"Buketon, now Bickton, was by Kinge Henry I. given unto John Janitor, soe called by his office, which was to keepe the goole, or prison, for malefactors within the county of Devon." We cannot follow all the changes of proprietorship, but at the close of the reign of Richard II., Bicton passed into the possession of Sir Robert Dennys "whoe newe builded the same, makinge it his principall place of his abode, and made a parke for deere, and addinge divers commodities and pleasures thereunto." His grand-daughter married to "Sir Henry Rolle the younger, who had issue by her Dennys Rolle, Esquier, the nowe possessor thereof." This was written about the year 1630 by Sir William Pole, and he adds, "the tenure of Bicton to keepe the gool of the county, which belongeth hereditaryly unto the same place," continued until 1787, when it was exonerated, and very wisely, for we never visited any estate in the British Isles less appropriate for the imprisonment of malefactors—anyone sure of being confined within the park-circuit of Bicton would have an irresistible temptation to commit a felony.

This noble domain became famous for its gardens and arboretum more than forty years since, entirely in consequence of Lady Rolle's taste and liberality. It is situated to the north of the road between Sidmouth and Exmouth, and we were admitted through the eastern entrance. The road here passes up the somewhat too-much extolled avenue of Araucaria imbricata. There are fifty of this Conifer, twenty-five on each side, and very fine specimens, but they are not avenue trees. An avenue should afford shade and shelter, and arching overhead be as a graceful, noble gallery leading to the mansion. The Araucaria is too formal, is all straight lines, and only looks well when flanked by densely, lighter-tinted trees. This avenue was planted on level ground by the late Mr. James Veitch more than thirty years since, and was for some time afterwards under his superintendence, as well as the Pinetum. Had the Araucarias been allowed to remain on the level ground their appearance would not only have been more natural, but they would also be in a much healthier state. Conifers are better not planted on mounds, and digging or forking amongst their roots, as was formerly the practice in this Araucaria avenue, cannot be condemned too much. Its continuance would have checked the growth of the trees, and it will even now require many top-dressings and mulchings to restore them to a healthy state. Mulching in summer insures the soil being kept in a moist and healthy condition, so as to encourage the formation and growth of fibrous surface roots. Nothing can be more suitable for mulching than short grass, such as the sweepings of a well-kept lawn, laid on about 2 inches thick, and repeated as often as it may be required.

Passing first to the Pinetum, we were prepared from the catalogue entitled "Hortus Lignosus Bictonensis," to find it one of the most extensive and best-arranged private collections in this country, or, perhaps, in Europe, and we were not disappointed. It was originally designed and furnished by Lady Rolle most munificently, the arrangement, we believe, having been under the superintendence of the late Mr. Loudon, the working plans he furnished being very skilfully carried out by the late Mr. Glendinning, who was at that time head gardener at Bicton. The formation of the lake adjoining was also carried out by him under Lady Rolle's directions, at a cost of many

thousands of pounds. The accompanying engraving gives a glimpse of a vista in the Pinetum.

The manner in which those and various other works of the most extensive kind have been furnished, are lasting proofs of Mr. Glendinning's ability. The Pinetum was originally about thirty-six acres, with a circuitous walk of nearly two miles, commencing at the house and terminating at the flower gardens. There are also shrubberies attached of about twenty acres and enclosed by iron railing, and more recently about eight acres have been added to the Pinetum, making it at the present time somewhere about sixty-four acres. When in its most complete state the arboretum contained more than three thousand species and varieties, but year after year deaths were allowed to occur in the Pinetum unnoticed, instead of being promptly repaired by the purchase of fresh specimens, so that when Mr. Begbie succeeded to the head-gardenership two years since, he found that no less than nine hundred of the specimens were gone. Lady Rolle would not allow the labels, marking where they stood and recording their names, to be removed, but they remain as a record of neglect, and her ladyship has requested Dr. Hooker, of Kew, to collect as many as can be procured of the species and varieties that are lost, and to do as much as possible towards restoring the Bicton Pinetum to its original strength.

We shall recur to the arboretum on a future occasion, but will now pass to another speciality of Bicton.

Its Pine Apples have been celebrated for many years. Even in Mr. Glendinning's days, now between thirty and forty years since, they were well grown in heat derived from leaves and tan, without the more modern system of having properly constructed pits with a good command of top and bottom heat. There is now a fruiting Pine pit heated with hot water and divided into seven compartments, each containing from twenty-five to thirty fruiting Pines. Sixteen varieties were grown here when the management devolved on Mr. Begbie in May, 1869. Monster sorts and monster fruit had been produced annually, and carried or sent to all the principal fruit shows in this country, and even to Paris, with the most gratifying results, as they turned out to be mostly prizetakers and grown by express. For various sufficient reasons it is unlikely that any of the Bicton Pines will be seen again on the exhibition boards.

Monster Pines were grown and obtained many prizes, and were so grown in very high temperature, strong or rather heavy

The Obelisk is only a Landmark.

soil, and often staked in the pots to keep them in position and from tumbling out. The system was kept up by waterings, steamings, and syringings, a large copper garden engine having often come into use twice daily, showing that large Pines can be grown with but few roots, and will grow and swell up well, aided chiefly by atmospheric moisture; but this extra size is obtained at the expense of quality in the fruit. The plan is now different.

As above stated, there are seven compartments for fruiting Pines. Large suckers are secured in succession as often as may be required—seven times in the year if preferred, taking thirty suckers at each time, care being taken that the suckers are of good size and healthy. They are detached from the stools, the bottom leaves carefully stripped and trimmed ready for potting, which is done as soon after as circumstances will permit. The pots for suckers are 7 and 8-inch pots, new, or thoroughly washed, carefully drained, and over the drainage are placed a few pieces of turfy loam.

The soil used is turfy loam, rather light, with all the fine earth shaken out of it, and to which a sprinkling of boiled inch bones has been added, and a little soot placed over the pieces of drainage turf. The sucker is placed rather low in the pot, and the soil rammed, so that when finished the plants are quite firm. The next operation is to get them plunged in succession pits as soon as possible. At Bicton all succession Pines are grown in rough deep wooden pits, using leaves and a little stable manure for heating purposes, than which nothing can answer better.

The batch having been plunged about July 1st, they are kept and wintered in their 7 and 8-inch pots according to size, and about the middle of March following, if all has gone well, the pots will be almost full of healthy fibrous roots. Eleven and 12-inch pots are used for the fruiting. The plants are moved quickly into a warm potting-shed, repotted in well drained pots, using turfy loam as before, rather light than heavy, a proper proportion of boiled inch bones added, and a small portion of soot. The soil is rammed in as hard as it is generally done with Heaths, but care is taken that the ball of earth is not injured. The plants are placed as deeply in the pots as possible, and the leaf beds being well turned up, and fresh sweet well-worked leaves added, the pots are plunged in a bottom heat of 80° to 85°, which is maintained until the pots are full of roots, when the plants will be broad-leaved, stubby, healthy subjects, so cheering to a practical gardener.

By the middle of June, if not sooner, the plants should be rested for two or three weeks, after which, if all is right as to sorts, they may be introduced to the fruiting-pit—say twenty-five or thirty Black Jamaicas and Smooth Cayennes. Thus treated they will start freely into fruit, and prove most useful during the winter months. Others, such as the Queens, follow

suit, and are, after having been rested on the cool-and-dry system, pushed into fruit early in January, and so they go on quite satisfied with a plan which, as Mr. Begbie said, "is neither Meudonian nor Hamiltonian, and may only be Bictonian, but as it gives an abundance of fruit of first quality, moreover said to be greatly superior to fruits grown on the 'express' method, I shall go on my system until I find a better, keeping the roots warm, and the heads cool."

We can testify that never were grown healthier, smaller-crowned Pines, and we have copied from Mr. Begbie's journal the Pines and the weight cut last July.

AMARANTHUS SALICIFOLIUS.

Of the genus Amaranthus there are species which have been long cultivated in gardens for their flowers—such as Love-lies-bleeding and the Prince's Feather (A. caudatus and A. hypochondriacus), which are still to be found in some old-fashioned gardens, and especially in cottage gardens; and one not cultivated for its flowers but for its lovely rosy-purple leaves, translucent in the sun, is to be met with in almost every modern flower garden. This is Amaranthus melancholicus ruber, not at all a melancholy-looking plant, which the others are. It was one of the introductions from Japan of our friend, the late Mr. John Gould Veitch; and to-day we produce a representation of, in its way, a not less beautiful member of the same family, Amaranthus salicifolius, from Manilla, which received, and deservedly so, the highest encomiums from all leading horticulturists at the meeting of the Royal Horticultural Society at Kensington on the 6th inst. Whether it is a distinct species or not we cannot at present say, but that it is not only entirely different from anything we know and singularly beautiful, that we can unhesitatingly affirm. Its habit and general character have been well represented by our engraver. It is impossible to conceive anything more graceful than the appearance of the plants shown last week at Kensington, for they looked like so many fountains weeping their waters, and it is equally impossible to give an adequate idea of the beauty of the colours of the foliage. The plants were about 3 feet high, and we described them as having long, narrow, graceful, weeping leaves, most of them purplish rose with an orange tinge, others bronzed-metallic green. The plants exhibited were lifted from the open ground. Messrs. Veitch add, that it is grown from seed sown in February, and is treated as a half-hardy annual, being gradually hardened-off and planted out in the borders in June. We have only to add, in the words in which we concluded our notice last week—it is quite certain that this Amaranthus will prove a great acquisition; and further that it will be so both for indoor and out-door decoration. We need scarcely remark that a first-class certificate was unanimously voted for it by the Floral Committee of the Royal Horticultural Society.

Amaranthus salicifolius.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The weather still offers a favourable opportunity for carrying on the war of extermination against the weeds; the ground also is in good condition for earthing *Celery*, the perfection of which depends a good deal on the care bestowed on this operation and its timely performance. Plant the principal crop of spring *Cabbage* on ground well manured, as previously directed. The East Ham is a good variety for standing over the winter; it is not so apt to run in spring as most other sorts. Prick out into beds, a few inches apart, a large quantity of Cabbage plants which have expanded their first two rough leaves. The July sowing of *Endive* may now be pricked out on a warm

border, and as the early plantation attains a proper size the plants should be tied for blanching. Continue to plant out *Coleworts* from the July-sown beds. They may be planted very closely, say on the average 9 inches apart. Embrace every opportunity when a wet day occurs to tie up and arrange *Herbs*, to string *Onions*, and to beat out and clean the seeds of any favourite vegetable that may have been saved. Make the last sowing for the season of Brown Cos and Hardy Green *Lettuce* on raised beds of light soil, where they may remain till spring, and be planted out to succeed those which are transplanted this autumn under walls and similar situations. The large pods of *Scarlet Runners* should be picked clean; these often give over bearing prematurely through the exhaustion occasioned by suffering the pods to run to seed. Another sowing of *Radishes* should be made on an elevated and warm border. Winter *Spinach* and *Turnip* beds must be kept hoed and thinned, the first to 9 inches or thereabouts. Follow up the plan of promptly clearing away the remains of crops as they successively decay. A proportionate reserve of land must be held for forward Peas and early spring-cropping generally. Those quarters which require trenching the ensuing autumn should be kept free of any further crop after this time of the year, that an opportunity may be afforded of getting the operation performed before the arrival of winter.

FRUIT GARDEN.

It will be an advantage to have the fruit-tree borders free and unshaded by any crop at this season. The effect of planting Endive, Turnips, and similar crops is to keep the border cold and wet, when, in fact, warmth and air are more particularly required. It would be satisfactory to see the width of borders reduced, could even a more limited space be secured exclusively to the wall trees. If no store of material (sods of sandy loam are good for the purpose) is in hand, no further delay should take place in collecting a sufficient quantity for carrying out any proposed renovation. Continue to attend to the gathering and storing of Pears and Apples as they ripen. Tomtits are now doing all the mischief they can to Pears. Some people, who are learned in such matters, tell us that they counterbalance any amount of evil they do by destroying legions of insects at certain seasons of the year, but I have doubts on this point, and have sometimes acted on them with evident advantage to the Pears, and without being able to notice any alarming increase of insects. Gather Peaches, Nectarines, and Figs as they ripen; this has been an uncommonly favourable season for the latter.

FLOWER GARDEN.

If Pansies are to be grown well the bed must be renewed yearly, and in order to secure a good spring bloom the young plants obtained as cuttings or side shoots from the old favourites, in addition to any new varieties which may be bought, should be soon planted. It will be requisite that the bed for their reception should be prepared, in order that they may be planted out at the end of the month. Auriculas will now begin to excite and require more attention. All decaying leaves must be removed, and occasional top-dressings be given. Examine seedlings that have been pricked out; if the roots are raised above the surface, which is often the case, re-insert them by making a notch in the soil with the handle of a budding-knife or a piece of ivory. Pinks should be planted out without delay. Keep a sharp eye for seed of Carnations and Picotees, and carefully examine all pods. The soil for potting-off the layers ought now to be in readiness, keeping it, if possible, under an open shed, as it is then fit for use at any time. Dahlias must, to secure success, have unremitting attention. Pluck off all blooms which are not promising, and cover, &c., as required. Take care that the blooms intended for exhibition do not chafe against the covers.

GREENHOUSE AND CONSERVATORY.

The weather is now very favourable, and many may hesitate in the work of introducing the house plants while the promise of a late summer is before them. It is dangerous, however, to trust anything to the weather at this period of the year. Cloudless days are very delightful, and thrice welcome just now, but it not unfrequently happens that they are succeeded by nights on which clear nipping frosts are also an accompaniment; therefore the kindly work should proceed uninterruptedly. Let it, however, be understood that these precautionary hints apply chiefly to plants whose tropical origin renders them peculiarly liable to injury from absolute cold. Where the opportunity of partial protection exists, many hardwooded plants may with advantage be allowed to stand out until the end of the month. Let a scrupulous examination be given to the condition of each plant, and defects in the soil or drainage of the pots at once remedied; clear off moss, remove insects, and replace stakes. Luculias and other winter-flowering plants growing in the border must be freely exposed to light and air, in order to have the growth well ripened and to insure a fine display of bloom. Also see that all plants are clear of black thrips, for this pest is particularly active just now wherever it is allowed to gain a footing, especially on Luculias and plants in a growing state. The ordinary precautions for obtaining a supply of common flowering plants throughout the winter months should be progressively continued. Violets should be potted or planted in a frame; Mignonette thinned and sown; Hyacinths, Tulips, and other bulbs potted and plunged; Pinks for forcing encouraged; and Cinerarias duly attended to. Roses in pots should occupy a fair share of attention. Young plants may yet receive a shift, and manure water may be applied to plants in activity.

STOVE.

Winter-flowering subjects should now receive extra attention, as also those succession flowers which have been retarded. Nothing but a light situation will be suitable after this period. Those who are compelled to grow such stock in the shade of late vineries or other forcing houses must be content to endure a partial failure. Let the Begonia family be duly estimated in this respect. Euphorbia jacquiniæflora, if propagated early and frequently pinched, will now form dense bushes; they are generally grown three in a pot, which is much better than single plants. Of course such plants as the winter Gesneras, Achimenes, Scarlet Pelargoniums, &c., will not be forgotten. When there is but one house for the accommodation of tropical plants, considerable care and attention are necessary to properly manage them at this season, as some, having completed their season's growth, require to be kept cool and rather dry, in order to ripen the wood, while others in free growth require to be encouraged with warmth and moisture. If there is no convenience in a cooler house, such plants as have made their growth should be placed together at one end of the stove, keeping them sparingly supplied with water at the roots, and giving air rather freely, which will generally serve to prevent any attempt at a second growth; and those requiring to be kept warm and moist should also be placed together at the opposite end of the house, where very little air should be given, using every care to keep the atmosphere about them moist. See that everything is free from insects, and keep the foliage of Ixoras clean by washing with a sponge and soapy water when necessary.—W. KEANE.

DOINGS OF THE LAST WEEK.

A HEAVY shower on the 8th and 9th, which flooded our walks and sent to waste thousands of gallons of water, which would have been valuable if we could have preserved it, has saved us from all thoughts of out-door watering at the end of the week, and what had been watered with sewage previously would just be the better fitted for the downpouring of the sweet water from the clouds. In looking round after the flood-showers of the morning of the 9th, we did not see that anything had suffered except some fine rows of Madame Vaucher Pelargoniums, the bright white looking a little dingy, and many petals being gone, and also some massive rows and beds of yellow Calceolarias. The wind and the rains have washed off the blooms in bushelfuls. A month or a fortnight ago we should not have so much cared, but from the middle of September there is but scant time for the young shoots to throw up similar dense masses of bloom. Hitherto, even when the weather was dry and hot, they have been everything that could be desired, and therefore in this respect we do not at present design to imitate some of our ablest coufières who have given up Calceolarias altogether, and substituted yellow-leaved Geraniums in their place; very pretty it is true, but not equal to the Calceolaria for a mass of yellow or orange.

We may here mention that from different reports which reach us, *Calceolarias* do best when treated as we advised years ago—namely, never to give them, if possible, any artificial heat. Much also depends on putting the cuttings in as late as possible under a cold pit or frame, for we are satisfied when they begin to root after Christmas. They will stand rougher treatment before they root than afterwards. These cuttings are generally 1½ by 2 inches apart, and put in rough sandy loam they lift with little balls, to be transferred to earth pits at 4 or 6 inches apart in March, and so as to receive a little pro-

tection. Thus treated it is rare we have on them any fly or insect.

KITCHEN GARDEN.

As the days shorten, we partially removed the Pea haulm, and soon will do so wholly, between our beds of Celery. The shade hitherto, morning and afternoon, has done good in rendering watering unnecessary, a matter of importance wherever water is scarce, and also as saving a good amount of labour. The beds of *Celery* run north and south, and, therefore, they had the full sun before and after midday, still the shade by their sides, which broke the strong afternoon sun, was of importance. By mistake some of our Dwarf White Incomparable Celery that came in second and third, was taken up, and it was very fair after ten days' earthing, with two or three weeks' tying-up previously; out of plants 16 inches in height, a length of 9 inches was very good. When earthed-up for three weeks such plants ought to have had nearly 12 inches of beautifully blanched head as sweet as a nut.

We have tried many kinds of Celery, reds, pinks, and whites, and we have found them all solid, sweet, and good, if they were grown with the help of sweet decomposed manure, were prevented becoming dry, and received a slight shade in their earlier stages. We would, however, recommend those who have little room to try a bed of the Incomparable, placing the plants about a foot apart each way. We have had several complaints from people who have acted on our recommendation, who say they cannot get on with it, it grows so slowly. Well, there is this objection to it—it will come very late, if you depend on seedling plants sown out of doors. It should not be sown later than March, and then in pots or pans where there is a little heat, as in the coolest part of a Cucumber-box, and it is as well to let it have a little heat after it is pricked out, but a small shallow box would hold a large number of plants at 1 inch apart, and when fully established they could be pricked out under a slight temporary protection in rich compost 3 or 4 inches apart, and be lifted with balls so as never to feel moving. A bed from 3½ to 4 feet wide will grow three rows in perfection. Then the earthing-up is a mere trifle in comparison to the taller-growing kinds; a foot in height may be considered a fair average. From plants not quite so much in circumference as the arm of a strong man, we have often seen a far greater bulk fit to go to table, than could be had from huge plants as large in circumference as a man's thigh, and fully a yard or more in height. These dwarf Celeries save much ground and labour, but we have nothing to say against the stronger-growing sorts where ground and labour are of little importance. We generally grow a little of the stronger reds, &c., for variety. The Incomparable was first sent out by Mr. Turner, of Slough.

Before these showers came the ground with us was so dry that it was of little use planting, unless we could have afforded to water well. Now we shall fill up every vacant place with Cabbages and Winter Greens, also Lettuces and Endive. The earliest Broccolis, Brussels Sprouts, and Borecoles are looking well, but it is advisable to have plenty in the shape of young plants, as it is easier to pull up in spring when the ground is wanted than to suffer from any deficiency in the supply. Where the ground is at all stiff and adhesive we would recommend throwing it into ridges—say 4 feet at the base, and planting the sides and apex with Lettuces and Endive. They are not likely to suffer from dryness now, but they will have a better chance of escaping damping in winter than those on the level. Last year we lost most of our Lettuces and Endive planted near the foot of walls and fences. Severe as the winter was, we scarcely lost a plant of those thus planted on steep ridges.

We sowed Radishes and Turnips, the latter to stand the winter. Our early kidney *Potatoes* have kept good after being taken up, but they were quite ripe; only one here and there has shown signs of disease. With respect to the advice lately given as to cutting down the haulm and removing it, in the case of late Potatoes, several parties have told us that the cutting-down has no effect on the crop so far as ripening is concerned; for after allowing the roots to remain for a month the tubers were as unripe, as soft and waxy, as when the haulm was cut down. All we can say is that such results are contrary to our experience. The early removal of the haulm prevents to a great extent the disease acting on the tubers. These tubers, left in the soil, however late the kinds, will not increase, or but little, in size; but according to all our experience they become more ripened and more mellow, and thus the tubers are more fit for all purposes, though smaller in size than usual. As the matter is of great general importance we should be glad to have, not opinions, but facts and experience bearing on either side of the question. Meanwhile, as the disease is likely to appear whenever we have a season similar to the present, we would earnestly advise, and especially where the kitchen garden is small, to grow only the earlier small-topped kinds in the garden, and to have the main supply for the mansion grown in the field, where fresh soil can be afforded every year, and where also more room can be given between the rows than the gardener in general can afford in his limited space, where crop must follow crop without a week's intermission, or even several crops must be on the ground at once. The same rule would hold good as respects Turnips and Carrots. The earliest are best and most easily obtained from the garden, but without great preparation and attention no old kitchen garden will grow Turnips and Carrots so sweet and rich in flavour as they will be in a field, where they only appear after so many years' rotation, and in fresh, almost to them maiden soil. If we were connoisseurs of Turnips we would never use one after August and September from an old garden if we could obtain them from an open field. We should not so earnestly advocate as as we do the enlargement of kitchen gardens, and the limitation of lawns, were it generally understood that the bulk of such roots and the rougher vegetables were to be cultivated well in an open field. We know that the cultivator and the consumer would be better satisfied. Of course we do not allude to those huge gardens that are seldom fully cropped, but show almost at any time large quarters in fallow, and which generally, like farm land, bear only one crop for the year. But the majority of kitchen gardens must be treated in a different way, the great question being, How much and how many successions can be obtained in little space? When that is long continued the produce must suffer in quality.

ORNAMENTAL DEPARTMENT.

We intended to have said much about plants and propagating, but our pen has gone so fast that we can only allude to one thing—namely, placing *cuttings* for next year's flower garden in pots and boxes. Some critics have written to us to say that they like best to insert their cuttings early in the open air, and to lift and pot or box them when struck. We say, Let everyone follow the plan that answers best. We have often adopted the plan when cuttings could be taken off early. Even then, however, the plants often felt the taking-up, and potting, or boxing, and this also involved time and labour. As we cannot well take our cuttings, even low side shoots, very early, we prefer inserting them thickly in pots or boxes at once and placing them under glass before there is any danger. We thus save taking up and re-boxing. Very shallow boxes from 2 to 3 inches deep will do for most cuttings. When the wood we can get hold of enables us to have them deeper we are satisfied if the soil is of that depth, and we can top-dress if we like afterwards.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

CUTTING AND BORING HOLES IN GLASS (*Amateur Gardener*).—We have no experience in cutting glass except with a glazier's diamond, but we extract for you the following from an American contemporary:—"Any hard steel tool will cut glass with great facility when kept freely moist with camphor dissolved in turpentine. A drill-bow may be used, or the band alone. A hole bored may be readily enlarged by a round file. The ragged edges of glass vessels may also be thus easily smoothed by a flat file. Flat window glass can readily be sawed by a watch-spring saw by aid of this solution. In short, the most brittle glass can be wrought almost as easily as brass by the use of cutting tools kept constantly moist with a camphorised oil of turpentine."

DOUBLE ANTIRRHINUMS (*W. H., Ayr*).—Double or semi-double Antirrhinums are by no means unusual. Some were advertised a few years ago by a London nurseryman, but they did not take, nor are they ever likely to be popular.

White Everlasting Flowers (*F. A. S.*).—They may be bleached by submitting them to the fumes of burning sulphur. The caterpillar that eats "the flesh of the Rose leaves," is the larva of a small moth, but we could not identify it unless we saw specimens.

Ailanthus glandulosa Seeds.—*Mrs. Corrie* and others wish to know where these can be procured.

Concreting Peach Border—Division Wall (*A Recent Subscriber*).—A depth of 2 feet will be sufficient for your Peach border. We would not concrete it; if the subsoil is dry it will require nothing, if wet you must drain it by laying the pipes in a slanting direction across the border. A main drain should be provided at the lowest point to carry off the water. If your house is in two divisions you will require a wall, not otherwise. It should be 9 inches thick to the ground line, and be carried up with 4½-inch work as high as your front wall. The division wall will support the plate of your glass division.

Maréchal Niel Rose in a Vinery (*X. Y.*).—We should advise you to let alone the vigorous Maréchal. Grow it at present without stopping the shoots, but shorten them back, about the end of February, to well-ripened wood. Do not then take too much off, as it requires long pruning. An occasional temperature of 70° in the late vinery would not be too much, though 60° would be far preferable; but as your plant is in a late vinery it will not be kept at 70° for long, except in hot sunny weather, when all plants can stand additional heat owing to additional light. Roses will not endure a forcing heat in the short days of winter.

Leaves Infested with Red Spider (*C. R.*).—The whole of the leaves sent are badly infested with red spider. Syringe them every alternate night for a week with a solution of 3 ozs. of soft soap to the gallon of water at a temperature of 120°, and water at the root with 2 ozs. of guano to a gallon, giving a good soaking.

Portulaca Wintering (*Inexperience*).—The majority of those used in gardens are annual, but some of them are perennial, as P. Thellusoni, which is grown in a light open soil, loam mixed with crocks and old lime rubbish, abundant drainage, and a little peat, giving only a little water occasionally to keep the plants from shrivelling. The shoots should be trained to a trellis.

Chorozema Leaves Eaten (*Idem*).—The leaf sent appears to be eaten by some caterpiller, but which we cannot say in the absence of a specimen. At night, after dark, place a white sheet, stand the plant on that without shaking it, and then shake briskly, and, if a caterpillar or beetle, it will fall on the sheet and may be secured and destroyed. It may, however, be slugs; search for them after dark with a lantern.

Wintering Hova carnosa (*Idem*).—It will winter in a greenhouse quite safely if you give no more water than will keep it from shrivelling. There is no necessity to shade or syringe for the cause you name; it would only tend to make the plant go off. Water sparingly, giving only just sufficient to keep the leaves plump or fresh, and do not syringe from now until the plants begin to grow.

Glass for Early Cucumber House (*Inquirer*).—Hartley's rough plate glass will answer perfectly, and the quarter-inch is the preferable thickness. Thin plate glass is worse than sheet for breakage.

Border Planting near Beech Trees (*Lizzie*).—The Beech trees, we presume, shade the border, and the plants put in require to be such as will grow under them. There is nothing that will look so well as Ivy, because it is the only thing which will thrive. It will grow on the soil, but not on the Beech, owing to the smooth bark. We would carpet the ground with Rægner's Ivy, margin the border all around with Stachys lanata to the width of from 18 to 24 inches, and on both sides of the Beech trees have circles in diameter half that of the border from the Stachys to the Beech trees. The circles should be twice their diameter apart, and we would fill them with Vinca elegantissima.

Various (*A Young Gardener*).—The best plan of getting a stock of Calceolarias for bedding is in October, before frost, to prepare a frame for cuttings, choosing a sheltered and well drained situation. Put in about 6 inches of good moderately rich loam with about a third of leaf soil well mixed, and cover with an inch of sand; then, before frost, take cuttings of the growing shoots with two joints and the growing point, removing the lowest pair of leaves; insert the cutting well up to the leaves and at about 1½ inch apart, water after putting in, and give protection only from frost. In severe frost protect with a double covering of mats and straw, and allow them to remain until a general thaw, then remove them gradually. In mild weather give abundance of air. At the end of March prepare in the open ground a place like a Celery trench, and plant in it the Calceolarias at 3 or 4 inches apart, watering well, and protecting from frost by mats over hoops. In May plant out where they are to remain, lifting with good balls. The best Peas for sowing in November are Dillistone's Early and Sangster's No. 1. It is not a good plan to burn the "noses" of Onions to make them keep, though it may be done if care be taken not to overheat the bulb nor burn too closely.

Tuberose Bulbs the Second Year (*S. W.*).—As a rule they are not worth keeping for a second year's flowering. They are so weakened by flowering as scarcely to be good for anything, though by taking care to have them well ripened the first year we have known them flower fairly the second season.

Lophospermum after Flowering (*Idem*).—Cut away all the old bare parts, encourage fresh shoots from the base, and keep the plants dry but without flagging. Keep them in a greenhouse.

Hyde Park (*Sarah Ann, Clara, and Amy Alice*).—A report will appear in a week or two.

Acacia lophantha, Mandevilla suaveolens, and Eucalyptus Wintering Out of Doors (*Delta*).—Except in a dry soil your prospects of wintering these safely even with protection is not great, though it is likely they would succeed against a south wall with protection. As you have duplicates it is well worth trial, and we should like to know the results. Saccharzias and Allamandas would probably winter in a greenhouse if you kept them dry, giving no more water than sufficient to maintain vitality. Six ornamental-leaved Begonias to grow in a greenhouse are—Marshalli, Victor Lemoine, Masterpiece, Amabilis, Picturata, and Beltine Rothschild. Now is a good time to plant out Roses from pots, they become established before winter. Mulch before frost with litter.

Propagation of Lemon-scented Verbena and Heliotrope (*J. C. H.*).—The Aloysia citriodora (Sweet-scented Verbena) and Heliotrope strike from cuttings of the growing points of the shoots inserted in sandy loam with a surfacing of sand, placing in a cold frame, shading from bright sun, and keeping close. After August, however, they require a bottom heat of from 70° to 75°. We think you fail from putting them in too rich soil not sufficiently sandy, and from keeping them too wet; the soil should only be moist. The cause of the Geranium cuttings turning black at the base and falling down is too much humus in the soil, and the evil may arise from watering with pond water containing decomposing matter. Why not put the cuttings in the open ground and let them take care of themselves? They do much better in that way than when pampered in pots, and do not need a tithe of the care in wintering.

Phalænopsis grandiflora Treatment (*E. M. N.*).—Grow it on a block of wood or cork. Oak wood is to be preferred, removing the bark, and place a little fibrous peat on the block; then put on the plant, covering the root slightly with sphagnum, and secure the plant firmly with copper wire. Sprinkle lightly with water two or three times a-day according to the season. The temperature you name is rather low for this Orchid, but it will succeed, only do not keep it too wet. The damp heat will lessen the necessity for sprinkling. Give it the warmest part of the house.

Treatment of Echeveria metallica glauca (*H. T.*).—Pot the plants in a compost of light loam two parts, one part old cow dung, one part crocks or broken bricks, and one part sand, with good drainage. Keep them in a greenhouse in a light airy position, and give no water in winter except to keep the leaves from shrivelling. When growing, water as the soil becomes dry. It may be planted out of doors at the end of May, and is very fine as an edging plant for beds; take up and pot before severe weather sets in.

Stopping Zonal and Double-flowering Geraniums (*T. B. S.*).—For flowering in November the last stopping should be given at once, and the trusses of bloom removed up to within six weeks of the time when you require them to flower. If the plants were recently stopped do not stop again now.

Tacsonia Van-Volxemi not Thriving (*Joseph Clark*).—Having had it three years without progressing, we would make for it a border 2 or 3 feet wide, and 2 feet deep, draining it well, and filling it with a compost of two parts fibrous loam, and one part each of peat and leaf soil, adding sharp sand freely. Plant out at once, and water so as to keep the soil moist, but no more, and as the shoots grow train them about a foot from the glass, though it puts out shoots with us and grows partly beneath a stage occupied by plants, and flowers and fruits quite as freely as on the roof, though it is there a mass of fruit and flowers. The other Passion-flowers treat in the same way. It is little use striving to grow them fine in pots. In a border they are magnificent. Water freely in summer.

Coloured-leaved Plants (*Eve*).—Your questions are rather indefinite. The plant which is red is, doubtless, Alternanthera magnifica; the one in black may be Coleus niger. If not, it may be Alternanthera amœna which is very dark this season.

Heating from a Kitchen Fire (*An Amateur*).—The Dublin firm are quite right. You cannot heat your greenhouse from the kitchen fire if the top of the boiler is higher than the level of the floor of the greenhouse. If the difference of level is small, and the top of the boiler is close, and you could have a slight rise to the farther end of the greenhouse, by raising the pipes above the floor, and taking the return-pipe to the bottom of the boiler, then it would do, not otherwise. Hot water will not go down. A small boiler, conical or saddle-backed, costing about £3, and 54 feet of 4-inch piping, would be necessary for such a house; 36 feet, would barely keep out frost. That would cost from 9*d* to 10*d*. per foot, if good piping. We would make the border as you propose, only all through or wider inside, and we would use no ashes. As economy is your object, a small stove, if of iron, with a flat head, better of brick with a stone or iron for the top to receive a vessel of water, would suit your purpose. If you wish to combine cleanliness, efficiency, and economy, have a tiled pathway either at the back or middle of the house, and underneath the tiles a small flue from a stokehole sunk at a so low that the bars of the furnace may be 18 inches below the bottom of the flue. You must have ventilation at the top as well as in front. Openings in the back wall would do, and so would a good opening at each end of the house under the apex of the roof.

Strawberries for North Yorkshire (*W. D.*).—Keens' Seedling, Dr. Hogg, and Vicomtesse Héricart de Thury. Plant now a foot apart each way. They do not require a strong clay; a moderately adhesive loam is best. Trench the ground before planting. Mulch the surface during the summer. If you enclose twenty stamps with your address, and order the "Garden Manual," you will have it post free.

Half-ripe Grapes Cracking (*Sussex Vicar*).—The box arrived in a deplorable state, with the juice dripping from it. Cut half through each lateral—that is, down to the pith between the bunch and the main stem, and keep the house as cool and as freely ventilated as you can. The sap is supplied to the berries faster than they can swell.

Mushrooms Eaten by Vermin (*A Subscriber*).—We never before heard of red spider attacking Mushrooms, but snails and woodlice are to be expected and to be guarded against, the first by looking for them at night with a lantern, the second by trapping in small pots with a little soft moss in them, along with a piece of potato or carrot. We think you must be mistaken as to the red spider in a cellar. We are rather in doubt as to your success, as we hardly know whether you have had a quart or a quarter—a vast difference. We like more heat in a Mushroom bed than 60° at spawning time. When the spawn is running, that is high enough. We should not think of making a bed anywhere from dung in an unprepared state, unless from experience we knew what we were about. It would be better to have the dung in a good state before taking it to the cellar—that is, all the extra steam gone, not wasted, and in that nice position when it is neither wet nor dry. We think with you that very likely your bed was too wet—a rather bad state, as then you cannot water. When tolerably dry, not dry, and well beaten, the manure will heat enough and keep a regular heat longer, and the spawn runs freely. When too wet we have wrapped the bits of spawn into a good handful of short dryish litter before putting it into the bed, and the plan answers well. Keep these things in mind in making the proposed new bed, but do not trouble yourself about the spawn in the old bed, as to how you are to get it out. Let it remain, or go and get fresh spawn for the new bed. The seedling Pansies have their petals eaten into holes probably by the Pansy fly (Agromyza violæ). We know of no remedy.

NECTARINES IN A GREENHOUSE FALLING (*A Subscriber*).—Very likely your Nectarines drop and shrivel up from want of water. From the time the fruit is set the soil should never be dry. After fairly stoning, a good watering to trees in-doors is necessary to secure a free swelling; not watering all the border at once, but at two or three times, with a day or two between. A thorough drenching all over is apt to throw the fruit off.

PAYING A GARDENER'S MOVING EXPENSES (*Tyro*).—You were quite right in paying the travelling expenses of the man when he came, as you express it, "to see and to be seen," before being engaged. In this respect you set a worthy example that ought to be generally imitated. When a wish is expressed to see a new servant before engaging him, then equity requires that the man's travelling expenses should be paid, whether he is engaged or not. We have known very distressing cases where this law of equity has been totally disregarded, and the most defenceless had to put up with what was to him a great loss. A case happened not long ago in which, after a long journey, the gentleman declined to see the man altogether, having in the meantime made other arrangements. All we shall say is, we would have declined to serve such an employer on any terms. We do not know what the legality of the matter may be, but common equity requires that the gentleman who wishes to see a servant before engaging him, ought to pay the travelling expenses at least. It is also common to pay the travelling expenses of a servant by rail or other means in going to a new place. We know of many cases in which gardeners have had all expenses paid at once. In other cases they received nothing, chiefly because they were too proud to mention it. In a few cases such expenses were refused when asked. There is, therefore, so far as we know, no general rule on the subject that would at all take the place of anything like a legal enactment. Still in most respectable places the practice is to pay the new gardener his travelling expenses, even without any previous understanding on the subject; but it is best in every way that all such matters should be settled before moving, as what would be a trifle to a gentleman, would in the case of long distances be often a serious thing to a gardener. To lessen the expense of moving we have known of many cases of great sacrifice in selling furniture, &c. This would open a wide question on which we cannot now enter, as to the propriety of gardeners' houses being furnished, and a per-centage charged for the use of all that was bulky. If no arrangement as to money has been made, and your new gardener is likely to suit, we would advise paying the moderate expenses of moving, as that encouragement in the case of a good man will certainly be more than repaid in that attention which nothing stirs up so thoroughly as a sense of kindness and a feeling of gratitude.

SCALE ON MYRTLE (*Idem*).—With regard to your fine Myrtle which has so much brown scale on it, you cannot do better than wash off the scale with weak soap water. The best and simplest cure we ever tried is to make some size or jelly glue water just as strong as, when you put your finger and thumb in it, and squeeze them together, you will find a little stickiness between them. Dip the head of the plant in such water, or syringe it well all over, and place it from twenty-four to forty-eight hours in a shady place, then rub the dry head of the plant through your fingers, and much of the glue, and insects, too, will fall off; then syringe heavily, with the plant laid down and turned over and over, with clear water at 120°. If there be only a few scale insects, it will be best to wash them off with weak soap water, and then syringe with clear water. If there are only a few, you may also try the phytosmegma advertised in our columns. It is just the thing for a lady to use—no filth, merely to blow through a little tube.

PLANTING FOR A FRUIT BORDER (*Idem*).—Whatever you fill your narrow border with will injure your fruit trees more or less. The Pyrethrum is best obtained from seed every year. We could easily satisfy you with bedding plants, and bulbs would be splendid in spring and early in summer. A row of Clarkia pulchella would give you rose purple, and Erysimum Peroffskianum behind it would give a row of orange, and, if you cut off the seed-pods, would last the season.

PAVING TILES IN ORCHARD HOUSE (*G. C.*).—The coolness of the tiles in the ground vinery must be owing, when the sun is shining, to the shade of the foliage or the amount of air. With your opening for air at each end at the top in such a season as this, we would have greatly reduced, except at midday, the 4-inch openings between the bricks on which the vinery rests. Everything is late this season, and to ripen fruit at all early and well we would shut in more sun heat by lessening the amount of air at bottom. We would also sprinkle the tiles with sulphur, or rather brush them over with a paint of water, soft soap, and sulphur. Even the top air we would much reduce from 3 P.M. to 9 A.M.

LIFTED VINE (*D. M.*).—We think the Vine has recovered from the lifting, as the growth is better. Well ripen the wood this year, and we think you will have fruit in the next. When Vines are twenty years old it is much better to plant young ones than to lift and replant. Young Vines will bear well the second year, and are far superior to old Vines lifted.

STOVE AND PATENT FUEL (——).—No flueless stove is fit for heating a conservatory. The fumes from the fuel always injure the plants.

PROPAGATING BEDDING PLANTS—TRANSPLANTING APPLE TREES (*J. W. L.*).—After the middle of September it is well to put Geranium cuttings in boxes or pots, and place them in a frame, pit, or house. Verbenas and plants of a similar nature strike in a sweet mild hotbed of from 70° to 75°. The Apple trees you ought not to remove until fully half the leaves have fallen, and in lifting preserve all the roots practicable. The Geranium leaf enclosed to us belongs, we think, to Culford Beauty, but we cannot name plants, and especially florists' flowers, from leaves.

PROPAGATING POINSETTIA AND CLEMATIS JACKMANNI (*Clematis*).—It is now high time to return the Poinsettia under glass, giving it a light airy position in a cool stove. The Clematis may be propagated by cutting off the ripened side shoots, putting them into sandy soil, and covering them with a hand-glass. A safer plan is now to layer the firm side shoots in pots sunk in the ground, making a cut at a joint as for Carnations, layering that part in the pot, and securing the shoot with a peg. The layers will be well rooted in twelve months.

ACHIMENES AND GLOXINIAS FAILING (*Disappointment*).—From the head of Achimenes sent, which is very fragmentary, we fail to recognise any recent attack of insect pests, and can only conclude that the plants are grown in too cold and too dry a structure, and have had too much or too little water, improper soil, and inefficient drainage. Which of these causes is the right one we cannot say, as you give us no particulars of your treatment.

LAWN SAND (*Mrs. A. S.*).—The lawn sand does certainly destroy weeds on lawns, especially Plantain, but our experience with it is limited.

VARIOUS (*Mrs. C.*).—An old but fine Peach is Violette Hâtive (English Galande), of hardy constitution, succeeding where most others do not. Red Rover is a good Rose, fiery red, and succeeds well against a wall, and so does Glory of Waltham, a crimson; both are Hybrid Perpetuals. Either would contrast well with the Tea varieties. Remove all the canes of the Raspberries of last year's growth, whether they have borne fruit this year or not, retaining only those of the current year, and of these select about six of the strongest on each stool, and cut all others away close to the ground, or, if further from the stool than a foot, pull them up. Remove about a foot of the points of the canes left, and secure them to stakes after the leaves have fallen.

TOPPING POTATOES (*H. C.*).—The chief objection to topping Potato haulms is that it tends to check the growth of the tubers, and if the Potatoes are about half-grown it is apt to cause second growth, and so bring on superfuberation. The chief causes of large haulm are too fresh manure and close planting. See Mr. Fish's remarks in "Doings of the Last Week" this day.

