain open until 10 o'clock at night.

THE APIARY.

By CHLORIS.

FIG. 18.—THE MAKING OF A BEE-HIVE.

1, base of the hive showing the alighting board at A; 2, body or brood-chamber; D and C, sides; E, E, iron band on which the upper frame rests; F, position of front of frame; 3, plan of the angle joints.

given some protection over the roots, and similar protection is also needed by the more tender *Arundinarias*, such as *A. falcata*, *Falconeri*, *A. nobilis*, and others. Among Alpine plants, the *Androsaces* should be kept dry by a handlight or some squares of glass placed over them.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Acquisition of sites.—If we except the Royal parks and those open spaces over which the public have obtained common rights, which were rendered inviolable by the Act of 1866, all other sites now utilised either as parks or open spaces in the London district have been secured by the municipal authority for London: in the past by the Metropolitan Board of Works and since 1889 by the later-instituted authority, the London County Council. These authorities have availed themselves of every opportunity of securing vacant land in all parts of the county, and have frequently paid large sums of money for small sites in congested and densely-populated districts. What are distinguished as L.C.C. parks are known as Victoria, Battersea, Brock-

Hive-making.—In order to save trouble when fitting up hives, it is desirable to make every part of new hives to a standard dimension, for then all the portions will be interchangeable. There are many patterns, all embodying the same idea, but the one illustrated at fig. 18 is one of the best. At diagram 1 is shown the floorboard. This requires little explanation, as the dimensions are clearly indicated. The portion marked A is the alighting board and, if it is desired, it may be made larger than the dimensions indicated. This would be an advantage during stormy weather, for heavily-laden bees are often blown to the ground when, if the wind is very cold, they perish. The hive should be raised on four legs, so that the floorboard is about 1 foot from the ground. At diagram 2 is shown the body of the hive or brood-chamber. The outside walls of this chamber should be made of ¾-inch boards at the least and, to make the joints watertight, the ends should be doubly rabbeted and nailed, as shown at diagram 3. If the inside pieces (C and D) are 8½ inches high, and strips of tin or iron are nailed, as at E, E, so as to stand above C and D about three-eighths of an inch, there will be left a sufficient space for the fingers to be inserted under the frame-ends when it is desired to remove it. But, besides affording a further grip of the frame, it leaves less space for the bees to propolise and, further, it provides fewer risks of bees getting crushed under the frame-ends. The front of the hive, when fixed at F, should have a passage-way about 10 inches long and ¾ inch high cut out in order to enable the bees to enter. A porch constructed over the entrance to the hive would serve to keep out the wet.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JANUARY 9—
London Branch B.G.A. lecture on "Garden Cities."

MONDAY, JANUARY 11—
R.H.S. Examination for Public Parks and Garden Employés.

TUESDAY, JANUARY 12—
Roy. Hort. Soc. Coms. meet. (Competitive Classes for Grapes. Lecture at 3 p.m. by Mr. C. D. McKay, on "the French System of Intensive Cultivation").
British Gard. Assoc. Ex. Council meet.

WEDNESDAY, JANUARY 13—
Ann. meet. Bolton Hort. and Chrys. Soc.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—38°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, January 6 (6 P.M.): Max. 45°; Min. 36°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 7 (10 A.M.): Bar. 30.2; Temp. 44°; Weather—Fair.

PROVINCES.—Wednesday, January 6 (6 P.M.): Max. 47° Cornwall and Ireland S. coast; Min. 35° York.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous and Border Plants, Liliiums, Bulbs, Azaleas, &c., at 12; Roses at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Perennials and Herbaceous Plants, Liliiums, Hardy Bulbs, &c., at 12; Roses and Fruit Trees at 1.30; Palms, Azaleas, Rhododendrons, &c., at 5; thousands of miscellaneous Bulbs, &c., at 11.30; 776 cases Japanese Liliiums at 1, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

The Absorption of Moisture by Leaves.

In a recently-published lecture on "The Absorption of Rain and Dew by the Green Parts of Plants,"* Prof. George Henslow endeavours to disprove the current view that the amount of absorption of water by the leaves of ordinary plants is normally but small.

Professor Henslow criticises Duchartre's experiments which showed that, with pot-plants, no water is absorbed by the leaves during the night or that the quantity absorbed is so small as to be negligible; according to the former authority, little or no absorption of water by leaves takes place at night except when the leaves are exceptionally flaccid at the beginning of the period of darkness.

This is a considerable admission. For plant-physiologists would not be disposed to deny on general grounds that wilted leaves of such plants as do not close their stomata in darkness may absorb a certain amount of water from the atmosphere. Professor Henslow does not appear to have made experiments in support of this suggestion, but he thinks that absorption of rain or dew by leaves may take place in the morning. To use his own words, "then, any part that may be the first to become dry will begin to transpire and so cause an indraught of dew in any neighbouring spot where it may have been retained" (p. 169).

It is not clear what is meant by "an indraught of dew" set up in consequence of transpiration. By far the greater amount of transpiration of water from leaves takes place through their stomata, and, in the process of transpiration, water-vapour escapes by diffusion from the inter-cellular spaces of the leaf through the stomata into the surrounding air. Now, diffusion is a molecular—and not a mass—phenomenon. It is not possible that the movement of molecules of water-vapour can produce an indraught.

Professor Henslow's experiments do not prove his thesis that an ordinary plant in the open absorbs water-vapour, rain, or dew in appreciable quantity. They show that if young shoots or leaves, or even older leaves, the cuticle of which is thin, are dipped in water or wrapped in wet blotting-paper they absorb a certain amount of water.

But facts of this kind, which are dealt with in the ordinary text-books, cannot be admitted as evidence of any considerable water-absorptive powers under ordinary conditions.

The present position of our knowledge on this subject may be briefly stated. In such parts of plants as are concerned with absorption of water, as, for example, in the root-hairs, the layer of water-proofing material (cuticle) present in other parts of the integumentary system (epidermis) is wanting. In special cases, for instance, in the leaves of epiphytes such as Tillandsias, where, owing to their situation and to their poorly-developed root-system, it is necessary for the leaves to undertake the work of supplying the plant with water, there are special uncuticularised water-absorbing cells. In ordinary plants a layer of cuticle covers the epidermal cells of the leaf, and with greater or less efficiency, according to the degree of its development, prevents the loss of water from the general leaf surface, thereby confining that loss to that due to stomatal transpiration.

We may go further, and say that the presence of rain or dew on the surface of a leaf may in the long run tend to provoke more active transpiration, and so cause actual loss of water. For it has been shown that the stomata open more widely when the leaf is actually wetted than even when it is in a saturated atmosphere. If, then, this widely-open state persists for some time after the rain or dew is removed, transpiration will proceed more rapidly than would have been the case had the leaf not been wetted.

Professor Henslow has made a good point in suggesting that wilted leaves may possibly absorb a certain amount of water from the air. We are not aware of any accurate experiments bearing on this question and would suggest that it is a subject which, together with the effects of spraying, would well repay careful investigation.

Plant-collecting in China.

We are indebted to Professor C. S. Sargent for further information extracted from a letter written by Mr. E. H. Wilson on October 1 last at Kiating, near Szechuan.

"The trip through the wilderness behind Mounts Omi and Wa proved fairly profitable, but, owing chiefly to bad weather, hard and uncomfortable. Above 4,000 feet altitude the country is of limestone formation. As is usual

with this rock, it is much broken up, forming steep cliffs and crags which present wild and savage scenery. Charcoal burners have destroyed all the forest, leaving in its place a dense jungle of shrubs; above 7,000 feet (to 10,000 feet) Bamboos form one absolutely impenetrable thicket. Nothing is more disheartening to a botanical collector than these Bamboo jungles. Practically nothing can grow in them but Bamboos. There is no traversing them, save by the recognised paths, unless there is time to cut a new track, and if there is the slightest rain falling at the time one is drenched through by the overhanging culms.

"I ascended the famous Mount Wa-wu, unvisited previously by any foreigner, but was very disappointed. The summit is only 9,200 feet altitude, undulating and park-like, clothed with a dense jungle of Bamboo scrub with Silver Fir and a few Tsuga interspersed. This mountain is sheer on all four sides for fully 4,000 feet. We ascended by a precipitous path up the north-north-east angle. Formerly magnificent trees of Magnolia, Davidia, Tetracentron, Æsculus, Betula, Acer, and Castanopsis were abundant on this mountain, but now only mere shrubs and the stumps of felled giants remain. Iron, copper, and lead are common in this region, and it is the making of charcoal for the smelting of these ores that has caused the total destruction of all forest trees. Even the soft-wooded Silver Fir is now used in making charcoal for lead-smelting. Had the weather been better, one might have got some enjoyment out of the trip. But wet through day after day, with bedding and clothing drenched, sleeping in the filthy dilapidated huts of the charcoal burners at night, and enveloped by dense mists nearly every day with a perspective limited to a radius of 40 yards, enjoyment was out of the question.

"By dint of much exertion I managed to secure quite a number of seeds, and also a certain amount of herbarium material. I saw many trees of Silver Fir and Tsuga, and also a few Spruces, but not a single new cone could I discover. I am afraid we shall have but poor luck this year in the matter of Conifers.

"Details of the seeds forwarded are given in the lists enclosed, but as some are of exceptional interest, a few extra details may be acceptable. Of *Lonicera*, several species are sent. Without instituting comparisons, *Lonicera* No. 942 and *L. subæqualis* may be instanced as of unusual interest. The No. 942 is possibly one of the forms of the variable *L. hispida*, but the flowers are enormously large, creamy yellow in colour. It inhabits thickets on Mount Wa, and is only known to me from this one locality. *L. subæqualis* is one of Rehder's new species; the fruits, which are red, globose, the size of a small Pea, and somewhat glandular, were heretofore unknown. I have sent several species of *Sorbus*—all interesting, but Nos. 874 and 941, on account of the curious colour (pale purple) of their fruit, are more than ordinarily so.

"The pubescent form of *Idesia polycarpa* (No. 962) has been given varietal rank by Dr. Diels. It occurs at higher altitudes than the type; unfortunately, there are very few seeds. The *Schizandras* are all ornamental in fruit, and No. 921, with large, rich maroon flowers and scarlet fruit a foot or more long, is very fine.

"*Styrax* (No. 884) is a very pretty species, forming a bush 4 feet high, with small leaves and ivory-white flowers. I enclose a fragment of this *Styrax* and also a flower and leaf of *Clematis* No. 868. This latter is the largest-flowered *Clematis* in the West of China and possibly in the whole of the country. It is evidently allied to *C. montana*, but, to my mind, distinct. The flowers are white—2 to 3 inches across, solitary, axillary, on stout peduncles 4 to 6 inches long.

"The *Piptanthus* (No. 885) forms a bush 3 to 6 feet high, and has rich, golden-yellow flowers.

* *Journal of the Royal Horticultural Society*, vol. xxxiv., pt. 2.

From the altitude at which it occurs (7,500 to 10,000 feet) it should be hardy. It is finer than *P. nepalensis*.

"Seeds of a number of species of *Actinidia* have been sent, and I should like to say a word in favour of this genus. The four or five Japanese species in cultivation in England of this genus are regarded as doubtfully hardy, and of very little horticultural value. *A. chinensis*, introduced by Messrs. Veitch, has so far failed to do itself full justice; but, in the years to come, I believe it will be one of the finest ornamental climbers in cultivation. In the west here, and to a lesser degree in Hupeh, there are many kinds of *Actinidia*, several of them undescribed. With their wealth of fragrant flowers, snow-white, salmon-red or yellow, *Actinidia*, with *Clematoclethra*, make the finest display of any scandent shrub in the west. The flowers are borne in myriads, and their fragrance is an additional attraction. The fruits of all are edible, and some, notably *A. chinensis* and *A. No. 934*, are delicious. A difficulty to the classifier and a drawback from the cultivator's point of view is the fact of the flowers being polygamous. However, in spite of this, I believe there is a future for these climbers, and I hope the Chinese species will be more amenable to cultivation than the Japanese appears to have been.

"Closely allied to *Actinidia* is the comparatively new genus *Clematoclethra*. Of this genus seeds of three species have been sent. What has been said in regard to the ornamental value of *Actinidia* applies equally to *Clematoclethra*, save that the fruits, though succulent and edible, in this latter genus are of little value. An interesting feature (shared by one or two species of *Actinidia* also) is that a large percentage of the ordinary foliage leaves are constantly snow-white, becoming pinkish with age. A light, well-drained soil, rich in decayed leaves and a sunny position, where they can remain undisturbed for years, are the essentials for the successful culture of both *Actinidia* and *Clematoclethra*.

"In addition to *Magnolia villosa*, of which I hope to send more seeds and a note later, seeds of one, possibly two, new species of *Magnolia* have been forwarded. These latter are large trees with ovate to obovate leaves, densely pubescent below. The fruits are irregular in shape, resembling those of *M. Yulan*, but much stouter. The flowers are unknown to me, but the country-folk describe them as rosy-pink."

OUR SUPPLEMENTARY ILLUSTRATION represents a hybrid *Nepenthes*, raised by Messrs. JAMES VEITCH & SONS, from a cross between *N. sanguinea* and *N. Curtisii* superba. The plant was exhibited by the raisers at the meeting of the Royal Horticultural Society on September 29, 1908, when the Floral Committee granted it a First-class Certificate. The pitchers of *N. Dr. John MacFarlane* have a shape similar to those of *N. Curtisii*, and are about 7 or 8 inches long. The tone of the body of the pitcher is brownish-red and there are splashing of a deeper colour, which add additional beauty. The interior of the pitcher, just below the handsome rim, is bright green, with frequent purple markings. The leaves are very broad, measuring as much as 5 or 6 inches across, a width greater than in the foliage of either parent. The plant bore five large pitchers and several smaller ones.

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, January 12, at 6 p.m., at the Hotel Windsor. The Rev. Canon HORSLEY will deliver a lecture on the "Flowers of Switzerland," which will be illustrated by unpublished slides of the people and scenery of the Bernese Oberland.

THE NICHOLSON LIBRARY.—Many of our readers will be interested to know that the books which belonged to the late GEORGE NICHOLSON, F.L.S., V.M.H., will be offered for sale at Messrs. SOTHEBY & COMPANY'S Rooms on Friday, the 15th inst. The first lot is numbered 617. It will be offered at 1 o'clock p.m. There are 66 lots.

CHANGES AT KEW.—On the retirement of Mr. W. BOTTING HEMSLEY, F.R.S., from his official position in the Royal Gardens, Kew, Dr. OTTO STAFF, F.R.S., has been appointed Keeper of the Herbarium. Mr. C. H. WRIGHT, A.L.S., is now the Chief Assistant in the Phanerogamia.

THE SELBORNE SOCIETY.—We are informed that this society has revived the old title of its magazine, which will henceforth be called *The Selborne Magazine (and Nature Notes)*, and will be published by Messrs. GEORGE PHILIP & SON, LTD., of 32, Fleet Street, E.C. All communications with regard to the society should be addressed, as heretofore, to the Honorary General Secretary of the Selborne Society, 20, Hanover Square, London.

PUBLIC PARK FOR LURGAN.—Public competition having been invited for plans for laying out 72 acres of land as a public park for the town of Lurgan, Co. Armagh, we are informed that Messrs. J. CHEAL & SONS have been awarded the first premium, and that their plan is accepted by the council.

THE "BOTANICAL MAGAZINE."—The January number of the *Botanical Magazine* contains illustrations and figures of the following plants:

ENCEPHALARTOS BARTERI, tab. 8232.—This tropical African species is described by Lt.-Col. PRAIRIE. It was originally met with during Dr. BAIKIE'S Niger Expedition of 1858, when it was collected by the late Mr. C. BARTER, "three miles south of Jebu on the Yorubna side." The species is described as resembling *E. villosus*. Its value for cultivation in this country appears at present undetermined, it being stated that at Kew the plants have rarely more than three leaves, and although carefully grown in a moist tropical house, only one of the stems has produced a cone. The largest stems ever received at Kew have not exceeded a foot in height. The female cone figured is one of a number received from Labo Labo on the Volta, early in 1908, having been sent by Mr. J. ANDERSON. A male cone collected by BARTER is also depicted.

ANGADENIA NITIDA, tab. 8233.—This Apocynaceous plant has been known as *Echites nitida*, *Odontadenia nitida*, *O. cordata*, &c. In MIERS' Monograph of the genus *Angadenia*, he included 26 species, but Dr. STAFF proposes to treat *Angadenia* in a narrower sense, limiting the name to a smaller group of forms more or less resembling *A. nitida*. The restricted genus includes MIERS' species *A. hypoglauca*, *A. coriacea*, *A. elegans*, and *A. geminata*, and appears to be confined to North-eastern Brazil, Guiana and Trinidad. *A. nitida*, which extends from Para, through Guiana to Trinidad, was received at Kew in 1906 from the Trinidad Botanic Gardens, where it was known as *Echites neriandra*. It grows freely in the tropical house at Kew, extending its shoots for several yards along the rafters under the roof. It flowers freely in July, and has the appearance of a small-flowered yellow *Dipladenia*. It is described as a useful plant for clothing a pillar in a tropical house.

ERIA RHYNCHOSTYLOIDES, tab. 8234.—This new species was originally described in the *Gardeners' Chronicle* for November 30, 1907, page

370, by Mr. JAMES O'BRIEN. The figure now published in the *Botanical Magazine*, like the original description in our own pages, has been prepared from a plant which was presented to Kew in 1908 by the Hon. WALTER ROTHSCHILD.

CLERODENDRON UGANDENSE, tab. 8235.—This species is described as differing from *C. myricoides* as figured in the *Botanical Magazine*, tab. 5838, in having much shorter, semi-orbicular calyx-lobes, a shorter corolla-tube, and larger, more deeply-coloured corolla-lobes. Seeds of *C. ugandense* were received at Kew in 1906 from Mr. M. T. DAWE, who had collected them in Voi, Uganda, 2,000 feet above sea level. The plants have grown freely in an intermediate house, quickly forming shrubs 2 to 3 feet in height, with long, slender, leafy branches terminated by loose racemes of blue flowers. Young plants raised from cuttings formed of the young shoots flowered freely in October. The species is recommended as a winter-flowering decorative greenhouse shrub.

LONICERA GIRALDII, tab. 8236.—Seeds of this new species were first obtained by Mr. M. L. DE VILMORIN from Szechuen in 1899, and with whom it first produced flowers in 1903. The figure has been prepared from specimens received from Messrs. VILMORIN-ANDRIEU in 1908. Although very nearly allied to *L. acuminata*, a Himalayan species, this Chinese plant, Mr. HUTCHINSON points out, is readily distinguished by the somewhat narrow leaves, which are clothed on both surfaces with a yellowish, somewhat stiff indumentum. The flowers are about 1 inch long, the corollas red, and the fruits globose and purplish-black.

ORPHAN FUND DINNER.—The Duke of RUTLAND will preside at the forthcoming festival dinner of this fund. Owing to a printer's error last week, it was announced that the Duke of PORTLAND would preside.

SEED FIRM EMPLOYEES DINNER.—The annual dinner of the employés of Messrs. DICKSON & ROBINSON, Seedsmen, Manchester, took place on December 22, at the Victoria Hotel, Manchester. Mr. ROBINSON, the senior partner, occupied the chair. The gathering afforded opportunity for the presentation of a timepiece, subscribed for by the employés, to Mr. W. P. ROBINSON, marking the occasion of his recent marriage.

"MY GARDEN DIARY."—This dainty annual, published by Messrs. SUTTON & SONS, contains excellent reminders of the work to be done in the various departments of the garden during each month in the year. These are based upon actual experience, and may be relied upon by amateur growers, whilst they will refresh the memory of professional gardeners. Space is left for the insertion of memoranda, and altogether the pamphlet is a most desirable companion for the gardener. The issue for 1909 has a cover beautifully illustrated with blue, pink, and white *Cinerarias*.

AGARICUS ELVENSIS.—Dr. M. C. COOKE, in the *Journal of the Royal Horticultural Society*, describes the reappearance of specimens of *Agaricus elvensis*, a species of Mushroom received by the late Rev. M. J. BERKELEY in 1865 from Wales. This species appears to have a predilection for the neighbourhood of Pear trees, for twice in Dr. COOKE'S experience it has turned up in gardens in which fragments of the Agaric had been thrown, and in both cases it made its appearance under the drip of a Pear tree. Dr. COOKE expresses the hope that there may be a future in store for *Agaricus elvensis*, whose esculent qualities, he says, are excellent.

A LARGE-FLOWERED IPOMŒA.—Mons CHABAUD, writing in the *Revue Horticole*, draws attention to the fine Convolvulaceous plant, *Ipomœa mexicana*. Unfortunately, the blossoms only open late in the afternoon and close on the following morning, but the delicious perfume, and the large size of its white flowers (6 to 8 inches in diameter) when they are open, compensate in a great measure for their shyness during the greater part of the day. The plant was described in 1854 by VERLOT, from the Botanic Garden at Grenoble. It is a tender plant, though it succeeds in the open in the south of France. In suitable conditions, it is a vigorous grower, and the flowers are said to be useful for cutting.

Publications Received.—*Fourth Report of the Board of Commissioners of Agriculture and Forestry of the Territory of Hawaii*, for the year ending December 31, 1907. (Honolulu: Bulletin Publishing Co.)—*Kew Bulletin of Miscellaneous Information, Appendix I.*—1909. Containing list of seeds of hardy herbaceous plants and of trees and shrubs. (London: Wyman & Sons.)—*Transactions of the Royal Scottish Arboreal Society, January, 1909.* Vol. XXII., Part I. (Edinburgh: Douglas & Foulis, Castle Street.) Price to non-members, 3s.—*Contributions from the Botanical Laboratory of the University of Pennsylvania.* Vol. III., No. 2. A comparative study of the genus *Pentstemon*, by Louis Krautter, B.S., Ph.D. (Philadelphia: The John C. Winston Co., 1,006-16, Arch Street.)—*The Estate Magazine* (January). Price 6d.—*Beautiful Flowers and How to Grow Them* (Part 6). Edited by Horace J. and Walter P. Wright. (London: T. C. & E. C. Jack.) Price 1s.

FLORISTS' FLOWERS.

SOME NEW FRENCH CHRYSANTHEMUMS.

THE Chrysanthemum is more popular in France than ever now and there are more raisers than at any time during the past 25 years. At the exhibitions at Tours and at Paris, seedling Chrysanthemums were shown in great quantity. Many of these varieties would have been warmly welcomed by our own growers 15 years ago. But with the present keen competition there is little chance for any raiser who has not already made a name in this country introducing his novelties into Britain. There is practically no room for him unless he specialises in the decorative or early-flowering section.

Amongst the raisers of large exhibition flowers there is practically only one name to be considered: that of M. Ernest Calvat. American, French or Belgian growers who cultivate the popular autumn flower for exhibition are still in a large measure dependent upon M. Calvat for all that is newest and best in the way of novelties, and with good reason.

In England the other French raisers, excepting M. Aug. Nonin, whose chief work has been amongst the decorative section of the flower, have had no chance of obtaining a footing.

M. Calvat's displays, both at Tours and at Paris this year, were quite up to his usual standard. At the former place they gained one of the leading awards, and at the latter a Grand Prix d'Honneur and 18 First-class Certificates. I have compiled a selection which includes the best of those which will be put into commerce.

Belle Estevelle.—A large Japanese variety with long-spreading florets, very full and double; colour a shade of rich golden yellow.

Calvat 1908.—A Japanese variety with rather broad florets, the tips incurving slightly inwards. The bloom is very full, compactly formed and of great size and substance. The tone is a beautiful, bright rosy-amaranth with a silvery reverse to the florets.

Paul Delaroche.—Another Japanese Chrysanthemum of large dimensions; the florets are of medium size, twisted and intermingling. It is a very compact and closely-built flower, with a pearly-blush colour slightly tinted and shaded with lilac-mauve.

Le Maroc.—A large Japanese variety of the Edwin Molyneux type, with very broad florets slightly pointed at their tips. The inside of the florets is of a rich, bright crimson; the reverse side is golden.

Ulysse Lafont.—Japanese, a large bloom, with rather narrow florets, and very full and double. It is a very close, compact flower of massive proportions, the colour being ochre-yellow shaded golden apricot. It forms an effective and distinct variety.

Henry Decault.—Also of the Japanese type and of fine form. The blooms are densely packed with long florets forming a spreading flower of striking effect. The tone is a very delicate and rich shade of pale rosy-amaranth.

of a medium size, arranged compactly, forming a deep solid flower of massive appearance. Colour pure white slightly tinted.

Thamara.—A very close, compactly-formed Japanese variety, having florets of a medium size. The colour is purplish-mauve with a reverse of silvery pink.

Cularo.—This also is a Japanese variety, the florets being rather broad. The flower is full, double and large in size, the tips of the florets being pointed. The colour is chestnut-yellow.

Alceste.—A fine Japanese bloom of great merit. The florets are of medium size and of a good length. It forms a big, solid, double flower. The colour is pale yellow.

FIG. 19.—CYCNOCHES WITH MALE AND FEMALE FLOWERS: THE MALE FLOWERS IN THE LONG RACEME; THE FEMALE FLOWERS IN THE SHORT SPIKE.

(See page 27.)

Ferdinand de Bièvre.—A Japanese Chrysanthemum with florets of great width. It forms a rather finely-built flower of spreading form. The colour is pale yellow. This variety was one of the biggest shown by this raiser.

Reine Fiammette.—A Japanese variety of large size. The medium-sized florets form a reflexing Japanese bloom of the old type. The colour is a pale rosy-amaranth with purplish shading.

Thais.—A Japanese bloom of medium size and very deep and globular in build. The narrow florets are richly shaded a chestnut-crimson with a golden reverse.

Miarka.—An old type of incurved Chrysanthemum. The big blooms have grooved florets

Mme. Travouillon.—A very large Japanese variety, shown in fine form at Tours. The long spreading petals are numerous and double to the centre. The colour is a bright lilac rosy-mauve.

Belle Trouchoise.—Another Japanese variety with very long florets. A big, imposing bloom, very effective in its rich shade of reddish salmon-rose and reverse of gold.

Cecilia Monteil.—A large, solid bloom of the Japanese type and with very long florets. The colour is pure white, but towards the outer edge it becomes shaded with pale purple.

Rev. W. G. Sharpin.—Of the Japanese section and with grooved florets. It forms a flower of

the greatest possible size and substance. The inside of the florets, which are of good breadth, are coloured a dull shade of old rose with a reverse of golden yellow.

Dr. Nicolas.—A large Japanese variety with rather broad, flat florets. The colour is deep purplish-violet with a silvery reverse.

Rachel l'Abbé.—A Japanese bloom of large size, with rather long, narrow, twisted and intermingling florets curling at their tips. It is a deeply-formed flower, the colour being white slightly tinted with green in the centre.

Mme. E. Bonnefond.—Another huge Japanese Chrysanthemum of much merit and forming a graceful, reflexing flower, very full and double. The florets are of a medium width. Colour a rich golden apricot passing to golden yellow.

General Sauret.—Another large Japanese bloom of great solidity and depth. The medium-sized, grooved florets are curly at the tips. This variety is of great promise. The colour is rich golden yellow.

Souvenir de Mme. Gagnaire.—A Japanese Chrysanthemum of the largest dimensions with very long florets which are of a medium width. The tone is a bright pinkish-rose with a reverse of silver.

Claudius Denis.—A very deep, medium-sized flower of the Japanese type with narrow florets. The colour is a rich golden yellow. *C. Harman Payne.*

CHRYSANTHEMUM FRAMFIELD PINK.

DURING the past two seasons this Chrysanthemum has been of a very poor colour in these gardens, and I should like to know if any other gardener has experienced the same difficulty with it. I obtained last spring a fresh stock of plants, which were treated in the way usual with other late Chrysanthemums. I find the variety *W. Duckham* a most useful late Chrysanthemum as a bush plant. It is of a colour greatly appreciated at this time of the year. *R. Richards, The Hermitage Gardens, Holmes Chapel.*

CHRYSANTHEMUM VIOLET LADY BEAUMONT.

This variety, raised some five years since, is never seen in a competitive stand of Japanese flowers, to which class it belongs; but as a late-flowering sort for Christmas decoration it is distinctly valuable. In sprays of half-a-dozen or so nice blooms on stiff stems, its rich surface colour of crimson and reverse of chestnut are distinctly effective. *E. M.*

CYCNOCHES MACULATUM.

OUR illustration at fig. 19 represents *Cycnoches*, which Messrs. Hugh Low & Co. obtained as *C. pentadactylon* (fig. 20), but which is doubtless *Cycnoches maculatum*, a species which has appeared in gardens frequently of late, sometimes under the name of *C. peruvianum*. The illustration is from a photograph kindly sent by Messrs. Low. The feature pointed out by them is that the specimen bears both male and female flowers. A similar plant, however, which flowered with Messrs. Low, was acquired by Sir Trevor Lawrence, Bart., K.C.V.O., whose Orchid grower, Mr. W. H. White, concludes that the larger flowers are of *Cycnoches chlorochilon*; and that, however closely united they may appear to be, the two species are growing together. Considering that both species are found in Nature in juxtaposition, this is very probably the case. The dissimilarity in the male and female flowers of *Cycnoches*, which are sometimes produced separately, and sometimes on the same inflorescence, has provided a botanical puzzle for many years. From time to time fresh evidence on the subject has been recorded in the

columns of the *Gardeners' Chronicle*. But still much remains to be known both as to the specific distinctness of some of the allied forms and as to the true character of their sexual forms.

Cycnoches Egertonianum in the male form produces a long raceme of purple flowers, and the variety *viride* has pale green flowers; but in 1813 there appeared at Westerbirt, then, as now, famous for its Orchids, an example in which the raceme bore flowers which were purple in some cases, green in others, and in one instance mottled green and purple.

A plant of *Cycnoches Warscewiczii* also flowered with both sexes present in 1879. We reproduce the illustration of this plant in fig. 21.

No more interesting class of plants than the *Cycnoches* can be found by reason of the won-

FIG. 20.—CYCNOCHES PENTADACTYLON. A, male; B, female flowers.

derful peculiarities of their floral structure. It is, therefore, to be hoped that the genus will be given the place it deserves in collections and that structural peculiarities will be noted and communicated.

Species of *Cycnoches*, best known by the less variable *Swan Orchid* (*C. chlorochilon*), grow well with the allied *Catasetums* and *Mormodes* in an intermediate or *Cattleya* house. They are best suspended in baskets or Orchid pans, and should have a well-marked growing season with plenty of water at the roots, and a thorough resting season when water must be withheld after the mature pseudo-bulbs show, by the turning yellow of the leaves, that active growth for the season is finished. From that time, until growth commences again, the plants should be given a rather lower temperature.

NOTES FROM A "FRENCH" GARDEN.

THE start with the hot-beds has been delayed by the snow and cold weather which have also been the cause of stopping the growth of the young Lettuces. As soon as the weather permits we shall start the hot-beds for Radishes, Lettuces and Carrots. The dry manure has been spread over a very large surface of the soil. The beds will be made 18 inches thick, and will be composed half of hot manure and half dry manure. As soon as the beds are ready the frames are set level and 2 inches deep of dry manure is placed inside, with soil in sufficient quantity to fill the frame to within 2 inches of the top. The soil is levelled and raked over as finely as possible and before the sowing of the seeds it is pressed down by means of a flat board. Some growers sow as many as 100 seeds of Early French Breakfast Radish in each light; but others object to this, since, when sown so thickly, the Radishes require ventilation at a time which is injurious to the Lettuces. We sow 250 seeds of Carrot Early Parisian in each light, and not more, for if the proper quantity of seeds is sown the plants will require no thinning in March. The seeds are covered very thinly with finely-sifted soil and the beds are again pressed down by means of a flat board. They are left for two or three days till the heat comes through the seed-bed into the frame, which may be known by the glass becoming dry. The little Black Gott Lettuces are then taken from their winter quarters, and after removing all decayed leaves, rejecting any plants which show signs of red rust or mildew, 35 Lettuces are put in each light. The lights are afterwards kept closed. If frost seems probable, the lights are covered with mats. If the cold frames and the lights have been put in position before Christmas, seeds of Early French Breakfast Radish may at once be sown. The planting of Passion Lettuces may follow, 25 plants being put under each light. If the variety of Lettuce to be cultivated is that known as Little Black Gott, it will be better not to plant until the end of the present month.

When a succession of salads is required, a few seeds of *Cos Lettuce White of Paris* or *Cabbage Lettuce All the Year Round* may be sown on the hot-beds among the Carrots; but if larger quantities are needed, a small bed of three lights or more can be made up for the purpose.

In the gardens around Paris, large quantities of Radishes being constantly in demand, some growers place a layer of 5 or 6 inches of manure on the ground, cover it with 2 inches of well-decomposed manure, and sow seeds of the early Radish already mentioned. The only protection afforded is that given by mats, which are supported by wire or sticks. These are only used if frost is anticipated. *P. Aquatias.*

THE AGRICULTURAL HOLDINGS ACT, 1908.

REMARKABLE INNOVATIONS.

(Concluded from p. 12.)

FREEDOM OF CROPPING.

THE new law which is laid down under this head represents perhaps the most remarkable of any of the provisions of the new Act. As regards freedom of cropping and disposal of produce, the new law overrides not only any custom of the country, but even any agreement made between landlord and tenant. In future, the tenant is to have full right to practise any system of cropping he chooses on his arable land and to dispose of the produce grown by him without incurring any penalty for departing from the old practice of leaving certain produce on the land.

As is often the case, he may have entered into the most solemn promises with his landlord to grow various crops in rotation for the benefit of the land. All these solemn promises now become null and void, subject only to

certain qualifications, the principal of which are as follows:—

1. The tenant must make adequate provision to protect the land from injury or deterioration. In the case of disposal of the produce, this "adequate provision" is to consist of the return to the land of the full equivalent manurial value of all crops sold off or removed when in so doing the tenant is acting contrary to the custom of the country or to his agreement with his landlord.

2. In cases where the tenant has a lease for some years, he must not crop the land or dispose of the produce in such a manner as to be contrary to his obligations as mentioned above during the year before his tenancy expires. If he holds only from year to year he must not so act either during the year before he quits the land or at any time after he has given or received notice to quit.

3. If the tenant actually injures the holding or is likely to do so by thus acting, the landlord may recover damages, and, if necessary, obtain an injunction restraining the tenant from further injuring the land; and if the parties cannot agree on the amount to be paid for the damage, this is to be fixed by arbitration.

4. Where the tenant carries out certain improvements merely for the purpose of avoiding injury to the land, which would otherwise result from his acting in the arbitrary manner above explained, he is not to be entitled to compensation for these improvements.

5. The landlord may still insist on the tenant carrying out an undertaking given by him not to plough up grass land.

COMPENSATION FOR DISTURBANCE.

We now pass to another important innovation which seems calculated to pave the way towards "fixity of tenure." Hitherto, when the owner of land has let his property to a tenant for a fixed period of years, he has naturally expected to get back possession of his land at the expiration of the agreed term. From the legal point of view this certainly appears to be reasonable enough; but it has been urged that certain landlords have sometimes exercised their rights very harshly in refusing to renew a tenancy, especially in the case of yearly tenants. The new Act therefore provides that if "without good and sufficient cause and for reasons inconsistent with good estate management" (whatever that may mean) a landlord (a) puts an end to a tenancy by giving the tenant notice to quit or (b) refuses to grant a renewal of the tenancy in cases where the tenant has made a written request for such renewal at least one year before the tenancy would expire in the ordinary course; or (c) demands from his tenant an increased rent on account of an increase in the value of the premises owing to improvements which have been executed by the tenant or carried out at his cost (and for which the tenant has not received some equivalent benefit from the landlord), then the tenant, if he leaves owing to any of these causes, is to be entitled not only to compensation for his improvements, but also for the loss or expense which he may thus unavoidably incur in connection with the sale or removal of his household goods or his implements of husbandry or his produce or his farm stock. The tenant cannot agree to give up his rights in this respect, as "contracting out" is expressly forbidden. It will be noticed also that nothing is said with regard to the manner in which the expenses of removal are to be estimated. The Act does not say whether the tenant is to be allowed just such an amount as might enable him to remove into a neighbouring farm, market garden, parish or county, or whether he may claim for the cost of removing from one end of England to the other. There are, however, certain steps which the tenant has to take before he can claim expenses of this nature, namely:—

1. He must give the landlord a reasonable opportunity of valuing the stock.

2. He must give the landlord written notice of his intention to claim compensation, and must be careful to do this within two months after he has received notice to leave or after the landlord has refused to renew the tenancy as the case may be.

3. In addition to giving notice of his intention to claim as mentioned in item No. 2, the tenant must also make his formal claim for compensation within three months after leaving the property.

4. Where the tenant, with whom a contract of tenancy was made, has died within three months before the date of the notice to quit, or before the landlord has refused to renew the tenancy, his executors, legatees, or next-of-kin, as the case may be, cannot demand any compensation for disturbance.

Before leaving this subject, it may be pointed out that, owing to slovenliness in the wording, numberless disputes are likely to arise in deciding as to whether the landlord has turned out his tenant or refused to give him a new lease "without good and sufficient cause and for reasons inconsistent with good estate management" so as to entitle his tenant to claim this compensation for disturbance. What is precisely meant by this vague wording will have to be decided by the law courts, and an enormous amount of litigation is likely to result unless an Explanatory Act is speedily passed. For this the draftsman of the Act can scarcely be held responsible, as the words were inserted by way of compromise during the debate in the House of Commons when the Land Tenure Bill came up for discussion in 1906.

REPAIRS TO BUILDINGS.

In addition to compensation for the erection or enlargement of buildings, a tenant will in future be entitled to claim for repairs to such buildings provided the buildings are necessary for the proper cultivation or working of the land, and provided also that these repairs are not such as the tenant is already under an obligation to execute. The tenant is not obliged to obtain the landlord's consent before executing such repairs, but is nevertheless obliged to give him written notice of his intention to execute them so as to give his landlord the option to carry them out within a reasonable time instead of allowing the tenant to do so.

RECORD OF CONDITION.

In the case of any tenancy entered into after January 1, 1909, either the landlord or the tenant may, at the commencement of the tenancy, require a record to be kept showing the condition of the fences, gates, roads, drains, ditches and cultivation of the land. This record has to be made within three months after the tenancy commenced, and if the landlord and the tenant cannot mutually agree on nominating a person to make such record, then, on the application of either party, the Board of Agriculture will appoint a suitable person and, unless the parties otherwise agree, the cost of making the record is to be shared between them in equal proportions.

Enough perhaps has been said to show that a statute of far-reaching importance is about to come into force. Time alone will show whether its effect will be precisely that which was intended by its promoters, but in any case it must be obvious that the new law demands the very careful consideration of both landlord and tenant. *H. M. V.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CHRISTMAS AT PADDOCKHURST.—A Christmas entertainment took place at Paddockhurst, the seat of Sir Weetman D. Pearson, Bart., on the 30th ult. Tea was provided for upwards of 500 tenants and employés, with their wives and families. The snow being thick on the ground, the aged and very young were conveyed to and from the house by motor-cars. During the afternoon Sir Weetman and Lady Pearson paid a visit to the tea room and said a word to each of those present. Subsequently the company adjourned to the heated motor-house, where a gramophone concert, followed by a cinematograph display, was given. Before leaving for their homes, each of the visitors received a present from the brand. *W.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The voting papers issued by the committee of this gardeners' charity show a list of no fewer than 73 candidates for election. If it is comforting to think that at least 18 out of that very large number will be elected, it is not otherwise than distressing to realise that some 58 out of the total number must be disappointed. Yet no fewer than 58 of the applicants have in the past been subscribers to the institution, or are widows of subscribers. Two candidates apply for the sixth time, three for the fourth time, and 11 for the third time. Fourteen candidates are already credited with more than 2,000 votes and five others have to their credit over 1,800 votes. Hence it will be seen that those candidates whose present totals are much below the latter figures have little hope of success. One applicant is aged 81, and two others are 80 years of age. The list of candidates includes 19 widows of gardeners and in only two cases were the husbands subscribers. *Subscriber.*

TABLE DECORATIONS.—I was pleased to see Mr. E. Molyneux's comments on the table decorations displayed at the November Show of the N.C.S. at the Crystal Palace. The exhibit which was passed by the judges and favourably mentioned by Mr. Molyneux was, in the opinion of many, distinctly better than any other. I do not agree with Mr. T. S. Williams' criticism (p. 451). The flowers were better grown and of a higher class than those in any other exhibit and the blending of the colours was charming and harmonious. The flowers were not pressed together and sufficient stalk was visible and the foliage ample and perfect. The white flowers were arranged in silver vases of refined pattern. For several years the table decorations have been of one stereotyped pattern, especially those found at the autumn shows; yellow and bronze have been the predominating colours; and the receptacles in which the flowers have been arranged of the so-called rustic pattern. Recently I heard a gardener protesting against the use of these stands or vases, saying that they were only so much tinsel. There is nothing handsome, striking or beautiful in most of the present-day table decorations; all other considerations are being surrendered to the securing of so-called "lightness." *W. J. G.*

RESTING FRUIT TREES UNDER GLASS.—In his admirable notes on "Fruits under Glass," p. 6, Mr. Harriss points out the need of allowing fruit trees under glass a period of absolute rest. In most cases that have come under my observation neither vines nor Peach trees are given the period of rest they require. Ventilation should be ample at all times during that period, even when frost is present. To obviate the danger of the water in the pipes becoming frozen, the fruit houses here are built in four sections, which embrace early, second early, mid-season, and late houses. They are separately heated from independent boilers, each separate stokehole being provided with two 9-foot boilers. The supply of water to each boiler is also separate. The water of any one system can thus be drained from the pipes by simply drawing a plug fixed over a drain. This can be done as soon as the leaves have fallen, except, of course, where there are late crops still hanging on the trees. The ventilators are thrown open to their fullest extent and no fears are entertained of burst pipes. It is better to have movable roof-lights; ours, unfortunately, are all fixed roofs. The strongest and best break of vines I ever saw was in ainery containing Gros Colmar, with a vine of Canon Hall Muscat on either side of the doorway. The roof of this house was entirely removed by high wind in December, 1892, and the vines were left exposed to all weathers throughout the winter, being sometimes covered with snow; the inside borders being often frozen hard. After the roof was replaced, the vines developed strong shoots and the crop of Grapes was exceptional, both in weight and in quality. Pot plants should be wintered in houses suited to their needs and not be allowed to interfere with the proper winter treatment of the fruit trees. *A. B.*

TROPICAL FRUITS.—As supplemental to the interesting article on "Tropical Fruits" in the *Gardeners' Chronicle* for December 26 last, I should like to add the following notes. First, with regard to the Kaki (*Diospyros Kaki*), it is satisfactory to learn that the fruit travels well from the south of Europe to the London market, as this leads to the hope that the supplies will be larger, so that the fruits may be retailed at a cheaper rate than 8d. to 10d. each. My experience of this fruit does not quite agree with that of Mr. Macmillan, who says that it has "a peculiar astringent flavour, for which a taste has to be acquired before it can be enjoyed." Some years ago, when the plant was first fruited at Kew, I had an opportunity of tasting it. My description of it at the time was that it had a flavour resembling that of the Apricot, with a slight suspicion of the Medlar. It must be remembered that, to eat it in perfection, it must be absolutely ripe, or even in a blotted condition. In a less ripened state the fruit is frequently preserved in syrup by the Chinese and Japanese. Samples of such preserved fruits have been shown

End grocers', are, or used to be, sometimes roasted. With regard to the Liches, or Lychee, as it is most generally spelt in the shops, it seems a great pity that we should get only the dried, shrivelled fruits in this country. The "sweet, jelly-like, opaque pulp," described by Mr. Macmillan, has, before it comes into the hands of the English buyer, mostly changed into a black, shrivelled condition, in the centre of which is the big, bony seed. The pulp or aril has, in this state, but little to recommend it beyond an ordinary Raisin or Muscatel; but, in the fresh state (in which condition I had an opportunity of tasting it at one of the international exhibitions), it is of a pale pink colour, cooling, refreshing, and of a delicious sub-acid flavour. Specimens of these pulpy arils, deprived of their seeds and preserved in syrup, were shown at the exhibition referred to, thus suggesting capabilities for their preservation and export in syrup, as is now so extensively done with the Pineapple. Referring to the Durian (*Durio zibothimus*), my experience is somewhat limited. Only once have I had a chance of smelling a

juice and should not be eaten until it is absolutely ripe or blotted. A ludicrous illustration of the necessity of this precaution was witnessed in the colonial market attached to the Colonial and Indian Exhibition in 1886, where more than one consignment from the West Indies was offered for sale. The really ripe fruits were pronounced delicious by the purchasers, whilst those who were unfortunate enough to get unripe fruits suffered from the milky juice coagulating with the warmth of the lips and sticking them together: thus considerable inconvenience to the eater and much fun for the onlookers were provided. This fact of the introduction of the fruit into London may be of interest to Mr. Macmillan, who says he is not aware that it has ever been seen in Europe. In conclusion, I may, perhaps, add that sliced Papau is frequently to be found in pickles from tropical countries, introduced on account of the papain, as an aid to digestion, as described by Mr. Macmillan.

WEATHER IN CORNWALL.—In some districts there appear to have been snowstorms

FIG. 21.—CYCNOCHES WARSCEWICZII, WITH MALE AND FEMALE FLOWERS.
(See page 27.)

at the several international exhibitions, so that the Kaki, or Chinese Date Plum, as it is sometimes called, might be also introduced to the English market in this form, or even crystallised with sugar. The name Persimmon, which seems to be the Covent Garden name for it, has apparently been adopted from the North American allied species, *D. virginiana*, the fruit of which is so astringent that it is impossible to eat it until it is dead ripe. A word or two may be added about the Cashew Nut (*Anacardium occidentale*), and this, perhaps, by way of a warning, for it is necessary that the kernel should be carefully removed from the hard, brown shell, which contains a powerfully acrid and vesicating oil, becoming black by exposure; while the oil from the kernel itself is sweet and of a pale yellow colour. The kernels, as occasionally seen in some of the best West-

raw, unripe Durian fruit, which was sufficient to prove the appropriateness of one of its names, "Civet Cat Fruit," and to endorse the following extract from Sir George Watt's *Dictionary of the Economic Products of India*: "It has a strong odour, considered by Europeans as highly offensive, which resembles that of putrid animal matter, combined with rotten Onions." With these opinions attaching to the fruit, notwithstanding all that has been said on the other side, it will probably be difficult for the Durian to capture the palate of the ordinary Englishman. The Sapodilla or Naseberry (*Achras sapota*) stands on a different footing from the Durian and deserves all that Mr. Macmillan says of it. It may be added, however, that, as the plant belongs to the Natural Order Sapotaceæ, which is a rubber or gutta-yielding family, it contains, in an unripe state, a proportion of elastic, milky

such as have not been experienced for 28 years, but beyond a little hail and sleet, with 2" of frost on one night, there was nothing here to show that such storms had occurred. Fuchsias are still flowering in the open garden, also Abutilons, *Eupatorium glabratum*, *Calceolarias*, *Nicotianas*, *Roses*, *Schizostylis coccinea*, *Heleniums*, *Veronicas* in variety, *Cliaanthus puniceus*, and the white variety; *Cytisus racemosus*, *Habrothamnus elegans*, which is splendidly in flower on an east wall; *Solanum jasminoides*, *Hydrangeas*, *Choisya ternata*, *Pittosporum*, one or two plants of *Rhododendron*, and *Camellias*. This list will show what mild weather prevails in this district. With these laggards of one season there are mingled flowers of *Polyanthus*, *Narcissus*, *Primrose*, and *Snowdrop*. R. W. Norman, *Heligan Gardens, St. Austell, Cornwall, Jan. 5.*

MUSCAT GRAPES, &c.—Mr. McIndoe (see p. 12) strikes the right note in respect to the wording of schedules in classes relating to Muscat Grapes. If his advice is followed much friction will be avoided in the future. Then there is that source of perennial trouble, "What are herbaceous plants?" I would suggest that the Royal Horticultural Society should issue a list of species and varieties that are to be considered as herbaceous plants; that such lists should be available for purchase by Horticultural societies who have classes for these plants in their schedules; and that copies of the lists should be handed to judges for their guidance (to be returned to the secretary on completion of their duties). If exhibitors in these classes will also purchase the list and exhibit only such plants as are enumerated, much friction will be avoided, and time saved to the judges. *J. Tunnington, Ferne Gardens.*

THE AUTUMN FRUIT-SHOW OF THE ROYAL HORTICULTURAL SOCIETY.—Whatever may be the result of the competitive classes instituted this year by the council of the Royal Horticultural Society for fruits and vegetables at the ordinary meetings it is certain that many gardeners and others who have regarded the Autumn Fruit Show as a sort of pomological Mecca will be greatly disappointed by its abolition. Certainly in the few classes to be established at each meeting there will be no substitute for the fruit show, any more than a series of similar classes for Orchids and other plants or trees and shrubs would compensate for the omission of the Temple Flower Show. These two annual shows, one in the spring and the other in the autumn, have proved to be strong attractions to gardeners from all parts of the kingdom and the discontinuance of one of these can only be regarded with regret. It will not perhaps be so much regretted by the habitual frequenters of the Society's numerous meetings, for, to them, doubtless, a great, if rather monotonous, show of fruit, repeated year after year, becomes in time unattractive. Whether it is possible to institute next October some more than usually attractive meetings or competitions is for the council to determine; but country gardeners and fruit growers, now deprived of their annual fruit exhibition and special attraction, certainly merit sympathy and consideration. *A. D.*

CATTLEYA MENDELII HIS MAJESTY THE KING.

—In to-day's *Gardeners' Chronicle* (January 2), at page 5, I read, anent my *Cattleya Mendelii* His Majesty the King, "whose picture, it is said, was accepted by her Majesty Queen Alexandria." The fact is that her Majesty greatly admired this *Cattleya* when she visited the last Temple Show and was graciously pleased to accept from me Mr. Lamont's painting of it. In acknowledging this painting, her Majesty was pleased to thank me for "such an artistic representation of such a magnificent flower." As "*His Majesty the King*" is considered to be the finest variety of *Cattleya Mendelii* yet seen, I think it is proper for me to add that, although the plant flowered for the first time here, it was, nevertheless, imported by Messrs. Hugh Low & Co., of Bush Hill Park, from whom I obtained it, together with several other imported and unflowered *Cattleyas*. *Francis Wellesley.*

SOCIETIES.

ROYAL HORTICULTURAL.

The following circular letter is being distributed by the Royal Horticultural Society for the purpose of obtaining information in regard to the "Scab" disease in Apples and Pears:—

WISLEY, RIPLEY, SURREY,

Dear Sir,—Some investigations in connection with the disease of Apples and Pears, known as "Scab," are being carried out at Wisley, and, being desirous of obtaining as full particulars as possible concerning the extent of the damage caused by this disease, I am venturing to send you a number of questions, with the request that you will be so good as to furnish me with replies to as many as possible and return the signed

form to me at the laboratory at your earliest convenience.

A considerable number of questions are asked, but it is felt that the larger the amount of information that can be collected, the greater the chance will be of suggesting a really efficient method of dealing with this disease, which probably does more damage at present than any other to Apples and Pears.

The replies received will be collated and a report upon the occurrence of the disease will be drawn up and will appear in the *Journal* of the Society. It is therefore hoped that growers will not think the trouble of filling in answers to these questions too great when they remember that their work will be for the benefit of the fruit-growing industry the country through.

I may point out that replies from those who are fortunate enough to be free from the disease are as important as from those whose fruit suffers.

If in doubt as to the disease in any particular case, I should be glad if you would send specimens to the laboratory that they may be examined.—Yours truly,

FRED. J. CHITTENDEN, Director.

SCHEDULE OF QUERIES

1. Has the Apple or Pear scab made its appearance among your fruit during the past season?
2. If so, what is your estimate of the proportion of the crop damaged by the disease? (a) Apples. (b) Pears.
3. What is the total quantity (estimated) of fruit damaged by the disease? (a) Apples. (b) Pears.
4. Are the damaged fruits allowed to rot on the ground or fed to pigs?
5. Do you find that the fruits slightly attacked tend to rot in the store more quickly than others that show no attack?
6. Is the disease, in your experience, more prevalent now than in years past?
7. What is the kind of soil and sub-soil on which your trees are planted?
8. Is any system of manurial treatment practised?
9. Are the trees growing in grass or in cultivated land? If in both, do you find any difference in the amount of disease under the different conditions?
10. Do you find the disease more prevalent in some parts of the plantations than in others? If so, what is the character of those parts?
11. Are the trees grown mainly dwarfs or standards? Do you find any difference in the amount of the disease on the two forms where both are grown?
12. About what age are the bulk of the trees? Do you find the disease worse on the older or the younger trees?
13. Are the trees systematically pruned in the winter? In the summer? Is all dead wood, both branches and twigs, cut out every year?
14. What is done with the prunings?
15. Have you noticed whether, in the case of your trees, the leaves are attacked or not? (a) In Apples. (b) In Pears.
16. Do you find any trace of the disease upon the shoots in the shape of small scabby spots or otherwise?
17. At what time and upon what part of the plant is the disease usually first noticed?
18. Are there (a) in the near neighbourhood any old and neglected orchards and (b) Crab Apples or wild Pears in any considerable number in the hedges, &c.?
19. Do you suspect any conditions, seasonal or otherwise, to favour the appearance and spread of the disease?
20. Do you find some varieties are more severely attacked than others? If so, what are they? Please indicate which varieties are caused to crack badly? (a) Apples. (b) Pears.
21. Do any varieties growing amongst others which are diseased remain free from the attack? If so, please give their names. (a) Apples. (b) Pears.
22. Have any remedial or preventive measures been tried, and with what success?

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 17th.—A meeting of this society was held on the foregoing date in the Coal Exchange, the building being filled with exhibits.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. Mr. Herdman), was awarded a Silver-gilt Medal for a group of *Cypripediums*, the best of which was C. × Germaine Opoix, Westfield variety, which was awarded a First-class Certificate. Other choice plants in the group were *Chondropetalum* × *Fletcheri* (see fig. 12 in the last issue), and *Cypripedium* × *King Edward*. *Cypripedium* *insigne* var. *Francis Wellesley* was brought before the deliberations of the committee, and was declared to be synonymous with C. *insigne*, *Harefield Hall* var.

DREWETT O. DREWETT, Esq., Riding Mill-on-Tyne (gr. Mr. Renwick), was awarded a Silver Medal for a group of *Cypripediums*, principally seedlings of *Cypripedium* *insigne*, many of which were of great merit. C. *insigne* var. *James Renwick* was awarded a First-class Certificate, whilst C. × *insigne* var. *Northumbria*, C. *Spicerianum* "Orchidhurst variety," and C. *insigne* var. *The Sultan* also received Awards of Merit.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), staged a large and choice group of *Cypripediums*, for which a Gold Medal was awarded. Amongst the plants shown were many elegant forms of *Cypripedium* *insigne*, C. × *Minos Youngii*, C. × *Fulshawense*, C. × *Thalia Rann Lea* variety, and C. × *Germaine Opoix*.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), was awarded a Silver Medal for a group of *Cypripediums*, which included C. × *Fulshawense*, C. × *Gaston Bultel* var. *King Edward*, and C. × *Euryades Sanders'* variety.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), was awarded a Silver Medal for a group of plants, including a specimen of *Odontoglossum crispum*, with 40 fine flowers on one inflorescence. *Cypripedium* × *Ardwickense* (parentage unknown) received an Award of Merit.

Mr. H. ARTHUR, Blackburn, was awarded a Silver Medal for a group of plants, which included some well-grown *Oncidiums*, *Cymbidium* × *Winnianum* and several varieties of *Cypripedium* *insigne*.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherly), staged a charming group of plants consisting principally of *Odontoglossums*. (Silver-gilt Medal.)

E. ASHWORTH, Esq., Wilmslow (gr. Mr. Holbrook), was awarded a First-class Certificate for a hybrid *Cypripedium*, the parentage of which was C. *insigne* var. *Sanderæ* × C. *insigne* var. "Laura Kimball." The quality of the seedling was good, and there was an entire absence of the tiny spots seen in C. i. var. *Sanderæ*. It is named C. × *Sanderæ-Kimball* Ashworth's variety.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), was awarded a First-class Certificate for a choice hybrid named C. × *Sir W. Houldsworth*, the parentage of which was not recorded. The plant was slightly past its best condition, but it has good qualities.

Mr. C. PARKER, Preston, was awarded a Silver Medal for a group of *Cypripediums*, which included several good forms of C. × *Leeanum*.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a miscellaneous group.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Fletcher), was awarded a Silver Medal for a group of plants, which included *Odontioda* × *Bohnhoffia*.

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver medal for a beautiful group of Orchids.

Mr. J. ROBSON, Altrincham, exhibited *Cypripedium* × *Evansianum* and C. × *exquisitum*.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, showed a large and valuable collection of Orchids.

Other exhibitors at the meeting were Messrs. KEELING & SONS, Bradford; Mr. J. BIRCHENALL, Alderley Edge; Mr. J. STOTT, Radcliffe; Mr. WEBSTER, Shackleton; Messrs. BOLTON, of Warrington; J. H. CRAVEN, Esq., Keighley; Messrs. MOORE & Co., Leeds; Messrs. LOW & Co., Enfield; Messrs. CHARLESWORTH & Co., Haywards Heath; and O. O. WRIGLEY, Esq., P. W.

MARKETS.

COVENT GARDEN, January 6.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

REMARKS.—There is a slightly better trade, but prices have not altered. Stocks in London are not quite so heavy as recently. *Edward J. Newborn, Covent Garden and St. Pancras, January 6, 1909.*

COVENT GARDEN FLOWER MARKET.

Owing to the severe weather of last week, prices advanced for all flowers and plants, but with the warmer conditions which followed prices have again dropped. Trade fluctuates greatly at this season of the year, and should another cold spell of weather occur, which appears likely, there will be a shortage of supplies, especially of good flowering plants. On Tuesday morning there were many empty stands, for growers find it more profitable to be engaged with their early spring crops than in marketing their produce when trade is uncertain. Many market nurserymen have finished with flowering plants by the end of the year. I have lately visited several nurseries and have found preparations already made for the spring trade. In one establishment I noticed both Ivy-leaved and Zonal Pelargoniums in large quantities in their flowering pots. It is possible to have some crops, and especially flowering plants, too forward, but in the case of the London trade, provided the weather is favourable, good flowering plants are always in demand early in the season.

POT PLANTS.

Good Chrysanthemums are still available, but in some instances, whilst the flowers are good, the foliage is sparse. *Ericas* are not quite so abundant as formerly. *E. hyemalis* is very good. *E. ovata* is pretty and of good habit. Good plants of *E. gracilis* in both the white and the normal red variety are still obtainable. *Azaleas* are not quite so well flowered as they were last week. *Genistas* are well flowered, but they are not selling readily. *Begonia Gloire de Lorraine* was in demand at Christmas, but since then this plant has not sold so well. The cold weather has stopped the demand for *Euphorbia pulcherrima* (Poinsettias), and well-flowered plants have realised good prices. *Marguerites* are remarkably good, considering the time of the year. *Hyacinths* in all shades of colours are now offered for sale; the white varieties are best. The blue kinds are of a pale shade, but pink and red varieties are moderately good. Very few Tulips in pots are seen, but boxes containing about 24 plants are over-plentiful. As bulbs generally were dear last autumn, it is surprising that so many growers have them in large quantities. *Solanums* have been over-plentiful and some plants left over since the frost have a rather bad appearance. Orange trees with ripe fruits in various sizes are very good. *Ferns* and *Palms* are not quite so abundant as formerly, but the supplies are equal to the demand.

CUT FLOWERS.

Chrysanthemums are still plentiful, and it is difficult to estimate their prices. Fine blooms of *Madame Charvet* are offered at 2s. per dozen. The blooms of this variety are not of the best colour this season, and care needs to be exercised in selecting the stock plants. *Roses* are plentiful but rather small. I noticed blooms of *Ulrich Brunner* or *Captain Hayward* on long stems, with beautiful foliage, but they were worth more than about 6s. per dozen. *Lilbert*, however, has risen in value to 8s. per dozen. Blooms of *Madame Abel Chatenay* are small, but prices are rather high, varying from 3s. to 6s. per dozen. *Lilac* from English growers is good. *Lily-of-the-Valley* does not advance in price; there is a great variation seen in the quality of this flower. *Violets* are plentiful, both from French and English growers. *Acacia* (Mimosa) from France is very pretty. *Ranunculus* in various colours have been making high prices. *Carnations*, which appeared likely to be scarce, are over-abundant; they are one of the most prominent features in the market. The blooms need to be very good to realise more than 2s. 6d. per dozen. *Eucharis* is cheaper, also *Tuberoses*. Many growers sell their *Tuberoses* on the stems. *Camellias* are also plentiful. *Roman Hyacinth* is very good and has been making better prices. Tulips are abundant; the majority are procurable with fairly long stems, though some are still rather short. Of ornamental foliage that of *Ruscus racemosus* is one of the most useful, as it lasts fresh for a long period; the American *Galax* leaves will last fresh for several weeks. *Asparagus*, *Smilax*, and other cut foliage is plentiful. *A. H., Covent Garden, Wednesday, January 6, 1909.*

GARDENING APPOINTMENTS.

- Mr. H. LLOYD, for 4 years Gardener to Major WYNDHAM PAIN, Beech House, Christchurch, Hants, as Gardener to the same gentleman at his new place, Bransgore House, Christchurch, Hants. (Thanks for contribution to R.G.O.F. box.)
- Mr. ARTHUR WALLING, for the past 3 years Foreman in Chevet Park Gardens, as Gardener to J. D. COBOLD, Esq., and Lady EVELYN COBOLD, at Holy Wells, Ipswich.
- Mr. J. E. ROBERTS, for the past 18 months General Foreman at Strensham Court, Worcester, as Gardener to Miss A. J. BEHRENS, Ripple Hall, near Tewkesbury, Gloucester. (Thanks for contribution to R.G.O.F. box.)
- Mr. G. W. LONGHURST, for the past 3 years Gardener to GEORGE BLACKALL-SIMMONS, Esq., Bradfield House, Berks, as Gardener to W. A. HORN, Esq., Wimbledon Park House, Wimbledon, S.W.

TRADE NOTICE.

Mr. F. W. RUSSELL, for some years Gardener at Paxton Park, St. Neots, and recently of Ashby St. Ledger's Gardens, Rugby, has purchased the Bienheim Nurseries, Ramsey, Hants., which until recently were carried on by the late Mr. Redman.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 2, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—The earlier days of the week were rough and wintry, with heavy falls of snow in nearly all parts of Great Britain, and of rain, sleet, or snow in Ireland. After Wednesday the general condition was much milder and quieter. The atmosphere became very humid and slight rain was experienced at times.

The temperature was below the average throughout Great Britain, the deficit being about 6° over the major portion of England, and rather more than 7° in England S.E. In Ireland, where the change to a milder condition arrived earlier, the week was warm for the time of year. The highest of the maxima occurred in most places on January 2, when they ranged from 55° in England N.W. and the English Channel to 49° in England E. During the earlier days of the week the day temperatures were extremely low in many parts of England, the thermometer sometimes standing between 14° and 20° for some hours. The lowest of the minima were generally registered on December 29 or 30, and were as low as 3° in England S.E. (at Swarraton on the 30th), 5° in the Midland Counties, and 7° in England E. (at Cambridge). In the other districts the readings ranged from 15° in England S.W. to 22° in Scotland N. and W., 27° in the English Channel, and to 29° in Ireland S. In addition to the very low readings quoted the following temperatures were registered at some supplementary stations. At Liphook the screened thermometer fell to 1° below zero on the 30th, at Buxton and Epsom to 4°, and at Great Billing, Northampton, to 6°, while at Tunbridge Wells the thermometer exposed on the snow descended to 2° below zero, and at Epsom to 8° below zero.

The mean temperature of the sea.—Except at Eastbourne and Aberdeen and one or two other places the water was again warmer than during the corresponding week of last year. The actual values for the week ranged from 51½° at Plymouth, to about 39° at Eastbourne and Scarborough, and to 36½° at Aberdeen.

The bright sunshine was less than the average in all districts, the percentage of the possible duration ranging from 17 in the English Channel to 11 in England E. and S.E., 1 in England N.W. and to 0 in Scotland W.

THE WEATHER IN WEST HERTS.

Week ending January 6.

Mild, damp, calm and gloomy.—The recent spell of cold weather lasted eight days, but on only three of these was the temperature exceptionally low. The first day of the past week was very cold, but since then the weather has been warm for the time of year. On the warmest day the temperature in the thermometer screen rose to 50°, and on the one cold night the exposed thermometer registered 21° of frost. The ground is now 2° warmer than is seasonable, both at 1 and 2 feet deep. Rain fell on three days, but the total depth was only one quarter of an inch. Nevertheless, owing to the melting of the snow which fell in the previous week, three and a quarter gallons of water, or more than twice the rainfall of the past week, passed through the bare soil percolation gauge, and two and a half gallons through that on which short grass is growing. The sun shone on an average for only 11 minutes a day, which is 1 hour 10 minutes a day short of the average duration for this period of the year. On five days no sunshine at all was recorded. This was a very calm week; in fact, in no hour did the mean rate of movement of the air exceed 8 miles. The average amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 7 per cent.

DECEMBER.

The coldest December day and night for at least 23 years.—Taken as a whole, this was a month of about average temperature. During the first three weeks the weather remained, as a rule, warm both during the daytime and at night, whereas the last nine days were all more or less cold, and for three consecutive days and nights exceptionally cold. On the warmest day the temperature in the thermometer screen rose to 52°, which is an unusually low extreme minimum for the month. The lowest maximum day temperature was 24° on the 29th, making this the coldest day I have yet recorded here in December. On the coldest night the thermometer exposed on the surface of the snow indicated 31° of frost, making this also the coldest night I have yet recorded here in December. Rain or snow fell on as many as 21 days, but to the total depth of only 2½ inches, which is one quarter of an inch below the average for the month. On the 23rd the ground was covered with snow to the m an depth of 5½ inches. This was a remarkably calm winter month. In fact, in the windiest hour the mean velocity only amounted to 13 miles—direction W.N.W. The average amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent.

THE YEAR.

Rather warm, dry and very sunny.—The mean temperature of the past year was slightly in excess of the average. The most unseasonably warm months were February, May, and October, whereas only April was as unseasonably cold. On the hottest day, July 3, the temperature in the thermometer screen rose to 83°, and on the coldest night, December 29, the exposed thermometer indicated 31° of frost. The total rainfall fell short of the average for the previous 52 years by 3½ inches. The only three months when the total fall exceeded the average were March, April, and August. Taking the year as a whole, the sun shone on an average for 10 minutes a day longer than is usual. The sunniest month of the year was June, when the record of bright sunshine exceeded the average by one and three-quarter hours a day.

OUR UNDERGROUND WATER SUPPLY.

The total rainfall for the last three months has fallen short of the average for the same period in the previous 52 years by 3½ inches, which is equivalent to a loss of 71,200 gallons on each acre in this district. Last year at the same time there was an excess of 61,300 gallons per acre. *E. M., Lerkhamsted, January 6, 1909.*

Obituary.

GEORGE FIELD MORRIS.—We regret to have to announce the death of Mr. George Field Morris, F.S.I., which took place at his residence, Cambridge Park, Wanstead, early on Saturday, January 2. Mr. G. F. Morris, who was born on September 2, 1831, may be said to have been the founder of the widely-known firm of Messrs. Protheroe & Morris, auctioneers, of 67 and 68, Cheapside, London, on its present lines, for he, in conjunction with Mr. W. H. Morris, about the year 1874, opened the City branch, then at 98, Gracechurch Street, and later at the present headquarters in Cheapside. As an auctioneer, when conducting sales, either indoors or out, in good or bad weather, his cheerful and pleasant demeanour always led to the best results. He conducted many sales at the old Auction Mart, Bartholomew Lane (now Parr's Bank), the London Tavern, Bishopsgate Street, and at Garraway's Coffee House, Change Alley, and was a well-known figure at the present Auction Mart, Tokenhouse Yard. The firm was started about 1830 as a nursery business at Highbury by Mr. Thomas Morris (father of Mr. George Field Morris) and Mr. Alexander Protheroe. In 1840 business was commenced at Leytonstone, where the firm even now possesses an establishment.

THE LATE GEORGE FIELD MORRIS, F.S.I.

At the age of 14 years Mr. G. F. Morris entered the nurseries and diligently acquired a knowledge of the trade. In 1860 he conducted his first auction sale, and from that time until his retirement in 1903 he pursued an active career not only as an auctioneer, but as a valuer and arbitrator in railway and other claims. Mr. G. F. Morris enjoyed the best of health, and, making a pleasure of business, he was always to be found in the same pleasant mood. He was smart and alert up to the last, the actual cause of death being heart failure. After Mr. G. F. Morris retired in 1903, the firm was carried on by the present partners, Mr. H. G. Morris, Mr. T. A. Morris, Mr. A. E. Protheroe, and Mr. J. B. Slade. Consequently there will be no change in the management of the business.

DEBATING SOCIETY.

READING AND DISTRICT GARDENERS'.

A meeting was held in the Abbey Hall on Monday, December 28. Mr. T. Tunbridge presided. Officers were nominated for 1909, and they will be elected at the annual meeting on January 11. The subject for the evening was "Strawberries in Pots," the lecturer being Mr. Durbridge, of the Gardens, Mappedurham House. Mr. Durbridge dealt with the general culture of Strawberries in pots and named the varieties he had found best suited for the purpose. The lecturer gave a few useful hints on the packing of Strawberries for transit by rail or post.

ANSWERS TO CORRESPONDENTS.

BEECH AND HORNBAM HEDGES: *A. E. M.* These may be cut any time between September and March.

COST OF DIGGING LAND: *W. R. C.* The usual cost of digging a moderately heavy soil, one spade deep, is from 2d. to 3d. per rod. The price will vary between the sums mentioned according to the texture of the soil, which cannot be accurately described in a letter, and the cost of labour in the locality.

HIPPEASTRUMS: *A. T.* *Hippeastrum Johnsonii* is a hybrid raised earlier than the year 1800 between *H. Reginae* and *H. vittatum*. It is of the class which loses its leaves and requires a long, dry rest each year. You ought to be able to distinguish between it and *H. alicium*, which has much more fleshy leaves and is practically evergreen. If your plant is *H. Johnsonii* and it has fully matured all its leaves, it is natural for them to turn yellow, indicating that the time for rest has arrived. With regard to the inflorescences in nature, they are allowed to die off, but in gardens they are usually cut. We do not know of an importer of South American Amaryllids. Some of the trade bulb-growers catalogue occasionally two or three species of *Hippeastrum*.

MUSCAT GRAPES: *G. D.* Muscat of Alexandria is undoubtedly easier to grow than Canon Hall Muscat. This latter variety does not set its fruits easily, even under favourable conditions, this being the chief reason that it is not more generally cultivated. The flavour is quite equal to Muscat of Alexandria. In size of berry and bunch Canon Hall is superior when seen at its best, which is very seldom. We advise you to plant the house entirely with Muscat of Alexandria, excluding the variety Canon Hall, as you appear not to have had any experience in growing Muscat Grapes of any kind. You should lose no time before securing the young vines for planting. Cut them back to three or four buds in about the middle of the present month. Plant them just when the buds are breaking into growth, which is usually about the end of March or beginning of April.

NAMES OF FRUITS: *E. Shaw.* 1, Ribston Pippin; 2 and 3, Cox's Orange Pippin; 4, Brabant Belle-fleur.—*D. & Son.* 1, D'Arcy Spice; 2, Old Hawthornden; 3, Reinette de Canada.

NAMES OF PLANTS: *Earl Soham.* Iris unguicularis.—*O. H.* 1, not found; 2, *Codiaeum intertextum*; 3, *C. angustifolium maculatum*; 4, *C. elegantissimum*; 5, *C. Johannis*; 6, *C. Mortii*; 7, *C. angustifolium*; 8, *C. Laingii*; 9, *C. pictum*; 10, *C. Queen Victoria*; 11, *Calanthe William Murray*; 12, *C. Bryan*; 13, *C. Sedenii*; 14, *C. vestita rubro-oculata*; 15, *Ophiopogon Jaburan variegatus*, of gardens.—*H. H. T.* 1, *Restrepia maculata*; 2, *Pleurothallis obovata*; 3, *Stelis ophioglossoides*; 4, *Bulbophyllum rufinum*; 5, *Aerides odoratum*; 6, *Brassia verrucosa*—*V. I. R.* 1, *Adiantum hispidulum*; 2, *A. Capillus-veneris*; 3, *Aspidium (Cytromium) falcatum*; 4, *Selaginella paradoxa*.

NERINE: *B. L.* There is a very fine scarlet Nerine named *Coruscans*, which flowers later than *N. Fothergillii* major.

TURF: *J. McG.* The larvæ are those of Melonlithids (Chafer larvæ). They were both dead when received, and their identification is difficult; but they are probably those of the common garden chafer. Trap them by placing, here and there, a grass turf upside down on the earth, or just below the surface. "Vaporite," if worked well into the soil, will destroy Chafer larvæ.

WATER FREEZING IN ORNAMENTAL POND: *S. J. M.* The goldfish will not be killed unless the frost is exceptionally severe. The water can best be kept agitated by a fountain or inlet that is allowed to run continuously. In exceptionally hard frosts even these methods will not avail.

COMMUNICATIONS RECEIVED.—*T. B.*—*F. Boulton*—*A. C. B.*—*J. G. W.*—*W. J. M.*—*W. H. W.*—*W. A. C.*—*W. W.*—*W. E.*—*G. W.*—*E. H. T.*—*Capt. Dorrien S.*—*H. M. V.*—*C. F.*—*T. H.*—*J. E. NEPENTHES × DR. JOHN MACFARLANE, BEING A HYBRID FROM *N. SANGUINEA* AND
N. CURTISII SUPERBA, RAISED BY MESSRS. JAS. VEITCH & SONS.
COLOUR OF PITCHER, BROWNISH RED WITH DEEP RED MARKINGS.

through the soil, with a long stalk, and broadly bipinnatifid; and still later, at some distance from this single frond, an axis of growth reached the surface and produced four other fronds of similar type—the contrast between this and the adjacent plant with normal fronds being very marked indeed. This spring, in order to report it, I extracted this plant and the reverted one and found that they were attached by a string-like stolon, which had first produced the one frond from some depth down in the soil, and then continued its way, until, reaching the surface, it produced the others. Mr. Fraser informed me on enquiry that all his plants had entirely reverted to the normal. We have here consequently a singular case of general reversion of a very marked form found in fair quantity (17 plants, I believe) and then a sudden and entire resumption of the new character by bud-sporting. Spores of the plants found have yielded a number of young *Blechnums* of very foliose character, indicating, I think, that they have inherited the capacity for subdivision, though this remains to be seen.

In another case, within my own experience, the severed base of a frond of a fimbriate crispum form of *Hartstongue* *S. v. Drummondæ* produced two buds, one of which developed a simple crispum or frilled form, the other a form with long, slender, attenuated fronds with ramose tips and spur-like basal lobes: all fronds being exactly alike and as different as possible from the type and from the plant yielded by the companion bud a quarter-inch away on same frond base. This case obviously belongs to the dimorphic category which embraces the *Cornubiense Polypody* (*P. v. cornubiense* or *elegantissimum*). In this instance the plants appear to be built up of a series of cells, in which there is a constant struggle between the normal plan of structure and the abnormal with alternate victories on either side. There is also a curious case in *A. F.-f. setigerum cristatum*. *A. F.-f. setigerum* found in the Lake District has fronds of a normal outline and somewhat bristly edges and points. From it, whether by crossing or otherwise, uncrested when found, a number of very charming cristate and pericristate varieties have been raised. It, however, not infrequently reverts, and I have a plant which partially reverted so far that some of the fronds were crested as before but without a trace of the setigerum character. Eventually, by a process of fission, the one crown became two, one being a constant pericristate setigerum, and the other, equally constant, a mere pericristatum, minus a trace of bristles. Here the two probably parental characters appear to have dissociated themselves in the process of fission to the extent, at any rate, that the crested form has discarded the setigerous character throughout in one case and retained it throughout in the other. That very beautiful, and indeed unique, hardy Fern *A. F.-f. Kalothrix* (beautiful hair), with hair-like, lucent fronds, is also apt, from time to time, to produce merely plumose fronds or portions of fronds of normal texture, and when its spores are sown there invariably results a large percentage of plants so characterised throughout. Apart from these dimorphic or multi-morphic variations, that of "truncation" may also be mentioned, a form which, odd as it is, has occurred in several British and one exotic species, viz., *Lastrea montana*, *L. Filix-mas*, *Athyrium Filix-fœmina*, *Scelopendrium vulgare* and *Polypodium hexagonopterum*. In all these the terminals of both frond and side divisions or pinnæ end abruptly and squarely, the midrib continuing for a short distance as a projecting thorn or bristle. Why in the Fern the lateral leaf tissues should be so suddenly and uniformly suppressed at a definite stage of otherwise normal growth is, like variation generally, a profound mystery, but we give it special mention here on account of its recurrence in the several distinct species named. *Chas. T. Drury, V.M.H., F.L.S.*

EXPERIMENTS ON THE VALUE OF NITRO-BACTERINE.

(Concluded from page 20.)

To these trials we will now devote our attention.

For details of Mr. Chittenden's results we must refer our readers to the original paper.

It is sufficient for us that, in these experiments, culinary Peas were the crop, and that they were cultivated on 2½ plots, each of which had an area of 2 square rods. The plots were in two series, one extending over well-cultivated land, and one over fallow land. Into the manual treatment of these plots we need not enter, the essential point of the trial being that pairs of similar plots, similarly manured or unmanured, were planted, one of the pair with seed treated with Nitro-Bacterine (the inoculated plots), the other with uninoculated seed.

Mr. Chittenden's conclusions are:—That "seven out of the 12 plots on which inoculated seed was sown gave smaller crops than the corresponding uninoculated plots, and one gave an equal crop."

He finds that "the total crop from the whole of the plots receiving inoculated seed was 450 lbs., while the total from the plots in which uninoculated seed was sown was 515 lbs. The uninoculated seed, therefore, gave a crop 14 per cent. heavier than the inoculated.

"The crop from the inoculated seed was no better in any way than that from the uninoculated, nor did it reach maturity earlier.

"It is concluded that the inoculation of leguminous crops with Nitro-Bacterine in ordinary garden soil is not likely to prove beneficial."

As will appear immediately, our own experiments confirm this last and all-important conclusion, but they do not confirm the somewhat surprising conclusions reached by Mr. Chittenden that inoculation generally decreases the yield.

We will first give a brief account of our own experimental results, and then return to this question of decrease of yield from inoculated seed. The experiments to which we desire to refer were conducted during the summer of 1908, in the grounds attached to the Botanical Laboratory of University College, Reading. Though on a smaller scale than the Wis-

ley trials, they were of much the same nature, and consisted in comparing the yield from culinary Peas (Sutton's Early Giant garden Pea) which had been inoculated with Nitro-Bacterine with that from uninoculated seed of the same variety.

The details of these experiments are given in an appendix to the present communication. Here we need only give the actual results.

CULTURE A—		lbs. ozs.
Inoculated seed: Yield	...	6 1½
Uninoculated seed: Yield	...	5 11
Increase in favour of inoculated seed =		6½
		= 7.1 per cent.

CULTURE B—		lbs. ozs.
Inoculated seed: Yield	...	6 3
Uninoculated seed: Yield	...	5 7½
Increase in favour of inoculated seed =		11½
		= 7.6 per cent.

CULTURE C—		lbs. ozs.
Inoculated seed: Yield	...	4 4½
Uninoculated seed: Yield	...	4 5½
Increase in favour of uninoculated seed =		1
		= 1.5 per cent.

Average increase in favour of inoculated seed = 5.6 per cent.

We had intended to defer the publication of these results till next year, when, as we hoped, we should have had others available for comparison. But having regard to the distinctly adverse results obtained at Wisley, it seems only fair to put them on record.

We do not know in what light Professor Bottomley will regard our results; but, for our part, we consider that, though they may be less discomfiting than Mr. Chittenden's, they can afford but cold comfort to ardent believers in Nitro-Bacterine. We may state our own conclusion thus:—*The increase of yield from inoculated seed is so small that it does not represent a sufficient increase of profit as to make the use of Nitro-Bacterine on ordinary garden soils of practical value.*

The detailed records of our experiments also indicate, like those of Mr. Chittenden, that this

APPENDIX. TABLE I.
NITRO-BACTERINE INOCULATION EXPERIMENTS.
BOTANICAL LABORATORY, UNIVERSITY COLLEGE, READING, 1908.

Treatment of Culture A.	Culture A.				Control A.				Treatment of Control A.
	Total Crop.		Marketable.		Marketable.		Total Crop.		
	No. of Pods.	Weight.	No. of Pods.	Weight.	No. of Pods.	Weight.	No. of Pods.	Weight.	
No manure. Watered with Nitro-Bacterine. ½ row once. ½ row twice. No seed-inoculation.	368	lb. 6 oz. 4	313	lb. 6 oz. 1½	275	lb. 5 oz. 11½	328	lb. 5 oz. 13½	Watered with nitrate of soda at the rate of ½ oz. to the square yard. ½ row once. ½ row twice.
Treatment of Culture B.	Culture B.				Control B.				Treatment of Control B.
No manure. Seed-inoculation only.	372	lb. 6 oz. 5½	318	lb. 6 oz. 3	303	lb. 5 oz. 7½	373	lb. 5 oz. 11	No manure. No seed-inoculation.
Treatment of Culture C.	Culture C.				Control C.				Treatment of Control C.
Manured with 4 cwt. super-phosphate and ½ cwt. potassium sulphate (rate per acre). Seed inoculated and soil watered twice with Nitro-Bacterine.	283	lb. 4 oz. 7	238	lb. 4 oz. 4½	248	lb. 4 oz. 5½	297	lb. 4 oz. 8½	Manured with super-phosphate and potassium sulphate as Culture C. Seed not inoculated. Soil not treated with Nitro-Bacterine.

Seed used: Sutton's Early Giant Pea; sown May 29. First picking July 24 (an early variety sown late to get a midsummer crop).
Soil: Fairly deep calcareous loam.
Weather: Dry, hot summer; plots watered equally from time to time.
Number of plants: Seedlings when about 4 in. high, thinned to 60 plants per plot. Rows running N.—S., 5 feet apart.

preparation is without effect in producing earlier crops. Thus two only out of six different "inoculated" plots produced more pods than their corresponding, uninoculated plots on their first pickings, and the plants on all the 12 inoculated and uninoculated plots began flowering at about the same time.

It remains to consider briefly the curious result of the Wisley series of experiments, viz., that the yield from inoculated seed was generally lower than that from uninoculated seed.

Though, as indicated in the introduction to this paper, it is not impossible that Nitro-Bacterine or any similar preparation might not, under certain conditions, exercise results the reverse of beneficial, yet we cannot but think that this lessened yield must be due rather to the method of experiment adopted than to an actual injurious effect on the part of Professor Bottomley's preparation. It appears from Mr. Chittenden's account of his experiments that he used a definite weight of seed for planting each plot (60 grams). Hence the number of seeds per row varied (within narrow limits) from plot to plot. Moreover, Mr. Chittenden does not record in his paper the number of seedlings which germinated, nor the number of plants which matured on each plot. Since the crop suffered from an attack of the Pea-weevil (*Sitones lineatus*), it may be that the chance death-rate was higher in some plots than in others. We have not been able to gather from Mr. Chittenden's paper what was the yield per plant. This, though a matter of no importance in practice, is one of fundamental importance in a trial of this kind. In such experiments, for the testimony of the results to be convincing, the number of plants and the yield of each must be recorded. We think that it would add materially to the value of Mr. Chittenden's results if he would publish the exact details as to the number of plants which actually grew and bore seed on each plot.

Till, therefore, further experiment confirms this adverse effect of inoculation, we need not speculate as to how it is brought about. We do not think that an unprejudiced reader of Mr. Chittenden's very elaborate results can doubt the truth of his main conclusion, for it is too much to believe that the bad luck of a higher chance death-rate can have always befallen the inoculated seed. Moreover, there are our own results, in which the same number of seeds were sown in each plot, and in which the same number of mature plants were cropped, which, as we have already indicated, confirm his main conclusions.

After all, the problem must be sent back to the laboratory, and science must know more before the question as to how *Pseudomonas radicola* may be exploited in the interest of horticulture can be regarded as solved. *Frederick Keeble, Sc.D. & D.M.Cayley.*

NEW OR NOTEWORTHY PLANTS.

IRIS HIMALAICA (Sp. n.).

THE following is the description of the new Iris which formed the subject of my article in the issue for January 2, p. 3:—Species, rhizome gracili repente elongato; foliis linearibus incurvis, 2-3 ped. longis, $\frac{3}{4}$ poll. latis, supra nitidis, infra glaucoviridibus; scapo solido, nunquam fistuloso, folia longe superante, capitulis pluribus; spathis bifloris 3 poll. longis; pedicellis spathis æquantibus; perianthii tubo triquetro $\frac{1}{2}$ poll. longo; segmentis externis, 2 poll. longis, 1 poll. latis, obovato-cuneatis, violaceis albomaculatis, imberibus; segmentis internis, $1\frac{1}{2}$ poll. longis, $\frac{3}{4}$ poll. latis, subpatentibus, violaceis, venis inconspicuis; styli ramis latis, convexis, carinatis, $1\frac{1}{2}$ poll. longis; capsulis trigonis 2 poll. longis; seminibus orbiculis, compressis, tenuibus. *W. R. Dykes, Charterhouse, Godalming.*

ASTER GRANDIFLORUS.

ALTHOUGH this plant was introduced into cultivation by Mr. Mark Catesby as long ago as the year 1720, it is comparatively rare in gardens. This may be accounted for by the lateness of its flowering season, which occurs during the month of November. Hence it is seldom seen in perfection out-of-doors. Last season, however, owing to the favourable mild weather during the autumn months, all the fine large flowers developed, making an effective display after the other starworts were past. The plant is of bushy habit, rather over 2 feet high, with stiff, rigid branches, each terminated by single, purple-blue flowers, about 2 inches in diameter. Unlike most of the other members of this family, this plant does not require any support, the growths being stiff and erect. The foliage is not conspicuous, consisting of small, linear, subamplexicaul leaves, those of the upper branches being reflexed and hispid at the edge. *A. grandiflorus* is found growing in dry and gravelly soil in the United States, extending from Virginia to Georgia. It is hardy in this country, and is easily propagated by division during the winter season, or early in spring. Its late-flowering habit should render it a valuable plant for the greenhouse, as it might be grown out-of-doors in pots, to be brought into the house just when the flowers are opening. *W. I.*

[Photograph by W. Irving.]

FIG. 24.—ASTER GRANDIFLORUS: A LARGE-FLOWERED SPECIES BLOOMING IN NOVEMBER.

SIMPLE METHODS OF KEEPING OUT COLD.

THE Spaniards have a proverb, that what will keep the cold out will keep the heat out, and the proverb may be reversed: what will keep heat out will keep cold out. All that was stated, in connection with the construction of cold stores (see *Gardeners' Chronicle*, November 7, 21, 28, 1908), for keeping plants at a low temperature, applies to the protection of plants from low temperatures. The cabinets described in those articles for keeping small quantities of plants or bulbs at low temperatures should answer equally well for preserving bulbs or plants from frost for a certain time, omitting, of course, the provision of ice or freezing mixtures. Frost attacks plants because the surrounding atmosphere is at a very much lower temperature than the plants are, and, therefore, heat passes from the plants to the surrounding air, their temperature being gradually lowered in the process. If the passage of heat from the plants and from the soil containing the roots can be prevented, or if its rate of passage can be reduced, the lowering of the temperature of the

plants themselves will be prevented or reduced. It need hardly be mentioned that no insulation, such as was described in the articles on "Cold Storage," will furnish heat to a plant. What insulation does is to prevent the passage of heat through the intervening medium. In the case of a cold store or cold cabinet it prevents the passage of the heat from the external air to the substances inside. In the case of plants to be protected from frost, it prevents the passage of heat from the plants to the outside air, and, therefore, prevents or reduces the lowering of the temperature of the plants. Any of the substances mentioned as insulators for cold stores or cold cabinets, if properly placed between the plants and the surrounding air, will keep out frost. In addition, there are several other substances, some of which gardeners have already found useful by practical experience. Such are brown paper, mats, cloths, and even ordinary newspapers. The reason the substances act as insulators is that they are all of a porous nature. They all contain minute air spaces, which resist the passage of heat through them. Still, dry air is one of the best-known insulators, and this has its application in the protection of plants from frost. Dry cloths, particularly woollen ones, dry brown paper, dry newspapers, and, in fact, any dry and porous substances will keep out the cold. But it is absolutely neces-

sary that the substances should be dry. Immediately they become moist they lose some of their insulating properties. Water evaporates at all temperatures and in evaporating absorbs heat. Hence heat is taken from the substances immediately in contact with it; thus, wet wraps produce cold, even in cold weather. The porous earthenware used for flower-pots is a good insulator, provided it is dry. When wet, it has the opposite effect. Almost any degree of protection may be obtained by the careful use of any of the substances named, if applied in sufficient quantity. Two sheets of brown paper should, if carefully applied, give more than double the protection of one, because of the air-space between them. In applying two or three thicknesses care should be taken that the air enclosed has not much chance of getting into motion. The paper or cloth should be so arranged as to break up the air space into as many sections as possible. Air currents, which are produced at all temperatures, are another source of cold. They set up evaporation. Evaporation uses up heat, and, therefore, cold results. *S. F. W.*

THE ROSARY.

NOTES ON NEWER VARIETIES.

THERE are many beautiful, new Roses still to describe, and I will now deal with the dwarf Polyantha or Pompon Roses, which are, at last, beginning to be better known and appreciated. I have also been requested to deal with all the best climbing Roses. Before proceeding with these two most interesting types, I should like to advise readers to include in their collection, if they have not already obtained them, a bed or two, or a long border of "Arethusa" (1903) and "Queen Mab" (1896), both of which were raised by Wm. Paul & Son. A grower asked me the other day "which I considered the two best China Roses?" My reply was these two most wonderful bloomers. I have a row of 300 of these planted alternately. They are a beautiful blend. "Queen Mab" is well known; the blooms are of a lovely rosy-apricot tint with an orange centre; the buds are pretty and of almost perfect shape. "Arethusa"

most beautiful edging plants for other Roses in beds; or they can, grouped by themselves, be used to form very rich colour-effects, but care must be taken to blend the colours nicely. I will now describe all the sorts that I have found worthy of cultivation:—

CÉCILE BRUNNER (*Ducher, 1880*).—This variety remains the queen of all this class of Roses. The blooms are of most distinct and exquisite shape, bright rose in colour: when open, the flower, owing to the colour of the bases of the petals, has a yellowish centre. In the late autumn the colour is intense. The plant is a fairly strong grower for a Pompon variety.

PHILLIPINE LAMBERT (*P. Lambert, 1903*).—My wife calls these our baby "La France." They are hardly that, the flowers not being so high pointed, but they are beautifully imbricated, very full, of a fair size, and produced in clusters of three to eight. The blooms all open well. In colour they are a lovely silvery-pink, and the buds are carmine-pink. The blooming is very free and perpetual, and the habit strong for a Pompon.

MIGNONETTE (*Guillot, 1882*).—The beautiful, soft, rose colour changes to nearly white; the small flowers are borne in very large trusses. With me it is a sheet of bloom during June and July; then it goes off in August, but flowers again in September. This Rose is especially effective when massed in a bed.

GLOIRE DE POLYANTHA (*Guillot, 1887*).—We call this Mignonette's little twin sister, but in colour it is a deep rose with a white base.

KATHERINE ZEIMET (*P. Lambert, 1901*).—A delicate, white variety, undoubtedly the best white Pompon. The very small, full flowers are borne in great clusters, and with me it is extraordinarily free. In addition to this it has, perhaps, the sweetest scent of any Pompon Rose.

MADAME ZELIA BOURGEOIS (*Vilin & Vilin, 1907*).—Another very sweetly-scented variety. The small, white, double flowers are very freely produced.

SCHNEEWITTCHEN (*P. Lambert, 1901*).—This Rose has, in large trusses, ivory-white, very small, semi-double flowers with golden stamens. I do not recommend it, however, as it does not last well, and the quickly-fading flowers give the whole an untidy effect.

SCHNEEKOPF (*P. Lambert, 1903*).—A pure white, fairly large, full flower that opens well, and is produced in large clusters. The growth is erect and bushy. It is to be recommended as a good Rose.

ANNA MARIE MONTRAVEL (*Rambaux, 1879*).—This has pure white, very tiny, full flowers with slightly imbricated petals. They grow in enormous trusses, a hundred or so flowers in each truss. The habit is very distinct.

PERLE DES ROUGES (*Dubreuil, 1897*).—The velvety, crimson flowers have the reflex of their petals cerise; they are small and double and are produced in large clusters. This Rose is the brightest of all the crimson Pompons. It is very free in flowering and is quite a little gem.

MADAME N. LEVAVASSEUR (*Levavasseur, 1902*).—This is nothing more nor less than a perpetually-flowering Pompon Crimson Rambler.

MAMAN LEVAVASSEUR (*Levavasseur, 1907*).—Sometimes called "Baby Dorothy Perkins," is a perpetually-flowering, dwarf-growing form of the well-known "Dorothy Perkins."

PRINCESS ENA (*H. B. May, 1908*).—I am informed this is a very pretty sport from "Madame N. Levavasseur." The flowers are rosy-pink, with small, white centres, and pale yellow stamens.

MARIE PAVIÉ (*Aléatière, 1889*).—I have only had this Rose one season, but think it one of the best. It has a full, large flower for its class, and one that lasts well. *Leonard Petrie, Gayton, Heltenham.*

(To be continued.)

FIG. 25.—ODONTOGLOSSUM MAGALI SANDER: SEPALS AND PETALS CREAM-WHITE, MOTTLED WITH ROSE.

is a clear deep yellow, very slightly tinted with apricot; its habit is exactly similar to that of "Queen Mab," and the blooms are of the same shape. From the last week in May till frost appears these are always literally a sheet of bloom. Indeed, there has never been any Rose yet introduced that can beat these two for freedom of blooming, and, unlike most other Chinas, they are nicely-shaped blooms, too.

COMTESSE DU CAYLA (*Guillot, 1902*) is a sweetly pretty flower in its bud state, but it is nothing like so free a bloomer as those already mentioned.

I will now consider the "Pompon" or dwarf Polyantha Roses. Most of them are of very dwarf growth, and have very small flowers, yet they are nearly all most distinct. I often think how greatly many gardens could be improved by a free use of these little gems in place of such a lot of bedding plants. Once properly planted, Pompon Roses are a joy for very many years, and they need so little attention. They form

LEONIE LAMESCH (*P. Lambert, 1900*).—The blooms of this variety are of an extraordinary colour, being coppery-red with a golden centre, shaded deep red and, as the flower ages, yellow. The blooms are produced singly and are of medium size. The plant has a very erect growth and strong habit for a Pompon. Taking both its flower and beautiful foliage into consideration, it is a very distinct and striking variety.

EUGENIE LAMESCH (*P. Lambert, 1900*).—This is of bushy growth and very dwarf. The colour is a beautiful orange-yellow, passing to clear yellow with age. The delicate little flowers are produced in clusters.

PERLE D'OR (*Rambaux, 1884*).—The flower is of a most striking and extraordinary colour, a coppery-orange, turning, when fully opened, to nankeen-yellow. The bloom is fairly full, but is not of a particularly nice shape: still, it is a lovely little variety and wonderfully free in blooming.

ODONTOGLOSSUM MAGALI SANDER.

(ROLFEÆ × ADRIANÆ VAR. F. K. SANDER.)

Our illustration (fig. 25) represents a flower of this superb *Odontoglossum*, for which Messrs. Sander & Sons were awarded a First-class Certificate at the Royal Horticultural Society, on December 22, 1908. It may be said that it came as a surprise even to Messrs. Sander & Sons, who did not expect that the introduction of the comparatively small *O. Adrianæ*, even in the highest form, as represented by their variety F. K. Sander, would produce such results, for it has indeed increased the already broad proportions of *O. Rolfeæ*, while the deep colouring and even distribution of the blotches are almost identical with the markings of *O. Adrianæ* F. K. Sander. The sepals and petals are cream-white slightly mottled with rose, the blotches being deep claret-purple. The lip is white with a yellow crest, and dark reddish-purple blotches; there being a rose-coloured ray in front of the largest blotch. The plant bore a very large spike of many flowers.

The Week's Work.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart.,
Leonardslee, Sussex.

Planting of trees and shrubs.—Proceed with the planting of all kinds of Conifers, such as Abies, Pinus, Picea, Cedrus, Cryptomeria, Larix, and Taxodium. It is usual either to trench the ground or prepare some good-sized holes for the trees. Whichever system is adopted, it should be recognised that it is impossible to exercise too much care in tree-planting. With species of Pinus success is more difficult of attainment than with other Conifers. But it is possible to give them such a start that they will make good-sized specimens in a few years. Spread out the roots evenly, work in as much fine soil as possible about them, and carry out the planting in every detail with care. Place a support to each tree immediately it is planted.

Montbretia.—It is not too late to lift Montbretia corms for the purpose of sorting the bigger ones out and replanting them. This operation is necessary every two or three years. The largest corms should be selected for planting in clumps or beds. The ground should be enriched with manure and a little sand may be added. Place the corms at distances of 3 or 4 inches from each other. Plant the small corms in some out-of-the-way place in the garden. After the planting has been done, the ground should be mulched with long manure. Montbretias have the best effect when planted in large breadths.

Erica.—Ericas may be planted at the present time. They do not require as much peat as is sometimes given them. They will succeed in a light loam if sand and leaf-mould are added. Some of the earlier-flowering sorts require a sheltered situation. *E. lusitanica* and *E. carnea* are finely in flower at the present time. They will last until the Almond-scented *E. arborea* and *E. Veitchii* flower in March or April.

Annuals.—Seeds of the best annuals should be purchased in order that they may be sown as time and opportunities present themselves. Some of the best sorts are here enumerated:—*Aquilegia cœrulea*, *A. chrysantha*, *Antirrhinum* "Fiery Belt" (coral red), *Carmine Pink*, and *Orange King*; *Chinese Asters*, including a distinct and pretty variety known as "Crushed Strawberry"; *Bartonia aurea*, *Begonias* of various types, *Calendula*, *Calihopsis*, *Candytuft*, *Centaureas* (Sweet Sultan), *Clarkias*, *Cosmos bipinnata*, *Cyanus minor*, *Nigella* "Miss Jekyll," *Delphiniums*, *Dianthus*, including the varieties *Salmon Queen* and *Vesuvius*; *Eschscholtzias*, including *Double Orange*, *Carmine King*, *Diana*, *Dainty Queen*, and *Rose Cardinal*; *Gaillardias*, *Godecias*, *Gypsophila elegans*, and other species; *Hollyhocks*, *Lobelias* in variety, *Lupinus polyphyllus*, *Marigolds*, *Nasturtiums*, *Nemesia strumosa*, *Linarias*, *Nicotiana*, *Sanderae* and *N. affinis*; *Phlox Drummondii*, *Papavers*, including the *Iceland* and *Shirley Poppies*; *Portulacas*, *Salvias*, *Salpiglossis*, *Saponarias*, *Scabious*, *Stocks*, and *Zinnias*.

Sweet Peas are very effective when grown in clumps, and the flowers can be cut conveniently. If the varieties are mixed in long rows they also make an excellent feature in the garden, and yield a great number of flowers. Such rows, however, should be grown in the supply garden rather than in the flower garden.

General work.—Sweet Peas sown in October should have a ridge of dry ashes placed on either side of the rows. Prepare a quantity of soil that it may be ready for use in potting and seed-sowing. The leaf-mould, loam, and other ingredients should be placed under cover where they will remain moderately dry. Protect border Carnations from sparrows either by stretching a netting supported by small sticks, or by straining some black cotton over the plants. Remove all decaying leaves from the Carnations growing in frames and admit air to the plants during favourable weather. Cuttings may now be prepared of such tender bedding plants as *Alternanthera*, *Iresine*, *Lobelia*, and *Pelargonium*.

Border Carnations.—These plants should be treated almost as *Calceolarias*, the difference

being that the *Calceolarias*, being in small pots, will require water, even though it be at long intervals. Spray them occasionally with an insecticide. The borders for their reception should be prepared in fair weather. Let the ground be deeply dug and a liberal application of cow manure be placed under the top spit. The roots will benefit from this manure, and more particularly in dry weather. An application of soot may be worked into the surface soil during the season the plants are making their growth. Good loam, cow manure, and soot are the chief necessities for *Carnation* roots, but sharp sand or road grit may be added if the loam is of a heavy nature.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Early Peach and Nectarine trees in pots.—In gardens where only limited conveniences exist for the forcing of fruit, the cultivation of early Peaches and Nectarines in pots has much to recommend it. A longer supply of ripe fruits may be thus maintained, which is a consideration of the greatest importance in districts where Peaches cannot be successfully cultivated out-of-doors. Trees which were started in December should now be in flower. Therefore the atmosphere of the house should be kept moderately dry, and the flowers should be pollinated in the middle of the day by passing a rabbit's tail carefully over them. Ventilate the house during favourable weather, but exercise care to prevent draughts of cold air. As soon as the fruits have set, any shoots not required for the extension of the trees may be pinched hard back. When and where the permanent shoots must be stopped will be governed by a study of the formation of the tree. Should there set a large surplus of fruits, some of those which are badly placed may be removed, but the final thinning of the fruits should be deferred until the stoning stage is past. Syringe the trees twice each day during fine weather, and damp the walls and paths in the house at frequent intervals. Should aphids appear on the foliage, the house may be lightly fumigated. As soon as it can be seen that the fruits are commencing to swell, occasional application of diluted liquid manure may be given. Weak soot water is also beneficial.

Early Peach trees in borders.—Let disbudding be commenced as soon as the shoots are large enough to handle. It is a good plan to disbud once just before the trees come into flower, so that it will not be necessary to repeat the operation until that stage is past. About half the shoots may be removed at the first operation, taking care to leave one or two shoots as near to the base of the bearing wood as possible, and another at the point of the shoot. When the trees are in flower keep the atmosphere of the house in the condition recommended for the pot trees; pollinate the flowers, especially those on the upper sides of the branches. Before the flowering stage is reached the borders should be examined, and, if they need moisture, a thorough application of clear, tepid water should be given. Fumigate the house just before the trees come into bloom. The atmospheric temperature at night should be 50° to 55°, varying according to the weather, allowing a rise of about 5° during the day. During sunny weather the temperature may even rise to 80°, provided the ventilators are open at the time. A little air may be admitted through the top ventilators during the night.

Strawberries.—When the flower-spikes can be seen the plants should be removed to a warmer house, placing them near to the glass. After that stage has been reached, liberal applications of liquid manure, alternated by some approved fertiliser, should be given two or three times each week, except during the time the fruits are setting. At this season of the year Strawberry flowers need to be pollinated very carefully with a camel-hair brush. Keep the atmosphere dry and admit air when possible. The minimum atmospheric temperature should be 60°.

Late vines.—Now that the fruit has been cleared from the latest vines, the borders will need some attention. If the crops have been satisfactory, it will be sufficient evidence that the roots are in good order. In such a case, water

the borders with clear water, and follow this by a liberal application of dilute, farmyard-manure water. If the vines have been unsatisfactory through shanking, or they have failed to finish their crops properly, some renovation will be necessary. Assuming that there are indoor and outdoor borders, the inside borders may be dealt with at the present time, without interfering with the prospects of the crop this season. The details of the renovation of such borders were fully explained by Mr. T. Coomber in this column a few weeks ago. See pp. 392 (Dec. 5) and 71 (Feb. 1), 1908.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Chrysanthemums.—As soon as any cuttings are sufficiently rooted let them be removed from the propagating frame. During the first few days after their removal from the atmosphere of the propagating frame the newly-rooted plants will be very susceptible to draught, therefore place them for a short time in a temporary frame, which should first be given a layer of the same material as that in which the pots were previously plunged, whether cocoanut fibre, refuse or ashes. Later, the little plants may be placed with earlier ones in a brick pit that can be securely protected on frosty nights. It is time to insert cuttings to furnish plants for general decorative work. If it can be avoided, neither weakly shoots nor those which have flower-buds upon them should be used for this purpose, but instead, sturdy growths which appear as suckers from the base of the old plants.

Carnations.—Inspect frequently the plants of *Souvenir de la Malmaison* for the purpose of removing any portions of leaves which show signs of the rust fungus. This is the best way to eradicate the disease from the collection, but care must be taken to burn the infected leaves directly they have been removed from the plants. Fumigate all *Carnation* plants at frequent intervals, remembering that the presence of a few aphids is sufficient to disfigure the leaves. Propagation of the winter-flowering kinds may be commenced as soon as good cuttings are procurable, but it is better to wait for a month than make use of inferior cuttings. Insert three or four cuttings in sandy soil around the sides of a 3-inch pot. Unless they are too long, the side growths, carefully pulled off with a "heel" attached, will form roots more easily than cuttings made in the ordinary way. Do not keep the frame-lights too close or the cuttings will commence to grow before they have formed roots. Do not allow the bottom heat to exceed 60° or 65°.

Richardia africana.—It being impracticable to fumigate these plants in the show house, it is necessary to watch carefully for the appearance of green fly, and to sponge them from the exterior of the spathes before they unfold. Make frequent applications of liquid manure to the roots.

Dormant bulbs.—These should be examined frequently in order that there may be no losses either through the bulbs being in too dry surroundings, or by any precocious individuals making growth: a condition which calls for their removal from the plunging material. The earliest batches of *Caladiums*, *Gloxinias*, and *Begonias* may now be introduced to heat. Many gardeners obtain good results by at once putting the tubers into pots and using ordinary compost, but others prefer to start the tubers into growth in boxes filled chiefly with leafy mould and sand. This latter method is to be preferred.

Violets in frames.—One of the most essential requirements of Violets is fresh air, and this must be frequently supplied to the plants in frames, whilst, at the same time, cold draughts are prevented. Remove any decaying leaves on any that show signs of disease as soon as they are observed, and stir the surface soil frequently. If advantage was taken of the mild weather at the beginning of December to apply a copious watering, no further water will be needed at the present time. Blooms which are required for vases should be gathered before they are fully expanded, and, if they are placed in a warm greenhouse for a few hours after being gathered, they will develop greater perfume.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE Bart., Burford, Surrey.

Calanthe, Eulophia, Catasetum, &c.—Plants of the *Calanthe vestita* section will now be passing out of flower. Since these plants require a period of thorough rest as soon as the spikes are cut, they should be placed on a dry shelf or in some other suitable position. Keep them well up to the roof glass of a house where the atmospheric temperature at night is maintained at about 60°. Afford them no more water at the roots until new growths develop from the base of the current season's pseudo-bulbs, when it will be time to repot them. The *Calanthes* of the *Regnieri* section like *C. Sanderiana*, and *C. Stevensii*, now opening their flowers, should be kept just moist at the roots until the flowers open, when water should be gradually discontinued. After blooming, the plants require the same resting treatment as those of the *C. vestita* group. *Eulophia guineensis* and *E. congoensis* should be rested with the *Calanthes*. As the leaves ripen and fall off from such species as *Catasetum*, *Cycnoches*, and *Mormodes*, let these plants be elevated to the lightest position available in the *Cattleya* house. Do not apply water at the roots until growth recommences, unless it is seen that the newly-made pseudo-bulbs are commencing to shrivel. All these deciduous plants are liable to become infested with white and brown scale-insects while at rest, therefore they should be periodically examined, for the purpose of cleaning them with brush and sponge.

Zygopetalum.—Plants of *Z. maxillare* that have overgrown the blocks of Tree Fern upon which they were imported, must now be given attention, as they will soon be starting into growth. Cut away as much of the old block as is possible without causing injury to the roots; wire the remaining part with the plant attached to a new piece of Tree Fern. Suspend the plant in a shady position in the intermediate house, and never allow it to become in the least dry. As soon as *Z. Mackayi*, *Z. crinitum*, *Z. Murrayanum*, *Z. brachypetalum*, and the hybrid *Z. Wiganianum* pass out of flower, they should be repotted, if this is necessary. Fibrous loam, peat, chopped Sphagnum-moss, and plenty of small, broken crocks, well mixed together, form a suitable compost for them to root in. Pot the plants exactly in the same manner as for an ordinary stove or greenhouse plant. Such varieties as *Z. Ballii*, *Z. leucochilum*, *Z. Clayi*, *Z. Protheroeianum*, *Z. Burkei*, *Z. Perrenodii*, and *Z. triste*, grow and root well in a mixture of *Osmunda* and *Polypodium* fibre in equal parts, with the addition of small crocks. The same compost will suit *Z. rostratum* and *Z. Roeblingianum*, if an equal ratio of chopped Sphagnum-moss be added. For several weeks after these plants have been disturbed by repotting much judgment is needed in affording water, it being safer to err rather on the dry than on the wet side. As the plants become re-established, gradually increase the quantity of water at the root and in the atmosphere. These *Zygopetalums* thrive best when arranged together in a shady corner of the intermediate house. Small yellow thrips are exceedingly fond of the young growths, and when once they have obtained a footing low down in the growths they are very difficult to eradicate. As a preventive against attacks, place the plants at least once a week in a house that is being treated with a nicotine vaporising compound.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Trees and shrubs in the London Parks.—It is often a matter of comment that the varieties of trees and shrubs in our London parks are restricted to a few genera and species. This is necessarily so because many desirable plants will not succeed in a smoke-laden atmosphere, or because the soil or other conditions are unsuited to them. This is especially true of Conifers generally, and in the more central parts of the Metropolis it would be a waste of time and money to plant them. We have to depend mainly upon deciduous trees for inner-town effects. Any form of plant life that possesses rough or woolly foliage collects the soot and other deleterious substances from the atmosphere, which soon render

the plants unhealthy. In addition to the various forms of deciduous trees and shrubs, Evergreen shrubs with smooth leaves are the most suitable for town-planting.

Some good shrubs for town-planting.—*Aucuba japonica* in all its forms is, without exception, the best Evergreen shrub that can be planted in smoky districts; the bushes are free in growth, soon becoming large-sized specimens. The male and female plants should both be planted, as this is necessary for the production of the beautiful scarlet berries. The variegation of the foliage is not so handsome as in the case of specimens grown under more favourable surroundings, but the symmetry of habit, together with the beautiful, broad, leathery foliage, places the *Aucuba* in the front rank of all other Evergreens. The *Skimmias* in all their varieties are also desirable town shrubs. The dwarf, bushy habit makes them valuable for placing in the front row of a shrubbery or border. The various forms of *Euonymus* are also useful, and these plants, being easily propagated, can be freely planted. Box, again, does splendidly in town parks, where the large bushes with shining, Myrtle-like leaves are always attractive. The Brooms, including *Cytisus albus* and *C. præcox*, find many admirers in spring, when they are in flower. The plants in a few years become "leggy" and need to be replaced with young specimens. *Olearia Haastii* is a shrub that flowers freely in the London parks, producing clusters of miniature white flowers. The *Osmanthus ilicifolius* adds another pleasing variety, reminding one of the Holly (*Ilex aquifolium*) that is freely employed in its many handsome forms. The large-leaved Hollies, such as the variety *Hodginsii*, are far superior for town-planting to the other kinds; they form large pyramidal trees. There are several variegated varieties that might be planted, but their beautiful markings are spoiled by the soot and other dirt in the atmosphere. *Tamarix gallica* is well worthy of inclusion in the list of useful shrubs. *Yucca gloriosa* and other species succeed and flower well with us. They form beautiful plants, thriving in almost any situation, and remain objects of interest for many years. The common Laurel (*Prunus Laurocerasus*) is one of the freest growing and most useful Evergreens, but the environment of a town causes it to lack that free and luxuriant growth that characterises it under more suitable conditions.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The propagation of bush fruits.—It is advisable to propagate a number of Gooseberry and Currant bushes each year in order to make good any gaps in existing plantations or to form additional plantings. Cuttings of the Black Currant require rather different preparation from those of White or Red Currants or Gooseberries. Select strong, well-ripened shoots about 12 to 18 inches in length, and with a sharp knife make a clean, straight cut across the base of the cutting directly under a node (joint). Cut the weak end of the shoot off at the top and insert the cutting without removing any of the buds. This latter point is important, as the best fruits are always borne on young wood, and, if the cuttings are prepared as I have recommended, there will be young growths produced every year from the ground, this being in every way desirable. The cuttings should be inserted firmly in the ground to a depth of four or six inches. Almost any position will suffice for the cuttings, but a shady border sheltered from drying winds is best. The three best varieties are Boskoop Giant, Lee's Prolific, and Black Naples.

Gooseberry and Red Currant.—Cuttings of these should have the buds removed on two-thirds of the length, leaving an upper portion of four to six inches long to form the foundation of the future bush. If the removal of the lower buds is neglected, the production of suckers will prove a perpetual source of trouble, especially in the case of Gooseberries. Excellent varieties of Red Currants include Comet, La Versaillaise, Mammoth, and Red Dutch, with Raby Castle and La Constante for the latest crops. The varieties of Gooseberries are so numerous that it is inconvenient to enumerate a selection here,

but, in some of the best catalogues, the nurserymen have published lists of varieties best suited for special purposes.

General work.—During frosty weather manure may be wheeled upon the fruit quarters, allowing it to remain in heaps until pruning is completed, when it may be spread over the ground and forked in amongst the trees. If any grafting has to be done later, let the trees to be grafted be headed down at the present time, leaving the branches sufficiently long to allow another few inches to be cut off them immediately prior to the grafting. The requisite scions should be prepared now and laid in the soil in a cool and shady border. They will keep perfectly fresh in such conditions until they are wanted.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

French Beans.—As the days lengthen there will be less cause for anxiety regarding the success of these plants. A maximum temperature of 60° and a minimum of about 55° will suit them admirably. Place them in the lightest position possible, and see that the roof glass is kept thoroughly clean. Maintain a moist atmosphere, otherwise the foliage will become infested with red spider. Liquid manure should be applied every alternate watering to those plants which are fruiting, and they may be syringed thoroughly in the mornings and early afternoons with tepid water. Damp the paths with farmyard manure water last thing in the afternoon. Further sowings should be made in 7 or 8-inch pots in a considerable heat. Support the young plants with neat stakes immediately they require it, and stop the points of the growths soon after they have made the first seed leaf. This will cause them to make two side breaks, and the plants in consequence will be kept dwarf.

Cucumbers.—Plants that were raised last month and have been potted into 6-inch pots may be planted out on a mild hot-bed. At this season of the year it is necessary to use a compost of lighter materials than might be recommended later. Let it therefore consist of decayed leaf-mould and a light, fibrous loam in equal parts, adding a little finely-broken charcoal. Place a neat stake to each plant in order to conduct the growth to the trellis. The atmospheric temperature should range from 60° to 70°, varying in accordance with the weather. Syringe the foliage twice each day with water which has been warmed to the temperature of the house. Pinch out the point from the growth directly it has reached the first wire. Plants in bearing should have as many of the old shoots cut out as can be spared, it being necessary to train in as much young growth as possible. Be careful to avoid over-cropping the plants. Cut the fruits as soon as they are fit for use, placing the ends in water. If any red spider is noticed on the plants, carefully sponge the foliage with water and soft soap. Vaporise the house occasionally with a nicotine vaporising compound to prevent attacks of thrip and aphid. The roots will need a surface dressing of light loam and leaf-mould. Do not allow them to suffer for want of moisture. Make further sowings of some reliable varieties in 3-inch pots and raise the plants over a brisk bottom heat.

Broad Beans.—Seeds may now be sown in boxes, placing the Beans 2 inches apart each way. Place the boxes in a cool house or frame. The plants will eventually be used for producing a very early crop in the open. The long-podded varieties such as Leviathan, Aquadulce, and Mammoth Long Pod are much to be preferred to the older, small-podded varieties.

Radishes.—Sow seeds of Radishes at intervals of a fortnight or so on mild hot-beds. If they are not allowed to become overcrowded they will develop crisp roots that will sure to meet with appreciation.

Cauliflowers.—Seedlings raised last month of such varieties as Early Forcing, Magnum Bonum, and Early Giant should now be pricked out into boxes, the plants being placed at distances of 3 inches apart. Make another sowing of the same sort in a gentle heat.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations. The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JANUARY 20—
Roy. Meteorological Soc. meet.

THURSDAY, JANUARY 21—
Gard. Roy. Benev. Inst. Ann. Meet. and Election of Pensioners at Simpson's Restaurant, Strand, 2.45 p.m. Linnean Soc. meet. Ann. meet. Brighton and Sussex Hort. Soc.

SATURDAY, JANUARY 23—
Ann. Dinner Soc. Franç. d'Hort. de Londres at Café Royal, Regent Street, W.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—38.7°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, January 13 (6 P.M.): Max. 46°; Min. 36°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 14 (10 A.M.): Bar. 29.3; Temp. 45°; Weather—Sunshine.

PROVINCES.—Wednesday, January 13 (6 P.M.): Max. 48° Cornwall; Min. 35° North Scotland.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY NEXT—
Border Plants and Perennials, Hardy Bulbs, Lilies, Azaleas, &c., at 12, Roses and Fruit Trees at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY NEXT—
Herbaceous and Border Plants, Bulbs, Lilliums, Spiræas, &c., at 12, Roses and Fruit Trees at 1.30. Palms, Azaleas, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY NEXT—
An importation of Burmese Dendrobes in variety, established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Rubber Culture in Ceylon.

Attention was drawn in our issue of October 3 last, to the developments which have taken place during recent years in the cultivation of rubber plants. It was pointed out how largely these developments have been due to the activities of the Government Botanic Departments in various parts of the world. Although the cultivation of rubber is being prosecuted with zeal in the tropical possessions of other nations, it is gratifying to be able to record that the pioneer work was carried on within the British Empire. The first important step was the introduction to Ceylon and elsewhere of the supplies collected by Mr. H. A. Wickham in the Amazon Valley and brought to Kew under circumstances of considerable difficulty. The expense of Mr. Wickham's expedition was borne by the Government of India, but, as Ceylon seemed to offer more suitable conditions, the young plants were despatched thither, and later this colony acted as the distributing centre for other British possessions. The staff of the Ceylon Botanic Gardens, moreover, carried out experimental work and made discoveries which were, in a large measure, instrumental in securing for rubber cultivation the position of a profitable industry.

The world's annual output of rubber is now about 69,000 tons, of which amount tropical America contributes some 64 per cent., tropical Africa 34 per cent., and tropical Asia the remaining 2 per cent. The tropical American yield is credited in the main to three plants, *Hevea brasiliensis* (Para rubber), *Manihot Glaziovii* (Ceära rubber), and *Castilloa elastica* (Central American rubber). Other species of *Hevea* and various species of the allied genus *Sapium* probably also contribute to the output of "Para rubber." More than one species of rubber-producing *Castilloa* have also been recognised, and recent observations point to there being other useful species of *Manihot* besides *M. Glaziovii*. The three plants mentioned may, however, be regarded as being the main sources of American rubber. They have all been introduced into Ceylon, and we may consider separately their histories in the colony.

Of *Hevea brasiliensis*, a supply of some 2,000 young plants was received in Ceylon in 1876, transmitted from Kew in 39 Wardian cases. These plants had been raised from the seed collected by Mr. Wickham in the Amazon Valley. A special garden was prepared for their reception at Heveratgoda in the low, moist country, and some were also planted at Peradeniya, about 1,500 feet elevation. The plants succeeded very well. Heveratgoda soon supplied plants to widely distant parts of the tropics, at first from cuttings and later from seed. As the plants became old enough to yield rubber—usually about their sixth year—experimental tapplings were commenced. To this end V-shaped incisions were made in the bark of the young trees, and the exuding latex collected in cups of cocoanut shell placed at the base of each trunk. In this manner the late Dr. Trimen, F.R.S., the then Director of the Gardens, obtained from one tree, during six years, by tapplings made in 1888, 1890, 1892 and 1894, a yield of over 10½ lb. of good, dry rubber. A definite step forward resulted from the experimental work of Dr. J. C. Willis, the present Director of the Ceylon Botanical Gardens, and Mr. J. C. Parkin, who carried out the investigations from 1897 onwards. They discovered the existence of the phenomenon known as "wound response." It was found that if a definite region of the bark was tapped several times at short intervals the yield of rubber increased considerably at each tapping. Many methods of coagulation of the latex were also tried, resulting in the preparation of the now familiar thin "biscuits." The net result was to show that Para rubber cultivation in Ceylon might be looked upon as a reasonably profitable industry. Planting made such rapid strides that, at the present time, there are in the colony some 180,000 acres under rubber crops. Definite evidence of the progress of the industry is afforded by the increase in amount and value of the exports of rubber from Ceylon during the past seven years. Whereas, in 1900, the quantity of rubber exported from the colony was but 8,223 lbs., of £859 in value, by 1908 it had increased to upwards of three-quarters of a million pounds, and was valued at £195,475.

It was thought at first that Para rubber would not succeed in Ceylon at elevations greater than about 500 feet, but the tree has

since proved to do well at heights even exceeding 2,000, and probably 3,000 feet should be regarded as the limiting altitude in the colony. The tree will grow at much higher elevations, but would not be likely to prove profitable.

The history of *Hevea* cultivation in Ceylon affords an excellent example of the usefulness of Botanic Gardens equipped with proper facilities for the carrying out of experimental work. If the Ceylon Gardens had done nothing else during their history than establish this industry they would have more than justified their existence. But, in addition, they were, as is well known, the means of introducing coffee, tea, and cinchona, to take only the more striking instances, all of which plants have played important parts in the economic history of Ceylon.

Ceära rubber (*Manihot Glaziovii*), another South American tree, was introduced into Ceylon by Kew in 1877, the supplies of seeds and plants having been obtained by Mr. Cross. By 1883 as many as 977 acres were reported as being under this plant. The yield of rubber, however, was very disappointing, and, with the rapid development of the tea industry about this period, the cultivation of the Ceära-rubber tree fell into neglect. The Para rubber tree afterwards gave more promising results and interest was transferred to it. Recently, however, it has been shown that rubber of very high value can be prepared in Ceylon from the *Manihot*, and it is not improbable that, in the future, it will be grown in places too high or too arid for the Para rubber tree but well suited to the more drought-loving Ceära plant.

Central American rubber (*Castilloa elastica*), known to the Spaniards as the *Ulé*, was introduced into Ceylon with the Para rubber plants in 1876. It was grown like the Para rubber at Peradeniya and Heveratgoda. Trees are now distributed about the island, but they have not been cultivated on an extensive scale, and comparatively little is known as to the yields obtainable from this species in the island, although experimental tapplings have yielded rubber of high value.

Amongst other rubber trees introduced into Ceylon are the Assam rubber tree (*Ficus elastica*), the familiar India-Rubber plant of this country. The avenue of this handsome tree leading into the Peradeniya Gardens is well known to visitors to Ceylon, the curious buttress-roots being very characteristic. No serious use has ever been made in the island of *Ficus elastica* as a rubber-producing tree.

From Africa there have also been introduced the Lagos silk rubber tree (*Funtumia elastica*), which has not proved successful owing to the young plants being very liable to defoliation by the attacks of a caterpillar, and the various rubber vines (*Landolphia* spp.) which, from their climbing habit, are not well adapted for estate cultivation.

LINNEAN SOCIETY.—The next general meeting will be held on January 21, at 8 p.m. The following papers will be read:—(1) Mr. ARTHUR W. HILL, "The Genus *Nototriche*, Turcz"; (2) Dr. PERCY GROOM, "The Longitudinal Symmetry of *Centrospermeæ*." Dr. OTTO STAFF, F.R.S., Sec.L.S., will exhibit a peculiar type of *Plagianthus* (Malvaceæ) from Western Australia.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The sixty-ninth annual general meeting of the members and subscribers of this Institution will be held at "Simpson's," 101, Strand, London, on Thursday next, January 21, at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the Institution for the year 1908; electing officers for the year 1909; and for the election of 18 annuitants on the funds. Also to consider the following notice of motion by W. A. BILNEY, Esq., J.P. (honorary solicitor):—"That every person having attained the age of 70 years who is in receipt of an annuity from the Institution and is eligible for a Government Old Age Pension of less than the maximum allowance of 5s. per week, or whose total income does not exceed £31 10s. per annum, may have such charitable annuity reduced as the committee may determine under Rule III. 6, so as to render him or her eligible to apply for a pension on the Government scale, provided always that such reduction does not involve the beneficiary in any pecuniary loss." The chair will be taken by HARRY J. VEITCH, Esq., V.M.H., treasurer and chairman of committee, at 2.45 p.m. The poll will be open at three o'clock and close at four o'clock precisely, after which hour no voting papers will be received. The annual friendly supper will be held also at "Simpson's" at 6 p.m., when W. J. JEFFERIES, Esq., of Cirencester, will preside.

ROYAL METEOROLOGICAL SOCIETY.—An ordinary meeting of the society will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Wednesday, January 20, at 7.30 p.m. The annual general meeting will be held at 7.45 p.m. An address on "Some Aims and Efforts of the Society" will be given by the president, Dr. HUGH ROBERT MILL.

GARDEN CHANGES.—Mr. T. H. SLADE, after managing the gardens at Poltimore, near Exeter, for nearly 14 years, is seeking a re-engagement, owing to the death of the late Lord POLTIMORE. Mr. SLADE is well known to our readers, and on several occasions has contributed to our weekly Calendar. During the time he has been at Poltimore he has carried out many improvements. He has also shown special skill in the cultivation of Carnations, and in the raising of seedling varieties. We hope Mr. SLADE will soon obtain a suitable appointment.—Mr. A. B. WADDS, who has also contributed a weekly Calendar to these pages, will be leaving Paddockhurst, Sussex, at Easter. He has been gardener to Sir WETMAN D. PEARSON, Bart., for the past ten years.

FLORISTS AND THE FACTORY ACTS.—Announcements have recently appeared in some of the papers to the effect that certain regulations, which exempted florists from the operation of various inconvenient sections contained in the Factory Acts, were rescinded. These statements are premature. It is only a few of the regulations referred to which are likely to be rescinded, and no order for rescission has yet been made. When the anticipated order is issued due notice of the fact will appear in these columns.

ROSES ELAINE AND REFULGENS.—These new Roses, of which illustrations have been published in these pages during the past season, are home-raised varieties, being seedlings of Messrs. WM. PAUL & SON, Waltham Cross, who exhibited and obtained awards for them at the R.H.S. meetings. We draw especial attention to them now, because in the article on page 19 in last week's issue these particulars were not given. Elaine is a H.T. variety and Refulgens a hybrid Sweet Briar.

GERMINATION OF THE STRANGLING FIGS.—It is well known that many of the tropical species of Ficus behave in their seedling and juvenile stages as epiphytes: that is, they grow upon other trees, in the crevices of which the seeds lodge and germinate. When growing in this way roots are produced by the seedling, and they extend downwards till they penetrate the soil; whilst in some forms other girdling roots embrace the trunk of the host. As soon as the roots have reached the soil their upper aerial parts thicken rapidly, and roots in contact with each other coalesce by a sort of inarching. In this way they soon enclose the host-tree in a hollow network, the meshes of which may become obliterated as growth proceeds. The unfortunate tree thus included may perish by strangulation if it happens to be one that increases in girth, and even if it does not thicken, e.g., a palm, it may be killed ultimately

FIG. 26.—FICUS PARASITICA STRANGLING A TREE OF ELAEIS GUINEENSIS.

by the shade produced by the Fig. Sometimes these Figs will grow as ordinary trees directly from the ground, without the support derived from other plants, but in certain species this only occurs when the Fig is growing fully exposed to light in the open country. Professor BENEY has made the interesting observation that, in the case of Ficus aurea, the seeds will not germinate unless exposed to light, and thus this plant can only establish itself in the forest when the seeds fall, or are deposited, upon the upper branches of the forest canopy. Other species, e.g., F. populnea, are less exigent as regards light, though their seeds also germinate more quickly in light than in darkness. In correspondence with this, these species do not always grow as epiphytes, even in the forest. The illustration in fig. 26 shows Ficus parasitica

upon Elaeis guineensis, the Oil Palm of West Tropical Africa, in the Botanic Garden, Peradeniya, Ceylon. Ficus parasitica is common throughout the eastern Tropics. In Ceylon it is found throughout the moist region up to about 4,000 feet elevation. It is a parasitic weed in the Peradeniya Botanic Gardens.

MR. W. BOTTING HEMSLEY, F.R.S.—Mr. HEMSLEY desires it to be known that, having retired from the Kew Herbarium, his address will be 24, Southfield Gardens, Strawberry Hill, Middlesex.

"WILLING'S PRESS GUIDE."—We have received the edition of this guide for 1909. It contains an alphabetical list of the principal periodicals published in this country. In addition, the periodicals are classified according to interest, professions, trades, religious denominations, sciences, and subjects. Those published in London are divided into morning, evening, weekly, monthly, quarterly, and so on. There is also a list of the provincial papers, divided into counties, and a list of the London addresses of Colonial and foreign newspapers. Altogether it is a most useful Press guide.

"LE CHRYSANTHEME," the journal of the Société Française des Chrysanthémistes (No. 109, 1908), contains many matters of interest. The number opens with a brief history of the flower, in which it is suggested that the Chrysanthemum as we know it is of Chinese rather than of Japanese origin, though prominence is given to the conviction of M. HAYASHI (*Journal Royal Horticultural Society*, December, 1906) that varieties similar to those at present in cultivation may be obtained by hybridisation of the wild species native to Japan. Among the other subjects dealt with in the number are methods of cultivation and of selection; the types common now in Japan; and the progress made in the flower during the past 25 years.

THE EXTERMINATION OF GOATS IN THE TERRITORY OF HAWAII.—It is interesting to Englishmen to learn that those in charge of the forest reserves of Hawaii are urging upon the legislature of that territory the need for the extermination of the goat within the established forest reserves. The recommendation recalls a famous episode in the history of St. Helena. The forests of that island were once rich in Ebony. Goats were introduced, and, becoming naturalised, increased in such numbers as to threaten the life of the forest trees. But goats were a very marketable commodity, securing, as they did, a high price from ships of call. Those on the spot, recognising the extent to which the goats were damaging the forest, petitioned for permission to destroy them. They received the laconic reply, "Goats are more valuable than Ebony." The goat was spared, the forest spoiled, and thus the permanent source of revenue was sacrificed to the transient source, for, after the destruction of the forest, the goat industry could not long survive.

TREES AND SHRUBS.

THE WITCH-HAZELS.

THE most valuable additions within recent years to trees or shrubs that flower even before winter is past are the Asiatic forms of Hamamelis. The oldest of these, H. arborea, is stated in the *Dictionary of Gardening* to have been introduced in 1862, but when it was awarded a First-class Certificate by the Royal Horticultural Society in February, 1881, it was then very little known. Previous to the introduction of that species, the only Hamamelis in gardens was H. virginica, native of a considerable tract of country in the United States, from whence it was

introduced in 1736. Examples are often to be seen in old-fashioned gardens, but it is the least showy member of the genus, the starry flowers, which are borne in considerable numbers in the autumn, being of a dull brownish-yellow tint.

HAMAMELIS ARBOREA.—This old-world species is the largest growing member of the genus. In this country its usual habit is to form a decided leading shoot, while numerous side branches are pushed out in a more or less irregular manner. The long, strap-shaped petals which go to form a starry flower are peculiarly crinkled and of a bright orange-yellow colour. The rich purple of the calyx is also another notable feature of this species. On a bright, clear day in late winter or early spring this *Hamamelis*, with the sun shining on it, stands out like a golden cloud. If sprays are cut and placed in water the buds will develop and the expanded blossoms last for some time.

H. JAPONICA.—The flowers of this species resemble those of *H. arborea*, but are rather

Gardens, Kew, brought the plant to notice. How this happened it is difficult to imagine, for the large, broadly-ovate leaves are distinct from those of any other species, while the flowers are larger than those of *H. arborea*. In addition, the petals are somewhat broader, and instead of being crinkled are almost straight, with hooked tips.

The order Hamamelidaceæ, which takes its name from the *Hamamelis*, is a comparatively small one, the best-known hardy members of it, beside the Witch-Hazels, being *Parrotia persica*, *Fothergilla alnifolia*, *Corylopsis spicata*, *Loropetalum chinense*, and *Liquidambar styraciflua*. W.

FLORISTS' FLOWERS.

THE CLASSIFICATION OF DAFFODILS.

THE issue, by the Narcissus Committee of the Royal Horticultural Society, of the classified

for their consideration from cultivators interested in Daffodils.

As to the classification in the present list, the addition of a new division (II. Short Trumpets) of secondary crosses, Trumpet \times Incomparabilis, and the suppression of the corresponding class of secondary crosses, the Burbidgei section, Incomparabilis \times Poeticus, will probably cause some dissent. For show purposes, Division II. is no doubt justified in the present condition of Daffodil seedlings, but I do not think it will be possible to maintain it, except as a sub-division, any more than the Burbidgei section. The most awkward result of the principle of measurements as affecting the present list appears to be in the case of the *Triandrus* hybrids. Snowdrop, Cecil Rhodes, and J. T. Bennett-Poë (Trumpet \times *Triandrus*) are in Division I. Countess Grey (Trumpet \times *Triandrus*, Mrs. Berkeley, and Robert Berkeley (*Triandrus \times *Incomparabilis*) are in Division II.; and Agnes Harvey, Ada, Betty Berkeley, and the Tazetta varieties in Division VII. Thus varieties which in common have the distinctive character of *N. triandrus* are dispersed in widely-separated divisions. I hope it will be possible eventually to provide a separate class, or sub-division, for *Triandrus* hybrids. It would add to the usefulness of future editions if the list were interleaved with blank pages, providing space for additions, corrections and notes. It is especially desirable that in a future edition the parentage of the varieties, so far as they are known or can be ascertained, should be added. To the raiser of seedlings, who is seldom a competitive exhibitor, such information would be especially valuable. The list would then form a record which would prove of great use to students of heredity. The question of parentage would entail some extra labour, and extra space would be needed for printing. But some saving is possible in the matter of space by giving merely initials, or by abbreviating the names of the raisers instead of repeating them in full. The Committee need not assume responsibility for the accuracy of parentages given. They would merely collect the information from the raiser.*

It is true that in respect to many varieties no record has been kept of the parentage: in others only the seed parent is known, and in others, again, what information there was has been lost. It is the more desirable to collect as much as is known into a permanent record. A. J. Bliss.

HEDSOR, BUCKINGHAMSHIRE.

(See figs. 27, 28 and 29, also Supplementary Illustration.)

THE beautiful residence depicted in our Supplementary Illustration is situated on high land overlooking the charming scenery of the Thames Valley. The garden front enjoys a magnificent landscape view, whilst at the back is a broad valley with wood-clothed hills skirting it around. Hedsor occupies the spur of a plateau broken by the river's bed. In the distance the land rises almost abruptly again at Cockmarsh, adjoining Quarry Wood, with the well-known riverside town of Cookham on the left. The district is situated in the midst of many towns and villages that are famed as river-side places, including Maidenhead, Marlow, Loudwater and Bourne End. On the occasion of our visit in November we alighted at Maidenhead. Though Bourne End is much nearer, the journey by road from Maidenhead is delightful, and leads past the gates of Taplow Court, which was described in our issue for June 6, 1908, and Cliveden, to which reference has often been made in the *Gardeners' Chronicle*. Hedsor forms only a part of the estate of Lord Boston, which also includes an old-time residence of most picturesque appearance known as the Wharf (see fig. 27) preferred by Lord and Lady Boston to the more modern and commodious mansion of Hedsor. The Wharf

FIG. 27.—THE WHARF HOUSE ON THE HEDSOR ESTATE.

lighter in tint, while the petals are not quite so crimped. The habit is very different, for *H. japonica* naturally forms an open bush, all the branches of which have an upward tendency. As a rule, *H. japonica* flowers somewhat later than *H. arborea*. The variety *Zuccariniana* is very distinct and beautiful. It differs from *H. japonica* only in the colour of the flowers, these being of a clear citron-yellow. This feature causes it to stand out markedly from all members of the genus.

H. MOLLIS.—This species is a native of China and the latest addition into gardens. It is commonly regarded as of recent introduction, Dr. Aug. Henry being in some instances, at least, credited with its discovery. In *Hortus Veitchii*, however, it is stated that this, the rarest and largest-flowered of all the Witch-Hazels found in Kiang-su in the district of Kiu-Kiang, China, by Charles Maries, and sent by him to Coombe, was for 20 years overlooked, till the late Mr. George Nicholson, late Curator of the Royal

list of over 2,000 varieties, marks an epoch in the history of the Daffodil.

From some points of view it is a pity that the old classification based more nearly on a "natural" system can no longer be retained. But for show purposes, for which this new list is primarily intended, and, on account of the authority with which it is put forward, probably everyone will accept the principle of measurements involved in the arrangement of the list as being the best, if not the only one, practicable. The actual scale of measurements in accordance with which the first five divisions are determined is not given. It is, however, intimated that "it is intended in a future edition not only to correct and modify the arrangement according to further experience," but also to elaborate further sub-divisions, especially with respect to the colours of the varieties in the present divisions or classes. It is probable, therefore, that in the meantime the Committee would welcome any suggestions

is very close to the river, and consequently on a much lower level than the modern mansion. It is a very old building. Its walls are clothed with climbers, and it is set in a delightful, old-fashioned garden. Because of his preference for the Wharf, Lord Boston has recently leased the Hedsor residence on a short tenancy, and the present lessee is Mr. Malcolm Aird, a son of the builder of the Nile Dam. There is not so much flower bedding practised at Hedsor as formerly, but notwithstanding this the gardens and grounds are very beautiful, and although summer bedding is not largely practised, the borders and beds are filled with a wealth of flowering plants of a hardy nature, together with Roses and other flowering shrubs and trees, including many Rhododendrons and Azaleas. In front of the mansion is a broad lawn, and surrounding it is a terrace with stone vases, the Ivy-leaved Pelargoniums in which were still in flower at the time of our visit. Towards the south-west is a fine herbaceous border backed by a clipped Yew hedge, and, as we saw it, gay with Michaelmas Daisies, Chrysanthemums, and other autumn flowers. Almost at the termination of

Lord Boston's estate. The estate has had a long ecclesiastical connection, as the old building known as The Priory betokens. The church was built prior to 1220, but whether the one now standing is the original structure we were not informed, although from its appearance it might be. It is a small edifice capable of seating not more than 130 worshippers. A tablet records, well-nigh without a break, the names of incumbents almost from the beginning. The little graveyard surrounding the church has an extraordinary appearance, for all the stones commemorating the dead are placed flat upon the grass. From the churchyard, looking northwards, is seen the curious building shown in fig. 28, and known as The Towers. It is a stiff climb to reach the spot, but the toil is amply repaid by the magnificent view. The Towers are a "ruin" built by a former Lord Boston for the purpose, no doubt, of enhancing the grandeur of the scenery, which takes in a wide sweep of the valley of the Thames. The walls of the ruin are built of flint, solidly enough, and a portion of the building is used as a residence by one of the employes. The upper part of the Ivy-clad Tower is used as a tea-room. Note the incon-

VEGETABLES.

PEAS.

NEW varieties of culinary Peas must be of exceptional merit to surpass in quality the best of those introduced during the past few years. Many of these newer Peas are not only highly productive, but also good in colour of pod and in maturing early. They also have the desirable qualities of withstanding a fair amount of drought, and resisting the attacks of mildew better than the older kinds. These are qualities that have doubtless been considered by the raisers, who have also aimed at securing short internodes and the production of the pods in pairs. Not only are some of these newer Peas large as regards pod, but the Peas themselves are of extraordinary size and of that marrow-like flavour so much appreciated in this vegetable. For market purposes the dealer prefers a fine dark pod, and I know of instances where large, pointed pods have been preferred to those with broad, square ends, although the latter were of excellent quality, well filled, and weighed from 6lb. to 8lb. per bushel more than the others. A good appearance doubtless helps to keep up the price, and, from a market point of view, it does not pay to grow the older, smaller-podded varieties.

The **PILOT** is a fine addition to the early section of culinary Peas, and was, I believe, sent out by Messrs. Alex. Dickson & Sons. It is round-seeded, therefore hardy: the pods are almost equal in size to those from the best stocks of **Gradus**. It may not be generally known that there are light and dark-podded forms of this very excellent Pea, and for private consumption deep-green Peas are usually preferred to paler ones. All growers of early culinary Peas should cultivate this variety.

LAXTONIAN.—This Pea was sent to me by Messrs. Laxton Bros., of Bedford. I consider the variety an advance upon some others of the early dwarf Peas. It is a sturdy grower, with short internodes, and produces a remarkable crop upon its 18-inch-long stems. Both the pods and Peas are of a deep green colour: the haulm is dark and the broad pods are nearly as large as those of the variety **Gradus**.

LIGHTNING and EXPRESS.—Gardeners who cultivated the old **Lightning** and **Express** varieties will be interested to know that these two excellent hardy Peas are being introduced in a "Giant" form. Since the introduction of so many excellent early marrowfat varieties, they have become less popular in this country; but on the Continent, where large size is less insisted upon, these kinds, and especially the free-fruited **Express**, are very popular. Both the varieties are very hardy under ordinary cultivation and produce early pods even if no protection is given them.

READING WONDER is a very dwarf, early variety. For a dwarf Pea it is in every way excellent and one that does remarkably well in shallow frames or under the protecting shelter of warm walls.

WORLD'S RECORD.—This variety is of the **Gradus** type, but it is dwarfer in growth by several inches and not quite so large in the pod as that variety. It has the advantage of being several days earlier and is of the best marrowfat quality.

INTERNATIONAL has for its parents two of the finest of all culinary Peas. From the size of the pods exhibited at the Holland House Show it is sure to become a favourite with gardeners. The haulm is tall growing, and in season it follows the **Gradus** section, but matures before **Duke of Albany** variety.

HARVESTMAN.—This is a distinct podded, heavy-cropping variety growing about 5 feet in height.

SNOWDROP is a blunt-ended pod of the **Thomas Laxton** type, growing about the same height as that variety.

FIG. 28.—THE TOWERS IN THE GROUNDS AT HEDSOR.

the lawn westwards an ornamental pond has been formed for the accommodation of Nymphæas and other water plants. Scattered about the lawns are several large oval beds planted with Rhododendron, and, in the well-kept turf, are planted Almonds, Thorns, Roses, Laburnums, and native trees. Lord Boston has in recent years planted many Conifers. Opposite to a summer-house is the avenue of Sequoias that will form a fine feature in future years. There is an enclosed Rosary that one alights upon unexpectedly, a tall hedge of Portuguese Laurel hiding it from view. On the right is a fine specimen of Weeping Ash. The Rose-garden is very pleasing, the centre being planted with Roses trained on festoons as a bell to a central pole. Animation is lent to the scene by the numerous statues of cherubs which adorn the Rose-garden. Of coniferous trees there are some large Cedars, and *Picea Cephalonica*, *Abies concolor*, *A. canadensis* and Yews in the grounds, but the most important Yew has disappeared. Two venerable specimens still stand in the ground leading from the kitchen garden to the village church of Hedsor, which is situated on

gruous combination of the crescent and the cross. The curious structures seen in fig. 29 are fish-traps. The grounds of the Wharf include a backwater from the Thames, with lock-gates. When the traps are dropped into the water these gates are opened, and, with the flow of water, the fish are trapped. Eels form the majority of the "bag," but roach, perch, carp and bream are occasionally secured. The pointed portions are detachable caps, which permit of the fish being taken when the traps are raised. A bridge leads over to an island, on which are a tea- and a bathing-house.

The kitchen gardens, glasshouses, and a small farmstead lie in the valley to the north of Hedsor. The kitchen garden occupies about four acres, and is surrounded by fine walls, on which are trained fruit trees. There are four ranges of glasshouses, with pits, &c., all in an excellent state of repair. The gardener is Mr. James Wood, who has had the care of the gardens for about 17 years, and who has done much in conjunction with Lord Boston in making Hedsor one of the most beautiful spots in the Thames Valley.

EVERGREEN DELICATESSE is worth a trial in gardens, being a good cropper of very fine quality.

REARGUARD.—I was much impressed by the qualities of this Pea as seen in one of the trials last summer. I look upon it as an advance on the older varieties that crop in the late summer and early autumn. Almost anyone can be assured of a fair amount of success with Peas during the earlier summer months and so long as moisture is present in the soil; but great constitutional vigour must be one of the foremost points about a main crop and late-cropping variety. Rearguard has all the good qualities possessed by Gladstone, and, as seen growing, was more heavily cropped with somewhat longer pods than that variety. The pods are dark green in colour. This Pea promises to become a standard variety. I believe it originated from the same source as The Pilot.

MAJESTIC is a very heavy-cropping variety, having the low-growing habit of Dwarf Defiance. It is recommended as a market Pea.

GLORY OF DEVON and ROYAL SALUTE are two fine Peas not often seen. They have many qualities to recommend them, producing pods of good colour, with Peas of excellent quality, and the haulm has a robust constitution.

TALL VARIETIES FOR MAIN CROP.—Amongst the taller-growing varieties, such Peas as Quite Content, Centenary, Alderman, Duke of Albany, and Telegraph, when cultivated from carefully re-selected stocks, are hard to surpass. Amongst the darker-foliaged, vigorous-growing varieties with good staying powers during hot weather and which mainly grow from 3 to 4 feet in height, I made special note of Superlative, one of the finest of this type for use in July. Distinction and Best of All have plain, dark-green foliage and produce a heavy crop of long, rather narrow pods containing Peas excellent in quantity. Perfection, Kaiser, New Model, Incomparable, and Masterpiece are all very fine Peas. Masterpiece is a wonderful cropper, and Incomparable is also an extra fine variety with a blunt-ended pod. Most of these varieties, if sown the second week in May, will, under ordinary conditions, give a gathering of pods at the end of July, and continue to crop until August.

EARLY TALL-GROWING PEAS.—This type includes varieties varying from 3 to 4 feet in height, that are, if anything, earlier fruiting than the dwarf varieties, with shorter internodes. Excepting that varieties of the dwarf type can be protected more conveniently and are suitable for planting near to sheltered fences and walls, there is otherwise no gain to the grower in their culture. The following varieties have, after repeated trials, been found excellent, and, with ordinary cultural care, will not fail to satisfy both as regards crop and quality:—Gradus, Early Giant, Early Morn, Ideal, Duchess of York, World's Record, Pilot, Thomas Laxton, and a good stock of All. Ideal is a Pea I prefer to any other in the early section. Sown in February in the open in exposed positions, on a well-drained soil, I can usually gather Peas the second week in June, although the dates vary from a day or two to sometimes a week, according to the weather conditions.

EARLY DWARF-GROWING PEAS.—Reliable varieties in this section are Little Marvel, a small-podded, very prolific variety, suitable for home use, Pioneer, Sherwood Green Gem, Mayflower, Chelsea Gem, Carter's Eight Weeks, and Reading Wonder. The three last named are very early of their class.

SECOND-EARLY DWARF-GROWING PEAS.—Apart from the foregoing Peas named, there are those of the dwarfier, second-early type, usually of free cropping quality and yielding Peas of excellent flavour. These include Daisy, Dwarf Defiance, Stratagem, King Edward, a fine square-ended pod of the type of Defiance; and Rentpayer, a desirable market Pea. There are doubtless other varieties amongst Peas that, for particular purposes may be valuable to some growers, yet those named, for high-class quality and general productiveness would not be easily surpassed. *Charles Foster.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

GRAPE MILL HILL HAMBURGH.—It is remarkable that this excellent variety of Grape is neglected. It possesses all the good qualities of the Black Hamburg variety and colours as well as Gros Maroc. The splendid "hammered" berries are as noble in appearance as those of the latter variety. I was disappointed to observe that it was not represented in the Wisley collection exhibited at the Horticultural Hall on September 29 last. I fear that inferior varieties have been sold as Mill Hill Hamburg, and, for this reason, the variety has fallen into bad repute. An excellent description of this Grape is given in *Hogg's Fruit Manual*. *F. B. S.*

GRAPE CANON HALL MUSCAT.—It is generally recognised that this well-known Grape was originally a seedling of Muscat of Alexandria, but no proof has been furnished as to such origin, and the late Mr. A. F. Barron stated that its origin is uncertain. Sports have originated from Muscat of Alexandria, but few of these have proved worthy of cultivation. One which originated on a Muscat of Alexandria vine in the great vinery at Chiswick presented all the external characteristics of the Canon Hall form, but proved to be very unsatisfactory. There is, however, one notable exception to the common rule of failure on the part of these sports. It will be remembered that the late Mr. William Cole, of Feltham, when at Ealing Park Gardens, was a first-class grower and exhibitor of Muscat of Alexandria Grapes. Some years later at Feltham, he grafted Muscat of Alexandria on to a stock of Lady Downe's Seedling, with the result that he obtained fine fruiting rods. On one of these branches a spur developed a distinct sport similar in bunch, berry and foliage to the Canon Hall variety. Vines were propagated from that sport, and two span-roofed vineries were planted with them. The crops of Grapes were excellent. After Mr. Cole's death, his sons continued in possession of these vineries. In a recent communication from them respecting the vines, I learn that whilst the first generation from cuttings did not always come true to character, the second generation has done so, and the sport is now thoroughly fixed. Altogether the second stock is a material improvement on that of the first. The fruits of this form set equally as well as those of Muscat of Alexandria. The bunches are always well filled with berries, and a better price is obtained for the Grapes than for the true Muscat of Alexandria. A vine of the Canon Hall variety was planted in one of the houses as a test; whilst it is similar in all other respects, the Feltham sport is superior in setting quality and it therefore produces heavier bunches. *A. Dean.*

THE AMERICAN CARNATION.—If the American or winter-flowering Carnation is to be judged by the standard of the few novelties noticed at a recent exhibition in Vincent Square, the only conclusion to be arrived at is that a turn for the worse has been taken. I am referring more particularly to such varieties as Mrs. Sarah A. Hill, Afterglow and Winona, all thin and papery in texture and inferior to varieties already in cultivation. The American Carnation is said to "improve with America's sun," and doubtless there is truth in the remark. It will take much sun, however, to raise Mrs. Sarah A. Hill to the standard of White Perfection, to render Afterglow a fit companion to Aristocrat, or to make Winona a flower equal to Winsor. Some of these Carnations, and in particular such as Afterglow, whose flowers have much blue in them, are ill-suited to an ordinary English winter, and quickly feel the bad effects of the fog and sunless days. Therefore, apart from the thinness of petal and other shortcomings, they are not likely to be regarded with much

favour. On the contrary, such varieties as Beacon, the magnificent vase of Victory staged by Mr. Dutton, or the superb white-flowered varieties from leading growers in Hampton, Balcombe and other places, unmistakably demonstrate the perfection to which this type of Carnations can be grown on this side of the Atlantic. A noticeable feature at the exhibitions is the number of pink-flowered seedlings from English raisers, no fewer than four of those displaying varieties of merit, Rose Felton and Evangeline being among those to which names had been given. These are of deeper colour-tone than Enchantress, and will be seen to advantage under artificial light. The only certificated variety, Rose Doré, is a superb flower from certain points of view, viz., size, shape, and length and strength of stem. The calyx, too, is all that can be desired. The shade of colour—between red and rose—is novel if not striking, and the flower is of exceptional fullness. As shown, the variety had many erectly-disposed petals towards the centre of the flower, and these reveal too much the less well-coloured parts of the flower. *E. H. Jenkins, Hampton Hill.*

APPLE AND PEAR SCAB.—It is to be hoped that the investigations that are being carried out by Mr. Chittenden, on behalf of the Royal Horticultural Society, concerning the Apple and Pear scab fungus may result in helping fruit-growers to prevent this disease. In spite of the great increase in the practice of spraying with the alkali and other washes, the disease seems to be more prevalent than ever. Apples are keeping very badly this winter. If I except Bramley's Seedling, nearly all other varieties are turning soft. What with "scabby" Apples and Pears, Black Currant mite, and Gooseberry-mildew, fruit-growers are experiencing a very bad time. *W. H. Y., Rotherfield Park Gardens, Alton, Hants.*

THE COMMON MYRTLE (see p. 17).—An old specimen of *Myrtus communis*, growing at the foot of a south wall in the kitchen garden here, produces every year its pretty white flowers, though in some years they are more abundant than in others. Four years ago I inserted in the spring several cuttings which rooted with freedom and became by the second autumn 18 to 24 inches in height. During July and August these small plants were covered with flowers, and these set fruits which eventually ripened. Out of curiosity, I separated the kidney-shaped seeds from the pulp of several fruits and sowed them in pots of fine soil, placing them in a warm greenhouse. The seeds germinated within a month, yielding a high percentage of plants which made excellent growth, the strongest reaching a height of 10 inches the first season. With the exception of the seedlings, all the other plants are grown out-of-doors during the summer, being generally housed with the *Chrysanthemums* in autumn. The soil of this district is largely composed of chalk, yet it never adversely affects the free development of the common Myrtle, either when grown in pots or as cultivated in the open air. In the last five winters, that of 1907-8 is the only one in which the points of the shoots upon the old plant were injured by frost. *Thomas Smith, Walmsgate Gardens, Louth, Lincolnshire.*

THE ABSORPTION OF WATER BY LEAVES.—In the article dealing with my paper (*Gardeners' Chronicle*, January 9, p. 24), it is said, "It is not clear what is meant by 'an indraught of dew.'" What I meant was, that, as transpiration is renewed by the oncoming of light, the dew deposited on the surface of a leaf during the night is presumably absorbed as soon as light causes transpiration to commence. Of course, no drop of water can enter a stomate if air be below, as the orifice is far too small to admit it. A point I wanted to emphasise was, the great ease with which any ordinary leaf (not provided with a very thick cuticle, like that of desert Xerophytes) can absorb water by either surface. If the upper surface of any leaf having no stomata be gently laid on water it will remain fresh for a long period, enabling axillary buds to develop into leafy shoots, if the stem and bud be attached and raised into the air. The stomata being on the surface exposed to air, transpiration can, of course, go on uninterruptedly. *George Henslow.*

CATTLEYA LABIATA.—Some few years ago I sent you some notes on growing this well-known early winter-flowering *Cattleya* on rustic blocks. At that time several horticultural friends told me the method would only answer for a year or two, when fresh blocks would be required. I enclose a recent photograph (not suitable for reproduction) of a plant which has been grown for seven years in this manner, having been transferred to fresh blocks but twice in that time. The gardener, Mr. Taylor, tells me there are 15 flowers on the plant. Elder wood was used each time, and this for two reasons: (1) it was thought that the bark, when freshly cut, is not liked by insects; (2) when decayed, the bark peels freely from the wood, thus allowing the living roots to be separated therefrom when it is necessary to move them to a new block. A mixture of peat fibre and Sphagnum-moss was affixed, by means of thin copper wire, to the blocks as a rooting medium. The plant in question is one of several grown thus in a roomy plant stove at Byram Park in this county, being suspended at a distance of about 3 feet from the roof glass. During the growing season these blocks require dipping in the water-tank almost daily, and they are regularly sprayed over with the syringe when the house is closed for the night. For placing in a lady's boudoir or drawing-room where there is an equable tem-

perature of from 55° to 60° no other floral object can be more appropriate at this time of the year. This note is not meant for Orchid specialists, but for that larger class of plant-lovers who, having a plant-stove at command, wish to grow a few good Orchids in it. *Yorkshire Gardener*, December 7.

methods of culture, except that during the summer months all the flower-heads were pinched off. The shoots were also pinched down to about 2 feet 6 inches from the ground, as I supposed the pinching might encourage the formation of tubers, but the result was no better. Our seed came from the Consul-General at Rome, and no doubt it is the correct variety. The experience of other cultivators of this *Fennel* would no doubt interest other readers. *R. B.*

ERYNGIUM PANDANIFOLIUM.—Those who are looking for something uncommon to plant in the herbaceous border, would do well to give this plant a trial. As its name implies, it is very like a *Pandanus*; the leaves of a well-grown plant are about 5 feet long, glaucous, concave, with spiny margins. It throws up high spikes of purplish flower-heads about 7 or 8 feet high, which, although not particularly pretty, always command attention. The group in these gardens threw up eight of these noble spikes last summer, causing many enquiries from visitors. It is described as being merely half hardy, but I should expect it to succeed in the south and west of England; it is certainly more hardy than the New Zealand Flax (*Phormium tenax*), as a clump of this in the same part of the garden was injured two winters back, whilst the *Eryngium* did not appear

old stubby besoms and large, hardwooded, feather-edged labels. When the pruning operation was completed and the prunings removed, all the moss-and-lichen-infested branches were syringed with hot, liquid lime applied to the trees through the garden engine, a calm day being chosen for doing the work. About a peck of new soot was stirred into the hot lime during the mixing in a 60-gallon tank, and the liquid was passed through a fine-meshed sieve into the engine before being applied to the trees. The men engaged in the work of mixing and applying the liquid lime to the trees wore white overalls. This dressing of liquid lime not only effectually rid the trees of the accretions indicated, but it also destroyed any insect larvæ that happened to be in the moss. The trunks of the trees, as well as the main limbs, were smeared over with the limewash, which was applied with an ordinary whitewash brush. In the case of dwarf-growing trees, the liquid lime could be applied through an ordinary garden syringe. The trees thus treated (at intervals of two or three years) always bore crops of fine fruit, free from the attacks of scab and other diseases to which neglected trees are subject. As regards the use of insecticides for destroying green and black aphides on trees in April and May, I used tobacco juice at the rate of 1 quart of nicotine juice to 4 gallons of water, this being applied to affected trees through a syringe late in the afternoon in calm weather. This spray not only destroyed the aphides then on the trees, but it also rendered the trees and foliage distasteful to the insects during the remainder of the year. The "sprays" described above are simple, perfectly safe, and effective in application. *H. W. Ward, Lime House, Raleigh.*

FIG. 29.—FISH-TRAPS ON A THAMES BACKWATER AT HEDSOR, BOURNE END.

(See p. 43.)

perature of from 55° to 60° no other floral object can be more appropriate at this time of the year. This note is not meant for Orchid specialists, but for that larger class of plant-lovers who, having a plant-stove at command, wish to grow a few good Orchids in it. *Yorkshire Gardener*, December 7.

ITALIAN FENNEL OR FINOCHIO.—I was much interested in the note on Italian Fennel that appeared in the *Gardeners' Chronicle*, December 19, p. 433, and hoped that the note might lead others to give their experience on the subject. For two years I have tried, without success, to grow Fenchio. In April, 1907, I sowed two batches of seeds—one sowing being made out-of-doors, the other in 5-inch pots. The seedlings were thinned to one in each pot, and they were planted out as good strong plants by the middle of May, into well-prepared, shallow trenches at distances of 3 feet between the trenches and 18 inches between the plants in the rows. Both sets of plants grew strongly, and had soil drawn up to their stems in September. In November and December when lifted there were no tubers, only fleshy tap-like roots quite useless for culinary purposes. In 1908 I tried again similar

to suffer. It is especially effective if planted on the lawn, whether as a single specimen or in a group. *A. J. Elgar, Killarney House Gardens, Co. Kerry.*

SPRAYING FRUIT-TREES.—For many years a good-sized orchard, situated in a portion of the Home Park, half a mile from a garden in the Avon Valley (Wilts.), was included in my charge. The trees, mostly Apples, were of immense proportions, requiring the aid of long ladders in gathering the fruit in early autumn. The trees had not been pruned for many years prior to my taking charge of them, consequently the branches had become infested with moss, lichen and other undesirable accretions. Therefore, when the trees had shed their leaves in the autumn, I had the branches well thinned out with a pruning saw, cutting out all ill-placed and unpromising growths in order to admit plenty of light and air among the branches retained for bearing fruit, but without in any way reducing the external dimensions of the trees. While the work of thinning-out the branches was being carried out, another staff of men followed on with the cleansing of the trees, removing the moss and lichen from the trunks and main branches with

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 12.—The first meeting in 1909 was held on this date in beautiful weather. It was a small exhibition, but it included several groups of Orchids, a magnificent display of stove and greenhouse plants, groups of Carnations, Alpine flowers, and Ferns.

The FLORAL COMMITTEE granted two Awards of Merit to new plants. The ORCHID COMMITTEE granted one First-class Certificate and three Awards of Merit. A variety of Pear named *Blickling*, which had already received the minor award, was granted a First-class Certificate by the FRUIT AND VEGETABLE COMMITTEE.

It was regrettable that only one stand of Grapes was entered in the new competitive classes for these fruits, probably because the announcement of these fortnightly competitions was not made sufficiently early.

At the afternoon meeting of the Fellows a lecture on "The French System of Intensive Cultivation" was delivered by Mr. C. D. McKay.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. H. B. May, Jno. Green, Jas. Walker, E. A. Bowles, G. Reuthe, R. Hooper Pearson, Walter W. Ware, W. Howe, Jno. Jennings, Jas. Hudson, N. F. Barnes, Arthur Turner, Chas. Dixon, H. J. Jones, J. F. McLeod, Herbert J. Cutbush, F. Page Roberts (Rev.), Chas. E. Pearson, E. H. Jenkins, W. J. James, George Paul, W. A. Bilney, R. C. Reginald Nevill, and C. T. Drury.

A magnificent group of ornamental-leaved and flowering plants was staged by Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea. It was similar to the fine displays that are made by this firm each year at the Temple Flower Show, but larger, as more space was available. The brilliant colouring and general high culture exhibited by the plants were subjects of remark, and the manner of their staging was exceptionally pleasing. A background was formed of *Cocos flexuosa*, and against these plants were arranged tall specimens of *Dracana Veitchii*, *D. Goldieana*, *D. Sanderiana*, *D. Victoria*, *Diefenbachia Fournieri*, *Heliconia illustris*, *Phoenix humilis Roëbelinii*, and other handsome foliage plants. The group also included a superb example of *Anthurium crystallinum* and specimens of *Alpinia Sanderiana*, *Davallia dissecta*, *Tillandsia tessellata*, *Alpinias* in variety, *Aralias*, *Pandanus*, *Selaginellas*, with a host of Ferns and

other graceful foliage plants. Tall stands carrying densely pitched plants of *Nepenthe Chelssonii* excellens, *N. Dicksoniana*, *N. Morganæ*, and other species served to break the continuity of the groundwork, whilst standard plants of *Codiaeums* and *Aralias* also furnished relief. Bright patches of colouring were afforded by groups of Orchids, *Coleus thyrsoideus*, *Crowea latifolia*, *Begonias*, *Primula* \times *kewensis*, *Camelias*, greenhouse species of *Rhododendron*, *Acacia leprosa*, and *Gomphia olivæformis*.

The same firm exhibited as a separate group plants and cut blooms of Carnations of the perpetual-flowering type. (Gold Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, exhibited a collection of Ferns, all of which had some peculiarity of habit or growth, the group being labelled curious Ferns. There were climbing species, others with such dense crests as to be totally different in appearance to the types represented. Many belonged to the so-called flowering species, in which some of the leaves are wholly concerned with spore formation. Some species, such as *Hymenodium crinitum*, a plant known as the Elephant's Ear Fern, were densely covered with hair. *Drymeria quercifolia* has leaves of two forms; the basal fronds resemble large Oak leaves, and are simple, but the fertile fronds are 3 feet in height and pinnate. Many of the species of *Polypodium* and *Drymoglossum* have long trailing rhizomes, which enable the plants to climb. Sometimes the rhizome is short and thick, resembling a hare's foot. *Oleandra articulata* has leaves similar to *Scolopendrium vulgare*, but they arise from long rhizomes. From these latter are given off long hair-like roots, and when these reach the rooting medium they bind the plant to the soil. (Silver-gilt Flora Medal.)

Some very fine Carnations of the perpetual-blooming type were shown by Mr. W. H. PAGE, Tangley Nurseries, Hampton. Most of the popular kinds were included in the group, which also contained large bamboo stands filled with flowers of *Lilium Harrisii*. (Silver-gilt Flora Medal.)

Another pleasing exhibit of these flowers was shown by Messrs. HUGH LOW & Co., Bush Hill Park, Enfield. The same firm displayed a batch of the elegant *Dracæna Victoria*; also *D. Prince Albert*, *Cyclamen* in variety, a variegated-leaved variety of *Cobæa scandens*, *Daphne indica rubra*, &c. (Silver Banksian Medal.)

Carnations of the perpetual-blooming type were shown in variety by Mr. H. BURNETT, Guernsey, who had, amongst others, the beautiful variety named after Mrs. Burnett. (Silver Banksian Medal.)

ARTHUR W. SUTTON, Esq., Bucklebury Place, near Reading, exhibited plants of *Cyclamen* grown from corms collected by himself in Palestine.

Mr. L. R. RUSSELL, Richmond, Surrey, showed varieties of the handsome-leaved *Bertolonias* and a batch of small plants—all excellently berried—of *Ardisia crenulata*. They were highly decorative little specimens, specially suitable for the embellishment of dwelling-rooms. (Silver Flora Medal.)

Hybrid Freesias were displayed by Mr. HERBERT CHAPMAN, High Street, Rye, Sussex. Varieties with a suffusion of citron colour were very pleasing; a few were tinted were shades of rose and lilac.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., arranged a pretty exhibit of Alpine plants in a setting of virgin cork; early-flowering subjects such as *Irish Hystrio*, *I. histrioides*, *Adonis amurensis*, *Cyclamen Coum*, *Colchicum hydrophilum* were planted in "pockets," with berried plants of *Pernettya*, *Aucuba japonica vera* and *Skimmia Fortunei* intermixed. At the back of the group were sprays of *Hamamelis arborea*, and the variety *Zuccariniana* (which has paler coloured petals than the type); *Daphne Mezereum* album. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, showed early-blooming species of hardy plants, including Snowdrops of the large-flowered *Elwesii* type, *Crocus etruscus*, *C. imperatii*, *C. Sieberi*, *Cyclamen Coum*, *Tulipa saxatilis*, *Iris unguicularis*, *I. reticulata*, *Helleborus niger* *Scoticus*, *H. n. angustifolium*, *Lachenalia*, and *Freesias*.

The Misses HOPKINS, Mere Gardens, Shepperton-on-Thames, arranged a small rock-garden exhibit.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., showed boxes of Alpine plants, principally species of *Saxifraga*; also a batch of flowering plants of *Primula obconica* of a selected strain. The exhibit had well-berried sprays of *Skimmia japonica* at the back.

AWARDS OF MERIT

were recommended to the two plants mentioned below:—

Begonia \times *Patric*.—This was shown by MM. M. V. LEMOINE ET FILS, Nancy. It is described as being from a cross between *B. socotrana* δ and a variety of *B. Pearcei* σ . The hybrid partakes more of the habit of *B. socotrana* than *B. Pearcei*. The plants shown were about 10 inches high, and compact in habit. The flowers were rather small, the petals being short. In colour they are rich rosy-pink, but by reason of the bright yellow anthers, they appear to have an orange shade. The foliage resembles *B. socotrana*. So far, the plants have not formed proper tubers, but rudimentary ones such as are common to the winter-flowering *Begonias* raised from crosses made between tuberous-rooted varieties and *B. socotrana*.

Chrysanthemum Maud Allan.—This is a pure-white Japanese decorative variety. The florets appear rather narrow, being slightly revolute at the margins. The value of this variety rests upon its late blooming quality and purity in colour. Shown by Mr. N. MOLYNEUX, Wickham.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, H. Little, W. Boxall, J. Forster Alcock, J. Wilson Potter, F. J. Hanbury, A. A. McBean, F. M. Ogilvie, C. H. Curtis, W. Cobb, H. G. Alexander, J. Charlesworth, H. J. Chapman, W. H. White, W. P. Bound, A. Dye, H. A. Tracy, H. Ballantine, Gurney Wilson, and C. J. Lucas.

Lt.-Col. G. L. HOLFORD showed a selection of hybrids, together with a grand specimen of the pure white *Vanda Watsonii* with four spikes. *Brasso-Cattleya* Mrs. J. Leemann variety *Rajah* has primrose-yellow and rose-coloured flowers.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. Collier), was awarded a Silver Flora Medal for a most interesting group, including Gatton hybrids, rare varieties of species and singular botanical Orchids. The best of the hybrids included *Cymbidium* *Lady Colman*, an elegant and delicately-coloured flower; the fine white *Cœlogyne Colmanii*, and *Spathoglottis Colmanii*, this latter being a very handsome yellow and crimson variety. The showiest plants included a selection of varieties of *Lælia anceps*. The most distinct was *L. a. Gatton Park* variety, with white flowers having the blue tint on the lip peculiar to several other albinos in the Gatton Park collection. Other varieties were *L. a. Hilliana* *Rosefeldensis* and *Cymbidium grandiflorum*.

Sir TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), showed a fine spike of a showy hybrid *Odontoglossum* resembling *O. Wilckeanum*, but of a deep mahogany-red colour with white margins and tips to the petals; also a *Maxillaria* resembling *M. callichroma*.

Messrs. CHARLESWORTH & Co., Haywards Heath, were awarded a Silver-gilt Flora Medal for a group which included a fine batch of white *Lælia anceps*, a number of the pretty *Cattleya Octave Doin*, and a selection of hybrid *Cypripediums*. Other good plants in this collection were the scarlet *Sophro-Cattleya Doris*, the massive *Cymbidium Holfordianum*, *Brasso-Cattleya Queen Alexandra*, the pure-white *Odontoglossum ardentissimum* album, *Saccolabium bellinum*, and a selection of hybrid *Odontoglossums*.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, secured a Silver Banksian Medal for a group of *Odontoglossums* and *Cypripediums*. Among these were *C. insigne* *E. J. Seymour*, a very distinct form of good shape; *C. Minos Youngi* variety, *C. Helen II.* and *C. triumphans*.

Messrs. JAS. VEITCH & SONS, Chelsea, in their magnificent group of fine foliage plants, already noticed, had two small groups of hybrid *Cypripediums*. Among the showiest were their varieties of *C. Coum* and *Carnarvon*. A small group of *Odontoglossums* and *Lycastes* was also included in the group.

Messrs. J. & A. A. McBEAN, Cooksbridge, staged an effective group composed principally of *Cypripediums*, the specimens of *C. Memoria Jerninghamia*, *C. aureum excelsum*, and *C. Thompsonii superbum* being very handsome. Other specially fine plants in the group were forms of *Cattleya Trianae*, including one with white flowers having a bright purplish blotch on the lip; a superb form of *Lælia anceps Schröderæ* of rich colour and of the shape of good typical *L. anceps*, and a clear white *Odontoglossum*.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent *Sophro-Cattleya* Mrs. Francis Wellesley, the plant being the sole seedling raised from a cross between *Sophrontis grandiflora* and *Cattleya labiata*. The plant is small and bore a flower resembling *Sophro-Cattleya Doris*. It was of good size and shape and of a peculiar shade of carmine-red, with an orange-tinted base to the lip, which has red veining.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), showed *Cypripedium Actæus* *Oakwood* variety (*Leeanum* *Clinkberry-anum* \times *insigne* *Harefield* Hall), a large and finely-formed flower; and *Odontoglossum ardentissimum* var. *Norman Cookson*. (See Awards.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a selection of *Cypripediums* which included *Cypripedium Helen II.* var. *Armstrongia*, *C. aureum Surprise*, *C. Maudia*, and two good seedlings of *C. insigne*.

Mr. A. W. JENSEN, Lindfield, showed a small group of *Odontoglossum crispum*.

H. J. BROMILOW, Esq., Rann Lea, Rainhill, Lancashire (gr. Mr. Morgan), showed *Cypripedium Aeson giganteum* in excellent form; also *C. Charlesworthii Bromilowia*, a charming albino with pale green and pure white flower. It differs in form from *C. Charlesworthii Bromilowianum* which secured a First-class Certificate and was illustrated in the *Gardeners' Chronicle*, October 31, 1908, p. 310.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), showed *Maxillaria Hubschii*, and a very fine specimen of *C. Fulshawense*.

Mons. MERTENS, Ghent, staged a selection of hybrid *Odontoglossums*.

C. J. LUCAS, Esq., Warnham Court (gr. Mr. Duncan), showed *Cypripedium Alciabades* *Chardwar* variety, and the curiously-striped *C. Harlequin*.

WALTER COBB, Esq., Rusper (gr. Mr. C. J. Salter), showed a hybrid *Cypripedium* from *C. insigne* *Sanderæ* \times *C. bellatulum* album.

HENRY LITTLE, Esq., Barons Halt, Twickenham (gr. Mr. Howard), sent the pretty and distinct *Cypripedium insigne Little's* variety.

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Black), showed *Cattleya Leda* *Thwaites' variety* (*Dowiana aurea* \times *Percivaliana*), a very pretty, rosy-lilac flower, with gold veining in the lip.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Percivaliana Charlesworth's variety.—A charming pure white flower, with a deep reddish-purple blotch on the front of the lip, and a chrome-yellow disc.

AWARD OF MERIT.

Cattleya Maggie Raphael "Westonbirt variety" (*C. Dowiana aurea* \times *C. Trianae Imperator*).—A beautiful and finely-shaped flower, of a delicate rose tint, the petals having a fine silvery-white veining. The front of the lip is of a glowing, deep, rosy-crimson colour, the base being tinged with purple and netted with golden veining. From Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander).

Vanda Watsonii.—An elegant species, allied to *V. Kimballiana*, but with pure white flowers. The plant bore four spikes. From Lt.-Col. G. L. HOLFORD.

Odontoglossum ardentissimum Norman Cookson, from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman).—A compact flower, having equally broad sepals and petals, white, with two-thirds of the flower heavily blotched with violet-purple.

CULTURAL COMMENDATION to Mr. H. Ballantine, gr. to Baron Sir H. SCHRÖDER, The Dell, Egham, for a large plant of *Masdevallia ignea*, bearing upwards of 70 flowers.

REMARKS.—The demand for American Apples remains good. There is also an improved sale for California Newtown Apples. Oranges generally are arriving in a bad condition: best samples sell freely. English Grapes are a good trade and their prices remain firm. Canary Tomatoes are arriving in a splendid condition. Prices generally for vegetables are lower. English Rhubarb has very little demand. Trade in all departments is very bad. E. H. R., Covent Garden, Wednesday, January 13, 1909.

REMARKS.—Trade is very steady and there is no alteration in prices. Stocks in London are increasing daily. Edward J. Newborn, Covent Garden and St. Pancras, January 13, 1909.

COVENT GARDEN FLOWER MARKET.

During the past week supplies have not been excessive and, in most instances, prices have advanced. Yet trade has not been very brisk. Many growers will not be marketing produce until their spring plants are ready. Bulbs and Azaleas are the more prominent subjects at the present time. French flowers are numerous; these are not all sold in the new market which was built specially for the purpose, and French flowers are a prominent feature in the ordinary flower market. What may be termed a retail trade is done by some salesmen in the flower market, and at the same prices as are charged to florists for larger quantities. At one time the growers would not sell produce except to persons engaged in the trade.

POT PLANTS.

Except in the case of bulbous plants and Azaleas, supplies are limited. Erica melanthera is seen in the market, and there are some fairly good plants of E. gracilis obtainable. Genistas are very good, also Marguerites in plants of various sizes. Another prominent subject is Begonia Gloire de Lorraine. Spiraea are not quite so abundant as they were a few weeks ago. A few Cinerarias are seen, but I have not included them in the price list. Narcissus in pots may be had, the variety being Obvallaris. Hyacinths improve in quality: the early white varieties are the best. Tulips are almost wholly sold in boxes, from which they can be easily transferred to pots or vases. Lily of the Valley can also be transferred to other receptacles from boxes without suffering much check. Lilioms of various kinds, Solanums and Chrysanthemums are seen, but best plants of Poinsettia (Euphorbia) are no longer procurable. Foliage plants, including Aspidistras and Kentias, are well supplied. There is usually a shortage of best plants of small Ferns at this season.

CUT FLOWERS.

During the past week there has been rather a better demand for flowers, and supplies generally have not been so large, except in the case of Carnations. Roses are well supplied; the variety Ulrich Brunner on long stems is worth 8s. per dozen blooms. Chrysanthemums are plentiful. Best quality blooms of Lilium are realising high prices, but ordinary blooms are very cheap. Callas are plentiful and good; fairly good prices are sustained for this flower. Azalea Fiederli, Camellias, Eucharis, and Tuberoses are all plentiful. Gardenias are dearer.

French flowers have been plentiful during the past week. A. H., Covent Garden, Wednesday, January 13, 1909.

BELLADONNA LILY IN POTS: *Bella*. It is not possible to obtain flowers of Amaryllis Belladonna in January unless the bulbs can be retarded, as is done in the case of Lily of the Valley crowns and many Liliums. As you say your bulbs flowered grandly in October last year, they can hardly be expected to flower again now, only three or four months afterwards. The foliage which you say the pot bulbs are now producing in abundance is already showing on those cultivated out-of-doors. If the Belladonna Lily is cultivated in pots in the same way as Hippeastrums, it may be obtained in flower during August and September. The best time to pot the bulbs is in June or July, when the roots become active. We would suggest that you grow a large batch of Hippeastrums (Amaryllis) to flower at the present time. This can be done easily by starting the bulbs early in December in a temperature of 60° to 65° and a bottom heat of 70° Fahr.

BROCCOLI DISEASE: *D.* The disease affecting the leaves of the Broccoli is due to a fungus—*Sphaerella brassicaecola*, a difficult pest to get rid of. Spray the plants either with weak Bordeaux mixture or with potassium sulphide, using the latter in preference to the former if the Broccoli are fairly well advanced in growth.

GRUB ATTACKING CARNATIONS: *Dumas*. The insect that had burrowed in the stem of your Carnation is probably the grub of an Anthomyid fly. But it had become damaged in transit, and correct determination was impossible. Please send another specimen. In the meantime remove all shoots containing grubs and burn them.

HORTICULTURAL INSTRUCTOR: E. H. T. Appointments as instructors in horticulture to school gardens under the Education Department of the various counties are not numerous. They are, as a rule, advertised in the gardening papers. The candidate is expected to have a general knowledge of the theory and practice of horticulture, and evidence of his capacity to teach is usually required. In addition he must have a good general education and possess satisfactory references as to his conduct and abilities.

LANCASHIRE CROWN BOWLING GREENS: *Hortus, New South Wales*. The distinguishing feature of these bowling greens is that the centre, or, as it is termed, the crown of the green, has a rise of from 6 to 12 inches from the outside portions. The players may bowl from any point of the green, except along the immediate edge of it. In the Scotch greens, or rinks, the bowls can only be trundled from given points. In laying out a bowling green, it is absolutely necessary to ensure perfect drainage. The means taken to obtain this will vary slightly, according to the nature of the soil. The following method has been adopted with success in the Liverpool parks and recreation grounds where 22 greens are provided for the game of bowls.—A trench is made 12 feet in width, and in the bottom of this is placed a layer, 4 inches in depth, of clinkers. On the top of this are placed the old turves taken from the top of the next trench. The sods are placed grass-side downwards, and they prevent the clinkers used as drainage material becoming choked with the finer soil. Above this layer of turves is placed soil to the depth of about 12 inches. After careful leveling this is covered with a layer of sea sand about ½ inch deep. Another trench, 12 feet in width, is dug out, and the process repeated until the bowling green is made. When all is well settled down and the surface again levelled, it is covered with the finest turf procurable. Subsequent rolling, top-dressing, and cutting must be given regular attention, in order to induce a growth of close, fine grass.

NAMES OF FRUITS: J. L. 1, Glou Morceau; 2, Hacon's Incomparable; 3, Uvedale's St. Germain.

NAMES OF PLANTS: A. W. Ornithogalum lacteum.—*Pine*. The Monterey Pine, Pinus insignis.—J. M. 1, Cypridium Calypso; 2, C. Harrisianum; 3, C. villosum.—H. H. B. 1, Selaginella Wildenovii; 2, Lastrea rigida; 3, Adiantum cuneatum; 4, Pteris longifolia.—*Hillfield*. A species of Tillandsia; send again when in flower.—H. H., Canterbury. 1, Salvia gneseraeflora; 2, Mimulus (Diplacus) glutinosus; 3, Codium (Craton) interruptum; 4, C. angustifolium maculatum.—W. H. B. Plantago Coronopus, a native species common in some districts. It will probably succeed under trees. We do not know where you can obtain seeds.

PEACH ROOTS UNHEALTHY: J. R. P. We find no sign of fungus disease in the roots. It is possible that they were attacked by eel-worm when very young, and that this attack, from which the specimens sent have recovered, has produced the malformations.

PRONUNCIATION: F. B. In this country the pronunciation of Latin specific words usually follows the ordinary English usage. Thus, gîgâs (g is hard), violâcêa (the â as in "date"), to quote your own examples.

VIOLETS DISEASED: W. H. W. The fungus attacking the leaves of the Violet is probably Cercospora violæ. Spray the plants with dilute Bordeaux mixture. It is doubtful whether the flower-buds will develop into good flowers, as the leaves are so badly attacked. Burn all the diseased leaves. Before using the frames again for Violet culture they should be disinfected and furnished with fresh soil.

THE WHORTLEBERRIES AND CRANBERRIES.

IN the middle years of last century a place given up solely to peat-loving plants was not an uncommon feature in the old-established and more famous gardens of the time. It was sometimes termed an Ericetum, sometimes an American Garden, and in it the Vacciniums and their allies occupied a not unworthy place. No grouping of shrubs could, one would imagine, be more pleasing than this. The usually neat and often dainty habit of the plants, their abundant and brightly-coloured flowers, the fine autumn colouring of many of the deciduous species, and, in the case of the Vacciniums, their handsome fruits, present together a sum of attractions which few other groups can equal. But the Ericetum had its day. Perhaps the formal or "geometric" arrangement that was usually preferred hastened its end. In some of these old gardens a few of the plants still survive on their ancient sites, the bulk of them having disappeared and but little trace of the original design remaining. Even now such places have a singular charm with their informal grouping of old Azaleas, Heaths, Vacciniums, and the like, rising from smooth, verdant lawn, and, pervading all, a sense of

age and dignity. I have a memory of such a spot in the romantic grounds of Dunkeld set amidst glorious trees and where the music of the hurrying Tay is ever in one's ears. At Castle Kennedy, too, there is still a fine collection of Ericaceous plants, many of large size.

The Vacciniums cannot lay claim to the exceptional attractions of Rhododendrons and Azaleas. Their charms are of a more subdued kind, and consist, chiefly in their neat, close habit and handsome fruits, and in their occasional rich autumnal colouring. The genus comprises at least 100 species, which are distributed over the northern parts of Europe, Asia, and North America, and occur also in considerable numbers on the mountains of South America. About a score of species have been introduced that can be grown out-of-doors in England, and three species are native. No race of plants is more characteristic of the lone places of the northern hemisphere. There is scarcely a moor or mountain side they do not help to cover.

The Natural Order to which they belong and to which they give the name—Vacciniaceæ—is represented in gardens by three other genera of hardy plants, viz., Gaylussacia, Oxycoccus, and Chiogenes. They are very frequently merged with the Heath family—Ericaceæ. The chief botanical difference between the Vacciniums and the Heaths is in the relative position of the corolla and ovary. In the Vacciniums and their allies the corolla is superior; in the Heaths it is inferior.

The Cranberries (Oxycoccus) differ from Vaccinium in their prostrate habit, wiry stems, and in the distinct form of the corolla, which has four comparatively long, narrow, reflexed segments. Chiogenes—of which there is but one species—is similar to Oxycoccus in habit, but has small, bell-shaped flowers and white fruits.

The Vacciniums prefer a soil of a peaty and sandy nature, but, provided lime is absent, almost any soil can be adapted to their needs by adding decayed leaves; they also like a naturally moist position. For Oxycoccus and Chiogenes the position may be semi-boggy. The Gaylussacias are not dealt with in the following notes.

VACCINIUM.

V. ARBOREUM (FARKLEBERRY).—This striking species is not often seen in cultivation now, although it exists in the Kew collection, and some years ago I noticed it in Mr. Anthony Waterer's nursery at Knaphill. As its name implies, it is a tree in its native home, which is the South-Eastern United States. According to Targent, it attains its largest size in Eastern Texas near the coast, where it is, occasionally, 30 feet high, with a trunk 8 to 10 inches in diameter. It has never got beyond the dimensions of a shrub in England, although it is recorded by Loudon to have been 10 feet high in the walled garden at White Knights. Probably it is only its most northerly form—the one found in the mountain valleys of North Carolina—that is hardy here. The leaves are evergreen, ovate or oblong, $\frac{3}{4}$ to $1\frac{1}{2}$ inches long, very slightly toothed, smooth and shining above, downy beneath. The flowers are gracefully pendent from slender stalks, and are either produced singly from the leaf axils

or in terminal racemes; the corolla is white, $\frac{1}{2}$ inch wide, bell-shaped, with five angular lobes. The berries are globular, $\frac{1}{4}$ inch in diameter, shiny black, with a dry, rather astringent flesh. The species was originally introduced to Kew by Mr. John Cree in 1765. It flowers freely during July and August, and is one of the prettiest shrubs in blossom at that season. The arborescent and more tender form from Florida would be well worth trying in Cornwall and similar localities.

V. ARCTOSTAPHYLOS.—So nearly allied is this species to V. padifolium that some authorities have made them forms of one. The true padifolium, however, is a native of the mountains of Madeira, whereas arctostaphylos comes from the Caucasus. It has larger leaves (the largest, indeed, of all hardy Vacciniums) and it, apparently, grows more freely than the Madeira plant. This interesting species is deciduous, and grows at least 10 feet high. Its leaves, which have an ovate-lanceolate outline, are sometimes 4 inches long and $1\frac{1}{2}$ inches wide, but their average length is 2 inches; they are finely toothed, dull dark green above, paler beneath and pubescent on the veins. The flowers usually hang from the lower side of short racemes produced in May from the naked wood of the previous year's growth. I have also seen them in September in the leaf axils of the current year's growth, but this was probably exceptional. The fruit is black and very palatable. An interesting theory, based by Sir Joseph Hooker on the geographical distribution of this species and its Madeiran ally (together with some other plants) is referred to in the note on the latter.

V. CANADENSE (CANADIAN WHORTLEBERRY).—Kalm, the Swedish traveller, who journeyed extensively in the Eastern United States in 1748, was the first to bring this species to the notice of botanists. It is a low, much-branched, deciduous shrub, with downy foliage and young wood. The leaves are from $\frac{3}{4}$ to $1\frac{1}{4}$ inches long, lanceolate, and dull green. It flowers in April, and the blossoms appear, four to six together, in a short, subcorymbose raceme, the corolla being short, campanulate, white tinged with red. The fruit is blue-black and very palatable; it is sent in large quantities to the markets of some of the North-East American towns. The species somewhat resembles V. pennsylvanicum, but differs in its much more hairy foliage and young shoots and its quite entire leaves.

V. CÆSPITOSUM (TUFTED WHORTLEBERRY).—So far as I know, this interesting little plant no longer exists in this country. If any reader of the *Gardeners' Chronicle* still possesses it, we should be glad to know of its whereabouts. It is one of the dwarfiest of Whortleberries—sometimes only 2 or 3 inches high—of tufted habit, and quite devoid of pubescence. Its leaves are obovate, toothed, and from $\frac{1}{4}$ to $\frac{3}{4}$ inch long. Loudon records its existence in the Glasgow Botanic Garden 70 years ago, where it is said to have produced numerous "exceedingly delicate and beautiful" flowers, white with a blush tinge. The berries are blue-black. The species has a wide distribution over North America, being found in regions as far apart as Labrador and the Rocky Mountains.

V. CORYMBOSUM (SWAMP BLUEBERRY).—Of all the exotic species, this is the commonest in gardens. It is one of the best growers of

the genus, and its leaves before falling often turn a fine red colour. Widely spread over Eastern North America and extending from Newfoundland as far south as North Carolina, it is one of the most variable of the species; at least a dozen forms or varieties being known. In the most suitable situations it grows 7 or even 10 feet high, and is often found in swampy ground or along the borders of watercourses. The leaves vary much in size according to the variety, or the vigour of the branch on which they occur; occasionally as much as 4 inches long by $1\frac{1}{2}$ inches wide, they may often be seen scarcely 1 inch in length; they are entire, pubescent on the midrib and veins beneath. The flowers are produced on the terminal part of the shoots of the previous year which remain without leaves, the new shoots springing from below the flowering portion. The corolla is narrow, cylindrical, white tinged with rose, and the fruit is black. It is said in North America to have a pleasant acid flavour. Several of the American "blueberries," once regarded as distinct species, have been reduced to varieties of *V. corymbosum*; they include *amoenum*, *fuscatum*, *marianum*, and *virgatum*.

V. CRASSIFOLIUM.—Although this species—a native of the South-Eastern United States—was introduced to England as long ago as 1787, and is now in the Kew collection, it is by no means common. This is due probably to its being rather tender. It is a trailing, evergreen shrub with thick oval leaves, little more than 1 inch in length. The white or rosy-coloured flowers are borne during May and June in short clusters, and are succeeded by black berries. It occurs wild from North Carolina southwards to Georgia.

V. ERYTHROCARPUM.—Besides its attractiveness as a garden shrub, this species is of peculiar interest in forming a connecting link between the Whortleberries (*Vaccinium*) and the Cranberries (*Oxycoccus*). It has the habit, foliage, and fruit of the former, but the flowers of *Oxycoccus*. It covers large areas in the higher Alleghanies, especially in North Carolina, where it grows to a height of 8 or 10 feet. The late Mr. George Nicholson collected it on Roan Mountain in 1893. It is one of the species known as Bearberries in the United States, on account of the fondness of bears for the fruit. First introduced to this country by the firm of Loddiges in 1806, it has never become common, although it was once thought that it might be worth a place in the fruit garden. It is a deciduous shrub, with ovate, pointed leaves 1 to 3 inches long, the margins set with fine, bristly teeth. Whilst young the leaves are tinged with red. The flowers appear singly in the leaf axils, borne each on a slender pendulous stalk. The corolla has the typical *Oxycoccus* form, with its four deep, narrow lobes curled back so as to leave the stamens standing up close together in a sort of erect column. The fruits are first green, then scarlet, finally black. At Kew they have a sweet, acid, and somewhat insipid flavour. Possibly they need the brighter sunlight of the Eastern United States to bring out their best qualities.

V. GLAUCO-ALBUM.—The only private garden I know to contain this species is that which belonged to the late Mr. Thomas Acton at Kilmacurragh, Co. Wicklow. Unfortunately, it is not hardy except in such warm localities as Kilmacurragh. Although Mr. Acton gave it to the Kew collection more than once, it has never succeeded there in the open ground or even

FIG. 30.—FROND OF ADIANTUM GROSSUM AS SKETCHED BY MR. WORTHINGTON SMITH.

Portion of pinnae magn. 2; spore and spores mag. 120.

(See p. 51.)

survived more than a single winter. It is a Himalayan species, being found in Sikkim at 9,000 to 10,000 feet altitude; also in Bhotan. It is a low shrub, remarkable chiefly for the intense glaucous bloom of the under-surface of the leaves, which are ovate-oblong, up to 2½ inches in length; firm or even rather hard in texture. The flower racemes are 2 to 3 inches long, and are rendered conspicuous by large blue-white bracts, which remain until the fruit is ripe. The corolla is white tinged with pink, and the fruits, each ¼ inch in diameter, are covered with the glaucous bloom so characteristic of the plant. *W. J. Bean.*
(To be continued.)

CULTURAL MEMORANDA.

FREESIAS AT CHRISTMAS.

FOR several seasons past we have not failed to produce a batch of *Freesias* at Christmas, and at the present time we have about 100 pots of these plants in bloom. These have been grown entirely without artificial heat, excepting on a few occasions, when the houses were

frames until frost appears, when they are removed to a structure from which frost can be excluded. A light shelf in a Peach house is suitable. Our first batch of plants was in flower at the beginning of December.

When flowering is over, the plants are placed on shelves in an early vinery, and they are given liquid manure and soot water to assist in maturing the bulbs, which I regard as one of the chief factors towards the successful culture of these plants. As the leaves begin to turn yellow, water is gradually withheld, but the plants are allowed to remain on the shelves in the vinery, where they are fully exposed to the sun. The bulbs thus become thoroughly ripened by the time they are required for their annual repotting. *Wilmot H. Yates, Rotherfield Park Gardens, Alton, Hants.*

CULTIVATION OF ACALYPHA HISPIDA (SANDERIANA).

THE cultivation of this plant is in no sense difficult, but at the same time it should not be treated as the Cinderella of gardens. Sometimes it is treated as a semi-aquatic and stood in a saucer of water.

Naturally, the plant, mismanaged after this

in the spring and summer months cuttings should be struck in November, December and January, and for later purposes March, April, and even May are suitable months. As soon as the cuttings have formed small roots, remove the lights from the propagating cases, and, when the roots have permeated the soil, take the plants out of the bed, and shortly afterwards re-pot them into large 60's in pure leaf-mould and the quantity of sand usual for potting purposes. Place them near the glass in a warm house. Unless this last rule is followed there is the danger of the cultivator having plants a yard in height and with few or no flowers. The plants as soon as they are well-rooted should be re-potted, and this should be repeated four or more times before full development; at each re-potting making use of the smallest pot possible. At the last shift it is well to employ a small quantity of artificial manure, or, if this is not done, apply manure water of a mild nature with great caution and for the most part during hot weather, when also the plants may be syringed lightly. If the syringing is done during dull weather the cells of the leaves, becoming distended with sap, rupture, and thus a diseased, rusty appearance is induced. This appearance is by some erroneously considered to be the symptom of a fungal disease. When the leaves are in this state it is advisable to ventilate abundantly, afford water in moderation and syringe sparingly. When the plants are in flower, syringing should be discontinued and the glasshouse kept moist by sprinkling the paths and walls, paying attention to the ventilation, as a warm, close atmosphere is injurious.

Frame cultivation cannot be recommended, the gardener then not having full control over aerial moisture and temperature. *Extract from Die Gartenwelt, No. 2, 1909.*

ADIANTUM GROSSUM.

WE are indebted to Messrs. F. Sander & Sons for the introduction of this handsome Fern from New Granada. Although discovered over 40 years ago by Alexander Lindig, and described and figured in various works since, living examples do not appear to have ever before been sent home. That the species is worth the attention of Fern collectors is evident enough from the drawing prepared by Mr. Worthington G. Smith (see fig. 30), from material supplied by Messrs. Sander, and that it is easily cultivated in a warm house has been proved both at St. Albans and Bruges. *A. grossum* belongs to a section of the genus which is characterised by simply pinnate fronds, and is represented among garden Ferns by *A. lunulatum*, *A. caudatum*, *A. Kaulfussii*, and *A. Balfourii*. In length of frond and size of pinnæ it is by far the largest of them, dried specimens showing a frond 25 inches in length, with 25 pinnæ, the largest 2 inches by 1½ inches, almost leathery in texture, and coloured a rich green. So far as dried specimens and cultivated examples show, the pinnæ on the same frond do not vary much in size, nor is the frond elongated and proliferous at the apex, as in *A. lunulatum* and *A. caudatum*. It is most nearly allied to *A. Balfourii*, the Socotran species, but that has smaller fronds proliferous at the apex, with the pinnæ subcircular, in opposite pairs, and nearly sessile.

A. grossum grows on the Andes of New Granada, at from 3,500 to 7,000 feet, and may therefore thrive in an ordinary greenhouse temperature. It forms a dense tuft of fronds, which are gracefully curved when of full size. There are not many gardens nowadays in which exotic Ferns are collected and cultivated with the connoisseur's spirit, and yet there is, even in the genus *Adiantum* alone, a considerable diversity of form and habit, with, at the same time, much charm of pose and colour—characters which should attract the horticulturist who is one because he has a feeling for plants. *W. W.*

FIG. 31.—PLANT OF ADIANTUM GROSSUM IN MESSRS. SANDER AND SONS' COLLECTION.

warmed only to exclude frost. The plants are, in consequence, very robust, the foliage being about 2 feet in height.

The bulbs are potted during the early part of July. About seven bulbs are inserted in a 5-inch pot, or 10 bulbs may be placed in a pot one size larger. The compost consists of loam, leaf soil, a little cow dung and sufficient sand to keep the whole porous.

The pots are placed in a cold frame, and the soil is not watered till new growths appear, but a mat is spread over them, and this is sprinkled occasionally, and the surroundings kept moist. When shoots appear the mat is removed and the plants exposed to as much fresh air as possible. They are slightly shaded from hot sunshine. The lights are only placed on the frame when the weather is wet.

The plants are supported by a separate stick to each growth. It is important that the plants be staked early, otherwise the growths soon become bent and, consequently, spoil.

As the plants grow, increased room is given in the frame to prevent them becoming drawn. They are accommodated in the cold

fashion, produces small, yellow leaves and miserable blossoms, for aquarium-culture does not suit its needs. In particular, the plants must be kept free of all insect pests, and in the young state, therefore, before they commence to flower, they should be syringed frequently with Tobacco water or other insecticide. Afterwards, when the flowers have opened they need to be fumigated, using for the purpose Tobacco paper or the ribs of the Tobacco leaf which do not injure the flowers. As a means to avert attacks by thrips Tobacco ribs in some quantity should be laid on the hot-water pipes, and moistened frequently with water. Stock plants should be placed in a warm house, in order to get them into growth before the cuttings are taken. Cuttings must be neither too soft nor yet too small in the matter of leaves, or they will be late in rooting and capable of making few roots. When cuttings are taken from "cut backs" the gardener should wait until the shoots have formed their characteristic leaves. The cuttings should be placed singly in small pots in very sandy, turfy loam or leaf-mould, and the cutting pots plunged in a bottom heat of 75° Fahr. If good plants are required

SOME MOISTURE-LOVING PLANTS.

ON many estates there are to be found derelict bog and waste, marshy places, the initial cost necessary to convert which into positions suitable for the planting of moisture loving plants would prove but small. Even in gardens where such natural facilities for these plants do not exist, the difficulty may readily be overcome by the introduction of water basins, pools or ponds.

It is always a bad policy to economise in the use of constructive material. For the exposed parts of large ponds containing 4 to 6 feet of water a thickness of 6 inches of concrete is not too much, while in small basins holding a depth of 2 feet of water, a 3-inch layer of concrete is adequate.

The most suitable compost for filling the basins consists of loam and peat in equal parts, care being taken to avoid using soil containing any appreciable quantity of lime, from which many plants show a decided aversion.

The soil, when settled, should be of sufficient depth to allow a clear foot between the crown of the plants and the water level.

A selection of plants is given below. All will grow freely in wet ground, unless otherwise stated. The *Astilbes* are closely related to the *Spiræas*, and many are known in gardens as *Spiræas* :—

Astilbe chinensis, though an old plant in gardens, is still one of the best dwarf species. It produces a fine effect during July, when the pink plumes of flowers stand up in great sheaves. It somewhat resembles *Spiræa astilboides*, the plant largely employed in gardens for forcing purposes.

A. Davidii is of more vigorous growth, the shoots often attaining a height of 6 feet. The flowers are of a deep purple-red colour. There is a white-flowered form known as "grande" well worthy of extended planting.

Aruncus make stately specimens when well established by the waterside; the gigantic, snow-white inflorescences are freely produced in July. *A. palmata* has deep-crimson flowers borne in flattish heads; a pink-coloured form known as "elegans" and a white form, "alba," are equally good as garden plants.

Spiræa camtschatica (syn. *gigantea*) and its less vigorous pink variety, *rosea*, are tall-growing subjects reaching quite 10 feet in height.

Dimorphanthus mandschuricus gives a fine effect with its large, compound leaves measuring more than a yard in length. There is a variegated silver form and also a golden variety: the former promises to be a plant of great merit. The *Dimorphanthus* succeeds best planted in ordinary garden soil.

Iris aurea and *I. ochroleuca* both have strong, erect, sword-like foliage, and are often 6 feet high when in flower. *I. aurea* has bright, golden-yellow flowers, those of *ochroleuca* being creamy-white with a yellow throat. Both species flower late in July. *I. lævigata* (Japanese Iris) should be planted on a large scale in a bog garden. These Irises embrace many fine combinations of colours: the snow-white variety is a plant of rare beauty. *I. sibirica orientalis* is the best garden-form of this species: it produces more flowers of a richer colour and greater substance than those of the type.

Gunnera manicata, when planted in positions favourable to its development, often produces leaves 7 to 10 feet across. A well-grown clump makes an effective addition to a pond or lake.

Rheum palmatum tanguticum is the best variety of the ornamental Rhubarbs, and will grow in any ordinary soil. The planting of *Musa ensete* by the waterside introduces a distinct form of leaf; unfortunately, the plant is not hardy, but is readily raised from seeds

sown in the spring under glass; plants in their second year furnishing specimens 8 feet in height. This *Musa* succeeds in a deep, well-manured soil. Amongst the best species of *Primula* for this purpose are *Primula rosea*, with bright, rosy-pink flowers; *P. Sieboldii*, white and carmine; *P. japonica*, crimson flowers; and *P. sikkimensis*, a yellow-flowered species. *Primulas* are most effective if planted in bold masses.

Rodgersia podophylla has bronze-coloured foliage similar in shape to that of the Horse Chestnut. The bronze colour is enhanced in sunny positions.

Some species of *Senecios* are valuable plants for water-side planting. *S. japonica* has deeply-cut leaves and orange-yellow flowers, the latter borne in flat heads. *S. clivorum* flowers a fortnight later than *S. japonica*. The colour of its flowers is yellow, and the leaves are unbroken and circular in outline. *S. Wilsonii* has enormous, cordate leaves and yellow flowers in erect, branching spikes. *S. macrophylla* has distinct, glaucous-grey leaves, and produces erect spikes of yellow flowers.

Yucca recurvifolia should be given a prominent position, as the plant is very beautiful when in flower. It thrives in ordinary soil.

WINTER-FLOWERING IRISES.

IN addition to the well-known Algerian Iris (*I. unguicularis*), with its many beautiful varieties, varying in colour from the deep purple-blue variety *speciosa* to the pure white variety *alba*, there are a few species belonging to the bulbous section of the genus which flower during the winter months. These winter-flowering Irises deserve protection against the weather, and, although they may be grown in warm, sheltered nooks outside, where they will develop their beautiful flowers, they are liable to be spoilt by rain and frost. Therefore, a hand-light or piece of glass should be placed over the plants when in flower to preserve them from injury. It is, however, when grown in pots or pans in a cold frame or Alpine house that they are seen to better advantage. With the shelter thus given, they produce a longer succession of flowers and they develop better. For this purpose the bulbs should be potted up in the early autumn, using a mixture of light, sandy loam and leaf-mould. Until the flowers begin to show, the pots may be plunged out-of-doors in ashes, then they may be brought inside to develop. The earliest in flower is *I. Vartanii*.

FIG. 32.—IRIS ALATA FLOWERING OUT-OF-DOORS ON DECEMBER 10, 1908.

Phormium tenax atropurpureum may also be included in this list, as, by reason of its leafage, it provides a welcome addition.

Cortaderia argentea, the Pampas Grass, enjoys a rich soil, and produces its magnificent plumes of flowers during the late summer.

Arundo Donax, the Great Reed, is a native species that grows 8 feet high. The stems arise as a thicket of lances supporting peacock-like leaves. The old canes should never be removed before the spring.

Cyperus vegetus and *Glyceria spectabilis* variegata are two good foliage subjects.

Several dwarf shrubs succeed in wet ground and of these may be instanced *Clethra alnifolia*, which produces white racemes of flowers in autumn. The leaves of *Oxydendron arboreum* furnish beautiful colour-effects in autumn. The double-flowered form of *Spiræa prunifolia* is, in spring, wreathed with its snow-white flowers resembling small buttons; the foliage colours richly in autumn. *S. japonica* (syn. *callosa*) in all its forms succeeds in wet ground; the best varieties are *Anthony Waterer* and *S. j. rubra*. *Thomas Smith, Walmsgate Gardens, Louth.*

I. Vartanii.—This pretty species comes from Palestine, and usually commences to flower in November, continuing through December. It belongs to the *reticulata* section, with four-sided leaves, armed with a horny point, while the flowers are pale azure blue.

I. alata.—The well-known Scorpion Iris is one of the most valuable winter-flowering plants, producing a succession of beautiful flowers of various shades of colour during the winter months. In mild winters it may be grown with advantage outside in warm, sheltered spots, where it makes an effective display. Having a wide distribution over the Mediterranean region, the plants naturally show a considerable range of colour, varying from deep blue to pure white, relieved with a crest of yellow. The illustration at fig. 32 is reproduced from a photograph taken on December 10 in the Royal Gardens, Kew.

I. Bakeriana.—Although this species is not usually in flower till February, the pretty, sweet-scented blooms are fully out in the Alpine house at the beginning of January. It belongs to the *reticulata* section, but the leaves are cylindrical and have eight ribs, instead of being four-sided. The plant comes from Armenia,

and is somewhat rare in gardens. It produces flowers with bluish-lilac standards, while the falls are creamy-white, blotched and spotted with dark violet. Two kinds in flower are both forms of *I. reticulata*.

I. reticulata var. *Histrio*.—A charming variety from Palestine has bright blue flowers blotched with golden yellow.

I. reticulata var. *histrioides*, from Armenia, has flowers larger than those of the type, being often 5 inches in diameter. These appear before the leaves, and vary in colour from purple-blue to light blue, with white spots on the fall and a narrow orange crest.

All the above, with the exception of *I. Vartanii*, are in flower now, and will be followed shortly by such species as *I. Danfordiæ*, *I. stenophylla*, and *I. Tauri*. *W. L., January 14.*

NOTICES OF BOOKS.

* "THE ENCYCLOPÆDIA OF GARDENING."

THIS handbook of 466 pages, crown 8vo., is a condensed "Dictionary of Gardening," of much use as a work of reference to the private gardener, plant cultivator, fruit-grower and, to a lesser extent, to the arboriculturist and forester. It gives the names of all kinds of garden plants cultivated in British gardens, the Natural Order to which they severally belong, common garden names and the botanical names according to the *Index Kewensis*, together with their native country. Much information concerning the best methods of cultivation is conveyed in the briefest possible manner. To take *Marantas* as an example. We are first given the common name, "Arrowroot plant, Ord., Scitaminaceæ, stove: herbaceous perennials. Orn. foliage. First introduced in 1732. Leaves, egg, lance, or heart shaped, roundish or oblong; greyish, purplish, or rose below, upper sides green, blotched or streaked with white, yellow, brown, purple, or rose." Then follow descriptions as to best kind of compost to use, and directions as to culture to be followed throughout the year, with a list of the species in cultivation. It is sufficient recommendation for this book to state that the present revised and amplified issue represents the 13th edition.

† THIRTY-NINE ARTICLES ON GARDENING.

ALTHOUGH this book might form an acceptable gift to many young people interested in plants and in gardening, and although some of the chapters are eminently practical; yet, on the whole, we do not see the object of republishing chatty articles of this kind, which are more suited for the pages of a newspaper than to swell the already crowded shelves of the botanist's or gardener's library.

The author is an enthusiast, and has travelled much. She has been in the Rockies, and has seen *Calochortus* and *Opuntia* growing together in British Columbia. She has visited that earthly paradise, Ceylon, and evidently knows something of the European Alps, as well as of the British Isles. Botanists who have travelled in foreign lands as well as in their own and have seen plants growing in their natural haunts on mountain side or in tropical forests, must necessarily have something to talk about, especially when they seem to be also at home among the wonderful treasures of *Few*.

The first thing, therefore, to notice about the little volume under discussion is its distinct originality and freshness. In these days when so much "literature" is taken out of books of reference, guide books, &c., it is a pleasure to come across journalistic work of this kind which is original and based upon the author's

own observations and experience as a cultivator of plants. Some of the chapters are, therefore, distinctly readable. Others, such as that on weeds, are less interesting, and in that short chapter more might have been said about the fascinating subject of the dispersal of seeds by wind, water, animals, &c., and less, we think, about what plants are regarded as "weeds" in different countries.

The coloured illustration of "Weeds" is not altogether intelligible, comprising *Androsace obtusifolia* (Switzerland) and *Gentiana campestris* (Norfolk). It is misleading to suggest that *Androsace obtusifolia* is often found as a weed in Swiss gardens; nor can we imagine that the widely-spread Field Gentian is a typical weed

as are the still larger plants of the handsome *Primula latifolia*.

In speaking of the drainage of rock-gardens we are very truly told that many Alpine plants, "notably, *Campanula cenisia*, have their long roots running among stones and shale so loosely piled together that you can pull it down easily with your hands and release the entire roots uninjured. Similar planting in this country, of course, would not succeed, unless we could insure an incessant water-supply such as the melting snows provide." Fortunately for this rare little *Campanula*, confined to so small an area in Central Europe, and hardly ever seen below 8,500 feet, it is often so much the colour of the loose stones among which it grows,

FIG. 33.—IRIS BAKERIANA: FLOWER PALE VIOLET SPOTTED WITH BLUE
(See page 52.)

in Norfolk gardens, though it may occur in some.

There is an interesting chapter on *Primulas*, and the remark that *P. auricula* "grows best high up on the banks when placed in cracks between stones" is a better description of the situation proper to this plant than that of a recent writer in this journal (Oct. 17), who said, "The *Auricula* grows naturally on the mountains of Southern Europe and flourishes in the natural loam to be found there; consequently, loam should be the staple of the compost." Those who have seen the beautiful, pale-yellow flowers of the *Auricula* in the Alps in May or June—and they are by no means easily found—know that it almost invariably grows on more or less precipitous, limestone rocks, and that it is as tightly wedged into the narrow crevices of rock

exactly as described by Miss Crocker, as almost to suggest a "protective colouring" in the vegetable as in the animal world.

Some carelessness appears in the use or non-use of capital letters and little points of that kind, e.g., we find "iris," "geranium," "rumex," "White Gentian," "Michaelmas daisies," "a grand White form," "a good Mauve variety," &c. Nor is it well to read, "every atom (of a plant in seed) was closely cropped off with shears." And why is it necessary to place in quotation marks that "*Heaths* or *Ericas* belong to the Natural Order of plants *Ericaceæ*?" These are trifles, and yet their frequent occurrence shows that the articles, if published at all, should have been carefully revised before being put together in book form. *H. S. T.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Evergreen Calanthes.—The following species of the evergreen section of *Calanthes*, namely *C. veratrifolia*, *C. Masuca*, *C. sylvatica*, *C. pleiochroma*, *C. citrina* and *C. japonica* are now actively growing. They will require frequent and liberal supplies of water, with an occasional application of weak, liquid cow-manure. The plants are more or less frequently attacked by brown scale insects, which must be kept under by sponging with some safe insecticide. The flower-spikes, as they push up, must also be kept free from green and yellow aphides, or they will disfigure the flower-bud. These Evergreen *Calanthes* are best cultivated in the intermediate house. They should not be elevated near to the roof glass, but will grow satisfactorily in a shady part of the house.

Vanda Watsonii, *V. Amesiana*, and *V. Kimballiana*.—At the cooler end of the Cattleya house plants of the new *Vanda Watsonii* grow fairly well, and several plants are now in bloom. A specimen with five spikes of pure white flowers is a lovely object. At this season every care is necessary to prevent moisture settling on the flowers, which would cause them to become spotted. When the flower-buds are properly developed and are just on the point of opening it will be necessary to gradually lessen the supply of water at the roots, but do not allow the roots to become so dry as to cause the terete leaves to shrivel. Treated in this manner the blooms keep perfectly fresh and free from spot for a period of several weeks. Plants of the winter-flowering *V. Amesiana* will require similar treatment, but this species needs a more decided rest after the flowers fade. The earlier-flowering plants of *V. Kimballiana* are now beginning to push out new roots from the stem, and the old roots are also commencing to grow. These may now be repotted or resurfaced as may be considered necessary. They succeed either in pots or teak-wood baskets, but whichever the receptacle used, good drainage is necessary. Pot them firmly in a mixture of *Osmunda* and *Polypodium* fibre in equal parts. Cut these materials up moderately fine and mix with them plenty of small crocks. Keep the compost about an inch below the rim of the pot or basket, and surface the remaining space with freshly-gathered *Sphagnum*-moss, making it quite solid in convex fashion. These *Vandas* require a light position in the Cattleya house. Sufficient water should be applied to preserve the surface moss in a growing condition.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Late Peaches and Nectarines.—Any pruning and training still to be done should no longer be delayed. When pruning the trees remove as many of the old branches, as can be spared, in order that plenty of young, fruitful shoots may be trained in, thus improving the general appearance of the trees. The greatest care must be exercised in pruning young trees which have been recently planted, for any neglect or mismanagement now will be followed by unsatisfactory results in later years. Any extra strong shoots made last season should be pruned severely or entirely removed. Do not attempt to get the trellis covered too quickly, as this sometimes leads to a deficiency of fruitful wood at the base of the branches. Keep the centre of the trees fairly well open, and endeavour to have most of the fruiting shoots on the uppermost side of the branches. The glass, woodwork, and trellis should be thoroughly cleansed by washing before commencing to train the trees. If the trellis is at all rusty it should receive a coat of paint, for a rusted trellis frequently causes canker by its rubbing of the branches. The trees may be thoroughly washed with a mixture of soft soap and sulphur in water. Only a soft brush must be used for applying this mixture to the young shoots, or the buds will be liable to receive injury. Be careful to make all the ties so loosely as to allow for the proper swelling of the wood. When the tying is done,

the surface of the borders should be carefully forked over, removing the loose soil in order that a top dressing of loam and lime rubble may be applied. In the case of old trees, some artificial manure or crushed bones will be beneficial. Syringe the trees with clear water on fine mornings.

Tomatos.—Provided that the winter-fruiting plants are still in a clean and vigorous condition, they may be encouraged to set further fruits. Cut away most of the old foliage and select some of the strongest side growths and lay them in, giving them plenty of room to develop. Apply a surface-dressing of loam to the roots, mixing with the compost a little lime rubble or wood ashes, also a little artificial manure. At this time of the year it is prudent to pollinate each flower individually. The plants which were raised from seeds sown in the autumn are nearly ready for their final shift into 10-inch pots. A fairly rich compost is necessary for pot culture. This should consist of loam, old mortar rubble, wood ashes and crushed bones. In potting, the soil should be made firm. Place the pots near to the glass, so that they may not become drawn. White fly is a very persistent enemy of the Tomato, and once this pest obtains a footing it is difficult of destruction. A good preventive is to fumigate occasionally with a nicotine vaporising compound. Let the atmospheric temperature be 60° at night, but during the day, by the sun's influence, it may rise even to 80°, provided there is a free circulation of air. Make another sowing to provide for a successional crop.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. Vicar Gibbs, Aldenham House, Elstree, Hertfordshire.

Jerusalem Artichokes.—This useful vegetable is neither fastidious as to soil, climate, nor situation. It grows very tall, and it frequently serves as a windscreen or is so planted that its growth may hide unsightly places during the summer and autumn. Unlike most other vegetables, Jerusalem Artichokes may be successfully cultivated on the same piece of ground for a number of years together, provided suitable manure is applied and the ground is properly prepared by deep tilt each year. The present is a suitable time to prepare the soil by trenching deeply and working into it a liberal quantity of farm-yard manure. If it is very stiff and retentive in character it will be well to add some burnt garden refuse, road scrapings, or old mortar rubble. Medium-sized tubers should be selected for planting. They should be placed 6 inches deep and 2 feet from each other in the rows. The rows themselves should be divided by spaces of 3 feet. The newer white variety is superior in every way to the old purple-skinned Artichoke. The tubers are more shapely and their flavour superior.

Rhubarb.—The supply of Apples is decreasing, and Rhubarb will, therefore, be in great demand. Larger batches of roots should be taken up at intervals and placed in a gentle heat, but, in addition, some of the roots in the open ground should be forced in the positions they now occupy. This latter practice is preferable to lifting the crowns and forcing them indoors, unless crowns are obtainable that have been specially grown for the purpose. By the indoor forcing system the plants are so weakened that they need two years at least to regain their vigour. Ordinary tubs or barrels with one end removed and its parts bracketed together so that it can be used as a lid are more convenient than the pots specially made for the purpose. A small quantity of long stable manure with some good Oak, Beech, or Spanish Chestnut leaves will be needed to create the necessary warmth, but care should be taken not to employ more than sufficient heat to cause the plants to grow as quickly as they do ordinarily at their proper season. If these details are carried out intelligently, the fermenting materials removed in good time after the forcing is over, the beds forked, and no more stalks pulled during the present season, the roots will be little the worse for the slight forcing.

Seakale.—Introduce batches of Seakale to the forcing house in sufficient quantities to meet the demand. It must be pointed out, however, that Seakale may be forced on the ground much in

the same way as Rhubarb, and although this method gives more trouble, the growths so cultivated are usually much stronger and of better quality. The roots which were taken off when the crowns were lifted for forcing, and tied into small bundles, should now be placed in boxes and put into cold frames, in order that they may be induced to start slowly into growth.

Salads.—Continue to make provision for maintaining regular supplies of Salads by sowing small quantities of seeds at regular intervals of such crops as Onions, Mustard and Cress and Chervil. See to the blanching of Endive and Lettuce. Keep a good quantity of Chicory and Dandelion roots in a warm corner where they will produce growths, that will, of course, need to be blanched.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Trees and shrubs (continued).—In addition to those mentioned last week, the following species are well suited for cultivation in parks:—*Berberis aquifolium* and *B. Darwinii*; *Hypericum calycinum* and *H. elatum*. *Hypericum calycinum* is useful for covering dry and shady spots and for forming a groundwork in the front of shrubbery borders. *Phillyrea angustifolia*, with its stout leaves, withstands smoke very well, as also do all the *Ligustrums* or *Privets*, notably *L. Iboti*, *L. japonicum*, *L. lucidum*, *L. Quihoui*, and *L. sinense*. The bright green leaves of the *Privets* are attractive, independent of their plumes of snowy white flowers. *L. ovalifolium* and its golden variegated sports, though not evergreen, are capable of retaining their foliage until very late in the year, and they start into growth again early in the following season. At midsummer the yellow varieties are amongst the most striking of town shrubs. *Spartium junceum*, when planted on poor soil, produces an abundance of fragrant yellow flowers. I planted several plants of *Choisya ternata* a few years since in a warm border, and so far they have done well, but have flowered only sparingly. *Cydonia japonica* makes a good-sized bush and flowers well. *Fatsia japonica* has also passed safely through three or four winters without protection, as have *Elæagnus pungens* and the varieties *aurea*, *argentea* and *variegata*. *Cotoneaster frigidula* and *Cratægus pyracantha* attract much attention when in berry. All the *Spiræas* do well, *S. Lindleyana* and other tall-growing species forming stately objects when in flower at the end of the summer. The numerous varieties of *Ivy* (*Hedera Helix*) make useful and interesting plants for covering walls, and the more common forms are excellent for planting under large trees or in places where grass will not grow. *Ivies* present much diversity in the form and size of their leaves; the contrast between the varieties *dentata* and *Caenwoodiana*, for instance, is very noticeable. Other useful subjects for shady nooks are the *Vincas*. The hardy forms of *Bamboo*, *Arundinarias* particularly, afford a graceful subtropical appearance if planted in clumps. *Rhododendrons*, though not first-class town plants, can be grown with success. They will thrive in any soils that are not exceptionally heavy or that do not contain a large proportion of lime or chalk; but succeed best in a light, peaty soil or sandy loam. When they are making their new growths copious supplies of water should be applied overhead.

Deciduous species.—Among the deciduous trees and shrubs, the variety of the Plane tree (*Platanus orientalis acerifolia*) attains a very large size and is capable of forming stately avenues. When used for this purpose the trees should not be planted nearer than 35 feet apart, but even a greater distance is better. These trees require plenty of water at their roots during dry seasons. They do not burst into leaf until danger of late frosts is practically over. *Ailanthus glandulosa* flourishes well in smoke-laden districts. It attains large proportions, and its foliage, as well as sometimes its flowers, are interesting and attractive. The various forms of the Ash, Horse Chestnut, Acer, *Cratægus*, Elm, Beech, Birch, Oak, Poplar and Willow succeed well, and all these should be used for variety in accordance with the space at the disposal of the planter.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Raspberries.—If this work has not already been done, the quarter devoted to Raspberries should now be made neat for next season. Assuming that last year's fruiting canes were removed soon after the crop was gathered, all that is necessary in this direction at the present time is to thin out any young canes that are considered superfluous, and tie the remainder neatly to the supports. In most private gardens the system followed is that of tying the canes to wires trained to upright posts. This system has much to recommend it, as by its use light and air can reach every part of the cane and the fruit is well exposed to the sunshine. If it is necessary to renew any of the uprights, the new ones should be made at least a foot higher than the canes are expected to grow. They will then be found convenient when netting the Raspberries for protection against birds, as the uprights will hold up the nets sufficiently high above the canes and allow head room for those who

canes on permanent plantations should now be cut down to the ground level, for the fruit will be borne on the new canes. Care must be taken to thin out the new shoots to a reasonable number early in the season, in order that the remainder may develop into strong, well-ripened canes, capable of bearing satisfactory crops.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Herbaceous plants.—Where there are large borders of herbaceous plants it occasionally happens that one or more of these need to be overhauled entirely. Before such a time arrives, advantage should be taken to obtain a large quantity of manure, leaf-mould, road-scrappings, and similar materials. In the first place it is necessary to mark out the positions in which you wish to place the principal plants, labelling any that it is considered unwise to shift. Some species, notably *Ostrowskia magnifica*, are known not to succeed well for a considerable time after disturb-

large plants which, making their growth late in the season, will allow the bulbs to flower before overshadowing them. The tall-growing species of Lilies should be placed in conspicuous positions to make a bold effect. If Lilies are moved at this date they should be planted again as soon as possible, taking care not to break the freshly-formed roots. If the soil is inclined to be heavy, place some sharp sand about the roots, also a sprinkling of flowers of sulphur. Irises should be planted in the same manner as Lilies. They require a freely porous soil. The best background for such a border is one composed of evergreen and deciduous shrubs. If these are selected with care their effect will add considerably to that afforded by the border. Should the background, however, be a wall, let it be covered with climbing plants rather than with fruit trees. Work in plenty of manure and leaf-mould and a sprinkling of soot as the work of replanting proceeds. On no account let the planting be continued in wet weather. In some cases the natural soil is so thin and stony that it is necessary to add rich loam and perhaps a little clay. On the contrary, very heavy soil may be much improved by the addition of leaf-mould and road-scrappings. When the replanting is finished, see that all the plants are properly and accurately labelled with labels that are likely to last in good condition for some time to come.

Calceolaria.—If the plants are in cold frames remove the lights on every fine day.

Cyclamen Coum.—The deep crimson flowers and dark foliage of this species are now peeping through the soil. We find it a good practice to place a little fine soil, with a small quantity of soot and artificial manure, over the roots. Similar treatment may be afforded *C. ibericum Atkinsii*, which flowers from February to April; and *Anemone blanda*.

FIG. 34.—IRIS RETICULATA VAR. HISTRIO: FLOWERS BRIGHT BLUE BLOTCHED WITH GOLDEN-YELLOW.

(See p. 53.)

gather the fruits. The canes should be tied at about 9 inches apart on the wires. When this has been done, clean thoroughly all weeds from the soil, and afterwards apply a mulching of farmyard manure. Raspberries being surface-rooting plants, the spade must not be used to dig between the rows, but if the surface appears hard it may be carefully picked up by means of a fork. Any planting which may have been postponed on account of the weather should be completed as soon as possible. If any new plantations have been made this season, the canes should be cut down to within 12 inches of the ground directly they commence to grow. The best red-fruited varieties are Superlative, Hornet, and Baumforth's Seedling. The best yellow-fruited varieties are Queen of England, The Guinea, and Yellow Antwerp.

Autumn-fruited Raspberries.—The autumn-fruited varieties are worthy of cultivation, provided this fruit is appreciated for dessert. Two excellent varieties are Belle de Fontenay and the newer one, November Abundance. The

ance. Afterwards take up the rest of the plants at one end and lay them in carefully and promptly. These plants will be needed to complete the planting when the remaining part of the border is done. The next operation is to take out a trench three spits deep and wheel the soil some distance away. The work of trenching may then proceed. Borders differ greatly in width, but a first-class border should be 8 to 12 yards wide and 100 yards in length. Many of the plants which grow outwards from the centre, as, for instance, the perennial Phlox and Michaelmas Daisy, will be found to have their centres in a very weak condition. The centres of such plants should not be planted again. A clump should be formed from crowns or pieces on the outside of the old clumps. It is not wise to plant large batches of any one kind of plant, excepting bulbs, as this would lead to there being large spaces without flowers at certain periods. Dwarf annuals may be planted or sown over ground containing such bulbs as Narcissus, and small bulbs can often be planted near to

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Propagation.—The propagating house should be thoroughly cleansed in readiness for raising and increasing the stocks of various plants. Seeds of such kinds as Begonia, Gloxinia, Streptocarpus and Coleus may now be sown. The cultural details connected with seed-sowing have been so often related in these pages that I will content myself with pointing out the need for observing the following points. Use clean pots and pans, and soil which is sufficiently moist at the time of sowing the seeds that it will not want water immediately afterwards. In handling the finest seeds extra care must be exercised. The present is a suitable time for inserting cuttings of such trailing plants as *Oplismenus Burmannii variegata* (*Panicum variegatum*), *Zebrina* (*Tradescantia*) *pendula*, and *Fittonia*. It will be necessary to insert further batches from time to time as young stocks of such subjects are more decorative than older plants, which, after use in the dwelling-house, are seldom of any further use for decoration. *Cordylines* (*Dracenas*) may either be propagated from cuttings, root-eyes, or by "ringing," according to the size of the plants required. "Ringing" is a good method for propagating *Codiaeums* (*Crotons*), and plants raised thus have generally longer and better leaves at their base than those raised from cuttings. Old plants of *Pandanus Veitchii variegata* usually have some well-coloured shoots at their base, and if these are taken off and inserted in sandy soil they are capable of making very handsome plants.

Euphorbia (Poinsettia) pulcherrima.—As these highly-decorative plants pass from the flowering stage they should be removed to a cooler house and rested by withholding water from the roots.

Mignonette.—A further sowing may now be made in firm soil. Very careful watering will be required when the seedlings appear upon the soil; they must not be subjected to much fire heat. Plants now showing flower need frequent applications of weak manure water.

Lachenalia.—*Lachenalias* may be given liquid manure. They should be kept as close to the roof glass as is possible without the tops being brought into actual contact with it.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JANUARY 23—
Ann. Dinner Soc. Franc. d'Hort. de Londres, at Café Royal, Regent Street, W.

TUESDAY, JANUARY 26—
Roy. Hort. Soc. Coms. meet. (Competitive Classes for Seakale, Rhubarb, Asparagus, Forced Vegetables and Salads. Lecture at 3 p.m. by Mr. W. D. Scott-Moncrieff, on "A Method of using Domestic Sewage in Horticulture".)

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39.4°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, January 20 (6 P.M.): Max. 42°; Min. 29°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, January 21 (10 A.M.): Bar. 30.4; Temp. 44°; Weather—Overcast.

PROVINCES.—Wednesday, January 20 (6 P.M.): Max. 47° Mayo; Min. 36° Durham.

SALES FOR THE ENSUING WEEK.

MONDAY AND TUESDAY—
Herbaceous and Border Plants, Lilioms, Bulbs, Azaleas, &c., at 12; Roses and Fruit Trees at 1.30, by Protheroe & Morris, at 67 and 68, Cheapside, E.C.

WEDNESDAY—
Thousands of Gladiolus, Begonias, Tuberoses, &c., at 11.30; Herbaceous Plants, Perennials, Lilies, Bulbs, &c., at 12; 982 cases Japanese Lilioms at 1; Roses and Fruit Trees at 1.30; Azaleas, Palms, Plants, &c., at 5, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY, THURSDAY AND FRIDAY—
Important Sale of Nursery Stock at the Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris, at 11.

FRIDAY—
Imported and Established Orchids, in variety, at 12.45, by Protheroe & Morris, at 67 and 68, Cheapside, E.C.

National Afforestation.

The advocates of the systematic afforestation of these islands will be encouraged by the second Report which has just been issued as a Blue Book by the Royal Commission on Coast Erosion and Afforestation. It will be remembered that the Commission has already issued one Report, but, inasmuch as in March last, its terms of reference were extended to include an enquiry as to whether the evil of unemployment might be relieved by the afforestation of suitable areas, the Commission in its present Report deals not only with land which may be reclaimed from the foreshore, but with the available land in all parts of these islands. Under its extended terms of reference the Commission, presided over by Mr. Ivor C. Guest, M.P., has held fifty sittings and has heard evidence from eighty witnesses.

The scheme is a bold one; indeed, it is not too much to say that its proposals for afforestation are the boldest ever put forward by a

properly constituted authority in this country. It is to be hoped that in its comprehensiveness it will not frighten men brought up in the atmosphere of compromise and accustomed to be satisfied with half measures.

Those who have had this experience will, at all events, welcome the scheme, not necessarily accepting it in all its details, but as serving as a basis for discussion. It is more than probable that legislation will not proceed on the exact lines now laid down, nor to the full extent the Commission recommend. At the same time it cannot be recognised too soon that one of the most essential conditions necessary for making British forestry a permanent means of increasing the national resources is that the industry shall be started on so broad a basis, and with such financial security as is only possible under the direct management of the State. It is perfectly conceivable, and the Commission have satisfied themselves on this matter, that, where spasmodic and local attempts have failed to make timber cultivation a remunerative industry, a general scheme, far-reaching and national in character, would succeed. In succeeding it would not merely provide a means of employment for able-bodied men, but would supplement the failing supplies of timber, and yield, in course of time, a substantial profit to the national Exchequer.

The essential Recommendations of the Commission are (1) that afforestation is desirable; (2) that the approximate area of suitable land in the United Kingdom, without material encroachment upon agricultural land, is 9,000,000 acres; (3) that 150,000 acres shall be planted each year; (4) that, to finance the scheme, an approximate sum of £2,000,000 will be required annually.

The expenses of afforesting, at the rate of 150,000 acres a year, are estimated to rise from £90,000 in the first to £3,131,000 in the fortieth year. After forty years it is expected that the forests will begin to be self-supporting. From the fortieth to the sixtieth year this stage would continue; from the sixtieth year the profit would progressively increase, until at the eightieth year the approximate equalised revenue would be about £17,000,000 a year, and the value of the forests would be £562,000,000 or £106,000,000 over and above the entire cost of their creation. A forest of 9,000,000 acres, in which the trees represent the various series of age-classes, may be expected to yield 9,000,000 loads of timber annually in perpetuity. Now, the importation of foreign timber from temperate climates, such as our own, into the United Kingdom in the year 1907, exceeded 8,500,000 loads, which is approximately the quantity which could be expected annually from the proposed scheme of afforestation. At the end of sixty years, when the whole of the 9,000,000 acres have been planted, it is estimated that the industry will keep, at the least, 90,000 men permanently employed. It should be remembered that the work of planting might be carried out with less or more rapidity according to the state of the labour market. Whilst the maintenance of the forests would give employment to a large number of unskilled men, the greater call for labour would be made in the forming of new forests. It is a satisfactory feature of forestry opera-

tions that much of the work can be done in the winter season, when the evil of unemployment is most acutely felt.

Much has been written on the questions of transporting, housing, and feeding the workmen, and the alleged difficulties have been urged as serious obstacles to the scheme, but surely there is no basis for such fears! The railway and water companies, and even private landowners, have occasionally to transport hundreds of men to remote mountain districts, far removed from road and rail, and maintain them whilst work is in progress. It can scarcely be doubted that the State would be able to deal effectively with such problems. The one essential thing to do is to get the men on to the land; means of subsistence would be devised easily enough. By drafting unemployed men into the country, where remunerative work abounds, much good, both in an economic and hygienic sense, would be brought about. Nor can tree-planting by means of unemployed men be considered a new departure, for, on a dreary, exposed hillside in Wales, as well as in various parts of England, the whole of the work, including clearing the ground of surface growth, pitting, and planting, has been carried out by drafts from the unemployed. Afforestation offers the most promising means of dealing in a scientific and permanent manner with the question of unemployment. It is also calculated to increase the value of the land, in some cases sevenfold, and it would provide an ever-increasing revenue for the State.

But this is not all, for, apart from the question of immediate labour, what industries would be opened up in years to come by the planting of waste grounds. At present there would be clearing, draining, fencing, and planting. Thinning would commence at about the tenth year, after which the erection of saw-mills for converting the timber would open a vast industry. A woodpulp industry would be almost certain to follow, and, when a sufficiency of Spruce timber became available, a great paper-manufacturing industry would arise. Spruce is more valuable now than Scotch Fir, because almost all the paper of the world is made from Spruce wood. The produce of about 5,000 acres would be required to keep each pulp-mill going, and the Spruce for this purpose would be felled at the age of thirty years. In the little kingdom of Saxony no fewer than 4,000 factories, employing 60,000 people, have been brought into existence by the development of woodpulp, paper, and other manufacturing industries in connection with her well-managed and highly-profitable forests.

With respect to the most desirable places in which to begin planting operations, we would suggest those counties where not only the greatest area of waste lands exist, but where other advantages are offered, especially in the matter of cheap land purchase and easy removal of the produce. Thus we have—in England—Yorkshire and Northumberland with 1,019,925 acres; in Scotland, Inverness and Argyllshire with 3,087,412 acres; in Wales, Breconshire and Merionethshire with 461,320 acres; and Ireland, Donegal and Kerry with 657,337 acres, exclusive of 172,436 acres of bog land.

It has been urged that tree-planting requires skilled labour, and that, consequently,

the unemployed are unsuited for it. But, as we have already pointed out, the preliminary work, indeed every operation, if we except the process of planting the trees, is such as can be carried out by any ordinary workmen under proper supervision.

Some of our readers may think that the Report of the Commission is of too sweeping a character. It will be remembered that a less ambitious scheme was urged in these pages (*Gard. Chron.*, Dec. 15, 1906, p. 401, and June 22, 1907, p. 409) by Mr. A. D. Webster in a series of articles on afforesting waste lands. He recommended the planting up of 1,000,000 acres, spreading this work over a period of 25 years, at the rate of 40,000 acres each year, and at a cost of £300,000 annually.

But public opinion, though of slow growth, matures quickly, and it may well be that the larger scheme will fire the enthusiasm of the people, and in spite of its ambitious character, or perhaps because of it, get itself adopted. If this proves the case Mr. Webster will be remembered as one of the pioneers of afforestation whose work in paving the way for the larger scheme actively contributed to its adoption.

We are perfectly satisfied that afforestation is needed for meeting the future demand for timber, that it is desirable as a means of keeping a considerable number of men upon the land, and that if it is carried out in a properly devised scheme under Government control it will eventually yield a profit to the Exchequer. For these reasons, and for the further reason that the establishment of a State system of forestry would permanently lessen the misery caused by unemployment in the winter season, we hope the Report will lead to prompt legislation.

OUR SUPPLEMENTARY ILLUSTRATION represents a hybrid flower raised by Mr. C. G. VAN TUBERGEN, Jun., Haarlem, from a cross between *Brunsvigia Josephinæ* and *Amaryllis Belladonna*. Mr. VAN TUBERGEN thus describes the circumstances:—"Principally with a view of ascertaining the parentage of the Kew variety of *Amaryllis Belladonna* (see illustration in the *Garden*, November 19, 1898, also notes in *Gardeners' Chronicle*, February 9, 1901, &c.), in the autumn of 1892 I artificially impregnated *Brunsvigia Josephinæ* with pollen of *Amaryllis Belladonna*. Seeds formed freely, as the two genera, *Brunsvigia* and *Amaryllis*, are very nearly related. As could be foreseen, with the slow-growing *Brunsvigia Josephinæ* as the female parent, a long time had to elapse before the seedling plants would be strong enough to reach flowering size. After 16 years of patient waiting, two of the strongest bulbs produced flower-spikes in September of last year. When the hybrid plants had been growing for a few seasons it became evident that they differed in habit from the Kew variety of *Amaryllis Belladonna*, which produces a leaf-stem of about 4 inches high, whereas my hybrids all bear the character of *Brunsvigia Josephinæ* in the foliage, leaves being formed directly above the neck of the bulbs. The infusion of the *Belladonna* blood is clearly shown in the bulbs, as these resemble those of the *Belladonna* and produce offsets freely, whilst *Brunsvigia* never produces offsets. A comparison of the Supplementary Illustration, which was drawn by Mr. WORTHINGTON SMITH from an inflorescence sent from my garden, with the engraving in the *Garden* above cited, leads to the conclusion that the Kew plant can no

longer be regarded as a hybrid between these species, unless it was a cross effected in the reverse way, taking *Amaryllis Belladonna* as the female parent. In that case the variety *Clanda* must have been used, it being the only variety of *A. Belladonna* known which produces a leaf-stem. The colour of the flowers of my hybrid was a clear, deep rose, suffused with carmine. A single spike produced 22 flowers.

FLOWER SHOWS AT THE ROYAL AGRICULTURAL SOCIETY'S EXHIBITIONS.—The flower shows held in connection with the exhibitions of the Royal Agricultural Society at Lincoln and Newcastle having proved successful, it has been decided to hold a similar horticultural exhibition at Gloucester on the occasion of the Agricultural Show in June next. The Royal Horticultural Society has promised its support, and will probably send a deputation. Mr. PETER BLAIR has been provisionally engaged as manager of the show. It is estimated that the cost will be £300, and should the venture result in a financial loss, half the deficit will be met by a local fund and the other half will be guaranteed by the Royal Agricultural Society.

"KEW BULLETIN."—The current number of the *Kew Bulletin* contains an interesting account of the successful attempt to naturalise *Rhamnus Purshiana*, D.C., the tree the bark of which yields the drug known to pharmacy as *Cascara sagrada*. *R. Purshiana*, now growing in the gardens at Kew, was raised from seed sent by Mr. F. R. S. BALFOUR from Washington. It has proved itself hardy, and, according to the investigations carried on by Dr. JOWETT at the Wellcome Research Laboratories, London, the cascara yielded by the Kew plants is indistinguishable in its action from that made from American bark. Hence, it would seem possible that, as Mr. F. R. S. BALFOUR originally suggested, an industry might be established for the growth of *Rhamnus Purshiana* in this country.

AGRICULTURAL CO-OPERATION.—The *Estate Magazine* for January, 1909, opens with a very optimistic article on co-operation and its beneficial effects on agriculture. According to the writer the Agricultural Organisation Society now numbers some 200 provincial associations, and will show a record of trade done during 1908 of about £850,000. The advance made by the cognate co-operative society, the County Gentleman's Association, has also been considerable, the trading account having grown from £8,000 in 1903 to £60,000 during the past year. Encouraging as these results are they show how much remains to be done before the practice of co-operation among the agriculturists of this country becomes as firmly established as is the case in different parts of the Continent.

ABERDEEN AND NORTH OF SCOTLAND COLLEGE OF AGRICULTURE.—Dr. JAMES W. H. TRAIL, Professor of Botany in Aberdeen University, has inaugurated a course of lectures for young farmers, under the auspices of this college. Hitherto these courses have been remarkably successful, students attending from all parts of the north of Scotland. Up to the present year lectures have been given in agriculture, agricultural chemistry, veterinary hygiene, and agricultural botany. This year a fifth subject—agricultural zoology—has been added. The opening lecture was delivered by Professor TRAIL in the botany classroom, Aberdeen University. There was a satisfactory attendance, students being present from Aberdeenshire, Kincardineshire, Banffshire, Elginshire, Nairnshire, Invernesshire, Ross, and Cromarty and Caithness-shire.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, February 8, at 8 o'clock p.m., when a paper will be read by Colonel Sir DUNCAN ALEXANDER JOHNSTON, K.C.M.G., C.B. (late R.E.), late Director-General of the Ordnance Survey, entitled "The Ordnance Survey." The annual dinner will be held at the Whitehall Rooms, Hotel Métropole, on Tuesday, February 16, at 6.30 p.m. The Council have decided that after the election of members in October, 1913, no examination candidate shall be eligible for election as a professional associate unless he has passed both the intermediate and final examinations of the institution. As a consequence of this change, after the present year, candidates for the intermediate examination will be allowed to sit at the age of 19, and for the final examination on completing their 21st year.

THE RAINFALL IN 1908.—An adequate supply of water is of such great importance to gardeners that, however much other folk may grumble at wet weather, our complaint is when the amount of moisture in the ground falls below an average quantity. Several correspondents have sent us their meteorological records for last year:—Mr. H. WILSON, The Gardens, Cole Orton Hall, Ashby-de-la-Zouch, informs us that the rainfall for 1908 has been less than in 1907, for only 23.38 inches fell in 1908, compared with 28.53 in 1907. Mr. WILSON states that the past season has been an excellent one for all garden crops, with the exception of Gooseberries. Rain fell on 180 days at Cole Orton Hall Gardens. At Leonardslee Gardens, Horsham, Sussex, Mr. COOK, the gardener, informs us that 28.78 inches of rain fell during 1908. Rain fell on 179 days. The first half of the year was the drier, which is unusual. The total rainfall for 1907 in these gardens was 25.94 inches. Mr. JAMES B. ALLAN, writing from Osberton Gardens, Worksop, states that the hottest day in those gardens during 1908 was July 2, when the thermometer registered 86° in the shade; the most severe frost was on the morning of December 29, when there were 24°. The heaviest rainfall was on August 20, when .68 of an inch was recorded in 24 hours. The rainfall in these gardens for the year amounted to 20.19 inches, being .99 of an inch less than in 1907. At Shugborough Gardens, Stafford, the rainfall for the past year was 31.98 inches. August was the wettest month, but the heaviest rainfall occurred on April 28, when .94 inch of rain fell. The year's rainfall at Davenham Gardens, Malvern, has amounted to 23.81 inches. March and April were the wettest months, the fall being 3.15 inches and 3.17 inches respectively. January was very dry at Davenham. In connection with the note by E. M. (page 32), a correspondent states that the rainfall in the extreme north-west corner of Middlesex was .53 inch above the average of the past 20 years. The increase was principally in March, April and July.

BIG GAME AS GARDEN PESTS.—The practice of horticulture in some parts of the Empire is attended with difficulties with which the cultivator at home is happily unfamiliar. Thus, according to a recent number of the *Agricultural Bulletin of the Straits and Federated Malay States*, beside the universal fungal and insect pests, bears are so destructive of the Cocosnut trees as to merit a price of £20 per head. Wild pigs, again, as the reporter regretfully states, do considerable mischief. But by far the most paying animal to destroy in quantity is the white ant. For the wholesale and complete destruction of this pest throughout the peninsula a prize of £5,000 is offered. To consider the ways of the ant has always been recommended as profitable, though surely it can be nowhere quite so remunerative as in the Malay States.

YEAR BOOKS AND ANNUALS FOR 1909.—Almost indispensable to the gardener, nurseryman, seedsman, and, indeed, to all business men in any way connected with horticulture are several of the following well-known publications:—

The Horticultural Directory and Year Book is issued for the 50th time this year. It contains, as heretofore, a list of the principal gardening establishments in the counties, a second list in which the names are arranged alphabetically, and the county and nearest railway station indicated. Then follows a list of head gardeners in the United Kingdom, also arranged alphabetically. There are lists of London and provincial nurserymen, landscape gardeners, horticultural builders, engineers, implement makers and sundriesmen, and of the principal nurserymen, seedsmen and florists on the Continent, in the United States of America, in Canada, and in Australasia. The parks, gardens, and open spaces under the charge of H.M. Office of Works and of the London County Council are indicated, and the date of acquisition is given with enumeration of the acreage. Lists of the principal horticultural societies in the United Kingdom and of the botanic gardens in the British Empire and a list of the principal

farmer. The following are among the subjects dealt with: Breeds of Poultry, Scheduled Insects and Pests, Cleveland Bays and Yorkshire Coach Horses, Clydesdale Horses, Care of the Foal, Flock Management and Lambing Difficulties, Profitable Cattle Farming, Useful Live Stock Medicines for Emergencies, Summary of Live Stock Sales for 1908, Small Holdings Legislation, and the Law of Agricultural Holdings, &c. The authors state in the preface that the legislation of the past few years has made drastic changes in the relationship of landlord and tenant. It gives the tenant greater freedom, but it also entails upon him added responsibilities. In the *Farm and Home Year-Book for 1909* he will find them set forth clearly, in a treatise written by a barrister who has given agricultural questions special attention. Also the Small Holdings Act embodies legislation, with the provisions of which all connected with agriculture should familiarise themselves.

Vinton's Agricultural Almanack and Diary 1909.—Beside the usual information looked for in an almanack we find a great many items of special interest to the farmer, for example, on cattle breeding, standards of feeding oxen, growing and fattening, cows in milk, sheep growing and feeding, horses at work, pigs grow-

us a diary and blotting-pad. There is a calendar for the whole year, which provides a space of nearly 3 inches square for each day in which notes may be entered. These pages are interleaved with blotters.

The Gardening Year-Book and Garden Oracle.—This compendium of gardening information is issued for the 51st year. The editor is Mr. GEORGE GORDON, a sufficient guarantor of its value to the gardener. A calendar serves as a reminder of the principal horticultural events during 1909, and to each day is appended a short note for some seasonable horticultural operation. Under each month are given directions for important work in the various departments of the garden. This is followed by a list of the new garden plants of 1908, several of which are illustrated from photographs. There are chapters on bulbous and tuberous-rooted plants, early-flowering Chrysanthemums, the propagation of plants by seeds, cuttings, and other methods, Roses for garden decoration, plants for conservatory and greenhouse decoration, hints on the culture of useful vegetables, fungoid diseases and insect pests affecting garden plants, and a list of useful garden receipts. Not the least valuable part of the book is the list of horticultural and botanical societies in the United Kingdom, with the names and addresses of their respective secretaries. In this connection it should be noted that the London Dahlia Union has now amalgamated with the National Dahlia Society, and does not exist as a separate organisation. Although the information relating to public parks and gardens is the most complete of its kind, we observe several notable omissions; it is but fair to add that it is stated "there are many towns in the United Kingdom possessing parks of which particulars have not been received." The work contains coloured plates of spring-flowering Crocuses and fancy Pansies.

(Photograph by H. F. Macmillan.)

FIG. 35.—PARA-RUBBER PLANTS IN PREPARATION FOR SHIPMENT FROM CEYLON TO SOUTH AMERICA.

fruit and flower salesmen and commission agents in London are given, together with a number of valuable recipes and tables connected with gardening. The new plants certificated in 1908 are enumerated and short descriptions given.

The Garden Annual and Almanack.—This work contains thousands of names and addresses, alphabetically arranged, of country seats, of the principal parks and gardens in Great Britain and Ireland, and of the names of the head gardeners employed, with corrections up to near the end of 1908. We find also a list of the chief horticultural societies, and a lengthy list of new plants, fruits and vegetables which have been certificated during the past year by the Royal Horticultural and other societies. There are likewise an almanack and a page of reminders of seasonable work for each month; a list of nurserymen, seedsmen and florists at home and abroad, and a mass of other matter in regard to trades having a connection with gardening.

Farm and Home Year-Book.—This annual publication is issued from the office of *Gardening Illustrated*. The book is designed to afford memoranda and hints of service to the

ing and fattening, periods of gestation of domestic animals, and of incubation of poultry, average prices of grain from 1886 to 1907. The tables of composition, manurial and compensation values of feeding stuffs are most useful, and other statistical tables make interesting reading for the agricultural world. The book is provided with a diary for the year, printed on good paper, showing a week at an opening on two pages, with plenty of space for memoranda.

Webster's Foresters' Diary and Pocket Book.—This is an invaluable Annual for all interested in forestry. It contains a list of the principal foresters and assistant foresters, forestry associations, trees suitable for various soils, methods of planting, prices of home-grown timber, a calendar of forestry work for the year, excellent articles on the afforesting of waste lands and the education of foresters, innumerable details connected with the planting of trees, measurement of timber, and other matters of importance. There are a few misprints, but these do not seriously detract from the value of Mr. WEBSTER'S book.

A Diary and Blotter.—MESSRS. JOSEPH BENTLEY, LTD., manufacturing chemists, Hull, send

TRANSPORTING PARA-RUBBER PLANTS.—In connection with the Ceylon rubber industry, which formed the subject of our leader last week, we reproduce a photograph in fig. 35 of a consignment of Para-rubber plants (*Hevea braziliensis*) established in Wardian cases for shipment from Ceylon to tropical South America. The journey by sea and land, via London, covers a distance of 12,000 miles at the least. In 1876 the first plants of this Brazilian tree were introduced into the Eastern tropics, through the agency of the Botanic Gardens of Kew and Ceylon, by means of the same kind of case as is shown in the photograph. In Ceylon the plants grew rapidly, and from these have originated millions of trees, now cultivated throughout Ceylon, Malaya, Mauritius, Africa, etc., for the production of rubber. Tropical America, the native habitat of the tree, is now following this example by cultivating this valuable tree, instead of depending, as hitherto, upon the rubber collected from trees scattered in the native forests. So difficult is it, however, to procure plants, especially reliable plants, to form plantations, that it is found necessary to import them from Ceylon.

NATIONAL AFFORESTATION.—In connection with the Report of the Royal Commission on this question, it is interesting to recall the fact that in an article published in these pages December 15, 1906 (p. 402), Mr. A. D. WEBSTER stated that he had "carefully computed that of the land up to 1,200 feet where timber would grow perfectly well, about 9,000,000 acres are available for afforesting purposes." This is the exact area now stated by the Royal Commission as being suitable for the purposes of afforestation.

JUBILEE FLOWER SHOW AT HAARLEM IN 1910.—The opening date for this show is now definitely fixed for March 23, 1910. Consequently, it will be open before Easter and remain open until after Whitsuntide (May 15). The show will be divided into a permanent exhibition in the open and three temporary shows in buildings. The co-operation has been obtained of Boskoop, Aalsmeer and other important horticultural centres. The show is expected to give a good idea of Dutch commercial horticulture. The first temporary show is to be held at Easter time, the second about mid-April during the flowering season of the bulb fields, and the third in the first days of May. Queen Wilhelmina and the Queen-mother are patrons of the society, which will hold this show to celebrate its half-centenary. The exhibition will be held under the patronage of Prince Henry of the Netherlands.

THE "NEW PHYTOLOGIST."—With the beginning of the present year, the *New Phytologist*, a British Botanical Journal, which, during its seven years of existence, has done valuable service to the cause of British botany, is to be enlarged and the price increased to 15s. per annum. The editor promises that notices of current botanical work shall be a prominent feature of the enlarged periodical. To all interested in the progress of botanical science this will be welcome news. The occasional reviews which have been published from time to time in the pages of the *New Phytologist* have been among the most valuable of its articles. We both think and hope that the greater prominence which is to be given to reviews of botanical work in general will secure for the *New Phytologist* an even larger sphere of influence than that which it has enjoyed hitherto. When we remember the very considerable number of botanical periodicals published in Germany, we cannot feel unduly proud of the fact that this country can only keep going some three or four. We congratulate the Cambridge Botany School on its decision to lend support to the editor of the *New Phytologist* in his enterprise.

A NEW SYSTEM OF MUSHROOM CULTURE.—It was discovered some few years ago that minute pieces of tissue from the centre of a Mushroom, if planted in a suitable bed, were capable of giving rise to mycelium and, therefore, of producing fresh spawn. Messrs. SUTTON & SON, Reading, utilise this method in the production of the virgin spawn, which they offer under the name of "Twentieth Century." We are indebted to Mr. ARTHUR W. SUTTON for the following account of the methods employed in the preparation of spawn:—"The old style of procuring virgin Mushroom spawn may be briefly described as follows: Experienced men searched old manure or compost heaps and pasture lands for the mycelium of the Mushroom, which is produced naturally in such places. This they sold to growers of the commercial spawn, who placed it in beds and allowed it to run through the material forming them. The 'stock' spawn thus obtained was in due course used to impregnate the compost, which, in the form of 'bricks,' is the medium through which the spawn is passed on to the market grower or amateur. This method was more or less unsatisfactory, since the mycelium of species other than the common Mushroom (*Agaricus campestris*) appears to have been occasionally mistaken for it, to the great disappointment of and loss to the grower. In 1897 a process was discovered of producing virgin Mushroom spawn by artificially germinating the spores, and the mycelium thus produced was sold in test-tubes by the manufacturers. The practice of propagation by spores

was, of course, a great step forward, and growers could for the first time be fairly certain that the spawn they purchased would produce the variety of Mushroom they wished for. However, even this system had its drawbacks, and it was hoped that a better one might be discovered. With this idea careful experiments were carried out, but it was not till some years later that the process by which our '20th Century' Mushroom spawn is now manufactured was put into practice. This method is known as 'tissue culture,' and originated in the discovery that mycelium could be produced from a portion of the Mushroom itself. The possibility of this, as the name of the method implies, is the underlying principle of the new culture. The process involves careful work in the laboratory, where all vessels used have to be sterilised, and dust and draught rigorously excluded. The manure employed has to be produced under special conditions and very carefully prepared, cleanliness being of the utmost importance. It is claimed for this process that not only can growers be quite certain that the spawn they purchase is true to name, but also that the improvement of varieties by selection is for the first time made possible, and it is a fact that the yield has already been largely increased. From a practical point of view there can be little doubt that the 'tissue culture' is an advance on propagation by 'spore germination,' which itself is an enormous improvement on the haphazard methods of ten or fifteen years ago."

EXPERIMENTS ON THE VALUE OF NITRO-BACTERINE.

In the spring of this year a culture material known as "Nitro-bacterine," for introducing into the soil those valuable bacteria which form nodules on the roots of leguminous plants was largely advertised. Its value and efficiency, at least with garden crops, have now been scientifically tested in a number of cases with almost uniformly unfavourable results. I would refer to the very complete series of experiments carried out on the inoculation of Peas with "Nitro-bacterine" by Mr. F. J. Chittenden, F.L.S., at the Royal Horticultural Society's gardens at Wisley (*J.R.H.S.*, vol. 34, part II., November, 1908). The following sentences occur in his summary:—"There was under no soil treatment a consistent increase in the crop due to inoculation. The uninoculated seed gave a crop 14 per cent. heavier than the inoculated in the aggregate. It is concluded that the inoculation of leguminous crops with 'Nitro-bacterine' in ordinary garden soil is not likely to prove beneficial." Dr. Voelcker also has given the material a trial at the Royal Agricultural Society's farm at Woburn, with results in no wise favourable to "Nitro-bacterine," and there is a mass of private testimony to the same effect.

In these circumstances, it will perhaps be of interest if I briefly record the results of an experiment on the inoculation of Peas and Beans with "Nitro-bacterine" at the S.-E. Agricultural College, Wye, Kent, which add further confirmation to these conclusions.

The varieties of Peas employed were Carter's "Eight Weeks," "Early Morn," and "Yorkshire Hero." Two sets of trials were carried out (1) on very poor soil just above the chalk, and merely dug over before sowing; (2) on well-manured, trenched ground intended for vegetable culture. Four rows of each variety—each row 21 feet long—were planted, and in each case a row sown with inoculated seed alternated with a row sown with untreated seed. The preparation of the culture material and the inoculation of the seed were performed precisely according to the instructions given and, in all details, inoculated and uninoculated rows were treated in an identical manner.

The following table gives the results, showing the total weight of pods obtained from each pair of rows, expressed in grams.

SOIL MANURED AND TRENCHED,

Variety.	Seed not Inoculated.	Seed Inoculated.
	Grams.	Grams.
Early Morn... ..	9,889	8,010
Yorkshire Hero	14,700	14,295
Broad Beans	13,142	12,091

POOR SOIL UNMANURED,

Variety.	Seed not Inoculated.	Seed Inoculated.
	Grams.	Grams.
Eight Weeks*	6,126	6,490
Early Morn... ..	5,694	5,291
Yorkshire Hero	11,760	11,097
Broad Beans	10,427	9,098

The "Eight Weeks" Peas on the good soil were somewhat damaged by pigeons, and the crop was not weighed. It will be seen that the produce from the inoculated rows in every case but one* weighed less than that from the corresponding uninoculated rows. Throughout the growth of the plants no difference between treated and untreated rows was distinguishable; both lots formed nodules on their roots to about the same extent, and the untreated rows came to maturity quite as soon as the others. There was no evidence of any kind to show that the slightest benefit had been obtained by the use of "Nitro-bacterine" on either type of soil.

The experiment was on a small scale, but so far as it goes, is conclusive, and serves to confirm many results obtained with "Nitrobacterine" this summer. Further trials on a larger scale on a "seeds" mixture are in progress on the College farm. *C. T. Gimmingham, Bacteriologist to the S.-E. Agricultural College, Wye, Kent.*

THE ROSARY.

NOTES ON VARIETIES.

CLOTHILDE SOUPERT (*Souper et Notting, 1890*).—Another very large flower for a Pompon, of the most delicately beautiful colour—the outer petals being pearly-white and the centre an exquisite rosy shade. It is a very full flower with pleasing foliage and succeeds best in a dry season. It is to be strongly recommended for planting.

MOSELLA (*Lambert & Reiter, 1896*).—A strong grower, often classed as a Hybrid-Polyantha Rose. The flowers are quite large and almost Camellia-shaped. The colour is white on a clear yellow ground. Although this Rose is not a favourite of mine, it is very floriferous.

GEORGE PERNET (*Pernet, 1889*).—A bright yellowish-rose, changing to peach colour. A fair-sized bloom for its class, and one that lasts well from start to finish.

MRS. W. H. CUTBUSH (*Cutbush*).—A very pretty, little, pale pink variety with flowers borne in clusters. It is of similar habit to Mme. N. Levavasseur, and is just as free as that variety.

ÄENNCHEN MÜLLER (*G. C. Schmitt, 1907*).—This pretty Rose has cherry-pink flowers with distinct, white centres. The flowers, which last fresh for a very long time, become on ageing exactly like little Cactus Dahlias. Although of very dwarf growth, the blooming is as free as with any of the Pompons. It is to be recommended as a good and pretty novelty.

AMY MÜLLER (*G. C. Schmitt, 1907*).—The large clusters of brilliant rose-coloured flowers are produced in great profusion. I have not yet secured this variety, but it is well spoken of.

ALICE CHARMION (*Dubreuil, 1907*).—Another promising new variety, having small, pale, flesh-coloured flowers pink in the bud state. The blooms are produced in large bunches.

CANARIENVOGEL (*Welter, 1904*).—The flowers are of a golden-yellow and orange colour, spotted with rose. The blooms are full and borne on erect stems. Canarienvogel has not done well with me, so I cannot recommend it.

MADAME E. A. NOLTE (*Welter, 1904*).—The colour of the flowers is a chamois-yellow, opening a lighter shade. I have only grown it this summer, but think very poorly of it.

PETIT CONSTANT (*Souper et Notting, 1904*).—A pretty little flower with rosy-carmine, reflexed, orange petals.

PRIMULA (*Souper et Notting, 1901*).—This variety has bright China rose-coloured flowers, with snow-white centres. It is most effective and pretty, but, with me, not free in flowering.

ROSALIND (*Paul & Son, 1907*).—This has bright pink flowers, but deeper coloured buds. It is said to be particularly good in the autumn, and I think it very promising.

RÖSEL DACH.—A full, bright cherry-rose coloured flower. I have only one plant which has not done well this, its first, season with me. The habit appears to be very dwarf.

AMELIE SUZANNE MORIN.—White, shaded with yellow, flowers. I do not recommend this as it is a poor thing.

ASCHENBRÜDEL (*P. Lambert, 1903*).—A fine variety, with most lovely peach-coloured flowers exceptionally freely produced in clusters of about a dozen. The growth is bushy and strong for a Pompon. The foliage is most beautiful, and the plants are grand bedders. *Leonard Petrie, Gayton, Cheltenham.*

ROYAL COMMISSION ON COAST EROSION AND AFFORESTATION.

(See also pages 56 and 58.)

THE second report of the Commission dealing with the question of afforestation has recently been issued as a Blue Book*.

To the original warrant of July, 1906, a reference, as under, was added in March, 1908:—

"To enquire and report whether, in connection with reclaimed lands or otherwise, it is desirable to make an experiment in afforestation as a means of increasing employment during periods of depression in the labour market, and, if so, by what authority and under what conditions, such experiments should be conducted."

The names of the Commissioners are as follows:—Hon. Ivor C. Guest (chairman), Sir W. H. B. folkes, Bart., Sir Leonard Lyell, Bart., Sir William Matthews, E. Stafford Howard, H. C. Monro, W. P. Beale, G. C. Frederick, John Galvin, H. Rider Haggard, Thomas J. Jehu, Arthur Levy Lever, R. Beattie Nicholson, Patrick O'Brien, William Somerville, Fraser Story, Thomas Summerbell, John Ward, A. Stanley Wilson, C. H. Grimshaw (secretary), and D. R. Daniel (assistant secretary).

The Commissioners were unanimous in their findings with the exception of A. Stanley Wilson, Esq., who is of opinion that the utilisation of unemployed labour will involve a greater cost than is anticipated; also that sporadic planting is inadvisable, and that sufficient allowances have not been made for losses by forest fires, insect pests, snowstorms, and similar troubles.

The following is a synopsis of the principal conclusions contained in the report:—

1. Afforestation is practicable and desirable.
2. Approximate available area in the United Kingdom without material encroachment upon agricultural land is 9,000,000 acres.
3. Best rotation to secure sustained timber yield requires 150,000 acres to be afforested annually.
4. Employment.

(a) *Temporary*.—Temporary employment is afforded annually to 18,000 men during the winter months. Further an almost equal number would indirectly derive employment in the incidental and subsidiary occupations connected with forestry. This figure might be increased in any year to meet exceptional pressure of unemployment.

(b) *Permanent*.—Permanent employment is afforded to one man per 100 acres afforested, rising to 90,000 men when the whole area has been dealt with.

(c) *Ultimate*.—The employment connected with subsidiary industries, i.e., conversion and manipulation, &c., of the timber crop, would afford occupation for a still larger population.

5. Any scheme of national afforestation should be on an economic basis.

6. *Labour*.—There are sufficient unemployed persons willing to submit to, and able to satisfy, ordinary labour tests, who could advantageously be employed without a period of special training.

7. *Finance*.—Afforestation represents a productive investment and should be financed by a loan. The annual sum required for the full scheme is £2,000,000. The interest on the loan should be defrayed out of taxation. The net deficit will be £90,000 in the first year, and will rise progressively to £3,131,250 in the 40th year, after which period the forest becomes more than self-supporting.

8. *Profits*.—After 80 years the net revenue from the forest, at present prices—which

promise to be materially enhanced—should be 17½ millions. This represents 3¼ per cent. on the net cost calculated at accumulated compound interest of 3 per cent. Looked at from another point of view, the State will then be in possession of property worth £562,000,000, or about £107,000,000 in excess of the total cost involved in its creation, calculated at 3 per cent. compound interest.

9. *Administration and control*.—The afforestation scheme to be entrusted to a special Board of Commissioners. In default of purchase by agreement, land to be acquired if necessary under compulsory powers.

10. *Disturbance*.—The acquisition of grazing areas for silviculture might necessitate a modification of the existing agricultural system on certain farms. There is no reason to suppose that the remaining lowland areas on such farms could not either be adapted to other forms of agriculture, or could not, in many cases, be profitably utilised for small holdings. The acquisition of grazing areas, private or common, should present no difficulty which cannot be satisfied by arbitration and reasonable compensation.

11. *Incidental*.—Afforestation creates a new industry; it does not compete with private enterprise. The conversion of comparatively unprofitable lands into forests enhances the productivity of the adjacent areas, and should promote the development of the small holdings movement. More than any other apparent remedy, afforestation will stem the tide of rural depopulation.

BOSAHAN CASTLE, CORNWALL.

BOSAHAN CASTLE, the residence of Sir Arthur P. Vivian, Bart., is situated on a point of land stretching out into the English Channel, from which fine seascapes are obtained. The mansion is a comparatively new building erected on a spot close to the site of an older but much smaller house. The new residence was erected some 24 years ago, when a large number of Conifers and other trees were planted. The situation being high and exposed, the plants suffer greatly from the effects of wind, but species of a tender nature have been disposed in dells, which are screened by tall forest trees. At the main entrance is a hedge of Fuchsia Riccartonii 12 feet in height and another of Escallonia macrantha, whilst on the south side of the castle is a very fine specimen of Cassia corymbosa 30 feet high, and covered, in late summer, with bright yellow flowers. Amongst rare and tender plants which were noticed on a south wall were Libonia floribunda, Bougainvillea, Sollya heterophylla, Tibouchina (Lasiandra) macrantha, Solanum jasminoides (with flowers in large masses), Berberidopsis in fine bloom, and, in a border close by, a fine plant of Rhododendron Nuttallii. Dracæna purpurea was also flourishing in the open, as were Fuchsias of many kinds. In a lake were masses of Richardia africana. I also noticed specimens of Phormium tenax 10 feet high and plants of Clethra arborea as tall, the latter being a mass of bloom. On another wall were noticed some fine plants of Lapageria rosea and the variety alba. I noticed trees of Benthamia fragifera 40 feet high and crowded with fruits. Bamboos flourish in this garden with the greatest freedom. Tree Ferns planted in glades under trees were in a delightful condition and appeared as though they were growing wild. Blue-flowered Hydrangeas were seen in the glades. Chanærops excelsa was growing freely and had seeded, the young plants coming up thickly under the trees. I noticed also some fine specimens of Pinus excelsa and other Conifers, some of them reaching to a great height, although planted less than 25 years ago. Mr. Cranford, the gardener and agent, entered the service of Sir Arthur Vivian when the new castle was built. He came from the extreme north of Scotland, where he was in the service of the Earl of Stair, Lady Jane Vivian's father. Visitors approach Bosahan Castle from the sea, boats being provided for that purpose. *W. A. C.*

* Second Report (on Afforestation) of the Royal Commission Appointed to enquire into and to report on Certain Questions affecting Coast Erosion, the Reclamation of Tidal Lands, and Afforestation in the United Kingdom. Printed for His Majesty's Stationery Office by Wyman & Sons, Limited, 109, Fetter Lane, E.C.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CHRYSANTHEMUM FRAMFIELD PINK.—May I inform Mr. R. Richards (see p. 27) respecting the colour of this Chrysanthemum, that my experience is the same as his? But, in addition to the colour being poor, the variety is shy in flowering, which makes it scarcely worth growing. This is regrettable, as the lasting properties of the flower and the stiff stems and ample foliage are good. *T. Down, Basing Park Gardens, Alton.*

FLOWERS AT ROSEHILL, FALMOUTH.—I send herewith a photograph of *Solanum Balbisii* (see fig. 36), taken on November 11 last. The plant

gans, with the exception of one month in 1908, has flowered every day for over two years. *Coleonema alba* (*Diosma ericoides*) has not been without a flower for a single day during the past three years. It is slightly sheltered by a bough of Yew. *Fragaria indica* is in fruit and flower all the year round, and birds carry the seeds everywhere, so that we have thousands of plants flourishing like weeds. *Calceolaria Burbidgii* has magnificent blooms, and is 5 feet high. In the beginning of January, 1908, we had a plant of *Brugmansia sanguinea*, 8 yards in diameter, and 12 feet high, full of flowers. The frost then killed it to the ground, but the stumps shot out again, and now it is 8 feet high and flowering freely. *Brugmansia lutea* grows equally fast. We planted some of its seeds, which came up and developed flowers of sanguinea type, so that insects must have fertilised it with pollen from its

Fuchsias, Roses, Hydrangeas, Salvias, Marguerites, Veronicas in variety are all in flower. *Nicotiana Langsdorffii* still has some flowers. *Primula obconica* flowers all the year round. The same plant of *Kniphofia* has been flowering continuously since March last. My gardener counted 140 odd plants in flower on January 1 inst. *Howard Fox, Rosehill, Falmouth, January 9.*

TRENCHING.—I have read with interest Mr. Beckett's excellent notes each week on the cultivation of the kitchen garden, but I do not agree with his remarks on trenching (p. 22), where he advises the bringing of the bottom layer of soil to the top, whatever its condition or nature may be. I have had a considerable experience in gardens in which the top soil has scarcely exceeded 1 foot in depth, with a subsoil of stiff, heavy clay. There are, doubtless, hundreds of gardens throughout the country of such a nature, and I am certain that if Mr. Beckett's advice was followed too literally, there would be failures among many of the crops, at least during the first season after trenching. The plan I adopt with ground having a very heavy subsoil near the surface is to take out all the soil which is good or fairly good from the first trench, and place it where it is required for finally filling in. I next break up the subsoil with a digging fork or pick, using the former whenever possible. After this has been done, a considerable quantity of road scrapings, or the old soil from the potting shed, which has been laid in a heap for a year or more, is placed in the trench, together with some manure. These materials are mixed with the subsoil, and more loose soil is applied. A layer of manure is placed over this, after which the trench is filled with the best of the soil from the next trench. In trenching at a subsequent season, some of the bottom soil will be suitable for bringing to the surface. *A. Shaker-ton, The Gardens, Forde Abbey, Chard.*

FIG. 36.—*SOLANUM BALBISII* IN BLOOM AT ROSEHILL, FALMOUTH, ON NOVEMBER 11: HEIGHT 6 FEET.

is 6 feet high, and remained in the same luxuriance of bloom until the middle of December. It still shows flowers, and the scarlet berries are very numerous, some of them over an inch in diameter. The plant survived last winter's cold without any protection. The peculiar feature of this *Solanum* is its elegantly-divided leaf and the conspicuous orange-coloured sharp spines, which densely cover the stems, both sides of the leaves, petioles, and sepals. The south-west of Cornwall has escaped the late cold snap, which must have deprived many English gardens of their exceptionally brilliant show of flowers in winter months. At Rosehill, we have a tree of *Acacia longifolia* flowering three to four months before the usual time. *Cytisus proliferus* is doing the same thing. *Cestrum ele-*

neighbouring cousin. The following plants are flowering freely in the open air:—*Abutilon Boule de Neige* and *A. megapotamicum* (the latter has survived about 12 years against a wall), "Crusader" and "Prince of Wales," the latter 10 feet high. *Desfontainia spinosa* is flowering freely, with many berries of good size. *Sparmannia africana* is in flower, with very large leaves. It grows rapidly, but its roots are not strong enough to prevent violent winds blowing it down. *Clianthus puniceus*; *Eupatorium micranthum* (*Weinmannianum*) is 10-11 feet high, full of seed, with a few flowers still in bloom. *Musa japonica* sends up suckers annually. Early in January, 1908, I had five plants in flower, with a few whorls of fruit set at the top of the arched peduncle. *Cyclamens, Ericas,*

THE CLASSIFICATION OF DAFFODILS.—The article by Mr. A. J. Bliss, printed on p. 42, is a timely and valuable contribution to the question raised by the publication of the new classification of Daffodils by the Royal Horticultural Society. Although all may not be able to follow him on certain points, as, for instance, the placing of all *Triandrus* hybrids in one class, yet his proposal for the printing of parentages is a practical one, and it is to be hoped that it may shortly be adopted. At present few raisers when showing their seedlings (with the notable exception of the Rev. G. P. Hlaydon) seem willing to give the information required. I cannot help thinking that they would do it did they realise the intense interest it gives to students and young raisers of the flower. The R.H.S. would be setting a good example by following out the suggestion offered by Mr. Bliss. *Narcissophile.*

PREPARATIONS FOR TRANSPLANTING TREES AND SHRUBS.—If the roots of large shrubs and trees be shortened at this season the plants can be shifted next autumn with every hope of success. Last year I removed a Yew hedge that had been planted 28 years; the length of the hedge was 60 yards. Not a single tree died, and the hedge appears little the worse for its disturbance. I also removed a large Yew weighing 2 to 3 tons, and this also is doing well. A circular trench 2 feet wide should be dug around the plant at a distance from the stem varying according to the size of the tree. If the specimen is from 6 to 10 feet high the distance should be 3 feet from the bole. This will afford a circle having a diameter of 6 feet inside measurement. The depth of the trench should be from 2 to 3 feet. When all the largest roots have been severed, any bruised portions should be trimmed with a sharp knife, as a clean cut heals quickly. During the summer a number of new fibrous roots will form close to the stem of the tree, and these will admit of a good ball of soil being removed with the tree. After pruning the roots fill in the trench again, well ramming the soil, and taking care not to bruise the ends of the roots. If the summer proves hot and dry, the trees must be syringed two or three times each day, and also be given an occasional watering at the roots. *A. Gooding, Earham House Gardens, Chichester.*

THE POTATO IN SCOTLAND.—The note which Mr. McDonald amplifies (see p. 13) was written simply to furnish a fact which hitherto, so far as I know, had never been published regarding the period when Potatoes were first cultivated as a field crop in Scotland. It is now many years since I first pointed out that the Potato had been a garden crop for a long time previous to the dates given by most authorities, but, in books and other literature published since, other authorities than Reid are still accepted as guides. Probably the same treatment will be accorded Donaldson's statement. Part of Mr. McDonald's note shows how facts are misstated. The Thomas Prentice referred to is doubtless Henry Prentice, who was not a common day labourer, but a market gardener of eccentric character, who cultivated ground east of Edinburgh and sold the produce in that city, to which it was transported in the manner described in *Cockburn's Letter* (Scott. Hist. Soc.) in creels, till a nobleman offered him the loan of a pony and cart. These Prentice accepted, but seems to have understood that the loan was without any time limitation. It was characteristic of this individual that he purchased his own coffin and kept it in his house for several years, had his gravestone prepared, and precontracted for his burial in Kestralrig Churchyard, where, after his death at the age of 85 years, he was interred in 1788. At least as early as 1746 Potatoes formed part of Prentice's crops. The Kilsyth Potato-grower was a factor named Grahame, who cultivated half an acre of the esculent in lazy beds. There is an excellent chapter on the field culture of the Potato in Berwickshire in Dickson's *Treatise of Agriculture*, written about 1764, from which it is evident that its cultivation was well understood, and, compared with the methods advocated at the same period in *Museum Rusticum et Commerciale*, it shows that the Scottish farmer was far in advance of his English contemporary. It was at about this time that notice first appears of "curi" in the haum of the Potato. In Somerville's *Agriculture of East Lothian* (1805) it is stated that the first serious attempt at field-culture was made on the farm of Craigilan, near Aberlady, about the year 1760, and that Potatoes were cultivated in fields for sale only in the vicinity of towns, the farmer's usual crop amounting to as much as supplied his family, and one-sixteenth of an acre for each of his farm servants. At this period the Kidney mentioned in my previous note was still esteemed one of the best kinds. This writer also records how it was customary for farmers to sublet part of certain fields to townspeople, who paid from £5 to £10 per acre for the sole purpose of growing Potatoes. I will add that the reason for the prejudice against the Potato was on account of its being considered a plant under the dominion of Aphrodite. As I hinted previously, the belief is not yet extinct. *R. P. Brotherton.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 12.—*Present:* E. A. Bowles, Esq., M.A., F.L.S. (in the chair), Dr. M. C. Cooke, Messrs. Hales, Chapman, Güssow, Fawcett, Worsdell, Saunders, Fraser, Holmes, Bennett-Pöe, Rolfe, and Chittenden (secretary)

Richardia discoides.—A large spathe of *R. africana* was exhibited having about half the outer part brown and dead. Similar brown spots had appeared upon the leaves. No fungus was present, and the Committee thought that, in all probability, the trouble was due to overfeeding.

Malformed Orchid.—From Mr. LYNCH, V.M.H., of Cambridge Botanic Garden, came a malformed flower of *Cypripedium Dominicanum*, with a normal flower for comparison. The flower had the sepals fused and a double lip; it was taken by Mr. SAUNDERS for further examination.

Diseased Carnations.—Specimens of diseased Carnations were received from Natal, where a very large number of plants had suffered at all stages. These were referred to Mr. SAUNDERS and other members of the Committee for further investigation.

Nomenclature of multigeneric Orchid hybrids.—The Chairman announced that the sub-committee

appointed to consider this question had arrived at the decision that the best solution of the question lay in coining names for each of the combinations of genera made, consisting of a commemorative name and the termination "ara." The full text of their finding will be laid before the Committee at an early date.

Parasitic Rose canker.—Mr. CHITTENDEN showed specimens of the Rose canker described in the *Journal R.H.S.*, Vol. xxxiv., p. 222. The Roses attacked had been imported from Germany three years since.

GHEENT HORTICULTURAL.

JANUARY 3.—At the monthly meeting held under the auspices of the *Chambre Syndicale des Horticulteurs Belges* and the *Société Royale d'Agriculture et de Botanique de Gand*, which took place on the 3rd inst., Certificates of Merit were granted to the following Orchids exhibited by Mons. F. LAMBEAU:—*Cypripedium insigne* Babette, *C. Leeanum* Laekense, *C. insigne* Lambeauium, and *C. aureum* Cyrus. Also to *Cypripedium* var. (Orphanum × *Boadicea*) shown by Mons. J. VAN SCHOOTE; to *Lælia anceps* alba var. *Stella* and *Cattleya Trianae* superba exhibited by Mons. VERDONCK. A Cultural Commendation was awarded to Mons. A. MAES-BRACKMAN for a fine specimen of *Cypripedium Albertianum*. Certificates of Merit were also given to *Begonia Gloire de Lorraine* var. *multiflora* præcox exhibited by Mons. A. RIGOUTS, and to cut flowers of winter-flowering *Carnation Grande Duchesse Olga* shown by Mons. F. DE BIÈVRE.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 7.—*Committee present:* E. Ashworth, Esq. (chairman), and Messrs. Smith, Thorp, Ward, Cowan, Shill, Warburton, Keeling, Holmes, Ashton, Cypher, Parker, Ball, and Weathers (hon. sec.).

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), exhibited a miscellaneous group, amongst which *Odontoglossums* were a feature. Two hybrid *Odontoglossums*, the parentage of which was not recorded, received Awards of Merit. These were O. × G. Weatherby, of a fine rich bronze colour, and O. × Martin; the latter resembled O. × *ardentissimum*. (Silver-gilt Medal.)

Messrs. HUGH LOW & Co., Enfield, were awarded a First-class Certificate for *Cattleya* × *Maggie Raphael* var. alba, an albino with a faintly-tinted lip.

Mr. J. ROBSON, Altrincham, received an Award of Merit for *Cypripedium* × *Leeanum* Chardwar variety.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), exhibited *Odontoglossum crispum* var. *Daphne*, to which an Award of Merit was granted.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalglish), staged a group of *Cypripediums*, for which a Silver Medal was awarded. C. × *Qeson* var. *giganteum* was awarded a First-class Certificate. Other choice plants in the group were C. × *Archimedes*, C. × *Naudii*, C. *Stepmanii* var. *superba*, and C. × *Harri-Villo*. C. × *Harri-Villo* received an Award of Merit.

Mr. H. ARTHUR, Blackburn, was awarded a Bronze Medal for a small group containing choice *Cypripediums*, of which C. *insigne* Harefield Hall variety was the most noteworthy.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), gained a Silver Medal for a group of Orchids. *Lælia* × *Cranstonii* received an Award of Merit.

Mr. C. PARKER, Preston, was awarded a Bronze Medal for a group of *Cypripediums*, which included C. *insigne* var. W. M. Dow, C. *insigne* var. *Dorothy*, and C. × *aureum* var. *virginale*.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. Mr. Herdman), received a Silver Medal for a choice group of *Cypripediums*. C. × *nitens* "Under Feli variety" and C. × *Leeanum* var. *Hercules* received Awards of Merit.

H. J. BROMLOW, Esq., exhibited a fine group of *Cypripediums*, many of the plants being of well-known species and varieties. C. × *Qeson* var. *giganteum* received a First-class Certificate, and a similar award was voted to C. *Charlesworthii* "variety Bromilowiae," a form quite distinct from the variety *Bromilowianum*. C. ×

Euryades "Heaton variety," C. × *Juno* "Rann Lea variety," C. *bellatulum* var. *Marjorie*, and C. × *Ainsworthii* received Awards of Merit. A Silver-gilt Medal was awarded to the group.

MESSRS. SANDER & SONS, St Albans, exhibited *Cypripedium* × *Lathamianum* Sander's variety, to which an Award of Merit was granted.

MESSRS. KEELING & SONS, Westgate Hill, Bradford, were awarded a Silver Medal for a group, Awards of Merit being granted to those following:—*Calanthe Veitchii* var. alba, *Cypripedium* × *Courtauldianum* var. *magnificum*, C. × *Bruno* "Keeling's variety," and C. × *Mons. de Curte* "Keeling's variety." A splendidly-cultivated plant of *Angraecum sesquipedale* was awarded a First-class Certificate.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Fletcher), staged a good group, to which a Silver Medal was awarded. *Odontoglossum* × *Lambeauium* var. *Triton* and *Cymbidium* × *Holfordianum* received Awards of Merit.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), was given an Award of Merit for *Cypripedium* × *Charlesianum* var. *Queen Maude*. The flower is green in colour and of fine proportions.

Messrs. WM. BULL & SONS, Chelsea, received an Award of Merit for *Odontioda* × *Cheloniensis*.

E. ASHWORTH, Esq., Wilmslow (gr. Mr. Holbrook), staged a group to which a Silver Medal was awarded. *Cattleya chocoensis* alba var. *maxima* received an Award of Merit.

MESSRS. JAMES CYPHER & SONS, Cheltenham, staged a very bright and attractive group of plants. (Silver Medal.)

Mr. W. BOLTON, Warrington, obtained a Silver Medal for a good group.

Other exhibitors were Mr. J. H. CRAVEN, Keighley, and Messrs. WM. OWEN & Co., Northwich. *P. IV.*

SCOTTISH HORTICULTURAL.

JANUARY 12.—The annual business meeting of this association was held at 14, South St. Andrew Street, Edinburgh, on this date. Mr. Whytock, the president, presided over an audience of more than 200 members. The report by the council showed that there was a steady increase in the membership, and that the work of the past year had been of a very satisfactory kind. Reference was made to the death of the late Marquis of Linlithgow, who was for two years honorary president of the Association.

The Chrysanthemum Show held in November was not a financial success. It was decided, on the recommendation of the council, to hold two excursions during 1909, one to Tulliallan and Dunfermline in July, and the other to Hopetoun in August. Lord Elphinstone was re-elected honorary president, Mr. Whytock president, and Mr. A. D. Richardson secretary and treasurer. The two vacancies in the vice-presidencies were filled by the election of Messrs. A. Johnstone and W. Tait, and the seven vacancies in the council by the election of Messrs. W. Brunton, W. Copeland, J. Dobbie, A. R. Henderson, D. T. Johnston, W. Mather, and D. W. Thomson. A series of papers for reading during the current session was submitted. Twenty-seven new members were elected at the meeting.

The next monthly meeting will be held on February 2, when the president will deliver his address, and photographs of flowers, fruits, &c., in their natural colours will be displayed by Mr. E. L. Brown.

HORTICULTURAL CLUB.

JANUARY 12.—The usual monthly meeting of this club took place at the Hotel Windsor on the above date, Mr. C. E. Shea occupying the chair. The Rev. Canon Horsley gave an interesting lantern display of views of the Swiss Alps, with which he has rendered himself thoroughly familiar by repeated tours accompanied by a considerable number of ladies and gentlemen who form private touring parties under his guidance. The lecture was announced to be on the "Flowers of Switzerland," but references to these were mainly confined to the subsequent discussion. Canon Horsley restricted himself, during the lecture proper, to a description of beautiful views of snow-clad Alpine ranges, deep gorges, magnificent cascades and splendidly rugged glaciers. Views

were presented in rapid succession to illustrate the progress of the party. As the Canon on these expeditions avoids the beaten track as far as possible, most of the views were fresh even to such of his audience as had visited Switzerland. The fact was incidentally mentioned that most of the principal glaciers are retreating with comparative rapidity up the valleys they have formed, as much as two miles being observed within recent memory. Another point observed by the lecturer in his explorations was what he termed the "zonality" of plant life, certain Alpine plants being only found between definite extremes of high and low level, so that when his party produced certain plants he could, with comparative certainty, tell the heights they had to climb to obtain them. *Gentiana acaulis* was mentioned as being the only *Gentiana* which varied greatly in colour. This species has tints from Oxford blue to Cambridge blue, pure white, and blue striped with green. A number of views were of the picturesque villages nestling under the Alpine heights, their deep overhanging caves, projecting balconies, curiously carved woodwork and stone-laden roofs, coupled with the quaint costumes of the inhabitants, forming very charming snapshots. A view of Meiringen before and after a devastating fire gave a striking idea of what a conflagration causes in a closely-packed mass of wooden dwellings. Mr. Shea, himself an ardent Alpine climber and explorer, confirmed the lecturer's remarks on the glacial phenomena.

COVENTRY CHRYSANTHEMUM.

JANUARY 14.—The annual meeting and dinner of this society was held under the presidency of the Deputy-Mayor of Coventry—Alderman A. H. Drinkwater—on this date. The annual report showed that there was a loss of about £8 on the annual show, but a balance in hand on the year's working of £11. The Deputy-Mayor and Councillor Batchelor, in proposing and seconding the adoption of the Report and Balance-sheet, said that considering the condition of local trade the society was to be congratulated on its Report. Alderman Armishaw, speaking with regard to the society's proposal to arrange a summer show, advised waiting until there was a boom in trade. The Report was adopted and the committee were re-elected. Mr. G. Griffin was re-appointed secretary and Mr. T. Smith treasurer.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

JANUARY 21.—The annual meeting of this Institution for the Election of Pensioners is being held on Thursday afternoon as these pages are sent to press.

RESULT OF ELECTION.

There were 73 candidates, and the eighteen whose names are given below were successful:—

Name	Age.	Number of Votes.
Emma J. Whitehurst ...	71	4,746
John G. Anstey ...	80	3,028
Matilda Ings ...	65	2,946
Henry Heims ...	68	2,908
Thomas Jones ...	44	2,903
John Burton ...	74	2,883
Henry Cooper ...	72	2,855
William Gardiner ...	73	2,825
Jane Noble ...	69	2,800
Harriett Heiman ...	64	2,681
William Cope ...	64	2,618
Henry Gage ...	74	2,569
Thos. C. Cushion ...	70	2,494
Edward Tibbles ...	64	2,449
George Lawrence ...	73	2,429
Joseph Throp ...	62	2,359
Joseph Talmage ...	64	2,350
William Reynolds ...	74	2,303

After the declaration of the poll and on the proposition of the committee, two additional candidates were elected. These were:

Nancy Wright. James Young.

Mr. Arthur W. Sutton generously offered the sum of £20 in the case of W. J. Williams; Mr. G. Munro will continue the pension to the candidate be selected last year.

CALEDONIAN HORTICULTURAL.

JANUARY 13.—The annual general meeting of the above society was held on this date, the occasion being the centenary of the society. The chair was taken by Mr. J. W. M'Hattie, Superintendent of Parks. The financial statement showed a balance of £177 0s. 5d. in favour of the income account; while, under the capital account, the credit balance of the life members' fund was £569 9s. The Chairman thought the society was carrying out its duties perfectly. The centenary will be celebrated by a show in September next, and everything will be done to make the event a great success. It was very unfortunate that, acting on legal advice, they were compelled to write off some £200 worth of the Metropolitan District Railway debenture stock. It was a peculiar fact that almost every exhibition had met with financial failure in the Waverley Market this year, and he believed that even the carnival was conducted at a loss. The Report was adopted. Lord Balfour of Burleigh was re-elected president; Lord Dunedin, vice-president; and Messrs. William Pirie, The Gardens, Dalhousie Castle, J. D. Adair, Shandwick Place, and A. Malcome, Duns, appointed councillors in place of those retiring.

ROYAL METEOROLOGICAL.

JANUARY 20.—The annual meeting of this society was held on the above date at the Institution of Civil Engineers, Westminster, Dr. H. R. Mill, president, in the chair.

The Council, in their Report, referred with pleasure to the increasing interest in meteorology which is apparent throughout the country, and they believe that this is in some measure due to the scheme of lectures inaugurated by the society. They also reported a further increase in the membership.

Dr. Mill devoted his presidential address to explaining "Some Aims and Efforts of the Society in its Relation to the Public and to Meteorological Science." He pointed out that the society is composed of Fellows whose interest in meteorology varies widely, and there is moderation in dividing the Fellows into no more than three orders—meteorologists, observers, and interested persons.

After Dr. Mill had been thanked for his address and for his services during the past year, Mr. H. Mellish was elected president, and Mr. F. Campbell Bayard and Commander F. W. Caborne, C.B., secretaries for the ensuing year.

CATALOGUES RECEIVED.

SEEDS.

- WM. THOMPSON & Co., LTD., Londonderry.
- WM. SAMSON & Co., 8 & 10, Portland Street, Kilmarnock.
- PENNELL & SONS, Lincoln.
- TILLIE, WHYTE & Co., 12, Melbourne Place, Edinburgh.
- D. G. PURDIE, 6, Waterloo Street, Glasgow.
- HOGG & ROBERTSON, LTD., 22, Mary Street, Dublin.
- PAUL & SON, 6, Wortwood Street, Old Broad Street, London, E.C.
- THOMAS S. WARE, LTD., Ware's Nurseries, Feltham, Middlesex—Also Begonias.
- THOMAS WYLLIE & Co. (late CUNNINGHAM & WYLLIE), 98, Mitchell Street, Glasgow.
- W. SMITH & SON, Exchange Seed Warehouses, Aberdeen.
- ARTHUR ROBINSON, 35, Canomile Street, London, E.C.
- W. P. BOUND, Station Road, Redhill.
- JAMES MURRAY & SONS, Deptford, London, S.E.
- CARTER PAGE & Co., 52 & 53, London Wall, London, E.C.
- FRANK DICKS & Co., 63, Deansgate, Manchester.

MISCELLANEOUS.

- T. CASNON, Millfield, Peterborough—Wooden boxes and trays for dispatching fruits, flowers, &c.
- AMOS PERRY, Enfield, Middlesex—New and rare hardy plants, Montbretias, Japanese Lilies, flower seeds, &c.
- FENNICK & Co., Delgany Nurseries, Co. Wicklow, Ireland—Hardy Trees and Shrubs.

FOREIGN.

- PETER HENDERSON & Co., 35 and 37, Cortlandt Street, New York Seeds.
- F. C. HEINEMANN, Erfurt, Germany Seeds.
- VILMORIN-ANDRIEU & Co., 4, Quai de la Mégisserie, Paris, France—General catalogue of Seeds and Plants.

SCHEDULE RECEIVED.

Cardiff and County Horticultural Society's Coming-of-Age Show, to be held on Wednesday and Thursday, July 21 and 22, in the Sophia Gardens and Field, Cardiff. Secretary, Mr. A. Maurice Bailey, 24, Duke Street, Cardiff.

DEBATING SOCIETIES.

BIRMINGHAM GARDENERS'.—The annual general meeting of this association was held on January 11th, Mr. Walter Jones presiding. Mr. Walter E. Collinge, late of the Birmingham University, has retired from the office of president, owing to his appointment at Berkhamsted. Dr. G. S. West, M.A., F.L.S., lecturer in botany at the University, Birmingham, was elected to fill the vacancy. The resignation of the chairman, Mr. Walter Jones, was also announced. Mr. Jones's resignation was accepted with regret, and a hearty vote of thanks was accorded for his past services. The vice-chairman, Mr. Thos. Humphreys, Curator of the Botanical Gardens, Birmingham, was unanimously elected chairman. Mr. C. H. Herbert was elected vice-chairman. The treasurer, librarian, and secretary were all re-elected.

BRIGHTON AND SUSSEX HORTICULTURAL.—The annual report for 1908 shows a financial loss on the year's working of £64 18s. 3d. Three flower shows were held during the past year, but the committee have decided to hold only two shows in 1909, viz., a Rose show on June 29 and 30, and a Chrysanthemum exhibition on November 2 and 3.

BRISTOL AND DISTRICT GARDENERS'.—The first meeting in 1909 was held on Thursday, January 14, at St. John's Parish Rooms, when the president, Col. Carey-Batten, presided over a good attendance of the members. A paper on "Odontoglossums" was given by Mr. Wakefield, gardener to Mr. Shipley, Elmfields, Westbury-on-Trym. The lecturer recommended September as the best month for potting these plants, because they are then able to recover from the check to the roots before the advent of the dull winter months. Although *Polypodium* and *Osmunda* fibre may be used with success, the lecturer preferred to employ peat of the best quality. Mr. Wakefield gave a list of *Odontoglossums* cultivated at Elmfield.

CHESTER PAXTON.—The opening meeting of the new session was held in the Grosvenor Museum, on Saturday, January 16, under the chairmanship of Mr. A. W. Armstrong. A lecture entitled "Winter Botany," illustrated by lantern slides, was delivered by Mr. J. D. Siddall. The lecturer dealt with various aspects of winter botany, and gave a list of British plants which are to be found in flower during the winter months. Particulars of several of the winter-flowering shrubs and berry-bearing plants were also given. The next meeting will be held on Saturday, January 30, when Mr. G. P. Miln will deliver a lecture upon the "Agriculture and Horticulture of Denmark."

CROYDON & DISTRICT HORTICULTURAL.—The annual report shows a satisfactory year for 1908. In all 22 meetings have been held, at most of which lectures and papers relative to horticulture have been given. There has been a greater number of exhibits at the meetings, the quality of the produce displayed being excellent. The annual dinner, held on January 22, proved successful. The spring show was held at the Horniman Hall, Croydon, on May 6. The number of exhibits was greater than at any previous spring show, although no prizes were offered for any exhibit. About 40 members and friends paid a visit to the Franco-British Exhibition on August 18, the occasion of the annual summer outing. Two meetings held in June and July were well attended, when visits were paid to the nurseries of Mr. C. F. Bause and to the Sydenham Recreation Grounds. The financial statement shows a balance in hand of £7.

ESHER COTTAGE GARDENERS'.—At a meeting of this society held on January 13, Mr. Edwin Beckett, V.M.H., gave a lecture on "Vegetable Culture," illustrated by lantern views. Her Royal Highness the Duchess of Albany was present at the meeting. Mr. S. A. P. Kitcat, the newly elected president, introduced the lecturer, who for some years was a resident in Esher. Mr. Beckett dealt with the culture of many of the more important vegetables, his remarks being illustrated by many specimens of the various kinds of vegetables grown at Aldenham. Many questions, asked at the close of the lecture, were answered by the lecturer.

READING AND DISTRICT GARDENERS'.—The annual general meeting of this society was held on Monday evening, January 11, in the Abbey Hall, Reading. There was a large attendance. The principal business of the meeting was the election of officers for the ensuing year, and the passing of the balance-sheet and report for 1908. Mr. Alderman Parfitt, J.P. (president) occupied the chair. The balance-sheet showed that the association is in a satisfactory financial condition. Mr. Alderman F. B. Parfitt, J.P. was again elected president. The meeting also appointed Mr. A. F. Bailey chairman, and Mr. H. C. Loader vice-chairman, for the ensuing year. The other officers, including the hon. secretary, Mr. Castle, and the committee, were also appointed. Several new members were elected.

REDHILL, REIGATE AND DISTRICT GARDENERS'.—The annual social gathering in connection with this society took place recently in St. Matthew's Parish Room, Redhill. The meeting proved a great success, the large room being well filled by members of the association and their lady friends. A musical programme of much excellence was carried out, and during an interval light refreshments were served. The chair was occupied by Sir Jeremiah Colman, Bart. (president of the association).

—The annual general meeting of this association was held on Monday, January 11, Mr. W. P. Bound presiding. The report and balance-sheet showed that the association closed its session with a balance in the bank of £14 3s. 2d., as against a balance of £22 12s. 5d. for the previous year. The loss was accounted for to some extent by a decrease in the membership, which had dropped from 225 to 190. The committee recommended that honorary members be asked to contribute a maximum subscription of 5s. Last year the honorary subscribers were not called upon to subscribe. The report and balance-sheet were adopted. Sir Jeremiah Colman, Bart., was re-elected president of the association for the ensuing year, Mr. W. P. Bound was re-elected chairman, and the other officers and committee were also appointed. The hon. secretary, Mr. Rose, was presented with an honourarium of £5.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 16, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather was generally rough and very unsettled. Rain fell frequently in the south and east, alternately with very fine intervals, while in the western and northern districts rain, sleet, or snow occurred nearly every day. In Scotland the snow which was experienced during the latter part of the period was very heavy, many places receiving successive falls yielding, when melted, more than 0.5 inch of water in the gauge; heavy snow was also general in the north of Ireland. All parts of the Kingdom were visited by a thunderstorm some time during the week, and in some localities the disturbances were severe.

The temperature was subject to frequent and violent changes in the north and north-west of the Kingdom. In Scotland and the north of Ireland the mean for the week was below the average, but in England and in Ireland S. it was above it, the excess in the Eastern, Central, and Southern Counties being more than 3°. The highest of the maxima were registered during the early days of the week at most stations, and varied from 54° in the Midland Counties to 49° in Scotland N. and W. Late in the week the maxima at some Scottish stations were very little above 32°. The lowest of the minima, which occurred generally during the latter half of the week, ranged from 18° in Scotland E. (at Balmoral), and 20° in England E. to 30° in Ireland S. and to 39° in the English Channel. The lowest grass temperatures reported were 9° at Crathes, 12° at Balmoral, 16° at West Linton, 19° at Cockle Park (Morpeth), 21° at Clacton-on-Sea, and 22° at Norwich.

The mean temperature of the sea.—The temperature was more than 4° higher than during the corresponding week of last year on the south-west coast of England, but in several other localities it was rather lower. The actual figures ranged from 49.7° at Plymouth and 49.0° at Newquay, to about 40.0° at Margate and Kirkwall, and to 35.5° at Aberdeen.

The rainfall (rain and snow) exceeded the average in all districts except England E. and N.E. The excess was very large in Scotland, the north-west of England, and north of Ireland, and also in the English Channel, but moderate elsewhere.

THE WEATHER IN WEST HERTS.

Week ending January 20.

The third mild week in succession.—Since the year began there has been no cold worth mentioning, either during the daytime or at night. On the coldest day during that period the highest temperature in the thermometer screen was only 2° colder than is seasonable, and on the coldest night (last night) the exposed thermometer registered only 10° of frost—or 5° of frost more than the average minimum for January. The ground is now 2° warmer at 2 feet deep, and 1° warmer at 1 foot deep, than is seasonable. During the past week rain has fallen on four days, but to the total depth of only about a quarter of an inch. There has been some percolation through both of the soil gauges on each day, but the amounts have been, as a rule, very small for a winter month. The sun shone on an average for 2 hours 24 minutes a day, which is 60 minutes a day longer than is usual at this period of the year. On one day no sunshine at all was recorded, but on one other day the sun was shining brightly for 6½ hours. The winds have been as a rule high, and in the windiest hour the mean velocity amounted to 20 miles—direction west. The average amount of moisture in the air at 3 o'clock in the afternoon was 8 per cent. less than a seasonable quantity for that hour. The winter Aconite came first into flower in my garden on the 17th, which is 3 days earlier than its average date for the previous 22 years, and also 3 days earlier than last year. E. M., Berkhamsted, January 20, 1909.

Obituary.

GEORGE H. SAGE.—The death of Mr. Sage occurred on the 13th inst. at the age of 50 years. Deceased was gardener to Earl Dysart at Ham House, Richmond, for some years, and later gardener at Bayham Abbey, Kent. Leaving Bayham Abbey, Mr. Sage subsequently commenced business as a horticultural sundriesman. He leaves a widow and seven children. One of the sons is at present engaged at Gunnersbury Park gardens, under Mr. Reynolds.

ENQUIRIES AND REPLIES.

THE PARADISE TREE OF BUENOS AYRES (see p. 402).—This is *Melia Azedarach*, figured in the *Botanical Magazine*, vol. xxvii., tab. 1066. The leaf as there portrayed exactly agrees with that of a seedling plant given to me. From its being called the giant Paradise tree, I concluded that it would not flower until it attained tree stature, instead of which it is said to flower when three years old from seed. Its English name of the common Bead tree, was given to it from its nuts having a curious natural perforation or hole through their centre, enabling them to be strung on thread or wire and used as rosaries, by the constant and assiduous use of which (known as telling their beads) good Spanish Roman Catholics believe they qualify for admission into Paradise. Hence the tree producing them is called the Paradise tree or *Arbor sancta*. G.

ACCIDENT TO GARDENER: Reader. (1) If the accident has permanently incapacitated him he can be dismissed without notice, otherwise he is entitled to the usual notice, or wages in lieu of notice. (2) Under the Workmen's Compensation Act, he is entitled to claim not more than half-wages during disablement. If he is under 21 years and his wages are less than £1 a week, he can be awarded any sum up to 10s. a week. He should give notice of his claim at once.

BLACK SCAB IN APPLES. F. C. We cannot determine from your description what the disease is. Send a specimen for examination.

BOOK WITH COLOURED PLATES. W. D. We do not know of a work such as you require, that can be purchased cheaply. An edition of John's *Flowers of the Field*, published by George Routledge and Sons, might be suitable. This edition contains 92 coloured plates of wild plants. The book can be obtained from our publishing department.

CELERY DISEASED: W. Truster. The plants are affected by a bacterial "rot." The decayed parts are full of a minute bacterium. Remove and destroy by burning all affected plants at once, and do not plant Celery on the same soil until a year or two has elapsed.

CHRISTMAS ROSE FAILING TO FLOWER: J. W. There is no disease present in the plant you send us for examination. The trouble is due to either unsuitable soil or surroundings. Break up the clumps and plant the younger portions in a fresh site.

CYCLAMEN BLOOMS FLAGGING: J. B. These flowers droop very readily in the dry, warm atmosphere of a dwelling-room. Instead of allowing them to remain in the room all through the night, remove them to a dark cupboard or a zinc-lined case where the atmosphere can be kept close. Florists always adopt a similar practice with their stocks of flowers at night time.

EMPLOYMENT IN THE LONDON PARKS.—Forms of application for employment as under-gardener or under-keeper may be obtained from the Chief Officer, Parks Department, No. 11, Regent Street, S.W. The age limits are from 25 to 40 in the case of under-gardeners, &c. Vacancies as gardeners are as far as possible filled by promotion, from the ranks of under-gardeners, of such men as pass the examination in practical horticulture held by the Royal Horticultural Society, and in the other ranks by promotion.

EVERGREEN OAK DYING: J. K. You should have forwarded a shoot for examination. From your letter we suspect the tree has suffered from drought or some other check to the roots. Next summer apply a heavy mulching of manure to the roots in order to retain the moisture in the soil. Soil overlying chalk is apt to become very dry in hot weather.

LAND FOR A FRENCH GARDEN: Plot. We cannot advise you in the matter. Insert an advertisement. Perhaps some firm of horticultural auctioneers and land agents may be able to assist you.

MANGOLD DISEASED: C. S. & Co. The root is attacked by a bacterial disease, probably the same as that described in the *Journal of the Board of Agriculture*, vol. ix., June, 1902. The specimen more resembles a Swede Turnip than a Mangold. There is danger in using the dung of cattle fed on these diseased roots—especially if applied to soil intended for a crop of Turnips. If there is any considerable quantity of diseased roots, cart them on to permanent grass land.

MEALY-BUG ON VINES: J. P. R. Instead of using the mixture you mention, we should advise you to dress the vines with a mixture of coal tar and clay. This is the most effectual and simple remedy. The coal tar and clay remedy consists of one part of the former to nine parts of the latter. The clay

should be dried and powdered, so that it may be passed through a ¼-inch sieve. Then measure the pulverised clay into a large flowerpot having a lump of stiffish clay put into the hole in the bottom; use a 3-inch flowerpot as a measure. When sufficient clay has been measured, add the proper quantity of tar. Mix these well together, and afterwards add sufficient boiling water to give the mixture a consistency similar to that of ordinary paint. Apply it with a stiffish paint brush to every crevice about the spurs and every portion of the affected vines, keeping the mixture well stirred during its application. Take every care to avoid injuring the buds. But before applying this remedy the vines should be pruned, and all the old, and somewhat loose, bark carefully and thoroughly removed, especially from the spurs, using the point of a blunt-edged knife for the purpose. Afterwards collect and burn all the material thus removed. This done, thoroughly wash the woodwork in the house with a solution of soft soap and paraffin, consisting of a ¼-lb. of the former and a port-wine glassful of the latter dissolved in one gallon of boiling water. Wash the glass with clear water, and the brick and plaster work with hot liquid lime, forcing this well into any crevices. Make good any holes by applying mortar. Openings in the putty in which the roof and other glass is embedded should be stopped with good white-lead putty. Then wash the vine rods thoroughly with a mixture of soft soap and petroleum of the strength indicated above, and afterwards apply the coal tar and clay remedy in the manner already described. Suspend the vines when dry in a horizontal position from the wires, over the pipes near the front ventilators, and let them remain in this position until the buds begin to push into growth naturally in March or early in April. Remove 3 or 4 inches deep of the surface soil from the vine border (smearing the brick and plaster work thus exposed with hot liquid lime) and then apply a good compost consisting of fibrous loam five parts, and lime rubble and horse-droppings, one part each. The whole should be well mixed before the compost is placed on the border. We have answered your question rather fully, as there is no use in employing half measures in dealing with such a formidable pest as mealy-bug.

NAMES OF FRUITS: A. L. B. These are beautifully coloured fruits of Cox's Orange Pippin.

NAMES OF PLANTS: Alba. I. *Epidendrum fragrans*; 2, *Trichopilia laxa*; 3, *Gongora maculata*.—*Foreman.* 1, *Pteris hastata*; 2, *P. longifolia*; 3, *Blechnum occidentale*; 4, *Selaginella laevigata*; 5, *Adiantum hispidulum*.—*M. Lamellan.* *Cytisus proliferus*. The *Rhododendron* (*Azalea*) is infested with thrips. Spray the plants with tobacco-water, or fumigate them by means of a nicotine vapouriser.

ROSE SHOOTS DISEASED: J. T. The canker is caused by a fungus—*Coniothyrium Fuckelii*. The disease commences as reddish-brown spots on the young wood, and when the bark becomes broken, frost aids in the formation of the larger wounds. The more badly affected branches should be cut away, as the fungus fruits freely on these, and the spores infest the young wood.

SOIL: R. P. The addition of lime to the soil is beneficial to most plants, but Ericaceous species are exceptions. If you use the turf for Tomatos, you may incorporate a quantity of wood ashes with it. At intervals, during the growth of the Tomatos, apply a top-dressing of some concentrated manure. For Roses, the turf, as you describe it, will be suitable without adding anything beyond the manure you mention.

COMMUNICATIONS RECEIVED.—W. C. P., we think you had better wait for some proof of such an extraordinary achievement.—D.—H. E. K. (the news is too late for insertion).—H. S. B., Shooter's Hill—W. M. A MARKET FRUIT-GROWER'S YEAR.

IN a series of articles, of which this is the first, it is proposed to record the principal proceedings which take place in the market fruit garden during each month.

The most important work in January has been that of pruning Apples, planting having been finished in December under excellent conditions, while the necessity of spraying Gooseberry bushes, to deter birds from picking off the buds, called for in some past seasons in January, has not arisen.

Last winter a plantation of Gooseberries near the homestead was attacked in December, and had to be sprayed then with lime and sulphur wash, to which a little caustic soda, perhaps unnecessarily, was added. Before the end of January nearly every fruit-bud had been picked by birds from trees of Old Greengage, Coe's Golden Drop, and a few other choice Plums in my private orchard, though field crops of cooking Plums were not touched. This season, up to the time of writing, not a bud, so far as I can detect, has been destroyed on a Plum tree or a Gooseberry bush.

The first operation in pruning was that of cutting back two-year-old Apple trees, planted in December. February or March is now recommended for this operation, but it

was carried out just after planting was finished, in order to prevent the wind from swaying the young trees. They will be gone over again in March, in order to repeat the trimming so far as it appears desirable in relation to cutting above the buds promising best for extension growth. The plan of leaving the cutting-back until the second season from planting appears to me to be theoretically unsound.

The Black Currant bushes, two years old, planted among the Apple trees, were cut back to three or four buds from the roots on each branch, on being raised from the nursery bed in which they had been grown from cuttings. It has been stated that the planting was done under excellent conditions. That is to say, under conditions which would be considered excellent by any grower who has not been converted to the new Woburn doctrine in favour of planting when the soil is wet enough to puddle. While prepared, on the basis of the results of trials reported by the Woburn authorities, to believe that ramming may be beneficial when the soil is in a comparatively dry condition, I am far from being convinced that planting in mud is beneficial.

Returning to the subject of pruning; it is desirable to mention that the treatment of Plum trees does not come into the records of January work, because a young plantation of this fruit was pruned in November, while an old plantation has to take its chance of later pruning. Having observed that when Plum trees are pruned in the winter, the fruit-bud below a cut, from which a new shoot is required, often dies off, probably from the action of frost, I have come to the conclusion that Plum pruning should be done in the autumn.

The second field of Apples to be pruned was one of nine acres; half the trees were planted in November and December, 1905, and the rest a year later. The outside row in the first half furnishes a lesson in relation to the extension system so far as it applies to young trees. The variety is Domino, and the trees as maidens were so uncommonly strong that they were planted to complete the piece of land after all the two-year-old trees had been used. They were cut back severely, and made splendid growth in 1906 and 1907. In the summer of 1908 they were remarkably well furnished trees for their age, and so strong that they were allowed to bear fruit on the main branches close to the trunk, and there only. These branches, being strong, had been allowed to grow long. With the check caused by fruiting, fruit-buds have formed along the entire length of the shoots made before last summer, while this season's shoots were so small and weak that they have now been cut back to two or three buds.

The next variety, Early Julyan, made the same good growth as Domino, but, as it did not mature fruit-buds in the summer of 1907, it is in full vigour. These two varieties, it is to be observed, naturally grow in excellent form requiring very little shaping, only Domino needs its inside laterals to be shaved off, as, otherwise, it grows too densely after a few years. There is a peculiarity about Domino not noticed in any other variety in my possession. The fruit-spurs terminate in stumps, or natural snags, with fruit-buds at their bases.

It may here be mentioned that, in the

second season after planting, most of the varieties blossomed on the first year's wood; but the bloom was pinched off, as one of the most expensive lessons learnt in my experience is the folly of allowing trees to fruit too soon. The result was that hardly any of the trees planted in 1905 blossomed to any considerable extent in 1908. They were engaged in free wood growth, as it was desired that they should be, and they showed very much less blossom than the trees in the other half of the field, planted a year later, which also had their blossoms pinched off.

Royal Jubilee is another variety which grows in good shape, the branches being sturdy and bowed outwards. Like the two varieties just named, its branches are nearly even in thickness, whereas some kinds produce a few very gross branches, double the thickness of the rest.

Cox's Orange Pippin is the only variety out of 16 varieties to show scab on the wood. Where it was on this year's shoots, close to the ends, the infected parts have been cut off and burnt. Where it showed lower down on branches needed to furnish the trees, the scabby eruptions were thinly coated with tar, by way of experiment. This variety will not withstand Bordeaux mixture of strength sufficient to kill the fungus. Even a wash containing only 8 lbs. of copper sulphate more than half defoliated the trees in a plantation now eight years old, and entirely ruined the crop for two seasons. The scab showed on trees only two years from planting—not on all, by any means, but perhaps on one-third of them. They will be sprayed with copper sulphate alone, 4 lbs. to 100 gallons, just before the buds burst, but not with Bordeaux mixture after the foliage is out. Probably a small trial upon some of them will be made with the lime and sulphur wash.

In connection with Cox's Orange Pippin, as with two or three other varieties, there is a point of interest to notice. The trees were raised on three stocks, the Crab, the Free (from Apple pips), and the Doucin, and the trees were kept distinct when planted, though in rows side by side. There is no distinct difference in the amount of growth made by the trees on the three stocks in the cases of Cox's Orange Pippin and two other varieties. In the case of Lane's Prince Albert, however, partly on the Crab and partly on the Doucin, there is a small advantage in growth in favour of the former stock. Lane's Prince Albert is the poorest grower among all the varieties, and trees two years from the planting have had to be cut back severely to shape them. Some of the shoots emerging from comparatively sturdy branches are miserably weak, while others are twice as large. There is also a tendency to form fruit-buds where wood-growth is wanted, as well as a tendency in the shoots to grow downwards. A special peculiarity of this variety is the cracking of the bark of wood even only two years old. No mycologist has explained the cause. It is not canker, because in trees planted eight years ago, and similarly affected, no development of that disease has occurred.

Duchess of Oldenburg is a troublesome variety to get into good shape, as its shoots lean towards the centre. Allington Pippin is another awkward grower. The shoots are free enough as to length, but slender, and, in spite of careful pruning, pointing in

all directions. It is a very free bearer, and inside laterals may be shaved off instead of being spurred, without any fear of not getting enough fruit-spurs. Beauty of Bath is growing sturdily, but unevenly, a few of the shoots on a tree being double the thickness of the others. Bramley's Seedling is the sturdiest grower in the plantation, having thick young branches, thinly disposed. Warner's King has more branches, with size enough and plenty of length. Gascoyne's Scarlet Seedling is vigorous and excellently shaped. There is only one row of Golden Spire, and that is one too many. Like Duchess of Oldenburg it is an upright grower, and should be planted much more thickly than most other varieties; but this is impossible in a field set out for horse-cultivation. The trees, of bush-shape on stems about 2 feet 6 inches high, are all 12 feet apart in their rows, and a little more transversely, so that a tree in one row is opposite to a bush in the next tree row. Black Currant bushes are between the trees; they are planted 6 feet from each other and from the trees.

In the case of Lord Grosvenor, there are two experiments to notice. One row was rammed when planted, two years ago, the trees being carefully selected, so as to be as equal as possible in size and vigour to those in the two adjoining rows. The trees in this rammed row have made a little more growth than those on one side of them, and a little less than those on the other side. Another row was not cut back until the second season after planting, the same precautions as are mentioned above being taken to ensure equality with the rows on either side of it. When the cutting-back was done, the young branches, of course, were much more thinly disposed than those on trees cut back in the season of planting. Moreover, they were forming fruit-buds nearly from their bases to their tips, and had to be cut back very severely to get at wood-buds. These trees have now made as much growth as the others, but are not as well shaped, for the simple reason that there was not the same choice in selecting a wood-bud to cut over as in the trees pruned in the first season.

An interesting observation in connection with this plantation of young trees is that less than a dozen spots of American blight (woolly aphid) have been found in the whole of the nine acres, although the nursery piece in which they were raised was infested. Further, it is worth noticing that out of over a thousand trees raised for planting out this season only two showed a speck of American blight on the roots. During the summer my young trees have been treated with methylated spirit about once a week, where the woolly aphid showed. This is by far the best remedy. It has been used without dilution even on the budded portion of stocks, favourite spots for the pest. It has proved harmless to the buds, while it has saved numbers of them from destruction by the enemy. Some of the stocks which had their buds thoroughly wetted with the spirit were labelled, in order to ascertain whether they would be injured by it.

Among the principal employments of labourers since Apple-planting was finished have been that of trenching a piece of grass-land and planting yearling Black Currants which had to be removed from their old quarters. They were cut back to three or four buds from the ground, and will form bushes for planting out in their permanent quarters next season. Other work has been chalking two fruit fields, from one of which some mite-infested Black Currants were taken up. They had been planted eight years, and were being shaded by Apple trees planted at the same time.

Cob Nuts are more densely covered with catkins than I have ever seen them before. *A Southern Grower.*

NEW OR NOTEWORTHY PLANTS.

EUPHORBIA SAPINII.

AMONG the many interesting plants introduced from the Congo and cultivated in the Botanic Gardens, Brussels, is the species of Euphorbia represented in fig. 37, which has been prepared from a photograph kindly forwarded by M. Louis Gentil, the gifted curator of that establishment. In some respects the plant resembles *E. bupleurifolia*, Jacq., native of South Africa, a well-known garden plant, figured in the *Botanical Magazine*, t. 3476 (1836). This has an erect, thick, succulent stem marked all over with the scars

opaque, green colour. According to Dr. E. de Wildeman, who has published a figure and description of *E. Sapinii* in the *Annales du Musée du Congo*, 1906, the flowers and bracts are very small and are produced on very short peduncles from the axils of the leaves. M. Sapin, who collected the plant in the Congo, says that its milk-like sap is irritating to the skin and even dangerous, a property which is common to the genus. Although not possessed of any showy character, yet *E. Sapinii* is just the kind of plant to please and interest those who cultivate succulent plants. An intelligent youth described it as a sort of carrot with a brown crocodile skin and leaves like long strips of soft green leather fixed on with sharp-pointed brown spines. It grows best in a moist tropical house. *W. W.*

FIG. 37.—EUPHORBIA SAPINII, FROM A PLANT IN THE BRUSSELS BOTANIC GARDEN.

occasioned by the falling away of the old leaves, and thus presents a reticulated appearance. The areolæ have the form of quadrangular tubercles which are umbilicated in the centre. The leaves, which are in a terminal cluster, are lanceolate, 4 to 6 inches long, bright green with a white midrib, and the flowers, which are yellow, are enclosed in conspicuous green cup-like bracts on an erect peduncle 2 inches long. In *E. Sapinii* the tubercles are swollen and mamillate, especially on the younger part of the stem; when young, they are green and each has a hard stipular spine which appears to fall off in about the third year, leaving the stem pale brown and rope-like. The Kew plant, kindly presented by the Director of the Botanic Gardens, Brussels, has a stem 4 inches high and 2 inches in diameter, a head of 15 fleshy leaves from 9 to 12 inches long and $\frac{1}{2}$ to $\frac{3}{4}$ inch wide, the upper half broader than the lower, keeled, the apex imperfect, the whole being of a uniform.

WEATHER AT ROTHAMSTED IN 1908.

THE meteorological records of the Rothamsted Experimental Station, Hertfordshire, for 1908 show that the year was characterised by a deficiency of rain, as was that of the previous year, 1907. There were but three months of excessive rainfall, and nine months which recorded a deficiency. The number of rainy days was, however, 184: being 12 days in excess of the average of the past 55 years.

The mean temperature of the year was slightly in excess of the average. The most unseasonably warm months were February, May, October, and November; whereas only April was unseasonably cold. There were six months of temperature above the average record, and six months below.

The bright sunshine showed five months in excess and seven months deficient. The sunniest month of the year was June, when the

record of sunshine exceeded the average by 50 hours.

There were 18 days on which snow fell. The total depth would probably aggregate to 2 feet; the greatest quantity of snow fell during Easter week. About 2 inches fell on Easter Sunday, April 19; about 6 inches on April 23; and about 3 inches on April 25. Such a fall of snow as that experienced during the Easter season has not occurred at Rothamsted since the year 1876. From April 11 to 14 in that year a great quantity of snow fell, which averaged more than a foot in depth, and drifts in the narrow lanes around the Rothamsted estate were from 3 to 4 feet deep.

January of 1908 gave 14 hours more than average sunshine; but both rainfall and temperature were less than the normal.

February, the "double-faced," was quite in accordance with ancient tradition. In its short space it treated us to hail, snow, frost, lightning, rain, and gales, to say nothing of the sudden changes that occurred as regards temperature, which, on the whole, was high compared with the average, while the rainfall and sunshine were deficient.

The comparative genial weather of the first three weeks of February encouraged both farmers and gardeners to proceed briskly with outdoor work. Gardeners who were fortunate enough to secure a good seed-bed, planted Onions, Parsnips, Broad Beans, and Early Peas extensively.

March was a month of "many weathers." On the 1st and 3rd days of the month about 3 inches of snow fell, and the amount of water from the rain and melted snow on these days measured about 22,600 gallons per acre. The total rainfall for the whole of March was nearly 3½ inches, being 1½ inches in excess of the average. The general character of March was cold, sunless, and gloomy.

May and June each gave a deficiency of rain, with a higher than average mean temperature and bright sunshine.

The three English usual harvest months of July, August, and September recorded a deficiency of rain, a lower than average temperature and of bright sunshine.

The three months of October, November, and December gave a small quantity of rain, especially November, which recorded the smallest monthly total of the whole year; less than 1 inch was measured, being 1½ inch below the average of the previous 55 years.

The last three months of the year were warmer than the average, more particularly October, and, to a less degree, November also. October and November recorded 36 hours of bright sunshine in excess of the average, while December was gloomy and gave 14 hours of sunshine deficient.

The following table shows the rainfall of each month for the past year of 1908 at Rothamsted, with the average amount of rain for each month of the previous 55 years, 1853-1907, and the difference of 1908 above or below the average record:—

RAINFALL AT ROTHAMSTED, HERTS.

Months.	Rainfall	Average	1908.
	1908.	Rainfall	Above or
		of	below the
		55 years.	average (I).
	Inches.	Inches.	Inches.
January	1.58	2.37	- 0.79
February	1.34	1.80	- 0.46
March	3.40	1.83	+ 1.57
April	3.28	1.85	+ 1.43
May	1.89	2.19	- 0.30
June	1.67	2.41	- 0.74
July	2.43	2.51	- 0.08
August	3.01	2.63	+ 0.38
September	1.56	2.43	- 0.87
October	2.26	3.17	- 0.91
November	0.82	2.60	- 1.78
December	2.07	2.32	- 0.25
Yearly Total	25.31	28.12	- 2.81

(I) The sign in the last column (+) signifies above the average, and the sign (-) below the average.

The rain gauge, which is one-thousandth part of an acre in dimension, stands 2 feet above the

surface of the ground, and is about 420 feet above sea level.

The above data shows a total rainfall of 25.31 inches, against an average for the previous 55 years of slightly over 28 inches, being 2.81 inches deficient. It is also 2 inches less than the record of 1907.

Calculating these figures up to the acre, we find that, during the whole year, 2,556 tons of water have fallen on each acre of land, which is about 284 tons of water deficient. The total rainfall for the last four months of the year fell short of the average for the same period in the previous 55 years of 3½ inches, which is equivalent to a loss of 76,197 gallons on each acre in the underground water supply of this district. Last year at the same time there was an excess of 60,859 gallons per acre.

The next table shows the mean temperature in the shade for each month of the year 1908 with an excess or deficiency at the Rothamsted station during the past 30 years, 1878-1907; also the number of hours of bright sunshine made by means of a Campbell Stokes recorder for each month, and the number of hours above or below the average record.

MEAN TEMPERATURE AND BRIGHT SUNSHINE AT ROTHAMSTED, HERTS., FOR EACH MONTH OF THE YEAR 1908.

Months.	Mean Temperature.		Bright Sunshine.	
	1908.	Above or below average.	1908.	Above or below Average.
	Degrees.	Degrees.	Hours.	Hours.
January	34.4	- 2.4	67	+ 14
February	40.8	+ 2.6	69	- 2
March	39.3	- 1.7	115	- 5
April	42.6	- 3.0	146	- 22
May	54.7	+ 3.4	198	+ 4
June	58.1	- 0.7	251	+ 50
July	60.5	- 0.3	205	- 20
August	58.3	- 1.6	202	- 2
September	51.7	- 1.2	158	- 5
October	52.4	- 4.3	120	+ 15
November	45.1	+ 2.6	78	+ 21
December	38.1	+ 0.3	30	- 14
For the year	48.2	+ 0.3	1638	+ 35

The mean temperature for the whole year was 48.2°, which is very little in excess of the average, although the three last months of the year recorded an aggregate of 7.2° higher than the normal.

The bright sunshine for the year amounted to 1,638 hours, being 35 hours in excess of the average, whilst last year the total sunshine was 49 hours deficient.

ROTHAMSTED CROPS OF 1908.

Under these climatic conditions the experimental hay crop at Rothamsted was, under all conditions of manuring, less than the average yield, ranging from 5 to 18 cwt. of Hay deficient, and considerably below that of 1907. As a set-off against the bulky crop of 1907, which was badly harvested, the crop of 1908 was cut and carried with very little trouble.

The produce of the experimental Wheat field was somewhat variable, about one-half of the plots under different manures gave above the average yield, while the remaining half produced a slightly lower than average quantity; but the quality as indicated by the weight per bushel was considerably above the average record, and ranged from 63lb. to 65lb. per bushel.

The experimental Barley crop was, under all conditions of manuring, except that of the farmyard manure plot, below the average in yield, and in some instances very considerably below, while the weight per bushel was higher than the average.

The root crops were variable, there being some good areas of Mangolds and Swedes and some very bad. The general character of growth was an excessive amount of leaf, which the lateness of the season failed to ripen in sufficient time for the lifting.

Potatoes on the whole were a large crop, but disease set in very badly after the tubers were harvested. *J. J. Willis, Harpenden.*

KEW NOTES.

THE GREENHOUSE.

This year the late-flowering Chrysanthemums were over a fortnight or three weeks earlier than usual. Flowering trees and shrubs, including *Spiræa prunifolia flore pleno*, *Spiræa arguta*, *Prunus japonica flore albo pleno* (a double white variety with extremely showy flowers), *P. Persica* var. *magnifica*, *P. pseudo-cerasus*, *Pyrus floribunda*, *Rhododendron Rosa Mundi*, and Lilacs, *Marie Legraye* and Charles X. are already in bloom. A few Azaleas (*Rhododendron indicum*), which have been forced gently, are also in flower. The small-flowered varieties obtusum (red), obtusum album, illuminator (magenta), and the popular *Deutsche Perle* (white) are especially worthy of culture.

Senecio grandifolius is a tall-growing plant, with large, dark green leaves, surmounted by a terminal corymb of yellow, Groundsel-like flowers, a foot or more in diameter. *S. Peta-sitis* is also in flower.

Two large specimens of the Chinese Jasmine, *Jasminum primulinum*, are amongst the brightest and most interesting plants in the house. The long, arching shoots are thickly studded with semi-double, Primrose-yellow flowers. The plants should be grown in the open, exposed to full sun in summer-time, and every encouragement be given them to secure well-ripened shoots. When forced, they should be placed in a plant-house having a minimum temperature of 40° till January, as excessive heat in early winter encourages the formation of growth instead of flowers. A beautiful *Acacia* at present in bloom is *A. longifolia* var. *magnifica*. *Richardia Childsiana* flowers perpetually.

A new introduction to gardens is *Erlangea tomentosa*, a Composite. The plants at Kew were raised from seeds collected in British East Africa by Mr. Diespecker. The flowers are pale heliotrope, and resemble those of a *Eupatorium*. The plants are about 3 feet high, and possess silvery-white leaves. On the side stages of the house, in addition to *Cyclamen*, *Begonias*, *Carnations*, &c., the following plants are noteworthy:—*Reinwardtia trigyna*; *Peristrophe speciosa*, one of the best Acanthaceous plants for a cool greenhouse, the carmine-purple flowers being freely produced for fully three months; two species of *Veltheimia*, South African bulbous plants producing numerous flowers on scapes 1 foot or more in height, are attractive. The blooms are tubular, pendulous, and rosy-red in colour, marked with yellow. *Begonia semperflorens* var. *gigantea* is one of the freest winter-flowering *Begonias*; *B. manicata* has branching cymes of pale pink flowers borne well above the handsome foliage. Two good foliage plants are *Bougainvillea glabra variegata* and *Cordyline australis* var. *lentiginosa*. The long, narrow leaves of the latter plant are dark red in colour. The plant is especially suitable for table decoration.

New Holland plants occupy a considerable proportion of the staging in both wings of the house. The *Epacris* are represented by some two dozen varieties, and one or two species. A few of the best species and varieties are *Arden-tissima* (rosy red), *Diadem* (rose), *Kinghornii* (pink), *E. hyacinthiflora* (pale pink), and var. *alba*, rose perfection (rich rose), *E. impressa* (rose), and var. *alba*, and *Lady Panmure* (white flushed pink). *Epacris* are peat-loving plants, but may be cultivated with less trouble than Heaths. The best of the *Ericas* in flower are *E. hymenalis*, *E. gracilis*, and var. *nivalis*, *E. mediterranea* var. *hybrida*, and *E. melanthera*. A plant of *Darwinia* (*Genetyllis*) *Hookeriana* is well furnished with inflorescences, but only a few of the involucre are at present expanded. The genus *Eriostemon* is represented by three species, all with white flowers, namely, *E. affinis*, *E. myoporoides*, and *E. pulchellus*. *D. D.*

BULBOPHYLLUM LEMNISCATOIDES, ROLFE.

This interesting *Bulbophyllum* was first noticed in a group of Showy Orchids staged by Sir Jeremiah Colman, Bart., Gatton Park, Reigate. The species was first collected in Java, and, differing so widely from the more showy Orchids, it attracted much attention. The pendulous raceme bears about 20 flowers, the concave sepals being very dark purple, with scat-

tered white hairs on the outside. Each petal bears a long, slender appendage of whitish colour mottled with rose, the whole inflorescence having a tassel-like appearance. The labellum is dark purple, the small petals and column whitish. The flower is of uncommon structure, but its slight resemblance to *B. lemniscatum*, a Burmese species, figured in *Bot. Mag.*, t. 5961, was sufficient to suggest a name for the species.

EXPERIMENTS ON THE VALUE OF NITRO-BACTERINE.

In the interesting comments in the *Gardeners' Chronicle* of January 9 and 16, upon the experiments carried out at the Royal Horticultural Society's Garden at Wisley, upon the value of nitro-bacterine in garden soil, attention is particularly directed to the remarkable fact that, in many cases, the produce from the plots which had received inoculated seeds was less than that from the plots which had received uninoculated seeds, but which had otherwise been similarly treated.

It should be pointed out that an error has crept into one of the paragraphs in the summary of the report bearing upon this point. The error makes the difference appear materially greater than it actually was. The yield from the whole of the plots receiving inoculated seed was 495 lbs. (not 450 lbs.), while the total from the plots in which uninoculated seed was sown was 515 lbs. The uninoculated seed, therefore, gave a crop 4 per cent. (not 14 per cent.) heavier than the inoculated. The weights are correctly given in the body of the report, but the error appears in the "Summary," from which quotations are made.

Perhaps the most remarkable part of the result, however, lies in the fact that 31 rows out of the 48 which were sown with inoculated seed gave a smaller crop than the corresponding rows sown with uninoculated seed. It is suggested that it would be interesting to see how far and in what direction the average yield of the plants which had been inoculated varied from that of the uninoculated. The details concerning this point are already in the press, and will appear in the *Journal* of the Society shortly to be issued, along with some other details bearing upon the use of nitro-bacterine.

Unfortunately, the figures relating to the numbers of plants in the rows of two of the varieties were accidentally lost; but we have those relating to the other two varieties used in 48 rows, the seed in 24 of which was inoculated, and in 24 not. For details as to the number of plants in the separate rows, reference may be made to the forthcoming report, but the main results may here be noted. In six rows of *Ne Plus Ultra*, in cultivated ground, grown from uninoculated seed, there were 353 plants which bore fruit, yielding, on an average, 98.7 grammes of pods. In the corresponding six rows, which were grown from inoculated seed, there were 384 plants, which yielded an average of 89.2 grammes of pods. Thus the average yield of the inoculated plants was 10 per cent. below that of the uninoculated, and four out of the six rows showed a decrease. In the six, uninoculated rows of the variety *Maincrop*, on the same soil, there were 266 plants, which bore an average of 110.5 grammes, and in the corresponding, inoculated rows, 240 plants, giving an average of 103.9 grammes. Here, again, there is a diminished average yield of 6 per cent. from the inoculated plants, and four out of the six rows showed a decrease. On the fallow ground, six, uninoculated rows of *Ne Plus Ultra* contained 297 plants, giving an average of 82.5 grammes to the plant, and the six corresponding, inoculated rows contained 291 plants, and gave an average of 80.8 grammes. In this case there was a diminished, average yield of 3 per cent. from the inoculated plants, and four out of the six rows showed a lower average than the uninoculated.

The six, uninoculated rows of *Maincrop*, on the same soil, contained 266 plants, which gave an average of 52.5 grammes; while the inoculated rows contained 204 plants, and gave an average of 61.7 grammes to the plant. In this variety, therefore, there was an average increase of 17 per cent. from the inoculated plants, but only three out of the six rows showed an increase.

In all, out of 24 rows of inoculated seed, only seven produced a greater average yield than the

FIG. 38.—*BULBOPHYLLUM LEMNISCATOIDES*.

corresponding uninoculated rows, and there was one giving an equal yield.

Like many other experiments of this nature, this has suggested the desirability of further investigation. The results obtained are far from showing that the decreased yield in these many cases is actually due to the inoculation with nitro-bacterine; but the results given in the report certainly suggest the question whether certain races of *Pseudomonas radicola* may not induce a smaller yield than that obtained when the races of *Pseudomonas* native to a particular soil are present therein, and the results outlined above emphasise this question, and, at the same time, give a very interesting corroboration of the results, upon which the conclusion that "the inoculation of leguminous crops with nitro-bacterine in ordinary garden soil is not likely to prove beneficial" was primarily based.

Finally, it should be emphasised that the experiment and the conclusion refer only to ordinary garden soil, and do not in any way show what may or may not be the result of using nitro-bacterine on newly-reclaimed land when such is brought under cultivation by means of leguminous crops. *Fred. J. Chittenden, F.L.S., Director R.H.S. Laboratory, Wisley.*

PINUS PINASTER.

I HAVE recently seen this remarkable tree in the Medoc country, where it is extensively planted for the purpose of holding in position the enormous sand dunes. By means of its long tap root it gets an effective hold upon the ground, and it is of value from the seedling stage until it is cut down for timber. The tree is of very rapid growth, but, in consequence of the soft character and coarse grain, its timber is of little value for carpentry, although it is used largely for rough beams and supports. It is exported from Bordeaux to Britain for use in mines and tunnels. The wood is used for fuel, sometimes for paving, and petrol and vinegar are extracted from it.

The most valuable product is resin. The young trees are allowed to attain a height of 18 or 20 feet before being tapped. In this operation a portion of the bark is planed from the ground upwards, leaving a thickness of about a $\frac{1}{4}$ inch on the wood; a hollow is then made at the base by cutting into the wood, and in the hollow space thus carved out an earthenware pot placed to receive the resin. The pot is supported on a nail, and is held in position above by a strip of zinc fixed in a carved cut. The zinc strip serves the further purpose of guiding the resin into the pot. The flow of resin lasts for about eight days, when the hollow is extended upwards by a further cutting in the form of a groove, and more resin is obtained. When the groove has been cut for about 3 feet up the tree the pot is moved and fixed again at that height, and every eight days the cutting is continued further up until a height of 10 or 15 feet is reached; the pot is afterwards moved upwards 3 feet at a time. When the first groove has been exhausted another is commenced at the base of the tree, beside the old one, and so the process is repeated until there are grooves all round the trunk, to the number of from 6 to 16. The wood that overgrows the wounds thus made is, in course of time, treated in a similar manner. The operation of tapping is performed by men who use a large chopper, similar in shape to the hammer used in nailing fruit trees, except that a sharp edge takes the place of the claw used for drawing nails. The collection of the resin is always done by women. By means of a large two-edged knife, they scrape out the resin from the pots into wooden buckets, which are emptied into large tubs sunk in the ground. When these are full, carts are sent with barrels to receive the resin, and it is sent to Bordeaux to be clarified.

Another industry connected with the tree is the collection of its seeds. In former times the seeds may have been extracted by putting the cones in hot water, but now they are obtained by placing the cones in the sun. They are arranged upright in immense beds, and when the scales open they are brought to a framework of hurdle-like construction, upon which a man rakes them backwards and forwards, when the seeds fall on a sheet beneath. They are collected in sacks, and a sackful is said to be worth 100 francs. As soon as the young trees have attained a few feet in height they are thinned out and, of the thinnings, those that are large enough are made into broom handles or used for fuel by the bakers. The branches are used for the support of Peas, Beans, and for similar purposes.

On the coast the trees are always more or less bent, and isolated trees, owing to the deficiency of lateral roots, are inclined at an angle of about 30° to the ground. *Pinus pinaster* is a handsome tree with rugged bark and fine, dark-green foliage. In spring its beauty is greatly en-

[Photograph by R. Stewart Lynch.]

FIG. 39.—TAPPING PINUS PINASTER FOR RESIN.

hanced by the contrasting golden flowers produced by a *Genista* and *Gorse* which grow on the open spaces. The French call this tree *Pin de Bordeaux* or *Pin maritime*. The English name, *Cluster Pine*, and the botanical name, *Pinaster*, are both justified by the fine development of cones. They are of yellowish-brown or fawn colour, and grow in large dense clusters around the base of the current year's growth, spreading like the rays of a star, hence *Pinaster*.

In England, *Pinus pinaster* makes a fine ornamental tree of pyramidal shape, 80 to 90 feet high, and should be planted wherever it is likely to succeed. It thrives well as a rule, though it is said not to flourish much above sea level. In exposed positions its top may sometimes be broken. The seeds must be sown on the site in which the trees are to grow, or seedlings must be prepared for moving by transplanting them when one year old. The young trees in England often require a

stake to keep them upright for the same reason as that which causes the trees on the coast of France to be so conspicuously inclined. Loudon records a tree at Croome 70 years old and 90 feet high. In the Cambridge Botanic Garden the growth of a young tree is about 2 feet per annum. No other Pine has become so widely distributed over the world. It is thriving at the Cape, and is spreading spontaneously in the neighbourhood of Cape Town. It is common in parts of Australia and New Zealand, and is found in China, Japan and Northern India, being reintroduced to Europe under other names. It is native of south-west Europe and the Mediterranean region. *R. Stewart Lynch, Paris.*

NOTICES OF BOOKS.

* SWEET PEAS AND HOW TO GROW THEM.

THE Sweet Pea has been grown as a garden plant in this country for generations, but, generally, until comparatively recent times in a half-hearted manner, as if not worth any particular attention on the part of the gardener. As a consequence, the flower remained pretty much as Father Cupani found it in the island of Sicily 200 years ago. Our author traces its history in this country from 1713. Page mentions in his *Prodromus*, published in 1817, only six varieties, one of them being *Painted Lady*, which the present writer remembers to have seen in 1849. In 1842 James Carter, a seedsman, named but six; and in 1860 this seedsman offered nine varieties.

In 1872 there were 12 in commerce, and some of these were given distinctive names. Greater advances were made in 1877 by Mr. H. Eckford, then gardener at Boreatton Park, who brought out several varieties of much promise. In 1885 Eckford introduced *Princess of Wales* and *Indigo King*; in the next year *Orange Prince*, and in the following years many lovely varieties were raised. Mr. Atlee Burpee, an American florist, has been very successful as a Sweet Pea breeder. Towards the end of the '90's he raised some famous varieties, viz., *Golden Gate*, *Maid of Honour*, *Aurora*, and others. Mr. Silas Cole has since introduced the fine *Countess of Spencer*, a flower with a wavy outline to the standard, whose coming has profoundly influenced the Sweet Pea world, for it has proved to be the forerunner of a new and popular section.

The chapters on cultivation out-of-doors afford useful information, and the illustrations given are helpful. Stopping and thinning the plants are properly insisted upon. The reader is shown how he should proceed in transplanting Sweet Peas from pots to the open ground; how to sow the seed in drills, and to earth-up the young plants. In the directions for gathering the blooms it is recommended that the stalks should be pulled out at their junction with the stem, and not broken off or cut with scissors or knife. Among the wavy varieties, many "rogues" arise for no apparent reason; whilst among plain standard varieties "rogues" are few.

Fortunately, Sweet Pea cultivators have not many diseases to contend with, but some are sure to come in time if too liberal treatment is afforded. We have already the so-called "streak disease," also a fungus that carries off the young plants, viz., *Brachysporium pisi*, and a mildew (*Erysiphe polygoni*), which is developed by damp weather following bright days. Then there lurks danger in *Penicillium trifoliarum*, which makes yellow blotches on the leaves; and the "Spot" fungus (*Ascochyta pisi*), which attacks the pods, and occasionally the leaves and stems. The reader will find a description of the methods of combating these foes in the last chapter of the book.

The Week's Work.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Figs.—The earliest Fig trees in pots will soon require more liberal treatment. Liquid manure may be given at every alternate watering, and an occasional sprinkling of some approved fertiliser may be made. Be careful not to overheat the water pipes at night. Forcing must only be done during the day-time, taking full advantage of the sunshine and closing the house early in the afternoons. Syringe the trees twice a day and damp the paths and other available spaces as often as necessary. Fig trees are very subject to attacks from red spider, and if this pest is not detected and checked it is capable of doing irreparable damage to both foliage and fruit in a very short time. The best way to treat it is to sponge the leaves with a weak solution of soft soap and sulphur. Stop the shoots at the third or fourth leaf, removing any weak and unfruitful shoots whose retention would merely tend to crowd the tree. The atmospheric temperature at night should not exceed 60° unless the weather is very mild, but during the day the temperature may be allowed to rise to 85° provided the top ventilators are partly open. Permanent trees which will fruit in succession to those grown in pots should be started into growth earlier or later according to the season at which it is desirable the crops should ripen. Nevertheless, it is advisable to start pretty early that the forcing may be done gradually. Assuming the trees are planted in well-drained inside borders, they will need frequent waterings. Trees that are well established will require manure water applied in a tepid state. Let the trees be given a thorough syringing morning and afternoon in fine weather, and the paths and other surfaces frequently damped. Admit plenty of air in the forenoon when the weather is favourable. Stop the shoots at the fourth or fifth leaf and remove any weakly growths or suckers. If any Fig trees have yet to be planted the work should be pushed forward. It is essential that ample drainage should be provided for new borders, and the drainage material should be placed on a concrete floor in order that the roots may be prevented from penetrating into the subsoil. The borders should be restricted to a moderate width and be given a depth of 2 feet 6 inches or 3 feet, which will include 6 inches of drainage material. Select some good loam and mix with it plenty of old broken brickbats, lime rubble, or wood ashes. Make up the borders in layers and see that each layer is made firm.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Brazilian Miltonias.—Examine such Miltonias as *M. spectabilis*, *M. Moreliana*, *M. Peetersiana*, *M. Virginalis*, *M. Bluntii*, and *M. B. Lubbersiana*. If any of the plants are in need of more root room, it should be given at once. It is important that the new roots shall not be injured, therefore the plants should be repotted before they commence to push out, so that, immediately on starting, they may penetrate into the fresh compost. The plants extend themselves rapidly in every direction, and, therefore, they require considerable space for rooting purposes. They succeed best in well-drained shallow pans, in a compost consisting of *Osmunda* and *Polypodium* fibres in equal parts. These should be chopped up moderately fine, mixing them together, and adding plenty of very small crocks. Make the compost quite firm, as the roots appear to delight in having a hard substance to cling to. Old plants having their leading growths well out on the edge of the pan having become bare in the centre, should be divided. Cut out all the diseased and useless pseudo-bulbs and dead roots. The best pieces, which need consist only of two pseudo-bulbs behind each new growth, may then be made up afresh into neat and compact specimens. Those pieces which have but few roots to hold them steady must be fixed down with small wooden pegs to the compost, as they seldom succeed if not made quite firm. The stronger-growing Miltonias, as *M. Clowesii*, *M. Pagnelli*, *M. Binotii*, *M. stellata*, *M. Lamarckii*,

M. Veitchii, *M. Clasiana*, *M. flavescens*, and *M. Cogniauxe* are best grown in pots, using similar soil. The pots should be made at least two-thirds full of broken crocks. *Miltonia candida* and the rare variety *grandiflora* may be treated in exactly the same way as *M. Clowesii*, but repotting should be delayed until growth commences. The scarce, white-lipped *M. cuneata* will soon be in flower, and must not be disturbed by repotting now. All these Miltonias grow very well in a cool, shady part of the intermediate house. During the active season, the plants should be kept moderately moist at the root, but when the flower-spikes appear afford water more freely. After repotting, it is advisable to damp between the pots at least once a day, or if the position be very dry, twice a day, increasing the number of times as the season advances. A strict watch must be kept on the small roots as they push forth, or woodlice may eat at them. These insects should be trapped with small pieces of Potato, Carrot, or Apple laid on the plants, taking care to examine the baits during the evening, last thing at night, and again early in the morning. After each watering of the plants some of these insects may appear on the surface of the compost; they may then be caught easily.

Epidendrum.—The rare *E. erubescens* is now in flower at Burford. It is a plant of scandent habit, and it is useless to try and make it conform to pot treatment. The grower must adopt some plan so that the roots from each new pseudo-bulb will have something to root into. A teak-wood raft with the rods about $\frac{3}{4}$ of an inch apart answers the purpose admirably. This should be made considerably longer than the length of the plant. First lay some peat and living Sphagnum-moss upon the raft, place the plant on the compost, and by means of small copper wire fasten it firmly to the woodwork. Suspend the raft perpendicularly in the lightest position available in the intermediate house, and spray it frequently to induce the moss to grow. The pseudo-bulbs delight to have the moss growing luxuriantly around their base. The dwarf-growing *E. polybulbon* is also in bloom. It is only conspicuous when bearing 50 or 60 flowers open at the same time. There are two distinct and good varieties of this species. One has sepals and petals of a brownish-yellow colour and the other is greenish-yellow, but both have pure white labellums. These *Epidendrums* are intermediate-house plants and grow freely in well-drained pans with a mixture of fibrous peat, Sphagnum-moss and small crocks.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Pelargoniums.—Varieties of the "show" section of *Pelargoniums* will now make faster growth, therefore train the shoots so as to allow room for development. This may be done by fixing a ring of wire just below the rim of the pot and gently drawing the shoots towards the wire with raffia ties; or by placing a few neat, stout stakes in the pots at angles of 45°, and securing the shoots to them as they grow. The shoots should now be pinched on all but the late-flowering plants. Keep the plants in a light and airy position, and fumigate them once a fortnight. The cuttings of Zonal varieties intended for flowering in summer and autumn which were inserted a month ago are now sufficiently rooted to be potted singly into 3-inch pots. A sandy loam with a little leaf-soil added may be used for these. Pot them firmly, and place them in an intermediate house. When the plant has become established, pinch out the leading shoot.

Climbing plants.—As a general rule, it is only the deciduous, climbing plants that require severe pruning, most stove and greenhouse climbers being better when the pruning is merely restricted to thinning-out weakly shoots and shortening the longer growths. Plants growing in borders should have the surface soil removed, after which a top-dressing of suitable soil to which a fair quantity of bonemeal has been added, should be applied. Natural manure should not be used, but small quantities of artificial manure may be applied when watering the borders. *Boussingaultia baselloides* is a capital pillar and roof plant for a cold house. If it is planted in a rich, loamy soil and given copious

waterings during the season of growth, it quickly makes luxuriant shoots 20 feet in length. Individually the flowers are small; but they are produced in pendant clusters and are very fragrant.

Fuchsias.—The old plants may now be pruned and cleaned, but do not repot them until they have started into growth. For the purpose of encouraging them to grow, place the plants in a warm house and syringe them each day. Plants that were rooted last autumn should be kept steadily growing, repotting them as often as necessary. If the side growths are duly pinched, these plants will quickly make pyramids and flower during the coming summer. *Fuchsias* grown as pillar or roof plants that have filled their allotted space should be severely pruned, treating them further as advised for pot plants until they break into growth.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

Value of trenches.—One of the most satisfactory methods of cultivating pod-bearing vegetables on light land is to prepare good trenches for them such as are used for Celery, Leeks and Cardoons. For Runner and Broad Beans or Peas the trenches should be taken out 18 inches to 2 feet in depth and 15 to 18 inches in width. The soil at the bottom of the trenches should be well forked up and the trenches afterwards filled three-parts as follow:—A liberal layer of good farmyard manure should first be placed in the bottom of the trench, and the remaining space may be made up with manure from an old hot-bed. Of all the various materials used in the kitchen garden none is more serviceable for most vegetables than a compost which has done service for 12 months or two years in portable frames. Such a compost should be made into a good heap out-of-doors and allowed to remain for a few weeks before it is used, adding to it a little soot, lime rubble, burnt garden refuse, and a small quantity of bonemeal. When these have been mixed together they will be found to promote the growth of almost every kind of vegetable. The soil taken from the trenches may be left in an unbroken condition, for the weather will break it up much more perfectly than can be done by the hand. The distance at which the trenches should be placed from each other will depend upon the average height of the crops, but in this connection it may be urged that in most gardens Beans and Peas are not given the amount of space they require. Rather than place rows of such tall-growing plants closely together, I prefer to grow another crop between each pair of rows. Such a crop may consist of three or four rows of Cauliflower or Broccoli. The sunlight will then reach the Peas and Beans quite easily, birds will be less troublesome, and heavier crops may be expected.

Digging and treading.—Complete this work as quickly as possible, it being essential that the soil, especially if it is of a heavy nature, should be exposed to the action of the weather during March.

Vegetables in frames.—Plants which were raised last autumn and have been wintered in frames, though requiring protection from severe frost, must not be coddled. On the contrary, take the opportunities afforded by fine days to remove the lights entirely. It is necessary that the plants shall become thoroughly hardened. On nights when there appears no fear of frosts, mats may be thrown over the glass, but the lights need not be perfectly closed. These remarks apply to autumn-sown Cauliflowers, Lettuces, Parsley, and suckers of Artichokes.

Cabbages.—Cabbages, like many other green winter vegetables, have suffered in some localities because the extremely mild weather in autumn caused the plants to make soft growth. If there appears a likelihood that there may be a scarcity, a small quantity of seed of early-maturing varieties had better be sown now, raising them in a gentle heat. Such plants may be expected to produce heads fit for use early in the spring.

Parsley.—Seeds should be sown very thinly in boxes, raising them in a gentle heat. If Parsley seeds are sown too thickly they are almost certain to damp off at the collar.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Winter spraying.—Assuming that all the fruit trees and bushes have now been pruned, advantage should be taken of a calm day to spray them with an alkali wash. A concentrated wash of this description is sold by nurserymen and sundriesmen, and I strongly recommend it as being convenient in its application and effective in its result. Not only does an annual spraying of this nature keep the trees perfectly free from lichen and fungal diseases, but it also destroys a great number of insect pests. A knapsack sprayer is a suitable means for applying a spray in a small garden or in the case of isolated trees, but if a large number of wall or other fruit trees have to be sprayed, then one of the larger machines now on the market will be more economical. Care must be taken to see that the spray reaches every part of the tree and also any vacant spaces on the walls, for on such walls there may be crevices containing insect pests. In cases where the trees have been neglected in this matter in past years a second application may be necessary, and it should be carried out just before the flower-buds expand. In the mixing and application of such caustic spray-fluids it is necessary for the operator to wear rubber gloves as a protection to the hands.