PLACING A VINE OUT OF DOORS (*Subscriber, Dublin*).—The wood being brown and hard, it will not injure the Vine in the least to place it out of doors. Put it in front of a wall or fence with a southern or warm exposure. It will be necessary to plant before winter, to place it in a house, or to protect the roots from frost. Cobæa scandens does not require any particular treatment in winter. Keep it rather dry at the root, but not so much so as to cause the wood to shrivel or the leaves to turn yellow prematurely. It will flower next year. Gloire de Dijon is a good climbing Rose for an arch if the situation is not very much exposed.

SELECT FRUIT TREES (*F. M.*).—At the distance you name you may have pyramidal trees on their own or the free stock, the Pear on the Pear, &c. *Apples:* Lord Suffield, Cox's Pomona, Dumelow's Seedling, Bedfordshire Foundling, Gooseberry, Cox's Orange Pippin, Melon, Pitmaston Nonpareil, and Blenheim Pippin. *Pears:* Beurré d'Amanlis, Louise Bonne of Jersey, Williams's Bon Chrêtien, Beurré Hardy, Beurré Diel, Marie Louise, Jean de Witte, Bergamotte Esperen, and Ne Plus Meuris. If you want an early kind, have Doyenné d'Eté, or if one for stewing, Catillac. *Plums:* Early Orleans, July Green Gage, Golden Gage, Victoria, Prince Englebert, Belgian Purple, Kirke's, Coe's Golden Drop, and Jefferson. *Cherry:* May Duke; and *Nut:* Cosford.

SEASIDE PLANTING (*W. H. S.*).—With one failure before you it is well not to be too speculative, but the following trees and shrubs are known to stand well—viz., Tamarisk, Euonymus japonicus, Hollies, double-flowering Furze, Evergreen Oak, Ligustrum ovalifolium, Sambucus racemosa (scarlet-berried Elder), Laurustinus; and for giving shelter plant thickly of the common Elder, than which nothing does better, and Ontario Poplar, and with shelter of this kind you may have Pinus austriaca, Laricio, and sylvestris; Picea nobilis, Pinsapo, Nordmanniana, grandis, Fraseri; Cupressus Lawsoni, macrocarpa; Junipers, Arbutus, Daphnes, Cotoneasters, and Berberis; Thuja Lobbii, Wellingtonia gigantea, Thujopsis borealis, Sycamores, Acacias, Elms, Beech, Portugal Laurel, and Yew.

REMOVING ROSE AND FRUIT TREES (*St. Edmund*).—The end of September is much too soon to remove Rose trees, Apricots, Peaches, &c. We should defer lifting until the end of October or beginning of November, allowing the leaves on the fruit trees to partially fall before the removal. In lifting, be careful to take up the trees with good roots, preserving all the fibres and soil firmly adhering to them, but remove that which is loose, and keep the roots from the influence of a drying air by covering with mats. Give a gentle watering after planting, but not if the soil be very wet, and mulch with litter round the stems as far as the roots extend. You may gather Tomatoes that have attained their full size, and they will ripen in-doors perfectly.

CATERPILLAR ON GRAPES (*S. S.*).—The only caterpillar in your enclosure was smashed. It is, in all probability, that of Opadia funebrana, which, though most partial to Plums, does attack other fleshy fruits in the autumn months. We fear no remedy can be suggested, other than the removal of all infected bunches. The species does not feed at all upon the leaves of the Vine.

ANTS ATTACKING PEACHES AND NECTARINES (*J. B.*).—The best way to destroy them is to search out their haunts and pour into them ammoniacal liquor from the gasworks; or guano will drive them away, if it do not destroy them. This persisted in throughout the summer will thin their numbers, and, when the fruit begins to ripen, with a brush draw a line about an inch broad along the bottom of the wall and the stem of the trees, employing gas tar, over which they will not pass, and repeat this once a-week as long as the fruit season lasts. We have known them come over the wall and up the ends, therefore make the line complete at the bottom, top, and ends of the wall. Have you tried equal proportions of arsenic and honey mixed and laid on saucers, with an inverted saucer over, and two or three thin pieces of wood between, so as to permit the ants to enter?

NAME OF PLANT (*P., Norfolk*).—Pavia macrostachya.

POULTRY, BEE, AND PIGEON CHRONICLE.

WORKING CLASS POULTRY PRIZES.

RESPONSIBLE as I fear I am for leading very many people into poultry-keeping, it will easily be believed I feel great interest in this subject as stated by your kindly correspondents. I am quite sure money would not be wanting, and I venture to suggest that if our trusted "WILTSHIRE RECTOR" can find time to "lick" the thing into shape, and will issue the needful appeal, we shall all confide in him, and there must be dozens of true fanciers who would gladly give their guinea to help so

good an object. I should be pleased, for one, to do so; and who but our good chaplain should start such a Christian—for it would or ought to be a Christian—undertaking?

Perhaps I may have a word or two further by-and-by; I only say now, the prizes should be worth winning. I have been disgusted sometimes—nay, often—in reading schedules of so-called "Cottagers' Horticultural Shows" at the amounts offered. Lady Bountiful "presents" a "special prize" of 5*s.*, or at the outside 7*s.* 6*d.*, and so on. I often wonder people are not ashamed to contend for their guineas in plate, and then offer to "poor" people the few shillings which are the rule, and at the same time expect them to be thankful to any amount for their very small mercies. And, as there ought to be an entrance-fee, I would suggest that it should not, if possible, exceed 1*s.* There are many difficulties that will easily suggest themselves to all acquainted with the subject, but I think they might be overcome, and trust they may be, if the matter be followed up.—L. Wright.

MANCHESTER AND LIVERPOOL POULTRY SHOW.

It was pleasing to find that this year not only did the entries in the poultry department far exceed those of former years, but that the general quality of the specimens exhibited had proportionably improved. The weather on the opening day was exceedingly fine, and the attendance far exceeded that at most previous meetings. All the arrangements for the poultry were excellent, though there was not sufficient help to pen the birds on their arrival so expeditiously as was desirable.

Grey *Dorkings* were good, but not unexceptionably so, many of the pens being evidently injured materially by overforcing, a failing that, like all excessive repletion, brings with it leg-disease in poultry. The class for Silver-Grey Dorkings was quite a failure. Heavy trimming in the *Spanish* class was noticeable to a great extent, and good pens were passed by the Judges entirely on this account. The *Cochins* were by far the best classes seen as yet this year, Mr. Taylor's Buffs and Mr. Sidgwick's Partridge being most praiseworthy, and shown in absolutely faultless condition. The Dark *Brahmas* were far superior to the Light-feathered, and, in fact, the Judges seemed to be perplexed to find any pen that was a worthy recipient of the third prize for the latter variety. Although the *Game* classes abounded with good birds, the bulk were either suffering from too recent dubbing of the cocks, or, on the other hand, were by far too young and undeveloped for competition. *Hamburghs* generally were the best-filled classes in the Show, the Blacks, the Golden-spangled, and the Pencilled of both varieties being such as have made the Lancashire breeders so celebrated for their specimens of these local favourites. *Polands*, which at most shows are but badly represented, were here not only shown in abundance but of an excellence for which we were quite unprepared. The uniform high perfection of the crests of the pullets must be especially referred to. *Crève-Cœurs* were abundant in the Variety class, as were Malays far beyond mediocrity, and also some first-rate White Dorkings. *Bantams* were hardly sufficiently matured to be seen to advantage, dubbing combined with heavy moulting having told considerably against them.

Of both the Rouen and Aylesbury *Ducks* it is difficult to speak too highly—in fact, both varieties have rarely been better shown. *Geese* were very superior in both classes, but the *Turkeys* were scarcely so good as those shown at some of the previous exhibitions this year.

We understand that the erection of all the pens, and their protection from sudden storms by means of awnings over the pens, but still leaving sufficient room for the comfort of the visitors, were carried out under the direction of the Messrs. Jennison, of Belle Vue, Manchester, and we cannot but suggest that many of the Lancashire and Yorkshire committees might enhance greatly the successes of their shows by becoming close copyists. The feeding and watering of the birds were in all cases very carefully carried out; and although so many other objects of interest were presented on all sides, we think no portion of the Show was more generally inspected by the public than the poultry department. We published last week a list of the awards, as well as the names of the Judges.

THE BIRMINGHAM POULTRY SHOW.

The prize lists for the next of the great annual exhibitions at Bingley Hall—the twenty-third of the series—which commences on the 25th of November, are in circulation, and will, we have no doubt, be regarded with satisfaction by every well-wisher of this important undertaking. They are more comprehensive than any which have been previously issued, the Council having evidently spared no pains to render them as useful and generally acceptable as possible.

The principal points to be mentioned are that ten-guinea silver cups, or other articles of plate, are offered for the best Dorking cock, for the best Cochin-China cock, and for the best Brahma cock; and for the best Black or Brown-breasted Game cock; £5 silver cups for the best Spanish cock, for the best Pencilled Hamburgh cock, for the best Spangled Hamburgh cock, for the best Black or Spangled Polish cock, and for the best Game cock among the Duckwinged, Black, and Brassy-winged, or White and Pile. It is expressly stated that where a bird takes one of these pieces of plate the money prize specified as the first for that particular class will be withheld. An extra prize of £5 is offered by Mr. H. Lloyd, jun., for the best Buff Cochin cock of the present year, bred by the exhibitor, who must reside within twenty miles of Birmingham. The winner of the cup for the best Black or Brown-breasted Game cock will receive an extra prize of £3 3*s.* from Messrs. M. Billing, Son, and Co., and the winner of the other cup for Game cocks a silver medal, value £3 3*s.*, from Mr. Ottley. Mr. J. Watts will give, in addition to any other prize, £3 3*s.* for the best pair of Hamburgh hens or pullets, and a few amateurs an extra prize of £4 4*s.* for the best pen of Black East Indian Ducks. The number of class prizes has been slightly curtailed by the omission of the following:—The fourth for Partridge Cochin cockerels, the fourth for Silver-pencilled Hamburgh cocks, the fifth and sixth for Golden-spangled Hamburgh cocks, the fifth and sixth for Silver-spangled Hamburgh cocks, the fifth for hens or pullets of the same variety, the sixth for Black-breasted Red Game cockerels, the sixth for hens or pullets of the same variety, the sixth for Brown and other Red cockerels, and the fifth for Duckwing or other Grey and Blue cockerels.

The schedule for Pigeons has been enlarged and improved by the opening of classes for young Carriers of the present year—"Black" and "Any other colour;" for Barbs bred in 1871; and for Silver Dragoons; a third prize of 10*s.* being allotted to the Fantails, of which there is generally a large muster. Over and above the class distinctions a few members of the Birmingham Philoperisteron Society offer three silver cups, value £3 3*s.* each, for the best pair of Carriers, the best pair of Fantails, and for the best pair of Dragoons. The Birmingham Columbarian Society give a silver cup, value £3 3*s.*, as an extra prize for the best pair of Antwerps, and one of the same amount for the best pair of any new or distinct variety not enumerated in the list. An extra prize of £3 3*s.* is offered by Mr. J. H. Dawes for the best Pouter cock; a silver medal, value £3 3*s.*, by Mr. Ottley, for the best Pouter hen; and a silver cup, value £3 3*s.*, by Mr. R. Fulton, for the best pair of Barbs hatched during the present year.

The entries in all departments will close on Saturday, October 28th, and intending competitors should make application to Mr. Lythall, the Secretary, for copies of the lists and regulations.

CRYSTAL PALACE POULTRY AND PIGEON SHOW.

We have received a copy of the schedule of the above Show, which is to be held on November 14th, 15th, 16th, and 17th, in the nave of the Palace, a place unsurpassed for an exhibition of this kind. Last year the Pigeons only were placed there, and the lights and surroundings added so much to the success of the Show, that the poultry are this year also to be exhibited in the nave.

Seldom have we seen better classified or more valuable prizes offered. There are thirty-five silver cups and extra prizes for poultry, and twenty-four for Pigeons, and money prizes amounting to nearly £1000. We little expected three years ago, when we first drew attention to the want of a Poultry and Pigeon Show in London, that one would in so short a time have achieved the success and taken the position amongst our annual shows that the Crystal Palace Show has done. This is due in a great measure to the energies of the Committee, the confidence placed in them by exhibitors and friends, and to the fact that London is in most cases in direct communication by rail with nearly every town in Great Britain.

There are separate classes for old and young birds in most of the varieties; the cocks shown singly, and pairs of hens or pullets. This is a great improvement, for last year in many classes old and young competed together. The poultry have three prizes of £3, £1 10*s.*, and 10*s.* The Pigeon prizes have been increased to £2, £1, and 10*s.* The Dorkings are divided into eight classes, with four cups distributed amongst them. The cocks have a separate class, and a cup to compete for. Cochins have ten classes and eight cups. The Whites have out of this number three. Dark Brahmas come next with four classes, Light the same number. There are six cups between them. Spanish have three cups and four classes. French are divided into four classes and two cups. Hamburghs are to be shown cock and hen together. Game have eight classes, the Duckwings competing by themselves. There are three cups and an extra prize distributed amongst the Game. Polish are divided into three classes, and a cup for the best pen. There is a separate class for Malays, and a cup for Any variety, and three money prizes in addition. Black or Brown Game Bantams have a class for old birds, cock and hen; all the young ones are to be shown as single cockerels and pairs of hens or pullets. And here we find a novelty—a cup is to be given for the best pair of Wheaten hens. All Game Bantam breeders know how necessary it is to obtain these birds if they wish to get some good chickens. Prizes are never offered to them, still a great many are distributed in different parts of the country, and, no doubt, we shall find a good entry of this very useful variety. There are three Selling classes with eight money prizes in each class. Last year nearly the whole of the birds entered in these classes changed owners.

The Pigeon schedule is, perhaps, the most comprehensive ever issued, including as it does nearly every variety. Pouters come first

and are divided into sixteen classes, including three for birds bred in 1871, and there are five cups for competition amongst them. Carriers have no less than nine classes. We notice a cup is offered for the best Blue or Silver bred this year. As this is an entirely new class, it will cause some interest amongst Carrier fanciers. Tumblers and Barbs have separate classes for old and young. There are also classes for Cumulets, Doves, and Pigmy or Austrian Pouters.

The entries close October 16th. All the birds are to be at the Palace on Monday, November 13th. The judging takes place on the 14th, and the Show opens on the same day. The winning pens are to be sold by auction at noon on the 15th, the Show closing at 4 P.M. on Friday, the 17th, when the birds will be packed and despatched as quickly as possible.

CHELTENHAM POULTRY SHOW.

This was held from the 29th to the 31st of August, and as regards the number of entries was a great success, upwards of 600 pens of poultry and Pigeons, many of them of great excellence, having been sent by leading exhibitors. Notwithstanding the number of visitors reached nearly 3000, we are sorry to learn that the affair has not proved a financial success, though the Secretary was untiring in his exertions to promote the interests of the Show.

Cochins.—*Cinnamon and Buff.—Cock.*—1 and 3, W. A. Taylor, Manchester 2, Mrs. Allsopp, Worcester. *hc*, R. Fulton, Deptford; D. W. J Thomas, Brecon. *Hens* —Cup and 3, W. A. Taylor. 2, J. R. Fowler, Aylesbury. *hc*, G. Heath Nailsworth; J Siehel Timperley. *c*, J. Bloodworth, Cheltenham. *Brown and Partridge-coloured.—Cock.*—Cup and 3, W. A. Taylor. 2, J. Stephens, Walsall. *Hens.*—1, W. A. Taylor. 2, Lady Gwydyr, Ipswich 3, E. Tudman, Whitchurch. *White.—Cock* —1, J Sichel. 2, Miss Brisbane, Cheltenham. 3, A. J. E. Swindell, Stourbridge. *Hens.*—1, J. Sichel.

Dorkings.—*Coloured.*—Cup and 1, J. Martin, Worcester. 2, J. Watts, King's Heath. *Silver-Grey.*—1, O. E. Cresswell, Hanworth.

Brahmas.—*Dark.—Cock*—1, T. F. Ansdell, Conway. 2 and *hc*, E. Barton, Truro. 3, J. K. Fowler. *Hens.*—1, J. Sichel. 2, T. F. Ansdell. 3, J. K. Fowler. *Light.—Cock.*—1 and *hc*, J. Bloodworth. 2, W. T. Storer, Brewood. 3, H. M. Maynard, Ryde. *Hens.*—1, H. Dowsett, Pleshey. 2, H. M. Maynard. 3, Rev. N. J. Ridley, Newbury.

Spanish —*Cock.*—Cup, 1, and 2, E. Jones, Clifton. 3, Mrs. Allsopp. *hc*, H. Beldon, Bingley. *Hens.*—Cup, 1, and 2, E. Jones. 3, H. Beldon.

Game.—*Black-breasted Reds.—Cock.*—Cup, C. Challoner, Whitwell. 2, R. Hall, Cambridge. 3, J. Fletcher, Stoneclough. *hc*, S. Matthew, Stowmarket. *Hen* —Cup and 1, S Matthew. 2 J. Fletcher. 3, W. H. Stagg, Manningford.

Game.—*Brown-breasted Reds.—Cock.*—1, W. Boyes, Beverley. 2, E. C. Pope, Falmouth. *Hen.*—1, C. Chaloner. 2, J. Carlisle, Earby, Skipton. 3, W. Boyes. *hc*, C. W. M. Laxton, Nantwich.

Game.—*Duckwing and other Greys and Blues.—Cock.*—1, S. Matthew. 2, C. Challoner. 3, E. B Pope, Falmouth. *hc*, S. Deacon, jun., Oundle. *Hen.*—1, S. Matthew. 2, W. Boyes. 3, C. Challoner.

Hoddans.—1, R. B. Wood, Uttoxeter. 2, Hills & Co., Brighton. 3, J. Drake, Ongar.

Creve-Cœurs.—1 and Cup, R. B. Wood. 2, J. Sichel. 3, J. K. Fowler. *hc*, Rev. N. J Ridley; J. J. Malden, Biggleswade.

Hamburghs.—*Golden-spangled.*—*Cock* —Cup and 2, J. Rollison, Ottley. 3, Mrs. J. Pattison, Dorchester. *hc*, W. H. Tomlinson, Newark-on-Trent; C. Parsons, Wolverhampton; G. F. Whitehouse, King's Heath; H. Beldon; H. Pickles, jun., Skipton. *Hens.*—1, J. Rollinson. 2, H. Beldon. 3, W. A. Hyde, Ashton-under-Lyne. *hc*, Miss C. E. Palmer, Odiham.

Hamburghs.—*Silver-spangled.—Cock.*—1, H. Beldon. 2, C. Parsons. 3, H. Pickles, jun. *Hens.*—Cup, H. Pickles, jun. 2, H. Beldon. 3, G. Brawn, Sandhills, Walsall. *hc*, Mrs. J. Pattison.

Hamburghs.—*Gold-pencilled—Cock.*—1, J. Rollinson. 2, H. Beldon. 3, C. Bloodworth. *hc*, S. Richards, Truro; S. Smith, Halifax. *Hens.*—1, C. Bloodworth. 2, H. Pickles, jun. 3, F. Perrin, Bristol. *hc*, C. Bloodworth; H. Moore, Weston-super-Mare; F. Perrin.

Hamburghs —*Silver pencilled—Cock.*—1, H. Beldon. 2, H. Pickles. 3, W. Mann, Kendal. *Hens*—1, H. Beldon. 2, W. Mann. 3, H. Pickles, jun.

Hamburghs.—*Black.—Cock.*—1, C. Sidgwick, Keighley. 2, H. Beldon. 3, C. Maggs, Melksham. *Hens.*—1, T. Walker, Denton. 2, C. Sidgwick. 3, C. Maggs.

Polish.—*Golden-spangled.—Cock.*—Cup, W. Harvey, Sheffield. 2 and 3, H. Beldon. *Hens.*—1 and Cup, H. Beldon. 2, W. Harvey.

Polish.—*Silver-spangled.—Cock* —1, H. Beldon. 2, H. Pickles, jun. 3, C. Bloodworth. *Hens.*—1, H. Beldon. 2, H. Pickles, jun. 3, J. Hinton, Warminster.

Polish —*Black with White Crest.—Cock.*—1, T. Dean, Keighley. *Hens.*—1, T. Dean.

Any other Variety.—*Cock*—1, J. Hinton (Malay). 2, Rev. N. J. Ridley (La Flèche). 3, F Wilton, Gloucester (Black Cochin). *hc*, S. Richards (Minorca); Mrs E. E. Llewelyn Bridgend (Sultan). *c*, Rev. A. G. Brooke (Malay). *Hens.*—1, F. Wilton (Black Cochin). 2, J. Sichel. 3, O. E. Cresswell (White Dorking).

Game Bantams.—*Black-breasted Reds.*—1 and Cup, J. Smith, Southwell. 2, J. R. Robinson, Sunderland. 3, T. W. Anns, Clapham. *hc*, Miss A. Reeve, Gotherington; Rev. F. Cooper, Cirencester; Williams & Straw, Southwell. *Brown-breasted Reds.*—1, J. Mayo, Gloucester. 2, W. Dahell, Southwell. 3, S. Stephens, jun., Ebley. *Any other Variety.*—1, Rev. F. Cooper (Duckwing). 3, Col Tickell, Cheltenham (Pile).

Bantams.—*White, Clean-legged*—1, H. Beldon. 2, S. & R. Ashton, Mottram. 3, Lady C. Morston, Falfield *Black, Clean-legged*—1, G. W Robinson, Halifax. 2, S. & R. Ashton. 3, J. Watts (Rose-combed). *Gold and Silver Sebrights.*—1, 2, and 3, M. Leno, Dunstable (Laced Bantams). *hc*, J. Watts (Silver).

Selling Class.—*Cock.*—1 and Cup, H. Beldon. 2, H. Dowsett (Dark Brahma) *hc*, H. Yardley, Birmingham; H. Lloyd, jun., Birmingham; J. Smith, Petworth (Coloured Dorking); Hon. Mrs. A. E. Hamilton, Woburn (Brahms); Mrs. C. P. Noel, Stourbridge (Black Spanish); S. Deacon, jun., Oundle; J. Watts. *Hens.*—Cup, H. Yardley. 2, J. N. Whitehead, Torquay (White Cochins). 3, W. P. Ryland, Erdington. *hc*, T. F. Ansdell; L. Callcott, Oundle (Silver-Grey Dorkings); J. Sichel; G. Tonkin, Bristol.

Ducks.—*White Aylesbury*—1 and 2, J. K. Fowler. Extra 2, G. Hanks, Malmesbury. *hc*, L. H. Ricketts, Banwell. *Rouen.*—1 and *hc*, J. K Fowler. 2 and 3, W. Stephens, Gloucester. *Black East Indian.*—1 and 3, G. S. Sainsbury, Devizes. 2, S. Burn, Whitby. *Selling Class.*—1, G. Hanks (White Aylesbury). 2, W. Stephens (Rouen). 3, Miss E Goodliff, Stilton (White Call). *hc*, R. H. Bush; W. R. Pratt, Oxford (Domesticated Wild).

CHICKENS.

Cochins.—*Cinnamon and Buff.*—1 and Cup, Lady Gwydyr. 2, W. A. Taylor. 3, C. Sidgwick. *hc*, C. Bloodworth; W. P. Ryland, Erdington; W. A. Taylor *Brown and Partridge-coloured*—1, C. Sidgwick 2, H. Lingwood, Needham Market 3, W. A. Taylor. *hc*, A. C. Travers, Falmouth *White*—1, A. D. Cochrane, Stourbridge. 2, R. Woodgate, Tunbridge Wells. 3, J. N Whitehead. *hc*, G. Shrimpton, Leighton Buzzard (2); J. N. Whitehead; J. Bloodworth (2); A. D. Cochrane; A. J. G. Swindell.

Brahmas.—*Dark.*—Cup, T. F. Ansdell. 2, Lady Gwydyr. 3, W. A. Taylor. *hc*, Hon. Mrs. A. B. Hamilton; D. Lane, Gloucester; F. Esser (2); J. D. Peake Chertsey; W. Birch, Barnwell; F. Sabin, Birmingham; B. F. Parrott, Henbury H. Lingwood; J. Watts. *Light.*—1, Rev. J. D. Hoystead, Chippenham. 2, J. Beeton, Erdington. 3, J. Pares, Guildford. *hc*, J. Bloodworth; T. A. Dean, Moreton-on-Lugg.

Dorkings (Coloured).—1, J. Martin. 2, J. Smith, Petworth. 3, H. Yardley.

Spanish.—1, Mrs. Allsopp. 2, J. Walker, Standiford. 3, R. Barrett, Stroud. *hc*, H. Brown, Putney Heath; A. Mollons, Standiford.

Game.—*Black-breasted Reds.—Cup*, C. Chaloner. 2, S. Matthew. 3, A. B. Dyas, Madeley. *hc*, —Jeken, Eltham. *Brown-breasted Reds.*—1, C. W. M. Laxton. 2, J. Fletcher. 3, A. B. Dyas. *Duckwings and other Greys and Blues.*—1, Barker & Charnock, Halifax. 2, C. Challoner. 3, W. H. L. Clare, Atherstone.

PIGEONS.

Carriers.—*Black.—Cocks.*—1, 2, and 3, R. Fulton, Deptford. *hc*, H. Yardley; E. Burton, Truro. *Hens.*—1, 2, and 3, R. Fulton. *Dun.*—1 and 3, R. Fulton. 2, H. Yardley.

Pouters.—*Cock.*—1 and 2, R. Fulton. 3, E. T. Dew, Weeton-super-Mare. *Hens.*—1 and 2, R. Fulton. 3, E. T. Dew.

Tumblers.—*Almond.*—1 and 2, R. Fulton. 3 and *hc*, J. Ford, London. *Any other Variety.*—1 and 2, R. Fulton. 3, J. Ford.

Jacobins.—1, W. H. Tomlinson, Newark-on-Trent. 2, F. Waitt. 3, R. Fulton.

Barbs.—1, 2, and 3, R. Fulton. *hc*, E. Burton.

Fantails.—1, H. Yardley. 2, A. M. Yetts, Reading. 3, R. Fulton. *hc*, H. Yardley; R Fulton; J. Loveridge, Newark.

Trumpeters.—1, R. Fulton. 2, H. Yardley.

Owls (English).—1, H. Yardley. 2, J. Watts. 3, T. King, Colchester.

Nuns.—1, E. T. Dew. 2, H. Yardley. 3, J. Watts.

Turbits.—1, E. T. Dew. 2 and *hc*, H. Yardley. 3, Mrs. E. Gregory, Taunton.

Dragoons.—1 and 3, R. Fulton. 2, H. Yardley.

Runts.—1, H. Yardley. 2, J. Watts. 3, H. B. Bourne. *c*, Miss M. Taylor, Brighton.

Antwerps.—1 and 2, H. Yardley. 3, H. P. Ryland, Birmingham. *hc*, W. H. Mitchell, Moseley.

Any other Variety.—1 and 2, R. Fulton. 3, J. Watts.

Selling Class.—1, G. Roper, Croydon (Jacobins). 2, E. Barton (Black Carrier). 3, R. Barrett, Stroud (Pouters). *hc*, Mrs. E. Gregory (Hyacinths); J. Watts *c*, R. Fulton; A. P. Maurice, Basingstoke (White Trumpeters).

Silver Cup for points in all classes of Pigeons, R. Fulton.

Mr. Teebay judged the poultry, and Dr. Cottle and Mr. Esquilant the Pigeons.

LEIGH POULTRY SHOW.

The eleventh annual Show was held on August 31st, when there were upwards of 140 entries of poultry and Pigeons. The awards were as follow:—

Game.—*Black-breasted Red.*—1, R. Southern, Westleigh. *Brown Red.*—1, C. W. Brierley, Middleton. 2, R. Southern. *Any other Variety.*—1, C. W. Brierley. *Cock.*—1, C. W. Brierley. 2, A. Haslem, Hindley (Brown Red). *Hen.*—1, C. W. Brierley. 2, A. Haslem (Brown Red). *Cockerel.*—1, A. Haslem (Brown Red). 2, A. Smith (Duckwinged). *Pullet.*—1, C. W. Brierley. 2, J. Horn, Middleton (Brown Red).

Spanish.—Cup, 1, and 2, C. W. Brierley. *hc*, N. Cook, Chowbent.

Cochin-China.—*Buff.*—1, N. Cook. 2, J. Watts, King's Heath, Birmingham.

Brahma Pootras.—1, N. Cook. 2, J. Watts.

Hamburghs.—*Golden-pencilled.*—1, T. Wrigley, jun., Tonge. 2, H. Pickles, jun., Earby. *Silver-pencilled.*—1, J. Platt, Deane. 2 and *hc*, H. Pickles, jun. *Golden-spangled.*—1, H. Pickles, jun. *Silver-spangled.*—1 and 2, H. Pickles, jun. *Black*—1, J. Chadwick.

Polands.—*Any Variety.*—1, P. Unsworth, Lowton. 2, W. Gamon, Chester. *hc*, H. Pickles, jun.; T. Waddington, Feniscowles; P. Unsworth.

French Fowls.—1, T. Waddington. 2, W. Fearnley.

Bantams.—*Game.*—1, Bellingham & Gill, Woodfield, Burnley. 2, J. W. Morris, Rochdale. *Any other Variety.*—1, J. Watts. 2, N. Cook. *hc*, J. & R. Ashton, Mottram. *Cock or Cockerel.*—1, G. Anderton, Accrington. 2, P. West, Abram. *hc*, A. Smith, Westleigh.

Any other Distinct or Cross-bred.—1, G. Anderton, Accrington (White Sultans). 2, J. Partington, Leigh (Andalusians).

Docks.—*Aylesbury.*—1, E. Leech, Rochdale. 2, J. T. Billinge, Pemberton, Wigan. *Rouen.*—1, R. Gladstone, jun., Court Hey, Liverpool. 2, T. Wakefield, Golborne, Newton-le-Willows. *hc*, R. Gladstone, jun.; J. Scotson, Little Byrom, Lowton (2); T. Burns, Abram; T. Wakefield. *c*, T. Burns. *Any other Variety.*—1, C. W. Brierley. 2, R. Gladstone. *hc*, R. & W. Barton, Westleigh; S. & R. Ashton.

Geese.—1 and 2, R. Gladstone. *hc*, E. Leech; E. Kenyon, Leigh; R. & W. Barton.

Turkeys.—*Any Colour.*—1, E. Leech. 2, J. Boardman, Leigh.

Selling Class.—1 N. Cook, Chowbent. 2, T. Wakefield. 3, J. T. Billings. *hc*, J. Horn, Middleton; P. West, Abram.

PIGEONS.

Tumblers.—*Any Colour.*—1, H. Yardley, Birmingham. 2, T. Waddington.

Carriers.—1, T. Waddington. 2, W. Markland. *hc*, H. Yardley.

Pouters.—1, T. Waddington. 2, H. Yardley.

Owls, English.—*Any Variety.*—1, W. Markland. 2, A. Jackson, Chequerbent, Bolton. *hc*, J. Watts; J. Chadwick, Bolton.

Dragoons.—*Any Colour.*—1 and 2, J. Holland, Manchester.

Trumpeters.—1, W. Gamon. 2, O. Percival, Manchester.

Fantails.—1, H. Yardley. 2, J. Chadwick (Blue).

Any other Variety.—1 and 2, T. Waddington.

Selling Class.—2, J. Nuttall, Bolton.

Judges.—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. Ridpeth, Handforth Hall, Wilmslow.

NORTHAMPTON POULTRY, PIGEON, AND RABBIT SHOW.

The first of a proposed series of annual shows was held on the 5th and 6th inst. in the Melbourne Gardens, Northampton. There were 190 entries of poultry and 53 of Rabbits. The following is the prize list:—

Dorkings.—1, R. Wood. 2, J. Watts.

Cochin-China.—1, H. Yardley. 2, H. F. Cooper.

Brahma Pootra.—1, Lieut.-Col. J. Lickell. 2, J. Watts. 3, W. Stevens. *hc*, Rev. N. J. Ridley. *c*, H. Yardley; Dr. Holmes.

Spanish.—1, Burch & Boulter. 2, M. Brown. 3, A. Thorneycroft. *hc*, J. H. Sharpe; H. F. Cooper.

Game.—1, B. Cox. 2, H. Yardley. 3, W. Bishop.

Hamburghs.—1, H. Yardley. 2, R. S. S. Woodgate. 3, W. R. Ticker. *hc*, C. Love; A. Goodrich.

Polands.—1, H. Yardley. 2, Lieut.-Col. D. S. Greene.

Bantams.—*Game*—1, Rev. F. Cooper. 2, M. Leno. 3, Bellingham & Gill. *hc*, C. E. Robinson; T. C. & E. Newbitt. *Any other Variety.*—1 and 3, M. Leno. 2, S. & R. Ashton. *c*, A. Storrar.

Any other Variety.—1, J. J. Malden. 2, R. S. Woodgate. 3, N. J. Ridley. *hc*, J. S. Price. *Chickens.*—1, P. Gurdon. 2, B. Cox. 3, W. Dring. *vhc*, M.

Leno; Hill & Co. *hc*, Mrs. F. Stephens; J. T. Parker; T. Hancock; W. Stevens; L. Watkins. *c*, J. Phillips.

Ducks (Any variety).—1, J. Collier. 2, S. H. Stow. 3, M. Leno. *hc*, C. Richards, jun. *c*, Rev. J. Worthington; R. B. Stafford.

Selling Class.—1, Birch & Boulter. 2, Rev. J. Worthington. 3, W. Nottage. *hc*, J. Collier; R. W. Smith; H. F. Cooper. *c*, H. F. Cooper.

PIGEONS.

Carriers.—*Cock.*—1 and 2, H. Yardley. 3, J. Watts. *hc*, T. Chambers, jun. *Hen.*—1, T. Chambers. 2, H. Yardley.

Pouters.—*Cock.*—1, W. Nottage. 2, H. Yardley. 3 and *hc*, T. Adams. *c*, Spence & Stiles. *Hen.*—1 and 3, H. Yardley. 2, T. Adams. *hc*, Spence and Stiles; T. Adams.

Barbs.—1 and 2, H. Yardley.

Dragoons.—1, G. Sonth. 2, H. Yardley. 3 and *hc*, F. Graham. *c*, Spence and Stiles.

Jacobins —1, C. Martin. 2, G. W. Mullis. 3, G. South.

Fantails.—1, H. Yardley. 2, F. J. Loveridge. 3, A. M. Yetts. *hc*, W. Bearpark. *c*, W. H. Tomlinson.

Turbits.—1, W. Bearpark. 2, G. Sonth. 3, H. Yardley. *hc*, T. Waitt.

Antwerps.—1, H. Yardley. 2, Spence & Stiles. 3, W. Nottage. *c*, J. W. Collinson; T. Chambers, jun.

Tumblers.—1 and 2, J. M. Braid. 3, T. Adams. *hc*, H. Yardley; Spence and Stiles.

Owls.—1 and 2, H. Yardley. 3, J. Watts. *c*, H. A. Saddington.

Any other Variety.—1, J. Watts. 2, H. Yardley. 3, W. Bearpark. *Chickens* (Special Class).—1, H. Nightingale. 2, J. M. Braid. 3, W. Nottage. *hc*, T. W. Swallow; H. Yardley.

Special Selling Class.—1 and 2, W. Nottage. 3, T. Chambers, jun. *hc*, T. Gamon; C. Higgins. *c*, Spence & Stiles; C. Higgins.

THE RABBITS.

This very interesting section of the Show was well represented by fifty-three entries—a result which must have been very encouraging to the Committee, who were indefatigable in their efforts to bestow due attention to all specimens under their care, and the feeding and the size of the pens for the Rabbits could not have been more satisfactory. The pens, we believe, were from Messrs. Turner, of Sheffield.

There were about twenty entries of Lops, including some excellent specimens, and the competition was close, requiring more than a casual glance to determine to which to award the badge of honour; yet we confess the Tortoiseshell buck of Mr. A. H. Easten with ears 21¾ by 4¾ was fully entitled to his creditable position, and the doe of Mr. Tomlinson, with ears 21 inches by 4¾ inches, was a fitting sharer in almost equal honours. A Fawn doe, with ears 21¼ inches by 4⅝, belonging to Mr. H. Cawood, completed the valuable trio. It is rarely, when colour is out of the question, that such a valuable class is brought together, and let us hope next year the Lops will be classified in respect to colour. The next, or Any other variety class, contained nineteen entries, comprising five varieties, from the large Belgian to the tiny Dutch, and there were not many, if one, which would not have carried off the honours in a class of its own. We trust from the present success that these fine varieties at a future exhibition will be found in at least three classes, for by proper classification alone can a just opinion be formed and comparison made. The beautifully silvered doe of Mr. S. G. Hudson was equal to her position, contrasting with the valuable White Angora of Mr. W. Corey, of large size, and with a little attention would present an almost perfect specimen of the Angora. To complete the trio of prize-winners, the excellent Himalayan of Mr. Esam was a true type of this pleasing variety.

The Selling class presented some valuable Rabbits, and the first-prize, a Fawn doe Lop with ears of 20½ inches by 4½, was well shaped and clear in shade, and was worthy of her position. The Dutch Blue buck of Master T. Adams came next in point of merit, and gave a correct idea of what a good specimen of this diminutive variety should be, being so well marked in those points essential to insure a prize. The Fawn Lop buck of Mr. W. Morbey should not be overlooked, as his points of excellence were very evident; and the Tortoiseshell Lop of Mr. C. Gravil and the highly commended and commended pens must not be passed over without a favourable comment.

The general healthiness of the whole specimens was very satisfactory; one or two only seemed to require a little attention from their owners in order to render them perfectly eligible to compete with their neighbours.

Rabbits.—*Lops.*—1, A. H. Easten, Hull. 2, W. H. Tomlinson, Newark-on-Trent. 3, H. Cawood, Thorne. *vhc*, H. Ridley, York. *hc*, Lewin & Robinson, Kettering (2). *c*, H. Tomlinson; J. S. Price, Potters Bar, Herts; J. Boyle, jun., Blackburn; J. H. Sharp, Melton Mowbray. *Any other Variety*—1, S. G. Hudson, Hull. 2, M. W. Corey, Northampton. 3, R. & G. E. Esam, Newark. *vhc*, J. Allen, Amphill. *hc*, A. H. Easten; H. Yardley, Birmingham; Mrs. Morley, Northampton. *c*, J. Boyle, Blackburn; S. G. Hudson; Lewin & Robinson. *Selling Class.*—1, Lewin & Robinson. 2, Master T. Adams, Northampton. 3, W. Morbey, Northampton. *vhc*, C. Gravil, Thorne. *hc*, C. Leat, Tiverton; S. Sabbage, Northampton (2). *c*, A. H. Easten; J. Boyle.

Judges.—*Poultry and Pigeons:* Mr. W. B. Tegetmeier, Finchley, London. *Rabbits:* Mr. C. Rayson, Ivy Lodge, Didsbury.

POCKLINGTON POULTRY SHOW.

This was held on the 7th inst. in an extensive field lent for the purpose by Mr. Thomas Whitehead. The entries for poultry were large, but some of the specimens were unworthy of prizes, and these were consequently withheld. For *Game* Mr. Boyes won most of the prizes, and the Dockwings shown by him were unusually good; in fact such birds are rarely seen. *Spanish* were of moderate quality, but the *Dorkings*, *Cochins*, and Game *Bantams* were very good. For the pens as well as single cocks of the last-named, excellent Black Reds were first. The first-prize Cochin single cock was an extremely good Buff chicken. The only other birds worthy of notice were the Aylesbury *Ducks* and Toulouse *Geese*.

The exhibitors of *Pigeons* had to find their own pens, and the effect was irregular, and we would advise a reform in this respect for another year. In this section Mr. Adams showed in great force, and carried off most of the prizes with birds of faultless quality and in the highest condition. The cage birds were a capital show for the time of year.

Game.—*Black-breasted and other Reds.*—1, W. Boyes. Beverley. *Any other Variety.*—1, W. Boyes. 2, W. G. Purdon, Driffield. *Chickens.*—1, W. White, Great Driffield. 2, O. A. Young, Great Dr ffield.

Spanish.—1 and 2, G. Holmes, Driffield. *Chickens.*—1, G. Holmes. 2, D. Maynard, Driffield.

Dorkings.—1, O. A. Young. 2, D. White. *Chickens.*—1, Miss B. Peirse. 2, D. White.

Cochin-China.—1, R. Dawson, Beverley. 2,—Inge, Barmby Grange *Chickens.*—1, R. Dawson. 2, O. A. Young.

Brahma Pootras.—1, O. A. Young. 2, Miss B. Peirse. *Chickens.*—1, D' Holmes, Chesterfield. 2, Miss B. Peirse. *hc*,—Ellerker, Welton.

Hamburghs.—*Gold or Silver-spangled.*—1, R. P. Moon, Driffield. 2, G. Holmes. *Gold or Silver-pencilled.*—1 and 2, G. Holmes. *Any Variety.*—*Chickens.*—1, G. Holmes. 2, Miss Peirse.

Farmyard Cross.—1, W. H. Young, Driffield. 2, G. Bromby.

Game Bantams.—1, W. Adams, Ipswich. 2, Pickering & Duggleby, Driffield. 3, J. Stavely, Driffield.

Single Cocks.—*Game* (Any variety).—1, G. Holmes. 2, O. A. Young. 3, W. Boyes, Beverley. *Spanish.*—1, G. Holmes. 2,—Steel, Pocklington. *Dorking.*—1, G. Holmes. *Cochin-China.*—1, R. Dawson. 2, Mrs. Smithson. *Hamburgh.*—1 and 2, G. Holmes. *Bantams.*—1, W. Adams. 2, G. Holmes. *hc*, G. Holmes Pickering & Duggleby.

Docks.—*Aylesbury.*—1,—Harrison, Warter. 2, G. Young. *Ducklings*—1, O. A. Young. *Any other Variety.*—1, O. A. Young. 2,—Balderson. *Ducklings.*—1,—Balderson. 2, O. A. Young.

Geese.—1, O. A. Young. 2,—Croft, Pinckham. *Goslings.*—1, O. A. Young. 2,—Croft. *hc*, Mrs. Singleton.

Turkeys.—*Poults.*—1, O. A. Young. 2, Mrs. T. Everingham.