American blight.—If American blight or woolly aphis is prevalent more severe measures will have to be undertaken. I have cleared this pest from badly-attacked trees by the application of undiluted paraffin, which was worked into the infested parts by means of a painter's small brush. This treatment must be applied now, whilst the trees are perfectly dormant. The stems and main branches may be treated with a strong solution of Gishurst's compound, applied by means of a scrubbing brush.

Protection of fruit trees.—In districts where past experience has proved the usefulness of protection against spring frosts it will be wise to see that everything is in readiness that the protection may be applied at any time at short notice. Apricots are the first to need such protection. Already the flower-buds are beginning to assume an appearance of plumpness. Tiffany or canvas fitted on roller blinds provide the best means of shading, as the cultivator can easily remove them up and down as circumstances require. Permanent coverings of thick material usually cause more harm than good.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Bulbs.—Many bulbs are already commencing to show their shoots through the soil, and these may require to be protected from mice and birds. These remarks apply also to Primroses and Polyanthus. The charming varieties Miss Massey and Sparkler attract sparrows very early in the season.

Rhododendrons (Azaleas).—Azaleas may be planted at the present time. The soil needs deep digging, not so much for the purpose of allowing the roots to descend to that depth as to permit of moisture coming from below. Therefore the soil should be dug two spits deep and the top spit kept at the surface. In some cases it may be necessary to add sand, peat, and leaf-mould, but where the staple is sandy loam very little else is needed, though it may be advantageous to put a little leaf-mould around the roots. Shake a considerable portion of the soil away from the roots of the plants and plant them somewhat shallowly but firmly. In large beds of deciduous Azaleas the plants should be interspersed with evergreen shrubs such as Rhododendron, Kalmia, and Skimmia. The appearance will then be less dreary in winter. There are numerous varieties of Azalea sinensis (mollis), and the best of them should be selected. In addition, A. amoena makes a fine display and A. hedifolia is one of the best for flowering late in spring. A. Vaseyi has flowers varying from white to flesh pink and makes very fine specimen shrubs.

Bedding plants.—Zonal and other Pelargoniums that have been wintered in boxes or store pots should now be potted up singly and placed in a light, warm position. Store plants

of Lobelia in moderate heat will soon produce growths suitable for cuttings. These should be taken off when 2 inches long and put into pans filled with light soil, covered with half an inch deep of fine sand. As soon as the cuttings have rooted they should be moved into a house or frame somewhat cooler. A little later they may be put into boxes or potted up singly. The double-flowering variety Kathleen Mallard succeeds well out-of-doors.

Seed-sowing.—Prepare some fine soil as advised in a previous Calendar and sow seeds of the Hollyhock in pots or pans. This grand border plant can be grown as an annual if the seed is sown sufficiently early. Under such cultivation the plants are not so liable to become attacked by the fungus, Puccinia malvacearum. Petunias and Verbenas should be sown during the next week or two and the trays or seed-pans placed in a temperature of about 60°. Seeds of tuberous-rooted Begonias, if sown now, will produce plants large enough to flower well late in autumn. Begonia seed is very small, and the packets should not be opened until the pots have been filled with soil. It is necessary to use a lens in order to see that the seed is evenly distributed over the soil. Place a piece of glass over the seeds and keep them moist and shaded, but not dark. The temperature should be about 65°. It is a good plan to soak Canna seeds in water for 24 hours before sowing them. Seeds of Marguerite Carnations may be sown at the present time and again towards the end of February. The plants will generally flower when they are six months old.

Lawns.—Prepare some fine soil and add to it a mixture of soot and bonemeal or a special lawn-grass manure. When an opportunity offers give the tennis court and any other part of the lawn a good sprinkling with this compost. When the mixture has become overgrown by the Grasses the lawns must be swept and rolled at frequent intervals.

THE APIARY.

By CHLORIS.

Hive making (continued).—In continuation of my note on this subject (see p. 23), I will now deal with the upper portion or hive proper. In fig. 40 is represented a sectional plan of a hive. A is the body box or brood chamber, which, with its porch (F), is placed on the floor (B).

FIG. 40.—SECTIONAL PLAN OF A STANDARD BAR-FRAME HIVE.

A, the body-box or brood chamber; B, floor; C, detachable chamber or lift; D, upper lift with roof; E E, legs; F, porch over entrance; G G G G, draught-excluding strips of wood.

The hive is raised on four legs, well splayed apart, to furnish extra rigidity, for if the legs are perpendicular to the floor the hive will most likely be blown over during boisterous weather. The floor and the alighting-board have already been described. The 1st floor is the lift (C). This is the same length and breadth as the brood chamber, but only 5 or 6 inches deep. Two, at least, of these lifts will be necessary when the bees are busy storing honey. D is the roof, which must be made perfectly water-tight, and to secure this it is necessary to cover it with sheet tin, or to paint it thickly. Should paint be used, a piece of calico should be stretched on and tacked down securely while the paint is wet. The calico itself should also receive a coating of paint. The parts lettered G represent strips of wood nailed over the joints to make the hive water-tight and to keep out draughts.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Deciduous flowering trees and shrubs.—These include a good selection for park planting. Of the Magnolias several useful species may be employed, including M. acuminata, M. conspicua, M.c. var. Lennei and the hybrid M. Soulangiana. The Tulip-tree Liriodendron tulipifera grows to a large size, and is attractive when in bloom. Laburnums in variety flower well, as do also the Robinias. Rhns glabra and R. typhina are objects of interest, not the least by reason of their beautiful autumn-tinted foliage. Amelanchier alnifolia and A. canadensis are amongst the most beautiful of early-flowering trees, and these are followed by the numerous species of Prunus and Pyrus. Catalpa bignonioides does well as a park tree and freely produces both its flowers and fruit. The Sea-Buckthorn (Rhamnus) is interesting, because of its sexes being on separate plants; the tree is a beautiful object, especially when in berry. The Mulberry thrives and fruits in the London parks. The many varieties of Hibiscus syriacus are also attractive: they form bushy plants that flower freely each autumn. The various kinds of Philadelphus are all good town trees and flower well; the Forsythias are pleasing objects in the early spring, when they are covered with their bright yellow blossoms. In addition to those mentioned, several species and varieties of Viburnum, Colutea, Cornus, Diervilla and Ribes impart further variety. The many beautiful varieties of Lilac (Syringa) are especially valuable for park planting, and several of the Elders are showy in flower and foliage.

Lawns and Grass-lands.—In public parks and gardens the area of Grass-land is considerable, and its proper maintenance is a matter of importance. Attention should now be directed to the turf, and the bush-harrow brought into requisition. In the case of playing fields any necessary renovation should have been made after the summer games had ceased, and the ground levelled, the surface afterwards dressed with well-rotted manure or soil of a rich nature. The dressing of soil is especially valuable if the land is of a light, sandy character, because it will provide a more durable surface. These materials should now be broken up and dispersed as finely as possible, and one of the best means of doing this is to cross and recross the plots with a bush-harrow. This implement is readily made by interlacing long, freshly-cut thorn bushes into a frame not unlike a large open hurdle. The brushing will break and scatter the particles evenly over the surface of the turf and freshen the Grass. After the brush a heavy roller should follow to consolidate the surface. It is only by a constant and judicious use of the roller, combined with proper mowing, that a good sward can be obtained. Should the ground be soft, the horses to the roller or mower should be provided with boots. Rolling should be done during dry weather. It is a struggle between wear and repair on all Grass plots that are much frequented by the public, especially on land that cannot be conveniently closed for a time. Such turf can only be renovated by pricking up the worn surface with a fork and sowing seeds afresh. In such cases the sowing should be done as early in the season as possible. Sometimes after turf has been used for a whole season for football the Grass is past repair and must be renewed. The ground should be dug deeply and a suitable seed-bed prepared by rolling and harrowing. A slight variation may be made in the variety of Grasses used, according to circumstances, but the following may be regarded as making a good and useful mixture: Poa pratensis, P. nemoralis, P. trivialis, Festuca ovina tenuifolia, F. rubra, F. durinacula and Cynosurus cristatus. The perennial Rye-grass may also be included, but it is not so much used as formerly. The Grasses named will form turf of a finer nature without the Rye-grass. Poa nemoralis is the best Grass for sowing in the shade and under trees. A little Clover, about 1lb. to each bushel of Grass seed, may be employed, but in some parks objection is taken to the use of Clover. The suckling Clover, Trifolium miasm, is to be preferred, especially on a light soil. Sow the seeds thickly in order to obtain a close turf as early as possible.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Appointments for February.

MONDAY, FEBRUARY 1.—Nat. Chrysanthemum Soc. Annual meet. at Essex Hall, Strand, at 7 p.m.

THURSDAY, FEBRUARY 4.—Linnean Soc. meet.

SATURDAY, FEBRUARY 6.—Soc. Franç. d'Hort. de Londres meet.

MONDAY, FEBRUARY 8.—United Hort. Ben. & Prov. Soc. Com. meet.

TUESDAY, FEBRUARY 9.—Ann. meet. Roy. Hort. Soc. (Competitive Classes for late dessert Pears). Hort. Club Ann. meet. and Dinner. British Gard. Assoc. Ex. Council meet.

WEDNESDAY, FEBRUARY 10.—Perpetual-flowering Carnation Soc. Annual meet. at Hotel Windsor, 4 p.m. Croydon & District Hort. Soc. Annual Dinner.

THURSDAY, FEBRUARY 11.—London Branch B.G.A. lecture on Kew Gardens.

FRIDAY, FEBRUARY 12.—Roy. Gard. Orphan Fund Ann. meet. and Election of Orphans.

WEDNESDAY, FEBRUARY 17.—Roy. Meteorological Soc. meet.

THURSDAY, FEBRUARY 18.—Linnean Soc. meet.

TUESDAY, FEBRUARY 23.—Roy. Hort. Soc. Coms. meet. (Competitive Classes for late dessert Apples. Lecture at 3 p.m. by Mr. Arthur W. Sutton, on "A Camping Tour through Syria to Petra in Arabia.") Surveyors' Institution Annual Dinner at Hotel Métropole.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39.4°.

ACTUAL TEMPERATURES:—LONDON.—Wednesday, January 27 (6 P.M.): Max. 32°; Min. 27°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, January 28 (10 A.M.): Bar. 30.3; Temp. 34°; Weather—Dense fog.

PROVINCES.—Wednesday, January 27 (6 P.M.): Max. 48° Co. Cork; Min. 27° Durham.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY.—Perennials, Lilies, Border Bulbs, Azaleas, Ferns, &c., at 12; 1,000 Roses and Fruit Trees, at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY.—Hardy Border and Herbaceous Plants, Lilies, Bulbs and Tubers, at 12; Roses and Fruit Trees, at 1.30; Azaleas, Palms, and Plants, at 5 o'clock; by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY.—Burmese Dendrobies, Pleonies, and other Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Munificent Bequest to Horticultural Science.

The need for research in horticulture has been urged again and again in these columns. Horticultural practice in this country leads the world; horticultural research lags behind.

We are glad therefore to be able to announce that, by the munificence of the late Mr. John Innes, an opportunity occurs for the foundation of a station for horticultural instruction and research of which this country may be proud.

Under the terms of the Innes bequest a

Trust will administer a sum which may not be far short of £10,000 a year, in the interests of horticulture. The full details of this bequest, which we have just received from the Charity Commission, are as follow:—

In the first place, a yearly sum of £350 out of the income of the charities will be applied by the trustees to various charitable objects.

An educational foundation is established, by means of which certain sums of money will be available for the maintenance of scholarships at the Rutlish Science School. These sums will be: In the first year, commencing from the date of the scheme, £64; in the second year, £114; in the third and every subsequent year, £154. This educational endowment will be administered as a separate foundation under the title of the Innes Scholarships.

The Merton Boys' Club, in which the late Mr. Innes was deeply interested, is to be maintained by means of a yearly sum of £200 paid to Mr. Edward William Pillinger, of the School House, Merton.

A portion of the grounds held with the house at Merton, formerly known as Manor Farm, is to be maintained as a park, which is to serve for the recreation of the inhabitants of Merton and Morden.

Subject to the provisions already mentioned, the charity and its endowments are to be administered for the purposes of an institution, which is to be called the "John Innes Horticultural Institution," the object of which is to be "the promotion of horticultural instruction, experiment, and research in accordance with the scheme."

The house above referred to, together with the outbuildings and appurtenances, and a portion not exceeding two acres of the land held therewith, is to be appropriated for the purposes of the institution.

The charity is to be administered by a body of trustees, who, for the purpose of advice, particularly on technical management, may delegate to a council such functions as they may determine.

The first trustees will be the trustees of the will, viz.:—Charles Clare Scott, Middle Temple, London, Barrister-at-law; Frederick George Courthope, of Southover, Lewes; William Ernest Reid Innes, of Roffey Park, Horsham.

Among their other functions the trustees are to provide land in the neighbourhood of Merton of sufficient extent, with the two acres attached to the Manor Farm already referred to, to establish a horticultural station, and to equip it efficiently, including the provision of buildings and lecture rooms. Further to establish and equip, or assist in such work, similar stations in other parts of the country.

The council will consist of twelve persons—three ex-officio members and nine representative members. The ex-officio members will be the three trustees of the charity.

The scheme provides that the representative members shall be appointed as follow:

Two by the Board of Agriculture and Fisheries, one each by the Royal Horticultural Society, Fruiterers' Company, National Fruit Growers' Federation, Hebdomadal Council of the University of Oxford, Council of the Senate of the University of Cambridge, Senate of the University of London, and the

Governing Body of the Imperial College of Science and Technology.

The functions of the council (subject to the sanction of the trustees) will be:—

1. To establish and maintain the institution for the purpose of affording practical and scientific training in horticulture.

2. To carry out investigation and research, particularly with fruit trees, shrubs, fruit, vegetables and flowers.

3. To endeavour to improve existing varieties, and to create or introduce new ones.

4. To further, generally, the interests of horticulturists.

With the consent of the trustees, the council may enter into arrangements with other institutions or bodies for establishing subsidiary stations and for carrying on similar work in different parts of the country.

The lands and monies available for carrying out these projects are:—

1. The house and grounds (11 acres) of Manor Farm, Merton.

2. Premises at Merton known as the Manor Club and Institute.

3. Ordinary shares of £1 each, fully paid, to the value of £24,350 in the Merton Park Estate Company.

4. Cumulative preference shares of £1 each, fully paid, to the value of £62,650 in the same company.

5. 16,800 ordinary shares of £2 10s. each fully paid in the City of London Real Property Company, Limited, amounting to £42,000.

6. 5,600 cumulative preference shares of £5 each in the same Company, amounting to £28,000.

7. Consols to the value of £65,200 set apart to provide for annuities bequeathed by the founder of the charity.

8. Accumulated funds on deposit with Messrs. Barclay and Company, Limited, North Street, Brighton, 4,000.

The gross yearly income from the bequest amounts, according to the report of the Charity Commission, to £10,000.

In view of this provision, there can be no doubt that the John Innes Horticultural Institution is the most munificent private provision ever made in this country for the furtherance of the interests of horticulture.

The need for such an institution is pressing; the money is now available. From this noble foundation there should arise a horticultural university in which research occupies the first place and the dissemination of the results of research—that is, advanced teaching—the second place. If the institution were to become primarily, or mainly, a school of elementary instruction, it would fail inevitably as a school of research, and thus a great opportunity would be lost. To guard against such a contingency must be the first and constant aim of the council.

As we were able to state in our last issue, there were 21 pensioners elected at the annual meeting from the list of 73 applicants. It may be pointed out that the two candidates placed on the funds at the suggestion of the committee had sought election on several previous occasions, and

The Gardeners' Benevolent.

their hopes of success were poor. The candidate who benefits by the generosity of Mr. Arthur W. Sutton is totally incapacitated for work, although but 40 years of age. Mr. George Munro, as last year, contributes a sum necessary to support one pensioner, but as this pensioner's name did not appear on the original list it need not be deducted therefrom. After our pages went to press, however, it was announced by Mr. N. N. Sherwood in a speech which he made during the proceedings which followed the friendly supper, that he would contribute a sum necessary to support two additional pensioners. It was understood that they would be two of three candidates to whom Mr. Veitch had previously referred as suffering from paralysis. This year, therefore, there remain 50 disappointed candidates; but it must be remembered that there were 20 more applicants than on any previous occasion.

It may be noted with satisfaction that the widow of a gardener who had subscribed to the institution for 45 years, headed the poll. By the beneficent rule which secures to a subscriber 100 votes for every year's subscription he has paid, this candidate started with 4,500 votes to her credit, or nearly 1,500 in excess of the number of votes obtained by the second candidate on the list of successful applicants. Reference to this matter is apposite, because a correspondent complains (see p. 76) that, whilst many candidates who had subscribed to the institution were unsuccessful at the election, several were elected who had never contributed to the funds. The present system certainly gives subscribers an advantage over non-subscribers. If the majority of those who support the institution desire to make the conditions yet more favourable to subscribers, they must do so by changing the character of the charity. If non-subscribing candidates were to be entirely excluded it would become a benefit society rather than a benevolent institution. It must be borne in mind that only a very small portion of the fund is contributed by those who are ever likely to receive allowances: the main part of the income is derived from gifts that are purely charitable. In a benefit society this is not the case. At the annual meetings frequent references have been made to this aspect of the institution, and there appears to be a general desire to maintain the benevolent character, which has been a marked characteristic during the 70 years of its existence. In that period a sum of £125,000 has been distributed, and the current disbursements amount to something like £4,000 a year. There are 240 pensioners at present receiving allowances. Then there is the Victoria Era Fund from which candidates for election, who have subscribed to the institution, are given assistance, which, in some cases, amounts to as much as £12 a year during the time they have to wait. The Samaritan Fund is available for assisting non-subscribing candidates previous to election, and for making temporary grants to meet urgent cases for relief.

Notwithstanding the success that has characterised the operations of this institution, the present position is one which must cause considerable anxiety. It has already been shown that the number of disappointed candidates is greater than ever, and some means must be sought by which a larger number

of deserving cases may be relieved. It was stated by Mr. Harry J. Veitch, whose efforts on behalf of this institution are as indefatigable as ever, that the 73 candidates were selected by the committee as being most deserving of help, but that the actual number that applied was approximately 100, which certainly increases the gravity of the situation.

There appeared to be considerable interest at the meeting as to the effects of the Old Age Pensions Act upon the policy of the institution. The addition to Rule III. 6, proposed by Mr. White on behalf of Mr. W. A. Bilney, the honorary solicitor, was accepted by the meeting after considerable discussion. This addition to the rules merely gives to the committee power to adjust the allowances to pensioners in such a manner that they will not prevent the pensioner from claiming a Government Old Age Pension. It is obvious that the Government scheme will not affect in the least a large number of those who apply to this institution for relief. The age limit in itself invalidates a large number of the pensioners, and in this connection it may be stated that 41 out of the 73 applicants this year are disqualified for this reason. In some few cases the private means of the applicant would be sufficient to render him ineligible for the State pension. But there are many cases receiving allowances in which modifications may have to be made in order that pensioners may take full advantage of the £13 per year obtainable from the State. We will suppose a pensioner is over 70 years of age, thus conforming with the age requirement of the Old Age Pensions Act. Provided that such a candidate or pensioner has no private means, this institution would be able, as heretofore, to make an allowance of £20 per year without standing in the way of the Government pension. Indeed, the annual income of any pensioner might be made up to, say, £25 per year by this institution granting £5, £10, £15, or £20, varying according to the private means. There are instances in which considerable sums would be saved the institution by thus placing every pensioner in a position to claim a State pension. The institution is hardly likely to continue to grant an allowance that would have the effect of making the income of the pensioner more than £25 per year. There is a feeling amongst subscribers that when this matter is perfectly adjusted and the most has been made of the State pensions, it will be possible to assist a much larger number of cases than is possible at present. This appears more than probable. As a subscriber said at the meeting, the adjustment is necessary, in order to ensure the greatest good for the greatest number. It was subsequently announced that the committee would consider this matter and after determining a course of action would communicate the result to the Press. In the meantime, there is not the slightest reason to doubt but that the committee will see to it that private charity does not operate to prevent the acceptance of State aid. It is to the interest of all concerned that there should be no overlapping, and we have every confidence there will be none.

In connection with the fact that Mr. Lionel de Rothschild will preside at the annual

festival in June next, it is interesting to state that already five other members of the Rothschild family have presided at similar festival dinners in support of the Gardeners' Royal Benevolent Institution.

OUR SUPPLEMENTARY ILLUSTRATION represents a hybrid *Sinningia* named after the late Dr. Maxwell T. Masters by Mr. Ernest Benary, of Erfurt. Mr. Benary, who exhibited plants at the meeting of the Royal Horticultural Society on July 21, 1908, states that this *Sinningia* was raised from a cross between the garden *Gloxinia* (*Sinningia*) and a species of *Gesneria*. The flowers are rose-coloured, drooping, and very freely produced, whilst their construction shows some trace at least of the influence of *Gesneria*. The leaf petioles are longer than in most *Gloxinias* and the roundish ovate leaf-blades are of a soft, silky nature. The Floral Committee recommended the plant an Award of Merit.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of this Society will be held at Essex Hall, Essex Street, Strand, W.C., on Monday, February 1, at 7 p.m. The chair will be taken by the President, Sir Albert Rollit, D.C.L., LL.D.

PERPETUAL - FLOWERING CARNATION SOCIETY.—The annual general meeting will be held in the Hotel Windsor, Victoria Street, London, S.W., on Wednesday, February 10, at 4 p.m. The spring show of the society will be held on March 24 in the Horticultural Hall, Vincent Square, Westminster. Particulars may be obtained from the Hon. Secretary, Hayward Mathias, Lucerne, Stubbington, Fareham, Hants.

HORTICULTURAL CLUB.—The annual dinner of this club will take place on Tuesday, February 9, at 6 p.m., at the Hotel Windsor, Westminster. Ladies are specially invited. The annual meeting will be held at 5.30 p.m.

AGRICULTURAL SCIENCE.—Two lectures will be delivered by Mr. A. D. Hall, M.A., Director of the Rothamsted Experimental Station, at the Royal Institution of Great Britain, Albemarle Street, Piccadilly, W. The first lecture will be on Thursday, March 11, and the second on Thursday, March 18, at 3 p.m. The subject of the first lecture is "The Fixation of Nitrogen by Bacteria in the Soil," and the following is the syllabus:—The fixation of nitrogen by the bacteria associated with leguminous plants.—History and description.—Attempts made to utilise these bacteria in practice; inoculation of soil and seed.—Preparation of pure cultures.—Reasons for the partial success obtained.—Fixation of nitrogen by bacteria living free in the soil.—What part do they play in nature?—The origin of the virgin soils rich in accumulated nitrogen. The subject of the second lecture is "The Effect of Fertilisers upon the Texture and Reaction of the Soil." Acid soils found in nature, their characteristics.—Acid soils of artificial origin, due to the continual use of ammonium salts as fertilisers.—Nature and cause of the acidity.—How the acidity brings about infertility.—The part played by micro-fungi in the soil.—The injury caused by nitrate of soda to the texture of the soil.—Deflocculation of clay caused by soluble alkalis.—Formation of sodium carbonate from sodium nitrate by the growth of plants.—Evidence for the existence of sodium carbonate in the Rothamsted soil receiving sodium nitrate, and its injurious effect upon the soil.

THE SURVEYORS' INSTITUTION.—The secretary informs us that the ordinary meeting, previously announced for February 8, was held on January 25. The annual dinner will take place on February 23.

"THE SWEET PEA ANNUAL AND SCHEDULE FOR 1909" is now ready. It may be obtained by non-members for 2s. post free, not 1s. 3d. as hitherto. The London exhibition will be held on July 23, and the provincial show at Saltaire on July 13. A new catalogue of Sweet Pea names and descriptions will be ready about the end of February; it will be sold at 6d. per copy. New members joining the society for 1909 will receive a copy gratis.

A NEW "PLANT LABEL."—Mr. C. E. WEST sends us samples of a new plant label known as the "Alu." The label material is aluminium, and it is claimed to be indestructible. By means of a narrow strip of the metal, known as the shank, the labels can be quickly attached to the stem of a plant without tying. The shank also admits of the label being inserted in the ground.

BOUGAINVILLEA CYPHERI.—As a general rule coloured illustrations of plants leave much to desire on the score both of beauty and of accuracy. An exception to this general rule is the excellent plate of Bougainvillea Cypheri and B. glabra Sanderiana issued in the *Revue Horticole*, No. 1, January 1, 1909. The bracts of the former variety are larger and of a somewhat less magenta colour than those of the older, better-known B. glabra Sanderiana. The text accompanying the plate does ample justice to the sensation which this latter variety created when introduced in 1806. Unfortunately, the newer variety, unlike B. g. Sanderiana, is difficult of propagation. On this account it has not yet become so widely known or grown as it deserves.

PUBLIC PARKS IN THE GERMAN EMPIRE.—The spending of money in the formation, extension, and improvement of public parks and recreation grounds appears to go hand in hand with the increase of wealth in Germany. One can scarcely scan German gardening journals or ordinary newspapers without becoming aware of the intention of this or that town to lay out an area for a park or public garden. We note in a recent number of *Die Gartenwelt* that the municipality of Stettin has decided to apportion 10 millions of marks for the acquirement of land for such purposes, and for the establishment of the so-called "Laubencolonien"—summer-house gardens. Of course it is solely in summer time in that country that a garden can be enjoyed at all, as in the winter months snow is the rule rather than, as in southern England, the exception. Tübingen is to have woods laid out in good landscape style, in combination with certain areas planted with trees, and the existing wood is to be brought nearer to the town. The town of Rixdorf will benefit to the extent of 55 hectares, i.e., nearly 140 acres.

FORCING LILACS IN DRESDEN.—Our readers are familiar with the discoveries of JOHANNSEN of the effects of etherisation on plants (*Gard. Chron.*, February 28, 1903, p. 142). It is interesting to learn from an article translated by Mr. F. LEDIEN from *Möller's Deutsche Gärtner-Zeitung*, and published in *Le Moniteur du Jardinier* (ix. 1, Jan., 1909), that these discoveries are now being applied commercially and that a considerable industry in the etherisation of Lilacs for winter forcing has grown up in Germany during recent years. The plants are raised in Dresden, etherised there, and then

distributed to such distant regions as Austria and Hungary, where they are forced. Beside etherisation, the hot-water method is also practised, but it has the disadvantage, in comparison with the ether method, that the plants generally are useless for forcing a second year. The varieties of Lilac used in the ether treatment are, beside Marie Légraye, Charles X., and the double varieties Léon Simon, Mme. Lemoine, and Mme. Casimir-Perier. The Lilacs for etherisation are grafted on stocks of *Syringa vulgaris*, grown for two years in the open, and then potted in June. A proper root development is induced by frequent transplantations during the early stages. Batches of plants are etherised weekly from the beginning of November, in order to provide cut-flowers. Towards the end of November larger numbers are treated to meet the Christmas demand for pot-plants. The process of etherisation lasts 24 hours, the plants are then put in a dark cellar or pit at a temperature of 25° C. (= 77° F.) for a fortnight. Then, the inflorescences being about 6 inches long, the plants are exposed to the light in order that the flowers may develop their delicate tints.

OLD GARDENS OF ITALY.—At a recent meeting of the Italian Circle of the Lyceum Club Mr. JOSEPH CHEAL, Crawley, delivered a lecture on the "Old Gardens of Italy." Mr. CHEAL said that Roman generals, no doubt, brought home marvellous tales of the gardens of Assyria, Babylonia, and Egypt, and that it was probably these accounts which fired the imagination of LUCULLUS, whose magnificent garden at Naples is described by POMPEY. The Emperor HADRIAN early in the second century seemed to have stimulated the taste for horticulture, and PLINY the younger, about the same time, not only designed gardens, but has left descriptions of some of the gardens of the period. For several centuries during the decline of the Roman power the love of gardening also declined. There was a great revival about the close of the 14th century. A great impetus to gardening seemed to have been given by LORENZO DE MEDICI, a friend of MICHAEL ANGELO. The MEDICI family had much to do with the creation of the beautiful villas and gardens around Rome and Florence.

WHORTLEBERRIES AND CRANBERRIES.

(Continued from page 51.)

VACCINIUM HIRSUTUM.—An interesting history belongs to this rare species. It inhabits little-frequented spots in the mountains of North Carolina, where it was first discovered some 70 years ago by Mr. B. S. Buckley. It was not introduced to cultivation at the time, and was lost sight of until 1886. In that year, Professor Sargent, whilst journeying through its native region, made enquiries amongst the inhabitants if any of them knew of a "hairy Huckleberry." He found at last a man who "had heard tell" of such a plant, and, before leaving, offered a reward of five dollars (a considerable sum of money, as he observes, in those parts) to anyone who would find and send it to him. The following summer Professor Sargent received a box of fruits of the true *V. hirsutum*, and afterwards young plants were sent to the Arnold Arboretum. In this way the species became established in cultivation. It was introduced to Kew in 1889, and has flowered and fruited many times since. It is a low shrub, rarely more than 2 feet high. In its native home it is said to grow in light, stony soil, in the shade of large trees. The leaves are ovate-oblong, entire, and 1 to 2 inches long. The flowers, which are produced in short racemes towards the end of May or the beginning of June, have a cylindrical corolla, $\frac{3}{8}$ inch long, with five small lobes, white, tinged with pink. The fruit is blue-black, globose, and hairy; it is juicy, and has an agreeable, although not very pronounced, flavour. The distinctive feature of this species is, of course, its hairiness, the young wood, the lower surface of the leaves, the flowers and the fruit being all densely covered with short hairs.

V. INTERMEDIUM.—The credit of the original discovery of this hybrid Whortleberry in England appears to belong to Mr. Robt. Garner, who found it in Maer Woods, Staffordshire, in 1870. But its existence in the British flora does not appear to have been recorded until 1886, when it was collected on Cannock Chase in the same county by Professor Bonney. It was then made the subject of an article in the 24th volume of the *Journal of the Linnean Society*. The late Mr. G. Nicholson also found it in the same locality in 1888. Its parents are *V. Vitis-Idæa* and *V. Myrtillus*, and its characters are fairly intermediate between the two species. On the whole, it is more suggestive of *V. Myrtillus* in habit, but its stems are not angular as in that species. It shows the influence of *V. Vitis-Idæa* in being nearly or quite evergreen. In shape, also, the leaves approximate those of the latter species, but they are not dotted on the under surface. The fruit is dark violet colour.

V. MORTINIA.—Growing on the slopes of Mount Pichincha, in Ecuador, this *Vaccinium* affords one of the few instances of a shrub, which, whilst hardy enough to thrive out-of-doors in several parts of England, occurs wild almost exactly on the equator. It has flowered occasionally in the open at Kew, but can only be regarded as half-hardy there. In Sir Edmund Loder's garden at Leonardlee, near Horsham, it appears to thrive to perfection. It is a small evergreen bush, 2 to 3 feet high, the finely-pubescent branches being thickly set with small, leathery leaves (seven or eight to the inch). The leaves are uniform in size and shape, being ovate, pointed, about $\frac{1}{2}$ inch long; they are toothed at the margin and speckled with minute black dots beneath. The blossoms are borne in numerous, small, drooping racemes in the leaf-axils. The corolla is rosy pink, cylindrical, and about $\frac{1}{2}$ inch long. The specific name is derived from "Mortina," a native name for the fruits, and one under which they are sold in the market of Quito. The species was originally introduced to this country by the Royal Horticultural Society through their collector, Hartweg.

V. MYRTILLUS (BILBERRY OR WHORTLEBERRY).—Except the Heather (*Calluna vulgaris*), there is no shrub more characteristic of British moors and mountains than the common Bilberry. On some of the loftiest summits of the English and Scotch mountains one may find this plant dwarfed almost out of recognition, but maintaining a sturdy existence where little else can survive. In ordinary situations it grows from 6 inches to 2 feet high, with very well-marked, acutely-angled stems. The leaves are from $\frac{1}{2}$ to 1 inch long, ovate, regularly-toothed, and green both above and below. The flowers are produced singly on the growth of the current season; they are pinkish in colour and wax-like in texture. The berries are about the size of Red Currants, but are purplish-black. As edible fruits they are the most valuable of British Whortleberries, being made into jellies, tarts, and puddings. A favourite way of eating them in some parts is with new milk or clotted cream. Winged game feed upon them freely. The Bilberry is found plentifully in every county in the three kingdoms, except, perhaps, the flat coun-

at its best, it is an ornamental and striking shrub. Its young wood is purplish and clothed with a short, dense pubescence. The leaves are evergreen, thickly set on the branches, of an almost uniformly ovate shape, finely toothed, and of a firm, leathery texture; they average about 1 inch in length. The flowers are round, bell-shaped, white, and produced from the leaf axils, four to six together, in a short raceme. The Bearwood specimen produces small, black fruits, and these, according to Douglas, have an agreeable flavour. V. LANCEOLATUM is simply a narrow-leaved form of this species. W. J. Bean.

(To be continued.)

ILEX PERNYI.

AMONGST the magnificent group of ornamental trees and shrubs shown at the Royal Horticultural Hall, Westminster, on December 22nd last, by Messrs. Jas. Veitch & Sons, of Chelsea, this remarkable looking Holly did not fail to attract

FIG. 41.—ILEX PERNYI A CHINESE SPECIES.

ties of East Anglia. It reaches over the greater part of Europe, and is found also in North Asia and Eastern North America.

V. MYRTILLUS VAR. MICROPHYLLA.—A variety of V. Myrtillus occurs in Western North America in the Sierra Nevada, at elevations of 7,000 feet, and thence northward. It is called var. microphylla, and is about half the size of the European plant in all its parts.

V. OVATUM—Douglas first introduced this shrub to England in 1826, during his famous journeys on behalf of the Horticultural Society in Western North America. It had, however, been discovered more than 30 years before by Archibald Menzies, whilst he was attached to Vancouver's great voyage of survey (1791-5). The species grows abundantly in Oregon and California, in association with the Redwood (*Sequoia sempervirens*). The finest plant, I believe, in this country, is at Bearwood, Surrey, being 10 to 12 feet high. It is hardy enough to survive the severest winter experienced at Kew, but gives one the impression that it would be happier in a milder locality. Seen

attention. It had been shown on a previous occasion—September 1, 1908—when a First-class Certificate was awarded to it by the Floral Committee.

Although new as a garden plant, Ilex Pernyi has been known to science for over 20 years, and specimens have been in the Kew Herbarium since February, 1887. It is a native of Central China, where it forms a tree 20 feet to 30 feet high. It was discovered in the neighbourhood of Kinchu by the Abbé Perny, after whom it was named by Franchet in *Plante Davidiana*, p. 69. The Abbé David (whose name is commemorated in the work mentioned) also discovered this Holly at Shensi and Patung, and Dr. Henry, I believe, records that the wood is valuable as timber.

The plants in Messrs. Veitch's collection are only 2 feet high, forming dense, compact growing evergreen bushes. They are remarkable for the peculiar rhomboidal or squarely-ovate leaves, which measure 1½ inches to 2 inches in length, the apical half being triangular and ending in a sharp cartilaginous spine. The lower

half is almost square, but is a little narrower at the base, and the margins are furnished with two or three spiny teeth.

One peculiarity noticeable in the illustration in fig. 41 is the sceming overlapping of some of the leaves, which spread out flatly from the wiry stems. This peculiarity can scarcely be regarded as characteristic, as the leaves on all branches do not overlap in this way. Looking at them from the front, they appear to be sessile, but each leaf has a very short stalk, scarcely one-tenth of an inch long.

Taken altogether, this Holly may be regarded as a decided acquisition to the evergreen trees and shrubs. John Weathers.

NOTES FROM A "FRENCH" GARDEN.

OWING to the favourable weather, the making of the hot-beds is considerably advanced, and in some gardens these beds are almost completed. In private gardens, or where the produce is sold locally, however, it is advantageous to spread the making of the hot-beds over four weeks in order to obtain a succession of Radishes and Lettuces. If this rule is followed two or three of the last-made beds may be sown with the Carrot "Bellot."

If it is intended to force Turnips in March we merely sow Radishes, and plant 42 Lettuces per light. The Lettuces will be ready at that period, and the beds can then be turned over to give a mild heat sufficient for the germination of Turnip seeds.

We are now planting the "Passion" Lettuce in the open, on ground previously well prepared and on which a layer of thoroughly decayed manure has been spread. Before planting these we usually sow a few seeds of Radish "Early French Breakfast," setting the Lettuces at 10 inches apart each way. In very rich soil and where there is a good supply of water they may be planted closer.

The salads supplied to the Paris market are of superb quality. English salesmen prefer the white strain, but in Germany, where many Lettuces are imported from France, the favourite is the brown-leaf Passion. In the first week of February we shall sow another batch of Cos-Lettuces (White Cos of Paris) and Cabbage Lettuce "La Perichonne" in a cold frame, as a succession to those sown on the hot-beds a fortnight ago. This latter batch will be pricked off in a few days in a cold frame, 150 to 160 plants per light.

We shall also sow the first lot of Cauliflowers "Driancourt and Lenormand" on a hot-bed 12 inches thick, putting 500 seeds in each light. They will be planted as an intercrop in the place of the first lot of Cos Lettuces grown under the cloches.

The Radish seeds planted in the first hot-beds made about the 15th January are now well up, and it will be necessary to place fresh manure round the frames so as to keep an even temperature.

Until recently it has not been necessary to cover the lights with mats at night, but now that the weather has become colder they are needed. P. Aquatias.

BEGONIA × PATRIE.

THE hybrid Begonia illustrated in fig. 42 was raised by Messrs. M. V. Lemoine & Sons, Nancy, and was exhibited by them at the meeting of the Royal Horticultural Society on January 12, when the Floral Committee granted it an Award of Merit (see *Gardeners' Chronicle*, January 16, p. 46). The parents are B. socotrana and a variety of B. Pearcei. The plant is of compact habit and the many inflorescences are borne in rather stiff bunches: the colour of the flowers is a rich shade of rose-pink.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The 50 unsuccessful candidates for the pension of the Gardeners' Royal Benevolent Institution at the recent election claim deepest sympathy, and one would have liked to see all of them elected. As matters stand, however, financial considerations do not allow of this, and many deserving cases have to be passed over. As the majority of the rejected candidates have been contributors to the funds of the society, I, in common with many others, consider that the time has come when subscribers should have an even greater advantage than they now enjoy over the non-subscribers. There are, possibly, good reasons why outsiders cannot be excluded altogether, but when a life member or a subscriber of several years' standing is ousted by a candidate who has never contributed one penny to the funds one is apt to think that there is considerable room for improvement. When trying to induce other gardeners to subscribe, I often meet with the objection that, even if the subscription is paid for years, a non-subscriber may, in the long run, be elected and the subscriber be passed over. This objection is certainly borne out by facts, for while subscribers up to 21 years' standing were rejected at the last election, and numerous life members shared the same fate, at least three non-subscribers were elected. This is the reason that gardeners do not largely join the society. W.

CHRYSANTHEMUM FRAMFIELD PINK.—If Messrs. R. Richards and T. Down will plant this variety in a bed or border of rich soil and stop the shoots once only they will have no cause for complaint either in regard to flowering or poverty of colour. I lifted six large plants in September, having cut around their roots with a spade about a fortnight before lifting, and they have furnished hundreds of large well-coloured blooms, the supply lasting well into the new year. Chas. Lawton, Welton House Gardens, East Yorkshire.

—My experience with this variety differs from your correspondent's, inasmuch as I get not only good plants, but plenty of richly-coloured flowers. Each leading shoot furnishes a good spray of from three to seven blooms, and I have only just finished cutting (January 22): most season's blooms can be had up to March. The system of cultivation I adopt with all single and decorative varieties is to strike the cuttings about the middle of February, and as soon as they are well rooted pot them singly into large 3-inch pots, transferring them into their flowering pots (10 inch) early in May. From the time they are first rooted the plants are given as hardy a treatment as possible, and in many seasons they are placed in the open at the end of March. The shoots are not pinched or stopped in any way, and it is to this that I attribute my success. The plants form good bushes, from 2 to 3 feet through, and with 24 to 30 shoots. They range from 2 to 4 feet in height. The quality and colour of the bloom, as well as the strength and hardiness of the stem, are infinitely better than in the case of any plant that has been stopped. No manure is given in the early stages of growth except a little bonemeal, but after the flower-buds are formed they are fed in no unstinted measure. Thomas Stevenson, Woburn Place Gardens, Addlestone, Surrey.

TRENCHING.—In reply to Mr. A. Shakelton (p. 61), I am not surprised to know that he has some hesitation in following my advice as to placing the bottom layer of soil at the surface. I know there are many other good cultivators who disagree with me on this subject. But, having practised this plan of trenching for more than a quarter of a century, I can recommend it as the quickest and most beneficial method of improving soil, and specially soil devoted to the culture of kitchen-garden crops. I, too, have had a considerable experience in different parts of the country and with a variety of soils. The gardens at Aldenham House have a subsoil known as London clay, and this clay ranks amongst the most unkindly of soils. The land which forms our kitchen garden has probably been cultivated for a century and a half. The

depth of the garden loam when I was first charged with the care of these gardens averaged from 9 to 10 inches, and it rested on a subsoil of pure clay. The whole has now been trenched to the depth of 3 feet, and I have always insisted on bringing the subsoil to the top. We now have a sufficient depth of good soil to cultivate all kinds of vegetables, and I shall be pleased at any time to show Mr. A. Shakelton what has been accomplished here. Ground devoted to the culture of vegetables is generally intended to serve this purpose for a great number of years; and without deep cultivation to provide a deep root-run, satisfactory results can hardly be expected. E. Beckett.

GRAPE MILL HILL HAMBURGH.—I think few persons will agree with F. B. S. that this Grape possesses all the good qualities of the Black Hamburg variety. In flavour it is distinctly inferior; the flesh also is hard, and much more resembles that of Gros Maroc than Black Hamburg. Mill Hill Hamburg does not colour nearly so regularly as Gros Maroc, and too often it is seen with a "foxy" tint. It is owing to its lack of good flavour and fault in colouring that it is not more often cultivated. E. M.

ERYNGIUM PANDANIFOLIUM.—In respect to Mr. Elgar's note (p. 45) on this interesting but uncommon plant, may I state that I became acquainted with it while at Bessborough, Co. Kilkenny, about seven years ago, where it was planted as an isolated specimen on Grass, in a fairly sheltered position under a wall. The specimen did remarkably well, although given no protection whatever. Later, when residing in East Kent, I procured a plant of the species, and though it was given a sheltered position, it suffered damage by cold during the winter of 1906-07. The following winter it was afforded light protection, and as a result it developed tall, candelabra-like flower-spikes, surrounded by a mass of handsome glaucous foliage. J. G. W., Eastwell Park Gardens, Kent.

ITALIAN FENNEL OR FINOCCHIO (see p. 45).—Last year I made an unsuccessful attempt to cultivate this plant. I purchased a packet of seed under the name of *Feniculum dulce* from each of two well-known English seed firms, and the result was two distinct varieties of plants. Not knowing which variety was the true Finocchio, I grew both side by side and under precisely the same conditions. Neither variety formed the desired enlargement at the base of the petiole. Except that I did not pinch or remove the flower-heads, my method of culture was similar to that adopted by R. D. In the *Journal of the Royal Horticultural Society*, June, 1907, p. 280, Florence Fennel is said to be "easily grown and deserving of being better known in England, and the heads were sold at 6d. each in the Paris markets in the winter of 1906." I have elsewhere read of them being sold at 9d. each in these markets. William Wingfield, Dodington, Nantwich.

NITRO-BACTERINE.—I have been interested in the results of the Reading experiments on inoculated Peas, as reported in the *Gardeners' Chronicle*. I would like to ask who has claimed that inoculated Peas bear heavier crops than uninoculated? I understood—but I have no papers at hand just at present—that the idea of inoculating Peas was to effect earlier maturity, not a greater yield of crop. I have always been led to believe that, in the case of Peas, phosphates, lime and potash will give weightier crops, but not increase of supplies of nitrogen. Market gardeners have been led to believe that they can get their crops ready for market a week, or perhaps 10 days, before those who do not utilise the assistance of these co-operating bacteria, and this, of course, means profitable returns, as they obtain the higher prices due to the supplies being few. Last year I found my inoculated Peas just over a week earlier than those uninoculated—same variety, of course, and identical treatment and soil. Are not, therefore, these experimenters wasting their time and perhaps public money in attempting the impossible—the production of heavier Pea crops from increase of nitrogenous supplies? (Rev.) J. Bernard Hall, Corbridge. [On p. 10 of Professor Bottomley's

pamphlet, entitled *Seed and Soil Inoculation for Leguminous Crops*, 1907, increased yield of leguminous crop is given as the first of the four advantages claimed for inoculation. Our correspondent should also note with respect to "earliness," that Professor Bottomley (*Loc. cit.*, p. 11) only claims that "in many cases inoculation hastened maturing of plants, thus allowing of an earlier marketing of produce with enhanced value," and that both the Reading experiments and those at Wisley and Wye do not constitute such cases; Nitro-bacterine having produced no effect whatever on "earliness" in those trials.—Ed.]

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 26.—The exhibition on Tuesday last represented most sections of horticulture. Groups of Orchids, Ferns, greenhouse flowering plants, Carnations, Alpine flowers, with a fine exhibit of Apples and another of vegetables constituted the principal features.

The FLORAL COMMITTEE granted an Award of Merit to a variety of Chrysanthemum.

The ORCHID COMMITTEE awarded two First-Class Certificates and three Awards of Merit to novelties.

The FRUIT AND VEGETABLE COMMITTEE did not make any award to a novelty.

The competitive classes for forced vegetables and salads were almost a failure.

At the afternoon meeting of the Fellows 51 names were added to the roll of members, and a lecture on "A Method of Using Domestic Sewage in Horticulture" was delivered by Mr. W. D. Scott-Moncrieff.

Floral Committee.

Present: H. B. May, Esq. (in the Chair), and Messrs. John Green, G. Reuthe, Chas. Dixon, H. J. Jones, W. Bain, Chas. T. Drury, T. W. Turner, Chas. E. Pearson, R. C. Notcutt, Herbert J. Cutbush, E. H. Jenkins, E. A. Bowles, W. Howe, C. Blick, Walter T. Ware, C. R. Fielder, John Jennings, and R. Hooper Pearson.

One of the brightest exhibits in the hall was a group staged by Mr. W. H. PAGE, Tangley Nursery, Hampton. It was composed mainly of bold vases of perpetual-flowering Carnations of the best kinds in commerce. At the back were tall stands filled with beautiful Lilliums, the species *L. speciosum* being shown in the red and the white varieties; there was also a large epergne of *L. longiflorum*. At either end of the group were numerous vases of Narcissus Golden Spur. The colours of the various subjects contrasted pleasingly. (Silver-gilt Flora Medal.)

Mr. H. BURNETT, Guernsey, staged varieties of the perpetual-flowering Carnation, all the blooms being finely coloured, and pleasingly arranged in a setting of suitable greenery. (Silver Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, also showed a choice exhibit of these popular flowers; adjoining the Carnations was a batch of Cyclamen, many of the plants being of the Salmon King variety. (Silver Banksian Medal.)

Messrs. WM. CUTBUSH & SON, Highgate, London, showed vases of Carnations of the winter-blooming type, the exhibit being charmingly arranged with small Palms and other graceful foliage plants. The selection of varieties represented the more popular kinds; the scarlet Robert Craig was exceptionally good. Messrs. CUTBUSH also showed an assortment of forced shrubs and other plants and a collection of Alpine plants. (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, showed an extensive exhibit of Davallias, comprising in all 55 species and varieties. The plants were bright and fresh in appearance. They were mainly decorative varieties, for which purpose the Davallias are especially useful. Several were climbing species. Some were large specimens, *D. brasiliensis* (with large elegant fronds), *D. effusa*, *D. fijiensis* magnifica, and *D. decora* being prominent. One of the most elegant of all the plants was *D. fijiensis plumosus*. (Silver-gilt Flora Medal.)

Messrs. JAMES VETCH & SONS, LTD., King's Road, Chelsea, exhibited greenhouse flowering

plants. At one corner of the group was a well-flowered batch of *Coleus thyrsoideus*. In front of this were small flowering plants of *Aphelandra aurantiaca* Roezlii, the blooms being of a rich orange-red tone. A pot-plant of *Acacia dealbata*, although only 2 feet in height, was flowering freely. The group also contained *Primula* × *kewensis*, *Crowea latifolia*, *Jacobinia coccinea*, *Lopezia miniata*, *Camellia Chandleri elegans*, and *Begonias*. Amongst the *Begonias* was the variety *Winter Gem*. This is the latest in flowering of Messrs. VEITCH's strain of winter-blooming *Begonias*: the flowers are deep rose with a scarlet sheen. In habit and foliage the hybrid resembles *B. socrotana*, one of the parents. (Silver Flora Medal.)

Two semi-circular groups of flowering plants were exhibited by the Marquis of SALISBURY, Hatfield House, Hertts. (gr. Mr. Prime). One was of *Euphorbia jacquiniæflora*, the racemes of intensely-coloured flowers being highly attractive. The other group was composed of *Begonia Gloire de Sceaux*, the plants being large, well-bloomed specimens. The plants in both groups exhibited skilful culture. (Silver-gilt Flora Medal.)

Messrs. SUTTON & SONS, Reading, displayed an exhibit of *Cyclamen*. There were batches of

Messrs. JOHN PEED & SON, West Norwood, London, arranged a long rockery with real stones. In the "pockets" were planted species of Alpines in flower, with dwarf shrubs and Bamboos at the back. Messrs. PEED also showed a large assortment of *Saxifragas* in small pots and pans. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, exhibited seasonable hardy flowers, having such early-blooming plants as *Anemone fulgens*, *Crocuses* in variety, *Freesia refracta*, *Snowdrops*, *Tulipa saxatilis*, *Lachenalias* in variety, *Cyclamen Coum* of the rose-coloured variety, and *Rosmarinus officinalis prostrata*. An adult specimen of *Juniperus hibernica compressa* was not more than 6 inches in height.

Messrs. JOSEPH CHEAL & SONS, Crawley, Sussex, showed boxes filled with Alpine plants, dwarf Conifers, hardy Ferns, species of *Primula*, *Tulip*, *Crocus*, *Cyclamen Coum*, &c.

The Misses HOPKINS, Mere Gardens, Shepperton-on-Thames, exhibited a small rock-garden exhibit, also tubers of *Tropæolum speciosum*.

Mr. HERBERT CHAPMAN, Rye, Sussex, again displayed blooms of hybrid *Freesias* as at the last meeting.

A number of photographs of floral subjects

Brasso-Cattleya Cliftonii, illustrated in the *Gardeners' Chronicle*, January 16, p. 34; the new *Odontoglossum Venilia* (*cirrhosum* × *Pescatorei*), white, spotted with dark red; *Cymbidium Woodhamsianum*, *Odontoglossum ardentissimum album*, *Xylobium leontoglossum*, with dense spikes of cream-coloured flowers spotted with pale red; *Odontoglossum Uro-Skinneri superbum*, with the labellum almost covered with bright red spots, and others.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. Collier), showed a very interesting group, in which were *Cælogyne Colmanii*, *Phaio-Calanthe Colmanii* (white, with yellow disc), *Spathoglottis Colmanii aurea* (bright yellow), *Dendrobium Kingianum album*, the singular *D. tetragonum*, with many of its large spider-like flowers, and others.

Messrs. HUGH LOW & Co., Bush Hill Park, were awarded a Silver Banksian Medal for a group of *Cypripediums*, including varieties of *C. aureum*, *C. salteri*, &c. Also, the bright orange-red *Lælio-Cattleya Charlesworthii*, *Rodriguezia secunda*, with one-sided racemes of rose-coloured flowers, and *Bulbophyllum Blepharistes*.

Mr. A. W. JENSEN, Lindfield, Haywards Heath, was awarded a Silver Banksian Medal for a small group of his very fine type of *Odontoglossum crispum*, all the flowers being large and of fine form. They included rose-tinted and fringed-petalled varieties, and two or three spotted forms.

Messrs. J. CYPHER & SONS, Cheltenham, secured a Silver Banksian Medal for a group in the centre of which was a specimen of *Cypripedium Mrs. William Mostyn* in fine condition, the large white dorsal sepal having very large deep chocolate-purple blotches. Others noted were *C. aureum Lambianum*, *C. Thompsonii*, *C. Mrs. G. F. Moore*, &c.

Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed a handsome form of *Lælio-Cattleya Golden Oriole*, with large bright chrome-yellow flowers having a rose-purple base to the lip veined with gold; *Sophro-Lælio-Cattleya Danæ* Holford's variety with several pretty reddish-rose flowers with deep yellow base to the lip; *Cypripedium Alabaster* (*Alcibiades superbum* × *Godseffianum*), and *C. Earl of Tankerville*. (See Awards.)

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed *Cattleya Trianae* "The Premier," which has been pronounced the finest-coloured *Trianae*. Its silvery-white, rose-tinted flowers have the petals and lip of extraordinary breadth and crimped at the margins. The front of the lip is ruby-crimson with nearly white margin, the disc is chrome-yellow, and the base, purple with white veining.

J. FORSIER ALCOCK, Esq., Exhims, Northchurch, showed *Cypripedium Beryl*, a very broad-petalled dark hybrid showing its two parents *C. Mrs. W. Mostyn* and *C. Beckmannii* plainly; also another *Cypripedium*. (See Awards.)

Mr. F. HANSON, Somerleyton Gardens, Lowestoft, sent cut spikes of two hybrid *Calanthes* which travelled badly and were not presentable.

Mr. F. McBEAN, Plumpton, staged a small group of very pretty varieties of *Cattleya Trianae*, one having white sepals and petals and a deep purple lip. Also various *Odontoglossums*, including a fine form of *O. Hunne-wellianum*.

J. B. H. GOODDEN, Esq., The Manor House, Yeovil, sent cut examples of two good light-coloured forms of *Lycaste Skinneri*.

AWARDS.

FIRST-CLASS CERTIFICATE.

Sophro-Lælio-Cattleya Marathon var. Vesuvius (*Sophro-Lælia Psyche* × *Cattleya Empress Frederick*), from Messrs. CHARLESWORTH & Co., Haywards Heath. A brilliant hybrid with flowers of good size and form, the sepals and petals being red with a yellowish glow, the petals also having a tinge of violet colour. The front of the lip is ruby-red, the base, yellow. The pretty dark scarlet *Sophro-Lælia Psyche*, obtained from a cross between *Sophronitis grandiflora* and *Lælia cinnabarina*, for some reason has never been a favourite, but combined with *Cattleya Empress Frederick* (*Mossia* × *Dowiana aurea*) it has produced, in its best varieties, some bright new colours.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshay, H. Little, J. F. Alcock, J. Wilson Potter, F. J. Thorne, A. Dye, J. Charlesworth, W. Cobb, H. G. Alexander, W. Bolton, Stuart Low, W. Boxall, J. Cypher, Gurney Wilson, A. A. McBean, and F. Sander.

Messrs. CHARLESWORTH & Co., Haywards Heath, were awarded a Silver Flora Medal for an excellent group, which included two finely-coloured new hybrids which secured the only First-class Certificates of the day. (See Awards.) Also remarkable in the group were the pretty

white, salmon, and crimson varieties, and a large assortment of mixed colours. All the varieties had been selected for their large flowers; the white blooms were of remarkable purity and possessed great substance of petal. The crimson, salmon, and white varieties had been selected for colour blending, especially when seen by artificial light. The plants possessed stout foliage, and gave evidence of good cultivation. (Silver Flora Medal.)

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr. Mr. Bain), showed spathes of *Anthurium Andreanum* with a wide range of colours. One spike was fasciated, presenting a double spathe on the one stalk.

Mr. L. R. RUSSELL, Richmond, Surrey, showed hardy evergreen shrubs of an ornamental character. The plants were small, compact specimens, and would be prized for decorative purposes in the conservatory or dwelling-room. (Silver Banksian Medal.)

Mr. G. REUTHE, hardy-plant specialist, Keston, Kent, showed a number of early-blooming, garden plants such as *Irises*, *Crocuses*, *Cyclamen Coum*, *Snowdrops*, *Daphne japonica*, and *Helleborus foetidus*.

taken by colour process was shown by Mr. H. MAUDE, Wisley. (Silver Banksian Medal.)

AWARD OF MERIT.

Chrysanthemum Golden Sunset.—This is a very attractive decorative variety, with smooth florets of rich yellow colour. It is stated to be a sport from the variety *Princess Victoria*. Shown by Messrs. ROBINSON & HEADEY, Dunstable.

FIG. 42.—BEGONIA × PATRIE: FLOWERS ROSE-PINK.

(See page 75.)

Lalio-Cattleya Felicia (*L.-C. Haroldiana* × *C. Trianae*), from Messrs. CHARLESWORTH & Co. A very fine flower, equal in size to *L.-C. calistoglossa*, and of a pale rose tint, the front of the lip being a dark purplish-claret shade.

AWARD OF MERIT.

Cypripedium Earl of Tankerville (*exul* × *nitens Sander's variety*), from Col. G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A very handsome *Cypripedium* in form and substance very remarkable, the almost circular white dorsal sepal bearing large chocolate-purple blotches, changing outward to rose-purple; the petals and lip being yellow tinged with red-brown.

Cypripedium Euryades, *New Hall Hey variety* (*Lecanum superbum* × *Boxallii*), from J. FORSTER ALCOCK, Esq., Exhms, Northchurch. A famous variety which originated in the collection of the late G. W. Law-Schofield. The dorsal sepal is white, heavily tinged with rose-purple on the reverse side, the colour showing through between the dark purple spots on the surface. The petals and lip are yellowish, tinged with purple.

Cypripedium "Our Queen" (*Lecanum dark variety* × *Stevensii*), from W. THOMPSON, Esq., Walton Grange, Stone, Stafford (gr. Mr. W. Stevens). A very pretty hybrid of good shape and resembling a good *C. Lecanum*, but rounder in form and with a shining, smooth surface to the whole flower. Dorsal sepal white, densely spotted with dark claret-purple, darkest where the spots unite to form the central band. Petals broad, undulated, yellowish, tinged with purple, excepting the margins. Lip pale green. *C. Stevensii* was obtained by crossing *C. Calypso* Oakwood variety and *C. Lathamianum* Albert Hye, both of which, as well as *C. Lecanum*, has *C. Spicerianum* as one of the parents. *C. Spicerianum* shows strongly in *C. "Our Queen,"* and the best features of the other species are reproduced.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (Chairman), and Messrs. W. Bates, E. Beckett, A. Dean, H. Parr, W. Pope, A. R. Allan, J. Davis, O. Thomas, G. Wythes, J. Vert, C. Foster, J. Hooper, G. Reynolds, W. J. Jeffries, J. Harrison, H. Markham, and J. Jaques.

UNIVERSITY COLLEGE, Reading (superintendent Mr. Chas. Foster), showed forced vegetables, including Lettuce, Chicory and Seakale, also Tomatos and Rhubarb. The Chicory was a good sample and had been grown without artificial heat: the blanching had been done by placing 8 or 9 inches of soil over the crowns. There were examples of Seakale cuttings ready for inserting and some very strong crowns of this vegetable raised from cuttings struck during April, 1908, and lifted in November last. (Silver Banksian Medal.)

An exhibit of vegetables was shown by Mrs. DENNISON, Little Gaddesden, Berkhamsted (gr. Mr. A. G. Gentle). They were principally Onions and Potatos, but in the centre of the group were Maltese Parsnips, Red Elephant, Intermediate and Summer Favourite Carrots, and Beets of the Crimson Ball and Long Perfection varieties. The Onions were of the large Ailsa Craig, Coconut and Record varieties. The Potatos were a remarkably fine sample, well matched in size and with clear skins. The varieties included a large selection. (Silver-Gilt Banksian Medal.)

MESSRS. JOSEPH CHEAL & SONS, Crawley, Sussex, staged 60 varieties of Apples, all well-coloured and plump, although shown so late in the season. Among the finer fruits were Bramley's Seedling, Annie Elizabeth, Gascoyne's Scarlet Seedling, Chelmsford Wonder, Sandringham, Jubilee, Sturmer Pippin, Crawley Reinette (an Apple of very attractive appearance), Paroquet, Lane's Prince Albert (one of the finest varieties in the collection), Bismarck, and Vicar of Beighton. (Silver Knightian Medal.)

COMPETITIVE CLASSES.

There were competitive classes for Seakale, Phubarb, Asparagus, Salads, and forced vegetables. Only one exhibit of Salads was staged: this was from Aldenham House Gardens, Elstree (gr. Mr. EDWIN BECKETT). The varieties included Mustard and Cress, Chicory, Blood

Red Beet, and Batavian Endive. They were all of the high quality for which produce from this garden is noted, and the display was awarded the 1st prize.

In the class for two dishes of Seakale there were two entries, the 1st prize being won by Mrs. TROTTER, Dyrham Park, Barnet (gr. Mr. H. Juniper); 2nd, Lady FOLEY, Ruxley Lodge, Claygate, Surrey (gr. Mr. H. C. Gardner).

Mrs. TROTTER was the only exhibitor in the class for Rhubarb, and was awarded the 1st prize, the variety being Royal Albert.

There was no entry in the class for Asparagus.

CHESTERFIELD AND DISTRICT CHRYSANTHEMUM.

JANUARY 19.—The annual meeting of the above society was held at the Hotel Portland, Chesterfield, on this date. Mr. W. Parks, Whittington Hall Gardens, occupied the chair.

The annual report showed that the spring flower show, held at Wingerworth Hall Gardens, was a record both in regard to the attendance and the amount of money taken, but the autumn show was not so numerously attended as was last year's exhibition. The income for 1908 amounted to £200, and the sum of £63 2s. had been disbursed during the year, including £30 to the Royal Gardeners' Orphan Fund, £21 to the Gardeners' Royal Benevolent Institution, £10 to Chesterfield Hospital, and £2 2s. to the Clayton Challenge Shield Competition. For 17 years the committee have adopted the practice of not retaining a greater balance than £50, the surplus being devoted to assisting deserving institutions. The president for 1909 is W. B. M. Jackson, Esq., and the spring show will be held at this gentleman's residence, Ringwood Hall, Chesterfield, on Whit Monday, May 31. No prize money will be offered at this show. The Chrysanthemum show is fixed for November 9 and 10. At the conclusion of the general business an essay on "Begonia Gloire de Lorraine" was read by Mr. Boulton, Brimington Hall Gardens.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

(ANNUAL MEETING.)

(The result of the election was recorded in our last issue.)

JANUARY 21.—The sixty-ninth annual general meeting of the supporters of this institution was held on the above date at "Simpson's," Strand. Mr. Harry J. Veitch, chairman of committee and treasurer, presided, and there was a good attendance.

Mr. George J. Ingram, secretary, read the minutes of the last meeting, and afterwards the annual report and balance-sheet for 1908. These latter were as follow:—

REPORT OF THE COMMITTEE.

The charity has been in existence 70 years; it has distributed in permanent and temporary help upwards of £125,000, and at no other period of its history has it done so much in the way of assisting the necessitous and suffering as in the year now under review.

At the commencement of 1908 231 persons—133 men and 98 widows—were receiving yearly allowances amounting in the aggregate to over £4,000. During the year 16—11 men and 5 widows—have passed away; of the men, four left widows, who, being necessitous and in every way deserving, were at once placed on the funds without election under Rule III., 10, to receive the widow's allowance of £16 a year. In addition to those who died, one widow has gone to Australia to reside with her son, and another widow has been removed to an infirmary by medical orders. There were, therefore, at the close of the year 217 persons on the funds, and the committee recommend for election this day 18 candidates from an approved list of 73 applicants. Although the number of beneficiaries will thus be increased to 235, or four more than at the corresponding period of last year, the committee deeply regret their inability to recommend a larger number, the more so as the claims for help are more numerous than ever before, the list of applicants this year showing an increase of 20 on that at any previous election.

The two special funds, the "Victorian Era Fund" and the "Good Samaritan Fund," still prove of the utmost value and usefulness by the timely help they afford. The former fund temporarily assists, whilst awaiting election, those unsuccessful candidates who have been subscribers to the institution, and the latter fund enables the committee to afford immediate assistance to applicants whether they have been subscribers or not in pressing cases of misfortune and distress, to whom otherwise they would have to turn a deaf ear, and the thankful letters from the recipients show how useful was the help given and with what gratitude it was received. It may be mentioned that the interest only from these funds is available, and any

special donations to either or both of them would be gratefully welcomed.

The annual festival dinner, which took place at the Hotel Metropole in June last under the presidency of the Right Hon. Lord Aldenham, was most successful, and the committee take this opportunity of tendering their grateful thanks to his lordship for his warm and sympathetic advocacy of the objects and aims of the charity as well as its needs. They also desire to offer their sincere thanks to those gentlemen who acted as stewards or collectors, to the horticultural Press for their continued gratuitous and invaluable help, to the donors of flowers, to those who so kindly decorated the tables, and to all other friends who helped to secure the success of the festival.

The committee have further to express their gratitude to those noblemen, ladies and gentlemen who have so kindly allowed their beautiful gardens to be opened to the public for the benefit of the funds of the institution, amongst whom may be mentioned the Right Hon. Earl Beauchamp (Madresfield), Lord Northbourne (Betteshanger), Mary Countess of Ilchester (Holland House), The Lady Battersea (Overstrand), Sir Frank Crisp (Friar Park), and E. J. Wythes, Esq. (Epping); thanks are also due to Messrs. Fisher, Son & Sibbery, Ltd., for opening the Royal Nurseries at Handsworth for the same purpose; the committee are also indebted to the Messrs. Geo. Munro Concert Committee for again most kindly allocating a portion of the proceeds derived from their well-known and successful annual concert. The committee venture to express the hope that other friends will assist the charity in similar ways.

With much gratification the committee refer to the generous kindness of N. N. Sherwood, Esq., for his gift of £25 for unsuccessful and needy applicants; to Arthur W. Sutton, Esq., for kindly giving a year's allowance of £50 for an applicant suffering from incurable paralysis, and to Geo. Munro, Esq., for his kind contribution of £16 towards the maintenance of an aged widow. The recipients were truly grateful for these unexpected bounties.

The services of the honorary treasurers and honorary secretaries of the several auxiliaries are keenly appreciated, and the committee gladly place on record their indebtedness for the kind and valued efforts of the following gentlemen on behalf of the work, viz:—

BRISTOL AND BATH.

<i>Presidents.</i>	<i>Hon. Treasurers.</i>	<i>Hon. Secretaries.</i>
Col. H. Cary Batten.	W. A. Garaway, Esq.	Mr. Geo. Harris.

WORCESTER.

Rt. Hon. Earl Beauchamp, K.C.M.G.	Mr. John White.	Mr. Percy G. White.
-----------------------------------	-----------------	---------------------

DEVON AND EXETER.

C. R. Collins, Esq.	Mr. W. Mackay.	Mr. W. Mackay.
---------------------	----------------	----------------

WOLVERHAMPTON.

C. T. Mander, Esq., J.P.	Mr. Bradley.	Mr. Tom B. Dobbs.
--------------------------	--------------	-------------------

BERKSHIRE, READING AND DISTRICT.

Mrs. Rowland Spurling.	Arthur W. Sutton, Esq., J.P., V.M.H.	Mr. L. Castle.
------------------------	--------------------------------------	----------------

LIVERPOOL AUXILIARY.

The Rt. Hon. The Earl of Derby.	A. J. Crippin, Esq.	R. G. Waterman, Esq.
---------------------------------	---------------------	----------------------

It is with much pleasure that the committee announce that Lionel de Rothschild, Esq., has kindly consented to preside at the 70th anniversary festival dinner in aid of the funds at the Hotel Metropole on Wednesday, June 23 next. They trust he will be well and liberally supported on the occasion by all friends of the institution and by all lovers of horticulture, so that the festival may again prove instrumental in obtaining the necessary means for carrying on the work. They have also to report that George W. F. Macnaughten, Esq., M.D., M.R.C.P., has kindly consented to accept the office of honorary physician to the institution.

Unhappily, each year the committee have to record the deaths of many subscribers and supporters. Amongst those who have passed away in the preceding year may be mentioned the Lord Hotham, H. L. Bischoffsheim, Esq., E. Bird Foster, Esq., Martin R. Smith, Esq., Henry Balderson, Esq., Geo. Bethell, Esq., Mr. W. Whalley, formerly of Addington Park, Mr. Geo. Ambrose, formerly chairman of the Wolverhampton Auxiliary, Mrs. Nettlefold, and Mrs. Rylands, the last-named lady very generously remembering the institution in her will by bequeathing it a substantial legacy. The loss of these good friends is keenly felt.

With regard to the Government Old Age Pension Act, it will be seen that the honorary solicitor has given notice of motion to be submitted to the subscribers at the meeting this day. Its intention—if the subscribers see fit to adopt it—is to enable the committee to act under Rule III., 6, should circumstances render it necessary and desirable to do so, without, however, causing any pecuniary loss to the beneficiary or applicant for help, and the committee would point out that, of those now applying through incapacity and distress, there are 41 whose ages alone render them ineligible for the benefit of State aid; the importance, therefore, of continued support to the institution is thus manifest.

In conclusion, the committee most earnestly appeal for increased means for this National Horticultural Society, which for 70 years has carried on its beneficent work with such comfort and help to the recipients of its benefits as cannot be overstated. As before mentioned, there are 73 applicants for aid, and if only 18 are elected there will be 55 unsuccessful candidates still on the list who will have to wait a whole year. Of those now appealing for aid—to whom in some cases the committee have already afforded a much-needed, temporary help—there are several who are nearly blind, whilst four aged 59, 56, 44, and 40 are

incurably and hopelessly paralysed. To enable assistance to be given to these and other pathetically sad cases the committee plead most earnestly for increased support, and they feel confident that, for such genuine and invaluable work, they will not plead in vain.

The Chairman made but few observations in moving the adoption of the report and balance-sheet, remarking that the report in itself explained the circumstances of the year very fully. The institution was still making progress, but even more help was needed than was at present forthcoming. Mr. W. Roupell, in seconding the resolution of adoption, stated that he had been connected with the institution since 1857. The resolution was adopted unanimously.

Mr. Arthur W. Sutton then proposed the reelection of Mr. Harry J. Veitch as treasurer, and, when Mr. Alex. Dean had seconded the motion, it was passed with acclamation.

Mr. G. J. Ingram was re-elected secretary on the proposition of Mr. George Monro, seconded by Mr. Wheeler. The retiring members of the committee were afterwards re-elected, with the exception of Mr. R. Milligan Hogg, whose retirement led to the appointment of Mr. Frederick Cooper as a member of committee.

Following the appointment of auditors and arbitrators, Mr. White, in the absence of Mr. W. A. Bilney (honorary solicitor) through indisposition, moved the following resolution:—

"That every person having attained the age of 70 years who is in receipt of an annuity from the institution and is eligible for a Government Old Age Pension of less than the maximum allowance of 5s. per week, or whose total income does not exceed £31 10s. per annum, may have such charitable annuity reduced as the committee may determine under Rule III. 6, so as to render him or her eligible to apply for a pension on the Government scale, provided always that such reduction does not involve the beneficiary in any pecuniary loss."

Mr. White observed that the adoption of this resolution would not commit the committee to anything, but, on the contrary, it would loosen their hands. The resolution was seconded by Mr. Denning. Considerable discussion followed, but it appeared to be generally recognised that whilst so many candidates had to wait several years for election to the funds, it was necessary that, in as many cases as possible, advantage should be taken of the State Old Age Pension.

Mr. J. Hudson said some arrangement of the kind was necessary in order to obtain "the greatest good for the greatest number." The resolution was adopted unanimously.

Scrutineers of the ballot were then appointed, and the result of the poll was declared at 5.30. (Details were published in our last issue.)

THE FRIENDLY SUPPER.

MR. SHERWOOD PROVIDES FOR TWO MORE PENSIONERS.

The committee and friends met at the friendly supper at 6 p.m., also at Simpson's. Mr. W. J. Jefferies presided, and proposed the toast of "The Gardeners' Royal Benevolent Institution." Mr. Harry J. Veitch responded. He said that he had already replied to this toast on 40 occasions at the annual festivals and suppers. He expressed the pleasure of those present at seeing Mr. N. N. Sherwood amongst them again. Respecting the institution, it was commenced by the election of two pensioners, now there were 240. They had disbursed £175,000 to needy gardeners or their widows, and the present distribution was approximately £4,000 each year. Amongst the disappointed candidates this year were three very bad cases of paralysis. It was distressing to the committee that they could not put more on the funds, and he (Mr. Veitch) pleaded for increased support to enable them to do so. Lionel de Rothschild, Esq., had kindly consented to preside at the next festival, and he would make the sixth member of that house who had presided at these functions.

Mr. N. N. Sherwood, who was given a very enthusiastic welcome, said he had been connected with the institution for 41 years, and his interest and sympathy were as great as ever. Mr. Veitch had referred to three cases of paralysis, and he (Mr. Sherwood) would be pleased to provide a year's pension for two of these to be selected by the committee.

Mr. W. Atkinson proposed the toast of "The Chairman," and Mr. George Bunyard that of "The Committee and Auxiliaries." Mr. George Monro replied for the committee, and Mr. R. S. Waterman (Liverpool) for the auxiliaries. Mr. Waterman remarked that although the Liverpool Auxiliary was now seven years old, none had been formed since!

On the proposition of Mr. Harry J. Veitch, the toast of "The Secretary" was received with great cordiality, and Mr. Ingram replied in an excellent speech.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES. (ANNUAL DINNER).

JANUARY 23.—The twentieth anniversary of this Society was celebrated at the Café Royal, Regent Street, on the above date. Sir Albert K. Rollit, D.C.L., LL.D., occupied the chair. The company included M. Huguenet, Editor of *La Chronique*, M. Lageat, M. Guilloud, Mr. George Schneider (President), and Messrs. T. Bevan, E. F. Hawes, Harman Payne, J. H. Witty, H. J. Jones, J. Mc Kerchar, D. Ingamells, Eric Such, C. H. Curtis, T. W. Sanders, Arthur Turner, Whitpain Nutting, J. Weathers, Hiehle, and G. J. Ingram.

After the toasts of the President of the French Republic and the King had been duly honoured, Sir Albert Rollit proposed the toast of the evening, that of "La Société Française d'Horticulture de Londres." He expressed his satisfaction at the useful work that had been done by the Society in the past, and congratulated the members on the admirable report for the past year. He referred to the commercial importance of horticulture, and stated that the trade in gardening produce between England and France was of very considerable extent. The Society is the means of many young men of both nationalities gaining an insight into nursery and other horticultural work in the two countries. The speaker referred to some of the aspects of French horticulture that Englishmen might imitate. The Society promoted a knowledge of the English and French languages amongst its members, and this was commendable, because nations that understood each other's languages are better able to understand each other's temperaments and feelings.

Mr. George Schneider, in reply, thanked Sir Albert Rollit for his appreciation of the work done by the Society. He regretted that death had thinned their ranks, but the Society has enrolled many new members during 1908. Apart from placing young Frenchmen in positions in England, the Society had been the means of finding situations for several young Englishmen in France.

Mr. Schneider referred to the death of their late Honorary President, M. Ouvrard, and

STATEMENT OF RECEIPTS AND EXPENDITURE FOR THE YEAR ENDING DECEMBER 31, 1908.

Audited and found correct { THOMAS MANNING,
JANUARY 19, 1909. THOMAS SWIFT.

stated that M. Ph. de Vilmorin, from whom a telegram was read, had consented to accept the post.

Mr. D. Ingarells proposed the toast of past presidents, to which Mr. Thomas Bevan replied.

At this stage of the proceedings a presentation was made to Mr. Harman Payne by the President, Sir Albert Rollit, of a silver plaque d'honneur. Sir Albert spoke in appreciation of Mr. Payne's international work in horticulture, and the plaque was awarded for his co-operation at the Retrospective Exhibition in Paris last November. The gift was from the National Horticultural Society of France.

The toast of the Chairman was proposed by Mr. G. J. Ingram and duly replied to.

Mr. Harman Payne made an amusing speech in French proposing the toast of the officers of the Society and offering the thanks of the meeting to M. Ripard for the floral decorations at the dinner. M. Ripard replied and proposed the toast of "The Press."

During the evening a telegram was dispatched to President Fallières sending the friendly greetings of the Society. The two caskets presented to President Fallières by the Corporation of the City of London and by the English members of the Legion of Honour and other French orders on the occasion of his visit to London in May last were on view.

A presentation of a silver bowl was made to Mr. George Schneider on behalf of the young members of the Society.

Instrumental and vocal music and recitations were rendered at intervals.

DEBATING SOCIETIES.

GARDIFF GARDENERS.—A meeting of this association was held on the 19th inst. Mr. H. R. Farmer presided. A lecture was given by Mr. F. Woods, gardener at Llanfrechfa Grange, Newport, on the Madresfield Court Grape. The lecturer stated that this variety can be as successfully cultivated as the Black Hamburg or any other ordinary kind. The formation of vine borders, their proper depth and composition, also ventilation, pruning and mulching, were explained in detail.

GROYDON & DISTRICT HORTICULTURAL.—At a recent meeting of this association Mr. Mark Webster, Kelsey Park Gardens, Beckenham, delivered a lecture on Nitro-Bacterine. In the practical tests he had given it during twelve months, success was not obtained. During his observations he alluded to the soils he had tried it in, and the poor subsoil he considered to be the best medium for inoculation. The lecturer stated that in many instances no benefit was observed from the use of this substance; the best results were obtained with a free use of lime. When used in conjunction with certain chemical manures it had deleterious effects. The seeds used for experiment were Peas. By the application of this culture the nodules containing the nitrifying bacteria were increased. The lecturer was of the opinion that the soil containing the roots of the Peas would be of benefit to successional crops.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending January 27.

A very cold week.—The last eight days and nights have been all more or less cold, but on only four of those days was the cold exceptional, and on no night did the exposed thermometer show more than 14° of frost. The ground, for the first time this month, is cold for the time of year. At 2 feet deep the temperature is 1° colder, and at 1 foot deep 2° colder, than is seasonable. No rain or snow has fallen for eight days, but on the first day of the week there was a rather heavy deposit of hoar frost on the funnel of the rain gauge. There has been no measurable percolation through either of the soil gauges for four days. The sun shone on an average for 2 hours 27 minutes a day, or for three-quarters of an hour a day longer than is usual at this period of January. On two days no sunshine at all was recorded, whereas on one other day the sun was shining brightly for over five hours. Calms and light airs have alone prevailed during the week, and for the last 96 hours the direction of the air currents has been constantly from the north-east. There was about a seasonable amount of moisture in the air at three p.m. E. M., Berkhamstead, January 27, 1909.

SCHEDULE RECEIVED:

Southampton Royal Horticultural Society's Summer, Carnation, and Autumn Exhibitions to be held on June 20, 21; July 23; and November 9 and 10, respectively. Secretary, Mr. C. S. Fudge, 7, Silverdale Road, Archer's Road, Southampton.

ENQUIRY.

TIMBER FOR FORCING HOUSES.—I shall be glad if any readers can give me their experience as to the best timber and the best mode of preserving it from decay, for the sills of forcing houses, which are constantly kept warm and moist. Seventeen years ago I tried pitch pine, and find that it does not last much, if any, longer than best red deal, which is now a very expensive wood. What is the average life of sills and wallplates, under such conditions, when treated with creosote or carbolineum? Has anyone tried the wood of Louisiana Cypress *Taxodium distichum*, which is said, in the subtropical climate of New Orleans, to last in contact with the soil for an indefinite period, and which is now on the market in England at a reasonable price? H. J. Elwes, Colesborne.

BERLIN INTERNATIONAL EXHIBITION: L. R. The exhibition, as announced in our issue for May 23, p. 325, will be held in the New Exhibition Hall of the Zoological Society, Berlin, from April 2-13. The address of the general secretary is Siegfried Braun, Berlin, N. 4, Invalidenstrasse 42.

CARNATION MAGGOT: W. E. As we suspected, your later specimens prove that the grubs are the larvæ of an *Anthomyia* fly. Plants already attacked must be thrown away. Protection from the fly may be afforded by of tarred one side of the stem of (or layer) the ground. collar pre-mother fly her eggs the stem, and if these are deposited a short distance from the plant the larvæ, which are not able to move easily, fail to reach the Carnation. The larvæ now being actually inside the plant spraying is useless. You might try fumigating with a nicotine preparation. The larvæ (grubs) do not crawl from plant to plant, but the pest is spread by means of the eggs laid by the mature insect (fly).

LANDSCAPE GARDENER: C. R. G., Massachusetts. You will find a short account of the career of Edward Kemp in the *Gardeners' Chronicle*, March 7, 1891, p. 311. He died on March 2, 1891. As, doubtless, you have the English gardening papers of that period in your library, you may gain from them further information.

LOBELIA COMPACTA: J. R. The plants are attacked by a fungus—*Botrytis cinerea*. This pest grows on every kind of plant refuse, and becomes parasitic only in the presence of considerable moisture and heat. The fungus is best kept in check by admitting as much fresh air as is possible in the plant-houses or frames.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time; they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers.

PLANTS: Africa. *Ornithogalum niveum*.—W. H. C. 1, *Selenipedium Schröderæ*; 2, *S. longifolium*; 3, *S. cardinale*; 4, *S. Sedenii*. These are called *Cypripedium* in gardens, but

they have botanical differences.—F. B. 1, *Schinus Molle* (Pepper Tree); 2, *Epidendrum coehleatum*; 3, *Rodriguezia* (*Burlingtonia*) *decora*.—T. T. 1, *Pellionia pulchra*; 2, *Dracæna rubra*; 3, *Cyperus alternifolius*; 4, *Carex japonica variegata*; 5, *Begonia discolor*; 6, *Selaginella involvens*.—B. S. 1, *Dracæna pulcherrima*; 2, *Chlorophytum elatum variegatum*; 3, *Cupressus funebris*; 4, send better specimen with flowers; 5, *Carex riparia*; 6, *Curculigo recurvata*.—E. W. *Veltheimia viridifolia*, a native of South Africa.—Foreman. 1, *Brassia Keiliana*; 2, *Restrepia trichoglossa*; 3, *Epidendrum polybulbon*; 4, *Calanthe rosea*; 5, *Lycaste plana*; 6, *Xylobium squalens*.—A. S. *Cedrus atlantica* var. *glauca*; this will grow with a single trunk.—G. H. B. 1, *Berberis Wallichiana*; 2, *Juniperus chinensis albo variegata*; 3, *Cupressus Lawsoniana*; 4, *C. L. erecta viridis*; 5, *C. L. aurea*; 6, *C. L. aureo-variegata*.

PEACH BUDS KILLED: Anxious. There is no disease present in the shoots. The buds have probably been killed by the paint you refer to. Hot-water pipes should not be painted, but coated with lamp-black and oil. We do not think the small amount of paraffin, with which the woodwork of the house was painted, was the cause of the trouble.

PELARGONIUM: J. H. B. The trouble is not caused by disease, but has resulted from some cultural defect or physical injury. It may have been due to an excess of moisture in the soil or to excessive doses of strong fertilisers. The *Phoenix* has been injured by some check, such as might be produced by cold or drought.

PRESERVING ORNAMENTAL GOURDS: H. C. The varieties of *Lagenaria* or bottle-gourds should have the thin outer skin removed, and after the Gourd has been thoroughly dried, it should be coated with thin oak-varnish. The green and white Malabar gourds should be gathered when quite ripe and dried in a greenhouse. Without any further trouble these gourds will retain their colours for about two years. Ordinary gourds, both smooth and warty, should be thoroughly dried on a shelf in a greenhouse, and be varnished afterwards with thin oak-varnish.

PRONUNCIATION OF PLANT NAMES: G. Prickett. The list that recently appeared in these columns will be re-issued in book form. The work is already in the press, and its publication may be looked for at an early date.

STEPHANOTIS LEAF: Puzzled. The discoloration is due to a fungus, a species of *Capnodium*. It is not usually parasitic, but follows injury by aphids, which must be kept down by the use of nicotine insecticides.

VANDA CŒRULEA: J. A. *Vanda cœrulea* is capable of adapting itself to tolerably wide limits in point of temperature. Its most essential requirement is the pure air of a well-ventilated house. If it is kept in a close, hot atmosphere, it generally fails to grow or flower well, after the first year or so. If the plants are now on the stage at some considerable distance from the glass of the roof, they would possibly become more satisfactory if suspended close to the ridge. If the *Orchid* house in which you have them is what is called the hot-house, remove the plants to the cool end of the *Cattleya* house and suspend them there. They require a good, bright light at all seasons. An atmospheric temperature of 55° to 65° Fahr. in winter is sufficient. In summer, keep the plants as cool as possible. *Vanda cœrulea* requires plenty of rain-water when making its growth. You can obtain the book mentioned from the publishing department of this journal.

WILLOW SHOOTS INJURED: R. W. J. The damage is not due to disease. The punctures have been caused by some insect, but we fail to find any of the creatures in the specimens received. Send further examples containing insects.

INHERITANCE OF ALBINISM IN ORCHIDS.

IN consequence of the important results recently obtained at Cambridge by Professor Bateson, Mr. Punnett and Miss Saunders in their Mendelian experiments with Sweet Peas and Stocks, the question of the inheritance of albinism has become one of great biological interest.

In Orchids, the raising of albino forms from seed is also of much practical interest. It may be useful therefore to collect in a brief note what has already been done by Orchid breeders in this direction.

Albino Orchids may be provisionally divided into two classes:—(1) True albinos with no trace of purple sap. (2) Tinged "albinos" with some purple sap.

The following list gives the results so far obtained in mating (a) true albinos with true albinos, (b) tinged "albinos" with tinged "albinos," (c) tinged "albinos" with true albinos. The records have been taken partly from the reports of the meetings of the R.H.S. published in this journal, partly from Mr. Rolfe's notes in the *Orchid Review*, and partly from personal notes and correspondence with Orchid breeders. The nomenclature adopted is that of the *Orchid Stud Book*, now being issued from the press.

I trust that the list is fairly complete, and I hope that any omissions will be at once supplied by Orchid breeders.

(A) TRUE ALBINOS × TRUE ALBINOS.

Paphiopedilum callosum Sanderæ, selfed by Mr. Norman Cookson, produced true albinos. Another batch, raised by Mr. T. Statter, also produced true albinos.

P. Lawrenceanum Hyeaum, selfed by Mr. Norman Cookson, produced nine plants, eight of which reproduced the true albino, while one plant is said to have reverted to an ordinary coloured form of *P. Lawrenceanum*. This apparent exception is remarkable, and a repetition of this experiment with larger numbers would be useful.

P. Lawrenceanum Hyeaum × *P. callosum Sanderæ*, raised by Messrs. Charlesworth, in 1900, produced the albino hybrid *P. × Maudia*, all the plants of which have so far proved to be true albinos. Another batch raised by Baron Schröder in 1907 also produced true albinos.

P. × Maudia × *P. insigne Sanderianum*, raised by Colonel Holford in 1908, produced the albino hybrid *P. × Rosettii*, 16 plants of which have so far flowered, all apparently true albinos. It may be noted here that while *P. insigne Sanderianum* so far appears to behave as a true albino, yet the presence of some dark-coloured hairs at the base of the petals suggests that this variety may possibly be a tinged albino like *P. insigne Sanderæ*. It would be interesting to know if the hybrid *P. × Rosettii* also has those dark-coloured hairs.

P. callosum Sanderæ × *P. bellatulum album*, raised by Mr. Cookson in 1907, produced the coloured hybrid *P. × Wottonii*, 25 plants of which have flowered, all apparently sap-coloured like the typical hybrid between *P. callosum* and *P. bellatulum*.

P. Lawrenceanum Hyeaum × *P. bellatulum album*, raised by Mr. Cookson, produced the coloured hybrid *P. × Lawrebel* resembling the typical hybrid between *P. Lawrenceanum* and *P. bellatulum*.

Cattleya Mossiæ Wageneri, selfed by Messrs. Charlesworth in 1907, produced a true albino with no trace of sap colour.

C. Mossiæ Wageneri × *C. Gaskelliana alba*, raised by M. Jules Hye, produced three true albinos, viz., *C. × Hycæ*, *C. × H. Suzanne*, and *C. × H. jungfrau*.

C. Mossiæ Wageneri × *C. intermedia alba*, raised by Colonel Holford, in 1906 produced the albino hybrid *C. × Mackayi Undine*, 14 plants of which flowered true albinos. In 1908 three true albinos of the same parentage were exhibited by Mr. R. G. Thwaites, also one by Sir Trevor Lawrence and one by Messrs. Veitch.

C. Schröderæ alba × *C. intermedia alba*, raised by Mr. Cookson, produced in 1907 the coloured hybrid *C. × Thayeriana*, similar to the hybrid raised by Mr. Orpet between the typical *C. intermedia* and *C. Schröderæ alba*.

C. Gaskelliana alba × *C. Harrisoniana alba*, exhibited by Mr. Thwaites in 1908, produced the coloured hybrid *C. × Williamsiæ*, four plants of which had coloured flowers like

the typical hybrid between *C. Gaskelliana* and *C. Harrisoniana*.

C. Gaskelliana alba × *C. Warneri alba*, raised by M. Peeters in 1904, produced the hybrid *C. × Peetersiæ*, five of which were true albinos with pure white flowers and green leaves, and two were coloured, having lilac-purple flowers with purple margins to the leaves.

C. Eldorado alba × *Lælia Perrinii alba*, according to a record in *Rev. Hort.* 1907, p. 31, produced coloured offspring bearing pink flowers.

Odontoglossum crispum xanthotes × *O. nobile album*, raised by Messrs. Charlesworth, produced in 1908 the hybrid *O. × armainvillierense xanthotes*, all of which have so far flowered true albinos.

Dendrobium nobile virginale, selfed by Mr. Thwaites, came true from seed. Another batch, consisting of several hundred plants raised from one capsule by Messrs. Armstrong and Brown, flowered in 1907 and 1908, and all were true albinos.

(B) TINGED "ALBINOS" × TINGED "ALBINOS."

Paphiopedilum insigne Sanderæ, selfed by Mr. Cookson, apparently came true from seed. Other batches raised by Mr. R. J. Measures, Messrs. Veitch, Mr. W. Bolton, and Colonel Holford all apparently came true from seed. It is not recorded, however, whether all these seedlings were tinged "albinos" like the parent, and it may be that some were true albinos.

P. insigne Sanderæ × *P. insigne Dorothy*, raised by Mr. Appleton, apparently all reverted to the ordinary type of *P. insigne*, with smaller, and in some cases less numerous, spots. This case is particularly interesting, because both parents have a yellow ground colour, which breeds true selfed in the case of *P. insigne Sanderæ*, but which, when crossed, reverts to the typical green ground colour of *P. insigne*.

P. insigne Sanderæ × *P. aureum Surprise*, raised by M. Peeters, in 1908 produced a typical green-coloured, spotted *P. insigne*, while soon afterwards Mr. J. H. Craven exhibited a plant of the same parentage bearing a yellow flower. In this connection it may be noted that in 1908 Colonel Holford raised eight plants from *P. insigne Chantini* Lindenii × *P. insigne montanum aureum*, both with yellow ground colour, and all the seedlings reverted to the green ground colour of the ordinary *P. insigne*.

Cattleya labiata Measuresii × *C. labiata Amesiana*, raised by Mr. Thwaites, in 1908 produced a considerable number of plants, all of which bore coloured flowers like the ordinary *C. labiata*.

C. Mossiæ Reineckiana × *Lælia purpurata alba*, raised by M. Peeters, produced both the tinged "albino" *Lælia-Cattleya* × *Canhamiana alba* and the ordinary coloured *L.-C. × Canhamiana* from the same capsule in the proportion of about two coloured to one tinged albino.

Dendrobium nobile Ballianum × *D. nobile Murrhiniacum*, raised by Mr. Gurney Wilson, produced 150 plants, all of which reverted to the typical colouring of *D. nobile*.

(c) TINGED "ALBINOS" × TRUE ALBINOS.

Paphiopedilum insigne Sanderæ × *P. callosum* Sanderæ, raised by Mr. Cookson, produced more than 100 plants, all of which were coloured like the typical hybrid *P. × Leonæ* (*insigne* × *callosum*).

P. insigne Sanderæ × *bellatulum album*, raised by Messrs. Armstrong and Brown, produced *P. × Helena* Armstrongiæ, a coloured hybrid less spotted than the typical hybrid *P. × Helena* (*insigne* × *bellatulum*).

P. insigne Sanderæ × *P. Lawrenceanum Hyeenum*, raised by Mr. M. Isaac, in 1908 produced a coloured hybrid like the typical *P. × Eucharis* (*insigne* × *Lawrenceanum*).

P. insigne Sanderæ × *P. × Maudia*, raised by Colonel Holford, in 1901 produced none but coloured forms. A coloured form of the same parentage was flowered in 1908 by Mr. Isaac, which resembled light forms of *P. × Eucharis* and *P. × Leonæ*.

Lælia anceps alba × *Cattleya Trianae alba*, raised by M. Peeters, in 1903 produced the tinged "albino" *Lælio-cattleya* × *Boylei* Kerchovæ. Another plant of the same parentage, raised by Mr. Mead, also produced a tinged "albino."

Dendrobium × Ellisii album × *D. nobile virginale*, raised by Mr. Thwaites, in 1907 produced 22 plants, all of which were tinged "albinos," but with more colour than the tinged parent.

GENERAL CONCLUSIONS.

The above facts show that when true albino Orchids are mated together the result may be all albinos, all coloured reversions, or both albino and coloured forms from the same capsule. These results are very similar to those obtained in the Mendelian experiments with Sweet Peas and Stocks at Cambridge. It seems probable, therefore, that the appearance of sap-colour in Orchids, as in Sweet Peas and Stocks, depends on the simultaneous presence of two complementary colour factors. If both the colour factors are present the sap is coloured; if either (or both) is absent the sap is colourless. Thus, the typical coloured forms of *Paphiopedilum callosum*, *P. Lawrenceanum*, *P. insigne* and *P. bellatulum* may be represented as carrying the two complementary colour factors C and R. The albinos of these species, on the contrary, will be carrying only one of these factors, consequently their sap is colourless. If *P. bellatulum album* be represented as carrying the factor C alone, and *P. callosum* Sanderæ, *P. Lawrenceanum Hyeenum*, and *P. insigne* Sanderianum (if a true albino) be represented as carrying the factor R alone, all the results in *Paphiopedilum* are so far clear. On this interpretation *P. insigne* Sanderianum (if a true albino) may be expected to give albinos when crossed with *P. callosum* Sanderæ or *P. Lawrenceanum Hyeenum* and coloured reversions when mated with *P. bellatulum album*. According to the Mendelian scheme in Sweet Peas there are five different kinds of albinos, and the possible matings between any two of them may give any one of four different results, viz.:— (1) All albinos; (2) all coloured reversions; (3) equal numbers of albinos and coloured forms; (4) three albinos to one coloured form.

The coloured reversions when selfed should give, on the average, nine coloured to seven albinos. It seems likely that similar results may be found in Orchids, and the appearance of five albinos and two coloured forms from the same capsule in the cross between *Cattleya Gaskelliana alba* and *C. Warneri alba* is certainly suggestive. From this it will be seen that individual albinos apparently identical may differ in their germinal constitution and, consequently, give different results in breeding. In view of this, it would seem desirable for Orchid breeders to adopt

some method of ear-marking individual albinos, whether imported or raised from seed. A distinct name would hardly be convenient for individuals which, to the eye, appear alike, but identification might be assured by putting the name of the importer or raiser in brackets after the name of the albino, together with a number showing the order of its appearance. For instance, the original *Paphiopedilum callosum* Sanderæ was first flowered from an importation by Messrs. Sander in 1894, and might, therefore, be called (Sander 1); another individual appeared in an importation by Messrs. Low in 1904, and might be called (Low 1), and so on. The hand-raised seed-

owing to the absence of a complementary pattern factor. The fact that the ghost form *P. insigne* Sanderæ breeds true when selfed, but gives the reversionary, dense form when crossed with other kinds of ghost forms like *P. insigne* Dorothy and *P. × aurem* Surprise, tends to confirm this view, though the evidence is yet hardly conclusive. The fact also of the yellow ground-colour of the flower of *P. insigne* Sanderæ breeding true when selfed and giving rise to the reversionary, green ground when crossed with other yellow ground varieties may also have a similar explanation. Further evidence in regard to these cases is necessary and may soon be forthcoming.

FIG. 43.—FRUITING SPRAY OF CORNUS CAPITATA (BENTHAMIA FRAGIFERA) FROM SPECIMENS SUPPLIED BY COLONEL TOTTENHAM.

(See page 83.)

lings of *P. callosum* Sanderæ might be distinguished in the same way, thus (Cookson 1), (Statter 1), and so on. In this way all the individuals of any particular albino could be distinguished for breeding purposes. The same principle might be applied to the tinged "albinos," which are equally interesting in their inheritance. The tinged "albino" *P. insigne* Sanderæ will presumably be carrying both C and R, the dense sap colouring of the ordinary *P. insigne* being reduced to a dilute or ghost form, probably

It is interesting to note that two such apparently similar forms as *P. insigne* Sanderæ and *P. insigne* Sanderianum have such a different germinal constitution and give such opposite results in breeding. No doubt albino breeders in future will take care to use *P. insigne* Sanderianum as a parent instead of *P. insigne* Sanderæ. At the same time, from the biological point of view, it is important to test all the yellow varieties, whether they be true albinos, tinged "albinos" or coloured forms. C. C. Hurst.

NEW OR NOTEWORTHY PLANTS.

SOBRALIA ELISABETHÆ.

ON two occasions previously Mr. Thomas Humphreys, the Curator of the Botanical Gardens, Edgbaston, Birmingham, has forwarded to us flowers of a singular white *Sobralia*, which, being imperfectly developed and withered were not identified. Again, a complete growth and inflorescence is sent, and, although the only expanded bloom is slightly abnormal in structure, it is evident that it is *Sobralia Elisabethæ* of R. Schomb, in *Verh. Beförder. Gartenb. Preuss. XV.* (1841), 137 tt. 1, 2, the plant described and figured being "dedicated to H.R.H. Princess Elisabeth of Prussia."

This species appears not to have been recorded as flowering previously in Great Britain. It belongs to the racemose section, its flowers being borne in terminal, flexuose racemes furnished with lanceolate bracts, the lower of which is leafy and over 2 inches in length, the upper not so long. The stem is 3 feet in height, and furnished with distant lanceolate leaves, 5 or 6 inches in length. The inflorescence in the figure cited shows that nine flowers may be produced in succession. In Mr. Humphrey's specimen four would be likely to develop. The expanded flower has ovate, acute petals and lanceolate sepals, both 2 inches long and white. The lip forms a tube over the columns, the front being expanded, emarginate, and crisped, white, with a chrome-yellow disc, and faint traces of rose lines from the base. The column, which is slender for the genus, has on each side an acute horn, which, in the specimen sent, is abnormally elongated and coloured yellow on the under-side. In point of beauty, it cannot compare with *Sobralia macrantha* and some other species, but it is highly interesting, among other points, in that it appears to be a white-flowered species, whereas the white *Sobralia macrantha* and most other white *Sobralias* are albinos of coloured species. In the original description the species is stated to be a native of Guiana.

CORNUS CAPITATA (SYN. BENTHAMIA FRAGIFERA).

THIS handsome tree is the subject of many notes and several figures in the *Gardeners' Chronicle*, from 1848 onwards. It is a native of the mountains of Northern India, from Kashmir to Khasia, and it extends into Burma and Western China, where it has been collected recently by Dr. A. Henry and Mr. E. H. Wilson. Lindley described and figured it in the *Botanical Register*, vol. xix., 1835, t. 1579, as a new genus, though Wallich had previously published it (*Kovb. Fl. Ind.*, vol. i., p. 431, and *Pl. Asiat. Rur.*, vol. iii., p. 10, t. 214) as a *Cornus*, and most botanists now agree in regarding it and two or three other species as constituting a section of that genus. Mr. W. B. Booth (gardener to Sir C. Lemon, of Carlow, Cornwall), furnished Dr. Lindley with the drawing and history of the plant, which was reproduced in the place cited above. Sir Anthony Buller sent seeds to Mr. J. H. Tremayne, of Heligan, Cornwall, in whose garden plants were raised in 1825. Booth described it as a very handsome evergreen, flowering in great profusion during summer and producing an abundance of large, globular, reddish fruits in autumn. Now it is a conspicuous fea-

ture in many gardens of Cornwall and Devon, is also hardy in Ireland, Western Wales and Western Scotland, and will bear ordinary winters in other parts of the British Islands. But it is really hardy only in the western counties, where it attains dimensions rarely equalled, I believe, in a wild state. In this journal for July 25, 1885, is an illustration of a group of trees in the garden of Mr. R. G. Lakes, Trevarrick, St. Austell, supposed to be the largest in this country. At that date they exceeded 35 feet in height, and the trunk of one was 5 feet in circumference at 3 feet from the ground. *Cornus capitata* is very striking, both in flower and in fruit. It may be explained that what is usually called the flower of this tree is a collection of small flowers, consolidated in a globose head, surrounded by an involucre of white or

FIG. 44.—FLOWER OF *CORNUS CAPITATA* (*BENTHAMIA FRAGIFERA*): WHITE.

cream-coloured bracts an inch to an inch and a half long; the whole having the appearance of a small *Clematis*. The fruit is yellow, with more or less red in it, and resembles a Strawberry, hence the specific name, *fragifera*. In structure, however, it is more like the Mulberry. I am not aware that the fruit is eaten in this country, but Collett, *Flora Simlensis*, p. 220, describes it as 1 to 2 inches in diameter, yellow, or, when ripe, tinged with red, and states that it is edible. Dr. Henry's Chinese collector described it to him as sweet and edible.

Cornus Kousa (*Benthamia japonica*), a closely allied species, recorded as having been introduced into this country in 1847, is apparently a much hardier species; yet it is very rarely seen in gardens. A figure of a flowering branch is given in this journal, vol. xix., 1896, p. 783, f. 135; and there is an illustration in the *Journal of the Royal Horticultural Society*, n.s. vol. xviii., p. 862, f. 194, representing a flowering specimen 13 feet high. From the description there given, this species should be grown where *C. capitata* will not succeed. A third species, *C. Hoangkongensis*, described by the writer in the *Journal of the Linnean Society*, vol. xxiii., p. 345, is not in cultivation. *W. Botting Hemsley*. [The specimen figured on p. 82 is from Colonel Tottenham's garden at Ballycurry, co. Wicklow. This garden is celebrated for its collection of tender trees and shrubs. The flower illustrated in fig. 44 is interesting in that it shows a departure from the normal four-bracteatate state characteristic of the Order.—EDS.]

WHORTLEBERRIES AND CRANBERRIES.

(Continued from page 75.)

V. PADIFOLIUM (*V. MADERENSE*).—Just inside the main entrance to Kew Gardens, on the outskirts of a shrubbery, there has been growing for at least 65 years a specimen of this *Vaccinium*. Sir Joseph Hooker saw it there in 1843. The species was first introduced from Madeira to this country by Francis Masson, in 1777, on his return from his collecting expedition to the Cape of Good Hope. (Masson, it may be remembered, was the first—and one of the most successful—of the long line of plant collectors sent out from Kew.) This veteran plant is now 6 to 7 feet high. It is one of the very few woody plants from Madeira that can be termed hardy in this country; at the moment I can only recall *Genista virgata* as another. The species is particularly interesting in a geographical sense. Its closest ally is *V. Arctostaphylos*, which is found in the Caucasus. So closely allied are they, indeed, that some authorities have made them forms of one species. This curious instance of geographical distribution, together with the fact that several Indian forms of the *Laurus* family are also found in the Canary Islands, has led Sir Joseph Hooker to observe that they point to "Spain and the Atlantic islands being the isolated western homes of the fragments of a flora that once extended over Europe and North Africa, but now, through climatic changes, elsewhere expelled from those great continents." The theory is also supported by the existence of *Rhododendron ponticum* in Spain and Asia Minor, and in a wild state in none of the intervening countries.

V. padifolium is a deciduous shrub in this country, but in Madeira it is a small tree, growing at altitudes of 3,000 to 5,000 feet. Its leaves are 1 to 2 inches long, ovate-oblong, pointed, and minutely-toothed at the margin. The flowers are borne in leafy racemes, springing from the nodes of the previous year's growth, each flower pendant on a short stalk. The corolla is open bell-shaped, with five well-marked angular lobes, large for a *Vaccinium*, and yellow, tinged with rose. The berry is blue, and is said to make an excellent preserve. The species grows very well in the Abbotsbury gardens, Dorsetshire.

V. PARVIFOLIUM.—It is doubtful if this species is now in cultivation, but, coming from Western North America, where it extends from North California to Alaska and the Aleutian Islands, it ought to be quite hardy in Great Britain. It is a shrub varying in height from 1 foot to 6 feet, with branches sharply angled, after the fashion of our native *V. Myrtillus*. Its leaves are like those of the Box, only smaller and thinner, being usually from $\frac{1}{4}$ to $\frac{1}{2}$ inch long and oval. The corolla is globular and pinkish-white, the berry pale red and of an insipid flavour.

V. PENNSYLVANICUM.—One of the dwarfest of the East American species, *V. pennsylvanicum* is also one of the most useful there as a fruit-bearer. It is a densely-branched shrub, and never appears to much exceed 1 foot in height, and is often only 6 inches or 9 inches high. In foliage and habit it resembles *V. canadense*, but is distinguished by its minutely-toothed and more acuminate leaves, and less pubescent twigs and leaves. The latter are quite narrow—from $\frac{1}{4}$ to $\frac{3}{8}$ inch wide—and from $\frac{3}{4}$ to $1\frac{1}{2}$ inches long. The flowers, which come in short, dense clusters, are white, tinged with red, and are followed by berries covered with a blue bloom. In the United States this is the earliest of the "Blueberries" to ripen its fruits, which are sweet and very palatable. It is often found as a dense carpet on rocky ground, where there is but a bare covering of soil. According to Mr. Dawson, of the Arnold Arboretum, it will grow under the shade and drip of trees—a useful quality if it retains it in this country. The species has some botanical affinity with *V. corymbosum*, but is readily distinguished by its dwarf habit, its

more open corolla, and by the more dense arrangement of the flowers.

V. PENNSYLVANICUM VAR. ANGUSTIFOLIUM.—A variety with even narrower leaves than the type—*angustifolium*—is found on the summits of the White Mountains of New Hampshire, and on the Adirondacks.

V. STAMINEUM.—Although but little grown in English gardens, this species is quite ornamental. It is a native of Eastern North America, from Maine south to Florida. Mr. J. Dawson, commenting on its behaviour in the Arnold Arboretum, says that few hardy shrubs of its tribe are more beautiful, and that it is worth growing for cut flowers. It is deciduous, 2 to 4 feet high, of neat habit, with dark, dull-green leaves, glaucous below, 1 to 2½ inches long, elliptical in outline, pointed, and thinner in texture than those of most *Vacciniums*. The racemes are distinguished by the leaf-like character of their bracts, in the axils of which many of the flowers are produced. The flowers are very abundant, and are rendered conspicuous by the bright yellow stamens standing out beyond the white corolla. The berry varies in colour from green to yellowish-white. The species blooms at Kew about the end of May; it was introduced to England in 1772.

V. ULIGINOSUM.—This is the second deciduous British species, not so common as *V. Myrtillus*, but still widely spread over the North of England, Scotland, North and Central Europe, North Asia, and North America. It may be readily distinguished from *V. Myrtillus* by its obovate, entire leaves, and smooth, round stems; and from *V. Vitis-idæa* by its deciduous leaves and black fruit. Like them, it has a creeping rootstock, and grows from 1 to 2 feet high, with smooth, dull-green leaves from ½ to 1 inch long. As in some foreign species, the flowers are produced at the leafless termination of the previous year's shoots, above the point whence issue the shoots of the current year; they occur singly or in clusters of two or three, and are pale red or white. The berries are as large as Black Currants, black, covered with a glaucous bloom, and, although edible, produce headache and giddiness if eaten in large quantities. They constitute a valuable food for mountain game.

V. VACILLANS.—A species from the Eastern United States, extending from New England to North Carolina. It is a shrub of stiff habit, sometimes less than 1 foot high, sometimes more than 4 feet. The leaves are of firm texture, entire, or very minutely-toothed towards the apex, and glabrous, except when young; they are ovate or oblong, 1 to 2 inches long, with a mucronate apex. The flowers are produced in close clusters on leafless branches, the pink corolla being ¼ inch long. The fruits are globular, black, covered with a blue bloom, and very sweet.

V. VITIS-IDÆA (THE COWBERRY).—The Cowberry, as this evergreen species is often called, is well known on moors and mountains in the northern half of England, and in Scotland as far north and west as Sutherlandshire and the Hebrides. It is a low, evergreen shrub, almost always under 1 foot high, with a creeping rootstock. The stems are wiry, round, but little branched, and covered, when young, with a short, dark down. The Box-like leaves are obovate, dark shining green, and freely speckled with black dots beneath. It is the only evergreen British species. The flowers are crowded 5 to 12 together, on short terminal racemes, and appear in May and June. The corolla is open bell-shaped, rather deeply four-cleft, and either white or pink. The berries, which ripen between August and October, according to climate, are red, and about the size of Red Currants. They are eaten cooked in some parts of England, and in Northern Europe are used for making a jelly, and in various other ways. The species does not thrive in the hot Thames valley like it does in the cool north. Besides inhabit-

ing North Europe and Asia, it is also found on the mountains of the Eastern United States.

V. VITIS-IDÆA VAR. MAJOR is a striking form, with larger leaves and berries; whilst var. *minor* has smaller leaves than the type. *IV. J. Bean.*

(To be continued.)

POINTS OF INTEREST IN THE AFFORESTATION REPORT.

It being important that the facts and considerations on which the Royal Commission bases its report (see *Gardeners' Chronicle*, January 23) should be widely known, we now give a short account of the chief conclusions reached by the Commission and of the evidence on which these conclusions are based.

The original terms of Reference to the Royal Commission on Coast Erosion, July, 1906, were to inquire and report as to the encroachment of the sea on the coast, the damage caused, and preventive measures to be adopted; whether further powers are necessary for local authorities or owners of property to enable them to give effect to schemes for protection of coasts and banks of tidal rivers; whether any alteration of law as regards management and control of the foreshore is desirable, and whether further facilities should be given for the reclamation of tidal lands.

Additional reference, March, 1908.—Whether it is desirable to make an experiment in afforestation as a means of increasing employment during periods of depression of the labour market, and, if so, by what authority and under what conditions such experiment should be conducted.

The report under review deals with the last only of the subjects just enumerated, and hence may be termed the Afforestation Report.

The principal conclusions (already published in these pages) may be summarised thus:—

Afforestation is practicable and desirable. Nine million acres are available for the purposes of afforestation.

By planting at the rate of 150,000 acres per annum, temporary employment would be found during the winter months for 18,000 men, and as many would derive employment in incidental and subsidiary occupations connected with forestry. When the whole area had been planted permanent employment would be afforded to 90,000 men.

The scheme should be on an economic basis: labour is available. The State should finance the scheme by means of a loan, and should entrust its control to a Board of Commissioners.

Afforestation will help to stem the tide of rural depopulation: being a new industry, it will not compete with private enterprise.

Afforestation in the long run will prove an investment of profit to the State.

PART I.—BRITISH FORESTRY GENERALLY CONSIDERED.

Percentage of forest land in various countries:

Austria	32.6
Hungary	27.5
Germany	25.9
Belgium	17.3
France	17
Holland	7.9
Denmark	7.2
England	5.3
Scotland	4.6
Wales	3.9
Ireland	1.5

Value of imported timber and timber-products, such as wood-pulp, was, in 1907, £32,326,117. Of this sum, £20,127,943 was paid for timber (8,513,937 loads) imported from countries with climates like our own: Russia, Scandinavia, Germany, France, Canada, &c.

The 9,000,000 acres of the Commissioners' scheme would, with our present forests, produce the amount now imported from countries with a temperate climate.

QUALITY OF HOME-GROWN TIMBER.

The reasons why home-grown timber is not, generally, of the highest quality, are many; but they all may be summed up in "the lack of

facility (in this country) for Forestry Education." Lack of proper education has led to improper methods of forest management. The too-open condition of our woodlands reduces their value for timber in two ways, viz., in yield and in quality.

Open cultivation, though suitable enough for certain purposes, viz., ornamental effect, game preservation, and wind screens, and though not harmful in the case of certain trees, viz., Oak, Ash, and Larch, lowers the quality of the timber in most cases, e.g., Beech, Common Spruce, and Silver Fir.

The defects due to too-open cultivation are excessive branching and hence, unduly knotted timber; too rapid growth and, hence, abnormally broad-ringed wood; short boles with excessive taper. Well-shaded wood is, moreover, of better quality than that from the insufficiently shaded trees grown on our open woodlands.

THE CLIMATE OF THIS COUNTRY IS FAVOURABLE.

The variety of soil, together with the equable nature of our climate, admit of the cultivation in this country of many trees which cannot be grown in Central Europe. Moreover, apart from theoretical considerations, there are many instances of successful results of British forestry; results showing returns, 60 years from planting, of £43 per acre, representing a net profit of £15 per acre (Scots Pine): in the case of Larch, a profit of £36 per acre 65 years after planting; mixed wood, 75 to 80 years old, realised £157 per acre net, representing a profit sufficient to give a rent of over £1 per acre per annum as contrasted with 7s. 6d., the value of adjoining land. The general conclusion come to by the Commission is that timber growing has proved profitable in the past, and that with modern methods it may be made profitable in the future.

In Germany, where systematic forestry has been practised for a century, the industry is profitable, the net return being £1 12s. per acre.

THE INCREASED PRICES OF TIMBER WILL BE MAINTAINED.

Timber is increasing in price, and during the past decade the cost of wood has risen from 20 to 50 per cent. This increase has been a steady one and will continue. Felling has exceeded planting, and the world's consumption of timber is increasing. The virgin forests of North America have been exploited, in many cases recklessly; a "timber famine," that is, a shortage of timber, is a possible contingency.

Even Canada is now importing certain classes of timber, e.g., Oak, Walnut, Hickory, &c. The quality of timber has deteriorated.

PART II.—UNEMPLOYED LABOUR IN RELATION TO AFFORESTATION.

The reader of this summary should observe that the Commission, having concluded on general grounds in Part I. that afforestation is economically sound, passes on to survey the problem from another aspect altogether. We might put the point of view thus:—Afforestation is good: if it can serve to reduce unemployment then it is still better.

SUITABILITY OF AFFORESTATION FOR UNEMPLOYED LABOUR.

Unemployment is of three kinds: chronic, seasonal, sporadic. Unemployment increases during the winter months, which is precisely the period when forest development demands most labour.

The work of forestry varies from heavy digging to lighter operations. Though the weaker members of the urban unemployed would be scarcely suitable even for the lighter work, selected men from the ranks of townsmen out of work might be employed.

Afforestation will find extra employment for the rural population during the winter months when the work on farms or holdings is slack. This actually occurs in France and Germany, where the permanent staffs of foresters are relatively small and they are augmented from rural workers when more labour is required. Thus, though not suited to the physique of certain sections of the urban unemployed, afforestation, by taking a certain number of suitable men, will relieve, in a definite measure, the stress of unemployment.

It is possible, in addition, to adjust the routine of an afforestation scheme without

detriment to that scheme in such a way that a larger acreage can be taken in hand during those periods of trade depression when unemployment is considerable.

Beside making a real contribution to the unemployed problem, afforestation will help to fix men on the land, and thus to check the exodus from the country to the towns. Estimating that much of the land which would be brought under tree cultivation now provides employment at the rate of one man per 1,000 to 2,000 acres, and that under forest it would provide employment at the rate of one man per 100 acres of forest, it follows that if the land were under forest it would maintain ten times the population now supported.

Indirectly, in industries arising from the regular and large supplies of timber available, work would be provided for a yet greater number.

PART III.—NATURE AND EXTENT OF SUITABLE LAND.

The kind of land which seems most suitable for afforestation is that classed as "Rough Mountain Land used for Grazing." Of such there are in Great Britain 13,000,000 acres. In Scotland over 3,500,000 are devoted to deer forests; in Ireland "barren mountain land," together with "bog and marsh," amounts to 4,343,284 acres. But, of these lands, much lies too high for afforestation purposes. On the other hand, there are areas not included in the above which would support forests, viz., poor tillage land which has gone down to grass, and the dunes along the coasts.

After considering all the evidence at their disposal, the Commission concludes that 9,000,000 acres are available in the British Isles, viz. :—

England	2,500,000 acres.
Scotland	6,000,000 acres.
Ireland	500,000 acres.

PART IV.—ADMINISTRATION: AFFORESTATION A TASK FOR THE STATE.

Not only are there fewer forests in Britain than in any European countries, but also there are fewer owned by the State.

The evidence in favour of State ownership is overwhelming: the capital requirements, the long period over which no returns are to be expected are deterrent to private enterprise. A beginning should be made forthwith, and compulsory powers of purchase should be obtained. Co-operation of land owners should not be excluded. The scheme should be administered by special commissioners, the area to be devoted to afforestation being divided into districts. The authority should be central, and its powers should not be delegated to local authorities. In Ireland the Land Purchase Act provides an opportunity for the acquisition of suitable land.

PART V.—FINANCE.

Assuming that 150,000 acres are afforested annually for 60 years, and that one-third of the area is worked on a 40 years' and two-thirds on an 80 years' rotation: that cost of freehold and expenses of afforestation equal £13 6s. 8d. per acre: that administrative charges equal 4s. per acre: that re-afforestation equal £6 10s. per acre and rate of interest is 3 per cent., and allowing that thinnings begin to be of value after 20 years, the 40 years' rotation area yields £60 per acre at the end of 40 years, and the 80 years' rotation area £175 at the end of 80 years, then the annual deficit rises from £90,000 in the first to £3,131,250 in the 40th year. From the 41st to the 60th year the forests become self-supporting. The revenue increases from the 61st year up to the 81st year, when an approximate equalised revenue of £17,411,000 per annum will be realised.

Further, the value of the property would then be £562,075,000, or £106,993,000 above cost. The equalised annual revenue of £17,411,000 represents a yield of £3 16s. 6d. per cent. profit. So much for the gist of the scheme. We hope those of our readers who are interested in this important subject will procure the Blue Book giving the full report. It may be obtained through any bookseller for sixpence, and provides more interesting reading than most current literature.

NOTICES OF BOOKS.

* "WAX CRAFT."

THE apiary is such a general accessory to gardens, both large and small, that no apology will be needed for introducing to the notice of our readers a book of some 170 pages bearing the above title. That the author is an authority on his subject may be inferred from the fact of his official position as chairman of the British Beekeepers' Association. He is, in addition, editor of the *British Bee Journal* and the author of several works on bee-keeping. The opening chapter deals with the history of beeswax and its early uses, and though the account is necessarily brief, it affords much interesting and informative reading. The second chapter shows how the wax is produced in the body of the working bee, and gives the composition of beeswax as compared with vegetable waxes. Other chapters treat of the methods of wax rendering, refining, bleaching, &c. Though it is generally known that beeswax is imported into this country from various parts of the world, it is interesting to learn the principal sources whence the supplies are derived. These are as follow:—Abyssinia, Australia, Brazil, Chili, East Indies, France, Gambia, Hayti, Jamaica, Madagascar, Mauritius, Mombasa, Niger, Senegal, Turkey, and U.S. America. Waxes from these different sources vary considerably in colour and quality, and consequently in price. Some are nearly white, while others range in colour to almost black. The price varies from £6 to £8 per cwt. wholesale.

Vegetable waxes are much used for the purpose of adulteration: for this the paraffins with a high melting point are mostly chosen. Japan wax, derived from the small fruits of *Rhus succedanea*, which comes into commerce in large, white or yellowish, hard cakes, when mixed with beeswax diminishes its malleability, rendering it more brittle and lowering its melting point. Carnauba wax, which is a deposit secreted on the leaves of *Copernicia cerifera*, known as the Brazilian wax Palm, is collected by shaking the substance from the leaves and then melting it so as to form moulds or cakes. Much of this wax is, in its imported condition, of a dull greenish-yellow colour, but it becomes lighter in the process of refining. When added to beeswax, this substitute hardens and raises its melting point. Carnauba wax is imported into this country in increasing quantities, not only for candle making but for making phonograph and gramophone records. Another Palm-tree wax which is included under beeswax adulterants is that from *Ceroxylon andicum*, from the Andes of Colombia. This is found not on the leaves, but as a flaky deposit on the trunks, from which it is easily scraped off. Its composition is similar to Carnauba wax, and it is used for making candles, for which purpose it is also used by the people of Colombia. Amongst other vegetable waxes classified by Mr. Cowan as adulterants of beeswax are those from the small berry-like fruits of several species of *Myrica*, chiefly *M. cerifera* and *M. cordifolia*, natives of North America and South Africa respectively.

Sapium sebiferum, better known as *Stillingia sebifera*, also yields a soft white wax or tallow, which covers the seeds and is easily removed by steaming. In China it is much used for candle making, but owing to its soft nature it is mostly mixed with the insect wax of China, which is secreted by the insect *Coccus Pe-la* on the leaves and stems of *Ligustrum lucidum* and *Fraxinus chinensis*. This is extensively used by the Chinese, not only for candle-making but for other purposes.

Common resin and mineral substances of an inflammatory nature, are also used for adulterating beeswax. It will therefore be seen that beeswax is one of the most extensively adulterated articles of commerce.

The concluding chapters of the book are devoted to the various uses of beeswax, such as the making of candles, wax flowers, models, artificial fruits, &c. A list is also given of more than 100 preparations containing beeswax in some form. The book is illustrated by 17 full-page plates.

* *Wax Craft: All about Beeswax: Its History, Production, Adulteration, and Commercial Value*, by T. W. Cowan. (Sampson, Low, Marston & Co.)

The Week's Work.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park London.

Bowling greens.—The game of bowls is now played with such science that the greens themselves are required to be as perfect as possible. The turf must be of the finest texture and perfectly elastic. The game is most popular in Scotland and in the North of England, where it is given every encouragement by most of the city and town corporations. In recent years the London County Council has constructed greens in nearly all the public parks under its control. In London the greens are made level, but in Yorkshire and Lancashire, I believe, they are made to fall several inches from the centre, or crown, to the sides or ditch. In some cases the fall is as much as 18 inches. The lawn I am going to speak about is one with a level surface. Such lawns vary in size, but one that measures 112 feet square can be recommended as most useful. It allows six rinks being played upon at one time, thus accommodating 48 players. A green of this size, being square, has an advantage over others, in the fact that it allows the game being played from any quarter of the green. When, by hard wear, the turf becomes worn near to the edges from which the players deliver their bowls, the play can be diverted to courses or rinks formed in a cross direction. It is primarily necessary that such lawns should be perfectly drained. If the subsoil is heavy clay, it must be drained with a pipe and rubble drain, or drains; but, on the contrary, if the subsoil is of a sandy or gravelly nature, the ashes to be recommended presently will provide sufficient drainage to allow the surface water to pass away. A few years ago, I constructed a green on a gravelly subsoil. The method of procedure was as follows:—After the size of the ground had been properly marked out, the soil was removed to a depth of 9 inches. The soil thus removed was utilised to form a bank round the green 6 inches high, or even more. The inner edge of the raised bank had a slope of about 6 inches to enable the Grass to clothe its surface and retain its angular position from the pressure of the players' tread. After the removal of this soil, the greatest care was taken to see that there were no hollows or places where the ground was likely to sink more than in others. The whole area was consolidated as much as possible. When this had been done, rough ashes were spread over the ground to a depth of 8 inches, and the ashes were afterwards compressed by rolling and beating into a space of 6 inches deep. The surface of the ashes was made perfectly level. Around the outside of the green, a ditch 1 foot in width was left, and lined next to the turf with boards 5 inches deep by 1½ inches thick. These were secured by wooden pegs placed at suitable intervals. Over and resting on the living boards was a narrow lattice frame, which served to carry away any superfluous surface water, and to keep the bowls clean while play was in progress. This lattice frame was fixed slightly under the surface of the turf, so that there would be nothing to prevent the bowls from running into the ditch. Over the level surface of pressed ashes was spread an inch deep of good loamy soil. On this soil was laid turves, each turf cut 1 foot square and 2 inches in thickness. In this case, we made use of local turf, and, unfortunately, it contained some suckling Clover, which occasioned considerable trouble for some time afterwards. Eventually the Clover was eradicated, and the green is now as good as might be wished for, although it was made at a low cost. For expensive greens, turf is sometimes conveyed hundreds of miles at great cost. But if ordinary turf is used, and proper attention afterwards given to rolling, mowing, and the supply of surface dressings, such Grass improves beyond expectations.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LOOER, Bart., Leonardlee, Sussex.

Rhododendron.—The planting of *Rhododendrons* should be pushed forward in dry weather. Spread some peat, manure and leaf-soil evenly over the soil. Set out the plants over the ground

in the positions they are to occupy. In many cases special soil will have to be prepared, and it is better, therefore, to plant the bushes more thickly than is usually done. It is more economical; the plants have the benefit of each other's shade over the roots, and when thinning is necessary owing to the growth of the bushes, transplanting can be effected easily. Rhododendrons are all the better for being repeatedly shifted whilst young. They should be planted shallow and the soil should be well rammed. Where Rhododendrons are planted on sloping ground, provision must be made for watering them. This can be best done by making a sort of basin around the stems of the plants. Among some of the best garden varieties and hybrids are Concessum (rose-pink), Edward S. Rand (scarlet), Francis B. Hayes (white, with dark spots), Ascot Brilliant (blood-red), Countess of Clancarty (rose-crimson), Mrs. Tom Agnew (white, with yellow centre), Sappho (white, with maroon spots), Purity (white, with a faint yellow eye), Scipio (rose, with red spots), Mrs. W. Agnew (pale rose), George Hardy (white), Helen Waterer (white, with crimson margin), J. M. Brooks (scarlet, with brown spots), James Nasmyth (rosy-lilac, with maroon blotch), Kate Waterer (rosy-crimson, with yellow markings), Lady Eleanor Cathcart (rose, with chocolate spots), Marchioness of Lausdowne (pale rose, with black spots), Gomer Waterer, Marie van Houtte (white, spotted with light red), Cynthia, Michael Waterer (bright scarlet), Minnie (blush white, with chocolate spots), Mrs. Holford (salmon-pink), Pink Pearl, and Lady C. Walsh (red, edged with pink). The following varieties flower in April and May:—Broughtonianum (rose-red), caucasicum album, limbatum (white and crimson), Auguste van Gee't (chocolate-coloured), nobleanum (scarlet), Vesuvius (crimson-scarlet), and Prince Camille de Rohan (white and rose). Some of the best garden Rhododendrons are those which have been obtained from Himalayan species, such as R. \times kewense, Luscombe's Scarlet, and Fosteri.

Seed raising.—It is inadvisable to sow any seeds at present, unless it is absolutely necessary. Dahlia seeds may be sown in pots or pans or in seed trays. Dianthus, Lobelia, Polyanthus and Primroses may be sown in a warm greenhouse or frame.

Climbing plants.—Examine the climbing plants, whether deciduous or evergreen, carefully pruning and training any that require attention in these matters. If any climbing plants have to be planted, the work should be done at once.

Summer-flowering Chrysanthemums.—These may be propagated now, as there are plenty of growths on the old stools that may be used for cuttings. If a large number of plants is required, the cuttings should be rooted in seed trays, and 50 cuttings can then be placed in one tray. When the cuttings have rooted they should be potted up singly into small pots and placed in a cool frame for a time.

Lawns and paths.—Keep the lawns and paths neat in appearance by sweeping and rolling them frequently. Prepare soil for use in top-dressing tennis-courts, croquet ground and similar places. A suitable mixture is one consisting of leaf-soil, loam, soot, lime and bonemeal. These should be well mixed together and turned several times. The compost should be kept dry and a top-dressing may be applied about the first week in March, covering the ground about one-eighth of an inch thick.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The fruit room.—Examine the Apples at frequent intervals and remove any fruits which show signs of decay, laying the remainder out thinly over the shelves and benches. Keep the room cool, not too dry, and allow sufficient ventilation to sweeten the air. There have been many complaints this winter that fruit has not kept well. Each season proves afresh the necessity of planting plenty of late varieties of both dessert and cooking Apples. Late Apples are always valuable, and for this reason the season should be lengthened as much as possible. Some of the best cooking Apples

in use from this date onwards include Newton Wonder, Lane's Prince Albert, Alfriston, Chelmsford Wonder, Annie Elizabeth, Dumelew's Seedling (Wellington), Norfolk Beefing, and the newer variety, Royal Late Cooking. Dessert varieties include Allen's Everlasting, Sturmer Pippin, Court-Pendú-plat, Brownlee's Russet, Cockle's Pippin, Lord Hindlip, and Claygate Pearmain. These varieties, if stored in a suitable place, will afford a supply of dessert fruits until very late in spring.

The Loganberry (see fig. 45).—The Loganberry is gaining popular appreciation, and it is being extensively planted in this country for market purposes. The plant is not at all par-

makes extraordinary growth, and this circumstance should be borne in mind when a site is being selected for its cultivation. In this garden the canes are trained on wire forming an arch over a pathway, the top of the arch being 10 feet high from the ground. The canes are planted on both sides of the arch, and they fill all the space on the wires. The foliage is ornamental in appearance and under this method of cultivation the fruit is fully exposed to the sun and air. It may not be possible to adopt this system in every case, but, whether or not, provision should be made for the whole length of the canes, for they usually fruit from top to base.

FIG. 45.—THE LOGANBERRY.

ticular as regards character of soil, and it is capable of growing well in positions where Raspberry canes will not succeed. In gardens where the Loganberry has not hitherto been planted, I would recommend that the plant be given a trial. It is not too late even now to make a plantation. Though not amongst the choicest dessert fruits, the Loganberry makes an excellent addition to culinary fruits. It is also suitable for bottling or for preserving with sugar in the ordinary way. When the Loganberry has become well established it

Blackberries.—There are several varieties of the Blackberry which are not only valuable for their fruits, but possess growths and foliage which are distinctly ornamental. Such varieties may very suitably be planted to run over old tree stumps, or to cover fences or low walls. The Parsley-leaved Bramble (*Rubus laciniatus*) is one of the best for this purpose. Wilson Junior is another variety bearing large fruits, but these only attain their best condition in favourable seasons, or in specially warm localities.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Heating the houses.—At the time of writing frosts prevail, and, in all probability, for the next two months frosts will occur at intervals. During such weather every effort should be made to maintain proper temperatures in the houses by carefully regulating the heating apparatus. In some gardens, through an inefficient heating apparatus and an insufficient supply of piping, it is impossible to keep the houses at the proper degree of heat during the night-time without continuous hard firing. At such times, the pipes being extremely hot, the atmosphere of the house becomes more than ordinarily arid, and if such conditions are allowed to continue for long together, they will cause great deterioration in the health of the plants. On occasions when the pipes are already unduly heated, and the boiler power is insufficient to maintain a proper temperature till the morning, the grower may be led to damp the houses heavily with the view of reducing the temperature of the hot air. In such conditions, if a sudden fall in the temperature occurred before daylight, it would cause loss of foliage to some species, although no such harm would be likely to accrue if the temperature were low and the atmosphere comparatively dry. Everything should be done as far as possible to avoid overheating the pipes, even in the hottest houses, and a means to that end is to cover at least the lower part of the roofing with some thick, dry material. For this purpose Archangel mats, which can be rolled on at dusk and taken off in the morning at daylight, are suitable. In addition to these mats, I find the lath roller blinds very useful to roll down over them. These when securely tied not only greatly assist to preserve an equable temperature inside, but will keep the mats from being blown off by wind. If at this time of the year, when the warmth from the sun is gradually increasing, the temperatures at early morning are too low, the heat of the houses should be increased by small, sharp fires, so that, by the time the sun shines, the fires will have ceased to give much heat. If, unfortunately, there is a big fire when the sun shines on the house, then draw out a portion of the fire and cover the remainder with a thin coating of damp ashes. Should the weather be likely to become cold again after mid-day, the fires should be thoroughly cleaned and revived before the heat in the houses becomes low. It is advisable to see that the flues and ashpits are kept clean, and that the pipes are kept full of water at all times, so that the boilers may do their work properly. Every air tap in the pipes should be opened several times each day, especially last thing at night, and again at early morning. The temperature of each division by night, as maintained by fire heat, should be as follows:—The *East Indian* or warmest house, 60° to 65°; the *Cattleya* house, about 60°; *Mexican* and *Intermediate* houses, 55° to 60°; and the *Odontoglossum* or *Cool* house, about 50°. On very cold nights the temperature may be allowed to fall a few degrees below those given, and in mild weather it may be a trifle higher. Whenever the thermometer shows that the temperatures of the houses are below the figures indicated, the atmosphere should be considerably drier than at any other time.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Herbaceous Calceolarias.—These plants may now be given their final potting. A suitable compost is one consisting of sandy loam with the addition of a little decayed cow manure. Do not give the plants too large a shift and, in potting, press the soil moderately firm. When the plants have been potted, place them on an ash, or gravel base in a cool house, where they will be exposed to the light but not to direct sunshine.

Insect pests.—Every effort should be directed towards the completion of the plant-cleansing operations before milder weather occurs. In the warmer houses mealy bug may put in an appearance at any time, and in the intermediate and cooler houses the insects will be apt to leave their hiding places as the days lengthen.

In all cases endeavour to destroy them before their numbers increase.

Yellow-spathed Richardias.—*Richardia africana* has its white spathes already expanded, but *R. Elliottiana* and *R. Pentlandii* will not flower until a later date. The tubers having had a long resting period, may now be potted. The plants root very freely and therefore require large pots. A suitable potting soil is one consisting of loam two parts and leaf-mould one part, with plenty of coarse sand or grit added to keep it porous. The use of fine gravel is also advantageous. The tubers should be planted rather low in the pots and the soil must not be rammed hard. These yellow species require more heat than *R. africana*. They should be given a position in full sunlight. No water will be required until the plants have started into growth, but afterwards copious supplies will be necessary.

Anthurium.—The species and varieties which produce decorative spathes may now be overhauled. Those which were repotted last year will probably merely require a little fresh surface soil. In cases where repotting is necessary the old soil should be washed from the roots in a pail of tepid water. Cut off any decayed roots and repot the plants into clean pots or pans which should be furnished with drainage material to one-third their depth. Let the potting compost consist of fibrous peat and loam, broken somewhat roughly, pieces of charcoal and plenty of silver sand. Keep the crown of the plant well above the rim of the flower-pot, and arrange the compost around the roots with the hand. A potting stick should not be used. A few pieces of fresh, living Sphagnum-moss should be inserted with the top layer of soil. Leggy plants may be shortened with advantage by cutting off a portion of the base, but taking care to retain a few fibrous roots. Anthuriums which have ornamental foliage are so susceptible to draughts and changes of temperature when forming new leaves, that it is better not to excite them into growth for some time longer. When, however, they commence to grow naturally they will need treatment similar to that recommended for those having ornamental spathes.

FRUITS UNDER GLASS.

By E. HARRIS, Fruit Foreman, Royal Gardens, Frogmore.

Queen Pineapples.—Prepare a pit for the suckers which were rooted last season. These young plants must now be potted and started into growth in order that they may have sufficient time to make strong fruiting plants for next year. They will need to be plunged into a bed of Oak leaves about 4 feet in depth having a temperature of 80° or 85°. If the leaves have been lying in a heap for some time already there will be a little warmth in them and this will be an advantage. Build up the bed in layers and tread each layer well, making the bed of a uniform firmness throughout. The bed should be made of such a height that when the plants have been plunged they will be as near to the glass as is possible without risk of injury. The compost used in potting should be a rich, friable loam from which the fine soil has been shaken. Add one 8-inch potful of ½-inch bones and a 6-inch potful of soot to each barrowload of loam. If the soil is inclined to be heavy a little charcoal may also be added with advantage. The compost must be thoroughly warmed before potting is commenced. The plants should be put into 10-inch or 12-inch pots according to the strength of the individual plants. Each pot must be well drained and the soil must be made firm. Any other plants requiring to be repotted should be given attention. They will need a hot-bed as in the case of the *Queen Pines*, and they must be potted in a similar manner. No water need be applied until fresh roots have been made. The atmosphere of the house, however, must be kept moist by frequently damping the walls and other surfaces. The plants themselves may be syringed frequently. Excepting on very cold nights, the temperature may be kept at 70°. Make full use of any sunshine that occurs during the day, but admit air only on very favourable occasions.

Charlotte Rothschild and Smooth Cayenne Pines.—Although these varieties may be grown suc-

cessfully in pots they succeed better and give less trouble if planted out in a bed. The system practised here for many years was to plant two batches of plants each year, one in March and the other in September. This method produced a supply of fruits almost all the year round. Preparations for putting out the spring plants should commence at once, so that the hot-bed and soil may become warmed before planting is commenced. The hot-bed should not be less than 5 feet in depth. The compost may consist of roughly-chopped loam, crushed bones and soot in the same proportions as I have mentioned for the *Queen* variety. Make the soil quite firm by treading. It should be about 1 foot in depth when finished. Plant the suckers about 2 feet apart each way. Shade them from the sun until they have become established in the new soil; syringe them two or three times a day during bright weather. Keep the atmosphere of the house constantly moist by damping the floor and other surfaces.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Onions.—Young plants raised from seed sown early last month will now require to be pricked off into other boxes of medium depth. Plenty of drainage material should be placed in them, and this drainage should be protected by placing the coarser parts of the compost over it to prevent fine soil from washing down. The compost should consist of two parts of light fibrous loam (well pulled to pieces with the hands), one part of well-decayed leaf-mould, and one part horse-droppings, obtained from an old Mushroom bed. The leaf-mould and horse-droppings should be passed through a sieve with a ¼-inch mesh. Add sufficient road grit or river sand, according to the nature of the loam, to render it porous. All these ingredients should be thoroughly mixed, and care should be taken to see that it is in a sufficiently dry state to prevent caking when pressed firmly together. Carefully lift the young plants with a pointed stick, preserving the roots intact as far as possible, and plant them with a small dibber, putting them 3 inches apart every way. Make the soil very firm. Prevent the seedlings receiving a check from chill. It is best to perform this work in a structure where the heat is similar to that in which the plants are growing. After applying a thorough watering with tepid water, place the plants as near the glass as possible. They may be syringed very lightly two or three times during the day. The temperature should never be allowed to exceed 60°; 55° is sufficient.

Autumn-sown Onions.—These succeed best when raised in a seed bed and transplanted to well-prepared ground. The transplantation should be accomplished as soon as the weather is favourable. Being perfectly hardy plants, their roots will commence to grow provided the ground is not frosty. Thanks to the severe frosts, ground which has been heavily manured and thoroughly trenched will now be in splendid condition for breaking down. A few days before the planting is done the surface should be pointed over with a fork, adding a good dusting of lime and soot, after which the surface should be raked finely. Place the plants at distances of 12 inches from each other, leaving 15 inches between the rows. *White Emperor* and *White Leviathan*, both excellent and distinct white-skinned varieties, are desirable sorts for early use, and *Giant Red* and *Lemon Rocca* are excellent varieties for affording late supplies.

Parsnip.—This vegetable requires a long season of growth, therefore, wherever possible, the seed should be sown some time during the present month. If the weather is unfavourable, it may only be advisable to sow yet on light soils. Unless the soil is a very suitable one, exhibition specimens can only be cultivated by boring holes at least 2 feet 6 inches deep with an iron bar, and filling these holes with finely-sifted material, such as the soil obtainable from beneath the potting bench. The rows should be planted 18 inches to 2 feet apart. There are several excellent varieties of Parsnips, but the best is *Tender* and *True*.

Celery.—Make a very small sowing of an early and quick maturing variety of Celery. The seeds should be sown in pans and placed in a gentle heat.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 8—

United Hort. Ben. & Prov. Soc. Com. meet.

TUESDAY, FEBRUARY 9—

Ann. meet. Roy. Hort. Soc. (Competitive Classes for late dessert Pears). Hort. Club Ann. meet. and Dinner. British Gard. Assoc. Ex. Council meet.

WEDNESDAY, FEBRUARY 10—

Perpetual-flowering Carnation Soc. Annual meet. at Hotel Windsor, 4 p.m. Croydon & District Hort. Soc. Annual Dinner.

THURSDAY, FEBRUARY 11—

London Branch B.G.A. Lecture on Kew Gardens.

FRIDAY, FEBRUARY 12—

Roy. Gard. Orphan Fund Ann. meet. and Election of Orphans, at Simpson's, Strand.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 3 (6 P.M.): Max. 54°; Min. 43°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, February 4 (10 A.M.): Bar. 29.8; Temp. 59°; Weather—Fine.

PROVINCES.—Wednesday, February 3 (6 P.M.): Max. 53° Cambridge; Min. 49° Lincolnshire.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous and Border Plants, Hardy Bulbs, Lilioms, Azaleas, &c., at 12; Roses and Fruit Trees, at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Perennials and Border Plants, Lilioms, Bulbs, &c., at 12; Roses and Fruit Trees at 1.30; thousands of Bulbs, Plants, &c., at 11.30; 784 cases Japanese Lilioms, &c., at 1, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Even before the nitrogen in the farmyard manure and other organic substances becomes available for the nutrition of crops, it is changed into nitrates by the activity of special soil bacteria.

Unfortunately, from all cultivated land there goes on a constant drain of this element, and not more than 75 per cent. of it added in manures is ever recovered in the crops, even under the most favourable conditions. On account of the soluble nature of nitrates they are rapidly washed out of the soil into the drainage-water, especially in winter, when no plants are present to absorb them, and a certain amount is decomposed with the formation of free nitrogen gas, which escapes into the air and is lost. Large amounts are removed in the crops, and as these or the products derived from them are transported into towns and other areas away from the land which produces them, it will be readily understood that soils which have been cultivated for centuries have been undergoing a process of gradual exhaustion of one of their most important constituents. The demand for supplies of nitrates, which has increased to an enormous extent both in the Old and New Worlds during the last 30 or 40 years, becomes intelligible after consideration of the points just mentioned, and the spread of intensive methods of cultivating the land is destined to increase the demand. About 1830 nitrate of soda was introduced from Chili and Peru, and since that date it has tended to stave off the nitrogen famine and keep up the crop returns. In 1860 it was assumed that the deposits would last for more than 1,500 years at the rate at which the fertiliser was then being used, but an increase of population and a great extension of cultivated areas along with increased intensive management of the soil have falsified the prediction. The world's markets are now consuming 1½ millions of tons of nitrate of soda per annum, and the exhaustion of the present source of supply is well within sight; a few decades will see an end of it. Temporary checks to the development of a nitrogen famine have been made by the addition of sulphate of ammonia to the list of fertilisers supplying this all-important ingredient, but no permanent alteration in the growing need for it could be expected from either of these materials.

That the food supply of the increasing population is bound up with the discovery of some new source of nitrogenous plant-food has become more and more evident, and the existence of a practically unlimited amount of nitrogen in the atmosphere has fired the imagination of scientific men and stimulated persistent research into the question of the conversion of the free nitrogen of the air from its inert gaseous condition to a combined state suited to the needs of all crops.

The efforts to utilise this constituent of the atmosphere for the production of a nitrogenous plant-food on an economical scale have been crowned with success during the last three or four years, and at the present moment two new fertilisers are being placed on the market. One of them, calcium cyanamide, introduced under the trade name of "Nitrolin" is obtained by heating the pure nitrogen of the air with calcium carbide (the well-known material used in bicycle lamps) in an electric furnace; the nitrogen is ab-

sorbed by the carbide, and calcium cyanamide is produced. It is a fine powder, somewhat like basic slag, containing 20 per cent. of combined nitrogen, an amount equal to that in the best samples of sulphate of ammonia. It contains also a certain amount of lime, which is of benefit upon soils deficient in that material. In comparative trials with sulphate of ammonia and nitrate of soda upon Potatoes, Cabbages, Wheat, Mangels, as well as many garden crops, it has proved itself an excellent substitute for these manures. Since it is liable to check germination and damage seedling plants, it is best applied to the land 10 to 14 days before sowing seeds. The application may be made at the rate of 10 wt. to 20 wt. per acre, and when intended for use as a top-dressing it should be mixed 10 to 14 days before application with one to four times its weight of finely-divided soil. Like sulphate of ammonia, it does not act immediately upon crops, but must first be nitrified or changed into a nitrate in the soil. It is adapted for use in all kinds of land, with the exception of those of an acid character or on light sands where the nitrifying bacteria are not abundant.

The other product whose nitrogen is obtained from the air is calcium nitrate, a compound which is certain to become a formidable rival of all nitrogenous fertilisers, and, with "Nitrolin," is destined to have a far-reaching effect on the production of the world's crops. As far back as 1786 Cavendish discovered that the combination of the nitrogen and oxygen of the air can be brought about by the passage through it of an electric spark. This fact has never been lost sight of by chemists and engineers, but its practical and economic application have not been attained until recently. Several methods of bringing about this chemical combination on a large scale are now known, but the process which is apparently giving the best results is that devised by Birkerland and Eyde in Norway. The union of the gases occurs in a specially-constructed electric furnace, the oxides of nitrogen being afterwards passed into water, and the nitric acid formed subsequently combined with limestone. The nitrate of lime produced is sent into commerce 75-77 per cent. pure and containing 13 per cent. of nitrogen—about 2 per cent. less than in nitrate of soda. It is a brownish substance without smell, very soluble in water and as active as nitrate of soda upon plant growth. Experiments both in this country and abroad have shown that its nitrogen is quite as efficient, unit for unit, as that in the latter manure, and on soils deficient in lime it is likely to be more effective.

The prophetic statement by Sir William Crookes that starvation may be averted through the laboratory, and his suggestion, that the production of electricity at a cost sufficiently low to make the manufacture of nitrates from the air a commercial success may be attained through the utilisation of water power, are now being realised. The danger of a nitrogen famine and its consequent bearing upon the growth of human food cereals has been removed by these new achievements of the chemist and engineer.

The first factory for the manufacture of calcium cyanamide was erected at Piano d'Orte in Italy, but others have been established in Austria, Germany and France. The

Since the investigations of Liebig, Boussingault, Lawes and Gilbert, during the first half of last century, into the nature and sources of the elements necessary for the nutrition of plants, the great importance of an adequate supply of nitrogen has become fully recognised by all who are concerned with the cultivation of the land. Among plant-food constituents nitrogen may be said to take first place, being at once the most costly, and, under the ordinary conditions which prevail in the garden or on the farm, the most effective element for increasing the yield of all kinds of crops. Without the constant addition of an abundant supply, either in the form of organic material such as dung, or as nitrate of soda or other chemical fertiliser, the cultivation of field and garden produce rapidly becomes unprofitable.

All kinds of plants, with the exception of those belonging to the leguminous class, take up the nitrogen which they require from the soil in a combined state, almost entirely as a nitrate of lime, soda, or some other base.

New Sources of Nitrogen.

North-Western Cyanamide Co.'s works are situated at Odda, near the southern end of the Hardanger Fjord in Norway, and from this centre the new fertiliser will be supplied to the United Kingdom and its colonies and the greater part of north-western Europe.

Nitrate of lime is manufactured by the Norwegian Hydro-Electric Co. at Notodden, in Telemarken, the energy for the electrical power being obtained from a neighbouring waterfall. The output of the factory is at present about 20,000 tons per annum, but in less than two years, when a new factory will be in working order, with power derived from the Rjukan Falls—the largest in the country—the production will be increased to 100,000 tons per annum.

The question of cost will largely determine the use to which the new fertilisers will be put. The unit of nitrogen in each is practically the same as in nitrate of soda and sulphate of ammonia, but the new products have a valuable asset in them in the form of lime, and with new improvements in the process of manufacture and a reduction in the cost of production a substantial lowering of price may reasonably be expected. In the meantime we can confidently recommend both of these products for trial in the garden during the coming season.

OUR SUPPLEMENTARY ILLUSTRATION represents *Angraecum Augustum*, Rolfe. This remarkable new species was shown by Sir TREVOR LAWRENCE, Bart, K.C.V.O. (gr. Mr. W. H. White), at a meeting of the Royal Horticultural Society on July 21, 1908, when the Orchid Committee gave it an Award of Merit. Botanically, it stands nearest to *A. Kotschyi*, although in habit it is not like that species. *A. Augustum* has thick, fleshy leaves which are light-green and slightly glaucous. The flowers are pure white, with pale greenish spurs tinged with brown at the tips. The species is a native of North-east Rhodesia, and plants were sent to Sir TREVOR LAWRENCE by Mr. AUGUSTUS OLD.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees of this Society will be held on Tuesday the 9th inst. The annual general meeting of Fellows will take place at 3 o'clock p.m.

BRITISH GARDENERS' ASSOCIATION.—The next meeting of the London Branch of this Association will be held at Carr's Restaurant, Strand, on Thursday, February 11, at 7.30 p.m. Mr. C. H. CURTIS will deliver a lecture on "Kew Gardens"; the lecturer's remarks will be illustrated by lantern views. All professional gardeners are invited to attend the meeting.

ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.—The annual exhibition will be held on August 19, 20, and 21, in the Duthie Public Park, Aberdeen, the exclusive use of which for the three days has again been generously granted by the Town Council. Among the prizes offered are two challenge cups and nearly a score of medals. Mr. J. B. RENNETT, 231a, Union Street, Aberdeen, is the secretary, and he will be pleased to furnish further particulars to intending exhibitors.

ABERDEEN UNIVERSITY.—The Dickie prize in botany at the Aberdeen University—the income of £100 granted by Professor TRAIL in 1902—has been awarded Miss A. M. RUSSELL for a collection of 300 specimens gathered within 10 miles of St. Cyrus.

"THE BOTANICAL MAGAZINE."—The February number of this magazine contains descriptions and illustrations of the following plants:—

ALPINIA BRACTEATA, tab. 8237.—This Zingiberaceous plant most resembles *A. nutans*, which is readily distinguished by its more compound inflorescence, and *A. Henryi*, which has the indumentum on the rachis more silky in texture. The species was introduced to European cultivation in 1820, and a plant flowered at Kew in 1864. The plant now figured was raised at Kew from seeds received from the Royal Botanic Gardens, Calcutta, in 1882. It flowered for the first time in a tropical house

genus *Oligobotrya* is intermediate between *Smilacina*, of which it has the habit and the terminal inflorescence, and *Polygonatum*, with which it agrees in having a gamophyllous perianth. This Liliaceous plant from China should be cultivated in a shady and moist border consisting of leaf-mould and peat. The plants grow about 3 feet high, and at Messrs. VEITCH'S Coombe Wood Nursery they succeed when treated in a similar manner to hardy *Cyripediums*.

ERANTHEMUM WATTII, tab. 8239.—This Acanthaceae plant (see fig. 46) was included in the *Kew Handlist of tender Dicotyledons*, 1899, page 225, as *Dædalacanthus parvus* (C. B.

FIG. 46.—ERANTHEMUM WATTII (DÆDALACANTHUS PARVUS).

in May, 1908. The plant grows as high as 7 feet and produces terminal racemes of white or pinkish flowers having a reddish-purple blotch in the interior of the labellum. The tip of the labellum is shaded with yellow. Like all *Alpinias*, the plant requires to be cultivated in a tropical aquatic house, where the soil about the roots can be kept in a mud-like condition while the stems are exposed to abundant sunshine.

OLIGOBOTRYA HENRYI, tab. 8238.—Mr. C. H. WRIGHT describes two varieties of this species. The typical variety has yellowish flowers, and the variety *violacea* is violet coloured. The

CLARKE, and in our own pages October 25, 1902, page 311, the species was illustrated under the same name. In the *Gardeners' Magazine*, 1901, page 644, Colonel R. H. BEDDOME described the plant as *Dædalacanthus Wattii*, this being the first description published. Dr. STAFF has now found it necessary to place this species and *Justicia nervosa* in the genus *Eranthemum*. *E. Wattii* grows from 8 to 10 inches high: it has ovate leaves and paniculate spikes of purple or violet-coloured flowers, both purple and violet-coloured flowers being produced on the same spike. It is a warm-house plant and should be raised

from spring-struck cuttings each year. If the tops are pinched back during the growing season the plants will quickly form shapely little pot-shrubs and flower freely. This species is at its best in July and August.

PINUS BUNGEANA, tab. 8240 (see *Gard. Chron.*, 1882, vol. 18, page 8, figs. 1 and 2).—This species is most nearly allied to *P. Gerardiana*. These two species and *P. chihuahuana* and *P. Lumholtzii* form a small group which the late Dr. MASTERS looked upon as distinct from the other species of the genus, owing to the deciduous leaf-scales and the leaves being in bundles of three with minutely-serrulate margins.

SORBUS VILMORINII, tab. 8241.—This species is said to be very distinct from the other species of the genus now in cultivation. It is a native of Szechuan and Yunnan in South-western China. SCHNEIDER, in *Bull. Herb. Boiss.*, 1906, ser. 2, vol. vi., p. 317, recognises two varieties of *S. Vilmorinii*, the typical variety which is now figured in the *Botanical Magazine*, and a variety called *setschwanensis*. This latter variety has smaller and more numerous leaflets than the type which approaches so closely to *S. microphylla*, a native of Sikkim, that it might readily be regarded as a geographical form of that species. *S. Vilmorinii* is a shrub 10 to 20 feet high. It has slender, unequally-pinnate leaves. The inflorescence is few flowered; the flowers are about one quarter inch across, and the fruit is globose-red and about one-third of an inch in diameter.

THE MASTERS' LECTURES.—Fellows will remember the intimate connection with the Society of the late Dr. MASTERS, F.R.S., who did much for horticulture by drawing constant attention to the various ways in which scientific discovery and research might be made serviceable to gardening; and it will also be remembered that a fund was established by subscription to perpetuate his memory in connection with the Society, and to carry on in some degree his work of science in relation to gardening. "The Masters' Lectures" have accordingly been founded, and the first two are to be given during 1909 by Professor HUGO DE VRIES, of Amsterdam, on (a) "MASTERS' 'Vegetable Teratology'" (June 22), and (b) "The Production of Horticultural Varieties" (September 28). *Extract from Report of Royal Horticultural Society for 1908.*

COUNTY LECTURERS IN IRELAND.—Mr. WILFRED MARK WEBB, F.L.S., has recently been acting as external examiner in agricultural botany to the Royal College of Science, Dublin, for the Department of Agriculture and Technical Instruction for Ireland. Most of these third year students will become county lecturers.

"GEO. MONRO LTD." CONCERT COMMITTEE.—The thirteenth annual concert will be held on Thursday, February 25, at the large Queen's Hall, Langham Place. Mr. GEO. MONRO will preside. This annual concert is held for charitable objects. We have before us the statement of accounts for the last event, which took place on February 20, 1908. The total receipts, including a balance of £46 14s. 5d., amounted to £279 17s. 8d. Donations were given to the following charitable institutions:—Gardeners' Royal Benevolent Institution, 15 guineas; Wholesale Fruit and Potato Trade Benevolent Society, 10 guineas; Surgical Aid Society, 6 guineas; Charing Cross Hospital, 5 guineas; Royal Ophthalmic Hospital, Covent Garden Lifeboat Fund, and GEORGE MONRO LTD., Outing Fund, 3 guineas each; and to GEORGE MONRO LTD., Pension Fund, 4 guineas. The remaining

sum was expended on the arrangements for the concert, except for cash in hand amounting to £61 10s. 9d. We are informed that the forthcoming event will be equal to any of its predecessors, and we hope that many of our readers will attend the function.

THE LEEDS PARKS.—The staff of the Leeds parks dined together on the 24th ult., their guests including Mr. S. F. WITHAM (chairman), Alderman CARTER, Councillors HINCHLIFFE, OWEN, and WADSWORTH. In submitting various toasts the visitors congratulated Mr. A. J. ALLSOPP and his staff on the condition of the parks and recreation grounds of the city, and also spoke in praise of the floral decorations carried out from time to time at the Town Hall.

LINCOLNSHIRE POTATOS FOR AMERICA.—It is reported in the *Times* that in the Holbeach district of Lincolnshire, which is one of the largest Potato-growing areas in England, heavy consignments of Potatos are being loaded for despatch to America. At Holbeach railway station alone the average weekly tonnage despatched is about 1,000 tons, and sometimes as many as 350 to 400 tons are sent away in one day. The Potatos are principally brought from the Holbeach Marsh district. The price the farmers are securing for the consignments sent to America works out at about 35s. per ton, and the duty payable is 37s. 6d. per ton. A very large quantity of Potatos from the district are also being sent to the London and provincial markets.

A PRUNING COMPETITION.—The Madresfield Annual Pruning Competition took place on the 30th ult. in the Home Farm Orchards, near Malvern. There were 20 competitors in two classes. Class A was arranged for pupils who have just taken one week's course of instruction given by a qualified instructor upon various kinds of fruit trees growing in the widely different districts covered by the club's area, which embraces a large portion of the western or fruit-growing districts of the county of Worcester. Twelve pupils, including several farmers' sons, entered the competition. Considering that it is impossible to learn the art of correct pruning in a week, the work was fairly well done. The Technical Instruction Committee allow 3s. per day to each satisfactory pupil, and a good "Saynor" pruning knife is given them in addition to the club's prizes of 20s., 10s., and 5s. respectively. Class B was open to men who had taken previous instruction and others who were nominated by members as capable men at the work. Each man was allotted three trees, previously selected as uniform as possible, and numbered beforehand by the appointed stewards. A ballot took place and the men drew numbers from a hat to correspond with the trees. Three hours were allowed to complete the work. The stewards had power to suspend any competitor who showed incapacity or unfairness. The judge based his awards from a fruit-grower's standpoint. He commended the work that was done, and said if there were more organisations of a similar kind in fruit-growing districts the quality of the fruit supply would be improved.

BENEFICIAL PARASITES.—Among the most interesting of the methods of experimenting in the destruction of insect pests is that which has been practised in various parts of the world, notably in America, and which consists in the introduction into the region suffering from a given pest of some parasitic enemy of that pest. This is, in effect, a bold effort to upset the balance of Nature, and one which, though it

may be fraught with a certain measure of risk, seems the only course likely to prove effectual where a pest is well established and widespread. Experiments of this kind are being conducted on a large scale by the entomological staff of the territory of Hawaii (*Fourth Report, Board of Commissioners of Agriculture and Forestry, 1907*). Thus there have been introduced into Hawaii colonies of parasitised (diseased) Orange aphid from California. From the diseased aphides large numbers of the parasite (*Trioxys*!) have been bred; but it has not yet been determined whether the parasite attacks the species of aphid common in the country. Similarly, ladybirds from Mexico have been introduced in the hope—not at the time of writing demonstrably fulfilled—that they would attack the Avocado mealy-bug (*Pseudococcus nipæ*). In other cases, as, for instance, in that of the Arizona dung-fly parasite, breeding operations have been undertaken on the parasite, and it has been demonstrated that it—the natural enemy of the dung-fly—has established itself in the home of its enforced adoption. The parasites, bred and set at liberty, were discovered subsequently in distant parts of the country, and where they were observed to be present the cattle appeared to suffer less than elsewhere from the attacks of the dung-fly, thereby supplying ground for the belief that the parasite of the fly was making its presence felt in the desired way, viz., by attacking the fly, its natural prey. There is certainly scope in our own country for cautious experiments along these lines, and we venture to hope that, at all events, some of our imported pests may ultimately be exterminated by imported parasites.

THE CARE AND PRESERVATION OF STREET TREES.—Anyone travelling in this country must be impressed by the marked difference with respect to trees and avenues which different towns present. Though it is a matter for congratulation that during recent years much has been done to beautify our towns by tree-planting; yet the fact remains that much more might be done, both in this direction and also in the care of town trees. Where, for example, shall we find in England a sight to rival that presented by the trees of the Champs Elysées in May? How many of our towns can compare as regards trees with the German provincial towns? We could wish that the *Bulletin* (No. 256) issued by the College of Agriculture of Cornell University might get into the hands and the contents into the heads of those municipal authorities who have failed to appreciate the importance of tree-planting as a means of concealing the stark ugliness or dreary monotony of much modern architecture, and, as we venture to think, of increasing the healthiness of towns. The *Bulletin* deals in simple fashion with such matters as the dangers to which town trees are liable; the proper mode of planting, protecting, and pruning, and the modes of "renovating" old trees. A similar pamphlet should be drawn up by some competent authority and distributed broadcast throughout this country. This is a subject to which the local horticultural colleges might well devote some attention.

ST. GALLEN.—The Naturalists' Society of the canton St. Gallen have resolved to form an Alpine garden. They have selected the Alp Oberkamor, at Hohen Kaslen, at an altitude of 1,650 to 1,750 metres. At present it is covered with a Conifer plantation, and presents interesting groups of rocks, well adapted for the purpose. The garden will not only afford a picture of the entire Alpine flora of the country, but it will form a preserve for those rare Alpine species which are becoming scarce even on the Alps.

VEITCH MEMORIAL MEDALLISTS.—At a recent meeting of the VEITCH Memorial Trustees, it was decided to offer Gold Medals to the Rev. W. WILKS, M.A., Secretary, and Mr. W. MARSHALL, V.M.H., Chairman of the Floral Committee of the Royal Horticultural Society, for valuable services rendered to horticulture. The following prizes of a medal and £5 each were also offered:—To the ROYAL HORTICULTURAL SOCIETY for the best group of Orchids at the Temple Flower Show, not exceeding 75 feet, and staged by an amateur who has never taken a medal at either the Temple or Holland House Flower Shows; to the CARDIFF AND COUNTY HORTICULTURAL SOCIETY for the best exhibit by an amateur, of 12 distinct varieties of cut sprays of hardy flowering shrubs (cut); and to the NATIONAL ROSE SOCIETY for competition at their exhibition in July next. At the same meeting, Mr. J. DOUGLAS, of Great Bookham, was elected a trustee in the place of the late Mr. G. NICHOLSON.

THE USE OF SULPHATE OF AMMONIA.—The following facts and figures relate to the manufacture and consumption of sulphate of ammonia during the past year (1908). According to MESSRS. BRADBURY & HIRSCH'S *Review of the Market for Sulphate of Ammonia during 1908*, the amount manufactured in the United Kingdom was 314,000 tons, of which slightly more than one half (161,000 tons) was produced in gas-works. Of this total it is estimated that no less than 235,000 tons were exported (roughly, two-thirds of the total manufacture), and that only 83,000 tons were retained in this country. The countries which take the largest quantities of sulphate of ammonia from us are, in 1908:—Spain and Portugal, 51,000 tons; Japan, 38,000 tons; France and Germany, about 24,000 tons each. When it is remembered that large quantities of nitrate of soda are also used both in this country and abroad, some idea is obtained of the greatness of the effort which the modern world is making to satisfy the "nitrogen-hunger" of the soil.

FUNGUS PESTS.—We have received from Cornell University several new bulletins issued by the Agricultural Experiment Station of the College of Agriculture. These bulletins form valuable additions to the series of publications issued by this University. *Bulletin No. 253* deals with the black-rot of Grapes and its control; *No. 255* with Bean anthracnose.

The loss caused by the black-rot fungus (*Guignardia bidwellii*) appears to have increased considerably in recent years in the State of New York. From comprehensive experiments made under the direction of the Professor of Horticulture, Mr. JOHN CRAIG, it is concluded that no better remedy exists than Bordeaux mixture. In one series of experiments thorough spraying reduced the loss by 80 per cent. Several sprayings are recommended, the first when the third or fourth leaf is showing; second with the same mixture when the blossoms are showing; third soon after the flowers have fallen. If further sprayings are required when the berries are swelling, ammoniacal copper carbonate should be used instead of Bordeaux, since the former fungicide does not discolour the Grapes.

BEAN ANTHRACNOSE or pod spot is due to the fungus *Colletotrichum lendemuthianum*, which affects the whole plant except the roots, and at the time of fruit formation appears as canker-like spots in the pod and also on the Bean-seeds themselves. Infected seeds give rise to infected plants; the first sign of disease being small black cankers on the seed-leaves. Since the fungus causing the disease occurs within the tissues of the seed, no external application of fungicides to the seed is effective. It is, of course, easy to kill the fungus by poison, but the seed is also killed. Similarly and for the same reason spraying the young plants is useless. The remedy, or rather the prevention, of the disease appears to rest with the seed-

raiser. It is shown that if, in seed-saving, he will reject all pods showing sign of anthracnose, he will save only clean seed, and such clean seed will give clean plants. We cannot speak too highly of the excellence of these bulletins. They are lucid, admirably illustrated, and eminently practical.

EXPERIMENTS WITH NITRO-BACTERINE.

In view of the interest aroused by the articles on "Experiments on the Value of Nitro-Bacterine," which have recently appeared in the *Gardeners' Chronicle*, it may be well to point out that, to many people, the results of the Wisley experiments do not appear to justify the sweeping conclusion that "the inoculation of leguminous crops with Nitro-Bacterine in ordinary garden soil is not likely to prove beneficial." On the contrary, they prove just the reverse, and are a complete vindication of all that has been claimed for seed and soil inoculation.

The experiments at both Wisley and Reading were conducted with great care, and are to be welcomed as the most extensive series of experiments on soil inoculation yet attempted in this country under scientific supervision. It has never been claimed that cultures of nitrogen-fixing bacteria will *always* increase the yield of a leguminous crop. The varying conditions of soil, culture, and climate have to be taken into account. It must never be forgotten that we are dealing with organisms which are alive, and are very susceptible to soil conditions.

As yet, our knowledge of soil conditions as affecting inoculation is very limited; but extensive experiments in America have clearly demonstrated some of them, and the Wisley and Reading experiments give further proof of the importance of providing the nitrogen-fixing bacteria with conditions suitable for their growth.

On p. 10 of *Seed and Soil Inoculation* it is stated that "Inoculation will be a failure when the soil is acid and in need of lime." Naturally, the application of superphosphate of lime and sulphate of potash to the plots would tend to increase the acidity of the soil. In addition to this, these acid fertilisers appear to have a directly injurious effect upon the introduced bacteria themselves, for in the U.S.A. *Farmers' Bulletin*, 240, it is specifically stated that the action of these concentrated fertilisers on inoculated seed is injurious. This injurious action

is fully confirmed at Reading and Wisley. The yield from inoculated seed on every plot treated with superphosphate shows a decrease.

The effect of lime on inoculation is well shown by the results on the following soil at Wisley. The plots dressed with lime at the rate of 40 bushels to the acre show:

Inoculated seed ...	4,702 grains weight of Peas.
Non-inoculated seed ...	4,182 " " "
Increase	520 grains or 12.4 per cent.

It should be noted that in each case where comparisons have been made between inoculated and non-inoculated plots, where there is a difference in the number of plants the number in the inoculated plot has been taken as the standard number and the non-inoculated averaged and brought to this standard. That this does not unduly favour inoculation is seen by the fact that in the limed plots if the number of non-inoculated plants had been taken as the standard the figures would be

Inoculated seed ...	4,139 grains weight of Peas.
Non-inoculated seed ...	3,624 " " "
Increase	515 grains or 14.2 per cent.

The effect of liming on inoculation was, according to the figures given in Table L, to give an increase in weight of Peas of 29 per cent., or taking the figures corrected for variation in number of plants, an increase of 12.4 per cent.

Yet Mr. Chittenden definitely states in his report (p. 250): "It is obvious that the addition of lime does not yield better results with the inoculating material in our soil." This surprising conclusion is arrived at because of the results on plots XXI. and XXII., where the plots were treated with lime, potash and superphosphate. But surely Mr. Chittenden would not seriously contend that a mixture of lime, potash and superphosphate is identical with lime alone in its effect upon soil bacteria. To demonstrate the fixation of nitrogen in laboratory cultures by the nitrogen assimilating organisms the presence of carbonate of lime in the culture solution is absolutely necessary. The usual amount added is .1 per cent. The same proportion of lime added as a mixture of lime, potash and superphosphate would be fatal to the organisms. Would it not be more accurate for Mr. Chittenden to state, "It is obvious that the addition of lime, potash and superphosphate does not yield better results with inoculating material on our soil"?

No one who knows anything of the action of the nitrogen-fixing bacteria in the soil would advocate the use of nitrogenous manures along with inoculated seed. Yet this is what was done at Wisley on eight of the 24 plots.

As long ago as 1897 Prof. Vines demonstrated that the presence of nitrates in the soil has an unfavourable effect upon the nitrogen-fixing bacteria. He says "the development of tubercles is much less when nitrate is present in the soil than when it is absent. As the amount of nitrate diminishes, the development of tubercles becomes more marked."

Even leguminous plants appear to prefer to absorb their nitrogen directly from the soil when they can, rather than admit the nitrogen-fixing bacteria into their tissues. They have to provide the bacteria with sugar in return for the nitrogen supplied, whereas when there is nitrogen in an available form in the soil they pay nothing for it. To attempt to decide the value of Nitro-Bacterine by inoculating plots to which nitrogenous manures have already been added is as absurd as to imagine that the value of nitrate of soda as a manure can be proved or disproved by adding it to soil already treated with sulphate of ammonia or calcium cyanamide.

In experiments on the value of a nitrogenous manure it is usual to compare the yield given by the manure with the yield from an equal plot untreated, which is taken as the control plot, and also with the yields from similar plots treated with other manures alone. Can one imagine anyone with a scientific knowledge of manures seriously stating that the way to test the value of nitrate of soda, for instance, is to

apply it to soil already treated with sulphate of ammonia, or to mix it with a substance, such as acid phosphate, which is known to largely neutralise any effect it may have? Yet in effect this is what Mr. Chittenden has done on eight of the Wisley plots. The yield from the inoculated seed on the fallowed ground at Wisley compared with the yields from the other manures alone is shown by the following table from Mr. Chittenden's figures:—

	Weight of pods. Grains.	Weight of Peas. Grains.
*Soil and seed untreated ...	18,077	7,093
Seed inoculated ...	19,604	7,963
Manure, 10 tons per acre ...	19,545	7,686
Limed 40 bushels per acre ...	9,733	3,624
Superphosphate and potash ...	13,249	5,216
Calcium cyanamide ...	8,290	3,157

* Number of plants brought up to number in inoculated plot.

Hence seed inoculation on the fallowed land gave a greater yield than any of the manures applied.

In Reading experiments we have a similar result.

	lbs.	ozs.
Soil and seed untreated ...	5	7½
Inoculated seed ...	6	3
Nitrate of soda ...	5	11
Superphosphate and potash ...	4	5½

Here again the inoculated seed, as stated by the authors, gave the largest yield, showing an increase of 7.6 per cent. over the control plot.