Pigeons.—*Pouters and Croppers.*—1, H. Adams, Beverley. 2, C. Anton, York. *Tumblers.*—1 and 2, H. Adams. *Barbs.*—1, H. Yardley, Birmingham. *Jacobins.*—1, R. Sanders, Beverley. 2, H. Yardley. *Fantails.*—1, C. Anton. 2, Pickering & Duggleby. *Trumpeters.*—1, C. N. Lythe, Cottingham. 2, R. P. Moon. *Owls.*—1, G. Holmes. 2, H. Adams. *Turbits.*—1, C. N. Lythe. 2, C. Anton. *Nuns*—H. Yardley, disqualified. 1, C. N. Lythe. 2, Pickering and Duggleby. *Carriers.*—1, H. Yardley. 2, G. Sadler, Boroughbridge. *Any other Variety.*—1, H. Adams. 2, C. N. Lythe.

CAGE BIRDS.

Canaries.—*Belgian* (Yellow or Buff).—1, J. Calvert, York. 2, W. Forth, Pocklington. *Half-bred Belgian* (Yellow or Buff),—1, J. Hodd. 2, Barwell and Golby, Northampton. *Common* (Yellow or Buff).—1, R. Hutchinson, Pocklington. 2, Barwell & Golby. *Marked* (Any breed).—1, H. Curtis. 2, No award. 3, W. Forth.

Goldfinch Mule.—1, C. Burton, York. 2, E. Hackers, York.

Redcap.—1, H. Curtis. 2, C. Burton.

Linnet.—1, H. Curtis. 2, E. Hackers.

Bullfinch.—1, W. Forth. 2, H. Curtis.

Parrot.—1, W. Wiltshire. 2,— Steel.

Collection.—1, G. Venables, Hull. 2, J. Calvert, York.

Rabbits.—C. Anton. *Buck.*—G. Shut. *Doe.*—1, C. Anton. 2, Master Gruggen'

The Judge was Mr. E. Hutton, Podsey, Leeds.

FAKENHAM POULTRY SHOW.

A Show of poultry, Pigeons, Rabbits, and Song Birds, open in the first season to the county of Norfolk only, was held in the spacious Corn Hall, Fakenham, on Wednesday, the 6th inst., and for a first attempt was most successful. There were nearly three hundred entries, and the Exhibition was numerously attended. The arrangements were excellent.

Adult *Dorkings* were in good condition, a pen of massive birds winning first prize. There was a close competition in the chicken class, both winners being Dark Greys. *Spanish*, with the exception of the first-prize pen, were not first-class. The *Cochins* were good in shape, but wanting in size and marking. Only the prize birds in *Brahmas* were worthy of notice. The *Game* and *Poland* classes were the best in the Show. The cup for the best pen of adults was won by an extraordinarily good pen of Brown Reds, and the cup for 1871 chickens by a grand pen of Golden Polands. The entries of *Hamburghs* were numerous. The first-prize pen of chickens contained an unusually good Silver pullet. Dark Grey Dorkings took both the first prizes in the Selling classes. A fair pen of Houdans was first in the Variety class. Aylesbury *Ducks* were very good, the first-prize birds being claimed directly the sale-office opened.

The classes for *Pigeons* were not well filled, Balds and Carriers only being worthy of notice. In Canaries Messrs. Cockle and Watson had it all their own way, not a single bird being entered by the Norwich fanciers. *Rabbits* were moderately good.

Dorkings.—1, E. W. Southwood. 2 and *hc*,—Woodhouse. *Chickens.*—1 and *hc*, G. P. Tricker. 2, W. Burrows. *c*, Mrs. C. North; Rev. G. Gilbert.

Spanish.—1 and 2, W. Woodhouse. *Chickens.*—1, E. W. Southwood. 2, W. T. Tye.

Cochins.—1. J. Bone. 2, Mrs. Bishop. *c*, W. Groom; Rev. G. Gilbert. *Chickens.*—1, R. J. Turner. 2, W. Young. *c*, Mrs. Bishop; Rev. G. Gilbert.

Brahmas.—1, W. Burrows. 2, F. Hardingham. *Chickens.*—1, T. Spurr. 2, Mrs. Bishop.

Game.—1, Cup, and 2, H. E. Martin. *hc*, G. P. Rouse. *Chickens.*—1 and *hc*, H. E. Martin. 2 and *c*, G. P. Rouse.

Hamburghs.—1, K. Middleton. 2, R. J. Oliver. *Chickens.*—1, K. Middleton. 2, W. Saul. *hc*, E. Branford. *c*, J. P. Case.

Polands.—1, 2, and *hc*, W. K. Pattrick. *Chickens.*—1, Cup, 2, and *hc*, W. K. Pattrick.

Any other Variety except Bantams.—1, Lord Hastings. 2, T. Spurr. *c*, T. A. Craske. *Chickens.*—1, W. Burrows. 2, withheld.

Selling Class.—*Cock or Cockerel.*—1, W. Woodhouse. 2, K. Middleton. *hc*, E. W. Southwood; J. P. Case; T. Spurr. *c*, E. W. Southwood; K. Middleton; H. R. Plattin. *Hens or Pullets.*—1, E. W. Southwood. 2, Rev. W. F. Dixon. *vhc* and *c*, W. Woodhouse. *hc*, H. E. Martin; W. Groom; J. Frankling; C. Winn; Rev. G. Gilbert.

Bantams.—*Game.*—1, H. W. Currie. 2, A. Taylor. *c*, J. A. Magnese. *Chickens.*—1, A. Taylor. 2, W. Woodhouse. *Any other Variety.*—1, C. Woods. 2, W. B. Horrex. *hc*, Mrs. Bishop.

Docks.—*Aylesbury.*—1 and *hc*, J. W. Nicholson. 2, Rev. G. Gilbert. *c*, Mrs. Bishop; W. Martin. *Any other Variety.*—1, R. Savory. 2, W. Woodhouse.

PIGEONS.—*Carriers.*—1, H. Thurlow. 2, E. Mayston. *Pouters.*—1, Withheld. 2, T. C. Baldwin. *Baldz or Beards.*—1 and 2, W. Woodhouse. *c*, W. T. Tye. *Tumblers.*—1 and 2, W. Woodhouse. *c*, H. Thurlow. *Barbs.*—1, G. Morling. 2, T. Miller, jun. *Fantails.*—1, W. Woodhouse. 2, T. C. Baldwin. *Antwerps.*—1 and 2, E. Mayston. *Any other Variety.*—1, H. Thurlow. 2, R. J. Turner. *c*, W. Woodhouse; W. Martin; R. Crane; Miss M. A. Raven (2). *Selling Class.*—1, H. Thurlow. 2, R. Crane.

CANARIES.

NORWICH.—*Clear Yellow.*—1 and 2, Cockle & Watson. *hc*, E. Patrick. *Clear Buff.*—1 and 2, Cockle & Watson. *hc*, J. Goodman.

NORWICH.—*Variegated Yellow.*—1 and 2, Cockle & Watson. *hc*, E. Patrick; R. Richardson, sen. *Variegated Buff.*—1 and *hc*, Cockle & Watson. 2, — Newland.

LIZARDS.—1 and 2, Cockle & Watson.

ANY OTHER VARIETY.—1, Cockle & Watson. 2, J. Newland. *hc*, Cockle and Watson; — Richardson, sen.

MULE.—1, 2, and *hc* (3).—J. Goodman.

ANY OTHER VARIETY OF BRITISH SONG BIRD.—1, W. Wright. 2, E. Patrick. *hc*, T. J. Miller, jun.

SELLING CLASS.—1, W. Wright. 2 and *c*, E. Patrick.

RABBITS.—*Lop-eared.*—1 and *hc*, G. Morling. 2, Master G. A. A. Rouse. *Any other Variety.*—1, Mrs. C. North. 2, A. Langley. *Extra Class.*—*hc*, J. Sharman.

JUDGE.—Mr. W. B. Tegetmeier.

WHITBY CANARY SHOW.

THIS was held on the 12th inst., in connection with the Flower Show. The following awards were made by the Judge, Mr. W. A. Blakston, of Sunderland:—

CANARIES.

NORWICH.—*Yellow.*—1, S. Bunting, Derby. 2, J. Close, Derby. Equal 2, Adams & Athersuch. *vhc*, G. Gayton, Northampton. *hc*, Mrs. Wilkinson; Porritt & Raw, Ruswarp; R. Hawman, Middlesbrough; J. Cleminson, Darlington. *c*, E. Mills, Sunderland. *Buff.*—1 and 2, Adams & Athersuch. Equal 2, Barwell & Golby, Northampton. *vhc*, G. Medd, Scarborough; Moore & Wynn, Northampton; J. Close; S. Bunting. *hc*, Bexson & Bennett, Derby; Barwell and Golby. *c*, J. Cleminson.

NORWICH.—*Evenly-marked Yellow.*—1, Barwell & Golby. 2, Adams & Athersuch. 3, Holmes & Doyle, Nottingham. *hc*, S. Bunting. *c*, Moore & Wynn. *Evenly-marked Buff.*—1, Adams & Athersuch. 2, S. Bunting. *vhc*, Adams and Athersuch. *c*, Moore & Wynn; Holmes & Doyle; E. Mills. *Unevenly-marked Yellow.*—1, J. Close. 2, S. Bunting. *vhc*, Bexson & Bennett; G. Medd. *hc*, M. C. Readman, Whitby. *Unevenly-marked Buff.*—1, Barwell & Golby. 2, Bexson & Bennett. 3, J. Cleminson. Equal 3, S. Bunting. *vhc*, J. Close; Barwell and Golby; Adams & Athersuch. *hc*, Moore & Wynn; Bexson & Bennett.

NORWICH.—*Yellow or Buff, Green, Grey, Buff, or Yellow Crest.*—1, Barwell and Golby. 2, Holmes & Doyle. *c*, J. A. Barber, Leicester; Moore & Wynn; S. Bunting; Bexson & Bennett; G. Clipson, Northampton.

BELGIAN.—*Yellow.*—1, M. R. Robinson, Middlesbrough. 2 and 3, W. Bulmer, Stockton. *c*, J. N. Harrison, Belper. *Buff.*—1 and 2, W. Bulmer. *vhc*, J. N. Harrison. *hc*, M. R. Robinson. *c*, L. Belk; J. Close (2).

YORKSHIRE.—*Yellow.*—1, J. Rowland, Saltburn. 2, J. Cooper, Middlesbrough. *c*, R. Hawman. *Buff.*—1, H. Ward, Skelton. 2, W. W. Johnson, Carlton, Northallerton. *c*, W. & C. Burniston, Newport, Middlesbrough; T. Waudby, Norton, Malton.

CINNAMON.—*Yellow.*—1, Barwell & Golby. 2, Holmes & Doyle. *hc*, W. W. Johnson. *Buff.*—1, Barwell & Golby. 2, E. Mills. *hc*, Moore & Wynn; J. N. Harrison.

LIZARD.—*Golden-spangled.*—1 and 2, Smith & Preen, Coventry. *c*, J. N. Harrison; Greenwood & Jackson. *Silver-spangled.*—1 and 2, R. Ritchie, Darlington. *vhc*, Smith & Preen. *c*, J. Taylor.

CANARY.—*Green.*—1, W. Lawson. 2, J. Stevens, Middlesbrough. *hc*, T. Allenby, Durham. *c*, Fairclough & Howe, Middlesbrough.

ANY OTHER VARIETY.—1, W. Bulmer. 2, W. & C. Burniston. 3, Moore and Wynn. Equal 3, R. Hawman. *vhc*, M. R. Robinson; L. Belk, Dewsbury (2); Fairclough & Howe. *hc*, J. N. Harrison.

CANARIES.—*Six Young.*—1, Hardy & Atkinson, Whitby. 2, R. Hawman. *c*, H. Dale, Whitby; T. Allenby; Mrs. Wilkinson; W. W. Johnson.

GOLDFINCH MULE.—*Yellow Marked.*—1, J. Stevens. 2, G. Bell, Whitby. *Buff Marked.*—1, P. Raynor, Whitby. 2, J. Taylor. *c*, J. Cooper. *Dark.*—1, R. Hawman. 2, J. N. Harrison. *c*, W. Cattle, Norton, Malton.

FOREIGN BIRDS.

PARROT.—1, Mrs. Weighill, Whitby.

LOCAL PRIZES.

NORWICH.—*Yellow or Buff.*—1, H. Dale 2, M. C. Readman. *hc*, R. Robinson; McLacklin & Brown, Whitby (2); Mrs. Wilkinson, Whitby. *c*, Mrs. Wilkinson; J. Gray, Whitby. *Marked, Yellow or Buff.*—1, M. C. Readman, Whitby. 2, McLacklin & Brown.

CANARY.—*Any other Variety.*—1, M. Taylor, Whitby. 2, Porritt & Raw, Ruswarp.

MULE.—1, J. Gray. 2, J. Pearson. Equal 2, J. Gray.

BULLFINCH.—1, McLacklin & Brown. 2, T. Harland, Grosmont.

GOLDFINCH.—2, T. H. Woodwark, Whitby.

LINNET.—1, W. Henderson, Whitby. 2, Porritt & Raw.

PIGEON-TRIMMING AT ALLERTON SHOW.

I REPUDIATE the charge of inequality of judgment brought forward by Mr. Yardley, also deny that I ever awarded a prize, or even a commendation, to a pair of Nuns in the disgraceful state in which I found Mr. Yardley's birds at the Allerton Show. The transparency of Mr. Yardley offering to bring the birds forward for inspection is sufficiently manifest. If they be now, as he says, "in pen feather," that is proof sufficient that they were in full feather one month ago. Yet this I consider of little importance, as the feathers were not "abstracted," but cut off.

But what will Mr. Yardley say to the fact that they have been again examined and disqualified at Pocklington Show last Thursday, and with the assistance of three of the Stewards, Messrs. E. Cundall, G. Smith, and John Silbum, two of the cut feathers "abstracted," and that they have now a place in my cabinet alongside of those I took out at Allerton Show?

Now, with respect to the sexes of the pair of Dragoons, Mr. Yardley, in quoting from my report, does not note that I awarded the prize at Allerton Show under a doubt, and made the remark with reservation; but the "conflicting feature" will be explained when I tell him that at Stanningley I had an excellent colleague in Mr. Dixon, of Bradford, who pronounced the birds two cocks at first sight, and this being also my opinion, they were left out altogether. According to Mr. Yardley this will be "novice" No. 2, and if he had been on the show ground he might have counted "novices" by the score, for it was the universally and freely-expressed opinion there that the birds were two cocks. I have no doubt but that my judgment is of too uniform a character for Mr. Yardley and the clique of trimmers he has taken upon himself to represent; but no threat that he can throw out will deter me from the course I have hitherto pursued.—E. HUTTON.

[Here the controversy must close.—EDS.]

JUDGING THE QUALITY OF HONEY.

HONEY is judged mainly by its colour; but owing to there being often a very great difference in the colour of the comb, and the additional fact that bees often put white honey in dark combs, and *vice versâ*, it is manifest that very great care must be exercised in taking into account both the comb and the honey. The proper way to judge honey is to strain it into glass jars. You can then readily judge of its colour. But then there are at least two other qualities to be considered—thickness and flavour. In judging of its thickness, it is necessary for the judge to know whether that quality was imparted in the first instance, or whether it is due to the action of light; for the chemical rays of light act upon honey very much as they do upon the iodide of silver on the photographer's excited collodion plate.

Take two bottles of honey from the same comb, seal them up perfectly tight, and keep them both at the same temperature, only one in the sunlight and the other in a dark room, and the former will gradually grow thick and finally assume a semi-crystalline shape, while the other will retain its original fluidity. This is one reason why bees always work in the dark, and why honey should always be kept in the dark or in opaque vessels.

It would be wrong to award a first prize to a jar of honey that had become thickened by the action of light, because it thereby becomes deteriorated. Still, honey, to be superior, should not be very thin.

Flavour is also a very important consideration, and must always be required. A good-flavoured dark honey may sometimes be superior to a white honey which looks much better. The thickness and thinness of honey depend upon the source from which it is gathered, rather than upon the secretive action of the bee, whether we admit that the insect makes or simply gathers it.—(*Scientific Press.*)

VALUE OF PRODUCE.—It is provided by the tenure of the manor of Brisingham, in Norfolk, "that all commoners pay hens' eggs and day's work with their plough to the Lord of the Manor." The quit-rents were paid by a small rental in money, and by three roots of ginger, valued at 1*d.*, 95 hens at 7*s.* 2*d.*, 17 capons at 1½*d.* each, 5 ducks at 10*d.*, and 539 eggs at 3*d.* a-hundred. The date of this document is in 1341, the 15th year of Edward III.

OUR LETTER BOX.

RICHMONDSHIRE AND STOCKTON POULTRY SHOWS (*Several Subscribers*)—The Committees did not advertise them; therefore, we conclude they do not care about the Shows being reported.

WHITE COCHIN SLIGHTLY YELLOW (*May*).—It is unquestionably desirable that a White Cochin cock should be dead white; but straw-coloured hackles and saddles are very common. They are not a disqualification, but they are a disadvantage, and in close competition would decide against their possessor. We are answering your question in the belief the colour is really straw, as compared with milk white, and not one of those darker shades, which in tender mouths are called "golden," or "anburn," and are in reality deep reds.

CHICKENS DYING (*A. S. L. M.*).—We have no doubt we could give you some advice if you afford the means, but your query is too vague. You do not mention the breed, food, locality, nor symptoms. We cannot even guess at an answer, if we are only told that "when about the size of Pigeons they turn black and die."

CHICKENS DWINDLING (*Subscriber*).—Do your chickens have plenty of sun? Have they a good grass run? Is the cucumber-yard paved? Is there a dunghesp or anything of the sort? The space you mention is small for fifty chickens, and unless they are supplied with artificial helps there is little hope of your rearing them. Where chickens have the advantage of the run of a kitchen garden, or of an acre or two of grass, they pick up a great deal of natural food, and can make-up with the dry corn you mention. For young and old, ground food is better and cheaper

than whole. There is less waste, and it goes farther. Try ground oats or barleymeal, sapply some ashes and road grit for dasting, and for bath. Give green meat if they have it not, especially lettuces that are going to seed. Give them the scraps and crumbs from the table. Try a little bread and milk. If the chickens have had only that which you name, your poultry-keeping is at best gallinaceous baby-farming. They evidently want a stimulant now, and we, therefore, advise you as soon as you read this to get a quartern loaf, enough strong ale to soak it, and to feed your chickens on that till they begin to rally. Then feed as we have advised. Wheat, barley, and maize for little chickens are as good as bread, cheese, and walnuts would be for an infant.

White Chinese Geese (*T. A. B.*).—It is impossible to say which would be the likelier to take a prize, as they could only go in a class for "Geese of any other variety." The White Chinese Goose is a long taper-necked bird with a yellow face, and having a large yellow knob on the forehead, projecting somewhat over the bill. The legs are yellow. It is a handsome bird, attains a large weight for the table, but has a most nomusical voice. It is considered inferior to the common Goose for the table.

Silver-pencilled Hamburghs (*C. E. M. T.*).—When you speak of "red feathers on the wing of Silver-pencilled Hamburghs," of course you mean the cocks, the hens never have it. It has long been a vexed question; some maintain it is wrong, and other excellent judges say it is immaterial. We believe the best Pencilled birds were always bred from those birds with brown patches on their wings. Pale washed-out colours are great disadvantages, and can never compete successfully with good, rich, bright foundation colour in Golden-pencilled. We quite believe the sun injures the plumage, but it does much for the health of the birds; it makes good, bright red, well-developed combs, such as are not seen in birds reared as you say, and you must put one against the other. It is not impossible nor very difficult to get both.

Cost of Fowl-keeping (*Bruno*).—It is always difficult to answer your question, but as you put it it is impossible. At what age are they sent? Where are they to be kept? Are you to have all, or to divide eggs? Are chickens to be reared? On hearing these particulars we will answer to the best of our ability.

Brahmas' Hocks (*S. B. S.*).—The feathers at the knee should not project. It is vulture-hocked. There is not the slightest objection to their being tied at the knee. It would, perhaps be too much to say the vulture hock implies impurity of blood, but it is a grave fault, and fatal to success. (*G. C. A.*).—Curling round the joint is not vulture-hocked. To project an inch from the joint is positively vulture-hocked, and very objectionable. The bird with the stiff feather is a hopeless case. The weights you mention are very heavy. A pound a-month is called good work.

Poultry Runs (*R. E. H.*).—Have the ground dug up about 12 or 18 inches deep, and the lower earth made the surface. If you have a cartload of fresh mould, put it on and scatter it. If you can, procure two or three cartloads of road grit, and make them into two or three heaps. The fowls will scratch for the grass mixed up with the grit, and by these means they will spread it. We have all our pens dug once in a week, and raked every day.

Young Turkeys (*Innocent*).—Advertise what you will sell them for, where you will deliver them, and price prepaid.

Writing on Pigeons' Wings (*H. L.*).—Marking ink will do.

Young Pigeons Dying (*Amateur*).—Old Pigeons frequently partially feed one of their young ones, the bird gets thinner and weaker, and though it may die with some food in its crop, it is really starved. This has been the case with yours. Oats are unsuitable. Peas alone are not sufficient; add old beans or Indian corn. Wheat they like, and the squeakers easily pick it up, which is an advantage.

Colour of Antwerp's Beak (*W. B.*).—Colour in an Antwerp's beak is no point, although shape is a very important one. *Vide* our article on the Antwerp in number for February 17th, 1870.

Pigeons' Portraits, &c. (*A. C. R.*).—Our last Pigeon portraits, those of the Short-faced Beard and Baldhead, were in No. 541, August 10th, 1871. Colour of eyelash immaterial; properly speaking Pigeons have eyelids, not eyelashes.

Eaton's Pigeons (*Alpha*).—Write to Mr. D. Wolstenholme, 3, Elizabeth Cottage, Archway Road, Highgate.

Food for Parrots (*C. P.*).—You will see very full directions in our No. 515, published on the 9th of February. You will see the Cheltenham report to-day; it arrived too late for publication in our last week's number.

Feeding Bees (*Barton Joyce, Notts*).—Your maiden swarm of July 16th, will have required a good deal of continuous feeding; but if you have already given the bees "a pint bottle every day" for any length of time, they must have had pretty well enough. We should advise you to examine or weigh the hive, and act accordingly. If it has glass windows, and you see any quantity of sealed combs, or if the contents weigh from 16 lbs. to 20 lbs., you should stop feeding till the middle of October, and then give two or three pints. Your second hive should be treated exactly in the same way.

Uniting Swarms (*C. R. P.*).—To join the bees of one stock to another, first drive one stock into an empty hive, and then drive the other stock into the same. Do this towards dusk, when the bees are all quiet at home. The next day, towards evening, you can dash out all the bees on the ground in front of the stock which you wish to keep, and out of which came one of the driven stocks the evening before. Use a little brown paper or tobacco smoke before you disturb the bees.

Winter Care of Bees (*Idem*).—Feed with an inverted pickle-bottle made to rest in a block of wood over a hole at the top of your hives. If your hives are of wood this is easy enough; if of straw like the ordinary skep, a little ingenuity is required to fit the block and bottle neatly on the hive, which must have a 2-inch hole cut out in the top. The block must have a piece of perforated zinc let into the underside, and the mouth of the bottle must be covered with a piece of leno or muslin so as to prevent the food from running down too quickly. Sugar boiled down in water to the consistency of a not too thin syrup is an excellent food. If you use coarse brown sugar strain it first. Feed in October, or now if your bees are starving.

A September Swarm (*A Beginner*).—We fear your September swarm (one of the latest we ever heard of), will be of no use to you. Could you not join the bees to some weak hive in your garden, if you have any? It would, of course, be possible to feed them up, but we should not recommend you to try it. As to your bottle-feeder failing, it is evident your food was too liquid, or perhaps you failed to cover the mouth of the bottle with leno or muslin of sufficient thickness. Try again, and buy your knowledge in the school of experience. We believe you may purchase Payne's hives at Messrs. Neighbours', Holborn, London. See their advertisement in these pages. It is impossible for your bees to find enough food in the fields and gardens at this time of year. The piece of comb which fell down may lie where it is.

Vegetable Marrow Jam.—*A Novice* wishes for a receipt.

REMARKS.

6th.—Hazy morning, rain at noon, fine afternoon; lightning at 7.55 P.M., rain in the evening.

7th.—Fine bright day throughout.

8th.—Dull in early morning, then fine, but rain in afternoon and evening, and heavy rain at night.

9th.—Wet morning, fair in middle of the day, but stormlike in the evening.

10th.—Fine in the early part, and, though afterwards cloudy and stormlike, no rain fell.

11th.—Very fine all day; the sun very hot, and, as there was but very little wind, it was rather oppressive.

12th.—Rather dull in early morning. Fine day, rather cloudy towards sunset, but very bright at night.

With the exception of the rain on Friday afternoon and night and on Saturday morning, a very fine and pleasant week, the mean temperature at 9 A.M. being lower than in any week since the beginning of July.—G. J. Symons.

COVENT GARDEN MARKET.—September 13

Trade continues quiet, but there is a better supply of Peaches, and prices for these are lower.

POULTRY MARKET.—September 13.

Since our last the Partridge season has begun. We hardly recollect ever seeing them so scarce, and the old birds are as three to one of the young. The latter are consequently selling well. Grouse remain very plentiful.

From observations taken near London during forty-three years, the average day temperature of the week is 66.0°, and its night temperature 44.4°. The greatest heat was 82°, on the 25th, 1832; and the lowest cold 27°, on the 25th, 1863. The greatest fall of rain was 1.68 inch.

SALT AS A GARDEN MANURE.

SALT as a manure has long been applied to garden and farm crops. Its principal use, however, in gardens has been in the destruction of weeds, for it is well known that in large quantity it is destructive to vegetable life; hence it is employed for scattering over walks, or they are watered with a strong solution of salt, to destroy the weeds and moss appearing on them. On the other hand, in moderate quantities its application is attended with very satisfactory results; for, as remarked by Mr. Johnson in the "Science and Practice of Gardening," page 119, "The day has long passed when it was disputed whether saline bodies are promotive of vegetable growth," and the same author continues—"It is now determined that some plants will not even live without the means of procuring certain salts."

Although salt, or saline matter, enters into the composition of all plants, it is evident, from the experiments made by Dr. Voelcker, that the application of a quantity of salt which proves beneficial to one kind of plant will be injurious to another. This he demonstrated by watering plants with water holding varied proportions of salt, and it is a remarkable fact that to most of the crops of the horticulturist even in very strong solutions it did not prove injurious. Even at the rate of twenty-four grains to a pint it "decidedly benefited Radishes, Onions, Lentils, and Cabbages," but "plants of Anthoxanthum odoratum (Sweet Vernal Grass) were killed by a solution containing twenty-four grains of salt per pint, after the lapse of one month." "Grasses are affected by salt more readily than any of the plants experimented upon." We may, therefore, conclude that salt in a certain quantity is beneficial to most vegetable crops, for we have Radishes or Raphaneæ, Crambe (Sea-kale), Brassica, including Cauliflower, Broccoli, Borecole, and Turnips; Liliaceæ, including Onions, Leeks, and Asparagus, and, I may add, many of our most beautiful bulbous plants, and those with succulent leaves. Dr. Voelcker remarks, "Bulbous plants and plants with succulent leaves are especially benefited by the application of salt;" also Lentils, Peas and Beans, and, may we not safely conclude all the order Leguminosæ, or pod-bearers, as the Dwarf Kidney Bean and Scarlet Runner? Dr. Voelcker mentions the Thistle as being benefited by salt, and we may consider the Globe Artichoke and Cardoon to be equally so. Mr. Johnson completes the list on the authority of Saussure—viz., Beetroot, Rhubarb, Potatoes, Jerusalem Artichoke, Carrot, probably also the Parsnip and Celery, as these two belong to the same natural order; so that salt is beneficial to every kind of vegetable crop.

Of the value of salt there can be no doubt; in fact, from its application this season, I have come to the conclusion that to the gardener it is one of the most valuable of manures. I have come to regard it as not only valuable, or, as stated by Mr. Thompson in "The Gardener's Assistant," page 121, "a necessary addition to the soil wherever marine plants, or such as naturally grow near the sea, are cultivated;" but to all, except it be Grasses; and even to these in small quantity, or less than for other plants, it is very beneficial. For some fruit trees it seems not to be so desirable as for others—for instance, the Apricot, Apple, and Cherry, but the Peach, the Pear, and the Plum are benefited by it.

I need say no more respecting its value, but will proceed to its application, of which there are several modes, but I shall only name two—namely, alone and mixed with other substances.

Salt applied alone.—As a top-dressing salt may be applied to every kind of kitchen-garden crop at the rate of ten bushels per acre, or half-a-gallon per rod. It may be given at the time of sowing, putting in, or planting the crop, but I consider it most advantageously applied when crops from seed have arrived at the thinning stage; to "put-in" crops, as Potatoes and Jerusalem Artichokes, it may be applied when they are well above ground, and before the first hoeing; to planted crops as soon as they are again rooted. Ten bushels per acre I think a sufficient quantity for a general dressing. Some crops will bear much more salt than the quantity named; for instance, Asparagus is not overdone at 1 lb. per square yard, or 43 cwts. per acre, and the best time to apply it is when the heads are appearing, and again early in May.

Cabbages may have repeated applications of salt, and so may most of the Cabbage tribe. Cabbages planted in September to stand the winter may in October be dressed, and again in March; Broccoli and Winter Greens after planting, and in October or early in November; whilst for most other members of the same family one application will be sufficient.

The value of salt as a manure may be estimated principally from its entering into the composition of plants; but it possesses other values—one being that it is destructive to predatory vermin as the slug, and is found a complete cure for grub in Turnips, and club or ambury in the other representatives of the Cabbageworts. It has also another most valuable property—that of protecting plants from injury from cold, or as it is stated in the "Science and Practice of Gardening," page 144, it protects "plants from suffering by sudden reductions of temperature by entering into their system, stimulating and rendering them more vigorous, impregnating their sap, and consequently rendering it less liable to be congealed." There can be no doubt of salt being advantageously used for plants of a succulent nature, such being liable to suffer in case of sudden reduction of temperature.

Salt mixed with other substances.—This, I believe, is the most satisfactory method, for all soils require to be constituted of several ingredients for the production of healthy plants. Gardens long enriched with stable or farmyard manure in time become sick or worn out. Lime-dressings have been advised, and are indeed very beneficial, often more so than dressings of stable manure. "When caustic lime, or, as it is more commonly called, quicklime is added to a soil, it decomposes the salts of ammonia which the soil contains, driving off the ammonia, but which is absorbed and retained by the alumina in the soil. Caustic lime also

promotes the rapid decay of vegetable and animal bodies in the soil "—(Science and Practice of Gardening, page 85). It has also been recommended to give dressings of fresh or maiden loam to long-cropped vegetable ground, choosing soil from a pasture, thus giving those very constituents which have been absorbed or taken up from the ground by every vegetable—viz., saline matters, and which are present in the maiden loam more than in old garden soil, because Grasses do not take up saline substances to nearly the same extent as garden crops. Fresh soil mixed with old causes a change in the products; it gives to old soil an addition of one or other substance required by vegetable crops, for it cannot be that fresh loam is richer, as without manure it will not grow many vegetables to a fitting condition: therefore it is not in the fibres of the Grass about which so much is insisted, but in supplying those compounds of which the soil has been deprived by a continued course of vegetable crops, and those compounds are principally saline.

Lime does good, but it is known that "when salt is mixed with moist earth and lime a considerable quantity of carbonate of soda and chloride of calcium is produced, owing to the salt being partially decomposed, the chlorine of a part of the salt uniting with the lime, whilst carbonic acid supplies its place, forming carbonate of soda. This having the property of combining with silica and rendering it soluble, may prove beneficial to plants by supplying them with that essential article of their food "—(Gardener's Assistant, page 121). Now, if we dress ground for Onions, one part with lime, another with salt, and a third with soot, the ground having in autumn been manured in the usual way, we find there is little, if any, difference between that limed and the part sown without the lime-dressing —the produce is not materially greater; but that dressed with salt produces more than the limed part, and the parts dressed with soot more still. This would show soot to be the most fertilising of the three, but in none of these cases is the dressing so good as when the whole are mixed—that is, the lime, salt, and soot, which afford much the better crop of Onions. A bushel of lime, soot, and salt mixed and sown broadcast over the ground intended for Onions and Carrots prior to putting in the seeds is good against the maggot or grub which infests these vegetables, and is sufficiently stimulating. It is also an excellent dressing for ground in March intended to be planted with every kind of vegetable crop. It is valuable both as a manure and as a preventive and destroyer of insect pests.

Everyone knows the value of guano as a manure. It is considered to contain most, if not all, the constituents required by vegetables. I am persuaded, however, though it may be highly fertilising, that it is not so beneficial by itself as when mixed with salt, one of the inorganic elements that in guano is reckoned of very inferior value. In some guanos there is a considerable quantity of lumps, consisting for the most part of common salt (chloride of sodium). In the best samples of guano the chloride of sodium is about 3.00; of a sample consisting of hard lumps the chloride of sodium has been found as much as 49.70. Ordinary samples of Peruvian guano contain 5.00 of alkaline salts, potash and soda. This quantity may be sufficient for cereals, but there is not evidently enough salt for kitchen garden crops, for I find crops dressed with guano alone do not produce so well as those dressed with one part salt to two parts guano, and at that rate 1 cwt. of salt to 2 cwt. of guano answers for every description of vegetable, but it should not be given in dry weather, for all the leaves upon which it falls it scalds or leaves a white blotch.

I may name a few of the cases in which I have found it most beneficial, though it answers well in all.

1, I had some beds of Onions, Carrots, and Parsnips on a plot of old garden ground, well trenched and in good heart. They were "set on"—were at a complete standstill, and grub already at work, making frequent wide gaps. They were dressed with the mixed guano and salt, about a peck to every two beds, each 4 feet wide and 40 feet long. This was previous to prospects of rain, and it fell as was anticipated. The grub was seen no more, the Onions are good, and the Carrots and Parsnips promise very well. Without the dressing there was no hope of a crop.

2, I have 1500 Celery plants on a plot of ground added to the garden last year; it is the virgin loam so much prized. The trenches were well manured. The Celery grew for a time, but afterwards came to a standstill. Guano alone was applied, but it did not improve anything but the colour of the plants; at last they were heavily dressed with the guano mixed with salt, and the Celery has grown well ever since. I have a like number of plants on old ground, and they have grown from the first, and have been dressed with guano mixed with salt I contrive to give it so as to keep it from the hearts.

3, Club, ambury, and all the grubs seemed to combine to prevent my getting a Cabbage to heart, Cauliflower to head, or Turnip to form. Hanging their heads in the sun was powerful evidence of what was gnawing at their vitals; they were dressed with the guano and salt, and they have reared their heads ever since, and are quite free of any grubs or pest of any kind.

Lastly, in a greenhouse that may have 30 feet of rafter I had some climbers in a border; they seemed to grow and flower finely up to July, when they came to a standstill. They are Passifloras Countess Nesselrode, Countess Guiglini, cærulea racemosa, Tacsonia mollissima, and T. Van-Volxemi. Guano water, &c., had no beneficial effect, but I gave them about a peck of guano and salt broadcast over the border (30 feet by 3 feet), and then washed it out of sight with water from a hose. The effect has been all that could be wished for; the plants are growing, flowering, and fruiting. The 30-feet length of rafter has been covered, and all the bars which there are to every rafter, and the shoots hang down in all lengths, from a few inches to 6 feet, and these, with the flowers and the hanging fruit, have quite a grand effect.

I am convinced that guano and salt in the proportions named will prove to be the manure of manures for Vines, especially those that have a tendency to mildew; also for Peaches, which never do so well as near the sea or within reach of its influence. It will also be good for all plants subject to mildew. Salt and lime are the most destructive of all to fungoid life.

Ferns are speedily destroyed by guano and salt, but it is remarkable that if freestone be sprinkled with it that the stone in a few days becomes quite green from the growth of moss: hence it may be of value in newly-formed rockwork.—G. Abbey.

THE LATE MR. THEODOR HARTWEG.

My late and much-esteemed friend, Theodor Hartweg, was, I think, the best plant and seed collector the London Horticultural Society ever employed. Professor Lindley said to him in my hearing and presence in the Council-room at Chiswick garden, "Well, Hartweg, the Council have resolved to send you to California, and if you find this single plant (Zauschneria) and send home seeds or plants of it in good condition, it will pay the Society for your mission if you send nothing else. Come over to my house, Acton Green, and see the dried specimen of the plant in my herbarium before you start." I may add that Hartweg found it and sent it home, and I was eyewitness to thousands of young plants being distributed to Fellows of the Society upon application, as well as thousands of other valuable plants sent home amongst his collections from time to time whilst he was in the employ of the Society. I had the pleasure of "writing out" all the reports of plants and seeds and their condition when sent home by him, to be placed before the Council of the Society when they met at their rooms, 21, Regent Street, with the exception of those of his first Mexican mission, consisting chiefly of Orchids, Fir cones, &c.

I am well aware that the Secretary and Vice-Secretary were not Hartweg's best friends at that time of day mentioned in your short notice of Hartweg's death. Hartweg told me at the time when all this ill-feeling was going on about himself, that he had a very great aversion to writing about any subject: hence this will show his unwillingness to write anything in the shape of a journal of his travels at the time for the "Journal of the Horticultural Society:" hence also the cause of his few bad friends. Animosity was carried to such a pitch against him on this account by a few only of the officials of the Horticultural Society, that a short time after he returned from his last mission for the Society the then Vice-Secretary would not accept of a set of the dried plants which Hartweg had collected, but returned them by me, and never even opened the parcel nor examined the specimens.

These recollections come very vivid in my memory now I have pen in hand, and I hope you will think no worse of me for placing them at your disposal.

I always found that Hartweg acted as a perfect gentleman in all his dealings with me at the time we were both in the employ of the Society. I have often heard him say that Mr. George Ure Skinner and himself discovered the large plant of Lælia superbiens both at the same time when in Mexico, and that they were both determined to have it, but could not get it then, for it was up a very high tree. Hartweg outwitted Mr. Skinner by

going early in the morning, taking with him a native and an axe, and chopping the tree down, at the same time conveying away the large Lælia. I recollect helping to unpack it at Chiswick on its arrival, and it just filled one large wooden case, and arrived in excellent health. "Plantæ Hartwegiæ," by Mr. G. Bentham, will commemorate his name, as well as the simple-looking little plant (Orchid) called Hartwegia purpurea, also Aristolochia gigas. Of the plants of a hardy nature introduced by him many have found their way here, and are growing and flourishing, especially his varieties of coniferous plants.—William Swale, *Avonside Botanic Garden, Canterbury, New Zealand.*

SIBERIAN AND SCARLET CRABS ON THE PARADISE STOCK.

In walking through the grounds at Sawbridgeworth with Mr. Rivers I was so much struck with the above that I cannot resist giving you a word or two as to their beauty. The trees were two years old, pyramids about 3 feet in height, eminently beautiful, being covered with their bright fruit; they would indeed form ornaments to any garden.

The Paradise stock seems here to be an article of the most extensive culture; for, to my surprise, Mr. Rivers pointed out to me a "quarter"—one piece—of 40,000, planted with the Nonesuch and Broad-leaved Paradise, all in the most exuberant health, and in another part of the grounds was a square of bush Apple trees on these stocks, 4 feet apart, every tree a picture of fertility, and such grand fruit I never before saw. Mr. Rivers said that many other stocks of this race (of which he has from sixteen to eighteen varieties in one bed, including Mr. Scott's "Pommier du Paradis"), all give the same, or nearly the same, fertility. The latter seemed a good variety of the Doucin, and quite distinct from the dwarf French Paradise (of which there are two sorts here), near which it was growing. Mr. Rivers pronounced it be a good stock.

Bush Apple trees planted 4 feet apart, the ground not dug, but kept clean with the hoe, should be in every garden. Mr. Robinson's cordons, both on the French and English Paradise, are very healthy, and are now some six or eight years old; they have failed to give any quantity of fruit, they have failed the last three seasons, still they are very pretty. At present, in my opinion, Apple bushes on the Paradise stock are much to be preferred to cordons; they bear more fruit, and are but little trouble.—Amateur.

DISA GRANDIFLORA GROWING AND FLOWERING IN THE OPEN AIR.

When some few years since the "Pride of Table Mountain," Disa grandiflora, long the opprobrium of the British Orchid-grower, yielding to the thoughtful and judicious treatment of Mr. Leech, was successfully flowered by that gentleman, great was the interest generally manifested by the Orchid-growing community. Since then far greater success than Mr. Leech's has been obtained by many growers of our acquaintance, and to meet this Cape diamond well grown and splendidly flowered in collections is not very rare.

We ventured to express an opinion as to the feasibility of the Disa being grown and flowered in the open air in a favoured spot in Ireland, if planted in the grassy verge near the edge of the water, so as to have its toes (roots) in it. The experiment has been tried nearer home this season, and, we are happy to say, with very satisfactory results. To Dr. Moore, of Glasnevin, attaches the credit of practically demonstrating that this gem of the South African Orchidaceæ may not only be grown and flowered successfully in the open air, but that the brilliant colouring of its flowers becomes vastly intensified when so grown, as compared with those of plants flowered under glass.

In the most interesting spot of the Glasnevin Gardens—the miniature artificial bog—we recently had the pleasure of seeing the Disa growing and flowering admirably, and, as remarked above, the colour of the labellum and of the divisions of the perianth was far more brilliant than we ever before saw it, or as was apparent in the splendidly-grown specimens to be seen in-doors in the same establishment. The plant, it appears, had been started in the usual way, and turned out in the open early in the present season, with what results has been just told.

We have little doubt from this and other experience of the Disa that in suitable and properly-selected spots it may be turned out and allowed to take care of itself in winter as well as in summer—in a word, treated as a hardy plant. We hope Dr. Moore will extend his experiments by letting his plant take its chance in the coming winter, and thus demonstrate the hardihood or otherwise of this most striking and interesting of the terrestrial section of the Orchidaceæ.—(*Irish Farmer's Gazette.*)

A FEW SUPERIOR MELONS.

I have this season tried the following varieties of Melons under precisely the same circumstances—viz., Golden Queen, Golden Perfection, Queen Emma, Trentham Hybrid, Colston Bassett Seedling, Dr. Hogg, Heckfield Hybrid, and Strathfieldsaye. All these are good varieties, and many of them well known to most of your readers.