If, therefore, the Wisley and Reading experiments do prove that seed inoculation is useless on ordinary garden soil, how much more do they demonstrate the uselessness of adding nitrates, superphosphates and calcium cyanamide to ordinary garden soils! *W. B. Bottomley, King's College, London.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE KEW BELLADONNA.—The hybrid figured and described in the *Gardeners' Chronicle*, January 23, is interesting, as it is another proof that *Brunsvigia* and *Amaryllis* readily hybridise. A comparison between the figure of Mr. Van Tubergen's plant and the Kew Belladonna, as represented by the figure published in *Gardeners' Chronicle* on October 29, 1898, p. 315, leads to the conclusion that both plants are very closely related. Bulbs of the Kew Belladonna have been distributed, during the last ten years or so, among a few people who are specially interested in bulbous plants. I have not yet seen either the plant or flowers of Mr. Van Tubergen's hybrid, but I believe he has the Kew Belladonna, and is, therefore, in a position to compare the two. With regard to the origin of this plant, which I still think is the loveliest of all bulbous plants capable of cultivation in the open air in this country, it was presented to Kew in 1889, by Mrs. Arbuckle, of Stawell House, Richmond. She had obtained it from Sir Henry Parker, who formerly resided at Stawell House, and whose gardener, Mr. W. Bovell, showed a plant of it in flower at a meeting of the R.H.S. in August, 1875. A note in the *Chronicle* of that year, p. 302, states that this plant was "a seedling raised by Lady Parker in Australia from a cross between *Amaryllis* Belladonna and *Brunsvigia* Josephinæ. This cross was first effected by the late Mr. Bidwill, and has since been several times repeated by Lady Parker." The Kew plants did not flower until we had them seven years. Mr. Baker then examined them, and could find no trace of the character of the *Brunsvigia* in the flowers. To settle the question, we crossed *Brunsvigia* ♀ and the Belladonna at Kew, and we have now bulbs from this cross, none of which, however, has yet flowered. I see no reason now to doubt that the Kew Belladonna was obtained as stated, and I think it would be only right that this plant should be known botanically as *Amaryllis* Parkeri. Mr. J. C. Bidwill was superintendent of the Botanical Garden, Sydney, New South Wales, when he died in 1853. In *Gardeners' Chronicle* for July 27, 1850, p. 470, there is an interesting note by him on the crossing of *Amaryllids*, from which I quote the following: "In Herbert's *Amaryllidaceæ*, p. 278, mention is made of some seedlings raised from *Amaryllis* blanda and *A. Josephinæ*

(*Brunsvigia*). In 1843, Mr. Herbert had the kindness to give me one of these bulbs, which was then, he told me, 20 years old, and was not so big as a goose's egg. It would not, in all probability, have flowered in England in 20 years more; in a more suitable climate, such as that of my present residence, it would probably have flowered in four years, but it was destroyed by accident. I never saw *A. blanda* in flower, and now possess only two seedling bulbs, given to me by Mr. Herbert, which are expected to flower this season. . . . If it should flower I will repeat Mr. Herbert's experiment. . . . I raised, in February, 1841, a vast number of seedlings from *Belladonna* by *Josephinæ*. . . . These seedlings flowered for the first time in 1847, and are extremely beautiful. The colour of the flowers is generally like that of *Passiflora Kermesina*, but varies in different specimens, and many are blotched with white: there are from 20 to 30 flowers on a scape. I could never keep the seedlings alive which I raised from *Josephinæ* crossed with *Belladonna*." This goes to support the suggestion that *Amaryllis* blanda was fertilised from the *Brunsvigia* to produce the Kew Belladonna, and as Mr. Van Tubergen's cross was the reverse way, that would account for the difference in habit he describes. It is quite possible that the plants brought by Sir Henry Parker from Australia were some of those raised in the Sydney Botanical Garden by Mr. Bidwill, Sir Henry having been Governor of New South Wales. I have seen 26 perfect flowers of the Kew Belladonna all open together on a single scape, which was about 3 feet high. *W. W.*

—Having seen the above note from *W. W.*, I should like to add a few words. First, as to the difference between *Amaryllis* blanda, Gawl. (*Botanical Magazine*, t. 1450), and *A. Belladonna*, L.; Herbert, who knew both these plants well and whose botanical and cultural knowledge of the *Amaryllids* were probably greater than that of any living man, stated, on pages 277 and 278 of his *Amaryllidaceæ*, that he considered the former a distinct species from *Belladonna*, and that *Brunsvigia Josephinæ*, Redouté, was so nearly allied to it that he included it in the genus *Amaryllis*. He said that *A. blanda* has a strong midrib to the leaves which sheath above the ground. Now this sheath, which is strongly marked in my plants of *A. blanda*, which I procured many years ago from Van Houttes' nursery, is also a pronounced feature of the Kew hybrid, for which I accept Mr. Watson's name of *A. Parkeri*. The sheath, however, is absent from all the other forms of *Belladonna* known to me, including the pale form sometimes sold as *A. blanda*, which was confounded with the latter in Herbert's time. Baker, however, in his handbook of *Amaryllidaceæ* (p. 96), treats blanda as a variety of *A. Belladonna*, and maintains *Brunsvigia* as a separate genus. In 1901, desiring to verify the alleged parentage of *Parkeri*, I raised a hybrid between *Amaryllis* blanda ♀ and *Brunsvigia Josephinæ* ♂, and these seedlings show the sheath more or less distinctly, whereas the plant raised by Mr. Hoog, and figured in your last number, has the leaves like those of *Brunsvigia Josephinæ*. It seems probable, therefore, that the influence of the female parent on the hybrids is much more marked than that of the male, and the sheath, which is so conspicuous a feature in *Amaryllis Parkeri*, proves, to my mind, that one of its parents was *A. blanda* and not *A. Belladonna*. Herbert states, what I find to be correct, that both *A. blanda* and *Josephinæ* are more tender than *A. Belladonna*, and that their leaves, when cut by frost or drought at the points, will not continue to grow like those of *A. Belladonna*. He says that whatever may be the growth of the leaves of *A. blanda*, it will not flower if it is left in a cold situation whilst dry, and that he lost both of his bulbs, which were of the original importation, by planting them in front of the stove. *A. Parkeri*, however, seems to thrive well in front of the stove at Kew, though in my colder soil and climate I have to treat it as a greenhouse plant exactly as I do *Brunsvigia*. *H. J. Elwes, Coleshorn.*

FREESIAS.—I have this season had an inflorescence with ten, and another with nine blooms. I should like to know if this is uncommon. As far as my experience goes, the stem usually develops fewer than eight flowers. *W. R. H.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—I was not surprised to read *W.*'s note on p. 76, as it is a most distressing fact that there were 50 unsuccessful candidates at the election. But *W.* should read the excellent leader on p. 72, which clearly explains the difficulties of the case. I am thankful it has been so clearly pointed out that if the non-subscribing candidates were to be entirely excluded the Institution would cease to be a benevolent institution. In such circumstances a much greater amount of support would be needed from benefit subscribers. It is desirable to repeat the words printed on p. 72: "only a very small portion of the fund is contributed to by those who are likely to benefit," for the main part of the income is derived from donations that are purely charitable. The votes at present allotted to subscribers are generous. If a gardener supports the fund in his early days he has a powerful lever in the shape of votes, and in a great measure can ensure election when he needs help. Mr. Waterman clearly expressed my view of our needs when he stated at the meeting that we required more auxiliaries or branches in order to make it a national horticultural charity. *G. Wythes.*

AFFORESTATION.—Much interest is being manifested in Scottish arboricultural circles in the report of the Commission appointed to enquire into this subject. This is not to be wondered at, seeing that Scotland is credited with having 6,000,000 acres of land suitable for afforestation. All who have studied the subject are thoroughly convinced that, as an investment, forestry is sound. Indeed, the returns from forestry are extraordinary, especially when compared with the profits from agricultural land. Forestry, under a proper system of management, is capable of giving a net profit of anything up to 15s. or 20s. per acre. The average rent of Scottish hill land is 1s. per acre. The commissioners, in their report, give the area of land suitable for afforestation in Scotland as 6,000,000 acres, but let us assume that only 5,000,000 acres were suitable. This area, which now only supports a mere handful of men, has in it the possibility of employing at least 35,000 workmen. Add to this the area at present under wood, and the number should not prove far short of 40,000 men; allowing each to have five dependents, this means a population of nearly a quarter of a million. It is to be seen what effect extensive tree-planting will have on the climate, which is already sufficiently damp. One cannot conceive of a return nowadays to the condition of things when ague from the marshes and consumption bred in damp houses thinned the population. What a gale in Scotland means to trees every Scotsman knows. As to what fires can do was proved pretty conclusively several years ago in the magnificent Rothiemurchus Forest owned by the Dowager Countess of Seafield. *K.*

NITRO-BACTERINE.—Will Mr. Chittenden tell us why it is thought useful to inoculate the seeds (Peas and Beans) before sowing? The microbes infest the roots; but the seed skin is soon thrown off. Would not the experiment be more satisfactory if the soil were inoculated as soon as the secondary roots begin to appear? I give the following experience for what it is worth. I had a narrow trench dug on a gravel path against a south wall; a man was employed to dig it and make a border for Scarlet Runners. Unknown to me, he half-filled it with cinders, and put very little earth upon them. I planted the Beans. They came up dwarfed, with more yellow and white in the leaves than green. I then watered them with Nitro-Bacterine in the "cloudy state." The Beans soon began to grow with green leaves, and bore a capital crop. The roots had, as a rule, plenty of nodules. *George Henslow.*

CYCLAMEN FLOWERS (see p. 64).—To prevent cut Cyclamen flowers from flagging, slit each stem for about three-quarters of an inch in an upward direction when arranging them in vases for room and dinner-table decorations. The result well repays for the extra trouble, as the blooms will last quite fresh for fully a week, sometimes more, if the rooms are not overheated. Before adopting this method, I always found the flowers would flag within a couple of hours after being cut. *A. Jefferies, Moor Hall Gardens, Essex.*

FADING OF CYCLAMEN FLOWERS (see p. 64).—It is necessary to cut half an inch off the ends of the flower stems and then split the stem up about an inch. The blooms will then last for weeks in a living-room without flagging. I have kept blooms fresh in a warm living-room for three weeks, and in a cool room for six weeks. *A. Simeson, The Goldings Gardens, Great Warley.* [Some specimens treated in this manner and kindly sent by our correspondent are now fresh, seven days after receipt.—Eds.]

SWEET PEA.—We shall be glad if you will publish the following:—The name "Mrs. J. Wilcot" given to the Spencer American Pea mentioned on p. 86 of the *Sweet Pea Annual* for 1909, should be "Mrs. Wilcox," and the variety there named "Grace Wilson" has been renamed "Mrs. B. Gilbert." *Gilbert & Son.*

WINTER-FLOWERING IRISES (see p. 52)—In his interesting note on these plants, your contributor, *W. L.*, fails to mention another species that would come under this heading, and which, though less showy than those he has mentioned, is still sufficiently interesting to be cultivated. I refer to *Iris palæstina*, an *Iris* with close affinities to *I. alata*, but of dwarfer habit and different colour. The colour is of a greenish-yellow, seen in some forms of *I. orchoides*. In mild seasons, freshly-imported bulbs will flower in November and through December, the usual time for flowering being in January. There is in existence a hybrid between *I. alata* and this species, raised by the late Sir Michael Foster, which is intermediate in character between the two, but it generally flowers later than either of its parents. The difficulty with these winter-flowering *Irises* is to keep them under ordinary cultivation beyond a year or two. Especially is this so with *Iris Vartanii*, and pot cultivation seems to be almost essential to give them the rest they need. *Juno.*

FOREIGN CORRESPONDENCE.

GARDENS OF HYÈRES.

THE increasing popularity of Hyères among British visitors to the Riviera should lead to the famous gardens of the neighbourhood becoming more widely known. At the chief of them, M. Nardy, the death of whose father was noted not long ago, continues to make improvements. He is now engaged on a new bank of "plantes grasses," which already contains young specimens of every *Aloe*, *Agave*, *Cactus*, and *Mesembryanthemum* known to Hyères as cultivated in the open air. The Berbers left some species of *Cactus* at Grimaud—for two centuries their capital in the Mountains of the Moors. These, despite its boast of "unique examples"—(meaning only the finest plants)—Hyères cannot yet match. The next best garden to that over which M. Nardy presides as an official is in the middle of the town, and belongs to Madame Clerc. Visitors are welcomed by the head gardener, M. Rossi, a citizen whose politeness and whose charm negative the suggestion contained in the ancient nickname "les Iroquois," applied to natives of Hyères by jealous rivals. *D.*

SOCIETIES.

ROYAL HORTICULTURAL.

THE following extracts are taken from the Report of the Council to be presented at the annual meeting of Fellows on Tuesday next, February 9th:—

THE ONE HUNDRED AND FIFTH YEAR.

The past year, though unmarked by any very important horticultural events, has been a year of quiet, steady progress for our Society.

WISLEY GARDENS.

The Wisley Gardens continue to increase in favour with the Fellows of the Society. All branches of work are showing good results, and improvements are being made as time and opportunity allow. The new laboratory is proving of great assistance to the educational work of the Society, and the result of the first year's work by the students is highly satisfactory, and

well repays the Council, the laboratory director, the superintendent of the Gardens, and the other officers for the time and labour they have devoted to it.

Then follows a report received from his Majesty's inspector.

It was also very gratifying to the Council to find that in general examination in horticulture open to the whole of Great Britain, the scholarship of £25 a year for two years offered by the Worshipful Company of Gardeners, was won by Mr. Perry, one of the students at Wisley.

In the local examination confined to the students at Wisley, Mr. H. E. Seaton took the first place, and has been appointed assistant demonstrator in the laboratory.

Experiments have been set on foot to illustrate (1) the effect of various methods of planting fruit trees; (2) the influence of pruning and not pruning in the first winter after planting; (3) of summer pruning; (4) the importance of planting trees at a correct depth; and (5) the effect of Grass over the roots of fruit trees.

GRAPE EXHIBIT.

At the fortnightly meeting on September 29, an exceedingly fine collection of Grapes grown in the vineries at Wisley, and comprising 30 varieties, was shown. The Grapes were magnificent, and, at the Council meeting, Mr. S. T. Wright, the superintendent of the gardens, and Mr. A. C. Smith, the assistant-superintendent, were complimented by the president on the excellent results they had obtained.

VISITORS.

The number of visitors to the gardens, admitted by Fellows' tickets during the year 1908, amounted to nearly 11,000 as compared with 8,818 in 1907. This is exclusive of horticultural parties which were admitted by special arrangement, and would increase the total to more than 11,500.

WISLEY TRIALS.

In order to protect the members of the various standing committees from the possibility of reproach, and to secure absolute freedom from bias, the Council have arranged that in future, when trials are being made at the gardens, the growing plants, flowers, or fruits, shall be inspected by a sub-committee composed of five members of the committee interested, and that everything so grown for trial shall be kept under a number only, and that the names, both of the varieties and of their senders shall not be disclosed until a decision has been arrived at, and samples are submitted to the whole committee at Vincent Square, together with the report and recommendations of the sub-committee. Thus, the judgments of all sub-committees at Wisley will be given under number only. Specimens of the produce for which a sub-committee shall have recommended any award, will be brought to Vincent Square at the next ensuing meeting, and the whole committee will then have an opportunity of considering the report and recommendations made by the sub-committee at Wisley. The committee having inspected the samples brought up, and adopted (or otherwise) the recommendations of their sub-committee, will send them up to the Council for its approval in the usual way.

WISLEY TITHE.

In 1907 the land tax at Wisley was redeemed; this year the tithe rent charge has been similarly treated, so that the land is now free from both these outgoings.

A VISIT TO WINDSOR.

On June 10, by the gracious permission of his Majesty the King, the Council and committees visited Windsor and the Royal Gardens at Frogmore. As guests of his Worship, the Mayor of Windsor (G. Bampfylde, Esq.), an excellent luncheon was enjoyed at the Guildhall, and after visiting St. George's Chapel, the Albert Memorial Chapel, and the State Apartments, an inspection of the Royal Gardens at Frogmore followed. The Council were much impressed by the admirable cultivation and order displayed in all departments of the garden, and desire to express their great thanks to Sir Dighton Probyn, V.C., G.C.B., and to Mr. Mackellar, his Majesty's head gardener, for the kind way they received the visitors.

DEPUTATIONS.

In response to invitations received, deputations from the Society attended the flower shows

of Truro, York, and Newcastle, and were in each city most cordially and hospitably received by the gentlemen responsible for the arrangements. The Council have, with much pleasure, accepted invitations to send deputations in 1909 to Birmingham and to Cardiff, and negotiations are in progress relating to another important horticultural meeting.

DEPUTATION FROM THE FRENCH HORTICULTURAL SOCIETY.

On June 23, 100 members of the Société Nationale d'Horticulture de France, with their president, M. Viger, and their secretary, M. Chatenay, were received by president and Council, and, after visiting the day's flower show, they were entertained at a luncheon in the lecture room.

SPRING BULB SHOW.

In the coming year, March 9 has been fixed for a show of forced spring bulbs, with a view to specially demonstrating which varieties of *Daf-fodils*, *Hyacinths*, *Tulips*, &c., are best suited for forcing. Exhibits of large or small collections are invited from amateurs and the trade. Medals will be awarded according to merit.

FRUIT SHOWS.

In consideration of the facts (1) that the annual autumn show of British-grown fruit is every year practically a repetition of the previous year's show; and (2) that many British-grown fruits cannot possibly be shown (or shown in perfection) at any one show of fixed date; and (3) that vegetables have been somewhat neglected in the past; the Council have decided to omit the great autumn show for one year, and in 1909 to substitute in its place a series of somewhat similar prizes for British-grown fruit and vegetables, but spread over the whole 12 months, so that everything may be seen at its best. Prizes will therefore be offered at every "fortnightly" show at Vincent Square during 1909, the schedule of which will be published on February 25 in the Society's *Book of Schedules*, price 6d.

AFFILIATED SOCIETIES' CHALLENGE CUP.

In connection with these fortnightly prizes the Council offer a challenge cup to be competed for by affiliated societies, hoping thereby both to stimulate the interest of the societies concerned, and also to bring them into somewhat more intimate touch with the parent society. The cup will be held for one year, and a Silver-gilt Medal awarded to the society winning the challenge, and also to the society obtaining the second place in the contest.

NEW LIFE FELLOW.

Sir Daniel Morris, K.C.M.G., V.M.H., the treasurer of the Society during the financially difficult years 1888 to 1891, has been appointed an Honorary Life Fellow of the Society in recognition of the great assistance he has rendered to horticulture in various parts of the world.

THE "JOURNAL."

Mr. Geo. S. Saunders, F.L.S., having resigned the editorship of the *Journal*, owing to ill-health, Mr. F. J. Chittenden, F.L.S., the director of the laboratory at Wisley, has been appointed his successor.

Four parts of the *Journal* have been issued to the Fellows during the year. To secure a more frequent circulation of the proceedings of the Society and of other information, the new editor has been requested to publish the *Journal* in quarterly, or four-monthly, parts. The smaller and more frequent issues will undoubtedly prove more acceptable to the Fellows for general use.

BEQUEST.

The Council very much appreciate and acknowledge with warmest thanks an intimation they have received from Lady Macleay of her intention to bequeath to the Society the very valuable gift of a complete copy of Curtis's *Botanical Magazine*. They venture to express a hope that it may be several years yet before it comes into their possession.

THE NICHOLSON MEMORIAL.

The Council have been requested to raise a fund for the establishment of a permanent memorial of the late Mr. George Nicholson, V.M.H., F.L.S. With this they most cordially agree. There are few, if any men, to whom the

present generation of gardeners owes a deeper obligation than to the author of *The Dictionary of Gardening*, a work which "has done more towards the standardisation of plant names and developing an interest in horticulture than anything published since London," in 1829.

Mr. Nicholson was for many years a most valued member of the Scientific Committee of our Society. He also took a very active part and keen interest in the re-establishment of examinations by the Society, and himself acted as one of the examiners. It is in view of this last point and after carefully estimating the amount likely to be subscribed, that the Council propose to establish a "Nicholson Prize," to be awarded annually, after examination, to the students at Wisley.

Subscriptions should be sent addressed "The Nicholson Prize Fund, R.H.S. Office, Vincent Square, London," and cheques and postal orders made payable to "The Royal Horticultural Society," crossed "London and County Bank."

THE DARWIN CENTENARY.

The centenary celebration of the birth year of Charles Darwin is to be held at Cambridge on June 22, the date curiously coinciding with the 50th anniversary of the publication of his *Origin of Species*. Representatives of Universities and other learned bodies, together with distinguished individuals, have been invited by the University of Cambridge to take part in the festival, and the Rev. Prof. George Henslow, M.A., V.M.H., has been appointed to represent the Royal Horticultural Society.

CLASSIFICATION OF DAFFODILS.

At the request of the Daffodil Committee the Council appointed a committee to consider the best way of avoiding the confusion, and consequent disputes, likely to arise from the recent multitudinous crossing, recrossing, and intercrossing of the old divisions of Magni-Medio and Parvi-Coronati. The committee have delivered their report instituting an entirely new system of classification, which the Council have accepted, and ordered to be used at the Society's shows. The report contains a list of every Daffodil known to the committee, together with the name of the raiser as far as it could be discovered, each flower known being allotted to its appropriate class. The report has been printed in a handy book form, and can be obtained from the Society's office, Vincent Square, at a cost of 1s. Experience may probably suggest some further modification of the new classification, which, for the present, has been experimentally adopted.

THE 1909 CODE OF RULES FOR JUDGING.

The Society's code of *Rules for Judging* has again been carefully revised and many alterations and additions suggested by the last few years' experience have been adopted. The Council cannot too strongly recommend a careful perusal of the code (price 1s. 6d.) to the secretaries of all local shows and their exhibitors.

CONFERENCE ON SPRAYING.

A useful and important conference on the spraying of fruit trees was held on October 16, when papers were read by Mr. Geo. Masseur, V.M.H., Mr. H. F. Getting, Mr. F. V. Theobald, M.A., and Mr. Geo. Hammond, to whom the Council are greatly indebted. They also desire to acknowledge with thanks the chairmanship of Colonel Warde, M.P., and Colonel Long, M.P., at the morning and afternoon sessions. Discussions followed the various papers; and the full text of the conference will be found in the Society's *Journal*, Volume xxxiv., Part iii.

RETIRING MEMBERS OF THE COUNCIL.

Sir Trevor Lawrence, Bart, K.C.V.O., V.M.H., Mr. George Bunyard, V.M.H., and Mr. A. H. Pearson retire from office. The two former have allowed themselves to be renominated. It is with great regret to the Council that Mr. A. H. Pearson, who has occupied a seat at the Council table for 10 years, finds himself unable to continue in office any longer. He has, during those years, done excellent work for the Society, and deserves the warmest thanks of the Fellows.

VICTORIA MEDAL OF HONOUR.

During the past year two vacancies in the roll of the Victoria Medal of Honour have occurred (through the loss of Mr. R. Martin Smith and Mr. George Nicholson), and Sir Jeremiah Col-

man, Bart. and Mr. Chas. Ross have been appointed by the Council to this distinction.

NEW CERTIFICATE

Of late years the want has been increasingly felt of some way of recognising skillful scientific work amongst plants. Even if such work does not immediately result in any great horticultural advance, it may either disclose the steps by which existing results have been attained, or it may lay the foundation and prepare the way for future development; and is, in either case, deserving of the Society's recognition. To meet this want the Council have created a new certificate, to be called "The Certificate of Appreciation."

ANNUAL PROGRESS

The following table will show the Society's progress in regard to numerical strength during the past year:

LOSS BY DEATH IN 1908.			
		£	s. d.
Life Fellows	13	0	0 0
4 Guineas	2	8	8 0
2 "	40	84	0 0
1 "	75	78	15 0
	190	4171	3 0

LOSS BY RESIGNATION, &c.			
		£	s. d.
4 Guineas	1	4	4 0
2 "	107	224	14 0
1 "	489	513	9 0
Associates	22	11	11 0
Affiliated Societies	27	28	7 0
	646	4782	5 0
Total Loss	776	4953	8 0

FELLOWS ELECTED IN 1908.			
		£	s. d.
Hon. Members	5	0	0 0
4 Guineas	6	25	4 0
2 "	601	1,262	2 0
1 "	589	618	9 0
Associates	42	22	1 0
Affiliated Societies	32	33	12 0
Commutations	8		
		1,283	8 0
		953	8 0
		1,283	8 0
		953	8 0
		1,008	0 0

		1,283	
		776	
		507	
		10,000	
		10,507	

The Council are pleased to record that the total number of Fellows, Honorary or Corresponding Members, Associates and Affiliated Societies is now 10,507, which is believed to be the highest number belonging to any British Royal Society.

LETTING OF THE HALL.

The annual revenue and expenditure account indicates the continued success of the hall as a financial asset. No fewer than 52 engagements (excluding the Society's own shows), covering a total of 160 days, have been accommodated, and the amount received (about £2,067) compares favourably with the year 1907, especially when it is remembered that this former year had two lettings of a value of £700, which have not recurred. The awning over the main entrance, and the kitchen constructed in the basement during the past twelve months, still further improve the comfort of the lessees. Bronze standard lamps are also to be erected at the main entrance. There are but few vacant dates left in the year 1909, and a good financial return is again anticipated.

COMMITTEES, &c.

The hearty thanks of the Society are again due to the members of the committees, the judges, the writers of papers for the *Journal*, the compilers of abstracts, the reviewers, the several examiners, and to the many others who, during the past twelve months, have done so much to contribute to the success of the Society's work, and to help maintain the high reputation it holds among the practical and scientific societies of the world.

By order of the Council,

W. WILKS, Secretary.

Royal Horticultural Society,
Vincent Square, Westminster, S.W.,
December 31st, 1908.

Scientific Committee.

JANUARY 26.—Present: Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Dr. A. Voelcker; and Messrs. S. Pickering, A. Worsley, E. M. Holmes, G. Gordon, W. Hales, J. W. Odell, and F. J. Chittenden (secretary).

Diseased Carnations.—Mr. SAUNDERS and Mr. DOUGLAS reported upon the diseased Carnations shown at the last meeting that, in all probability, they had died through attacks of stem eelworm. The soil used for potting was too light, and the plants were too old to yield the best results. Plants of two years of age were sometimes liable to sudden collapse, and those of a greater age even more liable to fail in this manner.

Grease bands.—Mr. VOSS reported that no moths had been caught upon grease bands on fruit trees at Enfield since November.

Alga, &c., on sewage sludge.—Dr. VOELCKER remarked that mosses, hepatics, and alga had developed upon certain samples of sewage sludge which had been kept at Woburn, but not upon others, which were kept under precisely the same conditions. The samples which contained the greatest amount of lime bore the largest amount and greatest diversity of growth, and it was thought that possibly the difference was as much due to the physical condition of the sludge as to its chemical constitution.

Scilla, &c.—Mr. WORSLEY showed an inflorescence of *Scilla hæmorrhoidalis*, a plant with rather inconspicuous flowers followed by larger, fleshy fruits. He also remarked upon the inconstancy of the arrangement of the spines in certain of the Cacti in various stages and at different ages, and stated that, in his opinion, the arrangement of the spines constituted an insecure basis for the classification of this family.

Fasciation.—From Sir TREVOR LAWRENCE, Bart., came a fasciated specimen of Anthurium bearing two spathe and spadices. Mr. E. H. JENKINS sent a fasciated specimen of *Daphne japonicum*.

Odontoglossum malformed.—A flower of an *Odontoglossum* having three stamens and a much reduced perianth was received from Mr. GURNEY WILSON, and referred to Mr. SAUNDERS for further examination.

Variation in foliage of Cyclamen.—Mr. BOWLES showed a large number of leaves of *Cyclamen hederæfolium* from his garden, exhibiting great and wide variation in the arrangement of the markings upon the foliage, especially in the extent of the whitish margin and median blotch which is usually present. He found the variations to be characteristic of, and retained by, the individual plants.

NATIONAL CHRYSANTHEMUM.

(ANNUAL MEETING.)

FEBRUARY 1.—The annual general meeting of the above Society was held in the Essex Hall, Strand, on this date. The President, Sir Albert K. Rollit, D.C.L., LL.D., occupied the chair.

The Report of the Executive Committee was presented, and from this we extract the following:—

EXTRACT FROM THE ANNUAL REPORT.

The dates of the shows for the current year have been provisionally fixed for October 6 and 7, November 3, 4, and 5, and December 1 and 2, but unfortunately it has not yet been possible for your committee to approach the Crystal Palace Company with regard to a renewal of the contract for reasons which are set forth in this report under the heading of finance.

The Floral Committee have awarded 47 First-class Certificates.

The Society's foreign corresponding secretary, Mr. C. Harman Payne, attended the Congress of the Société Française des Chrysanthémistes held at Tours in November and thence proceeded to the exhibition of the Société Nationale d'Horticulture de France at Paris.

One hundred and seventy members of the Society and friends visited the Royal Gardens at Frogmore on the occasion of the annual Outing on Monday, July 27. This was the largest muster at any outing for several years.

Arrangements have already been made for the 1909 Outing to be held on August 9 next, when a visit will be paid to the gardens of Sir Frank Crisp at Friar Park, Henley-on-Thames.

The annual dinner was held on November 26 at the Holborn Restaurant, the chair being occupied by the President. About 100 members and guests, including ladies, sat down to dinner.

It is with great regret that your committee have to report that they have not yet received the consideration money due from the Crystal Palace Company under the terms of the contract for any of the 1908 shows. They are still hoping, however, that the money will shortly be paid without extreme measures being resorted to. For this reason the ordinary prizes have not yet been distributed, but as soon as such

money is received from the Crystal Palace Company the prizes will be issued without a day's delay. Subject to the receipt of that money it will be observed from the statement of assets and liabilities that the Society's finances show a considerable improvement when compared with the previous year. The surplus of assets over liabilities has been increased during the year under review from £3 15s. 4d., to £102 18s. 9d., which will more than enable the committee to carry out the policy set forth in the last report, of re-transferring £25 to reserve account from the year's income.

On moving the adoption of the report and balance-sheet, the President congratulated the Society on its work during the past year. He said the exhibitions were all good, and particularly the great November show. A large number of new varieties had been brought before the Floral Committee, and many novelties had received the Society's Certificate of Merit. Sir Albert Rollit also stated the annual dinner was a success, the membership had considerably improved, and all special prizes had been paid. He hoped the finances of the Society, which, during the year, had been the subject of careful attention on the part of the committee, were now placed on a sound footing. The exhibitions at the Crystal Palace again cause some little difficulty in regard to finances, but in the past the accounts have always been settled in a satisfactory manner, and it is hoped all, or the greater part of the money, will soon be received.

Mr. T. Bevan seconded the motion for the adoption of the report, which was carried unanimously. A vote of thanks to the auditors, Messrs. Joseph Lake and R. F. Scammell, for their services, was duly accorded. The re-election of Sir Albert Rollit as President was proposed by Mr. J. T. Simpson, and carried with acclamation. Other officers were re-elected as follows:—Mr. John Green, Treasurer; Mr. Thomas Bevan, Chairman of the Executive Committee; Mr. E. F. Hawes, Vice-Chairman; Mr. C. Harman Payne, Foreign Corresponding Secretary; and Mr. R. A. Witty, General Secretary. Messrs. J. Lake and W. H. M. Dean were elected auditors.

The General Committee was next elected as follows:—Messrs. J. Emberson, R. F. Felton, A. Hemsley, D. Ingamels, E. Jones, F. G. Oliver, R. E. Reeve, G. Springthorpe, W. Wells, J. B. Riding, H. Runchman, and C. Noyce.

A vote of thanks to the chairman concluded the business.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 3.

A cold, dry, and dull week.—The day temperatures have been variable, but on the whole rather low for the time of year. The nights, however, remained cold until last night, when a change to a much higher reading took place. On the coldest night the exposed thermometer showed 18° of frost, whereas last night the same thermometer did not fall lower than 42°. The ground is at the present time 2° colder than is seasonable at 2 feet deep, but at about an average temperature at 1 foot deep. Rain fell on two days, but to the total depth of only about one tenth of an inch. There was a light fall of snow on the first of those days. No measurable quantity of rainwater has come through either percolation gauge for 11 days. The sun shone on an average for 1 hour 21 minutes a day, which is 35 minutes a day short of the usual duration at the end of January. On January 27 there was no record of sunshine here—about 80 feet above the Berkhamsted valley—owing to fog, whereas at 200 feet above the valley the sun was shining brightly all day long. Light airs have, as a rule, prevailed until yesterday, when the mean velocity for the windiest hour reached 18 miles—direction W. The average amount of moisture in the air at 3 o'clock in the afternoon fell short of a seasonable quantity for that hour by 5 per cent.

JANUARY.

A mild, dry, calm and sunny month.—Taken as a whole this was a moderately warm January. For the first 3 weeks the weather continued warm, but the temperatures remained low during the remainder of the month. The days were, as a rule, more unseasonably warm than the nights. On the warmest day the temperature in the thermometer screen rose to 51°—which is about an average extreme maximum for the month. On the coldest night the exposed thermometer registered 16° of frost—a high extreme minimum for what is usually the coldest month in the year. Rain, hail, or snow fell on but 11 days, and to the total depth of only one inch—which is 1 1/2 inches below the January average for the previous 53 years—during which period there have been only 6 Januaries as dry. Snow fell on 2 days, but at no time to a sufficient depth to cover the ground. The sun shone on an average for 2 hours a day, or nearly half an hour a day longer than is usual in this mid-winter month. This was the calmest January for 11 years, and in the windiest hour the mean velocity only reached 20 miles—direction west. The average amount of moisture in the air at 3 p.m. was 4 per cent. less than a seasonable quantity for that hour.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October last, the total rainfall has fallen short of the average for those four months by 4 1/2 inches, which is equivalent to a loss of 109,490 gallons per acre in this district. At the same time last year there was an excess of 46,370 gallons per acre. E. M., Berkhamsted, February 3, 1909.

MARKETS.

COVENT GARDEN, February 3.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c.: Average Wholesale Prices.

Table of cut flowers and plants in pots with prices per dozen. Includes items like Acacia (Mimos), Anemone fulgens, Azalea, Bouvardia, Calla aethiopia, Camellias, Carnations, Cattleyas, Chrysanthemums, Cyrtopediums, Daffodils, Eucariss grandiflora, Freesias, Gardenias, Hyacinths (Roman), Lilac, Lilia auratum, Lilium longiflorum, Lilium lancifolium, Lily of the Valley, Marguerites, Mignonette, Myosotis, Narcissus, Odontoglossum, Pancratium, Pelargoniums, Ranunculus, Roses, Spirea, Stocks, Tuberoses, Tulips, Violets, and Ferns.

Cut Foliage, &c.: Average Wholesale Prices.

Table of cut foliage and plants in pots with prices per dozen. Includes items like Adiantum cuneatum, Agrostis, Asparagus plumosus, Berberis, Croton leaves, Cycas leaves, Daffodil foliage, Ferns, and various plants in pots like Ampelopsis, Aralia Sieboldii, and Begonia.

Plants in Pots, &c.: Average Wholesale Prices.

Table of plants in pots with prices per dozen. Includes items like Cyperus latus, Daffodils, Dracaenas, Erica byemalis, Genista fragrans, and various other potted plants.

Plants in Pots, &c.: Average Wholesale Prices (Contd.).

Table of plants in pots (continued) with prices per dozen. Includes items like Liliom longiflorum, Solanum, and Tulips.

Fruit: Average Wholesale Prices.

Table of fruit prices with prices per bushel or per dozen. Includes items like Apples (Foreign), Bananas, Cape fruit (Peaches, Apricots, Plums, Nectarines, Cranberries, Custard Apples, Dates), Grapes, and various other fruits.

Vegetables: Average Wholesale Prices.

Table of vegetable prices with prices per dozen or per bushel. Includes items like Artichokes, Asparagus, Beans, Beetroot, Brussel Sprouts, Cabbages, Cardoon, Carrots, Cauliflowers, Celery, Celeriac, Chicory, Cucumbers, and Endive.

REMARKS.—The Grape trade continues fair, the demand from the provinces being moderately good. Trade in Apples is very quiet. A fair consignment of Palermo Blood Oranges arrived during the past week and met with a good demand. Cape Plums are selling freely. Pineapples are selling well; there being a good demand for the smaller fruits of best quality. A large consignment of Apples from Washington have sold at fair prices, 7s. 6d. to 9s. 6d. being an average price per case. Rhubarb is arriving from Essex, also from Leeds, but the quality is not good, and the stalks are much lighter in colour than usual. There has been a reaction in the Lemon trade, and prices have fallen considerably. Oranges also are cheaper, but this is principally owing to many of the fruits being unsound. Trade generally is fair. E. H. R., Covent Garden, Wednesday, February 3, 1909.

WOBURN FRUIT FARM EXPERIMENTS.

TWO reports on the Woburn Fruit Farm, by the Duke of Bedford and Mr. Spencer U. Pickering (Amalgamated Press, London), have come out almost simultaneously. The first is the *Ninth Report, relating to methods of planting fruit trees, with an appendix on studies in germination and plant growth, and on the action of heat and antiseptics on soils. The Tenth Report relates the results of experiments in the treatment of Nursery trees by fumigation and other methods for the destruction of woolly aphid (American blight), and for killing the Apple sucker, the aphid, and various caterpillars on trees in foliage.

It will be remembered that the Fifth Report gave the results of experiments in methods of planting fruit trees entirely at variance with those in general use and recommended as the best in all text-books bearing upon the subject. In the Ninth Report the results of repeated and new experiments of the same class are described. The result in the earlier experiments which attracted most attention, and called forth much sceptical criticism, was the benefit declared to have been derived

* Ninth and Tenth Reports of the Woburn Experimental Fruit Farm. (The Amalgamated Press, Ltd.) Prices, 2s. 6d. and 1s.

from placing trees with untrimmed roots into holes too small for the roots, making the roots point downwards and stamping the soil over them violently. A further announcement appears to have been made after the issue of the report to the effect that the violent stamping had been developed into ramming the soil over the roots until it was puddled. The Ninth Report gives the results of further trials in this direction, carried out at several places away from Woburn by skilled growers whose names are given, as well as on the Woburn farm itself. No fewer than 1,372 trees were used in these experiments. After deducting those planted in certain places where various circumstances spoil the experiments, average results are given in relation to the growth of 814 trees. The plan pursued in planting is thus described:—"A few forkfuls of earth were removed, so as to make a shallow hole: into this the tree was put, with the roots just as they happened to come, the earth was shovelled over them, and rammed with a heavy rammer till the whole was thoroughly puddled and shook like a jelly at each stroke." Finally a shovelful of loose earth was thrown over the rammed ground to facilitate hoeing.

On the Woburn farm and at Harpenden, where the trials were most extensive, a great majority of the rammed trees made more growth, even in the first season, than unrammed trees, while at some other stations the failures were nearly as numerous as the successes. The summary of results states that in the first season 59 per cent. of the trees made an excess of growth, 27 per cent. gave no definite results, and 14 per cent. showed a deficiency; while in the second season the percentages in the same order were 72, 17, and 11. The writer of the report attributes the benefit of ramming to the extra close contact of the soil with the roots produced by the process, and this appears to be a reasonable explanation. It is admitted that the rammed soil is not propitious to the growth of the roots in it; but it is pointed out that, before the end of the first season, the roots have penetrated into the loose soil beyond the small extent of the rammed earth. What experienced fruit growers will find it difficult to accept is the obvious implication that the puddling of the soil is beneficial to the trees. So long as the ground is not too dry, it is stated, its condition will be immaterial, and the failure of ramming in certain cases is attributed to the comparative lightness of the soil, which would prevent puddling.

As to the probable injury to some of the roots from ramming, it is argued that this is beneficial. "The continued life of the tree," it is added, "depends entirely on the formation of adventitious roots, and it is well known that the formation of these is fostered by a certain amount of injury to the old roots." Independent experiments to test this point were conducted on a small scale. The roots of some trees were notched all along their length, and these are reported to have made more growth than trees with uninjured roots. Similarly, trees with roots bruised and frayed by careless raising made more growth than others which had the injured parts trimmed off.

Seeing that in a separate set of experiments the moderate trimming of the roots of

trees, raised properly, proved beneficial, the inference is that it is advantageous to cut off sound portions of roots, but disadvantageous to remove bruised and frayed portions. In trials of root pruning under ordinary circumstances the removal of one-fourth to one-third of the roots of trees is represented to have given favourable results, while more drastic pruning did harm. Similarly, the pruning-off of all fibrous roots of not more than one-twenty-fifth of an inch in diameter is said to have produced a slight benefit in the case of young trees, but injury in that of trees eight to nine years old.

Not the least astounding result is that of an experiment in tying the roots of a tree together, and bending them in the form of a ball under the tree. This operation, it is reported, reduced the growth in the first season, but resulted in practically normal growth in the second year. Trees on trenched ground in a considerable majority of instances did better than those on untrenched ground; but an attempt is made to explain this by the statement that the soil where trenching proved advantageous was exceptionally favourable to deep rooting.

It must not be supposed that the favourable results of what are commonly regarded as bad practices in planting are reported to have been uniform. On the contrary, the evidence is more or less conflicting in many instances, the deductions being from the majority of the results. Fruit growers generally, it may be surmised, will require a great deal more evidence than has been obtained at present to convince them that planting in wet soil and puddling it by ramming, planting trees with bruised and frayed roots untrimmed, or bunching the roots and ramming them into small holes can be otherwise than disadvantageous. As already stated, the theory as to the benefit of trimming off a larger proportion of the roots than is usual and of notching them is that the formation of new roots near the surface of the soil is thereby promoted. But it cannot be supposed that this process would be favoured by leaving bruised and frayed roots untrimmed, a neglect not recommended in the report, in spite of its apparently favourable results; and as to bunching the roots, instead of spreading them out, it is contrary to all reason to suppose that this can be otherwise than a hindrance to the extension of new roots over the greatest area of nourishment. For the results of other experiments readers are referred to the report.

The Tenth Report is well worth careful attention. The fumigation with hydrocyanic acid gas of nursery trees and stocks raised for transplanting proved ineffectual for the destruction of the woolly aphid, and crude paraffin of various grades was fatal to some of the trees. The most advantageous treatment was immersion for ten minutes in water at the temperature of 115° F. Similarly, the treatment of growing trees for the same pest with crude paraffin or naphtha injured the foliage badly, and killed some of the trees. Lime and salt wash, tried for the destruction of the eggs of the Apple sucker (*Psylla mali*) on dormant trees, was not a success. This mixture also failed to kill the insects themselves on trees just coming into foliage. The Woburn winter wash destroyed only 5 per cent., and badly scorched the

foliage, while solutions of common salt and carbolic acid both failed. Thoroughly successful, however, was Voss's solution of nicotine, which, unfortunately, is expensive. It killed up to 95 per cent. of the insects, and did not scorch the foliage at all. For the destruction of several varieties of caterpillars paraffin emulsion proved most successful, particularly that made with Bordeaux mixture as the emulsifier. Nicotine also gave good results, but needed the addition of lead arsenate, at the rate of 12oz. to 10 gallons, to render the wash destructive to the caterpillar of the winter moth. In the destruction of the Plum or the Apple aphid, nicotine, because harmless to the foliage, appears to be by far the best remedy, although paraffin emulsion proved also effective.

In reading these Woburn Reports, no one can fail to appreciate the munificence of the Duke of Bedford in making provision for these important and costly investigations, or with the painstaking energy shown by Mr. Pickering in arranging and conducting the experiments.

POLYSTICHUM ACULEATUM GRACILLIMUM DRUERYI.

THE subject of our illustration is one of the most remarkable examples on record of what has been termed saltatory variation. The extent of this variation can be judged by comparing the parental form indicated in the lower right-hand corner with the typical frond of its offspring. The graceful habit of the plant is shown in the left-hand corner. A First-class Certificate was recently awarded to this Fern by the Royal Horticultural Society. The "sport" is of further interest, as being one of about a score of similar plants, with, however, individual variations of a minor character, which originated in a batch of about a hundred seedlings of *P. ac. pulcherrimum* found many years ago in Dorset by a farm labourer, and which, until a few years back, was believed to be barren. Isolated sporangia were then noted upon a plant in the possession of Mr. C. B. Green, of Acton, this plant having been raised from an offset of the original plant which I gave to Mr. Green. We both made sowings and obtained similar results. The majority of the plants so raised were mainly of the true parental type, but several reverted to an extremely near approach, not to *P. aculeatum*, but to *P. angulare*, a closely-allied but softer species, devoid of the glossy surface of *P. aculeatum*. Another, of similar type to the one depicted, *P. aculeatum pulcherrimum Drueryi*, was also certificated at an earlier date. In this the terminal pinnules of the frond are deeply serrate, forming a sort of fringe. A third plant in Mr. Green's possession remains to be exhibited, in which the fronds are far more decomposite and dense, on similar plumose lines to the divisilobe section of *P. angulare* raised by Col. Jones and Dr. Fox. *Chas. T. Druery, V.M.H., F.L.S.*

LÆLIO-CATTLEYA FELICIA.

THIS beautiful hybrid (see fig. 48, p. 100), raised by Messrs. Charlesworth & Co., Haywards Heath, Sussex, between *L.-C. Haroldiana* (*L. tenebrosa* × *C. Hardyana*) and *C. Trianae*, was awarded a First-class Certificate at the Royal Horticultural Society's meeting on January 26. The hybrid retains the fine proportions of *C. Hardyana*, with a remarkable introduction of deep purplish-claret colour on the front and edges of the side lobes of the lip. This extra deep colour is very effective in contrast with the silver-white, rose tint of the rest of the flower.

FIG. 47.—POLYSTICHUM ACULEATUM GRACILLIMUM DRUERYI.

FRUIT REGISTER.

STONE FRUITS FOR AMATEURS.

BEGINNERS in the warmer counties may cultivate Apricots, Plums, Peaches and Cherries, the methods of their cultivation and the principles of summer and winter pruning being easily understood. The Peach, Nectarine and Apricot require the warmth and protection of a south, west or east wall in the south of England and Ireland, but in the north of England, i.e., north of the Humber River and in Scotland generally, the wood and the fruit will not mature on any tree other than one having a due south aspect. In all parts of the country some kind of protection is needed against frost at the time of flowering. The young shoots must not be trained so closely together as to prevent the summer's sun reaching the wall or they will not mature sufficiently to form good blossom-buds. In some Yorkshire gardens Apricots are grown in rough sheds having merely a glass roof; and the trees, if frequently syringed with clear water, do not suffer from red spider, a great pest of all wall trees. The syringing must cease when the fruit on any of the trees begins to change colour. After the crop has been gathered syringing may be continued at intervals till the month of August is out.

Plums of the common and culinary varieties may be grown as low standard trees and bushes, and are not out of place on a lawn, provided they are afforded liquid manure at the roots occasionally in the winter. Pruning at the winter season will be found a simple operation if it be borne in mind that the fruit is produced by the well-ripened shoots of the previous year. The "spurs" should not be closer than 8 inches apart, and they need to be kept shortened back when they exceed 4 or 5 inches in length. It is only on the lower half of the one-year-old shoots that fruit may be expected to form: the upper half may be removed at the annual winter pruning.

The dessert Plums are the better for the protection of a wall or fence, or they may be grown in bush-form in a warm part of the garden. Excellent varieties of Plums are the Gages, viz., Bryanstone, a large, round fruit blotched with red, and ripening in September; Green Gage, a well-known variety, Denniston's Superb, a greenish-yellow fruit of a large size for a Gage, is a prolific bearer and very hardy, and about a fortnight earlier in ripening than the common Green Gage. Oullin's Golden Gage is of great size; the fruits are greenish-yellow and ripen in August. Reine Claude de Bavay is a large, delicious Plum, prolific in bearing, and of a hardy constitution. Three delicious Gages were raised by the late T. Rivers, viz., Early Transparent, Golden Transparent and Late Transparent. Amongst Plums other than Gages may be recommended Early Favourite, Grand Duke and Late Rivers—the two latter ripening in October and November—and Monarch ripening late in September. The Czar ripens about the end of July; it is a richly flavoured fruit, and the tree is very hardy. Some fine culinary varieties suitable for amateur cultivators are Autumn Compôte, Curlew, and Early Rivers. Of Damsons, the Crittenden's, King of the Damsons, The Shropshire or Prune and the Common Damson offer a good assortment. The Damson makes a good standard tree and a good boundary or shelter tree for a plantation of other kinds of fruit.

The Cherry is a favourite fruit with most persons, and the varieties are many; it will, however, be sufficient to give the names of some of the best, with the proviso that the earliest to ripen should be given wall space. Ripening in the month of June out-of-doors are Guigne Annonay, Semis de Burr, Bigarreau Jaboulay; in July, Large Black, Large Red, Empress Eugénie, May Duke (against a wall), Noir de Guben—a Bigarreau, as is also de Schrecken, Black Tartarian (against a wall), Elton—earlier

than the Bigarreau varieties; Governor Wood, light red in colour, with tender flesh; Monstrueuse de Metz, dark red, one of the largest Cherries, and Turkey Blackheart, a favourite Kentish variety. The Morello and Belle Magnifique, both prolific, culinary varieties, and very hardy, may, with advantage, find places on a north wall, as well as be grown as standards or bushes in the open garden.

APPLE AND PEAR STOCKS.

It may be said that all varieties of Apples succeed on the broad-leaved Paradise stock, but it is not the kind on which should be worked large-growing, horizontally- or fan-trained trees, such as are commonly planted on walls in the cooler parts of these islands. The trees on this stock produce fruit when very young, and the formation of growth is thus restricted, so that the wall space would be bare of branches for several years after planting if the Paradise stock was employed. In addition, such trees scarcely have the vigour the Crab stock imparts; so that, for carrying a large fruitful head for a great number of years, the latter is the better stock. These remarks apply likewise to the Pear, for the Quince stock may only be advised for single and double cordons on walls and bushes and pyramids. Not every variety of the Pear does well when worked on the Quince, but needs an intermediate graft of a Pear that unites with the Quince stock satisfactorily. Such are those early July Pears, Doyenné d'Été and Citron des Carmes, which make good and fertile trees; Fondante d'Automne, a large melting Pear, forms a well-shaped pyramid tree on the Quince when double-grafted. This last is in season in October. That delicious but uncertain variety when worked on the Pear stock, Gansel's Bergamot, for early fruiting should be double-grafted on the Quince. The fruit is ripe in October. Thomson's Pear comes into use in the same month as the last-mentioned, and should be double-worked on the Quince, likewise the Seckle or Honey Pear of the Americans. Of January and February Pears, Zéphirin Grégoire and Knight's Monarch make good cordons on the Quince, double-grafted, as do Ne Plus Meuris and Beurré Rance. The latter is a good bearer, but requires a place on a south wall. F. M.

CULTURAL MEMORANDA.

ASPARAGUS PLUMOSUS.

THE months of March and April are most suitable for repotting this plant. The best compost is one consisting of turly loam one-third, leaf-mould two-thirds, and a small quantity of horn shavings or an artificial manure rich in ammonia. The drainage in the pot should be sufficient to secure a free outlet for water and no more. After potting, which should be performed by hand with some degree of firmness, the plant should be placed on a warm bed in a house or pit of considerable height, not plunged, or but slightly. No shade is necessary as a rule. If enough syringing or sprinkling be carried out there is no danger of burning or scalding, and the conditions are just those most favourable to good growth: the more so if the walls and paths are frequently moistened. After a long period of cloudy weather a thin kind of shading may be employed during brief periods of strong sunshine for a few days. When this Asparagus is grown for cutting it is usual to plant it in a bed or border of soil, and train the main shoots on vertical rods or strings, from which it is an easy matter to detach them when wanted. Asparagus plumosus nanus, it may be added, is obtainable from seeds. The fronds of seedlings differ slightly from those made by divided plants, being thicker and the stalks weaker, so as to cause them to assume a more pendant habit. This variety may be grown in pots or in beds of rich soil, and, if so desired, the main growths may be fastened to thin Bamboo rods. F

WHORTLEBERRIES AND CRANBERRIES.

(Concluded from page 84.)

OXYCOCCUS.

O. MACROCARPUS (AMERICAN CRANBERRY).—In habit and general character this species differs but little from our native Cranberry (*O. palustris*). It has the same trailing, wiry, but stouter stems, with larger leaves and fruits. Botanically, it differs chiefly in the position of the flowers on the shoot. In *O. palustris* they form a small terminal cluster; but in the present species they spring from the axils of small leaves or bracts below the extremity of the branch. Above the flowers, consequently, there is always a portion of leafy shoot. The leaves are oval to oblong (those of *O. palustris* are more pointed), $\frac{1}{4}$ to $\frac{1}{2}$ inch long, and glaucous, white beneath. The flower is light pink, and the globose fruit red, and $\frac{1}{2}$ inch or rather more across. The cultivation of this Cranberry in the Northern United States has developed into quite an important industry. Hundreds of acres have been specially prepared for its accommodation, the land being arranged so as to allow of its being flooded when necessary. According to Mr. J. Dawson, the cost of this preparation is sometimes as much as £60 per acre. But often a crop of 500 bushels of Cranberries is gathered from one acre of well-prepared land in a single season. A figure of a fruiting branch, showing the extraordinary fertility of this plant, was given in the *Gardeners' Chronicle* for October 30, 1880 (p. 569).

O. PALUSTRIS (CRANBERRY).—Our native Cranberry extends over a large portion of the northern hemisphere. It is common in the Eastern United States and Canada, and reaches westward to British Columbia. It is abundant in Northern Europe, and is widely spread over the British Isles, but most plentifully in the north of England and the south of Scotland. In all these places, as well as in Northern Asia, its habitat is always the same—boggy situations on moors and mountains. In general appearance it is a small edition of *O. macrocarpus*. It has the same entirely prostrate habit and trailing wiry stems, but its foliage and fruit are smaller. The leaves are $\frac{1}{4}$ to $\frac{3}{8}$ inch long, ovate, pointed, and glaucous beneath. The rosy-pink flowers come in a cluster of five or less at the ends of the branches. The berry is red and about the size of a Red Currant.

The gathering and sale of Cranberries in Great Britain is not so important an industry as it once was. The draining and enclosing of boggy land which was carried on so extensively during the great French wars of a century ago, and up to the repeal of the Corn Laws, destroyed many favourite habitats of the Cranberry in this country. At Longtown, in Cumberland, near Solway Firth, it is said that in the Cranberry season £30 worth of berries used to be sold on one market day. They have an acid and astringent taste, and are used for tarts, preserves, and sweetmeats.

CHIOGENES.

CHIOGENES SERPYLLIFOLIA (CREEPING SNOW-BERRY).—In habit this curious North American plant very much resembles *Oxycoccus palustris*. It has creeping, very slender stems, and small, ovate, pointed leaves, but is readily distinguished from the Cranberry by the leaves being furnished beneath with rigid, rusty-coloured bristles instead of being glaucous. The flowers, too, are quite different; they are very small, produced singly on a nodding stalk from the leaf axils, and the corolla is bell-shaped. The fruit is white, globular, and nearly $\frac{1}{2}$ inch in diameter, with a delicate acid and aromatic taste. The whole plant, indeed, has an aromatic odour resembling that of *Gaultheria procumbens*. This plant has a wide distribution in North America, reaching from Labrador westwards to British Columbia, and south to Minnesota, Michigan, and North Carolina. It inhabits peat bogs and damp woods. W. J. Bean.

THE ROSARY.

CULTURAL NOTES FOR FEBRUARY.

WHEN the ground is dry and free from frost advantage should be taken of the opportunity to finish any arrears of planting, including rooted cuttings that have been "heeled in" temporarily.

Roses of the rugosa type and hybrid Sweet Briars are very ornamental subjects for grouping in gardens or pleasure grounds. They suc-

ceed in a smoky atmosphere, and for that reason they should be planted in town gardens. *Rosa rugosa* var. *Blanche Double de Coubert* is a very effective, double white variety, free in flowering and with very fragrant blooms. *Rosa rugosa atropurpurea* has carmine-crimson flowers. The *Penzance Briars* are an acquisition not only for their rich perfume but also because

of their attractive fruits during the autumn months. The frost will have loosened in the soil many stocks and cuttings planted last autumn or since that time. With this in mind, carefully examine all newly-planted Roses, especially the standard Briars, and tread the soil about them firmly and then give a fresh surface mulch of manure.

All hardy climbing Roses can now have their shoots thinned and secured to the arches, pillars, or pergolas over which they are trained. of 60° F. is ample, but it may be increased 5 or 10° more with sun heat, provided there is plenty of top ventilation but no cold draught. Just before or at the time the flower-buds develop the plants should be well fed with liquid manure and soot water diluted to a light-brown colour. This food should be given two or three times a week. The plants will now be benefited by plenty of atmospheric moisture during the day, but the conditions at night-time should be drier, when a little top ventilation may be afforded.

FIG. 48.—LÆLIO-CATTELEYA FELICIA: AWARDED A FIRST-CLASS CERTIFICATE AT THE MEETING OF THE R.H.S. ON JANUARY 26.

(See page 98.)

ceed in a smoky atmosphere, and for that reason they should be planted in town gardens. *Rosa rugosa* var. *Blanche Double de Coubert* is a very effective, double white variety, free in flowering and with very fragrant blooms. *Rosa rugosa atropurpurea* has carmine-crimson flowers. The *Penzance Briars* are an acquisition not only for their rich perfume but also because

The majority of the pot Roses should be brought into a cold house or frame in order that they may gradually be started into growth and pruned at intervals before being brought into heat. By this method the results will be much better, both in the quality of the growth and blooms, than if they are forced in excessive warmth. An atmospheric temperature

The early-grafted plants will now be ready for a shift into 5-inch pots, using good rich loam with a small proportion of decayed or spent hot-bed manure and a dash of river or washed sand. Pot firmly and afterwards place the plants well up to the glass. Keep the structure closed for a few days. After one watering at the roots a light syringing overhead will suffice for several

days, or until the new roots begin to ramify in the fresh soil.

Soft grafting will now be in full operation, and will continue until the supply of stocks is exhausted. The propagation of Roses on their own roots will follow. As a general rule, early in March is a suitable time for rooting the cuttings, as by then the bulk of the herbaceous grafting will be completed. If hot-beds are to be employed for the purpose, no time should be lost in getting the manure together. Horse manure, without straw, is the best material, and it should be turned over several times into a heap to ferment and dry. If the hot-bed is made up properly, it should, with an occasional lining of fresh material, furnish a steady bottom heat of 75°, declining to 65°, up till such time as the cuttings are well rooted. The depth of the bed at the back should be at least 3 feet 6 inches, with a fall of 6 inches to the front. The manure must be trodden firmly. The space required for a two-light frame will be about 8 feet by 10 feet. This will allow a clear margin of 1 foot all around the bed for fresh linings when the heat of the frame begins to decline. A two-light box frame is about 7 feet square, and the bed and frame must be adjusted to each other according to circumstances. I have used, with some success, hot-water circulating tanks under closed frames for propagating Roses from cuttings, but, on the whole, the old-fashioned hot-bed is the more satisfactory.

The Roses in borders will now be making good progress, and plenty of fresh air may be admitted by both top and bottom ventilators. Use the syringe freely to clean the shoots and to keep down insect pests. If mildew appears, paint the pipes with a solution of soft soap and sulphur. Towards the close of the day the atmosphere in the house should be kept dry.

Whenever possible soft water should be used for watering. At the present time it is advisable to give no more moisture than will be fairly absorbed by the evening. An occasional sprinkling of slacked lime over the surface of the beds and walks will, in a degree, neutralise any sourness in the old soil. The use of lime will counteract the growth of algæ; it will also sweeten the soil and be beneficial generally to the growth of the plants. *J. D. G.*

CYPRIPEDIUM "EARL OF TANKERVILLE."

THIS beautiful hybrid (see fig. 49) was raised by Messrs. Sander & Sons, St. Albans, from *Cypripedium exul* and *C. nitens* "Sander's variety." The raisers first exhibited the plant at the Royal Horticultural Society's meeting on January 9, 1906, when it was given an Award of Merit by the Orchid Committee. A part of the original specimen passed into the collection of Col. G. L. Holford, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), who exhibited it at the Royal Horticultural Society's meeting on January 26 this year, and from this plant our illustration was prepared. *Cypripedium exul* has never ranked high in the estimation of Orchidists, nor has it been of much value as an agent in hybridising. The present instance is, perhaps, the first really satisfactory cross, and in this case the good result has probably been due mostly to its combination with *C. nitens* "Sander's variety." There are numbers of hybrid *Cypripediums* with larger flowers than those of the Earl of Tankerville variety, but in form and marking it is difficult to imagine a more perfect bloom than that under notice. The flower is firm and wax-like in substance, with the dorsal sepal pure white, and a small, emerald-green base, bearing deep, chocolate-purple blotches, which change in the upper part to rose-purple. The remaining portion of the flower is yellow, tinged with purple-brown.

FLORISTS' FLOWERS.

SWEET PEAS.

It is a matter of some importance for cultivators to know that they are liable to purchase the same variety of Sweet Pea under more than one name. The descriptions in the catalogues may be a little differently worded, and this misleads the purchaser.

Amongst the best varieties for exhibition purposes and also for general garden decoration is one known as The King. This fine Sweet Pea has many good qualities in addition to that of size. It is a vigorous grower, and although some persons recommend it to be grown in slight shade I prefer planting it in an open position. The colour is best developed during bright weather, for in dull seasons the wings assume a magenta tinge that detracts from the appearance of the flower.

Mrs. A. Ireland is a new variety possessing good decorative qualities. It is the nearest to

ting near to obtaining a sun-proof scarlet. Prince of Asturias is a very fine chocolate-coloured variety. Not only are the flowers of a pleasing colour, but they are large and stout of petal. It should be grown for exhibition purposes, as the tone is suitable for mixing amongst lighter shades. The colour is pleasing even when seen in the flowers growing in the garden.

Paradise Ivory attracted much attention during 1908. This variety is wonderfully fine in flowering, the bloom being of a pleasing cream shade. The blooms are valuable when in the cut state, but the variety will be superseded, at least for show purposes, when Mrs. C. Curtis and the Primrose Spencers are better fixed. Mrs. J. Wilcox is the finest of the Spencer American type that I have noticed, and if the raisers can place a good stock of this variety upon the market they will earn the thanks of those who admire the striped forms of this flower. The growth is robust.

Evelyn Hemus is, without doubt, one of the

FIG. 49.—CYPRIPEDIUM "EARL OF TANKERVILLE": GRANTED A FIRST-CLASS CERTIFICATE BY THE ROYAL HORTICULTURAL SOCIETY ON TUESDAY LAST.

Jeannie Gordon of any of the Spencer form yet sent out. There are several other varieties described as nearly like this older variety, and when grown in comparison they will doubtless prove to be identical with it. Apple Blossom Spencer is, in my opinion, one of the finest Sweet Peas of recent introduction for planting in clumps in gardens. The flowers are less changeable in colour than those of many other kinds. This variety is very similar in many respects to Mrs. A. Ireland, yet quite distinct and altogether of a paler colouring. Some of the stocks of this variety are already quite fixed in character. George Stark is the finest scarlet variety yet raised. Seeds may not be had this season, as it is not yet placed in commerce. The flowers are not so affected by strong sunshine as others of a similar colour, and this is therefore a great advance in the direction of a "scarlet" that does not burn. There are several other seedlings which have the same good quality, thereby indicating that we are get-

most beautiful Sweet Peas ever raised. The colour of the flower blends and harmonises anywhere and everywhere, and never seems misplaced. The bine is healthy in growth, whilst the blooms withstand the weather well, although they are produced on long stems. Mrs. C. W. Breadmore need not be cultivated if Evelyn Hemus is grown, as they are very similar.

Elsie Herbert has qualities of habit and vigour equal to those of Evelyn Hemus, but the ground colour of the flowers is white instead of cream. The petals have a beautiful, pinkish edge, and it is the opinion of many that the variety is second to none for general beauty and usefulness.

The variety Constance Oliver has made a name for its raiser and is valuable to every exhibitor and lover of Sweet Peas. The long, strong flower-stems are crowned with mostly four, beautiful flowers of a creamy-yellow colouring suffused with an orange-pink tinge.

Etta Dyke has no equal amongst the white-flowering varieties, and may be relied upon to come true to character.

Mrs. Henry Bull is another of the cream-ground section that is finding general favour. In this section, although the differences in the flowers are not great, there is still sufficient distinction to allow of naming the varieties accurately at a glance. A cream ground suffused either with apricot-pink, orange-pink, or slightly-flushed pink is a very beautiful tone, and this type of Sweet Pea is valuable for all-round purposes.

James Grieve.—There are a few good stocks of this Sweet Pea which, when true to character, is not surpassed in depth of colour by any in the cream section. When seen growing in quantity the blooms present a somewhat greenish-yellow hue. The variety is very fine in flowering and forms one of the best of its colour for market purposes. Sweet Peas similar in character to Marjorie Willis are numerous, their nearest approach to colouring in the Spencer form is Prince of Wales. Most trade growers appear to have the type under varying names. At certain times, when at its brightest, the colour is pleasing, and the distinctive white blotch at the base of the standard adds to the effect. But there is a "Primula-sinensis pink" about the type that quickly fades into objectionable magneta shades, and the lower flowers upon the stem usually develop these shades before the top flowers are in perfection. If it can be shown on the same day as it is cut in large groups it is effective, but when sent the previous day from a long distance it is disappointing.

Maggie Stark may be classed with Helen Lewis. It is a variety with less substance in the petals than the true Helen Lewis, and somewhat brighter in colouring. Maggie Stark forms an effective variety for furnishing cut flowers, and may best be described as being between St. George and Helen Lewis. It is really a very greatly improved form of Evelyn Byatt. So far as I can discern, I cannot detect any difference between it and such varieties as Lord Althorp and Helen Grosvenor.

I should always include the variety Olive Ruffle in any collection of Sweet Peas. But it does not come true, and, like Audrey Crier, seems difficult to fix. At the same time it is a very desirable variety and deeper in colour than Constance Oliver and others of that class. The growth is of dwarf habit so far as I have observed. This does not affect the flower-stems or flowers which are mostly produced four upon each stem. There are other good varieties of recent raising, but as they are not all fixed or to be had in commerce, it would serve no useful purpose to write upon their merits. From my knowledge I may safely predict that the year 1909 will give us definite fixed improvements in some of the sections of this beautiful flower. Charles Foster.

NOTICES OF BOOKS.

* SCHOOL-GARDENING.

Those who have had to do with the organisation and management of school gardens know that many difficulties arise in the course of the work. The choice of ground is usually limited, the land is often in bad condition, and the work of the boys has to be arranged so that it will not interfere with their ordinary class work.

At the same time, if the teaching is to have any practical value, it is necessary that the ordinary routine of garden work should be followed as closely as possible, and this, with the rather uncertain supply of labour available, it is not easy to ensure. Above all, it is important that the best methods should be employed for carrying out even simple operations, and that some attempt should be made to explain clearly the meaning and value of each.

This little book is an attempt to meet such difficulties half-way. It contains little that is new, but offers useful advice as to the best methods of laying out school gardens and of planning the work. The descriptions and diagrams are clear, and should be of service, especially to inexperienced teachers.

A chapter is devoted to seed-sowing. The cultivation of the commoner garden crops is

* *School-Gardening*, by W. Francis Rankine. Pitman & Sons. Price 1s.

described at some length, and sufficient space is devoted to fruit culture, diagrams being given to illustrate correct methods of pruning, grafting and planting. Common diseases which attack garden crops are described, with their remedies, and lists of the best varieties are given in the chapters on fruit culture.

There is a short introduction by Mr. H. J. Wright, with whom we agree, that, in cases where the experience of the instructor has been limited through uncontrollable circumstances, this little work "should do much to establish the teaching on correct lines."

The Week's Work.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Roses.—The pruning of Roses trained on warm walls or planted in sheltered positions may be proceeded with. All dead wood and any weak growths should be removed. Train in strong, well-ripened shoots that may be required for furnishing the wall; any not required may be pruned to two or three buds. It is a good practice to train in some new shoots each year and to remove a corresponding number of the old ones, as this will impart fresh vigour to the plants. The shoots should be secured with tarred string, as this substance is more durable than ordinary string. Remove any of the surface soil that appears exhausted, replacing it with a fresh compost. Another plan of replenishing the soil is to make a trench at some distance from the stems and to refill it with fresh soil with which has been mixed a quantity of bonemeal.

Early blooming of Roses.—Among early-flowering varieties suitable for training against walls are Rosa sinica anemone (one of the very finest of all the early-flowering single Roses, the large petals being a delicate shade of pink); Viscountess Folkestone (creamy pink), Sunset (apricot), Niphotos (white), Catherine Mermet (pink), Reine Olga de Wurtemberg (red), Cheshunt Hybrid (maroon crimson, a fine variety for a wall), William Allen Richardson (deep orange yellow); L'Idéal (red, tinted yellow), Solfatare (sulphur yellow), Comtesse du Cayla (coppery carmine shaded with orange and yellow, an exquisite Rose when in the bud state), and Fulgens (crimson). The best-coloured blooms of the beautiful William Allen Richardson variety are obtained from plants trained against a west wall, which is also the best position for the well-known Maréchal Niel variety. The pretty and distinct Rose bracteata requires some slight protection in severe weather, and should always be planted against a warm wall. When the pruning and training of the Roses have been finished, the plants should be sprayed with a preparation containing nicotine, and another application should be given when the buds break into growth. This will ward off attacks of aphids.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Late-planted trees and shrubs.—Circumstances often necessitate the planting of trees and shrubs, the staking of trees, turfing, and other work being done late in the new year that would be better performed in the autumn. But with care such late work is generally successful, although the risk of failure is far greater as the summer approaches. In March late-planted trees and shrubs are often injured or killed by the cold winds.

Staking trees.—Standard trees should be secured to a stout stake immediately after planting; they will require special care in tying, so that the bark may not be injured by rubbing against the stake. The stems of all specimen trees planted by themselves should have from 7 to 8 feet of clear stem between the ground line and the branches; when less than this is allowed, there is a danger of the tops of the trees being broken by mischievous boys.

Best kinds of stakes.—The most serviceable stakes are Larch poles, with the bark intact, and the "ricker" poles, which, I believe, are of some imported coniferous tree. Both are straight and strong, and can be purchased in different sizes, ranging in length from 10 feet to 18 feet. The shorter lengths are best suited for newly-planted

trees, but for re-tying those that have been planted three or four years the taller stakes will be needed. Strips of sacking should, in all cases, be bound around the stem of the tree between the ligature and the bark. This will prevent injury from rubbing or from tightening of the string. Secure the plant very firmly as high up the stem as possible, using strong tarred cord for the purpose. Trees that have been planted a few years should have an occasional inspection to see that the string is not cutting into the bark. A young, fast-growing tree swells in girth considerably between the time of its planting and the time when it is stout enough to do without a support. During this period longer and stouter stakes become necessary, for when in full leafage the tree has to withstand a very great strain during strong winds.

Tree guards.—Some kind of tree-guard is necessary to protect Plane and other Avenue trees by the side of carriage drives. Ornamental guards are often employed, but a much less costly method of protecting tree stems is to place a narrow strip of small-meshed galvanised wire netting (usually about 18 inches wide) around both the stem and the stake. The netting should be made secure by lacing it together with wire.

RHODODENDRONS AND AZALEAS AS BEDDING PLANTS.

THERE is a varied assortment of flowering plants that will provide a display of flowers in spring, and a succession of bloom may be had from the time the earliest varieties of Narcissus and Tulips open until the summer bedding beautifies the gardens. We have, in addition to the spring bulbous flowering subjects, a large variety of "carpeting plants," such as Arabis, Myosotis, Violas, Polyanthus, &c.

It frequently happens that there is a time between the spring and summer displays when the beds are bare of flowers, especially if the weather is of such a nature that the work of planting the summer bedding subjects cannot be early proceeded with.

To avoid this "break" in flowering, I have for several seasons past filled a few beds with dwarf Rhododendrons and Ghent Azaleas. The showy flowers of these plants furnish a charming effect and one not easily excelled. Their flowering season follows that of the spring bedding plants, and they remain in bloom till the end of May or the first week in June. A few plants of Iris germanica mixed with the Azaleas enhance the effect. The bright purple flowers of the Irises provide a pleasing contrast to the soft shades of yellow, salmon-pink, &c., of the Azaleas.

After their flowering is over, the Rhododendrons are removed to the nursery, where they are planted in rows fairly close together. Directly they are planted the roots are given a copious watering, after which they are well mulched with manure, which, in addition to stimulating new growth, affords protection to the roots throughout the summer months. If a partially-shaded site is selected for them they will withstand the dry, hot weather of summer much better than if placed in an exposed position.

By the next autumn, flower-buds will have formed, and as new ones are produced each succeeding year the same plants can be used for several seasons. If two separate batches can be provided so much the better, as by using the plants in alternate seasons a period of 18 months in the nursery can be allotted to each, which is an obvious advantage. In the case of the Azaleas, the old shoots are cut hard back whenever the growth becomes irregular. By this method dwarf, bushy plants are maintained with plenty of healthy flowering growth. The Rhododendrons do not respond to this treatment quite so readily, but with the judicious use of the knife the plants can be kept dwarf and suitable for this method of planting for several years.

I have also used with good results for a similar purpose the light and graceful flowering Cineraria stellata, its beautiful shades of Aster-like flowers giving a charming effect. These, if raised from seeds sown about the end of July and grown in a cool frame or house, provide good plants for flowering during May. They can be plunged in pots, either in separate beds or mixed with other plants. If given a sheltered position, the Star Cineraria will continue to flower for three or four weeks. J. Rogers, Battersea Park.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Oncidium, &c.—The warmth-loving *Oncidium ampliatum* and the variety major will now be showing their flower-spikes, and the warm, moist atmosphere of the plant stove will be suitable for them until the flowers open, when they may be removed to a somewhat cooler structure. Immediately the spikes appear, water must be given sufficiently frequent to keep the roots moist. Plants of *O. Cavendishianum* that have their flower-spikes well advanced and are prominently showing their flower-buds should be placed in the warmest house, as the Mexican house, in which they made their growth, is rather too low in temperature for the proper expansion of the flowers. Any plants of *O. leucochilum*, *O. nigratum*, and *O. maculatum* that are showing their spikes and are at the warmer end of the *Odontoglossum* house should now be removed to the *Cattleya* house. Afford these *Oncidium*s sufficient water at the roots to keep the pseudo-bulbs in a fairly plump condition until the flowers open, when the quantity should be considerably lessened until growth recommences. Flowering plants of *Lælia harpophylla*, *Odontoglossum platycheilum*, and the cool-growing *Dendrobium tetragonum*, *D. æmulum*, *D. Kingianum* and its variety album, will also develop their flower-buds better if given similar treatment.

Odontoglossum citrosimum.—In the resting-house plants of *Odontoglossum citrosimum* are already starting into growth, but they should not be excited by heat or moisture to make any rapid advance, or they might grow away and fail to produce flowers at the proper season. Our plants of this species are in a dry atmosphere ranging between 50° and 55° at night, but rising several degrees by day with sun heat. They are kept in a comparatively dry condition at the root, thus causing the pseudo-bulbs to become somewhat shrivelled. Immediately the flower-spikes are seen pushing up through the centre of the new growths, the plants should be placed in a more genial atmosphere, and well supplied with water, after which, in a few days, the pseudo-bulbs will rapidly regain their former plump condition.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow Cornwall.

Stove foliage plants.—Such genera as *Alocasia*, *Calathea*, and *Maranta*, whose young leaves are mostly very tender, should be given any necessary repotting early in the year before the sun gains sufficient power to burn tender vegetation. The *Marantas* and allied plants are impatient of root disturbance, and it is usually the best plan to let them alone and be content with top-dressing those which are growing satisfactorily. At the same time, any plants in a poor condition or pot-bound should be repotted. A suitable soil is one consisting of peat, leaf-mould, and fibrous loam in equal quantities, with plenty of broken charcoal and sand. Potting must not be done too firmly. *Dieffenbachias* are more useful when dwarf, therefore the tops of the old plants should be cut off and rooted. Further stock may be obtained by cutting up the stems as in the case of *Cordylines*.

Caladium.—As soon as the tubers show signs of growing they should be potted. A suitable compost is one consisting of fibrous loam and peat (not finely broken up) in equal parts, to which should be added leaf-mould, dried cow dung, and silver sand. See that ample drainage is provided, as in the growing stage these plants require heavy waterings. After potting, place the plants in stove heat, applying but little water until they have developed foliage. A mild bottom heat, and frequent sprayings with tepid water, will induce free and vigorous growth. Keep the plants close to the glass, shading them only during the hottest part of sunny days: the humid atmosphere obtained by the frequent use of the syringe will prevent any burning of the leaves.

Eucharis grandiflora (amazonica).—Unlike most of the deciduous bulbs, this evergreen species is rarely grown for any particular season, so that no time can be stated for attending to their repotting. Except in the case of those which are showing flower scapes, it is usual to keep the plants slightly drier and cooler during

the winter. Plants which are doing well and flowering strongly at fairly regular intervals should not be disturbed, no matter how many years they have occupied the same pots, or how crowded the bulbs appear to be. The present, however, is a suitable time to repot those whose soil is in a bad condition. The bulbs should be washed free from the old soil in a pail of tepid water and repotted rather deeply in 10 or 12-inch pots, placing the bulbs closely together. Good loam, with one-fifth leaf-mould added and plenty of silver sand and some charcoal will be found a suitable soil. A plentiful supply of water is needed during the season of growth, but after the leaves have matured the plants require rather less water and a lower temperature.

FRUITS UNDER GLASS.

By E. HARRIS, Fruit Foreman, Royal Gardens, Frogmore.

Early Muscat vines.—When Muscat of Alexandria Grapes are required very early in the season, it is advisable that the vines be planted in inside borders only. By this system there is less chance of the vines receiving a check during the flowering stage. Before the vines burst into flower examine the borders, and, if dry, water them copiously with tepid water. It is not advisable to apply water to the vines when they are in flower, but it is equally bad for the borders to be dry. All laterals of a sufficient length to pinch should be stopped before the flowers expand. In most cases shoots should not be tied to the wires before the fruits have set. Care must be exercised to maintain an equable temperature in theinery when the flowers are shedding their pollen. A night temperature of 65° or 70° will be suitable. During the daytime the temperature may rise to 85° by sun heat, and this will cause no harm, provided there is no sudden fluctuation in the temperature, which can be prevented by giving close attention to ventilation. Let the flowers be artificially pollinated at mid-day by passing a rabbit's tail over them. The rods may be tapped occasionally also to assist pollination. Let the atmosphere be moderately dry, but should the surfaces of the borders become very dry they may be damped early on fine mornings.

Late Muscats.—As a rule theinery containing late Muscats should be prepared for forcing at the beginning of March. If it is deferred after that date there is a danger that the bunches may not perfectly ripen. Before starting the vines, thoroughly cleanse the house, and wash the rods with a mixture of soft soap and sulphur. Young vines when newly starting into growth are very subject to "bleeding." In such cases the cut surfaces should be dressed with Styptic.

The orchard house.—The buds on the trees, and especially those of Peaches and Nectarines, are swelling markedly. Therefore, the pots should be placed in position in the house, because if this is deferred the growing buds will be liable to suffer damage during the act of removal. Little pruning will be necessary if the shoots were properly stopped last summer, but any very strong growths should be pruned hard back and all weak growths not required for furnishing the tree removed altogether. In shortening the shoots, be careful to prune to a wood-bud, which can be easily distinguished from the flower-buds at this stage. Make a strong solution of soft soap and sulphur, and wash the stems with this mixture. Then place the trees on their sides and syringe the whole of the branches with similar mixture. Maiden trees should be cut back to five or six buds.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Strawberries.—The beds of established plants should be cleared of any dead leaves or other rubbish and the surface of the soil lightly dug with a fork; not deeply, or many of the roots will be injured. After this work is finished, and when the ground is hard with frost, sufficient manure should be wheeled on to the beds to provide a liberal dressing. In cases where the formation of new beds was decided upon last autumn, but it was found impossible to carry out the work at that time, the plants may now be planted. The land should first be trenched, working in plenty of farmyard manure as the digging proceeds. After the trenching has been done, a short time should

be allowed to elapse before planting the Strawberries, so that the ground may settle down again. Then spread some wood-ashes, lime, and soot over the soil and fork these in, not lower than the top spit. Consolidate the ground by treading, so that planting may be done firmly, and see that the crown of the plant is not placed lower or higher than the level of the soil. If it is decided to plant Strawberries next July or August, it is advisable to select the ground for the purpose now and to trench it as already recommended. In the intervening time the land may be cropped with early Potatoes. These will be ready for lifting in June and July, so that there will be plenty of time to get the ground into a proper condition for the Strawberries. This is a better practice than to leave the trenching until just before the ground is required for planting. Labour in summer-time is always scarce, and trenching is performed much better and quicker in cold than in hot weather. Plants that have been forced may be prepared for fruiting again in the autumn. They should be gradually hardened and planted out as early afterwards as safety will permit. Their chief requirements will be in the matter of watering till they are well established in their new quarters. In gardens where a number of young plants are planted each year, the runners should be layered as early in the season as possible, so that after they are well rooted they may be placed in their permanent quarters in good time. Such early-planted runners always produce the earliest and finest fruits. Royal Sovereign is one of the best varieties for early-fruiting, and I recommend Givon's Late Prolific for late-fruiting. Another late cropper is Laxton's Latest, a variety which will prolong the Strawberry season till the end of July.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Peas.—Suitable varieties may now be freely sown on ground in the open which has been deeply trenched and well manured. So many excellent kinds exist at the present time which are adapted for early crops, many being almost equal in point of flavour to the maincrop varieties, that gardeners may dispense entirely with the old round-seeded sorts. Wherever possible, I advise sowing the seeds in boxes, pots, or other suitable receptacles, raising them in a cool house, and afterwards, when thoroughly hardened, planting them out. Three or four sowings should be made in succession. For early use I prefer varieties which grow to a height of from 3 to 4 feet rather than the very dwarf kinds, although some of these latter are well suited for small gardens where stakes are difficult to procure. Suitable varieties for this sowing are Gradus, Early Giant, Early Morn, and Edwin Beckett. See that arrangements are made for trapping or destroying rats or mice. Plants which were raised early and which are growing in pots, boxes, or even planted out, under glass, should be top-dressed as required, and the growths neatly supported with stakes. Afford them all the light and air possible when the weather permits. Avoid hard forcing.

Broad Beans.—These should be sown at 1 inch apart in boxes and raised under glass for planting out. Select long-podded varieties. Batches of these Beans should be sown at intervals of from 10 days to a fortnight. I have always found that Beans do much better when transplanted than when allowed to remain in the ground where sown. They certainly come into bearing much quicker. Beans which may be growing in pots for supplying early crops should be assigned the coolest place. Place them quite near to the glass, where plenty of air can be admitted. Few vegetables are more easily injured by hard forcing than these, but most satisfactory results can be obtained if the plants are allowed plenty of air and a cool atmosphere.

Asparagus.—This vegetable can now be brought forward on mild hot-beds covered with portable frames. The chief requirement in the forcing of *Asparagus* is to place the roots in position and cover them immediately they are lifted, for if the roots are allowed to become dry the results are poor. Bury the crowns to a depth of about 3 inches and maintain a temperature of from 50° to 55°, which may be allowed to rise 10° more by sun heat in the afternoon after shutting up. The beds should be syringed twice each day.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, FEBRUARY 17—
Roy. Meteorological Soc. meet.

THURSDAY, FEBRUARY 18—Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39.5°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 10 (6 P.M.): Max. 41°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, February 11 (10 A.M.): Bar. 29.6; Temp. 43°; Weather—Dull.

PROVINCES.—Wednesday, February 10 (6 P.M.): Max. 47° Ireland S.W.; Min. 33° Yorkshire.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Border Plants and Perennials, Lilliums, Begonias, Azaleas, Ferns, &c., at 12; Roses and Fruit Trees at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

TUESDAY—

Unreserved Clearance Sale of Carnations and other Greenhouse Plants, Greenhouses, Piping, &c., at The Gardens, Warren House, Hayes, Kent, by order of the Executors of Martin R. Smith (deceased), by Protheroe & Morris, at 12.

WEDNESDAY—

Lilliums, Hardy Bulbs and Tubers, Herbaceous Plants, &c., at 12; Roses and Fruit Trees at 1.30; Palms, Plants, Ferns, &c., at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

A collection of Orchids from a private grower; also other Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Darwin Centenary.

The present year is the Anniversary of two events which are recorded for all time in the history of the world. On February 12, 1809, Charles Darwin was born, and 50 years later, in November, 1859, the *Origin of Species* was published. Therefore, we celebrate this year, in a twofold sense, the memory of Darwin: the centenary of his birth, the jubilee of the birth of his greatest work.

Though all will rightly claim to join in the celebrations, nevertheless, it is to the men who are occupied in laboratory, field or garden with the study of living things that the Darwin anniversaries will appeal with special force, for those whose occupations lead them to study Darwin's works in detail can appreciate most the compelling genius of the man. Each and every one of his published volumes would suffice to make or enhance the reputation of any professional man of science. The secrets which jealous Nature guarded since the world began are yielded up to the enchantment of his patient questioning. No aspect of Nature is too vast, nor none so small, for his enquiry.

Darwin's contributions to geology entitle him to rank with the great geologists. His contributions to zoology admit him to equality with the professors of that science. No contemporary botanist laid the science of botany under greater obligations than did Darwin. And beyond and above these several contributions to the individual sciences—contributions on coral reefs, cross and self-fertilisation of flowers, on Orchids, climbing-plants, earthworms, insectivorous plants, the expression of the emotions in man and animals, the power of movement of plants, and forms of flowers—there are his great works the *Origin of Species* and *The Variation of Animals and Plants Under Domestication*. Were they but mere compilations it had been no small feat for one man to publish such a mass of varied work. When it is recollected that all these special works contain the results of his own researches, then the outstanding ability of Darwin comes to be recognised.

Those great storehouses of facts, the *Origin of Species* and the work on variation contain, of course, much information collected from the most varied sources—not a little, as we are proud to remember, from the pages of this journal; but with what masterly generalship this motley array of facts is marshalled in ordered ranks! With what transcendent skill they are shown to contribute to the elucidation of that mystery of mysteries, the *Origin of Species*!

As when we are borne away from some rich landscape, the varied details merge in one another, and are lost, so, after some while of abstinence from reading Darwin's works, our memory plays us false, suggesting that his discoveries are concerned chiefly with variation. But when we revisit the landscape the details reappear the more strikingly in contrast with the illusion of sameness; so, as we turn the pages of this series of wonderful volumes, we realise that none but a genius could have produced work of such variety and worth.

There will be other opportunities during the present Anniversary year for considering in some detail certain of Darwin's several contributions to knowledge. In connection with the approaching celebration, the University of Cambridge is preparing a Darwin memorial volume—a testimony to the catholicity and profundity of his work. The publication of this volume will, in proving Darwin one of the most distinguished sons of Cambridge, reflect upon the University a lustre which time can never dull. Though the expression of genius is infinite in its variety, yet all men of genius have certain qualities in common: a singleness of purpose, an unquenchable truthfulness with respect to the work to be done, a power of imposing their influence on their fellow-men. All these attributes of genius are conspicuous in Darwin. His devotion to work, in spite of ill-health, in spite of the claims of family, in spite of easy circumstances, prove his singleness of purpose. His weighing of the evidence for and against his theories, his meticulous, sometimes painful care in saying only what he meant and no more, his ready admission of indebtedness to others, witness to his unflinching truthfulness.

His power of winning to his side the men

that count—Hooker, Huxley and Lyell—his power which is as strong to-day as ever of winning loyal and loving followers, testify to the magnetic influence which he exerts. But—and this is not so general among geniuses—Darwin was as great on the moral as on the intellectual side. To be great, said Whistler, is to be misunderstood, and, as ail the world knows, the *Origin of Species* evoked a storm of criticism. The survivors of those strenuous times must smile now when they recognise that, like other famous quarrels, this one was largely about words. No one can read the *Life and Letters* of Charles Darwin without venerating their subject. The biography is a contribution of the first order alike to literature and to science. It reveals Darwin's greatness, and from its perusal the reader rises up a better man.

We rejoice that this centenary is to be celebrated with due form and ceremony at Cambridge; we rejoice that Darwin's qualities were to such a high degree the expression of what we are fain to believe are typically British attributes—determination—it's dogged does it, as he used to say—love of fair play, steadfastness in friendship, and high courage. Our sole regret is that there should be no adequate national memorial to one whose works have contributed so much to the intellectual eminence of this country among the nations of the world.

The Royal Horticultural Society.

The proceedings at the annual meeting of the Royal Horticultural Society on Tuesday last were in every way satisfactory. The Report of the Council, which was published in these pages last week, shows clearly enough that the Society continues to enjoy unparalleled prosperity. That Report was so exhaustive that Sir Trevor Lawrence, who presided at the meeting, found little else to say regarding the year's work. In a few words, however, it was pointed out that a large measure of success has been already obtained at Wisley, and special reference was made to the work which is being done in connection with the Laboratory and in the training of students. Mr. Chittenden's trials with Nitro-Bacterine have been discussed in these pages, and in reference to these Sir Trevor Lawrence stated that in some experiments with Sweet Peas in his own garden at Burford, he obtained only the same negative results as have been reported by Mr. Chittenden.

In these days of motors, and other swift modes of conveyance, places that formerly were, to some degree at any rate, inaccessible, can be easily reached by considerable numbers of people, and it is a satisfactory circumstance that during the past year 11,000 visitors have been registered at the Wisley Gardens. These gardens have offered some valuable object lessons for practical gardeners; a remarkable instance occurred in the Vineries. The Wisley collection of Grapes is comprehensive, and the exhibit of numerous varieties in excellent condition which was made at one of the fortnightly meetings, was very creditable to the Superintendents responsible for their culture. In connection with the Society's examination, a considerable

development may be noticed in the arrangements that have been made for holding an examination in India at the invitation of the Indian Government.

Sir Trevor Lawrence referred to Sir Daniel Morris' appointment in connection with tropical agriculture, and Fellows will be glad that Sir Daniel Morris has again found it possible to accept a seat on the Council.

The intimation that the Council is taking steps to provide the Society with a first-class painting of Baron Sir Henry Schröder, Part., will be received with the utmost satisfaction. Baron Schröder's great liberality to the funds, and especially his munificent contribution towards the expenses of providing the Horticultural Hall, will ever be remembered with gratitude. But besides these acts of munificence Baron Schröder has exhibited from time to time magnificent collections of Orchids from his famous garden at Egham.

Mr. Gurney Fowler, in seconding the adoption of the Report, made one of those straightforward statements of income and expenditure that we have come to expect from the Treasurer. He told us that the surplus income over expenditure during the year amounted to £7,867. The receipts were £1,400 higher than in the previous year, but the expenses were increased only by £11. The income from subscriptions alone showed an excess of £1,000. In connection with this extraordinary growth in the Fellowship of the Society it is interesting to remark that since January 1 in the present year a sum of £10,483 has been received from annual subscriptions, this sum representing an increase of £843 over the amount received in the same number of days at the commencement of last year. A slight decrease in the receipts from shows is explained by the unfavourable weather which prevailed on several occasions during the time the exhibitions were open to the public. There has been a saving of £878 on the cost of the *Journal*, notwithstanding that four numbers have been issued during the year.

An interesting incident was the presentation by the President of two Veitch Memorial Medals on behalf of the Trustees, and two Victoria Medals of Honour, awarded by the Council of the Royal Horticultural Society. In order to show how worthily the medals were awarded, it is only necessary to say that the Veitch Medallists on this occasion were the Secretary of the Royal Horticultural Society, Rev. W. Wilks, and the Chairman of the Floral Committee, Mr. William Marshall. The Victoria Medals were presented to Sir Jeremiah Colman, Bart., whose magnificent exhibits of Orchids to the Society's meetings and to the Temple and Holland Park Shows have excited the greatest admiration, and to Mr. Charles Ross, who has enriched our collection of Apples to an extent unequalled by any other raiser. Particulars of the fruits raised by Mr. Ross have been printed in this journal.

Mr. Elwes initiated a discussion on the management of the Lindley Library, complaining that only £29 was spent by the Society in purchasing books during the past year. Several Fellows followed in a similar strain, showing that there is a real desire that the Library should be properly maintained and that it should be made as com-

plete as possible, particularly in works having the greatest horticultural value. The Rev. J. Jacob proposed that a sum of £1,000 should be taken from last year's receipts for this purpose. It was pointed out that the Library does not belong to the Society, but to Trustees, and therefore any money spent by the Society in the purchase of books is in fact a presentation to the Trustees. The Fellows appeared to think that these circumstances do not tend to the best interests of the Library, and it was suggested that the Society should commence the formation of a library which would be strictly its own property. This, however, might lead to considerable overlapping. If the discussion has the effect of stimulating the Council to increase its grants to the Trustees it will do good. We have again and again urged the interests of the Library, and we hope that the Council will treat this question in the most liberal spirit possible. The explanation of the present policy of the Council in saving several thousands of pounds every year, is that it is imperative to provide a satisfactory reserve fund. When this has been accomplished the Council will probably feel at greater liberty to adjust its income and expenditure in such a manner that there will be better provision even than now for carrying out desirable work for the extension of scientific horticulture.

FLOWERS IN SEASON.—Messrs. WILLIAM ARTINDALE & SONS, Sheffield, have forwarded flowers of their improved strain of *Primula obconica*. The blooms are exceptionally large for this species, and the colours are a great advance upon the rather washy magenta of the type. Some of deep rose-colour are especially pleasing. Messrs. ARTINDALE inform us that their plants have been continually in flower since last September, and that they are potted in ordinary soil and afforded a temperature of about 50°. The seeds were sown at periods from March to June.

BRITISH GARDENERS' ASSOCIATION (HASLEMERE AND DISTRICT BRANCH).—The next meeting of the Haslemere branch will take place on February 20, at 7.30 p.m., at the Co-operative Hall, Clay Hill, Haslemere, when Mr. GEORGE GORDON, V.M.H., will give a lecture on "Gardens of Roses," illustrated by limelight views. All professional gardeners are invited to be present.

NEW APPOINTMENT FOR SIR DANIEL MORRIS.—Sir DANIEL MORRIS, K.C.M.G., late Imperial Commissioner of Agriculture for the West Indies, has been selected for the newly-created office of Scientific Adviser to the Secretary of State for the Colonies on matters of an agricultural character relating to British possessions in the tropics.

LINNEAN SOCIETY.—The next meeting will take place on Thursday, February 18. A discussion on "Alternation of Generations" will be opened by Dr. W. H. LANG.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of this society will be held at the Institution of Civil Engineers, Great George Street, Westminster, on February 17, at 7.30 p.m. The papers to be read include: 1, "Report on the Phenological Observations for 1908," by Mr. EDWARD MAWLEY; 2, "The Cold Spell at the end of December, 1908," by Mr. WILLIAM MARRIOTT.

NATIONAL AURICULA SOCIETY (MIDLAND SECTION).—We are requested to announce that the dates of this society's show have been altered to Wednesday and Thursday, April 28 and 29.

THE INNES BEQUEST.—In our issue for January 30 was printed the details of the munificent bequest to horticulture made by the late Mr. INNES. In view of the importance of this bequest, the following biographical details are interesting:—The late Mr. JOHN INNES was born on January, 1829, and was educated privately at Brighton. At a comparatively early age he adopted a mercantile career, in the course of which he and his elder brother, the late Mr. JAMES INNES (of Roffey Park, Horsham), acquired a considerable amount of property in the City of London. In the year 1864 they became the founders of the City of London Real Property Co., Ltd., which continues as an institution of the highest repute. About the year 1867 the brothers acquired the Merton Park Estate, and from that date until his death the chief energies of Mr. JOHN INNES were directed to the development of that property, and the advancement of the welfare of the neighbourhood. Mr. INNES was the founder of the Boys' Club and the Manor Club, two institutions which have proved of the greatest advantage to the working classes of Merton, while the elementary schools of the parish were always the subject of his warmest interest. The Rutlish School, moreover, owes much of its success to the energy he showed when the ancient endowment was made available for starting it on its present successful career. It will be remembered that, under the scheme recently sealed by the Charity Commissioners, scholarships of the annual value of £154 are founded at the Rutlish School to be known as "John Innes' Scholarships." The sum available for the purposes of Horticultural Education and Research will yield an annual income of £5,500.

MR. GEORGE WYTHES, V.M.H.—Much sympathy will be felt with Mr. GEO. WYTHES, late gardener at Syon House, Brentford, in the bereavement he has sustained in the death of his wife on the 8th inst.

PRIZES FOR BEST CULTIVATED SMALL HOLDINGS.—The editor of *Lloyd's News* has sent us particulars of a new land culture scheme which our contemporary has promoted to advance the small holdings and allotments movement. The scheme has the approval of Earl CARRINGTON, President of the Board of Agriculture and Fisheries, who has described at a public meeting the conditions of the competition in Classes A, B, and C.

A GARDENER'S CATECHISM.—A correspondent has forwarded to us what we venture to think is a unique document. It consists of five folio pages on which are printed no fewer than fifty-eight questions which, as we gather, aspirants for the post of gardener to a particular employer are expected to answer before success can attend their applications. What they would be required to do afterwards is fortunately not stated. Anyone thinking of applying for the post must state, among other things, what has been his experience of pot Roses under glass; whether he has grown them to flower during November, December and January; the largest number brought into bloom for each month—scope here indeed—if the applicant had sole charge, if not, what charge—probably in the "counting house"—how long he had charge? Answers to the same questions must be repeated

for February, March, April and May. A similar series of questions relates to Roses planted out in borders under glass. With respect to Roses outside, only four questions are asked; for Tree Carnations seven, Souvenir de la Malmaison Carnations seven more. As to general greenhouse work, the applicant whose hand aches and whose head reels has to say what experience he has had with Ferns, bulbs, decorative and flowering plants for the house and general greenhouse work. Having done all this, the aspirant turns to the last page and finds it easy to answer the last ten questions: as to whether his knowledge of trees and shrubs is good, his experience of planting above the average, his knowledge of rock plants, also general outside gardening work, and of fruit cultivation under glass. His experience with Grapes, Peaches, Plums, Cherries; whether he has a good control of men and can get the full amount of work out of them, and whether he is strictly economical in his methods of working a place. Finally, this application-form concludes with a solicitous enquiry after the health of the applicant in the past and in the present. There is a silence, which can only be due to oversight or exhaustion, as to the future state of health of the successful applicant. Not a word occurs in the document on the subject of remuneration.

PUBLICATIONS RECEIVED.—*That Rock Garden of Ours*, by F. E. Hulme, F.L.S., F.S.A. With eight coloured plates and 42 illustrations. (London: Fisher Unwin.) Price 10s. 6d. net.—*The Journal of Botany, British and Foreign*, edited by James Britten, K.S.G., F.L.S. (February). (London: West, Newman & Co., 54, Hatton Garden, E.C.) Price 1s. 8d. **New York Agricultural Experimental Station, Geneva, N.Y.** Bulletin No. 304: Report of Analyses of Samples of Fertilisers collected by the Commissioner of Agriculture during 1908. Bulletin No. 305: Troubles of Alfalfa in New York, by F. C. Stewart, G. T. French, and J. K. Wilson. Bulletin No. 306: Control of Leaf Blister Mite in Apple Orchards, by P. J. Parrott. Technical Bulletin, No. 7: The Sporotrichum bud-rot of Carnations and the silver top of June Grass, by F. C. Stewart and H. E. Hodgkiss. Technical Bulletin No. 8: The Bacterial Flora of Cheddar Cheese, by H. A. Harding and M. J. Prucha. (Published by the Station.)—*The Agricultural Journal of the Cape of Good Hope*. (January, 1909). (Cape Town: Cape Times, Ltd.) Price 6d.—**U.S. Department of Agriculture, Bureau of Plant Industry.** Bulletin No. 135: Orchard Fruits in the Piedmont and Blue Ridge Regions of Virginia and the South Atlantic States, by H. P. Gould. Bulletin No. 137: Seeds and Plants imported during the period from January 1 to March 31, 1908. Inventory No. 14: Nos. 21,732 to 22,510. Bulletin No. 138: The Production of Cigar-Wrapper Tobacco under Shade in the Connecticut Valley, by J. B. Stewart. Bulletin No. 75, Part IV.: The Relation of the Etiology (cause) of Bee Diseases to the Treatment, by G. F. White, Ph.D. Bulletin No. 75, Part V.: A Brief Survey of Hawaiian Bee-Keeping, by E. F. Phillips, Ph.D. Bulletin No. 68, Part VIII.: The Grape-Leaf Skeletoniser, by P. R. Jones; Report of the Entomologist for 1908, by L. O. Howard. (From annual reports of the Department of Agriculture.) Circular No. 107: What can be done in Destroying the Cotton Boll Weevil during the Winter? by W. D. Hunter. (Washington: Government Printing Office.)—**Imperial Department of Agriculture for the West Indies.** Reports on the Botanic Station, Experimental Plots, and Agricultural Education, Antigua, 1907-8. (Barbados: Imperial Commissioner of Agriculture for the West Indies.) Price 6d.

A NOBLE AGAVE.

(See Supplementary Illustration.)

AGAVE ATTENUATA is a native of Mexico and has been known to cultivators since about 1834. It first flowered at Kew in 1861, after having been grown for many years in the Succulent House under the name of *A. glaucescens*. An excellent figure of this plant by Fitch was published in the *Botanical Magazine* in 1862 (t. 5333), where we are told that it was a very attractive

object during the whole winter. The expansion of the innumerable flowers on the long and singularly decurved spike was very gradual, and in August the spike still remained with a few imperfect capsules, and an immense quantity of young plants (bulbils) growing on the rachis. The leaves had by that time withered and the stem showed signs of decay, but suckers were produced from the base of the stem, and there was altogether a most abundant crop of young plants. The flowering of this species has been repeated at least half a dozen times at Kew since then, a plant of it being in flower in the Succulent House at the present time. This has a clear stem 7 feet long and an inflorescence about 9 feet long. Being monocarpic, the plant dies after once flowering. The prolific character of the inflorescence in this and other species of Agave should be borne in mind, a crop of bulbils usually being developed when the whole plant is in the last stage of dissolution.

The growth made by this species in New South Wales is sturdier than anything seen here. Messrs. Anderson and Co., of Sydney, state that the example shown in the Supplementary Illustration was planted in 1885, and that for many years it grew vigorously and was a magnificent specimen. The photograph was taken last July, when the flower-spike measured 12 feet in length and about 9 inches in diameter at the base. The flowers open slowly from the base upwards, the upper half of the spike as shown being still in bud; they are green, with yellow anthers. The small, supplementary spike shown in the illustration is noteworthy, being quite unusual. The leaves of *A. attenuata* are soft, fleshy, glaucous green and spineless; this and *A. Ellemetiana*, a near ally, being the only two broad-leaved species of Agave which have not spine-tipped leaves. The grandeur of the great Agave family has never been realised in British horticulture, always excepting the Tresco Gardens, where there is a good collection in magnificent condition. Where Agaves are allowed a little space they are usually half starved, being confined to small pots and wintered in sheds. They are not considered to be good enough for the glasshouse accommodation necessary for their full development; indeed, the few men who have thought such plants worth attention have been looked upon as "cranks." Still, Agaves are among the nobility of the vegetable kingdom, as anyone who has seen the collection at La Mortola and other places on the Riviera will admit. It would be difficult to find a more striking object or a more interesting plant than this example of *A. attenuata* must have been when it was in the full flush of its procreative effort. For 20 years it had made steady growth, and accumulated the life force which resulted in the putting forth in a few months of a pole-like spike bearing thousands of flowers to be followed by capsules of seeds and numerous bulbils. The curve in the spike is usual; one may wonder what it means. *W. W., Kew.*

LAW NOTES.

CLAIM FOR DISCOUNT.

At the Redhill County Court on the 3rd inst., Messrs. William Wells & Co., Chrysanthemum growers, Merstham, sued Mr. William Sydenham, of Tamworth, nurseryman, for £4 3s. 4d. for Chrysanthemums supplied. Defendant counter-claimed for £7 10s., agreed trade discount in respect of such Chrysanthemums, and £3 6s. 8d., the difference between the actual amount due for plaintiffs' account, and amount paid to plaintiffs generally on trading account.

Mr. William Wells said he had for some years supplied the defendant with ordinary Chrysanthemums, and allowed him the usual trade discount, but had refused to supply him with the novelties, as on a previous occasion defendant ordered 12 "Goacher's Crimson, 1902," but be-

fore he was supplied it was found that he had put them in his catalogue at 6d. less than he himself was offering them. When it was found out that he had been cutting prices, the plaintiffs refused to supply him. In each succeeding year defendant had made application for the novelties, but they refused to supply them until he agreed to ask the same prices as the plaintiffs in the second year. On November 15, 1906, defendant ordered certain Chrysanthemums from the catalogue, and plaintiff told him he would be supplied at a discount. On December 4 the plaintiffs issued a fresh circular, making a considerable reduction in the price of their "Early Singles," and on December 8, 1906, defendant wrote on the strength of this circular, ordering ten of each of their "Early Singles." In the circular, in notifying the reduction, the plaintiffs stated that no trade reduction would be allowed. The goods were supplied and the account delivered, to which the defendant took no exception, but on October 11, 1907, he sent £20 on account, and did not in any way claim a discount. He first raised a question about discount on December 18, 1907.

Mr. Hooper contended that the defendant had always been and was entitled to the usual discount.

His Honour gave judgment for the plaintiffs on the claim and counter-claim.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CHRYSANTHEMUM FRAMFIELD PINK.—The colour of this variety varies considerably. I have seen it at different places quite a good colour; but in these gardens we have never had any really pink blooms, they always came white, flushed with pink. I should advise Mr. R. Richards and Mr. T. Down to discard this variety, as I have done, in favour of Winter Cheer. It is very similar in growth; the stems are stiff, and the foliage remains more free from rust and mildew than some of the very late-flowering Chrysanthemums. The colour is a deep rosy-pink. I believe it is a sport from Framfield Pink, though the plants with us grow less tall than that variety. Winter Cheer succeeds best when potted singly in 6 and 7-inch pots, or three plants may be grown together in a 9-inch pot. For flowering at the end of December, the last stopping may take place at the beginning of July. If the flowers are cut immediately they are out they will last fully three weeks in water. The flowers may be disbudded to one on each stem, or they may be left in sprays, or the centre bud may be removed and the buds surrounding it left to flower. The former method produces the earliest flowers. Some very fine disbudded blooms were shown by a market-grower at the N.C.S. show in November last. *A. Jefferies, Moor Hall Gardens, Harlow.*

ERYNGIUM PANDANIFOLIUM.—I found this plant referred to by *J. G. W., Gardeners' Chronicle*, January 30, p. 76, in a garden in Jersey. The flower-heads are very small, about $\frac{3}{4}$ inch, and of no beauty; but the foliage is interesting as mimicking that of Pandanus in external form and internal structure, as both have long air chambers surrounded by similar cellular tissue. There are several species, e.g., *E. aloefolium*, more or less resembling monocotyledons in moist ground in Brazil. As air chambers are only characteristic of submerged plants, this group of Eryngiums corroborates the theory that monocotyledons were primitively derived from aquatic dicotyledons. We thus find many terrestrial plants retaining, by heredity, characters acquired when they were aquatic in habit. It may be noted that a leaf of a Banana has similar air chambers. *George Henslow.*

FREESIAS.—In reply to *W. R. H.*, p. 92, it is no uncommon occurrence here for Freesias to produce nine and ten blooms on an inflorescence, and occasionally we have had as many as 12 blooms on a single flower-spike. *Wilmot H. Yates, Rotherfield Park Gardens, Alton, Hants.*

—My batch of plants is flowering well this season. It consists of the same bulbs that I have used for seven years. The inflorescences on several of the stems bear 15, 12, 11, 10, and 9 blooms respectively. *R. A.*

GRAPE MILL HILL HAMBURGH.—As a rule I have great respect for the opinion of *E. M.*, but his remarks on p. 76 on this subject are certainly wrong. His description there agrees in every way with the Dutch Hamburg, a very inferior Grape (see Hogg's *Fruit Manual*, p. 384). I maintain that Mill Hill Hamburg has all the good qualities of the Black Hamburg, and the berries colour easier than those of that variety. *F. B. S.*

TWO HARDY WINTER GREENS.—Brussels Sprouts, Broccoli, especially the sprouting variety; most of the Kales and other green vegetables in general, have been much injured by frost in this district. On December 29 we experienced 29° of frost, when the plants were wet, and in consequence the damage was greater than if the foliage had been dry. Late Queen Broccoli and Hardy Sprouting Kale escaped injury, thus proving the extreme hardiness of these varieties. This hardy Kale is one of the most useful and reliable of winter greens. Other varieties, including the well-known Curled Kale, were damaged by the frost. *Wilmot H. Yates, Alton.*

TRENCHING.—Mr. Beckett (p. 76) says nothing as to how the first crops fared after trenching, although 2 feet of stiff clay had been brought to the surface, and this is the whole point of my objection. If there is a piece of ground at Aldenham with 10 inches of surface soil and 2 feet of heavy subsoil still untrenched, it would be interesting to see the first crops after it had been trenched. I quite agree with all Mr. Beckett says as to the value of, and necessity for, working vegetable quarters deeply, and fully recognise the good results that will be obtained after a few years, when the heavy material has been manured, broken up, and cultivated a few times; but the system I advocate, while producing the same result in the end, is much safer for the initial cropping. Since my former letter was written, two gardeners have furnished me with instances of failure through bringing the subsoil to the top. *A. Shakelton, The Gardens, Forde Abbey, Churd.*

I am pleased to read the testimony of Mr. Beckett at p. 76 as to the value of bringing to the surface the bottom layer of soil when land is trenched. Some persons appear to have a dislike bordering on dread at seeing the clay soil on the surface, forgetting or ignoring that it is amenable to a treatment in that position that will render it of immense value. What is so frequently termed "inert" soil is too often left below to remain inert. Many years ago, when in charge of a Sydenham Hill garden, I had to deal with a very tenacious kind of clay that formed part of the borings of the Penge tunnel. So unworkable was this clay that it was decided to burn it, and, with this heavy task accomplished, trenching was begun, and the lightly-burnt clay freely distributed as the work proceeded. In this way, and by adding all the light material available, this most tenacious of soils was rendered workable, and made capable of producing the finest crops. The benefits accruing from the burnt clay were a revelation to me, the soil being lightened, warmed, and drained by a single operation that was lasting in its results. *E. H. Jenkins.*

Had Mr. Beckett our soil to deal with, he would have been unable to follow his system, for nothing will grow in the subsoil, which is a barren, loamy sand, for a great number of years. When brought to the surface, even weeds cannot exist in it. *J. S.*

In recommending the raising of even the most unkindly of subsoils to the surface, Mr. Beckett is, perhaps, thinking of gardens where exceptional facilities are at command for carrying out the great amount of work necessary to render the soil suitable for an immediate crop. Having some knowledge of hard, impene-trable clods, which bake like bricks in the summer's heat when unalloyed clay is exposed by ordinary trenching, I am confident that a profitable crop of the majority of vegetables cannot be obtained in such ill-conditioned staple. If the trenched plot could be left fallow for a season, much might, of course, be done with it, but, failing this, double-digging seems the more rational course to pursue. Besides, those plots which the short-handed gardener finds time to deeply dig, are usually those upon which he relies for his best produce; he should certainly think twice before embarking on an enterprise

which seems likely to leave his soil in a worse state than before, especially if he has no ground to spare for experiment. Taking these things into consideration, I feel sure that I have misunderstood Mr. Beckett or, otherwise, that his advice was given subject to reservation. *Joseph E. Simms, Northwick Park Gardens, Blockley.*

HYBRID CYCLAMENS.—At the meeting of the Royal Horticultural Society, held on the 26th ult., a few flowers of some hybrid Cyclamens were shown by Mr. F. H. Chapman. These flowers were the result of crossing *C. ibericum* with *C. persicum*, and though not as yet of much merit horticulturally, they are of great interest, for it has long been supposed that *C. persicum* would not cross with any of the hardy species. It has often been attempted without success. In 1895, Sir W. Thistleton Dyer, in a communication to the Royal Society, gave an interesting sketch of the cultural evolution of the florist's Cyclamen. He chose this flower as being certainly of pure descent, in order to illustrate the view that evolution has proceeded by the accumulation of small "continuous" variations, rather than by sudden sports, or by natural hybridisation, and in the course of his remarks he said: "There is no question of hybridity; *Cyclamen latifolium* (*persicum*) has resisted every attempt to cross it with any other species." As he had consulted the leading growers, and relied especially for his facts on information supplied by Messrs. Suttons' hybridist, Mr. J. Martin, it may be assumed that they all concurred in this opinion. A year previous to seeing this, I fertilised a number of flowers of *C. persicum*, some with the pollen of *C. coum*, and some with that of *C. hederæ-folium*; but I got no seed at all from any of the crossed flowers. It may be noted that *C. ibericum* is one of the parents of the hybrid *C. Atkinsii*, the only one recorded in Johnson's *Gardener's Dictionary*; but other hybrids have been raised among the hardy species. Until they have been tested by further generations, and by repeating the original cross, caution is no doubt advisable with regard to the reputed hybrid parentage of these, as of any seedlings, even when every precaution has been taken. But Mr. Chapman is a careful and skilful hybridist, and, in the opinion of several experts who have seen the flowers, they are hybrids. Mr. Chapman has given me the following particulars of his crossings. He says: "I commenced three years ago, using *C. ibericum* roseum as the seed parent, and some large-flowered forms of *C. persicum* for pollen. The parent plants are in pans in a cold house, and the pollinating is repeated to a considerable extent. The first seedlings commenced to flower a year ago, and there was then no advance, but the colours varied. This year, a small proportion of the flowers are distinctly larger, but clumsy; the petals do not reflex neatly and regularly as in the seed parent, but flop about in an ungainly way. Those that resemble *C. ibericum* in other respects vary greatly as to colour." Though these seedlings of the first generation are not in themselves an improvement on existing forms, still, if they prove fertile, it may be hoped they will be the beginning of a race of hardy, large-flowered Cyclamens, with the same range of colour as now obtains in the florists' Cyclamen. It has yet to be proved whether the hybrids are hardy; but there is every reason, on Mendelian principles, to expect that, at any rate, they or some of their progeny will be. There is, likewise, the possibility of a correlation between size or colour and hardiness, so that only the smaller-flowered seedlings—those nearer *C. ibericum*—would be hardy, while the larger-flowered ones would retain the tenderness of *C. persicum*. But I think it is more probable that at least some among the seedlings will be found to combine the size and colour characters of the one parent with the hardiness of the other. Such a race would be a welcome addition to our early-flowering hardy border plants. *A. J. B.*

TRADE NOTICE.

MESSRS. NUTTING & SONS, LTD.

This private company has been formed with a capital of £20,000 in £1 shares to take over the business of seed merchants, carried on at 106, Southwark Street, S.E., as NUTTING & SONS, and to adopt an agreement with W. J. NUTTING, H. W. W. NUTTING, and H. R. NUTTING.

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 9.—The meeting on Tuesday last was the occasion of the annual general meeting of the Society, and, as is usual at this anniversary gathering, there was a fine display of exhibits of all kinds. No fewer than three Gold Medals were awarded—one for Orchids, another for cut flowers, and the other for a display of Apples. There was a good attendance of visitors. The only awards to novelties were conferred by the ORCHID COMMITTEE, which granted one First-class Certificate and two Awards of Merit; and, on re-consideration, the award granted to *Cypripedium* "Earl of Tankerville" (see p. 101, fig. 49) was raised to a First-class Certificate. The annual meeting took place at 3 o'clock. A short account of the proceedings is subjoined.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. C. T. Drury, Henry B. May, Jno. Green, T. W. Turner, G. Reuthe, W. J. Bean, J. T. Bennett Poë, J. Jennings, W. Howe, C. R. Fielder, R. Hooper Pearson, J. F. McLeod, R. W. Wallace, Chas. Dixon, Jas. Douglas, Arthur Turner, Chas. E. Pearson, Chas. E. Shea, W. Cuthbertson, F. Page Roberts, Herbert J. Cutbush, W. P. Thomson, E. H. Jenkins, M. J. James, George Paul, E. A. Bowles, and R. C. Notcutt.

An imposing display of Liliacs, Carnations and Daffodils was made by Mr. W. H. PAGE, Tangley Nursery, Hampton, for which a Gold Medal was awarded. The group was very large, and attracted much attention. There were bold stands, 5 or 6 feet in height, filled with choice blooms of *Lilium speciosum album*, *L. longiflorum*, and in the centre *L. speciosum*. Between these the exhibitor arranged vases of perpetual-blooming Carnations of varieties best suited for decorative purposes. The golden trumpets of the Daffodils showed in bold relief against the softer tints of the Carnations. The group was staged in an artistic manner.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, arranged an exhibit of greenhouse flowering plants, with many decorative Ferns and other suitable greenery. A novelty was seen in *Nottonia Grantii* from Uganda. The stem and foliage are succulent, as in some *Euphorbias*; the inflorescence consists of a head of small, red flowers, like a miniature *Nerine* set in an involucre. Other plants in the group were *Jacobinia coccinea*, *Colens thyrsoideus*, *Eupatorium vernale*, *Lopezia miniata*, &c. (Silver-Gilt Banksian Medal.)

Messrs. WM. CUTBUSH & SON, Highgate, London, N., displayed a very handsome exhibit of the perpetual-blooming Carnation, tall vases filled with large bouquets of such beautiful varieties as White Perfection, Fair Maid (pink), Victory (scarlet), Mrs. Burnet (salmon), with shorter receptacles containing a great number of other kinds, including the new Rose Doré, made a pleasing group. Messrs. CUTBUSH also showed a hybrid between the perpetual-blooming and the *Souvenir de la Malmaison* types named Lady Millar. The habit more nearly resembles the *Souvenir de la Malmaison* variety: the bloom is blush colour passing to a bright rose at the edge. The same firm also exhibited forced flowering shrubs and a rock-garden planted with many early-blooming Irises, Crocuses, Tulips, Hellebores, and other early-flowering plants. (Silver-Gilt Banksian Medal.)

Mr. H. BURNETT, Guernsey, showed beautifully-developed blooms of the perpetual-flowering Carnation, the colouring in the flowers being developed to a remarkable degree. The varieties were numerous and represented the best of those in commerce. (Silver Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, showed plants of the rose-coloured variety of *Daphne indica*, also a batch of *Cyclamen latifolium*, in which the Salmon King variety showed to advantage. The group also contained varieties with white, red, rose, crimson and other shades. On another table this firm made a very large exhibit of perpetual-flowering Carnations. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, showed an assortment of

greenhouse plants of both flowering and foliage types. In the centre of the display a batch of colouring was afforded by a group of *Rhododendron indicum*. There was also a batch of *Primula obconica* with very deeply-coloured flowers, and another of *Cyclamen latifolium*. Ferns of the elegant *Nephrolepis exaltata* Amerphofii, *N. e. Todeaoides*, *Adiantum gracillimum*, *Davallia epiphylla*, *Platyterium allicorne*, and other decorative varieties were intermingled in the group. (Silver Banksian Medal.)

Messrs. R. & G. CUTHBERT, Southgate Nurseries, exhibited a large floor group consisting mainly of forced plants of Lilac, Magnolia in variety as bushes and tall standard trees, *Forsythia suspensa*, Japanese Acers, *Prunus* species, *Pyrus floribunda* and *Azalea sinensis*. (Silver-Gilt Flora Medal.)

Messrs. SUTTON & SONS, Reading, showed an exhibit of *Primula sinensis* that occupied the whole of one of the longest tables. The plants were a very compact-growing type, with stout foliage and inflorescences carrying blooms of the largest size. They represented a mixed strain, in which were seen all the gradations of colouring formed in this useful winter-blooming plant; especially fine were those of crimson, rose, magenta and salmon shades. The exhibit was set forth in an attractive style, small Ferns, Palms and *Isolepis gracilis* being employed for relief. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, also exhibited a number of *Primula sinensis* in pots. The flowers were in most instances of fine quality and large size. The best white varieties were Moonlight and White Perfection; a fine outstanding pink-flowered variety was Pink Perfection. Other good varieties were Miss Caroline Ward (pink), Mr. Herbert Bennett (pale purple), Mr. J. A. Gardiner (a symmetrical flower of a bright pink tint), and Mr. Raphael (deep crimson). (Silver Flora Medal.)

Messrs. ROBERT SYDENHAM, LTD., showed Lily of the Valley in very fine condition, developed from retarded crowns. The pots in which these had been grown were without drainage material but contained moss-fibre.

Messrs. R. H. BATH, LTD., Wisbech, exhibited bulbous plants—Crocuses and Daffodils—grown in bowls containing moss-fibre.

Messrs. GEO. MOUNT & SONS, LTD., The Nurseries, Canterbury, showed a number of cut blooms of Roses, the varieties being Joseph Lowe, a new Hybrid Tea; Mr. W. J. Grant and Richmond. (Silver Banksian Medal.)

Mr. W. SEWARD, The Beeches, Hanwell, Middlesex, exhibited a large collection of *Cyclamen latifolium*. The inflorescences had a wide range of colour, whilst the leafage was dwarf and compact. The plants carried masses of blooms, and were capital examples of good culture. (Silver-gilt Banksian Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, showed a large number of plants of *Citrus japonica* as bushes beautifully fruited and their fruits approaching maturity. Mr. RUSSELL was likewise an exhibitor of a large number of the Witch Hazel *Hamamelis arborea*. (Silver Banksian Medal.)

Messrs. J. PEED & SON, West Norwood Nurseries, showed a rockery of rough stones planted in a natural manner with various species of Ferns, Sedums, bulbous plants, hardy species of *Cyclamen*, Narcissus, &c., intermixed with *Skimmias*, tree Ivies, *Bambusas*, *Ledums*, *Azaleas*, and *Cacti*. (Silver Banksian Medal.)

Mr. HERBERT CHAPMAN, of Rye, again showed his varieties of hybrid *Freesias*.

Messrs. T. S. WARE & SONS, Feltham, Middlesex, showed an extensive collection of *Primula obconica*. The plants had been selected for improvements in colour, size and form of the flowers, in height of the stalk and size of the trusses. (Silver Banksian Medal.)

Messrs. G. & A. CLARK, LTD., The Nurseries, Dover, arranged on the floor in a realistic manner a rock-garden exhibit. Separating the larger "bays" were grass paths and at appropriate spots, shrubs were utilised. The rockery was furnished with seasonable flowering plants. (Silver Banksian Medal.)

Mr. GEO. REUTHE, Keston, Kent, showed specialities in hardy-flowering plants, also Himalayan species of *Rhododendron*, *Daph-*

phyllum macropodum, *Lomatia pinnatifolia*, *Guevina avellana*, *Berberis japonica*, *Hamamelis arborea* var. *Zuccariniana*, *Berberis nepalensis*, *B. japonica* var. *Bealii* (with fragrant flowers), *B. dulcis nana*, and other interesting shrubs. (Bronze Flora Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., showed early-flowering hardy plants, including many tuberous and bulbous subjects. Amongst them we noticed *Iris reticulata*, *I. Danfordia*, a very dwarf species with intense yellow-coloured blooms; *Crocuses* in variety; *Snowdrops*, *Lachenalia*s, *Scillas*, *Freesias*, *Narcissi*, *Anemones*, *Adonis amurensis* and *Cyclamen Coum*.

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, showed species of *Crocus*, viz., *C. biflorus*, *C. Sieberi*, *C. Weldenii*, and *C. Imperati*.

Miss ALICE SMITH, Barnham, Bognor, made an interesting show of hardy *Primulas* and other flowers that had been grown in cold frames.

A small rock-garden exhibit was arranged by the Misses HOPKINS, Mere Gardens, Shepperton-on-Thames, with *Primroses*, *Daisies*, *Hellebores*, *Cyclamen Coum*, *Lithospermum prostratum*, &c.

Messrs. JOSEPH CHEAL & SONS, Crawley, displayed boxes of Alpine plants, also dwarf shrubs, including *Conifers*, suitable for the rock garden.

Plants of *Sarracenia purpurea* from the open garden were shown by Sir EDMUND LODER, Bart., Leonardslee, Horsham (gr. Mr. W. A. Cook).

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, Gurney Wilson, Norman C. Cookson, W. Bolton, H. Little, W. Boxall, J. Forster Alcock, Stuart Low, F. J. Hanbury, F. M. Ogilvie, G. F. Moore, J. Charlesworth, A. A. McBean, W. Cobb, W. P. Bound, W. H. Hatcher, H. Ballantine, H. A. Tracy, A. Dye, C. H. Curtis, H. G. Alexander, W. H. White, C. J. Lucas, and J. Wilson Potter.

Messrs. CHARLESWORTH & Co., Haywards Heath, were awarded the Society's Gold Medal for a display of Orchids, the middle portion of the group being composed of about 100 grandly-flowered specimens of *Phalaenopsis Schilleriana* literally laden with finely-developed, rose-pink flowers, borne on plants in the best possible condition of culture. Probably there has never before been staged at an exhibition such a magnificent display of this *Phalaenopsis*. In the centre was a selection of rare kinds, including the pure white *Phalaenopsis Schilleriana vestalis*, *P. intermedia Portei*, *P. Stuartiana grandis*, and others. At one end of the exhibit was a selection of *Laelio-Cattleya callistoglossa* and other *Laelio-Cattleyas*, a batch of the pretty *Cattleya Enid*, the scarlet *Renanthera Imschootiana*, the front portion of this group having an edging of the dwarf yellow *Oncidium cheiroporum*. At the other end was an excellent and varied display of hybrid *Odontoglossums*, also *Odontiodas*, *Brasso-Cattleya Queen Alexandra*, *Miltonia Hyeana*, &c. The whole display was edged with specimens of the brilliant scarlet-flowered *Sophranitis grandiflora*.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. Collier), exhibited a select group of rare and pretty species, including *Dendrobium macrophyllum*, the elegant white *D. aemulum*, *D. Kingianum album*, *Masdevallia cucullata*, with seven blackish-purple coloured flowers, *M. chimera*, and its variety *area*, *Restrepia striata*, two varieties of *Pleione yunnanensis*, and *Pleurothallis astrophora*, a very singular little species. Of hybrids there was a very fine specimen of *Dendrobium* raised at Gatton with large and beautifully-formed flowers; also *Phaio-Calanthe Colmanii*.

Col. G. L. HOLFORD, C.I.E., C.V.O., Westobirt (gr. Mr. H. G. Alexander), showed a noble plant of *Odontoglossum crispum-Harryanum* with four immense branched spikes bearing altogether 125 flowers, the largest spike having 61 blooms. The Lindley Medal was awarded to Mr. Alexander, the cultivator, for the extraordinary good culture seen in the specimen. The same exhibitor showed *Laelio-Cattleya Gold-*

finch superba (see Awards); *L.-C. Goldfinch* var. *Argus*, with bright chrome-yellow flowers with Indian-red coloured lip veined with gold; the beautiful *Cymbidium Holfordianum* with two flower-spikes; and *Cypripedium Helen II.* Holford's variety, a large, distinctly-spotted flower.

Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White), showed a fine branched inflorescence of the rare Mexican *Epidendrum erubescens*, which had been in bloom for many weeks, but was still perfect and with some flower-buds unexpanded.

Messrs. J. & A. A. McBEAN, Cooksbridge, were awarded a Silver Flora Medal for an elegant group of splendidly-grown white varieties of *Laelia anceps*, the flowers being large and finely developed on very strong spikes.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), received a Silver-gilt Flora Medal for a remarkable group containing many handsomely-blotched *Odontoglossums*, for which this exhibitor's collection is noted. Amongst unnamed varieties was a large-flowered *Odontoglossum crispum* with the inner parts of the segments of a deep reddish-purple, the like of which had not been shown before. Other choice plants noted were *O. crispum Mossiae*, with fine white flowers densely spotted with purple; varieties of *O. ardentissimum*; the new *Brasso-Laelio-Cattleya Cooksonii*, with yellow flowers heavily tinted with coppery-red, and which was obtained by crossing *Brasso-Laelia Gratrixiae* and *Cattleya Dowiana*; *Cypripedium Chapmanii* Oakwood variety, and others.

Messrs. CYPHER & SONS, Cheltenham, secured a Silver Flora Medal for an extensive group of choice *Cypripediums* which included *C. Mrs. Wm. Mostyn*, *C. Miss Louisa Fowler*, *C. Vandike*, and varieties of *C. aureum*. With these was a central arrangement of *Calanthe Bryan*, also hybrids of *Odontoglossum Pescatorei*, *Lycaste Skinneri*, *Angraecum eburneum*, *Vanda Amesiana*, and a bright display of the scarlet-flowered *Sophranitis*.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, obtained a Silver Flora Medal for a varied group, in which were *Cypripedium aureum Surprise*, *C. aureum virginale*, with eight flowers; *Saccolabium Harrisonianum*, *Dendrobium nobile virginale*, *D. speciosum*, *D. Wiganiae xanthochilum*, *Bulbophyllum cupreum*, and well-flowered plants of *Sophranitis grandiflora*.

Messrs. J. W. MOORE, LTD., Rawdon, Leeds, showed an interesting group in which *Cypripediums* were specially good. Amongst them were the beautiful, dark-tinted *C. Mrs. Francis Wellesley*, the fine *C. Tracyanum*, and a new form of *C. Harrisonianum*, or a closely-allied hybrid, with very dark and finely-formed flower; *C. Rothschildianum Dulcote* variety, *C. aureum compactum*, *C. a. Hyeanum*, *C. Sallieri* varieties, and *C. Chapmanii*. (Silver Banksian Medal.)

Messrs. JAS. VEITCH & SONS, LTD., Chelsea, were awarded a Silver Banksian Medal for an effective arrangement of choice *Odontoglossums* and hybrid *Cypripediums*.

M. MERTENS, Ghent, staged a small group of hybrid *Odontoglossums*.

Mr. F. McBEAN, Plumpton, showed varieties of *Cattleya Trianae* and *Odontoglossum crispum*. The *Odontoglossums* included a very pretty blotched variety, the markings being on a clear white ground.

The Duke of MARLBOROUGH, Blenheim Palace (gr. Mr. Hunter), sent *Cattleya Trianae* "Blenheim variety," a large and finely-coloured flower.

J. FORSTER ALCOCK, Esq., Exhims, Northchurch, showed *Cypripedium Helen II.* Exhims variety, *C. Leoniae Gratrix*'s variety, and *C. Leander* Exhims variety. (See Awards.)

W. BOLTON, Esq., Wilderspool, Warrington, sent *Cypripedium Iris magnificum* (Chamberlainianum magnificum × *Maudiae*), a very distinct flower, much larger than *C. Chamberlainianum*. The round dorsal sepal is white with a green base and has a dark purple centre with lines of the same colour. The lip is large and densely spotted with rose. The petals are broad but with some undulation as in *C. Chamberlainianum*, yellowish and veined with dark purple.

Sir W. MARRIOTT, Down House, Blandford, sent cut spikes of *Sophranitis-Cattleya Warn-*

hamiensis var. Cerise, and Sophro-Lælia Marriottiana.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, showed a notable example of *Cypripedium Euryades* "New Hall Hey variety."

Messrs. DUCHESNE, Watermael, Belgium, sent *Cattleya Schröderæ* The Giant with many large flowers of a uniform pale lilac tint, and of good shape.

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Black), sent his form of *Odontioda Bradshawia*, which has slightly broader segments and different red markings to the original plant of this raising.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum ardentissimum "Phæbe," from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman). A very beautiful form with new features in this variable hybrid, the flowers being of a deep reddish claret colour on the inner halves of the segments: the tips and margin pure white. The lip is also finely developed and distinctly marked.

AWARDS OF MERIT.

Lælio-Cattleya Goldfinch superba (L.-C. *Warnhamiensis* × C. *Dowiana aurea*), from Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. J. Chapman). A charming and profuse-flowering hybrid with bright yellow sepals and petals, and deep crimson-purple lip with orange lines at the base.

Cypripedium Leander "Exhims variety" (*villosum* × *Lecanum* variety), from J. FORSTER ALCOCK, Esq., Exhims, Northchurch. A handsome flower, with a large circular, white dorsal sepal that is blotched with deep rose-purple. The broad petals and lip are of a yellow shade tinged with light purple.

Fruit and Vegetable Committee.

Present: G. Bunyard, Esq., V.M.H. (Chairman); and Messrs. J. Cheal, W. Bates, G. Woodward, A. Dean, A. Beckett, A. R. Allan, H. Parr, G. Hobday, H. Hooper, J. Davis, W. Crump, C. Foster, J. Jacques, G. Kelf, J. Lyne, J. McIndoe, W. Poupert, H. S. Rivers, O. Thomas, C. G. A. Nix, P. D. Tuckett and G. Reynolds.

Prior to the commencement of business, it was decided that the secretary should send to Mr. G. Wythes, V.M.H., sympathy and condolence on the death of Mrs. Wythes.

The competitive classes in Late Pears brought four single dishes only, no entries being seen in the other classes. Lord FOLEY, Ruxley Lodge, Esher (gr. Mr. Gardiner), won the 1st prize with fruits of Glou Morceau; 2nd the Dowager Countess of ILCHESTER, Holland House, Kensington (gr. Mr. C. Dixon), with fair samples of Easter Beurré. Other varieties shown were Josephine des Malines and Bergamotte d'Espéren.

A few seedling Apples were presented, but none merited an award. One sample shown as new was Annie Elizabeth.

Mr. J. R. ALLAN, Osberton, Worksop, sent six good pods of *Vanilla planifolia*, for which a Cultural Commendation was awarded.

Messrs. G. BUNYARD & Co., Maidstone, staged a superb collection of 150 dishes and varieties of Apples. The whole collection presented an object-lesson as to the wealth of fine varieties suitable for late keeping, and the effectiveness of such storing as is adopted in the Allington Nursery. Amongst dessert varieties were Cox's Orange Pippin, Cornish Aromatic, Brownlees' Kusset, Mother Apple, Adams' Pearmain, Baumann's Reinette, Dutch Mignonne, King's Acre Pippin, Lord Hindlip, Scarlet Nonpareil, Braddick's Nonpareil, and Barnack Beauty. Of kitchen Apples the following were seen in excellent samples:—Smart's Prince Arthur, Golden Noble, Annie Elizabeth, Bismarck, Lane's Prince Albert, New Hawthornden, Alfriston, Lord Derby, Newton Wonder, Belle de Pontoise, Bramley's Seedling, and Hornead Pearmain. (Gold Medal.)

Messrs. JAS. CARTER & Co., High Holborn, staged a very fine collection of some 160 dishes of Potatos. Many white-skinned Potatos differ very little in the tuber, and thus in a large collection such as that exhibited by Messrs. CARTER, many necessarily bear a close resemblance to each other. That is par-

ticularly the case with the Up-to-Date strain. The chief test of distinctness is necessarily found in their habit of growth, season of cropping, &c. Amongst the white-skinned varieties were noticed Abundance, Factor, Maincrop, Dalmeny Radium, and Langholme Model; whilst of coloured varieties we may instance Mr. Breese, King Edward VII., Sunrise, Purple Perfection, Queen of the Veldt, Ruby Queen, Vicar of Laleham, and Sunrise as notable kinds. (Silver Knightian Medal.)

Messrs. CARTER, PAGE & Co., London Wall, sent a dozen punnets of very excellent and capitally-blanched Seakale of the old variety; also roots trimmed ready for forcing, and a few root cuttings. (Cultural Commendation of Horticulture.)

Mr. C. FOSTER, assistant director of Horticulture, University College Gardens, Reading exhibited a collection of forced vegetables of high merit, including capital Seakale, Linnaeus and Albert Rhubarbs, Witloof Chicory, Eclipse Tomatos, Golden Frame and Paris Frame Cabbage Lettuces, and some roots and crowns of Asparagus, showing one, two, three, four and five-years-old specimens. The Asparagus formed a valuable object-lesson in its development. (Silver Banksian Medal.)

THE ANNUAL MEETING.

The one hundred and fifth Annual General Meeting of Fellows took place in the Lecture Room at three o'clock. The President, Sir Trevor Lawrence, Bart., occupied the chair, and he was supported by the members of the Council and a representative gathering of the Fellows. The first business was the submitting of 72 names for Fellowship, and these were elected.

Sir Trevor Lawrence, in moving the adoption of the report, stated that there could be few Fellows who were not fully satisfied with the good work the Society had done and is continuing to do. It was a matter of satisfaction to the Council that the School of Horticulture at Wisley had attained to so high a position of efficiency in the short time it had been established. The report by the Government inspector was very gratifying. The scientific director had conducted some important experiments, including some with the nitro-bacterine on leguminous crops. Sir Trevor Lawrence stated he had conducted a small experiment of a similar nature with Sweet Peas, and his results were similar to those obtained by Mr. Chittenden.

The President referred to the excursion of the Council and committees to Windsor, and he had written to Sir Dighton Probyn expressing the admiration of himself and the other members of the party at the excellent manner in which the gardens were maintained in all departments, reflecting credit on the head gardener, Mr. MacKellar. The number of visitors to the gardens at Wisley had shown a great increase, and he referred to the excellent labours of the superintendent, Mr. Wright, and the garden staff generally.

The Society had sent deputations to important provincial flower-shows, and Sir Trevor Lawrence referred especially to the exhibition at York, which he declared was one of the finest shows he had attended.

The educational side of the Society, as carried on in the numerous examinations held under its auspices, had great value and importance. He had pleasure in announcing that the Indian Government had requested the Society to undertake an examination in India. The members were to be congratulated on the fact that Professor Hugo de Vries had consented to deliver two lectures in connection with the Masters Memorial. Referring to the late Mr. George Nicholson, it had been decided to perpetuate his memory by awarding annual prizes in connection with the students' work at Wisley. The number of Fellows was nearly 11,000, which was the largest membership of any Royal society in the United Kingdom. The Council desired to express their sense of gratitude to the secretary and other members of the permanent staff. Sir Trevor Lawrence next presented the Veitch Memorial and Victorian Medals to the Rev. W. Wilks, M.A., Mr. William Marshall, V.M.H., Sir Jeremiah Colman, Bart., and Mr. Chas. Ross respectively. The speaker next referred to the indebtedness of the Society to Baron Schröder, and it was with pleasure he announced that Baron Schröder

had allowed them to copy Professor Sir Hubert von Herkomer's portrait of himself to hang in the Hall. The President concluded by thanking the members of the committees and those who had read papers at the afternoon meetings.

The Hon. Treasurer, Mr. Gurney Fowler, in a very lucid manner referred to the financial position of the Society, and stated that whilst the receipts had increased by £11,000, the expenditure had exceeded those of the previous year by only £11.

Mr. H. J. Elwes, F.R.S., regretted that no remark on the Lindley Library was contained in the report. The sum of £29 expended during the year on the library was totally inadequate.

The Rev. J. Jacob supported Mr. Elwes in his appeal for the library, and suggested that the Council should apportion a sum—say, £1,000—to purchase books as occasion arose.

The President replied that the library was the property of the Lindley Library Trustees, and the Society was only in the position of custodians. He deprecated any sum being earmarked for the library.

Mr. J. McIndoe expressed regret that the Society undertook such work as the inspection of gardens, &c., in competition with those Fellows who were professionally engaged in this work as a means of livelihood.

LINNEAN SOCIETY.

JANUARY 21.—At a meeting held on this date Dr. Otto Stapf, F.R.S., Sec.L.S., exhibited male and female specimens of *Plagianthus Helmsii*, F. Muell. and Tate, and demonstrated with the aid of lantern-slides their peculiar leaf and floral structure, pointing out, at the same time, that it appears more natural to treat this species together with *Plagianthus microphyllus* and *P. squamatus* as members of a distinct genus, for which Mueller's name *Halothamnus*, originally applied to *P. microphyllus*, would have to stand.

The paper by Mr. A. W. Hill, M.A., F.L.S., entitled "The Genus *Nototriche*, Turcz.," was illustrated by specimens and lantern-slides. The genus *Nototriche* (Malvaceæ) includes some 70 species formerly placed in the genus *Malvastrum*, A. Gray. It is distinguished especially by the absence of an involucre and by the adnation of the peduncles and stipules to the petioles. The species are determined very largely by the character of the leaf lamina, which may be palmatifid or palmatisect, pinnatifid, bipinnatifid, or variously dissected and lobed. The shape of the stipules and the nature of the stellate hairs are also of value for taxonomic purposes, each species being found to have a definite and characteristic tomentum. Two types of flower are found in the genus: in the one case the petals are almost free, and are fused with the staminal column only at the base; in the other, including the majority of the species, there is a definite tube formed by the fusion of the petals with the staminal tube. At the base of each calyx-segment there is a glandular nectary. The carpels are beaked and dehiscent, and are often provided with long, silky, stellate hairs. In the paper several new species are defined, and the descriptions of those already known have been amplified and rewritten. The genus ranges from the north of Ecuador to the Cordillera of Santiago in Chili, some species being found in the Cordillera of Western Argentina. Only two annual species are known. The vertical range of this genus lies between 3,900 and 5,700 m. in Tropical South America, and is about 2,500 m. in Temperate South America. The highest recorded species are *N. flabellata* and *Friesii*, which have been found between 5,600 and 5,700 m.

The second paper, on the "Longitudinal Symmetry of Centrospermae," by Dr. Percy Groom, F.L.S., was also illustrated by curves shown on the screen. By means of measurements of many stems—primary, secondary, tertiary, and quaternary—of one species, *Atriplex rosea*, and of other *Chenopodiaceae* genera, namely, *Salsola* and *Chenopodium*, additional evidence is given that the internode-curve of alternate-leaved *Chenopodiaceae* is always of a zigzag nature, and can be analysed into two sub-curves. Of these, one represents the displacements of the leaves from the originally opposite arrangement at the successive nodes, and the other indicates the lengths of the modern representatives of the original internodes. In order to test whether or

no opposite phyllotaxis was the original type of arrangement throughout the Centrospermæ, and alternate phyllotaxis derivative therefrom by relative displacement of the leaves, measurements were made of the stems of various Caryophyllaceæ, Aizoaceæ, Amarantaceæ, Phytolaccaceæ, and Portulacaceæ. It is found that, throughout the cohort, in the case of opposite-leaved species, the internode-curves are regular or tend to be so, whereas, in alternate-leaved species, the internode-curves are invariably irregular. The irregular zigzag internode-curves of the latter species when analysed into two sub-curves, generally yield two more or less regular or consistent curves, which largely conform with those of corresponding stems belonging to more typical herbs.

The irregularities of the internode-curves of the alternate-leaved species are different, often utterly so, from those of the opposite-leaved species: the irregularities of the former are sudden, recurrent, and often very ample, whereas those of the latter are more gradual, less numerous, and probably largely due to the influence of external variations, which are not periodic.

LEEDS PROFESSIONAL GARDENERS'.

This gardeners' benefit society is a branch of the Grand United Order of Odd-Fellows. Gardeners between 18 and 40 years of age, residing in any part of the United Kingdom, are eligible for membership, but prospective members must have been engaged for at least three years successively in some branch of horticulture.

The forty-second annual report shows that 16 members have received sick benefits during the past year, the total amount paid to them being £71 0s. 10d. £20 has been paid in funeral allowances, making the total amount paid out of the benefit fund £91 0s. 10d. This fund now amounts to £1,564 13s. 11d., an increase during the year of £82 2s.

The amount of the distress fund is £3 3s. 4d., an increase of £1 6s. 2d., making a total increase in the whole of the funds or total saving for the year, of £83 8s. 2d.

Fifteen new members have been enrolled, two have died, and three have resigned. The membership totals 147, an increase of 10.

At the annual dinner, held on February 12, the Grand Master, Mr. George Bumby, on behalf of the members, presented to Mr. James Inman a framed emblem of the order as an appreciation of the long and valuable services he has rendered to the Lodge.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 21.—There was a good display of plants at the meeting held on this date.

In my last report I omitted to include a notice of a fine group of *Cypripediums* shown by O. O. WRIGLEY, Esq., Bury (gr. Mr. Rogers).

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), received Awards of Merit for *Cypripedium* × *Lilie* Mayall, and *Odontoglossum* × *Lilie* Mayall.

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), exhibited *Cypripedium* × *Ville-actæus*, to which an Award of Merit was given.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), exhibited a group of *Cypripediums*, to which a Silver-gilt Medal was awarded. The plants in the group were mostly well-known hybrids.

Mr. JOHN ROBSON, Altrincham, was awarded a First-class Certificate for *Odontoglossum* × *Wardiae*, a fine, bold, richly-coloured flower.

N. GALLOWAY, Esq., Great Horton, Bradford, was awarded a Bronze Medal for a group of *Cypripediums*, including *C.* × *Charlesianum*, *C.* × *Adrastus* var. *Marie*, and *C.* × *Lucienianum* var. *superbum*.

Mr. W. SHACKLETON was awarded a Bronze Medal for a group of *Cypripediums*.

A. WARBURTON, Esq., Haslingden, exhibited a group of *Cypripediums*; two new varieties of (*C.* × *Euryades*, viz., *C.* × *Euryades* var. *Tantalus* and *C.* × *E.* var. *Jacquard*, received Awards of Merit. (Silver Medal.)

C. PARKER, Esq., Preston, was awarded a Bronze Medal for a small exhibit of *Cypripediums*, which included some well-known forms of *C. insigne*.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), gained a Silver Medal for a group of *Lælias* and *Cattleyas*, amongst which were some well-flowered varieties of *Lælia anceps*. *Cattleya Trianae* var. *Donald* received an Award of Merit.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), staged a group of *Odontoglossums*, including the pure white *O.* × *ardentissimum* and several interesting hybrids. (Silver-gilt Medal.)

H. ARTHUR, Esq., Blackburn, was awarded a Bronze Medal for a small miscellaneous group of Orchids.

Messrs. JAMES CYPHER & SONS, Cheltenham, showed some noteworthy *Cypripediums*, *Lælias*, and *Cattleyas* in variety.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Fletcher), was awarded a Silver Medal for a miscellaneous display, in which were noticed several *Odontoglossums* of good quality.

Messrs. HUGH LOW & CO., Enfield, exhibited several choice varieties of *Cattleya Trianae*. P. W.

ABERDEEN CHRYSANTHEMUM.

JANUARY 30.—The annual general meeting of this society was held in the Christian Institute, Aberdeen, on this date. Mr. Andrew Davidson, chairman of directors, presided. The annual report stated that on the second day of the November exhibition unfavourable weather was experienced, and this was mainly responsible for a loss of £29 5s. 10d. The balance-sheet of the society shows £300 5s. 6d. assets: the expenditure for the year has amounted to £204 2s. 10d., leaving a balance in favour of the society of £96 2s. 8d. Hope was expressed that the members would endeavour to enlist the interest of their friends in the society, and thereby increase the membership and strengthen the financial position. The officers were elected, Mr. M. H. Sinclair being again appointed secretary.

SCOTTISH HORTICULTURAL.

FEBRUARY 2.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on this date. The president, Mr. Whytock, occupied the chair, and he gave a short opening address to a large gathering of the members. Mr. Whytock dealt chiefly with the position of the private professional gardener as it is affected by the market grower of to-day. Flowers and fruits can be purchased at very cheap prices, and at all seasons of the year, but a private garden properly equipped would yield produce of better quality and at a cheaper rate than could be procured by purchase. It was to be regretted that the flower shows in Edinburgh, which for many years past had been the most enjoyable meetings of the year, had undergone changes in their character, for there was a demand on the part of the public for other popular attractions in addition to the horticultural displays.

Mr. E. L. Brown displayed a series of photographs of flowers, fruits, &c., in their natural colours, obtained by means of the Lumière plates. Mr. Brown pointed out the advantage of these plates over ordinary ones.

Flower-spikes of *Moschosma riparium* were exhibited by Mr. W. T. STAWARD, Belford Hall, Northumberland, and Mr. JAS. L. SCARLETT, Sweethope, Musselburgh, exhibited and explained the "Symphonia" plant sprayer.

Twenty-five new members were elected. The paper at the meeting on March 2 will be by Mr. John Hunter, F.I.C., County Analyst, Edinburgh, on "Soil Science."

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 8.—The monthly committee meeting of the above society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on this date. Mr. Chas. H. Curtis occupied the chair. Eleven new members were elected. Two members were allowed to transfer from the lower to the higher scale. The annual meeting will be held at the above-named Hall on Monday, March 8 next, at 8 p.m.

NATIONAL FRUIT GROWERS' FEDERATION.

(ANNUAL MEETING.)

FEBRUARY 8.—The annual meeting of the National Fruit Growers' Federation was held on this date at the Royal Horticultural Hall, Westminster. Col. C. E. Warde, M.P., presided. The annual report showed that the members number about 400. The Council have secured the services of Mr. E. S. Salmon and Mr. F. V. Theobald, of the South-Eastern Agricultural College, Wye, as hon. advisors in mycology and entomology. The Council will appoint a member on the "John Innes Trust." Matters the society have considered include the increase of "black scab" in Potatoes, the rating question, and late delivery in the markets by the railway companies. In consequence of the Council's representation, the Board of Agriculture has removed the restrictions prohibiting the importation of Black Currant trees.

The report was adopted, and officers were re-elected. Mr. George Bunyard, V.M.H., and Mr. F. S. W. Cornwallis were appointed vice-presidents.

At the conclusion of the ordinary business various papers were read, including one by Mr. C. S. Martin, manager of the Toddington Orchard Co., Winchcombe, on "The Sale of Fruit and Vegetables by Weight." The most important difference of opinion arose over the standard weight of the half sieve for Plums, Cherries and Gooseberries. It was the opinion of the meeting that the weight should be 24 lbs. in the case of these fruits. In the case of light fruit the sieves should be uniformly filled and the net weight declared. As regards Strawberries, the opinion prevailed that the gallon basket should contain 5 lbs. and the chip basket 6 lbs.

Mr. A. D. Hall, Rothamsted, gave an address on the soils of the fruit-growing areas in Kent, Surrey and Sussex.

At the afternoon session a paper by Mr. A. Griffith was read on the committee's recommendations on rating and taxation.

HEMEL HEMPSTEAD HORTICULTURAL.

At the annual meeting of this society held recently, it was decided to hold a special Rose and Sweet Pea show on July 7, and a general flower, fruit, vegetable and farm produce show on August 18—this being the Jubilee year of the society. The subscriptions for 1908 show an increase of £22 over those of the previous years. The hon. secretary, Mr. J. W. Burrows, of Standish Gardens, stated that the society has a balance of £24 on the year's working. Mr. Burrows was again elected hon. secretary and collector, and he was given an honorarium of £10 10s. J. R. Drake, Esq., of Gadebridge Park, was elected president for 1909.

Obituary.

GEORGE A. DICKSON.—The announcement of the death of Mr. Geo. Dickson, head of the firm of Messrs. Dicksons, Nurserymen, Chester, will be received with regret. Deceased had been ailing for some time past, but was at business in the early part of last week; later, however, he was taken ill with an attack of pneumonia, and passed away at his home, Springfield, Newton, Chester, on Saturday, February 6. The late Mr. Dickson was born at Chester 74 years ago. He entered the Chester City Council in 1879, was elected mayor in the year 1886, and alderman in 1896. He retired in 1904. Mr. Dickson was one of a number of citizens who, for their long public services, were granted the honorary freedom of the city on the occasion of the Diamond Jubilee celebration. He was also a city and county magistrate. When the Royal Agricultural Show was held at Chester in 1893, Mr. Dickson acted as hon. secretary. Deceased leaves a widow and family to mourn his loss.

MARKETS.

COVENT GARDEN, February 10.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers such as Acacia (Mimosas), Anemone fulgens, Azalea, Bouvardia, Calla aethiopica, Camellias, Carnations, Chrysanthemums, Cypripediums, Daffodils, Dendrobium nobile, Eucharis grandiflora, Freesias, Gardenias, Hyacinths, Lilies, Lilium auratum, and others with their respective prices.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage plants such as Adiantum cuneatum, Agrostis, Asparagus plumosus, Berberis, Croton leaves, Cycas leaves, Daffodil foliage, Ferns, and others with their respective prices.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants such as Ampelopsis Veitchii, Aralia Sieboldii, Begonia Gloire de Lorraine, Cinerarias, Clematis, Cocos Weddelliana, and others with their respective prices.

Plants in Pots, &c.: Average Wholesale Prices (Contd.).

Continuation of the Plants in Pots table, listing items like Hyacinths, Isoplepis, Kentia Belmoreana, Latania borbonica, and Lilium longiflorum.

Fruit: Average Wholesale Prices.

Table listing various fruits such as Apples (Foreign and Domestic), Bananas, Cape fruit, Cranberries, Custard Apples, Dates, Figs, Grape Fruit, Grapes, Lemons, Limes, Mandarins, Nuts, Oranges, Peaches, Pears, Pineapples, Tangerines, and others with their respective prices.

Vegetables: Average Wholesale Prices.

Table listing various vegetables such as Artichokes, Asparagus, Beetroot, Brussel Sprouts, Cabbages, Cardoon, Carrots, Cauliflowers, Celery, Celeriac, Chicory, Cucumbers, Endive, Horseradish, Kale, Leeks, Lettuce, Mint, Mushrooms, Mustard and Cress, Onions, Parsnips, Peas, Potatoes, Radishes, Rhubarb, Salsafy, Seakale, Spinach, Savoys, Turnips, Tomatoes, and Watercress.

Table listing various types of Potatoes such as Kents, Snowdrop, Sbarpe's Express, Epicure, Up-to-Date, Lincolns, and others with their respective prices.

REMARKS.—There is no great alteration in prices. Supplies are plentiful, the demand being about an average one. Edward J. Newborn, Covent Garden and St. Pancras, February 10, 1909.

COVENT GARDEN FLOWER MARKET.

Trade appears to have improved a little, but there is no great change to record. I have heard it remarked that Covent Garden Market is simply a dumping ground for surplus stock, but this is not quite correct, for there are many growers who depend entirely on the market for the sale of pot plants, and large consignments of the best cut flowers are disposed of in this market.

POT PLANTS.

During unfavourable weather growers are careful not to send large supplies of plants that can be kept a little longer at the nursery, and buyers are equally careful not to purchase more than they require. Azaleas are too numerous to be valuable. Yesterday (Tuesday) I saw well-flowered plants sold for what they cost in Belgium before forcing. Some good Rhododendrons, including R. (Azalea) sinense, are seen. Cinerarias from Mr. Mott's and from Mr. Sweet's nurseries are good specimens. Plants of Erica melanthera are well flowered this year; this species finds increased favour with the florists. Plants of Lilium longiflorum sent by Mr. Holdrup are of especial quality. Marguerites are remarkably good from several growers. Spiraeas have rather tender foliage this season. Hyacinths in pots are to be had. Daffodils in several varieties are numerous. Good Callas are seen, but there appears to be little demand for them. Messrs. Butler Bros. are sending in plants of a round-fruited Capsicum; they are very pretty. In foliage plants variegated-leaved Funkias are prominent. The specimens of Aralia Sieboldii seen are well finished, but in many instances new growth will soon be starting, and then they will not withstand rough treatment so well. Aspidistras, Palms, and Ferns are well supplied.

CUT FLOWERS.

Supplies of Chrysanthemums still hold out. Varieties noticed include W. J. Crossley (a shade of bronze), Francois Pilan (yellow), Madame Charvet, Madame Felix Perrin, and Niveum. Roses are scarce, and best blooms are making high prices. There have been some fine blooms of Caroline Testout, Richmond, and Mrs. W. J. Grant, but they were not exposed for sale long. Carnations are plentiful and generally of good quality. Good fresh blooms make from 2s. to 3s. per dozen. The best of the mid-season varieties of Tulips are now coming in; the double-flowered varieties are sold for the highest prices. Vuurbak is the finest crimson-scarlet variety, and is one of the most expensive to purchase, the lowest price being 2s. 6d. per dozen blooms. Murillo and Salvador Rose are excellent double varieties.

Daffodils occupy much space in the market; they are arriving from all sources, but those from English sources are the best. Emperor is now very good, also Empress, whilst Victoria may be regarded as one of the best of the bicolor kinds. Sir Watkin is good. Golden Spur has no rival as a pure yellow trumpet Daffodil. Narcissus ornatus is abundant from all sources. Violets are plentiful; the Parma Violets may advance in price, but at present they are fairly plentiful. Eucharis blooms are plentiful again, and their prices have dropped. French flowers are arriving in good condition. A. H., Covent Garden, Wednesday, February 10, 1909.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 10. A week of striking contrasts in temperature.—The first three days were unseasonably warm, but since then the weather has remained cold for the time of year. The first day of the week proved very warm; the temperature in the thermometer screen in the middle of the day rose to 55 degrees, which is a remarkably high reading for so early in February. During the previous night the exposed thermometer only fell to 45 degrees, which is equally exceptional for so early in this month. By way of contrast it may be stated that four days afterwards the highest reading in the thermometer screen was only 35 degrees, while the exposed thermometer on the previous night registered 14 degrees of frost. The ground is now one degree colder at 2 feet deep, and two degrees colder at 1 foot deep, than is seasonable. Rain or snow fell on two days, but to the total depth of only about one-tenth of an inch. There has been no measurable percolation through either gauge for nearly three weeks. The sun shone on an average for only one and three-quarter hours a day, which is 22 minutes a day short of the average duration for the early part of February. On four days no sunshine at all was recorded. On the first three days of the week the wind remained high, and in the windiest hour the mean velocity amounted to 20 miles—direction, W.N.W. During the rest of the week light airs and calms alone prevailed. The average amount of moisture in the air at 4 p.m. exceeded a seasonable quantity for that hour by 4 per cent. E. M., Berkhamsted, February 10, 1909.

REMARKS.—Apples from France are selling freely at good prices. Californian Oranges are slightly cheaper but they continue to sell well. Denia and Valencia Oranges are also lower in price. Rhubarb is arriving in increased quantities; the demand is fair. Muscat of Alexandria Grapes are finished for the season. Vegetables are not plentiful. Savoys are dearer; also "Nigger" Beans. Madeira Beans are a shorter supply. Trade generally is quiet. E. H. R., Covent Garden, Wednesday, February 10, 1909.

ENQUIRIES AND REPLIES.

TIMBER FOR FORCING HOUSES.—After an experience extending over well-nigh 40 years, I unhesitatingly declare in favour of pitch pine for lasting qualities where a moist and hot temperature is maintained. There is a great difference in the quality of pitch pine, just as in other varieties of timber. I advise Mr. Elwes either to select his own logs at the timber yard, free from sap, and then make arrangements to have them sawn up into bars, wallplates, &c.; or to go to a local builder and contract with him to supply the timber without sap. In making the selection at the timber yard, a small advance on the ordinary prices may be expected. Ordinary pitch pine, taken haphazard, is worse than good common red deal. Best-quality red deal will last at least 20 years; selected pitch pine, absolutely free from sap, under the most trying conditions, will last half a century. A plant-house in my nursery, built 25 years ago of selected pitch pine, and used as a store, is as sound as when built. I tried to insert my pocket-knife into it to-day, but the wood was hard. The interior of the house has never had a paint-brush on it. The nursery also contains a range of glasshouses built 45 years ago, and the timber of which the houses are constructed is almost without a trace of decay. *A. J. A. Binn, Chorlton-cum-Hardy.*

—More depends upon skilful workmanship and careful painting than the kind of timber used. Moisture and heat are the enemies to guard against. Sills, ledges, and wallplates should be sharply bevelled and well coated with paint made of white lead. A span-roofed house, 60 feet long and 18 feet wide, built for me in 1880, was removed by the London County Council to Brockwell Park, S.E., two or three years ago, in good condition. The boiler was worn out, but everything else was sound, and the building can be seen as a show-house in the public park. No expense had been spared in the first instance, and the house had not been built by contract. The age of structures used by market-gardeners is never very great, and, in many cases, it does not exceed 10 years. *W. Roupell.*

—I have had experience in the construction of plant-houses with deal, pitch pine and teak woods, and I have come to the conclusion that there is scarcely any difference in the duration of these timbers. Three years ago we erected a new Peach house in these gardens, and instead of using an ordinary wooden frame for the fronts, we made a cement sill and built mullions of 9-inch brickwork or piers, with a 3/4-inch rebate of cement on them to form the casings for the front lights. The furniture for the ventilating gear was built in as the work proceeded. The piers should be built about four days before the wallplate to which the rafters are fixed, in order to allow time for the cement to set. All wood should be sufficiently bevelled to carry off the moisture from condensation, and the less mortising the better, as in such holes decay usually commences. Our houses are all built on the longitudinal purline system, so that there is no outside painting on the roofs, and no putty required for glazing, the glass being fixed by strips of lead, scalloped, tacked on the purlines and turned up over the glass. *James Sherlock, Fowley Gardens, Liphook, Hants.*

GARDENING APPOINTMENTS.

- Mr. P. J. CLINCH, for the past 7 years Gardener at Scribbles-town Park, Castleknock, Co. Dublin, as Gardener to Lady Mowbray and STURTON, Corbalton Hall, Tara, Co. Meath.
- Mr. JAMES MILLS, for the past 7 years Foreman at Broad-oaks Gardens, West Byfleet, as Gardener to Mrs. Brendt, Tandridge Hall, Oxted, Surrey.
- Mr. H. REYNOLDS, for the past 3 years Foreman in Pottaloch Gardens, Lochgilphead, Argyllshire, as Gardener to J. MUSKER, Esq., Shadwell Court, Theiford, Norfolk.
- Mr. F. HOWELL, late Foreman at Bramham Park, Boston Spa, Yorkshire, as Gardener to F. W. WIGNALL, Esq., Bank House, Tattenhall, near Chester.
- Mr. JOHN ED. HALL, for the past 34 years Foreman at the Castle Gardens, Castle Eden, Co. Durham, as Gardener to M. D'ARCY WYVILL, Esq., Constable Burton Hall, Constable Burton, Yorkshire.
- Mr. G. HYLAND, for the past 2 1/2 years Fruit Foreman at Aston Rowant Gardens, Oxon, as Gardener to Major HIBBERT, Ashby St. Ledgers, Rugby, and Braywick Lodge, Maidenhead.
- Mr. J. CAWKWELL, lately with Messrs. KENT & BRYDON, Darlington, as Gardener to W. BURDETT-COUTTS, Esq., M.P., The Grove, Witton-le-Wear.

CARNATION MAGGOT (ANTHOMYIA): W. E. Flies of species of *Anthomyia* are on the wing throughout the summer, appearing first in early spring. Hence successive generations of larvæ are kept up till November. After that time the pupa lie in the ground unhatched till spring or early summer. The flies may also live throughout the winter secreted in holes and crevices. The larvæ live some months and take three weeks to hatch.

CELERY DISEASED: W. W. See reply to W. Truster, p. 64 in the issue for January 23.

CYPRIPEDIUM UNHEALTHY: R. The growth appears to have been damaged by excessive moisture during a temporary fall in the temperature.

DYEING FOLIAGE RED: F. H. W. Place sufficient red aniline in rain-water to make a strong dye and boil it. Dip the foliage in this solution whilst still hot.

EGGS ON APPLE TWIGS: X. Y. Z. The eggs are those of the Lackey Moth, *Bombyx neustria*. The perfect moths may be observed on the wing in July and August, and are very pretty, but somewhat variously coloured. The eggs are laid in rings around the bark of the branch, and the caterpillars emerge during April in the following year. The caterpillars live in colonies surrounded by webs spun over the leaves. Cut off any shoots that are seen to be infested with eggs, and burn them. Examine the trees in May or June, and cut off the branches where colonies of larvæ exist, destroying them in a bucket containing some strong insecticide.

HYBRIDISATION OF VIOLETS: J. M., Greyfriar. The hybridisation of Violets, and *Violas* generally, is not easy. Emasculation can be effected, but it is difficult to make certain when pollination has taken place. The flowers must be emasculated in bud. If a fairly large bud is chosen, it is easy to expose the stamens by turning back one of the lateral petals. When so exposed, the stamens can be picked off by means of a fine pair of forceps. The stamens must be examined as they are removed to see that there is no loose pollen about. It is sometimes necessary to tear off the lateral petal in order to expose the base of the stamens sufficiently; but it is better to avoid this if possible and to turn back the petal into place after the operation is performed. The expanding of the uninjured petals is a useful guide as to the proper time for pollination. The process of pollination is best effected by taking a recently-dehiscent stamen from the male parent, holding it in a pair of fine forceps, and applying it to the stigmatic surface by gently rubbing the under surface of the stigma with it. For some reason, and it may be owing to the structure of the stigma, this method is not always successful in getting the pollen applied to the right spot, and it is sometimes found desirable to use a fine camel's hair brush, which is covered with pollen by being pushed into the throat of the flower which is to be used as the male parent. The brush is then rubbed on the under surface of the stigma of the castrated flower. If a brush is used, several brushes must be placed in readiness, as each must be sterilised between each operation by dipping into strong spirit. They cannot be used again till they are dry. These are the only methods of castration and pollination which we have found it necessary to adopt; they are successful in a fair percentage of cases, but there is no doubt that the operation is not an entirely simple one. The difficulty seems to lie in the application of the pollen to the receptive area of the stigma. In addition to this, one has to reckon with the sterility which is not an uncommon feature of hybrid *Violas*. If the sterility lies in the failure of the stamens to produce good pollen in sufficient quantity, it is worth while to try using the plant as the female parent before giving up hope of using it in crossing experiments. We doubt if it is possible satisfactorily to emasculate cleistogamous flowers. It would be very difficult to make certain that self-pollination had not

occurred before emasculation was carried out. In the case of hybrids, they would provide a very easy method of obtaining "selfs," and would save much labour in that part of the work.

MICE IN THE GARDEN.—Field rats and mice are easily killed by placing in their holes some moistened bran or meal, to which some white arsenic has been added. If poultry is present, a temporary enclosure of wire-netting should be put up where there are most mice, and where it is practicable to feed them for a short period. This will draw large quantities to the feeding-place, and they can be killed in this manner. The surplus poison can be dug in the ground, and the netting, if it be necessary, removed to a different part of the garden and used in the same way.

NAMES OF FRUITS: S. Nye. Bergamotte Esperein.

NAMES OF PLANTS: J. W. M. 1, *Rhododendrom ferrugineum*; 2, *R. hirsutum*; 3, R. Hammondii. —Foreman. 1, *Cœlogyne ochracea*; 2, *Cochliodia sanguinea*; 3, *Oncidium cheiroporum*.—A. C. H. *Cœlogyne* (next week).

NITROGEN: G. H. H. W. The probable explanation is that the soil in which Gorse lives is of a sandy nature and very light in texture. From such soils soluble substances, such as nitrates, are washed out readily by rain. The nitrogen fixed by the Nodule organism would sooner or later be converted by the action of other races of soil-bacteria into either nitrates, ammonia compounds, or free nitrogen. The last-named substance, if formed, escapes into the air; the two former substances would tend to be washed out from the soil, by rain. Hence no considerable accumulation of nitrogenous food-material occurs in the soil. At the same time it is to be observed that the Nodule organism does in fact enrich even poor, sandy soil in nitrogen to some extent. Thus Lupins are used largely and with success in Germany as a means of reclamation of waste, sandy soils.

ROCKERY: C. H. Your best course will be to cut a semi-circular pathway, 2 feet wide, through the site. This will provide one half-moon-shaped bed at the front and another bed behind it, the pathway intersecting. Collect sufficient soil to raise the half-moon-bed 5 to 6 feet high at its centre, and make the ends of the hindermost bed agree in height also. Place your stones so that they will support the soil in position, and each stone be practically on the same horizontal plane as its neighbour, forming little bluffs and declivities or down gradients behind each bluff. Your aim must be to represent an outcrop of rock, from the top and one face of which the weather has eroded hollows, fissures and crannies. These are destined to be the home of the rock plants proper. All the other spaces can be furnished with Alpine species of coarser growth, and low-growing shrubs and bulbous plants. When finished, your rock-garden should represent a series of irregular rocky ledges supporting the soil in position, the principal seams or joints of which must trend in one direction, e.g., from the highest point. Plants for such a rock garden may include *Arabis*, *Aubrietia*, *Saxifraga*, and *Arenaria* in many species, and *Lithospermum*, Alpine *Phloxes*, *Gypsophila repens*, trailing and tufted *Veronicas*, *Sedums*, *Primulas*, Alpine *Columbines*, *Linarias*, and *Saponarias*. All kinds of *Heather* and *Veronica Hectori* and *V. decumbens* may be used for the less dry sites. The plants will teach their own lesson. Those with long, whip-like roots and trailing growths will grow between horizontal layers of stone and drape their faces; those with slender fibrils and trailing growths, as in *Campanula*, will need gritty ledges. If you cannot get natural rock stone in sufficient quantity, it does not matter how your seams run. In such a case use every effort to cover with plants as much of the stone, clinker, or other supporting material as possible.

PARADISE RETRIEV'D.

THOSE who are acquainted with the scores of political pamphlets and the religious sermonettes of the latter half of the 17th century must be well aware of the discrimination the authors exhibited in labelling them with telling titles. They were followed, but at a far distance, by dramatists and others, among whom must be included a few writers on gardening, and *Paradise Retriev'd* is a good instance.

It is in some respects a remarkable book. For one thing, its author seems to have written and published it to confute certain propositions of the Rev. John Lawrence, who had already published *The Gentleman's Recreation*, in which the offensive statements had appeared and a concise treatise on fruit culture, *Paradise Retriev'd* is noteworthy as being far in advance of anything that had appeared on that subject up to the time of its publication in 1717. Its author was Samuel Collins, Esq., of Archester, Northamptonshire, and the cause of his rushing into print was that Mr. Lawrence, who was rector of a parish in his neighbourhood and had taken up fruit culture with great enthusiasm as a means of securing a crop of fruit, had recommended building tiles into

fruit walls: the tiles to be set at regular intervals and to extend outwards an inch and a half from the wall. Mr. Collins' curiosity having been excited on reading the description of this novel fruit-protector, made a journey to Yelvertoft Rectory, where, to his great disappointment, he found only "stuck about twenty tiles into an old dirt Wall with Lime." In this book he shows that these "horizontal shelters," as they came to be called, had never been proved by their inventor, and that they were ineffective as a means of warding off intense cold. The next year Mr. Lawrence published *The Fruit Garden Kalender*, in which he disclaims any connection with *The Lady's Recreation*, a kind of bookseller's book on gardening, but nothing appears concerning Collins' outspoken statements, so that one can hardly escape giving them credence.

At the same time it must be mentioned as proof of the great popularity attained by Mr. Lawrence as a fruit-grower that Hitt mentions his device of tiles, though with disapproval, as being in use as late as 1755.

While the above seems to have been the reason for Collins writing: indeed, in the preface to his book he declares that "the only motive that induced me to write was the sight I had of Mr. Lawrence and his Garden after reading his Book," yet it contains a good deal on fruit culture that must have been helpful to its readers. He modestly affirms that his own garden was "managed to a very great perfection," and as one peruses chapter after chapter it is obvious that gardening must have formed the chief employment of his life. He takes occasion to warn owners of gardens to be slow to change gardeners frequently, which seems, as in these times, to have been customary with too many employers, and demonstrates how a man of "middling capacity," if honest and industrious, is not to be lightly superseded, and almost certainly not without loss to the garden.

A few points in his teaching may be noted. He preferred trees to be the first year from the bud. He insisted on planting in October; but early planting, though not invariably the rule, must have been customary, for he quotes an old adage to the effect:—

He who would a good tree have
Must bring the old leaf to the grave.

Roots were to be shortened slightly previous to planting, and pruning deferred till the following February. Writing of Apricots, he gave it as his experience that old trees which had been "blasted" might be cut over with advantage, and that they would produce a sufficient number of young shoots in the course of three years to again cover the walls. The advantage of properly thinning fruit is dwelt upon, one of the reasons he gave being the better quality of the fruit as compared with that only slightly thinned; and not only is the necessity of laying in a limited number of shoots insisted upon, but an engraving shows how trees should be trained. Another engraving exhibits Pears trained as Espaliers, in which the branches have more space than any previous authority had recommended. The branches, it may be noted, were not trained straight, but slightly curved, a fashion which continued for some time. The evil of allowing moss to

vegetate on fruit trees is pointed out, and rubbing with "hair cloth" the remedy proposed.

A part of the volume is devoted to a separate *Treatise of Melons and Cucumbers*. He had already discovered that old seed of the former was to be preferred to new seed, the plants from which "spend themselves too freely in their vines without fruiting." He also asserted that fruit from old seed was "better tasted." The "Mellonry" was at this period an important adjunct to the garden, and Collins describes his own. This was an area of 19 yards by 16 yards, and it was enclosed on all sides but the south with a hedge of Yew, which on the north attained a height of 10 feet. In order to ensure the greatest possible warmth, the ground inside was excavated to a depth of 16 inches. As a further protection from wind there were 8-foot hedges of Willow between the lines of frames and ridges. The fullest details are recorded of how to produce both Melons and Cucumbers early and late by means of heated dung and grass, bell-glasses and frames. The treatise concludes with a warning "that Ladies should not be invited to this Place" lest the Melons should refuse to set, the last quaint words of the book being:—"I have been oblig'd at that time of fruiting to deny their entrance into the Mellonry." R. P. Brotherston.

NEW OR NOTEWORTHY PLANTS.

IRIS RETICULATA ATROPURPUREA.

A REMARKABLE form of *Iris reticulata*, which is as yet, I believe, undescribed, is now flowering here for the first time. It might even be given rank as a distinct species if specific names are given to *histrion* and *histrionoides*; but, if these are regarded merely as local varieties of *I. reticulata*, then this new form may be known as *I. reticulata atropurpurea*.

During last summer I received a few bulbs of *I. reticulata* from Marash, in Asia Minor, and this flower now appears among them, together with a very fine form of *histrionoides* distinguished by the fact that the deeper shades of blue on the falls occur rather as mottlings than as blotches.

The buds of the variety *atropurpurea* appear when the two four-sided leaves are only 2 or 3 inches high. They somewhat resemble buds of *I. Krelagei*, but differ in having veinings of purple-red on a whitish ground.

When the flower unfolds, the blade of the fall is seen to be of a uniform velvety-black, which fades a little to red-black at the edges. There is only the merest trace of a signal or ridge in the form of a minute touch of dingy yellow, but along the haft there runs a row of glistening black spines about a sixteenth of an inch in height. These stand out conspicuously on a black ground, which is bordered on either side by a slightly lighter, reddish groundwork veined with black-purple. The small, narrow standards are dark, blackish-red, widening at the top, with a characteristic outward curve, whilst the styles are of a somewhat lighter shade of red, especially at the edges. In one respect this *Iris* differs from all other forms of *I. reticulata*, namely, in having spathes that are veined and blotched with red-purple. In other varieties the spathes are either green or colourless, but in this case it is hard to distinguish the spotted spathes from the similarly spotted tube. W. R. Dykes, Charterhouse, Godalming.

EXPERIMENTS WITH NITRO-BACTERINE.

(Concluded from page 91.)

It has been shown that in the Wisley experiments on fallowed soil three lots of inoculated seed were planted under such conditions that, as definitely stated in the directions for using the cultures, inoculation would be either *useless* or a *failure*.

Comparing the total weight of Peas of inoculated seed with that of non-inoculated seed from the three plots where inoculation might be reasonably expected to produce good results, we have the following figures:—

Table H	Non-inoculated		Inoculated		Increase.
	Seed.	Gr.	Seed.	Gr.	
... 1	7,175	...	8,188	...	1,013
... L	7,093	...	7,963	...	870
...	4,182	...	4,702	...	520
	18,450		20,853		2,403

Increase in favour of inoculated seed = 13 per cent.

* Number of plants in plots equalised to number of inoculated plants.

We contend that it is both unscientific and unfair to add the results from plots which are known beforehand to be either unfavourable or injurious to inoculation, to those from plots on which it is stated inoculation may be beneficial, and then to draw a conclusion either for or against inoculation therefrom. If Mr. Chittenden's method is the correct one, it is quite easy to prove that any manure, if only sufficiently unfavourable conditions are taken, is useless on ordinary garden soil.

Further, we cannot accept Table J of the Wisley report as a fair statement of results. In order to obtain this table the produce of "maincrop" is omitted entirely, because in Table I there is a variation in the number of plants, although "maincrop" in both Tables H and I gives the largest increase for inoculation in weight of Peas. Surely the scientific method would have been to equalise the number of plants where there was a difference, as is done in the following table:—

Weight of Peas.		
Untreated ...	7,093 grs.	
Soil inoculated ...	7,175	= 1 per cent. increase.
Seed inoculated ...	7,963	= 10.8 " " "
Seed + soil inoculation ...	8,188	= 15.4 " " "

* Number of plants in plots equalised to number of inoculated plants.

These figures indicate the value of double inoculation. In the directions sent out with the culture material, it is recommended that the seed be inoculated, and then later the growing plants watered with the culture solution. It is definitely stated that this double inoculation will give the best results. Yet the effect of watering with the culture solution after seed inoculation was not tried at Wisley. The experiment described by Professor Henslow in last week's *Gardeners' Chronicle* is interesting as showing what may be the effect of watering with culture solution under certain conditions. Just a word about the Wye experiments. These certainly indicate that seed inoculation was useless on this ground. A probable reason for this is given by Mr. Gimingham in his report. He states that "both lots formed nodules on their roots to about the same extent." Evidently there were already present in the soil sufficient bacteria to produce a supply of nodules. In "Seed and Soil Inoculation" (p. 10) it is pointed out that under these conditions inoculation is useless. Hence the Wye experiments confirm one of the conditions under which it has been stated in Germany and America, as well as in this country, that inoculation will be useless, but they do not furnish "a triumphant proof" that inoculation is useless on ordinary garden soils, for we have inoculated seed on garden soil giving an increase of 10.8 per cent. at Wisley and 7.6 per cent. at Reading.

After all, the question of cost is an important factor in determining the practical value of any manurial material. Considering that seed sufficient for an acre of land can be

inoculated for less than 1s., the cost of testing inoculation on any garden soil is not a prohibitive one. There may be no result—as at Wye. On the other hand, there may be success, as at Wisley and Reading, where the inoculated seed not only gave an increased yield, but this yield was larger than the yield from equal plots treated with manures which would cost not much less than £1 per acre.

I quite agree with Dr. Keeble that further experiments are required, but these must be in field and garden as well as in the laboratory. We know something about the conditions under which the nitrogen-fixing bacteria work best in the soil, but many points are still obscure and require further investigation. We want to find out how these bacteria can benefit agriculture and horticulture, but this can only be done by recognising their limitations, and experimenting with them under conditions which give them a chance of doing their work properly. *W. B. Bottomley, King's College, London.*

THE CLEOMES.

THERE is no modern monograph of the Caparidaceae or Caper family, and identifications of plants of that family have accordingly to be based mainly on the descriptions given in local floras. The South American species were revised by Eichler in the *Flora Brasiliensis*, vol. xiii., part 1, and from the account there given, the Cleome shown in fig. 50 has been identified as *Cleome spinosa*, forma *spinosa*, Eichl.

Eichler divided Cleome into two main sections, one of which includes all the shrubby or tree-like species, in which the petals are gradually narrowed down to the base, so that they have no distinct claw; whilst the other consists entirely of herbs, in which the petals are provided with a distinct claw. *C. spinosa* belongs to the latter section.

Two of the shrubby or arborescent species have been introduced into cultivation, namely, *C. gigantea* (*Botanical Magazine*, t. 3137), a shrub widely distributed over tropical America; 3 to 5 feet high, and with greenish-coloured flowers; and *C. dendroidea* (*Botanical Magazine*, t. 3296), which, according to Gardner, who found it growing on the seashore near Rio de Janeiro, is a small tree attaining to a height of 10 to 14 feet. The flowers are blackish-purple, and the plant presents a beautiful object when in flower.

The eight other shrubby species inhabit rather restricted areas in the Andes of Venezuela, Colombia, or Peru, and the section as a whole appears to represent an archaic type in slow process of extinction. According to this view, the gradually narrowed petals met with in the shrubby section, being less differentiated, would be regarded as more primitive than the distinctly-clawed petals which are found in all the herbaceous species.

The herbaceous section includes a large number of species, among which are several cosmopolitan weeds, and it may, accordingly, be regarded as a more modern group. At any rate, most of the species are evidently more in harmony with prevailing modern conditions than are those of the shrubby section. The species are in many cases difficult to distinguish, but *C. spinosa* may be distinguished from most of its allies by the paired stipular prickles which occur one on either side of the base of the petiole. As defined by Eichler, it seems to consist of an unwieldy assemblage of forms, some of which are strikingly unlike. He describes it as being in the highest degree variable, sometimes almost glabrous, sometimes hirsute; the petioles and veins on the lower surface of the leaf prickly in some forms and unarmed in others; the bracts varying between orbicular-cordate and lanceolate; the flowers white, pinkish or deep purple; the ovary glabrous in some forms and glandular in others; and the gynophore sometimes as long as the pod, and in other cases only half as long.

Eichler distinguished three forms of *Cleome spinosa*, taking into account only the character of the prickles on the petioles and leaflets and the colour of the flowers:—

(a) *Forma pungens*.—Petiole unarmed (not counting the basal stipular prickles), or with one or two small prickles; flowers white or pale rose.

(b) *Forma spinosa*.—Petiole armed with stout prickles; flowers rose or deep purple (see fig 50).

(c) *Forma horrida*.—Petiole with crowded prickles; flowers white or pale rose.

According to these definitions, the plant illustrated in fig. 50 belongs to forma *spinosa*; while the plant represented in *Bot. Mag.* t. 1640, belongs to forma *pungens*, for the petioles are unarmed. Eichler, however, expressly referred the plant shown in the *Botanical Magazine* to his forma *spinosa*, apparently because the petals were of a deep-rose colour. The presence or absence of prickles is of greater systematic importance than a slight difference in the coloration of the petals, whilst the shape of the bracts probably affords a character of even greater value, and should certainly be taken into account in any attempt to sub-divide the species. Without monographic study, however, it would be unsafe to construct a revised classification of the forms hitherto placed under *C. spinosa*, and it seems desirable, therefore, to follow Eichler in the meantime. Nevertheless, having seen actual specimens of both the plant now figured and also the typical *C. spinosa* (which falls under forma *pungens*), I am convinced that they are specifically distinct from one another. Typical *Cleome spinosa*, which I have collected in waste ground at Ciudad Bolivar, the port of the Orinoco, has comparatively glabrous stems and leaves, unarmed petioles (except for the stipular prickles), suborbicular bracts and white flowers. The plant shown in fig. 50 has a densely glandular, pubescent stem and leaves, prickly petioles, lanceolate bracts and purple-magenta flowers. In fact, it has much more the habit of *C. Selloana*, Eichl., from which it differs in having the ovary and pod glabrous instead of densely glandular.

As to the history of the cultivated plant nothing seems to be known. Two plants were received at the Royal Botanic Gardens, Kew, last August, from Messrs. R. Veitch & Sons, Exeter, and flowering specimens were received for identification in September from Mr. W. E. Gumbleton; the figure was drawn from Mr. Gumbleton's specimens, with the exception of the separate large leaf and a few other details, which were drawn from material sent by Mr. R. C. Notcutt, of the Nurseries, Woodbridge. In order to aid identification, a short, popular description is now given.

An erect, herbaceous, sticky plant, about 3 feet high, emitting an odour not unlike that of mint, but a trifle fetid. The leaves fingered, the upper with five leaflets and the rest with seven leaflets each. The leaf-stalks are prickly, and at the bottom of the stalk a pair of prickles, one on either side, point downwards. The midrib of the leaflets is prickly on the under side. The bracts, or leaves below the flower-stalks, are lance-shaped and sharp pointed. The flower-stalks vary in length from 1 to 1½ inch. The sepals, which are awl-shaped, are under ½ inch in length and ascending. The petals are of a purple-magenta colour and nearly 1 inch long, including their stalks, which measure about ½ inch in length. While the upper parts of the petals are still folded together, the filaments begin to grow faster than the petals, and as the long anthers at the end are tightly held by the petals the six filaments bulge out in the middle in the form of a bow. It is interesting to note that this is clearly shown in a woodcut of a Cleome in plate No. 34 of Marcgraf's *Natural History of Brazil*, which was published as long ago as 1648. *T. A. Sprague.*

VEGETABLES.

CHICORY.

THE exhibition of Chicory as a forced vegetable at a recent meeting of the Royal Horticultural Society may attract attention to its value as a winter product. Recent frosts have done enormous damage to ordinary Brassica crops, and in that way greatly reduced the supply of fresh vegetables. From a late summer sowing, Chicory roots are obtainable in winter and, if these are lifted and safely stored, are available to furnish blanched heads. It is generally assumed that Chicory when blanched is only suitable as a salad. But it makes also, when properly cooked, an acceptable vegetable. Whilst Seakale may be regarded as more useful for the table, its cultivation necessitates far greater labour than is the case with Chicory. Seakale, if raised from seeds, must be sown in April, and the plants must be severely thinned. If grown from root cuttings and planted in April, considerable preparation and labour in the planting and subsequent treatment are needed. A sowing of the Witloof variety of Chicory may be made in drills 12 inches apart, and the plants in the rows should be thinned out to 9 inches apart. Sowings may be made in May, June, and even in July if the soil is exceptionally good. As soon as stout roots have formed in the autumn, some may be lifted, have their leaves cut off, and be placed in large pots or boxes filled with soil. They should be covered with inverted pots and placed in a warm structure from which sunlight is excluded. This process of producing heads, some 6 inches tall, and fairly compact, may be continued all the winter if the supply of roots is sufficient. The roots are white and fleshy, but, like those of Seakale, they are inedible. In reference to a different method of blanching, Mr. C. R. Fielder, North Myms Park Gardens, tell me that his way is to open a trench in the ground, 12 inches deep, and of slightly greater width. The soil thrown out is piled up on each side, thus making the entire depth of the trench about 18 inches. Into one end of such trench he puts the Chicory roots fairly close together. The sets have already been cut level at the base. He fills in round them and up to the top of the ridge with sifted soil from the potting bench; on this is laid some 2 feet thickness of warm manure. Splendid crowns result in about three weeks. Additional roots are treated in a similar manner to maintain the supply. A. D.

FLORISTS' FLOWERS.

THE NEW R.H.S. CLASSIFICATION OF DAFFODILS.

I HAVE been asked by several of those most closely interested in the subject to express my opinion of the new classification of Daffodils. My study of these flowers for over a quarter of a century gives me a claim to speak, and will acquit me of presumption in speaking plainly.

It appears to me that the procedure adopted in the issue of the classification has been unusual and unfortunate. According to the official report of the Royal Horticultural Society for 1908, "at the request of the Daffodil Committee, the Council appointed a committee. . . . The committee have delivered their report, instituting an entirely new system of classification, which the Council has accepted, and ordered to be used at the Society's shows." And the newly-classified list of Daffodil names printed by authority of the Council is enjoined "for use at all exhibitions of the R.H.S."

It would surely have been expedient, and in accord with all received custom in such deliberations, to have referred the report of the special committee to the Narcissus Committee as a whole, that they might have a full oppor-

tunity of considering such a sweeping innovation, before imposing it by edict of the Council upon the Society and the public. The more so, because the authors of the new scheme betray doubt as to its reception, by the expressions "for the present experimentally adopted," "if the principle involved in the present list should find acceptance." The large number of errors the list contains indicates undue haste in publication, and the only result at present of this precipitancy has been confusion. The schedules of one or two of the spring Flower-shows have been altered in accordance with the new classification; in others the old system is retained. The bulb lists of the chief professionals, including that of Messrs. Barr & Sons, which is counted a standard classic, are retaining the older arrangement.

I may mention here that, by some extraordinary blunder, the name of Mr. P. R. Barr, who originated the demand for some amended plan of nomenclature, and whose advice would have been invaluable, was omitted from the special committee. I myself was, unfortunately, prevented from attending. I believe I am at liberty to couple Mr. Barr's name with my own, and to

writes that it is exclusively for convenience at the shows, i.e., for experts, and that the old order might remain in use concurrently for ordinary purposes!

The manifest and insuperable fault of the new arrangement is that it absolutely abolishes any approximation to natural classification. It is all very well for its authors to write of being "compelled to fall back on purely arbitrary divisions," but to push this supposed necessity to extremes is to arrive at the obviously absurd and grotesque. The ridicule will be incurred even of "the man in the street" when he sees on a stand such evidently incompatible flowers grouped together as, for instance, those included in the new division 7. Here we have—

- (a) Ordinary Polyanthus Narcissus.
- (b) Triandrus.
- (c) Jonquil.
- (d) Hybrids of Ajax and Triandrus.
- (e) "Hyacinth," and similar varieties.
- (f) Odorus.
- (g) Tridymus.

Let us consider some of these items. To pass over the fact that the eye rebels against bringing

FIG. 51.—VIEW IN THE PLANTATION ADJOINING MR. NOTCUTT'S NURSERY.

(See p. 117)

say that we should both have strongly opposed the new classification as now published. Every expert with whom I have corresponded expresses himself in the same sense, and all agree in regretting that the criticism of the Narcissus Committee was not invited.

To me it seems in no single feature an improvement on the old order, but a revolution, indistinct in intention, and without results sufficient to compensate for the disturbance it has created. Its want of clear aim will appear from the widely different views of members of the special committee. One writes to me that the nature of the new arrangement matters little, but the one thing required is to get every single flower clearly ticketed with its own class-label. But if this is all, a very moderate alteration of the old arrangement would still serve, for a sub-committee appointed for the purpose could assign to its proper pigeonhole every flower as it arrives. Another member tells me that the new list is simply for "the man in the street," and not for experts. On the contrary, another

a, b, c and g into one class, it may be noted that a single seed pod of Ajax × triandrus (d) commonly yields single-flowered plants and multi-flowered, also flowers differing in length of crown. Moreover, the same plant is often single-flowered one season, and two or more flowered the next. Therefore, what are virtually identical plants are classed in the new list under three several divisions, e.g., 1, "Count Visconti"; 2, "Countess Grey"; 7, "Betty Berkeley"—"which is absurd," as Euclid would conclude. "Hyacinth" (e) is a short-cupped, single-bloomed flower, which occasionally "freaks" to twin flowers, just as *Poeticus ornatus* will do under certain conditions. Thus an accident is made to determine its class. Odorus (f) is a hybrid of Ajax and Jonquil, and is classed in division 7 because it bears two or more flowers. "Buttercup," although from the very same cross, is put into division 2 because it is usually single-flowered. But seedlings from this cross and from the same pod vary from one to three flowers permanently

or in successive years. In the latter case, *the flowers of the same plant* must be shown one season under division 2 and the next under division 7!

Again, under division 1 we have flowers so totally distinct by nature, and to the eye, as Ajax proper, Cyclamineus, hybrids of triandrus and bulbocodium. A child—let alone “the man in the street”—would refuse to squeeze things so dissimilar into one compartment. Did space permit, similar absurdities could be shown throughout the list. In brief, this is the principle of arbitrary division by measurement run mad. The old classification of Mr. Baker and

not be confused with them. Thus, pure Ajax and pure Poeticus should each form a division, and the expert will be at fault so rarely as not to matter in distinguishing, say, the pure Poeticus from its nearest hybrids. Any classification is really for the expert, in the first instance, for it is he who has to assign each new flower to its proper place in the system. I have been answered that division 4 of the new scheme admits of, and was intended to contain, a separate sub-division of pure Poeticus. But this concession appears to me to acknowledge in principle the superiority of the older classification.

It must be seen, too, that, in proportion as

NURSERY NOTES.

MR. R. C. NOTCUTT'S, WOODBRIDGE.

THIS nursery in the interesting little town of Woodbridge in Suffolk was established by a Mr. Woods, some 150 years ago, and was successfully carried on by that family until the death of the late Mr. John Woods in 1896. It was taken over by Mr. Notcutt in March, 1897, in conjunction with his nursery at Ipswich. That its formation has not taken place in recent years is plain enough, even on a casual inspection. It contains pleasant little nooks and other features that seem never to find a place in nursery grounds laid out in the present day. Many old-fashioned plants have been permitted to remain long after they ceased to have a commercial value, and, consequently, they are now fine specimens possessing much interest. Adjoining the nursery is a wood or plantation which, having but little economic importance, is put to a different use, and it might be almost described as a woodland pleasure-ground. We will not attempt to describe its sylvan effects in the different seasons, but direct the reader's attention to the illustration in fig. 51, which shows, although inadequately, that the paths are flanked with bulbs, which in spring-time light up the wood with their brilliantly-coloured flowers. Woodbridge being not far from the coast, the climate encourages the growth of shrubs that in many localities are insufficiently hardy for out-of-doors culture, but this occurs only in places more or less sheltered from the prevailing winds. At the same time, there are many plants that succeed but indifferently on this part of the East coast. So much is this the case, that those interested find it necessary to study the matter pretty closely. Mr. Notcutt's collection is, in the main, a selection of the best of those which have proved themselves suitable for the district. Several species of *Potentilla* were blooming finely at the end of last summer, especially *P. fruticosa*, which formed pretty little shrubs about 2 feet in height. *Buddleia variabilis Veitchii* and *magnifica* both succeed well, but the better of these new varieties appears to be *magnifica*. It is more vigorous at Woodbridge than *Veitchii*, and the flowers, being of darker colour, have the greater effect. The collection of shrubby *Spiræas* contains most of the known species, and *S. Menziesii* triumphans attracted our attention by its rich colouring. *Leycesteria formosa*, *Weigela*s, *Hedysarum multijugum* and *Bignonia grandiflora* all grow well and flower freely. Species of *Cistus* succeed remarkably well, forming fine little sub-shrubs like the specimen of *C. albidus* shown in fig. 52. An excellent variety was noticed in *C. ladaniferus purpureus*, which possesses rich colouring. There appears to be a big demand for Brooms, both standards and dwarfs, which are grafted in the spring of each year in considerable numbers, and grown in pots. Among the many species and varieties of *Berberis*, a variety of *B. stenophylla* named *gracilis* has very attractive foliage. The collection of *Hydrangeas* included *H. arborescens grandiflora*, for which plant Messrs. Paul obtained an Award of Merit from the Royal Horticultural Society on May 14, 1907. The flowers are white, and the plant may be recommended for culture out-of-doors. *Colutea cruenta*, a species of Bladder Senna, with reddish-yellow flowers, and growing about 5 feet high, appears not to be common, although a very old garden plant. Of the numerous Privets, one of the most ornamental varieties for cultivation as standards is *Ligustrum japonicum superbum*. It has variegated foliage of considerable size. Evergreen Oaks are largely grown, and these could be seen

FIG. 52.—CISTUS ALBIDUS IN MR. NOTCUTT'S NURSERY, WOODBRIDGE, SUFFOLK.

Mr. Peter Barr was an admirable piece of work, inasmuch as it contrived to be usefully arbitrary without doing unnecessary violence to the natural divisions. I maintain that, with certain omissions and additions, the broad framework of this arrangement must always be retained—*naturam expellas furcâ tamen usque recurret*.

There are other great objections to the new order. Where the work of disentanglement and arrangement has to be done is in the mass of modern intermediate forms; but the pure elements from which they have been bred should

natural classification is dropped, not only does form become more important in making divisions, but colour also. Any scheme claiming to be ready for actual use must provide for, and should improve upon, the old colour distinctions in each division. This is of the essence of a useful scheme, and it is not enough to suggest, as the new list does, that this may be added in a later edition. Even if its general principle were acceptable, which I deny, this new classification ought not to have been launched until more complete. *G. H. Engleheart.*

in various sizes, from seedlings in thumb pots to large plants from 5 to 6 feet in height.

We cannot, however, enumerate a tithe of the plants in the home nursery which covers an area of 20 acres. Passing to the collection of herbaceous, perennial plants, and annuals, we were particularly impressed by a magnificent bed of *Dierama* (*Sparaxis*) *pulcherrima*. The plants were 7 feet in height, and bore purple flowers on very slender but erect spikes that only bent a little under the weight of the seeds. The species is hardy, and succeeds best when the bulbs have remained undisturbed for a couple of seasons; Mr. Notcutt's plants were three years old from seed.

Another very interesting plant was *Cleome spinosa*, of which an illustration is shown in fig. 50. The illustration was drawn by Mr. Worthington Smith, who had specimens from Mr. W. E. Gumbleton, Queenstown, Ireland, and from Mr. Notcutt. The bed of plants in Mr. Notcutt's nursery was a picture of deep rose-coloured flowers, and the plants were 3 or more feet in height. The seeds were sown indoors, and the seedlings planted into the bed in May or June. Mr. Gumbleton's plants, we believe, grew less high, and the colour of the flower was rather developed. Mr. Notcutt's variety is either superior, or there was a difference due merely to local conditions and cultivation. The flowers have a curious appearance, owing to the extremely long styles characteristic of most of the *Capparidæ*. The plant commences to bloom in July or August.

Amongst a large collection of *Gladioli*, our attention was directed to the American novelty known as *Princeps*. This variety has very large flowers of great substance, and of a brilliant, bright scarlet colour with white markings. A bed of *Asclepias tuberosa* was in full bloom. We inspected a large collection of herbaceous *Phloxes* then in full flower, also collections of *Dahlias*, border *Chrysanthemums*, *Clematis*, *Roses*, and other plants, including many old species of herbaceous flowering plants now seldom seen in gardens.

In the fruit-tree department about 20,000 Apples are worked every year, and half that number of Pears. Most of the Pears are worked on the Quince stock, there being but little demand for Pears on the free stock. The collection of Plum and Cherry trees included about 5,000 trees of each kind. Conference is one of the very best Pears for the Woodbridge neighbourhood, and it crops splendidly. Winter Orange is an old Suffolk Pear, for which Mr. Notcutt obtained an Award of Merit from the Royal Horticultural Society in March, 1899. It is not a dessert variety, but for stewing purposes it possesses excellent qualities, and when cooked retains a very attractive red colour.

Some little distance away from the home nursery is another nursery known as Martlesham Field. This field has an area of about 23 acres. Here we inspected another collection of trees and shrubs, including a fine selection of species and varieties of *Tamarix*, which naturally enough succeed uncommonly well in this East Anglian district. The Judas Tree (*Cercis siliquastrum*) is a favourite tree in the gardens around Woodbridge and Ipswich, where one may frequently see specimens in the front gardens of the suburban villas.

Mr. Notcutt has also the Creek Farm, which consists of about 140 acres, part of which is let. Mr. Notcutt farms about 50 acres, and 20 acres are planted with nursery stock. At Creek Farm the principal features are *Roses*, and even late in autumn many of the plants, especially the hybrid *Teas*, were still blooming well. About 20,000 *Roses* are budded each season.

Altogether, Mr. Notcutt's nurseries are exceedingly interesting, especially the home nursery, for in this the plant-lover will be sure to find something of interest at any time during the spring, summer, or autumn seasons.

The Week's Work.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Paths.—The paths in the kitchen garden should be well drained and made with suitable material. In many cases Grass paths are favoured, and if well kept these are satisfactory. They are not to be generally recommended, however, as they will not withstand rough wear, and the cost of their upkeep is considerable. In my opinion, nothing is better than good gravel, bordered with Staffordshire tiles, which should be set in concrete. The present is a favourable time either for making new paths or putting old ones in a state of repair. If dwarf hedges of *Box* have become too large, the plants may be taken up, trimmed, and replanted: or this work may be deferred until the autumn.

Shallots.—Plant these without delay on ground which has been deeply dug and heavily manured. Fortunately, Shallots may be cultivated on the same ground for many years in succession, provided it is well enriched with manure each season. Shallots are perfectly hardy plants, and, to ensure good results, must be planted early. The rows should be made 1 foot apart, and the bulbs, which should be buried about two-thirds their depth and made firm, should be set at distances of about 9 to 10 inches apart. Wood ashes and soot should be liberally employed throughout their growing season.

Garlic.—Garlic requires practically the same treatment as Shallots, and may also be planted. A small quantity of Garlic is generally sufficient for any garden.

Lettuce.—Further sowings of both *Cos* and *Cabbage* varieties should be made in boxes and raised in a gentle heat. Earlier-raised plants should be placed from 8 to 10 inches apart in pits or frames as near to the glass as the growth of each variety will allow. The soil should be free from wireworm, and must afterwards be made very firm.

Turnips.—Make a small sowing, on a very mild hot-bed in frames, of Early Long Forcing. This variety I have grown for some years with the best results.

Leeks.—Another small sowing of Leeks should be made in heat, and seedlings of earlier sowings pricked off in boxes as they become ready.

Tomatos.—Plants raised last December should be encouraged to make growth so that they may be transferred to the final pots. They may be given a temperature of about 60°. Winter-fruiting varieties which are now bearing ripe fruits must not be overwatered, and the conditions of the house in which they are growing must be kept dry. Maintain a temperature of about 60° and admit air whenever possible. Make another sowing for successional crops, both in and out-of-doors. The plants can hardly be too forward for planting in the open ground provided the growth is sturdy.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Palms.—Experience soon teaches the plantsman that there are few pot-plants which resent root disturbance so much as *Palms*. As a rule, the healthiest specimens are those growing in comparatively small pots, and as these plants are the most useful for decorative purposes, it is always wise to leave them alone, no matter how full the receptacles may be of roots. But in the case of *Palms* which have not yet attained a required size, as well as those which are in an unhealthy state, potting becomes necessary. Peat is needed for very few species of *Palm*. Of those usually grown in gardens, it is necessary only for the species of *Cocos*. For most other *Palms* some good yellow loam, with a liberal quantity of broken charcoal and silver sand will be suitable. In dealing with a plant which has roots almost as deep as the pot it is to be placed in, it will be well to retain the roots but to dispense with nearly all the crocks. Place the roots immediately over the drainage hole and a few crocks around the massive roots, covering these

crocks with lumps of fibrous loam. This will provide ample drainage and be better than mutilating the roots, although in some cases root mutilation may not be followed by unsatisfactory results. If we except species which produce suckers, the stems of other *Palms* should not be inserted below the level of the soil. In the case of *Cocos Weddelliana*, the cause of failure is frequently that of deep potting. *Palms* require an abundance of moisture in the atmosphere as well as at the roots, and a moderately high temperature during the season of growth. Established plants that have filled their pots with roots may be benefited by frequent applications of liquid manure.

Bouvardia.—As *Bouvardia* plants pass out of flower they may be kept slightly drier at the roots. Surplus plants, which will not be required for propagating purposes or forming larger specimens, may at once be destroyed. Propagation is effected either by stem or by root cuttings, the latter method being the better.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Children's playgrounds.—The gymnasiums or children's playgrounds are divided into three classes—for the use of boys, girls, and men respectively. In the London parks there are altogether 16 separate gymnasia for girls and boys, about 12 for girls, women and boys under 10 years of age, and six for the use of men only. Each gymnasium and playground is under the care of an attendant, and those for girls and children are conducted by a female supervisor. The children's gymnasia are open from 9 a.m. until sunset, on every day except Sundays. Several of these playgrounds have a pit of clean, fine sea sand, which is renewed periodically, for the children to dig in and otherwise amuse themselves. The playgrounds are frequented by children at such times as the schools are closed, and they are much appreciated during the holidays. Provision is made for other amusements, such as swings, giant-strides, parallel bars, horizontal ladders, and skipping ropes. Each of these playgrounds contains a large open shed where the children may take shelter in wet weather.

Size of a children's playground.—This depends upon the space available, but in all cases the open-fronted shed should be as large as possible. Our playground measures 75 feet by 25 feet, and it is enclosed by high brick walls on three sides. Provision is made for lavatories, and there is a fountain of drinking water in the centre of the back wall. The covered shed is supported on columns, and it has a corrugated iron roof. There is an attendant's cabin at one end of the playground. A suitable floor must be formed either of wooden blocks or fine asphalt. It is advisable to enclose the swings, &c., with railings, in order to prevent the children crowding round them and receiving injury. On busy days a small number can be admitted into the enclosure at one time, and much confusion and trouble saved. There have been occasions when more than 8,000 children have in one day entered the playground at Victoria Park. Frequently, during the time of the children's holidays, as many as 4,000 and 5,000 may be seen at play.

The sand-pit.—The heap of sea sand has much to recommend it. It is simple, and it affords an amusement and recreation to a large number of children at one time. A large pit is dug out, generally about 50 or 60 feet square, and about 1½ to 2 feet in depth. The sides should be built of well-seasoned Oak timber about 2 inches in thickness; timber from an old ship serves admirably. A floor made with bricks, but not cemented together, is an advantage, and it is wise to place tarred paving around the outside, say, to a width of 4 or 5 feet, so that any displaced sand may be readily swept back again. Our sand is procured from Lowestoft. About 100 tons is a sufficient quantity for filling a good-sized pit. There is a little wastage, therefore in the spring-time the sand is either wholly renewed or an addition is made to it as may be desired. Although some authorities have condemned these sand-pits, no analytical test has ever discovered anything in the sand other than ordinary dirt. It has not been proved that such pits have an influence in the spreading of diseases.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Peaches and Nectarines.—If these trees were loosened from the wires early in winter in order to delay the development of the buds, they must now be trained. Assuming that the trees were disbudded, and the shoots pinched during last summer, very little pruning will now be necessary. Cleanse the trees with an insecticide, taking care to work the mixture well into the crevices or rough places in the bark of the old wood. Before commencing to train the smaller shoots, fasten the main branches securely to the wires in such a manner as to dispose the tree to the best advantage. Train in the smaller shoots between the branches and leave a space of from 6 to 9 inches between each shoot. When the training has been done a top-dressing may be applied to the roots of any trees that have showed signs of exhaustion through over-fruiting or other cause. The top-dressing should consist mainly of good loam and lime rubble, with some approved chemical manure added to it. A heavy mulching applied after the top-dressing has been made quite firm will also assist the trees in regaining their vigour. When the borders have been given this attention, the roots should receive a copious watering. It should be remembered that wall fruit trees suffer from drought more frequently than is generally supposed to be the case. Young trees that are growing vigorously do not require a top-dressing: the borders in this case should merely have their surfaces forked over lightly.

Peach-blister and leaf-curl.—Peach-blister is usually the source of considerable trouble, and it may, therefore, be useful to say that the preparation called "Medela" has been used in these gardens against this pest with success. This specific should be applied at the present time, according to the published directions.

General work.—Take advantage, during unsuitable weather for work out-of-doors, to prepare stakes and labels. All the varieties of fruits should be labelled plainly, it being much more convenient if the name of any particular tree is known in winter as well as in summer. Nets may be overhauled, it being more than probable that some of them require to be repaired. If any new ones are needed, the order for them should be sent early, for the vendors of such nets are usually inundated with orders after the commencement of the fruit season.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Masdevallias.—*Masdevallia tovarensis*, although at one time a very rare and expensive plant, is now well known throughout the country, and is much appreciated by all lovers of Orchids. Its pure white flowers, which are produced during the months of December and January, last a long time in perfection. Being a compact-growing plant, and developing its flowers well above the foliage, it is especially valuable as a decorative plant; the spike of two or three flowers is also extremely useful when other flowers are scarce, for wearing in buttonholes and for similar purposes. The inflorescences will continue to develop flowers for several successive seasons, but it is not advisable to retain the old spikes after they have once carried their complement of flowers, otherwise the plant is liable to deteriorate. The flowering season being over, the present is a suitable time to examine the plants, and any which are bare of foliage in their centres may be broken up and re-made into small, compact specimens. Healthy plants which have sufficient space wherein to grow should not be unnecessarily disturbed. In cases where the compost has become exhausted, the soil may be carefully removed and fresh material substituted. This is more easily done when the soil in the pots is dry. In repotting, the pots or pans used should be filled to about one-half of their depth with broken crocks for drainage, making this secure with a layer of rough Sphagnum-moss. As a potting medium, use good, fibrous peat and Sphagnum-moss in equal parts, taking care to add sufficient small crocks to ensure proper drainage and aeration. About

two months ago several small plants of this species at Burford showed no indication of flowering, but commenced to grow prematurely. They were repotted in a mixture of *Osmunda* and *Polypodium* fibre, intermixed with plenty of small crocks. Up to the present time they have lost no foliage, but appear to be in excellent health. Repotted plants should be very carefully watered till the young leaves are well advanced and the roots have obtained a firm hold of the compost, for if too much water be afforded, both roots and leaves will decay quickly. When well established, plenty of water at the roots is necessary. For the next two months the plants should be kept near the glass on the shady side of the intermediate house, after which time they may be removed to the cool house for the summer.

Cypripediums in the intermediate house.—Such species and hybrids as *C. Fairrieanum*, *C. purpuratum*, *C. Euryades*, *C. Hera*, *C. Arthuri-anum*, *C. Charlesworthii*, *C. Spicerianum*, *C. Sallieri Hyeatum*, *C. nitens*, *C. Actæus*, *C. Lee-anum*, *C. Alcibiades*, *C. Mons. le Curte*, *C. Mrs. Mostyn* and *C. insigne* and its varieties, that have finished blooming should now be given attention provided any have become pot-bound, or, being rare varieties, require dividing for propagating purposes. Strong healthy plants that may be required to form specimens and are already well rooted, may be put into pots 2 inches more in diameter than those they are now growing in. The pots should be made about one-third full of drainage, secured with a thin layer of Sphagnum-moss. When placing the plant in the centre of the pot, it is advisable to keep the base of the leaves just below the rim, so as to make watering easy. A compost consisting of equal parts good yellow loam, turfy peat, leaf-mould, and Sphagnum-moss, well mixed together, with the addition of a moderate quantity of small crocks, will suit any of the plants I have named, also such species as *C. villosum* and *C. Boxallii*. Both these plants are now opening their flowers. The best season for repotting is within a few weeks after the flowering stage. Annual repotting is not desirable. It is only when the old compost is sour, or has decayed, or division of the plants is necessary, that the operation should be done. After repotting the plants apply to the compost a light sprinkling over the surface. This should be continued for a few weeks each time it appears to be dry, after which time ordinary root-waterings should be given. Always keep the atmosphere fairly moist. Shade the plants from direct sunshine.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Tulips.—It is advisable, as soon as the Tulip growths can be seen through the soil, to apply a top-dressing consisting of some sifted leaf-mould with a little soot, lime and chemical fertiliser added. Such a top-dressing is also useful for Crocuses, Hyacinths, *Silene*, *Myosotis*, Wall-flowers and Arabis. Crocuses and Snowdrops growing in Grass more especially need such a top-dressing.

Ranunculus.—It is a suitable time to plant *Ranunculus*. The best soil is one composed of a rich, rather light loam into which has been incorporated some well-decomposed cow manure and sand. The bulbs should be planted about 2 inches deep and 3 inches apart. Planting may be continued until the middle of March if desired. Turban *Ranunculus* flower about the middle of May, and Persian sorts the end of May or beginning of June.

Tree Peonies.—These should be planted as soon as the weather is favourable; being gross feeding plants, they require a very rich soil. It is necessary to protect the young growths from spring frosts.

Tuberous-rooting Begonias should be examined with a view to starting them into growth. The largest tubers can be divided, should it be necessary to increase the stock. Afford sufficient warmth only to induce a slow growth at the start. The same remarks apply to *Cannas*. Seedling plants in pits and frames should be kept somewhat dry, as they withstand frost better in that condition.

Vacant flower-beds or borders should be deeply dug and manured. If they are occupied by spring bedding plants, the necessary manure must be placed ready at hand so that as soon as the spring-flowering plants have bloomed the land can be got ready for the summer bedding.

Cortaderia argentea (Pampas Grass).—The clumps of this ornamental Grass should be trimmed, the old inflorescences removed, and the plants generally made tidy. The present is a suitable time to plant the Pampas Grass. Select a position by the side of a stream or lake or a position on a Grass plot, but the site must be a fairly sheltered one, otherwise strong winds will break the plumes. The best soil for the Pampas Grass is a moderately light one, and one containing plenty of manure. As the inflorescences are developing in summer-time, copious watering at the roots will be of benefit. The Pampas Grass can be propagated by division of the clumps and from seeds; the latter should be selected from the finest plants.

The bog garden.—As dead and withered foliage will protect the plants from damage by severe frosts, the plants should not be made tidy until the winter is past.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Planting one-year-old vines.—The border should be prepared two or three weeks before the vines are to be planted, in order that the soil may become properly settled and suitably warmed. All the old soil should be removed, and advantage should be taken when the house is empty, to cleanse the woodwork or repaint it if necessary. The depth the border should be made will depend on the variety to be planted and, to some extent, on the width of theinery. For the first two years a width of 4 feet will be ample. In the case of late vines, the borders should be at least 3 feet deep, but plenty of drainage material must be provided. It is a mistake to plant late varieties of Grapes in shallow borders, as these require water too frequently. For early and mid-season varieties a depth of 2 feet 6 inches will be ample. The bottom of the border should be concreted, unless the subsoil is gravel, and a layer, not less than 9 inches deep, of material for drainage should be provided. The vine enjoys a rich, calcareous loam, containing plenty of vegetable fibre; the top spit of an old pasture is the most suitable material. Artificial manures and coarse bones should be added, and the quantity will be more or less according to the quality of the soil. I do not advise the use of farmyard manure for vine borders except as a surface dressing. Old mortar rubble and wood ashes may be freely employed, especially if the soil be of a heavy nature. In making the border, it is important to ram the soil as firmly as possible. The best time to plant is when growth is just becoming active. The roots should be spread out evenly, and for this reason they should be carefully separated with a pointed stick; this work will be facilitated by occasionally dipping the "ball" into a tub of lukewarm water. Make a hole of sufficient depth for the roots, spread them out to their full length, and work in some fine soil amongst them, arranging them carefully and near to the surface. The planting should be done as expeditiously as possible, and, as soon as completed, the roots should receive a copious watering, making the water tepid and applying it by means of a fine-rose can. Theinery should be kept warm and close, but artificial heat should be used very sparingly till the roots are active, or the vines will grow weakly.

Cherries.—The house should be fumigated just before the trees come into bloom. The Cherry is very impatient of forcing, and for this reason sudden increases in temperature are to be avoided, especially when the trees are in flower. At this stage the atmosphere in the house should be moderately dry and in constant circulation, but there should be no severe draughts of cold air. Tap the trees at mid-day to aid the dispersion of the pollen. Pot trees will require very careful watering until the fruits commence to swell.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 23—

Roy. Hort. Soc. Coms. meet. (Competitive Classes for late dessert Apples. Lecture at 3 p.m. by Mr. Arthur W. Sutton, on "A Camping Tour through Syria to Petra in Arabia.") Surveyors' Institution Annual Dinner at Hotel Métropole.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39.9°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, February 17 (6 P.M.): Max. 44°; Min. 31°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, February 18 (10 A.M.): Bar. 30.0; Temp. 43°; Weather—Fine.

PROVINCES.—Wednesday, February 17 (6 P.M.): Max. 49° Sligo; Min. 35° Scarborough.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous and Border Plants, Lilliums, Bulbs, Plants, &c., at 12; Roses and Fruit Trees, at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Perennials, Border Plants and Bulbs, Lilliums, &c., at 12; Roses and Fruit Trees, at 1.30; Palms and Plants, at 5; Miscellaneous Bulbs and Roots, at 11.30; Japanese Lilliums, at 1; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—

Special Spring Clearance Sale of Nursery Stock at Hollamby's Nurseries, Groombridge, near Tunbridge Wells, by Protheroe & Morris, at 11.

FRIDAY—

Choice Imported and Established Orchids, Orchids in Flower and Bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Orphan Fund.

A few weeks since we recorded the proceedings at the Annual Meeting of the Gardeners' Royal Benevolent Institution. In the present issue it is the turn of the Royal Gardeners' Orphan Fund. Just as in the case of the Benevolent Institution, this Report of the Executive Committee goes to show that a large amount of money has been subscribed for the purposes of charity. The year 1908 saw the Coming-of-Age of the Orphan Fund, therefore extra efforts were put forward to make the year one of greater progress than usual. The Duke of Bedford, president of the Fund, presided at the Annual Festival, and, in connection with that event, a greater sum of money was raised than at any similar Festival in the history of the Fund. In order to spread an interest in the work, especially amongst those young gardeners who have not felt themselves in a position to subscribe 5s. a year, the committee invited shilling contributions. This new means of appeal obtained a considerable degree of popularity, and resulted in the collection of a sum of £250. The shilling contribution, therefore, rendered considerable financial assistance, but beyond this it served to make the Fund better known to many who heretofore had displayed but little interest in it.

The proceedings at the Annual Meeting will be read with supreme satisfaction, for not only were 20 additional children elected to

the Fund, but after an appeal by Mr. Harry J. Veitch in favour of the candidates who had met with ill-success at the poll, the committee and general meeting resolved to place these also upon full benefit. We believe that the committee is well advised to thus employ to the full the funds at their disposal, rather than to save an amount each year greater than is necessary to provide for a proper reserve fund. Gardeners and others who have supported the Orphan Fund in the past will be the more encouraged in their liberality by such enterprising policy. It was pointed out at the meeting that the two candidates who received most votes were orphans of a gardener who had been a life member of the Fund, and who, in other directions, had done all he could for the charity during the time that he was in a position to afford help. This may be taken as a reliable indication that, if gardeners subscribe to the Fund, their children will be the more certain of obtaining support should it ever be necessary for them to appeal to the subscribers. During the 21 years that the Fund has been in existence, it has distributed the sum of £19,506. The total number of orphans who have received benefits is 253. The disbursements last year amounted to £1,621 7s. 6d.

Mr. Henry B. May announced that already there were nine candidates whose applications had been accepted by the committee, and who therefore will come up for election next February. Circumstances seem to show, therefore, that the list next year will be a heavy one. We have every reason to hope, however, that the support the Fund will receive during this year will be equally large, and that, at the next annual meeting, it may be found again possible to grant assistance to every child on whose behalf application is made for relief.

The Shropshire Show.

The Secretaries of the Shropshire Horticultural Society have sent us a copy of the schedule of prizes to be offered at the exhibition which will be held at Shrewsbury, on August 18 and 19 next. We do not find any important additions or omissions in the section for plants and cut flowers. Liberal prizes, amounting in some classes to £50, are again offered for groups of plants, and in others that are less exacting the prizes are proportionately high. In the classes for cut flowers there appears provision for almost every species that may be expected to be in season at that time. The principal class in the fruit department, as last year, is one for a collection of 30 dishes of ripe fruits in not fewer than 10 distinct kinds. The 1st prize will consist of a handsome silver Champion Cup, value 25 guineas (to be won three times), and £20 in cash, with the Society's Gold Medal. In the remaining prizes in the same class a sum of £55 is offered and two medals. The Cup was won for the first time last year by the Duke of Westminster's gardener, Mr. N. F. Barnes. Most of the other classes for fruit familiar at Shrewsbury are repeated, and an excellent display may be confidently anticipated.

The show of vegetables will be of less extent than usual, but this will not be due to any cutting down of the Society's own classes. It will be caused by the omission of most of the special prizes usually offered by

the principal seedsmen. We understand that an explanation of the absence of these classes is to be found in a new regulation which the Society has introduced to the effect that no condition shall be expressed in the schedule which would require the seeds to be purchased from the donors of the prizes. We for our part are, nevertheless, disposed to regard this regulation as introducing a salutary reform. The familiar cards stating that the produce has been grown from So-and-so's seeds have little, if any, value to the public; whilst they certainly detract from the general appearance and repute of the exhibition. Assuming that in all cases the exhibits have actually been raised from such particular seeds, the practice has the effect of implying that the superior quality of the produce is due solely or chiefly to that fact; whereas, the greater part of the credit rightly belongs to the cultivator, and therefore the exhibitor. It has been alleged again and again that sufficient care is not always exercised in the placing of such cards; but whether this is the case or not, the practice of admitting them to the exhibition is certainly susceptible of abuse, whilst the condition that only such exhibitors who purchase seeds from the firms offering the prizes may compete, serves to limit unnecessarily the number of competitors. It is to be hoped, therefore, that the trade will come to recognise that the new regulation which is designed to increase the prestige of the show is in no wise derogatory to that of the trade itself. Such being the case, the Society deserves all support. On another page a correspondent points out that it may be possible to evade the spirit of the Society's regulation, owing to the wording of the schedule in the few special classes that have been retained. If this is true and the intention of the committee is frustrated amended regulations will be required.

A further innovation is to be noticed with regard to the honorary exhibits. In future a definite number only of silver cups, and gold and silver medals will be awarded to non-competitive exhibitors, probably with a view to enhancing the value of these awards.

OUR SUPPLEMENTARY ILLUSTRATION.—Some years ago Messrs. CHARLESWORTH & Co., of Haywards Heath, raised and flowered a hybrid between *Lælia harpophylla* and *L. cinnabarina*, which they named *L. coronet*. Its flowers were of bright orange colour, similar to *L. harpophylla*, and they were larger than that species. In other respects, however, the hybrid possessed but little qualification as a garden plant. Like some other despised seedlings, it has made a very good parent, and when crossed with *Cattleya Schröderæ* it has produced a hybrid which retains the intensely bright and deep orange colour whilst the flowers are of good size and substance. The plant depicted in our Supplementary Illustration was shown by Messrs. CHARLESWORTH & Co. at the Royal Horticultural Society's meeting on March 17, 1908, when it obtained an Award of Merit. It is known as *Lælio-Cattleya Elinor*.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will take place on Tuesday, the 23rd inst. At 3 p.m. a lecture on "A Camping Tour through Syria to Petra in Arabia" will be delivered by A. W. SUTTON, Esq., J.P., F.L.S., V.M.H. This interesting lecture will be illustrated with lantern-slides.

EXAMINATION OF EMPLOYÉS IN PUBLIC PARKS.—The Royal Horticultural Society's fourth examination of the employés in public parks was held on January 11 last. As previously, the examination was partly *viva voce* and partly written, occupying about 3 hours and a half. It was held at the Society's Hall in Vincent Square, Westminster. One hundred and nineteen candidates entered, and of these 25 secured places in the first class, 40 in the second, and 37 in the third, leaving 17 candidates who failed to obtain the minimum marks required. No one candidate stands out prominently before the others, and the highest marks obtained fall considerably below those of 1908. It is encouraging, however, to notice that about 50 per cent. of the candidates in Class I. consisted of those who had been in the lower classes last year, and that other candidates of former years, if not yet in Class I., are higher in the list this year than they were previously. Reviewing the results generally, the examiners state that "there is still much room for improvement, the higher standard hoped for in last year's report having to be still held in anticipation. A complete knowledge of garden practice and the reasons for it; the values of phosphatic and nitrogenous manures, their comparative cost, and the quantities required; the art of curves and the power to express them neatly on paper; arithmetical calculations for land measures and simple cash computations—such things as these, added to a more extensive knowledge of gardening specialised for public parks, are necessary to raise the employés to the standard of really first-class craftsmen whose skill is to find expression in the gardens in which they serve. The higher places gained by most of the old candidates in the lists should be an encouragement to the less successful to persevere diligently with their work and try again next year."

APPOINTMENTS.—Mr. ARCHIBALD CLARENCE MILES, a member of the gardening staff of the Royal Botanic Gardens, Kew, has been appointed by the Secretary of State for the Colonies, on the recommendation of Kew, a Curator of Botanic Stations in the Agricultural Department of the Gold Coast. Mr. W. C. WORSDELL has been appointed deputy Professor of Botany at the South African College, Cape Town, South Africa, in the room of Professor H. H. W. PEARSON during his travels in Angola and elsewhere in the present year. *Kew Bulletin.*

CHANGES AT KEW.—Mr. WILLIAM DALLIMORE, who has had charge of the Arboretum at Kew for some years past, has been appointed to the New Museum for British Forestry, under Mr. HILLIER. Mr. ARTHUR OSBORNE, Foreman in the decorative department, will succeed Mr. DALLIMORE as Foreman in the Arboretum.

MR. CHARLES FOSTER, Assistant Director of Horticulture at the Reading University College, will remove to Sutton Place, Guildford, in July next to take up the position of director of a model farm which Lord NORTHCLEFFE is about to establish.

SCHOOL GARDENS IN STAFFORDSHIRE.—In the quarterly report of the Staffordshire Education Committee it is stated that the former system of evening gardens is to be superseded, as it has been found to overlap with the elementary day-school gardens. Four schemes are put forward in replacement, by which instruction in horticulture can be given. The scheme to be adopted in any place will depend upon local circumstances and the report of the instructor. The schemes are as follow:—(1) Allotment demonstration plots, (2) model cottage gardens in villages, (3) fruit demonstration stations, (4) evening gardens of fruit and vegetables.

SOUTH-EASTERN AGRICULTURAL COLLEGE.

—A meeting of the Governors of the South-Eastern Agricultural College was held at the Charing Cross Hotel on Monday, February 8. The Right Hon. Lord ASHCOTTE, who was elected chairman for the ensuing year, presided. The Principal, Mr. M. J. R. DUNSTAN, in his report, stated that the number of students attending the college courses was 127, the largest number on record for the spring term, and that the new horticultural course had commenced with 14 students.

VISITORS TO KEW DURING 1908.—The number of persons who visited the Royal Botanic Gardens during the year 1908 was 2,710,220. These figures show a decrease of 252,494 visitors over the year 1907, when the number of visitors was the largest yet recorded. During the last 10 years (1898-1907) 16,428,084 persons have visited the Gardens, giving an average of 1,642,808. The total number on Sundays was 1,321,384 and on week-days 1,388,836. The number of visitors on Sundays is the largest on record, being in excess of that for 1907 by 52,883. The increase is probably very largely due to the great number of French visitors during the summer. The total number on week-days was 1,388,836, the corresponding number for 1907, 1,691,213. The maximum attendance on any one day was 98,388 on August 3. The smallest number on any one day was 68 on January 21. The greatest number on a Sunday was 70,904 on July 26, and is a record number for a Sunday, showing an excess of 5,990 visitors over the figures for 1907. The smallest number on a Sunday was 1,032 on December 6. *Kew Bulletin.*

THE LATE G. H. SAGE.—Many of our readers will regret to hear that Mr. G. H. SAGE, whose somewhat unexpected death was recorded in these pages recently, has left a widow and young children almost or entirely unprovided for. We have received a letter from Mr. W. A. COOK, gardener at Leonardslee, Horsham, in which he states that a number of friends have decided to raise a sum of money for presentation to the widow, and it is hoped that gardeners will assist this fund to the extent of their ability. Mr. COOK states that the following sums have been already given or promised: Messrs. R. & G. CUTHBERT, 2 guineas; "X.Y.Z.," 20s.; J. JENNINGS, 10s.; H. G. SMYTH, 10s.; J. BARNSHAW, 2s. 6d. Others interested in this movement are:—Messrs. CHARLES DICKSON, JOHN MCKERCHER, CHAS. FOSTER, JOHN WEATHERS, JOSEPH GODSEFF, H. G. ALEXANDER, HERBERT J. CUTBUSH, W. J. WATSON, L. R. RUSSELL, C. F. WATERS, T. WALTERS, A. R. ALLAN, A. TAYLOR, A. R. SEARLE. Mr. W. A. COOK is the honorary secretary, and contributions may be sent to him. It is suggested that a shilling contribution, if generally supported, would be sufficient to meet the case.

THE KING'S VISIT TO BERLIN.—It is interesting to record that the whole of the floral decoration for the banquet offered by the British Embassy to their Majesties the KING and QUEEN during their recent visit to Berlin was entrusted to a London firm of florists—Messrs. FELTON & SONS, of Hanover Square. The flowers used for this purpose were scarlet Carnations, Lilies of the Valley and white Lilac. Owing to the fact that the flowers obtainable in the German capital were not of so high a quality as the best grown in this country, it was found necessary to arrange them in masses instead of lightly, as would have been done if finer blooms with longer stems had been available. Among the other floral decorations carried out by Messrs. FELTON in connection with the Royal visit were those of Messrs. WARING & GILLOW's Berlin establishment. Here the effect was produced by the use of "Mimosa" (Acacia), Violets, brown foliage, and mauve ribbons.

In carrying out this work, undertaken at three days' notice, 100 workmen and three interpreters were employed. Only the kindly aid of the Municipal Fire Brigade in the shape of two fire escapes enabled the men to place the floral and other decorations at the higher altitudes of the building. It is a matter of congratulation for Messrs. FELTON to know that both His Majesty KING EDWARD and H.I.M. the KAISER expressed their appreciation of the work.

RECREATION GROUND FOR SOUTHALL.—A new recreation ground has been secured by the Southall District Council, says the *Times*, and it is to be called Southall Park. After the completion of the erection of a new lodge at the entrance, Lord and Lady JERSEY will perform the opening ceremony, which has been fixed for May 1.

BERLIN INTERNATIONAL HORTICULTURAL EXHIBITION.

—The Prussian Horticultural Society (Der Verein zur Beförderung des Gartenbaues in den Preussischen Staaten) is making preparations for an international exhibition to be held about Easter in the newly-erected Exhibition Halls at the Berlin Zoological Garden. The honorary president of the exhibition is Herr VAN ARNIM-CRIEWEN, Minister of Agriculture. The Prussian Government has appointed official representatives of all foreign European states, and from these special exhibition commissioners are selected. His Majesty the KAISER, who, like all kings of Prussia since the year 1822, is the patron of the society, will give a prize of honour for the most excellent exhibit. Her Majesty the KAISERIN, who takes the greatest interest in plants and in flower shows, will award a Gold Medal for the best object of the florist's art, a silver medal for the finest specimen of German Rose culture, and a bronze medal for the best German Lily of the Valley. Her Imperial Highness the CROWN PRINCESS, as showing her sympathy in the exhibition, will give an award of honour. The city of Berlin has sanctioned prizes of a total sum of 6,000 marks, and many suburban authorities are also offering prizes. A guarantee fund has been raised of more than 100,000 marks. The entire building construction and the horticultural decorations in the two adjacent halls are so planned that the more decorative Hall I will be chiefly set apart for German exhibitors and their exhibits. The handsome orchestral space will be enlarged and made to resemble the castle terrace of the Achilleion, in Corfu, and its gardens. It is stated that Holland intends to have a special show, in which bulbs, Rhododendrons, Azaleas, fruits and vegetables will be chiefly represented. France is preparing for a private exhibition of novelties in plants, forced fruits, vegetables, and French floral arrangements. From Belgium will be shown stove and greenhouse plants, Palms, Azaleas, Araucarias, and hybrid Orchids. It is hoped that England will be well represented. About one-third of the available space will be occupied by foreign exhibits.

"ZEITSCHRIFT FÜR BOTANIKER."—The first number of a new German botanical periodical, the *Zeitschrift Für Botanik*, has just been issued. The *Zeitschrift* is edited by Professors JOST, OLTMANN and GRAF ZU SOLMS-LAUBACH, and published by GUSTAV FISCHER in Jena at the price of 24 marks per annum. The first number contains an account by HANS FITTING of his investigations, conducted for the most part in the Botanic Gardens of Buitenzorg (Java), on the effects of pollination, &c., on the flowers of Orchids. The number contains also a series of reviews of current, botanical research publications and classified lists of new literature. The names of the editors and publisher are a sufficient guarantee that the *Zeitschrift* will be a valuable addition to periodical botanical literature.

LAW NOTES.

OWNER'S RISK.

As an effort is again being made to get this question brought before Parliament, may I be permitted to state briefly the position?

The attitude of the railway companies.—Last year a well-known nursery firm in the north had 6,000 five-year Spruce trees rendered worthless in transit. A claim was made and the following was the reply received from the traffic manager of the railway company:—

I submitted your claim to a meeting of the Joint Claims Committee of the Scotch Railway Companies, held at Perth on 2nd inst., but regret to say could not get it passed for settlement.

The owners risk note which was signed at the time of forwarding clearly protects the company and relieves them from all liability, not only for loss, but also for injury.

I am exceedingly sorry that you should have suffered through this accident, but the difference saved by carrying your goods at the owner's risk rates, instead of company's, must amount to a considerable sum in the year, and should go some way at least towards covering your loss.

The attitude of the Courts.—The judge said if people would persist in taking advantage of these low rates and signing contract notes which relieved the company of all liability, he did not see how they hoped to recover. Judgment would be given for defendants—the railway company, with costs.

The official attitude.—Extract of report of Departmental Committee on Fruit Industry appointed by Lord Onslow, President of the Board of Agriculture, 1903.

With regard to the refusal of the companies to pay claims for loss or damage, especially in the case of fruit consigned at owner's risk, the committee are strongly of opinion that it would be a great advantage to all parties if carriage at owner's risk were done away with altogether. Mr. Hennell, as representing the companies, was clearly of this opinion, and stated that, when the Great Western Company framed their new scale for goods traffic, they made the rates at company's risk only, and that they did not, as a rule, give owner's risk rates between places where they controlled the traffic, on account of the friction which invariably arose. We believe that if the owner's risk rates at present in existence were slightly raised, say, 5 per cent. (which Mr. Vincent Hill suggested was the proper difference between them and company's risk rates—though the actual difference is generally much more, and varies enormously), and if all fruit, both by goods and passenger trains, were carried at company's risk in future, growers would gladly pay the small extra amount, and get rid of the present annoyances and loss occasioned by the non-payment of claims, or the payment of them only after much correspondence and delay.

In the event, however, of the owner's risk rates being maintained, the committee are of opinion that the exemption of a company from liability unless "wilful misconduct" is proved, is too stringent a condition; for, in hardly any case would it be possible for a consignee to obtain the necessary evidence, as that would have to be derived from the servants of the company itself. They consider that the term "culpable negligence" should be substituted for "wilful misconduct."

They are glad, however, to note that, according to Mr. Hennell, the railway companies seem inclined to take a more reasonable view of their liability, and to admit claims in the case of total loss, and sometimes in the case of damage, the assumption of this attitude being, no doubt, largely due to the representations made by the Board of Agriculture to the railway companies in Great Britain, the correspondence being subsequently presented to Parliament.

The attitude of the horticultural trade. It is universally felt that it would be a great gain if a Bill on the lines of Mr. Hooper's could be got through Parliament making the railway companies liable for "culpable negligence" or "gross neglect" instead of, as at present, being only responsible for "wilful misconduct." The latter no one outside the railway is ever able to prove. Then I believe it is a universal opinion that a simple arbitration court to settle disputes, or, as Mr. Morgan Veitch so ably advocates, a simple procedure in the county or borough courts from which, in matters of litigation between a railway company and a trader, there shall be no appeal where the amount of dispute is under £20.

The sheer absurdity of judges and railway companies' contentions that traders must send at the higher or company's risk rates is apparent by simply stating that the difference between the two rates on seeds and plants is often as much as 100 per cent.—in the case of Tomatos it is more, viz., 42s. 6d. owner's rate London to Glasgow, while company's risk rate is 100s. per ton.

Railways are now more than ever before, owing to their joint committees, a gigantic monopoly, and it is the duty of Parliament to find a way out for the public—the trader. The Board of Trade is no good *William Cuthbertson.*

NOTICES OF BOOKS.

* "THE BOOK OF NATURE STUDY."

In the second volume of this work Mr. Oswald Latter continues his remarks of invertebrate animals. The present contribution includes a most interesting description of bees. Though concise, it affords a good knowledge of what goes on in a hive. Perhaps more might have been said with regard to the economic aspects of these creatures, and the same remark applies to the article on ants, which is the next subject dealt with. Gardeners will be especially interested in the chapters on plant-lice and gall-flies. The gnat is given as a type of aquatic insect which can be reared easily in captivity and kept under observation; and a water-bettle (*Dyticus*) is used as an illustration of the beetles.

If a brief space can only be given to well-known forms, it is not to be expected that much will be devoted to creatures which have hitherto attracted but little attention. This is regrettable, because some of those students who become interested enough to study natural history might, with advantage, turn their attention to neglected animals. As a matter of fact, many observations still remain to be made upon the centipedes and millipedes, and not quite three pages of the *Book of Nature Study* are devoted to them.

Spiders receive a little more attention, as do the snails, slugs, and fresh-water mussels. The carnivorous forms of so-called worm-eating slugs have a special interest to the gardener, in that they will do no harm to vegetation and may be useful in keeping down earthworms.

Little more than one-third of the volume is devoted to the consideration of the aquarium, as well as of fresh- and salt-water plants and animals that most easily accommodate themselves to a life in restricted conditions. Miss Marion Newbiggin is responsible for this contribution. Several aspects of the aquarium are pointed out:—By its use the teacher may keep creatures which can be utilised as the subjects of lessons; the habits of aquatic creatures may be studied in a way and to a degree which could not be accomplished if the creatures were in their natural surroundings; and, finally, the aquarium shows how plants and animals mutually depend upon one another.

Careful directions are given for starting aquaria, and suitable algæ and aquatic water plants are dealt with. Of the larger animals suitable for a fresh-water aquarium, the pond tortoise of South Europe and various amphibia and a few fish are mentioned, and afterwards molluscs, crustacea, and insects. In a similar manner marine forms are described, of which the invertebrate forms belong to the classes already mentioned. In addition, though, we have sea-urchins and star-fishes, and those very common inhabitants of the marine aquarium, the sea-anemones and their allies. The concluding chapter has been written by Professor Arthur Thomson, and serves to illustrate that, in nature study, the outlook should be a general one, and that observations should not be confined to the creatures themselves, nor to their habits merely, but should also include their surroundings and inter-relationships. The title chosen is "The Haunts of Animals." The habitats dealt with include the seashore, the open sea, with its free-swimming population, the depths of the ocean, where everything is dark, and silent, and cold, and where there are no plants. Rivers, lakes, and ponds are also considered in connection with their inhabitants; whilst on dry land, liuks and dunes, meadowland and woodland receive attention. Lastly are considered the dwellers of the air.

* *The Book of Nature Study*, Vol. II. Edited by J. Breland Farmer, D.Sc., F.R.S. The Caxton Publishing Co. Price 7s. 6d. net.

The contribution gives many useful hints and much valuable information for those who wish to carry on that outdoor, observational work which should be the keynote of all nature study.

Hints as to shore excursions follow, and Professor Thomson describes a typical one. To the open sea he gives less attention, and, as the subject of the abysses of the ocean is removed from the direct scope of nature study in school, he passes over this with little comment. We commend Professor Thomson's further remarks to the consideration of every earnest exponent of nature study.

As in the previous volume, particular attention has been paid to illustrations. The photographs of pools with which Miss Newbiggin illustrates her chapters are extremely good. Such creatures as slugs, centipedes and woodlice are not usually represented by photographs, but the pictures by Mr. Hugh Main show that there are considerable possibilities in this direction. Mr. Berridge's photograph of a millipede is also very good, and so are those of bees and ants by Mr. W. P. Westell.

We are promised in the third volume chapters on the germination of seeds and the growth of plants by Miss Charlotte Laurie; Dr. Lang will deal with common plants and their structure; while trees, Ferns, and children's gardens will form the topics to be considered next. *W. M. W.*

* ALPINE FLORA.

MONS. CORREYON is well known as an authority on Alpine plants, and those who have visited his garden at Floraire are well aware that he can also grow them successfully. We had every reason, then, to look forward with pleasure to the appearance of the *Flore Alpine* when it was advertised as amongst the forthcoming books on horticulture. The expectation is realised on opening the volume, though, perhaps, not quite in the form we anticipated. The book opens with a brief introduction, and to this succeed 100 coloured plates by Mons. Robert of some 180 plants. The reproduction is, in many cases, remarkably good, and the tinted background forms an effective feature in each study. The work is so excellent that it is difficult to signalise any particular plate for praise beyond another, and there is hardly one that fails to reproduce accurately and artistically the plant it portrays. Perhaps we may be allowed to regret that the *Soldanella* is represented as mauve rather than blue. We have seen plants of the former colour, but one generally associates a more pronounced shade of blue with the flower than is depicted on pl. 66.

The general introduction to the letterpress follows the plates, and contains a brief account of some of the famous rock-gardens of Europe, among which those of this country easily predominate. A fine picture of the "Matterhorn" in Sir Frank Crisp's garden strikingly recalls the great mountain itself. In connection with this plate, we might incidentally remark that the reference should be to p. 248, not to 234, as given in the legend.

The description, together with cultural notes, of a good representative collection of Alpine plants then follows, and the hints respecting some of them are such as to make one realise the defects of our own climate. *Eritrichium* is said to need a certain degree of care! Of *Androsace glacialis*, perhaps wisely, nothing of cultural advice is offered. Its habitat is given, and the paragraph ends in a verse.

The names of the plants are given in English as well as in foreign languages—an advantage to the tourist, who might well add Mons. Correyon's volume to his bag when making an expedition to the Alps. The only serious fault we have to find with the book is on account of its weight, but the delicacy of the plates could, perhaps, hardly have been secured except on a heavily-loaded paper.

* *Flore Alpine*, by H. Correyon and Ph. Robert. Illustrated with 100 coloured plates. Geneva, 1908. Price 18s.

ÆSCULUS PARVIFLORA.

THIS species (see fig. 53) differs from other members of the genus in having a shrubby habit and in producing its flowers in the month of August, a time when most other shrubs have finished their flowering. The plant is a native of South-Eastern United States, and is usually to be seen near rivulets in moist situations, where it forms large, spreading clumps or thickets. Under cultivation in this country *Æsculus parviflora* forms a large, spreading shrub, reaching 10 or 12 feet in height and as much as 20 feet in diameter. The bushes spread by means of suckers, which are produced near the main stem, so that the plant does not encroach very fast upon other shrubs or trees with which it may be associated. The pure white flowers are borne in long, terminal thyrsoid racemes, sometimes more than 1 foot in length. The petals, usually four, vary in number, there being sometimes as many as seven: the upper are slightly longer than the lower petals. The stamens, which are long and thread-like and often three times the length of the corolla, form the attractive part of the flower. Each filament is tipped with a conspicuous red anther. The foliage resembles that of the Horse Chestnut, but is somewhat smaller. The plant thrives in a moist soil and delights in an open, sunny position. It forms a fine subject for the shrubbery, border or lawn. On account of the white flowers, the plant shows best when in bloom against a background of trees or tall shrubs. C. P. R.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

VEGETABLE COMPETITIONS AT SHREWSBURY.

—Competitors in the vegetable classes at the Shrewsbury show must have opened their eyes wide when they read their schedule of the classes at the ensuing show in August next. Those favoured classes which invariably brought great competition and the finest of vegetable products have entirely disappeared, and their places taken by small or single-dish classes for prizes offered by a Manchester and a Wordsley firm. It is stated—although whether correct or not I do not know—that this year the Shropshire Horticultural Society declined to accept any prizes lettered with conditions as to the sources from which seeds be obtained. If that is so, no one can complain. Nevertheless, its vegetable department, which has hitherto been such a popular one with exhibitors and visitors, must under the new arrangement materially suffer. That result, no doubt, the society has anticipated, and may have good reasons for the course it has taken. But there remains good cause to think that, in spite of the determination of the society to exclude special restrictions as to the source from which seeds are obtained, the conditions annexed to classes 109 to 116 and 117 to 126 rather override the society's intentions. In each of these classes the name is given of a variety which a particular firm has not only so named but of which it claims exclusive ownership. How are competitors to obtain these things, except from the firms in question, and is not that a method of compelling such purchases quite as bad as any methods or conditions which have previously prevailed? Assuming that any competitor showed Best of All or Scarlet Emperor as "New Exhibition Runner" Bean in Class 118, and this is quoted as an example, and a representative of the firm offering the prizes declares it should be disqualified, because not their "New Exhibition," specially on the ground that the competitor had purchased no seed from that firm, what would result? Would the judges be compelled to disqualify? Some authoritative statement should come from the society as to whether exhibitors in these classes are necessarily compelled to obtain seeds of the varieties from the firms offering the prizes or not. If the answer is yes, then the society's new conditions disappear. If it is no, then no competitor can be disqualified. *Vegetable.*

NITRO-BACTERINE.—The following experiments which I made during 1906 may be of interest:—The bacterium (*Pseudomonas radicola*) were obtained direct from the U.S.A. Department of Agriculture, and had been prepared on the cotton-wool system then in vogue. A field on which the usual rotation of farm crops had been grown was selected, and long beds, 1 foot wide and 50 feet long, were carefully prepared, each bed being afterwards sown with equal quantities of Clover seed. One bed was then watered with plain water and the other with bacterial culture. During the summer and following year the beds were constantly examined, but although the crops succeeded well, at no time could any difference be discovered either in the growth or amount of nodules on the roots between the two beds. The second experiment, on Sweet Peas, made at the same time and with the same culture, gave a different result. Ten new flower-pots were filled with a mixture consisting of equal parts cinder-ash and sand, which had been baked for an hour in a large furnace. Five of these pots were sown with 12 ordinary Sweet Pea seeds, the other five with 12 seeds, which had previously been soaked in the bacterial culture; all the pots were afterwards placed in a greenhouse and kept moist with rain-water from a tank inside. The uninoculated plants made very little progress, being dwarfed and appearing chlorotic, with very few flowers and no nodules

velopment of Apple scab such as seen last year was largely due to two successive rather cold and wet seasons that were far from being favourable to the production of good fruit out-of-doors. But now that through such climatic conditions scab seems to have got such a foothold is it wise to trust to a succession of warm, dry summers to check it, or should the trees be sprayed for that purpose? If any readers have had experience of home spraying, they may do well to let the world know the results. A. D.

MOISTURE-LOVING PLANTS.—Mr. Smith (p. 52) mentions a white form of *Astilbe Davidii* known as "grande," which he says is "worthy of extended planting." This white variety of *Astilbe*, so far, has not come under my notice, neither have I seen mention made of it before. There is, however, a species known as *Astilbe grandis* which differs in several particulars from *A. Davidii*. This is, indeed, a splendid plant for moist positions. The foliage is strong and vigorous, the individual leaves measuring often 2 feet in length. It grows to about 6 feet high, 2½ feet of which is composed of the erect slightly branching spike of white flowers. The inflorescence has not the plumose appearance of that of *A. Davidii*, and the plant has a stronger, holder habit than that species. Another addition to Mr. Smith's list might be *Artemisia lactiflora*, which also is a plant of recent introduction, and one specially adapted for half-

[Photograph by C. P. Raffill.]

FIG. 53.—ÆSCULUS PARVIFLORA FLOWERING IN THE ROYAL GARDENS, KEW.

on the roots, while the inoculated plants made rapid growth of a typical green colour nearly twice as high, and they produced many flowers at least a week earlier than the others. The roots carried a number of good-sized nodules. *Gurney Wilson.*

APPLE SCAB.—I saw during the early winter large quantities of Apples exposed for sale so affected by black scab as to be unfit for food. The sight of these fruits was all the more painful, because on sale with them were beautiful Colonial fruits absolutely free from fungal spots. At a Surrey gathering of agricultural co-operators recently, samples of Apples were submitted to me almost eaten up by the fungus. It would help in finding a remedy for this trouble if it were shown exactly under what conditions the trees were growing that produced such fruits, just as it would be interesting to learn from growers whose trees and fruits have been quite free from scab what forms of trees and methods of culture were adopted by them to secure immunity. It may be assumed that good culture has much to do with the absence of the fungus, and lack of culture, such as is sometimes seen in orchards, may account for its presence. Again, who has sprayed trees to protect them against this fungus? *We read so much about spraying, yet see so little of it.* Does it begin and end in a trial? It is fair to assume that the great de-

shady, moist positions. The foliage has no particular attraction; the great merit of the plant lies in the inflorescence which is borne on stems about 4 feet high, in a lax, graceful manner. The flowering period is the end of August and September. The plant may be readily increased by division or by cuttings. *Junc.*

HAMPTON COURT GARDENS.—At Hampton Court Palace gardens the long wall which extends from the main road to the Palace, and, again, some distance beyond it to the river Thames, presents a bare and uninviting aspect in winter. It is faced by a border some 7 feet in width only, which in summer-time is planted with a very great variety of flowering plants, some of them being 5 feet to 6 feet in height. Obviously, with such a narrow, crowded border, there is no opportunity for training plants against the wall. Were this long border made 20 to 30 feet in width, very fine effects might be obtained, and still leave ample room behind for the inclusion of wall climbers and shrubs. I would like to see, as an experiment, that portion of the wall from the garden entrance up to the high road specially planted with a view of making it a feature of attraction. The border in front should be planted with quite dwarf plants, such as would not in the least obscure the view of the plants on the wall. Flower gardening at this popular place of

resort has become somewhat stereotyped, and any break away from the present plan would be gladly welcomed. Along the wall, at intervals of 10 feet, are piers. These should be planted with a wide range of climbers, including the best varieties of climbing Roses. Some climbers might be planted for their handsome foliage only, but the range of selection is infinite. The intervening panels might be filled with plants, flat-trained to the wall, of Escalonia, Garryas, Ceanothuses, Cotoneasters, Cydonias, Forsythias, Magnolias, Viburnums, Fuchsias, Buddleias, Choisya ternata, Chimonanthus, and other shrubs. Flat-trained Heliotropes, Ivy-leaved Pelargoniums, Cassia corymbosa, and other tender plants, sunk in tubs, would greatly help in the scheme of decoration. A. D.

about August, and the plants put out sometimes in trenches, sometimes on the flat, but always earthed or moulded up. Naturally, in this country the seed would have to be sown earlier, and the crop requires much the same culture as Celery. "Finocchio" in Italy is eaten raw with salt, or cooked with butter and served up, as is the case here with Celery. Although this vegetable is not much known to English people, yet we have for some years supplied seed of it to those of our customers who have met with it when abroad. Sutton & Sons.

FINOCCHIO OR FLORENCE FENNEL (FENICULUM DULCE).—We have had no difficulty in growing this plant satisfactorily under ordinary garden cultivation. The edible part consists of the broad leaf-stalks, which, overlapping

so extensively used in Naples, and scarcely known in any other place, is referred by authors to *Feniculum piperitum*, D.C., a species very closely related to *F. officinale*. The plant is used while in the act of running to bloom, the stems, fresh and tender, are broken and served up raw, still enclosed in the expanded leaf-stalks. They are esteemed a great delicacy, and are obtained only from the end of March till June." J. Coult, Killerton Gardens, Exeter.

PINUS PINASTER.—In my article on this tree on p. 69, I appear to say, with reference to the collection of resin, that the pot receiving it continues to be moved up 3 feet at a time after a height of from 10 to 15 feet is reached. The pot is moved up 3 feet at a time until a height of 10 or 15 feet is reached, but not afterwards, for when that height has been attained a new groove is commenced. R. Stewart Lynch.

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 4.—*Committee present:* E. Ashworth, Esq. (chairman), and Messrs. R. Ashworth, F. W. Ashworth, J. C. Cowan, J. Cypher, W. Holmes, A. J. Keeling, C. Parker, J. E. Shill, F. K. Sander, H. Thorp, W. B. Upjohn, Z. A. Ward, A. Warburton, and P. Weathers (hon. secretary).

The number of exhibits were fewer than at the last few meetings.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), who has been a consistent exhibitor in the class for the Sander Cypripedium Cup, staged a splendid group of Cypripediums, for which a Silver-gilt Medal was awarded. Choice hybrids, including *C. × Victor*, *C. × aureum* var. *virginale*, and *C. × Mrs. W. Mostyn* were a feature of this display.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), exhibited Cypripedium *× Memoria Jerninghamia*, a distinct plant, the parentage of which was not recorded.

Mrs. S. GRATRIX received a First-class Certificate for Cypripedium *× Actæus* var. *Gratrixæ*, a very distinct variety with a pronounced green tinge throughout the flower and finely-marked dorsal sepal.

C. PARKER, Esq., Preston, was awarded a Bronze Medal for a small group of Cypripediums containing some distinct forms of *C. insignis*, in addition to several well-known hybrids.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), gained a Silver-gilt Medal for an exhibit of good *Odontoglossums*.

Mr. J. BIRCHENALL, Alderley Edge, exhibited *Scelochilus variegatus*, a botanical Orchid with very small flowers. *Zygo-Colar × Amesiana*, showed by the same exhibitor, received an Award of Merit.

Messrs. HUGH LOW & Co., Enfield, were awarded a Silver Medal for a group of choice plants, including several good hybrid Cypripediums. *Cymbidium × Wiganianum*, shown by Messrs. Low, gained an Award of Merit.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dagleish), was awarded a Silver Medal for a group of Cypripediums, which included *C. × aureum* var. *Hyeannum*, *C. × aureum* Vine-House variety (Award of Merit), *C. × Evansianum*, and a good form of *C. Spicerianum*. Warburton's variety. *Odontoglossum × ardentissimum* var. *xanthotes* and *O. sceptrum* var. *Masereelianum* were also shown by Mr. Warburton.

Messrs. JAS. CYPHER & SONS, Cheltenham, staged a pleasing display of well-grown Cypripediums, for which a Silver Medal was awarded.

Messrs. KEELING & SONS, Bradford, were awarded a Bronze Medal for a group in which two plants, viz., Cypripedium *× Actæus*, Grangefield variety, and *C. × Leeannum* var. *Dorothy*, received Awards of Merit.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a miscellaneous group of plants, in which were some good varieties of *Lælia anceps*, *Cattleya Trianae* var. *Holmesii*, a flower of commendable form and with a richly-coloured lip, received an Award of Merit.

FIG. 54.—SPECIMEN OF FINOCCHIO BROUGHT FROM ITALY BY MESSRS. SUTTON AND SONS.

THE OLD DOUBLE PRIMULA.—Mr. Leonard Sutton tells me that a type of *Primula sinensis* formerly existed which was completely double and destitute of anthers. As it set no seed, it was propagated by cuttings exclusively. Can any readers of the *Gardeners' Chronicle* put me in the way of obtaining a specimen of this type? In connection with a study of the inheritance of doubleness, its properties would be well worth investigating. W. Bateson, Grantchester, Cambridge.

FINOCCHIO.—We have just returned from our annual visit amongst our seed crops in the south of Italy, and, remembering that, in a recent issue of the *Gardeners' Chronicle*, there appeared an article on "Finocchio," we brought back one or two specimens which were grown at Naples (see fig. 54). Large quantities of this "Finocchio" are grown around Naples. The seeds are sown

one another at the base of the stem, form an enlargement varying in size from that of a hen's egg to the size of a man's fist. The plant does not form tubers as *R. B.* (see p. 45) imagines. The edible portion should be used before the plant develops its inflorescence, which it does very soon. The first sowing may be made in April or May, followed by, say, two successional sowings in the summer. Sow in rows made 18 inches apart, and thin the seedlings to 9 inches between each other. During dry weather the plant should be well watered. If it is desired to blanch the stems, a little soil can be drawn about them 10 days before the vegetable is required for the table. Long Sweet Fennel (*Feniculum officinale*, All.) is sown in the autumn for a spring crop. The tender stems of this plant are eaten just as it runs to seed. Vilmorin, in his *Vegetable Garden*, says: "The famous 'Carosella,'

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), received Awards of Merit for *Cypripedium* \times *Transvaal*, *Oakdene* variety, *C.* \times *Memoria* Lord Burton, and *C.* \times *Dicksonianum*.

H. ARTHUR, Esq., Blackburn, showed a small group of *Cypripediums*. (Bronze Medal.)

Other exhibitors were Messrs. ROBSON, Altrincham; SHACKLETON, Bradford; CRAVEN, Keighley; and BOLTON, Warrington.

COMMONS AND FOOTPATHS PRESERVATION.

FEBRUARY 5.—Lord Eversley presided over the monthly meeting of the Society held on this date at 25, Victoria Street, Westminster. The solicitors' report upon the provisions of Private Bills to be introduced into Parliament during the coming session, and under which Commons, Open Spaces and Rights of Way will be subject to interference, was presented. It was stated that while 31 Bills of this nature would come within the purview of the Society this year, the extent to which public rights would be interfered with was, on the whole, less than the average. The area of common land scheduled amounted to about 320 acres, the most serious proposal being that of the North-Eastern Railway to absorb 178 acres of Salt End Pasture on the banks of the River Humber at Preston. It was resolved to oppose this Bill. The Great Western Railway proposed to acquire portions of the Link Common, Malvern. Hungerford Common, Berks, and 9½ acres of Wormwood Scrubs, Hammersmith, but in each case the company had consented to add to the common an area equivalent to that to be abstracted. It was decided to make representations to the London County Council in order to provide that on the widening of the highway at Tavistock Square the Pine trees affected should not be cut down. The Society also determined to take steps to secure the reintroduction into Parliament of its Public Rights of Way Bill, the chairman stating that a number of members had undertaken to ballot for this measure. The final arrangements with regard to the amicable settlement of important footpath disputes being carried out by the Society in Herts. and Sussex were approved; and the recently-issued afforestation report was carefully considered. The general feeling was that, while in the case of some exceptionally large commons portions might possibly be devoted to afforestation without material injury to grazing rights, in the case of the less extensive open spaces an important class of small farmers and cottagers would be seriously affected if any portion was withdrawn for tree planting.

LEEDS PROFESSIONAL GARDENERS'.

FEBRUARY 8.—The members of this society held their annual dinner on this date. The chair was taken by the Rev. R. Warburton, M.A., and he was supported by the Grand Master of the Order of Oddfellows, Bro. G. Bamby.

The secretary, Mr. Geo. Carver, stated that the amount of sickness is 58 per cent. below the average. The official valuation showed the society to have a solvency of 20s. 3d. in the pound, with a surplus of £63.

It is suggested to devote the surplus funds of the lodge to the benefit of the aged and infirm members.

HORTICULTURAL CLUB. ANNUAL DINNER.

FEBRUARY 9.—As a fitting social pendant to the annual meeting of the Royal Horticultural Society, the Horticultural Club held its annual meeting and subsequent dinner at the Hotel Windsor on the above date, under the chairmanship of Mr. Harry J. Veitch.

The secretary's report of the progress of the Club was read at the annual meeting by Mr. E. T. Cook, and was highly satisfactory. The number of members has increased during the year, and there is a larger balance. A number of interesting papers and discussions have been read during the session, proving that the Club has its instructive as well as its social side. This has been steadily kept in view for many years past and it has added considerably to the attractiveness of the meetings.

About 80 members and guests, including ladies were present at the dinner. The

tables were beautifully decked with flowers, while a charming musical and vocal entertainment was provided by Sir Frank Crisp, who was present on the occasion and was heartily thanked for his kindness. Mr. George Paul proposed the toast of the Royal Horticultural Society in the place of Sir Albert Rollit, who had hoped to be present. The Rev. Joseph Jacob, M.A., responded in a brief but humorous speech.

The Chairman proposed that of the Horticultural Club, laying stress upon its educational utility, Mr. H. Morgan Veitch replying. The chairman's health was drunk with all the honours.

The visitors were welcomed by Mr. George Munro in an appropriate speech, Mr. P. Anderson Graham responding on behalf of the ladies and other guests.

The health of Mr. E. T. Cook, the honorary secretary, was next proposed, and, finally, that of Sir Frank Crisp, who had done so much on the present occasion to enhance the enjoyment of all present by engaging the services of Miss Emily Shepherd, Miss Carrie Herwin, and Mr. M. Fred Rome, Ernest Sewell, Samuel Masters, Charles Wreford, and Herbert Townsend, whose varied contributions of music, songs, humorous stories, experimental magic, and living marionettes served to delight the audience.

PERPETUAL-FLOWERING CARNATION.

(ANNUAL MEETING.)

FEBRUARY 10.—The annual meeting of the above society was held at the Hotel Windsor on this date. Mr. J. S. Brunton presided, about twenty members being present. The minutes of the previous meeting were read and confirmed. The hon. secretary, Mr. H. Mathias, read a letter from Lord Howard de Walden, president, regretting his inability to preside over the meeting. The chairman moved the adoption of the report, from which we extract the following paragraphs:

At the annual general meeting in 1908 the title of the Society was altered from "The Winter-Flowering Carnation Society" to "The Perpetual Flowering Carnation Society."

A scheme for the registration of the names of new varieties has been adopted. Nine new varieties have been registered during the year. A variety must gain at least 85 points to entitle it to a First-class Certificate, and 75 points to entitle it to an Award of Merit.

His Serene Highness Prince Francis of Teck has been graciously pleased to become a patron of the Society. The Right Hon. Lord Howard de Walden has accepted the post of president.

Two successful shows were held at the R.H.S. Hall, Vincent Square. The greatly increased competition in the amateur classes at the December show, and the high quality of the blooms in these classes have largely justified the policy of your committee in increasing the number and scope of classes for amateurs' exhibits.

As a means of helping amateurs, an expert grower was appointed to give an address on "The Cultivation of the Perpetual-flowering Carnation," in the lecture-room of the R.H.S. Hall, on the afternoon of the April show. On the occasion of the December show a question box was placed in the hall, and a number of visitors availed themselves of the opportunity of writing questions and placing them therein.

Your committee considered it desirable that the Society should be in a position to award medals of its own, and, after much deliberation, a drawing was approved, and a die cut. Donations to defray the cost of medals are earnestly invited, or if individual members will defray the cost of one or more medals and place them at the committee's disposal to be awarded as special prizes, they will be much appreciated.

Two cups have been presented to the Society, one by Lord Howard de Walden, and the other by the American Carnation Society. It has been decided that these two cups shall be held as challenge cups in perpetuity.

Your Honorary Secretary is in correspondence with Mr. Albert M. Herr, the Secretary of the American Carnation Society, on the subject of the compilation of a complete list of perpetual-flowering Carnations, with a view to the framing of a list of too-much-alike varieties.

The Society has lost seven members by resignation, 27 struck off for non-payment of subscriptions, and one by death, viz., Martin R. Smith, Esq., a vice-president of the Society. His loss is one that will be deeply felt, not only by the members of this Society, but also by every true lover of the Carnation. Fifty-one new members have joined during the year, and the total membership of the Society at December 31, 1908, was 173.

The resolution for adopting the report was seconded by Mr. L. J. Cook, and carried unanimously. A vote of thanks to the officers was proposed by the chairman, and special mention was made of the admirable manner in which the secretarial work was carried out by Mr. H. Mathias. Mr. E. F. Hawes as show superintendent and Mr. J. S. Brunton were also entitled to thanks. The vote was carried with acclamation. The adoption of the balance-sheet for the past year was moved by Mr. C. H. Curtis, one of the honorary auditors to the society,

who testified as to the able manner in which the accounts had been kept. It was resolved that the offices of hon. secretary and treasurer, which have previously been held by Mr. Mathias, should be held by separate persons. The following were elected to serve as officers of the society during the coming year: President, Lord Howard de Walden; treasurer, Mr. L. J. Cook; secretary, Mr. H. Mathias; exhibition superintendent, Mr. E. F. Hawes.

The retiring members of the committee were all re-elected, and the Rev. J. Jacob was also appointed on the committee. Messrs. C. H. Curtis and R. Pinches were re-elected auditors. It was decided to hold the annual dinner on the day of the spring exhibition, March 24, at 7.30 p.m., and Mr. Hawes was asked to undertake the arrangements.

BRITISH GARDENERS' ASSOCIATION. (LONDON BRANCH.)

FEBRUARY 11.—The monthly meeting of the London branch of the above Association took place on this date at Carr's Restaurant, Strand, W.C. There was a large attendance to hear Mr. Chas. H. Curtis lecture on "Kew Gardens." The lecturer gave a brief account of the history of these famous gardens, and described the more important features. The interiors of the Temperate House, the "North" Picture Gallery, the Museums, the Herbarium, the Lily House with the *Victoria Regia* in flower, and other interesting parts of the gardens were shown as lantern slides. At the close of the lecture Mr. Curtis, in answer to a question, stated the advantages offered to a young gardener who spends a period of two years at Kew. The opportunities for study and the experience to be gained were unobtainable elsewhere.

ROYAL GARDENERS' ORPHAN FUND.

FEBRUARY 12.—The twenty-second annual meeting of the supporters of this charity took place on the above date at Simpson's, Strand, London. Mr. Henry B. May, chairman of the Executive Committee, presided over a somewhat limited attendance. The secretary, Mr. Brian Wynne, read the minutes of the last meeting, and presented the report of the Executive Committee for 1908. This was as follows:—

REPORT OF THE EXECUTIVE COMMITTEE.

It is with great gratification and a deep sense of thankfulness that at the close of the twenty-first year of the existence of the Fund the Committee is enabled to present a Report which they believe will afford the liveliest satisfaction. The receipts from all sources in 1908 amounted to no less a sum than £2,694 1s. 9d. More than half of this amount was obtained by the appeal made at, and in connection with, the Coming-of-Age Festival held in May, which will be long remembered as an interesting event in the history of the Fund. The Committee acknowledges with deep gratitude their indebtedness to their noble President, the Duke of Bedford, for presiding on that occasion, for his Grace's sympathetic appreciation of the beneficent work which is being carried on, his eloquent commendation of the claims of the Fund to the generosity of all interested in gardeners and gardening, and for his munificent contribution of £250 to the Festival dinner list. To Mr. N. N. Sherwood and his sons, Mr. William and Mr. Edward Sherwood, whose practical sympathy with the objects of the Fund, from the day of its foundation, has helped materially in placing the charity in its present position, grateful thanks are accorded for their generous presentation of £391 Metropolitan Railway 3½ per cent. preference stock to endow the "Maybud Campbell Grant" of £15 per annum to an orphan girl selected to receive same under the Rules of the Fund. The appeal made on the initiative of Mr. H. J. Clayton, for a special Coming-of-Age gift to the Fund, to be raised by means of a shilling collection, resulted in the receipt of the handsome sum of £250, and the Committee tender their grateful thanks to all who assisted in bringing about such an appreciable addition to the Fund's exchequer.

The net result of the year's work is an increase in income over that of the previous year, amounting to £747 11s. 7d. This sum has enabled the Committee to increase the Allowances and Grants in Aid made to the poor children by the sum of £109 17s. 6d.; to add £506 7s. 7d. to the Reserve Fund, £85 to the deposit account, and to increase the balance carried forward by £77 9s. 2d.

At the commencement of 1908 there were 166 children receiving the full benefits of the Fund. Seventeen more were added to the roll at the annual meeting, held in February. At the close of December the number on the elected list was 104, whilst 21 of the candidates awaiting election, greatly being in need of assistance, were receiving compassionate allowances. The total sum distributed among the beneficiaries during the year was £1,621 7s. 6d., the highest total yet reached. The number of children elected to receive the benefits of the Fund since its foundation is 253, and the total

expenditure in weekly Allowances and Grants in Aid during the same period is £19,506.

The next Festival takes place on Thursday, May 6, at the Hotel Cecil, when his Grace the Duke of Rutland has most kindly consented to preside. The Committee make this announcement with extreme pleasure.

For some years past the Fund has greatly benefited by the exertions made on its behalf by the Committees of the Chesterfield and District Chrysanthemum Society, the Altrincham and District Gardeners' Mutual Improvement Society, the Chislehurst Gardeners' Mutual Improvement Society, the Bradford Chrysanthemum Society, and similar institutions. The Committee are glad to record the fact that during the year several additional societies of this character have caused their names to be enrolled among the regular contributors. To one and all who have helped the Fund in this way most cordial thanks are tendered. The Committee also again most gratefully acknowledge the valuable support accorded to the Fund by the owners of private gardens, who kindly open their establishments to the public from time to time in aid of this and other charities. In this connection special thanks are due to Mary Countess of Ilchester, Sir Frank Crisp, and Major John W. Dent, for valued contributions.

The Committee has again, unhappily, to deplore the loss the Fund has sustained by the hand of death. As former colleagues, the valued services of Mr. George Nicholson and Mr. C. E. Osman are gratefully remembered, as also are the active services rendered in the early days of the Fund by Mr. W. J. Brewer and Mr. Henry Hawkins; whilst in recent years Mr. W. Neild, Mr. R. Lye, and Mr. Joseph Lee, were all devoted adherents to the children's cause. The late Mr. J. Cawthra, of Bradford, and Mr. Benjamin Greaves, of Horsham, were annual contributors, and Legacies of £150, less duty, from the former gentleman, and £50 from Mr. Greaves, are thankfully acknowledged.

The members of the Committee who retire by rotation are Mr. W. Bates, Mr. G. L. Caselton, Mr. C. Dixon, Mr. H. B. May, Mr. J. W. Moorman, Mr. Whitpaine Nutting, Mr. G. Reynolds, and Mr. J. H. Witty. These members, being eligible, offer themselves for re-election.

To the Auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, the Committee again tender their sincere thanks for the valuable services they render the Fund from year to year by their exhaustive examination of the accounts. The retiring auditor is Mr. Barr, and with great pleasure the Committee recommends his re-election.

In concluding this Report the Committee again appeal with confidence to the liberality of all those who recognise the legitimate claims of necessitous orphans. In the ranks of gardeners, as in those of most other callings, there are many distressing cases of premature death. The breadwinner is suddenly removed from the scene of his labours, whilst still young, and therefore before he has had time and opportunity to provide for those dependent upon his industry. The widow, being often left with several children of tender years, she is unable to use her capacity for earning a living, because her presence and care are needed at home. Surely the cry of the children is one that we have no right or desire to disregard!

The amount of good that follows the disbursement of small sums to children is out of all proportion to the sums contributed, and not only is this the case, but in helping the children by ensuring to them the

necessities of life, the heavy lot that oppresses the young widow is materially lightened.

The Committee, therefore, believe that, in the future, as in the past, the Royal Gardeners' Orphan Fund will receive such a measure of support as will enable it to continue the work it has faithfully discharged in the past twenty-one years.

The Chairman, in proposing the adoption of the Report and Balance-Sheet, stated that there was little for him to tell the meeting, owing to the comprehensive character of the printed Report, which was circulated in the room. He, however, called attention to the increased receipts during the Coming-of-Age year, which amounted to £747 11s. 7d. over the previous year. The number of children elected to receive the benefit of the Fund since its foundation was 253, and the total expenditure in weekly allowances and grants in aid during the same period was £19,506. He called attention to the useful work that several societies, mentioned in the Report, continue to do in the interest of the Fund, suggesting that other societies might help in a similar manner. The "shilling" subscription was adopted on the suggestion of Mr. H. J. Clayton to signalise the Coming-of-Age year, and this was the means of raising a sum of £250. The resolution was seconded by Mr. Wm. Marshall, late chairman of the Executive Committee, who said that the Report was entirely satisfactory. The resolution was adopted with unanimity.

Mr. R. Hooper Pearson proposed a vote of thanks to the President of the Fund, the Duke of Bedford, K.G., for presiding at the last Festival Dinner. He said that the gratifying successes which had attended the efforts of the committee to raise a record amount of money at the Coming-of-Age festival were partly due to the President's presence on that occasion and to his munificent gift of £250. The resolution was seconded by Mr. W. J. Cutbush, and carried unanimously.

On the proposition of Mr. W. Roupell, seconded by Mr. George Gordon, a vote of thanks was passed to Mr. Edward Sherwood for his duties as treasurer during the year, and he was re-elected to fill the position. Mr. Rudolph Barr was re-elected auditor on the proposition of Mr. W. Poupart, and seconded by Mr. W. Bates.

Mr. A. Dean proposed that the members of committee who retired by rotation and whose names were mentioned in the Report, should be re-elected. After the motion had been seconded by Mr. W. Bates, the resolution was carried.

The Chairman then rose to propose the re-election of Mr. Brian Wynne as secretary to the Fund, at a salary of £200 per year. He stated that Mr. Wynne would in future devote his whole time to the work of the Fund, and that a new office had been taken by the committee in Surrey Street, Strand. The Chairman paid a high tribute to the manner in which Mr. Wynne had discharged his duties as secretary during the 10 years he had held that position. After the resolution had been seconded by Mr. W. Bates, it was carried with acclamation.

Scrutineers having been appointed, the meeting was adjourned until 4.30. On reassembling, the following candidates were declared duly elected:—

RESULT OF THE BALLOT.

	Notes.
Muriel H. Lee	394
Reginald T. Dyer	272
Louisa Dyer	263
John F. Campbell	245
Richard J. Lavington	224
Phyllis M. Lee	220

Arthur H. Warren	129
Eileen L. Lavington	107
Kate Tebutt	93
Albert E. Payne	90

Mr. Harry J. Veitch congratulated the committee upon the work of last year and on the number of candidates that had been elected. He said, however, that there were five who had been unsuccessful at the poll. Being unconnected with the management of the Fund, he did not know the exact resources at the command of the committee after the election that had taken place that day. But he appealed to the chairman to induce the committee to stretch a point in favour of the unsuccessful candidates. If this could be done, all present would be deeply grateful.

The Chairman stated that the committee had every confidence that the public would continue to assist the Fund. The circumstances of the disappointed candidates had been taken into consideration by the committee, and he thought that if it were the desire of that meeting that those candidates should be placed upon the Fund by resolution, the committee would not oppose the motion. In addition to those now before the meeting, there were nine fresh candidates on the list for next year. It looked, therefore, as if there would be a big list at the next anniversary meeting, and they must look to their friends for increased support if all the cases deserving of help were to be placed on the Fund. Mr. Veitch's motion was seconded by Mr. George Gordon, and carried unanimously.

The following candidates were therefore declared duly elected:—

Florence E. Ward	89
Edward G. W. Randall	86
Elsie Atkinson	83
Ann Laing	80
Hilda D. Whitlock	34

THE FRIENDLY SUPPER.

The same evening the committee and a few friends dined together at Simpson's. Mr. Henry B. May presided.

SCHEDULES RECEIVED.

National Sweet Pea Society's ninth annual exhibition to be held in the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Friday, July 23, 1909. Hon. Secretary, Mr. C. H. Curtis, Adelaide Road, Brentford, Middlesex.

Midland Carnation and Picotee Society's nineteenth annual exhibition to be held on July 28 and 29, 1909.

CASH STATEMENT FOR THE YEAR ENDING DECEMBER 31, 1908.

MARKETS.

COVENT GARDEN, February 17.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

REMARKS.—Tomatoes are very scarce and of poor quality. Vegetables generally are dearer, owing to the cold weather. Large quantities of Oranges continue to arrive; sound packages are realising similar prices to those of last week. The trade in Lemons and Bitter Oranges is very slow. Californian seedless and Jamaican Oranges are arriving in a splendid condition. Fruit from Cape Colony continues to sell readily except Plums, which are very plentiful and comparatively cheap. E. H. R., Covent Garden, Wednesday, February 17, 1909.

Maincrop	3 6-3 9	" " grey soil	2 6-3 0

REMARKS.—Supplies are large and the demand small. The London markets contain heavy stocks of Potatoes. Edward J. Newborn, Covent Garden and St. Pancras, February 17, 1909.

COVENT GARDEN FLOWER MARKET.

Hardy flower roots are already on sale, but the return of frost has stopped the demand for them. There are also seen Roses, hardy climbers, Conifers, and evergreens. The cold weather has also affected business in pot plants, but it does not influence the cut-flower trade quite so much.

POT PLANTS.

Azaleas are still the most showy plants in the market, and supplies are over-abundant. Good Marguerites are plentiful, also well-flowered Cinerarias and Cyclamens, but Genistas are only moderate, and their inflorescences do not last long during the cold weather. Begonia Gloire de Lorraine is soon affected by cold, but well-flowered plants are seen. Hyacinths are good, and, in addition to pots containing three bulbs, large quantities are now grown singly in 3-inch pots. Cyclamens, Primulas, Ericas, &c., are also grown and flowered well in small pots. Plants of Erica Wilmoreana in 4½ and 5-inch pots are well flowered. Solanums are not quite finished, but the berries are setting over-ripe, and fall off, unless very carefully handled. Some well-berried plants of Aucuba vera are seen, and these last for a long time. Capsicums, with round berries, are very pretty.

Ferns are not very bright in the foliage, but the new fronds will soon be developing. Supplies of small Ferns are well sustained. Palms vary but little, except that the demand has been very limited. Aspidistras do not sell readily, and there has been very little trade in tender foliage plants; as soon as milder weather sets in we may expect an improvement in business.

CUT FLOWERS.

Daffodils are more abundant and cheaper. The variety Emperor is good, also Victoria, Princess, Golden Spur, and Sir Watkin. Princes is seen in large quantities, but this variety is lacking in quality. Narcissus ornatus from English growers, and also from the Scilly Islands, is abundant. Soleil d'Or, White Pearl (Scilly White) and Paper White are plentiful. Early forced Roses are seen in larger quantities. Richmond is undoubtedly the finest red Rose now in the market; it retains its colour well, but growers inform me that it is not so prolific in blooming as Liberty. Caroline Testout seems to be the best early pink variety. Joseph Lowe is another Rose that forces well. Carnations are plentiful, and, with increased sunlight, the colours are better; there is no improvement in their prices. Gardenias are very scarce, but Eucharis blooms are more plentiful. Violets, both from English nurseries and from France, are over-abundant. Lilium longiflorum is not of the best quality, but we may expect a better supply soon. L. speciosum is always known in the market as L. lancifolium; the variety rubrum is rather pale in colour.

At the first sale of Liliums for 1909 at Messrs. Protheroe & Morris' Rooms, on the 16th inst., the bulbs sold readily, there being a brisk competition, especially for the finest bulbs, which were in splendid condition. Large quantities of Japanese Irises were also disposed of at good prices. A. H., Covent Garden, Wednesday, February 17, 1909.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 17.

Another cold week.—The present cold period has now lasted 11 days. Except on one day during the past week the weather continued cold, both during the daytime and at night. On the coldest day the temperature in the thermometer screen at no time rose higher than 37°, and on the coldest night the exposed thermometer registered 14° of frost. The ground still remains cold, being 1° colder at 2 feet deep and 2° colder at 1 foot deep than is seasonable. Light rains fell on three days, but to the total depth of only about one-tenth of an inch. A few flakes of snow fell on two of those days. A few drops of rainwater still come each day through both percolating gauges. The sun shone on an average for 3½ hours a day, or for nearly an hour a day longer than is usual in February. The winds have been light during the week, and have come almost exclusively from some northerly point of the compass. The mean amount of moisture in the air at 8 o'clock in the afternoon fell short of a seasonable quantity for that hour by 7 per cent. The double Snowdrop came first into flower in my garden in the spot selected for its observation on the 15th, or 6 days later than its average date in the previous 29 years, but 3 days earlier than last year. E. M., Berkhamsted, February 17, 1909.

TRADE NOTICE.

WALLIS BROS. LTD., HARPENDEN.

This private company has been formed with a capital of £2,000, in 41 shares. The objects are to adopt an agreement between A. R. SEARLE (trading as WALLIS BROS., horticultural sundriesman) and Mrs. F. WALLIS, and to carry on the business of market gardeners, fruit growers and merchants, dealers in agricultural and horticultural seeds, plants, &c. Registered offices, Ecclesborne Villa, Amcunbury, Harpenden, Herts.

Obituary.

SIR GEORGE KING.—The death of Lieutenant-Colonel Sir George King, K.C.I.E., F.R.S., LL.D., occurred on the 13th instant at San Remo. Sir George King was born in 1840, and entered the Bengal Medical Service in 1865. He was appointed to the Chair of botany at the Medical College and Director of the Royal Botanical Gardens, Calcutta, in 1871. In 1891, he was appointed additional director of the Botanical Survey of India, retaining the management of the gardens. His retirement took place in 1898. We shall publish an article on his life and work in the next issue.

WILLIAM YATES GIBSON.—We regret to record the death of this Aberdeen seedsman on the 7th inst. at the residence of his nephew, Dr. T. Best-Gibson. The late Mr. Gibson was a native of Lonmay, and, when about 17 years of age, he entered the service of an Aberdeen grocer. Some three years later he became connected with the firm of Messrs. Benjamin Reid & Co., seedsmen and nurserymen. He had been retired from business for some short time before his death, which occurred in his 80th year.

DEBATING SOCIETIES.

DERBYSHIRE GARDENERS'.—At a meeting of this association, held on the 22nd ult. a lecture was given by Mr. A. Shambrook, of Sutton Hall, on "The Culture of Cyclamen." The lecturer stated that the compost he considered best for the final potting of these plants was a mixture of loam, leaf-mould, and sand, with dried cow manure rubbed fine and a sprinkling of broken charcoal. The soil should not be pressed tightly. The plants must never be allowed to become dry at the roots. After the flowering season is over, active growth should be encouraged. The finest blooms are secured from plants about 15 months old.

BRISTOL AND DISTRICT GARDENERS'.—Mr. S. Shaddick presided over a large attendance of the members of this association on Thursday, the 20th ult., when a representative of the Bath Gardeners' Debating Society, Mr. Stokes, of Trowbridge, gave a paper on "Rock and Alpine Plants." The lecturer stated that some of these plants are natives of cold climates, whilst others are found in tropical regions. This question of habitat must be taken into consideration when planting a rockery. If a stream of water can be conducted through the rock-garden so that it trickles down between the stones, moisture-loving plants may be included. In the case of a large rockery a few rambling Roses may be introduced at the back. Mr. Stokes showed photographs of some noted rock-gardens.

—At the meeting held on Thursday, February 11, Mr. Tunbridge, a representative of the Reading Association, gave a lecture on "Hardy Ferns." Mr. Tunbridge exhibited a collection consisting of fronds of more than one hundred varieties, with their correct names.

READING AND DISTRICT GARDENERS'.—A meeting of this association was held in the Abbey Hall, Reading, on Monday, the 25th ult. The chairman, Mr. A. F. Bailey, presided. The lecturer was Mr. J. W. Odell, of The Grove Gardens, Stanmore, his subject being "British Wild Flowers in the Garden." Mr. Odell illustrated his paper with a comprehensive and beautiful series of photographic slides. Many illustrations of hard-wooded plants were shown, including the Wild Cherry, Crab Apple, Plum, and Dog Rose. These were followed by pictures of native aquatic, bog, rock, woodland and climbing plants; the lecturer also dealt with British Orchids. He deplored the practice of robbing the hedgerows and woods of plants intended for sale by itinerant hawkers. Several new members were elected.

—On Monday, February 8, Mr. W. Shipway, of Messrs. Sutton & Sons' Nursery, gave a lecture on "Lawns and Lawn Grasses." Mr. Alderman F. B. Parfit, President of the Society, occupied the chair. A number of lantern slides were used by the lecturer to illustrate his remarks. The following points were dealt with by Mr. Shipway: situation and aspect, drainage, preparation of the soil, turfing and seeding, sowing seeds, varieties of lawn grasses, clover in lawns, treatment of a new lawn, mowing and rolling, manures, &c. Four new members were elected.

REDHILL, REIGATE AND DISTRICT GARDENERS'.—A meeting of this association was held on February 8. Mr. Bonnd presided over an attendance of about 70 of the members. A letter was read from the secretary of the Royal Horticultural Society concerning the Affiliated Societies Challenge Cup. Mr. Wells, Merstham, gave a lecture on the culture of Chrysanthemums. The chairman announced that at the next meeting Mr. Cooper, from Reading, would give a lecture on Orchids.

BIRMINGHAM GARDENERS'.—The first meeting of this association for 1909 took place on January 25 at the Athletic Institute, Birmingham. Mr. C. H. Herbert presided. Mr. Thos. Humphreys, curator of the Botanical Gardens, Edgbaston, delivered an essay on "The History and Cultivation of the Rose for Suburban Gardens." The speaker's remarks were illustrated by lantern slides.

BOOK: A. D. B. We do not know of any modern work on the Pineapple. *The Culture of the Pineapple*, by D. Thompson, is out of print, but you may be able to obtain a copy from the second-hand booksellers.

EELWORM INFESTING CARNATIONS ROOTS: S. B. These pests can be killed either by dressing the land with voparite or with gas-lime. As the area is 2½ acres, perhaps it would be cheaper to use the latter substance, although it is a most objectionable material to employ. Land dressed with gas-lime should remain fallow for some months afterwards, or be allowed to carry some crop that is not particularly valuable. In any case, do not plant Carnations on the ground for some time to come, and when removing the old plants, take care to burn them in the garden fire.

ELÆAGNUS DYING: C. R. The fact of both the plants dying within a year of each other suggests their having reached an unsuitable rooting medium. You will find an account of these shrubs in any good book on trees and shrubs.

EMPLOYMENT IN THE LONDON PARKS: W. D. H. In the case of those parks under the control of the London County Council, forms of application for employment as under-gardener or under-keeper may be obtained from the Chief Officer, Parks Department, No. 11, Regent Street, S.W. The age limits are from 25 to 40 in the case of under-gardeners, &c. Vacancies as gardeners are as far as possible filled by promotion, from the ranks of under-gardeners, of such men as pass the examination in practical horticulture held by the Royal Horticultural Society; and in the other ranks by promotion. Conditions of employment in the Royal Parks, London, can be obtained from the respective superintendents.

GRAPES DISEASED: A. D. The berries are affected by black rot, caused by a fungus—*Guignardia Bidwellii*. As a rule the disease first attacks the leaves. These should be sprayed with the Bordeaux mixture at half strength before the flowers appear. Spray the vines again when the fruit is set with eau céleste (ammoniacal copper carbonate).

HYACINTH GROWN IN WATER: F. C. K. The bulb is a good specimen, and appears to be constitutionally sound. The roots have been killed by some check such as frost. Have you placed the vases in which they are growing in an exposed window on frosty nights?

HYACINTHS: J. P. The bulbs appear to be free from disease, and two of them have succeeded satisfactorily. There is some amount of decay at the base of the third bulb. It is not advisable to mix road sweepings with soil intended for potting purposes, especially when it has been obtained from roads in suburban districts where motorcars are prevalent. We notice that where the roots are injured most they are nearest to the pot: this suggests injury by frost.

LIQUID MANURE FOR A VINE BORDER: Anxious. Your letter affords no clue as to the strength of the liquid manure which you have applied. The artificial manure you mention is a concentrated food, and this, in addition to the manure water, should prove ample in the way of feeding. We do not advise using the liquid manure at a great strength; a little and often is much better than applying big doses.

MANURES FOR IDENTIFICATION: Gardener, Wales. Send the specimens to one of the plant sundriesmen.

NAMES OF FRUITS: G. H. Fearn's Pippin.—F. D. Sandringham.

NAMES OF PLANTS: F. Lurani. Cytisus filipes.—J. M. Cupressus nootkatensis (Nootka Sound Cypress).—Hoyt. Lælia anceps.—A. H. A species of Dombeya, probably D. Dawei, but the specimen was too small and incomplete to name with certainty.—Hillfield. Epidendrum radicans, often named E. rhizophorum in gardens.—T. B. 1, Bambusa palmata; 2, Arundinaria japonica (Métaké); 3, A. nitida; 4, A. nobilis, known

sometimes in gardens as A. falcata; 5, Cineraria maritima; 6, Santolina incana. (Thanks for 1s. contribution to the R.G.O.F.)—A. C. H. *Cœlogyne Mayeriana*.—H. T. S. 1, *Odontoglossum pulchellum majus*; 2, *Oncidium pulvinatum*; 3, *Cypripedium villosum*; 4, *Selenipedium (Cypripedium) Sedenii*; 5, *Cypripedium venustum*; 6, *Pellea (Platyloma) flexuosa*.—I. Y. 1, *Aërides odoratum*; 2, *Brassia verrucosa*; 3, *Oncidium flexuosum*; 4, *Masdevallia nidifica*; 5, *Stelis micrantha*; 6, *Pleurothallis rubens*.—R. H. O. 1, *Selaginella Kraussiana*; 2, *Pteris longifolia*; 3, *P. hastata*; 4, *Adiantum assimile*; 5, *Pteris cretica*.—W. R. 1, *Blechnum occidentale*; 2, *Lomaria discolor*.—A. G. *Helixine Soleirolii*, a Corsican plant.—K. and B. Not recognised.—S. R. *Billbergia nutans*.

NARCISSUS FAILING TO FLOWER: W. G. S. The inflorescence is present in each case and some check has arrested their development. This may be due to either some cultural error or a constitutional defect in the bulbs.

PEA KAISER: P. W. To have this variety suitable for exhibition purposes during the second week of August, you require to sow the seeds on or about June 1.

PLUM BELGIAN PURPLE: R. M. This is a valuable culinary variety, sometimes classed as a dessert fruit, ripening about the middle of August. The fruits are of medium size and roundish. The skin is deep purple, covered with a blue bloom. It is certainly worthy of a place in your garden. The Victoria variety is one of the most prolific in bearing, and an exceedingly valuable kind, but it is later than Belgian Purple.

PRESSING ORCHID FLOWERS: J. M. Orchids are amongst the most difficult subjects to press and dry, because almost invariably the flowers turn black. The best plan is to dry them in heated sand, but in this case you would require cabinets for storing them. Try pressing them with a hot iron between pieces of blotting paper. In this way some of the colour may be preserved. We do not know of a special work on the subject.

PRUNING A NEWLY-PLANTED PRIVET HEDGE: Vanda. You may prune the hedge now, but do not do the work in frosty weather. If the growths are cut to within 2 feet of the ground the plants will make a more bushy habit, as the lower buds will be forced into growth.

RHUBARB AT EXHIBITIONS: W. H. F. The question whether Rhubarb is a vegetable or a fruit is a very old one, but it admits of a simple solution, if the true definition of a fruit—the ovary and other parts of the flower which undergo a change as a result of fertilisation—is regarded. Clearly the stalk of the leaf is no part of the flower. Although Rhubarb is not, strictly speaking, a fruit, it is used as such for culinary purposes, and the compilers of a flower-show schedule should be careful to state that the inclusion of Rhubarb in an exhibit of vegetables or of fruits either is or is not permissible, as they may direct. Your case is only another example showing the need for care in framing a schedule for a flower show.

TEMPERATURES BELOW ZERO: A. G. R. During the long frost of January and February, 1895, temperatures below zero were registered—by verified thermometers suspended 4 feet above the ground in "Stevenson" thermometer screens—at Braemar, in the east of Scotland; Durham, in the north-east of England; Ketton, in the Midland Counties; Drumranlig, in the west of Scotland; and Colebrooke, in the north of Ireland, as well as at other meteorological stations in some of the above districts.

VIOLETS DISEASED: Mid-Sussex. The plants are attacked by the fungus *Cercospora violæ*. The fungus is present in the soil, and the plants can only be freed from the pest by planting them for a season in the open ground, after the old soil has been shaken from the roots and the diseased leaves removed.

MARGAM PARK.

(See figs. 55 and 56 and Supplementary Illustration.)

WALES abounds in places of interest to the garden lover as well as the historian and antiquarian. Such is Margam, a name derived from Morgan, the son of Caradoc ab Jestyn, and Lord of Glamorgan, who was a great benefactor, if not the actual founder, of the famous abbey, now in ruins.

The first name of the place was probably "Pendar," or "The Oak Summit," descriptive of the oak-wooded eminence 800 feet in height which forms its background. Though many centuries have passed, the same features remain, and the Oak to-day, in its monarchical stateliness, tranquilly surveys its modern, as it did its old-world, surroundings, and will witness the changes in the years to come.

About the middle of the 16th century a residence was built partly on the site of the old abbey by Sir Rice Mansel, Kt., who had purchased the property probably at the time of the Dissolution. The present mansion, however, a far more pretentious structure,

which took 14 years to erect, was completed in 1840 by the late C. R. Mansel Talbot, Esq., M.P., who, for many years before his death in 1890, was "Father of the House of Commons." A father to his own people also, both on his estates and over a wide encircling area. The whole county of Glamorgan benefited much—particularly its churches—by his beneficence.

It might be mentioned in passing that a bishopric was established at Margam at a very early date, probably by Morgan Mwynfawr—"Morgan the Courteous," son of the great King Arthur—but after several successions it was merged in that of Llandaff.

The Supplementary Illustration conveys an excellent impression of the mansion, but, unfortunately, does not include the pretty terrace garden, which occupies the space between the park wall and the house. Filled with masses of highly-coloured subjects of the usual summer-blooming varieties, at the time of our visit this garden was exceedingly

with great care from further decay by Miss Talbot, the present owner. A few years ago, seedling trees had taken possession of the crumbling portions of the walls, and had been allowed to grow to considerable size, but the masonry is now clear, and demolition from this cause has, consequently, been arrested.

The Margam Orange trees have a long history, and I therefore inspected one of the magnificent specimens with a feeling akin to reverence. The following quotation is from Lewis' *Topographical Dictionary of Wales*, 1833:—

"In the midst of the pleasure grounds is a splendid orangery, an unusual appendage to a gentleman's residence, but there is no record in existence showing the period of its establishment. According to tradition, this celebrated collection of Exotics was intended as a present from a Dutch merchant to Queen Mary, Consort of William III., but the vessel conveying it having been stranded on the coast here, the choice cargo was claimed as the property of the Lord, and a house 150 feet in length was built for

FIG. 55.—THE ORANGERY AT MARGAM PARK, GLAMORGANSHIRE.

gay. Distinctly-designed beds, in four large squares of Grass, surrounded by a still greater breadth of warmly-coloured gravel and relieved by erect plants of Irish Yews, form the arrangement of this garden. From the terrace, across the beautiful park, with its 500 head of deer, an uninterrupted view of the Bristol Channel is obtained, with the numerous passing craft which provide a constantly changing panorama; whilst landward, over a pretty undulated foreground, some of the local docks, with their forest of masts appear, and beyond is the curved outline of the lovely Swansea Bay, with the peninsula of Gower in the distance.

Descending by way of a broad, gravelled pathway and several flights of stone steps, the visitor comes upon the ruins of the ancient abbey, said to be the very earliest of the monastic houses set up in this part of the country. As a link with the past, and for their picturesque value in this spot, these ruins are most interesting, and are preserved

the reception of the plants. The late Mr. Talbot, in the year 1787, built a new greenhouse 327 feet in length, with a handsome Palladian front and a room at each end, and in 1800 a conservatory 150ft. long, with flues in the ground. There are about 110 trees in the greenhouse, all standards, planted in square boxes, and many of them 18ft. high; those in the conservatory, 40 in number, are traced against a trellis framing, where the fruit, which is usually abundant, attains its native size and flavour."

Two of the original trees still exist, and several others are certainly very old. The collection, by its vigorous health, testifies to the skilful care bestowed upon the trees. About 40 specimens, some of them 20 feet high, in large tubs, occupy in summer an ideal, greensward position encircling a water fountain. They are wintered in the large orangery, which is an exquisite piece of garden architecture (see fig. 55).

Tub gardening, now becoming more common, has long been practised at Margam,

and in the vicinity of the orangery may be seen beautiful and large plants of *Hydrangea hortensis*, *Brugmansia*, *Agapanthus*, *Citrus*, *Myrtle*, *Eugenia Ugni*; *Oleander*, *Lime*, *Camellia* and the lovely *Clethra arborea*, all in large tubs, with *Palms* and other foliage plants, making a distinct and admirable feature in harmony with, and indeed enhancing the architectural effect.

I quote again from Lewis' work as follows:—

"The evergreens cultivated in the grounds surrounding the orangery are healthy and luxuriant. Among these a Bay tree, supposed to be the largest in the world, sprouting from the ground in several branches, is the most remarkable, being upwards of 60ft. in height and 45ft. in diameter."

There are several fine "Bays," but the one above-mentioned is a giant, and now mea-

sure, a fine example of the Oak-leaf Beech and a good specimen of *Libocedrus decurrens*. I missed a veteran tree that had successfully withstood many a storm, for it had succumbed at last to a storm early in 1907. It was an old Chestnut, and was a landmark near the mansion.

Nestling between and protected by the fore-named trees, there is a wealth of good subjects, thriving in the utmost luxuriance. Hybrid *Rhododendron* and *Azaleas*, profusely flowered; *Hydrangeas* (most of them having flowers of the deepest of blue, and one of the plants measuring 20 feet across); *Olearia Haastii* and *O. macrodonta*, the latter species 18 feet through; *Rhus Cotinus*; *Arbutus Unedo*, and *A. Andrachne*; masses of *Phormium tenax*; *Halesia tetraptera*, 30 feet across; *Berberis vulgaris*, as large; and, on the wall of the church standing in the

grown, including *Arundinaria falcata*, *A. japonica* (syn. *Bambusa Métaké*), *A. nitida*, *Phyllostachys aurea* (syn. *Bambusa*), *P. nigra*, *Arundinaria Hindsii*, *Bambusa gracilis* and *B. palmata*. Mr. Milner informed me that these plants had been subjected to as much as 20 degrees of frost.

A Rose pergola garden has been developed within the last few years. The pergola spans a fairly wide Grass walk, and describes a semi-circle, the entrance being marked by a pair of Italian pillars. The wood-work is of Larch, stoutly built, but the arrangement suggests lightness. It is draped with *Roses* of the best colours, whilst at intervals are standards of the *Wichuraiana* and *Polyantha* varieties, sufficiently far from, but running the length of, the pergola on either side. The scheme produces a most pleasing effect, which is heightened by a background of the *Himalayan Briar Rose Leuchtstern* and other *Polyantha* sorts and species. Some Italian vases were prominent in a bed of tall Lilies, and there were beds of mixed *Larkspur* so placed as to complete a most artistic picture.

Space forbids me to dwell at length upon the other departments of the garden, or much might be written of the fruit trees in the kitchen garden, the cordon Pears and trained Peaches on walls, which invariably carry and furnish fine crops of delicious fruit, the *Roses* and herbaceous plants. About 800 plants of the best varieties of *Carnations* are cultivated; the display, when they are in bloom, can be easily imagined. A large number of plants of *Calanthe Veitchii* arrest attention, their health and vigour giving promise of good bloom later. In a back stove there are several big pots of *Eucharis grandiflora*, *Codiaeums* (*Crotons*), *Cordyline* (*Dracæna*) and the usual, useful, decorative plants. Orchids are represented by numbers of the more useful decorative species of *Cypripedium*, *Cælogyne*, *Dendrobium*, *Cattleya*, &c.; one house is devoted chiefly to *Odontoglossums*. Among *Anthuriums* I noticed one of the *Andreanum* type labelled "*Fletcherianum*," a large and very dark-coloured form. The indispensable *Begonia Gloire de Lorraine* is largely grown, also *B. Gloire de Sceaux*, the last-named forming specimens 7 feet in height (see fig. 50). The largest plant shown in the photograph (see fig. 56) was 5 feet high and 3 feet in diameter. The plants were raised from cuttings inserted in March, and they commenced to bloom in November, being then in 10-inch pots. One of the plants kept beautifully fresh, although placed in a dwelling room for a month. About 500 *Chrysanthemums* are grown in bush form, whilst about 200 others are cultivated expressly for large blooms. The cultivation of fruits under glass is attended with great success, and Mr. Milner ranks amongst leading fruit growers. *Madresfield Court Grapes* are produced of great size and perfect finish, as also are *Muscat of Alexandria*, *Black Hamburg*, *Black Alicante*, &c. *Indoor Peaches* and *Nectarines* are also of the best. The whole establishment is managed with that skill and forethought which commands success.

To such a generous patron of gardening as Miss Talbot, the splendid results achieved must indeed be gratifying. A. P. Rowler.

FIG. 56.—WINTER-FLOWERING BEGONIA GLOIRE DE SCEAUX AT MARGAM PARK. LARGEST PLANT 5 FEET HIGH AND 3 FEET IN DIAMETER.

sure 80 feet in height and 60 feet in diameter, a superbly-clothed pyramid. The following also, with their dimensions, are perhaps equally noteworthy:—*Picea Morinda* (syn. *Smithiana*), 95 feet; *Platanus orientalis* (*Oriental Plane*), with a spread of 90 feet; *Liriodendron tulipifera* (*Tulip tree*), 100 feet; *Sequoia gigantea*, 90 feet; *Quercus Ilex*, 65-70 feet high, and a diameter of 75 feet. Two grand Stone Pines (*Pinus Cembra*) occupy sites at either end of the orangery, and a specimen of *Pinus halepensis*, a Pine rarely seen in this country, 75-80 feet high, in capital condition, is also worthy of note.

Beside these are some veteran *Larch* and massive *Beech*, *Sycamore*, *Elm* and *Lime*

grounds, *Magnolias*, *Wistaria*, *Myrtle*, *Roses*, &c., seemed to fully appreciate their sacred privilege; I admired also *Clianthus puniceus* doing well against a wall.

THE BAMBOO GARDEN

is a modern institution, but here, at least, it is eminently successful. Mr. Milner, the head gardener, with true instinct, discovered both the spot and the treatment, and, aided by conditions of pure air and wind shelter, the progress made in six or seven years has been extraordinary. A plant of *Arundinaria falcata* is 18 feet or more in height, and 24 feet across; while a plant of *A. nitida* is scarcely less. About twenty-four varieties are

GARDEN VARIETIES OF ABUTILON.

THOUGH some of the original species of Abutilon have been long grown in this country, the garden varieties, which are now so numerous, are of recent production. The first stimulus to the raising of hybrid forms was the introduction from Brazil, in 1871, of the bronzy-red flowered *A. Darwinii*, which, in addition to its other desirable qualities, flowers very freely in a small state. A year after this, viz., in 1872, M. Lemoine, of Nancy, distributed the pure white-flowered variety, *Boule de Neige*, of whose origin I can learn nothing. At all events, this beautiful form soon became popular, and even to-day holds its own as one of the best of Abutilons with white blossoms.

The intercrossing of these two was taken in hand by many raisers, notably by Mr. George, of Putney, and MM. Lemoine and Delaux in France. A noticeable fact in connection with the union of these two varieties is the wide range of colour found in the progeny. In some of them, the original colour of one or other of the parents is completely eliminated. The same thing occurs in the now popular Javanese *Rhododendron*, for the union of the white-flowered *Rhododendron jasminiflorum* and the deep orange-coloured *R. javanicum* resulted in the production of the pink-flowered hybrid *Princess Royal*.

Returning to the Abutilons, it may be noted that it was not long before many garden varieties, with blossoms of varied tints, were put into commerce. By the early 'eighties, white, pink, yellow, purple, as well as different shades of red, were represented among them. A glance at the list of plants certificated by the Royal Horticultural Society serves to show that the whole of the seven varieties of this class that were so honoured, received the Certificate between 1875 and 1882. From that time Abutilons became very popular, and remained so for some years; then came a period when this section appeared to be somewhat overshadowed by the variegated-leaved forms, of which there are several in cultivation. Of late, however, there are signs of increasing interest in Abutilons as flowering plants, stimulated, perhaps, to a certain extent, by newer forms sent here from the Continent. Some of these are characterised by very large flowers, more or less semi-double in character, which, instead of being strictly drooping, as are most of the others, are disposed horizontally, or nearly so. Though distinct, they are, to my mind, less pleasing than the older kinds, but no doubt they are admired by some. One of this class, viz., *Triomphe*, with pink flowers, was noted in good condition at the last Holland Park Show. A second variety of this section, *Jour de Fête*, has straw-coloured blossoms. In both, the flower-stems are shorter and stouter than in the forms generally seen, and are therefore able to support the flowers in an almost horizontal position. There are many purposes for which Abutilons may be advantageously employed in gardens. They may be grown as bushes and used for the embellishment of the greenhouse or conservatory throughout the summer months. In this way the blooms are, from their pendulous character, not always seen to the best advantage. Hence they are, by some, grown as standards, and thus the flowers are brought more on a level with the eye. For furnishing the pillars or walls of a greenhouse many of the varieties are very suitable; but the finest position of all is, I think, when they are trained to clothe the roof of a glass structure, as may be seen in No. 4 greenhouse at Kew. Treated in this way they flower profusely, and produce a canopy of drooping, bell-shaped blossoms.

During the summer months Abutilons may be planted out-of-doors, and they are often used in mixed beds of flowering plants.

Of the numerous varieties in cultivation,

Boule de Neige is a good white, *Golden Fleece* a fine golden-yellow flower, *Sanglant* a rich red, and *rosæfforum* a silvery-rose variety.

Among variegated-leaved varieties are:—*Thompsonii*, an old and tall-growing form, whose lobed leaves are mottled with cream; *Souvenir de Bonn*, a form of *A. striatum*, in which the handsome, lobed leaves are broadly but irregularly edged with white; *Savitzii*, something like a less vigorous form of the preceding, but much more freely variegated; *Darwinii tessellatum*, whose leaves are curiously checkered with different shades of yellow and green; and a variegated-leaved form of the slender-growing *A. vexillarium*, often met with under the specific name of *megapotanicum*.

Of the original species may be especially mentioned *A. insigne*, *A. striatum*, *A. venosum*, and the just-mentioned *A. vexillarium*.

One of the best of all Abutilons is *A. vitifolium*, but to see this in perfection the south-west of this country, or some parts of Ireland, where it flourishes outdoors, must be visited; for under greenhouse treatment it is not, as a rule, a success. *W.*

TREES AND SHRUBS.

TREES AND SHRUBS FOR WINTER EFFECT.

TREES and shrubs that are decorative in the dull days of December and January can be purchased cheaply and cultivated easily, yet in many cases Laurels and Privet are the only subjects planted.

A winter-garden in the open may be easily formed. Its situation should be sheltered from the north and east winds, not that the plants require shelter, but because the plants can then be inspected with more comfort during cold weather. If shelter is not naturally afforded by the contour of the ground or by big trees, it can easily be secured by planting Austrian and Scotch Pines, the dark green of the former contrasting well with the glaucous foliage and brown trunks of the latter. These, with a clump or two of Birch, and perhaps a few Hollies, will soon be high enough to break the cold winds, and, in addition, be pleasing to the eye in winter. No tree is more beautiful in this country in winter than the Birch, with its silvery-white trunk and graceful, drooping branches. It thrives in poor, stony soils, and there are very few well-drained soils of any kind in which the Birch will not grow. Some of the Willows are particularly prominent in winter by reason of the colour of their leafless stems, but more especially *Salix vitellina* in its red- and yellow-stemmed varieties. *S. daphnoides* (the Violet Willow) with bluish-white bloom on its branches, and *S. triandra* with purplish-brown stems are both to be recommended. The Willows are most effective when growing near water, though they also do well on drier ground. The colour is more intense on the young stems, therefore the trees should be pruned hard just as growth is commencing, after which the young shoots will develop to a height of 6 feet or more by the following autumn and furnish a fine display of colour after the fall of the leaf. Some of the Cornels also have coloured stems in the winter, the bright-red of *Cornus alba* and *C. a. var. sibirica* being particularly showy. *C. stolonifera var. flaviramea* has yellow-coloured stems. These Cornels are the better for being cut down annually; the young growths reach a height of 3 feet to 4 feet. *Rubus biflorus* is a native of the Himalayan region. The intensely blue-white canes grow to a height of 8 feet or more; they give a touch of colour to the garden in winter; so also does *R. lasiostylus*, a comparatively scarce plant from China, which has bluish canes which grow rather shorter than those of *R. biflorus*. *Kerria japonica* has

bright-green stems suitable for winter effect, as also are shoots of the lesser-known *Stephanandra Tanakæ*. The latter is a low-growing, spreading plant, possessing very little ornamental value except for its winter effect. *Fraxinus excelsior var. aurea* (the Yellow-barked Ash) displays its golden branches to advantage during the winter; the weeping variety is also a desirable plant.

There are several shrubs which flower during the winter, of which the *Hamamelis* (*Wych Hazels*), with their twisted, golden-yellow petals; *Prunus Davidiana* in its white and pink forms; the rosy-pink *Erica mediterranea hybrida*, which blooms all through the winter; the February-blooming *Erica carnea*; and the red and white varieties of *Daphne Mezereum* can be recommended. The bright-yellow, trailing *Jasminum nudiflorum* can be trained informally on pillars or old tree stumps, and in a warm corner *Lonicera fragrantissima* and *Chimonanthus fragrans* will open their sweet-scented flowers. In the early spring *Spiræa Thunbergii* displays its tiny, white, star-like blossoms; the peat-loving *Andromeda floribunda* and *A. japonica* open their white, bell-shaped flowers; while *Viburnum Tinus*, the mauve-coloured *Rhododendron præcox* and the crimson *R. nobleanum* are all capable of brightening the garden at this season. *J. Clark, Bagshot, Surrey.*

NOTICES OF BOOKS.

* BRITISH BASIDIOMYCETES IN THE BRITISH MUSEUM.

THE series known as the British Museum Catalogues have justly attained to an important position in scientific literature. For the national collections are sufficiently extensive to enable a catalogue of any single series to rank as a monograph, and in the book before us we have an admirable volume thoroughly deserving of a high rank amongst those which have already been published. Mr. Worthington Smith is already well known to the readers of the *Gardeners' Chronicle*, and it is with special satisfaction that we greet his well-planned and well-executed book. Only those who have attempted something of the same kind are aware of the great labour involved in the preparation of such a monograph, and Mr. Smith is to be congratulated on the skill and thoroughness with which he has carried out his task. The book is, of course, one that will appeal to the specialist rather than to the general reader. Fungi, and especially the Basidiomycetes to which this volume is exclusively devoted, are often difficult to identify, even with the aid of a good description. This arises largely from the lack of constancy in their characters, and furthermore, from the fact that many of them change a good deal in colour and general appearance as they mature. Even the spores are not always trustworthy, and we think Mr. Smith has shown a wise discretion in omitting to give their measurements as a means of identification. In his fig. 8, portraying the basidia and spores of the Mushroom, he shows what great variation may obtain within the limits of a single individual in characters that *à priori* one would have been inclined to rely upon. We can, of our own experience, fully confirm the variation shown in this particular instance, and we recall the circumstance that the facts themselves were called in question by certain people, when they were stated some years ago.

Where we have been able to test the book, we have found it accurate and reliable, and the figures, of which there is a considerable number, are such as we should have anticipated from so skilled and careful an artist. *J. B. F.*

* *Synopsis of the British Basidiomycetes*, a descriptive catalogue of the drawings and specimens in the department of botany, British Museum. By Worthington George Smith, F.L.S. London: Printed by order of the Trustees of the British Museum, 1908. Price 10s.

NOTES FROM A "FRENCH" GARDEN.

WORK in the French garden now largely consists of preparing the hot-beds for the forcing of Cos Lettuces. A few years back Cos Lettuces early in the season were worth from 8d. to 10d. each, and special hot-beds containing three rows of cloches only were prepared for their culture. But this entailed much work, as the outsides of the beds required continual attention to keep them in position, owing to the constant treading when passing along the narrow paths. Of late years this system has been abandoned, and the bed made as for accommodating frames, the outside portions being carefully formed with long, strawy manure. Cos Lettuces require a very mild and constant heat, therefore the hot-bed should be formed of one-third fresh manure and two-thirds dry manure. The beds need not exceed 9 inches in height when finally trodden down. The necessary soil is placed on the beds in ridges until the adjoining bed is finished, and then a board is placed parallel to the path to enable the operator to level the soil. When this is finished short and broken manure is placed in the pathway to the level of the soil, to prevent the latter

the culture of Cos Lettuces may be allowed to last about a fortnight, so that when the crops from the first beds are marketed there will be a succession lasting three or four weeks.

We have sown our first batch of Endive for the season, using the variety La Parisienne. This is earlier, although smaller, than the variety La Rouennaise, which is grown in cold frames at the beginning of April or in the open at the end of that month. Early Endive requires a uniform amount of warmth when in the seedling stage, and light and frequent waterings when planted under a cloche. It must never be neglected in this latter respect, and for this reason Early Endive is only cultivated in those gardens where it is possible to give it regular attention.

HARDY FLOWER BORDER.

THE GREEN-FLOWERED HELLEBORES.

ONE of the most handsome plants in bloom here now (January 8) is *Helleborus corsicus*. Willd. (*H. argutifolius*, Viv.), a native of Cor-

capsules in profusion, showing their saturnine-red seeds, about Christmas time.

H. corsicus sows itself freely, even on the hard stone path, but a sharp look-out should be kept for the seedlings, as slugs are very partial to them. A few seedlings are now beginning to appear.

The native Bear's-Foot or Setterwort (*H. foetidus*) is also now at its best. This grows wild near here in rocky woods, and is something like a small edition of *H. corsicus*, being evergreen and bearing numerous close panicles of verdant green (*vert pré*) cup-shaped flowers tinged with dull purple, which stand out well above the pedately-divided leaves.

H. viridis, native or perhaps only a denizen, is later, but is now pushing up its few-flowered stems which appear before the digitate leaves. This species is entirely herbaceous, and has a few varieties which are worthy of a rocky corner in the wild garden.

All these Hellebores are easily grown in any rich deep soil in shady places, but it is as well to remind those who wish to raise seedlings that the seed should be sown as soon as ripe, since it quickly loses its germinating power if allowed to get at all dry. The seedlings generally flower when 2½ years old.

Hellebore flowers are very interesting to study. What appear to be green petals are really sepals, the petals consisting of numerous small green bodies, shaped like trumpets (nectaries) which soon fall off. One may compare with these flowers those of the Winter Aconite, whose arching stems are now forcing their way through the ground. Here again what appear to be yellow petals are really sepals, surrounding the true petals. *G. B. Milne-Redhead, Mil-lard's Hill, Frome.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM T. B. HAYWOOD (DRURYI × SUPERBIENS).

A REMARKABLE instance of the long duration of the flowers of this hybrid has been noticed in the gardens of F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), where flowers which opened on October 10 last year are only now fading.

Instances of *Cypripedium* continuing for a long time in flower by means of a succession of blooms are not uncommon, but for individual flowers to remain in a good condition from October to February is remarkable.

ODONTOGLOSSUM ARDENTISSIMUM "PHEBE."

This hybrid was shown by Mr. Norman C. Cookson at the meeting of the Royal Horticultural Society on February 9, when it gained a First-class Certificate. The colour of the sepals and petals is claret-red, save for a band of white at the margins. The handsome colouring, combined with good form of segments and finely-developed and distinctly-marked lip, go to make the plant one of the best of the hybrids yet raised from *Odontoglossum ardentissimum*.

FINE PLANT OF ODONTOGLOSSUM CRISPO-HARRYANUM.

We have illustrated many examples of the excellent culture to be seen in the collection belonging to Colonel Holford, C.I.E., C.V.O., but rarely one that surpasses the specimen of *Odontoglossum crispo-Harryanum*, now shown at fig. 58. This plant was exhibited at the Royal Horticultural Society's meeting on February 9, and the Orchid Committee recognised the culture displayed by awarding the grower, Mr. H. G. Alexander, a Lindley Medal. One inflorescence alone bore 61 flowers, whilst the aggregate number on the plant was 125.

FIG. 57.—ODONTOGLOSSUM ARDENTISSIMUM "PHEBE"; COLOUR REDDISH-CLARET WITH WHITE MARGIN. AWARDED A FIRST-CLASS CERTIFICATE BY THE ROYAL HORTICULTURAL SOCIETY ON FEBRUARY 9.

from becoming displaced. Some persons make a broadcast sowing of "Bellot" carrots to form a successional crop to the Lettuces, but, owing to the constant removal of the cloches, the Carrots have not a favourable opportunity for proper development, and it needs a very experienced person to ensure success with them. The Lettuces should be planted as follows:—With a line, mark the position of the outside row of cloches which are placed at a distance of 1 inch apart. The next row of cloches alternates with the first, and so on until the end is reached. Three or four days after the cloches are placed in position and when the heat from the fermenting material has thoroughly warmed the soil, one Cos Lettuce, "Green Flat of Paris," is planted in the centre of the bell-glass, with three Cabbage Lettuces in a triangle around it. After these have been planted about seven to ten days another Cos Lettuce is planted in the angles of the cloches outside. A small aperture is made for admitting fresh air to the cloches by pressing the soil in one spot just under the rim of the glass with the closed fist. The preparation of hot-beds for

sica (see fig. in *Gardeners' Chronicle*, April 13, 1907, p. 232). One of the plants bearing 13 trusses of flowers, is about 30 inches high, and has smooth, leathery, trifid leaves, the leaflets being ovate-lanceolate, glaucous beneath and sharply-toothed. The flowers, with nearly flat, spreading sepals, are about 2 inches across, yellowish sap-green (*vert eau-de-Javelle*), nodding in panicles of about 18 to 24, overtopping the leaves.

H. corsicus is sometimes mistaken for the true *H. lividus*, Ait. (*Bot. Mag.*, t. 7903), a very scarce plant, which is a native of Majorca, and perhaps Corsica, but from a horticultural standpoint the plants are quite distinct. True *H. lividus* has dull purple-grey flowers, tinged with green, and it used to grow in the Botanic Garden of Trinity College, Dublin.

H. corsicus is a most useful plant for a north border. It is evergreen, and beginning to flower early in December, it continues until the end of February or March. Even then the persistent sepals give the plant a very handsome appearance. I grow it with a background of Butcher's Broom and the Gladwyn Iris, which latter bears

THE ROSARY.

NOTES ON CLIMBING VARIETIES.

MANY of the most beautiful climbing Roses lack the quality of perpetual flowering; it is to be hoped that during the next few years the raisers of new varieties will furnish some that show improvement in this respect.

As a help to those who are still desirous of planting for the coming season, I append the names of those sorts that I consider the best in this section. This late planting is now best delayed until March, as in January or February, even if the weather is open, the temperature of the soil is very low and an unestablished Rose feels the effects of frost at the roots most

"Climbing Devoniensis," "Climbing K. A. Victoria" (the blooms are identical with those of the type; unfortunately it is a poor climber, the shoots being insufficiently vigorous), "Climbing La France" (this also with me refuses to climb much), "Climbing Mrs. W. J. Grant" (another great acquisition to the climbing section, but not very vigorous), "Climbing Niphotos," "Climbing Papa Gontier," "Climbing Perle des Jardines" (succeeds best under glass), "Crimson Rambler," "Dorothy Perkins" (very rampant), "Conrad F. Meyer," "Dr. Rouges," "Dundee Rambler," "England's Glory" (a good Rose, very free in blooming and having an extra good Tea scent), "E. Veyrat Hermanos" (a shy bloomer till thoroughly established, when it is free enough, and is one of the most beautiful Roses I know), "François

SOME NEWER VARIETIES.

ARD'S RAMBLER (*Alex. Dickson & Sons, 1908*).—Judging from plants seen growing in quantity at the raiser's nursery, this variety is to be strongly recommended. The blooms are of enormous size, with great stiff petals, and are perfectly formed. The colour is a velvety orange-crimson, with the base of the petals shading to rosy-carmine. Like "Ard's Rover," it is deliciously and highly perfumed. Though not such a vigorous growth, it is sufficient for covering a house-side. The foliage, too, is very fine. It may be considered (in growth) intermediate between "Ard's Rover" and "Ard's Pillar." Planted in pots and grown under the same conditions as "Maréchal Niel" and kindred kinds, it has outdistanced them in growth. Should it prove as free a bloomer as

FIG. 58.—ODONTOGLOSSUM CRISPO-HARRYANUM FROM THE COLLECTION OF COLONEL G. L. HOLFORD, C.I.E., C.V.O. THE PLANT CARRIED 125 FLOWERS.

acutely. When planting is delayed until March, or even as late as April, prune "hard" at the time of planting:—

"Aglala," "Aimée Vibert," "Alister Stella Gray," "Ard's Rover" (the very best of its colour for a house-side or high wall and one of the sweetest-scented, rampant-growing (Roses), "Billiard et Barre," "Blairii No. 2" (the blooms are scented like a Honeysuckle), "Bennett's Seedling," "Blush Rambler" (very rampant in growth, producing blooms with a delicious scent), "Bouquet d'Or" (a very free grower; quite the best of the Dijon class, all of which have a pleasing Tea scent); "Carmine Pillar," "Climbing Caroline Testout" (this is a great acquisition in climbers, but be sure and get the true climbing type, because the first three plants I had refused to climb at all).

Crousse," "Gloire de Dijon," "Grüss an Tep-litz," "Hélène," "Hiawatha" (very rampant, and quite the best of the Wichuraiana Roses: the foliage is beautiful), "Lady Gay" (very like Dorothy Perkins, but with prettier foliage, and has the scent of the Sweet Briar), "La Marque" (needs a warm, dry situation), "Mme. Alfred Carrière" (deliciously fragrant), "Mme. Bérard" (the petals are a very beautiful shade of salmon-yellow and are set off by the handsome foliage), "Mme. Hector Leuilliot," "Mme. Jules Gravereaux," "Mme. Moreau," "Maréchal Niel," "Minnehaha" (a vigorous grower), "Mrs. F. W. Flight," "Rêve d'Or," "René André," "Reine Olga de Wurtemberg," "Tea Rambler," "Thalia," "The Garland," "The Wallflower," "Wm. Allen Richardson," and the "Yellow Banksian."

"Ard's Rover," it will be a valuable addition to red climbing Roses.

EVANGELINE (*Walsh, 1907*).—A hybrid Wichuraiana. The flowers are borne in large clusters, the petals being 2½ inches in diameter. They are white, with the tips carmine-pink. The foliage is large and of a coppery colour.

FLOWER OF FAIRFIELD (*Schulltheis, 1908*).—This variety is claimed to be a perpetual-flowering Crimson Rambler of the same habit of growth as the older variety.

GOLDFINCH (*Paul & Son, 1907*).—A Rose of beautiful deep golden-yellow colour in the bud, but when open of a pale orange, shaded with violet, changing later to lemon-white. The flowers are semi-double with orange-coloured stamens, and are produced in numerous large trusses.

This new Rambler is a seedling from "Helene," and a very rampant grower.

LADY WATERLOW (*Nabonard, 1902*).—Although scarcely new, I have included it in my notes, as it deserves to be better known. It is a Hybrid Tea variety, and is one of the most delicately-beautiful climbing Roses. The flowers are very thin, but freely produced. The colour is a clear salmon-pink, with large crimson, almost Picotee-edged petals. This is a beautiful Rose for table decoration.

MRS. O. G. ORPEN (*Benj. R. Cant & Sons, 1900*).—This Rose has become very popular for decorative purposes in dwelling-rooms. It is a climbing damask, and has the most beautiful flowers. They are large and single, and are produced in trusses. The colour is a bright rosy-pink, with golden anthers.

STARLIGHT (*Paul & Son, 1908*).—Another pretty addition to the single-flowered varieties. The blooms are large, the petals being of much substance. They are white, suffused with a velvety rose, contrasting well with the deep green foliage.

TAUSENSCHÖN (*Schwartz, 1906*).—I consider this the most beautiful of the new climbing Polyantha Roses. It is wonderfully free, and is of similar growth to Crimson Rambler. The ground colour is like the tint of Peach blossom, but it changes to a rosy-carmine and the blooms are sweetly scented. The inflorescences develop 10 to 15 blooms in a bunch. It promises to become a most popular Rose.

TRIER (*Lambert, 1904*).—This is a German-raised Rose, and is really perpetual in flowering. It produces large trusses of semi-double, pale fawn-white flowers. Being a climbing Polyantha Rose, it offers opportunity for raising other autumn-flowering Roses of its class.

WHITE DOROTHY (*Benj. R. Cant & Sons, 1908*).—This is a white sport of the well-known Dorothy Perkins variety. I have not yet seen it, but should imagine it to be a valuable addition to the climbing Wichuriana class.

SINICA ANEMONE (*F. Schmitt, 1895*).—On a south wall, with no protection given, I have a fine specimen of this lovely single-flowered Rose. The blooms are large and silvery-pink, shaded with rose colour. *Leonard Petrie, Gayton, Cheltenham.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Angræcum, Aerides, Vanda, &c.—Such aerial-rooting Orchids as *Angræcum sesquipedale* and *A. eburneum* having just finished blooming for the season, the increasing light and warmth from the sun will induce the roots to start into growth. Before this takes place the plants may require attention. In cases where, through loss of leaves, they have become bare some distance up the stem, they must be let down lower in the pots. Clear out the old Sphagnum-moss and replace the drainage with clean crocks, covering these with fresh moss. Those plants which have not lost many leaves may be left undisturbed, merely resurfacing them with Sphagnum-moss; all long, rambling roots should be brought very carefully to the surface of the pot. The rare *A. Kotschy* appears to thrive best when fixed to blocks of wood, and suspended from the roof, where it can be sprayed several times daily. These *Angræcums* enjoy the warm, moist atmosphere of the East Indian house, or a shady corner of the plant stove, while most of the smaller-growing species, as *A. bilobum*, *A. articulatum*, *A. arcuatum*, *A. Sanderianum*, *A. citratum*, *A. hyaloides*, *A. fastuosum*, and *A. Ellisii*, prefer a warm, shady position in the Cattleya house. The scandent-growing *A. Scottianum* should be tied up to neat sticks or small teak rods. The present is also a good time to top-dress or repot *Aerides*, *Saccolabiums*, *Sarcanthus*, *Aracanthus*, *Vanderendium*, and the warm-growing *Vandas*, as *V. Sanderiana*, *V. cristata*, *V. coerulescens*, *V. Parishii*, *V. Roxburghii*, and *V. lamellata*. Remove all scale-insects and other pests before commencing to top-dress. The roots should be treated in every respect as is advised for the *Angræcums*. These epiphytic plants should be watered sufficiently frequently to in-

duce the Sphagnum-moss to grow over the surface. All the plants must be carefully protected from strong sunshine. *Vandas* of the suaviss and tricolor section should now receive plenty of water at the roots, as they will soon commence to throw up their flower-spikes from the axils of the leaves. A cool, shady end of the Cattleya or intermediate house is the best place for these *Vandas* at all seasons.

Shading.—The sun's rays are now becoming too powerful for some species of Orchids, particularly *Cypripediums*, *Odontoglossums*, *Phalænopsis*, *Aerides*, *Saccolabiums* and *Vandas*; also such plants that have recently been repotted. Therefore blinds or shadings should be at once fixed in their places.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Figs.—Fig trees generally succeed better in pots or in restricted borders under glass. At the same time there are, in favourable localities, many warm corners in the fruit garden where a Fig tree would repay for better cultivation than it usually receives. In some gardens may be seen trees which should bear good crops of fruit but which seldom do so. As a rule this result is due to the neglect of one or two important points in cultivation. Perhaps the most frequent reason for ill-success is the fact that the roots of the trees having nothing to restrict them, have found their way into rich, heavily-manured ground. This causes the trees to make a large quantity of strong growth which fails to mature. The growths are generally left too thickly together during the summer, and they are, therefore, severely injured by frosts in winter, or, failing this, they are severely pruned in spring. These conditions aggravate the evil, for they tend to produce growth in the following season even stronger than ever. In order to check such exuberant growth it is necessary to cut a deep trench at about 3 or 4 feet from the wall, severing all the roots with a sharp knife and searching for any tap roots that may be growing straight down into the subsoil. The roots can then be restricted to a small space by means of a wall, or, failing this, the trench may be filled with chalk and stony soil, which should be thoroughly rammed as the work proceeds. This will greatly check growth in the first season. Train the shoots thinly over the wall space, and the trees will then make short growths in the following season. These will thoroughly mature, and bear fruit in the ensuing year. When any young Fig trees have to be planted, select for them a south or south-west aspect, and if a narrow border extending by the side of a hard gravel walk or roadway is available, no further preparation will be necessary, otherwise the roots should be restricted in the manner I have already described. Ordinary garden soil is suitable, but if fresh soil has to be procured, do not employ a rich, loose compost, but instead a light soil. This should be well rammed. When the trees reach a fruiting condition, nutriment can be applied with advantage in the form of liquid manure, and in summer a mulch will be beneficial. The most suitable varieties for out-of-doors culture are: (1) Brown Turkey; (2) Brunswick; (3) White Marseilles.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Late-fruiting vines.—The Grapes in late houses have usually to hang on the vines for a much longer period than is the case with early or mid-season varieties. It is, therefore, the more important to perfectly clean the rods at this season, particularly if they have been affected with mealy bug. In the first place, give the house a thorough cleansing with soapy water, paying particular attention to any holes or crevices that would be likely to conceal the insects. This done, remove any loose bark from the rods and then scrub them with a stiff brush, using a solution of soft soap and sulphur at the rate of 2 ounces of soft soap and 2 ounces of sulphur to a gallon of water. The rods may be again washed just as the buds commence to break into growth. Before tying up the vines, let the whole of the trellis be painted with paraffin oil, which should be well worked into the holes. Lime-wash all the exposed brick-

work. Carefully fork over the borders and remove an inch deep of the old soil. Then apply a top-dressing of chopped loam with a liberal mixture of old mortar rubble, wood-ashes and a chemical vine manure. Should the borders be approaching to dryness, thoroughly soak them with clear water before starting the vines into growth. The date for starting them must depend to a great extent upon the locality. In order that they may keep well, the Grapes should be perfectly matured by the end of October. Appley Towers and Black Alicante do not require such a long season of growth as Lady Downe's Seedling or Gros Colmar. If these two latter varieties cannot be given a separate house they should be cultivated in the warmer part of the house containing the other varieties. Lady Downe's Seedling is, perhaps, the best late-keeping Grape.

Propagation by vine eyes.—The buds should be selected from well-ripened shoots of last season's growth. Leave about half-an-inch of wood both above and below the bud, and place the "eyes" in 3-inch pots filled with loamy soil, with a little fine brick rubble added. Press the wood into the soil so that the bud is level with the surface. Plunge the pots in a moderately warm hot-bed and lightly spray them two or three times each day. See that the soil is not allowed to become too wet before roots have formed and the bud has started into growth, otherwise the shoot will decay. As soon as the roots have reached the sides of the pots, shift the young plants into 5-inch pots, using a compost of fibrous loam, brick rubble, and a small quantity of crushed bones. The compost must be thoroughly warmed before being used. Plunge the pots again in a hot-bed, and give them rather more warmth and moisture than in the earlier stages.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LODER, Bart., Leonardslee, Sussex.

Liliums.—If any *Lilium* bulbs have still to be planted, this should be done as soon as possible. They may be planted in the borders of herbaceous plants or in beds containing *Rhododendrons* or *Azaleas*. Rare or choice varieties may be provided with sheltered corners. *Liliums* succeed best in rich loamy soil with some decayed manure and sand mixed with it. Plant the bulbs from 4 to 6 inches deep according to their size. *L. tigrinum Fortunei* is perfectly lovely in the autumn, and if bulbs are planted now they may be expected to yield a bright display of flowers in September and October next. The growths reach 6 or even 8 feet in height, and some of the inflorescences develop as many as 26 flowers. *L. auratum* and its improved variety *L. a. platyphyllum*, also *L. a. vittatum*, *L. Brownii*, *L. pardalinum*, *L. testaceum*, *L. Kramerii*, *L. speciosum*, *L. s. var. Kretzeri*, and *L. s. var. Melpomene* all succeed out-of-doors.

The Alpine garden.—The Alpine garden should be overhauled: given a spring cleaning, so to speak. It will be necessary to treat the portions on which are the earliest plants first. Already *Narcissus minima* and *Anemone blanda* are observable. First clean the plants and ground from weeds and moss. Then top-dress the plants with some fine soil, prepared as recommended in a former calendar. Sprinkle it evenly over the surface, lifting up the plants with one hand and adjusting the soil about their stems. The *Androsaces* should be covered with small lights or squares of glass, for if they receive too much wet in rainy weather they may perish. *Cypripediums* may be planted if it is done immediately, choosing moist and shady positions for *C. acaule*, *C. calceolus*, *C. spectabile*, and *C. pubescens*. Plant them in a considerable depth of peat and leafmould, as the roots require a cool medium in the summer.

Bedding plants.—*Pelargoniums* rooted in boxes should now be transferred to small pots, using a moderately-rich soil mixed with sand and leafmould. When potted, place the plants near to the glass in heated frames, or on a shelf or stage in a greenhouse. The potting should be done moderately firmly, and the plants be kept in a rather close atmosphere for a week or two afterwards. Very little water will be needed until the roots ramify in the new soil. Any plants that have become drawn should have the points of their growing shoots pinched out in order to induce a bushy habit.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Freesias.—Do not neglect to afford generous treatment to plants which have passed out of flower. Manure water may be applied to the roots up to the time when the leaves turn yellow. On the first appearance of this yellowing of the leaves the water supply must be lessened, continuing the decrease until water can be safely withheld. At that time the plants should be exposed to full sunshine in order that the bulbs may thoroughly ripen.

Gloxinia and Achimene.—Shake the tubers out of the old soil and lay them closely in boxes containing a light compost in which an abundance of sand is mixed. Gloxinias require stove heat, but a slightly lower temperature will suffice for Achimenes. When the tubers have made growth an inch or so long, they should be placed in their flowering pots. Tuberous-rooted Begonias require similar treatment if we except the high temperature.

Humea elegans.—Do not allow plants of this species to become potbound until they are in their final pots. Humeas succeed best in a cool, well-ventilated house where the foliage may be kept dry, and waterings are not required frequently.

Lapageria.—Examine Lapageria plants frequently and take every means to prevent injury occurring to the succulent growths arising from the base. During the season of growth abundant supplies of water should be given to the roots, supplying it as cold as possible.

Gloriosa superba.—The tubers of this valuable stove twiner should now be repotted into large pots having ample drainage. A rich, loamy soil is most suitable. Apply copious waterings during summer.

Winter-flowering plants.—Such species as *Coleus thyrsoides*, *Jacobinias* (*Justicias*), *Reinwardtias*, and *Begonia Gloire de la Reine*, which have finished flowering, should be pruned and placed near to the glass in a warm house. They will then produce growths suitable for making the cuttings which are necessary for raising plants to flower next season.

Ferns.—Any necessary repotting or top-dressing should be carried out before the new fronds have so far developed as to be liable to injury during the process. As with Palms, so with Ferns, it is often wise to let well alone, remembering that in nature most Ferns thrive very well with but little soil about their roots. Nevertheless, repotting has to be done occasionally. Peat is usually recommended for Ferns, but it is not absolutely necessary if good pasture loam that is not too heavy is obtainable. Such loam, if mixed with leaf-mould, broken charcoal, and plenty of silver sand, will suffice well enough. Ferns which have rhizomatous roots must not have these completely buried in the soil. Such species thrive better when provided with perfect drainage and only a shallow rooting medium.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Vegetable Marrows.—Seeds should be sown singly in small "60" pots for early supplies and germinated in a gentle warmth. Endeavour to forward the development of the plants by planting them under portable frames on mild hotbeds, so that good crops may be cut from the middle of April onwards. When safe to do so, the frames could be removed and the plants top-dressed. These plants will be in full bearing when those of most persons are being planted, and will continue to furnish fruits until frost destroys them in the autumn. Good results may also be obtained by growing the plants in large pots, afterwards planting them in vacant spaces in a fairly light position of a fruit-house or similar structures and training the shoots to a trellis. Moore's Cream, Pen-y-Byd, The Sutton, and Perfection (a splendid green variety), are all suitable for this method of culture.

Potatos.—Advantage should be taken of the warmer part of the day to attend to the earthing-up of any Potatos under glass which are already showing above the soil. The compost used should be one consisting in equal parts of well-decayed leaf-mould and light loam free from wireworm. These materials must be thoroughly

mixed and warmed before they are applied. As the days lengthen and the sun gains in power, air may be admitted more freely, especially when the wind is from a warm quarter. Tilt the lights in the opposite direction when the wind is from the N. or N.E. Prepared sets may now be more largely planted, either in unheated frames or skeleton shelters, where ample protection can be afforded them against frost. Except in the warmest parts of the country, it is not advisable to plant Potatos in the open ground for at least another fortnight, unless one is prepared to take every precaution to afford protection from cold winds. It is time that the whole of the tubers intended for planting should be laid out thinly either on suitable trays or shelves. Keep them in a cool and light store to make sturdy shoots previous to planting.

Cucumbers.—Plants put out on well-prepared beds last month should now be coming into bearing. They will require constant attention as regards the stopping and training of the shoots. Avoid overcropping while the plants are young. A surface-dressing of well-prepared material should be frequently applied in small quantities. Maintain a brisk heat and moist atmosphere, damping the paths with manure water early in the afternoon. Seed for a successional crop should be sown singly in small pots and raised in a bottom heat.

Seed sowing.—Seed of Aubergines, commonly known as Egg Plants, should be sown immediately in considerable heat. Pot the seedlings off singly as soon as they are large enough to handle, and afterwards place them near the glass in a temperature of from 60° to 70° F. Brussels Sprouts, Early Broccoli, Cauliflowers, and further batches of Parsley and Celery should be sown under glass in boxes.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Paths and roadways.—These are best formed of good, binding gravel; but this material rapidly deteriorates, and, therefore, requires renewing frequently. The present is a suitable time for carrying out any renovating work that is necessary. The channels and gulleys by the roadside should be put in order, and the catchpits cleared out so that the surface water may readily pass away when heavy rains occur. Break up the surface of the old gravel, and apply a fresh layer of fine, recently-dug hoggin. If this is spread evenly, and then rolled with a heavy roller, the surface will remain smooth and firm during dry weather. Gravel is apt to lose much of its binding quality after long periods of wear and exposure to winds. Good binding gravel is not to be easily procured. If it contains much sand or small pebbles, it will not remain so solid during dry weather; whilst if it is clayey, it clings to the feet in wet weather. Mitcham and Croydon gravel has been largely used for path-making, especially in places on the south side of London, and Wheathampstead and Hertford gravel is much sought after in North London. Supplies even from these districts vary greatly in quality. Several methods have been adopted to keep the surface of paths smooth and firm during hot weather. Crushed cockle shells spread very thinly over the surface is beneficial, as is also finely-sifted sand. The frequent use of the water cart in dry weather is a necessity. The roller can be used to the best effect on mornings following rain. This will roll in the fine pebbles that become dislodged by constant traffic, and benefit the surface generally.

Forming new paths.—Where there is a considerable amount of traffic, the paths should be from 12 to 15 feet wide. Proper drainage is of great importance, and the necessary gulleys and gratings must be provided for at distances which will vary according to the nature of the ground, whether level or rising, and according whether the subsoil is of a retentive or porous nature. The ground should be excavated to a depth of 10 inches, and in the bottom of the trench should be placed a layer 6 inches deep of hard material, such as broken bricks, concrete, or clinkers. Over this hard core place 4 inches deep of gravel, putting the rougher at the bottom, and reserving the finer for binding on the surface. Consolidate the materials as the work proceeds by using a heavy roller.

Roads.—Ordinary pit flints of a medium size are suitable for repairing the surface of carriage roads. After breaking up the surface with a pickaxe and spreading the fresh flint, add a layer of about 1 inch of fresh hoggin or binding material, and then bring the roller into requisition to make the surface smooth, but the centre of the road should be slightly higher than the sides so that water may pass quickly away. New carriage roads should be made by excavating the soil to a depth of 17 inches, and placing in the bottom 12 inches of hard material, next 4 inches of flint, and then 1 inch of hoggin. The usual width for a carriage way in a public park is 25 feet. In large parks a small steam roller is of great service, and it can be well employed on the roads.

Drains.—Proper provision for the removal of the surface water is of the utmost importance. A 6-inch or 9-inch drain, according to circumstances, should be placed down the centre of the new roadway, with an easy fall to the outlet or main drain. The gulleys should be placed about 200 feet apart on level ground, but if there is much fall to the roadway they will require to be closer. Many roadways in the London parks are kerbed with stone pitchers, which vary in size, and may be obtained of granite, Purbeck, or York stone.

THE APIARY.

By CHLORIS.

Preparing frames and sections.—When frames are used in the hives, it is necessary to place either a portion, or a whole sheet, of foundation in each frame. If this is not done the bees will build their combs in any direction but that desired by the beekeeper. It is an advantage to use a strip of comb only as a starter when a swarm is newly placed in a hive, for the bees are then gorged with honey for comb-building, and if whole sheets are used, then no use is made of this supply. Further, if sections of drawn-out comb or shallow frames are placed above the queen-excluder zinc, then the bees are compelled to store in the supers, because there is no room in the brood chamber. Some may say then it will be an advantage to use "starters" at all times, because of the saving of foundation, but this is not so. When bees are transferred in the spring or autumn into bar frame hives, it is advantageous to use full sheets of foundation, otherwise the bees would fill a greater part of the remaining space below the starters with drone comb, whereas a swarm

FIG. 59. APPLIANCE FOR FIXING COMB FOUNDATION IN FRAMES.

rarely builds drone comb during the first season. The best foundation on the market is that known as "weed" foundation. Always secure the foundation to the top bar. Too much care cannot be taken to make it quite fast. If no wiring be contemplated then that which weighs seven or eight sheets to the pound may be utilised, but when wiring is resorted to, then the thinner quality—that which is 9 or 10 sheets to the pound—may be used with safety. Some persons use a board when wiring foundation in a frame. Take a piece of wood (A in fig. 59) $\frac{3}{4}$ inch thick and cut it so that it will exactly fit inside a brood frame; then prepare another board (B) that will fit inside a shallow frame. Place these two pieces back to back, and between them place two strips of wood (C, C) about three-quarters of an inch thick, as in the figure. These will project at the top, bottom and sides. The dotted line in the illustration represents the larger board which is used for fixing the comb in brood frames, and the smaller one for shallow frames. In fixing up frames, never allow the foundation to reach to the bottom bar, but allow for stretching. For sections, use whole sheets of wax. If a little glue is put on the edge of the foundation it will make it secure.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Appointments for March.

THURSDAY, MARCH 4—Linnean Soc. meet.

SATURDAY, MARCH 6—
Soc. Franç. d'Hort. de Londres meet.

MONDAY, MARCH 8—
Ann. Meet. United Hort. Ben. and Prov. Soc. at Hort. Hall, Westminster.

TUESDAY, MARCH 9—
Roy. Hort. Soc. Coms. meet. (Bulb Exh. in Hort. Hall, Westminster. Lecture at 3 p.m. by Mr. W. S. Murray, on "Bulb-growing in Holland"). British Gard. Assoc. Ex. Council meet.

THURSDAY, MARCH 11—
London Branch B.G.A. lecture on "Insect Pests."

WEDNESDAY, MARCH 17—
Roy. Meteorological Soc. meet.

THURSDAY, MARCH 18—Linnean Soc. meet.

TUESDAY, MARCH 23—
Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. by Mr. K. Lloyd-Praeger, on "Rock Gardens").

WEDNESDAY, MARCH 24—
Perpetual-flowering Carnation Soc. Sh. at Hort. Hall, Westminster. Annual dinner in the evening.

THURSDAY, MARCH 25—Torquay Spring Fl. Sh.

TUESDAY, MARCH 30—
Cornwall Daffodil and Spring Fl. Soc. Exh. at Market Hall, Truro (2 days). Bournemouth Spring Fl. Sh. (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—40.5°.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, February 24 (6 P.M.): Max. 41°; Min. 30°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, February 25 (10 A.M.): Bar. 30.2; Temp. 38°; Weather—Overcast.

PROVINCES.—Wednesday, February 24 (6 P.M.): Max. 45° Ireland S.W.; Min. 34° Eogland E. coast.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Perennials, Lilliums, Azaleas, &c., at 12; Roses and Fruit Trees at 1.30, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

TUESDAY, WEDNESDAY, THURSDAY, FRIDAY—
Sale of First Portion Nursery Stock, at St. John's Nurseries, Worcester, by order of the Receiver for the Debenture Holders of R. Smith & Co., Ltd., in voluntary liquidation, at 11.30, by Protheroe & Morris.

WEDNESDAY—
Herbaceous Plants, Bulbs, &c., at 12; Roses and Fruit Trees at 1.30; Palms, Plants, &c., at 5, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported and Established Orchids, at 12.45, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

The problem of alternation of generations in plants, which is of great interest to morphological botanists, formed the subject of discussion at the meeting of the Linnean Society on the 18th inst. As most gardeners know, a Fern plant leads, as it were, a double life. In completing its life-cycle, it passes through the Fern stage and the prothallial stage. The Fern plant bears spores and is hence termed the Sporophyte. The spores, on germinating, give rise not to a new Fern plant, but to a simpler structure, the green, heart-shaped prothallus. Since the prothallus forms the male and female reproductive cells, or gametes, it is said to constitute the Gametophyte or sexual generation. Thus, in

the full life-cycle a Sporophyte generation alternates with a Gametophyte generation. Similar phenomena are presented in an almost equally striking manner by the Mosses and Liverworts. In these groups, as in the Ferns, two generations alternate with one another.

The Moss plant bears the male and female reproductive cells, and so, like the prothallus of a Fern, is to be regarded as the Gametophyte. As the result of fertilisation of the egg-cell, a type of structure entirely different from that of the Moss plant itself is produced. This structure grows out from the Moss plant as a capsule borne on a stalk. The capsule when ripe contains spores which germinate without fertilisation and give rise each to a Moss plant. Hence this peculiar structure, the capsule with its stalk is a Sporophyte, and takes a place in the life-cycle of the Moss similar to that taken by the Fern plant in the life-cycle of the Fern. It is noteworthy that, whereas in the Ferns the two generations are capable of independent existence, in the Mosses the capsule generation (Sporophyte) lives as a partial parasite on the Moss plant. But more noteworthy for our immediate purpose are the striking dissimilarities in form presented by the Sporophyte and Gametophyte.

During the 19th century it was proved that this alternation of generations is not confined to Mosses and Ferns, but occurs also in as precise, though less obvious, a manner in the higher plants. Among the flowering plants this remarkable alternation is disguised owing to the fact that the generation bearing the sexual cells—the Gametophyte—is attached to, and so dependent upon the flowering-plant itself—the Sporophyte—as to seem part and parcel of it. In more recent times this alternation of generation has been shown to occur also among the lower plants, such as the Algæ.

It would have been surprising indeed if such impressive and general phenomena had not engaged the attention of botanists and if the search for the meaning of alternation of generation had not led to considerable controversy. Much attention has, in fact, been given by botanists to this question and much controversy has arisen. Long ago the botanists engaged in the study of alternation formed themselves into two opposing camps. In the one camp were those who held the antithetic hypothesis, in the other those who maintained that of the homologous nature of the alternating generations. According to the antithetic hypothesis, the two generations—Sporophyte and Gametophyte—are not comparable; the Sporophyte is something which did not occur originally in the life history of the forerunners of plants now possessing it, but which has been intercalated. On this view no strict comparison can be instituted between the members (leaves, &c.) of the one generation and those of the other. According to the homologous theory, the two generations are comparable. If we omit various considerations based on recent discoveries bearing on the minute structure of the nuclei of the two generations, we may perhaps fairly say that but for one other hypothesis this was the position of affairs which the botanists met to discuss. The other hypothesis just referred to is that put forward by Professor Bower, who has championed with great ability the antithetic

theory. The suggestion put forward by Bower was that the kind of alternation now exhibited by Liverworts, Mosses and Ferns came about, or assumed its present proportions, as a consequence of the adoption of a land habit by plants which previously had been denizens of the water. In the circumstances in which the newcomers to the land found themselves they were able, or were constrained, to make provision for their wide and economical distribution. This was effected by spores: minute, cheaply-produced, reproductive cells, which do not require to be fertilised, but which are capable of independent growth. The more efficient the spore production the greater the power of the plant to increase and multiply and occupy the earth. The Fern plant and the Moss capsule represent successful devices evolved for the purpose of copious spore production.

This view, though, of course, hypothetical, had the merit of conferring on the antithetic hypothesis a precision as to ways and means which was lacking from the opposed, homologous hypothesis. The latter hypothesis appeared to content itself with the affirmation that the two generations, though they look so different, are, nevertheless, comparable, with respect to their several members, one with the other. The holders of this view were able to bring forward much evidence in support of their contention. They could, for example, point to the discoveries of Farlow, Lang, and others in apospory and apogamy. In some Ferns the fronds of the Sporophyte may fail to bear spores and give rise to that which, on the antithetic theory, they ought to be incapable of producing, viz., a prothallus. Conversely, a Fern prothallus may, in certain circumstances, give rise, without preliminary fertilisation of an egg-cell, to a Fern plant, a Sporophyte.

Recognising, apparently, that the homologous theory, though supported by strong evidence, was, after all, in a sense a negative theory, that is, that it did not offer a clear suggestion as to how the Sporophyte has its remarkable and distinguishing properties, Dr. Lang, who opened the discussion at the Linnean Society, made a valuable and, as it would seem, a probable suggestion.

Dr. Lang's hypothesis is that the different forms of the two generations are due, not to any essential differences in the specific cell from which each of these two generations springs, but to the different environmental influences which operate on these initial cells. Thus, in the Fern, whereas the spore develops on moist earth, free from all association with the Fern plant which formed it, the egg-cell develops within the tissues of the prothallus enclosed, and is provided with food material from the prothallus. These different environments suffice, according to Dr. Lang, to induce in the Sporophyte and Gametophyte of the Fern the differences of development which lead the fertilised egg-cell to become a Fern plant and the spore to become a prothallus.

The introductory paper by Dr. Lang was admirably lucid. The discussion which followed was opened by Professor Bower, who paid a warm and well-deserved tribute to Dr. Lang's work, admitted that he was prepared to modify his well-known views on the antithetic nature of alternation, but maintained that an intercalation of Sporophyte had occurred in the history of plants which show alterna-

tion and that the origin and course of this occurrence must be determined before the antithetic theory can be discarded.

Dr. Scott pointed out that Lang's hypothesis does not supersede the homologous hypothesis, and that it is a theory not of origin but of cause. He welcomed the suggestions of Dr. Lang as helpful in suggesting an explanation of the great differences between Sporophyte and Gametophyte in the Mosses and Ferns.

Dr. Farmer made the important point that the evidence of the behaviour of the nucleus in what is termed the reduction division must not be counted on in support of theories of alternation; reduction of chromosomes being a phenomenon common to animals and plants and thus of even wider generality than alternation.

Both Professor Oliver and Mr. Tansley made valuable contributions to a discussion which was conducted in so charming a manner as to disappoint those who expected that opposing views on abstract, scientific subjects would lead to acrimony. Dr. Prain, in a few felicitous words, brought the meeting to a conclusion.

LINNEAN SOCIETY.—At a meeting to be held on March 4, at 8 p.m., a paper on "The Montane Flora of Fiji" will be read by Miss L. S. GIBBS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a largely attended meeting of the committee held on February 23, under the presidency of Mr. HARRY J. VEITCH, and including Mr. W. A. BILNEY, the honorary solicitor, it was unanimously resolved that, in view of amendments to the Old Age Pensions Act which will probably be proposed by the Government during the present session of Parliament, no immediate steps should be taken for the alteration of annuities payable by the institution. At the same meeting £45 was voted from the Good Samaritan Fund in several sums to six gardeners and two widows of gardeners who were in distressed circumstances and in urgent need of assistance.

PRESENTATION TO A GARDENER.—Mr. W. H. BAILEY, on leaving Bevendean Gardens, Oxshott, was recently presented with a clock by the members of the Oxshott Cricket Club in acknowledgement of his services as honorary secretary.

A GARDENER'S GOLDEN WEDDING.—Mr. and Mrs. ALFRED COLE, of Pant-y-fynon, Llandudno, celebrated their golden wedding on the 20th inst. Mr. COLE is a son of the late WILLIAM COLE, Senr., late of Fog Lane Nurseries, Withington, near Manchester, and well remembered as one of the celebrated plant-growers of thirty years ago. Mr. ALFRED COLE was gardener for some years to the late JOSEPH BROOME, of Wood Lawn, Didsbury, and Sunny Hill, Llandudno. At Llandudno he proved himself to be not only a clever Orchid grower, but a good all-round gardener.

"THE DAHLIA NEWS."—This little monthly journal, the organ of the New England Dahlia Society of Boston, Mass., U.S.A., still continues to flourish. We have just received No. 11 of Vol. 2 for January, 1909, and find its contents, limited as they must necessarily be, just as varied and interesting to the grower as ever. The contributors are by no means confined to America, and articles appear at intervals from Dahlia specialists in England, France, Germany and elsewhere.

MR. M. MOODY, gardener to F. D. GODMAN, Esq., F.R.S., South Lodge, Horsham, will retire at the end of March. Mr. MOODY, who will continue to reside in Horsham, has had the charge of this garden for 31 years, 27 of which have been spent in the service of F. D. GODMAN, Esq. A successor has been found in Mr. T. H. SLADE, late of Poltimore Gardens, Exeter.

LADY GARDENERS.—The first annual dinner given to lady farmers and gardeners by the Women's Agricultural and Horticultural International Union took place recently at the Criterion Restaurant. Mrs. CHARLES CHAPMAN, hon. treasurer of the union, presided over a large attendance. Miss L. DUNINGTON, in proposing the health of "The Guests," stated that the union sought to improve the industrial conditions under which women worked in agriculture and horticulture, to obtain and maintain an adequate rate of payment for work done, to endeavour to provide employment, and to establish a high standard of perfection.

FRENCH GARDENERS IN LONDON.—On the occasion of the annual dinner of the Société Française d'Horticulture de Londres, recently held at the Café Royal, under the chairmanship of Sir ALBERT K. ROLLIT, Officer of the Legion of Honour, a telegram in the name of the company present was despatched to M. FALLIÈRES, the President of the French Republic, offering the cordial and respectful salutations of the meeting. In reply, Sir ALBERT ROLLIT has received a very cordial message from the Palais de l'Élysée, thanking him as chairman, Mr. G. SCHNEIDER, and Mr. HARMAN PAYNE and the members of the society for their kind salutations.

EFFECTS OF FROST.—From reports which have reached us, it appears only too probable that the severe frosts this season have caused considerable damage to garden and nursery stock. Tea Roses especially have suffered greatly, and some reports even indicate that a very large percentage of the standard Tea Roses throughout the country have been killed outright. The usual vagaries are noticed in respect to shrubs, whilst some that are not reputedly tender have been killed, others that might have been expected to succumb, have so far escaped injury. Mr. FIELDER, of North Mymms Park Gardens, Hertfordshire, states that whilst *Olearia Guianiana* and other species are killed, the greenhouse plant of former years *Choisya ternata* is perfectly healthy. Mr. HUDSON, of Gunnersbury House Gardens, Middlesex, states that he finds that frost is more injurious to Bamboos if the roots are rather dry than when they are growing in a moist situation. This is interesting, because the reverse is the case with most other plants. There is some satisfaction in the knowledge that during periods of frost the damage to vegetation frequently appears greater than it really is. We hope that such is the case now, and that when the season of growth begins it will be found that many plants survive for which but little hope is at present entertained.

JUBILEE FLOWER SHOW, HAARLEM, 1910.—The complete schedule for this event has now been published in a volume of 80 pages in the Dutch language. It may be remarked that the competition is open only to Dutch exhibitors, and that it is expected that many additional special prizes will be given by patrons and societies, &c. The prizes in the schedule are 75 gold medals and about 2,500 other prizes. The judges will be chosen from among the horticulturists of all nations. The permanent show in the open (from March 23 till May 16) will consist of 200 classes for beds and groups of Hyacinths, Tulips, Narcissi, Crocuses, and other bulbous

plants, herbaceous perennials, rockeries, Conifers, Aucuba, Azalea and Rhododendrons, Buxus, Ilex, Prunus, and other shrubs. The first special show (March 23 to 31) contains 275 classes, principally for Hyacinths, Tulips, Narcissi, Crocuses, Amaryllis, and other bulbous plants in pots. A special feature will be the class for bulbs and plants, retarded in ice. There are classes for *Azalea mollis* and Rhododendrons, Roses, Lilacs, and other forced shrubs, stove and greenhouse plants, and cut flowers. The second special show (April 15 to 27) will have 300 classes of the same general character as those of the first show, but the third special show (May 7 to 12) will not afford an opportunity for showing Hyacinths, but will probably have the character of a special show of Orchids and decorative floral art. The regular meetings of the committee for judging new bulbous plants will be held in the show buildings every week. The permanent exhibition in the open will have the greatest interest for foreign visitors, and although the artistic and suitable arrangement of bulbous plants is a rather difficult matter, there is every prospect that a good effect will be obtained, for already four local exhibitions of the same nature have been organised in the bulb district. The Noordwijk section of the Bulb Growers' Society has done so already, the Sassenheim section quite recently, and the Hillegom section is even this season preparing a local show, which may be considered as a valuable trial for the Jubilee Flower Show to be held next year.