Colston Bassett Seedling, Dr. Hogg, and Heckfield Hybrid are rather new varieties, at least they have not long appeared in the nurserymen's catalogues. To those who do not know them and wish to grow a number of varieties, I recommend them as being worthy of a place in any collection, and especially Colston Bassett Seedling. It has a strong constitution, is very prolific, and of excellent flavour. Golden Perfection, although an old variety, still holds its ground and merits a place among the best varieties. Golden Queen I consider a great acquisition, much superior to any other variety that I have grown or seen. It has a robust constitution and sets freely. The fruit swells well (from 4 to 5 lbs., three fruit on a plant), and in flavour it is everything that a first-rate Melon ought to be, while for its handsome appearance it stands without a rival. This Melon, I feel sure, needs only to be known to be extensively cultivated.—Owen Thomas, *Drayton Manor.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Primula japonica (Japanese Primrose). *Nat. ord.*, Primulaceæ. *Linn.*, Pentandria Monogynia.—"Mr. Fortune, writing to Dr. Hooker, says, 'It was met with by me, in full flower, in gardens near Yedo, in May, 1861. I saved its seeds at the time, and sent them home to England, but they failed to vegetate. Plants also were lost on the voyage. Since that time I have made many efforts to introduce it into England, but only last year succeeded in getting seeds to vegetate. For these seeds I am indebted to W. Keswick, Esq., of Hong Kong, and Messrs. Walsh, Hall, & Co., of Yokohama, which gentlemen have thus the honour of introducing a very lovely plant into English gardens. It is perfectly hardy in England, and is now, April 26th, in full bloom in Mr. Bull's establishment at Chelsea; there are several varieties, all beautiful, and no doubt we soon shall have many more.'" Its flowers are crimson, and in whorls, forming a pyramid.—(*Bot. Mag.*, *t.* 5916.)

Abutilon Darwinii (Darwin's Abutilon). *Nat. ord*, Malvaceæ. *Linn*, Monadelphia Polyandria.—Native of South Brazil. Flowers orange red, striped with crimson.—(*Ibid.*, *t.* 5917.)

Dendrobium barbatulum (Small-bearded Dendrobe). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Western India. Flowers white.—(*Ibid.*, *t.* 5918.)

Grevillea intricata (Inwrapping Grevillea). *Nat. ord.*, Proteaceæ. *Linn.*, Tetrandria Monogynia.—Native of Western Australia. Flowers white, partly pale lemon.—(*Ibid.*, *t.* 5919.)

Darlingtonia californica (Californian Darlingtonia). *Nat. ord.*, Sarraceniaceæ. *Linn.*, Polyandria Monogynia.—Native of California. See Journal of Horticulture, vol. xx., p. 460.—(*Ibid.*, *t.* 5920.)

Eranthemum cinnabarinum *var.* ocellatum (Eyed Scarlet Eranthemum). *Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia.—Native of Moulmein. Flowers crimson. The name "eyed" is applicable to the pink and yellow-encircled blotches on the leaves.—(*Ibid.*, *t.* 5921.)

Cypripedium niveum (Snow-coloured-flowered Lady's Slipper). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Malayan Archipelago. Flowers white, dotted with reddish purple. See Journal of Horticulture, vol. xx., p. 339.—(*Ibid.*, *t.* 5922.)

Utricularia montana (Mountain Bladderwort). *Nat. ord.*, Lentibulariaceæ. *Linn.*, Diandria Monogynia.—Native of the West Indies. White-flowered. It differs from other species by being terrestrial.—(*Ibid.*, *t.* 5923.)

Sedum glandulosum (Glanded Stonecrop). *Nat. ord.*, Crassulaceæ. *Linn.*, Decandria Pentagynia.—Native of Sardinia. Flowers lilac.—(*Ibid.*, *t.* 5924.)

Episcia chontalensis (Chontalensian Episcia). *Nat. ord.*, Gesneraceæ. *Linn.*, Didynamia Gymnospermia.—Native of Central America, being first found in the Chontales region of Nicaragua. Flowers white, with a slight tinge of pink. Leaves margined with brown purple lobes.—(*Ibid.*, *t.* 5925.)

Lithospermum Gastoni (Gaston's Gromwell). *Nat. ord.*, Boraginaceæ. *Linn.*, Pentandria Monogynia.—Native of the Pyrenees. Flowers dark blue, with white eye.—(*Ibid.*, *t.* 5926.)

Tacsonia speciosa, "introduced from New Grenada by the late Mr. Bowman, might have been seen last summer flowering in great beauty in one of the greenhouses at Chiswick. It is quite distinct, in the clear rosy red or carnation colour of its flowers, from any of those previously cultivated. It proves to be the Tacsonia speciosa of Humboldt, Bonpland, and Kunth, a plant which Dr. Masters, who has made the Passion-flowers a study, regards as a variety of Tacsonia tomentosa. There are, indeed, he observes, some half-dozen Tacsonias which are so variable that it is impossible to separate them by any absolute character.

"For decorative purposes we have here a rapid-growing climber, with downy branches, and shining deeply three-lobed leaves, downy beneath, with hooked serratures, and having on the petioles four to six pairs of stalked glands. The stipules are leafy, obliquely ovate, dentate, prolonged into a slender point. The flowers are axillary, the tube cylindrical, green, 3 to 4 inches long, the sepals externally green, internally red, the petals pure rosy red or carnation colour. The coronet is in two rows, the upper of small whitish purple-spotted tubercles; the lower, near the base of the tube, membranous, white, and deflexed. It is a splendid accession to an already beautiful group of greenhouse Passion-flowers, and appear to be a free flowerer, requiring only the ordinary treatment of conservatory climbers."—(*Florist and Pomologist*, 3 s., iv., 169.)

Plum—*Duke of Edinburgh*.—"For this fine new Plum we are indebted to Mr. Dry, Hayes, Middlesex. It is one selected from a numerous batch of seedlings for its handsome appearance and very productive qualities. The name Duke of Edinburgh has been given to it on account of its resemblance to Prince of Wales, to which it has quite a brotherly similarity, not only as regards its general appearance and character, but also in the quality of the fruits. The Prince of Wales, as is well known, is one of the best of culinary Plums, and a most abundant bearer, and such is the character of this new variety, with, however, a marked improvement in flavour.

"The Duke of Edinburgh has fruits large, roundish, inclining at times to obovate, and having a shallow suture. The skin is light purplish, with an extremely dense coating of light-bluish bloom. The stalk is short and stout, inserted in a slight cavity; the flesh reddish yellow, thick, juicy, moderately rich, and separating freely from the stone. It is a very abundant bearer. The leaves are like those of the Green Gage. This Plum was exhibited before the Fruit Committee in August, 1869, and was awarded a first-class certificate."—(*Ibid.*, 193.)

MORE FRUIT AND VEGETABLES WANTED.

Perhaps one of the chief reasons why there is so much intemperance in this country is to be found in the difficulty of obtaining any good fruit at a reasonable price. How small a per-centage of the inhabitants of London have ever tasted a Peach, for instance! Grapes are a luxury only within reach of the wealthy, and, except sour Apples and Oranges, the poorer classes have no fruit which they may call their own. For some reason or other fruit appears to become more scarce each year in this country. Nectarines and Apricots, once common, are now rarely seen, and in a few years will probably disappear altogether. The same may be said of Hautbois Strawberries, which a quarter of a century ago were as plentiful as Gooseberries. It would be an inestimable boon to all dwellers in cities if large depôts of fresh fruit and vegetables, to be procured at reasonable prices, were to take the place of the dirty little greengrocers' shops, where stale Cabbages and unripe mouldy fruit are retailed at exorbitant charges. Nor should this be impossible, for there are few trades more profitable than market-gardening; but the truth is that great improvements have yet to be effected in the packing of fruit and vegetables, and in the cooking of the latter. When fruit arrives even at the greengrocer's shop it is too often in a damaged and "unfresh" condition, and vegetables, which equally suffer in transit, are only purchased as luxuries for the simple reason that, apart from their cost, few people know how to cook them in such a manner that they may be used as substitutes for animal food. It is to be hoped that one of these days some method will be discovered by which fruit and vegetables may be packed and transmitted with as little damage as Australian beef and mutton, and the market for these articles be placed on a more satisfactory footing than it rests upon at present.—(*Pall Mall Gazette.*)

ROYAL HORTICULTURAL SOCIETY.

September 20th.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair Mr. William Paul, of Waltham Cross, sent three very large bunches of a new Grape, called Winter Muscadine. Each of them was between 4 and 5 lbs. in weight. The berries are white, and become yellowish when ripe, and the flavour is that of the Royal Muscadine. The Committee, while admiring the magnificent bunches, were of opinion that they were not quite ripe, and requested Mr. Paul to exhibit it a little later in the season. Mr. Earley, gardener to C. M. Inglehy, Esq., Valentines, Essex, sent a bunch of Black Hamburgh Grapes, cut from the parent of the great Vine at Hampton Court. Though the bunch was one of sixteen grown on a rod 18 feet long, it was of large size, and the berries were large, well-coloured, and of good flavour, shewing that there is still considerable vigour in the old Vine. Mr. William Paul sent a collection of eighteen different varieties of Plums. Mr. George Lee, of Clevedon, near Bristol, sent fruit of Pond's Seedling, or Fonthill Plum, with the accompanying account of it—

"Clevedon, September 19th, 1871.

"Dear Sir,—I sent off this morning a little box containing four Plums, another sport, but the whole tree this time. The graft was from Fonthill, but you will see the fruit is not so tapering at the stem, is darker, a little earlier, and the wood buds and leaves quite distinct from that variety.

"The tree is about ten years grafted, is about 7 feet high. It was grafted about 6 inches from the ground. The first shoot the graft made, about 2 feet in length, was quite void of any buds; the next year it started from the extremity, but has grown very slowly compared with other trees of the same age and under the same circumstances, girth above and below the graft 4 inches. I measured another Fonthill tree, same age; this is 12 feet high, and girth above and below the graft 7 inches; but they are and have been in a nursery for want of room, but removed. The branches of the sport have been several times cut back; the under ones are about 1 foot 9 inches, and those towards the top about 1 foot in length. I have not the least idea what the stock is, but I will try and ascertain by taking up some roots. The ordinary size of the fruit is about four times that of the Plums sent. It is sometimes quite egg-shaped, and very distinctly spotted all over.—I remain &c., George Lee."

Mr. H. Eckford, Coleshill Gardens, Highworth, sent a seedling Nectarine, called Coleshill, the flavour of which was inferior. Mr. W. Paul sent a dish of Pears, among which were Summer Franc Réal, Poire Pêche, Williams's Bon Chrêtien, and Autumn Bergamot. Messrs. Rivers & Son, of Sawbridgeworth, sent a collection of ten small pyramidal Plum trees, literally studded with fruit, and they were the admiration of the Committee. They consisted of Belle de Septembre, Late Black Orleans, Autumn Compôte, Imperiale de Milan. To these a special certificate was awarded. Mr. R. Fenn, The Rectory, Woodstock, exhibited three dishes of Apples—one, the Ribston Pippin on the Apple stock, another the Ribston Pippin growing on its own roots, after being grafted on a seedling from Blenheim, and a third the Ribston Pippin grafted on a stock raised from seed of the Blenheim Pippin. The fruit of the last was certainly altered in its character and appearance. Mr. Squires, gardener to H. G. G. Ludlow, Esq., Heywood, Westbury, sent a dish of Nectarines, called Heywood Seedling, but the flavour was not equal to other varieties in cultivation. Messrs. Sutton & Son, of Reading, sent a brace of very handsome Cucumbers, called Marquis of Lorne, cut from a plant which has been producing fruit since May last.

Mr. J. May, The Gardens, Hayling Island, Hants, sent a dozen Shallots, weighing 4 lbs. They were considered by the Committee the finest they had ever seen, and were awarded a special certificate. Mr. Piccirillo, of Wigmore Street, sent four heads of Garlic of immense size, weighing 2 lbs. 6 ozs., and two roots of the Giant White Tripoli Onion, one weighing 3 lbs. 13 ozs., and the other 3 lbs. 11 ozs. Their circumference was 2 feet 1 inch. They were awarded a special certificate. Messrs. Criscuolo, Kay, & Co., Gracechurch Street, sent a collection of Italian Onions, among which were the Red Maggiola, Early White Maggiola, and Blood Red Tripoli. They were awarded a special certificate.

Mr. Thomas Simpson, the gardens, Broomfield Lodge, Chelmsford, sent tubers of what was supposed to be a graft hybrid between the Potato and the Jerusalem Artichoke, but in the opinion of the Committee no union had taken place between the two tubers. Collections of Potatoes were exhibited by Mr. R. Fenn, of Woodstock, Messrs. Sutton & Son, of Reading, Messrs. J. & C. Lee, of Hammersmith, and Mr. Richard Dean, Bedfont, to each of which a special certificate was awarded. Mr. Fenn also exhibited a collection of seedling Potatoes of a very interesting character, illustrating his mode of crossing different varieties to obtain those varieties he is desirous of establishing in general cultivation. The collection was awarded a special certificate.

Prizes were offered for the best and second best dish of dessert

Apples, and were awarded to Mr. Gardiner, gardener to E. P. Shirley, Esq., Lower Eatington Park, Stratford-on-Avon, and to Mr. Craddock, gardener to Lord Willoughby de Broke, Compton Verney, for Ribston Pippin.

The best dish of Pears was Bon Chrêtien Fondante from Mr. Bray, gardener to E. A. Sanford, Esq., Nynehead Court; the second best being Jersey Gratioli from Mr. Tranter. The other dishes shown were principally Williams's Bon Chrêtien and Marie Louise.

The only collection of Tomatoes came from Mr. Earley, Valentines, Essex, and consisted of the Red Cherry, Orangefield, Tomate de Laye, and a kind called Earley's Defiance.

Floral Committee.—W. Marshall, Esq., in the chair. Before proceeding to other business Dr. Denny moved the following resolution, which was seconded by W. Beattie Booth, Esq., and carried unanimously—viz.,

"That this Committee is desirous of recording their deep regret at the loss they have recently sustained by the death of their much-esteemed Chairman the late Rev. Joshua Dix, whose genial and kindly disposition, and universal courtesy attached each member personally to himself, and whose business-like habits, in conjunction with his knowledge and love of floriculture, pre-eminently fitted him for the post he filled.

"Moreover, devoting as he did a large portion of his time and energies with untiring zeal to the advancement of floriculture, and to maintain the usefulness, popularity, and honourable position of the Royal Horticultural Society, his loss will long be felt and deplored not only by the Committee over which he so ably presided, but by all connected with the institution."

It was further resolved that Mrs. Dix be written to, and the sorrow of the Committee expressed at the loss which she and they had sustained.

Prizes were offered on this occasion for the best twelve double Zinnias. Mr. G. Wheeler, Warminster, was first with large, very double flowers, varying in colour from bright scarlet to orange and buff, others being purplish rose; Mr. Bray, gardener to E. A. Sanford, Esq., Nynehead Court, Wellington, was second, and Mr. B. Porter, gardener to Mrs. Benham, Sion Lodge, Isleworth, third.

For Double Stocks there was also a class, but no exhibitor came forward; and of twelve Pentstemons there was only one stand, which came from Mr. Porter, Isleworth, and took a first prize.

For three feathered Celosias a second prize was given to Mr. S. Thorn, gardener to E. Buckingham, Esq., North Hall, Hampstead. There were classes for Helichrysums and Begonias in pots, but no exhibitor came forward except Mr. Bull, who had a first prize for well-flowered plants of Begonias Glitter, Miniata, and Carminata, the others being leaf kinds.

Messrs. Veitch sent a group of plants for which a special certificate was given. Among them were several Agaves. A. rotundifolia received a first-class certificate, and of the others A. scabra was of a glaucous hue, while A. streptacantha was of a sea green. Vriesia brachistachys, with yellow and brilliant crimson spikes, had a first-class certificate. In the same group were several plants of the Amaranthus salicifoline, introduced by Mr. John Gould Veitch, which was figured last week, as well as the pretty dwarf Thymus citriodorus aureo-marginatus with dark green leaves, deeply edged with yellow; a fine pan of the singular Venus's Fly-trap, Dionæa muscipula, Cattleya maxima, Lasiandra macrantha floribunda, one of the most showy of Melastomads, but in the specimen exhibited with only one flower, and that of a colour much wanted in our exhibition plants—namely, violet; Oncidium trulliferum, Cattleya Devoniensis, and Aphelandra aurantiaca Roezlii, with splendid orange scarlet flowers and leaves veined with grey.

Mr. Denning, gardener to Lord Londesborough, Grimstone Park, Tadcaster, sent a fine group, for which he received an extra prize and a special certificate. In this were three magnificent plants of Vanda cærulea, two of them with one spike each respectively with fourteen and fifteen flowers, and the other with two spikes. The effect of the masses of large pale blue flowers was superb. In the same group were fine examples of Oncidium macranthum, Epidendrum dichromum amabile, Lycaste Schilleriana, together with Odontoglossum Galeottianum, white, barred with brown at the base of the petals, and streaked with yellow on the lip, and Peacatorea Wallisii, white, tipped with purple, and the lip violet purple, except towards the base. This had a first-class certificate. Mr. Denning likewise sent three fine plants of Dendrobium chrysanthum, one plant having a flowering length of raceme 2 feet in length, covered with the rich yellow crimson-spotted flowers. Mr. Bull sent an Alocasia, stated to be a hybrid, but very like Lowii. From Mr. Russell, Mayfield, Falkirk, came a magnificent cut spike of Saccolabium Blumei Dayanum 20 inches long, crowded with flowers, but bifurcated near its lower extremity. It may be questioned whether this was not a case of fasciation—the union of two flower stems. We believe this exhibition was recommended to the Council by the Committee as being worthy of a medal. A special certificate was also given Mr. Russell for a fine cut spike of Cattleya elegans.

From Messrs. Carter & Co. came Capsicum Princess of Wales, used in the public gardens at Milan for bedding, where it is said its red pods last season were much admired after the leaves had been destroyed by frost. The same firm also sent the Begonia exhibited at the previous meeting. From Messrs. Cripps, Tunbridge Wells, came Begonia Pearcei rosea, a showy variety with large pale red flowers.

Mr. Barrance, Burton Road, Lichfield, sent Bronze Geranium Earl of Lichfield, a pretty variety; Mr. Wilson, gardener to W. Marshall, Esq., Enfield, double-flowered Geranium Katie Marshall, a seedling from Triomphe de Thunnesnil, with fine large scarlet flowers, but deficient in size of truss; Mr. G. Smith, Edmonton, several seedling Zonal Geraniums with very large fine-formed flowers, but not, apparently, from the want of buds, blooming in long succession. Mr. Thorn sent grafted Fuchsias, dark and light kinds being worked on each other. From Mr. W. Paul, Waltham Cross, came a fine collection of Roses, and splendid collections of Gladiolus and cut flowers of Geraniums. For the last two as well as for the Roses a special certificate was given. Mr. Knight, Hailsham, had a first-class certificate for climbing Rose Princess Louise Victoria, which was exhibited on June 21st. It is of a perpetual character, and of robust growth.

Mr. Green, gardener to W. Wilson Saunders, Esq., Hillfield, Reigate, had a first-class certificate for Hechtia argentea with silvery leaves; the same exhibitor also had Adamia versicolor with purplish lilac flowers, and small globular blue flower buds produced in great abundance.

Of new Dahlias there was a large number. Mr. Turner, Slough, again exhibited John Standish and Mrs. Saunders, which had a first-class certificate at the last meeting. Mrs. Waite which had a second-class certificate then, had one of the first-class. Livonia, beautiful rose, had one of the first-class, also Mephistopheles, large, rich maroon. Second-class certificates were given for Master McGrath, magenta; Ranunculus, Yellow Standard, and Bucks Lass. We also noticed Black Bess, claret; and George Eyles, the latter very showy, golden yellow edged with red. From Mr. Turner came also two stands of Pompon Dahlias, comprising North, White Aster, and other showy little varieties. Mr. Rawlings, Romford, had second-class certificates for Golden Beauty, yellow, and Mrs. Bennett, lilac. Mr. Lidgard again exhibited Model, which had a second-class certificate at the last meeting. Mr. Parker, Maiden's Green, Winkfield, had a first-class certificate for Admiration, an extraordinarily showy Fancy Dahlia, yellowish cream ground streaked with purplish crimson, and a certificate of the second class for John Batten, dark maroon. Mr. Wheeler, Warminster, and several others also exhibited seedlings, but as none obtained even a second-class certificate, it is useless describing them.

Mr. Eckford, gardener to the Earl of Radnor, Coleshill, exhibited several fine seedling Verbenas, of which the following had first-class certificates—namely, Lady Braybrooke, white, rose eye, fine; Lady Gertrude, pale lilac, with a purple eye; and Mauve Queen, purplish lilac.

Messrs. Osborn & Son, Fulham Nurseries, exhibited flowers of several varieties of Hibiscus syriacus, and fruit of several kinds of Pyrus, &c.

IVY WITH ROSES.

One of your late correspondents inquired whether Ivy and Roses could be grown together upon a wall. I was indebted to the lamented Donald Beaton for having given me instructions how to effect this. He recommended that strong-growing Roses should be planted at the same time as the Ivy, which would prevent the latter gaining the pre-eminence. This plan I adopted upon a long wall 10 feet high, selecting the strongest of the Bourbons, and of course taking care to have plenty of well-rotted dung, &c., at their roots. The result fully bore out the excellency of the advice, for the Ivy-covered wall was a marvel of beauty, with its wreaths of Roses, especially in the autumn when Roses became scarce; the background of dark green giving a charm to the flowers which could scarcely be appreciated unless seen.—Hortator.

LA VERSAILLAISE RED CURRANT versus APHIDES.

In your issue of the 7th inst. I was pleased to observe Mr. Luckhurst's testimony in favour of the apparent capability of this variety to resist the visitation of the aphides, which so universally attacked the majority of the fruit trees all over the country during the past season. I regret, however, my inability to corroborate Mr. Luckhurst's experience therein, inasmuch as with me La Versaillaise was amongst one of the first infested and consequently injured. Hence I am inclined to infer that causes other than the mere inherent constitution of this particular variety must be assigned to the immunity enjoyed by the bushes in question—an inference further supported by the fact that in a few instances the common red variety, which is distributed over the greater portion of the garden here, chiefly in a single row by the sides of the walks, escaped with impunity; whilst in other instances the villainous crew attacked in "high force," then apparently swept over the garden

in drifts, and commenced to exercise their predatory propensities irrespective of variety.—WILLIAM GARDINER, *The Gardens, Lower Eatington Park, Stratford-on-Avon.*

CATERPILLARS ON SCOTCH FIRS.

I SEND you a small branch cut off a Scotch Fir tree in a young plantation, which you will perceive is entirely covered with a peculiar kind of caterpillar. Numbers of Scotch Firs are affected in the same way, but though there are Larch and Spruce Firs on all sides of them, the caterpillars have not touched one, but have confined their depredations to the Scotch Firs. We have never had an instance of the kind before, and I shall feel much obliged if you or any of your correspondents can tell me how to get rid of the caterpillars. I have had them picked off the young trees by hundreds, but it is almost impossible to take them all off in a large plantation.—JOHN MASSY, *Lareen House, Kinlough, Bundoran, Ireland.*

[The Fir spray was truly enveloped by the caterpillars. They are the larvæ of the Pine Saw-fly, Tenthredo Pini. They are great scourges of the Pines in Germany. The woodpecker eats the caterpillar, and the field mouse the pupæ, into which form the caterpillar usually passes in the soil beneath the trees. Dusting with quicklime might destroy them. We shall be glad to hear from correspondents on this subject.—EDS.]

NEW BOOK.

Hardy Flowers: Descriptions of Thirteen Hundred of the most Ornamental Species, &c. By W. ROBINSON, F.L.S., &c. London: F. Warne & Co.

THIS is a very useful volume, and the nature of its contents will be best made known by two extracts:—

"The only phase of the culture of the subjects embraced by this book that requires any elucidation from me, is the culture in pots, a way in which but few persons will grow them. But, for the reputation of these plants, it is very desirable that they should not be shown in the wretched condition in which they are usually seen at our shows. Anything that really requires to be stated as to the general culture of hardy perennials in the open air, in borders, &c., will be found under the head of the Mixed Border; while the culture of the fastidious alpine plants is fully described in 'Alpine Flowers.'

"We are pre-eminently great at exhibiting; our pot plants are far before those of other countries; specimens are to be seen at every show which are models not only as regards beauty, but as showing a remarkable development of plant from a very small portion of confined earth exposed to many vicissitudes; yet in one respect we have made no progress whatever, and that is in the pot-culture of alpine and herbaceous plants for exhibition purposes.

"Prizes are frequently offered at our flower shows for these plants, and usually awarded, but the exhibitors rarely deserve a prize at all, for their plants are usually badly selected, badly grown, and such as never ought to appear on a stage at all. In almost every other class the first thing the exhibitor does is to select appropriate kinds—distinct and beautiful, and then he makes some preparation beforehand for exhibiting them; but in the case of our hardy subjects, anybody who happens to have a rough lot of hardy miscellaneous rubbish exhibits it, and thus it is that I have seen such beauties as the following more than once exhibited: a common Thrift with the unremoved dead flower-stems drooping over the green leaves; a plant of Arabis albida out of flower; the Pellitory-of-the-wall, which has as little beauty in flower as out of it; not to speak of a host of worthless things not in themselves ugly, but far inferior to others in the same families. What would become of our shows if the same tactics were carried out in other classes? Even the most successful exhibitors are apt to look about, a day or so before a show, for the best flowering cuttings of such things as Iberis correæfolia, and, sticking four or five of these into a pot, present that as a "specimen." Now, what is so easily grown into the neatest of specimens as an Iberis? By merely plunging in the ground a few 6-inch pots filled with rich soil, and putting in them a few young cutting plants, they would, 'left to Nature,' be good specimens in a short time, while with a little pinching, and feeding, and pegging-down they would soon be fit to grace any exhibition. So it is with many other things of like habit and size—the dwarf shrubby Lithospermum prostratum, for example; a little time and the simplest skill will do all that is required. Such subjects as the foregoing, with tiny shrubs like Andromeda tetragona and A. fastigiata, the Menziesias and Gaultheria procumbens, the choicer Helianthemums and dwarf Phloxes, and many others enumerated in the selections of exhibition plants at the end of this volume, might be found pretty enough to satisfy even the most fastidious growers of New Holland plants.

"The very grass is not more easily grown than plants like Ibarises and Aubrietias, yet, to insure their being worthy of a place, they ought to be at least a year in pots, so as to secure well-furnished plants. Such vigorous subjects, to merit the character of being well grown, should fall luxuriantly over the edge of the pots, and in all cases as much as possible of the crockeryware should be hidden. The dwarf and spreading habit of many of this class of plants would render this a matter of no difficulty. In some cases it would be desirable to put a number of cuttings or young rooted plants into 6-inch pots, so as to form specimens quickly. Pots of 6 inches diameter suit well for growing many subjects of this intermediate type; and with good culture and a little liquid manure it would be quite possible to get a large development of plant in such a comparatively small pot; but if very large specimens were desired, a size larger might be resorted to."

"PHLOX SUBULATA (*Mossy P.*).—A pretty dwarf kind, with creeping, tufted stems, densely clothed with narrow moss-like leaves. *Flowers*, in April and May, in great profusion; pinkish purple, with a darker centre (sometimes white), in few-flowered corymbs; lobes of corolla wedge-shaped, notched, rarely entire; tube of corolla arched. *Leaves*, from ¼ to ½ in. long, awl-shaped, or narrow-lance-shaped, fringed on the edges, pubescent, rigid. A variety, *P. setacea*, has smaller flowers, with a straight tube, and a paler centre; its leaves also are not ciliated on the margin; the white-flowered form is grown under the name of *P. Nelsoni*. North America.—The rock garden, borders, in tufts, on the edges of beds of low shrubs, in the small rings at the base of standard Roses, and in many like positions, in rather moist, sandy loam. Division.

"VILLARSIA NYMPHÆOIDES (*Common Villarsia*).—An attractive British aquatic, with simple leaves (like those of a Water-lily but smaller) floating on the surface of the water. *Flowers*, in summer; yellow, borne singly on stalks as long as those of the leaf. *Leaves*, heart-shaped or roundish, on long stalks; stems creeping and rooting at the base, dichotomous, and ascending to the surface of the water, with a single leaf at each of the upper branches, and a terminal tuft. Europe and Asia, and many places in England and Ireland. —— Lakes, ponds, and quiet bays in streams. Division."

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 18.

SURELY the little moth called the Vapourer (Orgyia antiqua), is one of the liveliest of his family, or at least the male of the species, for while he is gyrating in the summer sunshine his better, or at least his plumper, half sits in comparative obscurity, deprived by nature of the power of flying. What there is of antiquated aspect about the species to give rise to the Latin name I can hardly determine; the English name was suggested by the peculiar mode of flight of the male insect. But though called a vapouring, it is really such an irregular capricious movement as to be scarcely definable; and this moth can, if alarmed, career along at a pretty good speed in a straight line, though a zigzag course suits it best when at ease. Seen about the London parks and squares, it is occasionally designated by the bypasser as a brown butterfly, from the fact of its being on the wing in the day, and it is chased by many a child with varying success. The fact is interesting, that only one British species is known which closely resembles the one before us, and it is as rare as its relative is common.

The caterpillar of the Vapourer moth must at some time or another have come under the notice of every gardener who keeps an eye upon the insect life about him, as all gardeners might be expected to do. It appears to feed on all sorts of trees and shrubs, and even on low plants too, should it fall by accident upon anything to its taste. I fancy the species has rather a partiality for cultivated, or at least for enclosed ground, though it is also found in woods, fields, and other localities in the open country. It can hardly be said to occur in sufficient abundance to do any positive injury, yet I have seen some fruit trees nearly denuded of their leaves by the jaw work of these caterpillars, for they are very voracious feeders. One of the singular circumstances connected with the history of the Vapourer is the fact that the moths, chrysalids, and caterpillars may all be found together at a certain period of the summer. This is because the eggs are hatched a few at a time, not simultaneously, as in many species, so that there may be an interval of a couple of months between the emergence of the first young caterpillar each season and the appearance of the last. Mr. Newman first noticed this circumstance in print, and it partly explains why the ravages of the caterpillar are comparatively inconspicuous—namely, that the individuals are not all feeding at the same time, but appear in successive batches.

In the winter months a glance at the walls or fences of a garden, or the bare twigs, will often reveal the cocoon and eggs of this species, since it passes the winter in the latter condition. If the horticulturist is a sworn foe to all caterpillars, large or small, troublesome or harmless, he will probably squash or burn these, and nip these germs of life in the bud. But is it not surprising that these eggs stand the severest cold of winter without having their vitality impaired, though the shell is much

thinner than that of birds' eggs? It has certainly in most cases a remarkable toughness as well as elasticity. The contents of the eggs of butterflies and moths are also fluid, yet when plunged in strong freezing mixtures they do not solidify. These eggs of the Vapourer are, as already remarked, deposited in the cocoon, yet not to any extent protected thereby, though some theories have been spun out of this fact, and also out of that of the winglessness of the female—theories which it is really scarcely necessary to touch upon. One thing is certain—that the eggs of the Scarce Vapourer are deposited in exactly the same situation, and they are hatched in the course of a week or two. Occasionally, also, the eggs of the commoner species are some of them hatched the same summer.

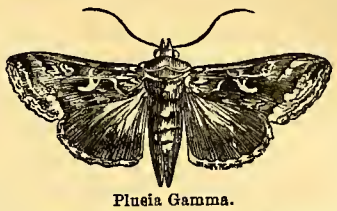
Different caterpillars of the Vapourer vary much in colour, but the full-grown female caterpillar can generally be distinguished from the male by its greater size, and, as I fancy, it is not quite so hairy. The ground colour is shades of grey, brown, and pink, the most prominent peculiarities being the fine "brushes" of hairs, which are elevated on the back, and a slender tuft in the last segment, while from the second segment there spring two pencils of hairs, which are black and diverge from each other. In constructing its cocoon this caterpillar removes its investiture of hairs, and weaves them in with the silk, of which it has, seemingly, but a poor supply.

Another hairy caterpillar, which is common upon fruit trees about London in the month of September is that producing the moth called the Daggers (Acronycta Psi), the species receiving its name from some peculiar marks in the fore wings, variously compared to the shape of a dagger, or to that of the Greek letter *psi*. The perfect insect is frequently to be seen reposing on the trunks of trees in June. The eggs of the species have not as yet come under my observation, but I suspect they are deposited on the leaves of the trees on which the caterpillar is found, not on the trunk or branches. It appears to be partial to the Pear, though feeding rather indiscriminately on trees, rarely upon shrubs. This caterpillar may be at once recognised by a singular lump of a deep black, which rises from the fifth segment, and which is long and perpendicular; at the anal extremity of the body is a smaller and broader protuberance. The colour generally is a mixture of yellow and black: the head is black and very shining, as is the case with all the Acronyctas. It is rather curious that another species, A. tridens, so nearly resembles this in the imago state that few entomologists can distinguish them. The caterpillar is markedly different, proving the genuineness of the species. It is far less abundant.

Another autumnal moth, much larger than the two just described, and which appears to be pretty generally distributed throughout the British islands, is the sombre-looking creature called the Old Lady (Mania maura), and it is a frequenter of gardens. It is not at all an active species, though it will flap along in a sort of stealthy manner to the sweet compounds which insect-hunters spread sometimes upon the trees as baits for moths. In fact this Old Lady, like other ancient dames two-footed and not six-footed, has several peculiarities. Mr. Newman observes that "it is fond of resorting to summer-houses, boat-houses, sheds, &c., in the interior of which it may frequently be observed in the daytime sitting on the inner surface of the roof. I once counted twenty-eight in a boat-house at Godalming. A marked specimen has been noticed to return to the same house after being repeatedly rejected." Quite true to character this, old ladies are generally obstinate. But the Old Lady moth has another penchant, which is decidedly not one in which we can sympathise, and this was first pointed out to me by a non-entomologist. In addition to the resorts above named the Old Lady moths are often found in certain places of retirement which it is hardly necessary to name; and this taste is not much more to the credit of the species than the partiality shown by some of our butterflies for decaying or decomposing animal matter.

The caterpillar of M. maura, like those of some other Noctuæ, feeds both upon low plants and trees; when in a garden it prefers fruit trees. I think that in some seasons the caterpillars feed occasionally during the winter on such plants as Dock and Chickweed, being hatched in the autumn. It ascends the trees in spring with the first appearance of leaf-buds, and is full grown during May. This caterpillar is not often observed, as I believe its habit is to extend itself upon the branches during the day, where its dull brown hue matches very nearly with the colour of the bark. It is of good size, with a small head, and has a very velvety feel.

The insect shown in our figure is one which has at times been the source of some alarm to gardeners, and not without a show of reason. In our gardens the caterpillar is common enough at times to be deemed a pest, and yet, as far as I know, it does not do us material injury; partly because it feeds on various plants, and therefore its ravages are less marked than if it attacked only one or two species, and partly because the moth shows no special liking for cultivated ground, but flies about and deposits its eggs indiscriminately, preferring open places to woods. The Silver Y, or Gamma moth (Plusia Gamma) occurs throughout Great Britain and Ireland, being on the wing in greater or less numbers from the end of May to October. The species is one which all young entomologists are sure to make acquaintance with pretty soon in their excursions, and before long they get to regard it as somewhat of a nuisance. The singular silvery mark which adorns the wings of P. gamma is found in other species of the same genus; and unquestionably, if this moth were not so common it would be regarded with admiration.



Plusia Gamma.

We discover the caterpillars of the Silver Y both in the kitchen and the flower garden feeding on a great variety of plants, but rarely or never ascending trees. I have seen Hollyhocks almost defoliated by them, and Newman states that in his garden he has noticed them every year upon a Hop vine. This caterpillar belongs to what are known as the Half-loopers, and when it is reposing it arches its back and tucks in its head. The colour is greenish, marked with white stripes. There appear to be two broods of the caterpillars annually, one feeding-up in early spring, the other in the autumn, some individuals of each brood growing more slowly than the rest of their brethren.

Kirby and Spence give a dismal account of the devastation committed by this moth in one instance. They say, "In the year 1735 it was so incredibly multiplied in France as to infest the whole country. On the great roads, wherever you cast your eyes, you might see vast numbers traversing them in all directions to pass from field to field, but their ravages were particularly felt in the kitchen gardens, where they devoured everything, whether pulse or pot herbs, so that nothing was left besides the stalks and veins of the leaves. The credulous multitude thought they were poisonous, report affirming that in some instances the eating of them had been followed by baneful effects. In consequence of this alarming idea herbs were banished for several weeks from the soups of Paris. Réaumur has proved that a single pair of these insects might in one season produce 80,000." With all deference to so great a name, I feel inclined to doubt whether the latter fact is to be regarded as unquestionably demonstrated. We may keep down the Gammas within certain limits by the adoption of several plans. The eggs may be looked for as they are deposited in small clusters on the leaves, or the caterpillars may be hunted up at early morning especially, for it is true in this, as in other species, that as the early bird catches the worm, so the early gardener secures the caterpillars. A good quantity of the pupæ of the species may be got by exercising a little observation at the right season, as they are not subterranean, but spun up in white cocoons of silk in different plants. Or lastly, to while away an idle hour, the horticulturist might take a net and chase the perfect insects which come freely to flowers, but it can hardly be expected that many will adopt this mode.—J. R. S. C.

NOTES AND GLEANINGS.

There are no less than fifty-nine species of Urtica, more or less distributed over India, most of these possessing textile fibres of great strength and utility. A few of the family are armed, and possess a great deal of venom in their sap; of the latter class we possess on the north-east frontier, and in Burmah, the powerfully-stinging U. heterophylla. However, its pain is only transient; but there is a terrible tyrant of the woods, U. crenulata, which inflicts dangerous symptoms and awful sufferings for ten days, on the slightest touch. Swellings, sneezings, contractions of the jaws, and other tetanic signs rapidly follow a single prick. In the Calcutta Botanic Gardens a French traveller and a workman were stung, and each suffered the above penalty of contact. It was many years afterwards that in the forests of Assam I first made ocular

acquaintance with the "Demon Nettle," as it is called in the island of Timor, another habitat of this ferocious weed. These dreaded guardians of the wilderness attain a stature of 10 or 12 feet, the stems about as thick as a human arm; they are equally shunned by man and beast, and wherever their dense columns are viewed, a hasty retreat is the rule. Occasionally, a high wind will carry the invisible particles and spicula of the pest into a clearing, and soon inflict pains and ailments on the naked squatter. I never feared the plant by daylight, having a quick eye and a ready hand; but it is on those occasions of being benighted or losing your way in such trackless regions that the danger falls on the wanderer sudden and unexpected. With thick backwoods clothing and stout buffalo-hide gloves, my face ran the one sole risk; but it was otherwise with my half-clad native followers and the laden elephants. The latter wise creatures I really believe are guided by acute powers of smell, and I frequently noticed they seemed to swerve from the straight line of travel in alarm at something unseen, probably this vegetation, as we moved along in the darkness, with merely a course set by the stars or the compass!

The Snowy Nettle (Urtica nivea), is unarmed, still more common, and attains the same size as the last-described species: it is known as Bun Rhea, or the wild Rhea, in contradistinction to Boehmeria, or true Rhea, to which it is closely allied. My canoemen, woodsmen, fishermen, &c., all used this very valuable fibre; after beating and washing off the pulp, we employed it for almost all the purposes of hemp, but it is very far superior for all aquatic purposes, as it does not readily rot by moisture or exposure.

Boehmeria, the Rhea of commerce, is largely cultivated in the frontier villages, being the material of which the nets, fishing lines, &c., of the country are manufactured. The fibre is solely stripped off by women and children with the rudest tool imaginable, and hitherto no machine has been found to equal it for cleanness of produce, though, of course, a very slow mode of manipulation. It is one of the most handy plants, also one of the many economic products which were originally introduced into north-east India by the Shans, a people of the Siamese stock. The tool above mentioned merely consists of an old knife blade and a flat piece of bamboo, held together in the fingers to act as a plane.—Eos.—(*English Mechanic and World of Science.*)

THE REV. JOSHUA DIX.

It is with the most painful feelings that we have to record the decease of the Rev. Joshua Dix, M.A., which took place at Langley, near Slough, on the 12th inst. Long a member of the Council of the Royal Horticultural Society, ever taking an active interest in horticulture, and especially in its floricultural branch, his sympathies were too wide to be restricted to this one branch alone, and as a member of the Council of the Society, and as the first Chairman of the Floral Committee, we have reason to believe it was through his influence that much of the useful work which of late years has been carried out by the Society was undertaken. As a member of Council and as Chairman of the Floral Committee, he had at once an opportunity of rendering invaluable service to the Society by representing in the proper quarter any misunderstanding that may have arisen between the governing body and the practical element of the Society. His uniform courtesy and geniality endeared him to all who had the privilege of his acquaintance, and the active members of the Society will long cherish the remembrance of the pleasant days when Mr. Dix laboured in the midst of them.

After the meetings of the Committees of the Royal Horticultural Society yesterday for ordinary business, they adjourned to initiate a memorial to the memory of the late Rev. Joshua Dix. It was proposed by the Rev. H. H. Dombrain, and seconded by Dr. Hogg, that a portrait of the Rev. Joshua Dix be procured, and, with the permission of the Council, suspended in the Council-room of the Royal Horticultural Society, at South Kensington. A subscription list was opened in the room, and upwards of £20 was subscribed. Due publicity will be given to the subject, and it is hoped that all who knew Mr. Dix, and valued the work he has done for horticulture, will aid in this laudable object.

Influence of the Scion upon Stock in Inducing Variegation.—A well-marked illustration of this has recently been noticed by us at Mr. Noble's nursery at Sunningdale. The Golden-variegated Weeping Mountain Ash, two years grafted, standard high, on the common Mountain Ash (Pyrus Aucuparia), had in four separate cases thrown out from the stock variegated shoots—one from the very base close to the ground, and the others about half-way up, about 3 feet or 4 feet from the base. The variegation was whiter than that of the graft, and seemed to be first developed along the midrib of the leaflets, some leaves being only affected in this way, while others had the colour also developed along the course of the main veins.—(*Florist and Pomologist*).

EUCHARIS AMAZONICA CULTURE.

The Eucharis amazonica is one of those plants which amply repay all the attention bestowed upon them. When in bloom, who does not admire their snow-white flowers, contrasting so well with the fine glaucous foliage when in good health? One of its greatest recommendations is, that it can be had in flower at any time by a little forethought and attention to its growth. We find them very useful to come in about Christmas and the spring months. Now is a good time to look them over and see if any require fresh potting; if so, let it be done at once, carefully shaking out the bulbs, as the roots are easily broken off. Arrange the bulbs according to their sizes, putting the large ones into their flowering-pots at once, but not too many bulbs of the largest size in one pot; if too close together the foliage has not room to fully develope, and the flowers suffer. The smaller ones, being put into small pots, will require a shift whenever the roots appear at the side of the pots. This lot can be grown on in autumn—a month or six weeks later than the large ones—and will make a fine succession of bloom the following spring. We find a good fibry loam, chopped up rather rough, with a good quantity of old Mushroom dung sifted through a fine sieve, with a sprinkling of silver sand well mixed, suits them well. In potting, great care should be taken to have the pots well drained, as they are very impatient of stagnant water, although, when growing, they delight in plenty of moisture both at the roots and in the atmosphere.

After potting they should be placed where they can have a temperature of from 65° to 70° at night, with a rise of 16° by day. They are all the better of a little shade on bright days. After they are in full growth a little manure water may be given with advantage; and if a little soot is mixed with the above water, it gives the foliage a brighter appearance. Grow them on in this temperature until about the middle or end of September, the smaller bulbs later, as recommended before, and gradually harden them off until they can stand in a temperature of from 50° to 55°. If there is not much room at command, lay them on their sides under a stage where they can have the benefit of light. Here they may remain for about six weeks, giving little or no water, but syringing them well every day. When wanted to start, let them be taken to the potting-bench, examine the drainage, give them a rich top-dressing; if found to be rather dry, place them in a bucket of tepid water until the ball is thoroughly wet. By plunging the pots in a bottom heat of 80°, with top heat at from 60° to 65°, attending to them well with water both at the roots and syringing frequently through the day, if properly treated before, they will soon begin to throw up their flower stems. We have had plants in bloom which stood for four and five weeks in an entrance-hall in the month of January.—(*The Gardener.*)

PROTECTING FRUIT FROM WASPS.

Wasps and large blue flies have been troublesome within the last fortnight. Before that we did not see a wasp without chase being given, and in most cases he was caught. Whenever they show themselves earlier, the true policy is to give them tempting bottles to go into and drown themselves in the sweet rich liquid. When once their feet are wet and their wings drenched they are powerless to ascend by a smooth glass surface. When they come on us so suddenly there is little chance of enticing them when comparatively few in numbers, though such bottles will help to thin them. We have had as yet no opportunity of testing the mode of killing them advertised in our pages. For a simple trap nothing is better than two hand-lights, the lower one set on four bricks, with a hole or two made in the apex of the glass; the upper glass is set on the top of the lower one, and the space between carefully stuffed with moss, and covered with sand; or stiff clay may be used. A saucer with sweet liquor and decaying fruit is placed in the centre of the lower glass. Wasps and large flies soon

find it out, and after taking what they want, very seldom have the wisdom to go out as they came in. Like higher races of existence whose soaring ambition too often proves their ruin, they fly upwards, find the holes in the hand-light, get through, and fly about in the upper glass until they fall down exhausted. Those who cannot bear the sufferings even of a wasp unmoved, may put all such quickly out of pain and trouble by lighting a paper dipped in brimstone in the lower glass in the evening, and the fumes will be almost dissipated before the morning.

The best security for in-door crops is to stretch some fine gauze netting over the openings intended for ventilation, so as to allow the air freely to pass, and yet keep out wasps and even small flies. On walls—after syringing well to dislodge ants and woodlice, and tarring the bottom of the wall, or even running a cordon of fresh soot along—much may be done to keep away all intruders by covering with fine Nottingham netting, making it secure to the top and bottom of the wall by list or tape. Small pieces may be used to cover individual fine fruit, but it is often difficult to fasten it properly about the stem when the footstalk, as in the case of Peaches and Nectarines, is short. We have often used cotton wadding with good effect, placing it thinly round the fruit, the paper side inwards and the woolly side outwards. Hardly any insects will venture on the loose cotton, as their feet become clogged up and entangled. Put on very thinly, the flavour and colour were little injured.

One of our cheapest resources, however, for fruit out of doors when insects and birds threaten to have more than their legitimate share, is to gather a good quantity of fruit before it is fully ripe—so ripe as to tempt the marauders, and then assist them to ripen with a little heat in rather a close vessel, so as to prevent the juices of the fruit evaporating. We often help Peaches, Nectarines, Plums, Apples, and Pears in this way, and, full of rich juice, no one would know at the dinner-table that they had not been taken ripe from the tree the same day. The birds have begun on some of our latest and hardest Pears, and for that there is no remedy, as they would shrivel if gathered. When the first Pear of Williams's Bon Chrêtien was picked, we took that as a hint to gather a lot of the most forward fruit, and to place them, covered up at first, where they would, after a little full exposure, be juicy and mellow. Much may be done in this way to secure untouched fruit when other means are wanting.—R. F.

BICTON.—No. 2.

The Residence of Baroness Rolle.

The Vines at Bicton could not have been in a satisfactory state in 1869, neither are they at the present time. Several new Vine borders, however, have been made by concreting, dividing, draining, and ventilating. The late vinery in the kitchen garden is a fine house 68 feet long by 16 feet 6 inches in width, the Vines in which are planted in an inside border at about 2 feet apart. These Vines are said to have been planted about twenty years, and soon afterwards mildew is said to have taken and kept possession almost to the present time. Scraping off the Vine bark in the winter, and proper dressings, followed by summer sulphurings seem to have conquered the mildew, for we could detect little, if any. Want of drainage was a great defect, for water was reached within 30 inches of the surface. Excavations were made, concreted, drained, air-pipes laid, and divided into compartments for six borders. The divisions are only brick thick, and give each Vine its own compartment. Replanting a vinery by this plan, the having to sacrifice a whole house for two or three years, is superseded. The question is, whether it is necessary to replant at all, unless by mistake a worthless sort may have been introduced; the roots being so perfectly under control, they can be fed, top-dressed, root-pruned, soil added, and even lifted without injury to the following crop. It is, therefore, only when having found that a bad variety—and there are some of them much talked of just now—that you may have to dig it out, relay your drainage, change the soil, and plant another.

Mr. Bagbie considers the system of air-drains commencing on the front of the Vine border and ascending into the house of great importance, not only as a purifier of the soil, but by a judicious opening and closing of them a much higher root temperature may be secured than by the ordinary method. When we were at Bicton, in mid-August, 73° to 75° was the heat in such borders, and during the summer the average, Mr. Bagbie said, is over 78°, secured by sun heat alone, by opening the air-pipes about 9 A.M., and shutting them at 4 P.M., and this heat, be it observed, is not taken near the surface, but at the bottom of the border next to the drainage. The concrete is laid at 4 feet from the surface, over which at least 1 foot of clean rubble is laid. A 6-inch air-drain-pipe is placed in the centre of each compartment, over the drainage was placed turf in sods of 3 inches in thickness. All was carted in dry weather, and when the soil was neither too dry nor too wet. Over every layer of sods was added a good sprinkling of boiled inch bones, a little soot, and some rough clean plasterers' rubbish. The rougher the soil the better, porosity being the first consideration. Mulchings and waterings in summer the Vines delight in, and rich water too. There is here a row of 4-inch pipes communicating with the drainage and surface of the border, two for each compartment, placed near where the Vines are planted, and by which a supply of liquid to the roots is given when the surface may not require it. There is a large main drain along the front of the border, so as to insure perfect drainage at all times. The borders are not covered in winter by any other material than a surface-dressing of rotten manure, which excludes frost, and encourages the growth of fibrous roots near the surface.

The Heath and New Holland house is a noble structure of 96 feet in length by 17 feet in breadth, and 13 feet in height, with stone table in the centre, stone shelves at each side, and a broad path all round the house. Lady Rolle took great interest in the Heaths, of which she had one of the most extensive collections, and would not allow any other plants to be grown in the same house. Mr. Glendinning had taken great pride in the Heaths, and left them in the best of order. There are now less than one-third, and there were no more when Mr. Bagbie arrived here in 1869.

The Camellia house, besides the Heath house, was designed and erected by Mr. Glendinning, and they bear traces of his talent, both being models of their kind. The house now called the Camellia house, and where Camellias are planted out and fill the house, affords an enormous supply of cut flowers from October until April; indeed, there are few if any places in England which could have supplied during the last winter sixteen dozen of cut flowers daily for sixteen days, and after a short cessation repeated the process without injury, but rather to the advantage of the plants, which remained loaded even then. This house was formerly the orangery, and Oranges were in those days grown in tubs, and were very fine trees.

Some years ago Lady Rolle wished to have her Orange trees near the house, and, therefore, had a noble orangery erected adjoining the mansion, and so placed as to be in connection with the library. It is ridge-and-furrow-roofed, 87 feet in length by 52 feet in width, and 21 feet in height, with a handsome Portland stone path down the middle, and branching off towards the private chapel. Owing to some neglect under former management, either in the concreting, draining, or soil of the borders in which they are planted, the Orange trees, once the pride of Bicton, are now a sad picture. Three parts of them are dead, the others following them rapidly, and gone beyond any gardener's skill to recover.

The kitchen garden includes about four acres, and furnishes an ample supply throughout the year of every kind of garden produce for a large establishment.

There are two specimens of Wistaria sinensis, one measuring 4 feet 8 inches at the base, and covering the roof of a tool shed 54 feet long by 15 feet wide. The other tree runs 72 feet on the coping of a wall, and is a truly grand sight in early spring, when it flowers profusely, and also in early autumn. Near this stands the standard Wistaria, which was supported originally by stakes, but is now nearly self-supporting. Pinus macrocarpa close by is 71 feet high, and measures 8 feet 2 inches at the ground, and at 3 feet, 7 feet 4 inches. This tree has often shown pollen, but as yet has not coned, yet Mr. Cox, of Radleaf, in Kent, has had it coned there, but it has not shown any pollen. Abies Morinda has also coned at Radleaf, and seedlings raised from home-grown seeds are now 9 feet high. Wellingtonias have not done so, and we should much like to hear if it has done so elsewhere in England.

The flower garden on the east and west is bounded by magnificent Magnolia walls, which produce an enormous quantity of blossom during the autumn months. At present they scent the air for a very great distance. Those walls are valued very highly by Lady Rolle, who justly will not allow any other plants to have a place there; no other wall-clother being entitled to compare with it.

Beech trees at Bicton *are* clothed with Ivy, but branching trees, Mr. Bagbie observes, suit it best, and on those it has

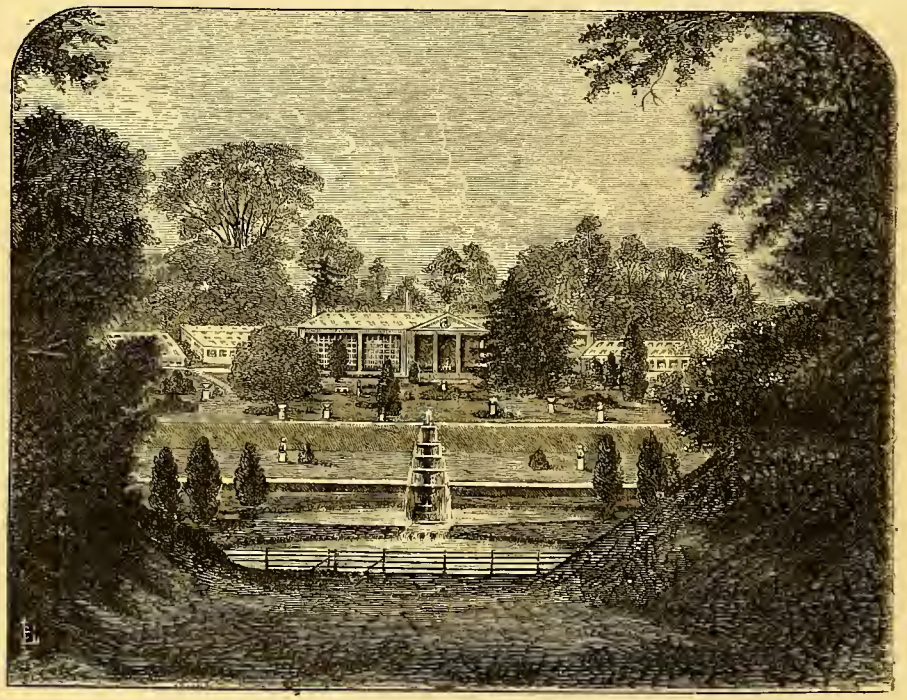
reached to the top. Smooth trees it does not ascend so rapidly, no doubt owing to the smooth surface.

Bicton is a model in all the departments of gardening, and when the errors of the past are rectified, which they will be in a year or two, no place will excel it in gardening. All the minor details are cared for, and we will here quote Mr. Begbie's own words—"For this I give great credit to the old workmen employed in the gardens, old men, some of them born and reared about the place, and who have such an abhorrence of weeds in all shapes, that they never require to be told to keep them underground. I wish it to be put on record that they are industrious, hard-working, and obliging men, of whom I am proud; and I have great pleasure in ascribing three parts of the merit of keeping the place, as it should be, clear of weeds and rubbish, to them. I have yet another word to say of my foremen and young gardeners, for to them is due much of the merit of having cleaned out mealy bug and other filthy insects from the houses and plants. Noble fellows I shall call them, that have never thought of the hours they so freely toiled on from sunrise to long after sunset, and that without fee or reward. All honour to them, I shall ever regard them as 'friends in need, therefore friends indeed,' and I have great pleasure in recording my feelings regarding them."

We have paused to consider whether we could by our pen do justice to the ornamental garden around the house, and have concluded that we could not. If there were arrangements of ribbon borders, or systematic combinations of beds, we could have drawn plans and detailed the planting. But the beauties of the Bicton flower garden are not so constituted. They arise from rich flower beds, placed so as to agree with the very varied surface of the turf; therefore we called in the aid of the draughtsman, and the views with which he has supplied us will enable our readers to estimate that which we should fail if we attempted to describe. Adjoining the mansion is a temple facing the church, from which there is a view of much of the ornamental garden—our artist has represented this, and the view from the church up to the temple.

We will conclude with a few desultory notes.

The whitening applied to the glass for moderating the light and heat from sunshine is toned with Brunswick green. Thea



viridis is in the open air, and unprotected throughout the winter. Coffea arabica was in berry in the stove. The Bamboo, Bambusa arundinacea, had thrown up stems 12 feet high this year, though killed down to the surface last winter. Many bush Camellias endure the winter without protection, and so does Abutilon vitifolium. It bloomed last April. We saw stored away the old stems of Bananas entirely coated with the relics of mealy bug. Those now growing in the stove are among the most healthy we have ever seen. The system of culture is to cut down the stem as soon as it has perfected fruit, its place to be supplied by one strong sucker which has been fostered by its side. Cycas revoluta endures the winter. Alpinia nutans grown out of doors was in flower in mid-August. The fernery is very well stocked with small but vigorous specimens.

In the figgery three crops are ripened annually—namely, in March, July, and October.

Among the specialties now at Bicton is the culture of Ginger for preserving, and Mr. Begbie has obliged us with the following details of its culture. "The desserts have to be supplied with home-grown Ginger during the year. I have endeavoured to calculate how an acre of glass devoted to the growth of this plant would pay. From 10 to 12 lbs. yearly have been considered as an ample supply, which has, I believe, been generally grown in a pigeon-holed Melon pit, and at other times in a deep frame; the *modus operandi*, I am informed, having been to keep the Ginger roots in boxes of dry earth, which were placed in the Palm house during the winter months, and so placed that the heat did not get too low in winter. In early spring—about the 1st of March—the roots were overhauled and planted in pans or pots, and put into one of the Pine stoves to vegetate. When the plants had made from 2 to 3 inches of growth they were then divided, potted into 3 or 4-inch pots, and were afterwards grown in heat until the pots were well filled with roots, and then planted out in a deep pit or frame on a bed of leaves, over which suitable soil to the depth of 12 to 15 inches had been placed, so as to get warmed sufficiently for the reception of the plants. After planting, all that was required was to take proper care in airing, watering, and syringing, as the case may have been. The Ginger harvest is past, and about a quarter of a hundredweight of Ginger sent to the house for preserving purposes. This leaves me with ample stock for the acre of glass, if such a project was likely to lead to fortune.

"My stock is all grown in 10-inch pots, and when full of Ginger the pots contain from half a pound to one pound each. I begin about this time (mid-August) to withhold water very gradually until the tops are well matured, as well as the roots; afterwards, which will be early in September, the pots are laid on their sides, being dry and properly ripened.

"The winter treatment is precisely the same as for Caladiums, which should be kept in a temperature not under 60°.

"Now all will be right until early spring, say March 1st,

when the pots should be introduced into heat in a Pine pit, Melon or Cucumber frame, where there will be a bottom heat of about 80°, with top heat in proportion. The roots, if they have been properly cared for or attended to, will soon show their young growths as thick as a mat, and when they have sprung from 2 to 3 inches take and divide them into small bits with shoots to each; pot in 3 or 4-inch pots in sandy fibrous loam and peat in equal parts, to which a good sprinkling of silver sand has been added. Put them back again in the Pine Melon, or Cucumber pit, for a time, or until the pots are well filled with healthy roots, then repot before they become pot-bound. If time is plentiful use 6-inch pots; but you will have now reached the 1st of April, when there is generally plenty of work on hand, so they should be transferred to 10-inch pots, using the same sort of soil, with the addition of a small portion of well-decayed cow or deer manure. When this last potting is over place the pots in an early vinery, where they will not be too far from the glass, and where they will have plenty of light. Be careful not to use cold water; always use water of at least the same temperature as the house in which they are placed. I prefer it to be warmer, say 80°, which should be about the root temperature if the pots are placed on a shelf over the hot-water pipes, as is the plan here. Water sparingly, syringe slightly, and keep the plants exposed to light. On no account allow them to get drawn; rather stop the tops, so that they may throw out more young shoots.

"We have now arrived at the 1st of May, when we look out our lights, four in number, 9 feet by 3 feet, and, if necessary, have them painted and glazed, so as to have them in good order and as nearly air-tight as possible. We then turn over our leaf heap, and make up a good bed of sweet, warm, oak or other leaves, 3 or 4 feet deep, and well line outside the rough wooden pit, which is a fixture of about 6 feet deep at the back by 4 feet in front, and is made up of rough deal slabs, with a level planed piece of deal top and bottom, so that the lights fit properly, and exclude cold air.

"We have then our 10-inch pots all ready, and plunge them quickly to the rims, taking care the bottom heat does not exceed 90°. This formidable operation, or rather simple one, being accomplished, the summer treatment is precisely the

same as that given to succession Pines—80° to 90° bottom heat; top heat may range between 70° at night to 100°, or even 112° by day, with air and moisture.

"Attend well to sprinklings and waterings—the plants will enjoy liquid manure, properly diluted, occasionally; that from deer dung is proper.

"Stop the shoots when they reach the glass, taking care that only a few are so stopped at a time; but they are the better of not being overcrowded."

At the earliest opportunity we purpose publishing the "Catalogus Lignosus Bictonensis," with Mr. Beghie's experience in raising seedling Conifers.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as that portion of land intended for trenching falls in hand, let that operation be set about. Stiff tenacious soils had better be ridged, so that a large surface may be exposed to the action of the weather. Let all the remaining summer *Cabbages* of a solid character be cut-over in order to obtain a good succession of sprouts. The late sowing of Brown Dutch *Lettuce* should be got in without delay. The cultivation of *Watercress* should not be omitted in the series of salads. A damp shady border is not unsuitable, but wherever the advantage of a small stream is possessed preference should be given. If the trimmings from the bunches are thrown in throughout the season a regular supply of fresh young Cress may be obtained.

FRUIT GARDEN.

Those who have not completed Strawberry planting should do so. The prolific Hautbois planted now 6 inches apart on well-manured beds will succeed well. The housing of fruit should now have constant attention. Let it be borne in mind that it is not requisite to gather all dessert Pears or Apples from a tree at one period, it is far better to collect them at two distinct periods; a more complete succession would be obtained by such means.

FLOWER GARDEN.

Hollyhocks and Dahlias will still require occasional looking-after to secure them against the effects of high winds which may now be expected. Unless seed is wanted cut away decayed flowers and useless shoots, for, although late, every care should be taken to preserve them in beauty for as long a time as the season will permit. Herbaceous plants will likewise require the stalks of decayed flowers removed, and such as are still in bloom carefully tied-up. Asters, some Phloxes, &c., will now be making a fine show, and should have corresponding care

bestowed on them. Let the borders be cleaned and neatly raked over, filling vacant places with spare Chrysanthemums, spring-struck Pansies, or spring-flowering bulbs. As the season is now considerably advanced, the propagation of all the more important bedding-out plants should be brought to a close as quickly as possible; late-struck cuttings are bad to keep through the winter, through having an insufficient number of roots and ill-matured wood. Let Scarlet and other Geraniums struck in the open ground be taken up and potted immediately they have made roots; they will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure to harden them for the winter. For the same purpose Verbenas, Petunias, &c., struck in pans and intended to be kept in them through the winter should be placed in a similar situation, at the same time stopping the points of the shoots. It should, in fact, be a point to keep them as hardy as possible by fully exposing them until they are placed in their winter quarters. Mignonette for winter and spring flowering may yet be sown. I have always advocated layering Carnations and Picotees early, and if my directions have been followed out, the layers should now be well rooted. The compost for potting should be turfy loam well rotted. This must be beaten with the back of a spade, but by no means pass it through a sieve, as it is highly essential that the soil should be porous; to this may be added one-fourth river sand and a small quantity of rough charcoal. On taking off the layers from the parent plant or stool, it will be necessary to cut back that part of the stem by which it was attached to the joint which had been divided. Should any of the leaves be withered they must be removed, and two pairs of the lower ones may be shortened. The soil for potting the plants should be sweet. Do not put manure or any other exciting agent in the compost. Put a pair of layers in each pint pot, then water to settle the soil about the roots, and when dry place them in a cold frame on a stratum of sand. The old stools may be planted in the open border, they will often produce in the succeeding summer a good quantity of pipings, which cannot fail to be highly useful to the amateur if he wishes to increase his stock of them. Auriculas will soon require a share of the florist's attention; examine the pots to see none are soddened with wet; if so, immediately look to the drainage. Pansies and Pinks which have been planted out must be carefully tended, the large earthworms being apt to pull them up. If these are troublesome pour a small quantity of lime water in their holes. Take care of the seed of the early flowers, shade and thin the blooms, trap earwigs, and draw-up the soil round the crowns of the roots.

GREENHOUSE AND CONSERVATORY.

All the more tender greenhouse plants should now be housed, and the few remaining out may be allowed a short time longer, provided the weather continues dry. As the majority of our massing plants require for their preservation only sufficient protection to secure them from the direct action of the frost, pits of the most inexpensive character are generally found adequate for the purpose. It is a very common, and at the same time a very injudicious plan, to thrust the general stock of cuttings into greenhouses, vineries, or, in fact anywhere and everywhere, to the injury of the plants, which are excited when they should be at rest, and by no means to the advantage of the proper occupants of the houses, as the plagues of insects and mildew are too often introduced by the crowding-in of Verbenas, Calceolarias, and other bedding stock. It is a good time to set about the construction of store pits if proper accommodation is not already possessed. They should be excavated to the depth of 18 inches, and drained so that no water can enter; a few layers of turf and a framework of wood to receive the lights, mats, or whatever may be provided, will complete the necessary preparation. The employment of heating apparatus might in many cases be obviated by following the practice of sinking pits, allowing only the glass roof to be exposed to the weather. In France and Belgium Camellias, Oranges, and many tender greenhouse plants are preserved uninjured through severe winters by the adoption of this plan. The precaution most necessary in this country would be efficient drainage, moisture being almost as bad as frost. Proper attention to this and ventilation would make them fit receptacles for a vast number of tender plants. The Persian and other Cyclamens should be examined and repotted when necessary. Those autumnal Roses which have undergone a course of preparation in order to have good blossoms through October and November, should be got into shelter towards the end of the month. Any ordinary greenhouse will do, and no fire heat will be requisite for a long time. They should have a light situation not far from the glass, and should receive frequent waterings with tepid and clear manure water in a very weak state. The Lachenalia family should now be brought forth and potted; such on a greenhouse shelf will flower in February. The Heliotropes, Scarlet Geraniums, &c., should also have a light situation very near the glass.

STOVE.

All stove plants which had been removed to the conservatory or other structures should now be taken back to their permanent stations without delay, both for their own sakes and for the sake of a general arrangement in other structures. Give a most liberal ventilation at this time, not forgetting, however, to accompany it with much warmth, for the hardening of growths is not carried out by means of chilling draughts, but by high temperatures, accompanied by a free perspiration from the leaves of the plants. Much attention must be given to watering under the above circumstances. The Orchids are scarcely an exception as to the above atmospheric conditions They, too, must be hardened into ripeness in the pseudo-bulb.

PITS AND FRAMES.

The whole winter's arrangement as to the disposal of these structures should be determined on soon, and a regular scheme laid down and progressively acted upon according to the order of the affair. In an ordinary garden it is quite a puzzle with a limited number of such to apportion them to the purposes in hand. The half-hardy things require a frame or two; some surplus stock belonging to the greenhouse or conservatory, but not quite good enough to be placed there at present, require wintering; the Neapolitan Violets want a frame. Where matters of this kind are not sufficient for the purpose, attention should be immediately given to some turf pits as adverted to in this day's calendar.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

RAN the Dutch hoe among all growing crops where we could find room for it, as the smaller the weeds the more quickly does a day of sun make them disappear. A loose surface is also desirable, as it prevents caking and cracking, and allows the rain to pass more freely. We sowed a few pieces of Lettuces on the chance of their standing thickly over the winter. These generally stand best when the mere surface of the ground is stirred, and what lies beneath is rather firm. We planted out lots of Lettuces and Endive to come in at the end of autumn. As soon as possible we will throw-up some wide-based, sharp-topped ridges, and plant each side and the apex with smaller plants to stand the winter. The harvesting has interfered with a good many of these little jobs, and we suppose we are in the same predicament as many gardeners who see every day what is wanted to be done, and yet cannot find time to do it. It requires much discrimination to attend under these circumstances to subjects which would suffer, or prevent regular successions, by delay. We sowed Radishes of kinds in a nice open place for the last crop which we shall have without any protection. We will soon sow where we can place old sashes or a mat over the plants in a cold night. We often think that sweet crisp Radishes early in spring are more relished when there is a cessation of their appearance in the coldest winter months. A man who has a Cucumber at his table every day in the year, cannot enjoy the first crisp Cucumber in February or March, like the man who does not see a Cucumber for a month or two. It is quite a mistake to let ladies and gentlemen be glutted with any one thing. The very idea of comparative scarcity often gives an additional zest.

We cleared the ground as fast as we could of Peas and early Broad Beans, and after threshing them will use the straw for various protecting purposes; the ground will be turned-up and planted. We have used the crowbar for some strong late plants. Part of the ground will be trenched for next year's root crops, and in their case the rough manure will be thrown to the bottom of the trench.

We pruned back the *Cucumbers* in the small pit that have borne all the season, treated as previously described. They seemed too good to be thrown away, more especially as we can turn the nice young plants that are to succeed them into 6 and 9-inch pots, and thus have them strong before we remove the old ones. We have in a pit a few plants grown over the surface of a bed in the common way, and these, showing freely, will

keep up a good supply before the young plants come in after we remove the old ones, which, but for having younger ones, we feel rather unwilling to do. One plant that bore through last autumn and winter we allowed to remain, and it has been as fruitful all the summer and autumn as the young plants turned out in January. We would here note, for the benefit of the inexperienced, that good plants turned out own and allowed to fruit much before Christmas, unless they receive additional attention, and be in the most favourable circumstances as respects light, &c., will not do much good afterwards. It is well, where a regular succession is required, to have a set of plants to fruit in the beginning of winter, and another set to be allowed to fruit little or not at all until the shortest day is passed.

Quantities of long dung, which we would be sorry to say no to, we have had well watered with sewage and other water, shaking out the shortest, to be mixed with turfy loam for Mushroom beds. Such heaps when worked thus will be greatly reduced in bulk, and will therefore in a half-decomposed state be useful for hotbeds, the bottoms of Mushroom beds, dressings for Strawberry beds, and for digging down in ground to be left trenched, or rather ridged up for the winter. We can allow but very little to have such a frost-sweetening and mellowing.

Mushrooms.—Owing to so much new work we have never been able to repair our old shed—the best and most successful place we ever had, except cellars, for Mushrooms in the hottest months of the year. We have had a fair supply from the Mushroom house, but we do not think the growth was equal to that obtained from the shaded shed open on one side, but the draught of air considerably regulated and modified by hurdles placed along, with branches drawn through them. We have often found that this sifting of the air suits the Mushroom better than anything like a keen open draught, as the latter does away with that close muggy atmosphere in which the Mushroom naturally delights. We have commenced clearing out the oldest exhausted beds from the Mushroom house, the rotten manure being valuable for potting and surfacing purposes when well exposed to the air. We have put in the first piece of a bed, which we shall make rather thin, in order that we may be able to spawn it all the more quickly. For other successions that will take us into the cold months, the beds will be made thicker, so as to retain an equal temperature longer. As we have no Mushrooms this season except those which we have had from the last-made beds in this house, we have been obliged to omit doing what we did every year when we had beds in the shed out of doors, and therefore could give the Mushroom house a rest, and that was to shut up the Mushroom house closely and fumigate it once or twice with burning sulphur before clearing out the beds, and giving the house a regular cleaning before putting up the first bed in the autumn. This sulphur-smoking would pretty well dispose of all living vermin in the house, and therefore slugs, snails, and woodlice would be very scarce if we did not take them in with the material of which the beds are made. As it is, such intruders after the smoking with sulphur rarely troubled us until the spring. After such smoking the house must be well aired and sweetened before a bed is made, as burning sulphur is as great an enemy to all sorts of fungi as it is to intruding insects and snails.

FRUIT DEPARTMENT.

For late vineries plenty of air should now be given, even if in dull days a little fire heat should be used to keep up the temperature.

We went over the dwarf trees as fast as we could, removing the small secondary shoots so as to give more light and air to ripening fruit and maturing buds. A little of this work done now gives a better chance for an autumn sun to perfect the maturing process. Fruit of all kinds must be looked after, and tomtit must be warned not to touch the Pears and best Apples. A few fallen ones he might work his sweet will on as a sort of wages to him for the insects he destroys. Many a morning we have seen from our bedroom window four of these pretty little birds going from twig to twig and examining the under sides of every leaf in search of fat insects. The worst of it is, that like a rat or a blackbird, the finest fruit is selected. We never knew of such quantities of quite green fruit being carried off by mice, rats, and birds as in the earlier months of this year. It was quite common to find a good handful of green Strawberries collected in a corner, and yet hardly a bit of them seemed to be touched.

We almost finished clearing *Strawberry* rows and beds of their runners, and extra buds when the stools were very large, leaving most of the leaves on the plants. Cleared all the runners from Strawberry plants in pots, set them a little thinner for the sun to play on them more fully, and in all cases where the ball was like a cheesecake with roots, put a pinch of soot over the surface of each pot, using rather more of the fine dust than could be taken between the thumb and finger, and not quite so much as might be held between the thumb and two fingers. Pure dry soot is a different thing from what is often sold for such, with its make-up of dust, sawdust, &c. This is best spread over the surface of the pot beneath the leaves with the fingers, and then it is advisable to sprinkle the plants slightly all over from the rose of a watering-pot, and then the soot clings to the soil and will not be washed over by the good waterings that will follow shortly afterwards. Nothing tends more to give a fine healthy green to the foliage than this little soot. The same effect would be produced by clear soot water, but, then, it is difficult to clear it without a little quicklime, though that in moderation does no harm and gives a hint to worms and slugs to keep out of the way.

We find that with few exceptions all fruit is later than usual this season, and we have had to forward some a little by artificial means. So many enemies attack it, too, in this fine weather, that it is often advisable to gather Peaches, Nectarines, Figs, Pears, Plums, &c., before they are fully ripe, and allow them to mellow and ripen in a place of safety. In some cases where the juices of the fruit are fully retained, the flavour is even improved by the process, and the fruit is juicy rather than mealy or mellow.

We gave a good watering to the late Peaches in the orchard house, which we hope will help us for some time yet. Borders in general will now want less watering. We were forced under peculiar circumstances to keep a number of pot plants in the late vinery, but we have partly pruned, at least of all young growth, the earliest vineries whence the fruit had been cut, and we set the plants in them so that the soil and air of the late vinery, now coming in, should be drier. A little fire is put on in most days, on every day the least shady or cold, and air given accordingly, and a little air left on constantly at night, so that no condensed vapour should rest on the branches. Most of the laterals, too, have been shortened or removed, doing it gradually so as not to check root action, in order to admit more light into the house. The pipes have been painted several times with flowers of sulphur and milk, as it is better to keep away red spider than send it away after it comes. The floor was all finely raked so that the surface might almost be dust dry, whilst a little moisture was left beneath. When all the plants have been removed we frequently paint the stages and wall with lime and sulphur. It gives more light to the house by reflection, and the sun heat will bring out some of the fumes of sulphur, but so mild as not to hurt the Vines at all, whilst it seems to say to all intruding insects, Beware. Many gardeners in largish places are never able to devote even their fruit houses to their legitimate purposes; but where plants must be kept, much will depend on being able to thin or remove them as the fruit approaches maturity, and the long-keeping of such fruit as Grapes depends much on the dryish pure atmosphere round them.

ORNAMENTAL DEPARTMENT.

Lawns, walks, beds, and borders have been greatly benefited by the rains, as the ground, heavily cropped, was getting very dry. When walks are all right as respects cleanliness, a comparatively light roller, to be moved by one man, makes all smooth and neat. One walk rather out of the way we could not get at in time, and we see that in places it is a little green. The rest of the walks, treated as lately described, are as bright as can be, and do not show the trace of a weed as yet. Where the lawns are fresh laid, and rather rich stuff has been used to make all level, wormcasts are apt to appear. Sweeping these off at whatever time is apt to leave the grass discoloured behind them, and future rolling will not make it all right to the eye. We seldom sweep for this purpose, but we have long found that a wooden roller from 9 to 12 inches in diameter, and 4 feet in length, acts better than broom and roller. If in the least damp, any part of the heaps which the roller does not press down is taken up, and the cleaning of the roller, when encrusted, with a piece of iron or spatula, acts far better than a sweeping with a broom, for the grass is left beautifully green behind it. The first time we saw these light wooden rollers was at Tingrith more than thirty years ago, and they were then used early in the morning that the dew might be spread, so that the ladies might sooner walk on the lawn with thin-soled shoes. Then was the idea suggested, how useful such simple

rollers would be for putting wormcasts out of sight, and we have used them ever since. When a game of croquet is to be played early in the day, the roller helps much to dissipate the dew, as well as to leave the ground smooth and level for mallet and ball. It is of importance to have such things made so light as to be easily managed by a man or a stout boy. In these days, when in most gardens labour power is generally less than the requirements, it is well to avoid machines requiring two or more men to work them.

The heavy rains of last week rendered picking over the beds necessary, so that the bright fresh bloom should not be interfered with by that which was faded or discoloured. The points of strong Pelargonium shoots in beds may now be picked out, as that would throw more strength into the trusses showing and coming, as many as the weather will allow to arrive at maturity.

We placed many plants in pots out of doors where they could be rendered quickly secure in any sudden change.

We top-dressed Salvias, Chrysanthemums, and Coleuses in pots; cut down Pelargoniums, and prepared for fresh potting those first pruned back; also potted Ferns. The chief work, however, when we could get at it was putting in all kinds of cuttings for the flower garden next year. As stated the other week, we use chiefly shallow wooden boxes not too large for a man to move easily. We almost envy some who can obey the advice so often given about having all such cuttings potted and established before winter. We rarely pot anything; the rooted cuttings must stand thickly in boxes until spring. We should look in vain for room for pots of what we even now need, and that is much less than formerly. At the same time, where room can be afforded, it is right and advisable to pot singly; but we never could do it, and the plants succeed very well, nevertheless. In putting cuttings in and potting, let us urge on beginners to use as much as possible fresh sandy soil, however poor.—R. F.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Hyacinths, Narcissus, Tulips, &c.*

John Scott, Yeovil, and Merriott Nurseries, Crewkerne.—*Catalogue of Flower Roots.*

Robertson & Galloway, 157, Ingram Street, Glasgow.—*Catalogue of Dutch Roots, and of Plants for Winter and Spring flowering.*

Baltet Frères, Grande Pépinière de Croncels, à Troyes.—*Catalogue Raisonné.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*Idem*).—We do not know what you wish for by asking for "a book on the botany of plants, such as those in a greenhouse." Do you mean descriptions of the plants? Perhaps "The Cottage Gardeners' Dictionary" would suit you. You can have it from our office if you enclose 7*s.* 2*d.* with your address.

Potatoes Influencing their Neighbours (*F. H.*).—We do not think that kidney and round Potatoes grown near each other and flowering at the same time would have their tubers affected, although their flowers were cross-impregnated. The seeds would produce cross-breeds from such intermixture.

Arbor-Vitæ Browned (*H. D.*).—We should attribute the brownness to ill-health, and we think the manure given during the past two years is most likely the cause. We should advise your at once removing the surface soil down to the roots, removing all the old soil you can from amongst them, replacing with fresh turfy loam enriched with one-third of decayed leaves, and giving a good watering. The tree, judging from your drawing, being very open, we would not prune but tie in the shoots or branches so as to form a more compact specimen, and this by giving warmth and preventing the wind acting on the otherwise open head, will enable you to secure a better growth next season. Water early in summer and until the growth is complete, but with your light soil over clay it is well to look to the roots. See that the water does not lodge in the subsoil.

Pruning Espalier Apple and Pear Trees (*X. Y. Z.*).—The longitudinal branches or shoots at their extremities being required for extension, should be trained in at their full length without stopping or pruning until the extent of trellis or wireing be covered, and then they should be treated the same as the shoots on the branches.

Dicksonia antarctica Browned (*Ignoramus*).—We should attribute the browning of the fronds to the draught you speak of, but the atmosphere may be too dry, and an attack of thrips may have been the result. Look well to the under side of the fronds, and remove to a position where the air is more still. It can hardly have too much water, the drainage being good.

Protecting Filberts from Squirrels (*G. M., Berwickshire*).—We know of no better means of keeping off these animals than netting the trees, and the nets require to be small, or the squirrels find their way through. We have no experience of any application to stems that would keep squirrels from ascending, and should be obliged if those who know any mode of keeping off these creatures would communicate it. It would be a shame to resort to the gun.

Pandanus and Alocasia metallica (*R. T. J.*).—Pandanus javanicus variegatus and P. utilis will succeed in a greenhouse with a temperature not lower than 45° in winter, keeping it rather dry, or with no more water than enough to prevent the foliage from shrinking. Alocasia metallica may also be wintered in a warm greenhouse; but to do well in summer it requires a night temperature of from 65° to 70°, and 75° to 90° by day, with abundant moisture and slight shade.

Reduction of Wages (*Short Wages*).—We can hardly advise you how to act, as we do not know all the circumstances. Your course, to be straightforward, was to have declined the reduction of your wages when you moved to the country place in June. If you have received these reduced wages since—whether you had something to make up the loss in other ways or not—we fear your taking the reduced sum for three months would be a bar to your legally demanding what you were paid at the other place. Why did you consent to take a fourth less wages, or even seem to do so?

Fungus on Strawberry Leaf (*F. E. P. Eastcliffe, Chepstow*).—The fungus on the Strawberry leaf is an immature Myxogaster. It is impossible to name it in the mucous condition before the spores are developed.

Trees for Boulevard (*W. D. jr.*).—Either Limes or Oriental Planes.

Ophiocaryon paradoxum (*T. H. T.*).—It is a tree hitherto found only in British Guiana, on the banks of its rivers. The generic name is literally "Snake-nut," and refers to the embryo of the seed, which, as you say, "is like a small snake curled up." The genus belongs to the natural order Sapindaceæ; the leaves are pinnate, the flowers small and in panicles, the fruit like a small round walnut. The natives use the seeds as a remedy against snake bites, but they have no known medical power. The seeds are often imported as curiosities. We cannot answer your other queries.

Glastonbury Thorn (*H. Bedwell*).—It is not true that there is a Thorn growing where Joseph of Arimathea pitched his staff, for he never was in England. There was, and probably is, at Glastonbury Abbey, a Thorn, which, as Loudon observes, "comes into leaf in January or February, and sometimes even in autumn, so that occasionally in mild seasons it may be in flower on Christmas-day." It is only a variety of the common Hawthorn, and known to botanists as Cratægus Oxyacantha præcox. Plants may be purchased of nurserymen, and they leaf and bloom eccentrically wherever they are grown.

Planting an Orchard-House (*W. B.*).—You do not tell us what use you are going to make of the back wall, but if that is to be covered a trellised path would be best. For the border in front 7 feet would be ample, and provided it is properly drained, 18 inches in depth would do. The soil, if good, may answer, but for clean growth we would prefer maiden loam. We like people to think for themselves, and do what they can for themselves. We want you, therefore, to calculate for yourself the loads of fresh loam you would want if it were all to be fresh or half fresh. A single horseload will in general contain a cubic yard; if your depth is only half a yard, you will see how far that one cubic yard will go, and can calculate accordingly.

Vines Mildewed (*Sussex*).—Your Vines having the mildew twice in succession, we conclude that the situation is low, the house ill-ventilated, though you say there is abundance of air, or the drainage imperfect. The present dull season is enough to cause mildew in an unheated house, as the ventilation must have been limited to keep up the required temperature. Apply a little fire heat; it will be very beneficial in ripening the wood, and at once dust every part of the Vines with flowers of sulphur, and repeat this in two or three days. In winter, after pruning, dress the canes with a composition of 4 ozs. of soft soap, and enough sulphur to bring a gallon of tobacco water to the consistency of paint, applying the mixture with a brush at a temperature of 120°. Next season, if the mildew appear, sprinkle guano and salt over the border—two parts guano to one of salt, and one peck per rod, and give a thorough soaking with water 5° higher than the temperature of the border, washing in the guano and salt thoroughly, and dust the infested parts on its first appearance with flowers of sulphur. Except in hot seasons, Lady Downe's and similar kinds will not succeed without fire heat. The rain-water tank we presume is covered. The vegetables attacked with mildew would not communicate it to the Vines, and to keep it from the vegetables dress liberally with guano and salt—two parts guano to one of salt, supplementing with a good watering if dry weather follow.