SEED FOR THE TROPICS.—The question of the advisability of drying seed for export to tropical countries is considered in a brief note by Mr. MAIN in a recent number of the *Agricultural Bulletin of the Straits and Federated Malay States* (12, vii., 108). Mr. MAIN, who is the Superintendent of the Government Plantations, Perak, states that, according to his experience, it is quite unnecessary to subject flower and vegetable seeds to a special drying process before despatching them from England to tropical countries. He has compared the germination capacity of seeds from ordinary paper packets which had been packed in brown-paper parcels with that of seeds which had been specially dried and packed in hermetically-sealed tins. Mr. MAIN found that whereas the former showed a germination of 85 per cent., the latter did not exceed 55 per cent. Unfortunately, Mr. MAIN does not state with what kinds of seeds his experiments which gave these results were made. Our readers will recollect that we have more than once drawn attention to this subject. The method of drying, when carried out with proper precautions, does not in such cases as those of which we ourselves have had experience lead to any material reduction in the germination capacity; though it does lead to a somewhat slower rate of germination. It would be interesting to know the result of a carefully-planned experiment, in which samples of seeds of known histories and germination capacities were exported at various seasons, some specially dried and enclosed in sealed tins, others undried and packed merely in paper. Mr. WATSON in sending seeds to tropical climates from Kew, has not found it necessary to dry and enclose them in sealed tins (see *Gardeners' Chronicle*, January 13, 1906, p. 20).

PUBLICATIONS RECEIVED.—*Handbook on Pruning Roses*. (Second edition). (The National Rose Society).—*Trees and Shrubs of the British Isles*, by C. S. Cooper and W. Percival Westell, F.L.S. Sixteen full-page coloured plates and 70 full-page black and white plates drawn direct from Nature, by C. F. Newall. (London: Dent & Co.) Price 1s.; Part I.—*The Estate Magazine*. (February). Price 6d.—*The Cross-Breeding of Farm Plants*. Extracts from Press opinions of Messrs Gartons' experiments and results.—*The Life of Philibert Commerson*, by Pasfield Oliver. (London: John Murray). Price 10s. 6d. net.

THE LATE SIR GEORGE KING.

THE death of Lieut.-Colonel Sir George King, K.C.I.E., LL.D., F.R.S., F.L.S., M.B., &c., was briefly announced on p. 128. All who had the pleasure of knowing him personally will regret the loss of an amiable and modest friend. Yet this regret will be tempered by the knowledge that the deceased had little pleasure in life during the last two or three years, and death came as a relief from much suffering.

Sir George King was a native of Scotland, and was born on April 12, 1840. He was educated at the Aberdeen Grammar School and University, where he took the degree of M.B. In 1865 he entered the Bengal Medical Service, and was for some years house surgeon of the hospital attached to the Medical College in Calcutta. From early years botany was his favourite study, and he was appointed to the chair of Botany at the Medical College in 1871, and the same year became superintendent of the Royal Botanic Garden, Sibpur, Calcutta. Some years elapsed before King became an active contributor to botanical literature. Probably his numerous duties and delicate health—for he was never very robust—prevented him; but the following extract from a 1902 edition of the guide to the Calcutta garden is an appreciation of his qualities as a gardener and a botanist: "When he assumed charge, the garden was still suffering from the effects of the devastation caused by the two great cyclones of 1864 and 1867; so much so, that, as a scientific institution, it was necessary largely to remodel it, and, as a place of public resort, practically to remake the whole. The tireless energy of the new superintendent, combined with his genius for landscape gardening, in a few years completely altered the aspect of the place, increasing incalculably its value as a scientific centre, and bestowing on it all the charms that, as a pleasure ground, it now possesses. The herbarium, which had only begun to recover from the effects of the depletion advised and effected by Wallich, during Dr. King's incumbency again attained to a rank commensurate with the needs of a garden of such importance, and, whether for the quantity or the arrangement of its contents, is now of a value undreamed of when the Wallichian distribution took place."

Subsequently King was made superintendent of the Cinchona Plantations in Sikkim, and in 1876 he published *A Manual of Cinchona Cultivation in India*. His work in connection with this establishment was enormous for one on whom so many other duties devolved. The cultivation of Cinchona, with the preparation of quinine, is now one of the most important Government industries in India, and it has brought this valuable drug within reach of the poorest of the vast numbers of the poor in that country.

In 1891 King was appointed Director of the Botanical Survey of India, in addition to his other offices. If he published little during the first 20 years of his life in India, he made up for it afterwards, and one marvels how he found time for so much. Some account of his more important publications may be of general interest.

Sir George was the founder of and by far the largest contributor to the *Annals of the Royal Botanic Garden, Calcutta*, a large quarto serial. The first volume appeared in 1888, and it has now reached the tenth volume. But that gives no idea of the extent of this great work, illustrative of the flora of India, as the so-called parts are equal in size to ordinary volumes. The first volume, for example, consists of two such parts and an appendix; the whole devoted to a monograph of the species of *Ficus* of the Indo-Malayan and Chinese countries. There are about 200 pages of letterpress and 232 plates. Sir George made a special study of this genus, he also elaborated the species of *Ficus* for Hooker's *Flora of British India*, and wrote several papers on the physi-

ology of the genus. The second volume contains monographs by the same author of the Indian species of *Artocarpus*, *Quercus* and *Castanopsis*. Of *Quercus* alone 82 species are described and figured, comprising many of the handsomest trees of India. The eighth volume of the *Annals* is of special interest to horticulturists. It is the joint work of King and R. Pantling, and consists of four thick parts, illustrating the Orchids of Sikkim by 448 coloured plates. In this connection it may be mentioned that Part I. of the fifth volume of the *Annals* contains "A Century of Indian Orchids," by Sir Joseph Hooker, with 101 coloured plates; and Part II. of the ninth volume contains "The Orchids of the North-Western Himalaya," by Mr. J. F. Duthie. These number 173 species, belong to 45 genera, and they are represented in 151 partially-coloured plates. It is true that there is a little repetition, but the Orchid flora of India is perhaps the richest in the world, area for area, probably exceeding 1,200 species, outnumbering those of any other family.

Concurrently with the *Annals*, King published his "Materials for a Flora of the Malayan Peninsula" by instalments, which first appeared in the *Journal of the Asiatic Society of Bengal*, and were afterwards issued separately. The first in-

THE LATE SIR GEORGE KING.

stalment is in the 58th volume of the *Journal*, dated 1890, and the last in the 74th volume in 1907.

The classification is the same as in Bentham and Hooker's *Genera Plantarum*, and, with the co-operation of some other botanists, the work has been brought down to the end of the Labiatae, forming four octavo volumes bearing both the original and a consecutive pagination.

Several collectors were engaged in gathering and preparing specimens for this work, which reveals the immense wealth of the arboreal element in the vegetation of the peninsula. A very large number of new species are described, many of them valuable timber trees. Taking a family remarkable for its timber trees, the Dipterocarpaceae, for example, 62 species belonging to 11 genera are described, two-thirds of which were previously unknown. Such is a sample of the kind of work to which Sir George devoted what one may truthfully designate every minute of his spare time. Doubtless he worked too hard, but he has left his mark on all that he touched, especially the now beautiful Calcutta garden. The late Dr. Otto Kunze, who was a keen critic, in his *Um die Erde*, says "the herbarium and library were rich and a pattern of what they should be; the gardens tastefully laid out and more like a pleasure ground than a botanic garden."

LAW NOTES.

THE POISONS AND PHARMACY ACT, 1908.

DRAFT REGULATIONS.

The Privy Council has now approved of the draft Regulations which it is proposed to bring into force with reference to the working of the new Poisons and Pharmacy Act, and unless the Privy Council should see fit to alter its decision in the interval, these Regulations may be made effective at any time after March 28 next, that is to say, 40 days after the draft Regulations were first promulgated.

It is encouraging to find that amongst the Regulations it is proposed to adopt, the following special provision is made in favour of the horticultural trade.

"In granting licenses for the sale of poisonous substances for use exclusively in horticulture, preference shall be given to nurserymen, florists, seedsmen, and other persons whose business is specially connected with horticulture."

It will also be observed that in addition to the power possessed by His Majesty in Council to vary the Regulations themselves from time to time as may be deemed necessary, the Regulations also reserve the right to revoke or suspend a license. Subject to this power, licenses will remain in force for one year, so that application will have to be made for renewal of a license annually. The fee payable on the granting of a license is £1 1s., and for renewal of license 2s. 6d. Various forms are appended to the draft Regulations, but it will be sufficient for present purposes to give the form of application only. The Regulations themselves are as follow:—

REGULATIONS REFERRED TO IN THE FOREGOING ORDER IN COUNCIL.

1. A license shall not be granted to any person unless the local authority are satisfied that he is fit to be entrusted with the sale of the poisonous substances.
2. In granting licenses for the sale of poisonous substances for use exclusively in horticulture, preference shall be given to nurserymen, florists, seedsmen, and other persons whose business is specially connected with horticulture.
3. Applications for licenses and renewals of licenses shall be in the forms set forth in Schedule A to these Regulations, and shall be sent to the local authority at such time as the local authority may direct.
4. A license and a renewal of a license shall be in the forms set forth in Schedule B to these Regulations.
5. A license shall continue in force for one year, but may be renewed from time to time for one year at a time, subject to the same provisions as in the case of a grant of a license.
6. A license may be revoked or suspended for such term as the local authority think fit, if the local authority are satisfied that the licensee has failed to comply with the requirements of these Regulations or of the Poisons Acts, or that the licensee is not a fit person to be entrusted with the sale of poisons.
7. A licensee shall, on being required to do so by any officer of the local authority or any police officer, produce his license, and any renewal thereof.
8. The fees charged in respect of the grant and renewal of a license shall be such as the local authority may determine, not exceeding in the case of a grant of a license, 21s., and in the case of the renewal of a license, 2s. 6d.
9. A license shall not authorize the licensee to sell or keep open shop for the sale of poisonous substances except from or on any premises within the area of the local authority which granted it, and for the purpose of these Regulations, a municipal borough the council of which is a local authority for those purposes shall not be treated as forming part of any county.
10. Every local authority shall keep a register of the licenses granted by them for the time being in force, and any person shall, at all reasonable times, upon payment of such reasonable fees as may be fixed by the local authority, be entitled to inspect and to make copies of, or take extracts from, the register.
11. All poisonous substances shall be kept in a separate store or cupboard apart from any other goods, and poisonous substances shall not

be sold at the same counter as articles of food for human consumption.

12. A poisonous substance shall not be sold except in an enclosed vessel or receptacle as received from the manufacturer, distinctly labelled with the word "Poisonous," the name of the poison, the name and address of the seller, and a notice of the special purpose for which it has been prepared.

13. Liquid preparations shall be sold only in bottles or tins, easily distinguishable from ordinary bottles or tins, and the word "Poisonous" shall be indelibly marked on each bottle or tin.

14. Solid preparations shall be securely packed in such a manner as to avoid, so far as possible, the risk of breaking or leakage from transport, and the package shall contain a notice that it must be destroyed when empty.

15. For the purposes of these Regulations the expression "poisonous substances" means the poisonous substances to which Section 2 of the Poisons and Pharmacy Act, 1908, applies for the time being.

FORM OF APPLICATION FOR LICENSE.

THE POISONS AND PHARMACY ACT, 1908.

I, _____ of _____, carrying on the trade of _____ at _____, hereby apply for a license to sell and keep open shop for the sale of the poisonous substances to which Section 2 of the Poisons and Pharmacy Act, 1908, applies for use exclusively in connection with*

I undertake to comply with the provisions of the Arsenic Act, 1851, the Pharmacy Act, 1868, and the Regulations made by order in Council under the Poisons and Pharmacy Act, 1908.

(Signed)

Date.

*Here insert either "agriculture" or "horticulture" or "agriculture and horticulture." H. M. V.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE NEW R.H.S. CLASSIFICATION OF DAFFODILS.—Mr. Engleheart's letter of protest and criticism, page 116, regarding the new R.H.S. classification of Daffodils is welcome in that it voices with authority the dissatisfaction of many who feel that their opinion is of too little weight to warrant their giving expression to it. In the notes contributed a few weeks ago, being under the impression that the list was published with the full authority and concurrence of the Narcissus Committee of the R.H.S., I assumed that there was nothing to do but accept it and hope that the inconsistencies and deficiencies, some of which I alluded to, and which, as Mr. Engleheart says, are obvious, would be removed by future alterations and additions. It appears, however, that the Narcissus Committee as a whole was not consulted before the publication of the report of the Special Committee, and that neither Mr. P. R. Barr nor Mr. Engleheart were represented on that committee. That being the case, the authority attached to the present classification list is very much weakened, and we may, therefore, hope that it may be altogether recast. For exhibition purposes (and by that I do not mean from the point of view of the experts or judges, but in the interests of the managers of shows and of competitive exhibitors) some principle of classification according to measurements is inevitable, for the public, and even the judges, are always more or less influenced by size. Indeed, it is quite reasonable that flowers of the short trumpet type, such as *Giant Incomparabilis* and *Leedsii*, should not be expected to compete either with pure *Ajax* on the one hand or with the *Incomparabilis* and *Leedsii* varieties on the other. The principle of classification by measurements does form a part of the old arrangement, but, as Mr. Engleheart says, it could and ought to be combined with more consideration for the natural divisions and affinities, and more account should be taken

of colour distinctions. No one will ignore the difficulties of the task, which have been greatly increased by secondary crosses in varying degrees and by the introduction of distinct species, such as *N. triandrus* and *N. cyclamineus*. Though some degree of arbitrariness cannot be avoided, it need not, I think, be so glaring as, for instance, is displayed in the case of *Triandrus* hybrids and in Division 7 of the new classification. Whatever system be adopted, I strongly agree with Mr. Engleheart that the pure species should be kept in separate divisions, and not mixed with the hybrids. A. J. Bliss.

FREESIAS.—I am enclosing some spikes of this flower, each inflorescence having 12 blooms, with a corresponding number on the side sprays. We have had as many as 13 blooms on the main stalk, with eight and five flowers respectively on the lateral sprays from the same flower stem. Our plants, which exceed 2 feet in height, are potted in 5 and 6-inch pots. G. Elwood, *Swanmore Park Gardens*.

Our plants have not produced more than nine flowers on an inflorescence, but this season the majority of bulbs developed side shoots that flowered, there being a total of from 30 to 35 flowers per bulb. This I attributed to a liberal feeding with manure water after the plants had flowered. The manure enables the new bulbs to develop, and to gradually but thoroughly ripen. H. Juniper, *Dyrham Park Gardens, Barnet*. [Some excellent spikes of *Freesia* accompanied this note.—Eds.]

EXPERIMENTS WITH NITRO-BACTERINE.—Since Professor Bottomley's article on experiments with Nitro-Bacterine (*Gardeners' Chronicle*, February 6) contains several statements liable to mislead the general reader, it would seem desirable that these statements should be taken as they occur and examined more closely. Firstly, although in the Wisley trials four of the plots were dressed with lime in addition to sulphate of potash and superphosphate of lime, while in the Reading trials the soil was a calcareous loam, Prof. Bottomley still maintains that the application of these mineral manures would tend to increase the acidity of the soil. It is also stated by Prof. Bottomley that these fertilisers appear to have an injurious action on the introduced bacteria themselves, and statements contained in the *U.S.A. Farmers' Bulletin*, 240, are cited; he claims that it is there "specifically stated that the action of these concentrated fertilisers on inoculated seed is injurious." As a matter of fact, reference to the above bulletin will show that the remarks in question concern the method of sowing the seed, and read as follows:—"The action of concentrated fertilisers drilled with inoculated seed is injurious; this is especially true if the seeds should be still moist after treating with liquid culture." How this injurious action is "fully confirmed" by the Reading and Wisley trials is not easy to perceive, since these unfavourable conditions were not present in those trials. Further, in the discussion of the beneficial results obtained by the application of lime to Plots XIX. and XX., it is pointed out that, in order to demonstrate the fixation of nitrogen in laboratory-cultures by the nitrogen-assimilating organisms, the presence of carbonate of lime is absolutely necessary. This is true as far as it goes, but for some reason or other, Prof. Bottomley considers it politic not to mention that potash and phosphates are equally indispensable. In using the very general term nitrogen-assimilating organisms, he includes a large number of bacteria differing greatly in their physiological and morphological characters. Whilst the addition of carbonate of lime is necessary to the growth of such organisms as *Azotobacter* and *Clostridium*, it has been shown by several investigators that many organisms are able to fix nitrogen equally well in the absence of carbonate of lime; the nodule organism is one of these. Would it not have been better for Prof. Bottomley to confine his attention to the nodule organism as related to the Wisley and Reading experiments instead of indulging in a dissertation on the requisite conditions for the culture of organisms not at present concerned? As regards the culture of the nodule organism itself, various American and German bacteriologists have advocated the addition of acid potassium phosphate or even of

free organic acids to the culture solutions and jellies; hence it will be seen how very slightly Prof. Bottomley's remarks on carbonate of lime and its use in laboratory cultures bear upon the consideration of the Wisley trials. In addition, his statement that "the same proportion of lime applied as a mixture of lime, potash and superphosphate would be fatal to the organisms" is very vague and quite as irrelevant as his foregoing one. Again, in his consideration of the Wisley trials, we are presented with a specially-compiled table of results, which, he states, shows that the seed-inoculated, unmanured plot gave a greater yield of produce than any of those receiving various forms of manure. This, at first glance, would seem to indicate a decided increase to be due to inoculation, and a decrease due to the use of potassic, phosphatic and nitrogenous manures, as far as the fallowed land is concerned. If, however, we tabulate the yields of the corresponding plots on the cultivated land, we find that the seed-inoculated plot produced the smallest crop in the series of six plots.

PLOT.	Weight of Peas.	
	Weight of pods, grams.	Weight of Peas, grams.
Soil and seed untreated	25.540	10.303
Seed inoculated	19.507	8.179
Manure, 10 tons per acre	23.674	9.653
Lime, 40 bushels per acre	24.559	9.681
Superphosphate and potash	27.017	10.788
Calcium cyanamide	25.692	9.696

This table is given, not to demonstrate the futility of inoculation, but to indicate to the general reader how inaccurate and useless it is to compare yields from plots in absolutely different series as was done by Prof. Bottomley in the case of the Wisley and Reading results. An explanation of these very erratic yields will, no doubt, be found in Mr. Chittenden's report (p. 238), in which he says: "One point was particularly noticeable on the fallowed ground; the soil there was appreciably deeper at the northern end, the bottom of the slope, than at the southern end, owing to the washing down of the finer particles of soil during the heavy autumn and winter rains of 1907-8, and this had a marked effect upon the yield of the fallowed land." This, in itself, would seem to account for the abnormally high yields of the untreated plots and for the gradually decreasing yields of the two rows of plots (cultivated and fallowed land) taken from the lower to the higher numbers. If, further, we take into consideration the disposition of the two plots in each series of experiments, we shall find that, irrespective of soil- or seed-inoculation, the plot nearest the lower or northern end of the experimental field gave, in the majority of cases, the heavier crop. All the plots, 1-2, 7-22 (with the exception of 13 and 14) conform to this rule, constituting as they do two-thirds of the total number of plots. This is shown in the following table:—

Cultivated land,	Northern plot.	Weight of Peas in grams.	
		Northern	Southern
7 and 8	9	10.050	9.681
" " 9 and 10	11	10.788	9.067
" " 11 and 12	15	10.620	9.697
Fallowed land, 15 and 16	17	7.963	7.093
" " 17 and 18	19	7.686	6.513
" " 19 and 20	22	4.702	4.182

As this point has not been brought to the notice of the reader in any of the reviews on Mr. Chittenden's report, it seems desirable that it should be mentioned in this article. H. B. Hutchinson, *Rothamsted Experimental Station, Harpenden*.

VEGETABLE PRIZES AT SHREWSBURY.—

I was pleased to see the letter by *Vegetable* in your last issue. If the committee had contemplated the change they have made I think they should have given the trade notice at the last exhibition, or have sent a deputation to the largest prize donors to ask their opinions. The trade has liberally supported Shrewsbury, and to a great extent made it the show it is. I feel sure it would soon fall to pieces as a horticultural show were the trade support or exhibits withheld. The committee said they would accept no prizes with any stipulations, and yet they have accepted prizes from certain firms, allowing them to stipulate their own fancy names. In offering prizes at Shrewsbury and other places, I have done it to encourage the gardeners to do their best in friendly

competition and have their exhibits judged by impartial judges. I fail to see what is the difference in my offering prizes for vegetables or Sweet Peas grown from my seeds or in stipulating on particular names. Suppose, for instance, I offered prizes for Sweet Peas under the name of "Sydenham's Sky Blue," and so on, and they were found to be nothing more than old standard varieties under new names, what would the public say? The committee have been badly advised when they say they will only give a limited number of awards to the non-competitive exhibits. These exhibits have been a great feature at Shrewsbury. The trade have gone to enormous expense to bring their very best. Now the committee as good as tell them they do not appreciate this help: they would rather favour only the competitive exhibits by giving them, what I think, unnecessarily large prizes, thereby encouraging the covetous man to come and win all the money he can, whereas the unselfish man, who often makes a ten times more interesting exhibit, is to have the cold shoulder. I shall watch with considerable interest how these new regulations are carried out, feeling sure there will be considerable trouble, which will be most unfortunate, if not disastrous, to the former good and liberal reputation of the society. *Robert Sydenham, Birmingham*

Our attention has been called to a letter in your last issue under the nom de plume of *Vegetable*, which we think it advisable to answer to prevent any disputes arising hereafter. On reference to paragraph 4 on page 4 of the schedule your readers will find it stated "that no condition shall be expressed in the schedule as to the seeds, &c., being purchased from the donors of prizes." The committee had no intention of preventing these donors specifying any particular varieties of vegetables or flowers to which such should be confined, but they declined to permit any restrictions to appear stating the seeds must necessarily be purchased from such donors. By way of obviating any compulsion on the part of intending exhibitors to purchase their seeds from these donors, we may mention that such exhibitors will not necessarily be debarred from competing in these trade classes through not ordering seeds direct from them, as it is presumed the donors supply the trade with their produce for sale in the usual way, and consequently any exhibitor can procure such through his own seedsmen without running any risk of disqualification when the judges make their awards. We imagine it will be the duty of these donors to see that the competitors in their respective classes have complied with their requirements. We take this opportunity to call the attention of your readers to a printer's error on page 29 of the schedule in the third line of notes, viz., "No trade cards will be allowed on any of the exhibits in Classes 134 to 165," which should read Classes 131 to 165. *The Hon. Secretaries.*

THE LINDLEY LIBRARY.—From the report which was printed on p. 105 of the proceedings at the Annual Meeting of the Royal Horticultural Society, held on the 9th inst., it appears that a discussion took place respecting the ownership of the Lindley Library. The report says: "It was pointed out that the library does not belong to the Society, but to trustees, and that, therefore, any money spent by the Society in the purchase of books is, in fact, a presentation to the trustees." This suggestion is so calculated to mislead ordinary readers and to do serious mischief, that it ought not to be allowed to pass without notice. Trustees are not trustees for themselves, but for other persons; and, although the legal ownership of property held in trust is in the trustees, the beneficial ownership is in the persons for whom they hold it. The instrument declaring the trust will show for whom and for what purposes the property is held, and any gift to the trustees is a gift to them only as custodians for the benefit of others. The botanical library of the late Dr. Lindley was, to the best of my recollection, sold by his executors to, and was paid for by or for, the Royal Horticultural Society, and was vested in trustees for that Society. The instrument declaring the trust ought to be held by the trustees, or by their solicitor; and a copy of it ought to be in the possession of the Society, or of their solicitor. I do

not remember having ever seen this document; but it is incredible that it should be so drawn up as to render a gift of books to the trustees a gift to them, except for the benefit of the Society. A gift of money or of books by the Society to the trustees for the library can hardly be a misapplication of the Society's property. It seems a legitimate dedication of its property for a particular purpose for its own benefit. Moreover, the mere fact that persons who are not Fellows of the Society may be allowed to use the library, can hardly prevent it from being the property of the Society. But in order to set the question at rest the trust deed should be submitted to some competent lawyer. *Lindley, East Carleton, Norwich.*

THE INFERTILE DOUBLE PRIMULA SINENSIS.

—Professor Bateson can no doubt obtain from Messrs. Cannell & Sons, Swanley, plants of the old *alba plena*, Marchioness of Exeter, Annie Hillier, King of the Purples, and others all absolutely double, and such as have been in commerce for many years past. These plants have to be increased by severing side growths and rooting them in small pots as cuttings, or, as some growers do, heap up sandy soil about the plants in the pots. Others again layer the side growths to induce them to root, and then remove them from the parent plants and pot them up separately. A few years ago wonderfully fine specimens of these double Chinese Primroses were grown about Leatherhead, Mr. Mease, at Downside, having had plants, 18 inches across, carrying large heads of bloom. These Primulas, like double Primroses of the *Acanthis* section, are pure doubles. They are all products of thrum-eyed flowers, that is, those which have as singles their clusters of anthers or pollen cases prominent. These anthers have developed into petals, and hence the flowers are barren. All these doubles originated from single flowers, which gradually sported and became thus florally demoralised. *A. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 23.—An exceptionally fine display of flowers and fruits was made at the meeting held on Tuesday last in the Society's Hall, Westminster. The building was filled with groups of early bulbous plants, forced trees, and shrubs, Orchids, Carnations, Roses, hardy flowers, and other subjects. The attendance was large, the building at times being crowded with visitors.

The FLORAL COMMITTEE granted an Award of Merit to a rose-coloured variety of Freesia; the ORCHID COMMITTEE conferred three First-class Certificates and six Awards of Merit; and the FRUIT AND VEGETABLE COMMITTEE recommended a First-class Certificate to the well-known Apple Barnack Beauty.

At the afternoon meeting in the lecture-room 67 new Fellows were elected, and a lecture on "A Camping Tour through Syria to Petra in Arabia" was delivered by Mr. Arthur W. Sutton. The room was crowded with an appreciative audience. It will be remembered that Mr. Sutton gave this lecture to a meeting at the Horticultural Club (see *Gardeners' Chronicle*, October 26, 1907).

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. H. B. May, Jno. Green, T. W. Turner, G. Reuthe, Arthur Turner, F. Page Roberts, Chas. E. Shea, W. Cuthbertson, W. P. Thomson, W. J. James, E. H. Jenkins, E. A. Bowles, W. A. Bilney, R. C. Notcutt, J. F. McLeod, W. Howe, C. R. Fielder, Herbert J. Cutbush, W. J. Bean, R. Hooper Pearson, A. Kingsmill, J. T. Bennett-Poë, Chas. Dixon, Jas. Douglas, R. W. Wallace, Walter T. Ware, J. Jennings, C. Blick, George Paul and W. G. Baker.

A group of remarkably fine plants of *Richardia Elliottiana* was shown by Mrs. LESCHALLAS, Highams, Windlesham, Surrey (gr. Mr. W. Farmer). The spathes were not only of extra large size, but were of the richest yellow colour. (Silver-gilt Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, displayed Ghent Azaleas in variety, the

plants, although of small size, being crowded with blossoms. They also showed *Acacia ovata*, *A. cordata*, *Erica codonodes Veitchii*, *Daphne indica rubra*, and a collection of Carnations of the perpetual-blooming type. The Carnations made a pretty display, some being suspended in baskets hanging from slender arches. (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, showed an assortment of decorative Ferns, batches of *Primula obconica* and *P. kewensis* ×, and standard plants of the scented-leaved *Pelargonium Clorinda*. (Silver Flora Medal.)

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, showed a batch of hardy Rhododendrons in bloom, the plants having been lifted from the open garden early in January and developed under glass. The varieties were *The Countess* (white, slightly tinted with rose), *R. arboreum Wellsianum*, and *Handsworth Early Red*. At the back of the Rhododendrons was a row of forced Lilacs. Messrs. VEITCH also exhibited a batch of greenhouse flowering plants, including *Kalanchoë Dyeri*, *Crowea angustifolia*, *Coleus thyrsoides*, *Begonia*, &c., whilst on the table they usually furnish with greenhouse plants were large groups of *Cyclamen latifolium* and *Primula sinensis*. The Cyclamen especially were remarkable for their wealth of blooms and general good culture. (Silver-gilt Flora Medal.)

Messrs. R. & G. CUTHBERT, Southgate, exhibited a large group, consisting of forced hardy plants of many species of deciduous Magnolias, inclusive of *M. Lenné*, *M. speciosa*, and *M. alba superba*; also numerous plants of *Azalea sinensis* in variety, *Forsythias*, *Pyrus*, *Prunus*, *Syringas*, both single and double-flowered, and *Staphylea colchica*. All the plants were in splendid bloom. (Silver-gilt Flora Medal.)

Messrs. W. CUTBUSH & SON, Highbury, London, N., showed a collection of forced flowering trees and shrubs, another of perpetual-blooming Carnations, also a variety of Alpine and early-flowering hardy plants arranged as a rock-garden exhibit. The Carnations were very attractively displayed, there being large bunches of all the popular kinds in tall and short receptacles arranged with greenery. The forced plants included Lilacs, Azaleas, *Boronias*, *Prunus triloba*, Magnolias, *Staphylea colchica*, *Nanthoceras sorbifolia*, &c., set in Ferns and small Palms. The Alpine plants included early-flowering, bulbous, and other plants, Irises being a feature, especially *I. reticulata* in variety and *I. orchioides*. We also noticed the dwarf-blooming *Tulipa pulchella*, with pretty carmine-rose-coloured flowers. (Silver-gilt Flora Medal.)

Mr. W. H. PAGE, Tangley Nursery, Hampton, again made a very fine display with Carnations and Liliums, not so large as the exhibit he staged at the last meeting, but, though smaller, of equally fine quality and arrangement, the group being one of the most artistic and brightest in the building. (Silver Flora Medal.)

Mr. H. BURNETT, Guernsey, again demonstrated his skill in the culture of the perpetual-blooming Carnation by a display of choice blooms of this popular flower. The colours in the numerous varieties exhibited in this group were remarkably well developed, and the size of the blooms and substance of petal were also good. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, exhibited a group of Lilacs in flower. The exhibit was arranged as a semi-circle on the floor of the building, and, in addition to the Lilacs, were small specimens of *Clematis indivisa* and *Prunus sinensis alba plena*. The inclusion of graceful Bamboos gave a pleasing touch of greenery to the display. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, showed Primulas of the ordinary florist's and the star or stellata types. Nearly all were of named varieties, the best of the stellata varieties being *Red Rover*, *Scarlet Gem*, *Lady Emily* (white), *Countess of Radnor* (a fine deep red), *Unique* (white with a yellowish eye, surrounded by a zone of pink), *Blue Lady*, and *White Spray*. Amongst the older type were some of the *Queen Alexandra* variety with exceptionally large blooms, *Mrs. C. F. Raphael* (pink), *Moonlight* (white), *Mrs. Marlow* (rosy-carmine), *Mrs. Kennard* (rosy-purple), and *The Czar* (almost heliotrope). (Silver Banksian Medal.)

Messrs. SUTTON & SONS, Reading, showed *Primula sinensis* "The Duchess" of the normal type, and a variety in which the foliage partakes of the Ivy-leaf type.

Mr. G. MOUNT, Nurseryman, Canterbury, showed, as at the last meeting, the hybrid Tea Roses Liberty, Richmond, and Joseph Lowe. (Silver Banksian Medal.)

Messrs. J. PEED & SON, Nurserymen, West Norwood, showed a rockery decorated with various lowly Alpines, such as *Ericas* of hardy species, Cacti, Snowdrops, *Helleborus*, *Primula* × *kewensis* finely flowered, various *Saxifragas*, *Lachenalias*, including a variety named Ruby. (Silver Banksian Medal.)

Mr. A. CHAPMAN, Rye, showed *Cyclamen ibericum* seedlings; also examples of *Iris Danfordia*.

The GUILDFORD HARDY PLANT CO. showed examples of *Hedera minima*, *H. conglomerata*, *Saxifraga valdensis*, *S. burseriana*, *Adonis aureus*, hybrids of *Helleborus orientalis*, *H. caucasicus*, and *Shortia galacifolia*.

Mr. GEO. REUTHE, Keston, Kent, again showed rare and interesting shrubs; also bulbous plants, coloured Primroses, Snowdrops, Hepaticas, Primulas, and other early-blooming plants. (Bronze Banksian Medal.)

Messrs. THOS. S. WARE, LTD., Ware's Nursery, Feltham, displayed rock-garden plants arranged on an improvised rockery composed of real stones. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, displayed an assortment of bulbous flowers, some as cut blooms and others as pot plants.

The Misses HOPKINS, Mere Gardens, Shepperton, again displayed a rock-garden exhibit, as at the last two meetings.

Messrs. G. & A. CLARK, The Nurseries, Dover, showed a garden rockery, similar to the one they displayed at the last meeting, and planted with Irises, Trumpet Daffodils, hardy Primroses, both single and double-flowered, small Conifers, *Taxus* of species, and *Thymus* of low, creeping habit.

Messrs. EGGETT & SON, Nurserymen, Thame, showed a few hardy Ferns arranged in a rock-work exhibit.

Miss ALICE SMITH, The Bungalow, Bognor, showed a small-sized garden rockery planted with suitable species of plants.

Water-colour drawings and studies depicting scenes in Kentish gardens and sketches in colours of flowers were shown by Miss JOSEPHINE GUNDRY, Foot's Cray. (Silver-Gilt Flora Medal.)

Miss COX, The Cottage, Rose Hill, Dorking, also showed several studies in water-colours of flowers excellent in colouring and pose.

AWARD OF MERIT.

Freesia Rose Queen.—A variety of *Freesia*, with considerable rose colour in the flowers, was shown by Messrs. BARR & SONS, and received an Award of Merit.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), de B. Crawshaw, W. Boxall, G. F. Moore, J. Forster Alcock, W. Thompson, F. Sander, F. M. Ogilvie, R. G. Thwaites, J. Charlesworth, A. A. McBean, W. H. Hatcher, W. P. Bound, J. Cypher, W. H. White, H. G. Alexander, A. Dye, C. H. Curtis, H. A. Tracy, H. Ballantine, Gurney Wilson, W. Bolton, C. J. Lucas, N. C. Cookson, Stuart Low, and F. J. Hanbury.

The premier award, a Silver-Gilt Flora Medal, was given to Messrs. SANDER & SONS, St. Albans, for a varied group, in which rare hybrid *Odontoglossums* were conspicuous. The finest of these included the large and handsomely-blotched *O. crispo-Harryanum* Brugense, raised by Messrs. SANDER at Bruges. Other handsome *Odontoglossums* were *O. Irene* (*O. triumphans* × *O. Kegeljanii*), a good yellow flower blotched and barred with reddish-brown; *O. Helenus* (*O. Harvengtense* × *O. Coradinei*), a distinct and pretty variety; *O. gemmatum* (*O. triumphans* × *O. elegans*), curiously showing the colour and form of *O. triumphans* in an intermediate shape; *O. Vuylstekei*, of a distinct type; *O. Nysa* (*O. Hunnewellianum* × *O. triumphans*), coloured yellow with brown markings; *O. Vulcan* (*O. crispum* × *O. Vuylstekei*), a well-formed and richly-coloured flower; and *O. Hellemense* (*O. harvengtense nobilior* × *O.*

crispum, blotched variety). At one end of the group were some magnificent plants of *Phalaenopsis Schilleriana*, one having eight spikes bearing together about 100 flowers. Other notable plants were *Cattleya Trianae* Rajah; *Cypripedium villosum*, Sanders' variety, large, with much blackish-purple in the dorsal sepal; *Calanthe hololeuca*, pure white; *Oncidium splendendum*, and others.

Messrs. CHARLESWORTH & CO., Haywards Heath, were awarded a Silver Flora Medal for a fine group rich in *Odontiodas*, for two of the best of which see "Awards." Among the rarer hybrids were *Brasso-Laelio-Cattleya Cooksonii*, with pretty, yellow flowers, veined and tinged with bronzy-rose; a good selection of hybrid *Odontoglossums*, including several forms of *O. Ossulstonii*, *O. crispo-Harryanum*, and *O. amabile*. Among the *Cattleyas* was a distinct form of *C. Trianae*, with light-coloured flowers; and with the *Cypripediums* the pretty *C. Rossettii*, many varieties of *C. aureum*, and other rare forms.

Monsieur MERTENS, Ghent, was voted a Silver Banksian Medal for a select group of hybrid and seedling Orchids. Among others were good forms of *O. laudatum*, *O. amabile*, and *O. Vuylstekei*.

Messrs. CYPHER & SONS, Cheltenham, secured a Silver Banksian Medal for a group of rare *Cypripediums*, which included the best varieties of *C. aureum*, *C. vill-exul*, and *C. Beekmannii*. With them were *Miltonia Bleuana*, *Dendrobium Melpomene*, *D. Leechianum*, *Masdevallia macrura*, &c.

Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. Collier), staged an interesting little group, in which *Bulbophyllum comosum* bore five spikes of white flowers; *Cirrhopetalum Mastersianum*, a pretty umbel of copper-red blooms; *C. retusiusculum*, several reddish heads of bloom; *Dendrobium Mortii*, an Australian species of the *D. teretifolium* class, many slender, white flowers. Among the hybrids were a dark *Zygo-Colax* near to *Z. leopardinus* and the latest new Gatton hybrid, *Dendrobium Lady Colman* (see Awards).

Colonel G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander), sent *Laelio-Cattleya Pizarro*, Westonbirt variety (*L. Jongheana* × *C. Dowiana aurea*), a rose-coloured flower with gold veining and disc to the lip; and the handsome *Cattleya Trianae Mooreana* (see Awards).

Messrs. J. & A. A. McBEAN, Cooksbridge, staged a select group, principally *Odontoglossums*, among which were a handsome, large-flowered, spotted *O. crispum*; a large, yellow *Odontoglossum* blotched with brown, raised from *O. Wilkeanum* × *O. crispum*; and a good form of the white *O. ardentissimum*.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, sent the handsome bluish-white *Cattleya Trianae Lowia*; *Odontoglossum crispum* Carmania, *Dendrobium chesingtonense*, and *Cypripedium chrysotoxum* Victor.

R. G. THWAITES, Esq., Streatham (gr. Mr. Black), sent *Dendrobium chesingtonense* "Buttercup," yellow with dark eye; *D. c. Kingcup*, buff-orange with maroon centre, and the singular hybrid *D. atro-Brymerianum*. (See Awards.)

Mr. H. A. TRACY, Amyand Park Road, Twickenham, showed *Odontoglossum crispum* Jamesianum, an effectively blotched variety; *Cypripedium Eurybel* (*Euryades* × *bellatulum*), and an elegant form of *Cycnoches peruvianum* with five flower-spikes.

G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page), showed *Cypripedium* Gracæ "W. F. Page" with several pretty white flowers marked with purple; two very dissimilar hybrids of *C. Beekmannii*, and *C. Bridgei magnificum* (see Awards).

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), sent his dark-coloured *Odontoglossum* Queen Alexandra var. *Theodora*, *O. Zena*, and other interesting *Odontoglossums*.

Mr. F. McBEAN, Plumpton, showed *Cattleya Trianae* "F. McBean," a bluish-white flower with very broad petals and fine lip-coloured purplish-rose in front.

W. WATERS BUTLER, Esq., Southfield, Edgbaston (gr. Mr. Jones), sent *Cattleya Trianae*, *C. Enid magnifica*, *Dendrobium Wardianum album*, and *Odontoglossum Pescatorei album*, all of good quality, well-grown and distinguished as Southfield varieties.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed the handsome *Odontoglossum Smithii* (*Rossii rubescens* × *crispo-Harryanum*), illustrated in the *Gardeners' Chronicle*, December, 1905, p. 427, in fine condition.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Trianae Mooreana, from Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander). A remarkable variety, large, of fine shape, and unique in colour. The sepals and broad petals are silver-white tinged with rose, the petals being the darker and having a claret-purple band on the tips. The front of the lip is deep claret-purple; the disc is pale yellow.

Laelio-Cattleya Pizarro, Westonbirt variety (*L. Jongheana* × *C. Dowiana aurea*), from Col. G. L. HOLFORD. A charming hybrid with large rose-coloured flowers with gold veining on the lip.

Odontioda Lutetia (*O. luteo-purpureum* × *C. Noezliana*) from Messrs. CHARLESWORTH & CO. This, in the variety shown, proves to be a very handsome hybrid with flowers as large as those of *O. luteo-purpureum* and of a yellowish ground colour, tinged and blotched with cinnamon-scarlet.

AWARD OF MERIT.

Odontioda Keightleyensis (*O. cirrhosum* × *C. Noezliana*), from Messrs. CHARLESWORTH & CO. A very elegant hybrid with slender-branched spikes of blood-red flowers showing the influence of *O. cirrhosum* very distinctly.

Cycnoches peruvianum Tracy's variety, from Mr. H. A. TRACY, Twickenham. Flowers greenish-white, sparsely spotted with purple; the rayed lip white. Inflorescence more dense than in the type. The plant bore five spikes.

Cymbidium Woodhamsianum *Orchidhurst* variety (*Lowianum* × *eburneo-Lowianum*), from Messrs. ARMSTRONG & BROWN. Flowers larger than in *C. eburneo-Lowianum*, greenish-white with red-brown markings on the lip.

Dendrobium Lady Colman (*Artemis* × *Findlayanum*), from Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. Collier). One of the largest and most beautiful *Dendrobiums* yet raised, the blooms rivalling the best forms of *D. Wardianum*. The ground colour is white with the outer halves of the segments rose-pink. The lip has a deep maroon disc with a white band in front, the apex being rose colour.

Cypripedium Bridgei magnificum (*Godseffianum* × *Argus Moensii*), from G. F. MOORE, Esq. (gr. Mr. Page). Dorsal sepal blackish on green ground, with a narrow white margin; petals broad, deep rose on the outer halves.

Cypripedium Curt-mannii (*Mons. de Curte* × *Beekmannii*), from G. F. MOORE, Esq. A very fine flower with large dorsal sepal, green at the base and white above, distantly spotted with purple. Petals broad and shining, mahogany brown on the upper sides, lighter below with a few dark spots. Lip yellow tinged with brown.

BOTANICAL CERTIFICATE.

Odontoglossum cariniferum, from DE B. CRAWSHAY, Esq. A rather rare species, originally introduced from Central America in 1848. It bears a branched inflorescence. The flowers have brownish lanceolate sepals and petals keeled at the back, and whitish labellum.

CERTIFICATE OF APPRECIATION.

Dendrobium atro-Brymerianum (*atro-violaceum* × *Brymerianum*), from R. G. THWAITES, Esq. (gr. Mr. Black). A very interesting hybrid, the habit of the plant being intermediate between the two parents, but the flowers are nearer to those of *D. atro-violaceum* and show little of *D. Brymerianum*, even the fringed lip of which gives no indication. Flowers greenish with small purple spots, and dark purple veining on the lip.

Fruit and Vegetable Committee.

Present: J. Cheal, Esq. (in the Chair), and Messrs. W. Bates, A. R. Allan, E. Beckett, A. Dean, G. Hobday, H. Parr, J. Vert, J. Davis, P. D. Tuckett, J. McIndoe, O. Thomas, H. S. Rivers, W. Barnes, H. Markham, W. Poupart, and C. G. A. Nix.

Mr. A. POUPART, Twickenham Green, sent a fine sample of Barnack Beauty Apple (see Awards). Mr. POUPART also sent a superb

sample of blanched Seakale, for which a Cultural Commendation was awarded.

A sample of home-made Orange jelly, exhibited by Mrs. MILLER, Marlow, was highly commended. A Silver Banksian Medal was given to this lady for a collection of preserves in bottles.

A collection of bottled fruits sent by Mr. POUPART, jun., Twickenham, was one of the best exhibits of preserves ever displayed in the Hall by an amateur. The fruits represented varieties of Plums, Apricots, Peaches, Nectarines, Raspberries, Currants, Morella and Sweet Cherries, and Blackberries. (Silver-gilt Knightian Medal.)

O. P. SEROCOLD, Esq., Taplow (gr. Mr. R. Bullock), sent a collection of well-kept Apples in about 40 varieties. Amongst the best varieties were Baxter's Pearmain, Melon Apple, Tower of Glamis, Cox's Orange Pippin, Ribston Pippin, Adams's Pearmain, Dumelow's Seedling, Cox's Pomona, Newton Wonder, and Dutch Mignonne. (Silver Knightian Medal.)

Messrs. W. SEABROOK & Co., Chelmsford, displayed a collection of some 36 dishes of Apples, many of the samples being exceptionally good. The more noteworthy were Dutch Mignonne (specially good, as it was in several other exhibits), The Queen, Blenheim Pippin, Barnack Beauty, Beauty of Kent, Gloria Mundi,

Orchard, Hershaw, was awarded the 1st prize for Claygate Pearmain; 2nd, Mr. H. G. WADLOW, Peterborough, for Cox's Orange Pippin. The other variety was Duke of Devonshire.

In the class for six dishes (open to trade growers only) two exhibits were staged. Messrs. JAS. VEITCH & SONS, Chelsea, were well 1st with fine fruits of Sturmer Pippin, Northern Sky, Dutch Mignonne, Lord Hindlip, King of Tompkin's County, and Reinette du Canada; 2nd, Messrs. W. SEABROOK & Co.

FIRST-CLASS CERTIFICATE.

Apple Barnack Beauty (see fig. 61).—This variety is a good late market Apple, and it received an Award of Merit on March 14, 1899. The Committee raised the Award to a First-class Certificate on this occasion, believing that the variety is not so well known as its worth merits. The fruit is of medium size, greenish-yellow in colour, with red on the side next to the sun. The flesh is yellowish.

Scientific Committee.

FEBRUARY 9.—Present: E. A. Bowles, Esq., M.A., F.L.S., F.E.S. (in the Chair); Messrs. C. T. Druery, H. T. Güssow, G. S. Saunders, A. Worsley, J. T. Bennett-Poë, W. Hales, F. J.

FIG. 61.—APPLE BARNACK BEAUTY, AWARDED A FIRST-CLASS CERTIFICATE BY THE R.H.S. ON TUESDAY LAST.

Bismarck, Schoolmaster, and Bramley's Seedling. (Silver Knightian Medal.)

Messrs. T. RIVERS & SONS, Sawbridgeworth, exhibited a large group of Orange trees and gathered fruits, the whole forming a very attractive exhibit. The Oranges included Achilles, Seville, White, Silver, Egg, and Brown's Navel. There were also Imperial Lemon, Shaddock, and Citrons, in all a remarkable collection of the Citrus family. (Silver-gilt Knightian Medal.)

COMPETITIVE CLASS FOR DESSERT APPLES.

Contrary to expectation, the amateur class for four dishes brought 11 collections for the two prizes that were offered. Some of the fruits shown, whilst well-kept examples, were not regarded as late varieties. Mr. MARKHAM, Wrotham Park Gardens, Barnet, was awarded the 1st prize for medium-sized but well-coloured fruits of May Queen, King of the Pippins, Cox's Orange Pippin, and Baumann's Reinette; 2nd, Col. BORTON, Cheveney, Hinton, Kent (gr. Mr. J. W. Whittle), with Calville Rouge, Christmas Pearmain, Barnack Beauty, and Melon Apple. The judgments were for appearance rather than for table quality, and russet varieties were not favoured.

Only three dishes were staged in the single-dish class. Mr. J. WATKINS, Dairy Farm

Chittenden (hon. secretary), and Gurney Wilson (visitor).

Malformed Orchids.—Mr. SAUNDERS reported that the flower of *Cattleya Trianae* referred to him from the last meeting showed three perfect stamens surrounding the pistil, three very short and regular petals, and three sepals shorter still. Mr. SAUNDERS showed drawings illustrating these points.

Albinism in Orchids.—Mr. GURNEY WILSON exhibited specimens in illustration of the inheritance of albinism in *Dendrobiums*. He found that *Dendrobium Murrinianum* crossed with *D. Ballianum*, the former not a pure albino, though pale, the latter nearly white, gave seedlings almost exactly like typical *D. nobile*. *D. nobile alba* (virginale) which, when selfed, gives quite white seedlings, when crossed with *D. Findlay-anum* gives *D. "Cybele,"* all the seedlings being alike, and no light forms among them. Similarly, *Dendrobium Wardianum album* crossed with *D. nobile alba* gives all coloured flowers. These "reversions" to coloured forms confirm the results that have been obtained in crossing Sweet Peas and Stocks.

Floral proliferation in Cyclamen.—Mr. L. Lawrence (gr. to R. GREGORY, Esq., of Shoreham) exhibited a plant of *Cyclamen*

showing floral proliferation. The seed was from Lowe's *Cyclamen Salmon Queen*, and this was the only plant which had produced such flowers. All the flowers on the plant were alike, and every one had five perfect flowers arising from within the calyx, probably axillary to the sepals, though apparently alternating with them, and surrounding the central corolla, &c.

Hippocastrum pardinum.—Mr. A. WORSLEY exhibited flowers of a form which he regarded as belonging to this species. He considered the species to be a variable one, and the form figured in the *Botanical Magazine*, v., t. 5645, not to be the one most commonly met with.

Notonia Grantii.—This interesting Composite with bright-red heads of flowers and Kalanchoë-like in habit, about 3 feet in height, a native of Uganda, was exhibited by Messrs. J. VEITCH. It was recommended that a Botanical Certificate be awarded to it. It is figured in the *Botanical Magazine*, t. 7691.

GHEENT HORTICULTURAL.

FEBRUARY 7.—A monthly meeting of the *Chambre Syndicale des Horticulteurs Belges* and *Société Royale d'Agriculture et de Botanique de Gand* was held on Sunday, February 7.

Certificates of Merit were awarded to Mons. TH. PAUWELS for *Cypripedium aureum vertumé*, *Miltoniopsis Pauwelsianum* (M. Roezlii × *vexillaria Leopoldii*), *Cypripedium "Ville de Paris,"* and *Cattleya Trianae* var.; to Mons. M. F. LAMBEAU for *Cypripedium Queen of Italy*, *Miltonia Bleuana* var. *splendissima*, *Cypripedium aureum Bruxellense*, *Lælia anceps Sanderiana*, *Lycaste Skinneri* var. *Bellemense*, *Miltonia Bleuana* var. *Prince Charles*, *Cypripedium aureum "Surprise,"* *C. aureum "Pomone,"* *Lælio-Cattleya Warneri-Digbyana*, and *L.-C. Digbyano-Mossiae* var. *Queen Alexandra*, to Mons. EM. PRAET for *Cattleya Trianae* var. and *Cypripedium Lecanum Clinkaberryanum*; to Mons. VERDONCK for *Dendrobium nobile virginale*; to Messrs. DUCHESNE & LANTHOINE for *Odontioda Watermaelensii*; to Mons. H. DE CONINCK for *Cattleya Percivaliana splendida*; to Mons. V. HEURSEL for *Cestrum Smithii* and *Libonia igani*; to LOUIS VAN HOUTTE, PERE, LTD., for *Bilbergia Forgetiana* and *Sansevieria Laurentii*; to Mons. AUG. HAERENS for *Azalea Mme. Aug. Haerens*, *Azalea President Alexis Callier*, and *Azalea Brillanta belgica*; to Mons. LOUIS DE SMET for *Anthurium Rothschildianum rotundiflorum perfectum*; to Messrs. HAERENS & WILLE for *Azalea Christmas Cheer* × *Mme. John Haerens*; and to M. OCT. VANDER CRUYSSSEN for a seedling *Azalea* known as *President Arthur De Smet*.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 15.—A meeting of the Executive Committee was held on this date at Carr's Restaurant, Strand, Mr. T. Bevan occupying the chair.

The Hindhead Chrysanthemum Society was admitted in affiliation. The secretary placed before the committee an interim financial statement, and the relations with the Crystal Palace Co. were fully discussed. It was resolved that all the medals awarded at the Society's shows be handed to the exhibitors, and that 10s. in the pound of the prize money be also paid, with an intimation that the committee hoped to pay the balance if and when the debt due by the Crystal Palace Co. be paid.

The question of the 1909 shows was then discussed, and, under the altered state of affairs, it was considered advisable to hold only one, instead of three, the prospective receipts for the year not justifying a greater expenditure. Upon the motion of Mr. Curtis, it was resolved that a show and conference of early-flowering varieties be held. Subject to arrangements being concluded, the show will take place some time about the middle of October, either at the Horticultural Hall or Earl's Court.

One-third of the Floral Committee retiring by rotation, the following gentlemen were elected to fill the vacant places:—Messrs. P. A. Cragg, Moorman, J. B. Riding, W. Wells, Seabrook, and W. Newton. The Finance, Schedule, and Publications Committees were re-elected as at present constituted.

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS.

FEBRUARY 16.—A largely-attended annual meeting of the Royal Society for the Protection of Birds was held at the Westminster Palace Hotel on the above date. The proceedings included the presentation of the Society's Gold Medal to Mr. A. Holte Macpherson, F.Z.S., as winner in the Society's international competition for an essay on "Comparative Legislation on Bird Protection."

Sir William Anson referred to the excellent educational effect of the Bird and Tree Challenge Shield Competitions in elementary schools, of which he has knowledge in his own county. Other speakers included Julia Lady Tweeddale, the Earl of Stamford, Captain Tailby, Mr. Meade-Waldo, Mr. Trevor Battye, Mr. Montagu Sharpe (chairman of council), and Mr. Champion B. Russell; and among those also present were Lady Forester, the Hon. Mrs. Arthur Henniker, the Hon. Mrs. Boyle ("E.V.B."), Mr. Dresser, Dr. Penrose, Mrs. Sturge, Mr. W. L. Fisher, and Mr. Ernest Bell.

DEBATING SOCIETIES.

CARDIFF GARDENERS.—A meeting of the above association was held at St. John's Schools, Cardiff, on February 9. Mr. H. R. Farmer presided. A lecture was given by Mr. M. Toy, Foreman, Castle Gardens, Cardiff, on "Perpetual-flowering and 'Malmesbury' Carnations."

At the meeting of the society held on February 16, Mr. H. A. Gerhold, chemist, Penarth, delivered a lecture on "The Cultivation of Sweet Peas."

SALISBURY AND DISTRICT GARDENERS.—A meeting of this society was held on February 3, Mr. S. W. Tucker presiding. The meeting was devoted to a debate on various subjects, including the origin of the florists' Cyclamen and the best mode of cultivating it; the advent and growth of the Sweet Pea and the best method of culture; the cultivation and exhibition of Turnips; the cultivation of Cinerarias; and the best methods of growing herbaceous Calceolarias.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 24.

The most sunny February day for 10 years.—The present cold period has now lasted 18 days. During the past week, however, the low temperatures have been at night, the mid-day readings being nearly all more or less above the average. Consequently the daily range of temperature has been unusually large for a winter month.

MARKETS.

COVENT GARDEN, February 24.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eo.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices. Columns include flower name, quantity, and price (s.d. s.d.).

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage items and their prices. Columns include item name, quantity, and price (s.d. s.d.).

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants and their prices. Columns include plant name, quantity, and price (s.d. s.d.).

Plants in Pots, &c.: Average Wholesale Prices (Contd.).

Table listing various potted plants and their prices (continued). Columns include plant name, quantity, and price (s.d. s.d.).

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices. Columns include fruit name, quantity, and price (s.d. s.d.).

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices. Columns include vegetable name, quantity, and price (s.d. s.d.).

REMARKS.—Nectarines are arriving from the Cape in a splendid condition and are making good prices, but this week will probably see the last consignment for the season. The Grape trade generally is quiet; best Black Alicantes are in demand. There is a good trade in Canary Tomatoes, especially those selected in handle baskets; they are averaging 5s. per dozen lbs. Prices for vegetables are slightly firmer owing to the very cold weather. Oranges continue to arrive in large quantities, and meet with a good demand. E. H. R., Covent Garden, Wednesday, February 24, 1909.

REMARKS.—Trade is still slow. There are large stocks of cheap varieties in London, but best quality tubers of Up-to-Date and Maincrop varieties are not over plentiful. Edward J. Newborn, Covent Garden and St. Pancras, February 24, 1909.

COVENT GARDEN FLOWER MARKET.

The cold weather has had a bad effect upon trade in all departments, but especially the trade in plants. Hardy flower roots such as Sweet William, Wallflower, Carnation, Primrose, Hollyhock, Digitalis, Aquilegia, Arabis, Pæonia, Delphiniums, and other common border plants are seen in large quantities. When the weather changes there should be a good trade in these plants. Trees, shrubs, and a variety of other hardy subjects, including Rhubarb roots, Cabbage plants, &c., are procurable. Before the enlargement of the market most of the hardy produce was sold outside the flower market, but now accommodation is available inside, except during the busy spring season.

CUT FLOWERS.

Daffodils are the leading feature amongst cut flowers: they are over-abundant, but supplies may not continue to be so great, as the outside crops may not be in time to succeed those grown under glass. Golden Spur is the leading yellow variety; Emperor is very good, but the colour is not quite so bright as Golden Spur. Horsfieldii is a popular bicolor, but Victoria is the better of the two, and it comes in at a useful time. The variety Queen of the West, shown by Mr. W. T. Ware on Tuesday, should claim the attention of market growers. It is a pure lemon yellow flower of the King Alfred type, having a giant golden spur. The various sorts of Narcissus are supplied in large quantities. N. ornatus is down to the lowest prices, but when the first early supplies are over they may be more valuable. Best blooms of Liliun longiflorum have not been over-plentiful, and have made advanced prices. Blooms of L. lancifolium rubrum are now a better colour. Callas are abundant and are offered at low prices. Camellias are slightly dearer. Carnations are seen in large quantities, generally they are very good. Enchantress seems to have fallen in favour, the newer Mrs. H. Burnett variety and others of a deeper shade taking its place. Lilac is good, both the coloured and white varieties. Though we have many new varieties the old Charles X. is extensively grown. Large supplies of Violets arrive from various provincial growers, and also from abroad. We have seen the last of Chrysanthemums for the season. Roses improve week by week. Richmond, if not so prolific in blooming, is certainly a finer Rose than Liberty. Joseph Lowe must become a popular market Rose, for it forces well, and blooms recently seen in the market have been of a very good colour. Early-flowering Tulips are nearly finished.

POT PLANTS.

Bulbs are the leading feature. Hyacinths of various colours are of the best quality. Tulips also are good; the double varieties grown in pots command good prices. Daffodils are over-abundant, and to clear the stocks must be offered very cheaply. Cyclamen are well-flowered, and Chinese Primulas are better in this respect than the first plants; P. obconica is also good. Erica persoluta alba is seen in well-flowered plants. Mignonette, Intermediate Stocks, Cinerarias, Genistas, Rhododendrons, and Azalea mollis are all prominent on the stands. Whilst the cold weather continues there will be but little trade in foliage plants. A. H., Covent Garden, Wednesday, February 24, 1909.

NEW INVENTIONS.

AN ADAPTABLE HOE.

MR. M. O. WHITEHORN has secured patent rights for a hoe which can be used either as a Dutch or drag hoe by adjusting the same blade. The change is effected by means of a lever, which withdraws a stud that holds the blade in position, whether straight, as in the Dutch hoe, or at an angle, as in the drag hoe. In order that soil shall not clog the working parts, the socket is seamless, and the stud fits closely. The tool is made in three sizes, with 4-inch, 6-inch, and 8-inch blades. Either can be used in the one socket and handle.

A LAWN-MOWER CARRIER.

THIS very simple device is intended for attaching a lawn-mower to a truck or hand cart when conveying it from place to place. An iron rod is bent in the shape of a double "S," and one part is hooked over the axle, whilst the rollers are placed on the other. The machine is then slung up and attached to the barrow handles or iron stays at the side. For suburban and jobbing gardeners the device should prove useful. It will, at the least, be a gain to suburban residents if these machines are conveyed from garden to garden noiselessly, for the dragging of them through the streets is a minor public nuisance. The inventor is Mr. W. COVILL, Cheltenham.

Obituary.

MRS. ROBT. WARD.—We regret to record the death of this lady at the Botanic Garden, Georgetown, British Guiana, on January 6, 1909. The late Mrs. Ward was known to many Kewites as Miss Jessie Newsham, having been one of the lady gardeners employed at Kew, which place she left in August, 1900. She married Mr. Ward, an old Kew gardener, in April, 1908, and soon after returned with him to British Guiana. She gave birth to a son on January 2, four days before she died. Before going to Kew she studied at Swanley for two and a half years, having gained a Kent County Council scholarship. She made many friends, and both at Kew and Swanley her early death is deeply regretted.

A GARDENER'S NOTICE: C. S. C. You are right in thinking that it has been judicially decided that a head gardener is entitled by custom to one month's notice. There is, however, no reported decision with regard to anyone in your particular position, and it is purely a question of custom for the judge to decide. Under the peculiar circumstances of the case your employer would probably accept a week's notice, but to be quite on the safe side we should advise you to give a month's notice if there is no reason for any haste. By so doing it would also put you in a better position if in your next situation you wished to insist on receiving a month's notice.

ASSESSMENT FOR RATES: S. F. Glasshouses are rated as buildings and not as agricultural land, and where any property consists partly of agricultural land and partly of buildings the gross estimated rental of the buildings is to be calculated on the rent at which they would be expected to let to a tenant from year to year. As you have a 21 years lease, it does not follow that the assessment should be equal to the rent you pay. If you are dissatisfied with the valuation, you should apply to the assessment committee for your district.

MUSHROOMS: L. G. The house you mention may be converted into a profitable Mushroom house. You should obtain the requisite quantity of manure from stables in which the horses are mainly, if not entirely, fed on hay and corn. Shake the long straw out and retain only the short straw and droppings for forming the Mushroom bed. Turn this material over every day for a few days to allow some of the volatile gases to escape. This must be done until all danger of violent fermentation is past. Then place the manure in your house in sufficient quantity to form a bed on the floor 18 inches in depth after it has been trodden well together all over. This done, insert two or three ground-thermometers at short intervals on the bed to ascertain the degree of heat. These should be examined daily after the bed has been formed two or three days, and when the heat has declined to 80° Fahr., with no prospect of its rising again, the bed will be ready for spawning. You can obtain good spawn from any of the nurserymen or sundriesmen whose names appear in our advertising columns. Break each brick of spawn into six or seven pieces and insert these pieces separately about 8 inches apart underneath the surface of the bed, drawing the manure back with one hand and pressing the individual pieces of spawn into the openings with the other. The rough side of the spawn should be placed downwards and the smooth side barely underneath the surface of the bed, pressing the displaced manure over and about the several pieces of spawn. The bed should then be covered over to the thickness of between 1 and 2 inches with sifted garden or field soil. It should be

sufficiently moist to allow of a firm, smooth surface being presented after beating with the back of the spade. The whole should then be covered with 12 or 15 inches thickness of litter—that which has been rejected when preparing the manure will answer well. The surface of the bed should be kept moist. Treated in this manner, it should begin to yield Mushrooms in eight or ten weeks from the time of inserting the spawn. The sooner you make the necessary preparations the better. We would rather not estimate the amount of crop you are likely to take per week from your house—so much depends upon circumstances.

NAMES OF FRUITS: A. E. E. Mannington's Pearmain.

NAMES OF PLANTS: H. Hibernia. The Codiaëums or Crotons are as follow: 1, Laingii; 2, variegatum; 3, Johannis; 4, Davisii; 5, interruptum; 6, this is Cordyline (Dracæna) Cooperi.—W. F. B. Photinia serrulata.—A. E. E. 1, Cupressus Lawsoniana; 2, Thuja occidentalis.—W. F. B. 1, Abies balsamea; 2, A. numidica; 3, Cupressus species in a juvenile stage and, therefore, impossible to determine; 4, Berberis japonica (B. Bealei is a synonym of B. japonica).—D. H. Sparmannia africana, an excellent plant for conservatories, and one which grows and flowers well in a dwelling house.—O. R. 1, Oncidium pubes; 2, Odontoglossum hastilabium; 3, Brassia brachiata; 4, Oncidium ornithorhynchum.—Knowledge. 1, Cypripedium Calypso (Boxallii x Spicerianum); 2, C. villosum.—G. H. 1, Cedrus deodara; 2, Cryptomeria japonica; 3, Viburnum Tinus; 4, Berberis aquifolium; 5, Choisya ternata; 6, Abies nobilis.—A. S. Ornithogalum lacteum.—W. J. F. 1, Begonia metallica; 2, Abutilon Savitzi; 3, Begonia Gloire de Sceaux; 4, Oncidium flexuosum.—E. C. B. 1 and 2, Carex tristachya (syn. japonica), the type and variegated variety; 3, Cyrtomium Fortunei.

POTATO SCAB: Potato, Oxon. The tubers are affected with Dry Scab, caused by Stemphylium atrovirens, better known as Phellomyces. Diseased tubers should not be used for "seed," and the land in which they were grown will be infected. It should be well limed, and not used for planting Potatoes or root crops, except Turnips, for some years to come.

PURCHASING A NURSERY: G. H. W. There is still opportunity for the energetic man to be successful in a market nursery business. But competition is keen, and every method must be adopted to so fit in the cropping of both the land and the houses that no sooner is one crop finished than another is ready to take its place. It is essential that a good market shall be near at hand, or payment of freights will take a large proportion of the profits. Kent and Middlesex are both great fruit-producing counties, the supplies from these parts being mainly sent to the London markets. Although, as you state, much foreign produce is sold in this country, it is generally at a time when our own fruits and vegetables are out of season. The demand for home produce is always good.

SNOWDROPS: J. McC. The plants are affected with the Snowdrop mildew—Sclerotinia galanthina. The plants should be destroyed and the ground treated with lime.

TRADE PAPER: Nurseryman. The Horticultural Trades Journal is published by the Horticultural Printing Co., Junction Street, Burnley.

VINE ROOTS UNHEALTHY: J. C. M. There is no disease present in the roots you send. The trouble is due to some cultural defect or an unsuitable rooting medium. Overhaul the border, cut away the dead portions of the roots, and encourage the formation of new ones near the surface by placing some fresh loam, enriched with suitable manurial properties, on the border. At the same time see that there is proper provision for drainage.

LEAF-SPOT OF ODONTOGLOSSUM URO-SKINNERI.

FOR some time past my attention has been directed to the occurrence of numerous black spots on the lower surface of the leaves of *Odontoglossum Uro-Skinneri*. The appearance presented by these diseased leaves is, I believe, well known to growers of the species in this country, and is commonly attributed to unsuitable cultivation. The material which I have investigated was kindly supplied to me by Mr. Norman C. Cookson, to whom I am also indebted for observations upon the effect produced by a change in cultural conditions.

The spots (fig. 62) are found chiefly on the older leaves, the younger leaves being almost, if not entirely, unaffected. They are often crowded together, and vary greatly in size, the smallest being barely visible to the naked eye, while the largest, elliptical in shape, may attain a longer diameter of half a centimetre. In this latter condition the spot is slightly raised above the surface of the leaf, and presents the appearance of a blister. Each spot is surrounded by a translucent border, and all stages in the de-

velopment of the spots may be found on the same leaf.

The anatomical structure of the leaf presents xerophytic characters (fig. 63). The outer cell-wall of both the upper and lower epidermis is thickened, and possesses a well-defined cuticle. The stomata, which are entirely confined to the lower surface, are sunk in pits, with the formation of a pronounced outer cavity (fig. 64). The cells of the mesophyll gradually increase in size from the lower to the upper surface, where they constitute a large-celled aqueous tissue.

Transverse sections through the region of the spots show an accumulation of a brown mucilaginous or gummy substance beneath the lower epidermis. In the initial stages this substance is present only in the respiratory cavities of the stomata, from which it exudes into the

FIG. 62.—LEAF-SPOT OF ODONTOGLOSSUM URO-SKINNERI. (NAT. SIZE.)

stomatal openings (fig. 64). In more advanced stages it collects in large masses, spreading through the hypodermal cells and into the internal tissues of the leaf (fig. 63). In the interior of the leaf this mucilage is colourless, and may be traced as a white, glistening substance, filling the intercellular spaces. Towards the epidermis it gradually becomes a deep brown, at the same time becoming harder, and this gradual fading away of the brown colour towards the centre of the leaf may indicate that it is the result of oxidation.

The gum appears to be excreted from the cells into the intercellular spaces, and thence it gradually accumulates beneath the stomata. It is this accumulation which raises the epidermis and forms the blister-like structure.

In no case were wounds of any kind to be found upon either the upper or lower epidermis, and all idea of the disease being due to an initial injury may be dismissed.

Where the gum is present, the intercellular spaces are much enlarged by the separation of the cells along the middle lamella (fig. 65), but otherwise the cell-walls appear to be quite normal. The cell-contents are greatly disorganised, and there is a partial or complete disappearance of the protoplasm, nucleus, and chloroplasts. A marked alteration takes place in the chloroplasts. They lose their regular outline, increase greatly in size, split into a number of smaller bodies, and finally disappear. Hence in an advanced stage of the disease the cells are found without any trace of chlorophyll, the protoplasm and nucleus are also completely disorganised and the cells become empty, presenting a strong contrast to those of the normal healthy portion of the leaf.

In the *Annals of Botany*, vol. ix., 1895, Massee describes a "spot" disease of Orchids in which the characteristic is the plasmolysis of the cells, the complete disappearance of the chloroplasts, and the formation of highly-refracting, hyaline spheres. These spheres were found to be rich in tannin, and, contemporaneously with their formation, the cytoplasm becomes turbid and the primordial utricle tinged with brown. Massee also shows how this "spot" can be produced when drops of water were allowed to rest on the leaves and the temperature was suddenly lowered. He finds no trace of fungi or bacteria, and concludes that the Orchid disease known as "spot" is of non-parasitic origin, the initial cause being the presence of minute drops of water on the surface of the leaves at a time when the temperature is exceptionally low and the roots copiously supplied with water.

The leaf-spot of *Odontoglossum Uro-Skinneri* differs in many respects from that described by Massee. There are no pits formed in the leaf, but, on the contrary, the epidermis is raised above the surface of the leaf, and the spots appear only on the lower side. The sections bear no general resemblance to tissues invaded by *Plasmodiophora*, and the enlarged vacuolated spheres are not produced. Again, the accumulation of gum in the intercellular spaces, which is a pronounced characteristic of this disease of *O. Uro-Skinneri*, is not noted by Massee.

The nature of the gum is difficult to determine. It is very insoluble; it reacts to many of the aniline stains, and, colouring red with phloroglucin and yellow with thallin sulphate, suggests that it is a substance of the nature of vanillin. Gums or mucilages are frequently met with in plant-tissues, but always as the result of some pathological condition. The first process in the healing of wounds is the sealing up of the exposed surface by a gummy substance, which prevents the too rapid loss of water. These wound gums appear to be formed as an excretory product in the natural process of healing, but little is definitely known as to their origin. Many gums which appear to be of much the same chemical composition are also formed in the plant as the result of fungal or bacterial action. The production of Gum Arabic, for instance, has been traced to the action of certain bacteria, and numerous well-known diseases of plants in which gum is produced, such as the Red-string of the Sugar-cane, the Gummosis of the Beet-root, the Black-rot of the Turnip and Swede, &c., have been proved to be due to a similar cause. The common gum flux of the *Amygdaleæ* has been attributed to the action of a *Coryneum*.

In the leaf-spot of *Odontoglossum* there was no sign of any fungus to be found. But special

staining and examination under a high power of the microscope revealed the presence of numerous bacteria (fig. 65). These occupied notably the cells surrounding the tissues in the initial stages of gum formation, and could be seen almost filling the cavity of the cells. Although the subject requires further investigation, it is probable that these bacteria have some

lence in the first place. This Orchid, in its native habitat, Guatemala, exists at a high elevation, in cool, shady places. Cultivation in too moist and, possibly, too heated an atmosphere produces conditions which are inimical to the health of the plant. *M. C. Potter, M.A., F.L.S., Botanical Laboratory, Armstrong College, Newcastle-upon-Tyne.*

The lip is oblong, three-quarters covered with brown in the horseshoe form seen in a good flower of *O. triumphans*, and showing the small blade and apex and crest of that species. The column is that of *O. triumphans*, with brown wings and anther cap. *de B. Crawshay.* [This description was received a week or so before Messrs. Sander & Son exhibited a plant from the same cross at the R.H.S. meeting on February 23.—EDS.]

FIG. 63.—TRANSVERSE SECTION THROUGH REGION OF SPOTS, SHOWING GENERAL STRUCTURE OF LEAF AND ACCUMULATION OF GUM UNDER LOWER EPIDERMIS AND EXTENDING INTO THE INTERNAL TISSUES.

destructive action upon the protoplasts, and that from this action result the escape of the cell-contents and their conversion into the gummy substance, filling up the intercellular spaces. According to the researches of Greig Smith, Gum Arabic is not derived from the cellulose, but is due to the action of *Bacterium acaciæ* upon such carbohydrates as levulose, saccharose, maltose, or mannite. In the present case there is no softening or swelling of the cell-walls, and, doubtless, certain carbohydrates present in the cell-contents may provide the material from which the gum is derived, under the influence of the invading organisms.

Attempts made to induce the disease upon healthy plants by inoculation with bacteria isolated from the diseased leaves have been unsuccessful. It must be remembered, however, that infection is often very critical and uncertain, and depends upon conditions sometimes difficult to approximate.

It has been noted that the spot is more prevalent when the plant is grown in a very moist or almost saturated atmosphere, and in such conditions it is very liable to spread. In a dry atmosphere, on the contrary, the spot does not increase, and if a plant affected with it is re-

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM HUNIADES (*O. HUNNEWELLIANUM* × *O. SCEPTRUM*).

THE hybrid, as represented by the first plant to bloom, can hardly be called interesting, except for the fact that it has proved the smaller species to be the stronger. In form and colouring it is almost a duplicate of *O. Hunnewellianum*, the lip alone showing a form somewhat more like *O. sceptorum* than the remainder of the flower. It was raised by Mr. Sander at Bruges. *de B. Crawshay.*

ODONTOGLOSSUM LANDOLPHUS (*O. ANDERSONIANUM* × *O. ROLFEÆ*).

THIS hybrid was also raised by Mr. Sander. The first one to flower is rather a pleasing and interesting plant. The sepals and petals are clear, bright yellow, the sepals having one brown spot almost at the apex, and the petals being unspotted and having a median area of lighter yellow, so often present in the unspotted forms of the female parent.

The lip is unspotted, somewhat orbicular, with the right-angled shoulders of *O. Andersonianum*, and likewise the colouring in the channel. The column is white. The influence of the smaller-flowered parent is dominant, and the entire blotching of *Rolfeæ* is suppressed, except the spot in the sepals, which is almost always present like an island in a sea in that hybrid.

Analogous in the suppression of the spotting is *O. Rolfeæ Fathleen*, lately in Mr. Bradshaw's, now in Mr. Butler's collection. Doubtless some of the plants will show more influence of *O. Rolfeæ.* *de B. Crawshay.*

ODONTOGLOSSUM POLYPHEMUS (*O. KEGELJANII* × *O. TRIUMPHANS*).

IN raising hybrids of *O. Kegeljanii*, many people may say I wasted time, but, in effect, they have a different character to all others, and eventually the later generations may prove good acquisitions.

This one bloomed a month ago, and, as might be expected, it has rounded and filled up the form of the female parent, retaining the rich yellow ground just shaded by green in the centre of the sepals. The sepals have two bars and a great apical blotch of rich glossy brown, like *O. Kegeljanii*, almost covering their surface.

The petals are of similar yellow colour, with reddish-brown basal markings and a large blotch beyond.

FLORISTS' FLOWERS.

THE AURICULA.

THE hon. secretary of the National Auricula Society (Southern Section) stated at the annual meeting held recently in London that the list of members belonging to that special society was larger than at any previous time in the society's existence. This is very satisfactory, and is evidence that this charming, old-fashioned garden flower is increasing in favour with those who value flowers for their intrinsic worth, as well as for their historical associations. One sometimes hears comments on the difficulty in cultivating Auriculas. I have frequently received complaints of plants not succeeding, but, on investigation, the cause was found to be due either to ignorance of the ordinary rules of culture, or to neglect. If *Pelargoniums* or any other garden plants are attacked by green fly, and no means are taken to destroy the pest, there will soon be an end of the *Pelargonium*. The Auricula also is liable to be attacked by aphid, and this must be destroyed by fumigations. The woolly aphid, which lives and thrives on the stem and roots, can be destroyed by frequent fumigations with XL-All compound, or, if the roots are carefully examined at the time of repotting, the aphid can be effectually brushed off.

Auriculas should be overhauled before the end of February to ascertain that the roots are in a good condition and provision for drainage perfect. When this has been done a clean flower pot of similar size should be ready in which to replace the plant. Those who possess a heated house for Auriculas should place their plants in it now. If it is intended that the

FIG. 64.—A STOMA WITH GUM IN RESPIRATORY CAVITY AND EXUDING INTO STOMATAL OPENING.

moved to a drier atmosphere, the spot already developed is checked, and instead of the epidermis being raised as a blister, it may even begin to sink at the larger spots.

Clearly bacteria play a considerable part in the development of the disease and the formation of the gum, but unsuitable cultural conditions are also largely responsible for its preva-

FIG. 65.—INTERCELLULAR SPACES FILLED WITH THE GUM, AND BACTERIA INSIDE THE CELL.

plants should all be in flower at the same time, the edged flowers should be placed in heat before the selfs, although a few of the edged flowers, such as *Acme*, will come into flower with the selfs under similar treatment. Some care is necessary in watering the plants, for as the season advances the growth is very rapid, and the plants suffer if they are allowed to

become at all dry at the roots. Too much moisture will be equally bad and cause the plants to become drawn and the leaves flabby. Those who possess garden frames only should see that the glass is covered at night-time with thick mats. Careful attention must also be given to proper ventilation of the frames; the lights, when opened, should always be tilted in a manner that will protect the plants as much as possible from cold winds. Rooted offsets should now be removed carefully from the parent plants, placing two or three around the edge of a small flower pot filled with fine, sandy soil. They may be placed in hand-lights, where they will soon become established. The offsets which were put in small pots about September should be repotted: they will, with good treatment, form strong plants and flower well next year. By keeping insect pests from the plants and giving careful attention to ventilation early in the morning in fine weather, satisfactory results will be obtained. *J. Douglas.*

THE ROSARY.

CULTURAL NOTES FOR MARCH.

PRUNING will require attention towards the end of this month. Roses that have been injured by the frost should be pruned to the first dormant bud. Hardy climbing Roses on walls, arches, fences or pergolas should be first attended to. Prune the bushes moderately and cut out any unripe or weakly shoots, and, where they are crowded, thin out the weaker and nail or tie the remaining shoots to the walls or trellis-work. The following varieties growing in a sheltered position on a south aspect or against a wall may also be pruned lightly during the present month. Leave all the long, ripened shoots their full length, and only shorten the points of the shoots if they are soft and unripened:—Cheshunt Hybrid, Gloire de Dijon, Carmine Pillar, Madame Berard, Climbing Caroline Testout and Aimée Vibert. There will be a difference of several weeks between northern and southern districts for practising pruning. The work must be regulated, not only in accordance with the local conditions, but also with the type of Rose. The Moss, Provence, China, Hybrid China, Austrian Briar, Sweet Briar and other summer-blooming Roses may also be pruned early during March, but their principal stopping and thinning should have been done after they had flowered last summer. What is required now is to cut away late-developed and unripened shoots, and also any suckers. The shortening within reasonable limits of long rampant shoots should also be done. After these are pruned, varieties of the hybrid perpetual type should be given attention. In order to obtain a succession of blooms some of the bushes should be trimmed 10 or 12 days in advance of others. Vigorous-growing shoots should be shortened to one-third of their length, or even more severely, according to the variety; the weaker-growing kinds should be cut most severely, leaving only four or six buds. Pillar Roses should be cut hard back, but in this case it is only the old-flowering wood which must be shortened, for the shoots of last season's growth must be left intact. Many persons prune Roses by rule of thumb, and deal with all types on similar lines, but the need of each class is different, and calls for special treatment.

Standard briars that have suffered damage by frost should be cut back to uninjured wood and the surface mulching on the beds made good. If the presence of manure on the beds is objectionable, a light layer of soil can be spread over it.

The seed beds wherein are planted briar seeds should be examined occasionally, as the seeds will begin to germinate at the end of this month. A little fine sandy soil scattered over

the drills will be of benefit to the young seedlings. Syringing will also be an advantage.

Hot-beds made during the latter part of February for the raising of Roses from cuttings will now be in a suitable condition for inserting the shoots. There is an abundance of suitable wood for the making of cuttings. Place one cutting, or not more than two, in a small pot filled with sandy loam and leaf-mould and surfaced with white sand. make the cuttings firm in the soil and water with tepid water. The heat of the bed should be about 75° when the pots are plunged. It is advisable to place a layer of cocoanut fibre or clean sawdust in the frame in order to absorb excessive moisture which may arise from the bed. If this does not suffice, a little ventilation must be given at the back of the frame for a few hours in the middle of the day, but not such as would perceptibly lower the temperature. The frames should be covered with mats or litter during the night. The cuttings will not require much water until after the second or third week of planting. Then the atmosphere of the frame will become much dryer and shading from direct sunlight must be practised during the daytime.

Roses planted out in houses should be kept dryer at their roots after the blooms are cut, but an occasional syringing after pruning will assist them to form the new growths on which the later crop of flowers will be produced. This advice refers specially to Noisette, Tea and Hybrid-Tea Roses. It is only certain kinds of Hybrid-Perpetual Roses that can be depended upon to produce a second crop of flowers in a glasshouse, therefore it is not advisable to plant Roses of that description.

Rose cuttings in the open are liable to become loosened in frosty weather; they should, therefore, be carefully examined after the frost has disappeared and the soil about them made firm by treading.

The treatment of pot Roses is now of a routine character, proper conditions of ventilation and moisture, according to external conditions, being the chief requirements. An occasional sprinkling of some suitable fertiliser, alternated with weak liquid manure, will assist the plants when they are forming their flower-buds, give increased vigour to the foliage, and additional substance to the petals. The application of manurial stimulants must be discontinued when the blooms begin to show colour.

Grafted Roses may still be repotted. Place the plants near to the glass and do not neglect to fumigate them when necessary. Water must be sparingly applied until the new roots begin to ramify in the soil. *J. D. G.*

NOTICES OF BOOKS.

* ROCK-GARDENING.

THE opportunities for foreign travel, formerly the privilege of the few, have rapidly been abundantly extended to the many, and a profitable industry—that of the manufacture of guide-books—has been thereby called into existence. Guide-books vary much in quality. At the one end of the scale are those written by authors who thoroughly know their subject, curt, to the point, compressing the maximum of serviceable information within the narrowest limits of space. At the other end we encounter the innumerable stories of rather aimless wanderings told by discursive and not over-critical ramblers.

Similar conditions, *mutatis mutandis*, occur in other pursuits which engage the interest of a large and heterogeneous public. In amateur gardening the cult of the rockery is now well to the fore, and the publishers, who presumably know their public, are busily catering for all sorts and conditions of aspirants.

No doubt the volume before us will appeal to a particular class of readers, though they will

* *That Rock-Garden of Ours*, by F. Edward Hulme, F.L.S., F.S.A., with 50 illustrations by the Author. T. Fisher Unwin. Price 10s. 6d. net.

probably not be drawn from the ranks of people who call themselves rock-gardeners. In fact, it is a little difficult to justify the title of the book at all, except, perhaps, that in the first chapter Mr. Hulme gives a few directions as to their relative positions to be occupied by the soil and the stones. For the rest, the book rather reminds us of Ruskin's treatise on sheepfolds, which excited a not inconsiderable, though wholly temporary, interest in agricultural circles.

Indeed, Mr. Hulme uses the term mainly, as it seems to us, to indicate a rather remarkable wild garden, wherein are to flourish all the wild plants that have already made themselves prominent in these islands. But, however beautiful Coltsfoot, Cinquefoil, and many other plants of the same sort may be, they are hardly in place except in the wildest of wild gardens. Even the author himself seems to recognise this, for he hints at their devastating powers of reproduction and extension. Few cultural directions are given—nor, indeed, are they, for the most part, necessary—for the denizens of such a rock-garden as Mr. Hulme had in his mind, and he is thus able to devote the greater part of his pages to the antiquarian and other lore that attaches to the objects of his admiration.

The text is illustrated by 50 plates, partly in colour and partly in half-tone. They are of uneven character; some are good, but others are blurred and indistinct. Incidentally, we might remark that the figure of a Daffodil, referred to on p. 56, is not to be found on Plate 1., as stated, but on Plate XXIV.

It might, perhaps, be gathered from the foregoing, that we think but poorly of Mr. Hulme's book. This is by no means entirely the case; but we do think that the title conveys a mistaken impression, which is fair neither to the reviewer nor to the general reader. If the author had called his book a gossip about common plants we could have found no fault with him. *J. B. F.*

* LIFE HISTORIES OF FAMILIAR PLANTS.

THIS book is not addressed to the professed botanist but to "that large and growing class of Nature-investigators who derive pleasure from seeking the why and the wherefore of details in plant structure and the relationship of these details to animal life."

While acknowledging his indebtedness to distinguished observers in the past in the same field of work, the author puts forward in each chapter his own suggestions as to the solution of various plant problems.

Some of these invite criticism, if not from the Nature-investigator, certainly from the botanist.

The Cowslip flowers rather later than does the common Primrose, but that this fact is directly due to the delay caused by the growth of the thick stalk on which the umbel of flowers is borne seems at best doubtful, nor can we readily agree that the larger size of the Primrose flower is directly associated with the larger supply of nutritive material available owing to the absence of such a stalk. The Cowslip, again, is not by any means confined to low-lying pastures, but occurs in great abundance on the slopes of downs and in similar situations. It seems unlikely, moreover, that the spotted Orchis has been aided in the struggle for existence by the fact that its mottled leaves have any resemblance to the spotted body of an adder.

It may well be that browsing animals are more familiar than is man with the "snake in the grass," and with the frog and his like, but this theory of immunity from grazing animals, secured to the Orchis by virtue of its spotted leaves, demands stronger evidence than is forthcoming here. The leaves of the common Arum are similarly spotted, but are of very different size and shape, and could hardly be mistaken by any browsing animal for a viper.

The book is extremely well illustrated with 86 plates, reproduced from photographs and microphotographs.

* *Life Histories of Familiar Plants*, by John J. Ward. Cassell & Co. Price 6s.

NURSERY NOTES.

THE READING PRIMULAS.

It scarcely needed a visit to Reading to show that the Chinese Primula is as popular a greenhouse plant as ever. It blooms at a time when dwarf-flowering plants are few, and there is no sign that any other species is likely to oust it from its present high position as a decorative plant. Every florist knows how suitable Primulas are for furnishing vases in dwelling-rooms, and how their qualities in this respect have been improved since crossings have been made with the star or stellata section.

But if these facts were sufficiently well known, a visit to Reading served, nevertheless, to show that Messrs. Sutton & Sons are in no way relaxing their efforts to improve and develop their strains. Thus they are, so to speak, assisting the plant, as best they can, to maintain its hold on the public. When it is remembered that their collection includes about 14,000 flowering specimens, that there are 300 to 400 distinct stocks, and yet that only 60 sorts are catalogued, it can be better imagined what an immense amount of detail has to be recorded and studied merely for the sake of keeping the stocks true. But more than this is necessary. The strains have not only to be maintained at the present high merit, but, where possible, this must be increased. Cross-fertilisation between varieties in themselves cross-bred, goes on every year; it is by this method that most of the novelties are obtained. Cross-fertilisation, however, is but one step—a step that leads often to bewildering variation. At this point the process of selection commences. Not the old process of attempting to "fix" characters by continued selection from a batch, but selection of individuals, which, being pure dominants or recessives, will be certain to come true from seeds if the flowers are self-fertilised. As Messrs. Sutton do not catalogue any novelty that cannot be perpetuated by seeds, nor any of which a considerable quantity of seeds cannot be obtained at one time, it follows that many novelties appear in the collection from time to time which are never introduced to commerce. Some of them are sterile. Others, again, produce seed, but have not the property of coming true from seed, and if these were to be perpetuated, it could only be done by layers or side growths, as in the case of the old *alba plena* and other varieties with perfectly double flowers. Such an instance is found in *Giant Lavender*, which, being incapable of breeding true from seed, is what is described as a heterozygote; there are others of the same class, including some of the seedlings obtained from the *Duchess* strain crossed with *Crimson King*.

In previous notices of the Reading Primulas, we have referred to the attempts that are made to apply the principles of heredity, commonly expressed in the term Mendelism, to the cross-breeding experiments. The plants form excellent material for demonstrating these principles, and for proving some of the elementary truths which Mendel first discovered. On our recent visit we were shown in one house batches of plants representing first crosses, such, for instance, as from *Crimson King*, and *Snowdon*. Being the first seedlings after the cross, they are termed the F_1 generation, and, in most cases, all the plants were similar to each other, and intermediate in their characters between the parents. This is what we should expect; but when a plant from the F_1 generation is self-fertilised, the seedlings (F_2 generation) vary in a constant proportion, some being pure "dominants," others recessives, and still other impure dominants. When the pure dominants and pure recessives are again "selfed," they reproduce themselves true from seeds as often as the process is repeated. They are, therefore, "fixed," but not in exactly the manner that gardeners have been in the habit of meaning by that term. It would be more correct to say that they are *pure*. The impure domi-

nants, upon selfing again, split up, and so on. These things are the same, of course, in all plants; the Primulas are merely convenient plants to illustrate hereditary principles that apply to cross-breeding in plants and animals alike. Occasionally the sum does not work out as it should do, and, for reasons that at present are unexplainable, except by the somewhat unsatisfactory assumption that the operator must have made a mistake in making his records. It is always—or nearly always—in regard to colour that unexpected results are obtained, and it has to be remembered that some of the colours are not pure in themselves, but combinations of several colours, therefore the results of crossing are the less certain. In the characters which have to do with the habit of the plant, or with the foliage, and even colour of stem, the proportions in the F_2 generation are Mendelian. The Fern leaf, for instance, is a recessive character in Primulas, and can always be depended upon to breed pure when a cross between a Palm and a Fern-leaved variety is self-fertilised.

much the same manner. All these and other circumstances are of the greatest value to the student. The work of the practical breeder furnishes facts from which the scientist is often able to deduce principles that, in their turn, are valuable to the breeder. It may be said that at present horticulturists have not benefited to the extent they might reasonably expect from Mendel's principles, but at the very least Mendelism has shown them the value of the F_1 generation. In days gone by practical men have often destroyed their seedlings of florists' flowers because, after the first cross, they failed to exhibit any superiority over the parents; now they know that even when this is the case one plant should be selfed in order to see what it is capable of producing in the F_2 generation. In this matter alone the waste of effort there has been is beyond estimation. A second point is the uselessness of attempting to "fix" by selecting from a batch. De Vries' experiments have conclusively shown that selection should be from individuals. In these two matters gardeners have no longer

FIG. 66.—PRIMULA SINENSIS GROWING ON THE ROCKS AT PING-SHAN-PAI, WESTERN CHINA. (NAT. SIZE.)

Among the most interesting results in crossing are some which have reference to what is termed correlation. In most plants there are certain characteristics which are so opposite to each other that they seldom develop in the same plant; whilst there are others that are almost always to be found when certain others are present with which they correlate. A few Primulas shown by Messrs. Sutton at the last meeting of the Royal Horticultural Society illustrated this point. The moss-like foliage of the old variety *Magnifica* has been united with almost all the colours in Primulas, but, nevertheless, it has so far been found impossible to get the *Duchess* strain to take on this type of leaf, although repeated trials have been made. As a rule, the result of such a cross has been to produce a kind of Ivy-like leaf, perfectly distinct from the other types of leaf, but not in itself decorative. This type of foliage is usually correlated with star-like flowers of poor quality, as judged by the florist. But the plants exhibited at the meeting had long lobes to the leaves, and correlated with this character were the lobes of the flowers themselves lengthened in

any excuse for working by the old, wasteful and comparatively ineffective method.

To refer to some of the many noteworthy varieties:—*Giant Crimson* is a variety which represents as well or better than any other the development of the Reading strains. Of good habit, the plant bears strong, erect spikes of flowers which measure from 2 inches to 2½ inches in diameter. The colour has been much improved in the past few years, and it is now intensely vivid and full. We were informed of a curious circumstance in the history of this variety. One of its parents, nine or ten years ago, had "Primula blue" flowers. In subsequent breeding it never produced a plant with blue flowers until last year, but it has repeated the effort again this season. It is worth while pointing out here that a name is often retained for a fresh and improved stock. Whilst particular stocks of *Crimson King*, *Snowdrift*, or *Rosy Queen* are catalogued for sale, other stocks varying but little from these, but always on the better side, are in course of development, and, when these latter stocks are large enough, they

are substituted for the earlier ones, usually without any change in the name. It is this procedure that explains why "Blue Fern-leaved" is a better plant to-day than it was five years ago.

In regard to cultivation, there is nothing beyond the resources of the Reading establishment. The excellent houses are filled with plants of such perfect development, no writer can easily exaggerate the high culture exhibited. We were impressed with the effect of the proper temperature treatment in the development of colour in the well-known variety, "Czar." Certain plants had been cultivated in as cool conditions as could safely be imposed, and the flowers in their rich violet-blue and magnificent zone were so superior as to be distinguished from others at the merest glance. We do not intend to retail to the reader a list of the varieties cultivated at Reading: their names and characteristics are already catalogued. It is sufficient to say that almost all colours are obtainable, either with Fern, Palm, or Moss-like foliage; that the Giant type is so true that even when cultivated in 2½-inch pots the flowers are still 2 inches or more in diameter, and that the stellata section is variously coloured and capable of producing such perfect plants as the specimen illustrated at fig. 67.

We invite the reader to compare the figure just mentioned with fig. 66, which portrays a native specimen of *P. sinensis* growing in a very restricted district in China. The illustration is reproduced from a photograph taken by Mr. E. H. Wilson, and is probably the best yet published of the species in its natural home. It may be pointed out that the plant shows considerable difference from a plant now in the Reading collection, which is believed to be of the same species, and interesting in the fact that the flowers are perfectly free from a trace of "eye" or zone.

Only a concluding word can be said of the Cyclamens. The view reproduced in fig. 68 will serve to show the wealth of the collection. The seed is sown in October in pans, and the seedlings are pricked out singly into 2½-inch pots as soon as they are ready for the change. They flower, therefore, when about 14 or 15 months old. The strains are excellent in every way, as is the culture afforded the plants. Efforts are being made to develop a large-flowered type with scented flowers. "Scented Rose" is a considerable step in this direction.

THE TRAINING OF FRUIT TREES:

It is common belief that the management of wall trees is less perfect than in former years. Certain it is that some young men of the present time have little skill in training fruit trees, having never been taught how to nail shoots straight nor to place them at the correct angle. I believe there are some persons who consider that nothing is gained by being particular in arranging the shoots of fruit trees, though a slight consideration will show that to be an error of judgment. When all the shoots of a fruit tree are disposed at regular distances from each other there is no overcrowding in one part of the tree and waste of space in another. Further, each branch receives as much of the sun's rays as another, and the young growths of the current year have ample room to develop without encroaching on the old or fruit-bearing portions. This is an important consideration, which was the objective of a former race of gardeners by whom the training of hardy fruit trees was attended to with the greatest care. It is true that none of the earliest writers on gardening had a very clear conception of the importance of training and pruning, and well into the eighteenth century advice on the subject is occasionally encountered which shows how long a time it took to break down old prejudices. Hitt, whose work was published in 1755, is supposed by some to have been the first to treat

seriously of pruning and training, but as early as 1717 a gentleman named Collins published a small treatise by the name of *Paradise Retriev'd*, in which the subject is treated in the most enlightened manner. But one gathers that the writer was rather more intent in proving other authorities of the period to be wrong in their methods than in publishing his own, which were right. Earlier still, that accomplished gardener, John Reid, of Rosehaugh, a place still famous for fruit, wrote on this subject. He demonstrated, though in a rather confused manner—not to be unexpected in a man whose acquaintance with English was at best but slight—how wall trees should be managed to give the best results. This was in 1688, 34 years previous to the first English writer who approaches the subject from the true standpoint. It is not to be denied that Hitt carried his training to extremes, just as Forsyth did later, and

sun's rays reach the bricks and warm them; another, that none but vigorous shoots are permitted on the trees; these being capable of producing quite as large a crop of fruits as is able to mature. B.

AQUILEGIAS.

THERE are few flowers more decorative or refining in their effect on our herbaceous borders than the comparatively neglected Aquilegias. Their period of flowering is not quite so prolonged as that of the *Viola*, yet in many instances, as in that of *A. chrysantha*, the "Golden Columbine," it has lasted in flower in my garden for nearly three months. The Aquilegias have come to us from various regions; from the Altai Mountains in Siberia, from the Alps and the Pyrenees, from Guatemala in

FIG. 67.—A SPECIMEN OF MESSRS. SUTTONS' STELLATA TYPE OF CHINESE PRIMULA.

later still other gardeners whose pet theories are to be found in the pages of the contemporary gardening Press. Fundamentally, these old practitioners operated on correct lines, though at an enormous waste of energy, and, no doubt, not always successfully, because all else was made subservient to pruning and training. No one would now be so injudicious as to appraise these at more than their true value. One of the most remarkable improvements of Collins—considering the fact that his contemporaries plashed the shoots of fruit trees one over the other, and that Bradley, at the same period, imagined he was making an advance in allowing a space of 4 inches between the shoots of Apple trees—was that he regulated the shoots of stone fruits at 4 to 5 inches apart. One of the benefits resulting from training the shoots far apart is that the

South America, from Canada, from California, and from the Rocky Mountains.

One of the finest of the Aquilegias, and most graceful in habit, is *A. cœrulea hybrida*, "divinely tall, and most divinely fair," as Tennyson sings of Helen of Troy. The original colours of this beautiful Columbine were blue and white, but when crossed with *A. chrysantha*, it became suffused with yellow and invested with spurs of greater length. *Aquilegia californica hybrida* is a remarkable combination of deep orange and bright scarlet; though, in virtue of its peculiarly pendulous tendency, in which respect it resembles several notable Roses, its beauty is half concealed. *Aquilegia canadensis*, whose colours somewhat resemble those of *A. californica*, is extremely effective in certain situations; so also is the uniquely-coloured

A. Skinneri, which has delicate green sepals and yellow petals, with strongly contrasting spurs of brightest orange-red. It is a native of the northern regions of South America. *Aquilegia glandulosa*, whose colours are white and blue, is a species which is easily increased by careful division of the fibrous root-stock. It is of closely-tufted habit, and does not grow to any great height, forming in this respect a contrast to such commanding forms as *A. californica* and *A. coerulea hybrida*, which, when in flower, can be seen and admired from any part of the garden. A derivative from this variety called *A. Wittmaniana*, though possessing considerable fascination, is not equal in beauty or graceful formation to the parent flower. The late Dr. Stuart, of Chirnside, in Berwickshire, the distinguished originator of the "Violetta" race of rayless miniature *Violas*, raised the grandest of all *Aquilegias*, which bears his name. He used to assure me that *Aquilegia Stuartii* could not be grown successfully except by earnest cultivators, since it requires very careful attention in its earlier stages, and a deep, fertile soil. I have been informed by Messrs. Cocker, of Aberdeen, who introduced the variety to commerce, that it was the result of a cross between *A. coerulea* and *A. glandulosa*, though others have attributed part of its origin to *A. Wittmaniana*.

After cultivating *Aquilegias* for many years with even more pleasure and success than I anticipated, I have come to the conclusion that, whether we consider the length of time during which it blooms with such splendid profusion, its utter indifference to atmospheric conditions, its strikingly beautiful formation, or its lustrous golden hue, *A. chrysantha*, if not so varied or highly artistic in its aspect as *A. californica* or *A. coerulea hybrida*, is the most valuable, and assuredly the most enduring, of them all. Nothing in my garden is more impressive in early summer than long lines of *A. chrysantha*, with innumerable flowers of the brightest Primrose hue glittering beneath the blossoms of overshadowing Apple trees.

Though less refulgent than the Eastern Lily, the Carnation, or the Rose, the *Aquilegia* has a dainty beauty of its own, and is, as this contribution, I hope, sufficiently proves, of much value for garden decoration. *David R. Williamson, Manse of Kirkmaiden, Wigtownshire, N.B.*

The Week's Work.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Late planting.—Where circumstances have arisen to so far prevent the planting of fruit trees, the work may still be done. The chief advantage of autumn planting is that the roots form new growths before the very cold weather sets in, and thus they become partially established before winter, and are better able to withstand drying winds and hot weather during the succeeding summer. When planting is left until the spring extra care is needed to enable the trees to get a good start. The ground should have been previously prepared as advised in a former Calendar, and a dry day selected for the planting. The soil should be in a proper condition for working—neither too wet nor too dry; on no account plant when it is in a wet condition. After the planting is completed mulch the trees with some light manure, that from a spent Mushroom bed being suitable. If the weather continues dry, watering may become necessary; the trees may also be syringed early in the afternoons in dry weather, as this will assist in keeping the wood plump and fresh.

Orchards.—In improperly tended fruit plantations the trees are never pruned, whilst spraying with an insecticide or dressing them with lime is never thought of. Though rather late for the work, the trees may still be overhauled, and it will be better to do this now than to wait till next winter. Cut out all the dead or badly-

placed shoots, and thin the remainder sufficiently to allow the sunshine and air to penetrate to all parts of the tree. Old orchard trees are often dense thickets of shoots, producing only inferior fruits. By a system of proper treatment these trees may be made to bear good marketable crops. When the shoots have been thinned choose a calm day for spraying the trees with an alkali wash, and, if time permits, give them a second spraying after an interval of a week or two. Any grass growing immediately beneath the trees, and for at least a yard beyond the spread of the branches, should be dug in. After this a good dressing of lime should be applied, followed by a mulching of farmyard manure. The trees will derive benefit from this treatment the first season.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Onions.—On a fine day, when the ground is sufficiently dry and the soil in a workable condition, advantage should be taken to prepare and sow the principal bed of Onions. First make the ground thoroughly firm, and rake the surface level; then sow the seed thinly in shallow drills drawn at distances of 10 to 12 inches apart. Apply a dressing of soot and wood-ashes. Then carefully cover the seeds and again rake the surface finely. Onions raised in heat early in the year should still be grown in a temperature of from 50° to 55° F., being placed as near to the glass as possible. Any surplus plants which have not been pricked off may, if thoroughly hardened, be planted out in a sheltered position on ground of a fine tilth, in rows 1 foot apart, and the plants at distances of 6 inches from each other. Under this treatment Onions invariably make serviceable bulbs, and no amount of cold after this date will injure them, provided they have been properly prepared for exposure. Any selected bulbs intended for seeding should be planted in a sunny position sheltered from cold winds. Plant the bulbs 18 inches apart in the rows, and make the rows at distances of 2 feet.

Green crops.—February has been an exceptionally dry month in this locality. There have been no rains, but a continuance of dry, frosty weather, which has had the effect of injuring most of the green crops. Whole breadths of Sprouting Broccoli, especially the earlier varieties, have been completely destroyed, also many of the white Broccoli. Of this latter vegetable, Late Queen and Model have proved to be the hardier with us, and amongst Borecoles or Kales the least injured have been the Scotch, Cottager's, Labrador, and Chou de Russie varieties. The last-named sort received a First-class Certificate from the Royal Horticultural Society in April, 1907, after trial at Wisley. Late plantings of Brussels Sprouts have also been affected by frost. Ground that has been dug or trenched has benefited from recent weather, especially in gardens where the soil is heavy.

Seakale.—This has proved to be especially valuable now that green vegetables are scarce. Care should be taken to provide for a continuous supply by introducing successional batches into the Mushroom house or other suitable structure for forcing. Seakale may be also forced in the open should circumstances require this method to be adopted. The cuttings intended for cultivation next season should be grown gently in a cold frame. They will be ready for planting by the end of March or early in April, but care must be taken not to force them in the slightest degree.

Spinach raised last autumn has in many cases withstood the cold weather remarkably well. As soon as the conditions are favourable the ground about the plants should be weeded, hoed and given a dressing of soot, repeating these operations about every ten days. Make an early sowing of this vegetable on a south border, planting the seeds in drills drawn one foot apart. Early Spinach may also be grown on a very mild hot-bed in frames: it is surprising what a large quantity of this valuable green vegetable can be produced from an ordinary three-light frame.

Celery and Chicory.—The latest varieties should now be lifted and stored in sand or ashes under a north wall. The heads will remain in a good condition for a much longer period if stored in this way than when left in

the ground. Chicory may also be taken up and treated in the same way as advised for Celery.

Parsnips are much better when allowed to remain a considerable time in the ground, but they should now be lifted and stored in sand in a cool place.

The herb garden.—Examine the plants carefully with a view to replacing any which are becoming exhausted. Some will need to be propagated from cuttings, others by division. The herb border is an interesting feature in a garden, and it is the more interesting when it contains a large number of varieties.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

The propagating department.—Many of the stock plants intended for furnishing a supply of cuttings will now be in such a condition that the work may be commenced. There will be a plentiful supply of cuttings of such plants as *Agelatum*, *Lobelia* and *Koniga* (*Alyssum*). Zonal *Pelargoniums* that have been wintered in store pots, and are now potted singly in smaller pots, should be given warmer conditions so that they may grow rapidly and form strong plants by the time they must be hardened. Some of the autumn-rooted plants of Ivy-leaved *Pelargonium* should be allowed to develop three or four shoots and be trained as pyramids. Others may grow naturally for pegging down as a groundwork to such plants as *Fuchsias*. The pyramids will be useful as "dot" plants over a carpeting of *Violas*, *Harrison's Musk* (*Mimulus*), *Verbena*, *Phlox Drummondii*, and similar dwarf-growing subjects. Old *Fuchsias* should be started into growth and repotted.

Flower seeds.—Many flowering plants can be easily raised from seeds, and they are especially valuable when cuttings of other plants have failed to survive the winter. Tuberous-rooted *Begonias* will form good plants in the one season from seeds sown at the present time, whilst those of the *semperflorens* type are invaluable for summer bedding. Prick off the seedlings in suitably-prepared pans or boxes as soon as they are large enough for transplanting and give them a further shift into small pots when they are ready. *Petunias*, *Verbenas*, *Ageratums* and *Lobelias* can all be raised from seeds. Sweet Peas should be sown in 5-inch pots, placing five or six seeds in each pot. Germinate them in a cool house, and when the shoots are 6 or 9 inches in length, pinch out the tops in order to induce a bushy growth. It may be advisable to shift them into 6-inch pots before they are planted in rich, deeply-dug soil in the open. *Schizanthus wisetonensis* and *Nemesia strumosa* are suitable annuals for planting in the flower-beds. They should be raised in a cool house and planted out at the end of May.

Sub-tropical garden.—Some of the most suitable plants for the sub-tropical garden are *Grevillea*, *Acacia*, *Ficus*, *Canna*, *Eucalyptus*, *Musa*, *Solanum*, *Wigandia*, *Ricinus*, *Nicotiana*, *Palms* and *Ferns*. *Acacia Lophantha* is easily propagated from seeds. *Abutilons* may also be readily raised from seeds, but the most suitable plants are those about 2 to 3 feet tall, and these are best grown from cuttings, inserted during the previous summer. Two good *Abutilons* for the sub-tropical garden are *A. Thompsonii* variegata and *A. Savitzii*. The leaves of *A. Savitzii* are blotched with silver. The *Cannas* also furnish a wealth of material in their numerous varieties both foliage and flowering. Those with bronze-coloured stems and leaves are effective when intermixed with free-flowering plants such as *Petunias* or *Fuchsias*. They may also be massed for their floral effect. The best method of increasing *Cannas* is by division of the root-stock in early spring. There are several species of *Eucalypti* suitable for the sub-tropical garden. One of the best is *E. Globulus* (the Blue-gum tree). Others are *E. citriodora*, *E. Gunnii*, and *E. cordata*. All the *Eucalypti* may be readily raised from seed. The Castor-oil plant (*Ricinus*) forms a handsome subject in its beautiful foliage, especially when planted by the side of a rivulet or in the foreground of a shrubbery. It grows very quickly from seed. Those with green foliage, of which *R. zanzibarensis* is the best, are the most hardy, but they are not so pretty as the coloured varieties, of which *R. Gibsonii* is a good example.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Masdevallia.—The present is a suitable time to break up old plants, or to afford increased root room to the Chimera type of *Masdevallias*, which consists of such species as *M. Chimera*, *M. bella*, *M. Backhousiana*, *M. Wallisii*, *M. Carderi*, and *M. Chestertonii*. These plants should be grown in shallow, teak-wood baskets, as their flowers are produced from descending stems similar to those of a *Stanhopea*. No crocks are required for drainage, and only a moderate quantity of fibrous peat and Sphagnum-moss for a rooting medium, which must not be too lightly compressed. These *Masdevallias* are very liable to attacks of red spider, but this pest may be prevented by frequently spraying and sponging the under-sides of the leaves. Afford the plants the same atmospheric temperature as advised for *M. tovarensis*. Any plants of *Masdevallias* which require a cooler treatment, such as *M. Harryana*, *M. Lindenii*, *M. Veitchii*, *M. ignea*, &c., that have deteriorated through loss of roots and foliage, may be repotted at this season. It is not advisable to disturb strong, healthy plants of these species at present, but to pot them at the end of August or the beginning of September. All plants that are repotted should be kept well shaded from direct sunshine, and any flower-spikes that appear should be pinched off immediately they are perceptible.

Calogyne.—Plants of the warm-growing *Calogyne asperata* (Lowii) and *C. pandurata* may now be safely potted should they require more root room. *C. asperata* thrives well in a mixture of good fibrous loam, *Osmunda* fibre and Sphagnum-moss in equal parts, and plenty of small crocks. The fibre and moss should be cut up rather small and incorporated with the loam. *C. pandurata* grows well in the *Osmunda* and *Polypodium* mixture. When repotting the plant, it is not advisable to pot up more than two bulbs behind the leading growth. Give it plenty of room to grow, as the rhizome will extend itself several inches each year. The flower-spikes will soon be pushing up in the centre of the growths, therefore good supplies of water must be given until the new pseudo-bulbs are completed. The flower-spikes of the rare *Calogyne Sanderae*, which for many weeks have appeared to be in a stationary condition, will soon begin to develop their flower-buds. Keep the plant well up to the roof glass of the intermediate house, where it will not be exposed to the least sunshine. When the flower-buds advance afford the plant frequent waterings at the root.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Ipomoea.—Such species as *I. hederacea* and its varieties, and *I. rubro-cœrulea*, are useful greenhouse twining plants. Seeds should be sown in heat, and the young seedlings potted into light, rich soil, keeping them for a time in a warm atmosphere. When they are repotted into their final pots a heavier soil may be used, and the potting should be done firmly.

Coleus.—Cuttings may now be taken from the plants retained from last year. Insert them in sandy soil in the propagating house, and keep them shaded until they have made roots. A good percentage of desirable varieties may be raised from seeds, but the plants which appear first are almost invariably of coarse growth and poorly marked. Hence they should be rejected.

Canna.—Plants flowering in the greenhouse should now be repotted, using a rich soil. The choice varieties may easily be increased by root division, but it is necessary that each piece of severed root-stock should possess a bud and a few roots.

Tree Ferns.—During their season of active growth, Tree Ferns are benefited by a slight increase in temperature. Even when they have attained to a large size repotting is not often necessary. Should the soil in which they are growing be exhausted, and it should not be considered advisable to use larger receptacles, much of the exhausted soil may, in the case of *Dicksonias*, be removed, and the plant repotted in the same tub; the work should be done just before the new growth commences. When grown in a warm house *Cyathea*s quickly make

tall stems. When these become too tall they may be cut off to a convenient length and be placed into pots containing a few inches of soil. Such work should be done now, and these large cuttings, as they may be termed, will quickly form roots and produce surprisingly large fronds. The lower portion of the stem may be utilised for planting on it *Davallias*, *Selaginellas* and similar plants. When Tree Ferns are actively growing abundant moisture in the atmosphere is necessary, and the fronds must not be exposed to direct sunlight. Tree Ferns growing in a conservatory or other place where the surroundings cannot be kept sufficiently moist, should have their stems frequently damped during hot, dry days.

Forced shrubs.—As soon as these have finished flowering they should be removed to a warm house to complete their growth. Pick off the old flowers and any seed vessels that may have formed and prune any plants that require it, remembering that the shoots should never be cut so severely as in the case of similar species growing out-of-doors. Afford the shrubs a liberal treatment in the matter of manuring, &c., as success or otherwise in flowering next spring will depend largely on the quality of the growth made now.

Blinds.—These should be overhauled and fixed at an early date on those houses where they are needed. The sun for a few hours in the middle of the day is very powerful, even early in this season.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Early pot vines.—After the flowering is over and the young berries are swelling freely, the vines can be forced rather harder than hitherto, as both the roots and the upper portion of the vine will be in active growth. Keep a moist atmosphere by constantly spraying all available spaces in the house, also damp the paths with liquid manure when the ventilators are closed. This will assist in keeping down red spider, and be otherwise beneficial to the foliage. The roots must be liberally fed with diluted liquid manure, alternated with some approved fertiliser, given two or three times a week. Take care not to overcrop the vines or the quality of the fruits will be impaired. Six to eight bunches of Grapes on each rod will yield an ample crop. Attend to the stopping of the laterals as often as they require it, and cut out those shoots which are not wanted. The temperature of theinery at night-time may be raised to 70°. During the daytime it may reach 85° or 90° if the top ventilators are opened a little. Close the house early in the afternoon after charging the atmosphere with moisture.

Early vines in borders.—As soon as it is determined which are the best bunches, all those not required should be removed. Thinning the berries should be commenced when they are about the size of Peas. This operation requires great care and the characteristics of each particular variety need to be studied when the bunches are thinned. Black Hamburgh, although a free-setting Grape, does not need so severe thinning as *Madresfield Court* or *Foster's Seedling*. After the bunches are thinned, the borders should receive a good dressing of well-seasoned farmyard manure, the properties from which should be thoroughly washed into the soil with tepid water.

Mid-season vines.—Attend to the disbudding of these. First remove the weak, useless growths, and when it has been determined which are the strongest and best shoots, the final thinning may be done, but sufficient shoots should be left to properly furnish the trellis with foliage. Borders that are full of healthy roots should have liberal and frequent applications of stimulating manures.

Melons.—Plants which were raised at the beginning of the year should be stopped when their shoots are about half-way up the trellis. This will encourage the development of the lateral shoots and hasten the plants into flower. Do not attempt to pollinate the flowers till three or four are open on each plant, otherwise the crop will be uneven and disappointing. Pinch the laterals below the trellis at the first joint. Those which are showing fruit may be stopped at the second leaf beyond the fruit. Make fresh sowings as often as necessary. At this time

of the year ripe fruit can be had in about 12 weeks from the time of sowing. The hot-bed, which was necessary for Melon culture at the beginning of the season, can be dispensed with.

Strawberries in pots.—The earliest plants, having passed their flowering stage, must be given more liberal treatment with regard to moisture, both at the roots and in the atmosphere. Thin out the fruits to six or eight upon a truss, and securely stake and tie each truss to prevent their stems being broken. Stakes, for this purpose are furnished every season by the prunings from outdoor fruit trees. Syringe the plants two or three times every day with tepid rain water and damp the floor of the house frequently. Close the house early in the afternoon and syringe the plants at the same time. Apply liquid or artificial manure at every alternate watering. It is a good plan to have a large batch coming on slowly in a cool house. From this batch the strongest plants may be selected when they commence to develop their flower-spikes, removing them to a warmer house as required. Before removing any plants from out-of-doors, clean all dead leaves from them, and, after laying the plants on their sides, thoroughly syringe them with a solution of soft soap and sulphur in water.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Delphinium.—Young plants raised from seed sown last season may now be planted out in the borders. Slugs are fond of the young shoots, therefore care must be taken to protect them from these pests. Seeds may be sown for raising plants to furnish successional flowers. *D. nudicaule*, sown now, will produce its rich, orange-scarlet flowers in August and September. Others that will flower by the end of the summer, if sown now, are *D. cardinale*, *D. Brunoniaum*, *D. grandiflorum*, *D. sulphureum*, and *D. formosum*. It is a good plan to plant the large-growing *Delphiniums* in a nursery or reserve garden during the first season, as those with the best flowers can be selected for planting in the permanent borders.

Pyrethrum.—These hardy border plants are valuable alike for the flower garden or for furnishing cut blooms. They should now be planted where they are intended to flower.

Pansies and Violas.—Sow the seeds in shallow boxes and place them in a frame with a little bottom heat. The seeds should be sown thinly, as the seedlings are liable to damping. As soon as they are large enough, prick out the seedlings into other boxes and afford them cold treatment. Later they should be planted in the open on well-manured ground, where they will furnish a display of flowers during the summer months. Plants that were put out in the autumn for spring flowering should be examined and have any decayed leaves removed. If birds are troublesome, sprinkle the plants with water in which a little paraffin has been placed: the sprinkling should be repeated at frequent intervals.

Wallflowers.—Any blanks should be filled with fresh plants. Take care to preserve plenty of soil about the roots in transplanting, and do this work without delay, making the soil quite firm. Any of the spring-bedding plants that have failed may also be made good from the reserve garden.

Clematis.—The plants should now be pruned and made tidy. Shorten the shoots somewhat severely, and top-dress the soil as may be necessary. Mice are very destructive to *Clematis*, and it may be necessary to place traps for these pests. Among the large-flowering varieties notable kinds are *Fairy Queen*, *Gipsy Queen*, *Ville de Lyon*, *Madame Van Houtte*, *Belle of Woking*, *Alba Magna*, *La France*, *Mrs. Hope*, and *Queen Alexandra*. The free-flowering *C. montana* and its rose-coloured variety are excellent climbing plants for a variety of purposes.

Planting shrubs.—This work should be proceeded with as soon as the conditions admit. In the case of impoverished soils, some fresh material should be afforded, such as leaf-mould, road scrapings, or cow manure. The border itself should be given a top-dressing of manure. Lilacs especially enjoy this manurial assistance, and the result is seen in the superior blooms and increased growth. Conifers may still be planted.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 8—
Ann. Meet. United Hort. Ben. and Prov. Soc. at Hort. Hall, Westminster.

TUESDAY, MARCH 9—
Roy. Hort. Soc. Coms. meet. (Bulb Exh. in Hort. Hall, Westminster. Lecture at 8 p.m. by Mr. W. S. Murray, on "Bulb-growing in Holland"). British Gard. Assoc. Ex. Council meet. Hort. Club meet.

THURSDAY, MARCH 11—
British Gardeners' Association (London Branch) meet, at Carr's Restaurant, Strand. Lecture on "Insect Pests."

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—41°0'.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, March 3 (6 P.M.): Max. 33°; Min. 23°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 4 (10 A.M.): Bar. 29.3; Temp. 36°; Weather—Bright.

PROVINCES.—Wednesday, March 3 (6 P.M.): Max. 38° Ireland S.W.; Min. 29° Yorkshire.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Perennials, Border Plants, Spring-flowering Bulbs and Tubers, Azaleas, &c., at 12; Roses and Fruit Trees, at 1.30; at 67 & 68, Cheapside.

WEDNESDAY—
Herbaceous and Border Plants, Lilliums, Bulbs, and Tubers, at 12; Roses and Fruit Trees, at 1.30; Palms and Plants, at 5; Miscellaneous Bulbs, Palm Seeds, &c., at 11.30; Japanese Lilliums, at 1.30; at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

It will be of interest to recall the circumstances under which the volume (see *Gardeners' Chronicle*, December 12, 1908) entitled *The Methods and Scope of Genetics* made its appearance. About a year ago the University of Cambridge received from an anonymous source an offer to endow, for the space of five years, a professorship in biology. The offer was accompanied by a suggestion that the professorship, if founded, should, in bearing the title "The Darwin Professorship," serve to commemorate Darwin's unique services to biology.

The University, whilst accepting the generous gift, decided wisely that it could not attach the name of Darwin to a professorship the endowment of which was not permanent. But it took the step most calculated to ensure this permanency by inviting Mr. Bateson to occupy the chair. Ancient custom, which finds yet an abiding place within the venerable walls of our older Universities, decrees that a newly-elected professor shall, on assuming his office, deliver before the members of the University an inaugural lecture. To a stranger coming from some distant seat of learning, such an occasion, invested with the chill decorum which reigns in academic

spheres, might seem a distasteful, almost barbarous, relic of the method of trial by ordeal. But to Professor Bateson, at home in Cambridge and known as one of the most distinguished of her men of science, the occasion had, we imagine, no such sinister import and but served him as an opportunity for informing the world in general of recent progress in the experimental study of evolution.

Bateson's ordeal was in the years which are passed, during the patient time when, alone, and heedless of the talking Darwinians, he pursued the only way of experimental enquiry into the problems of Variation and Heredity which Darwin himself had first shown to be within the range of experimental science. The volume, embodying the substance of Bateson's inaugural lecture, must, we think, convince all who read it that the new modes of research comprehended in the term "Genetics" mark the most important and fruitful departure from the conventional methods of enquiry which has occurred in recent times. It justifies the high claims put forward not so long ago by Bateson himself on behalf of the discoveries associated with the name of Mendel; and it is a splendid record of the work which we owe to Bateson and his colleagues—Mr. Punnett, Miss Saunders, Mr. Doncaster, Miss Durham—as well as to other workers, such as Mr. Hurst and Professor Biffin in this country, and de Vries, Correns, Tschermak, and other investigators in foreign lands.

The term Genetics was proposed, as our readers are aware, by Bateson himself as a more comprehensive substitute for the older descriptive phrase, "hybridisation and plant-breeding." To quote his own words used during an earlier inaugural address, namely that given at the opening of the Third Conference on Hybridisation and Plant Breeding, called by the Royal Horticultural Society in 1906:—"The study of hybridisation and plant-breeding . . . has become a developed science, destined, as we believe, not merely to add new regions to man's knowledge, but also to absorb and modify profoundly large tracts of the older sciences . . . the science itself is still nameless, and we can only describe our pursuit by cumbrous and often misleading periphrasis. To meet this difficulty I suggest . . . the term Genetics, which sufficiently indicates that our labours are devoted to the elucidation of the phenomena of heredity and variation: in other words, to the physiology of descent."

The new name was well chosen. It has stood the test of time and has passed not only into our language but into the languages of the civilised world. The new name was wanted, for it marked the introduction of a new method.

The new method was discovered by Mendel, whose work, forgotten for a time, was brought to light again by de Vries and other investigators. To no one more than to Bateson is it due that the work of Mendel has served as a model and an inspiration for modern research in Genetics.

There is no need, in this place, to describe the discoveries which Mendel made. They have been recounted with characteristic vigour by Professor Bateson and by his pupils. One aspect of Mendel's work deserves, however, more prominence than, as far as we can remember, it has yet received.

Judged by his experiments and by the theory of segregation which he built on the results of his experiments, Mendel was a genius among men. But he showed his genius most by beginning at the beginning. His predecessors had grown grey and weary in the endeavour to discover how the almost infinite complexity of one organism, the offspring, compares with the equal complexities of the parents. The task was superhuman. They failed. Mendel, recognising intuitively that the complex of characters—whose sum is the individual—is made up of a series of simple characters, fixed his gaze on those individual, simple characters. His genius manufactured common sense. By the study of the simple characters individually he showed that law and order reign in inheritance. Into the eager hands of Bateson came the Mendelian key. He and his pupils and co-workers first verified the results of Mendel's experiments and then set themselves to solve the more complex cases which, unsolved, seemed to limit the application and use of the new knowledge.

What striking success has followed upon their efforts readers of the *Evolution Reports* and of the inaugural lecture may learn. Foremost in interest from a horticultural standpoint is the discovery of the meaning of reversion. Tall Sweet Peas breed true. Of dwarf Sweet Peas both "Cupids" and "Bush" breed true. Now Cupid crossed with Bush gives Tall. The explanation is of the simplest, Cupid is tall minus something; "Bush" is tall minus something else. In other words Cupid, in sporting out of tall, did so by losing a certain factor which made for height. Bush, in arising from Tall, did so by losing another factor, which also made for height. When Cupid and Bush are mated together each supplies one of the missing links of tallness and both necessary factors for tall are thus present in the offspring, which are therefore Tall.

Similar results have been obtained by Bateson and Punnett in the case of flower-colour of Sweet Peas. Two white plants, though breeding true when selfed, may give, when crossed, purple-flowered offspring. The albinos each lack one of the two necessary factors for colour: one albino lacks one, the other the other colour factor. Coming together they supplement each other's deficiencies and colour results "by reversion." As shown by Hurst in a recent issue of this *Journal*, the facts are substantially the same in albino Orchids. The mysteries which have so long enshrouded the mode of inheritance of colour in flowers are slowly disappearing and the laws of such inheritance are discovering themselves.

When a theory admits of the replacement of vague and indefinite ideas by precise and definite conceptions—and this is what the Mendelian theory does in the case of reversion—it proves its value as an instrument of thought. Those who refuse to profit by the aid of such vindicated theories must be content to remain behind in the march of progress. Though we have devoted considerable space to the subject of reversion because of its horticultural interest, it must not be supposed that this is the only or chief matter dealt with in the pages of the volume on Genetics. A theory of the nature and inheritance of sex, based on Mendelian studies and

supported by weighty evidence, is brought forward, and evidence of the dependence of structure on chemical constitution is offered. For an account of these and other subjects of equal interest we must refer our readers to the work itself.

It is unnecessary to say that the most careful perusal of "The Method and Aims of Genetics" will repay all who are concerned with the work of hybridisation and of plant-breeding. Those, too, who are interested in the wider aspects of the science of Genetics will find much which will compel their careful thought, for Professor Bateson does not shrink from indicating that this new knowledge obtained by breeding experiments with plants and animals has bearings of the most profound importance on the welfare of the race and on the treatment of social problems.

Horticulturists, more perhaps than any others, have the right to congratulate Professor Bateson on the constant care and success with which he has ministered to the growth and education of his god-son Genetics.

ROYAL HORTICULTURAL SOCIETY.—The next meeting will be held on Tuesday, March 9. At 3 o'clock a lecture on "Tulips and the Tulip Mania" will be delivered in the lecture room by Mr. W. S. MURRAY.

HORTICULTURAL CLUB.—The next House dinner of the Club will take place on Tuesday, March 9, at 6 p.m., at the Hotel Windsor. Professor BOTTOMLEY will further discuss the question of "Soil Inoculation," in reply to Mr. CHITTENDEN's criticisms in the *Journal of the Royal Horticultural Society* based on the Wisley experiments. Mr. CHITTENDEN will be present and take part in the discussion.

THE ROYAL SOCIETY.—Among the 15 names of gentlemen nominated by the Council of the Royal Society for election to the Fellowship of the Society are those of Mr. A. D. HALL, Director of the Rothamstead Experimental Station, and Dr. A. B. RENDLE, Keeper of the Department of Botany, British Museum.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this Society will be held at the Horticultural Hall, Vincent Square, S.W., on Monday, March 8, at 8 p.m.

THE NATIONAL HORTICULTURAL SOCIETY OF FRANCE has recently held its annual election of officers and committees. We understand that Mr. HARMAN PAYNE has the unique distinction for a foreigner of being appointed a member of the Floral Committee of the society's Chrysanthemum section.

WEED-KILLERS.—Under the title "Weed-Killers and their Application," Mr. F. PILKINGTON SERGEANT publishes, in the *Pharmaceutical Journal and Pharmacist* for February 20, the first of a series of articles on "Horticultural Preparations." Mr. SERGEANT classifies the weed-killers in general use into the highly poisonous arsenical compounds and the so-called non-poisonous compounds. He gives recipes for the preparation of the more serviceable arsenical weed-killers from which we give the following details:—Arsenious oxide, 1 lb.; sodium hydroxide, 1 lb.; water, six pints. The mixture is boiled till clear, diluted to one gallon, and then to it is added any suitable aniline dye to serve as a warning colour to the user. This concentrated solution is diluted, before use, with 98 per cent. of water. A gallon

of the diluted liquid suffices for four square yards of path. It is recommended that (1) the paths should be sprayed with the preparation during dry weather, preferably on a warm, sunny afternoon; (2) during the spraying, the borders of the paths should be protected; (3) the paths so treated should be swept on the following morning in order to avoid disastrous consequences to birds, &c. This precaution has the additional advantage that thereby the worms, which have died on the surface, are removed. Of the so-called non-poisonous weed-killers, those in most frequent use include crude hydrochloric acid diluted with 40 parts of water; 4 per cent. of sulphuric acid; and 1 per cent. sodium hydroxide. These substances are, of course, poisonous, and should not be used by anyone not conversant with their properties. Rock salt and lime powdered and sprinkled on the paths are effective, but have the drawback of disfiguring the paths temporarily. Among other materials mentioned are lime and sulphur in the proportions of 8 ounces sulphur, 8 ounces lime, and one gallon of water; the mixture to stand for 24 hours and to be diluted with one gallon of water. This mixture is very effective on cinder paths, but is apt to discolour porous tiles and paths dressed with red-sandstone gravel. As will be seen from the foregoing, Mr. SERGEANT'S article is very valuable, and may be commended to all who have the care of considerable areas of paths. It insists, very properly, on the danger of the indiscriminate use of the highly poisonous arsenical compounds. At the risk of repetition, we would point out that those desirous of using any of these poisonous substances should first inform themselves of the properties of the substances and of the precaution to be adopted in their use.

BOARD OF AGRICULTURE LEAFLETS.—These are now issued in sectional form, the pamphlets relating to kindred subjects being bound together in separate volumes. That on "Fungi Injurious to Farm and Garden Crops" contains a very complete description of the American Gooseberry-mildew disease, and is illustrated with coloured pictures showing the disease in its various stages. Others of the greatest use to the gardener are those entitled as follows:—"Fungi Injurious to Fruit and Fruit Trees," "Insect and Other Pests Injurious to Fruit Trees and Bushes," "Insect and Other Pests Injurious to Farm and Garden Crops," "Forest Trees and Their Diseases," "Manures and Feeding Stuffs," and "Cultivation of Fruit Trees and Farm and Garden Crops." The cost of each volume is one penny, and they can be had post free from the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W.

EXHIBITION OF BULBS AT HILLEGOM, HOLLAND.—In April next an open-ground flower show will be held at Hillegom, Holland. This kind of show was a great success last year at Sassenheim. The principal idea is to show how to obtain the best results from planting Dutch bulbs in small and large gardens, in borders, terraces, and lawns, and to make the most effective combinations in beds and groups, combined with evergreen and early-flowering shrubs. The show ground occupies more than three acres and is divided into two parts. One part will be a French garden and the other part an old Dutch garden. In the centre of the old Dutch garden is the town hall, an interesting, old-fashioned building, just opposite which is the church situated on a hill near a small brook (old Dutch "gom"—hence the name Hillegom). The church was erected in the fifteenth or sixteenth century. A draining mill which can be seen from the show ground is used to pump the water from the low land into the leading canal. There is a beauti-

ful view from the steps of the town hall over the bulb fields in this drained land into the low-lying, green, peasant lands of the old Haarlem Lake. The show will be divided into a permanent exhibition in the open, and temporary shows in large tents—the latter being intended for cut flowers and forced plants. Cultivators of Rhododendrons, Lilacs, and clipped plants (Forms), &c., will also exhibit their best products, so that the show will be interesting for florists and nurserymen as well as for amateurs. The opening date is fixed for April 8, and the exhibition will close at the end of the first week in May. The great international exhibition of bulbs will be held next year at Haarlem.

DISEASE RESISTANT COFFEE.—For many years past the existence of *Coffea arabica* has been menaced by the disease, due to the fungus, *Hemileia vastatrix*. No effective cure or prevention of the disease has as yet been discovered, and, mainly for this reason, the Coffee plantations of Ceylon have almost totally given place to Tea culture, whilst plantations of Java and Madagascar yield less produce each year. Liberian Coffee (*Coffea liberica*) is better able to withstand the malady, but its market value is less than that of *C. arabica*, and, therefore, the planters have not adopted it to any great extent. Hybrids of the two species have so far failed to yield any useful results. A new species, discovered growing wild on the shores of the Oubanghi, Central Africa, by M. DYBOWSKI, and named *C. congensis*, which has been grown since 1903 in the botanical garden at Ivoloïna, has so far remained free from disease. Its market value is stated to be fully equal to that of the best qualities of Arabian Coffee. Whilst the present crop of *C. congensis* has not suffered from the disease, *C. arabica*, planted at the same time, has been entirely destroyed.

FRUITS FROM CAPE COLONY.—The Government of this colony has instituted a scheme for the inspection of fruits intended for export, and those consignments that satisfy the requirements are branded "Passed by Government Inspector." The Trades Commissioner for the Cape of Good Hope has been informed from Cape Town that shippers of fruit who have not agreed to the conditions of the Government inspection scheme are branding their boxes with the words "Extra Selected" and "Selected," which are the terms used to indicate the grades of fruit shipped under that scheme. The Trades Commissioner desires to point out that any Cape fruit so branded upon which do not also appear the Government inspector's stamp with the Arms of the Government of the Cape of Good Hope and the words "Passed by Government Inspector" is not shipped under Government inspection.

THE "RETROSPECTIVE" CHRYSANTHEMUM SHOW IN PARIS.—This exhibition was a great success, and the credit of its organisation must be accorded to M. GEORGE GIBault, the able and learned librarian of the National Horticultural Society of France, assisted by his deputy, M. LE TEXNIER, and several other members of the society. As this was the first retrospective flower show ever held, it has been asked to what will the next one be devoted. Another dealing with some other flower is sure to follow. In the meantime we have heard the question asked: A retrospective Chrysanthemum show cannot be held in England? As a souvenir of the show, the National Horticultural Society of France decided to strike a special commemorative plaque d'honneur to be awarded to the two principal exhibitors, M. RENÉ MOMMÉJA and Mr. HARMAN PAYNE.

"LE CHRYSANTHEME."—This interesting publication, the official organ of the French National Chrysanthemum Society, has reached its 110th number. It contains an article on "Le Chrysanthème, Fleur du Japon" (illustrated) by M. MOMMÉJA, notes on the Chrysanthemum "retrospective" show at Paris by M. NONIN, an account of the Paris show (illustrated) by M. G. CLEMENT, a continuation of the report of the congress at Tours, and other matter.

HORTICULTURE AT THE WHITE CITY.—Mr. W. H. ADSETT has been appointed hon. secretary to the horticultural and agricultural section of the Imperial International Exhibition to be held at Shepherd's Bush. It is intended to hold two international flower shows during the season. Several of the leading continental firms are arranging to provide specimens of their bedding-out, and it is hoped to secure an adequate British representation. Full details may be forwarded by the hon. secretary, Administrative Offices, London, W.

HORTICULTURAL SHOW AT SOUTHPORT.—The Royal Lancashire Agricultural Society will again hold a horticultural exhibition, owing to the success which attended the show at Manchester last year. The exhibition will be held at Southport, and Mr. PETER BLAIR has been appointed manager.

PUBLICATIONS RECEIVED.—*Kew Bulletin of Miscellaneous Information.* (No. 1, 1909). (London: Wyman & Sons, Ltd.) Price 2d.—*The Queensland Agricultural Journal.* (January). (Brisbane: Anthony J. Cumming, Acting Government Printer).—*The Transvaal Agricultural Journal.* (January). (London: West, Newman & Co., 54, Hatton Garden, E.C.).

VEGETABLES.

SCARCITY OF GOOD WINTER VEGETABLES.

OWING to the severe frosts the green crops have been much damaged, and prices for all green vegetables are, in consequence, much above the average. Leeks appear to have gone off badly, doubtless owing to the mild season of last year causing the growth to be soft. I do not consider sufficient use is

made of such vegetables as Celeriac. This should be sown early, like Celery, and when lifted, packed in soil or sand in a cold store that is just frost-proof. Celeriac is a delicious vegetable in season from November to the end of April, and it is not only valuable as a cooked vegetable, but also, like Beetroot, for salads. Frequently, in a severe winter, Celery is badly injured by the cold, and then Celeriac is doubly valuable. Chicory is not often used as a green vegetable, but it is by no means an inferior one. It should be forced so that the top growth is compact and somewhat like Seakale before it opens out. Chicory grows so readily, that it is worth a trial. The Witloof or Brussels variety gives the largest crown growths, but too much heat should not be employed in forcing, otherwise the top growth is weakened. Cooked as is Seakale, and served with melted butter, it is an excellent winter vegetable, and may be had at a small cost from December to May. The Cardoon is worthy of more attention as a winter green vegetable. Although, to obtain extra fine heads, special culture is necessary, good Cardoons may be had at a small cost by sowing the seed in small pots in frames and planting the seedlings out in trenches, afterwards blanching and finally lifting them in November, or at the approach of frost. They will remain good for a considerable time if lifted carefully and placed where frost cannot injure them. Excellent roots may be had by sowing in the open in trenches in light soil, or on the flat in the case of heavy land, late in April or early in May. A distance of 18 inches from plant to plant and 3 feet between the rows will allow of the growth of stalks sufficiently long for any purpose, and these I find are more hardy than the larger ones started under glass. The Cardoon is a gross feeder and requires plenty of moisture. I recently saw French-grown Cardoons in Covent Garden Market, and these, at wholesale price, realised 10s. per dozen. Endive, such as the large, round-leaved Batavian, grown in quantity for winter supplies, makes a splendid green vegetable, and though by no means hardy, with timely shelter or lifting into a cold house, will give variety. For cooking purposes it should not be blanched, but grown as hardy as possible, and it is surprising what a lot of good edible material a well-grown plant contains.

For years I have advocated growing the distinct varieties of Winter Cabbage. These I have always found hardy, as having a short leg or stem they better escape damage by frost. Such kinds as Christmas Drumhead, St. John's Day and Little Gem are most valuable in seasons like this. They are somewhat like a small Drumhead Cabbage, the hearts being remarkably firm and of excellent edible quality. Those sown in the summer for winter use are most valuable, because they have few waste leaves and the hearts are much protected.

Spinach Beet, sown on a well-drained border in August, will give a good supply of green leafage, and though liable to be damaged by frost, I have found a little loose litter sufficient to protect them and to preserve the winter supply. The plant is much hardier than many people imagine.

Roots enter largely into the winter supply, and Scorzonera and Salsafy are both valuable. Scorzonera is not grown so extensively as Salsafy, but both are useful winter roots, as they furnish a supply from November to April. Their cultural requirements are simple, and they may be grown in a not over-rich soil. The yellow-fleshed Turnip is of greater value than the white in such seasons as this, being more solid and a better keeper. As regards Potatoes, those who have room for the Black Congo and the Fir Apple varieties would find them a welcome addition at this season, as they give variety. The small but delicious Stachys tuberifera or Japanese Artichoke is excellent fried in butter and served on toast. The White Artichoke should not be overlooked, being a good winter vegetable. *G. Wythes.*

NELUMBium SPECIOSUM VAR. OSIRIS.

(See Supplementary Illustration.)

THIS very beautiful variety of the Lotus family flowered in Gunnersbury House Gardens during last summer. I had previously cultivated several varieties of *Nelumbium speciosum*, but the opportunity was taken to make a fresh trial with some of the best. Upon the previous occasion I attempted to acclimatise them in a heated tank out-of-doors during the summer months. I tried this with all possible care for three seasons, but the rhizomes gradually became weaker and weaker, and I had to give up the attempt. The plants produced strong, healthy foliage, but rarely a flower of good quality. Last year the plants were cultivated under glass, and the results were much more satisfactory. The varieties of *N. speciosum* are truly noble plants, both in foliage and in flower, being quite a feature during the season. There are, in all, some 15 varieties of *N. speciosum* described in the French and German catalogues. These vary in colour from pure white to rose and crimson shades, some having double and some single flowers. The best six, in my opinion, are *N. speciosum* var. *Osiris* (the illustration shows the flower natural size); *N. s. album* (pure white); *N. s. album plenum*; *N. s. Shiroman*; *N. s. japonicum roseum* (rosy-lilac with white base); *N. s. Pekinense rubrum*, perhaps the finest red; and *N. s. roseum plenum*, with large double, deep pink flowers.

Our plants are grown in tubs of from 24 to 28 inches in diameter and about 10 inches in depth. The tubs are first crocked as for any other plant and then a layer of turfy loam is put on, which, with a thin layer of finer soil, some under and some upon the rhizomes, is all that is needed. The finer soil might contain with advantage a small proportion of leaf-mould and some coarse sand or shingle. The plants were cultivated in a house heated much the same as a stove during the season of growth, but a little more air was admitted when the foliage had matured. By having a hole at the side of the base of each tub the water could be changed occasionally; afterwards the tubs were filled again to the rims.

Each flower will last from four to six days, but the buds are also very beautiful. A free use of the syringe is sufficient to prevent red spider, which appears to be the only insect-pest to trouble them. Only three rhizomes were placed in each tub and this number is ample. So far, they have not been examined since they were stored in a temperate house last autumn, but I think I shall take them out and replant them before they start into growth.

During a holiday last summer I saw a pool of the type (*N. speciosum*) luxuriating in a sunny position in the garden of one of the largest hotels at Lugano. This was early in August, and the flowers were then coming on; I counted some fifteen or sixteen that in a few days would make a fine display. I have seen them out-of-doors at the Villa Carlotta on the Lake of Como. Last year also I saw cut flowers of the same (*N. speciosum*) in the florists' shops at St. Moritz. These had evidently been cut in the bud stage, and by so doing it is possible to keep the flowers fresh much longer. The supply of the cut flowers is from Italy, as I was informed by Mr. Leopold de Rothschild, who takes a great interest in these plants.

The essential is a very warm and sunny position, such as prevailed where I saw them growing out-of-doors. In this country we can hardly expect to succeed with *Nelumbiums* except in the most favoured conditions, or under the protection of glass.

First-class Certificates have been awarded by the Royal Horticultural Society to *N. s. album plenum* (shown as *N. s. Shiroman*), August 27, 1901, and *N. s. Osiris*, July 21, 1908. In each case flowers were exhibited from these gardens. *Jas. Hudson, Gunnersbury House Gardens, Middlesex.*

FORESTRY.

TREATMENT OF PLANTATIONS WITHOUT REGULAR THINNING.

We have from time to time published notes from our correspondent Capt. Henry Rogers on this subject. The system of treating plantations without regular thinning was adopted by him in 1857, and in 1894 we published a note on the subject. Since then Mr. Rogers has kept us informed of the results, contributions on the subject having appeared in our issues of June 17, 1905, p. 386, and December 8, 1906, p. 388.

Mr. Rogers now writes:—"The last cuts, 20 feet wide leaving 80 feet of trees unthinned, were made in May, 1895. These cuts were planted with three rows of trees, 6 feet between each row. The centre row was formed of Silver Fir, there being a distance of 12 feet between

high. I intend, ultimately, to have the Larch which remain among the Douglas Fir cut out, and I hope that the Firs will develop without side branches. This season we have planted 50 trees of the Douglas Fir to fill vacancies caused by the death of trees planted in previous years. The young Douglas Fir trees have a tendency to form more than one head. We are careful to remove these in the month of May."

NOTES FROM A "FRENCH" GARDEN.

Work in the French garden has been greatly interfered with by the cold weather, but the making of the hot-beds can be proceeded with in frosty weather, especially if all the materials have been prepared beforehand. During cold mornings the manure should be brought into the frame ground and placed about the frame to keep up the temperature therein. It is

heat should be too great and destroy their germinating powers.

Cauliflowers sown early in February are growing well. They must receive abundance of ventilation whenever the weather permits, for every effort must be made to have them sturdy. We do not intend to plant Melons under cloches this year, as the results are not always satisfactory. Instead we shall use the bell-glasses for a crop of Tomatos, which will be planted early in May. The seeds have already been sown on a mild bed, originally prepared for our first sowing of Lettuces in January. The manure of this bed has been turned over, and some fresh material added. We have sown 50 seeds under each cloche in a rich loam. The seedlings will be pricked off in the middle of March in frames that have previously housed a batch of Lettuces, which will have been harvested by that time.

Melons to succeed Passion Lettuce grown in cold frames should now be raised from seeds. The frames will be at liberty for the

FIG. 68.—VIEW OF THE CYCLAMENS AT READING. (See p. 149.)

each tree; the other two rows were Beech, at 6 feet apart. In May, 1905, I thinned the Larch trees in the thick parts to 8 feet apart, felling any that had scars on them in case they should be affected with the Larch disease. On November 20 I planted 400 Douglas Fir, that were 2 feet to 2½ feet high. There was some delay in receiving the trees, caused in their transit, and the roots suffered, resulting in the death of some of the trees. In 1887, when this plantation was 30 years old, a Douglas Fir was planted among old Oak and young Larch trees. This Fir grew up amongst the other trees without any large branches, and became, in 1907, as high and as large as the Larch near it which had been planted 30 years before. This induced me to plant Douglas Fir at distances of 6 feet from any other tree and 6 feet from each other. In November, 1906, I planted 493 trees of Douglas Fir from 2 feet to 2½ feet

not advisable to allow the mats to remain on the lights after 8.30 a.m., even though frost is present, because the plants would become drawn in the dark. The crop of Lettuces under the lights are growing well; they should have any of the outer decayed leaves removed as soon as opportunity permits.

We have sown our first batch of Endive on a very hot bed, composed of three-quarters fresh manure and one quarter old. We generally sow a pinch of seeds when the heat has reached the top of the bed in order to test if the conditions are suitable. If the seeds germinate well within 48 hours, the conditions are favourable for sowing, and the seed should be scattered very thinly. The manure around the frames outside must be changed every week. The mats are kept over the lights until the seeds germinate. Some do not place the seeds below the soil, but on the surface, in case the

Melons early in April. They are set on a bed of manure 2 feet high after treading, and sufficient is placed to accommodate one light. The manure is made level, and mats are placed around the beds to shelter the frames from the wind. A layer of soil is placed in the frames, and the seeds are sown 1 inch apart either way in the centre of the frame. The glass is covered with mats until the seeds germinate. As soon as the seedlings appear they should receive as much light as possible, and, in the middle of the day, whatever the weather may be, a little ventilation on the side opposite to that from which the wind is blowing. This is necessary to change the atmosphere in the frame as well as to harden the young plants.

Next week we shall sow our main batch of early Celery, using the variety Chemin. For a winter crop we use Green of Paris. *P. Aquaticus.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE R.H.S. DAFFODIL CLASSIFICATION.—I would like to make a few remarks on Mr. Engleheart's article on the R.H.S. Daffodil Classification which appeared in your issue of February 20 last. First, his opening paragraph about the constitution and procedure of the special committee is misleading. I have a copy of the minute of the Council before me, and the name of Mr. P. R. Barr was not included. Probably, remembering the services of Mr. W. Barr at the time of the last Daffodil Conference, they chose him instead of his brother, as both of them are recognised by all Daffodil people as high authorities. Secondly, Mr. Engleheart ignores that part of the introductory remarks appended to the classification, in which it is distinctly stated, "If the principle involved in the present list should find acceptance, it is intended in a future edition not only to correct and modify the arrangement according to further experience, but also to indicate which varieties are considered to be self-yellow and self-white, large and small trumpets, &c., &c." This surely fully answers his remarks, and also those of Mr. Bliss (see p. 139) about Division 7, and the making of a special class for pure Poeticus varieties. Every division can be subdivided very easily, almost to any extent. To me the practical and, of necessity, debatable point will be how far such subdivision is to be carried. Thirdly, I cannot follow Mr. Engleheart in his comparison of the present classification of the R.H.S. with the botanical one of Mr. Baker, and the semi-botanical one of Mr. Peter Barr. He might as well compare the purely florist classification of Tulips with that of the same Mr. Baker published in the *Journal of the Linnean Society* (vol. xiv., p. 275). I would rather compare it with the colour classification of the Sweet Pea Society. It does not profess to be in any way natural or botanical, and so I think it will avoid many possible pitfalls. "It is for garden and show purposes." Personally, I regard it as one-seventh garden and six-sevenths show. Fourthly, some such authorised list of flowers was badly wanted. There is no recognised standard or classification in existence; and I would ask Mr. Bliss and Mr. Engleheart whether Peach should be shown as a "Medio" or a "Parvi," or whether Mr. Goodwin's Arnold Rogers is a "Magni" or a "Medio," and then, when they have answered according to their lights, why the exact opposite should not be held by myself? There is no National Daffodil Society, and I hold that the R.H.S. ought to take the lead, and that, in doing as it has done, it has done a great service to those who exhibit flowers. The classification is not complete, and it will take time to arrive at anything approaching perfection. Rome was not built in a day; neither can anyone conversant with the difficulties of pigeon-holing the huge number of old and new Daffodils expect it to be done at once. The issuing of some list which, to give it its lowest value, may be taken as a basis on which to build up a more perfect scheme is in itself the best thing that could have happened. Had the R.H.S. waited until a more complete list had been made, it is highly probable that Daffodil shows might be a thing of the past before it ever saw light. *Joseph Jacob.*

VEGETABLE PRIZES AT SHREWSBURY.—The esteemed secretaries are evidently under a misapprehension as to the rules of the seed trade in relation to the selections and names adopted by a particular firm. They conclude that any seedsman will have in stock any of the seeds named in the Schedule Classes 109 to 126, but I do not know of any seedsman in the kingdom other than the firms named in the schedule who has them. If I apply to my seedsman for seed, from such firms as named, of "Moneymaker" Tomato or of "New Standard" Carrot, he will tell me that he does not stock varieties under those names, but that he has superior sorts with other names. If I ask him to obtain from the said firms the varieties as named in the schedule he will probably decline to do business in that way. But if he does so, it is obvious that he must obtain the seeds from these firms, and whether I get them directly or indirectly

through my seedsman, the principle of compulsion is there plainly enough, and the new conditions of the society are essentially violated. Mr. E. Murrell, in his classes, makes no conditions. His offers are most honourable. Will Messrs. Pritchard & Sons and Mr. John Wilson say whether "Selected Champion Onion," and "Excelsior" are other than selected globular forms of Ailsa Craig? I do not know whether all of Messrs. Baker's Sweet Peas are in commerce. As to the Eckford Peas, they are all in commerce. *Vegetable.*

—Instead of being censured and criticised for the alterations in this schedule, which I consider undoubted improvements, the committee and hon. secretaries are to be congratulated. By their action they have come into line with the Royal Horticultural Society and the Royal Caledonian Horticultural Society. I have often wondered why they did not do it years ago! *William Cuthbertson.*

—I am well aware, from personal experience of the inner workings of a horticultural society, that flower shows often owe much to the trade. The officials are usually ready to acknowledge that help, whether it be in the form of subscriptions or exhibits. Until enlightened by Mr. Sydenham's letter in your last issue, I was of the opinion that the object of the trade was to secure a good advertisement for their wares, but it seems that they are actuated by the benevolent object of "encouraging gardeners to do their best in friendly competition!" *A. C. Bartlett.*

STOKING GARDEN FURNACES (see pp. 379, 417, vol. xlv.).—By smothering a fire with coal, a great quantity of the combustible gases escape without being consumed. On one occasion I was stoking a crucifix boiler, and the damper had been shut rather close, so that the coal had not burnt through. When I broke the coal which had coated together on the top, the flame caused an explosion of gas, which had accumulated in the top chamber of the boiler, and I was blown against the stoke-hole wall. In stoking, much depends upon the kind of fuel that is used. Small coal, such as is employed in the North of England, is the most difficult to regulate. Anthracite coal gives no trouble if there is a good draught in the furnace, but when all the advantages are considered, coke is one of the most satisfactory fuels. I agree with Mr. Jenkins (p. 417, December 12, 1908), that different boilers require different treatment, but neither Mr. Jenkins nor the writer (on p. 379) mentions the most essential points in stoking. The heating capacity of the boiler must be first considered. Some years ago trials were made to ascertain the number of feet of 4-inch pipes a boiler was capable of heating, but the trials were made in comparatively warm weather, and the flues of the boiler were quite clean. The same boiler would not heat on a frosty night more than half the cubic space that the trial credited it with, especially if the flues, tubes, &c., were not clean. Herein lies the great advantage of the upright tubular boiler, for there is no chance of the tubes becoming coated with soot. Notwithstanding this, I do not agree with Mr. Jenkins as to their superiority over horizontal boilers. I have stoked two of the largest upright tubular boilers made by the Thames Bank Iron Company. They required a large amount of fuel, and were eventually replaced by horizontal, terminal saddle boilers, with the result that there was a great saving of fuel. The heating power of these upright "tubulars" was very great. On one frosty morning I started big fires under them at about 4 a.m., and after attending to the other fires I found two boiling fountains; the 2-inch safety pipes through the roof were throwing out boiling water at a tremendous rate. In stoking, the first thing is to keep all parts of the boiler thoroughly clean, and if this is entrusted to an ordinary labourer or stoker, it is a matter of chance whether it is done properly. An inexperienced man was sent to clean out a boiler and the flues, and after he had finished I cleared out nearly as much soot and ashes from the side flues as he had taken out. The great secret of an efficient boiler is in the setting. The flowpipe should have a good rise and a sufficient fall for the return, so as to set up a pressure of cold water at the bottom of the boiler. The pipes through the houses need have

no more rise than is sufficient to prevent an accumulation of air at the joints. When the water in a boiler or pipes begins to "kick" or "jump," it is a sign of faulty arrangement. In regard to "feeding" a furnace, I was taught, in the case of a saddle boiler, to push the burning fuel to the back and to fill up the front, but sufficient fuel should be left on the bars to cause combustion. If treated as recommended at p. 379, there would be a danger of getting an air space at the back, and this should be avoided at both the front and the back. The most economical method of stoking is to well fill the furnace and leave the damper out to the fullest extent until the fuel has burnt bright, then shut off the draught below and put the damper in, leaving sufficient space only for the smoke to escape. A most successful cultivator once said that by doing his own stoking he saved more than he could make by giving his attention to the plants. Now that fuel is so much dearer, it is of great importance that stoking should be done economically. *A. H.*

TÉLEMLY SWEET PEA FOR WINTER FLOWERING.—These charming flowers are useful for decorative purposes at a time of the year when other flowers are scarce. The seeds should be sown in pots early in September, and the plants placed in a fairly cool greenhouse before the advent of frost. They will yield a wealth of flowers from the end of January onwards. Care must be taken not to give them too much artificial warmth, or the dropping of the flower-buds before expanding will be the result. *L. E. Walker, The Gardens, Barton Hall, Bury St. Edmunds.*

EUPHORBIA JACQUINIÆFLORA.—The excellent plants of this species staged by Mr. Prime at the meeting of the Royal Horticultural Society on January 26, were admired greatly by all who saw them. The plants were not only remarkable for their brilliant inflorescences, but also for the vigour and wealth of the foliage which was present on the stems down to the soil—ample testimony that they had received proper cultural treatment. The cuttings from which the plants were raised were not inserted until June, thus proving that a long succession of flowering may be maintained by successional propagation. This is, of course, widely practised in the case of *E. pulcherrima*, with this difference, that while late propagation of the latter species invariably means loss of stature and, usually, size of the coloured bracts, the plants of the subject of our note were not affected in these respects. Those who cultivate this plant for winter blooming cannot too often be reminded that no class of soil, nor admixture of soils, can possibly counteract the mischief caused by over-watering. What constitutes over-watering will, of course, depend upon the subject itself, but the soil in which sparse-rooting laticiferous plants such as this *Euphorbia*, are grown, should always be on the dry rather than the moist side. One frequently notices peat soil used for this plant, but a far greater degree of vigour may be secured by the use of a rather strong loam, freely interspersed with finely-pulverised old plaster. When such has not been available I have used with much success burnt clay finely broken up, adding sand freely and a little leaf-mould. Firm potting is necessary, and so is ample provision for drainage. So impatient are these shrubby *Euphorbias* of much root moisture that applications twice weekly during the growing season will often suffice. The best cuttings for propagation are obtained from planted-out specimens that have had no moisture at the roots for a month or six weeks at least. Where pot-grown plants have to be relied upon for cuttings, a similar period of rest in a dry, warm house should be afforded, the plants being cut back in each case below the region of flowering. Much the best cuttings are those taken from the leaf axils, cutting them out with a heel attached, by means of a sharp knife, plunging the bleeding base into dry silver sand, and inserting them forthwith. Cuttings produced from the tops of branches, or young shoots, and, in particular, such as are produced in great heat and moisture, often damp off quickly. Sand, loam, and finely-powdered brick-rubble in equal parts is a suitable mixture for the cuttings which, if inserted under a bell-glass and placed in a bottom heat of 75°, will form roots within a month. *E. H. J.*

APPLE SCAB (see p. 123).—Our trees have been sprayed for several years, and people remark how clean they appear. The amount of "scab" on the fruits is reduced the first year after spraying, and this pest can eventually be got rid of altogether if the treatment is continued. I advise the spraying to be done in November or December, and again in February, using an alkali wash. The spray should be fine and thoroughly applied; a fine sprayer attached to a length of hose is the best means of securing an even distribution of the fluid. It will need one man or a boy to work the pump whilst another man manipulates the hose. In this manner a large number of trees can be treated in a few days. *W. A. Cook, Leonardslee Gardens.*

A WARNING TO ROSE BUYERS.—On the 24th ult. at Tywyford, Berkshire, there were three men hawking pot plants and Rose trees. Being a rosarian, I looked at the trees, all named, tied, and the roots nicely packed. Seeing so many labels, I wondered what varieties they had; amongst the many names I saw John Hopper, Crimson Rambler, Dorothy Perkins, Gloire de Dijon, Marechal Niel, and many other well-known Rose names. On examination they were, without a doubt, all "Rosa arvensis," one of the many Dog Roses. Surely a stop should be put to such dishonest hawking! *Elisha J. Hicks.*

POLYSTICHUM ACULEATUM GRACILLIMUM DRUERYI.—In the note accompanying the figure of this Fern (see p. 98), we are vouchsafed the interesting information that another plant, from the same sowing and the same parent, is also possessed of no fewer than four names, i.e., *Polystichum aculeatum pulcherrimum Drueryi*, three being the same as in the sister plant. The fact that both plants received a First-class Certificate from the Royal Horticultural Society brings us to the pertinent question what the Floral Committee was thinking of when it allowed this violation of Article 29 of the Vienna Code of International Rules of Botanical Nomenclature. We are further informed that a third plant, distinct from its two sisters, remains to be exhibited, and it is not without some curiosity that we look forward to its appellation. We might also ask by what process of reasoning a sport can be said to revert to an allied species, a feat performed—we are assured—by several plants from the same batch? *Tyro.*

LAW NOTES.

ACTION FOR WAGES.

JOHN LOCK, gardener, recently sued Mrs. W. H. Bright, in the Bath County Court, for £4 8s. wages, alleged to be due to him. Defendant paid the sum of £2 4s. into Court, but denied liability. Plaintiff declared that he was employed by Mrs. Bright as a gardener. He stayed there for about 16 months, when his employer dismissed him, paying him a week's wages in lieu of notice. In the absence of any agreement he claimed he was entitled to a month's notice or a month's salary in lieu of notice. Lock admitted that in addition to his gardening work he looked after a couple of cows and did a little work in the house. He was engaged as a gardener, however, and was always called "Gardener." His Honour held that a gardener was entitled to a month's notice, and gave judgment for plaintiff. Mr. Long applied for leave to appeal, but his Honour refused, remarking that he did not think a poor man ought to be put to the expense of providing litigation in the House of Lords.

TRADE NAME DISPUTE.

THE action brought by Messrs. Alexander Dickson & Sons, Ltd., Royal Irish Nurseries, Newtownards, County Down, seedsmen, nurserymen, and florists, claiming an injunction to restrain the defendants, Alexander Dickson, Joseph Dickson, and Alexander Dickson, jun., from selling any Roses or seeds not grown or propagated by the plaintiffs as "Dickson's," or from carrying on the business of nurserymen or seedsmen under the name of "Alexander Dickson & Sons" or "Alex. Dickson & Sons," has been finally settled by the Court of Appeal.

The Lord Chancellor, in giving judgment, said that the plaintiffs for over half a century traded under the name of Alex. Dickson & Sons. They carried on business as horticulturists, principally in Newtownards, but also at Ledbury, in Herefordshire, and they had a seed business in Royal Avenue, Belfast. On December 5, 1900, they were incorporated under the name of Alex. Dickson & Sons, Ltd. In 1901 they opened a shop in Dawson Street, Dublin, and in 1906 they bought a tract of 17 acres at Blackrock and established a nursery there. They had a valuable trade name. The defendant came to Dublin about 1875, and he opened a shop in Capel Street some 12 years ago under the name of the Ashbourne Agricultural Company, and he also put the name "Alex. Dickson" on the sign-board. He carried on the seed business, and did not raise or grow Roses or carry on horticultural business. After the plaintiffs opened the shop in Dawson Street it occurred to the defendant that it would be desirable to go into the nursery business in order to compete with his new Dublin rivals, and accordingly in 1905 he bought for £1,000 the site of a nursery at Woodlawn, Dundrum, which he subsequently called "The Home of the Rose." All this was perfectly legitimate; but in February, 1907, there was a tender for seeds advertised by the Department of Agriculture, and plaintiffs and defendant both competed for it. The plaintiffs got the contract, and immediately the defendant advertised himself as Alex. Dickson & Sons, Woodlawn Nurseries, Dundrum. Thus the defendant literally adopted the old and valued trade name of the plaintiffs expressly for the same business which had made the name famous, and the question which the Court had to consider was whether this act was lawful. The Master of the Rolls had granted an injunction against its use. Upon the whole case, he was of opinion that the judgment of the Master of the Rolls was right, and that the appeal must be dismissed, the costs to be paid by the appellants.

Lord Justice FitzGibbon and Lord Justice Holmes concurred.

Accordingly the appeal was dismissed with costs, but the form of the injunction was altered restraining the defendant from carrying on the business of nurseryman or seedsman either in the name of Alexander Dickson & Sons or Alex. Dickson & Sons, or in any name or any manner so as to mislead or deceive the public.

NEW INVENTIONS.

A POTATO PLANTER.

THIS contrivance is used for making holes in the ground when planting Potatoes and bulbs. At one end is a pair of steel jaws, and each jaw is connected with a separate handle. When they are closed and the handles apart, a wedge is formed that is pressed into the soil by the foot. By closing the handles, the two sides forming the wedge are parted, displacing the soil. The tool is claimed to be a saver of labour and a useful implement at bedding-out time. It is made by the "Veriquic" Planter Co., 51, Week Street, Maidstone.

TOOL FOR LAYERING CARNATIONS

THIS appliance has a formidable appearance, having butt, nozzle and trigger as in a revolver. But it is intended for increasing not destroying. The trigger, when released, sends forward a knife or knives, which partly severs the shoot as in layering. In course of time roots are emitted from the region of the cut without any further trouble, and when they have developed sufficiently, the layer is potted in the ordinary way. A great deal of ingenuity has been expended in producing an article to do work that the more clumsy pocket-knife might accomplish. The makers are Messrs. Cumming and Sanders, 118, Camden Road, London.

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

FEBRUARY 23.—*Present:* Mr. E. A. Bowles, M.A., F.L.S., F.R.S. (in the Chair); Sir J. T. D. Llewelyn, Dr. A. B. Rendle, Rev. W. Wilks, Messrs. J. L. Arkwright, J. W. Odell, W. Hales, R. Hooper Pearson, A. Worsley, E. M. Holmes, W. Fawcett, F. J. Baker, A. W. Sutton, R. A. Rolfe, G. S. Saunders, J. T. Bennett-Poë, W. Cuthbertson, G. Massee, and F. J. Chittenden (hon. secretary).

Diseased Parsnips.—A report was received from Mr. Güssow concerning the Parsnips with scabby spots shown at the last meeting, from Mr. GREGORY. They were attacked by the fungus *Plasmopara nivea*, which appears first on the leaves. This fungus also attacks Carrots and Parsley.

Malformations in Orchids.—MR. GURNEY WILSON, F.L.S., sent the apical portion of a pseudo-bulb of *Dendrobium nobile* bearing a shoot from which roots had grown as in a vegetative shoot, and a flower, the lateral petals of which were coloured like the labellum. He also sent a dimerous flower of *D. nobile*, with the lip suppressed and the two lateral sepals coherent. A *Cypripedium* from Sir JEREMIAH COLMAN having two dorsal sepals was also shown.

Mendelism in Orchids.—MR. R. A. ROLFE showed flowers the result of crossing *Epidendrum evectum* and *E. xanthinum*. The former of these is purplish in colour, the latter yellow. The first cross gives *E. x kewense*, and flowers of this hybrid were shown. Seedlings had been raised from *E. x kewense* after self-fertilisation, and of these, one which flowered earlier was practically a reproduction of *E. x kewense*, while of two others (flowers of which were shown) one showed partial reversion towards the purple *E. evectum*, the other toward the yellow *E. xanthinum*. He also showed the result of re-crossing *E. x kewense* with the original parent *E. evectum*, the resulting plant having a purple flower not quite so dark as the parent. Mr. ROLFE said that *E. x kewense* re-crossed with *E. xanthinum* gave a yellow flower. Other plants of the crosses were yet to flower.

Colour changes in Carrots.—DR. C. B. FLOWRIGHT sent the following note concerning the colour changes occurring in Carrots, together with illustrative specimens. The portion of a Carrot sent is interesting as showing the condition common last year, viz., the longitudinal splitting of the root from the crown downwards, exposing the medullary portion, which shows no tendency to cleave. The exposed portion shows a tendency to development of chlorophyll. On the edges of the cortical portion no chlorophyll is seen, but minute specks, tending to become confluent, of a red colouring matter (carotin) have been freely developed. The specimen sent is of an ordinary garden Carrot, the fissuring of the out portion is thought to be due to dryness at the time of growth. In the smaller specimen different colour changes have taken place. The exterior has freely developed a green tint mottled with patches of purple. The roots have been exposed on the surface of the ground all the winter. The purple is quite superficial. It is interesting to note that this brilliant change has taken place in the least coloured variety, for these small ones are, as a section shows, of the pale variety grown for cattle, and popularly known as "stock Carrots." Incipient colours are often shown in the exposed roots of other plants, for example, blue discoloration, as wood root-stocks are frequently mottled with blue stains when they are pulled and left exposed to the light and air.

Potato tuber diseased.—MR. G. MASSEE showed a Potato tuber having a black patch (dry scab) about 2 inches square, the result of the attack of the fungus *Stemphylium (Phellomyces) atrovirens*. This disease has been very prevalent in Scotland this season, and considerable damage has been done to the crop. The present example came from Oxford. The spores are known to remain alive in the soil, and capable of infecting Potatoes for several years. Diseased tubers should, therefore, not be used for "seed," nor should Potatoes be grown on the

same land as that on which the diseased crop was grown.

Apple containing germinating seed.—Mr. F. J. BAKER showed an Apple containing germinating seed, and made some remarks upon the result of allowing seed to dry thoroughly before sowing. He considered that seed of many plants which had been allowed to remain as long as possible within the fruit gave better results than seed removed early and kept for some time before sowing.

Variation in Primula sinensis.—Mr. A. W. SUTTON showed a number of plants of *Primula sinensis* having leaves of a shape approaching those of Ivy. He said that occasionally such plants were observed, but they had not until last year set any seed. Seeds had, however, been obtained from three plants last year, and this had given a considerable number of plants with leaves of the form of the parents, and with petals of a very similar form, the form of the latter being apparently correlated with that of the former.

Cinerarias dying.—Mr. W. J. JAMES sent a plant of *Cineraria*, one of about 150 which had died out of some 3,000. It was found that the base of the plant had been attacked by the bulb mite, *Rhizoglyphus echinopus*, in great numbers, and that these had caused the death of the plant.

DUMFRIESHIRE AND GALLOWAY HORTICULTURAL.

FEBRUARY 20.—The annual general meeting of this society was held in the committee room of the Dumfries Town Hall on this date. There was a moderate attendance, presided over by Provost Nicholson, Maxwelltown, chairman of the directors. The secretary and treasurer, Mr. Robert G. Mann, submitted the annual report, which showed that the income for the past year, including a balance of about £22 from the previous year, had amounted to £252 5s. The expenditure had been £246 6s. 4d., leaving a credit balance of £5 18s. 8d.

The Chairman intimated that he did not desire re-election, and suggested Provost Lennox, of Dumfries, to succeed himself. This was agreed to, and the following other directors were appointed:—Messrs. Jas. Henderson, F. W. Malloch, Jas. McLeod, J. M. Haining, J. M. Stewart, C. Murray, R. A. Gignor, and Taylor. Mr. R. G. Mann, "Herald" Offices, Dumfries, was re-appointed secretary and treasurer.

ROYAL METEOROLOGICAL.

FEBRUARY 17.—On this date Mr. E. Mawley read his "Report on the Phenological Observations for 1908." The most noteworthy features of the weather of the Phenological year ending November, 1908, were the severe frosts early in January, the exceptionally heavy fall of snow and remarkably low temperatures in the latter part of April, and the marked periods of unusually wet and dry weather during the summer. In February and March wild plants came into blossom in advance of their usual time, but throughout the rest of the flowering season were more or less behind their average dates. Such early spring migrants as the swallow, cuckoo and nightingale made their appearance very late. The only deficient farm crop was that of Barley. The yield of Wheat, Oats and Beans was rather above the average, that of Peas and Hay very good, while the crops of Turnips, Mangolds and Potatos, taken together, were the most abundant for many years. The yield of Apples was under average, and that of Pears and Plums much under average. On the other hand, the crops of Currants, Gooseberries, and Strawberries were almost everywhere unusually good. As regards the farm crops, this was the third good year in succession, although, compared with 1906 and 1907, the yields in 1908, except in the case of Turnips, Mangolds and Potatos, were very inferior to those of either of those years.

Mr. W. Marriott read a paper on "The Cold Spell at the End of December, 1908." The weather during December was generally mild until Christmas Day, when a considerable change took place in the distribution of barometric pressure, and the weather assumed a wintry character. Gales occurred in many places, and snow fell more or less over the British Isles during the following week. The

most remarkable feature, however, was the intense cold which prevailed over the central and south-eastern portion of England from the 28th to the 31st. The temperature on the 28th did not rise above 25° over a considerable portion of the Midlands, while on the 29th it remained below 25° over practically the whole of England (except the south-western counties) up to within about 20 miles of the coast. On the 28th, 29th and 30th, over the greater part of the country, the minimum thermometer fell below 20°, while over a considerable area it fell below 10° on the 29th and 30th. At several places the lowest temperature recorded was about zero. At Berkhamsted the thermograph showed that the temperature remained below 25° for a period of 58 hours—a most unusual occurrence. Mr. Marriott stated that the isobaric charts indicated that during this period there was a ridge or wedge of high pressure between two cyclonic systems, and that the conditions were thus favourable for the production of great cold. For the month of December the cold was very exceptional, as the only instances in the neighbourhood of London or at Greenwich, in which the maximum temperature was below 25.5° for the day, were the following: 1796, 25th, 19.5°; 1798, 28th, 19.5°; 1816, 22nd, 24.0°; 1830, 24th, 22.0°; 1855, 21st, 23.2°; 1874, 31st, 24.5°; 1890, 22nd, 23.7°; and 1908, 29th, 25.4°, and 30th, 23.3°.

PAUL LÉCOLIER, Celle-Saint-Cloud, Paris—Trees, shrubs, fruit trees, Roses, &c.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending February 27, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—During the early days of the week the sky was nearly cloudless over a large part of England and Scotland, but subsequently there was a good deal of cloud, and later in the period nearly all districts in Britain experienced snow or sleet, and Ireland sleet or rain.

The temperature was a little above the average in Ireland and Scotland, and below it in England, the deficit being greatest (more than 5°) in England S.E. The highest of the maxima occurred on the 21st or 22nd at nearly all stations, and ranged from 57° in England N.W. and 56° in Scotland E. to 52° in England S.E. Late in the week the maxima were generally low, no higher than 36° in many English localities and below it at some stations. The lowest of the minima, which were recorded on irregular dates, varied from 14° in England S.E. and S.W., and 15° in the Midland Counties to 26° in Ireland N. and to 31° in the English Channel. The lowest grass readings reported were 2° at Llangamarch Wells, 9° at Birmingham, 11° at Oxford, Greenwich, and Kew, 12° at Hereford, and between 14° and 20° in most other places.

The mean temperature of the sea.—On many parts of the coast the water had a very similar temperature to that during the corresponding week in 1908, but at Kirkwall it was more than 4° in excess, and at Eastbourne more than 4° colder. The actual values ranged from 47.3° at Plymouth, and nearly 47° on the south-west coast of Ireland, to about 40° or below on the east and north-east coasts of England, and at Eastbourne.

The rainfall was much below the average generally; at a few places in England and Wales and also at Douglas (Isle of Man) there was no measurable quantity. At Armagh on Wednesday morning the rain in the gauge and in pools on the ground was observed to be very black.

The bright sunshine exceeded the normal in England and also in Scotland N., but was below it in Ireland and the west and east of Scotland. The percentage of the possible duration ranged from 52 in the English Channel, and 43 in England S.W. and S.E., to 20 in the east and west of Scotland, and to only 10 in the north of Ireland.

THE WEATHER IN WEST HERTS.

Week ending March 3.

The fourth week in succession of cold weather.—The present cold spell has now lasted nearly a month, and the past week has been the coldest of that period. At no time during the week did the temperature in the thermometer screen rise above 37°, and on the coldest night the exposed thermometer registered 15° of frost. The ground is at the present time 4° colder at 2 feet deep, and 5° colder at 1 foot deep, than is seasonable. Snow fell on 3 days, and on 1 day the ground was covered for a short time to the average depth of 2 inches. There has now been no measurable percolation through either of the soil gauges for nearly 6 weeks. The sun shone on an average for 1½ hours a day, which is only half the average duration for the end of February. Calms and light airs have alone prevailed during the week. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 5 per cent.

FEBRUARY.