Vines for Vineries (*Balham*).—For the house in which you wish to ripen the Grapes in June, we would have four Black Hamburgh, two Frankenthal, one Black Champion, two Buckland Sweetwater, two Foster's White Seedling, and one Trouéren Frontignan. For the other house, to maintain a supply to the end of the year, though some will hang well until March or later, we advise two Mill Hill Hamburgh, one Black Muscat, one Mrs. Pince's Muscat, one Madresfield Court Muscat, two Alicante, one Lady Downe's, two Muscat of Alexandria, one Bowood Muscat, and one Trebbiano. The whole of the last require a good heat, but are not otherwise more difficult to grow than Hamburghs, succeeding admirably in a border partly inside and partly outside the house, the Vines being planted inside. The border not being ready now we would defer planting until March, but securing the Vines early, and pruning them in December so that they will just reach the wires. The parts cut off will be available for propagation from eyes, keeping the canes out off with their ends stuck in moist soil until required for insertion. One inch of bones and old mortar rubbish are good for forming Peach tree and every description of fruit border. We omit, however, the lime rubbish, and give instead one part in six of marl, employing good, rich, and rather strong loam for Peach borders.

Vine Leaves Spotted (*Amateur*).—We cannot find any trace of insects on the leaf sent us, and we think the brown spots are a result of the leaves being wet whilst the sun's rays fell powerfully on them. Give a little air at night, and you need not fear for the fruit.

Vine Border Making (*J. H. S.*).—We have several times seen pond mud for Vine borders, but it never answered well unless it was exposed to air and sweetened for two years before being used. The preparation would greatly depend on the nature of the mud. On the whole, unless we were sure of the sweetness we would use none of it, and even then use it sparingly. To your using two parts of this mud, one part of stable manure, and only one part turfy loam with a little lime rubbish, we attribute the weak state of your Vines. The richest salmon and the fattest pork are good things, but not quite the things to feed infants on.

We would prefer three parts turfy loam, half a part of old rough brick and lime rubbish, one-fourth part bruised boiled bones, and a like quantity of sweet rotten manure, and, if not sweet, more bones instead. As soon as the Grapes are cut we would certainly take up carefully the Vines you mean to save, and replant them in such a sweet compost as stated above, and the sooner you do it the better the Vines will succeed. Do not mind taking them up entirely—that is what we should do, tracing out the roots carefully, and preventing them becoming dried, saving every root possible however small, and when all were up wrapping them in a mat with damp litter until the border were ready to plant them in again. Then we would plant carefully, spreading out the roots some 6 inches from the surface, and damping them with water at about 80°. Then we would mulch the border with warm dung from 9 to 12 inches thick, add more in winter, rough-thatch to keep off the wet, and we should expect the old Vines to do rather better than the young ones. We think so much mud has been your drawback.

Vines with Peaches (*H. Brace*).—If you plant Vines in front and Peaches against the back wall, it would be as well to run a low wall along the middle of the house, but so low as not to be seen. That will be sufficient to keep the roots separate. We do not, however, give you much hope of full crops on the back walls unless your Vines are trained to single stems on the spur principle, and these stems of Vines are from 4 to 6 feet apart. If the Vines are closer together there will not be enough of light for the back wall. On the whole, with wide openings we would prefer Vines on the back wall; but if your roof is rather shaded the Vines will soon cease to do much good on the back wall, and only that which is near the glass will bear. With Vines up the roof at 5 feet apart, however, we have seen fine fruit on the back wall from top to bottom. There is no secret, however, in the matter. To have good returns from the back wall you must let the sunshine reach it. For the depth of border, from 20 to 24 inches will be good, with rubble and drainage beneath the border. We would make the border inside the whole width, but divided as above, if you depended on the back wall. The border outside might ultimately be as wide as the house, but we would prefer the outside border to be from 3½ to 4 feet wide at first, and add a couple of feet or so every second year. Three parts of turfy loam, one of rough lime rubbish, one-fourth part of crushed bones, and one-fourth sweet decayed manure will answer well. The height of the back wall must depend on the construction of the house. With a sloping roof you will have a nice slope with a front wall a foot high and the back wall 16 feet in height; but if you have front glass, say wall and glass 6 feet in height, then a back wall of 15 feet or so would do, as the front light lets in the winter and spring sun. We do not approve of such a size of pane for common houses as 24 by 36 inches. We would rather have the panes 12 by 18 inches. We should be perfectly satisfied with 26-oz. glass.

Planting Vines Inside or Outside (*Feeling His Way*).—We should decidedly plant the Vines inside the house. For such a border forty bushels of half-inch bones would not be too much. We would sooner use more than much manure with the turfy soil.

Fernery Painting (*E. P. S.*).—We cannot perceive the necessity for the extra strong heat, for on the removal of the plants, and, of course, the source of moisture, the house will soon dry if air be given. Of course fire heat must be afforded, so as to maintain the proper temperature, and from the increased ventilation the amount will need to be greater. We would first of all have all the woodwork thoroughly washed, and then allow a few days for drying, proceeding with the painting at once, and admitting air constantly, and whilst about it give three coats of paint. The great difficulty is with the climbing plants, and especially the Lygodiums. You will need to cover them over with canvas or other material, so as to keep them from being sprinkled with the paint, for if it falls on them it will leave its mark. With air the painting will not injure the climbing plants and Ferns. In about a week you may return the Ferns to the house. The reason of the climbing plants not doing well is the shade. Afford them more light, and they will no doubt flower satisfactorily.

Mesembryanthemum glaciale Flowering Out of Doors (*A. R.*).—It is rather unusual, because it is not commonly placed out of doors in summer, though nothing is finer for sunny rockwork than this class of plants.

Rubbing off Young Figs (*Idem*).—Young Figs now the size of walnuts have no chance of ripening, and would be best removed at once. We never leave any larger than a bean or hazel nut.

Scale on Peach Trees—Mealy Bug in Vineries (*W. T.*).—The fruit being off the Peach trees, syringe them a few times with a solution of 2 ozs. of soft soap to the gallon, using it at a temperature of 160°, and when the leaves have fallen dress with a composition formed of tobacco water as sold by the manufacturer, adding to every gallon 4 ozs. of soft soap, and enough flowers of sulphur to bring the whole to the consistency of paint. Apply it with a brush, and be careful not to dislocate the buds. Repeat the application before the buds begin to swell. This is for the scale. For the mealy bug—the Grapes being cut, shut up the house closely, and sprinkle the floor all over with guano, putting it on the paths quite one-eighth of an inch thick, and then syringe the Vines with all the force you can command from an engine or syringe, using water at a temperature of 140°, adding to every gallon a wineglassful of spirits of turpentine, repeating in a fortnight. Apply on a calm evening. When the leaves fall, have the house thoroughly cleaned and painted, and the Vines dressed (stripping off all the loose bark) with the composition named for the Peach trees, and adding to every gallon a fluid ounce of spirits of turpentine. When you commence forcing, place hot dung within the house, and turn it over frequently, so as to cause the vapour to pass off more freely. Syringe the Vines morning and evening, except when in flower, up to the time of their changing colour, and keep a strict watch on the Vines, and if any insects are seen remove them with the hand. Lay the Azaleas infested with mealy bug on their sides, and syringe them with water at a temperature of 140°, turning them round so as to apply the water with force to every part of the plants. Repeat this as often as you notice one bug on the plants.

Alternanthera magnifica Propagation (*Amateur, T.*).—Take cuttings of the growing points now with two joints and the growing point, removing the leaves from the lowest joint, cutting immediately below it. Insert the cuttings an inch apart in pans, filled to within half an inch of the rim with two parts light loam, one part leaf soil, one part sandy peat, and one part silver sand, giving fully an inch of drainage, and a good sprinkling of the rough of the compost, which should be sifted, over the drainage, and the half inch filled up with silver sand. Water gently, and place the pots in a hothed of from 70° to 75°, shading from bright sun, and keeping just moist. When well rooted remove to a house with a temperature of 45° to 50°, and keep near the glass, well aired. The old plants may be taken up in October, potted, and wintered in a like structure, and should be kept rather dry. In February they will give you cuttings that will strike freely in a hothed, and being potted off when rooted and grown on will make nice plants by May. The cuttings in pans should be pricked off in pans about 3 inches apart in March, or potted off singly, grown on in heat for a time, and then be gradually hardened off prior to planting out.

Various (*T. H. D.*).—As the fruit is cut, the leaves falling, and the soil is very dry, we would water the inside Vine borders sufficiently to prevent the roots suffering from being very dry. Then, as you purpose starting the house in February, we would top-dress in January, and use more water then, just to make the soil kindly moist, using water at a temperature of about 80°, as the soil will be cool. Unless there is a sediment in the boiler, in which case it is as well to empty the pipes in summer, we would prefer allowing the water to remain, as then there is less corrosion and less oxide of iron formed than if fresh water were often added. We would empty the iron tank, scrape off the rust, and well paint the inside. A little oxide of iron, however, will not injure Vines or plants, but an excess would tell on tender roots. If you expose the water for twenty-four hours previous to use, add a spadeful of quicklime for a rather large tank, and allow it to settle for that time; you will find the most of the rust will be precipitated to the bottom.

Abutilon Wintering (*S. W.*).—The Abutilons are not hardy, though A. striatum is nearly so, succeeding in sheltered situations against a south wall. The species you name we do not know. Passiflora cardinalis does not generally succeed in a conservatory, but requires a stove. We think it is from cold and too much moisture that the leaves are spotted. Keep the plant drier at the roots. It may do better another season.

Dividing Arabis and Cerastium (*S. A.*).—Now is a good time to divide the Arabis and Cerastium if the soil is light, but if it is wet and heavy spring is preferable. Beta chilensis now in pots may be planted out, and it will survive the winter as well as Beetroot. Coprosma Baueriana variegata is not hardy, though it is likely it would succeed out of doors in dry soils and warm situations.

Housing Chrysanthemums (*A Young Amateur*).—The Chrysanthemums should be taken into the house before frost, in general about the second or third week in October. They will continue to flower up to January. Hyacinths that were flowered in pots last year are not of much value for flowering this winter, and we would plant them out now in the open borders, covering the crown with 1½ to 2 inches deep of soil. If you continue them in pots they will probably do fairly, but they will not bloom nearly so well as fresh bulbs, and the best time to repot them is the present. Camellias and Azaleas should be placed under glass without delay, and if they require repotting it may then be done, but it is perhaps best to repot them immediately after flowering. This, however, is a good time when the spring potting has been neglected, and the plants are in small pots and need a shift.

Temperature for Phormium tenax Veitchianum (*Capella*).—It requires a greenhouse temperature, or 40° to 45° from fire heat.

Plant for Greenhouse Back Wall (*A. A.*).—The back wall of your greenhouse facing east will be suitable for a Camellia, providing the wall to the south is not of greater height than the greenhouse; if so, we fear the wall would shade the house so as to deprive it of too much solar heat. If there is a chance of a Vine succeeding on the rafters, there is no doubt of a Camellia succeeding well against the wall, providing a proper border be formed, and the bedding plants on the stage be not allowed to cover the foliage of the Camellia.

Heating with Hot-water (*W. R. Armstrong*).—The plan may be made to work with several air-pipes, but even then not very satisfactorily. It is always best to have the flow-pipe higher than the top of the boiler.

Wasps in a Vinery (*R. W. T.*).—Sulphur cannot be burned in any house to destroy insect life without injuring every plant having leaves there. You may exclude wasps from the vinery by nailing over the openings hexagon netting, putting it on inside, and so as to work clear of the lights. In addition to this we half fill a few dozen soda-water or lemonade bottles with beer, the stronger the better, as they are attracted by its smell, and, being very fond of it, drown themselves. They care nothing for Grapes with us so long as there is plenty of beer for them to drown in. When the smell of the beer passes away the wasps are slow of entering, therefore empty occasionally and replace with fresh.

Insects in Frames (*A Trouble*).—We cannot, from your description, form any idea of what the insect is. It cannot be thrips, as it does not attack at the surface of the soil. It is probably one of the small mites that are abundant where there is decaying vegetable matter. Dusting with quicklime will drive them away.

Caterpillar (*Miss J. M.*).—It is the larva of the Privet Hawk-moth, Sphinx ligustri. Not uncommon.

Name of Insect (*E. S.*).—The moth you enclosed is the Sphinx Convolvuli, or Bindweed Hawk-Moth. It is uncommon. We cannot be sure what the other moth is which you mention; probably it is the Sphinx Ligustri, or Pivet Hawk-Moth.

Names of Fruits (*John Ormandy*).—1, Scarlet Leadington; 2, Ravelston Pippin. (*G. J. C.*).—It looks like Black Prince, but we cannot name Grapes with certainty from a few berries. (*W. Morgan*).—Beurré de Capiaumont. (*C. F.*).—The Plum is the Goliath. (*A. O. R.*).—2, Beurré Diel; 3, Nouveau Poiteau; 4, Louise Bonne of Jersey.

Names of Plants (*J. T.*).—We have repeatedly given notice that we can only name six specimens from one correspondent at the same time. We have also said we cannot name from leaves only. You have sent more than twenty specimens, and many of leaves only. If you will select six flowering plants and send fresh specimens we will name them. (*Oswell*).—Vallota purpurea; sometimes called the Scarborough Lily. (*C. A. J.*).—Your plants are, no doubt, seedlings (self-sown), of Physalis Alkekengi, the Winter Cherry. It is a plant of annual duration only, dying in the winter. As to the Cuphea, we do not consider it by any means unusual for it to sow its seeds. (*A. W.*).—The very interesting plant you send is the Jussulloa parasitica of Ruiz and Pavon, a charming plant, a native of Peru, where it is considered a great

rarity. (*Acton Castle*).—We omitted to mention the Monkey Flower, Mimulus cardinalis, as being one of the plants sent by you to be named. (*W. C., Foto Island*).—Bupleurum fruticosum. Its congeners are known by the English names "Hare's-ear" or "Thorough-wax." (*T. M. Shuttleworth*).—Another interesting and beautiful plant, the Tricyrtis hirta of Hooker, one of Mr. Fortune's introductions from Japan. (*M. T.*).—The Purple Orach, a variety of Atriplex hortensis. (*H. T. M.*).—1 Sempervivum Haworthii; 2, Crassula arborescens; 3, Kleinia repens; 4, Sedum hybridum; 5, Reineckia japonica variegata; 6, Campanula garganica; 8, Asplenium fiabellifolium. (*W.*).—Polygonum cuspidatum, a shrubby Japanese species.—(*C. B., Hampshire*).—Physianthus albens, a very interesting tropical American Asclepiad, an old inhabitant of gardens. (*Bill*).—The Bluebottle, Centaurea Cyanus; and the Hares's-foot Trefoil, Trifolium arvense. (*W. H., Ayr.*).—1, Dolichos lignosus (otherwise D. gibbosus), a native of the Cape of Good Hope; 2, Myoporum parvifolium, native of southern Australia. (*W.C., A Reader*).—1, Polygonum cuspidatum (as above); 2, French Honeysuckle, Hedysarum coronarium; 3, Abutilon Thompsoni.

POULTRY, BEE, AND PIGEON CHRONICLE.

HEADS.

We believe the different types of skulls among fowls to be as distinct as those of the human race. We are not singular in that respect. How often have we heard at shows criticisms on awards and surprise expressed that a prize should be given to such a "coarse-headed brute?" As a rule, and where competent judges act, the decision is a right one. Nothing in the shape of the head sins against the requirements of the breed, but it does against beauty. We want in breeding to produce and continue the most perfect specimens of the race. In choosing, then, we should closely examine every point, and none is more important than the head.

Let us begin with Cochins. The best head we ever saw was one of the earliest among the celebrated strains. It was the Lovell. The name was adopted because the birds were brought from China by a captain of that name. We differ from many of the modern judgments because this character is not sufficiently noted and cared for. Large size, great weight, heavily-feathered legs are looked for and rewarded. But they cause a fleshy, wrinkled, and dull face, with an exuberant comb (erect for this show only) to be passed over. We want the small neat head; the scanty comb, perfectly upright and full of serrations; the bright eye, almost projecting from the face; and the look of quiet intelligence that is a real characteristic of the breed. We have seen some that had the expression of the Malay, and the cauliflower face of an old Spanish cock. We are bound to admit these belonged to birds of great weight, but they also belonged to birds of great age. We want the weight that is gracefully carried by youth accompanied by a smiling face, and not the unwieldly heaviness of senility.

Just as much as we admire the intelligence and cheerfulness of the Cochin, so do we appreciate the hard cruel expression of the Malay. He should always look as if he had a concealed creese, and was ready to "run a muck, and tilt at all he met;" and his mate a sort of cross between Helen McGregor and Mrs. Brownrigg. (A traveller some years since was asked to define a consul, and replied, "He should be a cross between Lord Aberdeen, then Foreign Secretary, and a Bow Street runner.") Anything pleasant in the face of a Malay would be out of place. Everything about them is hard; the body feels as though it had been dipped in Styx, and the face is the index to the disposition. Take, again, the Game cock—his sharp fearless look, no cruelty in his eye; assurance and conceit are there; and denuded of comb and gills, he walks as it were on tiptoe, that his gait may carry out the promise of his head and face.

The Spanish cock is the aristocrat of the yard. We should not be surprised if some called him the Castilian. His round head, white face, red comb, and piercing black eye tell you he is conscious of his worth and position. It is a different expression from any of the others. Not so intelligent as the Cochin, so cruel as the Malay, so bold and saucy as the Game, he has, nevertheless, an air and sense of dignity that become him and his nation; and if you were called upon to find a snuff-box-bearer among fowls for one of the old kings of Spain and the Indies, you would fix on the Spanish cock.

Our old useful friend the Dorking expresses none of these; there is nothing smiling in his face, but his round head and well-shaped forehead give promise of good qualities, and those who seek them generally find them. His partner is also a thrifty and good helpmate; she looks as though she performed her duties well, and she does. None of the pride of the Spanish about her; she does not put her children out to nurse, she brings up her own. The Brahma, with his useful head and cheerful face, giving earnest of his good properties, seems to us the Sir Balaam (in his good days) of poultry.

"Honest, punctual, and so forth,
His word would pass for more than he was worth."

It is a face of sterling quality, and it does not lie. It, however, when surmounted by his pea comb, does not fail to be quaint.

If we take the French breeds we have there entirely different types. Take the saucy fussy Houdan. If there be any comparative physiognomy, and if man and bird can represent the same character, then a Houdan cock and Lemaitre both represent Robert Macaire. The likeness is ridiculous. The skull of the Houdan is small, but being bearded and top-knotted it does not show. A quiet, self-possessed, and well-bred fowl is the Crêve-Cœur; his large, round, well-shaped head gives promise of good qualities, and he has them. The reverse is true of La Flèche; he has an ugly mis-shapen head, which promises nothing, and does not disappoint its possessor.

We purpose making a collection of skulls, and being the Professor Donovan of poultry.

POULTRY EXPERIENCE PURCHASED.

However gratifying it may be, when we have climbed that steep hill called Experience, and have at length reached the delightful summit of Perfection, still to come to grief so often on the journey (and we invariably do so just as we appear most certain of success), is very trying to the best-regulated temper.

For the benefit of any amateur whose knowledge of poultry lore may have been as limited as my own, let me tell how I "purchased experience," with a splendid White Cochin pullet, that grew and prospered so well that in my fertile imagination I was already the happy possessor of handsome cups, and first prizes innumerable. But one morning while feeding them, I noticed that the bird "on whom my hopes were built," had an unusual protuberance in the breast, and on closer inspection found it was decidedly crop-bound. I gave it several doses of castor oil, yet as day by day went on, it got no better, and I said to myself, "J. K. L., I charge thee 'fling away ambition,' for you never did, and you never will get so much as an 'H. C.' towards the realisation of all your brilliant visions." Now, I never had the pleasure of a *tête-à-tête* with a learned poultry-keeper, since I am not acquainted with one, or I should have listened with reverence to his advice, and I obtain no sympathy from the "head of the family," who considers the study of hens and chickens very tame and insipid. "Better study flowers, and Ferns would be a far more lady-like occupation," and ends his advice with a parting shot (very much *sotto voce*, I admit), something about "little things." And really *I* consider, since my poultry cannot get "highly commended," the judges ought to award something to my unwearied energy and perseverance, because for the last five years, with nothing to back me but my purse and my enthusiasm (and I positively affirm that the two are inseparable), I have slowly learnt my lessons in experience. Again, my invalid neighbour complains of the perpetual cock-crowing, the servants of the extra work "them dirty brutes" make, and I am periodically informed by the "head," that those horrid pets of mine have got into the garden, and for the third time have eaten all the young plants; and all these little drawbacks are calculated to damp the ardour of their warmest friends. But I am digressing; *revenons à nos moutons*, my crop-bound pullet.

On referring to "our Journal," I found you had advised "An Anxious Reader," apparently in the same difficulty as myself, "First to secure the bird firmly, clip away the surrounding feathers, cut open the crop, and remove all the food there, carefully sew up the wound, and for a few days feed the bird on soft food only." These directions I followed to the letter, and I was so deeply impressed by my own skill and ability, that I felt confident I had only to receive a few lessons at the school in Edinburgh to become a very formidable rival to Messrs. Jeg, Blake, & Co., but my proposition to that effect was so hopelessly quashed by the "head," that I gave up the idea on the spot.

Well, my patient seemed to progress favourably, and my hopes were again in the ascendant; still I noticed she could not hold up her head as formerly, so I imagined the wound must still be very stiff, and that time would restore it; but time did not, for at the end of three months she still walked about with her neck very much contracted, and we both seemed to lose heart together (only she lost flesh as well), and one day while carelessly looking over a stray number, I dis-

covered the cause of my unsuccessful surgery. "Be careful not to sew the two skins together," and making this moral I will end my letter.—J. K. L.

[We shall be proud if benefited exclusively as promised in your P.S. If we can do anything to effect the conversion of *that* "head of the family," command our services. To be unfortunate and without sympathy is a superlative trial.—Eds.]

POULTRY-KEEPING UNDER DIFFICULTIES.

No. 2.—BREEDING.

In commencing to keep prize poultry, I would advise the outlay of not more than £1. For this sum you may obtain an imperfect cock and hen of a good strain, or a sitting of eggs from one of the best breeders. In the latter case, select one on whom you can depend, because you are entirely at his mercy.

I commenced with a cock and two hens, for which I paid £1, but the cock showed a little Dorking in his fifth toe. However, they were equal to my experience. I bred some chickens from them, and then sold the old birds for what I gave. I expended little on food for I risked only £1 on the birds, and I lost nothing my first year.

There is no wisdom in throwing pearls before swine, because they would be trampled under foot, and so would good chickens in my first year. The great danger is in expending too much money at first. When this is done without experience, the new fancier often sickens and dies—not respected by all poultry friends who knew him.

The next year I launched-out and bought a sitting of eggs from a well-known Birmingham breeder for 15*s*., and hatched and reared thirteen, I think, out of fifteen. Out of this lot I sold one for £1 10*s*., one for £1, and three for 10*s*. each. The best cockerel I kept for a stock bird for the next season, and sold him, as stated above, for £1 10*s*. This hatch paid well, but I was disappointed in not having a single bird that could be called good—free from glaring defects. The crooked combs could not be made straight, even when the sprigs were cut off; nor the lop-comb to stand even with splinters. I waited for the mottles to feather-out, and the shallow to become deep, but they did not.

If, after the first or second year, a few good shows be visited, and such books as the "Poultry-keepers' Manual," published at the Journal office, be carefully studied, more money may be safely risked on stock birds. The object of the breeder should be to produce birds better than his old ones.

I prefer stock birds to be not less than one, nor more than three years old. If the male bird be the same age as the hen, I should prefer them two years old; if of different ages I do not care which is the older of the two. It is said by some that a cockerel and a hen will breed the majority cockerels. This year I have bred from a cockerel and a hen, and the majority are pullets. In choosing birds to cross be careful to select those that have the points extra good which are wanting in your own. Golden-buff is safer to breed from than lighter shades, although a lighter-coloured hen mated with a darker cock will often produce a fair number of chickens of a good gold colour. Take care that the secondaries of the male bird be sound in colour. Beware of falling combs, or your trouble and expense will probably end in disappointment. A crooked comb is as troublesome, with this difference, that the falling comb does not show itself till the bird is seven or eight months old; whereas the crooked comb can be detected at the end of two or three months. The birds from which it is intended to breed had best be kept by themselves to prevent mistakes in eggs, and to insure stamina. Two hens will lay from forty to sixty eggs, a greater number than it will be advisable to set in such a space as I have described.

I set three sittings of nine or ten each. The second and third lots are given to the breeding hens to afford them as much rest as possible. Each sitting-hen has a house to itself, and is furnished with a nest 18 inches square, made in one corner by nailing two pieces of wood together 4 inches deep. Oat straw well rubbed is used for the nest, which is made on the floor in a slight hollow. Each hen is allowed half an hour in a morning, never more; in fact, they seldom take the time allowed. Cochins do not like to leave their nests as a rule, so each hen is lifted off by placing the hand under the breast and allowing the legs perfect freedom; there is then no struggling. When the hens are off their nests let them have a run the first thing. This will insure their speedy return to their yards, when they should have as much wheat or barley as they will eat, plenty of fresh water, something to dust in, and some green food. The eggs should be sprinkled with water during the last ten days when the hen is feeding. During the period of hatching the empty shells should be removed, or they will sometimes adhere to eggs not hatched, and prevent the egress of the chick.

Unfertile eggs may be detected at the end of a week by holding them, when it is dark, between the eye and a candle. The opaque ones are good. Eggs when laid should be dated and placed in bran, with the thin end downwards, till they are put under the hen. Some say this is unnecessary, unnatural. However, it answers, and is as convenient as laying the eggs on their sides. Eggs kept in the way I have described may be safely set at the end of three weeks. Of course, the sooner an egg is set the better. From sittings of ten I average eight or nine chickens.—W. J. Peace, *Driffield.*

HANDICAPPING POULTRY EXHIBITORS.

The idea is certainly novel, but I am afraid that is the most that can be said for it. The originator of the idea says, "I breed five or six different kinds of fowls," and then he complains of the results of his exhibiting, and mentions the names of several exhibitors who are generally to the fore. Now I think I can suggest a remedy that, if tried, will very soon banish all thoughts of handicapping out of his mind. It is simply this: Breed one, or at the most two kinds. Then if he breed from well-bred birds and pay proper attention to them, not only will he require no handicapping, but I warrant that he will beat all the exhibitors he has named, and, moreover, will himself be classed amongst the very men he has mentioned as noted exhibitors.

He is, perhaps, little aware how few birds many of our noted exhibitors actually breed. My experience leads me to say that to make poultry pay you must either go into the fancy almost as a trade, or you must be content to keep one or two breeds and breed them only. If you exhibit on a large scale you must attend, either personally or by a deputy who can be thoroughly relied on, and who is a first-rate judge, at nearly all the shows, so that not only your birds are properly attended to, but better birds than your own are bought wherever there is a chance of getting them reasonably. Anyone attending shows who is really a judge has an enormous advantage in picking up birds reasonably, and this is one of the main sources from which many of our noted exhibitors get their birds; and if the gentleman who has written the paragraph as to handicapping has not done this I can well understand his non-success. To breed five or six varieties I consider almost more than anyone can do with success, and especially if he exhibit only birds bred by himself. Many amateurs make the same mistake that he has done. I did it amongst the number, and never till I settled down to one breed did I find it either profitable, or was I really successful at exhibitions.

There is also one other great objection to handicapping—that is, the admission, by being handicapped, that your birds are inferior to others. Now this is not a pleasant reflection, and if I did not think that my birds could hold their own with any in the kingdom I should soon give up exhibiting; and I am certain that nothing tends more to raise the quality of poultry of all kinds than the laudable desire to breed birds to take their share of prizes at good exhibitions, and how much greater is the pleasure of winning with birds bred by yourself it is needless for me to say.

I am afraid I have spun a very long yarn on a very dry subject; but still I feel confident if amateurs generally, and especially those whom I call the head of their profession, the actual breeders of exhibition poultry, will breed only one or two sorts with proper attention and choice in selecting the breeding stock, success must and will reward their endeavours, and they will hold their own against all comers.—T. E. Kell.

AYLESBURY POULTRY SHOW.

Noted as Aylesbury has ever been for the excellence of its poultry shows, and the success throughout the kingdom of its local breeders, few persons could have anticipated so good a collection as that which was exhibited on the 13th inst. The profusion of excellent silver cups, the gifts of the nobility and gentry of the neighbourhood, no doubt had its influence in promoting this result, equally with the well-known appointments always attendant on the Aylesbury shows.

The Grey *Dorkings* were one of the finest collections of chickens we ever saw, the cup being taken with a pen of very dark, high-conditioned, single-combed chickens shown for the first time. A pen of unusually good White Dorkings were second, and Greys third. It

was the impression of all who saw them, that even had the prize birds been taken away, a first-rate class would have still remained. *Brahmas* were an equal treat to visitors, both Light and Dark-feathered birds being among the prizewinners. *Spanish* were not numerous, but very good. Lady Gwydyr's Buff *Cochins* and Mr. Sidgwick's Partridge-feathered were marvellously well shown, and this remark is equally applicable to Mr. Matthew's *Game* fowls. The Spangled *Hamburghs* were remarkably good, but the Pencilled were far behind those shown in this district in former years. That Mr. J. K. Fowler had it entirely his own way in *Geese* and *Ducks* would be almost anticipated; they were a show in themselves, but it must be remarked that the cottagers' pens of Aylesbury Ducks were closely competing. The best pen of Rouens weighed 15½ lbs. the pair, the Aylesburys 16½ lbs., and the cup Geese (Grey), 54 lbs. the pair. A grand collection of *Pheasants* amply repaid the attention of visitors. A pair of that rare variety known as the Swinhoe Pheasant took the first prize, and a large display of Silver and Gold Pheasants called forth continued remarks of approbation from visitors. All kinds of *Bantams* were included in a general class, Silver-laced Sebrights and Blacks taking the prizes.

Dorkings (Any variety).—Cup, J. Martin, Clainca. 2. O. E. Cresswell. Hanworth. 3, J. Smith, Shillinglee, Petworth. *hc*, C. A. Barnes, Chorley Wood; J. Smith; Rev. E. Bartrum, Great Berkhampstead: Miss E. Williams, Henllys, Berriew; J. Clift, Dorking; L. Patten, Hillmore, Taunton. *c*, Rev. E. Bartrum; T. W. Tapping, Hartwell.

Brahmas (Any variety).—Cup, H. B. Morrell, Caer Mawr, Clyro. 2, M. Leno, Markyate Street, Dunstable. 3, Lady Gwydyr, Stoke Park, Ipswich. *hc*, Hon. Mrs. B. Hamilton, Ridgmount, Woburn (2). *c*, Rev. E. Alder, Etwell Vicarage, Derby; H. Lingwood, Creeting, Needham Market; J. K. Fowler, Aylesbury.

Spanish.—Cup, Mrs. Allsopp, Worcester. 2, W. Davy, Brixton. 3, E. Jackson, Finchfield, Wolverhampton. *hc*, Mrs. Allsopp, Worcester; S. Burn, Whitby; F. James, Peckham Rye.

Cochins.—*Buff.*—Cup, Lady Gwydyr. 2, H. Tomlinson, Gravelly Hill, Birmingham. 3, C. Sidgwick, Ryddleaden Hall, Keighley. *Partridge.*—Cup and 2, C. Sidgwick. 3, H. Lingwood.

Game.—*Black-breasted and other Reds.*—Cup, S. Matthew, Stowmarket. 2, T. Dyson, Halifax. 3, J. Fletcher, Stoneclough, Manchester. *hc*, J. Fletcher; W. E. Oakley, Atherstone (2). *c*, W. Adams, St. Clements, Ipswich. *Any other Colour.*—1, S. Matthew (Duckwings). 2, W. Dunning, Newport, Salop (Duckwings); J. Goodwin, Liverpool (Red Piles).

French Fowls (Any variety).—Cup and 2, J. J. Malden, Biggleswade (Crêve-Cœurs). 3, Hills & Co., Brighton (Houdans). *hc*, C. A. Barnes (Crêve-Cœur); W. Dring (Houdans): Hon. Miss B. Hamilton (Houdans); J. K. Fowler (Crêve-Cœurs) (2). *c*, C. A. Barnes (Houdans).

Hamburghs.—*Gold or Silver-pencilled.*—1, J. Wing, Oxford (Silver-pencilled). 2, S. & R. Ashton, Mottram (Gold-pencilled). 3, R. S. S. Woodgate, Pembury, Tunbridge Wells (Gold-pencilled). *Gold or Silver-spangled.*—Cup and 3, Mrs. Allsopp (Silver-spangled). 2, E. T. Gardom, Newcastle (Golden-spangled). *hc*, Ashton & Booth, Broadbottom, Mottram, Manchester. *c*, G. Brawn.

Bantams (Any variety).—Cup and 3, M. Leno (Silver-laced). 2, S. & R. Ashton, Mottram, Manchester (Blacks). *hc*, M. Leno; Rev. F. Cooper, Ampney Crucis, Cirencester (Duckwings); Bellingham & Gill, Woodfield, Burnley, Lancashire (Black Reds and Red Piles); W. Adams (Brown Reds and Black Reds). *c*, S. Stephens, jun., Ebley, Stroud (Brown Reds).

Ducks.—*Aylesbury* (Prizes offered by S. G. Smith, Esq., M.P.) Cup, J. K. Fowler. 2, H. Jones, Hartwell, Aylesbury. 3, W. Castle, Stone. (Cup presented by Lady A. de Rothschild).—Cup, 3, and *hc*, J. Hedgea, Aylesbury. 2, J. Funge, Long Marston. *c*, W. Stonehouse, Whitby. *Rouen.*—Cup and 2, J. K. Fowler. 3 and *hc*, S. H. Stott, Preston.

Geese (Any variety).—Cup and 2, J. K. Fowler (Grey and White). 3, M. Kew, Oakham (Grey).

Pheasants (Any variety).—1 and 3, M. Leno (Swinhoe and Gold). 2 and *hc*, J. K. Fowler (Silver, Gold, and Kelledge).

Selling Class.—1 and 3, J. K. Fowler (Aylesbury and Houdans). 2, J. Wing, Oxford (Silver Fowls). *c*, H. Yardley, Birmingham (Grey Dorkings).

Extra Stock.—*Turkeys.*—*hc*, Lord Cheaham, Latimer (2).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, officiated.

WHITBY CANARY SHOW.

The duties of an honorary secretary are endless; so are his anxieties. He has his pleasures, too—that is, pleasures of a kind, pleasures which to anyone in his senses would be considered pains. The beginning of the thing (I'm talking about the getting-up of a show) is awfully jolly, but the end thereof is weariness. The intermediate state is——"a mixture of hopes and fears." Thank you. That expresses it very nicely: a mixture of hopes and fears. The line is not mine, but it will do. I was going to say (when a white *piqué* so naïvely suggested the other idea) that the intermediate state is one of perspiration, copious and suppressed, hot and cold; the final agony on the eve of the close of entries being a sleepless night, with cold drops trickling down one's back like little shots, the committee meantime slumbering peacefully, alike unmindful of the Hon. Sec. or his anxieties. I was not astonished, then, to know that the Hon. Sec. for Whitby had been suffering from those symptoms which the annual return of the Show induces, having experienced them myself when placed in similar circumstances; nor will I deny that some slight misgivings as to the success of the Show occasionally arose in my own mind when I remembered how early in the season it fell, and what a poor year it had been for rearing young birds, and I pictured to myself the ample staging only very sparsely covered with cages judiciously spaced out to make a little go a great way. But I received intimation from the white *piqué* that the mercury had risen in the executive barometer. "All our old friends—Moore & Wynn, Bexson, Bulmer, Harrison, Hawman, Gayton, Burniston, Mills, Stevens, and a host of new ones have turned up, and we received nearly two hundred entries this morning," and——ever so much more, all enclosed in a scented envelope, on which "J. R. W." struggled in a Laocoon kind of monogram.

The two hundred entries had swelled to nearly 250, when, after a two-hours drive through some of the picturesque scenery of the Esk, I was set down at the door of the Congress Hall, and found myself face to face with the first collection of young birds entered for competition this season; so numerous an entry at such an early day, showing the high estimation in which the Whitby Show is held, and attracting by its intrinsic excellence many well-known fanciers, anxious to get a first peep at the budding beauties of the year. Among the familiar faces of many who were scanning the cages with severe criticism, I saw Mr. Wallace, Mr. Hawman, Mr. Bulmer, Mr. Mills, Mr. Young, Mr. King, Mr. Burniston, and many others whose faces are well known to me, but whose names I forget, all good men and true, men who are the mainstay of our exhibitions, entering every feather which has a chance, and many which have no chance, of winning, simply from kindly feeling and a desire to support a hobby in which they feel interested. To all such, greeting.

I must dispose of Moore & Wynn, by saying that they are still in the moult, and being short of preparation failed to stay the distance; but I hear of some dark youngsters in the Northampton stable destined to play a prominent part at future meetings.

In Clear Jonques, Mr. Bunting, of Derby, was first with a sensation bird, which found a ready purchaser at its catalogue price, £3, and ought, like many other high-priced yearlings, to pay its way. My attention was directed to it later in the day by men who ought to know a high-class bird when they see it, some of whom affirmed it was painted, while others discovered a microscopic tick; but my own opinion was, that it had only received a true Derby polish, and that the tick which ultimately reduced itself to one imaginary minute feather in front of the left eye, and an illogical inference that tweezers had been applied to others which might have been there, never existed at all. I don't know how Mr. Bunting will like all this, but as the bird must be well known in Derby, it may be that these remarks may be noticed in as kindly a spirit as that in which they are penned. I only mention what some thought and said. The prize award will show what I thought and did. Mr. Close, of Derby, and Messrs. Adams and Athersuch, of Coventry, were second, a good length behind Mr. Bunting. There being large entries in some of the classes, the Honorary Secretary for Whitby at once complied with my request, that I might award extra prizes, and supplemented the permission by a generous intimation that the extras need not of necessity be third prizes. Such a liberal policy speaks for itself. No. 7, Barwell and Golby, Northampton, was the second best bird for colour, but upon close examination I think it will be found to be scarcely eligible for exhibition in a Clear class.

Mealy Norwich were strong in numbers and excellent in quality, Adams & Athersuch winning easily, taking first and second, with Barwell & Golby special second with a nice bird. Messrs. Smith and Preen, of Coventry, had a good entry in this class, but by some mistake of their own, it found its way into Class 6, and their representative there into the Clear class. But for this error their Clear Mealy would have run into a place. The "mentioned" birds all had merit, and the competition was so close that I was glad when I turned my back upon the forty-six Clear birds, and got to the Variegated classes.

In Evenly-marked Jonques Barwell & Golby made a decided mark with their bird, which, when one or two I know of are out of the way, will take some beating. But I wish they and other no-doubt well-intentioned exhibitors would have doors to their cages, and not make it necessary to extract half a dozen screws before a bird can be got at; besides, there is great risk of a bird escaping when the entire front of the cage is removed. I say nothing of the unnecessary and uncalled-for waste of time to the Judge. If security be the object, a simple padlock will answer all purposes, and the key can be lodged with the Secretary. Think of this when you send your birds to the next show. Adams and Athersuch were a good second; and Messrs. Holmes & Doyle, of Nottingham, third with one not quite A1 in exactness of marking, but of grand quality. Mr. Bunting also showed a good bird, marked and capped, and Moore & Wynn sent their hero of many fights, who was in such a dilapidated state that I hardly recognised him. But when I mused over his fallen greatness, and wrote *sic transit* against his number, he whistled *resurgam*, and said that even if he were, like his owner, not so young as he once was, he would still, like him, be heard of to greater advantage before the end of the season.

Adams & Athersuch had no difficulty in scoring first again in the Evenly-marked Buffs with a grand bird, a very good mealy edition of Mr. Hawman's famous Jonque, which is, I believe, a nephew of Messrs. Adams & Co.'s bird, and was bred by them. Mr. Bunting's second was neat, very neat.

In Ticked Jonques Mr. Close's first was of delicious colour and quality. Mr. Bunting's second, too, was good, and the v.h.c. of Bexson & Bennett, of Derby, a credit to the firm. Mr. Readman, of Whitby, was mentioned with one of the right kind.

Barwell & Golby came in alone in Ticked Buffs. I heard a person say it was an awful bird. Bexson & Bennet made a good race for second with a very fine specimen which in nine years out of ten would have been first; but Barwell & Co.'s bird gave nothing a chance. Mr. Bunting would not be left out in the cold, and Mr. Cleminson, of Darlington, beat all the commended birds, earning a special third.

In Crests it was Bridgenorth election again—"all on one side. Barwell & Golby showed one of the best Crests I have seen for years, perhaps *the* best. The bird has nothing to boast of in its markings, nor is its colour extraordinary—on the contrary. I think, however, it is a hen. Still the colour it has is the right quality. Its crest is its chief attraction, and that feature is something beautiful—flat, well filled in behind, of good large silky feathers, close, compact, and dense,

and with splendid entrance and centre. Holmes & Doyle earned second place more from their bird (a rich Jonque variegated) being high up in Norwich properties than from the excellence of its crest. As a rule, the birds in this class were backward in condition, and the greater portion only earned a simple commendation.

Belgians were meritorions, but out of show condition. Mr. Robinson, of Middlesbrough, was first in Yellows with a bird a long way above the average; Mr. Bulmer, of Stockton, running him very closely, taking second and third and all there was to offer in the Buffs; Mr. Harrison, of Belper, and Mr. Robinson having to succumb. But it is almost impossible to say what "position" birds are like when out of condition.

The Yorkshire classes I was not much struck with, and I pass over the Cinnamone, in which Messrs. Barwell & Co., Holmes & Doyle, and Mr. Mills, of Sunderland, shared the honours, to get at the Lizards, and say a word of praise for Smith & Preen's Golden-spangled birds, and Mr. Ritchie's (Darlington) Silvers—they walked in.—W. A. Blakston.

(To be continued.)

PIGEONS OF EGYPT.

[The following notes have been obligingly sent to us, in answer to a correspondent's inquiry, by the Secretary of the Birmingham Columbarian Society.]