Exceptionally cold, dry, sunny, and calm.—This was an exceptionally cold February, but the mean temperature was not nearly as low as in the same month in 1895, when it was as much as 8° lower. There occurred a few days of warm weather at the beginning of the month, but during the rest of it there was only 1 day when the mean temperature rose above the average. On the warmest day the highest temperature in the thermometer screen was 55°, which is a high extreme maximum for the month. On the coldest night the exposed thermometer indicated 20° of frost, which is rather a low extreme minimum for February. Taking the month as a whole the nights were much more unseasonably cold than the days. Rain or snow fell on only 8 days, and to the total depth of less than half an inch, the average for the month being 2 inches. It is now 13 years since there has been here such a dry February. On one day the snow lay for a short time to the depth of 2 inches. Throughout the month there was no measurable percolation through either of the percolation soil gauges. The sun shone on an average for 3 hours a day, or for 40 minutes a day in excess of the average—making this the sunniest February for 10 years. It was the calmest February for 7 years. During the windiest hour the mean velocity reached 20 miles—direction W.N.W. The average amount of moisture in the air at 3 o'clock in the afternoon was 5 per cent. less than a seasonable quantity for that hour. In only two previous Februaries in the last 24 years has the air been as dry at that hour as it was on 2 days towards the end of the month.

THE WINTER.

Rather cold and sunny and remarkably dry.—Taking the winter as a whole, it was rather a cold one. December proved of about average temperature, while January was rather warm, and February exceptionally cold. On the warmest day the temperature in the thermometer screen rose to 55°, and on the coldest night the exposed thermometer registered a temperature only 1° above zero, which is, with three exceptions, the lowest extreme minimum for any winter during the past 24 years. The total rainfall amounted to only about half the average quantity for the season, which was principally due to the exceptional dryness of January and February. The heaviest fall of snow occurred on December 29, when the snow lay to the average depth of 5½ inches. The sun shone on an average for 1 hour 56 minutes a day, or for a quarter of an hour a day longer than is seasonable.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October, the total rainfall has been 6½ inches, which is just half the average quantity for the same 5 months in the previous 53 years—equivalent to a loss in rainfall on each acre in this district of 145,000 gallons. At the same time last year there were 25,790 gallons per acre in excess of the average amount. E. M., Berkhamsted, March 3, 1909.

MARKETS.

COVENT GARDEN, March 3.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal saesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Acacia, Anemone fulgens, Azalea, Bonvardia, Calla aethiopica, Camellias, Carnations, Cattleyas, Cypripediums, Daffodils, Dendrobium nobile, Encarnas, Freesias, Gardenias, Hyacinths, Lilacs, Lilies, and Tulips.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and their prices, including Alantums, Agrostis, Asparagus plumosus, Berberis, Croton leaves, Daffodil foliage, Ferns, Galax leaves, Hardy foliage, and Ivy-leaves.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants and their prices, including Ampelopsis Veitchii, Aralia Sieboldii, Begonia Gloire de Lorraine, Cinerarias, Clematis, Cocos Weddelliana, and Grevilleas.

Plants in Pots, &c.: Average Wholesale Prices (Cont'd.).

Table listing various potted plants and their prices, including Hardy flower roots, Hyacinths, Isoplepis, Kentia Belmoreana, Latauia borbonica, Lilium longiflorum, and Tulips.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples (Foreign and Domestic), Bananas, Grape Fruit, Grapes, Lemons, Limes, Nuts, Oranges, Pears, Pineapples, and Tangerines.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Asparagus, Beans, Beetroot, Brussels Sprouts, Cabbages, Carrots, Cauliflowers, Celery, Cucumber, and Lettuce.

REMARKS.—Californian Apples are dearer, but Oranges from the same country are selling slowly. Supplies of French Apples are shorter, but their prices are about the same as those of last week. Bitter Oranges are cheaper. Lemons have slightly advanced in value. English forced Rhubarb has a poor demand, accounted for by the cold weather. Foreign Tomatoes are arriving in a better condition, and are cheaper. Trade generally is quiet. E. H. R., Covent Garden, Wednesday, March 3, 1909.

Table listing various plants and their prices, including Kents, Snowdrop, Sharpe's Express, Epicure, and various Lincolns and Dunbards.

REMARKS.—Trade is moderate; there is an increased demand for best samples of Up-to-Date variety. The wintry weather has checked supplies, and there is a prospect of the large stocks in London becoming considerably reduced. Edward J. Newbourn, Covent Garden and St. Pancras, March 3, 1909.

COVENT GARDEN FLOWER MARKET.

It is stated that the floral decorations used in connection with Court functions last week represented a value of £1,000; but the market was not greatly affected, save in the cases of Roses and Carnations of special quality. The average price for good Roses is 5s. to 9s. per dozen blooms. Some extra fine blooms have sold for 15s. per dozen. Carnations need to be very choice to sell for more than 2s. 6d. per dozen blooms. All kinds of Narcissus are abundant, and prices are lower than they may be a week or more later. Those from the Scilly Islands arrive in large quantities and are sold very cheaply. Best blooms of Golden Spur, Horsfieldii and Emperor are worth not more than 5s. per dozen bunches. Encharis has been more plentiful, but Gardenias are scarce. Lilies vary; flowers of the best quality have a tendency to increase in value. Blooms of L. auratum are rather small. Some of L. longiflorum are good, but others are of indifferent merit. L. lancifolium blooms are also smaller than usual. Callas are exceedingly plentiful. Violets from English growers have been down to the lowest prices, owing to the large supplies received from France. Acacia dealbata (Mimosa) is very good. Several varieties of Acacia are imported during the season; just now it is the true A. dealbata that is seen.

POT PLANTS.

The cold weather has caused trade to be dull, yet some things have sold fairly well. Azaleas are still plentiful; also Daffodils in various sorts. Tulips and Hyacinths are well supplied in pots and in boxes. Ericas are good, especially E. persoluta alba and E. Wilmoreana. Marguerites have a better demand, but some of the forced Spiraeas are rather "thin"; others are very good. Rhododendrons are well flowered. Cyclamen and Primulas are both of better quality than is usual at this season. All foliage plants are plentiful, but the demand is poor. A buyer complained to me that Ferns bought in the market soon faded; this is not surprising, for though they do not show any damage whilst they are exposed to the cold, the fronds turn black as soon as the plants are put into warmth. Trade in hardy plant roots has been very slow; also in trees, shrubs, climbers, &c. A. H., Covent Garden, Wednesday, March 3, 1909.

DEBATING SOCIETIES.

BATH AND DISTRICT GARDENERS'.—A meeting of the above society was held in the Foresters' Hall on February 8, Mr. T. Parrott presiding. Mr. Garnish, of the Bristol Association, read a paper on "Bulbs for Pots." The culture of bulbs in pots, especially those for spring-flowering, was ably dealt with by the lecturer. A meeting of this society was held on February 22, under the presidency of Mr. T. Parrott. Mr. Mowbray A. Green gave a lecture, illustrated with limelight views, on "Garden Cities." The lecturer dealt at length with such noted garden cities as Bourville, Port Sunlight, and Letchworth.

BRISTOL AND DISTRICT GARDENERS'.—A meeting of this association was held on Thursday, February 25, Mr. A. O. Shelton presided over a good attendance of the members. A lecture upon "Barren Soils" was given by Mr. Arnold, gardener to Earl Bathurst, Cirencester House. The lecturer described the best methods of successfully working various soils. Shallow soils resting on a stony or brashy subsoil should have a layer of manure placed at the bottom when trenching; they should also be liberally top-dressed and mulched with manure. Deep soil with a subsoil of gravel is generally deficient in potash and lime. Stable manure and wood ashes were recommended in this case. A deep loam, with a clay subsoil, often requires draining. In the case of a heavy soil with a sandy subsoil, deep cultivation is necessary. Heavy clay lands should be thoroughly drained and the surface burned to a depth of 12 inches. Such lands are improved by the addition of sand, grit, builders' rubbish, and lime.

CHESTER PAXTON.—The third of a series of lectures by Mr. N. F. Barnes, Eaton Hall Gardens, was given at the meeting held on February 20. The subject on this occasion was "A Visit to the Centenary Exhibition at Ghent, with notes by the way." Mr. Barnes' remarks were illustrated by a number of lantern slides. The lecturer gave an account of the town of Ghent, and a description of the exhibition. Special reference was made to the collections of Hippeastrums shown by Major Holford, and by Messrs. Ker & Sons, of Liverpool. The collection of Orchids staged by Major Holford was the finest and most representative display of Orchids in the show.

The meeting held on Saturday, February 27, was the last of the session. The Curator of the Grosvenor Museum, Mr. Alfred Newstead, contributed a paper, illustrated by lantern slides, on "Familiar Wild Birds in relation to Gardens and Orchards." The lecturer not only described the habits and life history of these birds, but also dealt with the economic aspect of the subject. He explained minutely the nature of their food, and showed which birds are beneficial to the horticulturist and agriculturist, mentioning that some species are wholly insectivorous, whilst others feed partly on insects and partly on fruits, grain, &c. He instanced the results of Prof. Newstead's post-mortem analysis of the stomach contents of some birds in his report recently published by the Board of Agriculture.

GROYDON & DISTRICT HORTICULTURAL.

The ninth annual dinner of this association was held on Wednesday, February 10. Some eighty members and friends were present. Mr. J. J. Reid (President) was in the chair, and Mr. E. H. Jenkins (President of the Kingston Gardeners' Association) occupied the vice-chair.

A meeting of this society was held on Tuesday, February 16. The evening was devoted to a lecture and demonstration on "Table Decorations." The lecturer was Mr. R. Edwards, Beechey Lees Gardens, Sevenoaks. The lecturer stated that harmony of colour was essential in a table decorated with flowers, for whatever flowers be brought into requisition they must be of shades unopposed to each other. The decoration should be appropriate to the season. When Iceland or Shirley Poppies are used it is a good plan to put the cut stems in boiling water or just burn the ends with a lighted candle or match. Where flowers are required to be preserved for several days the water should be changed daily, and a little sugar may be added with beneficial results. Flowers for travelling are best cut overnight when dry and the stems immersed in water.

DORCHESTER GARDENERS.—An address on "Lawns and Lawn Grasses" was delivered on Monday, February 22, to the members of this association by Mr. Shipway, of Messrs. Sutton & Sons, Reading. The lecturer dealt with the formation and upkeep of lawns, bowling greens, tennis grounds, &c. The lecture was illustrated with lantern slides. Mr. Shipway stated that beautiful lawns, in the great majority of cases, are much more easily and cheaply obtained from seeds than from turves.

READING AND DISTRICT GARDENERS.

A lecture was given before the members of this association by Dr. Keeble, of the University College, Reading, in the Abbey Hall, on Monday, February 22, the subject being "Applied Mendelism." The president, Mr. Alderman F. B. Parfitt, occupied the chair. Dr. Keeble stated that comparatively little was yet known regarding Mendelism or the abstruse laws governing heredity, which had puzzled scientists for many ages. The fact that like produces like was correct only in a degree, for in the course of experiment under Mendelian Laws it was frequently found that the hybridisation of two flowers would result in blooms of quite a different shade and character to those of either parent. For example: two white Sweet Peas crossed produced a purple; this was due to latent characters which could only manifest themselves when in conjunction with other complementary characters which came together as a result of hybridisation. Hybrids always embodied the colour, habit, and constitution of both parents, though one only might be evident, but the influence of the recessive qualities came out in the second generation. Thus if tall Peas were crossed with dwarf Peas the result would be tall Peas only; but the second generation produced by self-fertilising these hybrid plants would give 25 per cent. dwarf and 75 per cent. tall, proving that the characters of the dwarf parent had been carried through a generation without visibly showing. At the close of his lecture Dr. Keeble answered many questions.

REDHILL, REIGATE AND DISTRICT GARDENERS.—Mr. W. P. Bound presided over the fortnightly meeting of this association, held at the Penrhyn Hall, on Monday, February 22. A lecture was given by Mr. Cooper, of St. Albans, on the "Culture of Orchids." The next meeting of the society will be on March 8, when Mr. Daisley, of Worth, will lecture on "Vegetables for Exhibition."

WARGRAVE AND DISTRICT GARDENERS.

At the usual fortnightly meeting of this association, Mr. T. Haskett, of Hennerton Gardens, read a paper on "The Cultivation of the Florists' Cyclamen." The lecturer gave details for seed sowing, and the best compost to use. He recommended the sowing of freshly-gathered seed in preference to that which was a few months old. An equable temperature was necessary for the young plants, because sudden changes were detrimental to their well-being. The method of potting the young plants was carefully described, as well as watering, ventilation, shading, &c. Insect pests were referred to, and the best methods of destroying them were given.

SCHEDULES RECEIVED.

Perpetual-Flowering Carnation Society's sixth exhibition, to be held in the Royal Horticultural Hall, Westminster, on Wednesday, March 24. Show superintendent, Mr. E. F. Hawes, Royal Botanic Gardens, Regent's Park, London.

Royal Caledonian Horticultural Society's spring flower show, to be held on April 7 and 8 and centenary exhibition on September 8 and 9. Both shows will be held in the Waverley Market, Edinburgh. Secretary, Donald Mackenzie, 23, Rutland Square, Edinburgh.

Durham, Northumberland, and Newcastle-on-Tyne Botanical and Horticultural Society's summer show, to be held in the Recreation Ground, North Road, Newcastle-on-Tyne, on Wednesday, Thursday, and Friday, July 28, 29, 30. Secretary, Mr. J. Wilfrid Pace, Emerson Clamber, Blackett Street, Newcastle.

Royal Ulster Agricultural Society's horticultural show, to be held on the society's premises, Balmoral, Belfast, on Thursday and Friday, July 22, 23. Secretary, Mr. Kenneth MacRae, Balmoral, Belfast.

Clevedon Horticultural Society's 33rd annual flower show, to be held on Tuesday and Wednesday, August 3 and 4, in the Clevedon Hall Paddock; also Clevedon Chrysanthemum show, to be held in the Public Hall, Clevedon, on Tuesday and Wednesday, November 9 and 10. Hon. secretary, Mr. Frank Leckington, Branch Hill, Clevedon.

Huntingdonshire Daffodil and Spring Flower Society's show, to be held on Tuesday, April 27. Hon. secretary, Miss L. L. Linton, Stirlloe House, Buckden, Huntingdon.

Sandway and District Horticultural Society's fourth annual exhibition, to be held at Sandway, on Monday, August 2. Hon. secretary, Mr. W. May, Sandway Lodge Gardens, near Northwich.

ANSWERS TO CORRESPONDENTS.**ALPINE PLANTS FROM ITALY OR NAPLES: F. S.**

It is not advisable to send them by rail, because the freight is considerable, and much damage is done to plants at the various depots on the frontiers, where they may be overhauled. The journey by rail occupies about 48 hours. Your better plan is to consign them from Naples by steamer. Ascertain from the London agents the date of call, and have them ready for shipment direct to England. Packed tightly in boxes, with plenty of soil and moss about their roots, they should travel safely, but the safest way to send them is in Wardian cases.

BOTTLING PEAS: C. C. To bottle green Peas, shell the Peas, put them into dry, wide-mouthed bottles and shake them together so that they may lie in as little space as possible. Cork the bottles closely and seal the corks. Bury the bottles in the driest part of the garden and take them up as they are wanted. They ought to keep good for some months. Or, try this recipe. Choose Peas which are large and fully grown, though not old. Put them into perfectly dry, wide-mouthed bottles; shake them down, cork securely, and cover the cork with bladder. Tie a wisp of hay round the lower part of the bottles to prevent their knocking against each other in the pan, put them side by side in a large saucepan, and pour into it as much cold water as will reach the necks of the bottles. Put the saucepan on the fire, and let the bottles remain standing for two hours after it has reached boiling point, then take the saucepan off, but do not remove the bottles until the water is cold. Seal the corks and store in a cool, dry place.

CARNATIONS: H. W., Sussex. The plants are infested with rust disease—*Puccinia Arenariae*. Spray them with a rose-red solution of permanganate of potash.

CYCLAMEN: W. L. The plants are attacked by a mite similar to that which infests Begonias and Gloxinias. Dip the foliage in tobacco-water, repeating the operation at intervals.

FLOWERING SHRUBS IN WINTER: D. M. You will find all the information you require in the article by Mr. Osborne, on "Hardy Trees and Shrubs Suitable for Forcing," published in the *Gardeners' Chronicle*, December 12, 19, and 26, 1908.

HYACINTH BULB ROTTEN: H. & S. The interior of the bulb is full of a bacterial rot. The bacteria may have been present in the bulb from last season, or may have entered from the soil when planted last autumn, through some bruised spot.

IVY-LEAVED PELARGONIUMS: J. R. and H. S. There is no disease present in the shoots. The injury has been caused by some insect-pest such as green-fly or red-spider.

MANURE FOR POTATOS: Sussex. You may use the manures you mention, but it would be advisable to supplement them with a manure containing potash. A good stimulant for Potatos is composed of superphosphate two parts, and one part each of sulphate of ammonia and sulphate of potash. The compound should be applied at the rate of about 10 cwt. per acre.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: C., Peterboro. The Apple you have sent us is a very fine specimen. We have compared it with the variety Annie Elizabeth and fail to find the least difference between them. The description of this variety in the *Fruit Manual* exactly fits your fruit.

PLANTS: F. K. 1, *Cœlia Baueriana*; 2, *Epidendrum vitellinum*; 3, *Lælia bapophylla*; 4, *Pleurothallis Barberiana*.—*F. C. P.* 1, *Bulbophyllum cupreum*; 2 and 3, *B. Pechei*.—*Filices.* 1, *Peris umbrosa*; 2, *P. cretica*; 3, *P. serrulata cristata*; 4, *P. serrulata*; 5, *Adiantum Capillus-veneris*.—*A. J. W.* *Saccolabium giganteum*.—*Anxious.* *Schaueria calicotricha*.—*J. M. S.* *Schaueria calicotricha* (syn. *Justicia flavicoma*).

NECTARINE LORD NAPIER: Anxious. The failure of the trees to produce flowers cannot be attributed to early forcing, as the flower buds are formed in the autumn of the previous year. The trouble may be due to the wood being insufficiently ripened last autumn. The damaging of the foliage by soot in August may have been the cause, as this would entail a check to the tree at the time the foliage was about to put into the stem and buds much reserve food. Other reasons for non-flowering may be advanced, such as a too vigorous development of wood growth, indicating the need for root pruning, or an unsatisfactory rooting medium.

PLANTS FOR A WINDOW-BOX IN LONDON: B. S. In addition to the plants you mention, you can use Marguerites, Fuchsias, Begonias—both the semperflorens and the tuberous-rooting kinds; Nasturtiums, Campanulas (especially the varieties of *C. isophylla*), Petunias, Heliotropium, Mimulus (Musk), Ericas and Sedums. The small polyantha Roses of the Mme. N. Levassieur type are very pleasing for this kind of gardening. The front of the box should be draped with Lobelia, Zebrina, Lysimachia Nummularia (Creeping Jenny) or similar plants. We have also noticed Asparagus Sprengeri doing well in London window-boxes.

POTATOS WITH SCABBED SKINS: S. & Co. There is no disease present in the tubers. The injury is due to some mechanical irritant in the soil, such as would be caused by ashes in the manure, or sand.

RECREATION GROUND: H. R. G. To keep the recreation ground in first-class order would take five men. If the paths are made of gravel they will require frequent and constant attention. The area of the ground does not allow of much being devoted to sports, therefore all the Grass plots will require frequent mowings, and the verges to the paths and beds will need to be kept in a neat condition. The beds and borders will require considerable work to maintain them in a proper condition, and, if the district is a populous one and there are many children, some time of each day will be taken up in keeping order and clearing up waste paper and other refuse. Recreation grounds are usually open seven days in each week, and they are allowed to remain open each day from early morning until sunset, which far exceeds an ordinary working day. In calculating the strength required therefore, all such details are taken in consideration.

TULIPS FAILING TO FLOWER: Gardener. The failure of your bulbs to flower is probably due to one of two causes; either the bulbs were not sufficiently matured last autumn, or they were started in too much warmth.

VIOLETS: T. V. The plants are attacked by a fungus—*Cercospora violæ*. Burn the affected plants and spray the others with dilute Bordeaux mixture. Do not plant Violets in the same soil for several seasons.

WINTER-DRESSING FOR VINES: E. G. The loose bark should be first removed from the rods, and especially about the neighbourhood of the spurs. Afterwards coat the vines with the following mixture: Coal tar one part and clay six parts; dry the clay so that it will readily pass through a fine sieve. Work the clay and tar thoroughly together, adding sufficient boiling water to make the mixture of the consistency of paint. In applying the preparation avoid coating the buds. Keep the mixture well stirred during the process of application.

A MARKET FRUIT GROWER'S YEAR.

FEBRUARY of the present year has been remarkable alike for dryness, extraordinary abundance of bright sunshine, and the occurrence of frost nearly every night. At my own station less than a quarter of an inch of rain has been registered. The frosts, for the most part, have been slight or moderate, but approaching the severe type in the last week. Even the slight frosts, however, have sufficed to render the ground hard nearly every morning, until thawed by the sun's rays.

The persistence of night frosts must be regarded as highly propitious to the outlook for the fruit crops, as they, probably assisted by the dryness of the soil, have so effectually checked the development of buds on all kinds of fruit trees and bushes that these, being much more backward than usual, are the less likely to suffer damage from late frosts. With respect to Gooseberries and Plums, this backwardness is also a safeguard against bud-eating by birds, as, when the buds are late in swelling, there is more food of other kinds available for these feathered destroyers. Long before this stage last season, nearly all the buds of choice

varieties of Plums in my home orchard had been picked off, and Gooseberry buds, also near the homestead, had been attacked, necessitating spraying to protect them. At present not a bud has been taken off a Gooseberry bush, so far as has been noticed in many inspections, and only a few Plum buds from two trees close to the sleeping quarters of a great number of sparrows. A year ago the pruning of Gooseberry bushes, always deferred until the buds are on the point of bursting, was in full swing, but this season it has not yet commenced. Apart from the fact that birds cannot disbud the bushes so easily before pruning as after that operation is done, the work can be carried out best when any damage of this kind has been completed, as then, and not before, disbudded portions of shoots can be trimmed off.

With respect to one Gooseberry plantation, there is a special reason this season for late pruning. Last year a great many of the bushes were badly attacked by the fungus Botrytis, which caused the leaves to turn white at the tips and die prematurely, resulting in the berries developing merely to half size. Some of these diseased bushes are now dead, and portions of others. What to cut away, therefore, cannot be seen easily until the healthy buds have swollen almost to the point of bursting. The bushes in this field had borne great crops since they were planted in the autumn of 1902, or, at least, from 1904 onwards, and, in spite of artificial manuring two or three times, some of them have apparently been injured by the strain by cropping. They were heavily manured in January with kainit and basic slag, and will be given two dressings of nitrate of soda later in the season in the hope that their vigour may be restored. It is worth notice that on the experimental plots at Hadlow, Kent, managed by Dr. Dyer and Mr. Shrivell, Gooseberry bushes that have never had any potash supplied to them, like those on adjoining plots which had received potassic manures, were found last summer to be badly affected with Botrytis.

The principal kinds of work carried on in February have been the forking over of fruit and nursery stock plantations, the planting of fruit stocks for grafting or budding, the pruning of Apples and Plums, and the winter spraying of Apples and a few choice Plums. With respect to the first-named operation, it may be said that, in consequence of repeated hoeings having been rendered almost useless by the frequent rainfall of last spring and summer, the plantations were more thickly covered with weeds, chiefly Grass, than in any previous year. The oldest Apple plantation, indeed, resembled a meadow by the end of the autumn, and does so still, for, as the Black Currants have been dug out of it, and the trees are sufficiently mature, it is to be left in Grass, which will be cut twice in the season, and left to rot and form a mulch on the ground. As the trees have grown out too much for horse cultivation, and it would cost at least £5 an acre to have the land dug and hoed sufficiently to keep it free from weeds, a trial of the effect of leaving it in Grass, to save expense, is to be made. The soil of this field, it may be explained, is of so fine a texture that even a slight shower after hoeing is sufficient to set weeds chopped

up growing afresh. This accounts for the great expense necessary to keep it clean, which, indeed, is almost impossible in a showery season. Possibly White Clover will be sown on the land, and at any rate, manures calculated to cause indigenous Clovers to grow have been, and will hereafter be, sown, while farmyard manure will be placed around the trees in some seasons.

The most distressing work of the month has been the necessary treatment of King of the Pippins and Potts's Seedling Apples, both badly cankered, in spite of their having had cankered spots cut out and tarred from the first appearance of the disease, and badly-affected branches cut off and burned later. By persistent treatment Potts's Seedling has been greatly improved, but King of the Pippins is hopeless, as the canker breaks out at intervals right up the branches, and on young shoots and fruit spurs. Some of the trees have been cut nearly to the ground for grafting, and those least affected have had Plums planted between them, so that they may be dug up in a season or two. Neither of these two varieties should ever be recommended to market growers, although they are to be seen in most selected lists of varieties. There are 90 of one variety and 120 of the other, very fine trees apart from the pestilent malady from which they suffer.

The winter wash used consists of 20 lbs. of freshly-burned quicklime, 20 lbs. of flowers of sulphur, and 12 lbs. of caustic potash to 100 gallons of water. The sulphur is first beaten up well into a stiff paste to mash all the lumps, and then diluted and poured over the lime, so that the former will be boiled by the slaking action of the latter. After being well stirred, the mixture is covered with sacks for half an hour, and then well stirred again. When the boiling action is nearly finished the caustic potash is added and well stirred in, causing a fresh boiling action. Sufficiently diluted, this mixture is strained into a water barrel, and made up to 100 gallons for conveyance to the tubs in the plantation that is to be sprayed. This wash, applied very freely, so as to cover trunks and branches completely, has been used for Apples, and will be used shortly for Gooseberries, without the caustic potash, which might do damage to well-swollen buds. It has been used twice on choice Plums, which now look as if they had been thickly white-washed, the object being that of preventing birds from repeating the destruction they worked last season. This wash is supposed to have some effect in preventing scab, even when applied to dormant trees. For this purpose copper sulphate alone, 4 lbs. to 100 gallons, is better, and this has been applied to young Apple trees liable to scab, particularly Cox's Orange, which showed scab on the wood to some extent, though young shoots thus affected were cut off and burned. But for comparatively old trees the mixture named above is preferred, because it cleanses the trees of Moss and Lichen, and possibly does a little good in destroying hibernating insects and eggs. Both washes, of course, are to be used only on dormant trees, but lime and sulphur, without the caustic potash, have been applied successfully to Peaches and Apples in foliage in two seasons by the Bureau of Plant Industry in the United States. *A Southern Grower, February 25.*

NEW OR NOTEWORTHY PLANTS.

A NEW GENUS OF CACTACEÆ.

THIS is the title of a joint paper by Drs. N. L. Britton and J. N. Rose in the *Journal of the New York Botanical Garden*, vol. ix., pp. 185-188, plates 48-51. The paper, which is most interesting, is illustrative and descriptive of the home of the plant hitherto known as *Cereus giganteus*, therein described as a new genus under the name of *Carnegiea gigantea*. Whether this change will meet with general acceptance is doubtful, especially as the authors do not indicate the characters upon which their genus is based. Without differential descriptions it is impossible for anybody except an expert to form an opinion. Few botanists possess so wide a knowledge of the North American flora as the gentlemen responsible for this change, and fewer still, perhaps, take so restricted a view of generic limits, judging from their treatment of the species formerly referred to the genera *Sedum* and *Cotyledon*. The Cactus in question is one of the most interesting of the family, and some particulars of it, with a landscape in which it appears as the most conspicuous feature, are to be found in this journal, vol. xx., 1883, p. 264, the illustration being now reproduced at fig. 69. Later, in 1890, Kew imported a stem, which on its arrival had no roots and weighed 12 hundredweight. This flowered in July, 1891, when the stem was 14 feet high, and it was figured in the *Botanical Magazine*, t. 7222.

According to Britton and Rose, *Cereus giganteus*, as we shall continue to call it for the present, known in its home by the name *Sahuaro*, is the most remarkable and striking plant in the desert vegetation of the South-West. It grows on hillsides in Southern Arizona and South-eastern California, and Northern and Central Sonora, sometimes reaching a height of 60 feet, branching at from 12 to 20 feet above the ground. *Carnegiea* is dedicated to Mr. Andrew Carnegie, the founder of the Carnegie Institution of Washington, which possesses a laboratory at Tucson, Arizona, "surrounded by typical specimens of this unique plant."

Dr. Britton describes (*Studies of West Indian Plants*, No. 2, p. 561) another new genus of Cactaceæ, under the name *Harrisia*, in honour of William Harris, superintendent of Public Gardens and Plantations of Jamaica. To this he refers the old *Cereus eriophorus*, *C. gracilis* and *C. undatus*, together with five new species. In this instance, again, the essential characters of the genus are not indicated, although doubtless embodied in the description. They are night-flowering Cacti, with slender, erect, cylindrical stems bearing fluted branches. Plates 22 and 23 of Pfeiffer and Otto's *Abbildungen und Beschreibungen Blühender Cacteen* represent two of the species of this proposed new genus. W. B. H.

LOMATIA OBLIQUA.

AMONG the seeds collected in Chili in 1902 and brought home by Mr. H. J. Elwes were some of a Proteaceous plant which he gave to Kew, where plants were raised from them. They were at first thought to be a strange species of *Embothrium*, but subsequent comparison with dried specimens in the herbarium proved their identity with *Lomatia obliqua*—a common shrub in Chili, Peru, &c. Mr. Elwes found the plant between Quilon and Junin, at an altitude of from 3,000 to 4,000 feet. Its flowers were collected in the valleys of the Andes in Chili by Bridges, who noted it as being from 10 to 20 feet high; he also found it in Valdivia and Chiloe, where it is known as "Raral," and grows from 20 to 40 feet high. Hartweg found this species in abundance between Cunebu and Lima, in Peru, where it forms a small tree, known as "Garoo," and is appreciated for the variegated appearance of its wood when polished. At high elevations it is a shrub 6 feet or so high, with short branches and small leaves. Some of the plants raised at Kew were distributed, and a few were planted in a border outside the temperate house. Here they have grown well, the largest being now a sturdy bush over 6 feet high, with erect branches crowded with perfectly healthy leaves, notwithstanding the try-

ing character of the weather this winter, which has injured many plants known as hardy. We may, therefore, assume that this *Lomatia* is sufficiently hardy to be grown outside in the warmer parts of the British Islands, and as such it is a really interesting addition to hardy evergreens. It has the habit of *Embothrium coccineum*, but the branches are sturdier; the stout, leathery, smooth, bright green leaves are distinctly ovate, with crenate margins, the largest being 4 inches by 2½ inches, the smallest only

FIG. 69.—CEREUS GIGANTEUS GROWING IN ARIZONA.

about one-fourth that size; the petioles are coloured brown. Flowers have not yet been produced by cultivated plants, but judging by herbarium specimens they are of the same character as those of the cultivated *Lomatias* of which *L. ferruginea*, also Chilian, is by far the best. This has decomposed leaves and racemes of bright red flowers. It is best known through the grand example at Castlewellan, where it has proved not only a handsome, hardy evergreen, but also a beautiful summer-flowering shrub. This species may be quite as hardy in England as *L. obliqua*, but, so far as I know, it is grown only as a greenhouse plant. H. H.

FRUIT REGISTER.

LATE DESSERT APPLES.

It was somewhat of a surprise to find at the competition for dessert Apples at the Royal Horticultural Society's meeting on February 23 that such autumn and early-winter varieties as Cox's Orange Pippin, King of the Pippins, and Baumann's Red Reinette were exhibited as dessert Apples. Certainly the conditions of the schedule left the season of any variety quite open, but it was very natural that competitors should assume that preference at this late period of the winter would be given to the latest-maturing Apples, and it may be imagined that the particular competition was instituted specially for such varieties. It is expressly laid down as one of the conditions governing these competitions on page 37 of the Society's *Book of Arrangements* that "in all cases flavour and quality will have the chief consideration, and judges will have the option of tasting." In the case in question not one of the fruits was tasted for flavour or quality, the judges doubtless demurring to taste as many as 48 fruits. But it may well be asked how could flavour and quality be tested except by tasting? The way out evidently was to ignore flavour and consider only colour and appearance; hence, early-winter-maturing Apples having bright colour and, therefore, more pleasing appearance, were placed before varieties that are reputedly of the highest excellence in late winter, though not highly coloured or of such attractive appearance.

In the first prize collection of six dishes from trade growers there were such late dessert Apples as Sturmer Pippin, Northern Spy, Dutch Mignonne, Lord Hindlip, Reinette de Canada, and King of Tompkins County. Not one of these excellent but somewhat sombre-coloured varieties were seen in the two prize collections in the class for four dishes. Naturally, such judgments bother competitors very much.

Some kind of consistency, as well as unanimity of decision, is badly needed in judging dessert Apples in late winter. Which is most desirable, to make awards to varieties ever so highly coloured and beautiful, yet much past their best, or to others less coloured or beautiful, but full of crispness, juiciness and flavour? That is a point which it seems needful to satisfactorily determine. I do not complain if judges think colour and beauty the dominating features of dessert Apples. It is a question of taste, but such features seem more to befet an Apple competition in the autumn than in late winter, when table excellence should be the dominating quality.

The late competition should serve to bring out the keeping qualities of Apples, and I could wish that the competition might be repeated in April for that purpose. Of good late keepers, Adams's Pearmain, Sturmer Pippin, Claygate Pearmain, Lord Hindlip, Boston Pearmain, Brownlee's Russet, Cockle's Pippin, Dutch Mignonne, Braddick's Nonpareil, Manning's Pearmain, King of Tompkins County, Barnack Beauty, and Scarlet Nonpareil make a baker's dozen hard to beat. 7

ORCHID NOTES AND GLEANINGS.

CATLEYA TRIANÆ COURTAULDIANA.

In the report of the Ghent Quinquennial Show in the *Gardeners' Chronicle*, April 21, 1888, is the following passage: "Perhaps the greatest interest centred in any one object was created by a cut three-flowered spike of a grand form of *Catleya Trianæ*, superb in form and size, and with the additional attraction of a bright crimson marbling on the sepals, and a similar broad feather of crimson spots up the wide and conspicuous petals. All agreed that such had never arrived before, or anything like it, and it was suggested to call it *C. Trianæ* var. *Courtauldiana*, as it was brought from that gentleman's collection by Mr. O'Brien."

The plant which flowered in the collection of the late Sydney Courtauld, Bocking Place, Braintree, for the first time on the occasion cited, gave flowers perfectly normal in every respect, and yet it seems to have failed to produce the ornate crimson spotting afterwards, or, at least, there is no record of it. At the present time it is in flower in the Orchid nurseries of Mr. H. A. Tracy, Amyand Park Road, Twickenham, who obtained a very small plant of the variety at the dispersal of the Courtauld collection. The flower is of fine form and shape, and the sepals and petals of a light rose-pink, the petals showing a disposition to produce a coloured band, but in a very slight degree. The lip is of good shape, the front being purplish-crimson, with a pale lilac, crimped margin, and some broad gold lines from the base. It would be interesting to know whether anyone has flowered it in its original form.

AMERICAN NOTES.

ORCHID SHOW AT BOSTON.

THE Massachusetts Horticultural Society expects to have a good Orchid show at Boston in May, 1910. The Society hopes to attract some, at least, of the European growers, and offers in one class a gold medal and 1,000 dollars in cash as a first prize. Many other large money prizes and medals are offered. Special attention will be given to plants of rarity and value, as well as trees and herbaceous subjects likely to prove hardy in the Bay State.

CARNATIONS.

Yellow Carnations are not as popular in the United States as in England, and although this may be in part due to the fact that there are few really good kinds that are profitable to grow commercially as cut flowers, yet the fact remains that growers generally are shy of them. The new variety, J. Whitcomb Riley, was well shown both at Chicago and at the Indianapolis Convention of the American Carnation Society, and is a very beautiful flower, as well as a fine grower and free flowerer. The raisers are said to have received an offer from a British firm for the whole of the stock, in which case it would not, of course, be sent out here. More than one prominent grower has told the writer that no yellow variety will ever be taken up with any spirit in America.

It is singular that the gold medal of the above Society should have been awarded to a "variegated" variety, as the flaked kinds are called here, for such sorts are not really popular. Bay State, the variety so honoured, is a bold flower, and will doubtless be largely grown. Pink Carnations, although their name is legion, are not in many cases satisfactory. There is a dullness about the tints that is not pleasing, and many that came out with a flourish will be discarded. Rose Pink Enchantress is being thrown out in one, at least, of the very largest of the Chicago establishments, and, strange as it may seem, the old Mrs. T. W. Lawson is being more largely planted on account of its fine shipping qualities and its excellence as a

mid-winter bloomer. Winona is very highly spoken of, the colour being clear and good. It has probably come to stay. In red flowers, Victory seems to have slightly the advantage over Beacon. Robt. Craig has probably seen its best days, while growers are buying the new O. P. Bassett in enormous quantities.

ANTIRRHINUMS.

are among the most pleasing of the spring flowers offered here other than Roses, Carnations, and bulbous stock. Some of the soft yellow or light chrome tints of pure self colour are very beautiful now among the earliest ones, while later in the season the deep reds are popular. The plants are raised from seed or cuttings in summer and autumn, the earliest being benched in September or thereabouts, and, as these frequently come in at a time when Roses are scarce, they prove a paying crop, as they need but little heat. H. R. R.

THE ROSARY.

NOTES ON PRUNING ROSES.

As the month of March comes round one of the most important operations, namely, the proper pruning of Roses, has to be undertaken. Never be in too great a hurry to commence the work, especially in the case of newly-planted Roses. By pruning too early the result is thin, sickly growths, which never give satisfaction. Whereas, if patience is exercised, the work deferred till the sap is running freely, and the shoots pruned to plump, healthy eyes, the result is blooms nearly as early, and, given other proper attentions, stout, healthy growths, with correspondingly fine flowers. Where unable to make a clean cut with a sharp knife, use secateurs—those with a drawing action of the blades are the best for the purpose. When using a knife always hold the plant firmly with the hand, otherwise there is a danger of loosening the roots, and this is easily done in the case of newly-planted Roses. Wear an old glove on the hand that is not used for the knife. Look over the plants daily, planning where the knife shall go, and at the same time rub off any pushing buds that will not be wanted. Scratch these off neatly with the thumb-nail. Whenever on cutting the pith appears brown, cut lower if possible to where the pith is white. Remove altogether dead, weak and overcrowded shoots to the base from where they start. Speaking generally, three or four growths are quite sufficient to retain. It is always best to do any necessary thinning-out in October, as the wood left for the following season is then better able to ripen. Each year one can generally cut away old shoots from most varieties; try and discard all wood more than two years old, thereby making room for younger shoots from the base, as by this means the youthfulness of the plant is maintained. Always cut to an outward bud, having in mind at the same time the future shape of the plant. Standards may be pruned in the same manner as dwarfs, excepting only that, if of weak growth, they may, in some cases, be cut a little less severely. With climbing and rambling Roses it is best to get rid of as much old wood as possible in October, so that now, speaking generally, there will be only a little dead wood to remove here and there. In their first season of planting, these Roses should be cut back to about 2 feet from the ground. Newly-planted dwarf and standard varieties are better if they are cut back to within three or four eyes from the base their first season. Any that are planted in the spring instead of autumn should be pruned before being planted. March is the best month for spring planting of Roses. In dealing with established plants, shoots must still be cut back severely, if exhibition blooms are required. For ordinary garden decoration the shoots may be left longer; for forming bushes or hedges, still longer; whilst for furnishing pergolas, pillars, &c., thinning

and removing the dead wood, also old wood where it can be spared, is all that is necessary. Then also the idiosyncrasies of the various sorts have to be considered, and as it would require too much space to deal fully with this question, I must refer readers to the excellent work published by the National Rose Society entitled *Handbook on Pruning Roses*.

Vigorous, medium, and moderate growers of the different hybrids and species all need different treatment. For example, Pom-poms only require their old flower-stems removing and a little thinning. Tea Roses, which should be pruned the last of all—the second week in April being quite early enough—are often damaged by frost. Any injured wood must be cut away to where the shoot is sound and the pith white, the more vigorous sorts, except where the wood is damaged, being very sparingly pruned. In ninety-nine out of every hundred gardens where Roses are grown the plants are pruned ignorantly. It is nearly always a case of "spare the knife and spoil the Rose," though in some cases many sorts are spoiled by cutting away the flowering wood. It is essential that the growth and character of the individual Rose be studied, remembering, though, that all, by being pruned severely the first season after planting, have thereby the foundation laid of a sound and healthy plant.

Finally, when all the Roses are pruned and the prunings cleared away, remove gradually the soil heaped up around those which have been protected from frost in this manner. Next fork in a very light top-dressing of well-rotted cow-dung: a small handful of soot may be dusted around each plant, or a dressing of some artificial manure. But in all cases use stimulants sparingly, and do not apply any artificial fertilisers to newly-planted Roses. After the pruning is done, when buds are breaking in places where they are not wanted, i.e., where the shoots would crowd too much, grow inwards, or cross one another, scratch them off neatly with the thumb-nail. *Leonard Petrie, Gayton, Cheltenham.*

FORCING BY CLOCHES.

THE cloche is, perhaps, better known in gardens in this country by the name of bell-glass, and although its use is not so extensive as in France, most gardeners are more or less acquainted with its value for forcing purposes. Those who have read the weekly articles by Mr. P. Aquatias on the "French" garden in these columns, will recognise the great part the cloche plays in this system of intensive culture. Such a garden is necessarily restricted to a relatively small area, mainly because of the great cost of the manure; therefore everything must be done to make the fullest possible use of the cloches and frames, and to have another crop ready to occupy the hot-beds directly one has been harvested. The diagrams shown in fig. 70 represent the methods of arranging the cloches so as to obtain the best results in forcing Lettuces. The top portion of the diagram shows the cloches placed over four Lettuces, the central one being of the large Cos type, whilst the three around it are Cabbage Lettuces. In the angles between the bell-glasses and *outside* the latter, Cos Lettuces are also planted. The three Cabbage Lettuces are removed after about a fortnight, and the Cos variety occupies the whole of the cloche, where it develops into a large specimen. As soon as this is cut, at the end of April, the cloches are rearranged so that half those previously growing outside are now covered. This will be readily understood by noticing the direction of the arrows.

There is still a batch uncovered, and this remains so until about the middle of May, when the second batch is harvested. The third figure of the diagram shows the final stage, with the cloches placed over the third batch.

NOTICES OF BOOKS.

*** PLANTS AND THEIR WAYS.**

THE subject-matter in this book is arranged in the form of short lessons, describing the structure and functions of plant organs. Each lesson is accompanied by practical work of an experimental kind to be carried out by the class—a feature specially to be commended.

A few errors, such as "syneigidæ" for "synergidæ," have been left uncorrected, but they are not numerous.

† NATURE STUDY.

PROFESSOR DAVIS describes his book on nature study as a "reader for the higher classes

The range of the book is remarkable, including, as it does, both botanical and zoological sections, and, although the information is necessarily much condensed, it is always clear, and the wider point of view, so often absent from books intended for use in schools, is not lost sight of.

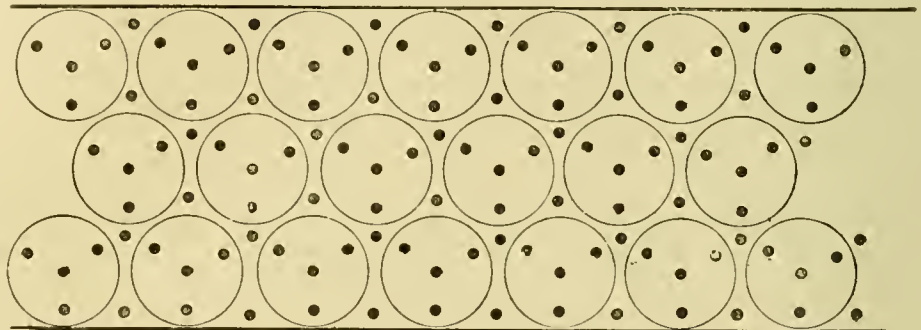

The illustrations, from original photographs, are well selected and reproduced.

THE MEMORIAL VOLUME OF THE DARWIN-WALLACE CELEBRATION.

THIS volume issued by the Linnean Society is a memento of a memorable occasion.

On July 1, 1858, the Society held the most important meeting recorded in its long and

Young of Cos Lettuces - Dis-Arrangement of the Cloches in Position

Dis-Arrangement of the Cloches in Position

Dis-Arrangement of the Cloches in Position

FIG. 70.—ARRANGEMENT OF CLOCHES IN FRENCH GARDEN.

of schools," and it should prove extremely useful to teachers, not only as an aid to class work, but also for reference out of school.

The needs of the teacher in town schools—often dependent, to some extent at least, on museums and natural history collections—have evidently been considered, and much useful and accurate information concerning members of both plant and animal kingdoms has been brought together.

* By Ernest Evans. (Dent & Co.)

† By J. R. Ainsworth Davis, M.A., F.C.P. (Dent & Co.)

distinguished career, for it was on that date that the joint paper by Darwin and Wallace "On the Tendency of Species to form Varieties; and on the Perpetuation of Varieties and Species by Means of Selection" was communicated to the Society by Sir Charles Lyell and Sir Joseph Hooker.

On July 1, 1908, the fiftieth anniversary of that event was celebrated in a manner worthy of the event and of the Society.

The memorial volume, giving a full record of the proceedings is not only a valuable souvenir

to the members of the Linnean Society who were present at the celebration, but also a document of importance to the historian of biology.

As our readers will remember, the Society, in order to celebrate the fiftieth anniversary of the reading of the paper, presented Darwin-Wallace medals, struck in honour of the occasion, to men eminent in biology both in this country and abroad: to Dr. Wallace, Sir Joseph Hooker, Dr. Francis Galton, and Sir E. Ray Lankester as representing British biologists who have contributed, by their advocacy and by their investigations, to the wider acceptance of Darwin's work; to Professors Haeckel, Weismann and Strasburger as representatives of the great band of foreign naturalists who count themselves among Darwin's followers.

A full report of the admirable series of speeches made by the president of the Linnean Society, Dr. D. H. Scott, by the recipients of the medals and by representatives of the universities and other learned bodies, is given in the

portraits, with which the volume is adorned. The place of honour, at the beginning of the volume, is occupied by a reproduction of Flamung's well-known engraving of Darwin; whilst at the end are a series of portraits of Wallace, Hooker, Haeckel, Weismann, Strasburger, Galton, and Lankester.

On the cover, which is not attractive, are figures of the Darwin-Wallace medal, bearing on the one side an effigy of Darwin and on the other one of Wallace.

The Linnean Society is to be congratulated on the dignified and adequate way in which it has recorded the jubilee of a great event.

DYNEVOR CASTLE.

DYNEVOR CASTLE, the residence of Lord Dynevor, is situated near to the picturesque town of Llandilo, on an eminence from which the upper reaches of the Towy Valley and, be-

notable trees. An Ash, in particular, is of an immense size; its old branches are carefully braced, and the decayed parts filled in to prevent further rotting.

The old castle of Dynevor, now in ruins, was originally erected as a Royal palace by Roderic the Great, Sovereign of all Wales, and for centuries was the seat of the government for South Wales. Overlooking the fertile Vale of Towy, and the meandering river of the same name which washes the foot of the wooded hills hundreds of feet below, and on one side standing on the verge of a sheer and deep precipice, its position in the days of primitive warfare, all but impregnable, would be of great strategic importance. The walls of the old quadrangle are in good preservation, and, after centuries of opening and closing, an oaken door remains still solid and apparently fit for further centuries of service.

I noticed a Rose garden, the ground of the beds being clothed with common Musk. This

FIG. 71.—DYNEVOR CASTLE, CARMARTHENSHIRE.

volume. A perusal of these speeches, particularly those of Sir Joseph Hooker, Francis Galton, Sir William Thiselton Dyer and Francis Darwin, will convince the younger school of biologists—if conviction be needed—of the high scientific worth and of the fine character of the naturalists of the past generation.

It is unfortunate that by some error of binding pp. 17 to 32 appear twice in the volume; though these pages are indeed fit to survive, it scarcely enhances their value to survive twice.

In addition to the record of the meeting at which the Darwin-Wallace medals were presented, the memorial volume contains the programme of the proceedings at the reception by the President and Council in the evening of July 1; a reprint of the papers by Charles Darwin and Alfred Russel Wallace, read before the Linnean Society on July 1, 1858; and selections from Malthus's "Essay on Population," which suggested the idea of natural selection.

No less valuable than the letterpress are the

yond, the Carmarthenshire beacons offer a landscape of great extent and beauty. The castle is a somewhat modern, quadrangular structure (see fig. 71), crowned at each of the angles with a cupola. The family of Dynevor has a most interesting genealogy, and the members of this ancient Welsh house still sacredly maintain many of the old customs and traditions of Gwalia. The family name is "Rice," a corruption of "Rhys," from the famous knight, Sir Rhys Ab Thomas, who supported King Henry VII., and whose prowess long continued to be sung by the bards of Wales.

There is a herd of old Welsh white and black cattle in the park, and the tinkling of tiny bells from the necks of these animals is reminiscent of Swiss pastures.

In all parts of the grounds are stately trees. On the north side of the castle is a group of Oak, Beech, and Spanish Chestnut of great age, forming a dense canopy; and in the direction of the old castle ruins are many other

Rose garden is composed of a series of circles, with Grass intersections.

Camellias do well out-of-doors at Dynevor, so do the Himalayan species of Rhododendron, as, indeed, they do in many parts of Wales. The same remark applies to Kalmias, which deserve to be more generally cultivated. I noticed a plant of *Kalmia latifolia* 20 feet broad and 12 feet high. The flower garden is most informal in design, and appears to have been evolved from what at one time were vegetable, fruit, and, possibly, flower gardens combined; some of the old fruit trees still remain. A tree of the Golden Hedgehog Holly, of considerable dimensions, a deciduous Cypress, and a tree of *Cryptomeria japonica*, 60 feet high, were all of interest. I noticed several fine trees of Scotch Fir, and a notable specimen of *Liriodendron*, the Tulip Tree.

Overlooking the deer park on the north side of the mansion is a formal flower garden, the design being worked out in Box. The colour of

the flowers used in this garden is almost exclusively scarlet.

The kitchen garden and greenhouses are situated nearly a mile from the castle. There is an old vinery, heated with a flue. The greenhouses accommodate plants that are useful for decorative purposes in the mansion, and there are fruit houses planted with Peach, Nectarine, and other fruit trees. It is not an easy matter in this locality to grow good fruits out-of-doors, as there is so much moisture in the atmosphere.

A fine plant of *Taxus adpressa* occupies a position at the end of a long, broad walk in the kitchen garden. The tree is 16 feet high, and 30 feet across. Intersecting the kitchen garden, in addition to a good wall for the culture of fruits, are several large Box hedges.

In the park is an interesting church, which has been built on the site of an ancient Roman temple, the foundations of which were discovered some years ago. There is a well, too, in the neighbourhood, which ebbs and flows, the stream issuing therefrom being called Nant-y-Rheibio, "the bewitched well." Giraldus Cambrensis supposed it to have some dependence on the fluctuation of the tides, but the sea at the nearest point is about 20 miles distant.

The gardener at Dynevor is Mr. A. Richardson, who has occupied the post for several years and has carried out many improvements. *A. P. Rowler.*

THE ALPINE GARDEN.

SAXIFRAGA DR. RAMSAY.

WE owe to Mr. Robert Lindsay, of Kaim's Lodge, Midlothian, the beautiful silvery Saxifrage which bears the name of the late Dr. Ramsay, himself an ardent horticulturist. The plant was raised by hybridising the two silvery Saxifrages, called *S. Macnabiana* and *S. lantoscana superba*, and in its habit it largely partakes of the latter parent. The rosettes of silvery-grey are very handsome, and the plume-like spikes of flowers are arched over after the fashion of *S. lantoscana superba*, in itself one of the most charming of this class of Rockfoils.

The individual flowers are beautiful, the purity of the white ground being the more effective on account of the presence on the petals of a few red spots. *Saxifraga Dr. Ramsay* is both a good grower and a free-flowerer, but those who wish plants to increase do not care to have too many flowering rosettes at one time, since those which bloom die. However, this variety produces rosettes freely enough, and, by taking the young ones off and repeating the process year by year for a time, a good stock of plants may be obtained. At the same time, this and other Silvery Saxifrages are more beautiful when they are in good-sized plants. Like others of its class, *S. Dr. Ramsay* succeeds best in a soil containing a little lime, and those who have not this in their soils can easily supply it by the addition of old mortar rubbish or pieces of limestone in chips.

TEUCRIUM PYRENAICUM.

The Pyrenean Germander (*Teucrium pyrenaicum*) is a beautiful little Alpine plant of value, although in many gardens it is not one of great permanence. In light and dry soils I have seen it as dwarf as 3 inches, although it is sometimes as much as 7 or 8 inches in height. The plant is prostrate in its growth, and forms a little mat of roundish, downy leaves, notched at the margins, and bearing in summer a number of small clusters of pretty little creamy-white and purple flowers. It is a plant which appeals rather to the specialist in such flowers than to the cultivator of Alpine flowers with more showy blossoms. The Pyrenean Germander does not, however, seem to be perfectly hardy, and this appears to result largely from the fact that the leaves are so woolly that the rain lodging about them causes them to decay in very wet seasons. Slugs are serious enemies to the plant, and in

gardens where these pests are numerous, it is necessary to entrap them. In wet districts the plants should be sheltered in winter and spring from heavy rains. The stock is increased by division, and the divisions should be grown on in pots until they attain a fair size, the pots being filled with loam, sand, and grit, and placed in a frame or an Alpine house. A similar compost may be used on the rockery, where the plant should occupy a position well exposed to view and on a level terrace or gentle slope. *S. Arnott.*

The Week's Work.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Black Currant gall-mite or big bud.—Before the bushes burst into leaf, carefully examine them to see if they are infested with this pest, picking off any of the big buds and burning them without delay. Should the bushes be badly infested, grub them up and burn them, and plant any fresh bushes as far from the old site as circumstances will allow. A remedy strongly recommended by various growers is to spray during March, April, and May with ordinary soft soap and Quassia mixture, the quantities being 2 ounces of the former to 4 ounces of the latter, dissolved in 1 gallon of water.

Vines out-of-doors.—It would seem that vines in the open are not so common nowadays as formerly. This is to be regretted, for, apart from the question of the fruit ripening, the foliage is extremely attractive. Even where the fruit does not ripen sufficiently for dessert purposes, it can always be utilised for the making of wine. A south or south-west wall is the best position in which to plant out-door vines. They will thrive in any good soil; but when preparing the ground for planting, on no account use rank farmyard manure. The use of too much of this commodity is probably the main cause of mildew, which is the greatest pest of outdoor vines in this country. Defer the planting of young vines till about the month of May, when the ground will be warm, and root action will soon commence. Suitable varieties are Royal Muscadine, Sweetwater, and Strawberry Grape. The work of pruning established vines (if these have not already been attended to) should be commenced at once, after which they should be washed with an insecticide such as Gishurst Compound to clear the rods of red spider and other insect pests.

General remarks.—The extremely severe weather recently experienced has acted beneficially in retarding the fruit-buds, thus affording them a better chance of escaping the ill effects of spring frosts. Whenever the weather is too bad to allow of work in the open, anything that can be done under cover should receive attention. The fruit in the fruit room will require examining for the purpose of removing any that are decayed. Exercise care in ventilating the fruit room, and admit no more fresh air than is absolutely essential, as an excess at this time of the year causes the fruits to shrivel.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Forwarding crops under glass.—Everything possible should be done to raise under glass many kinds of vegetables which would have been sown in the open ground had the weather been more favourable. By adopting this course, little time will be lost, as, the seed germinating under much more favourable conditions, the subsequent growth will be more satisfactory. The seedlings must be pricked off when quite small, either into boxes, unheated frames, or, in southern localities, merely improvised shelters. Under no circumstances should they be "coddled," but, on the contrary, air must be admitted whenever possible.

Cauliflowers.—Plants of early-forcing varieties that were potted up into 8 and 10-inch pots and are now growing in a cool temperature may, if the pots are well filled with roots, be introduced to a temperature from 50° to 60° and

exposed to as much light as possible. Give them a surface dressing of well-decayed cow manure and fibrous loam and let the roots be at all times well supplied with water. For a successional crop, another batch may be potted up either from seedlings raised last November or from plants which have been wintered in an unheated frame. Select the strongest plants, lift them with as large a ball of earth as possible, and pot them very firmly. Some of the same batch should also be planted out in unheated frames, or, failing these, hand-lights or cloches may be used, care being taken to select a sheltered, sunny position. Prick off young seedlings immediately before the third leaf is made, and sow small quantities of suitable varieties once a fortnight.

Kohl Rabi.—Seeds should be sown thinly in boxes about the middle of the present month in a gentle heat. Prick off the young plants as soon as they are large enough, and plant them out in an open position in well-prepared ground at the middle, or towards the end of April.

French Beans.—If these plants are not overcrowded, but are kept clean and in only a moderately warm atmosphere, they will now give abundant crops. Alternate waterings of diluted manure water should be afforded. The foliage should be thoroughly sprayed with tepid water twice daily on bright days, and the atmosphere must be kept moist. The most suitable place at this season for these plants is on shelves in the intermediate house. Make further sowings once a fortnight.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir EDMUND G. LOOER, Bart., Leonardslee, Sussex.

Seed sowing.—The details connected with seed sowing will now claim attention. Prepare a sufficient quantity of rich soil, which should be composed of rotted loam, leaf-mould, and silver sand. Next get some shallow seed trays, boxes, or pots, and prepare these. If boxes are used, a layer of coarse soil, or the siftings from the soil will be all that is required in the matter of drainage for such as will contain annuals, as these will not remain in the boxes for any length of time. The boxes intended for seeds of Conifer, Rhododendron, Erica, or similar plants will need to be clogged. No time should be lost before sowing seeds of Begonia, Lobelia, Marigold, Dianthus, Stock, Aster, Campanula, Salpiglossis, Phlox, and any other tender or half-hardy annual that may be desired. The boxes may be placed on a half-spent hot-bed; one that was recently used for Asparagus will answer well. Sow the seeds thinly and prick off the seedlings into boxes or pots as soon as they are large enough to handle.

Sweet Peas.—An endeavour should be made to have Sweet Pea flowers over as long a period as possible. Those that were sown in the autumn will now require thinning-out and staking. First place some short brushwood stakes on either side of the plants; these will afford a little shelter from winds and will also serve to support the Peas. The larger stakes, 7 to 8 feet in height, should be placed outside the smaller ones. When this has been done, rake the ground level, and apply a sprinkling of ashes and soot on each side of the row. Sow another batch of seeds in $\frac{1}{2}$ -inch pots, placing three or five seeds in each pot. These may be thinned out afterwards if all the seeds should germinate. Place the pots in a frame, or, if in a greenhouse, on shelves near to the glass. Sow also a batch of seeds out-of-doors, selecting well-tilled and liberally-manured soil. A good effect is obtained by sowing in clumps. If this method be adopted, a hole should be taken out, and half a barrowful of manure put at the base. Then fill in the soil and mix with it some soot and bone-meal, afterwards applying a few inches deep of rich soil on the surface. The seeds should be sown in the rich soil. Sweet Peas raised in pots may eventually be planted out in similar positions prepared in like manner. If long rows of Peas are desired, then dig out the trench as one would do for Celery. Among some of the best varieties and colours are Helen Lewis, King Edward VII., Queen Alexandra, America, John Ingham, Countess Spencer, Frank Dolby, St. George, Sutton's Queen, Flora Norton, S. J. Castle, Dorothy Eckford, Henry Eckford, and White Spencer.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Pineapples.—Pot-plants which are ripening their fruits will mature more satisfactorily if they can be removed to a light, dry house. Water them sparingly with clear tepid water. The earliest plants of The Queen, now developing their fruits, require to be treated more liberally in regard to heat and moisture than hitherto; the walls and other surfaces should therefore be damped frequently to create a humid atmosphere. Growth must be aided by liberally feeding the plants with diluted farmyard manure and guano, applying these alternately. In the afternoon the water may sometimes be weakly diluted with guano water and syringed about the base of the pots. While the plants are in flower syringing must be discontinued and the atmosphere kept moderately dry, but when the flowering stage is past growth must be again encouraged. Maintain a minimum temperature of not less than 70°, which, during the day, may be allowed to rise to 85° or 90° from the heat of the sun, but a little air should be admitted at the top of the pit. Close the lights early in the afternoon before the sun loses its power. Plants which were potted last month will now be rooting freely into the new soil, and it will therefore be safe to water them well with clear tepid water. Maintain the atmosphere in a humid condition, admitting air only on favourable occasions, and closing again early in the afternoon directly after syringing. Pot up the suckers from plants which have fruited, and place them in a warm and moist atmosphere, where they can be shaded from bright sunshine till rooted.

Cucumbers.—As soon as the roots of the earliest plants which are now fruiting appear on the surface, apply a top-dressing of loam mixed with a little decomposed horse manure. It is better to add a moderate top-dressing at frequent intervals than to give a large quantity at one time. Maintain a moist atmosphere, and syringe the plants in the morning and again at closing time in the afternoon. See that the roots are kept well supplied with water, using liquid manure and some approved fertiliser two or three times a week. Regulate the growths on the trellis, and stop the shoots at the second or third leaf. Do not allow the plants to carry more fruits than they can properly bear or they will soon become exhausted. To prevent red spider, syringe the foliage occasionally with a weak mixture of soft-soap and sulphur.

Obstruction of daylight.—Should the roof glass on any of the fruit houses have been affected by fogs, have it thoroughly washed, otherwise plants will become drawn.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Stove Aquatics.—The most successful method of cultivating these plants is to devote a house to them containing a central tank, but in cases where this cannot be done a few species may be grown in tubs. Aquatics add greatly to the interest of the collection of stove plants. All water should now be run out of the Water-Lily tank. The tubers should be removed from the old soil and placed separately in pots either of damp moss or wet sand, taking care to label each sort. The evergreen floating species should be placed in tubs or pans of warm water. Thoroughly cleanse the tank and see that there is no fault in the hot-water pipes which heat the water. Some authorities recommend planting the tubers of *Nymphaea* in tubs or large flower-pots and sinking these in the tank, but I find it more satisfactory to grow them in mounds of soil placed in position in the tank itself. The soil should consist of good heavy loam broken coarsely, and to which has been added a fourth part consisting of dried cow manure. If the loam is light, some clay should be mixed with it. After having allowed the soil to remain a couple of days in the house to warm, it should be made as firm as possible, remembering that the plants grow naturally in soil which is under considerable pressure from the water above. Plant the tubers about 3 inches deep, and place over the soil a good layer of gravel or coarse sand. The water should be warmed to a temperature of about 70°, and allowed to rise to

not more than 80° as the season advances. Such tall-growing aquatic plants as *Nelumbiums*, *Cyperus Papyrus*, *Sagittaria montevidensis*, &c., may be planted between the *Nymphaeas* and around the sides of the tank. *Hedychiums*, well rooted in pots, may be partially submerged in the water.

Primulas.—A pinch of seed of the single varieties may now be sown to provide a batch of plants for early flowering. Preparations should be made for rooting the growths of the old double-white variety. Lightly prick over the surface soil and cut away, with a pair of scissors, some of the lower leaves. Afterwards heap around the root-stock a top-dressing of sifted loam and leaf-soil, with plenty of silver sand. The soil may be easily kept in place if the pots are either sunk into empty pots a size larger, or a collar of cardboard is placed inside the rim of the pot. If the plants are given an intermediate temperature and the soil kept moist, the shoots will have rooted in about two months, when they should be removed and potted singly.

Hard-wooded plants.—For the next few weeks great care must be taken as regards ventilating the house in which these plants are grown. They need an abundance of air, but at the same time are most susceptible to draughts. Watering also requires judgment, and this is especially the case with *Boronias* and *Leschenaultias*. As the flowers of the *Epacris* fade, the plants should be rather severely pruned and placed, for a short time, in a warmer house. When the new shoots are about an inch long, repot the plants firmly in peat and sand, paying proper attention to the drainage. *Ericas* passing out of flower require similar treatment, although they should not be pruned quite so severely; merely requiring to have the weakly growths thinned out. The late-flowering *Heaths* must be kept in a well-ventilated house and as cool as possible without frost.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Blinds and other shadings.—At this time of the year there are frequent periods of exceptionally bright weather, and unless precautions are taken the foliage of Orchids is liable to become scorched by the sun's rays, especially if there are any flaws in the glass. The danger is greater at this season than at any other time of the year. Presuming that all the blinds and other shading materials are fixed in their proper places, it will be necessary to use them with discretion, for, although recommending caution in this respect, I do not advise shading the plants more than is necessary. It is better to err in giving too much shading than too little, as far more injury is likely to accrue to tender plants from too much sunshine than from too much shade. In cool houses where *Odontoglossums*, *Masdevallias*, &c., are housed, the temperature, when the sun is shining brightly, will quickly rise above 60°, especially on clear, bright, cold mornings, when the air outside is perhaps much colder than 40° and too cold to admit through the ventilators. In order to regulate the temperature of the greenhouse at such times it is advisable to lower the blinds.

The Cattleya and intermediate houses should be shaded when the sun is bright and continuous, but only on that side which is fully exposed to the sun's rays. The Mexican division which contains such plants as *Lælia anceps*, *Vandateres*, *Odontoglossum citrosimum*, &c., unless facing direct sunshine, will need no shading for the present, but so soon as the leaves begin to feel warm to the touch shading should be afforded.

The East Indian or warmest house contains a number of distinct species of Orchids, and many require very great care in the matter of shading, therefore, immediately the sun has sufficient power to raise the temperature 6° or 7°, the blinds should be used. With regard to providing suitable positions for the many distinct species which occupy the East Indian house, it is advisable to arrange such species as *Catasetum*, *Cynoches*, *Mormodes*, *Thunia*, *Dendrobium*, *Cyrtopodium*, &c., on the lighter side, and *Cypripedium*, *Aerides*, *Angraecum*, *Mystacidium*, *Vanda Lowii*, *Phalænopsis*, *Cirrhopetalum*, *Bulbophyllum*, the warm-growing *Cœlogynes*, &c., on the shady side, where they

may at all times be easily protected from direct sunshine.

Intermediate and cool houses.—The blinds on the *Cattleya*, Mexican, intermediate and cool houses should, when drawn down, be 5 or 6 inches above the glass. This may be easily arranged by fixing neat wooden rafters or iron rods from top to bottom of the roof. When the blinds are arranged in this manner abundance of light and air passes between the glass and the blinds, the benefit of which cannot be over-estimated. The blinds on the East Indian house need not be elevated above the roof glass, and the material of which the blind is made also for the intermediate and cool houses should be of a closer texture than that used for the *Cattleya* and Mexican divisions, in order to keep the houses as warm as possible. Many cultivators are obliged to grow such species as *Cattleya*, *Lælia*, *Epidendrum*, *Cœlogyne*, *Cypripedium*, *Cymbidium*, *Miltonia vexillaria*, *Vanda suavis*, *Trichopilea*, and numerous other Orchids in a house having an intermediate temperature, and it is found inconvenient or impracticable to separate them for the purpose of placing some species on the light and others on the shady side of the house; in this case it is best to shade all.

Some growers use blinds made of wooden laths and these are useful and convenient for covering the roofs at night-time when the weather is very cold.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Spring-flowering bulbous plants.—The various bulbs planted during autumn, including *Hyanthids*, *Tulips*, and *Narcissus*, are pushing through the soil, and as soon as the snow has completely disappeared, the surface soil of the beds will require to be carefully stirred with a small hoe. The *Crocuses* are pushing through the turf, and will soon make rapid growth. The blooms will require to be protected from the sparrows. Black cotton, supported on small sticks and twined about the plants in a kind of web, is the best form of protection. The birds are startled when they come in contact with the cotton. At one time it seemed that the varieties with yellow flowers were the only ones attacked by sparrows; but in recent years they have destroyed the flowers irrespective of colour.

Pits and cold frames.—Rooted cuttings of *Antirrhinums*, *Pentstemons*, *Calceolarias*, and *Violas* that have been wintered in cold frames require the soil to be loosened between the rows, and on sunny days several copious soakings of water should be given. These plants will soon be well rooted and ready for transplanting direct from the frame to where they are required to flower. *Antirrhinums* are easily raised from seeds, which should be sown at once. They are best massed in beds of distinct colours, such as crimson, yellow, and white. The *Pentstemon* is also easily propagated from seeds. This plant has few equals for massing in beds or borders. The great variety of colours and the beautiful pencilling in the throats of the flowers always evoke admiration. Innumerable are the bedding arrangements of other plants that associate well with the *Viola*. These flowers are almost indispensable; their value as edging plants on long herbaceous borders, or for planting in beds by themselves or as a groundwork to other subjects is very great. *Coxcombs* and *Celosias* are much used in the London parks for furnishing flower-beds during the summer months. Their plumes of purple, crimson, golden, yellow, and lemon-coloured flowers are especially attractive. A sowing of both *Celosias* and *Coxcombs* should now be made. When the seedlings are well above the seed-pan, place them near to the glass in a considerable heat, but guard against damping, which is a source of great danger to these plants in their early stages.

Lawns and edgings.—Attention should now be given to the rolling and mowing of lawns that are kept closely cut by mowing machines. The edges and verges on the side of paths should have the turf cut neatly and evenly, for nothing appears so untidy as a badly-kept edging, either by walks or around flower-beds. All mowing machines should have been repaired and set in proper order before this date. After the close of each season they require overhauling and readjusting, whether they be hand, horse, or motor mowers.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, MARCH 17—
Roy. Meteorological Soc. meet.

THURSDAY, MARCH 18—Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty years at Greenwich—41.7°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, March 10 (6 P.M.): Max. 43°; Min. 36°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, March 11 (10 A.M.): Bar. 29.7; Temp. 36°; Weather—Overcast.

PROVINCES.—Wednesday, March 10 (6 P.M.): Max. 42° Ely; Min. 34° Durham.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Perennials, Bulbs, Liliiums, &c., at 12; Roses and Fruit trees at 1.30, by Protheroe & Morris, at 67 & 63, Cheapside, E.C.

WEDNESDAY—

Hardy Border plants and bulbs, Liliiums, &c., at 12; Roses and Fruit trees, at 1.30; Azaleas, Palms, &c., at 5, by Protheroe & Morris, at 67 & 63, Cheapside, E.C.

FRIDAY—

Choice Established Orchids in large variety, by Protheroe & Morris, at 67 & 63, Cheapside, E.C.

Imperial Training in Horticulture.

The task of cultivating the land of the Empire is becoming more and more one for trained horticulturists. The increasing complexity of modern life causes an increase in the number of commodities indispensable to that life. The natural or agricultural rate of production being too slow to meet the demand, it has to give place to intensive methods which are essentially horticultural in their character.

Our point of view is strikingly illustrated by the custom which is growing up in various tropical regions of holding what are called "agri-horticultural shows" in the place of the purely agricultural and purely horticultural shows common in our own country. Though the word agri-horticulture is ungainly enough, it is expressive of the modern trend of development of the science of the cultivation of the earth.

In treating of the training of horticulturists for the Empire, we have not primarily in mind the training of men for service in the Government Botanical Gardens at home or abroad. Kew provides, in a manner not to be rivalled elsewhere, the technical education and practical experience necessary for the men who are to fill official posts of this kind, and in the present, as in the past, Kew men are giving an excellent account of themselves in all parts of the civilised world.

But even with respect to such posts as these more might be done than is at present

attempted. For botanical gardens are becoming also experimental stations. Now, the director of an experimental station requires special training of a kind not yet available at Kew. In such a man practical skill in the science of horticulture should be combined with a knowledge of the methods of experimentation.

We are concerned for the moment with the need for training young men who possess some small available capital, or, in default of capital, a fair endowment of energy, and who are willing to emigrate to one or other part of the Empire in order to till the soil.

It would be well for the Empire if the home country were engaged in preparing and sending out year by year colonists who had a knowledge of the methods of horticulture already implanted within them.

The reader may ask: Is it likely that any system of training at home will be of real value in the novel conditions which the emigrants are likely to encounter? Will it not be better to send them as boys to the new countries, there to learn their work by experience?

When the diverse conditions under which horticulture is carried on are considered: when the climate of Canada, severely continental in type, is contrasted with the insular climates of our tropical, island possessions: when regard is paid to the varied produce of the Empire, it may well seem as though the experience to be gained at home could be of but little service to the emigrant in his new surroundings.

Nevertheless, we believe that to draw such a conclusion would be to make a profound mistake. The successful horticulturist learns by experience to control, in as large a measure as is humanly possible, the conditions under which his plants are growing. He knows, consciously or unconsciously, the ideal conditions for certain plants, and proceeds sagaciously to provide the closest approximation to those conditions. His plants, like all plants, have simple wants—water and air, sunlight and warmth, together with small quantities of soluble compounds such as nitrogen and phosphorus. Some plants, it is true, need more water or light than others. But the peculiarities of the plants which grow at home are as wide as those that grow anywhere.

Therefore, the knowledge he has gained here will stand him in good stead abroad. He will make mistakes; but so he does at home. He will be confronted with special difficulties; but so he will be wherever he may practise his craft.

The training which he had at home would, moreover, unless it were of an inadequate kind, teach him caution; for it is only the half-trained who think they have nothing to learn.

It would be a good thing if the men going out from these shores to grow fruit in British Columbia, rubber in Malaya, or tea in Ceylon were men trained in the general, universal principles of horticulture, and not men, trained or untrained, selected haphazard by the careless hand of chance.

For this purpose no small horticultural college, with its good intentions and necessary limitations, would suffice. Such a horticultural station as that contemplated by the Innes bequest might, without detriment to the home interests which should be its first

care, form a centre for such Imperial training. What is wanted is an Imperial Institute of Horticulture; an institution amply endowed and supported by the constituent members of the Empire. Such an institution would not, of course, be a teaching body only; it would investigate as well as instruct. Nor would it exist solely for the service of the colonies and dominions of the Empire; it would benefit also the home country. An institution of the kind would not only train men to go abroad and train men for home horticulture, but it would attract men from the colonies themselves. To it would come men from the east and from the west in order that they might learn the latest word of horticultural wisdom.

This is no place to discuss detail: as, for instance, whether anyone should be admitted to study at the Imperial Institute of Horticulture before he had worked for a term at the practice of horticulture, or whether the manual and mental parts of the work should be carried on simultaneously—we refrain from using such words as "practical" and "scientific" in antithesis. To do so is ridiculous; for, if science is not practical and if practice is not scientific, then both are nonsense.

The proposal thus outlined in briefest fashion may seem, even to those who sympathise with the aspirations suggesting it, too bold to be likely of realisation. It is true that such a scheme would require the expenditure of a large sum of money. But when the importance and the magnitude of the work which such an institution would perform are considered, it cannot be doubted that the money would be well expended. Other industries, great and imposing, it is true, but, nevertheless, of lesser magnitude than those of agriculture and horticulture, have their "Charlottenburgs." In this country we are still without a Chair of Horticulture at any of the universities, and it is not long since the first Chair of Forestry was established. Why, at the next Imperial Conference, should not such a proposal as that outlined here be given consideration?

OUR SUPPLEMENTARY ILLUSTRATION.—At the Royal Horticultural Society on October 27 last year Colonel G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), staged one of those magnificent groups of Orchids for which his gardens have become famous. One of the most admired plants in the group was *Lælio-Cattleya Lustre gigantea* (C. Luddemanniana × L.-C. callistoglossa), which was accorded an Award of Merit. The beauties of the flower consisted not only in its fine colouring, but more particularly in the remarkable arrangement of its segments. The plant is of dwarf and compact habit, and the flowers, therefore, appear unusually large in comparison to the size of the growths. The sepals are white, tinged with rose; the petals crimped and decurved, white, tinged and mottled with rose, the mid-ribs being white. The lip is deep claret-purple, lighter towards the front, which has a light violet shade, the base having deep, golden-yellow lines, and the front a branched reticulation of a yellowish tint. It is interesting to note the features of *Cattleya Warscewiczii*, which, with *Lælia purpurata*, were the parents of L.-C. callistoglossa, appearing so marked in the flower of L.-C. Lustre, whose fine substance is also derived from that parent.

THE "BOTANICAL MAGAZINE."—In the issue of this publication for March, there are illustrations and descriptions of the following plants:

CYCAS MICHOLOITZII, tab. 8242.—This species was discovered in Annam by Mr. W. MICHOLOITZ when collecting on behalf of Messrs. SANDER & SONS. A plant sent home by him in 1904 and a complete series of herbarium specimens were placed at the disposal of Sir W. T. THISLTON-DYER, whose formal description of the species was published in *Gardeners' Chronicle*, 1905, vol. xxxviii., p. 142, figs. 48 and 49.

SAXIFRAGA SCARDICA, tab. 8243.—A form of *S. scardica* was figured in the *Botanical Magazine*, 1905, tab. 8058. That form is most usually met with in Alpine gardens, but Mr. SPRAGUE pointed out at the time that it was not the typical state of the species. The typical *S. scardica* now figured is a rare plant, and it is stated to have been introduced to cultivation in this country by Mr. R. FARRER, of Ingleborough. A living plant was presented to Kew in 1908 by Mr. E. H. JENKINS. The differences exhibited by the two forms are described as follows:—In *S. scardica* proper the lower leaves are acute with 9-15 intramarginal pits, the 3-II flowered stems are reddish, and the reddish subacute calyx lobes are distinctly glandular-pilose. In the form figured at t. 8058, for which Mr. SPRAGUE proposes the name *S. scardica* variety *obtusata*, the lower leaves are subacute, with 5-II intramarginal pits; the 1-3 flowered stems are green, and the green, obtuse calyx lobes are relatively free from pubescence.

PSEUDERANTHEMUM SETICALYX, tab. 8244.—This is the species that was described by C. B. CLARKE in the *Flora of Tropical Africa* as *Eranthemum seticalyx*. The specific name has reference to the attenuate calyx-lobes, not to the presence of setæ, for the calyx is glabrous or nearly so. There are several species of *Pseuderanthemum* which may be grown so as to get them to flower in winter. These include *P. albiflorum*, *P. Andersonii*, *P. cinnabarinum*, *P. igneum*, and the species now figured, which last may also be grown so as to flower in late summer. These Acanthaceae plants require the temperature of an intermediate house.

NIGELLA INTEGRIFOLIA, tab. 8245.—For illustration and description of this species see *Gardeners' Chronicle*, 1908, xlv., p. 226.

RUBUS KOEHNENIUS, tab. 8246.—The figure of this plant was prepared from a plant purchased from Mr. SPÄTH, of Berlin, in 1890, under the garden name of *R. moriofolius*. It differs, however, from SIEBOLD's species so named, and Dr. FÖCKE (*Engl. Prantl. Pflanzenfam.*, vol. iii., pars iii., page 28) found it necessary to treat it as a distinct species referable to a small East Asian group, the *Corchorifolii* of the section *Batothamnus*. At Kew this plant forms a rounded bush 3 feet high. It blossoms towards the end of May, and its fruit ripens in July. The plant thrives vigorously in a border of loamy soil, and can easily be increased by means of suckers. Its attractions as a shrub for the garden lie in its fine, lobate leaves and in its abundant and distinct white flowers.

LINNEAN SOCIETY.—At a meeting to be held on March 18, at 8 p.m., the following papers will be read:—1, Miss STYLL LONGMAN, "The Dry Rot of Potatoes"; 2, Mr. A. HORNE, "The Structure and Affinities of *Davidia involu-crata*," Baill.

MR. W. BUOD is retiring after 47 years' service as head gardener to Mr. DALGETY and Captain DALGETY his son, at Lockerby Hall, Romsey, Hants. He will be succeeded by Mr. W. BAXTER, from Melchet Court Gardens, Romsey, where he has served as foreman for the past ten years under Mr. G. HALL, who is so well known as a leading exhibitor of Japanese Chrysanthemums.

ROYAL GARDENERS' ORPHAN FUND.—From February 26 last the address of the office of this fund will be Milton House, Surrey Street, London, W.C. The secretary is Mr. BRIAN WYNNE.

MR. J. F. BAILEY.—At the annual meeting of the Royal Society of Queensland, held at the Technical College, Brisbane, on January 29, Mr. J. F. BAILEY, Director of the Botanic Gardens, Brisbane, was elected to the presidency, in succession to Mr. J. C. BRUNNICH, F.I.C. The late president took for the subject of his retiring address, "The Land we Live On." Speaking of the economic position of Queensland, he showed that whilst Queensland could grow practically all the food stuff she requires, she still depends largely on outside markets. If only a narrow strip of 6 per cent. of the whole of Queensland were cultivated, Queensland could produce a wheat crop equal to about that of the United States.

TRIALS OF DAHLIAS.—The National Dahlia Society, in addition to holding two exhibitions in September next, has arranged for three trials of Dahlias for the purpose of determining the varieties best adapted for garden decoration. These trials will be as follows:—Garden Dahlias, in association with the Royal Horticultural Society, at Wisley Gardens; Cactus Dahlias, in conjunction with Mr. J. T. WEST, at Shenfield; and Pompon Dahlias at Slough, under the care of Mr. CHARLES TURNER. The garden Dahlias at Wisley will be grown under a distinctive name, and two plants of each variety intended for trial should be sent to the superintendent in April, addressed, if by rail, R.H.S. Gardens, Horsley Station, L. and S.W.R.; or, if by post, R.H.S. Gardens, Wisley, Ripley, Surrey. A post-card should, in either case, be sent announcing the despatch of plants. In connection with the other trials, new varieties of Cactus and Pompon Dahlias are alone invited, and these will be grown under numbers, in conjunction with comprehensive collections of varieties in commerce. Two plants of each variety should be sent not later than the end of May. Those desirous of including their novelties in the trials should notify their intention to Mr. E. F. HAWES, Royal Botanic Gardens, Regent's Park, N.W., and send with the notification the names of the varieties intended for trial. These names will be registered in numerical order, and the corresponding number with address label will be returned ready for despatch to the trial ground. All packages should be sent carriage paid. On arrival they will be carefully planted, be supported with a single stake, and grown without disbudding. The plants will be inspected on convenient dates by a special committee of the National Dahlia Society.

THE HORSE GUARDS' PARADE: A SUGGESTED IMPROVEMENT.—London, which is always to its citizens a fascinating place, may yet become a splendid city. It has unrivalled parks, and no lack of stately buildings, but, by reason of its haphazard growth, it lacks the ordered majesty which should belong to the metropolis of a great empire. Statues, some of great beauty, some unworthy of their subjects or of any city, have been dumped down in obscure corners, or in crowded thoroughfares. Fine buildings rub shoulders with mean houses, and great avenues of adequate proportions are but few. Recent improvements, however, prove that these disabilities are becoming widely recognised, and that artistic ability is available to remedy some at least of these defects. Kingsway is a noble thoroughfare in the making. The Marble Arch improvement is a notable success. Mr. J. W. SPEAIGHT, to whom London is indebted for the idea of this latter improvement, has now turned his attention

to the amelioration of that dreary stretch of desolation—the Horse Guards' Parade. Mr. SPEAIGHT would transform this into a great Place of parade ground, broad walks, and avenues, wherein the statues of British military heroes should be gathered together—a British Valhalla. The plans, which Mr. SPEAIGHT, with the collaboration of Mr. C. E. MALLOWS, F.R.I.B.A., has now prepared, represent a good idea finely developed. The cost—some £60,000—is not considerable, and the work would provide employment both for skilled and unskilled labour. It is to be hoped that all who are eager for the beautification of London will lend their active support to the scheme.

MR. W. J. SIMPSON, late gardener at The Grange, Sutton, Surrey, and one of the most expert cultivators of Sweet Peas, has removed to Stoke Rochford, Grantham, as gardener to H. W. JEFFERSON, Esq.

*** LAWN.**—We have received a pamphlet on this subject by W. J. STEVENS. The author rightly insists on the necessity there is for providing a good foundation for the lawn at the commencement. It is impossible to obtain good results if the ground is likely to fall afterwards here and there and thus show depressions when the Grass should be level or have an even slope. The details of lawn-making with turf and with seeds are carefully explained, it being advised that one or the other method should be adopted, according to local circumstances. As a rule, however, the best sward can be obtained by sowing seeds, it being next to impossible to get turf free from weeds. Short descriptions of the principal kinds of Grasses are given, and information with respect to the renovating and manuring of lawns, as well as methods of destroying worms and Moss. The pamphlet concludes with an article by Mr. HEARNE, of Lord's Cricket Ground, on the formation and management of cricket and tennis grounds.

PUBLICATIONS RECEIVED.—*One and All Garden Books: Stocks.* By R. P. Brotherston. (London: Agricultural and Horticultural Association, Ltd.) Price 1d.—*Bulletin de la Societe Nationale d'Acclimatation de France.* (Paris: 33, Rue de Buffon).—*Bulletino della Societa Botanica Italiana.* No. 1.—*List of Herbaceous Perennials Tested in the Arboretum and Botanic Garden Central Experimental Farm, Ottawa, Canada, with Descriptions of Flowers, and Other Notes.* By W. T. Macoun. (Bulletin No. 5, Second Series). (Ottawa: Government Printing Bureau).—*U.S. Department of Agriculture: Bureau of Plant Industry.* Circular No. 23. Potato Diseases in San Joaquin County, California. By W. A. Orton. *Bureau of Entomology.* Bulletin No. 66, Part IV.: Some Insects injurious to Truck Crops. The Leafhoppers of the Sugar Beet and their relation to the "Curly-Leaf" condition. By E. D. Ball, Ph.D. Bulletin No. 75, Part VI.: Miscellaneous Papers on Apiculture. The Status of Apiculture in the United States. By E. F. Phillips, Ph.D. Circular No. 104: The Common Red Spider. By F. H. Chittenden, Sc.D. Farmers' Bulletin No. 344: The Boll Weevil Problem, with special reference to means of reducing damage. By W. D. Hunter. (Washington: Government Printing Office).—*Agricultural Bulletin of the Straits and Federated Malay States.* (February). (Singapore: The Methodist Publishing House).—*Johnston on Small Holdings and Allotments.* Second and Revised Edition. (London: Effingham Wilson, 54, Threadneedle Street, E.C.) Price 16s. net.—*The Estate Magazine.* (March). Price 6d.

NOTES FROM A "FRENCH" GARDEN.

THE recent snowy weather has been very harmful in the French garden. Work had to be entirely suspended, and the numerous sowings which in ordinary conditions would have been made were inevitably delayed. This weather has emphasised the importance of having everything in readiness for the making of the hot-beds, and the ground prepared before Christmas for the crops in the open.

Although the weather has caused much delay, it would be unwise to make the hot-beds thicker than usual with a view to making up for lost time, as plants, especially seedlings, suffer from excess of heat as well as from cold.

The snow has cooled the beds that were made in January and February, and the paths between the frames will have to be filled up again with hot and strawy manure.

In many places the mats have been kept continually on the lights, and this has been prejudicial to the crop of Radishes. As soon as the weather permits the plants will be pulled out. The Lettuces also will require attention, as they have many decayed leaves.

The first Lettuces planted in January will be ready for harvesting shortly. We generally cut the Lettuces early in the morning, and put them in hampers, head downwards. This is to prevent dirt from getting between the leaves: they are carried to the shed to be packed.

If Cauliflowers sown in September have not grown satisfactorily, they should be planted now, but if the plants are strong and healthy, it is preferable to wait till the Lettuces are cleared before planting them among the Carrots.

We are now sowing another batch of Cauliflower "Lenormand," to be planted in the open amongst the Cabbage and Cos Lettuces at the beginning of May.

Endive sown in the middle of February will be ready for transplanting on a hot-bed 9 inches in height when trodden down. We shall allow 140 to 150 plants per light. The lights are kept closed until the plants are well established, after which they receive a little ventilation.

For a succession we generally sow some seeds in the hot-beds, on which are reared the young Melons. The plants are pricked off a month after sowing.

We are sowing Celery, and, as the snow has delayed this work, a hot-bed will be requisitioned. One batch is of the variety Chemin; this is employed for early cropping. The variety Long Winter Green is used for the main batch. A few seeds of Celeriac Improved Parisian will also be inserted.

Melons sown in the middle of February will now require to be potted into 3-inch pots filled with rich, loamy soil. The soil is not made firm at the roots, and the pots are well filled so as to avoid them holding too much water. The plants are plunged in a hot-bed which has been prepared a few days earlier. We insert from 90 to 100 plants in each light, which are kept closed for eight or ten days, after which they can be opened a little in the middle of the day, to assist in hardening the plants.

The main batch of Melons should be sown in the middle of March to have them ready at the beginning of May to utilise the frames and lights until then occupied by the Carrots and Turnips. We sow two lots of seeds at an interval of a few days, in case the first batch fails.

In some of our frames we have planted a crop of Lettuces without sowing Carrots amongst them. As soon as the Lettuces are cleared, we shall remove the frames and the lights, put the soil in a convenient place, and then turn the manure over and well tread it. After this operation the frames and the soil will be replaced in their original positions. These beds will then be ready for the sowing of Turnip Early White. To sow Turnips in the frame we have a special appliance a little shorter

than a light, viz., 4 feet 3 inches by 4 feet 4 inches. It is made of 11 pieces of wood nailed at equal distance across 10 similar pieces. At the place where the slips of wood cross is fixed a small peg 1 inch in length. When this tool is pressed on the soil it makes 110 holes, into each of which are placed three seeds of Turnip. The lights are kept closed till the young plants come up, when a little ventilation is permitted and the quantity increased gradually, some being allowed even at night-time. When the cotyledons are well developed, all save one plant are removed from each hole.

Tomatos that were raised from seeds sown on February 20 will be pricked off in beds which have previously carried a crop of Lettuces. The beds will be prepared as for the sowing of Turnips.

We are planting early Potato Henot in a well-sheltered bed. The tubers are very even in size, and the haulm is small. We plant them in rows made 2 feet apart and allow 18 inches between the plants in the rows. By the middle of May they will be fully earthed up, when we shall plant Tomatos between the rows, and this crop will occupy the ground when the Potatos are lifted. *P. Aquatias.*

LAW NOTES.

REPAIR OF NURSERIES.

AN action of considerable interest to nurserymen was recently tried before Mr. Justice Jelf, at Nottingham Assizes, in connection with a dispute which had arisen between Messrs. J. R. Pearson & Sons, of Nottingham, and their late landlord.

The land which formed the subject-matter of the action had formerly been occupied by Messrs. Pearson as nursery ground, but it was afterwards sublet by them. When the lease ran out, the landlord of the premises, Mr. Charlton, brought an action for damages, mainly on the ground that the land had not been left in proper condition.

Putting the matter briefly, the dispute principally turned on the construction of a clause in Messrs. Pearson's lease, which provided that the land should be given up at the expiration of the tenancy "in good state, plight and condition." In addition to this, the landlord contended that the land had not been used "in a husbandlike manner, according to the custom of the country."

Messrs. Pearson, as defendants, thus had to defend the manner in which the land had been left by their under-tenants, and they raised a variety of interesting objections to the landlord's claim. They pointed out that the lease contained no restrictive conditions as to cropping, and that a nurseryman could not claim for compensation or tenant-right on his leaving the land, and ought, consequently, to have a free hand as regards cultivation and manuring.

In summing-up the case to the jury, the learned judge declined to regard the points put forward by the defence as relevant to the issue, and stated that, in his opinion, the case turned entirely on the wording of the covenant in the lease to the effect that the land should be given up "in good state, plight and condition." So far so good, and if the matter had been left to the jury at this point, they would have had merely to determine the simple question as to whether the tenants had or had not left the land in this state. But the learned judge went further than this, and expressed the opinion that the tenants would not be leaving the land in good state, plight and condition unless they actually left it in just such a state as they would yield it up to a son or a brother, or as it was during the middle of their tenancy, i.e., in the height of condition as regards cultivation and manuring. If the learned judge was correct in adopting this point of view, it will be seen that a nurseryman who holds under a lease in these terms is in a position of extreme hardship, inasmuch as he, like the market-gardener, can be called upon to leave the land at the end of his tenancy in first-class condition (and not merely in fair condition), although, unlike the market-gardener, he can claim no com-

ensation from his landlord for improvements or special manuring.

Fortunately for Messrs. Pearson, the case came before a jury composed of men familiar with agricultural conditions from the practical point of view, and, somewhat to the surprise of those present in court, they entirely disregarded the summing-up, and gave a verdict for Messrs. Pearson on all points.

Had the case come before a jury of another type, the result might have been disastrous for Messrs. Pearson. It is a practical instance of the unsatisfactory position of the nurseryman, which has more than once been described in these columns. The case also furnishes an additional argument in favour of the remedy which has been urged many times in these pages, that, in disputes between nurserymen and their landlords, all matters of fact should be compulsorily referred to the arbitration of a single practical man, as is already the rule in the case of market-gardeners. The simplest way to achieve this object would be to extend to nurserymen the same easy machinery for arbitration which is granted to market-gardeners by the provisions of the Agricultural Holdings Act. *H. M. V.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE R.H.S. DAFFODIL CLASSIFICATION.—

I desire to say that I was wrong in attributing to the R.H.S. Council the want of mature consideration in issuing this new scheme. It appears that the Council did exactly as requested by the Narcissus Committee, i.e., authorised first the appointment of the Special Committee and then its recommendations when received. The blame must rest with the Narcissus Committee, of which I am myself a member. It should have appointed its own sub-committee and fully considered its report before passing it to the Council for its imprimatur. Mr. Jacob gives an erroneous impression by his account of the omission of Mr. P. R. Barr's name from the Special Committee. Mr. Barr was the original mover for a revision of the classification, and his name was necessarily one of the very first chosen by the Narcissus Committee. Its subsequent omission was owing to a pure but most unfortunate misconception. I need hardly explain that in making this correction I am not in any way depreciating the work of Mr. W. Barr. I will not occupy space by answering Mr. Jacob on the general question of this classification. He apparently stands alone in his advocacy. The experts in the subject seem to be united in their strong disapproval, which will probably have been effectually expressed elsewhere before this is in print. *G. H. Engleheart.*

I fully recognise the great service conferred by the Daffodil Committee in compiling and issuing this List. They are the most competent, and, indeed, the only body who could do so with the necessary experience and authority, and, moreover, since a new classification was urgently needed, it was certainly wiser to issue it now, though necessarily imperfect, than wait, perhaps indefinitely, for a more complete or perfect scheme. But the List was admittedly tentative, and, hence, invited the expression of opinions of those interested. Anyone who has thought about the matter at all will have realised how difficult the task is and how impossible it would be to make a perfect scheme that would satisfy all interests. But Mr. Jacob says: "It does not profess to be in any way natural or botanical. It is for garden and show purposes. Personally, I regard it as one-seventh garden and six-sevenths show." It seems to me that this fully justifies Mr. Engleheart's criticism, and, without going into any question of degree, I plead that regard might be paid to other points of view. Mr. Engleheart's letter is, I think, evidence that it would be possible to do so with advantage, and that, so far from its value for show purposes being diminished, the classification would be improved, would gain in general usefulness and authority, and, what is especially desirable, it would appeal to a far wider circle than those who are only, or primarily, interested

as exhibitors. Referring to doubtful cases, Mr. Jacob asks whether certain varieties should be classed in one division or another, and adds that, whatever view might be taken, he is ready to argue the case for the other side. The opinion of an individual, even if he is an expert, has only a limited value. It varies with the degree of his experience and is influenced by his special interest in the flower—as exhibitor or grower, gardener, breeder or botanist. It is just such debatable cases, where there seems to be as much to be said for one side as the other, that illustrate the necessity for the widest possible expression of opinions, and it is in such cases especially that considerations from the point of view of the breeder and botanist would be helpful in making a satisfactory decision. *A. J. Bliss.*

DAMAGE BY SNOW.—I am sending you a photograph (see fig. 72) of the wreck made by the heavy fall of snow last week on Mr. W. Wood's place at Dartford Heath, when seven houses, 300 feet long by 12 feet wide, completely collapsed, although fires were going. As there were 23° of frost, scarcely any of the contents of the houses were saved. Amongst the plants lost were over 20,000 young Tomatos, besides Carnation and Chrysanthemum cuttings, so that practically the whole of the season's crops are ruined. Having known

Broccoli, and Brussels Sprouts on highly-manured or loose soil. Under such conditions, nearly all the Winter Broccoli has collapsed, and many of the Brussels Sprouts are of little value, because there are no compact buttons, only loose leafage that is scorched in the open field on hard, poor soil. Green vegetables in general are in a much better condition, although not by any means entirely undamaged. The Broccoli crop, even in fields, has suffered severely in a few instances. Kales, more especially the old cottager's type and scotch, show their superiority over other green vegetables during such winters as this, and are valuable in any household or market. Such seasons as the present teach us that it is unwise to rely upon one sowing of any of the winter and spring green vegetables, and that smaller, less succulent plants are superior to larger, sappy specimens for withstanding severe frosts. The Spring Cabbage crop is looking anything but promising. The 26° of frost experienced just after Christmas, in spite of its suddenness, did our plants no harm. Fortunately they were securely covered with snow, and they looked very fresh after the thaw. Now they look unhealthy, for the many frosts during February—both wind frosts and rime—without any covering or rains to help them, have caused the plants to dwindle to very small proportions. The best course to take is to commence forming a gentle

NAMING OF MULTIGENERIC ORCHID HYBRIDS.—Having carefully studied the circular issued by the sub-committee of the Orchid Committee of the Royal Horticultural Society, it appears to me that a much simpler and more intelligible plan might be adopted than any of the half-dozen described. Plan No. 1, as at present adopted, involving the combination of parts of the names of the different genera combined in the hybrid, is, to my mind, open to a practicable modification as follows, which considerably shortens the compound names without, however, sacrificing, for the Orchid expert, their significance. By the present system, several syllables of each genus are used; thus, in the examples given, we have *Anguloa* × *Lycaste* = *Angulocaste*, *Anætochilus* × *Hæmaria* = *Anæctomaria*, and so on; a trigenic hybrid *Sophrontis* × *Cattleya* × *Lælia* thus becoming *Sophrælaiocattleya*. So that it is quite obvious that, as the circular states, for multigenic hybrids of very complex character, the names would become ridiculously long and unmanageable. A careful study of the generic names shows, however, that each genus in its name has a single syllable or dissyllable, sometimes more than one, which could be adopted as its symbol, and used in conjunction with others in such a way that there would hardly be more syllables than genera. This, at any rate, is a great step in the right direction, while those acquainted with Orchids could at a glance read off the symbolic syllables, and see at once the composition of the plants, so far as the genera involved were concerned. It is absolutely hopeless to attempt to do more than this; that is, to indicate the varietal parentage in addition. Having thus indicated the nature of my suggestion, I will illustrate it by comparing the list of bigeneric and trigenic hybrids already named and cited in the circular under consideration, with the compound names on my system:—

FIG. 72.—PLANT HOUSES DESTROYED BY SNOW IN A MARKET NURSERY.

Mr. Wood for a great many years as a worthy man and good grower, I am making an appeal on his behalf, and shall be glad if you will find room to publish the photograph in your next issue, with my letter, as I feel sure that many will contribute to help a man over such a disaster. I shall be glad to acknowledge direct, and through your columns each week, any subscriptions given, if you will kindly allow space for that purpose. The following donations have been promised:—H. O. Larsen, £10 10s.; James Sweet, £10; Joseph Rochford, £10; Geo. Monro, Ltd., £10; J. Nielsen, £3 3s.; A. J. Monro, £2 2s.; R. Copley, £2 2s.; A. W. Pollard, £2 2s.; H. B. May, £1 1s.; Robert Piper, £1 1s.; James Walker, £1 1s.; Mrs. Monro, £1; F. Horne, £1; R. Seymour Copley, £1. *Geo. Monro, March 11.*

CABBAGES AND THE FROST.—Most of the life of the winter vegetables has been squeezed out by alternate freezing and thawing. They are looking very flabby and dejected. There was a prolonged growing period last autumn, and such is scarcely the best weather for preparing green crops for withstanding a severe winter. If there is one cultural point emphasised more than another during the present winter, it is the folly of growing such crops as Winter Broccoli, Spring

hot-bed, and to raise a few thousand young, healthy plants of the smaller early-heating varieties, such as Sutton's April, or any selected type of Ellam's Early. Plants raised at this season grow away very quickly. Everything must be done to prevent a shortage in the supply. It is usually possible to find suitable spots for pricking-off frame-raised plants a few inches apart, to be moved during April, with a small ball of earth, to their final positions. When they are established there, light applications of nitrate of soda will assist in the early formation of dark, tender, succulent leaves. Soluble fertilisers are never more economically employed than for adding colour and succulence to such produce. It renders them so tender that the supply rarely equals the demand, which is always a healthy sign to the purely market man. Perhaps the quickest hearting of all the Cabbages suited to spring sowing is "Earliest," which has received two awards, and ought to be grown in every private garden. *Charles Foster, Reading.*

FROSTS AT MONMOUTH.—On the morning of March 4 we registered 25 degrees of frost, and on the 5th inst. 32 degrees. Fortunately, for some subjects, the ground was covered with about 8 inches of snow. *T. Coomber, The Hendre Gardens, Monmouth, March 8.*

Group Genera.	Hybrid as Named.	New System.
1. <i>Anguloa-Lycaste</i>	<i>Angulocaste</i>	<i>Angcaste</i>
2. <i>Anætochilus-Hæmaria</i>	<i>Anæctomaria</i>	<i>Hæmaecta</i> or <i>Anæria</i>
<i>Dossinia-Hæmaria</i>	<i>Dossinimaria</i>	<i>Dossaria</i>
<i>Macodes-Hæmaria</i>	<i>Macomaria</i>	<i>Macoria</i> or <i>Macria</i>
3. <i>Chondrorhyncha-Zygopetalum</i>	<i>Chondropetalum</i>	<i>Chonalum</i>
<i>Batemannia-Zygopetalum</i>	<i>Zygobatemannia</i>	<i>Zygannia</i> or <i>Batalum</i>
<i>Colax-Zygopetalum</i>	<i>Zygocolax</i>	<i>Zygalax</i>
<i>Aganisia-Zygopetalum</i>	<i>Zygonisia</i>	<i>Aganialum</i> or <i>Zygalia</i>
4. <i>Cochlidia-Odontoglossum</i>	<i>Odontioda</i>	<i>Cochlossum</i> or <i>Odontoda</i>
<i>Miltonia-Odontoglossum</i>	<i>Odontonia</i>	<i>Miltossum</i> or as hitherto

These last two, it will be noted, are named approximately or quite on the briefer system I advocate, and it is useless for me to go through the entire list, as the above are sufficient to show how compound names can be built up in a short compass, and yet indicate all the genera involved. I have, indeed, gone through them all, and found no difficulty whatever in applying the system. For *Cattleya* and *Lælia* some objection might be raised to the use of such similar-sounding terminals as "leya" and "lia" for these genera; but, to my mind, the first essential is a clear label, or written or printed record, rather than a pronounced name, which, in practice, is little used. Turning now to the trigenic hybrids cited, we have *Brassavola-Cattleya-Lælia* = *Brassocattlælia* reduced to *Brassatlia*, and *Sophrontis-Cattleya-Lælia* = *Sophrælaiocattleya* reduced to *Sophratlia*, which is surely a step in the right direction, since, from the very outset, the orchidist who gripped the principle and knew the generic names could read them off instantly, quite as well from the abbreviated forms as he could from the long and cumbersome ones, which, moreover, are rendered impracticable where many genera may be involved. I take, for instance, by way of test, eight genera as they stand seriatim on the list, viz.: 1, *Anguloa*; 2, *Lycaste*; 3, *Anætochilus*; 4, *Hæmaria*; 5, *Dossinia*; 6, *Chondrorhyncha*; 7, *Zygopetalum*; and 8, *Aganisia*; and, with a little ingenuity, arrive at this: *Chondroszygan-gochæmagalum*, i.e., nine syllables, as representing all the eight genera. This is bad enough, I admit, but it is only about half as long as the seven generic names combined in the circular as an example of unwieldiness. In my

bumble opinion, it is a practical impossibility to invent a system of nomenclature which can embrace an unlimited number of genera in one name. The one I suggest will certainly deal with a fair number, embracing the great majority of likely combinations, and that, at least, is something. It would, however, be essential that the naming be done or approved by the Orchid Committee of the R.H.S., so far as British productions are concerned, since it is obvious that different combinations of the same symbolic elements are not desirable, though they would none the less indicate the composition of the hybrid to the expert, and it is practically only the expert who is concerned. *Chas. T. Druery, V.M.H., F.L.S.*

ANOTHER HYBRID FRUIT FROM LUTHER BURBANK.—In the current number of the *Revue de l'Horticulture Belge*, published on March 1, the "Wonderberry" is described by a correspondent named Albert Dervaes as the latest product raised by Mr. Burbank. This most curious hybrid fruit has the alternative names of Sunberry and Sugarberry. It is described as the results of a cross between two species of Wild Solanum (*S. guianense* and *S. villosum*). The first of these species is a native of the western side of South Africa, and the second of the western side of Eastern America. While neither of these species produces edible fruit, this specific hybrid produces a profusion of delicious berries, which are both sound and wholesome. There is also the additional advantage that they come quite true from seed like a natural species. The plant is not more than 18 inches high by a little more in diameter; the flowers show themselves about the end of May and succeed one another without interruption till very late in the autumn. The fruit or berry is of a blackish-blue colour of the size of a large Black Currant, and is produced in clusters of six in such abundance as to entirely cover the plant. The first fruits ripen early in July, and the same plant continues to yield fruits until late in autumn or until the first frosts. The fruit is either eaten raw or cooked or made into jam. The culture is easy and requires less care than either that of Haricot Beans or Tomatos; any soil suits it provided that it be not too highly manured, the result of which is only to produce a more luxuriant vegetation without increasing the amount of fruit. Seed may be sown under glass in April, and in the open ground in May. The seedlings may be planted out when danger of frost is over at a distance of three-quarters of a yard apart, after which they require no further care than hoeing between the rows and keeping free from weeds. They require no artificial manures. At the end of the season, when the plants go to rest, if the crowns are protected with dead leaves, they will shoot vigorously the following spring. *W. E. Gumbleton.*

NITRO-BACTERINE TRIALS.—As Mr. Hutchinson stated in your issue of February 27 that I made "several statements liable to mislead the general reader," will you kindly permit me to reply to these charges under three headings? (1) *Concentrated fertilisers.*—The continuation of Mr. Hutchinson's quotation from the *U.S.A. Farmers' Bulletin*, 240, reads as follows:—"Floors used for drying inoculated seeds should be thoroughly scrubbed and rinsed, especially if the same floor space has served for mixing fertilisers." And the last clause reads: "Fertilisers should be spread and mixed with the soil, or drilled, previous to sowing the seed, and if the drill has been used for this purpose all parts with which the seeds may come in contact should be cleaned." I leave it to the reader to judge which is the more misleading, to state, as Mr. Hutchinson does, that the reference "concerns the method of sowing the seed" only, or to state as I did that "the action of these concentrated fertilisers on inoculated seed is injurious." (2) *Action of lime.*—Mr. Hutchinson states that when speaking of the growth of the nitrogen-assimilating organisms in a culture solution I "consider it politic not to mention that potash and phosphates are equally indispensable." Mr. Hutchinson might as fairly complain that I do not mention water and some form of sugar as being indispensable. Mr. Hutchinson is wrong when he states that I include a number of different bacteria under the term nitrogen-assimilating organisms. All through the article I was speaking only of the

nodule-forming organism (*Pseudomonas radicola*). Prof. Chester, of Delaware, one of the greatest authorities on soil organisms, definitely states that the presence of carbonate of lime is necessary to fixation in laboratory cultures. What, then, becomes of the charge of writing "a dissertation on the requisite conditions for the culture of organisms not at present concerned"? (3) *Comparative tables.*—The alteration of Mr. Chittenden's figures in the table I gave was made at the suggestion of Dr. Keeble (vide *Gardeners' Chronicle*, p. 36) as being a more scientific method of comparing the yields. Had I quoted the figures as given by Mr. Chittenden in his report, they would have shown a still greater advantage for inoculation—an increase of 17.4 per cent. for seed inoculation, and an increase of 20.7 per cent. for seed and soil inoculation. My comparison of the yields from the plots on the fallowed land is said to be "inaccurate and useless" because taken "from plots in absolutely different series." I was under the impression that the experiments on the cultivated land formed one series, and those on the fallowed land another series. That Mr. Chittenden also thought this is shown by the three comparative tables G, O and P, given in his report. I am glad that Mr. Hutchinson has given the table comparing the yield of inoculated seed only with yields from other manures on the cultivated land. Certainly the lowest yield is from the inoculated seed, but then the addition of 10 tons of manure to this soil also decreased the yield! Can a garden soil, which gives a decreased yield when manured with dung, be truthfully called either a poor or an ordinary garden soil? *W. B. Bottomley, King's College, London.*

INOCULATION WITH NITRO-BACTERINE.—In a leaflet that is being circulated by the Nitro-Bacterine Distributing Agency, Prof. Bottomley criticises the results of experiments with Nitro-Bacterine carried out this summer. Referring to the experiments at Wye College, a brief account of which appeared in the *Gardeners' Chronicle* for January 23, he states that in this case "evidently there were already present in the soil sufficient bacteria to produce a supply of nodules," and goes on to say that, "In *Seed and Soil Inoculation* (p. 10) it is pointed out that under these conditions inoculation is useless." All this is very true, but I should like to point out that in making these statements Prof. Bottomley seems to be reducing to a very small minimum the number of cases in which inoculation is likely to result in an increased crop in this country. One of the soils on which the Wye experiment was carried out was very poor indeed and low in organic matter, and had not borne a leguminous crop for many years—just the type of soil on which, according to *Seed and Soil Inoculation*, inoculation is necessary. If, in such a soil as this, "there were already present . . . sufficient bacteria to produce a supply of nodules," it, at least, seems unlikely that there are many cultivated soils in this country which do not already possess a sufficient supply of nodule-bacteria. The advantage of inoculation, when a leguminous plant new to a district is introduced or on reclaimed land, as proved in Germany and America, is indisputable; but in this country, where most of the land has been under cultivation so long, its value has not yet been demonstrated. *C. T. Gimmingham, Bacteriologist to the S.E. Agricultural College, Wye, Kent.*

THE TRAINING OF FRUIT TREES.—I was pleased to see the remarks of B., p. 149, on this subject. Speaking generally, it is a fact that fruit trees upon walls are less carefully trained than was the case even a few years ago. Men who have been educated in gardening routine in what are looked upon as good schools are some of the greatest sinners in this phase of fruit culture. I venture to say that if the trees were subjects for a horticultural exhibition, and prizes offered for them, we should quickly see a change in wall-tree training. It is quite as easy to train a Peach tree correctly as it is to cross the branches with young shoots or tie or nail others in just as they grow, with an almost semi-circular bend. Any ordinary labourer is put to train the trees, and often without any instruction, except to get them done quickly. As a rule, fruit trees are allowed to retain too many shoots. The crops would be much better if less bearing wood were retained. *E. M.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 9.—A large and successful meeting was held in the Society's Hall, Vincent Square, on Tuesday last. The building was filled with exhibits, some of them overflowing into the annexes. This was partly in consequence of the competitive classes for forced bulbs. In addition many trade growers showed large groups of bulbous plants, so that the exhibition was composed largely of Hyacinths, Tulips and Narcissi. Orchids made a fine display, the chief honour for these flowers going to Sir JEREMIAH COLMAN, Bart. Awards were also given for groups of Alpine plants, Begonias, Camellias, Carnations, forced shrubs in flower, and other spring-flowering plants. The NARCISSUS COMMITTEE assembled for the first time this season.

Not much was brought to the notice of the FRUIT and VEGETABLE COMMITTEE, and this body made no award to a novelty, neither did the FLORAL nor NARCISSUS COMMITTEES, but the ORCHID COMMITTEE granted five First-class Certificates and two Awards of Merit.

At the three o'clock meeting in the lecture room an address on "Tulips, and the Tulip Mania" was given by Mr. W. S. Murray.

Floral Committee.

Present: W. A. Bilney, Esq. (in the Chair); and Messrs. Chas. T. Druery, E. A. Bowles, Jno. Green, T. W. Turner, J. W. Barr, R. Hooper Pearson, C. R. Fielder, W. Howe, J. Jennings, Herbert J. Cutbush, Chas. Blick, J. F. McLeod, Jas. Douglas, W. J. Bean, E. T. Cook, Arthur Turner, Chas. Dixon, Chas. E. Shea, Chas. E. Pearson, W. Cuthbertson, W. P. Thomson, E. H. Jenkins, W. J. James, and George Paul.

Mr. L. R. RUSSELL, The Nurseries, Richmond, Surrey, exhibited about 50 plants of *Rhododendron (Azalea) indica* trained in a semi-globular shape and finely flowered. These were good examples of Madame Van der Cruyssen, Professor Walters, Comte de Chambord, President Oswald de Kerchove, Phœbus, &c. (Silver Flora Medal.)

Messrs. W. PAUL & SON, Waltham Cross, contributed a showy floor group consisting of a number of choice Camellias, flowering Peaches, Almonds, Pyrus, &c. (Silver Flora Medal.)

Messrs. HUGH LOW & CO., Royal Nurseries, Bush Hill Park, Enfield, showed a miscellaneous collection of greenhouse and hardy subjects, and among them *Daphne indica rubra*, *Erica codonodes Veitchii*, *Acacia cordata*, *A. acinacea*, *Grevillea alpina*, and a collection of perpetual-flowering Carnations. (Silver Banksian Medal.)

Messrs. W. CUTBUSH & SON, Highgate and Barnet, showed forced plants, including *Rhododendron Jacksonii*, *R. canadensis*, hardy *Azaleas*, *Pyrus Malus Scheideckeri*, *Magnolias*, &c. The same firm exhibited seasonable hardy flowers. (Silver Banksian Medal.)

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed *Lachenalia Coston Gem*, a variety of *L. pendula* having yellow flowers of small size and furnished with a red calyx; two new Hybrid Tea Roses named Mrs. Sophia Neate and Rhea Reid; *Clematis montana rubens* and seedlings of *Azalea sinensis*.

Messrs. J. CARTER & CO., High Holborn, London, exhibited on the floor of the Hall growing examples of lawn Grasses in trays, forming a piece of sward about 20 feet by 8 feet. This plot was surrounded by a serpentine border of flowering and evergreen plants. (Silver-gilt Banksian Medal.)

Mr. H. BURNETT, Carnation specialist, Guernsey, exhibited perpetual-flowering or tree Carnations as at recent meetings. (Silver Banksian Medal.)

Mr. W. H. PAGE, Hampton, Middlesex, again made a beautiful display with Carnations, Daffodils, and Lilliums. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, showed an interesting collection of Begonias in about 50 species and varieties. Some of the inflorescences, such as in *B. manicata* and *B. Verschaffeltii*, were developed on tall stems, 2 feet or thereabouts in height. Several of the semperflorens type were especially floriferous; *B. s. gigantea rosea* has finely-coloured blooms. *B. Saturne* of the *manicata* type has very strong flower-spikes and numerous blossoms. Others of interest were *B. ascotiensis*, *B. fuchsioides*, and *B. Wellsiana*. (Silver Flora Medal.)

Messrs BEES LTD., Mill Street, Liverpool, showed a batch of the new *Primula malacoides*. The plants were extremely floriferous, some of them, in 4-inch pots, having 20 or more inflorescences. The plant is a splendid acquisition amongst greenhouse subjects for winter blooming. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, staged miscellaneous flowering and foliage plants of a decorative character, including many handsome Ferns. Small pot-plants of Clematis in batches of white, mauve, lavender, and other shades were set in groups of Cinerarias, *Primula* × *kewensis*, *Rhododendron* (*Azalea*) *indicum*, and *Primula obconica* of an improved strain, with Ferns as a groundwork. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, exhibited 250 Hyacinths in about 60 varieties. All were shown in large massive spikes of blooms in almost all colours. Messrs. VEITCH also showed *Boronia megastigma* and its golden-flowered variety, *Crocea angustifolia*, small plants of Orange in flower, and a grand display of *Rhododendron* (*Azalea*) *indicum*. (Silver Banksian Medal.)

A batch of *Lachenalias*, some as pot and others as basket plants, was shown by the Marquis of SALISBURY, Hatfield (gr. Mr. Prime). Those in baskets were especially fine; the culture throughout was good. (Silver Banksian Medal.)

Sir EVERARD HAMBRÖ, Hayes, Kent (gr. Mr. Grandfield), showed a very large number of hardy flowering plants, including masses of *Primula cortusoides*, *P. floribunda*, *P. Forbesii*, *Crocus* King of the Whites, *Kalmia glauca*, hardy Heaths, Saxifrages in great variety, and many other Alpine plants, all well cultivated and excellently displayed. (Gold Medal.)

Messrs. BARR & SONS, 11-13, King Street, Covent Garden, London, exhibited bulbous flowers, mainly choice varieties of Narcissi. Notable flowers were Admiral Togo (a sturdy Ajax variety), White Lady (of the Leedsii section), Bridesmaid (white), Fairy Queen (white), and Constellation. Messrs. BARR also exhibited a collection of Alpine and hardy garden plants, Crocuses being a feature; one with lavender-blue flowers, named *Bleu Celeste*, was especially pleasing, the pans in which this was shown being masses of flowers. Harlequin is a striped pale mauve variety with a deep violet base. There were also Tulips, *Lachenalias*, Scillas, and Anemones in variety.

Mr. G. REUTHE, Keston, Kent, again showed *Rhododendrons*, rare and choice flowering shrubs, and an assortment of seasonable hardy flowers. *Iris histrioides* major and *Saxifraga Bursieriana* were prominent in this exhibit.

Messrs. R. WALLACE & Co., Kilnfield, Colchester, showed on a table a rockery planted with a number of dwarf, hardy subjects. The design was boldly laid out, and on a large scale would afford a pleasing feature in a villa garden. (Silver-gilt Banksian Medal.)

Messrs. THOMAS S. WARE, LTD., The Nurseries, Feltham, also showed a rockery; also plants of *Veltheimia viridiflora*, *Iris reticulata*, *Dicentra* (*Dielytra*) *spectabilis*, &c. (Silver Banksian Medal.)

Messrs. JOHN PEED & SON, Mitcham Lane, Streatham, S.W., showed a rockery planted with Alpine species of low growth, and succulents. This firm also exhibited a batch of *Lachenalia aurea*, *L. luteola*, and *L. Nelsonii*. (Silver Banksian Medal.)

Messrs. G. & A. CLARK, nurserymen, Dover, showed a small rockery planted with hardy Primulas, &c.

Mr. P. HORTON, Cravenhurst, Seaford, Sussex, exhibited a small collection of Hyacinths, Narcissus in variety, *Veltheimia*, *Crocus*, *Iris histrioides*, &c.

Messrs. JOSEPH CHEAL & SONS, Crawley, Sussex, showed Alpine plants arranged amongst rockwork and with a row of dwarf Conifers and small shrubs such as are suitable for planting on a rockery.

COMPETITIVE EXHIBITS OF FORCED BULBOUS PLANTS.

THE competitive classes arranged for forced bulbous plants were generally well contested. The prizes in most instances were offered by the Dutch Bulb Growers' Association. Hyacinths were especially well shown, and it is doubt-

ful if finer spikes of these flowers have ever before been staged at this early date. The Tulip and Narcissus grown in moss-fibre, in bowls or ornamental pots without drainage material, served to demonstrate the value and utility of this material for growing bulbous plants.

In the class for 18 Hyacinths of distinct varieties open to amateurs, the premier prize of six guineas was awarded to the Hon. VICARY GIBBS, Aldenham, Elstree (gr. Mr. E. Beckett), for a superbly-grown collection, which included *L'Innocence* (white), *Electra* (blue), *City of Haarlem* (yellow), *Jacques* (pink), *Schotel* (pale blue or porcelain), *La Grandesse* (white), *Lady Derby* (pink), and *Menelik* (purple-violet or dark plum colour). The examples throughout showed great cultural skill. The second prize of five guineas was won by L. NOBLETT, Esq., Monkswell, Wavertree, Liverpool. The varieties King of Yellows, King of Blues, Morendo and Isabella (pink) were particularly fine. The remaining prizes were won by the Duke of PORTLAND, Welbeck (gr. Mr. J. Gibson); H. S. BARTLETT, Esq., Shooter's Hill; the Marquis of SALISBURY (gr. Mr. Prime), and Mr. A. G. GENTLE, Little Gaddesdon, in this order.

In the class for 12 Hyacinths, open to amateurs, there was good competition. The 1st prize was won by A. EARLE, Esq., Childwell Lodge, Wavertree, Liverpool (gr. Mr. Hutchinson), with excellent examples of King of Blues, Goliath (blue), Mont Blanc, Morendo and others; 2nd, F. STEWART JESMOND, Green Lane, Wavertree, Liverpool; this exhibitor showed King of Blues, *Schotel* and *City of Haarlem* exceptionally well; 3rd, Lord HOWARD DE WALDEN, Audley End, Saffron Walden (gr. Mr. J. Vert). The 4th and 5th prizes were won respectively by E. G. MOCATTA, Woburn Place, Addlestone, Surrey (gr. Mr. F. Stevenson), and Mr. G. DYKE, The Gardens, Garston Manor, Watford.

Four pans of Hyacinths.—The schedule required 10 bulbs of one variety in each pan, and this class made a particularly fine display. Those shown by the Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson), were much superior to all others and won the 1st prize: the varieties were King of Blues, *City of Haarlem* (yellow), *La Grandesse* (white), and Morendo (pink); 2nd, the Hon. VICARY GIBBS, who showed King of Blues, *L'Innocence*, *City of Haarlem* and Lord Balfour (rose and crimson); 3rd, Lord HOWARD DE WALDEN. There were six entries in this class.

The class for trade growers brought three competitors, the 1st prize being the Gold Medal of the Dutch Bulb Growers' Society, Haarlem. It was won by Messrs. R. & G. CUTHBERT, Southgate, N., with a fine collection arranged in groups at the western end of the hall. The plants were staged in semi-circular groups of one variety and in a setting of small *Adiantum* Ferns. Among the finer examples were *Simplicity* (white), *Lord Derby* (pink), *City of Haarlem* (yellow), *L'Innocence* and *Linnaeus* (red), Messrs. JAS. VEITCH & SONS, LTD., Chelsea, also staged a very fine collection of 250 pots of Hyacinths in some 50 of the leading varieties, the plants being particularly well grown. Messrs. GLEESON & Co., Watford, was the other exhibitor.

Bulbs grown in moss-fibre or similar material.—The prizes in these classes were presented by Mr. Robert Sydenham. There were classes for six Hyacinths, six Narcissi and six Tulips respectively. The best Hyacinths were shown by Hon. Mrs. GUY BARING, 116, Cadogan Square, S.W.; 2nd, Miss C. A. MITCHELL. Mrs. BARING also won the 1st prize for Tulips; 2nd, Lady TATE, Streatham (gr. Mr. W. Howe), who was 1st for six vases of Narcissi; followed by R. HOLMES, Esq., Tuckwood, Norwich.

Narcissus Committee.

Present: H. B. May, Esq. (in the Chair); and Messrs. W. Poupert, Joseph Jacob, Henry Backhouse, W. F. M. Copeland, Arthur R. Goodwin, E. M. Crossfield, P. Rudolph Barr, Walter T. Ware, Geo. H. Engleheart, Alex. M. Wilson, G. W. Leak, G. Reuthe, H. Denison, J. T. Bennett-Poë, A. Kingsmill, Robt. Sydenham, J. Duncan Pearson, W. Wilks, E. A. Bowles, F. Herbert Chapman, Christopher Bourne, Henry B. Young, and James Walker.

Lady TATE, Park Hill, Streatham (gr. Mr. W. Howe) filled a large table with bulbous and other flowers, including Tulips, Daffodils, Hyacinths, *Lachenalias*, *Hippeastrums*, *Azaleas*, *Richardia*, *Dicentra* (*Dielytra*), arranged with Ferns, *Retinospora piceifera*, *Helxine*, *Pilea muscosa*, and having a row of Bamboos at the back. The group made a bright display of colour and was much admired. (Silver-gilt Banksian Medal.)

Messrs. ROBERT SYDENHAM, LTD., Tenby Street, Birmingham, exhibited Lily of the Valley, Narcissi, and Hyacinths growing in moss-fibre and all finely flowered.

Messrs. CARTWRIGHT & GOODWIN, Blakebrook, Kidderminster, showed Narcissi in variety. The exhibit was characterized by the extreme refinement of the blooms and their excellent colouring, especially in the flowers of the Pœticus and Leedsii sections. Notable examples were Cirlet, Sunset, *Aspasia*, Victoria, Waterwitch, *Blakewell*, Lucifer, Beauty, Fairy Queen, Scarlet Eye and Chaucer. (Silver-gilt Flora Medal.)

Messrs. W. CUTPUSH & SON, Highgate, staged a collection of Hyacinths in pots, even as to height and length of flower spike. We noted the following fine specimens: Grand Maitre, Lord Balfour, *Schotel*, Ornamente Rose, General Havelock, *Lady Derby*, *La Grandesse*, *City of Haarlem* (one of the finest of the yellow varieties), and General von Heyden. A collection of Narcissus shown by this firm was also a comprehensive one. (Silver-gilt Banksian Medal.)

Messrs. R. H. BATH, LTD., Wisbech, showed a great assortment of bulbous plants in pots and bowls, having Hyacinths, Tulips and Narcissi in all the best early-flowering varieties. Those in bowls grown in moss-fibre without material for drainage were especially useful for indoor decoration. (Silver Flora Medal.)

The Rev. JOSEPH JACOBS, Whitewell Rectory, Whitchurch, Salop, showed Narcissi, including the trumpet varieties Sarah Bernhardt and Hoboken Fairy, a refined variety with a soft yellow coronet and lemon-coloured calyx. There were also varieties of *N. Pœticus* and *N. Tazetta*.

Narcissus Queen of the West and *N. Cirlet*, shown by Mr. WALTER T. WARE, Bath, and Messrs. CARTWRIGHT and GOODWIN respectively, were awarded Certificates of Commendation for their value as forcing varieties.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshaw, R. Brooman-White, J. Wilson Potter, W. Bolton, Gurney Wilson, W. Waters Butler, H. Ballantine, H. A. Tracy, H. G. Alexander, A. Dye, W. H. White, W. H. Hatcher, J. Cypher, J. Charlesworth, W. Cobb, A. A. McBean, F. J. Hanbury, R. G. Thwaites, H. J. Chapman, G. F. Moore, F. Menteith Ogilvie, J. Forster Alcock, W. Boxall, H. Little, P. Sander, Stuart Low, and Sir Jeremiah Colman, Bart.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. Collier), was awarded the Society's Gold Medal for a grand group composed largely of Gatton hybrid *Dendrobiums*, *Spathoglottis*, *Phaio-Calanthes*, &c., together with an interesting selection of rare and pretty species. The new hybrid *Dendrobiums* included *D. Duchess of Albany* (a pretty pearly white), *D. sulphureum* (yellow), *D. Purity* (white, with purple disc), *D. Chessingtonense* Gatton Park variety, *D. Goldfinch* and many others, but none of them was equal to the handsome *D. Lady Colman*, which gained an Award of Merit at the last meeting, and which was again well shown. The centre of the group was of scarlet, yellow and crimson *Epidendrum O'Brienianum* and *E. Boundii*, the *Dendrobiums* being arranged in sections throughout the group. *Cymbidium* *Lady Colman* was very fine; the selection of yellow *Dendrobiums*, the patch of the white variety of *D. nobile*, and the fine *D. Cybele* Gatton Park variety were very attractive. At one end was a selection of pretty and curious species, including *Dendrobium tetragonum*, *Bulbophyllum comosum*, with five heads of white blooms; the yellow form of *Sophranitis grandiflora*, *Epidendrum polybulbon*, &c.

Messrs. CHARLESWORTH & Co. Haywards Heath, staged a bright and effective group, the plants in which were all of very high quality,

and for which a Silver-gilt Flora Medal was awarded. Among the hybrid *Odontoglossums* were several superb forms of *O. ardentissimum*, one especially being very large and finely blotched with dark purple. Other hybrids noted were good scarlet-red *Odontioda Craveniæ* and *O. Bradshawiæ*, the white *Brasso-Cattleya Queen Alexandra*, *Lælio-Cattleya Empress Frederick*, *L.-C. Sheila*, a pretty white flower, *L.-C. Katie*, of a clear yellow, and others. (See Awards.)

Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed *Lælio-Cattleya Arbaces* (*C. labiata* × *L.-C. Cassiope*), a perfectly-formed flower of fine substance of a bright rosy-lilac colour with a deep purple front to the finely-crimped labellum.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for a group in which new hybrid *Odontoglossums* were well represented. These included *O. Thalia* (*Andersonianum* × *excellens*), a pretty canary-yellow flower uniformly spotted with red-brown; *O. Verona* (*Adrianiæ* × *Vuykstekei*), cream-white, spotted with chestnut-red and tinged with red on the petals; *O. Hebe* (*Lindleyanum* × *Rolfæ*); *O. Solon* (*Adrianiæ* × *ardentissimum*), of fine shape, white, heavily marked with

ruby-red colour, a thin irregular cream-white line running round the central portion and a similar transverse line partly across the middle, the crest of the lip being yellow with red blotches on each side and in front. Its parentage is uncertain, but it might be *Cochlioda Noezliana* × *Odontoglossum ardentissimum album*. Mr. GOODSON also showed *Cattleya Schröderæ The Prince*, a very fine flower with crimped petals and lip, the latter having a velvety-purple front.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent *Odontoglossum crispum Carmania*, a finely-blotched variety, and the new *O. Wyonianum*. (See Awards.)

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), showed *Odontioda Bradshawiæ Oakwood* variety (*O. crispum Graireanum* × *C. Noezliana*), a fine flower of a uniform reddish-scarlet colour and yellow crest; *Odontoglossum percultum Oakwood* variety, white, beautifully blotched with purple; and the handsome new *Odontioda Bradshawiæ Cookson's* variety. (See fig. 73.)

Messrs. HUGH LOW & Co., Enfield, staged an effective group of *Dendrobiums*, fine varieties of *Cattleya Trianæ*, *Cymbidium Wigania-*

FIG. 73.—ODONTIODA × BRADSHAWIÆ COOKSON'S VARIETY: AWARDED A FIRST-CLASS CERTIFICATE AT THE ROYAL HORTICULTURAL SOCIETY'S MEETING ON TUESDAY LAST.

purple; *O. Helenus* (*harvengtense* × *Coradinei*), quite a new form with primrose-yellow flowers closely speckled with cinnamon-brown. Among other *Odontoglossums* was a very remarkable and beautiful imported form with the sepals and petals of a good *O. triumphans* and a broad sulphur-coloured lip, much fringed, and bearing one large blotch in the middle. Also in the group was a fine selection of *Cattleya Trianæ*, together with the very large pure white *C. Trianæ Queen Alexandra*. *Zygonisia Sanderi* (*Aganisia lepida* × *Zygopetalum*) is an interesting novelty with cream-white flowers heavily blotched with violet. For others, see Awards.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, staged a group of good *Odontoglossum crispum*, *O. Pescatorei*, *Cattleya Trianæ*, *Lælio-Cattleya Callistoglossa* and a number of their *Cypripedium Countess of Carnarvon*, which varies very much in form and colour, but is always good and lasts a long time in bloom.

H. S. GOODSON, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Dav), showed *Odontioda Goodsoniæ*, a charming hybrid and probably the finest in shape and richest in colour of any yet raised. The flower is large, the petals and sepals equally broad and of a glowing

num, *C. Holfordianum*, *Aërides Vandarum*, &c. (Silver Flora Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged an effective group of good *Cypripediums*, *Cymbidium Woodhamsianum*, *C. eburneum*, *C. Ballianum*, *Odontoglossum*, &c.

Messrs. JAS. CYPHER & SONS, Cheltenham, were awarded a Silver Banksian Medal for a group in which were good *Cattleya Trianæ*, well-flowered *Odontoglossums*, including *O. Cervantesii*, *Cypripedium Milo Westonbirt* variety, *Sophranitis grandiflora*, *Epiphranitis Veitchii*, *Aërides Vandarum*, &c.

Monsieur MAURICE MERTENS, Mont St. Amand, Ghent, was awarded a Silver Banksian Medal for a very interesting group of pretty hybrid *Odontoglossums*.

J. FORSTER ALCOCK, Esq., Exhims, Northchurch, sent *Cypripedium W. Hopkins*, a distinct flower of fine shape.

H. A. INNES, Esq., Croft Spa, Yorks., sent two light varieties of *Cattleya Trianæ*, a very large and good *Lycaste Skinneri alba*, and a fine dark *Masdevallia chimæra*.

Mr. W. P. HORTON, Cravenhurst, Seaford, staged a group of *Odontoglossums*, *Cypripediums*, and *Dendrobiums*.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Schröderæ "Mrs. F. Sander," from Messrs. SANDER & SONS, St. Albans.—A pure white variety, large and of fine shape, the broad labellum finely crimped at the margin.

Odontioda Bradshawiæ Cookson's variety (see fig. 73), from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman).—This hybrid is a near approach to the ideal scarlet *Odontoglossum crispum*, long hinted at by the Orchidist. The flowers equal those of an ordinary *O. crispum*, the greater part of the sepals and petals being of a clear cinnabar scarlet colour, with lighter margin flecked with rose colour, the tips of the segments being cream white. The crest of the lip is yellow, with a red blotch in front, the apex tinged with rose.

Sophr-Cattleya Thwaitesii (*S. grandiflora* × *C. Mendelii*), from R. G. THWAITES, Esq., Cheshington, Streatham (gr. Mr. Black).—A hybrid comparable to the handsome *S.-C. Doris*. The sepals are carmine-red, with the silvery ground colour showing in places. The petals are broad, reddish-rose, slightly darker on the veining. Lip cowslip-yellow, with the margins of the side lobes and the front lobe red. A pretty flower of true *Cattleya* shape.

Cattleya Trianæ "Grand Monarch," from F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth).—A perfect giant in stature and a model in form. The sepals and very broad petals are bright rosy-lilac, the front of the lip purplish-crimson, the disc orange, with some dark lines at the base.

Brasso-Cattleya Cliftonii magnifica (*B.-C. Digbyano-Mossii* × *C. Trianæ Uplands* variety), from Messrs. CHARLESWORTH & Co., Haywards Heath.—A further advance on the beautiful type illustrated in the *Gardeners' Chronicle*, January 16, 1909, p. 34. In the present variety the sepals and petals are silver-white, tinged with rose, the broad, fringed lip being rich ruby-crimson in front.

AWARD OF MERIT.

Odontoglossum Wyonianum, from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis).—A pretty, clear white flower, unique in marking, the small, confluent, dark-red-purple blotches being arranged in the middle portions of the segments in a very attractive manner. The spring crest of the labellum is yellow, with some red markings.

Brasso-Lælio-Cattleya Cooksonii (*B.-L. Mrs. Gratrix* × *C. Dowiana aurea*), from Messrs. CHARLESWORTH & Co.—A very effective cross with yellowish flowers tinged and veined with copper-red, the lip being fringed.

BOTANICAL CERTIFICATE.

Chytroglossa Marileoniæ, from Messrs. SANDER & SONS.—A charming dwarf species with elegant racemes of pretty flowers.

CULTURAL COMMENDATION.

To Mr. H. Ballantine (gr. to Baron Sir H. SCHRÖDER, Bart.), for *Cymbidium insigne*, with three very fine spikes.

To Mr. Salter (gr. to WALTER COBB, Esq.), for an enormous *Cœlogyne cristata alba*, heavily bloomed.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (in the Chair); and Messrs. Jos. Cheal, E. Beckett, Alex. Dean, H. Parr, G. Hobday, Jas. Gibson, Henry Hooper, H. Markham, Chas. Foster, G. Reynolds, P. C. M. Veitch, Jno. Lyne, J. Davis, A. R. Allan, Jas. Vert, F. Perkins, Owen Thomas, Jno. Harrison, C. G. A. Nix, P. D. Tuckett and A. H. Pearson.

Messrs. SUTTON & SONS, Reading, exhibited, Lettuces and Radishes forced by the "French" system of forcing these salads. The Lettuces were (Cabbage) *Commodore Nutt*, *Improved Tom Thumb*, *Early Paris* and *Golden Frame*, and (Cos) *Nonsuch* and *Little Gem*. Radishes included *Earliest of All*, *Paris White-tipped* and *Sutton's Forcing French Breakfast*. The beds were made and sown with Radishes and Carrots in December, amongst which the Lettuces exhibited were transplanted from sowings made under cloches in October. (Silver Banksian Medal.)

The Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. Ed. Beckett), showed especially fine samples of Onion Ailsa Craig, for which a Silver Banksian Medal was awarded.

P. NELKE, Esq., Woodlee, Virginia Water (gr. Mr. G. Basket), showed seven varieties of Apples, all plump and well preserved, the varieties being Cox's Orange Pippin, Court-pendú-plat, Hereford Winter Quoining, Ribston Pippin, Dumelow's Seedling, King of the Pippins, and Old Nonpareil. (Silver Banksian Medal.)

Messrs. WILLIAM WOOD & SON, North British Wharf, Wood Green, showed bottles for preserving Grapes in water. The bottle lies flat on one of its sides and is filled from a hole in the centre of the upper side. The mouth is curved upwards and none of the water can escape from the neck when refilling and run over the Grapes (see fig. 74).

COMPETITIVE CLASSES FOR APPLES.

Four dishes, distinct, shown by amateurs.—

There were three competitors, the 1st prize being awarded to Sir MARK E. COLLET, Bart., St. Clare, Kemsing, Sevenoaks (gr. Mr. M. Nichols). The varieties were Newton Wonder, Bramley's Seedling, Alfriston and Hambling Seedling; 2nd, Viscount ENFIELD, Wrotham Park, Barnet (gr. Mr. H. Markham).

In the class for one dish, Lt.-Col. BORTON, Cheveney, Hunton, Maidstone (gr. Mr. Whittle), won the 1st prize with the variety Belle du Bois; 2nd, Hon. VICARY GIBBS (gr. Mr. Ed. Beckett), with Bramley's Seedling.

In the classes for trade growers Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, staged eight dishes of culinary Apples, the varieties being Newton Wonder, Lane's Prince Albert, Betty Geeson, Belle de Pontoise, Bramley's Seedling, Wadhurst Pippin, Alfriston and Lord Derby. The fruits were finely preserved, and Messrs. VEITCH received a Silver Knightian Medal as the 1st prize.

SCOTTISH HORTICULTURAL.

MARCH 2.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on this date. The president, Mr. Whytock, was in the chair, and there was a large attendance of members. A lecture was delivered by Mr. John Hunter, F.I.C., County Analyst, Edinburgh, on "Soil Science." Mr. Hunter said lime was not an oxidiser; it might neutralise acidity in a water-logged soil, but it would not prevent the acidity from reappearing unless the soil were properly aerated. The principal value of draining land was not to carry off water, but to ventilate the soil, which was necessary for the existence of the living organisms which it contained, and to draw off the heavy carbonic acid which existed to the extent of 60 to 70 per cent. in the air of the soil, but which was not required for the liberation of the essential elements of plant life.

Fourteen new members were elected. The paper at the meeting on April 6 will be by Mr. L. B. Stewart, Royal Botanic Garden, Edinburgh, on "Insectivorous Plants."

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

(ANNUAL MEETING.)

MARCH 8.—The annual general meeting of this Benefit Society was held on the above date at the Horticultural Hall, Westminster. Mr. Thos. Winter, vice-chairman of committee, presided. The Secretary read the annual report and balance-sheet.

EXTRACTS FROM THE REPORT.

The year has been marked by steady progress, both in the number of members that have been enrolled and the amount of money that has been invested, the total sum invested this year—£2,700—being £500 more than in 1907.

BENEFIT FUND.

Although the number of members has increased considerably, the net gain on the year being 44, the sick pay for the year amounted to £485 4s. 6d., being about £5 more than in 1907. The above amount is apportioned to members paying on the higher scale at 9s. 2d., and to members paying on the lower scale at 6s. 1d. The new rule allowing members to withdraw twice the amount of interest on the last balance of their account in the books of the Society has been much appreciated. The membership now stands at 1,288, made up as follows, 741 on the higher scale, and 547 on the lower

scale. During the year 21 members have lapsed, and seven have died, the sum of £81 7s. 11d. having been paid to the nominees of the latter.

The subscriptions to the Benevolent Fund have amounted to £238 9s. 5d., and the payments from the same £118 4s., this sum including the money paid to members over 70 years of age. Two widows of deceased members were given £5 and £2 respectively from this fund, these being the only special grants made during the year.

We regret that so little advantage is taken of this fund, as we think that members recovering from an illness might more largely avail themselves of the benefits accruing from it. The sum of only 30s. has been withdrawn from the Convalescent Fund. The amount paid into the fund in 1908 was £11 5s. 6d., to which sum Mr. Sherwood contributed £5 5s.

The expenses of the Management Fund have been reduced by about £22 when compared with 1907.

The assets held by the Society amount to nearly £35,000, the subscriptions last year being £2,030 0s. 10d.

In proposing the adoption of the Report, the Chairman dealt with the principal points, and drew attention to the useful work being carried out by the Society.

Votes of thanks were cordially offered the officers and committee, and these were re-elected.

KINGSTON GARDENERS'

MARCH 4.—At the meeting of this association held on the above date, Mr. C. P. Raffill, of the Royal Gardens, Kew, gave a lecture entitled, "Holiday Rambles," the subject being illustrated by lantern slides. Mr. Raffill discoursed on the subjects of the pictures, which included views of the Rhododendron Gardens of Cornwall. Sir J. T. D. Llewelyn's gardens at Penllergare; the Botanic Gardens, Birmingham; the Botanic Gardens, Liverpool; and finally, the Blackburn public parks, in which not only was the smoky, grimy atmosphere of

FIG. 74.—A NEW BOTTLE FOR PRESERVING GRAPES. (See text.)

that Lancashire town too plainly in evidence, but also the injurious effect these deleterious substances have on vegetable life. The contrast between vegetation growing in Cornwall and Lancashire was very marked.

UNION OF FRENCH HORTICULTURAL TRADERS.

We are informed by Mr. George Schneider that at the last meeting of the Committee of L'Union Commerciale des Horticulteurs et Marchands grainiers de France, presided over by Mons. A. Truffaut, it was decided after due consideration of the propositions contained in the Report of the Commission on the Revision of Tariffs to be submitted to the French Parliament, to protest against any new duties or increase of duties on the importation of plants, flowers, fruits and vegetables. The Union Commerciale is of opinion that French horticulture is sufficiently protected. The adoption of new or increased taxes might cause other countries to create or increase tariffs which would sensibly affect the exportation of French products, such as flowers, fruits, and Palms from southern, and plants and trees from western parts, of France, as well as early vegetables and fruits from the Paris district, these products forming the most important part of French horticulture.

It was decided that a deputation should wait upon the President of the Commission and also that Mons. Deloncle, M.P. for the Department of Seine, and Mons. Arago, M.P. for the Alpes Maritimes, should be asked to use their influence and to oppose all new taxes and any increase of existing taxes on such produce when the discussion of the Bill takes place in the French Parliament.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 6, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather—The general condition was very wintry throughout the whole Kingdom. Snow fell in considerable or large amounts in almost all localities, the heaviest falls occurring either about the middle or at the end of the week. Thunder was heard at Gordon Castle on Tuesday afternoon, and at Tavistock on Friday afternoon.

The temperature was much below the average, the deficit amounting to nearly 10° in the Midland Counties and England S.W., and to more than 10° in England S.E. The highest of the maxima were registered on rather irregular dates, but in most places either very early or quite late in the period. They ranged from 49° in the English Channel, to 41° in England E. and Scotland N. During the greater part of the week the thermometer remained below 40° over the Kingdom generally; on some occasions in central and south-eastern England it remained at about 32° or below it all day. The lowest of the minima were recorded, with some exceptions, between the 3rd and 5th. In England S.E. the thermometer descended to zero (at Marlborough on the 3rd), and in Scotland E. to 1° (at West Linton on the 5th), while readings as low as 7° and 8° respectively were recorded in England N.W. and the Midland Counties. Over nearly all parts of the Kingdom the minima were below 20°, but in the English Channel the lowest value was 28°. From thermometers on the grass the lowest readings reported were 5° at West Linton (on the 5th), 4° at Llangannarch Wells (on the 4th and 5th), 3° at Canterbury and Balmoral, 5° at Hereford, 6° at Aspatria, 7° at Kew, and 8° at Cardiff.

The mean temperature of the sea.—At nearly all stations except Cleggan the water was colder than during the corresponding week of last year. The greatest difference being about 4° at Margate and Eastbourne. The mean values for the week ranged from 45.9° at Plymouth, and 45.2° at Cleggan, to about 39° at Kirkwall, Pennan Bay, and Burnmouth, to 36.1° at Eastbourne, and to 35.6° at Margate.

The rainfall (rain or snow) exceeded the normal in all districts except Scotland N. and W. and Ireland S., the excess being large in nearly all parts of England. At some places in the south-east of England the snow measured on Thursday morning yielded more than an inch of water, and at Dungeness as much as 1.9 inch. More than an inch was also measured over a large part of the Midlands and northern England as the result of the snowfall on Saturday, the largest quantity reported being 1.3 inch at Sheafle and Fulbeck. Some places further south experienced a large amount of rain and snow; at Shaftesbury the gauge yielded 1.64 inch. At Buxton and Huddersfield the depth of snow after the fall of Saturday averaged 10 inches, while at Ulcombe, Kent, on Friday morning the depth on the level was 12 to 15 inches.

The bright sunshine was generally rather above the average in the western districts, and below it in the east. The percentage of possible duration ranged from 38° in Ireland N., and 34 in the English Channel, to 19 in England E., and 18 in the Midland Counties.

THE WEATHER IN WEST HERTS.

Week ending March 10.

The wettest week as yet this year.—The present term of cold weather has now lasted nearly five weeks. Throughout the past week the days and nights have been all more or less cold, and on the coldest night the exposed thermometer registered 19° of frost, which is the lowest reading but one of the above-mentioned cold period, and the lowest in March for ten years. The ground is at the present time 3° colder at 2 feet deep, and 4° colder at 1 foot deep, than is seasonable. Rain, hail, snow or sleet fell on all but one day, and to the total depth of 1½ inches—making this the wettest week as yet recorded here this year. On one day the ground was covered with snow to the average depth of 2 inches. As much as 6 gallons of rain and melted snow have come through the bare soil percolation gauge, and 5½ gallons through that on which short grass is growing. The sun shone on an average for 3½ hours a day, which is about the average duration for this period in March. On three days no sunshine at all was recorded. Light airs and calms have alone prevailed during the week. The mean amount of moisture in the air at 9 o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent. E. M., Berkhamsted, March 10, 1909.

DEBATING SOCIETIES.

CROYDON & DISTRICT HORTICULTURAL.—At the fortnightly meeting of this society, held on Tuesday, March 2, a lecture on "Manures" was given by Mr. W. Rowson, Falkland Park Gardens, a member of the society.

IPSWICH AND DISTRICT GARDENERS.—A large number of the members of this association were present at the Co-operative Hall, on Wednesday, March 3, when a discussion took place on "The Violet, its culture and varieties." A paper was announced to have been read by Miss H. C. Philbrick, of Halstead, who was unavoidably prevented from attending.

WARGRAVE AND DISTRICT GARDENERS.—At the last meeting of this association a short practical paper on "Primula Culture" was read by Mr. W. Glen, of Shiplake. The lecturer gave details on the subjects of seed-sowing, soils, pricking-off, potting, and ventilation.

Obituary.

EDWARD SHUTTLEWORTH.—We regret to record the death at Putney on the 5th inst. of this well-known Orchid grower and collector in his eightieth year, after a somewhat long illness. Deceased was better known to the past generation of Orchid growers, having been employed in Knight and Perry's Nursery at Chelsea. He afterwards entered the establishment of the late William Bull, later taking charge of the Orchid collection of Mr. G. H. Bunney, of Stratford. On the dispersal of this collection in 1872, he again entered the service of Mr. William Bull, who in the following year sent him as collector to the United States of Colombia. He made several successful journeys, sending home large consignments of Cattleyas, *Oeontoglossum crispum*, *Oncidiums*, *Miltonia vexillaria*, *Masdevallias*, and other plants. Among many introductions his name is recorded in *Masdevallia Shuttleworthii*, *Stanhopea Shuttleworthii*, *Smilax Shuttleworthii*, and *Dieffenbachia Shuttleworthii*. He retired from horticultural life some 15 years ago, after being in business with Mr. John Carder, who so lately predeceased him, and Mr. J. C. Charlesworth. The remains were laid to rest at Mortlake Cemetery on the 11th inst.

ENQUIRY.

BURNING CLAY SOIL.—Can any reader inform me what is the best method of burning clay for garden purposes? My first attempt has not been successful. After starting a fire I built up the clay around it, then a layer of small coal slack, and again clay. I found a difficulty in keeping the fire from being smothered, and much slack was left unburnt. Ought air passages to be left in the heap? *L. F.*

ADVICE IN ORCHID GROWING: *L. F. P.* We dare say there are openings for Orchid experts, but cannot undertake to advise you as to the fees you should charge. You will need to advertise.

BEGINNER IN FLORISTS' BUSINESS: *V. B.* We cannot advise you in respect to finance beyond the fact that, if you have to borrow money at the commencement, you will be likely to experience considerable anxiety before it is repaid. If you are diligent and keep out of debt, you will probably succeed.

BEGONIA GLOIRE DE LORRAINE: *Nemo.* Propagate the plants from cuttings and grow them on in a warm house, affording increased pot-room as required. This Begonia thrives best in its early stages when placed on a shelf near the glass of the roof. It makes an excellent subject for planting in baskets.

BULBS: *B. Hodgson.* The bulbs were infested by the grubs of a small fly, and by the bulb mite (*Rhizoglyphus echinopus*). The little beetles are members of the family *Brachelytra*, and they were probably feeding on the decayed vegetable matter. In the bottle there were, besides these beetles and bulb mites, a number of small worms belonging to the family *Enchytraeidae*, and nearly allied to the earth-worms. They are decidedly injurious to the roots of plants. Vaporite or apterite would be likely to kill them if mixed with the soil. The bulb mites might probably be killed by the same means, but no liquid insecticide appears to be of any use against this pest.

COELOGYNE CRISTATA: *T. H.* This Orchid does not require a high temperature; a cool intermediate house is suitable. The cause of failure to flower is usually due to an insufficiency of water at the roots during the plant's season of active growth, when too much rain-water can scarcely be given. *Coeogyne cristata* should be shaded from the sun in summer and never be thoroughly dried off at

the roots. Insert cuttings of *Hydrangeas* of mature growth when available. The plants may also be propagated readily by division.

FIBRE FROM CHINA: *J. J. F.* The fibre appears to be Hemp (*Cannabis sativa*), or an allied species.

FORCING SEAKALE: *J. R. B.* Very good samples of Seakale may be grown in the cellar you mention during winter and early spring, seeing that a temperature of from 54° to 58° is maintained. The quickest and best way to establish a plantation of Seakale that will provide plants for forcing purposes as required, is by utilising the extremities of the roots taken up each year for forcing. These are cut into lengths of 4 or 5 inches, and kept in a box containing dry sand until the following March, when, the condition of the ground permitting, these root-cuttings or "thongs," as they are commonly called, are dibbled in rows formed at about 15 inches apart, putting the sets at distances of 9 inches in the rows, and covering them with about 1 inch of soil. After this has been done, apply a surface dressing of short manure between the rows and plants to the depth of 1 or 2 inches. It is only necessary afterwards to keep them free from weeds and remove the flower-stems as they appear, until November or December, when they may be lifted for forcing. A deep, light, loamy soil enriched with short manure is the best rooting medium for Seakale. Root-cuttings treated as described will furnish strong plants for forcing next winter and following spring. In raising plants from seed, the seeds should be sown thinly in March or April in prepared ground in drills drawn 2 inches deep and 12 inches apart, closing in the soil over the seed with the feet, treading and raking the ground level afterwards. Thin the seedlings to 6 inches from plant to plant in the rows, and apply a mulching of short manure. Plants thus raised will be ready for transplanting in March, 1910, after the crown buds have been removed so as to prevent the plants running to seed during the summer. If you have any established plants of Seakale in your garden, you might take up a score or two, cut the roots into lengths as recommended, and plant the root-cuttings forthwith in the manner indicated to furnish plants for lifting to force in December next and onwards. If you plant in this month or April, one-year-old, two-year-old, and three-year-old seedlings, the three-year-old seedlings should furnish you with good plants for forcing next December, the two-year and one-year-old seedlings supplying respectively good forcing roots in the two following years. For Rhubarb, see next week's issue.

GRUB IN GARDEN SOIL: *Ashtonian.* One of the specimens you sent as wireworms is the grub of a ground beetle. These insects and their grubs are carnivorous, feeding on other insects, &c., and not on vegetable food, so that they are in no way garden pests, but the reverse. They may be easily distinguished from the wireworms by the quickness of their movements. They run fast, while the wireworms are slow in their actions. They are the grubs of the skipjack or click beetles, but we cannot tell you to which species they belong, as the grubs resemble one another very closely.

MUSHROOMS DISEASED: *H. K.* The Mushrooms are affected by a minute parasitic fungus, *Hypomyces perniciosus*, which, when once introduced, spreads very quickly under the conditions of temperature and moisture essential for the rapid growth of Mushrooms. According to a leaflet on this disease, issued by the Board of Agriculture and Fisheries, numerous Toadstools and other fungi suffering from the parasitism of different kinds of *Hypomyces* are common in woods and pastures every season, and spores are probably introduced into the Mushroom bed along with the manure or road sweepings commonly used. In some instances it is certain that the spawn is infected before it is placed in the Mushroom bed. When infection occurs through the introduction of spores into the house by wind or other causes, the disease may be confined to certain portions of the bed, and the prompt removal of infected Mushrooms as soon as the slightest symptoms are observed may check the

disease from assuming the proportions of an epidemic. When a house or other structure in which Mushrooms are grown has become infected, it should be completely emptied and thoroughly sprayed, both roof, walls, and floor, three times at intervals of 10 days with a solution of sulphate of copper—1 lb. of sulphate to 15 gallons of water. During this period of spraying, the house should be kept warm and moist, for the purpose of favouring germination of the spores of the parasite, which are destroyed with greater certainty when growing than when in a resting condition. After removing the soil and manure of an infected bed, great care should be taken in cleansing the tools, boots, and even clothing; otherwise there is great risk of infecting other beds.

NAMES OF FRUITS: *G. T. O.* We do not recognise the Apple. It is probably a local variety.—*C. Luke.* Darling Pippin.

NAMES OF PLANTS: *H. J. W.* *Thuja Lobbii* var. *zebrina*. *T. Lobbii* is known also as *T. plicata* and *T. gigantea*.—*Nemo.* 1, *Satureia montana* (Winter Savory); 2, *Eriobotrya japonica* (Loquat); 3, *Aloe socotrana*; 4, *Cotyledon*, send when in flower.—*C. O.* 1, *Pteris hastata*; 2, *Adiantum formosum*; 3, *Cyperus alternifolius*; 4, *Oncidium barbatum*—*H. Q.* 11. *Brunfelsia calycina*, known in some gardens as *Franciscia calycina*.—*T. T.* 1, *Pleurothallis lateritea*; 2, *Stelis ophioglossoides*; 3, *Bulbophyllum auricomum*.—*S. A.* You should number the specimens. The Fern is *Asplenium lucidum*; the tall, grass-like plant *Panicum plicatum*; the flower *Polygala Dalmaisiana*; the plant with prickles *Euphorbia splendens*; *Eupatorium Weinmannianum* is the specimen having white flowers; that with thick leaves, having a red mid-rib, is *Elæodendron orientale* (syn. *Aralia Chabrieri*).—*R. E. J.* 1, *Sprekelia formosissima*; 2, *Begonia Ingramii*; 3, *B. metallica*; 4, *B. hydrocotylæfolia*; 5, *Eranthemum pulchellum*.—*W. B. M.* We cannot recognise the plant either from the drawing or the description.

PALMS WITH DEAD FOLIAGE: *W. T. C.* The plants have suffered from the unsuitable atmosphere of the dwelling-house during the protracted cold weather.

PROPAGATING PELARGONIUM RASPAIL FOR FLOWERING IN WINTER: *F. R. D.* Plants propagated any time during March or April will flower well the following winter. They should be potted firmly in good loam, with some manure added. Place them in the open in a position fully exposed to the sun during the summer. About the first week in September they should be transferred to the greenhouse. All the flower-stems should be removed until about one month before they are required to be in flower. The house in which they are grown should be light and airy, as they will not succeed in a close, stagnant atmosphere. Do not use manurial stimulants too freely until late in the spring, when growth will be especially active, and the plants can make use of much food.

THE LOQUAT: *Nemo.* This plant—*Eriobotrya japonica*—is easily cultivated in any ordinary greenhouse. It thrives also in the open garden in sheltered positions in warm districts. If grown in pots, the roots need plenty of room.

WORMS IN STABLE MANURE: *C. W.* These are worms belonging to the family *Enchytraeidae*, and nearly related to the earth-worms. They are injurious to the roots of plants, but they may be killed by soaking the soil thoroughly with lime water. Vaporite or apterite would probably kill them; the latter proved fatal to them in a laboratory experiment, but that is no proof that it would succeed under other circumstances.

VERSAILLES AND PETIT TRIANON.

THE gardens of Versailles have so often been described in detail that it is not necessary to attempt the task again. For many years now it has been the fashion to hold them up to scorn. But, however much one may condemn them and the school of landscape gardening of which they are the most famous example, Versailles is, nevertheless, not lacking in attraction. The splendour of the design is unequalled among the gardens of the world. Then, the associations of the place and the emotions they inspire in the foreigner's mind lend to the gardens a certain charm. The thoughts of the English visitor are strongly coloured not only by memories of Louis XIV. and Le Nôtre, who laid the foundations of the scenes around, but by memories also of those events, so full of menace, that occurred here in the early years of the French Revolution.

In the present condition of the gardens there is a strong contrast between the scheme itself and the mode in which its details are carried out. A certain air of neglect and decayed grandeur overhangs the place. The flower-beds are filled with the most ordinary of bedding plants, and are edged with the ugly and old-fashioned Box-edging. The walks are rough, and the famous *tapis vert* is a very ordinary piece of lawn by no means well kept (see Supplementary Illustration in *Gardeners' Chronicle*, November 14, 1903).

Perhaps the strongest emotion Versailles inspires is that of melancholy.

The most astonishing feature of Versailles is the Orangery (see Supplementary Illustration in *Gardeners' Chronicle*, December 26, 1903). On a deeply-sunk area on one side of the Chateau are congregated some hundreds of Orange trees in tubs. The labour and expense of attending to these plants and housing them every winter are certainly not justified by their appearance. The greater proportion of them should be burnt right away. One hundred or one hundred and fifty years ago the cultivation of Orange trees in tubs was very general. The fact that the plant produced one of the most precious of all fruits, as well as the fragrance and associations of its blossom, gave it an interest in the gardens of northern Europe which it scarcely possesses to-day. And an Orange tree in a tub is scarcely ever an object of beauty. These specimens at Versailles are very much the opposite. The French as a nation have a deserved reputation for a strong artistic feeling and a deeply-rooted sense of economy. It is difficult to understand how they continue to tolerate this Orangery at Versailles, which outrages both.

PETIT TRIANON (see Supplementary Illustration in *Gardeners' Chronicle*, November 21, 1903). A very different scene awaits him who enters the grounds of Petit Trianon, close by. Here is an "English Garden" of the Continental type, and decidedly one of the best of its kind. In the first place, it is not too large. In the intricacies of some of the larger "English Gardens" of the Continent—like that at Munich, for instance—the stranger is speedily bewildered. But here, at Petit Trianon, the area is small enough to be completely traversed in a comparatively short time, and the gentle curves and windings of its walks give a pleasant diversity of prospect without obliterating the visitor's sense of locality. This garden was made by Marie Antoinette in her early and happier days in France. The ideas of Le Nôtre had dominated the garden-making of Europe for a century or more; this and other gardens of the same type expressed a feeling of revolt against them.

There is but little flower gardening at Petit Trianon. It owes its charms to its noble trees and shrubs, to its pleasant disposition of water, path and lawn, and, perhaps not least, to its contrast with the more famous garden close by.

There are many fine trees of particular interest at Petit Trianon—especially those of American origin. The deciduous Cypress (*Taxodium distichum*) is represented by six specimens growing on the edge of the lake and averaging 50 feet in height. A Tulip-tree (*Liriodendron tulipifera*) is about as high. Weymouth Pines (*P. Strobus*) are here in some quantity, and one of them is 10 feet in girth of trunk and nearly, or quite, 100 feet high. The American White Ash (*Fraxinus americana*) is of a similar stature. A white Oak, probably *Quercus bicolor*, is 50 feet high. *Populus deltoidea* has a trunk 12 feet in girth, and there are several very striking examples of the Poplar with hairy young wood which we know as *P. nigra betulæfolia*, the characteristic rough burrs on the trunk being remark-

ably developed. *Populus canescens* is about 100 feet high and 14 feet in girth of trunk. *Pinus Laricio* var. *Pallasiana*—the variety with erect-growing branches—is 80 feet high and its trunk 9 feet in girth. Other species represented by fine specimens are Cedar of Lebanon, *Carpinus caroliniana*, *Fraxinus pubescens*, an old tree of *Morus rubra* (uncommon in Britain), a large *Sophora japonica* (near the villa), and the true red Spruce (*Picea rubra*).

The little hamlet of picturesque cottages which Marie Antoinette built to give diversity to the scene still remains, but the buildings are not kept in good repair. Here, as in the gardens of Versailles, the effects of time are very evident, and the management lacks either the means or the will to combat them. B. J. W.

SOME OF THE NEWER SWEET PEAS.

A SWEET Pea of great beauty, though somewhat too susceptible to atmospheric influences, commemorates the name of Henry Eckford, who did so much to develop this flower. Several years have elapsed since the variety was introduced, but it has not yet been entirely superseded. As much, perhaps, may be said of the success of my own namesake, also raised by Mr. Eckford, which now stands alone in the Eckfordian catalogue under the head of "Indigo Blue." The finest varieties raised by the late Mr. Eckford were Dorothy Eckford and Queen Alexandra. Whether in dimensions, in faultless form, or in perfection of colour, those ideal representatives of purest white and richest scarlet will not easily be surpassed. At present, however, the predominating forms are the Spencer hybrids, with their fantastically "waved" or "crenulated" standards, to whose excessive multiplication some prominent horticulturists are beginning to object, on the ground that older and—as they deem them—more valuable varieties are in danger of being forgotten. Among the most prominent of the latest Spencerian hybrids is a notable one entitled "The King," by Messrs. Dobbie & Co., and "King Edward Spencer," by Mr. Atlee Burpee. It is probably the largest, and one of the most brilliant in colour, of all Sweet Peas of its own peculiar hue, but requires a fertile soil and a warm summer to develop its possibilities. In the coolness of autumn it perceptibly declines. Etta Dyke, whose synonym in America is the White Countess Spencer, is, perhaps, the most eulogised of all pure white Sweet Peas of this special description. Very beautiful are also the Primrose, Ramona, and Apple Blossom Spencers; likewise the beautiful lavender-coloured Asta Ohn, raised and named after his daughter by Mr. Henry Ohn, the Chinese head-hybridist of Mr. Lister Morse, of the Santa Clara Nurseries, in California. Mr. Morse recently sent to me several unnamed Spencerian hybrids, whose appearance during next summer I await with interest. Among named varieties that I have not yet seen in flower are Mrs. Walter Carter and Dobbie's Mid Blue, the former of which is said to resemble the variety Mrs. Charles Foster, while the latter is unquestionably an exquisite production. The Marquis and Mrs. A. Ireland

are, in their way, equally charming introductions. Two of the loveliest of recent Spencer hybrids are Mrs. Routzahn and Mrs. Henry Bell. Their most formidable rival in delicate beauty and refinement is Evelyn Hemus, which, notwithstanding the present keen competition in form and colour, seems likely to endure. *David R. Williamson.*

WEEDS AND HOEING.

ALTHOUGH the deleterious action of weeds upon crops is well known to all practical cultivators of the soil, very few accurate determinations have been made of the amount of reduction in yield of a crop which is produced when weeds are allowed

Comparing plots 4 and 5 with plot 1, we see that in the wet season of 1907, allowing the weeds to grow reduced the crop about 60 per cent., the loss in the drier year 1908 being about 50 per cent. The serious character of these figures is obvious.

An interesting and unexpected result is recorded on plots 4 and 5. The yield on No. 5, from which the weeds were removed by hand only, is practically the same as that on No. 4, which was kept clean by hoeing. Stirring the ground and leaving a natural mulch upon it is usually supposed to be conservative of soil moisture, leading indirectly to an increase in crop. This, however, has not been the case in these experiments, neither in the wet nor the drier season; it would appear from

PINUS RIGIDA.

WHILST *Pinus rigida*, Miller, cannot be described as one of the most ornamental of Pines in English parks and gardens, it is an interesting species, and fills an important place in the sylvia of Eastern North America. The species is found in a wild state as far north as New Brunswick, and reaches southwards to Georgia and the western slopes of the Alleghany Mountains. It is abundant in the central portions of this area, where it covers thousands of acres of dry, sterile land, in which scarcely any other tree would thrive.

Pinus rigida bears its leaves in groups of three, each leaf being usually from 2½ to 4 inches long. The shoot is yellowish-brown and glabrous, and the winter bud is about ½ inch long. The cones are remarkably variable in size, shape and arrangement. The branch shown in fig. 75 was taken from a tree growing in the Queen's Cottage Grounds at Kew Gardens. The tree, a bushy specimen not much more than 20 feet in height, was blown down during a recent gale, when the upper branches were seen to be covered with clusters of small cones interspersed with older and somewhat larger cones, as seen in the illustration. The smaller, clustered cones are 1 to 1½ inches long, and both in size and arrangement resemble those figured by A. B. Lambert in his *Pinetum*, t. 19, and described as *P. rigida*, small-coned variety. Lambert's tree was growing in 1803 at Pain's Hill. The shape of the cones is more or less ovate, but, as stated above, this is a variable character, forms of *Pinus rigida* being known with almost orbicular cones. The cone-scales are furnished each with a short, stiff, recurved spine. The tree

FIG. 75.—CONE-BEARING BRANCH OF PINUS RIGIDA.

[Photograph by E. J. Wallis.

to compete with it. During the last two seasons experiments have been carried on at the University College Farm, Reading, to test the influence of weeds in this respect, and incidentally to determine the value of hoeing.

Mangels were grown on half an acre of ground, which was divided into five plots arranged as indicated in the table below: the yields are given for both seasons:—

		Yield	
		1907.	1908.
Plot 1.	Not weeded after setting out the plants	15½	16½
" 2.	Hoeed once after setting out the plants	39½	30½
" 3.	Hoeed twice after setting out the plants	37½	36½
" 4.	Kept quite clean by hoeing	39½	38
" 5.	Kept quite clean by hand weeding only, no hoeing being done after the plants were set out	40	38½

the results of these experiments that the benefit of hoeing is almost entirely due to the destruction of the weeds which otherwise would have competed with the crop.

Reviewing the returns on plots 1 to 4, we see that:—

	1907.	1908.
Hoeing once added...	17½	13½
Hoeing again gave a further increase of	4½	6½
Several hoeings later only added	1½	1½

In the early part of the summer the seeds of weeds were found to germinate freely, and the plants grew at a rapid rate, and very soon almost smothered the young mangels. The first hoeing, however, in June got rid of these weeds, and the comparatively few which came up later were easily kept in check. *John Percival.*

retains its cones for about 10 or 12 years. It has also another peculiarity common to but few species, i.e., the production of adventitious shoots on the trunk and primary branches. So numerous are these at times that parts of the trunk are almost covered with short twigs.

Pinus rigida does not form so large a tree as some other Pines. Sargent gives its maximum height in a wild state as 80ft, but it is more usually 50 to 60 feet high. The largest trees known to me in the British Isles are in the fine arboretum at Arley Castle, near Bewdley, where there are three notable specimens, the tallest of which, according to Mr. Robt. Woodward's *Hortus Arleyensis*, was 79 feet high and 5 feet 11 inches in girth five years ago. The other two are both 7 feet 2 inches in girth, and respectively 69 feet and 66 feet in height. These trees were planted about 1820 by

Lord Mountnorris, who was then the proprietor of Arley. A larger specimen is recorded as having existed at Woburn in 1840: it was 75 feet high and 11 feet in girth, but it is improbable that it still survives.

This species is one of the Pines known as "Pitch Pine." It is not, however, the most valuable of that name, for that distinction belongs to the more southern and tender *P. palustris*. The timber contains large quantities of resin, but is little used now except for fuel and charcoal-making. Some years ago large numbers of this tree were planted in Germany on the supposition that it was the tree which produces the real "Pitch Pine" timber. But neither in that country nor in our own is it likely to rival our native *P. sylvestris* as a forest tree, whatever the soil or position may be. *W. J. Bean.*

PLANT NOTES.

SCHIZANTHUS.

To have a good batch of *Schizanthus* in bloom during May, the seeds should be sown about the latter end of August. The soil used should be a light-textured compost, and the seed-boxes should be placed in a cold frame during the germination of the seed. The seedlings should be transplanted when large enough to handle, placing four in a 3-inch pot. Stand the pots on a shelf in a greenhouse in which a temperature of from 50° to 55° is maintained. They will also succeed in a cold frame if kept well up to the glass, otherwise they will become drawn. As soon as they are well rooted they should be potted into 6-inch pots, using a compost consisting of two parts loam and one part leaf-soil, with the addition of a little silver sand and crushed charcoal. When growth is well established pinch out the points of the principal shoots to induce a bushy habit.

The *Schizanthus* requires plenty of fresh air, which promotes a sturdy, vigorous growth. Guard against mildew, and, should it appear, dust the plants lightly with flowers of sulphur. By the middle of January the plants will be ready for their final potting, which should be in 10-inch pots, using the compost recommended above, to which may be added some concentrated plant manure. Do not make the soil too firm in potting, as this will impede the free growth of the roots. Care in watering is very necessary when the plants are newly potted; it is advisable to keep them on the dry side until they are well rooted. At this stage it will be necessary to stake the plants, using tall bamboo canes for the purpose. Fasten the growths neatly to the stakes with green raffia, taking care not to tie them too tightly.

It is beneficial to syringe the spaces between the pots on bright days, and a light spray overhead is desirable in the afternoon. When the pots are filled with roots, the plants are benefited by a small quantity of an approved fertiliser. Soot-water and farmyard liquid manure are also suitable fertilisers for the *Schizanthus*.

Schizanthus retusus is very useful for furnishing blooms for cutting, the flower-stems being stiff. It forms an elegant basket plant. *J. Gardner, Eaton Hall Gardens, Chester.*

TRITELEIA UNIFLORA.

This plant is valuable for the embellishment of the greenhouse at this season of the year. It has star-shaped flowers that vary from white to porcelain-blue. The period of flowering lasts about three months.

The cultivation of *Triteleia uniflora* is simple. The best receptacles are pots or hanging baskets, and it thrives best in a compost of loam, leaf-mould and sand. When baskets are used the pendulous habit of the flowers are seen

to advantage. The bulbs should be started into growth before being placed in the receptacles in which they are to flower. Place them in damp moss or partially-decayed leaf-soil about the middle of September in a cool, shady position, and in three or four weeks the new growths will be sufficiently developed for the plants to be potted. If pots are used, seven or eight bulbs should be planted in a 6-inch pot. After potting, they should be placed in a cold frame and watered as required; frost must not be allowed to reach the plants, and at the end of November they should be afforded an atmospheric temperature of about 55°, when they will commence to throw up their dainty little flowers.

After the season of flowering is over, the root-stocks may be planted out permanently in a warm, sheltered aspect on a rockery, or they may be dried off, have the old soil shaken from their roots, and be stored until the following season. *J. O. Edwards, Plas Isaf, near Ruthin.*

DAPHNE COLLINA.

ALTHOUGH a native of the south of Italy and introduced to British gardens so long ago as 1752, this plant is but rarely met with in cultivation. It is an erect, evergreen shrub from 2 to 3 feet high, with obovate, deep-green leaves, glabrous and shiny above and somewhat hairy beneath. The deep pink flowers are produced in terminal heads and are deliciously fragrant. The period of flowering is from January to March. Here, in the north of London, a plant has been in flower during the past month, and in spite of the vagaries of the weather, it has produced its flowers abundantly, without any protection beyond that afforded by a small quantity of straw shaken between its branches. I find it is by no means fastidious in regard to soil, as any good garden mould suffices for its needs. This fact, coupled with its complete hardiness and free-flowering qualities, should commend it as a desirable subject for planting in gardens, especially as the blooms are produced at a season when flowers are most appreciated.

ADONIS AMURENSIS.

THIS is an extremely useful plant at this season of the year, and noteworthy on account of its complete hardiness and early-flowering character. Its tufts of graceful Fern-like foliage and glistening golden-yellow flowers are produced toward the latter part of January and throughout February. The flowers are about 2 inches across, and, when well established, are greatly appreciated by everyone. This winter-blooming plant delights in a rich soil, and should on no account be disturbed when once planted. It is a native of Manchuria and Siberia. *Adonis Kiknasaki* is quite distinct from *A. amurensis*, although it may probably prove to be a geographical form of the older species. It is a native of Japan, and is distinguished by its extreme earliness. The lemon-yellow-coloured flowers are more cup-shaped than those of *A. amurensis*, and the foliage is much more finely divided. Here, on a London clay soil, this plant has been in flower during the last few weeks in the open border, though not protected in any way. *E. J. S., Finchley.*

THE ALPINE GARDEN.

GERANIUM TRAVERSII.

THERE are many truly exquisite things among the dwarf Geraniums, or Cranesbills, and probably none is more appreciated by rock gardeners than *G. argenteum*, with its silvery leaves and delicate flowers. Yet it is excelled by its allied flower from the Antipodes, for *Geranium Traversii*, from New Zealand, is even more beautiful. The silvery leaves, resembling to some extent, those of *G. argenteum*, are not

so finely shaped, yet they are prettier, the silvery colouring being more satin-like in its appearance, and the delicate carving of the margins as fine. The foliage is larger, and the plant as a whole is taller, although equally suitable for the rock-garden. The flowers, also, are larger, and those of the type are of a very beautiful colour, best described as very light purple, streaked with carmine. There is, however, a rarer, white-flowered variety, called *elegans*, which, in the front of a border, is very beautiful.

EPIGÆA REPENS.

ONE of the most exquisite trailing shrubs of moderate growth is *Epigæa repens*, variously known as the Mayflower and Trailing Arbutus. It is far from common, and there are many who find it difficult to cultivate. In its native land, North America, where it extends from Newfoundland for a considerable distance into what was long known as the North-West Territory, and southward into Michigan, Kentucky, and Florida, it loves sandy and rocky woods, and delights particularly in the shade of evergreen trees. In practice, we find that, in some parts of Great Britain and Ireland, it requires special care.