The Egyptians are great admirers of Pigeons. M. de Norr says, "The houses of Upper Egypt are vast dovecots, in which the owner reserves only a chamber for himself, and there he lodges with the hens, chickens, &c., exposed to the devouring insects which beset these animals." The Egyptians spend much time on Pigeons. They have many singular varieties, but, like most earnest fanciers, they keep the best for themselves, so that it is difficult to obtain even a sight of their best birds. Out of the varieties which are to be found in Egypt may be mentioned Turbits, Owls, Turn-crown Barbs, Tumblers, Lahores, Swifts, and hosts of others, no doubt, with which I am not familiar. Lahores are said to be Indian Pigeons; such may be the case, but I know they are cultivated extensively in Alexandria, for I have on several occasions seen them unshipped at Liverpool from that place. Swifts are Egyptian birds, and remarkable ones; they are almost unknown in England, therefore I briefly describe them. They have a round head, short thick beak, and a very singular-looking pale yellow eye. They are actually small birds, though in appearance they are large. Their wings and tail are unusually long, and give the bird a novel appearance. The legs of these birds are short. Their colours are various; the most striking are those with a bronzed appearance and light hackle. Pied and spangled ones seem the most numerous. Why they are called Swifts I cannot comprehend. It cannot be from the speed at which they fly, for, like most birds with long pinions, they cannot fly fast. The long wing is most desirable in birds that have to perform great distances, but the short and sharp-pointed wing for speed. Owls, of course—that is, the smaller and better kind, are peculiar to Africa, as most fanciers know; in fact, that fruitful portion of Africa abounds in high-class Pigeons.—J. W. Ludlow.

PIGEON-TRIMMING AT ALLERTON SHOW.

I shall be glad if you will insert the following in your next issue. Being a member of the Allerton Committee I was appointed Field Steward to the Pigeon department, and to accompany the Judge during the time he was making his awards on the day of the Show, and I most distinctly state that I not only saw Mr. Hutton examine the Nuns in question, but also witnessed him take out of their necks several dexterously-cut feathers, which I presume had been trimmed for the purpose of obtaining even marking.

Respecting the Dragoons I do not exactly remember what he said further than this, that he believed them to be two cocks, but in consequence of their being so young he could not positively determine, and so gave them the benefit of the doubt.

Threats are at all times considered poor argument, and in this case I think it may be taken as an attempt to destroy honesty of purpose.—D. Clayton, *Washington Street, Girlington.*

[We are induced to insert this because we are informed that letters have been written endeavouring to injure Mr. Hutton. —Eds.]

FOUL BROOD—TRANSPORTING HIVES.

I have sent you a small piece of brood comb from a hybrid stock of bees, which I am afraid is afflicted with the foul brood disease. You will observe that some of the cells are empty, and I perceive here and there a young bee struggle out, and this morning, when I cut from the frame the piece sent, I distinctly saw some of the smaller grubs move. The stock is a late artificial swarm, or rather a number of brood combs taken from a yellow stock and placed in a position previously occupied by a black stock, and this is the first batch of brood from the young queen. There are five frames of brood, and all alike. I have removed two frames, but have no others in stock with which to replace them, without taking them from other hives.

I have also bought a lot of bees in Suffolk, in old-fashioned hives (eighteen), which I have to bring to London. Will you give me a little advice on the subject? My own idea is to cut a hole in the top of each hive (about 3 inches), secure on the top with plaster of Paris and long pins a piece of wirework or zinc perforated, put a piece of a lath through to support the combs, stop the entrance with clay, pass a piece of cord round to secure the hive to the floor-board, and send a light spring van to fetch them. I have plenty of empty Woodbury hives with frames, if you think it would be best to put two stocks together, as advised by Mr. Pettigrew, and make nine strong ones of the eighteen.—T. F. W.

[We have carefully examined your comb, and have come to the conclusion that there is as yet no decided proof of its being affected with foul brood. Some of the brood was dead and in a state of decomposition, but this may have arisen from the lapse of time since the piece of comb was excised. Examine your hive in the course of two or three weeks, and if you find dead and putrid larvæ, or numbers of sealed cells having minute perforations in the centre of the covers, you may then decide that you are troubled with this dread disease.

Your proposed plan for removing your hives may answer very well, but the method we have always adopted and recommended for the safe conveyance of straw hives which have to travel any considerable distance, is to procure some coarse open canvas, or what is known as cheese cloth, and cut it into squares just sufficient to allow of the four corners being tied together over the crown. Remove the hive from its bottom board, and put it down on the middle of the cloth, quickly securing the ends over the top. Then take a long piece of stout string and tie round the hive about an inch from the bottom. During carriage care must be used that the hives do not rest on a flat surface. If the bottom boards had two pieces of wood 1 inch square nailed 10 inches apart across their upper surfaces, the hives could stand on them, being secured, if necessary, by cord. A spring van, with plenty of straw on the bottom, might convey the hives safely; but we have generally preferred the rail, where it was practicable, for long distances. If you desire to have fewer but stronger stocks, and to transfer them into frame hives, you would save yourself considerable trouble in their transport; but the combs would be hardly secured enough for some time to come to enable them to resist the shaking they would get. If you could transfer the combs now, feed liberally, and defer the removal of the hives until winter or early spring, we should advise your doing so. You would save expense and trouble in cloths and carriage.]

HIVING ITALIAN BEES.

Several parties have written to me saying they find it more difficult to hive Italian than black bees, and wish to know why it is so. The reason I would give is this: They are naturally more lively, more energetic, and when aroused and in a state of excitement, the excitement is more intense. Hence the disturbance caused by swarming or issuing from the hive does not so readily abate as with the black bees; they are consequently longer in clustering, and when clustered, the heat generated is far greater; they do not, therefore, cluster compactly, but the cluster is larger or more spread about than with black bees. Thus it happens that when one attempts to hive them immediately after they cluster, they are sure to take wing in large numbers; when they are shaken down, and when turned out of the hiving dish, or cloth spread to receive them, they spread out over a large surface, and, like hot ashes, are very difficult to handle. This is nothing against them, however, as it proves their more energetic disposition. It is well to allow the cluster to become well settled, and if convenient sprinkle with cold water. Where artificial swarming is practised, this trifling difficulty does not appear. When not under a state of excitement they are more easily managed, as their labours seem to wholly engross their attention, and a card of comb may be lifted from the hive and not a dozen bees leave it, and the

queen will often continue laying as if nothing had occurred.—J. H. Thomas.—(*Canada Times.*)

[We have had considerable experience with Ligurian bees, and have hived many swarms of them, but we have never found any greater difficulty in inducing these bees to "settle," than with swarms composed entirely of the ordinary variety. Mr. Thomas is quite correct in his ideas regarding their more easy management where artificial swarming is practised.—Eds.]

OUR LETTER BOX.

A Prize Dorking Cock (*An Old Subscriber*).—The cock has done well. Success is unmistakeable evidence, and in your place we should perpetuate the strain. You must be the judge of appearances. If he seem in vigorous health we should put him, not to hens, but to strong forward pullets, not more than two or three. It will probably be his last season.

Houdan Cockerel Hoarse (*E. W.*).—Camphor given in pills two at a time, the size of a garden pea, will probably restore the crowing capabilities of the Houdan cock, but as you say he is in perfect health we advise you to let well alone. At the same time watch him; if, as we think likely, the dumbness is the result of cold, it may get worse, and that is not desirable at this time of year. Bread and ale are very good things for a cold. While on the subject of crowing we can answer another question from "*Gallus*," who says his cocks crow day and night, and wishes to know if a narrow strap round the throat will prevent it. If buckled very tight it will prevent it, but it is injurious to the bird.

Sending Fowls by Railway (*Ducklings*).—Get a round basket high enough for the cock to stand upright in, and roomy enough for the three birds to squat in. Cover it with coarse canvas, put some nat straw at bottom, and despatch your birds. Send them off by a night train, and they will want no food nor attention. There is no physic for Ducks, and therefore when anything is amiss we always try change of food. Discontinue the potatoes and Indian corn. Give the ducklings some gravel mixed up with their food. If they are in confinement give them in the vessel with their meal a sod of growing grass with plenty of mould. These are very conducive to digestion.

Consequences of Non-prepayment.—"A man, signing himself 'R. H. Ellison,' wrote to me a fortnight ago from Roby, near Liverpool, asking me to send him some Partridge Cochins which I had advertised for sale. I am sorry to say I complied with his request. The letter appeared to be genuine, and was written on deep black-edged paper. I have not heard from the man since, though I have written to him for the money, and all I can find out is that he sends for his letters to the Roby post office, and has had many lately.—Fred. Temple Hillyard, *Southam, Warwickshire.*" [Inform the Liverpool police.—Eds.]

Cottingham Show.—Mr. R. P. Moon, of Driffield, informs us that he won the first prize for Trumpeter Pigeons.

Our Pigeon Portraits (*A. C. R.*).—Since the Fantail in No. 512, the following portraits have been published by us:—The Turbit, No. 523; the Jacobin, No. 526; the Owl, No. 533; and the Beard and Baldhead in No. 541.

Pigeon Book (*W. H., Leeds*).—It will be the same as the last edition, and will be ready in a week.

Skins of Himalayan Rabbits (*J. D. C.*).—The skins of the Himalayan Rabbit are not so valuable as those of the Silver-Grey, yet both are of use to the furrier, who will generally purchase them if in the season. If they are not purchasers themselves, they will furnish you with the address of dealers who will, and at more than the price you name per skin.

Turning-out Belgian Hare-Rabbits (*Idem*).—They and Silver-Greys also are profitable for turning down; the former to increase the size of the common Rabbit, and the latter to increase the value of the fur. Both are sought after for the purpose just now, yet they should be five or six months old to insure their doing well, and should have some protection from the cold. We would advise the spring, or even now if four months old, to be fully grown by the breeding season. We recommend the introduction of the largest specimens obtainable, especially of the Belgians.

Uniting Bees (*R. F.*).—If you can shift your two hives, a foot at a time, rather nearer to each other, it would be as well to do so; but if not able to do so, perhaps you could manage to drive the bees of both stocks into the same empty hive, and then shake them into the one they are intended to occupy. There would be little risk of fighting, or of many bees being lost by returning to their former stand. We should not recommend your putting the expelled bees into an empty side box. We have known bees refuse to unite under such circumstances, and to be individually killed as they attempted to leave the hive for forage or exercise, to say nothing of a general slaughter.

What is Foul Brood? (*Idem*).—The disease called "foul brood" consists in the death and decomposition of the brood. The cells so affected have usually little perforations in their centre, and on the sealing being removed there will usually be found the remains of the tenants in a more or less advanced stage of corruption. Some healthy larvæ may be brought to maturity in the vicinity of, or surrounded by cells so affected. Eventually, however, the entire breeding space becomes so clogged-up with the remains of the victims of the disease, that the queen cannot find room for her eggs, the bees gradually dwindle away, the hive perishes altogether and is visited and robbed by the bees of other stocks, who convey the contagion into their own habitations. Even the honey the diseased stock may contain is contaminated, and will be the vehicle by which the malady will be conveyed from one colony to another. When its existence is discovered in any hive, burn the combs and bees; if the hive is not very valuable burn that also; if otherwise, thoroughly cleanse it by scraping and boiling water, and wash it out with a super-saturated solution of chloride of lime. If you can refrain from using the hive for a couple of seasons, so much the better.

Foul Brood (*D. N. Cantab*).—Although the piece of brood comb sent seems to possess some of the symptoms which indicate the presence of the disease, yet we are not quite satisfied on the point, and hesitate to pronounce a decided verdict. We should recommend the combs to be examined in three or four weeks' time, and if, in addition to the present symptoms, some of the cells have perforations in their covers, with a dark viscous fluid within, and the hive's interior gives forth a nauseous smell, your friend may at once condemn the combs, frames, and bees to the fire, treating the hive as advised to another correspondent. We believe that there are two kinds of the disease called foul brood, one malignant and incurable, the other not malignant, and not only curable by treatment, but such as may die out of itself. The latter may, and often does, pass into the former.

Feeding Bees (*R. W.*).—You had better remove the super entirely, passing the string through as you did before. You will probably find less honey in the comb than when you previously examined it. Having removed the super, you will be able to ascertain, by lifting the stock, whether it requires feeding, and if so, you will have no difficulty in using the bottle-feeder. If your hive is made of straw, you may put down the weight of hive, combs, and board, at about 10 lbs. or 12 lbs., and deduct that amount from the gross weight. If made of wood a larger allowance must be made.

REMARKS.

13th.—Fine day, but at times oppressive and stormlike; heavy clouds at sunset, afterwards very clear till 9 P.M., at which time a very peculiar cloud (more like the smoke from a distant fire) suddenly spread nearly all over the sky, the parts between looking an intense blue from the contrast.

14th.—Rather dull all day, but no rain.

15th.—Rather dull in early morning, but very fine after, the sun being bright with a cool breeze.

16th.—Fine morning, lovely day, wind rising at night.

17th.—Very fine all day, but quite cool in the evening.

18th.—A similar day, but if anything more chilly and autumn-like in the evening.

19th.—A rather dull and autumnal-looking day, and cloudy at night.

Cooler than last week, but temperature still above the average. Dry easterly winds prevalent, and no rain during the week.—G. J. Symons.

COVENT GARDEN MARKET.—September 20.

Business transactions continue to be of the usual character at this season. We have a fair supply of Peaches and Nectarines, but that of good descriptions of Apples and Pears of home-growth is somewhat limited. French varieties comprise Duchesse d'Angoulême, Louise Bonne, and Jersey Gratioli. Hothouse Grapes are abundant.

From observations taken near London during forty-three years, the average day temperature of the week is 64.4°, and its night temperature 63.4°. The greatest heat was 80°, on the 4th, 1859; and the lowest cold 17°, on the 2nd, 1853. The greatest fall of rain was 1.39 inch.

RUBUS DELICIOSUS.

I MAKE no apology for contributing the following additional information to that given at page 179 in reply to your querist "G. S.," relative to this very showy shrub.

In 1866 or 1867 seeds of the Rubus deliciosus were purchased at Stevens's rooms, Covent Garden, by David A. Patterson, Esq., of Dalnagear, who, at his town residence, Restalrig Park, has one of the most interesting collections of both hardy and tender plants in the vicinity of Edinburgh. A portion of those seeds which he kindly gave to me produced several plants; one of which flowered here in May, 1869, and another bloomed about a week later in the neighbouring garden of I. Anderson-Henry, Esq., of Woodend; these plants having been, in so far as I can learn, the first that flowered in Europe. In May of the present year my plant had attained to over 4 feet in height, by fully as much in diameter, and for fully four weeks it was profusely covered with large, showy, white blossoms, resembling, in size and appearance, those of the white-flowering wild Dog Briar, to which the plant also approximates so closely in the peculiar arching branched habit of its growth that visitors frequently remarked, "That Wild Briar is blooming remarkably early;" and only on a closer inspection did they detect the difference by the absence of spines and the undivided form of the leaves. Only two of the flowers have as yet produced berries, and these only partly developed, or having but a few of their pips full-sized. When fully grown they are likely to resemble those of the Cape Berry of North-west America (R. nutkanus) in size and flattened roundish form. The few pips were of a dull, hoary, purplish colour, and had a pleasing, luscious, somewhat musky flavour; but whether they deserve the specific name applied to them by the discoverer, Dr. James, more than thirty years since, can only be satisfactorily ascertained when fully-developed berries are produced.

The plant belongs to the lobed, not pinnate-leaved section of the genus Rubus, and has permanent shrubby branches, instead of these being biennial, as in the common Raspberry and Brambles. Dr. Torrey, the American botanist, by whom it was first described, merely supposed its flowers to have been purplish, and accompanied this part of his description by a (?), which Loudon and others have omitted: hence the apparent discrepancy. Dr. Hooker, however, has no doubt of its being the true R. deliciosus, from an inspection of specimens sent to him by Mr. I. Anderson-Henry. From a portion of the seeds which were kept a year longer before sowing, and then lay over a year before vegetating, other plants have been grown, which are expected to flower next year, from some of which, or by fertilising the blooms of one plant with those of another, it is hoped that berries will be more readily produced. The seeds grown from the afore-mentioned imperfect berries have also been sown with this view. That some exotics thus become fruitful which were almost barren at first is exemplified by the Berberis dulcis, the original plants of which scarcely yet produce any fruit, while their descendants of only a few years old are bending under their berry-loaded branches.

I may mention that the R. deliciosus was figured and described by me in the horticultural columns of *The Farmer* in 1869, and it was also figured and described in the "Villa Gardener" for September, 1870, page 280.—William Gorrie, *Trinity, near Edinburgh.*

ROSE GOSSIP.

Your correspondent who a week or two since inquired about the best Tea Roses, appears to be without three kinds, which, in my opinion, are amongst the very best—viz., Madame Falcot, Madame Bravy, and Devoniensis. The first of these is, if not the very best Tea-scented Rose, very nearly at the head of them. It is true and distinct in colour, hardy, of a nice bushy habit, and exceedingly floriferous. Early in the season it is scarcely full enough, but in the autumn no fault can be found with it in this respect. The second is not very floriferous, but it is a good Rose, well shaped, and distinct, and pretty hardy. There is little or no difference between it and Alba rosea. Devoniensis your correspondent must know, and I wonder he does not grow it. Although an old Rose it is not yet approached in its particular colour. Rubens, which is somewhat like, and which flowers more profusely, has not the substance of Devoniensis.

Your correspondents who a little time since mentioned some good garden Roses, omitted one of the very best—viz., Anna Alexieff, a hardy robust Rose of a bright pink or rose colour, and remarkably floriferous. One of them recommended Prince Léon, and I must say to my great surprise, for it is not brilliant nor choice in colour, and it is a wretched grower. I had it several years ago, but I really could hardly keep it alive. I would strongly advise amateurs who are without this Rose not to get it, for I am certain it will disappoint them. It is certainly a nice-shaped Rose, though it is not even in that respect a model. There is not sufficient depth of petal.

I often see it asked, "Which are the best twelve Roses?" In answer to this question I have seen Roses recommended which I should not place in the first thirty-six. Either, therefore, people's tastes differ considerably, or some soils and situations suit some Roses better than others. Very likely the differences in the answers to this question arise from both of these causes. Certainly there is a good deal in the soil, for I can never obtain blooms of such intense and vivid colouring as those grown at Waltham Cross and Cheshunt. Some people believe that to obtain this brilliant colour the soil should contain a large portion of iron in some form, and I am inclined to think that this is so. If you will permit me I will tell you which I think to be the best twelve Hybrid Perpetuals—this as a means of eliciting the opinions of other growers on the point. If I were limited to twelve Hyhrid Perpetuals, then I would choose Marie Baumann, Baroness Rothschild, La France, Louis Van Houtte, Countess of Oxford, Mdlle. E. Verdier, Madame Vidot, Charles Lefebvre, Marquise de Castellane,

M. Noman, Edward Morren, and Comtesse de Chabrillant' and I estimate them in the order named.

Marie Banmann is perfect in form, beautiful in colour, very constant, and a good grower. The only fault I have to find with this Rose is that the flower stalk is not stout enough to keep the bloom erect. Baroness Rothschild is perfect in form and most beautiful in colour. What can surpass its pinky shell-like petals? It is, too, a famous grower, has splendid foliage, and is very constant. There is only one drawback, it is not very sweet-scented. If it had but the odour of La France it would be a flower almost too good for this world. La France is a splendid Rose, and so distinct too. It evidently has Tea blood in it. I admit that it is not choice in colour, but its form is to my mind perfection; and then its scent—what Rose equals it in this respect? Take a bloom just at it is opening, blow it open, and what an odour seems to be set free. La France is, too, a good grower, and wonderfully floriferous, and I am even now not quite sure that I ought not to have placed it at the head of the list. Certainly it is first-rate, and will not soon be pushed aside. Louis Van Houtte, a Rose of 1869, has been so well shown this summer, and is so choice in colour and so sweet-scented, that I have no hesitation in setting it down as first-class. The "if or but" in this case is, Is it a good grower? I hope it is, but I do not feel quite sure about this. Countess of Oxford, another of the 1869 Roses, is also a splendid addition to our very choicest varieties; it is very distinct in colour, having that fine, dark, vivid scarlet crimson tint which is, so far as I can recollect, only seen in that good, when caught well, though very inconstant Bourbon, Rev. H. Dombrain. The drawback to this flower, and it is the only one I can name, is that it is not a fine-scented Rose, for it is certainly a good grower and very constant.

My next Rose, Mdlle. E. Verdier, is also a Rose of 1869, and is good in every respect but one—it is not highly scented. It has a good waxy very light pink petal shading to white, grows well, and is constant. Madame Vidot is an especial favourite of mine, and when it comes all but white, as it often does, I know of no Rose which I would exchange for it. I shall never forget a bloom of this Rose which Mr. Cant once exhibited in a stand of twelve some years ago—I forget where it was, but the Rose was photographed in my mind's eye, and there it is now. Madame Vidot is a good grower, but it must be propagated every two or three years, if you would obtain good healthy wood and fine blooms. Charles Lefebvre is a flower too well known and appreciated to make it necessary to say much about it. I place it thus low down in my selection because it is not highly scented, and has not a nice habit of growth. The growth is strong enough, but it is too fond of sending out one or two very gross shoots at the expense of the rest of the plant. The individual blooms are, perhaps, the finest that we at present have, and those who saw the three blooms which that clever florist Mr. Keynes showed some years ago at South Kensington (set up, horrible to say, in blacking or ginger-beer bottles), will not easily forget the sight.

Marquise de Castellane is a fine addition to our clear light pink Roses. In one word, it is a pink Baroness Rothschild, and I can hardly say more in recommendation of it. This is also a Rose of 1869, thus making four first-class Roses added to our lists in that year. M. Noman is a fine-shaped, thick, and deep-petalled flower, and was last year very constant with me. This wet season, however, did not suit it, and almost all the buds turned brown and rotted without opening. In an ordinary season this is a Rose that I am sure will give great satisfaction to the rosarian.

Edward Morren, when good, is grand indeed, and really does by far surpass that good old useful Rose Jules Margottin; it is larger, much more brilliant in colour, and I think of a better form. What a pity it is that one only gets about one good bloom in a dozen. If it were but constant it would be the best Rose out—at least, so I think. The last Rose of my selection is the good old Comtesse de Chabrillant. Some call it a formal Rose, but in my eyes it is perfect in form, and its clear bright colour, its constancy, good growth, and fine foliage, in my opinion, fairly entitle it to the position I have assigned it.

Of coming Roses I know but little. I understand on good authority that Mr. G. Paul has a very fine seedling called R. Marnock, from Duke of Edinburgh, of a dark maroon colour, but I have missed seeing it, and therefore cannot of my own knowledge say anything about it. I have, however, no doubt from what I hear that it is a fine flower.

Mr. William Paul showed a new Rose called Princess Beatrice at one of the meetings of the Floral Committee this spring, when it took a first-class certificate. It was not quite sufficiently out when shown, but that it was a good Rose was then evident, and a personal inspection of a number of plants of it in Mr. William Paul's nursery enables me to say positively that it is an exceedingly fine new Rose, one that every rosarian ought to add even to the choiceet collection, and one that will remain in the lists for many a day. I fear I shall tire your patience, and so I will now stop, though when wound up on this subject I hardly know when to do so.—P., *Essex*.

TRIAL OF PEAS AT SEAHAM HALL, SUNDERLAND, 1871.

ALL of the following varieties were sown on the same day, March 4th.

NAME.	In flower.	Height.	Ready.	Average number of peas in a pod	Remarks.
		feet			
Auvergne	June 27	6	July 30	5	Good variety.
*Advancer	„ 18	3½	„ 19	6	Good variety.
*Carter's Leviathan	July 3	7	„ 26	6	Good tall variety.
*Blue Scimetar	„ 1	4	„ 27	4	Good useful variety. Best for a dry season.
Bishop's Longpodded	June 12	3	„ 20	6	Good dwarf variety.
*British Queen	July 8	7	„ 28	6	Very good tall variety.
*Champion of England	June 22	6	„ 20	6	Very good.
*Carter's Invicta	„ 3	5	„ 7	5 to 6	Good new sort.
*Competitor	„ 3	8	„ 29	5 to 6	Tall variety, large peas, and good flavour.
*Climax	„ 10	4	„ 19	5	Very good useful sort.
Champion of Scotland	July 2	7	„ 26	5	Cannot recommend this, bad flavour.
*Dickson's Favourite	June 19	6	„ 6	5	Good useful kind.
Dwarf Sugarloaf	„ 26	3	„ 20	6	A useless variety.
†Dickson's First & Best	„ 5	4	„ 6	5	One of the best early vars.
Eley's Essex Rival	„ 18	7	„ 23	—	Good.
†Eastes' Kentish Invicta	„ 5	7	„ 7	5	Very good new sort.
*Evershed's Marrow	„ 20	5	„ 28	6	Good.
*Epicurean	„ 8	6	„ 23	—	Good.
†Fortyfold	„ 22	7	„ 23	—	Good useful kind, and good cropper.
*Glory of Cassel	„ 22	6	„ 19	6	Good.
Grotte	July 13	7	„ 20	—	Tall late kind.
†Hundredfold	June 27	8	„ 20	6	One of the best.
Harrison's Glory	„ 16	3	„ 21	6	Good, but not the best.
*Huntingdonian	„ 18	8	„ 23	6	A good tall variety.
*Hallett's Large	„ 19	7	„ 22	5 to 6	A fine tall variety.
Imperial Green Marrow	„ 27	7	„ 21	5	A good useful Pea.
Imperial Wonder	July 2	8	„ 29	—	Too large to be recommended.
King of the Marrows	June 29	8	„ 24	—	Too large to be recommended.
†Little Gem	„ 8	2	„ 10	5	Can highly recommend this for general use.
*Laxton's Quality	„ 8	7	„ 12	—	Good new kind.
†Laxton's Quantity	„ 8	7	„ 28	—	Good. Rightly named. One of the best.
†Laxton's Alpha	„ 7	6	„ 12	5	Good.
†Laxton's Supreme	„ 27	7	„ 20	6	Very good. Highly recommended.
Maclean's Wonderful	„ 28	3½	„ 28	6	Good.
Mammoth Dwarf	„ 28	3½	„ 30	5	
*Maclean's Prolific	„ 22	5	„ 20	6	Good.
†Maclean's Premier	„ 30	3½	„ 14	6	One of the best.
Mumstead Marrow	„ 30	7	„ 28	5 to 6	A good tall variety.
Nonpareil Marrow	„ 30	8	„ 22	5 to 6	Good tall variety.
Nelson's Vanguard	„ 11	3½	„ 15	—	Very good.
†Ne Plus Ultra	„ 30	8	„ 24	5 to 6	One of the best for general use. Highly recommended.
Paradise Marrow	„ 27	8	„ 20	5 to 6	Good.
*Prizetaker	„ 18	8	„ 26	6	Good dark green variety.
Peabody	„ 1	2	„ 28	4	A useless variety.
†Princess Royal	„ 27	3½	„ 26	6	Highly recommended.
†Ringleader	„ 3	6	„ 6	6	Good early variety; one of the best.
Surprise	„ 22	7	„ 26	5	Good.
*Sangster's No. 1	„ 6	5	„ 10	6	Very good early kind.
†Suttons' Early Champion	„ 6	5	„ 8	6	Good.
†Taber's Perfection	„ 6	5½	„ 7	—	Good. The pods are warty, much like those of Grotte. Too tall for general use.
*Tom Thumb	„ 11	3	„ 26	—	Good.
The Australian	„ 12	8	Aug. 8	6	
Veitch's Perfection	„ 27	3½	July 28	6	A good useful Pea, of good flavour.
Waterloo Prolific	„ 30	7	„ 28	—	
†Dwarf Branching	„ 11	3½	„ 30	6	One of the best; very prolific. Highly recommended.
†Yorkshire Hero	„ 28	4	„ 89	6	A good useful sort.

The preceding are the results of the trial of Peas at Seaham Hall this year. Fifty-six varieties were tested. It is due from me to say how satisfactory it is to find the great care taken by the trade in keeping the sorts so select. I actually find out of so many kinds scarcely two Peas resemble each other. Those marked with an asterisk (*) I can recommend, and those with an obelisk (†) I can highly recommend as the most useful kinds.

I may say I have had six practical gardeners to assist me in deciding on their merits. All the kinds have grown so tall, owing to the wet season, that the extreme height cannot be taken as a standard. As to flavour, the trial was made in the raw state, which I think is not a good criterion. Although some gardeners pretend to judge of the quality in the raw state, I have failed as yet to master this part of judging. I must highly recommend to the notice of gardeners Maclean's Little Gem. I consider it the best Pea; it requires no stakes, has a good flavour, is early and productive; can be grown in rows only 1 foot 6 inches apart, and the produce is equal to or more than that of the tall varieties, taking into consideration the same space of ground. It should, however, be trenched 2 feet deep, and be well manured.—Robert Draper, *Seaham Hall, Sunderland.*

TILLANDSIA LINDENIANA CULTURE.

This very remarkable and handsome Bromeliaceous plant was introduced from Brazil a few years ago by Mr. Linden, of Brussels, in honour of whom it is named. It was exhibited at the Paris Exhibition and also at the St. Petersburg Show in 1869, where it excited much astonishment and admiration by its extreme beauty. The leaves of this plant are crowded round the base of the stem, spreading out on all sides, slightly recurved towards the ends, and thus forming an elegant vase-like plant; they vary in length from 9 to 18 inches, and are about an inch across at the base, tapering upwards to a point, dark green on the channelled upper side, the veins on the under side being of a deep reddish purple. The flower scape rises from the centre to the height of 12 or 18 inches, the upper portion or spike, some 6 or 7 inches long, clothed with distichous, imbricating, boat-shaped bracts, which are about 2 inches in length, dark green, suffused with rosy pink towards the edges. The flowers are, perhaps, the largest of any known species of this genus, measuring 2 inches or more in diameter; the colour is light violet, shading-off into azure blue, with a feathery streak of white running up into it from the base of each petal, forming a brilliant ornament to the plant house, and that, too, of a colour which is exceedingly rare amongst the denizens of our stoves.

Tillandsia Lindeniana (with, indeed, many other plants belonging to the order Bromeliaceæ), is well deserving of a place in every garden where stove accommodation can be afforded it, combining as it does such extremely beautiful flowers with a neat and compact habit of growth.

There is, perhaps, no class of plants so easily cultivated as the Bromeliads, and yet we seldom see them grown in a satisfactory manner. The soil best adapted for them is a mixture of peat and loam in about equal parts, with a good quantity of sand mixed in it. Large pots are not at all necessary, but it is very essential that good drainage should be secured; in addition to this these plants have another means of subsistence, which, however, is too frequently overlooked or disregarded by the majority of gardeners either through ignorance or carelessness, but if anyone will take a glance at these plants their peculiar construction will at once be apparent. Their leaves are all sheathing at the base and form large cavities which hold water, and as the upper surface of the leaves in most instances is channelled, they conduct whatever water falls in a state of nature into the before-mentioned cavities, and this undoubtedly is of material advantage to the plants. Yet how frequently have we seen men who consider themselves good gardeners, deliberately empty the water out, and hence, as a consequence, the miserable and unsatisfactory condition in which the Bromeliads are usually seen. My advice, therefore, is, Always apply water to these plants upon the leaves, so that the latter may have a constant supply standing in these natural receptacles, for this is in my opinion of much greater consequence than the soil in which the plants are potted.—Experto Crede.

POTATOES.

Your correspondents, "D., *Deal*," and Mr. Thos. Rivers, in No. 515 of this Journal, cannot, I think, have the "true Early Rose," but a kind almost identical in appearance externally, the American Red, for when first dug nine-tenths are in size and shape as nearly alike as two peas, and would deceive five out of six observers; but cut them and cook them, and you will then detect the difference. The true Early Rose is, I maintain, one of the finest Potatoes grown. I have grown it for the last three years with many other kinds, both English and American, which are lauded to the skies, but not one have I found to come up to the Rose in any one particular. Mind, I am writing with reference to early kinds. The Rose I have is anything but "watery," "nasty," "uneatable," "harsh," and "unpleasant," as described by Mr. Rivers. This is my experience of the kind—that it has not been over-extolled, that it is fit for the table in sixty days after planting, that the yield is enormous, that the flavour cannot be surpassed (at least, I have not met with any one kind to equal it, and I have tried every reputed "first quality," both English and American), that it is anything but "watery," "earthy," "dry and harsh," as described by Mr. Rivers. This is what I have found it. In this respect, at sixty days, though as large as a very large duck's egg, it is like most other new Potatoes; at seventy days the tubers begin to ripen somewhat, and then burst in boiling, and for a third of their thickness are somewhat floury; when fully grown and ripened they literally fall to pieces in cooking. They continue to retain this quality till they begin to start, towards the end of April with us, but if its eyes are rubbed off it continues a month or six weeks later, which is quite as much and more than obtains with most other early kinds.

I have grown the subjoined, and up to this date have discarded all but the Early Rose and Harrison's, a Yankee late Potato.

Rivers's Royal Ash-leaf	Early Handsworth	Early Sovereign
	Dalmahoy	Rocks
Mona's Pride	American Reds	Climax
Myatt's Ashleaf	Goodrich's Early	Owen's
Early Rose	Flukes	Blues
Early Goodrich	Red Ashleafs	Christie's
Jackson's White	Paterson's Victoria	Harrison, and a host of
Prince of Wales	Regents	local varieties.

This year I have planted the Red-skinned Flourball and the Early Racehorse. The latter I have tried, but it does not come up to my Early Rose in any way (size, earliness, and flavour). The Early Rose is not what can be called a rank grower; but, then, I do not plant Potatoes in over-rich ground, so that this may account in some measure for size and quality. I plant but a single eye, and in drills, and earth-up but once. Should an eye have the appearance of throwing out many side shoots I cut it in two. My average yield is 5 lbs. to 7 lbs. from every eye. If the eye is planted entire the yield has come up in five out of six roots lifted to 7 lbs., if cut in two, 5 lbs. For seed I do not let the tubers get over-ripe. I cannot imagine climate can affect their qualities.

I have no hesitation in recommending this fine Potato, despite all that has been written against it. I could supply anyone with a small quantity of the kind I have. I would not be bothered with sending away from this a large order, for I am no farmer, but cultivate a few things for home consumption, and by way of introducing superior kinds of vegetables. I have found the Goodrich valueless. The Harrison's in my opinion is the finest late Potato grown, yield 490 bushels to the acre with me. It keeps well, and is as floury as the Early Rose. I cannot imagine the Flourball will beat the Harrison's; should they, then I shall patronise them instead.

I am curious in Peas, and have tried every known kind. The Ringleader, Laxton's Supreme and Prolific, the Prizetaker, and Drew's Dwarf bear the palm.—K.

TEA ROSES.

It gave me much pleasure to find myself supported in my appeal for Tea Roses by such an experienced hand as Mr. W. Paul. I must, however, repeat, that in my experience the Tea Rose can be grown without even the protection of a wall. On referring to my Rose book before me, I find I have somewhat over sixty varieties of Tea-scented Roses. My garden, a fine rich loam, runs down to a river; it faces south, but is more open to S.W. and N.E. winds than it ought to be. My Teas are planted in borders by themselves, in lines north and south. I had about 250 of them, mostly on the Manetti stock, but a good number on short Dog Rose stocks, planted out all last winter, and though I had a week's skating on the river at their feet, I did not lose a single Tea Rose, though I lost a few Perpetuals. The only protection my Roses had was about 3 inches of old hotbed manure and half-rotten leaves over the surface of the beds, put on at the beginning of November. I need not say that I did not let them see the knife until quite the end of March. I cut my first blooms this spring about the third week in May.

Your correspondent, "CORNUBIA," gives a list of his Teas, and asks for a list of the best twelve. I congratulate him if he has succeeded with Monplaiser. I have tried it in every form, and I think it a regular imposter, and so has every Rose-grower with whom I have "chatted" this year; it will not open, and not one flower in two thousand would be fit to put in a stand at any country show. My advice is, work Maréchal Niel on every plant of it you may have. Adrienne Christophle is most uncertain, it so rarely opens a perfect flower, but yet is, undoubtedly, a fine Rose; it will not, however, do on the Briar, it is not strong enough; my best are on the Manetti stock. I now give my list of twelve, with the stocks on which I grow them. D stands for Dog Rose, M for Manetti budded low, the junction being 2 inches underground:—

Souvenir d'un Ami, rose. D or M.
Comte de Paris, pale flesh. M.
David Pradel, rose and lavender. M.
Louise de Savoie, lemon. D.
Madame Bravy, white, rose centre. D or M.
Rubens, white and rose. D or M.
Souvenir d'Elise, white and blush. D or M. The best Tea.
President, pale rose and salmon. M.
Niphetos, pure white. D or M.
Madame Willermoz. D or M.
Moiret, fawn. D or M.
Souvenir de David, crimson. M.

To these I must add—

Madame Margottin, Madame Charles, Madame Falcot (yellow). D or M.
La Sylphide, cream, centre fawn. M.
Bongère, rosy bronze. D.

These I have tried some time and can thoroughly recommend. There are several new varieties which promise to be great acquisitions, but only having had them one season I cannot as yet speak positively—viz., Catherine Mermet, Belle Lyonnaise, Tour Bertrand, Jean Pernet, and Unique.

The following cannot be grown out of doors—viz., Elise Sauvage, La Boule d'Or, Smith's Yellow, Marie Sisley, and Reine du Portugal. They make, however, fine pot plants.

Tea Roses on the Manetti stock should be turned out of pots in May, well mulched, and freely dosed with liquid manure (I use guano water), mulched again in autumn, and not pruned till March.—STIFF SOIL, *Somerset*.

HORTICULTURAL PARIS IN 1871.—No. 2.

THE SUBURBS.

IF one is surprised at the manner in which the Parisians have resumed their wonted life when they now look round on the blackened ruins of their public buildings in the interior of their city, one is still more surprised when he gets outside and sees the awful destruction that the civil war has occasioned. None who have ever visited Paris can forget the wonderful changes wrought under the Empire in the line of boulevards and roads that debouche from the Arc de Triomphe, especially the charming Avenue de l'Impératrice with its beautiful villas, neatly laid-out gardens, and handsome surroundings. Now on all this the "fell dogs of war" have been let loose, and, alas! all is changed. Houses are knocked about, trees destroyed, gardens rooted up, lamp-posts broken, while in other places the desolation is complete. Go down to the Porte Maillot, or rather where the Porte Maillot was, and you see one mass of ruins. Of the railway station at Auteuil not a stone remains. If one wants to see what the modern implements of war can do, let him turn aside into the Avenue de Reuil, and go into the garden of what was No. 50 in the Avenue. There is literally not one stone left upon another; there is not a tree in the garden that has not been cut off by the "obus" from Valerien; there is not one in which you cannot see balls or pieces of shell, while whole piles of them are to be found in different parts: yet this was evidently a pretty villa with a well-tended garden. What did the proprietor think when he returned to his favourite residence? and what would you think, my good reader, if your pretty villa had shared a similar fate? It was a melancholy sight, and yet withal it spake something of the character of the owner that, amidst all this ruin, his men were at work clearing away, and had planted out a bed or two of Pelargoniums, which were shedding a trifle of gaiety on the desolate scene.

How well known to all visitors to Paris was the Bois de Boulogne, that dear resort of all who could afford a fiacre or boast a trap! When the Prussians surrounded the city all that portion of the Bois which was close to the enciente was cut down by order of General Trochu, and now this space is all bare; in fact, one can see that the fortifications were a mistake, or, at least, if they were to be of any use, that neither trees should have been planted nor houses built near to them. As you drive on further into the wood the destruction is not so great as one might have imagined it would have been; and I dare say after some time, provided there be no more revolutions, it may resume somewhat of its former appearance. Driving along from the Porte Maillot to Point de Jour, Passy, &c., on every side you see traces of the frightful civil war that disgraced Paris in the months of March, April, and May, when the city was ruled by the Commune, and when wretches gathered out of every nation, the *forçats* of the galleys and the gaol birds of France, held high revel in the palaces and buildings of the City of the Seine. Had the Prussians committed one-tenth part of this destruction they would have been regarded as worse than Goths and Vandals—they are regarded by some Frenchmen now as pretty nearly as bad. But all this has been the work of Frenchmen; and it is enough to make one feel sad at heart to think that all this was done in the nineteenth century, in the very capital of what is called civilisation.

But you want to know, perhaps, how individuals have suffered by it. My friend Mr. Douglas wrote a paper in the Journal two weeks ago, in his usual practical style, on the Phlox, and gave the names of some good and select varieties. Now, there is no one to whom we are more indebted for the improvement of this flower, or so much so, as to poor Lierval, who had for many years given great attention to it. No sadder history than his is to be told in connection with the war. Some years ago he left his former comparatively mean establishment for a new one, on which he had expended the savings of many years. He had built a new dwelling-house, a fine range of iron greenhouses, and some wooden ones also; he had gathered together a fine collection of stove and greenhouse plants, Palms, Ferns, &c. When the siege commenced he removed there with one son about fourteen. In the beginning of December he was seized with small pox, and that terrible disease acting on a feeble body, rendered still more so by anxiety and insufficiency of nourishing food, carried him off. He did not die of starvation as it was reported. His son-in-law then undertook the care of the place; but, alas! what could he do? The severest winter known for many years in France came on apace; fuel became scarce, none could be had for heating greenhouses and stoves, while people were perishing from cold, and so Lierval's collection was doomed. An effort was made to get some of the plants into the dwelling-house and so save them, but it was fruitless. Then came the shells from Valerien, and now blank and utter destruction marks the place; the garden is overgrown with weeds; the houses filled with pots, in which may be seen the skeletons of the plants that last autumn were in the fulness of beauty; and the ruin is complete. Of all his fine collection but one plant remains. His houses are greatly injured, his family have no means to re-establish the business, and unless they can obtain some compensation from the Government it will be hopeless. In a garden near at hand the collection of Phloxes has been saved. Some fine varieties will probably be sent out this autumn or next spring, for, being hardy, they did not require the care and attention that the house-plants did; and lovers of this beautiful flower may help the widow by ordering collections of these novelties, among which I saw some really fine things. I would gladly transmit such orders.

One cannot look round on such destruction as this inflicted on men who hated war and loved peace, without feeling strongly the terrible wickedness of such a wanton and unprovoked war as this last. I shall in another paper detail what I saw at the more southern portion of the suburbs, at Bourg-la-Reine, &c. Truly in the language of the Hebrew prophet, "they have laid the pleasant land desolate."—D., *Deal*.

RESULTS OF THIS YEAR'S SPRING AND SUMMER.

IT would, I think, be interesting if some of your readers were to give us their experiences during this season. It has been so unprecedentedly vicious, that especial value must attach to all plants that have done well through it. We ought to have notes from England, Ireland, and Scotland, as it would be interesting to know the effects of the season in each locality.