Our winters and the late frosts which too frequently follow them do not appear to be favourable to the *Epigæa*, and frequently it is killed by a severe frost following a mild and open winter. I am anxious to impress this upon those who seek to cultivate this shrub successfully, as it will be found that it is generally necessary to afford it some protection against the inclemencies of late spring. It also needs a sandy or stony soil, and the shade of evergreen trees. The shade should not be too great; low evergreen shrubs are sometimes too dwarf to give the *Epigæa* the necessary amount of light as well as the desired shade. Protection is best afforded by means of a handlight, which is kept over the *Epigæa* at nights, and, when severe frosts occur, during the day. The light should be opened at other times, by setting the top angleways across the lower part. If the plants are in the open, it is better to have this top shaded with whitening, or some of the shading material sold for the purpose. Under such conditions, watering is necessary, and, consequently, there should be free drainage.

Epigæa repens is a creeping or trailing plant, with rather rounded, evergreen leaves, pointed at the top, often somewhat heart-shaped at the base, dark green, usually smooth above, but hairy beneath. They are rather leathery to the touch, and are arranged alternately on the creeping branches. The flowers naturally constitute the greatest attractions of the plant. The dry, rather hard, imbricated sepals surround a tube-like flower, spreading out into an open corolla, generally composed of five lobes, and of pink colour. Wax-like in its appearance, the flower is of great beauty, and the association of the flowers in clusters at the end of the branch adds to their charm. The branches are from 6 to 15 inches long, but with us they seldom attain the latter length. The propagation of *Epigæa* is best effected by layering after flowering, which is generally from March to May.

ERODIUM CHRYSANTHUM.

A RARE and pretty Heron's Bill is that called *Erodium chrysanthum*, and, although it first came under my observation some years ago, it never seems to become more plentiful in gardens. The cultivation presents some difficulties, and it is not surprising to find the plant quoted in a recent catalogue at the high price (for one which has been in cultivation for a fair length of time) of 5s. per plant. *E. chrysanthum* is, indeed, more expensive than when first put into commerce, and this is a bad sign in itself of the character of a reputedly hardy plant.

Erodium chrysanthum has one powerful enemy in the slug. This is, I believe, the worst

enemy of the *Erodium*, and every ingenuity is required to baffle its attentions by means of zinc rings, notched if we please; brass gauze rings (which are better than those of zinc); rings of soft and lime, and so forth. With due care these devices may serve in gardens where slugs abound; but there must be no stray leaves either of the *Erodium* or adjacent plants hanging over the circlet, or the slug will find its way over the barrier. The circlet must be deep enough in the ground to prevent the slug from getting underneath.

Years ago my attention was drawn to this Heron's Bill in a somewhat noted nursery. "Here," said the nurseryman, himself a lover of Alpines, "here is *Erodium chrysanthum*. This rare plant will only do in the shade." Naturally, I followed this suggestion, but the

KILLARNEY HOUSE, CO. KERRY.

SITUATED in the romantic district of Killarney, the beauty spot of Ireland, is Killarney House, the seat of the Earl and Countess Kenmare. It was my pleasure to visit the gardens and grounds of this domain during August of last year, and never shall I forget the magnificent scenery which a view from the terrace in front of the mansion affords. The landscape is of impressive grandeur, and Nature is assisted in the scene of magnificence by the art of the landscape gardener, who has formed terraces that are the sites of much floral beauty. With great skill these terraces are connected with the receding slopes of the wilder pleasure grounds and still further distant park, wherein are flowering shrubs in great variety

in cloud or mist. The highest (3,410 feet) is Carrantuohill, the highest mountain in Ireland.

The mansion is a comparatively modern structure, the outside walls of which are furnished with climbers, including Magnolia, Jasmine, Passiflora, Genista, Ceanothus, and *Carpenteria californica*.

A portion of the grounds known as her ladyship's garden is laid out in the Italian style. The flower-beds are enclosed with dwarf hedges of clipped Box and Yew. Some are worked to designs, one representing the Prince of Wales's feathers, another the Kenmare coat of arms, &c. The flower-beds and borders have been planted on an elaborate colour scheme, in which the newer varieties of Antirrhinums, with flowers of various shades, are largely utilised, combined with Marguerites, Violas, and Begonias. A part

FIG. 76.—KILLARNEY HOUSE, THE RESIDENCE OF EARL KENMARE.

plant died. Recently, however, I have seen this dictum in favour of shade entirely controverted. In an Irish garden I saw it last year, quite happy in the sun, with its pretty yellow flowers above the graceful Fern-like foliage. I believe that it requires protection from slugs, a dry soil, and a sunny situation. With these it should survive our winters, save in the far north and the wet west, in a satisfactory way. However, it is difficult to say what is certain to suit this flower, and this note is penned with the diffidence taught by experience in dealing with "miffy" subjects, however beautiful they are. *Erodium chrysanthum*, with its lemon-yellow flowers, its silvery foliage, and tufted growth, is lovely enough to deserve all the care we can give it. *S. Arnott*.

together with many Conifers, Bamboos, Ferns, and Heaths. There are long vistas of trees that stretch for more than a mile, only ending at the water's edge of the largest of the lakes of Killarney. This is a large sheet of crystal water, some seven or eight miles long and four or five wide, containing islands whereon are ruins of historical abbeys, castles, and towers. These islands are covered with a profuse vegetation, the water scene being in harmony with its surroundings and conveying a sense of quiet and repose. Looking beyond this great lake, are seen immense tracts of wild Heather and bracken Fern, leading up to huge, almost purple, ranges of rugged, rocky mountains which rise, nearly perpendicular in places, many hundreds of feet. Innumerable peaks stretch as far as the eye can penetrate, but these are frequently lost

known as the Upper Fan garden has a totally different style of bedding, the bright colours of *Calceolaria amplexicaulis*, *Salvia patens*, and a pretty variety of pink Phlox gave a pleasing effect. On descending a flight of steps the Lower Fan garden is reached, wherein are large numbers of Lavender and other old-fashioned herbs and flowers. Single Dahlias, in front of a background formed by a hedge of English Yew, afforded a bright display of colouring. On returning to the upper terrace the middle terrace was seen. This has designs worked out in *Viburnum Tinus* in the Grass, whilst others are outlined in *Berberis Darwinii* and *Pernettya*. The enclosures were filled with *Lobelia cardinalis*, *Verbena venosa*, Scarlet Queen *Salvia*, and other bright flowers. The border shrubs are kept closely trimmed, but

these scrolls appeared to be too harshly clipped and mutilated. A Yew hedge, with turrets clipped in the top, divides each of these terraces. At one end is a pergola formed of Yew, and this adjoins the western garden, wherein are numbers of flower-beds designed in Box. The beds in summer-time are filled with Marguerites, Pinks, Pentstemons, *Salvia patens*, Marguerite Carnations, and other showy flowers. Some large tubs were filled with pink-flowered Ivy-leaved Pelargoniums; they were most effectively arranged on the upper terrace. The borders close to the windows of the mansion were filled with an assortment of sweet-smelling flowers. Leaving the terrace gardens by a fine ornamental wrought-iron gate, the hardy flower garden is reached. This contains a fine collection of

Lardizabala biternata, *Trachelospermum jasminoides*, and *Solanum jasminoides*. The flower-beds were filled with pink and white-flowered Phloxes, *Pentstemon Salmon Queen*, *Clarkia*, the double rose-flowered *Godetia*, an excellent bed of *Lavatera trimestris rosea*, and others.

Near to the pergola are a tea-house and a dairy, the buildings being surrounded by Roses, with beds of annuals and other flowers. There were also borders planted with *Violas* in large masses of one colour. The *Camellia* grows finely in the open in this Irish garden.

The path leads to an avenue, where the choicest and rarest of flowering shrubs are planted, including many not regarded as hardy. The plants are in robust health and grow luxu-

KEW NOTES.

ARDISIA CRENATA.

ARDISIA CRENATA is also known in nurseries as *A. crenulata* and *A. crispa*. For some weeks past, a batch of plants of this species has been a conspicuous object in the greenhouse. It forms a small, erect shrub, with dark green, leathery foliage. The inconspicuous, white flowers are produced in panicles, and are succeeded by bright red berries about the size of Holly berries. The berries hang for a long time so that the plants bear often crops of two seasons at the same time.

Ardisia crenata is readily increased from either seeds or cuttings, but the best plants are ob-

FIG. 77.—THE LAKES AS SEEN FROM KILLARNEY HOUSE GARDENS.

choice plants arranged in groups of various sizes and in harmony of colour. It was new to me to see *Agapanthus umbellatus*, both the white and the blue varieties quite acclimatised and remaining out-of-doors all the winter; the plants are sheltered by one of the finest hedges of *Cupressus macrocarpa* in the United Kingdom. There is an enclosed tennis-court at the top end of these borders. At one side of the court is an arched pergola, which is much the best example I know of this kind of work. Through an opening in this hedge is a garden devoted to Lilies. Near this is a part known as the Daisy terrace. It is encircled by a pergola furnished with a wealth of climbers all growing in the greatest luxuriance; many were of species not hardy in the midlands of England. The plants included *Carpenteria californica*, *Berberidopsis corallina*,

riantly. Amongst them I noticed *Escallonia montevidensis*, *E. Philippiana*, *E. langleyensis*, *Berberidopsis corallina*, *Desfontainia spinosa*, *Pittosporum* in variety, *Olearias*, *Xanthoceras*, and *Solanum jasminoides*. A splendid specimen of *Daphniphyllum glaucescens*, the Azorean Laurel, *Quercus glabra*, *Eupatorium Weimannianum*, immense clumps of both the green and variegated varieties of *Phormium*, the New Zealand Flax: also Bamboos in variety, one of which, *Arundinaria nobilis*, was flowering in different parts of the garden.

This account of Killarney House is very imperfect, but it may convey some idea of the beauty of Earl Kenmare's home in this picturesque spot. Mr. A. J. Elgar is the capable and enthusiastic head gardener. *W. Crumf, V.M.H.*

tained from seeds. They should be sown in pots, filled with sandy soil, in spring. The receptacles should be plunged to the rim in a propagating frame till germination commences. The young plants should be potted singly into small pots and stood on a damp surface in the propagating house. During the summer months hot-house treatment should be afforded, but care must be taken not to allow the roots to become dry or the plants will shed their leaves. When well rooted in the small pots, they should be transferred to others 4 inches in diameter, in which they should be wintered. A suitable potting soil consists of equal parts peat, fibrous loam, and leaf-mould, to which is added plenty of coarse sand. The following spring the largest plants should be potted into 6-inch pots, and the remainder into pots a size smaller. The plants

should be given a light position in an intermediate house, where, during the summer, they will flower. An increased amount of ventilation at this stage will assist fertilisation and help to harden the plants. There is a white-berried form named *alba*. As young plants produce the best results, a few seedlings should be raised each year and grown on without stopping the leading shoots. *A. O.*

The Week's Work.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Chrysanthemums.—The earlier batches should now be transferred into 6-inch pots, using a heavier compost than that employed for the first potting, and making the soil rather firmer than on the previous occasion. For a few days after the plants are repotted keep them in a somewhat close atmosphere and lightly syringe them when the weather is fine in order to prevent the foliage from flagging. Afterwards gradually inure them to fresh air, and do not employ fire heat except in circumstances when frost cannot be excluded by means of the outside coverings.

Flowering shrubs.—These plants require but gentle forcing to bring them into flower at this season. As soon as the flowers show colour remove the plants to the show house. Hydrangeas in growth require more manure water than the generality of forced shrubs, and it is only by liberal feeding that larger flower-heads can be obtained.

Vallota purpurea.—These beautiful bulbous plants which frequently thrive luxuriantly and flower abundantly in cottage windows are, curiously enough, often the despair of the gardener. Healthy plants, not too pot-bound, should be given merely a top-dressing. Repot the others in a mixture of fibrous loam, leaf-mould and sand. Use comparatively small-sized pots, and do not press the soil too firmly. All the plants should be placed to make their growth in a light position on a moist base in an intermediate house. Plenty of moisture, both in the atmosphere and at the roots, will now be beneficial. When the plants have completed their growth, remove them to a cooler house or frame.

Clivia (Imantophyllum) miniata.—If the plants in flower are removed to the coolest part of the house, their flowering season will be greatly prolonged. Copious waterings and frequent applications of manure are essential during the period of growth. *Clivias* growing in large pots do not often require repotting, although they must not be permitted to become excessively pot-bound, or the quantity and quality of the blooms will deteriorate. Large plants requiring attention may be divided, and thus furnish a quantity of useful plants of smaller size. Plants potted firmly in good soil in 5 and 6-inch pots flower freely, and are most serviceable for house decoration. After dividing and potting, place the plants in a warmer house until they have completed their growth. Besides *Clivia miniata* and its varieties, the more uncommon species, *C. Gardenii*, and the reputed hybrid, *C. cyrtanthiflora*, are both deserving of more extended culture.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Filberts and Cobnuts.—The pruning of these trees should be left till late in the season, allowing the young growths to remain until there is a plentiful supply of catkins to pollinate the female blooms. The female blooms usually open in March or April, but they may be somewhat later this year. The stem of the tree should be kept clear of all suckers, unless the latter are required for purposes of propagation. Young trees are generally planted with a short leg, but, in any case, it is advisable to keep the stem clear of branches for at least 2 feet up from the ground. The method of pruning generally practised in this country is to prune the trees to the shape of a goblet or basin, this having been proved the most remunerative form of culture by market growers. Young trees should on no account be planted in rich or recently-manured

ground. Cobs and Filberts do exceedingly well in poor, stony soil, or on sloping banks where it is often difficult to cultivate other fruit trees; but owing to Nut trees being so accommodating in the matter of soil and situation, it frequently happens that they are much neglected. These Nuts are a very profitable crop, and well repay a reasonable amount of care and attention. When the pruning is completed, fork the ground over and dig in all leaves and rubbish, at the same time working in a little lime. Young trees are best transplanted in the autumn; but if it should be found necessary to plant them now, this can be safely done provided reasonable care is taken. Some suitable varieties are Kentish Cob, Early Prolific Filbert, Cosford Cob, and Merveille de Bollwyller. There is also a purple-leaved variety which, apart from its fruit, is well worthy of a place in the shrubbery for its ornamental foliage.

Bush fruits.—It is usual in gardens where birds are very destructive to the fruit-buds of Gooseberries and Red Currants to defer pruning till the trees have started into growth; but these trees must not now be delayed any longer, as, owing to the sun's increasing power, the buds will advance rapidly. It is better to prune at the proper time, and either net the fruit bushes or dress them with one of the many compositions on the market for warding off birds. A second application should be given if repeated heavy rains render the first ineffectual.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Thunias.—*Thunia Marshallii*, *T. Bensoniæ*, *T. alba*, *T. candidissima*, *T. pulchra*, *T. Brymeriana* and *T. Veitchii* are now commencing to develop new growths from the old stems, and it is therefore time to repot them. Turn the plants out of their pots, shake away all the old soil, shorten the dead roots to about 1 inch and clean them thoroughly of all scale insects. The usual mode, and a convenient one, of cultivating *Thunias* is in clumps of six or eight stems, as the effect, when each stem produces its drooping raceme of flowers, is much better than when the plants are cultivated singly in small pots. The flower pots should be of various dimensions according to the size of the stems. My practice is to place about eight of the strongest stems in pots of 7 or 8 inches in diameter. These should be half-filled with clean crocks, using good-sized pieces, and placing them in an upright position so that the water can readily pass away. Over the drainage place a thin turf of fibrous loam with the grass-side downwards. The new roots will penetrate this before the appearance of the flower-spikes, and the plants will derive great benefit. For the compost, use one-half good fibrous yellow loam, one-quarter peat, and for the remainder chopped Sphagnum-moss and small crocks. Plant the stems about 2 or 3 inches apart, and use neat sticks for holding them firmly in their places. Keep the surface of the compost about half-an-inch below the rim of the pot to facilitate watering. When repotted, place the plants in the lightest position in the East Indian house, or the warm plant stove, and elevate them so that the tips of the old stems will almost touch the roof glass. When these are extra long, bend them over and tie them down, so that the young shoots may be brought nearer to the light. For the first few weeks after the potting afford water sparingly, but as soon as the roots are seen to be pushing freely through the compost and the new shoots are progressing satisfactorily, the quantity of water may be increased, and when fully established, an occasional application of weak liquid cow manure will be beneficial. *Thunias* produce their flower-spikes at the apex of the new growths, and as these spikes generally appear about the middle of May, it is advisable to grow the plants on as rapidly as possible.

Chysis.—In the Cattleya house, plants of *Chysis bractescens*, *C. aurea*, *C. Sedenii*, *C. Chelsonii* and *C. Lliminghii* produce their flower-buds in conjunction with the young growths. These plants are now commencing to grow, but only sufficient water to keep the roots moist should be applied, for if kept too wet they may fail to bloom. Suspend them near the roof glass, where they will obtain plenty of

light, heat and air. The plants should not be repotted till after the flowers have faded.

Lælia anceps.—The present is a good time to repot this species and its varieties. Unless the compost is worn out, there is no need to disturb well-rooted plants which have sufficient space for growing. When repotting established plants, the old roots may be left untouched, and if the old compost is firm and in good condition, place the whole mass into a larger pot. Make the drainage perfect, and add fresh material consisting of Osmunda fibre and Polypodium in equal parts. A little chopped Sphagnum-moss should be given in addition, and plenty of small crocks. Mix these materials well together and pot rather firmly. In dividing up worn-out specimens, cut away the dead roots and useless pseudo-bulbs, leaving about two bulbs to each leading growth. After repotting, some judgment is needed in affording water to the plants so as to prevent decay and the loss of old roots. It is a good plan to give only a slight watering around the edge of the pot till the plants are re-established. After this stage the amount of water, heat, atmospheric moisture and ventilation may be gradually increased.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Chrysanthemums.—Young plants that are to be bedded out, being well rooted, should be potted up singly and placed again in the frames. When a week has elapsed pinch the points from the shoots. The plants will be fit to put out into their permanent positions in the first week in May, according to the locality.

Dahlia.—Remove some of the sturdy shoots that are now growing from the started tubers, and insert them in small pots containing sandy soil, placing them in a warm propagating frame. When the cuttings have become nicely rooted they should be shifted into pots one size larger, and, as soon as they have recommenced to grow, they may be removed to cooler quarters.

Gladiolus.—The ground intended for *Gladioli* having been deeply dug in the autumn should now be forked over. The soil may then be expected to be in good condition at the end of the present month, when the corms should be planted. *Gladioli* succeed best in moderately light soil. In districts where the natural soil is heavy it is necessary to add a liberal quantity of leaf-mould and sand, mixing these materials with the staple.

Nicotiana.—Seeds should now be sown in boxes containing fine soil. As soon as the seedlings are large enough to be handled, prick them out into small pots. *N. Sanderae*, being richly coloured, contrasts well with the white flowers of *N. affinis*. *N. sylvestris* is a fine plant for larger borders. Under good cultivation it grows 6 to 8 feet in height, and produces huge inflorescences of white flowers. Plants of *N. Sanderae* now flowering in the conservatory, if taken good care of, may be planted out early in June; they will produce a good effect earlier than plants raised this season.

Salpiglossis.—Seeds should be sown thinly in shallow boxes. Prick out the seedlings as soon as they are large enough into other boxes, keeping them near to the roof glass.

Mignonette.—Sow a pinch of seed on a warm border after the surface of the ground has been raked very fine, selecting *Machet*, *Golden Queen*, or any of the large-growing varieties. *Mignonette*, being pretty hardy, often succeeds well from an early sowing, provided such thinning is done as is necessary to provide each plant with sufficient space.

Herbaceous plants.—In the event of fine weather, a commencement should be made to fork over the surface of the ground in the borders. It is assumed that all the spots where bulbs are growing are sufficiently indicated by means of labels. If it were otherwise, forking could scarcely be done without causing serious injury. If it is thought desirable, some cow manure or bonemeal may be added as the work proceeds, also some soot and lime around the bulbs and tender plants now pushing through the soil. On frosty mornings manure may be wheeled on to the ground for providing a mulch for the shrubs at the back of the borders. Be careful to renew any labels that are likely to fail during the season. Zinc labels are the best

for this purpose. Let them be all written in one style, and placed in the ground at the same angle.

Narcissus and Polyanthus.—Clean the sites where Narcissus will presently flower in the Grass, and apply a dressing of soot and bonemeal. Polyanthus and Primroses should be cleaned and the surface of the soil around them pricked over and given a dressing of manure, such as decomposed cow manure or a mixture of soot and bonemeal.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Early Peaches and Nectarines in pots.—It will be necessary to pay more attention to cultural details directly the fruits have passed their stoning stage. During bright sunny weather the pots must be examined two or three times a day, so that water may be applied to the roots before the soil becomes too dry. Manure water may be given at shorter intervals than hitherto. As soon as it is seen that the fruits have commenced to swell for the second time, apply a surface-dressing of rich compost. It is advisable to plunge the pots in litter, or some other suitable material, to prevent the soil becoming dry quickly, and provide an equable medium for the roots. The final thinning of the fruits may now be carried out. Let each tree carry such a crop as will be proportionate to its size and strength; on no account allow any trees to be overtaxed, otherwise the quality of the fruit will be poor. From 12 to 18 fruits may be considered a fair crop for most trees. Stop the leading shoots when they have made three or four leaves, and cut back any fruitless wood to the growth nearest the base. The temperature may now be safely increased, if it is necessary to hurry the crop; but it will be better to take advantage of sunny weather by closing early in the afternoon than to use much fire heat.

Early Peach trees in borders.—Before commencing to tie in the young growths, remove those shoots not required for fruiting next year, leaving only one shoot at the base, and another at the point, of the current bearing wood, unless it is intended to remove some of the old branches at next season's pruning. Now is the time to note those branches it is intended to cut out, so that sufficient young wood may be laid in to replace them. The young growths should be brought to the under-side of the trellis, for if this is left till pruning time there is danger of their being damaged. As soon as the fruits have "stoned," they may be safely thinned to the number necessary to furnish the crop. Remove first those less exposed to the sun, then thin out the others, leaving them evenly distributed over the trees. About one fruit to each square foot of space is generally sufficient, but young trees which show signs of making gross wood will be the better for bearing a larger crop. Syringe the trees with rain-water in the morning and at closing time, and should red spider appear on the leaves, syringe them with a solution of soft soap and sulphur. An occasional light fumigating with a nicotine compound will keep aphid in check.

Mid-season trees.—Do not neglect disbudding, but carry out the operation at intervals. Where fruits have set very thickly, it is advisable to pull off all those on the under-side of the trellis at once. Apply root waterings when necessary, and stimulants to established trees carrying full crops of fruit. Syringe the trees twice daily, and frequently damp all the surfaces in the house.

Late trees.—Trees which are being retarded for the latest supply must not be subjected to cold draughts, these being injurious.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Tomatos.—Although the winter-fruiting plants are now more or less exhausted, any that are still healthy and appear to be capable of producing fruit for six weeks or two months longer should be encouraged to do so. Remove all surplus growths, and apply a good top-dressing of rich material, also manure water when water is needed. The pollination of the flowers should be attended to daily. Winter Beauty and Sunrise have again proved invaluable varieties for

winter-fruiting. It is assumed that successional plants have now filled their final pots with roots; therefore, place them in the position in which it is intended they should ripen their fruits, choosing the lightest place possible. These are best trained up the roof of a warm house, keeping the growths at a distance of about 8 inches from the glass. No manure water should be given the plants until a good set of fruit is obtained. Maintain the atmosphere dry and buoyant, especially during dull weather and when the plants are commencing to flower. Admit air daily, if only sufficient to cause a slight circulation, for stagnant conditions favour disease. Another sowing of seeds should be made.

Vegetable Marrows.—The seedlings raised at the time previously advised should now be sufficiently advanced to be put under frames on mild hot-beds. Care should be taken to select a warm day for transferring the plants. Two plants may be put under an ordinary light. Plant them on ridges, but do not cover up the whole of the fermenting material with soil until the plants have made a good start. Maintain a temperature of from 50° to 55°, allowing this to rise with sun heat. Syringe the plants on fine days, and close the frames early in the afternoon. Add fresh linings to the frames when necessary, and thoroughly cover the glass with protective material every night. Spare plants may be potted into larger pots or boxes, and, if placed in available spaces in fruit or intermediate houses, they will be useful. Sow more seeds in 2½-inch pots.

Sorrel.—By careful treatment a small bed of Sorrel will produce abundant supplies. Care should be taken to select only the best varieties for cultivation. Sow seed thinly during the present month in shallow drills about 9 inches apart, and thin the seedlings when large enough to handle until they are 3 or 4 inches apart. They may be transplanted either the following autumn or spring. Old plants can also be transplanted satisfactorily, and, if given a thorough top-dressing of well-decayed manure every year, a bed will continue in good condition for a long time. Sorrel succeeds well in a western aspect.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Animals and birds in public parks.—In many public parks birds and even animals are kept in a state of domestication. In the parks belonging to the London County Council there are large aviaries, also enclosures for animals. They have proved of interest to large numbers of visitors. At every enclosed park containing a stream or sheet of water there are collections of waterfowl. These include both white and black swans, many varieties of geese, and a large quantity and variety of both fancy and common ducks. Some of the aviaries are constructed to hold small birds of the type of finches, redpoles, and yellow hammers; others are made for larger birds, such as ravens, owls, jackdaws, jays, and magpies. The golden, silver, and common pheasants all have attractive and striking plumage that is comparable in beauty with that of the peacock or turkey, which may be seen in the enclosures in company with deer and goats. The pouter, tumbler, and other fancy types of pigeons are also to be seen in many parks, in company with the common wood pigeon, which has become plentiful, and is increasing in numbers in our town pleasure grounds. Squirrels have been introduced, but these have not proved a great success. Guinea pigs are housed and fed at several parks, where they find plenty of admirers, particularly amongst juveniles, whose love of Nature is now stimulated largely in the schools. It would astonish many if they could see on a fine Sunday morning, principally in the East of London, the numbers of persons who frequent the parks carrying cages wrapped in a dark cloth kerchief. Each of these cages contains a bird, which is brought to the park for the purpose of teaching it the notes from other songsters. Formerly these men were mistaken for bird trappers. I have counted, soon after 6 a.m., fully 50 men lingering about the small bird aviaries for this purpose. These leave their homes in the congested streets thus early from their desire to obtain the best songster. Prizes, I am informed, are offered at competitions for the best songsters thus trained.

Special attendants.—The birds and animals are, in most of the London parks, cared for by a special officer, who is appointed to feed and to attend to their requirements, including the breeding and rearing of the young.

Wild birds.—The restful nature of public parks, the protection afforded birds and their eggs by the Wild Birds' Protection Act, and the provision for their further guarding in the parks' by-laws encourage wild birds to remain and increase. Though I have no actual record of all the birds to be met with, I may enumerate some of them. The house sparrow is always plentiful, and is constantly fed by visitors. This bird becomes so tame as to almost take food from the hand. Starlings are at times numerous; the robin can always be found, while the black-bird and song thrush are plentiful even in Victoria Park. The carrion crow will, at times, build its nest in lofty trees; but these are destroyed, because this crow is an enemy of the duck, destroying its eggs as well as the young birds. Chaffinches and greenfinches are to be met with, also the white throat, wren, tit, and wagtail. A few years ago I saw two kingfishers in a wooded portion of the middle lake in Victoria Park. The moorhen is always with us, it breeds plentifully. There may be several other birds of a migratory nature, including the seagull, which visit the parks in London in winter. During winter and very cold weather, small birds are supplied with pieces of fat and other food, these being suspended in some of the shrubberies.

The aviaries can be made any size, and they are best partitioned into divisions. The height should permit of the attendant being able to cleanse them regularly and easily. They can be made either square, octagonal, or circular in shape, and in an artistic and ornamental design. Temporary glass sides to shelter the inmates from cold winds are an advantage. Small birds are most interesting; they will live in captivity a long time, but they rarely breed.

THE APIARY.

By CHLORIS.

The weather until nearly Christmas was very warm for the season of the year, and thus the bees, being active, made severe inroads into their stock of sealed stores. As soon as warmer weather is again experienced, any hives that had not a good stock of food when last examined in autumn should be inspected. If the store be low, a cake of candy should be placed over the cluster. Disturb the bees as little as possible when examining the hives. One of the best foods will consist of a little warmed honey well mixed with very fine, powdery loaf sugar until it is of the consistency of soft putty. When the weather becomes still warmer and more settled, then liquid food may be given with advantage. There is no doubt that success in apiculture depends upon having a strong stock of bees when the honey flow commences, and this time varies according to the locality and source of honey. In some districts fruit trees are the main source from which the nectar is gathered; in others, Clover; and yet again the apiary may be situated in a seed-producing district. It will be necessary to commence feeding the bees about six weeks before the expected honey flow commences, to enable the colonies to be ready to store in the supers at the right time. After bees have commenced carrying honey and pollen in spring the queen commences egg-laying. Often the supply of one or both is interrupted by a spell of bad weather, but the brood requires feeding, or it will perish if the supply in the hive has been consumed. One may frequently see in the spring the signs of starvation in the hives, without opening a single brood chamber. Whenever larvae, which look like white grubs, are discovered upon the alighting boards, the inmates of the hive are not in a flourishing state. There have been too many mouths to feed, and the "workers" have dragged some of them out of the comb; under these circumstances a bottle of syrup should be given. In instances where the hives have a good supply of sealed stores, take a knife and remove the cappings over the honey, or it may suffice if the cappings are bruised. A comb bruised about every nine or ten days will be ample, beginning with the centre comb.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W. C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MARCH 23—

Roy. Hort. Soc. Coms. meet. (Lecture at 3 p.m. by Mr. K. Lloyd-Praeger, on "Rock Gardens").

WEDNESDAY, MARCH 24—

Perpetual-flowering Carnation Soc. Sb. at Hort. Hall, Westminster. Annual dinner in the evening.

THURSDAY, MARCH 25—Torquay Spring Fl. Sb.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—42.3°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, March 17 (6 p.m.): Max. 44°; Min. 26°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, March 18 (10 a.m.): Bar. 29.2; Temp. 47°; Weather—Sunshine.

PROVINCES.—Wednesday, March 17 (6 p.m.): Max. 45° Ireland, S.E.; Min. 37° Durham.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Hardy Border Plants, Bulbs and Tubers, Azaleas, Ferns, &c., at 12; Roses and Fruit Trees at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

TUESDAY, WEDNESDAY, AND THURSDAY—

Unreserved clearance sale of the Orchids, Stove and Greenhouse Plants, at the Deepdene Gardens, Dorking, by order of the exors. of Lily, Duchess of Marlborough, by Protheroe & Morris, at 12.30.

WEDNESDAY—

Herbaceous Plants, Lilies, and other Bulbs and Tubers, at 12; Miscellaneous Plants and Bulbs, Japanese Lilliums, &c., at 1; Roses and Fruit Trees, at 1.30; Azaleas, Rhododendrons, Palms and Plants, at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Duplicates from the "Rosslyn" collection of Orchids, also imported *Odontoglossum crispum*, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

* The
Orchid
Stud-Book.

The issue of this work is an important event in the history of the hybridisation of Orchids. Orchid hybrids—specific, generic and multigeneric—have increased in numbers during recent years at so great a rate that an authoritative catalogue such as is here provided has become a pressing need. The art of the hybridist has so outstripped that of the systematist that, as Buffon said of botany in general we may say of Orchid hybrids in particular, "it is easier to learn the subject than its nomenclature." Therefore any considered contribution to the problem of naming Orchid hybrids is to be welcomed.

Though not all experts will agree with certain of the proposals put forward by Messrs. Rolfe and Hurst, none will dispute the high qualifications which they bring to their task nor deny them a tribute of admiration for the determination and industry with which they have grappled with the difficulties that had to be faced. Some idea of the magnitude of these difficulties may be gathered from the fact that the supplements, which contain additions only up to the end of 1907, occupy 73 pages, or almost one-third of the entire work! The authors propose to issue from time to time further supplements in the *Orchid Review*, and therefore invite raisers to send particulars of hybrids flowering for the first time to the Editor of that journal.

The scope of the book is outlined in the

* *The Orchid Stud-Book*, by Robert Allen Rolfe and Charles Chamberlain Hurst. (Kew: Frank Leslie & Co., 12, Lawn Crescent.)

preface, which is followed by a brief but valuable history of Orchid-hybridisation. The historical account opens with an extract from our pages in which the late Dr. Lindley described in 1858 *Calanthe Domini*, the first hybrid Orchid raised in Europe. It was in connection with the introduction of this hybrid that Dr. Lindley remarked to Mr. James Veitch, "Why, you will drive botanists mad!" It would be interesting to know whether, when using these words, there flashed before Dr. Lindley's mind the recognition of the fact that the production of Orchid hybrids would overthrow the then current view of the sterility of species and their hybrids, *inter se*, or whether he saw with prophetic insight the bewildering difficulties of classification and nomenclature which the advent of such hybrids was to cause.

In any case, Messrs. Veitch cheerfully took the risks and continued to raise hybrids. Dominy, their expert, achieving one success after another, made for himself a name which will last as long as Orchids continue to fascinate. Following Dominy's example, an ever-increasing number of hybridists turned their attention to Orchids, crossing species with species, genus with genus, introducing fresh "blood," either specific or generic or both, into hybrids already formed till it has become impossible for any but a specialist to trace the derivation of the more complex of these extraordinary cross-breeds.

The next part of the Stud-book gives a useful account of the methods of hybridising Orchids and of raising seedlings.

Then follow the two essential parts of the book, each of which contains an enumeration of Orchid hybrids. The first of the two lists (Part I.) consists of an enumeration of the species and hybrids which have served as parents in the production of hybrids. The names of the parent plants are arranged alphabetically, and after each pair of parents is given the name of the resulting hybrid. Part II. includes an alphabetical list of existing hybrids, each accompanied by parental names, references to descriptions and figures, name of the raiser or exhibitor, date of first flowering, synonym and notes. References to original records are given wherever possible. The references to hybrids exhibited at the meetings of the Royal Horticultural Society are taken from the *Gardeners' Chronicle*, which has published unbroken records since the time of the epoch-making *Calanthe Domini*. Among other sources of information to which recourse is made are the *Journal de la Société Nationale d'Horticulture de France* and the *Orchid Review*. The work concludes with an index of synonyms.

There can be no doubt that it will not be always easy to look up references—and the work of course is a work of reference, but this defect is due to the intricacy of the subject rather than to any shortcomings on the part of the authors. Lack of system of nomenclature has led to this confusion: one raiser adopts a Latinised specific name, another prefers a name in the vernacular, often the Christian and surname of an individual. The attempt of the authors to introduce order where disorder reigns has led them to propose many new names in place of

old names; but whether the new will replace the old in general usage remains to be seen.

In framing their system the authors have adopted the following rules:—

The sign of hybridity \times between generic and specific name serves to distinguish a hybrid from a natural species.

Hybrids between species receive specific names. Such specific names are Latin, Greek, or Græco-Latin, and consist of one word or of two short words connected by a hyphen. Words of more than six syllables are excluded. Reciprocal specific hybrids bear the same name, but when sufficiently distinct receive an additional varietal name. Hybrids between forms belonging to different genera receive generic names compounded of those of the parent genera or of convenient parts of such generic names. Secondary hybrids—hybrids of hybrids—are dealt with in a similar manner.

For our part we are inclined to think that this method will be found impracticable. The end of inter-crossing genera is not yet in sight, and a reform adopted now ought to have regard once and for all to future contingencies. If this view is accepted we are of opinion that one of the yet more arbitrary, but in the long run more logical proposals now before the Scientific and Orchid Committees of the Royal Horticultural Society will have to be adopted.

But to return to the Stud-book; existing names not in conformity with the rules laid down have been modified. Thus the hybrid between *Cattleya Dowiana* and *C. Eldorado* appears in the book as *C. \times Ingramia* and not under its usual appellation of *C. \times Lady Ingram*. *C. \times Suzanna*, a name given five years later to the result of the same cross, and which is in accord with the rules, is left as a synonym. *Brasso-Cattleya \times Veitchii* is preferred to the earlier *Brasso-Cattleya \times Digbyano-Mossia* on the ground that the latter prior name has seven syllables. For the same reason *Brasso-Cattleya Maronia* replaces *Brasso-Cattleya \times Madame Charles Maron*, because the latter consists of three distinct words. *Brasso-Lælia Digbyano-purpurata* appears as *Brasso-Lælia Veitchii*. Names formed by joining the specific appellations of the two parents without abbreviation have generally been avoided as too long, though this is not always the case. *Odontoglossum \times crispum Hallii*, and *O. \times Hallio-crispum*, the latter being the reversed cross, are both included under *O. \times Cooksonii*. In a similar way *O. \times spectabile* includes both *O. \times crispo-Harryanum*, and *O. \times Harryano-crispum*. It appears to us that such alterations will cause no small amount of unnecessary confusion. Who, for instance, would recognise the well-known *Cypripedium* Baron Schröder under the name given in this list, viz., *Paphiopedilum \times Schröderi*? This hybrid from *Cypripedium Fairrieanum* and *C. ornatum* has always been known in gardens under the former name. *C. Germaine Opoix* and *C. Gaston Bultell* are given merely as synonyms of this hybrid, yet all three plants are totally distinct.

It is a matter for discussion whether it would not be better to treat the secondary hybrids as florists' flowers and to name them always in the vernacular. A better case could certainly be made out for treating first hybrids as the authors have done in this work

than for applying the Latin system in respect to merely cross-bred varieties that have little more specific value than a collection of Pelargoniums or Roses. Paphiopedilum Schröderi, if the sign of hybridity is omitted, might to all appearance be a true series, and, if the sign of hybridity is always to be used in literature, the frequent repetition will become exceedingly troublesome. It has to be remembered also that there is another serious objection to the changing of existing names. When old plants are given new names the amateur is in danger of purchasing plants he already possesses in the belief that he is acquiring novelties. The authors' rules indeed are opposed to the spirit of one of the Vienna recommendations, viz., Article 50, which states that: "No one is authorised to reject, change or modify a name because it is badly chosen, or disagreeable, or because another is preferable or better known, or because of the existence of an earlier homonym, which is universally regarded as non-valid, or for any other motive either contestable or of little import!"

We fear that the insistence on original records will also lead to mistakes. Take for an example *Lælio-Cattleya Berthe Fournier*. This hybrid was originally raised on the Continent, and it was recorded as a cross between *L.-C. elegans* and *Cattleya Dowiana*, but it afterwards turned out that one of the parents was *Lælio-Cattleya Schilleriana*, which, although a totally different plant, is known in some gardens as *L.-C. elegans*. More recently Mr. Alexander raised for Colonel Holford a hybrid between the true *L.-C. elegans* and *Cattleya Dowiana*. Following the first record it was named *L.-C. Berthe Fournier*, although there was not the slightest resemblance between it and the original *Berthe Fournier*, which, as we have shown, was obtained from a different parentage.

In conclusion we would add that though our criticisms, if well founded, indicate that Messrs. Rolfe and Hurst have not effected a final solution of a most intricate set of problems, we have, as we stated at the outset, a very deep feeling of gratitude for their work. This feeling we are convinced will be shared by all who are aware of the notable contributions made by the authors, both in the present *Stud-book* and in their former works. No system of classification and nomenclature of Orchids can, by the nature of the case, be perfect. The *Stud-book* makes a definite step toward the evolution of order out of chaos.

OUR SUPPLEMENTARY ILLUSTRATION portrays a plant of *Fritillaria askabadensis* flowering in the Royal Gardens, Kew. The species is comparatively new to cultivation. It was first exhibited in this country by Miss WILLMOTT, V.M.H., who received an Award of Merit from the Royal Horticultural Society for a specimen shown on March 25, 1907. The species was originally discovered by SINTENSIS, near the village of Kasakala, close to the town of Askhabad, growing in chalky soil, at an elevation of 1,000 metres above sea-level. These places are in the Trans-Caspian province of Russia. The plant resembles in stature the well-known *Crown Imperial*, *F. imperialis*, but the flowers are smaller and pale yellow tinged with green. A description of the plant by Mr. J. G. BAKER is given in our issue for April 12, 1902, p. 238.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Society's Committees will take place on March 23. In the afternoon a lecture on "Natural and Artificial Rock Gardens" will be delivered by Mr. R. LLOYD PRÆGER.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, March 22, at 8 o'clock, when a discussion will take place on the paper read at the last meeting by Mr. GEORGE HEAD on "Giant London." The Council have accepted an invitation from the South Wales and Monmouthshire Committee of the Institution to hold the next country meeting at Cardiff on May 20 and 21.

THE PERPETUAL-FLOWERING CARNATION SOCIETY will hold its sixth show on Wednesday next, 24th inst., at the Royal Horticultural Hall, Vincent Square, Westminster. The exhibition arrangements will be undertaken by Mr. E. F.

the Holland House show will be held on July 6 and 9, and Wolverhampton show on July 13, 14, and 15. A silver vase, value £50 (or its equivalent in cash), is offered for the most meritorious and effective display in the show, the competition being open to all exhibitors. A 1st prize of £40 is offered for a display of miscellaneous plants, in or out of bloom, arranged with cut flowers and foliage for effect, with £30, £20, and £10 as 2nd, 3rd, and 4th prizes respectively. For a group of ornamental foliage plants arranged for effect, £25, £20, and £12 10s. are offered as prizes. There are numerous classes for Sweet Peas. In a class for 72 Roses of distinct varieties, prizes of £20, £12, £7, and £3 are offered. There are numerous classes for fruit and vegetables.

M. ERNEST CALVAT.—This well known French Chrysanthemum raiser has received further recognition of his services in connection with hor-

FIG. 78.—FRITILLARIA ASKABADENSIS: FLOWERS YELLOW, TINGED WITH GREEN.

(See also Supplementary Illustration.)

HAWES, Royal Botanic Gardens, Regent's Park. The secretary is Mr. HAYWARD MATHIAS, Lucerne, Stubbington, Fareham, Hants. The honorary treasurer, Mr. LAURENCE J. COOK, writes us as follows.—"I would remind readers of the *Gardeners' Chronicle* that the exhibition will probably be the finest show of Carnations ever seen in Europe, and, from an artistic point of view, perhaps, in the world. There are two fine cups and gold and silver medals and many prizes for competition."

THE COMING OF AGE OF THE WOLVERHAMPTON FETE.—The committee of this flourishing fête is this year celebrating the 21st exhibition. At the annual show, on July 13, 14 and 15, substantial prizes are to be offered in most of the classes, and those interested should write to the secretary, Mr. W. E. BARNETT, Snow Hill, Wolverhampton, for a copy of the schedule. Both the Holland House and Wolverhampton shows have, unfortunately, of late years been held on the same date as this floral fête. This year,

the French Government has appointed him Officier d'Académie. The "palmes académiques" are usually bestowed upon professors, journalists, and literary workers in France who contribute to the public instruction. M. CALVAT has certainly done much to popularise the culture of Chrysanthemums in a special way.

BERLIN HORTICULTURAL SHOW.—This international horticultural show, which will be held from April 2 to 13 next, will probably attract many visitors from all parts of Europe. An excursion is being organised by the National Horticultural Society of France, which offers to its members an eleven days' trip for £16. Besides visiting the Berlin show, the party will be provided with hotel and travelling expenses to Cologne, Hamburg, Dresden, Leipsic, and Frankfurt. The members of the jury will commence their sittings on April 1. Several English horticulturists have accepted invitations to officiate as members of this body.

A FRENCH NATIONAL CARNATION SOCIETY.—A new special society has recently been formed at Antibes (Alpes-Maritimes) having for its special care the culture of the Carnation. Its title is La Société Nationale des Giletlistes. The officers include Dr. POIRAULT, president; and several vice-presidents. The general secretary is M. JULES GREC, of Antibes.

THE NATIONAL SWEET PEA SOCIETY'S PROVINCIAL SHOW.—This takes place on July 13, at Saltaire, a village which derives its name from Sir TRUS SALT and the river Aire, which runs close by. The village was built in the 'sixties to accommodate the workpeople employed in the Saltaire Mills, then newly erected, and it was considered a model village, with a beautifully-situated and well-designed park. The show will be held in the park, as have been the exhibitions of the Saltaire, Shipley and District Rose Society since it was formed in 1903. The association has been remarkably successful; the amount of money taken at the gate at the first show in 1902 was only £18, but last year it amounted to £214. With the exception of a band, no attractions are offered but those of the floral displays. In 1907 the National Rose Society held its provincial show at Saltaire.

PARIS SPRING SHOW.—Our readers may be reminded that the spring exhibition of the National Horticultural Society of France will be open from May 17 to 23.

MR. J. COUTTS, who was recently appointed a departmental foreman at Kew, has been head gardener at Killerton Park, Exeter, for several years, where he has carried out many improvements.

NAARTJES.—At some of the Colonial fruit shows of the Royal Horticultural Society during the last few years, visitors have come across the word Naartje applied to certain kinds of South African Oranges. It appeared as if Naartje was merely a South African name for all varieties of Oranges. Further inquiry showed that this was not the case: for example, at the Natal exhibit of some two years ago at Vincent Square, "Oranges" and "Naartjes" were shown side by side. The former term included St. Michael and Navel Oranges, the latter various varieties which might all be classed as Mandarins or Tangerines. Mr. R. A. DAVIS, Government Horticulturist to the Transvaal, has published a paper on the subject in the *Transvaal Agricultural Journal* for January of this year. The term Naartje, he says, "stands, in South Africa at least, for all possible sorts of Mandarins and Tangerines." Mr. DAVIS suggests that some agreement should be come to amongst the South African colonies, either to drop the name Naartje, and ship fruits as either Mandarins or Tangerines (a matter of difficulty when the difference between some classes is almost imperceptible), or to class all as Naartjes, and quote the particular variety to which the fruit may belong.

PUBLICATIONS RECEIVED.—*The Journal of the Board of Agriculture of British Guiana*. (January). (Demerara: The Argosy Co., Ltd., Georgetown). Price 1d.—*Government of the Gold Coast's Report upon the Botanical and Agricultural Department for the year 1907*. (Gold Coast: Government Printer).—*U.S. Department of Agriculture*. Farmers' Bulletin 343: The Cultivation of Tobacco in Kentucky and Tennessee, by W. H. Scherffius, Collaborator, and H. Woosley and C. A. Mahan, Special Agents, Tobacco Investigations, Bureau of Plant Industry. (Washington: Government Printing Office).—*The Agricultural Gazette of New South Wales*. (January). (Sydney: Government Printer). Price

6d.—*The Philippine Agricultural Review*. (November, 1903). (Manila: Bureau of Printing).—*Claremont Pomological Club*. Bulletin No. 1: "Mealy Bug and Fumigation." (California: Claremont, Los Angeles County).—*Beautiful Flowers and How to Grow Them*, edited by Horace J. and Walter P. Wright. Part X. (London: T. C. and E. C. Jack). Price 1s. net.—*Lawes Agricultural Trust*. Rothamsted Experimental Station, Harpenden. Annual Report for 1903, with the supplement to the "Guide to the Experimental Plots," containing the yields per acre, &c.—*Two Essays on Sweet Peas and How to Grow Them*. (a) For Amateurs and Exhibition, by Walter A. Voss, F.C.A.; (b) For Market Growers, by W. F. Emptage, A.A.E.B. (London: W. Speaight & Sons, 98 and 99, Fetter Lane, E.C.) Price 1d.—*Annual Report of the Board of Regents of the Smithsonian Institution*. Showing the operations, expenditures and condition of the institution for the year ending June 30, 1907. (Washington: Government Printing Office).—*Kew Bulletin of Miscellaneous Information* (No. 2), containing Diagnoses Africanæ; XXVII. New Orchids; 33 Varieties of the Oil Palm in West Africa; the Section Microcos of Grewia in Africa, &c. (London: Wyman & Sons, Ltd., Fetter Lane, E.C.) Price 4d.

THE FERTILISING VALUE OF SNOW.

So far as we are aware, Professor Frank T. Shutt, M.A., F.I.C., chemist, Dominion Experimental Farms, Ottawa, has furnished us with the first complete analysis of snow.

The author thought that a chemical examination of snow might furnish results that would prove interesting, especially from the agricultural standpoint, since the greater part of such nitrogen compounds as the snow contains must eventually serve to fertilise the soil. The collection of the snow samples examined was made in the arboretum of the Central Experimental Farm, an area of 65 acres devoted to the growth of trees and shrubs.

The atmosphere of this locality, while naturally not free from smoke, is stated to be fairly pure—for Ottawa is not a city characterised by tall chimneys, and, besides the few residences on the farm, there is only a single line of a little-used railroad in the immediate vicinity.

Snow has lain since November, but the examination did not commence till nearly the end of February. With the exception of the first collection, which represents the surface 1½ inches of the accumulated snow, the samples submitted to analysis were all freshly-fallen snow, care being exercised to collect either during the snowfall or within a few hours of its cessation.

Not one of the samples appeared in the slightest degree dirty or soiled, but were of the purest whiteness; nevertheless, on melting, there was on the surface of the resulting water or clinging to the sides of the vessel a certain amount of sooty material, and frequently also there was a slight deposit.

The tabulated data are as follow:—

Date of Collection.	Nitrogen, parts per million.		
	As Ammonia.	As Nitrates.	Total Nitrogen.
1907.			
February 21	288	136	424
" 25	354	300	654
March 4	205	170	375
" 4 (12 hours after preceding)	218	170	388
" 15	457	330	787
" 20	342	128	470
" 25	144	111	255
April 8	198	94	292
" 10	313	107	420
" 17	655	317	972
" 25	401	333	734
May 4	115	65	180
Average	308	163	471

From the wide fluctuations noticeable in the nitrogen content of these samples, it is evident that the condition of the atmosphere of a locality may change both frequently and considerably, though it may also be supposed that the size of

the snowflakes and the temperature of the atmosphere during the fall exert an influence on the filtering and solvent powers of the snow.

The author thought it quite probable that when the period since the preceding snowfall had been a brief one, say a day, there would be a smaller nitrogen content than when a longer period, several days or a week, ensued, but the data do not show that this was always the case. Nor were there found any marked differences in purity between samples collected at the beginning and towards the close of the same snow-storm, though in this matter data from one fall only, viz., that of March 4, is presented.

From the above data it is estimated that one pound of nitrogen per acre is furnished to the soil from an average winter's snow at Ottawa.

It is not supposed that the whole of the fertilising, or, to speak more correctly, the agricultural value of snow, lies in the nitrogen it possesses; nevertheless, we have in these data some support for the widely-accepted belief that snow is a direct fertiliser. It is very evident, however, that the value of snow in this respect has been greatly over-estimated by agriculturists.

From the Rothamsted investigations we find that 69 samples of rain gave an average of 0.70 parts of nitrogen in one million of rain; while in seven samples of dew and hoar-frost were found 2.79 of nitrogen in parts per million. That is to say, the Rothamsted rainfall is 1½ times as rich in nitrogen, and the dew and hoar-frost is 5½ times as rich as the Ottawa snow. *J. J. Willis, Harpenden.*

NOTES FROM A "FRENCH" GARDEN.

It has been necessary to water some of the hot-beds to stimulate the growth of the Carrots and to force the Lettuces to form hearts. Two circumstances have tended to cause this dryness: (1) our beds were made up of long and strawy material; (2) they were built on the level ground, and this method allows of the moisture draining away. But the same circumstances prevented a lot of damping off which would otherwise have taken place amongst the plants during bad weather, and, therefore, the advantages of this method deserve to be widely known.

Manure is now being prepared by passing it through a fine sieve for spreading among the Carrots after all the Lettuces have been taken away. This manure will be made to thoroughly cover the roots of the Carrots, thus preserving their fine colour. Watering will be necessary to level the soil and clean the leaves.

The Cauliflowers of the variety Driancourt, raised in the autumn in the open ground, have been given abundant ventilation in order to get them sufficiently hard to transplant them at the end of the present month. The ground having been heavily manured, is now ready for their reception. They will be planted 2 feet apart each way, and Spina'h "Monstrous of Viroflay" and Lettuce All the Year Round, which were raised early in January, will form the intercrop. The Ox Heart Cabbages planted last November, being somewhat backward, have not suffered much from inclement weather. Late frosts in April are more prejudicial to this crop. The ground about them is now being hoed deeply, and the drills in which they were planted are being levelled, in order that the soil may be brought around the stems of the plants. The only further attention they will need will be ample watering.

The Passion Lettuces planted late in January were somewhat loosened in the ground by the thawing of the snow. We have had to tread the beds in order to make the ground firm again. This may have damaged the intercrop of Radishes. We are now planting another batch of this variety, which was saved in case the first plantation failed. Passion Lettuces under lights must be well ventilated day and night, as it will be necessary soon to remove the frames and lights, and place them over the Melons.

A batch of Globe Artichokes (*Cynara Scolymus*) are now being planted in the open at distances of 2½ feet. The ground has been deeply dug and heavily manured. These plants were wintered in frames in pots. A batch of young shoots is being inserted in 2½-inch pots. The shoots were taken from the old stools. The cuttings will be placed on a hot-bed. It was formerly our custom to insert them directly into their permanent quarters, but the young plants, being later, failed to produce any flower-heads in the summer and were too tender to pass through the winter.

Seeds of Cardoon de Tours are being sown. Though this variety is very thorny, it is by far the best, on account of its eating—and keeping qualities. Three seeds are inserted in a 2½-inch pot, and the pots are placed on a hot-bed. The seedlings are thinned out to one in each pot, and the single plants retained are gradually hardened for planting out at the end of the day.

The manure around young Me'ons is changed

COST OF PLANTING FOREST TREES.—In the Cardiff papers for March 6 mention was made of a proposal by the City Corporation to plant some 40 acres of land near their reservoirs in Breconshire with forest trees. Scotch Fir was suggested, and the waterworks engineer is reported to have stated that about £8 per acre would be the cost of planting. I am aware that this price can be supported by the figures at which nurserymen undertake forest planting; but such "contract-planting" is unsatisfactory, because the price paid is inadequate, second-rate trees are often used, and the work is hurriedly and badly done by men who are paid piecework at a rate so low that they must needs cover the maximum of ground in the minimum of time. There are two very strong reasons why all forest-planting in this country should be well done at the present time, firstly, because the industry is in an experimental stage, and we are only feeling our way, and, secondly, because the public are sympathetically watching the industry, and it will be unfortunate if their ardour is damped by failure due to bad work and mismanagement. The Cardiff City Corporation will

show; therefore *D.* need not be surprised at this variety taking a high position. As to Baumann's Red Reinette, its flavour is so poor that I consider land wasted that is devoted to this variety. The flesh is much too hard and dry. King of the Pippins I place in the same category, or nearly so. Sturmer Pippin is a dry and tasteless thing. King of Tompkins County is a good-flavoured Apple in April when properly stored. Any Apple known to an experienced judge can easily be awarded its proper prize without cutting. *E. M.*

LIGNUM NEPHRITICUM.—A reference to *Lignum nephriticum* in the issue for February 6, p. 96, induces me to add a few words to the answer there given as to the botanical source of this wood, which, I was under the impression, had never been satisfactorily determined. So far back as 1859, a list of products, about which information was wanted as to their botanical origin, was drawn up by Sir William Hooker, assisted by the great pharmacologist, Daniel Hanbury, and printed in the 3rd edition of the *Admiralty Manual of Scientific Inquiry*, under

FIG. 79.—VIEW FROM THE TERRACE AT KILLARNEY HOUSE, SHOWING THE LAKES AND THE MOUNTAINS IN THE BACKGROUND.

(See page 180.)

every week, in order to maintain the necessary heat. The Melons raised in the middle of February are having their shoots stopped at the second leaf. *P. Aquatics.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

WOOD'S GRAPE BOTTLE.—When this bottle was submitted to the Fruit and Vegetable Committee of the R.H.S. on the 9th inst., the criticism passed upon it generally was with respect to the form of the neck. As was shown in fig. 74, p. 175, the neck is curved. As a result, it was found that only 6 inches of the stem below the bunch could be inserted into the bottle. That was held to be an objection. It was suggested the neck should be slanting and rather longer in order that as much as 10 inches of the wood may be inserted. *D.*

be well advised if they assure themselves that their work is well done, even if the increase in cost compels them to curtail the acreage that they plant. *S. W.*

CATLEYA TRIANÆ COURTAULDIANA.—In response to the enquiry which I notice in your issue of the 13th inst., p. 163, I may state that *C. Trianæ Courtauldiana* flowered in my collection a few years since. Its feature was a very dark lip, but there was nothing in the flower of extraordinary beauty. *Jeremiah Colman, Gatton Park, Surrey.*

LATE DESSERT APPLES.—I agree with the judges awarding prizes to Cox's Orange Pippin even in March, if the fruits are preserved in proper condition, for none can equal this favourite variety when not in the least shrivelled. Such fruits do not need tasting, for it is known that Cox's Orange Pippin retains its high flavour so long as it remains plump. A judge knowing this Apple would not think of cutting the fruits at a

the title of "Botanical and Pharmacological Inquiries and Desiderata." In this list the following paragraph occurs:—"Lignum nephriticum. —This rare wood was sent to the Paris Exhibition of 1855 from Mexico. To what tree is it to be referred?" Again, in another edition of the *Admiralty Manual*, published in 1871, Professor Daniel Oliver was associated with Hanbury in drawing up a new list, entitled, "Inquiries Relating to Pharmacology and Economic Botany," and, in this, information is again asked for in the following words: "This rare wood, noticed by some of the earliest explorers of America, is a production of Mexico. To what tree is it to be referred? Its infusion is remarkable for having the blue tint seen in a solution of quinine." The fact of its being a native of Mexico would put it out of the running as being the produce of *Moringa pterygosperma*, which is a soft-wooded tree of India, where it is known as the Horseradish tree. Perhaps this note may be the means of bringing out some further information on this interesting wood, which is sometimes known as Bois de nephritique. *John R. Jackson.*

TALL CONIFERS AT KNEPP CASTLE.—At Knepp Castle, Sussex, the seat of Sir Merrick Burrell, Bart., there is a specimen of *Taxodium sempervirens* 97 feet in height and 18 feet 6 inches in girth at the base. It would be interesting to know the height of the tallest tree of the species in Britain. In the Royal Horticultural Society's *Journal*, October, 1892, on the occasion of the Conifer Conference, the heights are given of some of the best-known Conifers in Great Britain. The tallest *Taxodium* was 75 feet. How much has that tree grown in the 17 years that have since elapsed? There is also a very fine specimen of *Picea cephalonica* at Knepp; it is 79 feet high and has a girth of 13 feet 3 inches. In the report of the Conifer Conference there are only five trees mentioned that were more than 100 feet high. These were *Abies Douglasii*, 120 feet; *Abies excelsa*, 103 feet; *Abies Menziesii*, 110 feet; *Abies pectinata*, 111 feet; and *Larix europæa*, 100 feet. *W. A. Cook, Leonardslie Gardens, Sussex.*

APPLE SCAB.—A. D. (pp. 123 and 157) opens up a subject of great importance to fruit growers, viz., the placing of clean samples of Apples upon the market. I have about half an acre of land planted for about 15 years with Duchess of Oldenburg Apple. These trees gave splendid crops of fruit, both in size and colour for the first eight or ten years. Since then the crops have hardly paid for the gathering, owing to so much of the fruit being affected by scab. The trees are half standards, on the free stock, with clean, healthy bark and plenty of fruit spurs. They were planted rather closely together, but owing to their upright habit of growth, assisted by careful pruning, they do not shade each other to any great extent. Little spraying has so far been done, but we are thinning the trees and shall then spray them with a solution of copper sulphate. We had four long rows of Apple trees, two of Ribston Pippin and two of Cox's Orange Pippin. The trees of Ribston Pippin were badly cankered and were cut down. On pruning the trees of Cox's Orange Pippin recently, I was surprised to find endless signs of canker on them, and especially on the row nearest the Ribston Pippins. This indicated that the spores of the fungus are dangerous to healthy trees, as we have other trees of Cox's Orange Pippin in another orchard and on similar soil which are quite free of canker. *H. C.*

Some varieties of Apples are more subject to scab than others. Why should not these varieties be double-grafted upon poorer kinds which produce healthy shoots and are free from scab? One source of encouragement to the fungus is deep planting. Trees should not be planted deeper than the ground line mark appearing on their stems when received from the nurseries. Apple grafts require to be kept as high and as dry as possible, but dressing and spraying the trees are the best, and, indeed, the only means of getting rid of this fungal pest. *John Smith, Horticultural Instructor, St. Helen, Ipswich.*

I have sprayed the trees annually now for nearly 20 years with at first my own mixture of caustic soda (Greenbank's 98%) and pearl ash, but more recently with an alkali mixture which entails less trouble in preparation, but I regret to say we get much more scab than is pleasant to look upon. I have come to the conclusion that there are other causes answerable for the yearly attack of this pest, worse in some seasons than others, than the want of spraying, which, according to some writers, is a safe and sure remedy. Combined with a cold subsoil of heavy and retentive material, which is too common here, we get, I might almost say annually, a spell of cold, unless weather, lasting often a fortnight, just after the fruit is set. That is the period when the foundation for "scab" is laid; the leaves, too, are affected with a fungal growth, which is against proper progress. Some varieties feel the effect of this disagreeable weather more than others, notably Warner's King: this is partly owing to the various times at which varieties open their blossoms. Some writers would say, spray again with other antidotes, such as Paris Green, &c. That is all right when the result of such treatment turns out as one could wish, but, having been once seriously deceived by results of such spraying, I am decidedly cautious of attempting these summer sprays. Some years

ago the greatest so-called expert in spraying advised me to use Paris Green, and gave me full instructions as to quantity. I used the wash at half the strength recommended, with the result that the trees were singed in their leaves, many losing them. Stirling Castle, Lane's Prince Albert, and Cox's Orange Pippin were affected most. Never shall I forget the sight of some hundreds of trees in this state of defoliation. The worst of it was that the damage did not end with that year. Where the subsoil is heavy and retentive of moisture it is naturally more cold and ill-adapted for the growth of fruit than that of a more porous nature like a pure loam. Extra deep trenching is much the best remedy under such circumstances, but not the bringing of the bottom soil to the top. *E. Molyneux.*

POLYSTICHUM ACULEATUM GRACILLIMUM DRUERYI.—With reference to Tyro's remarks (see page 157) under the above heading, I may say that, in other quarters, I was complimented by those who saw the plant on the appropriateness of the name. Two out of the four names, or, rather, parts of the one name, are specific ones; the next in order is descriptive, and distinguishes the Fern clearly from the one of the same section previously certificated; while the last, as indicating the raiser, who is the same in both cases, cannot lead to any confusion. I may, however, say that I intended that my name should appear in this case in parenthesis (Druery), as indicating the authority for the name, but by some slip it was entered and certificated as per heading, and I have not considered it worth while to alter it. As regards Tyro's reference to the Vienna Congress, I think the R.H.S. would experience difficulty if it attempted to enforce these regulations upon the varieties of plants submitted to its committees for awards. I have myself studied the voluminous Vienna reports, and confess myself utterly baffled in my attempts to comprehend its rules and regulations, and the recommendations, exceptions, reservations, and so on which qualify nearly every one of them, owing to the impossibility of abolishing the basis of established nomenclature on other and less systematic lines. It is imperative to give fancy names to the innumerable varieties of florists' flowers, &c., which present comparatively slight differences of form and colour; but it is a different thing altogether when we deal with what may be termed pedigree plants, like most of our Fern varieties, where it is possible to divide them into sections and give them descriptive names by which their special character is indicated, without the need of referring in every case to a descriptive catalogue. Inside Fern circles the names are no trouble at all; it is only outsiders who make a "bogy" of them. My own plumose Lady Fern, for instance, *Athyrium felix-foemina plumosum Drueryi*, becomes simply P.D., and *Polystichum angulare divisilobum plumosum densum* is simply Jones's *densum* to those who are in the cult, and I say again that it is they who are chiefly concerned, while those outside the cult who desire to take up the study, can, by the aid of these names in print in recognised standard books, see how useful they are when properly arranged and classified. As regards Tyro's reference to the reverted seedlings, it is not stated that they reverted to another allied species, but that they had a strong resemblance to it, which, considering the great similarity between the two species concerned, is not very wonderful. All three British species of *Polystichum* are very close allies. *P. lonchitis*, the Holly Fern, for instance, is only distinguished from *P. aculeatum* by its being pinnate instead of bipinnate, and if it sported in that direction, could not be discriminated from the latter. In point of fact, it has occurred several times that *P. aculeatum* has appeared mysteriously among *P. lonchitis* seedlings, very probably as merely bipinnate sports of *P. lonchitis* itself. *C. T. D.*

SCHEDULES RECEIVED.

Brighton and Sussex Horticultural Society's eighteenth annual Rose and Sweet Pea exhibition, to be held in the Dome and Corn Exchange, Royal Pavilion, Brighton, on June 29 and 30; also **Chrysanthemum show**, to be held in the same buildings on November 2 and 3. Secretary, Mr. J. Thorpe, 53, Ship Street, Brighton.

Penarth Rose Society's show, to be held in the Penarth Cricket and Football Field, on Wednesday, July 7. Hon. secretary, Mr. H. A. Gerhold, Windsor Road, Penarth.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 9.—*Present:* Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the Chair); Rev. W. Wilks, Dr. F. Keeble, Messrs. C. T. Druery, A. Worsley, W. Hales, J. Arkwright, de B. Crawshaw, J. Douglas, H. J. Chapman, G. Massee, A. W. Hill, H. T. Güssow, G. S. Saunders, A. W. Sutton, E. M. Holmes, J. T. Bennett-Poë, J. Fraser, R. Hooper Pearson, H. J. Veitch, and F. J. Chittenden (hon. secretary).

Beetle in stem of Yanda teres.—Mr. G. S. SAUNDERS reported that he had examined the stem of *Yanda teres* sent to a recent meeting of the committee, and found that the beetle boring into it was a species of *Xyleborus*, not a native, nor, so far as could be ascertained, recorded as occurring in Europe up to this time. The plants attacked were sent by Mr. ROGERS from a greenhouse at Bury, Lancs.

Spots on leaves of Lapageria.—Mr. MASSEE reported that he had examined the leaves of *Lapageria* shown at the last meeting and found that the roundish brown spots upon them had been caused, not by a fungus, but by drip.

Orchid hybrids.—Mr. H. J. CHAPMAN showed *Odontioda Bradshawia* Oakwood var., raised by crossing *Odontoglossum crispum* var. *Graireanum* (white) with *Cochlioda Noezliana*. The flowers showed no trace of blotching, but were almost of one shade of colour throughout. Another form, *Odontioda Bradshawia* Cookson's var., raised from *Odontoglossum crispum* × *Cochlioda Noezliana*, had a deep mauve margin to the brick-red segments, and showed distinctly the deeper coloured blotches upon the lighter ground colour. The difference in colour and markings in these two varieties forms an interesting problem in heredity.

"Vegetable" asbestos.—Mr. HOLMES reported that he had examined this material, sent to the last meeting, and could find no trace of vegetable structure in it. The substance was creamy white in colour, and was lamellated, fairly soft to the touch, and resisted fire. Chemical analysis showed it to contain alumina in large quantities, magnesium, calcium, and smaller quantities of sodium and silica. Mr. HOLMES considered that the analysis pointed to this being of mineral origin, and not of having been derived from "a Cactus from China," as the sender had suggested. It appeared to be nearly allied to the substance known as "mountain leather."

Bulb on inflorescence.—Mr. WORSLEY showed an inflorescence of *Lachenalia tricolor* having a small bulb occupying the position of a terminal bud on the inflorescence.

Aberrant Orchid.—From Mr. G. W. MILLER, of Wisbech, came a specimen of *Cypripedium Pitcherianum* Williams' var., with a well-formed double lip.

Fasciation in Euonymus japonicus.—Mr. J. FRASER showed fasciated branches of *Euonymus japonicus*. The fasciation had followed after severe cutting back of the stem. Numerous buds had started in growth from near where the cut had been made, and among them some had produced fasciated shoots.

Malformation in Tulip.—Rev. J. JACOB sent a flower of Tulip having on the mid-rib of one of the perianth pieces on the outer side two small horn-like growths. The structure was similar in character to those seen in crested flowers, and was apparently the commencement of a crested growth.

LINNEAN SOCIETY.

MARCH 4.—A meeting was held on this date, Dr. D. H. Scott, F.R.S., president, in the chair. Miss L. S. Gibbs read a paper entitled "A Contribution to the Montane Flora of Fiji, including Cryptogams, with Ecological Notes." The Fiji group consists of 200 islands, only 80 of which are inhabited; Viti Levu is about 4,100 square miles in area, with forest-clad mountain ranges, the highest point being Mount Victoria, 4,000 feet in height. The botanical history of

the group begins with the visit of H.M.S. "Sulphur" in 1840, and in the same year the Wilkes Expedition touched at the islands. The "Herald" called in 1856, and Dr. Seemann visited the group in 1860-61, and embodied his results in his *Flora Vitiensis*. Mr. Horne, Director of the Botanic Gardens at Mauritius, spent a year collecting, in the late '70's.

Thanks to these investigators, the flora of the lower parts of the chief islands are fairly well known. The author, therefore, decided to confine her investigations to the region lying 2,900 feet or more above sea-level, and the three spring months of August, September, and October were spent at Nadarivatu, the highest inhabited point.

From the collections, the flora may be described as Indo-Malayan. They contain about 40 new species and many new records. Thus, of the eight species of Piper, Mr. C. de Candolle

sideing. The balance-sheet showed that the annual income of the society during the past year had amounted to £191 13s. 6d. The surplus in hand from the show was £8 6s. 4d., and it was stated that the society was in a very fair financial position. Lady Bathurst was elected president of the society for the coming year. It was resolved that the name of the society be the Gloucestershire Rose and Sweet Pea Society, and that steps should be taken to become affiliated with the National Sweet Pea Society. Mr. M. Ll. Baker was re-elected chairman of the society, Mr. J. Manners treasurer, and Mr. S. Gibbons hon. secretary. The committee was re-elected, with the addition of Major Organ, and Mr. Conway Jones was reappointed chairman of the committee. The rules were revised to meet the inclusion of Sweet Peas in the society's schedule, and the schedule committee was re-elected as last year.

known to be unfavourable to inoculation. Eight plots were treated with nitrogenous manures, and four with superphosphate. Was it fair to sum up the total yields of crops grown under both unfavourable and favourable conditions and draw a general conclusion therefrom? By so doing Mr. Chittenden showed a decrease of 65 lbs. or 14 per cent. (since corrected to 20 lbs. or 4 per cent.) from inoculated seed. If the comparison were made of the totals grown under conditions favourable to inoculation, there was a decrease of 7 per cent. on the cultivated land, but the large increase of 18 per cent. on the fallowed land.

No comparison was made in the report of the yield from inoculated seed alone with the yield from the other manures alone. On the cultivated land inoculated seed gave the lowest yield, but dung also gave a lower yield than the yield from the untreated (control) plot. On the

FIG. 80.—SCROLL BEDDING IN THE GARDENS OF KILLARNEY HOUSE.
(See p. 181.)

found five to be new, and of Peperomia, all seven proved novelties. The introduction concludes with some observations as to the origin of the flora, and is followed by a systematic enumeration of the whole collection.

An animated discussion followed, in which the following engaged:—Dr. A. B. Rendle, Mr. R. A. Rolfe, Prof. P. Groom, Dr. O. Stapf, Mr. J. Hopkinson, Mr. A. P. Young, Mr. T. A. Sprague, Mr. A. Groves, and Mr. Clement Reid. The author replied to the various questions put, and concluded by a display of lantern-slides from her own photographs.

GLUCESTERSHIRE ROSE AND SWEET PEA.

MARCH 5.—The annual meeting of the members of this society was held at the Guildhall, Gloucester, on this date, Mr. Conway Jones pre-

HORTICULTURAL CLUB.

MARCH 9.—At a meeting of the members of this club on the above date, Professor Bottomley spoke on soil-inoculation, and replied to criticisms which Mr. Chittenden had published in the Royal Horticultural Society's *Journal*.

Professor Bottomley prefaced his remarks by complimenting Mr. Chittenden on the care and thoroughness of his experiments, which were the most comprehensive of any yet made on Peas in this country. The results, however, did not appear to justify the conclusion arrived at by Mr. Chittenden. It was stated that "the experiment was planned to ascertain whether any benefit was to be derived from the inoculation of leguminous crops under any conditions in such a naturally poor soil as that of the Wisley garden." Twelve out of the 24 plots were treated so as to produce conditions which are already

fallowed ground inoculated seed gave the highest yield, an increase over the control plot of 17 per cent., if the report figures are taken, or 10 per cent., if correction is made for the variation in number of plants in the two plots. Table J. was unfair; because on two plots (15 and 16) there is a difference in number of plants of Maincrop. The yield of Maincrop, which gives the largest increase on plots 13 and 14, is omitted, although there is no mention made of any variation in the number of plants. The scientific method would have been to make a correction for this fact. This would have given an increase of 1 per cent., 10 per cent., and 15 per cent. for soil inoculation, seed inoculation, and soil and seed inoculation respectively.

Again, there was a difference in the action of lime alone and the action of a mixture of lime superphosphate and potash on the nitrogen fixing organisms. The U.S.A. Department of Agricul-

ture had shown the beneficial effect of lime on inoculation. At Wisley, on the limed plots, inoculated seed gave an increased yield of weight of Peas on both cultivated and fallowed land—an increase of 4 per cent. and 29 per cent. respectively. The mixture of lime, superphosphate and potash gave a decreased yield in both cases—a decrease of 16 per cent. and 27 per cent. respectively. On the fallowed land Mr. Chittenden ignored the beneficial effect of lime alone, because lime was added to the super and potash mixture which gave a decrease. As the American instructions for using inoculating material state that concentrated fertilisers should be spread and mixed with the soil previous to sowing the inoculated seed, it would be interesting to know the date when Mr. Chittenden applied the superphosphate mixture.

MR. CHITTENDEN'S REPLY.

The following is a summary of Mr. Chittenden's reply: An attempt was made in the Wisley experiments with nitro-bacterine to compare the yield of 12 pairs of similarly-treated plots, assuming that if equal weights of seed were sown on each of the plots, other conditions being equal, the crop from the two plots would be the same. But, on the fallowed land, for instance, there was sometimes great variation in the number of plants of one or two varieties on the two plots to be compared, owing to factors which were not commensurable. In such cases the yield from the variety most variable in this respect was entirely ignored, or (and in any case) from these plots no general conclusions were drawn.

was drawn), as was stated in the report, was 3.61 per cent. Yet Prof. Bottomley inferred that the reason of the failure of inoculation to produce any benefit on this soil was that it was so rich in organic matter that the nodule-forming organisms were unable to do their normal work. As Prof. Bottomley was aware, ordinary field soils usually contain at least 5 per cent. of organic matter, and garden soils contain as a rule very much more, 10 per cent. being not unusual. If his strictures were accurate, then practically no cultivated soil in the country was likely to benefit by inoculation, because it contained too much organic matter.

What evidence had Prof. Bottomley that the soil was too rich in organic matter for the bacteria to do their work? *On every plot, as stated in the report, the Pea roots were well supplied with nodules.* The trial was really a contest between the bacteria already in the soil and those added in the nitro-bacterine, and the former showed to the better advantage. It remained for Prof. Bottomley to show why this was the case.

It had been assumed that the bacteria in four of the plots were killed or injured by the application of potassic and phosphatic manures. These manures were applied and mixed with the soil (which had been limed) long before the seed was sown. The lime was present in sufficient quantity to prevent any acidity in the soil. That the manures had no injurious effect was evident from the presence of nodules on all the roots. Professor Bottomley also assumed that the manures had been sown in such a way as to injure the bacteria of the seeds, i.e., bacteria sown with the seeds. This was not the case.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 4.—*Committee present:* Messrs. E. Ashworth (Chairman), Thorp, Cowan, Ward, Keeling, Warburton, Holmes, Upjohn, Ashton, Parker, Low, and P. Weathers (hon. sec.).

Z. A. WARD, Northenden (gr. Mr. Weatherley), was voted a Silver-gilt Medal for a showy group of plants, mainly of *Odontoglossums*, one of which, *O. × Beauté Celeste*, or *O. × eximium* "Ward's variety," received an Award of Merit.

Mr. J. ROBSON, Altrincham, was voted an Award of Merit for *Odontoglossum crispum* "Supreme," and a similar Award for *Cypripedium × Actæus* "Robson's variety."

Messrs. A. J. KEELING & SONS, Westgate Hill, Bradford, were awarded a Bronze Medal for a small miscellaneous group.

Messrs. MOORE & Co., Leeds, staged a group for which a Silver-gilt Medal was awarded. *Odontoglossum × Lawrenceanum* var. "Distinction" received an Award of Merit.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a group of *Cattleyas* and *Lælias*. *Cattleya Trianae* var. *Lowiae* was given an Award of Merit.

A. WARBURTON, Esq., Haslingden (gr. Mr. Daigleish), staged a group of *Odontoglossums* (Bronze Medal), another of *Cypripediums* (Silver Medal), also a miscellaneous group (Silver Medal). *Cypripedium × Euryades* var. King Edward VII. was voted a First-class Certificate.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Fletcher), obtained two Silver Medals, one for

FIG. 81.—VIEW OF MESSRS. SUTTON AND SONS' "FRENCH" GARDEN EXHIBIT STAGED AT THE ROYAL HORTICULTURAL SOCIETY'S MEETING ON THE 9TH INST.

(See report published in last week's issue, p. 174.)

Professor Bottomley had drawn up tables showing what he considered the figures ought to have been if the number of plants on the two plots had been the same. This he had done by an unscientific method of calculation, for (1) there was no evidence that the plants on the respective plots were of the same strength to start with; (2) the plants were not growing (since the space was the same on each of the plots and the number of plants varied) under equal conditions of space; and (3) the number of plants (owing to an accident already explained) of two varieties is unknown. Prof. Bottomley had attempted to rectify the tables, knowing, as a rule, the number of plants of only one of the four varieties, and sometimes not even that. No one could say from the data available what the total yields would have been if the number of plants had been equal in the pair of plots.

Prof. Bottomley made a comparison between the yields obtained from half an area which received a light dressing of dung, with a like portion that was not manured, apparently to show that the soil of the Wisley garden was so rich in organic matter that it would not respond to an extra amount of manure. *Why did he not compare the yields from the whole of the areas which received these different treatments respectively?* This would have shown that even such a light dressing of dung had the effect of increasing the yield of Peas.

What were the facts with regard to the amount of organic matter in the soil? The loss, on ignition, of the cultivated soil (from which the only general conclusion in the report

He also failed to give weight to the evidence adducible from the report regarding the need for lime in this experiment; if he had carefully considered it he would have found that lime made no difference whatever to the results of the trial.

In conclusion, Mr. Chittenden considered that more investigation was necessary before any hope could be entertained of getting much, if any, benefit from inoculation of leguminous plants on cultivated soil, since it was first necessary to prove that the bacteria were not only alive but were of greater virulence than those already in the soil.

In the discussion which followed, the following gentlemen took part:—Dr. Keeble, Messrs. J. Walker, C. E. Pearson, Arthur W. Sutton, and W. A. Voss. Mr. Arthur Sutton suggested that Mr. Harry J. Veitch, the chairman, should put an acre or so of land at the disposal of Prof. Bottomley for the purpose of further experimenting with nitro-bacterine. Mr. Veitch, in closing the discussion, expressed himself as willing to adopt Mr. Sutton's suggestion so far as his own nurseries were concerned, but advanced the opinion that it would be more satisfactory if the Council of the Royal Horticultural Society were to set apart a piece of ground at Wisley for use by Prof. Bottomley. In acknowledging a vote of thanks, Prof. Bottomley accepted the proposal, with the proviso that Mr. Chittenden should help him in the recording of the experiments, since Mr. Chittenden would be on the spot, and Wisley is not too accessible for a busy man whose work is in London.

Odontoglossums and the other for a general display.

Mr. J. STOTT, Radcliffe, was awarded a Bronze Medal for a small group of *Cypripediums*.

Mr. W. SHACKLETON, Gt. Horton, near Bradford, was also awarded a Bronze Medal for a group, principally of *Cypripediums*.

FEBRUARY 18.—There was a good display of plants at the meeting held on this date.

Z. A. WARD, Esq., Northenden, showed a group of *Odontoglossums*, including many choice hybrids. (Silver-gilt Medal.)

R. ASHWORTH, Esq., Newchurch, exhibited a group of *Odontoglossums* in competition for the "Ward" Cup. (Silver-gilt Medal.)

J. MCCARTNEY, Esq., Bolton, was granted a similar award for a general display, chiefly of *Cattleyas* and *Cypripediums*.

G. SHORLAND BALL, Esq., Burton, Westmoreland, was awarded a Silver-gilt Medal for a beautiful display of miscellaneous Orchids, in which were two fine specimens of *Dendrobium glumaceum* and several choice forms of *Lycaste*.

H. J. BROMILOW, Esq., Rainhill, Liverpool, exhibited *Cypripediums*. (Silver-gilt Medal.)

Messrs. A. J. KEELING & SONS, Westgate Hill, Bradford, showed a miscellaneous exhibit, in which were numerous plants of great interest. (Silver-gilt Medal.)

Silver Medals were awarded A. WARBURTON, Esq., Haslingden, for *Odontoglossums*, and another for *Cypripediums*; Messrs. JAS. CYPHER & SONS, Cheltenham, for a general display of Orchids; Messrs. HUGH LOW & Co., Enfield, for *Cattleyas*; Messrs. HEATH & SONS, Cheltenham,

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 13, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—The general condition continued wintry and unsettled. The sky was mostly very cloudy or quite overcast, and falls of sleet or snow occurred in nearly all parts of Great Britain, while rain, sleet, or hail was experienced in Ireland. Precipitation was less frequent in the north-west of England and west of Scotland than elsewhere. Thunder was heard at Gordon Castle on the 10th.

The temperature was again below the average, the greatest divergence being about 4°5' in the Midland Counties and England S.W., and the least 1°7' in Scotland N. The highest of the maxima occurred on the 7th or 8th in most parts of England, and on the 12th or 13th elsewhere. They ranged from 53° in Ireland S. to 47° in Scotland E. and England N.E. The lowest of the minima, which were registered on the 7th or 8th over the greater part of the kingdom, but on the 12th in several Scottish localities, ranged from 8° in Scotland E. (at Nairn on the 7th), 20° in Scotland N., and 22° in England N.E. and Ireland N., to 31° in England E., and to 35° in the English Channel. The lowest grass readings reported were 16° at Buxton and Markree Castle, 17° at Llangunnawell, 18° at Balmoral, Huddersfield, Sheffield, and Newton Rigg, and 19° at Cockle Park (Morpeth) and Dublin.

The rainfall exceeded the average in the north-east of Great Britain and also in the English Channel, just about equalled it in England E., S.E., and S.W., and was less in Ireland, Scotland N. and W., England N.W. and the Midland Counties. At Crathes and Balmoral the quantity of melted snow measured on the morning of the 7th yielded 1.49 inch, and 1.96 inch in the two respective gauges.

The bright sunshine was less than the average in all districts. The percentage of the possible duration ranged from 29 in the English Channel, 25 in Ireland S., and 22 in England S.E. to 13 in Scotland W., 11 in England N.E., and 8 in Scotland E.

THE WEATHER IN WEST HERTS.

Week ending March 17.

The sixth week in succession of cold weather.—The present cold period has now lasted nearly six weeks, during which time there have occurred only four unseasonably warm days, and only one warm night. Throughout the past week the days have been, as a rule, much more unseasonably cold than the nights, the highest reading in the thermometer screen on four days ranging only between 35° and 38°, or from 13° to 10° below the average for the middle of March. On the two coldest nights, however, the exposed thermometer indicated 18° of frost. The ground is now 4° colder at 2 feet deep, and 6° colder at 1 foot deep, than is seasonable. Some snow or hail fell on five days, but the total measurement amounted to less than half-an-inch. On one day the ground was covered with snow to the average depth of 2 inches. About one and a half gallons of rain-water has passed through both percolation gauges during the week. The sun shone on an average for one and three-quarter hours a day, which is less than half the usual duration for this period of the year. Two days proved altogether sunless, while on two other days the record of bright sunshine amounted to less than half-an-hour. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 7 per cent. E. M., Berkhamsted, March 17, 1909.

Obituary.

CALEB FENNER.—We regret to record the death, on the 8th inst., at Reading, of this well-known cultivator of Roses and Dahlias. Deceased was manager in the late Charles Noble's nurseries at Bagshot for 16 years, and for 23 years he was gardener to the late T. W. Girdlestone at Sunningdale, Berks. During the time he was with Mr. Girdlestone he raised many single Dahlias, including the Tom Thumb varieties. He was also successful in winning many of the principal prizes for Roses throughout the country. Deceased was in his 81st year. He leaves a widow, eight sons and four daughters. The remains were interred in Reading Cemetery on the 15th inst.

ENQUIRIES AND REPLIES.

THE BURNING OF CLAY SOIL (see p. 176).—The most important item in the burning of clay soil is to secure a strong body of heat before applying too much clay to the heap. The fact that L. F. had much slack coal left unburnt is proof that the body of fire was at the start insufficient. In starting the fire or laying its foundation some root stumps grubbed a year previously should form a centre around which to build. If the burning is a large one, several stumps should be employed and freely interspersed with logs of wood and lumpy coal, or coke and coal, the whole being moderately saturated with tar or some old tar barrels used in the burning. A plentiful supply of cleft Oak, Pine, or Apple logs should then be built up, freely mixing lump

coal with the first few layers, after which a thin layer of clay with small coal should be applied, gradually adding more clay till the heap is well covered in. Success in such matters depends upon securing a great heat at the start and maintaining such a heat for some time. Air passages are not essential, though such might prove helpful in certain instances, but the fire could easily be smothered in its early stages by the application of too much clay. The subsequent feeding of the fire should, therefore, be gradual. E. J.

—Two great difficulties attend the burning of stiff soils, the one arising from the heat engendered being so great as to bake instead of to disintegrate the materials composing them, the other, that the heat may not be raised sufficiently high to alter the inorganic constituents contained therein from a passive to an active or available form. The first difficulty arises from permitting too great a draught of air, and, consequently, causing a rapid and often through draught, a partial but excessive combustion. The second difficulty arises from either the heap being made up too closely or too open. In the former case, the too free access of air occasions the fires to burn languid, and consequently deficient heat through absence of sufficient draught; whilst if the clay or sod is packed too closely, the absence of air retards combustion, and thus necessarily the amount of heat required for the due perfection of the process, and combustion will not infrequently be stopped altogether by the interstices becoming filled with ashes, and by that means almost wholly excluding the atmosphere. As soils vary so much with respect to their capacity for burning for manure, no hard and fast rule can be laid down to suit every case. On soils which are very stiff and that do not contain much vegetable matter, great care is required in order to form clamps that will burn thoroughly, without too great a degree of heat or too little. One of the principal rules to be observed is to commence by having a rough log of wood, and build up around this a few upright pieces of tree loppings or the like, then surround these by some root-chunks, upon which to erect the sods on end (never commence by building the sods on the ground). Only the three or four first sods which are placed in the middle should have their grassy sides presented to each other, each succeeding row being placed with the grassy side next to the earthy side of the preceding row, the whole to be set up as compactly as possible. When the heap is thus erected of a dome shape fire should be applied at the bottom, in the flues left for draught. Any clay with a moderate degree of sward will thus, if carefully attended to, produce a quantity of ashes suitable to the wants of the gardener. It may be mentioned that, in calm weather, heaps should be made as open as is consistent with arrangements necessary for a due draught by means of flues left at intervals; in windy weather the heaps should be formed as close and as large as possible, labourers being continually employed to stop up every crevice, particularly those on the leeward side, for which purpose the whole of the sods should not be heaped up at first, but a few left scattered about in order to apply in the manner named. Soils burned in this way which contain only a small amount of vegetable matter will frequently require the aid of Furze, underwood, hedge clippings, small coal, or other inflammable materials to assist the operation. All inexperienced hands use too much fuel, get their fires too fierce, lay their stuff too hollow, make a great deal of smoke—whereas the less they make the better—get their heaps to a red heat, and burn through in a week or ten days. The consequence is that, when these heaps are opened, instead of ashes, or lumps that will turn to ashes by exposure to the air, out roll knobs as hard and as useless as brick-ends. J. J. Willis.

ANSWERS TO CORRESPONDENTS.

ALBERTA MAGNA: *Franciscus*. The plant forms a shrub or small tree, and is a native of Natal, at elevations of 3–5,000 feet above the sea-level. In this country it should be treated as a greenhouse plant. The soil best suited for it is a compost of loam and peat. It forms a fairly large Laurel-like plant, and is best cultivated in a border. The species has flowered in the Temperate House at Kew.

ham, for a miscellaneous exhibit; and J. McCARTNEY, Esq., Bolton, for Cattleyas and Lælias.

First-class Certificates were awarded to the following plants:—*Cypripedium* × *Lady Ursula*, a fine hybrid between *C.* × *Mrs. Tantz* × *C. insigne* Harefield Hall variety, shown by S. GRATRIX, Esq.; Whalley Range; *Cymbidium* × *Holfordianum*, shown by R. ASHWORTH, Esq.

Awards of Merit were granted to *Odontoglossum* × *Lambeauium* Ashworth's variety, shown by R. ASHWORTH, Esq.; *Cypripedium villosum* Keeling's variety, *Spathoglottis* × *aureo-Viellardi*, and *Sophronitis grandiflora* var. *maxima*; these three were shown by Messrs. A. J. KEELING & SONS; *Cypripedium* × *Prospero* Oakdene variety, *C. aureum* var. *vertumne*, and *Odontoglossum* × "W. C. Price," these three exhibited by E. ROGERSON, Esq.; *Cattleya Triana* var. "Sir Lees Knowles," shown by J. McCARTNEY, Esq.; *Cypripedium* × *Iris* var. *magnificum*, shown by Mr. W. BRITISH GARDENERS' ASSOCIATION. (LONDON BRANCH).

MARCH 6.—The first social evening held by this branch took place at Carr's Restaurant, 264, Strand, on the above date. The meeting was in aid of the Branch funds. Mr. E. F. Hawes presided. Notwithstanding the inclement weather, more than 70 members and friends assembled. During an interval in the proceedings, the Chairman, in a brief speech, set forth the objects of the association, and invited any gardeners who were not members to join the association.

DEBATING SOCIETIES.

BATH AND DISTRICT GARDENERS'.—A largely-attended meeting of this society was held on Monday, March 8. Mr. T. Parrott presided. A paper on "Pelargoniums" was read by Mr. Edwards. He said that about 700 varieties were awarded certificates by the Royal Horticultural Society in the period between 1860 and 1890, and of the 170 species of Pelargonium which were known nearly all were natives of South Africa. The four sections of Pelargonium were all distinct from each other, and except in one instance they had refused to be interbred. The instance was that of a Zonal and Ivy-leaf, of which an accidental cross between the two had been secured by M. Lemoine about 30 years ago. Pelargoniums were readily raised from seed, while they could also be increased by cuttings and pieces of the root. The best time to sow the seed was in March or April, in a temperature of 60°.

BICKLEY AND DISTRICT HORTICULTURAL.—A meeting of the above society was held on March 4, under the chairmanship of Mr. J. Hunter. A paper was read by Mr. Legg, of Hamilton Lodge Gardens, Bickley, on "The Cineraria and its Culture." The paper gave full details for the culture of this popular greenhouse flower.

BRISTOL AND DISTRICT GARDENERS'.—At the meeting held on Thursday, March 11, Mr. Scott, of Downside Gardens, gave a paper on "Border Carnations." The lecturer said July is the best month for layering, and autumn the best time for planting. Wood ashes mixed with the soil proved very beneficial for Carnations, which should be planted firmly.

PORTISHEAD.—Under the auspices of the Somerset County Council, the second lecture on "Gardening" was given on March 9 in the Parish Room, Portishead, by Mr. J. Eittle. The lecturer spoke on vegetable culture, giving practical hints on thinning crops, hoeing, weeding, watering, and feeding the different sections of vegetables, namely, those grown for their roots, leaves, fruits, seeds, and pods.

READING AND DISTRICT GARDENERS'.—A lecture was given in connection with the above society on Monday, March 8, in the Abbey Hall, Reading, by Mr. W. F. Giles, of Messrs. Sutton & Sons, the subject being "Vegetables, Old and New." The lecture was illustrated by a collection of about 100 lantern slides. Mr. A. F. Bailey (chairman) presided, and there was a large attendance of members. Mr. Giles opened his remarks by tracing the history of some of the common vegetables. Mr. Giles showed pictures taken from *Gerarde's Herbal*, published in 1597, showing the type of vegetables of that time, and also, by way of contrast, varieties of the present day. Thomas Andrew Knight, afterwards President of the Royal Horticultural Society, made the first recorded cross with culinary Peas in 1787.

TORQUAY GARDENERS'.—At the fortnightly meeting of this association, held on Friday, March 6, Mr. G. Wilson read a paper entitled "Some Notes on Vine Culture." Mr. W. A. Masterman, vice-president, presided. Mr. Wilson gave a detailed account of vine culture under glass, dealing with the raising of the vines, making of borders, planting and general treatment, pruning (summer and winter), thinning, ripening, and the general management of the vineyard.

ASPARAGUS: *Head Gardener.* There are several varieties or selections of Asparagus. If you are desirous of cultivating the largest, nothing can surpass that known as the Giant French, but as an all-round variety, few, if any, are superior to a true type of Connover's Colossal. Perfection is also an admirable variety. It produces heads of the highest quality. Palmetto, an American variety, may also be recommended. Where large quantities are grown these might all be included in the collection. Asparagus generally does very well on the flat, providing the land is well drained, especially so on light soil, but, generally speaking, in cold, wet districts and where the land is very heavy, the crop does better when the beds are slightly elevated above the ordinary level. The roots are then naturally drier owing to the alleys between the beds acting as drains. There are many excellent patent manures specially prepared for this crop. In addition to these fertilisers, common salt may be applied once a year. The lighter the soil the more salt is necessary.

BEECH-COCCUS: *W. A.* An account of this pest, with measures to adopt for its eradication, was given in the issue for October 10, 1908, p. 257.

BOOK OF CARPET BEDDING DESIGNS: *M. H. D.* We know of no work on this subject other than those that are out of print.

BORONIA MEGASTIGNA: *A. H.* If you take cuttings now and insert them in pots and place them on a greenhouse shelf, covering them with a bell-glass, some will be likely to make roots. In order to make success more certain place an old plant in a warmer house than that in which it has been growing, and, after two or three weeks take cuttings from this plant and insert them in pots filled with sandy peat. Place these in a propagating case or under a hand-light. The pots to receive the cuttings should be made up some days before using. If the soil is thoroughly watered when the pots are made up, no water will be required again for a week or 10 days after the cuttings are put in.

CHICORY: *J. R. B.* This vegetable may very well be forced in such a cellar as you describe. It is easily grown and forced, and the produce commands a fair price. Seed should be sown thinly in April in drills 2 inches deep and 15 inches apart, and the seedlings thinned out to about 9 inches in the row. We assume your cellar is quite dark now, as shown by the diagram. The proposed admission of light through thick ground glass fixed in a portion of the domed roof, as shown in the second diagram, would be an advantage to the crops in some stages of growth. When the subdued light is not required, the glass could be covered with mats or other light-obstructing material. We would not recommend you to try Asparagus, as the produce obtained in the conditions afforded by your cellar would probably lack sufficient size and quality. *My Gardener* will furnish you with useful information regarding the subjects you mention. This book can be obtained from our publishing department.

DAFFODIL WITH THREE FLOWERS: *E. A. H.* The abnormality is not uncommon. It is the result of fasciation or fusion of growth.

DAFFODILS FAILING TO FLOWER: *W. G. & Co.* This may be usually attributed to one of two causes. The bulbs may have been unduly forced into growth soon after they were potted, or they were imperfectly ripened in the previous autumn.

DOUBLE-SPATHED RICHARDIA: *G. C. W.* This abnormal development is not uncommon. The second spathe is merely a leaf which has assumed the character of the floral bract. There are no extra organs of reproduction present, nor even a rudimentary spadix.

FUNGUS IN SOIL: *E. P. P.* The soil is infested with a slime fungus, probably *Fuligo* varians. Water the ground with a weak solution of permanganate of potash.

LAND FOR A MARKET NURSERY: *S. R.* There are so many circumstances to be taken into account, it is essential that the site should be visited by an expert. It is an advantage for the land to slope from south to north, provided the slope is moderate. The land appears too light for fruit culture. With

regard to the water supply, if the pond does not furnish a sufficient quantity, a well could be sunk, and a small motor pump utilised to convey the water to a tank at the highest level. We repeat, however, that a satisfactory report can only be made after inspection. You do not even state how the pond is to be kept filled with water.

LILAC: *J. R. B.* You could force Lilac during the winter and early spring months. The plants could be grown out-of-doors for forcing purposes. They only require simple cultural treatment to induce them to form bushy plants, well furnished with flower-buds, and capable of being taken up (at intervals of a fortnight or so) with balls of soil adhering to the roots. Stand the plants closely together on the floor of the cellar on a little garden soil, and cover the roots with similar mould. Afterwards water through a rose to settle the soil about the roots. The atmosphere of the cellar should be maintained in a moist rather than a dry state. Lilac trees for forcing may be obtained at a very moderate price per dozen or per hundred from any nurseryman doing a wholesale and retail trade in shrubs. It might be worth your while to buy a few dozen Lilacs now, purple and white varieties, although the purple variety will yield white flowers when forced in the dark. For "Etherisation of Lilacs" see *Gardeners' Chronicle*, March 9, 1904, p. 187, and April 2, 1904, p. 228.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *A. W. G.* *Daphne Laureola* (Spurge Laurel).—*R. L.* 1, *Cupressus* species (cone required for more complete identification); 2, *Cupressus Lawsoniana aurea*; 3, *Abies magnifica*; 4, *Cedrus Libani*; 5, *Thuja dolabrata*; 6, *Cupressus Lawsoniana filiformis*.—*A Reader.* 1, *Asplenium nidus* (Bird's Nest Fern); 2, *A. bulbiferum*; 3, *Gymnogramme ochracea*; 4, *Begonia metallica*; 5, *B. semperflorens rosea*; 6, *B. manicata*; 7, *Cotyledon intermedium*; 8, *Eurya latifolia variegata*.—*A. H.* 1, *Cyrtomium falcatum*; 2, *Blechnum brasiliense*; 3, *Adiantum hispidulum*; 4, *A. formosum*; 5, *Abutilon megapotamicum variegatum*, syn. *A. vexillarium variegatum*; 6, *Sedum Sieboldii*.—*J. Clark.* The Orchids are *Cattleya Trianae* and *Cælogyne graminifolia*.—*T. B.* *Clerodendron Thomsoniae*, the correct name of the plant known in gardens under the name of *C. Balfouri*.—*F. G.* 1, *Epidendrum glumaceum*; 2, *Oncidium cheiroporum*; 3, *O. pubes*; 4, *Eria bicolor*.—*H. H.* 1, *Phaius grandifolius*; 2, *Masdevallia simula*; 3, *Spiranthes colorata*.—*J. W. C.* *Ardisia crenulata*.—*F. H.* 1, *Selaginella viticulosa*; 2, *S. Wildenovii*; 3, *Pteris tremula*.—*Hibernica.* 1, *Cordylone* (*Dracæna*) *Regina*; 2, *D. fragrans*; 3, *D. ornata*; 4, *D. amabilis*; 5, *Codiaeum* (*Croton*) *volutum*; *C. Evansianum*.—*R. S., Surrey.* *Magnolia fuscata*, native of China; first bloomed in England in 1802. It is very fragrant in the afternoon.—*C. E. F.* *Bryophyllum calycinum*.

PANSIES AND "FRENCH" GARDENING: *An Old Reader.* There are plenty of ways of disposing of stocks of Pansies and Violas. That there is a good market for early vegetables and salads can be determined by making enquiries in almost any provincial town at the present time, for it will probably be found such produce is unobtainable there. We cannot, however, describe your plan as "wise" or "silly," because we have no knowledge of your experience and business ability. There is a demand for such things, and you must determine for yourself whether or not you can produce them and sell them at a profit at the prices they are likely to realise.

RHUBARB: *J. R. B.* Rhubarb may be forced successfully in your cellar. Plants may be raised from seed sown in the manner recommended in last week's issue (p. 176) for Seakale; but it would take some time to obtain by this method plants fit for forcing. The better way would be to obtain a sufficient number of old stools of Rhubarb. These may be divided into pieces, each having one or more buds. The divisions should be planted in ground which has been trenched from 2 to 3 feet deep, and two or three good layers of manure incorporated with the soil in the process of trenching. A space of 2 to 2½ feet should be allowed between the rows, and the same distance from plant to plant in the rows. Rhubarb is a gross-feeding plant, and therefore requires generous treatment. Royal Albert, Dancer's Early Scarlet, and Myatt's Victoria are excellent varieties. The last-mentioned variety is not so early as the others, but, if liberal supplies of manure are worked into the soil, it produces stalks of great length and thickness, and of first-rate quality. In planting, keep the crowns of the individual plants level with the surface of the soil, and make the latter firm about the roots. Afterwards apply a surface-dressing of half-rotted manure to the depth of 3 inches. No Rhubarb should be taken from the plants the same year that they are planted, but the lower stalks should be removed from the plants as soon as they appear. The plants will be ready for forcing in two or three years.

SOIL AND MANURE FOR ANALYSIS: *S. C. A.* If you are a Fellow of the R.H.S., you can have soils and manures analysed for a small fee by the Society's Consulting Chemist, Dr. A. J. Voelcker M.A., 22, Tudor Street, E.C. If you suspect eelworm to be present in the manure, on no account use it for Cucumber culture.

STACHYS TUBERIFERA: *R. B.* The tubers may be purchased of the nurserymen and seedsmen. They should be planted at the end of the present month or in April, and in successive batches till the buds can no longer be kept in a dormant state. Choose a warm, open site for the beds or rows, and a fairly good, not over-rich soil. If it be clayey, mix leaf-soil and sand with it to the depth of 8 inches, incorporating these materials with the staple. The soil should then be consolidated by tramping it all over, and made roughly level. With a small draw-hoe make drills 2 to 3 inches deep and 8 to 10 inches apart, and in these lay the tubers lengthwise, cover them, tread over the lines lightly, and make the surface level. Instead of planting in drills, the tubers may be dropped into holes made with a dibber. Weak manure water may be afforded when the plants are in active growth, and plain water in very hot weather. The stems may be allowed to lay on the soil, or they may be supported with Pea-stick spray. The crop may be lifted and stored in sand in a cellar, or left in the ground with a covering of Fern or litter, so that they may be get-at-able in frosty weather. We think that this is the better way, the plant being quite hardy in this country. The common names of the plant are Crosnes (French) and Chinese Artichoke. Prepare and cook the tubers like Potatoes or Jerusalem Artichokes.

VIOLETS DISEASED: *T. B.* The plants numbered (2) are affected with a fungal disease. Spray them with a weak solution of the Bordeaux mixture, or, better, burn the stock and start with fresh plants in another quarter of the garden. The other leaves are infested with spider. Spray the foliage with tobacco water, Quassia extract, or one of the other common insecticides.

WOOD ASHES: *W. A.* If the quantity of wood burned in the house is considerable, the ashes should be saved for garden purposes. They form a useful source of potash manure and are useful for top-dressing lawns and vegetable crops, mixing with potting mould, dressing Rose-beds, lightening heavy land, and other purposes.

CULTURE OF CUCUMBERS.

BEFORE the Cucumber disease (*Cercospora melonis*) became so prevalent, it was possible to maintain a continuous supply of fresh Cucumbers from May to September inclusive; in fact, I have cut, from plants raised in April, superb young fruits in October, the plants at that date being as fresh and green as one could expect.

Unfortunately, this cannot be done to-day, and in those instances where the plants early fall a prey to the leaf-spot, they may cease to be profitable in less than half the time I have instanced. In some cases, indeed, the young plants are attacked before they are 2 feet high. In two instances known to the writer, and where new glass-houses were erected on a fresh site, the first-planted crop was completely destroyed by disease before bearing at all. A second batch of plants was so badly attacked that it was cleared out, but a third planting gave a fairly good, though, of course, late, and, therefore, much less profitable, crop.

During the last two seasons there have been fewer complaints concerning early outbreaks of the disease, and in the majority of instances the first fruits have been cut before any very serious loss of foliage has resulted. The disease spreads rapidly: a spot or two may appear to-day, and a week hence probably not a sound or unaffected leaf can be found in the

house. It is difficult to find an effective remedy. Carbolic acid diluted with water and applied to the floors of the houses has been found very destructive of leafage, and in some instances the "cure" was as bad as the disease. Greater dryness, too, has been tried within the house, also in the hottest weather the top ventilators have been left open at night-time, with the result that the former practice has promoted a rapid increase of red spider, while the latter plan has hindered the development of the fruits. It is to be regretted that heat and moisture, the conditions essential to success in the case of a tropical subject like the Cucumber, are the conditions also best suited to the rapid increase and spread of the disease. The only remedy or safeguard against the disease would appear to be that of cultivating two crops of plants where one sufficed before. But in conjunction with this there must be a complete clearance of the houses, sulphuring the structure two or three times, a bountiful application of whitewash to all possible parts of the house, and a general wash down before making a fresh start, the young plants being prepared elsewhere.

But, disastrous as the results of this fungal disease are, cultural errors are responsible for a loss equal, if not, indeed, greater, than that caused by the fungus, and this is all the more to be regretted because it is preventable. It is by no means clear why so many Calendar writers recommend the almost identical practice either of "stopping the plants at 3 feet high," or when they have reached "the second or third wire," the latter recommendation implying that all Cucumber houses are built on the same plan. The practice of stopping is said to promote early fruiting, but I have never experienced this. Moreover, I consider it to be wrong in principle, as well as in practice, to take the leading shoot out of a climber or twiner such as the Cucumber while the plant is really in its infancy. Whilst doing this does not appreciably hasten the production of laterals, it does, by enforcing an early fruiting of the lower parts of an immature plant, diminish and hinder the fruit-bearing character of the plant as a whole. For special purposes it may be desirable to place a limit to fruit production, or to promote the earliest possible fruiting, so that the crop can be cleared to give place to a second one. It is another matter altogether when the plant is expected to produce a profitable market crop, and which it can only be made to do by permitting it to cover its allotted space with laterals in the shortest possible time. To effect this the main stem should be permitted to grow unchecked until it has reached to within 1 foot of the ridge in a house 10 feet or 11 feet wide and 7 feet or 8 feet to the ridge. In a house 20 feet wide, with rafters, say, 12 feet in length, the stopping may be done at about 6 feet up the roof, by which time the plants will have attained to a certain stability and be showing abundantly for the first crop of fruits. During this growth of the main stem, a large number of laterals will have formed lower down, and will be already set with fruits—usually one at each joint, or two, and even more fruits in certain varieties. The Cucumber plant is capable of producing a limited number of fine fruits on the main stem. Indeed, the handsomest and best-proportioned fruits are mostly produced thereon. It is not prudent, however, to permit an early fruiting on the main vine, as by so doing the bearing capabilities of the first laterals are impaired. All laterals developed within 1 foot of the soil are best removed, as the fruits must not touch the soil. Above this height all fruit-bearing laterals should be stopped at the second fruiting joint, the subsequently-formed sub-laterals,

which appear very quickly, being stopped at the first joint. A new "break" is usually trained in from the first joint on the lateral. In this manner the fruiting is continued up the plant. In the worst instances of Cucumber training I have seen, the main stem had grown to a height of 4 feet or 5 feet, as is done with the Tomato, and with the whole of the laterals suppressed from the start. The roots were deeply buried in rich soils, with the result that the leaves were nearly of the size of Rhubarb leaves, but not a fruit was to be seen. As a matter of fact, all the fruiting laterals had been cut away. Incredible as this may appear, I have seen at least two instances of the kind, and in each case promptly advised the grower to pull up the plants and burn them.

In the raising of the Cucumber plant from seeds a single seed should be placed in a 3-inch pot filled with light, rich soil. An endeavour should be made to promote a quick growth, so that the stem below the cotyledon is not more than 6 or 8 inches in length, as the ground level of the plant at that time is practically its level to the end. I never earth up the cotyledonous stem at all, the plant being supported by its first-formed or main roots and the innumerable fibres that develop thereon. In not a few instances known to me this portion of the stem has been buried deeply, the result being undue grossness of growth and a lack of fruitfulness.

A point of importance is that the house should be ready for the plant, and that the latter has not to wait for the former. A check at this stage will result in the lower laterals proving fruitless. With a bottom heat of 75° F. the seedlings appear in a couple of days, and four or six days later the young plants should be raised a few inches and finally removed from the seed-frame. When the second or third rough leaf has been made the seedlings may be planted out, the house and soil being warmed in readiness. The planting-out will depend on the season of the year and the way the young plants are produced, though, as a rule, from 14 to 21 days must elapse after the appearance of the seedling before it is ready for transplantation to its permanent quarters. In certain instances the plants may require a week longer than this.

The question of bottom heat for Cucumbers has been debated many times, and while it is essential to the production of good winter fruits, it is by no means necessary, or even desirable, for the summer crop. It is best that the rooting area should be of a restricted character, so that the roots may be under the direct control of the cultivator. The mounds of earth in which the plants are placed should be only moderately firm—not so firm as to be practically impervious to the supplies of moisture afforded, nor yet so loose as to permit the water to pass away without benefiting the plant. The subsequent treatment resolves itself into thinning, tying, watering and top-dressing. The Cucumber delights in moisture and very rich soils. Formerly the plants were grown on freshly-made beds of dung within the house, but beds or mounds of soil produce far better results. Much moisture is needed when the fruits are developing, and, if the weather is hot, watering cannot easily be overdone. Unless heavy supplies of root moisture are applied when a full crop of fruits is hanging, there will be a big percentage of long-pointed and undeveloped fruits.

Atmospheric moisture is of importance at all times; though when the plants are in flower the afternoon syringing or damping should be dispensed with for a day or two. An excess of moisture settling on the blossoms at that time causes decay in the young fruits. In connection with

the fruiting of these plants the much-debated point of pollinating the flowers arises: this, whilst absolutely essential when seeds are required, is neither necessary nor desirable in the production of Cucumbers for the table; moreover, it destroys some of the symmetry of the fruits. *E. H. Jenkins.*

ORCHID NOTES AND GLEANINGS.

BULBOPHYLLUM DAYANUM

THE genus *Bulbophyllum*, including *Cirrhopetalum*, is very remarkable, the different species displaying the greatest diversity of structure. Many of them have the labellum, petals, and sepals decorated with hair-like appendages, which, in some cases, as, for example, in *Bulbophyllum barbigerum*, seem to be almost constantly moving. *Bulbophyllum Dayanum*, illustrated in fig. 82, is a native of Burma, and was originally described in the *Gardeners' Chronicle*, 1865, p. 434, from a plant which flowered with the late Mr. John Day, at Tottenham. For a long time afterwards the species seems to have been lost, but in late years it has appeared occasionally, the specimen now illustrated being supplied by Mr. James O'Brien, of Harrow-on-the-Hill.

The plant is of compact growth. The pseudo-bulbs are of a dark shade of chocolate-purple, and the under-sides of the leaves are suffused with the same colour. The flowers are borne close to the pseudo-bulb, and rest on the surface of the Sphagnum-moss around the plant. The sepals are of a greenish Citron yellow, speckled with claret-purple spots, and furnished at the margin with orange-yellow coloured hairs. The petals are claret coloured, with a narrow, white border; they are fringed like the sepals. The labellum is yellowish, tinged with rose, and marked with projecting, deep crimson spots; it is four-ridged. The column is yellowish and speckled with crimson below.

ODONTIODA GOODSONIÆ.

THIS beautiful hybrid (see fig. 83) was exhibited by H. S. Goodson, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day), at the Royal Horticultural Society's meeting on March 9. It was flowering for the first time on a very small plant, but, owing to the deep, ruby-red colour of the flowers, and the attractive cream-white markings on the segments, it was considered one of the most beautiful and remarkable of the *Odontiodas*. The parentage of the plant is not definitely known, but it was suggested that the parents were *Cochlioda Noezliana* and a white or sparsely-spotted form of *Odontoglossum ardentissimum*. The crest of the lip is yellow, with red markings.

VANDA CÆRULEA.

THIS lovely *Vanda* is seldom seen at its best condition when under cultivation. It is found on the dry, grassy slopes of the Khasia Mountains in Eastern India in the neighbourhood of the Brahmapootra, at an elevation of 4,000 feet above sea level. The plants are found in great numbers on Oak trees, which are small, gnarled, and sparingly leafy, so that the *Vandas* are fully exposed to the sun, air, and wind. The atmosphere is humid, especially during the rainy season, but at no time is it fully saturated with moisture. The plants cling, by their roots, tenaciously to the rough, dry bark, and often completely cover the boughs. In the flowering season the temperature averages 70°, and the atmosphere during the daytime is dry; but in July and August, when rains are frequent, the temperature is a little higher, whilst in winter it falls much lower. Under these conditions of summer heat, autumn drought, and dry, cool air of winter, the most beautiful of Indian Orchids flourish, such as *Dendrobium Devonianum*, *D. Dalhousianum*, *D. Farmeri*, also species of *Cœlogyne*, *Bulbophyllum*, *Cymbidium*, and a few species of *Cypripedium*. *F. Newman.*

VEGETABLES.

CHICORY.

I WAS pleased to read *A. D.'s* note (p. 116) on "Chicory as a Forced Vegetable." Good and regular supplies of Chicory (*barbe de capucin*) during the winter and spring months are a *sine quâ non* where French cooks are in care

The soil, having been dressed previously with well-decomposed manure, and afterwards deeply dug, should be trodden over and raked level preparatory to drawing drills between 1 and 2 inches deep and from 12 to 15 inches apart. The rows should run north and south, and into the drills should be sown the seed of the Witloof or white-leaved Chicory at any

FIG. 82.—BULBOPHYLLUM DAYANUM, WITH STRUCTURAL DETAILS OF FLOWER.

of the kitchen. I have cultivated Chicory extensively in years gone by, not only as a salad ingredient, but more especially as a vegetable. The heads resulting from well-grown roots resemble Seakale, and when stewed and served with melted butter form a choice second-course vegetable. A deep, light and moderately rich soil is suitable to the growth of Chicory.

time from the middle to the end of April for producing large, well-developed roots for forcing during November and the five following months. Draw the soil over the seed in the ordinary way, tread the surface, and rake it well. The roots will, if well grown, attain the size of moderately large Parsnips. When the seedlings have attained to a height of

about 1 inch thin them out to 9 inches from plant to plant in the row. The only after-treatment necessary between thinning the crop and the covering of the roots for forcing is a vigorous weeding and stirring of the soil between the rows three or four times during the months of June, July, August and September. When the large leaves of the plants have decayed and have been removed towards the end of October or early in November, according to the season or locality, place a little sifted wood or coal ashes around the crowns of the individual plants preparatory to covering those required for forcing with wooden troughs. These are made of two boards 9 inches deep and ends of the same width, the trough being 8 feet long. The ends are made 1 inch higher than the sides to keep the lids in position when placed thereon. Cover the troughs when they are in position over the Chicory with fermenting tree leaves to the thickness of between 2 and 3 feet. The heat thus imparted to the interior of the troughs and the ground in which the Chicory roots are growing will result in the production of good, solid, well-blanching heads. Fresh troughs should be brought into use at intervals of a week or 10 days, in order to maintain a succession. Three

BROCCOLI AND FROST.

Snow's Winter White and Christmas varieties were planted in this garden for the purpose of furnishing a supply of Broccoli throughout January. We had a good supply from those plants that had formed heads and had been lifted and planted in a cold Peach-house before the frost set in; but many were left in the garden, as they were not ready for lifting, with the result that all these have been destroyed by the frost. Purple Sprouting Broccoli has also been ruined by the cold weather. The result is disappointing, as if the kinds mentioned had been hardy, like the later sorts, we could have maintained a supply of this vegetable in winter. Among the later kinds grown here are Standwell, Late Queen, Safeguard, and Eastertide, all of which have escaped injury by frost. The variety last mentioned appears most damaged. If they had been planted on rich soil, I do not suppose they would have done so well. I certainly do not agree with those who recommend plenty of manure for Broccoli, but deeply-dug ground is essential and also a very firm soil when planting. There are many who plant Broccoli after Peas or Potatoes without even stirring the soil. On rich, loose ground Broccoli make luxuriant growth, and produce very fine heads if no frost

plant-stakes and labels are now sent us from abroad; while the little bundles of split wood that we see exhibited for sale at many shop doors are slowly but surely ousting our Kentish "pimp" from the market. Three-quarters of a century ago Oak bark sold in the London market at 14 guineas per ton; while that of the Sweet or Spanish Chestnut brought 11 guineas, and Birch and Larch 7 guineas per ton. To-day, however, matters are different and lucky indeed does the wood-manager consider himself who can sell his carefully-stripped and well-harvested Oak bark at one-fifth of the above-named price; while, incidentally, it may be mentioned that the cost of labour is now about one-fourth higher than formerly. At no very remote date, throughout the length and breadth of the land bark-stripping or "flawing" was an event of the year in Oak woodlands, and was considered as an industry of purely British origin. Now, however, except in a few isolated instances, the picturesque hut of the bark-stripper, the suppressed thud of the wooden mallet, and the far-reaching trestles of creamy white bark (the latter the pride of the woodman, as indicating first quality), are things of the past. Foreign competition and the substitution of chemicals and foreign barks for tanning leather have dealt a deathblow to this industry.

But this is not all, for, apart from the great fall in price of the bark, the loss in the way of labour to both young and old is very considerable. Thus it has been estimated that no less than 1,200 persons used to find employment during the "barking" season for, at least, two months of each year. Whether the industry will ever be revived is very doubtful, though it is generally admitted that the results obtained by substituting chemicals for the Oak bark in tanning leather are anything but satisfactory.

Charcoal-making has proved no more enduring than bark-stripping and is now rarely engaged in. Yet not a century ago the hut of the charcoal burner was a prominent feature of our woodlands, and the finest charcoal was considered to be that produced in some of the old forest-remains of southern and eastern England. The Kentish forests at one time supported many of the familiar charcoal burners, and very brawny and thrifty were these denizens of the woodland, with their rustic-wooden huts and piles of rifted firewood. But times are changed. Foreign imports have hushed for ever the ring of the axe and the merry laugh of the quaintly-clad charcoal burner.

Not so very long ago the cultivation of Osiers for basket-making formed an important occupation in many parts of England and Ireland; but here again preferential carriage rates, combined with greatly increased labour expenses, over which we have little or no control, have caused this highly-remunerative industry of our forefathers to become almost a thing of the past in many parts of the country. The result is that the Osier beds of the Thames and Ouse valleys have almost ceased to exist. French and other Continental Willows have all but ousted the British trade from the market, and, strange as it may seem, it is nevertheless a fact that two brothers engaged in Willow culture, one in the Channel Islands and the other only a short distance from the metropolis, are, by the action of the railway companies, placed on almost the same footing as regards delivery of their produce to the London market. I know of many instances where Osier beds, once well-kept and highly-remunerative, are at the present time mere jungles of almost useless underwood.

Faggot-making, too, is no longer a paying industry in this country, for the little bundles of cleft wood and "fire-lighters" of foreign importation have, as already stated, all but replaced our "pimps." The reason for the fast-dying-out of this industry is not far to seek when it is explained that, in order to compete with latter-day substitutes, the fire-lighting faggot has to be delivered in the London market at the

FIG. 83.—ODONTIODA GOODSONII: FLOWER RUBY-RED WITH WHITE MARKINGS. (See p. 194.)

or four dozen troughs will be necessary. When the produce has been cleared from the first batch of troughs, place the latter over the rows of roots in continuation of the third and fourth lot of troughs. As the season advances from winter to spring, only sufficient covering of leaves to exclude light and air will be necessary. Where very early supplies of Chicory are required, roots may be taken up and placed in a warm house in deep boxes, with the crowns about half an inch above the surface of the soil, in which they are placed perpendicularly. Other boxes of similar dimensions are placed over them to exclude the air and light. After the first cutting is made, the same roots, if allowed to remain in the boxes, will produce a second, though less abundant, crop of blanched leaves. The finest examples of Chicory are obtained by forcing undisturbed roots. Moreover, a saving of labour is also effected. I have forced Seakale in the same manner with most satisfactory results. The troughs, if stored in a dry place when not in use, will last sound for several years. H. W. Ward.

appears, but on firm ground the plants grow very sturdy, and can, therefore, better withstand severe weather. High moulding of the soil about the plants is also to be recommended. I find the first week, or thereabouts, in April a suitable time for sowing early Broccoli, the third week best for the main crop, while the first week in May is suitable for very late kinds. A. J. Long, Wyfold Court Gardens, near Reading.

FORESTRY.

DECLINING WOODLAND INDUSTRIES.

WHETHER owing to preferential carriage rates, foreign importation, or cheaper Continental labour, many time-honoured woodland industries have either become crippled or almost extinguished in this country. As instances, I may quote the stripping and harvesting of Oak bark, the cultivation of Osiers for basket-making, the manufacture of charcoal, faggot-making, lath-rending, and the once highly-remunerative growth of coppice wood for Hop poles. Even

ruinously low figure of from 2s. 3d. to 2s. 6d. per 100. But this is not all, for, with the decline of the small faggot, the larger or oven faggot, from which the others were made, has sadly decreased in value, and faggots which, even in our own days, brought from 18s. to fully 20s. per 100, are now almost a drug on the market.

With the decline of Hop-growing, a blow has been given to the cultivation of Hop-poles which, up to late years, were greatly in demand at almost extravagant prices. Now many of the coppice woods which produced these poles have with the Hop-gardens been grubbed out.

Plant-stakes and labels, which once were made from our home-grown wood, are now sent in neat bundles from abroad, and at such low

with a bold front the changes which time has brought about in the way of preferential carriage rates, keen foreign competition, or cheaper Continental labour. *A. D. Webster.*

TREES AND SHRUBS.

CUPRESSUS MACROCARPA.

I RECEIVE so many inquiries from all parts of Britain from enthusiasts respecting this tree, that a few remarks in respect to its adaptability as a hedge-forming plant may be of interest to readers of the *Gardeners' Chronicle*. I am sure, also, that it would be very helpful if others in different parts of England would give their experience of this tree as a subject for forming a

macrocarpa would probably suffer from drought if planted in light soil.

There is a variety named Lambertiana very like macrocarpa, but somewhat darker in colour and not nearly so close-growing. It is classed as synonymous with *C. macrocarpa*, but I think there is considerable difference between them. *A. J. Elgar, Killarney House Gardens, Co. Kerry.*

GRISELINIA LITTORALIS.

To many gardeners this hardy evergreen shrub may be unknown. Yet it is very handsome. Propagation with cuttings of mature wood can be carried out in the month of August or, with better results, in December. *G. macrophylla* is a fine species, with larger and more shining leaves. As this species cannot be rooted from cuttings, it should be grafted on *G. littoralis*. *F. M.*

KNIPHOFIA MULTIFLORA.

THIS species has several points of interest; it blooms very late in the season, and it is one of the few species of *Kniphofia* in which the individual flowers are erect. It was discovered by Mr. J. M. W. March, growing on the mountains of Natal, at an elevation of 5,600 to 6,000 feet above the sea-level. A plant flowered in the Royal Gardens, Kew, in the Cape House, in November, 1900, and this is the same month as the plants shown in fig. 84 flowered in Mr. T. Smith's nursery at Daisy Hill, Newry, in the open. *Kniphofia multiflora* is still rare in cultivation. At the time the plant flowered at Kew we also received a specimen from Mr. W. E. Gumbleton, which had flowered in his garden at Belgrove, Co. Cork. The plant is figured in the *Botanical Magazine*, tab. 7832.

NOTICES OF BOOKS.

* THE AMERICAN APPLE ORCHARD.

THIS highly-instructive handbook is intended primarily for the American cultivator of Apples for home and export purposes. The Apple is the most widely-known and prized tree fruit of the temperate zone. The extreme northern and southern agricultural regions are practically outside the Apple-growing sections; and even within the Apple-growing country there are great differences in distribution. The leading States, as shown by the number of Apple trees reported in 1900, were as follow:—Missouri, 20,040,399; New York, 15,054,832; Illinois, 13,430,006; Ohio, 12,952,625; Kansas, 11,848,070; Pennsylvania, 11,774,211; Michigan, 10,927,899; Kentucky, 8,757,238; Indiana, 8,624,593; Virginia, 8,190,025. Some of these States rank above others because of their size. There are several well-recognised Apple-growing sections—the Lake Ontario, the Mississippi Valley, the Allegheny, the Nova Scotia, and the Pacific coast sections.

The author insists on porosity in the soil so as to enable the roots to extend downwards to a considerable depth, and, unless this condition be natural, or it can be brought about by the cultivator, the trees suffer from the exigencies of the weather, or are liable to be uprooted by the wind. Moreover, a *hard pan* at a short depth below the surface prevents the escape of moisture, and Apple trees are impatient of a water-logged state of the land, becoming unhealthy and dying out early. As a preventive measure, nothing is better than deep drainage. Hence a gravelly subsoil is better suited to the Apple than a clayey, impervious soil, if rich plant food be

* *The American Apple Orchard*, by F. A. Waugh. Published by Orange Judd Company, New York. Crown 8vo. A sketch of the Practice of Apple Growing in North America at the beginning of the 20th Century. Illustrated. Kegan Paul, Trench, Trubner & Co., Ltd., London. 6s. net.

FIG. 84.—KNIPHOFIA MULTIFLORA AS IT FLOWERED IN NOVEMBER LAST IN MR. SMITH'S NURSERY AT NEWRY.

rates as to defy competition in this country. Lath-reading, too, which in Bedfordshire, Buckinghamshire, Hertfordshire, and many other English counties was, a few years ago, a thriving and paying home-work, is now almost unknown, owing to the comparatively small cost at which the foreign material is placed on our market. This, too, has decreased the sale and consumption of Scotch Fir timber, from which the best class of builders' laths were made. These, however, are only a few of the many industries of British woodlands which have been crippled or quite lost sight of from one or several causes over which we have little or no control; but it behoves us to meet

hedge. My own experience goes to show that there is no other shrub to compare with it, for at all seasons it is of a delightfully refreshing green colour, very close-growing and neat. It has, I believe, an unfortunate habit of dying off after a certain number of years (perhaps someone can state the cause), but if a plant dies the gap can be easily filled up by planting a small tree and at the same time tying down some branches of the adjoining trees. The magnificent hedges in these gardens have been planted about 26 years, and in that time only two or three plants have died. I have not noticed any ill effects from the extraordinary wind storms which are often experienced here. *Cupressus*

provided. In these matters the author is in agreement with orchardists in our own country.

On the eastern slope of the Allegheny Mountains, a soil known as Peter's black loam is well adapted for Apple culture. In Western New York, the Miami strong loam is another suitable soil. It is found in great abundance in Wayne county, N.Y., one of the best Apple-growing counties. The Miami silt loam is the chief basis of the Apple-growing district in Clinton county; whilst, in the famous Clay county, the Marion silt loam is the principal soil developed; and Norfolk loam and Norfolk silt loam on the Delaware peninsula form the chief soils of the Apple-growing land. In this district Apple culture is coming to be a big and profitable industry. The same kind of soil is good for growing Potatoes.

Windbreaks are much needed in the United States for protection from cold winds, and in summer for the protection of the maturing fruits. But, although it is doubtful if windbreaks mitigate low temperatures directly, they offer resistance to the wind, and, in that way, reduce the evaporation from the twigs, which is the chief cause of injury in winter. The windbreak does good by holding the snow on the ground, also fallen leaves and litter of all sorts, and it thus prevents severe freezing of the soil. In some parts the windbreaks are of greater usefulness in the summer than in the winter, as wind waving and unsymmetrical growth of the crown are averted by their use.

Some persons object to them on the score of their taking up space which might otherwise be utilised for fruit trees and such windbreaks are apt to harbour insects, predatory birds, and weeds. The author considers that the only situations where they are useful are bare sides of hills, where the land is not protected from the quarter whence the wind mostly comes. A windbreak may consist of coniferous trees or deciduous trees which are more rapid in growth, and easier to establish. Advice is given on many subjects, including the starting of an orchard, the raising of a stock of trees, interplanting, and evils of wide planting. Annual plants afford the soil protection against the summer heat. For these crops, Broad Beans, Vetches, Cow Peas, and Clover are in common use, and they are sometimes ploughed in to serve as green manure.

* ARTIFICIAL MANURES.

THERE are still some gardeners who are apt to look askance at artificial or mineral manures. When enquiry is made of them why they avoid the use of such fertilisers, it is usually found that they have given them a trial and that the trial has proved the reverse of satisfactory. If the enquiry is pushed still further, it is discovered that the trial has been made without the adequate knowledge of the properties of the substances used or of the dangers attaching to the use of improper quantities.

Since, however, there is no room for doubt as to the value of "artificials" when properly employed, either alone or in conjunction with natural manures, it is to be hoped that this little book may fall into the hands of cultivators who desire guidance on the subject of the use of artificials.

It is written in an extremely simple and direct manner, under such headings as Artificial Manures and How to Use Them—The Kinds of Artificial Manures: What They Do and When to Apply Them—Artificial Manures for Garden Vegetables, for Fruit Trees and Bushes, and for Flowers. With this useful guide, the gardener, if he will follow carefully the advice given, will discover, as, of course, most of his colleagues have already discovered, that artificial manures are indispensable to successful cultivation.

* *Artificial Manures and How to Use Them in the Garden, Orchard and Allotment*, by Professor John Percival, Director of the Department of Agriculture and Horticulture, University College, Reading. 1s. Published by the Author, Northcourt Avenue, Reading.

NURSERY NOTES.

JAMES CARTER & CO., FOREST HILL.

MANY who visit this nursery during the winter months might imagine that it was wholly devoted to the cultivation of *Primula sinensis*. At this time of the year the majority of the glass-houses are occupied by this greenhouse plant, and, for the time being, at any rate, *Primulas* are the chief concern of the establishment. This year the stock embraces some 16-17,000 plants grown almost wholly for seed production.

We cannot estimate the number of varieties this large collection represents, but it embraces almost all the best kinds in commerce, including many fine productions raised at Forest Hill. The chief thing that impresses us when inspecting such a varied collection is the great and rapid improvement that has taken place in this

tion of "bouquet." The bouquet *Primula* originated in these nurseries about 10 years ago. It is probably the result of extraordinary vigour. The main axis is short, but the leaf and flower-stalks are stout and the foliage dense and robust. Then there are those known as the "Giant" type, with flowers of relatively enormous size. They are distinct in appearance from any of the others, but are nearest to those known as the ordinary single *Primulas*, amongst which many of the gems of the race are found. Amidst so much variety in single plants it is not surprising that there are some with double flowers, and these, especially in the stellata breed, are extremely pleasing. In all the semi-double flowers we examined, complete anthers were present and pollen was plentiful. We were informed that it was not difficult to obtain seeds from any of these double kinds, and it is perhaps remarkable that the varieties breed so true to type, although

FIG. 85.—PRIMULA "PRINCESS MAY" FROM MESSRS. CARTER'S COLLECTION.

Primula. It is, indeed, a triumph for the florist. As a wildling, *Primula sinensis* is a plant of no remarkable beauty, but it is little short of marvellous what our cultivators have done with it since the time of its introduction, early in the nineteenth century. Many florists' flowers have been in cultivation for so long that their origin is lost in obscurity, but with the greenhouse *Primula* we can trace its progress step by step, and almost foresee in what direction further advance is trending. There seems to be no finality in the plant's capability for change, and even in the leaves great diversity exists. But it is in the inflorescence that the most marked differences occur; in one instance we meet with a lax flower-spike, bearing its blossoms in tiers, graceful and plume-like, whilst another type buries its flower-spike so low amongst the foliage as to warrant the appella-

one house may contain many kinds. No inter-crossing appears to obtain in these plants under cultivation, except by the set purpose of the hybridiser. Each flower is artificially pollinated by means of a little brush, and this work is one of great importance in a nursery where plants are especially cultivated for seed production. It is well known that pollen is more readily disseminated when the weather is fine and dry, and, although early plants are the finest, those that open their flowers later always give the largest amount of seed. The first batch is sown about the end of June, but others raised a month later, although they make smaller plants, give much the best results in seed production. Flowers that are opening now find brighter and drier conditions than those that are in bloom, say, about Christmas time.

It is curious in this matter of seed production

how the varieties differ. The beautiful Princess May variety (see fig. 85), with its enormous blooms of exquisite pink shade, is an example of a poor seeder. Very large batches of this plant are needed to ensure even a moderate supply of seeds, and so we find large quantities of this choice Primula at Forest Hill. From half the number of plants of such a variety as Holborn Queen, a choice white kind, a larger quantity of seed can be gathered. The capsules remain on the plants until June, when they are gathered, placed in boxes, and thoroughly dried in a warm greenhouse. It is afterwards a simple matter to break the seed vessels, and, after separating the larger portions of the husk by means of a fine sieve, to secure the well-ripened seeds. Seed-formation has been termed the highest effort of a plant, by which is meant that all the energies of the organism are directed in this end. It certainly has a great effect upon the colour of the flowers, for, as the capsules begin to swell, the tones become much paler, and it is only in the very youngest blooms that the true colour is seen. The plant generally becomes affected by the strain, and loses a great deal of its vigour in consequence. But this notwithstanding, the Forest Hill plants exhibit first-class cultivation, and although they were all more or less in seed-bearing, they made a fine display, and showed the skill of those responsible for their culture. It is interesting, in view of recent knowledge in plant-breeding, to know that by simply selecting and inbreeding, a variety can be "fixed" in a comparatively short time. In some cases the progeny comes true from seed after four or fewer generations, but in others it takes longer. We saw this process of selection in one case, where three plants of a certain batch that showed advance were placed by themselves. They were to be, or had been, pollinated, and it is expected that finer offspring will be obtained from them.

We may enumerate a few of the best varieties. Holborn Crested is a flower of a beautiful pink colour, having fimbriated petals and deeply crested foliage. It belongs to the "giant" race, the beautiful blossoms, notwithstanding the fimbriation, being of perfect form. King Edward is a charming white variety, with very great substance of petal, and producing its flowers in large trusses that are set off by handsome foliage. The variety named after the Princess of Wales has its flowers flaked with carmine. They are small, but of extremely delicate appearance. Elaine is still one of the best of the white kinds; it is very robust in habit, and bears large, stout trusses of bloom. There are two types, one bearing leaves of the Fern character, whilst the other has the ordinary Palm-shaped foliage. Both stocks breed true from seeds.

Orange King shows its colour in the unopened flowers. The orange shade becomes less marked as the blossoms expand, but even then the tone is pleasing. The flowers are small, but efforts are being made to improve it in this direction, and if this is successful, the variety will demand much attention. Vivid is a double-flowered variety of a magenta tone, very free in blooming, and with tall inflorescences.

There is a set named after the colours of the separate varieties, including Holborn Scarlet, Holborn Rose, Holborn Crimson, Holborn Pink, Holborn White, and Holborn Magenta. They are all useful kinds and amongst the most desirable colours. One of the newest is Holborn Coral. Among the late-flowering varieties, we may instance Late White, scarcely one of the plants being in bloom so late as April 15.

The skill and care which Messrs. Carter have expended in the work of crossing and selecting are amply repaid by the excellent results which have been obtained. A collection of Primula sinesis is among the most interesting of objects, both from a botanical and a horticultural point of view, for it provides the most striking illustration imaginable of the variability of a pure species.

The Week's Work.

PLANTS UNDER GLASS.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Succulent plants.—All the species of Cacti which, during the winter have been kept dry at the root, are now showing signs of renewed activity, and this is the best time for carrying out any necessary repotting. As these plants thrive and flower best when grown in comparatively small pots, it is not necessary to repot healthy specimens every year. When it is necessary to repot a plant, shake the greater part of the old soil from the roots, examine them carefully, and cut away any diseased portions. As Cacti are not greatly affected by such pruning, it is advisable to cut well into the healthy part. Good fibrous loam and sand, with plenty of broken brick rubble or limestone, is the most satisfactory compost for most succulent plants. Epiphyllums and Rhipsalis, however, require a little peat or leaf-soil added. Crock the pots well, and pot firmly. Tall plants, and those with weak stems, will require the support of stakes, which should be placed in position as the potting proceeds. Any plants which have decayed at their base should have the live portions removed and be treated as cuttings. If the diseased part is cut away and the remainder exposed to the air for a couple of days before being inserted in dry, sandy soil, the plant will readily form roots. For the next four months these plants should be watered freely, and syringed twice, or even more frequently, on bright sunny days, to induce them to complete their growth by the beginning of August, thus allowing sufficient time for them to become thoroughly matured before winter. If a light, well-ventilated, and heated house can be devoted to them, their culture will be comparatively simple. A small collection grown with mixed plants should be given the sunniest part of the house—greenhouse or tropical, according to the needs of the different kinds. Stout leather gloves should be worn when handling the prickly species, especially in the case of Opuntias, which are not so inoffensive as they appear to be.

Camellias.—These plants now require a slightly higher temperature and a moist atmosphere. The plants should be syringed twice daily to cleanse the leaves. When they have finished growing, remove the plants in pots to the open air. Also freely ventilate the house for those planted in beds and borders.

Violets in frames.—As the sun gains power the plants should be shaded during the hottest part of the day to preserve the colour of the flowers. This may be done by lightly white-washing the glass of the lights, which, during bright sunshine, should be drawn up and tilted to their utmost capacity. The frames should be ventilated whenever conditions permit. Keep the surface soil well stirred, and remove all runners that appear on the plants. Apply occasional waterings with liquid cow manure, and immediately afterwards a light watering with clear water.

Stove plants.—To compensate for the increased evaporation due to ventilation, the plants should now be syringed more heavily, and the damping down should be done more frequently.

THE FLOWER GARDEN.

By W. A. COOK, Gardener to Sir Edmund G. Loder, Bart., Leonardslee, Sussex.

Carnations.—Make preparation for planting out Carnations that have been wintered in frames or under the protection of a south wall. The best soil for Carnations is a good loam resting on a well-drained subsoil. It is advisable to give them a fresh site every season, or, if this is not practicable, to apply a considerable quantity of fresh loam, and fork this into the staple. It is assumed that the ground was well trenched last autumn, and some decayed cow manure placed in the trenches; but if this preparation was not made, it had better be carried out forthwith. Carnations should be planted in the positions where they are to flower at about the end of March. They should be set at distances of about 1 foot each way. If the plants are very pot-bound, it may be necessary to loosen the roots a little by the use of a fine-pointed stick. Every plant should have its roots in a moist con-

dition before it is removed from the pot. In planting, let each be inserted about half an inch deeper than it was in the pot. Press the soil moderately firm, and scatter a little soot over the soil as a deterrent to slugs. In order to trap wireworms, slice some Carrots, and place these slices at different positions in the soil, examining them from time to time in order to destroy the pests. If sparrows should prove troublesome, either stretch some black cotton round about the growths of the plants, or protect the whole of them by means of netting. It is necessary for us to net all our Carnations at this season; but later, when there is more vegetation, the birds are less troublesome.

Giant Ten-week Stocks and Chinese Asters.—Sow seeds of the best varieties of Stocks and Asters thinly in shallow boxes filled with moderately light soil. Prick out the seedlings as soon as they are large enough to handle into other boxes. Such Asters as Ray, Crushed Strawberry, Azure Blue, Ostrich Plume, and varieties of the Comet type are invaluable.

Nemesia.—Sowings should now be made thinly in boxes. The seedlings whilst still small are very liable to damp off, and they must be shaded from strong sunshine.

Salvia "Bluebird."—Sow seeds of this Salvia, and also of S. "Fireball," these being very valuable for bedding purposes.

Lawns and garden paths.—Grass used for tennis lawns, croquet, and bowling greens, or other portions that are subjected to a great deal of traffic, should now be given a liberal dressing of the preparation which was recommended in the *Gardeners' Chronicle* for January 30, or a sprinkling may be made of one of the lawn fertilisers obtainable from the trade. In either case, the dressing should be well brushed in, and, after rains, the Grass should be frequently rolled. Sow fresh seeds wherever the Grass appears to be failing, taking care to sow the proper Grasses for the particular purpose the lawn is intended to serve. Garden paths should be given attention as soon as possible, regraveling them or forking them over, rolling them, and attending to the drainage. A garden path should be both useful and of smart appearance; nothing detracts more from the appearance of the garden than untidy paths.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Deciduous Calanthes.—Take these plants out of their pots, cover the old drainage material with a layer of rough Sphagnum-moss, and after shaking the soil away from the pseudo-bulbs, lay them in an upright position on the moss. In a week or two hence new roots will be seen pushing out from the base of the young growths, when the plants should be repotted. In the meantime, select a sufficient quantity of good turfy loam (free from wireworm), and lay it in a convenient place in order that it may become moderately warm before using. Loam is the principal soil needed for Calanthes, and some cow-dung should be mixed with it. The dung should be collected, spread on a mat or boards, and exposed to the sun until dry. It should afterwards be sifted through sieves of various sizes, finally using one with a very fine mesh. Keep the prepared manure dry until required. Previous to laying the pseudo-bulbs on the moss, cut off the dead roots to about an inch in length. The stumps thus left will be found useful to keep the bulbs steady in the fresh soil till the plants become established. Examine the base of each bulb for scale insects, and thoroughly cleanse them of these pests by using a stiff brush and suds made of soft soap. When the plants are ready to be repotted, select clean pots of sizes varying according to the requirements of the cultivator, as the plants can be grown singly in small pots, or several bulbs may be placed in larger ones. Half fill the pots with clean crocks, and cover these with Sphagnum-moss, or a thin turf of loam, as advised for Thunias last week. The soil should consist of one-half loam, one-fourth cow-dung or well-decayed leaf-soil, and one-fourth finely-chopped Sphagnum-moss, adding some small crocks and coarse silver sand. In potting the plants, shake the soil down till it is moderately firm, filling to within 1½ inches of the rim. Place the pseudo-bulbs on the surface, add more soil, press this firmly on to the old roots,

burying the base of the bulb about half an inch, and make the surface level. This will leave space for watering, and will also allow for a top-dressing of loam when the plants are about half-way through the growing season. These plants must be given the best and lightest positions if placed in the East Indian house; but *Calanthes* may be grown to perfection in the plant stove, Pine pit, or Cucumber houses. Do not water the plants at the roots for two or three weeks after the potting, but damp between the pots twice daily. The soil may afterwards receive an occasional light sprinkling from a fine-rosed can, but much discretion must be exercised, for a wet soil at that stage will cause the tips of the roots and leaves to turn black and decay. When the roots have a firm hold on the sides of the pot, and the plants are in vigorous health, abundance of water should be alternated with weak liquid cow-manure. Strong, direct sunshine should only be permitted to reach the plants when the new pseudo-bulbs begin to form. Deciduous *Calanthes* may be rapidly increased by removing the old back pseudo-bulbs and inserting them thickly in flower-pots filled with Sphagnum-moss. The best position for them is on a dry shelf near the glass, and the moss should be sprinkled whenever it appears dry. They will soon commence to grow, and may afterwards be repotted.

Calanthe Regneri.—Late-flowering varieties of this species will now be in bloom. These will also require repotting after the spikes are cut and growth has recommenced. This section of *Calanthes* is far more serviceable to those who live in the neighbourhood of large towns and smoky districts, as the flowers escape the fogs which are so prevalent at the time when the earlier varieties bloom.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Carrots.—If the varieties sown early in the New Year were quick-maturing sorts, and the plants were partially thinned while still small, they should now be sufficiently developed for use. The rows should be carefully examined as the vegetables are required, thinning the roots at intervals. Successional sowings will need to be partially thinned, as previously advised, as soon as the second leaf is made. Carrots under glass should be syringed twice on bright days, and the lights must be closed early in the afternoon. Occasionally, before watering, apply a dressing of soot and specially-prepared vegetable manures. Frequently stir the soil between the rows. Sowings may now be made out-of-doors, but before doing this give the soil a thorough surface dressing of wood ashes and soot. Should extra fine roots be required, it will be necessary in most cases to make deep holes, by means of an iron bar. Fill the holes firmly with very fine specially-prepared soil, preferably old potting soil which has done service for pot plants, taking care to add plenty of soot and wood ashes. New Intermediate belonging to the St. Valery type is probably one of the finest all-round Intermediate Carrots, and as a short-rooted variety Model is not only an excellent sort, but it is well adapted for shallow and hot soils.

Beetroot.—Beetroots raised early in frames should be thinned out as soon as they are large enough. It is a capital plan to apply a top-dressing of either finely-sifted leaf-mould or manure from a spent Mushroom-bed. Beetroot should never be overcrowded, and least of all when grown under glass. Another sowing of a Turnip-rooted variety may be made in an unheated frame or on a warm border in the garden. Old roots which have been clamped together for the winter, or stored in the root-shed, should now be taken out. Any growths they have made should be rubbed off, and the roots stored thinly in sand or ashes under a north wall, where they will keep sound for many weeks.

Seakale Beet.—Seeds of this vegetable, sometimes known as Spinach Beet, may be either sown under glass and pricked out on well-prepared ground exposed to sunshine, or sown in drills, 18 inches apart, in the allotted position. The end of March is a good time for sowing the seed thinly in boxes, in gentle heat. Plant out the seedlings after they have made the second leaf and the plants are well hardened.

It is also advisable in large establishments to devote a cold frame to forwarding a few plants, allowing the same distance as advised for sowing outside, and planting them in about 18 inches of rich soil, which should be made very firm.

Cabbages.—These vegetables in many instances have been seriously injured, and no time must be lost in making them good as far as possible. Plants which were put out as reserves and slightly protected will now prove invaluable. Frequent hoeings will do much to stimulate new growth. Make a slight application of manure.

FRUITS UNDER GLASS.

By E. HARRISS, Fruit Foreman, Royal Gardens, Frogmore.

Fig trees in pots.—The fruits on the earliest trees which were started into growth in December will soon be showing signs of ripening. Make frequent applications of manure water, and, to further assist the trees, apply a liberal top-dressing of well-decomposed cow and horse manure. If it is necessary to hurry the ripening, it will now be safe to have an atmospheric temperature of 65° at night; but the temperature should be allowed to fall several degrees if the night is unusually cold. Spray the trees with rainwater early on fine mornings, and again at closing time in the afternoon. Frequently damp the floor spaces in the house. Stop and regulate the growths so that all the shoots and leaves will be exposed to the light and air. As soon as the fruits have actually commenced to ripen, it will be necessary to omit the use of manure water. At that stage the atmosphere should be kept rather drier than hitherto, discontinuing the syringing, but being careful to keep the roots thoroughly well supplied with water.

Fig trees in borders.—Established trees which are growing in shallow and restricted borders need very frequent root waterings, and if these are not afforded with unremitting regularity, there will sure to be some fruits fall from the trees. Trees that are bearing a full crop need liquid manure given them at every alternate watering, and it will be useful to apply a liberal mulching of decomposed horse manure. Give timely attention to stopping the shoots, and thus prevent overcrowding. Cut out any weak, unfruitful wood which can be spared. Red spider must be prevented or eradicated. The best remedy is to sponge the leaves with a weak solution of soft soap and sulphur. Ventilate the house freely during bright, genial weather, opening those ventilators at the top of the house. Close them early in the afternoon, after spraying the trees.

The season.—The present season has been one of the worst I have known for forcing fruits. The cold weather, with little sunshine, has had a retarding influence, and the crops generally are a few days later than usual. But nothing will be gained by the use of an excessive amount of fire heat, for growth made under such conditions is of a most unsatisfactory nature. It will be useful to cover the roof glass with garden mats or tiffany during very cold nights, and retain heat in this way. Such crops as Melons, Cucumbers, Pineapples, and Tomatos, being usually cultivated in low houses or pits, may be easily protected in this manner. Discretion in ventilating the houses during the early part of the day, coupled with an endeavour to obtain as much value as possible from sunshine by closing them again early in the afternoon, are the chief means the cultivator has for forwarding his crops.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Propagation of fruit bushes.—Cuttings inserted in the ground earlier in the season have probably been loosened by the action of frost. It will be necessary to examine them and make the soil quite firm again about each one.

Newly-planted trees.—If stakes were not placed to trees at the time of planting, the latter will be sure to have become somewhat loosened. Therefore, examine every specimen, and fix stakes at once in cases where they are required. Any newly-planted trees that were not pruned immediately after planting must be given attention at once. Do not prune them severely, as they are not likely to make much growth during the first season. Some cultivators would not prune them at all this year:

but when this is not done, it is usually necessary to prune them severely in the second season in order to obtain the required shape.

Apricots.—Do not use nets or any other covering for the protection of the flowers against frost except when circumstances make it imperative. By overshading, the object in view may easily be defeated, for its effect upon the flowers is to increase their tenderness and render them more susceptible to harm from cold winds or frosts.

Figs.—Although the season is so far advanced, it has not been safe in all localities to untie the bundles of Fig growths that were tied in the autumn as a means of protection. In the early part of March as much as 25° of frost have been registered. But the protective material must not be allowed to remain any longer. Its use at any season has a disadvantage, for it renders the shoots more liable to injury from late frosts. If the growth upon established trees are kept well thinned out by frequent pinching, it is possible to get the wood so thoroughly hardened by autumn that it will withstand the frosts of an average winter. I would only protect Fig trees as a last resource, or in localities where experience has proved that such protection is absolutely necessary. Trees that have been bundled and matted must still be given some protection on frosty nights.

Preparations for grafting.—Make everything necessary for this operation, for, in the event of warmer weather, the sap will rise readily in the stocks. Most growers have their own special mixture of grafting clay, but in cases where it is inconvenient to prepare such clay at home, the French cold-grafting wax sold as "Mastic l'Homme Lefort" may be recommended as a substitute.

PUBLIC PARKS AND GARDENS.

By J. W. MOORMAN, Superintendent of Victoria Park, London.

Boating.—This is one of the most popular pastimes in the London parks during the spring and summer months. The privilege of letting the boats was formerly granted to contractors, but the L.C.C. now has its own boats, and lets them direct to the public. They are, therefore, obtainable much cheaper than formerly, and they are better supervised. The hire of a sculling or pair-oared boat is 6d. per hour, and the same charge is made for a canoe. Each boat is only permitted to carry a certain number of persons, varying from one to four. No boat can be retained for a longer period than one hour. Both at Battersea and Victoria Parks there are motor launches, each capable of carrying from 40 to 50 persons at a time, who are conducted around the ornamental water at 1d. per head. The demand for boats is greatest from April to October, but boats can be hired at any time of the year, unless there is ice on the water. In a busy season, the motor launch at Victoria Park will carry as many as 56,000 persons, and, during the same period, the small boats are hired by 40,000 persons, the charge for these latter being 6d. per hour. Very often damage is done to the boats, not necessarily wilfully, but mainly because of inexperience in handling them, and a boatbuilder is constantly employed carrying out necessary repairs.

The boats.—The best boats are built of Mahogany, but some are made of white or Spruce wood. A double or pair-oared skiff, measuring 21 feet by 3 feet, is a very useful craft for this kind of work, and it will carry four persons. Outrigger skiffs, to carry two persons, are 18 feet long and 3 feet wide; whilst the gigs, that carry only one person, are of the same length, but a few inches narrower, being only 2 feet 6 inches in width. Canoes are made of several sizes; that known as the "Rob Roy" is generally made from 15 feet to 17 feet long.

Maintenance of the boats.—The boats, when new, are very highly varnished. They are coated with what is known as boat varnish—a different material to ordinary wood varnish. Even if the boats do not require much in the way of repair at the end of the season, they should be thoroughly cleansed and revarnished. If they are in a very old condition, it is better to paint, grain, and varnish them. The sculls or oars need the leathers on the handles greasing occasionally; and as the blades show wear, they should be protected with slips of sheet tin, zinc, or copper.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MARCH 30—
Cornwall Daffodil and Spring Fl. Soc. Exh. at Market Hall, Truro (2 days). Bournemouth Spring Fl. Sh. (2 days).

APRIL 2-13—
International Horticultural Exhibition at Berlio.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—44.5°.

ACTUAL TEMPERATURES.—
LONDON.—Wednesday, March 24 (6 P.M.): Max. 51°; Min. 43°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—Thursday, March 25 (10 A.M.): Bar. 29.1; Temp. 52°; Weather—Overcast.

PROVINCES.—Wednesday, March 24 (6 P.M.): Max. 50° Bury St. Edmunds, S.E.; Min. 48° Durham.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Hardy Border Plants, Bulbs, and Tubers, at 12; Roses and Fruit Trees, at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Norris.

WEDNESDAY—
Herbaceous Plants, Lilies and other Bulbs, at 12; Roses, at 1.30; Azaleas, Rhododendrons, Palms, and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Norris.

FRIDAY—
The collection of established Orchids formed by the late Lord Burton, 500 Cattleya labiata, and an importation of Dendrobium Jamesianum; at 67 & 68, Cheapside, E.C., by Protheroe & Norris, at 12.45.

The Temperature of Respiring Plants.

The fact that living organisms, both plant and animal, respire is well known. It is also well known that the process of respiration, which may be described roughly as one of oxidation, results not only in the release of energy whereby the organism does the work of living, but also in the production of energy in the form of heat.

The usual method of demonstrating this production of heat consists of inserting a thermometer into the midst of each of two heaps of soaked Peas or similar objects, the one heap consisting of dead, the other of living material. When careful precautions are taken against loss of heat by radiation, it is possible to observe that the thermometer in the heap of living, respiring seeds records one or two degrees of temperature more than that recorded in the control heap of dead, and, therefore, non-respiring seeds. Such a small difference in temperature is not impressive, and, indeed, is misleading. Professor Peirce, of Stanford University, California, has introduced a new method by the aid of which it is possible to demonstrate that the amount of heat liberated by germinating seeds, opening flower-buds, or other living objects, is much more considerable than is indicated by the results obtained by the old methods of experiment.

The essential of the new method consists in the use of the well-known Dewar flask

as the vessel in which the respiring object, seed, flower, or other is placed. The Dewar flask, known popularly as the thermo flask, was invented by the distinguished chemist after whom it is named for the purpose of experimentation with liquid air. It consists of two glass flasks, silvered or unsilvered, fused together at the neck, but otherwise separated from one another by a space from which the air is exhausted. Such an apparatus makes an admirable non-conductor, and it is, of course, on this property of non-conduction that the general use of the thermo flask depends. Hot liquids placed in it retain their heat for many hours; conversely, and for the same reason, cold liquids remain cold.

Using such flasks, Professor Peirce found that, when filled with germinating Peas, a thermometer plunged through a plug of cotton wool in the neck of the flask, and so brought into contact with the Peas, registered at the beginning of the experiment 17° C. On the following day the temperature registered was 19° C. in the morning and 23° C. in the evening. During subsequent days it rose steadily and reached a maximum of 56° C. (= 132° F.), or many degrees above fever-heat, on the eighth day. In the control-experiment, which consisted in placing dead Peas in a similar flask under like conditions, the temperature showed no rise at all during the eight days.

Another series of experiments made independently by Professor Molisch confirm these remarkable results. Professor Molisch used large quantities—from 6 to 10 lbs.—of living leaves, and, taking precautions to prevent loss of heat by radiation, found that the temperature within the mass of leaves rose very rapidly and extraordinarily. In the course of 12 to 15 hours the temperature of a mass of *Pyrus malus* leaves rose to 59° C. (138° F.); Hornbeam to 51.5° C., Lime to 50.8° C., and so on. The leaves of other plants, e.g., evergreens such as Ivy and Conifers like *Abies excelsa* gave less striking results. As in Professor Peirce's experiments, so here there is no question of the heat having been produced by fermentation set up by micro-organisms. Indeed, Professor Molisch found that if the experiment was stopped before the highest temperatures were reached, the leaves were alive and fresh. When the experiment was continued after the highest temperatures had been attained, the thermometers recorded at first a gradual fall of temperature and a subsequent and second rise due to the respiratory activity of fungi and other micro-organisms.

He interprets the fall of temperature which takes place after about 15 hours as being due to the death of the leaves, and concludes that the leaves of such plants as Apple and Hornbeam actually kill themselves by the high temperature set up by their respiratory activity. In the overcrowded and insulated situations in which the leaves find themselves they die of fever.

Professor Molisch himself points out that these high temperatures set up by masses of cut leaves are not altogether normal, and are, in fact, to be ascribed in part to "wound-fever." As has been shown by various observers, wounded plants, for example, cut Potato tubers, develop, as a response to the stimulus of wounding, a "wound-fever." Shortly after the operation a cut Potato, re-

spiring more actively, develops more heat than it would have developed had it remained intact. Just as in animals and man himself wounding may be followed by fever, so it may be in plants.

Nevertheless, these high temperatures set up in masses of leaves are by no means due altogether to "wound-fever," for cut-off branches with intact leaves show a similar though smaller rise of temperature. It will be recognised that no such temperatures as those here recorded would be developed in a plant under normal conditions, for the heat would be dissipated both by radiation and conduction. Nevertheless, these facts are of great practical and theoretical interest: of practical interest in showing that large masses of grain, tubers, roots, &c., closely packed, may readily suffer from overheating; of theoretical interest in indicating that high, local temperatures may be developed in the plant. Now, many of the normal chemical operations which the plant carries out are operations which proceed more swiftly at a higher than at a lower temperature. These experiments of Molisch and Peirce indicate that a transitory, local heating up of the plant may take place as the result of its increased respiration, and that, in consequence of the higher temperature, the rate of many vital processes may be accelerated.

ACANTHUS MONTANUS.—This tropical species of *Acanthus* is not often seen in gardens in this country, yet its decorative value entitles it to a place in the stove. The plant has a double attraction, for not only is the inflorescence stately, but the foliage is also of a highly decorative character. The bracteoles are veined with light purple, causing the flowers to appear of that colour, although the species is sometimes described as rose-coloured. The three-lobed lip of the corolla is perfectly white. In our sketch (fig. 86) by Mr. WORTHINGTON SMITH, the leaf is given in outline only, and does not show the beautiful marbling of yellow and green on the lamina. The leaves arise close together, and spread themselves quite horizontally, giving a somewhat stiff appearance, which is further accentuated by the spinescent character of the plant. The inflorescence is drawn in our sketch to a natural size from a plant exhibited by Messrs. JAMES VEITCH & SONS, at the meeting of the Royal Horticultural Society, December 22 last, when the Floral Committee conferred on the plant a First-class Certificate. The whole character of the plant, in common with other *Acanthaceae* species, is spiny.

SURREY EDUCATION COMMITTEE.—Mr. A. E. BURGESS, for several years lecturer in gardening to the Hertfordshire County Council, has been appointed inspector of school gardens under the Surrey Education Committee. The post became vacant by the resignation of Mr. JOHN WRIGHT, V.M.H., who felt himself unable to continue the duties. During the past three years Mr. HORACE J. WRIGHT has carried out the work on behalf of his father, and the Education Committee recently offered him the permanent inspectorship, but other engagements prevented him from giving his whole time to the post. Prior to his appointment in Hertfordshire, Mr. BURGESS was head gardener and assistant instructor under the Essex County Council, and also conducted classes in nature study and in horticulture for teachers. There will be this year in Surrey some 106 blocks of school gardens and 2,000 lads receiving garden instruction.

LINNEAN SOCIETY.—A meeting of Fellows will be held on Thursday, April 1, at 8 p.m., when the following paper, amongst others, will be read:—"Results of Breeding Experiments with Peas, showing Mendelian Phenomena," by Mr. A. D. DARBISHIRE.

ENGLISH VISITORS TO THE BERLIN SHOW.—The following gentlemen have accepted invitations to act as jurymen at the International horticultural exhibition at Berlin:—Messrs. STUART H. LOW, GEORGE PAUL, HARRY J. VEITCH, S. T. WRIGHT, LOUIS SANDER, and R. HOOPER PEARSON. The Council of the Royal Horticultural Society on Tuesday last deputed Sir DANIEL MORRIS, K.C.M.G., V.M.H., D.Sc., and Mr. HARRY J. VEITCH, V.M.H., to represent the Society on the invitation of the organising body to send two delegates. The members of the jury will meet on Thursday, April 1, at nine o'clock a.m., and the show will be open to the public from April 2 to April 13.

* **A BOOK ON HARDY FLOWERS.**—M. PHILIPPE DE VILMORIN has recently edited a new edition of *Les Fleurs de Pleine Terre*. It is a comprehensive and instructive volume, containing nearly 1,400 pages, and illustrated with 1,800 small woodcuts, beside several full-paged plates in colour. The French landscape gardener, M. ED. ANDRÉ, supplies several garden plans in colour. We note that at the outset some attention is paid to the raising of seeds and to the various methods of raising flowering plants for outdoor culture. Every flower named is enumerated in alphabetical order, and the author under each separate heading deals with the etymology, the habitat, synonyms, culture, &c., of the plant in question. Throughout this portion there are many cross references that will help the reader in any research he may be engaged upon. The second part of the volume contains many tabulated and selected lists for various purposes. There are comprehensive lists of plants classed according to their nature and use. The rock-garden receives attention, and there are several views in M. VILMORIN'S own rock-garden at Verrières. A glossary of botanical and horticultural terms is given, and the names of flowers in several of the European languages find a place in the closing pages of the book. In the calendar of seed-raising and planting the period of flowering of each plant is added, and in another calendar the flowers are arranged in lists month by month, according to the flowering season of each. The classification of flowers according to colour is useful, as is also the examples of planting beds and borders for obtaining a succession of bloom from June to autumn.

DEEP TILLAGE IN THE KITCHEN GARDEN.—

The discussion upon this subject which has taken place recently in these pages, and which we propose to bring to a close in the present issue, has arisen from differences in respect to methods rather than to any lack of appreciation of the advantages to be obtained by trenching. These advantages have been described again and again in these columns, and no experienced gardener would think of questioning them for one moment. Mr. BECKETT aims at efficiency and, having considerable resources at his command, he regards labour and expense of quite secondary importance. He knows perfectly well that the roots of most vegetables, the tap-rooted ones especially, are capable of growing very deeply into the soil; therefore, he knows that the sooner the bulk of soil can be brought into an equal condition

of fertility, we will say 2 or even 3 feet deep, the sooner he will have a perfect root medium for his crops. In this he is right, and most of our readers who have joined in the discussion are well aware that the results of

the deep tilling practised in the Aldenham House gardens are unexcelled. How long the process of converting the deeper soil to a fertile condition is to last in a particular garden must depend upon circumstances. If a poor

FIG. 86.—ACANTHUS MONTANUS, A STOVE FLOWERING PLANT. (See p. 200.)

* *Les fleurs de pleine terre*, by Vilmorin, Andrieux et Cie., Paris.

subsoil can be brought to the surface and made fertile by the action of the weather and by the adding of suitable materials in one year, so much the better, but if circumstances are not favourable the process must be continued for several years. In cases, for instance, where the area of ground available for cultivation is very limited, or where labour is scarce, it may be necessary to proceed slowly, but it has not been shown that in the interval it is possible to cultivate vegetables of the same quality as those Mr. BECKETT habitually exhibits.

THE "WOOD" FUND (see p. 171).—Mr. GEORGE MONRO sends us the following list of additional contributions on behalf of Mr. W. WOOD, Dartford Heath, who recently sustained great loss to his plant houses owing to a heavy fall of snow:—The total amount published on p. 171 was £56 2s. The following amounts have been given or promised since:—Sams, W., £1 1s.; Wright, F., £2 2s.; Rochford, E., £5; Gray, H. P., £1 1s.; Rochford, John, £5 5s.; Ryder, E., £1 1s.; Humphrey, W. E., 10s. 6d.; Monro, Geo., Junr., £1 1s.; Wills, E., 10s. 6d.; Kingsmill, Andrew, 10s.; Cypher, James, & Sons, £1 1s.; Veitch, James, & Son, £5 5s.; Mott, E. C., £2 2s.; Aquatias, Paul, 2s.; Howard, Henry, 2s. 6d.; Clark, G. & A., 10s. 6d.; Watkins, A., £1; Barter, J. F., £1 1s.; total £85 8s. We are glad to record the generous way in which Mr. MONRO's appeal on behalf of Mr. W. WOOD is being met, and hope that those sympathisers who have not yet sent subscriptions will do so without delay.

PUBLICATIONS RECEIVED.—*The Agricultural Journal of the Cape of Good Hope.* (February.) (Cape Town: *Cape Times*, Ltd. Price 6d.)—*Clay's Successful Gardening.* (Fourth edition.) By Professional, Amateur, and Market Growers. (London: Clay & Son, Stratford.) Price 9d. net.—*Rock, Wall, and Water Gardens.* (Colchester: R. FLORISTS' FLOWERS.

SWEET PEA "HENRY ECKFORD."

As the Rev. D. R. Williamson said on p. 177, this flower has great beauty, but it requires shading from hot sunshine in order to colour perfectly. Its colour is a rich salmon, exquisite in texture and finish. There is a Spencer (waved) counterpart of "Henry Eckford" in existence, although it has not yet been put on the market for sale. It has two names, "Nancy Perkins," under which it received the Award of Merit of the National Sweet Pea Society, and "Earl Spencer," the name under which it has been well shown by Mr. Cole, gardener to Earl Spencer. Among Sweet Pea enthusiasts this Spencer form of "Henry Eckford" is much talked about. It is expected to be purchasable in the autumn of this year, but few growers have any large quantity of it, and the demand is expected to exceed the supply. A nice point

is available, it is best to sow the seeds in boxes or pots, and transplant them early in April. If there is no frame, the seeds may be sown in deep boxes about half filled with soil, using a sheet of glass over the top and taking care to admit plenty of air during the day. By this method the plants are preserved from birds and slugs whilst very young.

If lard buckets are used, one or two plants are enough in each. After planting care must be taken never to allow them to become dry. An occasional dressing of artificial manure will be of great benefit, for the tubs soon become filled with roots. The manure can be used in a dry state, and sprinkled on the soil, or it may be well stirred into water. Some varieties are more adapted than others for tub culture. Among the best for this purpose are Etta Dyke (white), Yellow Hammer (primrose), Queen Alexandra (scarlet), Geo. Herbert (rose), Frank Dolby (lavender), Chrissie Unwin (cerise), and Countess of Northbrook (pale pink). Never let a seed pod form, or the plants will soon cease to bloom, but if the flowers are cut before going to seed it is possible to keep the plants in flower from June until October.

Should the plants get too high, take the tops out. This will cause the side shoots to flower more freely. The best stakes are formed of dark bamboo canes, which can be bought of

FIG. 87.—A TURF-CUTTING MACHINE.

arises—Are "Nancy Perkins" and "Earl Spencer" the same? For all practical purposes they are, and no doubt they will be bracketed by the National Sweet Pea Society as like varieties. The reduction of the list of names is a consummation much to be desired. Will the National Sweet Pea Society ever take its courage in both hands and decide to recognise only one name for synonymous varieties, or, as it prefers to term them, "too much alike varieties"? Only when it does this will the list be reduced. *Correspondent.*

SWEET PEAS IN TUBS.

In some town gardens it may be necessary to grow Sweet Peas in tubs. Oil barrels cut in half and painted green will last for years. If these are too large, a lard bucket, painted, will answer the purpose well enough. Holes should be drilled in the bottom, and a good layer of crocks or rough cinders should be put at the base for drainage. On this put a layer of rotted manure, then nearly fill the tub with some good soil, bonemeal and manure. The soil should be made moderately firm by ramming. If oil barrels are used, put in each barrel 10 or a dozen seeds, but thin the plants out to five when all danger of losing them is past. Five plants will give better results and more blossoms than if 12 were left. If a cool frame

horticultural sundriesmen. Place one or two stakes to each plant, then twine some green twine from one to the other. The tendrils will cling to this, and, with just an occasional tie, the plants will always look neat and tidy. Sweet Peas in tubs can also be used for covering a trellis or wall, provided something is put for them to cling to. For a small garden I do not think there is a better way to grow Sweet Peas than this. *Geo. Herbert.*

A TURF-CUTTING MACHINE.

The turf-cutting machine shown in fig. 87 has been in use for some years past in Messrs. Stannig's garden and grounds near Preston. In Cuerden Hall Gardens we have stripped 1½ acres of turf in 30 hours. There was barely a yard of sward without a clump of rushes, but that made no difference to the working of the machine. But it is of little use if the ground contains many stones; on one occasion the blade came in contact with a large stone, and the man guiding the handles was lifted nearly two feet off the ground. Fortunately this only happened a few times.

Two horses are required to draw the machine, also a man to guide the handles and another to lead the horses. The pace is about equal to

that of slow ploughing. There are circular knives, one on either side of the back roller, and they are 12 inches apart. These determine the width of the turves. They can be regulated to cut to any depth, and the knife or plate underneath cuts the sward far more evenly than does an ordinary hand-worked turf-cutter. The turves may be left in their places on the ground until required for removal. We have another useful implement to cut the turves the desired length. Guided by a line, the operator pushes the cutter before him at a moderate speed. The blade can also be regulated to the desired depth. In this district turves are cut to a width of 1 foot, but only about 16 inches in length, which allows them to be placed in their new position with forks. The objection to this smaller size is that there are many apertures requiring to be filled with fine soil. *Wm. P. Roberts, Cuedon Hall Gardens, Preston.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE FRUIT CLASSES AT THE R.H.S. MEETINGS.—When I saw the *Book of Arrangements* for 1909, I thought that one reason for discontinuing the autumn fruit show was in order to have classes at the usual fortnightly meetings that would serve to bring before the public such varieties of fruit as could scarcely be shown at their best in September or October. But, like your correspondent *D.*, in your issue of March 13, I am greatly disappointed that prizes were awarded to varieties like Cox's Orange Pippin and King of the Pippins when exhibited in February. Although such varieties can be kept in good condition till late spring (I have had Cox's Orange Pippin good in May), it does not follow that, with the great majority of growers, this would be the case. The rule that an exhibitor may not exhibit in two classes, differing only in the number of dishes, prevents him from showing in both the collections and single-dish classes, and, therefore, the classes are not so well filled as they might be. *Pomona.*

D., p. 163, appears to be a little hurt because the exhibits of late Apples at the R.H.S. meeting on February 23 and the judgment on them were not in accordance with his own views. The class, as scheduled, made no reference to varieties, but left the choice entirely with the exhibitors. If the class had been one for Grapes, instead of Apples, are we to assume that well-preserved bunches of Muscat of Alexandria, Madresfield Court, &c., would have been inadmissible? *D.* gives the varieties exhibited by the trade firms, and says that not one of these sombre-looking fruits were to be seen in the amateurs' prize collections. I agree with *D.* that February is early for an exhibition of late Apples, and, as *D.* says, April would be more suitable, when the qualities could then be better judged. The Fruit and Vegetable Committee sits fortnightly, and if *D.* or any other person cares to exhibit at these meetings in April good dishes of any of the late varieties of Apples, they will not be overlooked, but awarded recognition according to their worth. *Double D.*

NARCISSI FOR FORCING.—At the meeting of the Royal Horticultural Society held on March 9 the Narcissus Committee awarded Certificates of Commendation to two Narcissi for their value as forcing varieties. A Narcissus that will respond to early forcing is very valuable, but there is such a wide difference between the variety that is destined chiefly for a "show" flower and one that ranks as a market flower. In view of the fact that the Daffodil had for two months prior to March 9 been a leading feature in the flower markets, whilst the large number of varieties exhibited at this exhibition were also forced, that date does not appear to be a particularly suitable one on which to decide the forcing value of any variety. Adaptability to forcing, and in particular "early forcing," is a splendid quality in a Narcissus, particularly if the flower is of a desirable tone. *E. C. Jenkins.*

TRENCHING (see also p. 201).—The discussion on this question is, from my point of view, interesting. I can hardly hope or expect to convince those who are known to be strongly opposed to the system I have recommended. Mr. A. Shakleton enquires how the first crops fared after the work had been accomplished. My answer is, quite satisfactorily. In following my system, a certain amount of trouble is necessary during the first season or two after trenching, but, having once accomplished this, the difficulty is overcome. Many can bear witness as to the crops obtained here during the first year after the work has been carried out. I am glad Mr. Shakleton and I are at one as to the value of a deep tillage of the soil; the great difference seems to be as to the method in producing it. My contention is that the sooner this can be achieved the better, but few gardeners are in a position, even if they wished, to deep-trench the whole of their kitchen garden in one season. Mr. G. H. Jenkins is not far wrong when he states that some persons appear to have a dislike bordering on dread when they see clay soil on the surface, forgetting how soon this may be brought to good use, and that what is so frequently termed inert soil is too often left below to remain as such. In answer to *J. S.*, I have had a great many kinds of soil to deal with, but never one such as he describes, where the subsoil is so bad that even weeds cannot exist in it. My advice is, take extreme measures and trench the whole of it to the depth I recommend, and do the best to alter the character of such soil as quickly as possible. If Mr. E. Simms is under the impression that I recommend bringing unkindly subsoil to the surface only to those who have exceptional facilities for carrying out the work he is mistaken. I am of opinion that the more inferior the subsoil the greater need is there for deep trenching and taking drastic measures for bringing this to the surface, where it can be more conveniently dealt with both by the aid of the weather and by adding suitable ingredients. I can assure Mr. Simms that he has not misunderstood me and that my advice was not given subject to reservation. *E. Beckett.*

I agree with Mr. Beckett's mode of trenching when cultivation has been long pursued and when the subsoil has become disintegrated and decomposed by the roots of plants, &c.; but I do not believe in burying the topsoil and replacing it by a crude subsoil, as this system would result in the loss of years of profitable cropping. In our garden the subsoil is impregnated with salts of iron, which, when brought to the surface, are detrimental to the growth of vegetation. Bastard-trenching may be recommended with advantage on such land, and in another year, when the subsoil has had plenty of manure, &c., incorporated with it, the ground may be trenched. I am inclined to think that a person who advocates bringing subsoil to the surface, no matter what its condition, has not had much practice in breaking up land. It is one thing to break up new land and quite another to trench a garden that has been cultivated for a century and a half. Few gardeners have the spare labour to trench to a depth of 3 feet, but good crops can be grown on land that has been manured and bastard-trenched. *G. H. H. W., North Hants.*

I am pleased to read the testimony of Mr. Beckett (p. 76) as to the value of bringing to the surface the bottom layer of soil when land is trenched. On taking charge of these gardens, 10 years ago, I found the surface soil was only 9 inches in depth, the subsoil being a very stiff clay. In my first year the land was well dug, receiving at the same time a good dressing of London manure, but with very poor results. I therefore resolved to adopt Mr. Beckett's advice on trenching. I selected two plots to start with. I had them dug three spits deep, and the bottom layer was brought to the top. Having plenty of manure at my disposal, the trenches were filled with dung that had been exposed to the influence of the weather throughout the winter. In the spring the land received a liberal top-dressing of wood ashes, with soot and lime added, and these materials were lightly forked in. The crops planted on this land were Peas, Scarlet Runners, Broad Beans, and Winter Greens. The results were excellent in the first year. I made drills for the Peas and Beans with a spade and covered the seeds

with old potting soil. The Peas grew 2 feet above the average height and yielded splendid crops. The other crops were equally successful. I have now completed the trenching of the whole of the garden, with the best results. It appears to me that Mr. Beckett's critics are influenced by theory and not by practice. *Thos. Paleman, Node Gardens, Welwyn.* [This correspondence must now cease.—Eds.]