I write from the north centre of Ireland. During the early part of the season we had a long, cruel, binding drought, scorching sun, bitter east wind, and hard—very hard frosts every night. I had terrible work in keeping alive a large plantation of dwarf Pears and Plums planted in the middle of March. After this drought there came on the ground (cold as ice, be it remembered, with constant frosts) two months of in-

cessant heavy rain. The consequence was that the more delicate Tricolor and Bicolor Geraniums were perished, and went back every day. Impératrice Eugénie, Crown Prince, Goldfinder, Bullion, Safrano, and Duke of Edinburgh grew small by degrees and beautifully less, till they reached the vanishing point. The only new varieties I had that did really well were Waltham Bronze and Princess Louise; these I think remarkably beautiful. So, though to a less degree, is Plutus. I never saw E. G. Henderson and Her Majesty do so well. They colonred most beautifully, altogether eclipsing their performances last summer; Beauty of Calderdale, also, and Kentish Hero were first-rate. The Tricolors were all dull with me till the end of August, when they improved. I find no kinds at all comparable to Lady Cullum and Sophia Dumaresque. I do not think Mrs. Pollock, Louisa Smith, Sophia Cusack, or Sunset worth growing, at least not in this soil and climate.

Now about Geraniums grown for their bloom. In such a season none but those with stout petals had a chance. The much-vaunted Violet Hill was nowhere; much the same may be said of the two Wilsii's, both very pretty in a good summer. I had many new kinds on trial this year, and I unhesitatingly endorse Mr. Thomson's award last year, and give the palm to Vesuvius. It is wonderfully good. I know no bedding Geranium which gives so much bloom on the same surface. I suspect the nurserymen do not like it, because it does not give them enough wood to propagate a great stock quickly; they condemn its colour for not being intense enough. It is a light, but a most glowing scarlet, and looking from some distance on a bed with about twenty different kinds on trial in it, you could pick out Vesuvius as the most brilliant spot by far. Omega does not bloom so freely. Charley Casbon is not so good a flower, and is looser in its truss, and more easily knocked about. Memnon is, I think, very good indeed, and a useful colour; so is Géant des Batailles. I think very highly of the colour of Claude Lorraine, a very purplish shade of crimson, with a flush of vermilion on some of the petals, but it goes too much to leaf and wood. In a dry season I daresay it would do much better, or perhaps if sunk in its pot. Jean Sisley I have not, and I have only seen it as a very small plant fresh from the nursery. It has a high character, but I should fancy that it resembles Charley Casbon in the flaccidity of its petals.

Will Mr. Thomson be kind enough to give us a comfortable article from Drumlanrig, and tell us his experiences of the year, and whether Vesuvius is his last as well as his first love?

Double Geraniums are of no use whatever here as bedders, and so I pass on to other things.

In Tom Thumb Ageratum we have a treasure—an invaluable colour, low-growing, early blowing. I hope to have next year two match beds of Vesuvius edged with this. Imperial Blue Pansy has not done so well with me this season as it did last year. I suspect there is something in its bed that it does not like. Still, as it is in fair blow now, and began its work in March, it must be acknowledged as first-rate.

I think I never saw Iresine Herbstii such a good colour all through the season. Iresine Lindeni has also done well. Coleus Verschaffelti will not do with me; it merely exists. This is curious, for I know places fifteen miles further north, where there are beautiful beds of it this year—beautiful, though not equal in hue to other years. Still it has grown luxuriantly there, while with me, in a sunny situation, it is stunted and brown.

I excessively admire Abutilon Thompsoni, but I wish some one who has used it extensively and successfully would tell the exact way to manage it, as it is apt to be scraggy. It has a vein of delicacy in it, and requires a genial situation.

By far the best bedding-out in this part of the country is at Loughcrew, the seat of Mr. Naper, where, in spite of a very cold climate, the genius of Mr. Burns, the very clever gardener, produces wonders. Well, there are two beds there, each with a centre of Abutilon edged with Lord Palmerston Geranium. These beds are not 6 yards from each other, and yet in one bed, and that one, too, which received by far the strongest plants at bedding-out time, the Abutilon is scarcely more than half the size it attains in the other, simply because it is not quite so well sheltered from the north-east. Some other time I should like, if you allow me space, to enter more into detail about the gardens at Loughcrew. [You shall have all the space you need.—Eds.]

I must, before I conclude, say that I find no Aster so satisfactory a bedder as the Victoria. It has so strong and vigorous a stem, that it resists rain and wind better than any other variety. I have a bed now in bloom which has been a thing of beauty for six weeks, and as yet shows no sign of decrepitude, while a match bed of Pæony Asters went to smash entirely in the wretched weather we had three weeks ago. I should like a centre of Victoria Aster, a broad band of Abutilon, and an edging of Iresine Lindeni.—Q. Q.

HYDE PARK.

Old George Stephenson being asked, "What is coal?" answered, "Just a bottled-up sunbeam." And the researches of more scientific investigators, but not more practical men, have confirmed the truth of the great, original-minded engineer's definition—have proved that the amount of heat required for a plant's growth is exactly proportioned to that which it will yield on the combustion or decay of it and its products. "The bottled-up sunbeam" is one of the main features of the system pursued by Mr. Gibson with such grand effects when he was at Battersea Park—the system of planting-out natives of warmer climates than our own that they may grow and flourish during our summer and autumn, and afford a relief from the excess of colour which so often renders modern flower gardens painful to the eye. With the view of securing a greater amount of heat in the ground, the beds intended for plants from warm parts of the globe are placed in a sheltered position, and so that the sun may warm one or other of the sides throughout the day. A site larger than the proposed bed is dug out 9 inches below the general level, and 18 inches or more of brickbats are placed at the bottom and round the sides, which are made with a slope towards the sun. Over the brickbats turf is laid grass-side downwards at the bottom, the compost is filled in, and the outsides covered with a thin layer of soil and turf. By these means it is conceived that a considerable amount of heat is stored up in the brickbats and soil of the beds during warm days, and that this accumulated heat prevents the soil becoming so much cooled at night and during cold weather as it would otherwise be. Good drainage is likewise secured, and on the advantages of this in preventing the soil becoming soured, and the roots inactive from stagnant water, it is unnecessary to dwell. Moreover, good drainage of itself contributes to an increase of heat in the soil, as it enables the warm rains of summer to pass downwards, as well as the heated air. But apart from all this, there can be little question that many plants from regions bordering on the tropics, and even within them, will live out of doors in this country. Many Australian plants, for instance, would be killed in a New Holland house if the temperature fell below freezing, although in their own country they are often exposed to slight frosts. This may be accounted for by their growths being less perfectly ripened under artificial conditions than they are under natural conditions—we all know how much more liable the gross, succulent shoots of plants, even hardy in Britain, are to be injured by frost, than those which are firm and well ripened, especially if there be any excess of moisture. The term subtropical, however, has acquired a wider signification than that which confines it to plants from the warm parts of the earth; for as now used it may be said to include plants hardy and plants not hardy which recommend themselves by their beauty of foliage, picturesque habit of growth, and distinctness of character. With such plants judiciously employed fine effects have been produced in the public gardens of Paris, at Battersea Park, and in other places, and the system was introduced a year or two ago into Hyde Park to a limited extent, this year to a greater extent, and in future years, when the preparations shall have been made, we may look forward to its acquiring, with the increased scope, a greater development and a higher degree of perfection than it has hitherto done.

In giving an account of the most noticeable features of the subtropical portion of Hyde Park—that portion which lies between the Drive, parallel to the Great Western Road, and an imaginary line north of Rotten Row—we shall commence at the Albert Gate end of the Drive. Here we find on the western side of the ground, and extending towards Rotten Row, a series of circles, about 4 feet in diameter, variously filled, some of them consisting of beautiful cushions of Alternanthera magnifica, edged with the minute silvery-leaved Antennaria tomentosa or Sempervivums, others of golden-leaved Pelargoniums Crystal Palace Gem and Robert Fish, edged with Alternanthera magnifica and margined with Echeveria secunda glauca and E. glauco-metallica, a hybrid between E. metallica and E. glauca dwarfer than the former, having the glaucous colour of the latter, and in many cases varying considerably in its outline.

At the back of these beds are others of larger size, kidney-shaped or scroll-like, variously filled, some containing Rhododendrons. One of the most striking consists of Canna Bihorelli, a bold-leaved sort with orange-red flowers, and Canna discolor, carpeted with Coleus, and edged with a dark-leaved Beet; another pleasing bed is of Coleus Verschaffelti, intermixed with Centaurea candidissima, edged with the golden-variegated form of Euonymus japonicus, and margined with Echeveria secunda glauca.

Turning back now, and making a fresh start eastwards along the Drive, we find a series of small circles round standards of Robinia inermis, similar to those just described, and for the most part similarly filled; and further back a number of variously-shapen beds. In the intervening spaces are plunged, care being taken to secure ample drainage by a bottoming of brickbats, &c., or placed in tubs, Palms, Bananas, Dracænas, and other ornamental-leaved plants. The finest of these are Chamærops excelsa, Fortunei, and humilis; Latania borbonica, Monstera deliciosa; noble specimens of Seaforthia elegans and robusta, two of the most beautiful Palms that occur in the whole arrangement, or, in fact, that could be employed; Phœnix dactylifera, P. reclinata, the Variegated New Zealand Flax quite equal to some of our best exhibition specimens, many fine plants of Dracæna indivisa, and two or three specimens of the magnificent Abyssinian Banana, Musa Ensete. The last-named are all that can be desired as regards growth, but the leaves are much torn by the wind, showing its unsuitability for all but the most sheltered positions, and there it has a grand effect. Kindred plants to this in appearance, though not in size, are Musa superba and Strelitzia angusta, which have their foliage uninjured by wind. Among the beds at the back the most noticeable are one of Caladium esculentum, carpeted with Tradescantia zebrina, and edged with the prettily blotched Farfugium grande; then an arrangement in which are two heart-shaped beds with Dracæna indivisa in the centre, surrounded with Alternanthera amœna, dotted alternately with Sedum Fabaria, edged with Golden Feather Pyrethrum, and margined with Echeveria secunda glauca. These beds, and others like them, are the perfection of horticultural mosaic work. So even in height, so brilliant in colour, and yet so chaste, it is difficult to conceive how they were produced. We know the Alternanthera is dwarf, but we know the Sedum is not so dwarf—but Mr. Gibson informed us that he struck the ends of the flowering shoots of the Sedum, which was easily effected, and thus produced a nondescript plant and an effect which cannot be too much praised. Mr. Gibson makes no secret of the means which he adopted—he would not resort to "a dodge," but the means used to secure the end may be worth knowing, and imitated extensively with the best results. Intervening between the two beds just alluded to is one of Begonias, carpeted with Tradescantia zebrina, edged with a bronze-leaved Pelargonium, and margined with Mesembryanthemum linguum, a thick, fleshy-leaved species with large yellow flowers. The next arrangement is four half-moon beds of Purple King Verbena, Golden and Bronze Pelargoniums, surrounding a circle of that pretty little ornamental Grass Dactylis glomerata variegata, edged with Echeverias. Then we come to a fine heart-shaped bed of Eucalyptus globulus, India-rubber, and Musa superba, carpeted with Coleus Verschaffelti, edged with Salvia argentea, and margined with Echeveria metallica. At the opposite end are two more heart-shaped beds, one of which consists of Iresine Herbstii in excellent condition, with the pretty and useful white-edged Euonymus radicans variegatus as an edging; and in another plants of Musa superba are plunged. Some Rhododendron beds here are interspersed with Acacia lophantha and Aralia papyrifera, which serve to relieve the outline of the Rhododendrons while not in flower. The next arrangement is four demi-lunes of dwarf bronze-leaved Geraniums, interspersed with Viola cornuta, having for its centre a circle of Fuchsias panelled with dark and light kinds alternately. These are surrounded with Iresine Lindeni, which is everywhere very effective, edged with Golden Feather Pyrethrum, and margined on the ramp of the bed with Echeveria secunda glauca.

We now turn westward along the north side of Rotten Row, finding plunged on our way fine specimens of Dracæna indivisa. One of the first and most striking beds we come to is Caladium esculentum, carpeted with Coleus nigricans, and edged with Centaurea acanthifolia, with leaves beautifully cut. At the back of this is a large bed of Ferdinanda eminens, one of the most noble of the plants used in subtropical arrangements; and adjoining this are beds of Castor-oil Plants, carpeted with Solanums, of Erythrina crista-galli, and of the scarlet-flowered Canna Van Houttei, with the dwarfer bronze-leaved Canna expansa nearer the edge of Golden Fleece Geranium, with a margin of Euonymus radicans variegatus. Passing on we come to a pleasing circle of Solanum Warasewiczioides, with Cyperus alternifolius as a carpeting, and at the back of it a large shrubbery diversified with Tritomas, Acacias, and Abutilons; then to a circle of Cannas; and, reaching the corner of the footpath we find a half-moon of Wigandia caracasaana, than which no plant used in subtropical gardening is productive of a more superb effect, noble in habit, and its leaves like the richest fabrics of the loom. Like crimson-clad soldiers in line stands a row of Chilian Beet, the leaf-stalks as well as the blades of which are beautifully coloured, the one most brilliant, the other of a rich but sombre greenish bronze. A bed of Solanum marginatum is singularly effective by its silvery foliage; in fact, this and S. robustum, of a rich cinnamon colour, are two of the most effective of the genus—indeed, of subtropicals. Among other beds here are one of Eucalyptus globulus, another of the graceful Yucca recurva; others of Cannas Van Houttei, limbata, Chatei, and expansa; Castor-oil Plants; Indian-rubbers; Polymnia grandis, Caladium esculentum, Aralia papyrifera, and Aralia Sieboldii, variously carpeted, chiefly with Coleuses, edged with golden-leaved plants, and margined with Echeverias and other succulents. As prominent among these yellow-leaved edging plants must be mentioned Mesembryanthemum cordifolium variegatum, which here as elsewhere in the bedding-out has been used with the happiest effect, and which can be safely recommended from the variety of situations in which it is to be seen—under trees, in sun, and in shade—as a most desirable plant where a dwarf cream yellow edging is desired.

At the east end of the Serpentine is a dell, in which there is a mixed collection of plants—Tritomas, Cannas, Yuccas, Rhododendrons, &c., near the water, and a bank of shrubbery rising to the road above. The whole is neatly arranged, and it is worthy of note that in the valley, with its roots almost in the water, Aralia Sieboldi has stood the last two winters without the loss of a leaf. The position is by no means sheltered, being exposed to the full sweep of the east winds, though the plant is a little screened from their force by being in a hollow; yet its low position near the water would be in the last degree unfavourable to it in those severe frosts with which we in the valley of the Thames are so often visited, and the only conclusion to be arrived at, is that Aralia Sieboldi (like the Aucuba japonica, which was grown in a greenhouse when first introduced, and is now known to be one of our hardiest shrubs), is much more hardy than is generally supposed.

We will now cross the Park to Stanhope Gate, between which and the Marble Arch there is a long series of beds filled with flowering plants and those remarkable for their leaf-colouring. This portion of the Park, though considerably shaded by great Plane trees, is simply a large flower garden, with the turf close-shaven, like so much velvet, and of the brightest green. That there are no brown patches is in a great measure due to the use of the economical watering-hose on wheels, which, on being connected with the supply pipe, affords without further labour a watering much more efficient than could be given by hand. Not a fallen leaf could we see, not even the scattered fragments of paper, the remains of fusee-boxes, and the numerous odds and ends which are so often left to disfigure our public places; no, everything is as clean and as neat as in the best private gardens to which the multitude have not access. Proceeding from Stanhope Gate towards the Marble Arch, all the beds on the right-hand side are edged with Golden Feather Pyrethrum, and margined with the silvery Cerastium tomentosum, while the circles on the left are edged with Iresine Lindeni, one of the finest of our new bedding plants, much more richly coloured than I. Herbstii, and standing the weather well, the outer ring or margin being neat rosettes of Echeveria secunda glauca. The long beds on the same side are edged with Iresine Lindeni, with a margin of blue Lobelias and Dactylis glomerata variegata planted alternately. The beds in this part are chiefly masses of Calceolarias and Pelargoniums, the best of the latter being Amy Hogg, Cybister, Chieftain, Mrs. Laing, Vulcan, Lord Palmerston, and Waltham Seedling. The last-named produces its dark crimson flowers in the greatest profusion, and in this respect is evidently one of the very best. Forget-me-not, deeper in colour than Christine, is scanty of bloom. Excellent, scarlet, is good. The only Calceolaria employed is Gaines's Dwarf, and this, wherever it is met with, forms dense masses of golden blossom, proving itself, here at least, to be

one of the most effective varieties that can be grown for bedding purposes. One arrangement on the left consists in the first bed of Culford Rose in the centre, triangles of the golden-leaved Crystal Palace Gem at each end, and the spaces at each side of Mrs. Pollock, which, however, is here by no means bright in its leaf-colours. The next oblong consists of the silver-variegated Queen of Queens intermixed with Purple King Verbena, an effective combination. The third oblong is the same as the first, and the fourth the same as the second.

We now come to a splendid series of beds, in which the oblongs on the right are filled with Pelargoniums, mostly of the kinds already named; Gaines's Dwarf Calceolaria, Heliotrope Miss Nightingale, a very free-flowering kind, and Ariosto Improved Verbena, interspersed with Pelargonium Annie, silver edged. The whole of these beds are edged with Purple King Verbena, and margined with Iresine Lindeni. It is, however, on the other side of the walk that the bedding is seen to the best advantage—it is superb, and a triumphant example of what may be done by the use of plants with coloured foliage alone without the aid of flowers. The circles are filled with Alternanthera magnifica, edged with Iresine Lindeni, and margined with Sempervivum californicum. These are very fine, but much more so are the five oblongs with rounded ends; three filled with Coleus Verschaffelti, presenting a broad mass of rich brownish crimson, outside of which is a line of the silvery-leaved Centaurea candidissima, an edging of Golden Feather Pyrethrum, and a margin of Echeveria secunda glauca. The two intermediate beds consist of the pretty gold-mottled Abutilon Thompsoni, beneath which is a carpeting of Coleus nigricans.

The next combination consists of heart-shaped beds at each end, Iresine Lindeni being used in the one case and Alternanthera magnifica in the other, the edging being Antennaria tomentosa and Mesembryanthemum linguum, a grass-green, fleshy-leaved, yellow-flowered succulent. The oblongs are filled with silver-leaved Pelargoniums and blue Lobelias intermixed; with Purple King Verbena and Queen of Queens or Hendersoni Pelargoniums; with Ariosto Improved Verbena and Mrs. Pollock Geranium, or Beauty of Oulton; with Heliotrope Miss Nightingale, Gaines's Dwarf Calceolaria, &c.

The next series of beds extends from Mount Street to Grosvenor Gate. The edgings of those on the right consist of Blue Lobelias, the margin being alternate plants of Viola lutea grandiflora and the pretty white-variegated form of Dactylis glomerata. On the left Purple King Verbena and Alternanthera magnifica are used, the latter not strong enough to be apparent above the rich marginal line of Golden Feather Pyrethrum. The yellow-flowered Viola on the right has also a rather rough appearance, though blooming freely—a drawback, no doubt attributable to the season being so much more favourable to the production of leaves than of flowers. In this group there are effective beds of Pelargoniums Duchess of Sutherland, Lucius, Madame Vaucher, Madame Rudersdorff, Beaton's Indian Yellow, Mrs. Laing, Dr. Lindley, an excellent variety both for beds and pot culture, Golden Fleece, Crystal Palace Gem and Luna, intermixed with Viola cornuta, and Mrs. Pollock. Gold is the prevailing colour in this arrangement. We now come to a mixed bed, the arrangement of which is so complicated as to baffle description without a diagram, but very pleasing in its effect. Its principal components are Palm Grass, the hoary-leaved Solanum marginatum, and Dracænas, the ground beneath being carpeted with Alternantheras, Mesembryanthemum cordifolium variegatum, and Iresine Lindeni, with an edging of blue Lobelias, and an outer line of alternate plants of Dactylis glomerata variegata and Viola lutea. Two heart-shaped beds of Alternanthera versicolor on the opposite side of the walk are edged with a pretty little green-leaved Thyme, name unknown; and after passing a bed of Rhododendrons, and light and dark Fuchsias, we come to two more heart-shaped beds of Alternanthera magnifica, surrounded with Echeveria secunda glauca. In this section of the bedding-out, Pelargonium Rev. J. Dix, deep scarlet, Lucius, before noticed, and Chieftain, are conspicuously good. There are also some beautiful beds of Alternantheras which are much admired.

The last division to be noticed in this part of the Park i that extending from Grosvenor Gate to the Marble Arch. The first combination is one of three beds—namely, a long parallelogram with a circle near each end. This has a very good effect. The circles are filled, one of them with Mrs. Pollock Pelargonium, the other with Crystal Palace Gem, surrounded with a line of Iresine Lindeni, and outside of this is Echeveria secunda glauca. The parallelogram is chiefly occupied with Coleus Verschaffelti richly coloured, set in a bordering of Centaurea candidissima, and edged with Golden Feather Pyrethrum. Next we come to a series of circular and oblong beds with rounded ends. In these Coleus Verschaffelti and Centaurea are introduced with splendid effect. An oblong of Pelargonium Queen of Queens, intermixed with Verbena Ariosto Improved is very good; so are several beds of Waltham Seedling Pelargonium, Golden Fleece, and Crystal Palace Gem. Before arriving at the Marble Arch we pass several large and small circles. These are very neatly planted with Pelargoniums surrounded with Lobelias, alternating with Alyssum variegatum, and an outer ring of Iresine Lindeni. Finally, we have a figure-8 bed centred with Coleus Verschaffelti set in Centaurea edged with blue Lobelia, with a margin of Iresine Lindeni. This bed is very telling, so is the small circle of Pelargonium Excellent, at the end next the Marble Arch.

The last part of the bedding which we shall attempt to describe—and we can only attempt to do so—is that respecting which three young ladies wrote to us a fortnight ago, saying they had heard it was the smartest piece of bedding anywhere to be seen. "When you get to this place you must take out your note-book and give us in 'our Journal' a crayon sketch of the semicircular bed, &c." We are very sorry to disoblige any ladies, and especially young ladies, so we took out our note-book and made a pencil sketch of the arrangement while the shades of evening were drawing on ("Young ladies like that," said one of the Editors with a nod and twinkle in his eye), but it was not to the sketcher's satisfaction, and he therefore wished to be excused from making a public display of his artistic talents, whilst confessing the necessity of a drawing to give an adequate idea of the arrangement; wherenpon he grew sour, and declared that the group was not quite perfect—there was some irregularity in the balancing, but the effect as a whole was very beautiful, and that the superb beds of Alternantheras and Coleus by Park Lane were far more chaste. The bedding here referred to is that at "the Temple," the house where Mr. Chamberlain, Mr. Gibson's esteemed *aide* lives. In front of this there is a horseshoe bed, the ends of which are planted with a great variety of subjects, cut off from the rest by a band of Alternanthera magnifica, which is also extended along the middle of the horseshoe, meeting at intervals circles of Centaurea, whilst segments of circles on each side of the middle band are filled with the brighter-coloured Alternanthera amœna and A. versicolor. The same arrangement is continued all round, and the whole is margined with Echeveria secunda glauca. Two heart-shaped beds near the centre of the horseshoe are planted with Pelargoniums Mrs. Pollock and Variegated Stella, edged with Alternanthera magnifica, and bordered with Sempervivum californicum; two more, one on each side of these, consist of silver variegated Pelargoniums and blue Lobelias intermixed, and Mrs. Pollock, edged with Alternanthera versicolor and margined with Mesembryanthemum linguum. In the circles the materials used consist of Coleus Verschaffelti, Centaurea candidissima, Bronze Pelargoniums, Alternantheras, Golden-feathered Pyrethrum, Mesembryanthemum cordifolium variegatum, Iresine Lindeni, Sempervivum californicum, and Echeveria metallica. Between the beds are plunged plants of Musa superba, the Bird's-nest Fern, Chamærops, Caryota, and next the walk Acacias.

The bedding-out at Kensington Palace is also most efficiently carried out, and many of the beds being less shaded, afford even a better floral display than those in the Park.

It will thus be seen that Mr. Gibson, even in his first few months of management, has done great things in improving and rendering more attractive London's greatest park; but we expect from him greater things in the future, when the means shall have been afforded to make the necessary preparations. The London parks are the property of the rich and the poor; to the one and the other they are capable of yielding much enjoyment and instruction, and by neither is the amount of damage done worthy of consideration, save when the London "rough" has a "demonstration."

PLUMBAGO CAPENSIS CULTURE.

The following is the mode of culture which I adopt. Having received a plant of Plumbago capensis in January last, when it was in a 4-inch pot, and little more than 6 inches in height, in March I shifted it into a 5½-inch pot, and in the latter part of May I gave it a second shift into a 7½-inch pot, as by that time it had made good growth. In June I cut some of the leading shoots, for the first and last time using the knife. The plant is 2 feet in height, is now in flower, and has been so

for the past three weeks. It has thirty-two trusses of splendid flowers. All the time it has been kept in a cool greenhouse. The compost I used was three parts fresh loam, and one part leaf mould, adding a little manure and silver sand, as the plant is a gross feeder. It should never be allowed to get too dry.—J. N., *Ennis*.

MESSRS. SUTTON'S COLLECTION OF POTATOES AT KENSINGTON.

The interest that is felt in the cultivation and varieties of this useful root was evidenced by the collections which were put up at the Royal Horticultural Society's Meeting on the 20th inst. Four good collections were staged. Mr. Fenn's was remarkable as the product of years of unceasing energy and skill in cross-breeding and cultivation; Messrs. Lee's was a fine example of good growth; Mr. Dean's also contained some fine specimens of culture; while that of Messrs. Sutton, of Reading, of which I would now write, was remarkable for the large number of varieties staged. They call for no special remark as to size and appearance. They had evidently not been grown for exhibition, were the samples of an average field crop, but they gave one an excellent opportunity of seeing some of the many varieties which now puzzle cultivators quite as much as florists' flowers. The collection contained the following varieties, they comprised three divisions—viz., new varieties sent out in 1871, American Potatoes, and a general collection.

Of the first division there were—1, Giant White Mammoth; 2, Giant Red Mammoth; 3, Canadian Kidney; 4, Erdington Monarch; 5, Ramston Kidney; 6, Early Red; 7, Red Fluke; 8, Golden Zone; and 9, Nuneaton Seedling. The last two seemed from appearance to be good Potatoes in their respective classes, but as I have ever maintained, one can never judge from appearances.

The second division contained the following American varieties:—

10. Early Goodrich
11. Bresee's Prolific
12. Pranse Seedling
13. Pink-eyed Rusty Coat
14. Peach Blossom
15. Early Rose
16. Peerless
17. King of the Earlies

Most of these I have myself grown, many of them are good croppers; and if people do not study much the flavour of a Potato, or like them, not *au naturel*, but mashed or fried, they may answer, but in a small garden and for general use avoid them. Besides these there were Red-skinned Flourball, sent out by Messrs. Sutton in 1870, and samples of some which had been sent out as such by other firms, and certainly bearing very little likeness to the real Simon Pure. My opinion of this Potato has not changed. For baking purposes it is admirable, but it is too large for steaming, and not of sufficiently good quality.

The third division contained:—

18. Bovinia
19. Red Regent
20. Early Shaw Improved
21. King of Potatoes
22. Royal Ashlea f
23. Drummond's Prolific
24. Wood's Scarlet Prolific
25. Early Emperor
26. Prince of Wales
27. Dalmahoy
28. Dawe's Matchless
29. Early Giant King
30. Improved White Rock
31. Walker's Improved Regent
32. Paterson's Scarlet Blue
33. Haigh's Kidney
34. Scarlet King
35. Paterson's Victoria
36. Snowball
37. Flourball
38. Fortyfold
39. Myatt's Ashleaf
40. Fluke
41. Milky White
42. Early Oxford
43. Red Farmer's Glory
44. Paterson's Field White
45. Paterson's Red Kidney
46. Early Coldstream Fox's Seedling
48. Sutton's Early Racehorse
49. Wellington
50. Paterson's Regent
51. Skerry Blue
52. York Regent
53. Lapstone (true)
54. Paterson's Albert
55. Headley's Seedling
56. Early Walnut Leaf
57. Belgian Fluke
58. Red Ashlea
59. Negro (black flesh)
60. Paterson's Perfection
61. Paterson's Early White
62. Oxfordshire Kidney
63. Early Ashleaf
64. Fir Apple Potato (very curious)

Some of these sorts are well known and bear high characters, some are unknown to fame, and many I have never seen before to my knowledge, nor tasted. I know that Royal Ashleaf, Myatt's Ashleaf, Lapstone, and Haigh's Kidney are good amongst the kidney-shaped Potatoes. I know, too, that many whose judgment I highly value esteem King of Potatoes, Dawe's Matchless, Paterson's Victoria, Early Racehorse, Skerry Blue, and Headly's Seedling very highly. Amongst round Potatoes—Dalmahoy, Wood's Scarlet Prolific, Improved Regent, Early Coldstream, York Regent, and Early Oxford are good; others seemed to me from their appearance and weight as likely to be valuable, such as Golden Zone, a round clean-looking Potato, and Snowball. There may be, and doubtless are others that are good, but in the Potato appearances are often deceitful, and it is not until the tubers are cooked that their merits can be determined on. It is, however, a satisfaction to see the Potatoes that are brought before the public; and the eminent firm whose collection I have thus briefly passed in review well deserved the special certificate awarded them, in thus enabling the frequenters at the Royal Horticultural Society's meetings to see so large a number brought together.—D., *Deal*.

THE PROPER WIDTH OF ORCHARD HOUSES.

This is a subject which in my opinion requires some discussion. I am now about to speak of the maximum width of span-roofed houses; in short, the best width to be selected for large span-roofs. The house at Chiswick is 30 feet wide; this gives good growth but not high-flavoured fruit. There are now numerous houses of this width, seemingly built after Mr. Foster's plans for Mr. Pearson, of Nottingham; now, as a rule no houses of this width give fruit of fine flavour, the low ventilation is too weak, so that the trees at a little distance from the sides give good growth and fine fruit to look at, but generally failing in flavour. I know this from much experience, and am often reminded of Mr. Bewley, of Black Rock, Dublin, one of the first to grow orchard-house trees, and he grew them well in what he called "hovels"—small orchard houses—I never saw finer Peaches in pots. Well, he thought of leaving his teacher, Mr. Rivers, far behind, and accordingly built a house 40 feet wide, which his teacher told him would not do, as the ventilation was not enough. After some experience this proved quite correct, as the Peach trees gave fruit of inferior flavour, and the house was turned to some other purpose.

The span-roofed houses, each 100 feet long and 24 feet wide, at Sawbridgeworth, have never yet failed in giving fruit of the finest flavour. They are ventilated with shutters 20 inches wide, on hinges opening downwards, the lower part of the aperture being 20 inches from the surface of the soil. The roof is fixed, without any apertures in it, but at each end just under the gable is an obtuse triangular space about 9 inches in depth, and 22 inches wide, for the emission of the heated air. These are unglazed and always open. Nothing can be more perfect than this simple mode of building, the only fault is a want of height. They are 12 feet in height to the centre of the ridge; they should be 15 feet (as recently advised by Mr. Rivers), for the large standard trees now touch the glass, and although they bear quantities of fruit, they annually require severe pinching and winter-pruning. I may remark, that it is curious to observe these fine standards growing in the calcareous clay over which the orchard houses are built. The soil is like a well-trodden path, and is never stirred, neither are the trees watered, still it is evident that the abundance of water given to the trees in pots standing near them is sufficient to keep them in fine and vigorous health.

It will, I think, be seen from my description of these simply and cheaply-built houses without ornamentation, that thorough low side ventilation is the most perfect of all; and although in a house 30 feet wide it may remedy the defect of too much width, so as to give Peaches of good flavour, I have reason to doubt it from all that I have experienced, and am inclined to adhere to the width so thoroughly carried out in the houses at Sawbridgeworth—viz., 24 feet, which, as I well know, produces the finest-flavoured and largest Peaches I have ever eaten, besides which the trees are such pictures of health and vigour.

It would be interesting to hear from some of your correspondents as to their experience in the width of orchard houses, for, as far as mine goes, I should rather advise 20 feet than 30 feet as the width of them. There is another point on which I should like to hear the opinions of others, and that is the unbroken roofs of span-roofed houses. Almost universal at Sawbridgeworth, this is not, as a rule, followed elsewhere, and hence much expense is incurred, most persons fearing a lack of ventilation—an idle fear, as I think I can prove by stating the cause of the thorough ventilation of those entire-roofed houses. In sunny weather the air is rapidly rarefied and ascends to the roof, where the temperature is often 100° and 105°. This is comparatively a vacuum, and the cool outer air, rushing in from the bottom, so rapidly ascends to the roof

—escaping at each end—as to move every leaf, and thus the air of the house even in a sultry day is in motion, and every leaf aërated. This I opine is the cause to a great extent of the extreme health and vigour of the trees; whereas openings in the roof do not allow of the accumulation of heat, hence the rush of air is less violent and less effectual. This is, perhaps, a new idea, but I think quite sound.

I may also observe that one house of the same length and width, with an unbroken roof, and the apertures at each end enlarged and closed in winter, is used as a forcing house, and in this house are the same signs of vigour and health in the Vines and trees. This system will allow us to have orchard houses with a maximum width of 24 feet, built at a much cheaper rate than those of Mr. Ayres or Mr. Pearson, and yet equally effective.—Inquirer.

GOLDEN CHAMPION GRAPE.

When discussing with others the merits and demerits of this Vine last spring, I felt bound to speak favourably of it so far as my experience then went, reserving my full opinion until I should have had another season's practice in its culture. Having again grown and fruited Golden Champion in two separate houses under somewhat different treatment I feel better able to speak without reserve on the subject, and shall now give my candid opinion.

At the outset allow me to assert that my opinion has undergone no change as regards the high qualities of this Grape; but I am rather more convinced that after a few more years, when its peculiar cultural requirements shall be better understood, Golden Champion will have a place in most vineries. But now to speak of it as I have found it. Here, as regards growth (on its own roots of course), it has fully maintained its reputation, producing in both houses canes equal to those of most other varieties. The spurs of last year broke freely into fine short-jointed laterals, with one or two fine-formed bunches on each. With a few exceptions which occurred in the early house, the berries in the house named set very thickly, and swelled with a rapidity far surpassing any other Vine in the house, showing the necessity of running the scissors several times among the berries long before the proper time for final thinning. This rapid swelling was constantly sustained until the fruit had attained the dimensions of ordinary Grapes when ripe; at this period it slackened, and then the second swelling and the ripening followed.

The berries on this Vine were of the usual oblong form, of a golden amber colour, and each was a mouthful. Spot, I am sorry to say, was present on a few of the berries on two of the bunches. This blemish shows itself just under the skin, and its effect is anything but pleasant. It in a great degree mars the beauty of a bunch, no matter how perfect it may be in every other respect. Besides, when the berries attacked begin to colour this blemish takes more or less the character of a spreading wound, which renders necessary the instant removal of the affected berries, in order to prevent the disease being communicated to those next them.

As regards the hanging properties of Golden Champion after it is ripe, I have found that it will not keep long without shrivelling, although by this the flavour of its fruit is not in the least impaired.

Having described the behaviour of this Vine in an early house chiefly planted with Hamburghs, I shall now speak of the Vine in our intermediate or Muscat house. This Vine, from the day it was planted—three seasons ago—has been less robust in growth, with the peculiarity of having its berries round and flattened at both ends instead of oval. Only two bunches were permitted to ripen this year, owing to the weak growth of the Vine as compared with that in the early house. These bunches ripened in the fullest sense of the word without spot or blemish. I have just cut the last. It had a flavour dangerous to try, so rich and so peculiarly agreeable—more so than I ever experienced on any former occasion.

Now we shall see what effect wind and hot vapour have upon the fruit of the Golden Champion. To test both I allowed one bunch to remain; it hung close to the front ventilator, so closely that when air was admitted the bunch was constantly swayed to and fro by the current. The other bunch was situated immediately over the gutter on the flow-pipe, and within 18 inches of it; it was consequently subjected to an incessant flow of hot vapour day and night from the time the house was started until colouring commenced, when no water was allowed in the troughs. Those two bunches were not in the least injuriously influenced, but were all that could be desired when ripe.

In conclusion, it will be seen that I have no reason to complain of this Grape as far as my experience has gone. It has done well with me both in a moderately early house, where the temperature has been kept also moderate; but, if possible, I think it ripened its fruit better in the Muscat house, though in the latter case the wood was not to be compared for strength with that in the other house. Another hint: I find when thinning the fruit of the Golden Champion that the most scrupulous care must be exercised to avoid handling; the most tender touch will leave a lasting mark, and the faintest scratch becomes a vulgar scar when the skin gets expanded by age and the growth of the fruit.—A. Kerr, *Carbet Castle.*

Carter's Cricket Club played its last match for the season—Married *versus* Single members—at Dulwich on the 16th inst., and the result was a victory for the Single by one run. Score: Single, 87; Married, 86. The match was followed by the annual dinner, at which thirty-five members of the Club sat down. After the usual toasts had been proposed and responded to, the Secretary gave a *résumé* of the doings of the Club during the past season, when it transpired that four matches had been won, three lost, and five drawn.

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 19.

I suppose almost every person of any observation is well acquainted with the external appearance of a wasp. We have all seen this insect if we are not blind. We have not all felt it, though; no! and those who have not may be regarded as having—a pleasure yet in store? Well, not exactly that, but the sting of the wasp, except with certain peculiarly constituted individuals, is not really so painful as common report alleges. I conceive the wasp is in many things an individual grievously calumniated; he is the victim of spite, which has been nursed and fostered by successive generations until even his exterior is regarded as disgusting, and an adjective coined from his name is expressive of a disposition anything but amiable in the human family.

What are the leading charges against the wasp? First and foremost, it is said, he is a notorious thief, and spares no sweets which come within his reach, attacking also other produce at times. Granted that he does, yet other species of insects are just as annoying and predacious as he is, and they are not visited with such extreme censure. Moreover, it must not be forgotten that the wasp is also carnivorous, and kills and carries off other insects, even at times our pertinacious enemy the blowfly. Secondly, he is charged with being highly malicious and spiteful. "The wasps," says a foreign author, "are a race of dangerous brigands which live by rapine, are incessantly fighting battles, and exist only to do harm. They are an excitable race it is well not to cross. If great heat adds to their natural irritability they savagely attack those who annoy them, and pursue them to a distance." Very dreadful indeed! Perhaps the Continental wasps are worse in demeanour than our British specimens.

My own experience corresponds rather with that of Mr. Cox, who observes, "The wasp is not vicious, but simply resentful. It does not attack or sting unprovoked, and if allowed peacefully to pitch upon us without previous hunting, it will most probably do us no injury." And I have myself even hunted them (by accident)—that is to say, I have struck them down when chasing other insects, and have found that when liberated from the net they were usually only too glad to take their departure, though now and then an individual would perform some gyrations in the air in one's vicinity for a short time, the attention being necessarily concentrated upon these gyrations until the offended Hymenopteron went off. "But," exclaims some one, "wasps *are* malicious. I have seen one at rest, and he (or more properly she, for the male wasps are stingless), kept thrusting the sting out, as if longing to employ it on somebody." Quite true, I have seen that also; but what is there in the fact? Why simply this, that the wasp's sting is a most important weapon to its owner, and it is incumbent upon the insect to keep it in good order. The movement of the sting in and out of the sheath is a merely mechanical act, on a par with the "dusting and brushing" operations gone through by many insects. I do not think it can be proved that wasps are quarrelsome amongst themselves to any great extent, cer-

tainly not so markedly as are the hive bees. They will pounce upon bees of all kinds, it is true, whenever they have a fancy for so doing, and take their honey if they can get it. "This is thieving?" Well, of a sort, but we do not expect high morality amongst the Vespine tribes. The gardener, as it seems to me, is the individual who has most reason to inveigh against wasps —more so than the fashionable lady in her drawing-room, or the shopman behind his counter; yet I have not noticed gardeners so bitter against the wasp as they are against others of their insect enemies.

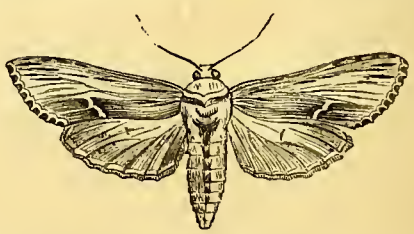
Just now in many districts wasps are numerous enough to be troublesome, and they are fond of entering vineries and hothouses, as well as tolerably impartial in their attacks upon ripe fruit out of doors. But if they do much mischief to fruit under cover it is surely a good deal the fault of the gardener. A friend remarked to me once, "I can't tell how it is; other people get back money they have lent, but whenever I do such a thing I never get repaid." The answer naturally was, "The remedy is simple—don't lend any more." So it is with regard to hothouses: prevention is the plan to pursue. Keep the wasps out, and they cannot do harm. Tolerate no broken nor even badly cracked panes, and when the windows are necessarily open cover with netting to exclude uninvited visitors.

Some confusion of ideas will be found even amongst educated people regarding the economy of the wasp. We have two notable British species which particularly frequent gardens and the abodes of men. The tree wasp (Vespa norwegica, alias britannica) is less common, at least in the south of England. Mr. Harding, in "The Entomologist" of 1865, gives some account of the proceedings of a colony of this species which he observed near Deal, in Kent, and I believe other instances of its occurrence southward have been noted of late, but I have no recollection of having seen this species or its nest since insects have come under my observation. The nest in this species is attached to a branch, and specimens of it may be seen in various museums. Rennie thinks that this wasp has a particular liking for the Silver Fir. The tree wasp is rather larger than the better-known species; in its habits and modes of building it is similar to its relative, with the exception noted as to the locality of the nest. Upon this, however, I am not going to offer any further remarks, confining myself to the common wasp, Vespa vulgaris.

The nest of this species is almost invariably constructed in the ground. Sometimes it may be excavated for the purpose, if a tempting spot on a bank presents itself, but no doubt, whenever possible, the queen wasp selects some hole already existing which may suit her purpose, such as the deserted lair of a rat or mouse. The survivors of the last season are often seen in the spring busily engaged in researches about the hedges rows and fields. These are much larger than the ordinary females, perhaps four times their bulk; whether they can sting with fourfold virulence I really cannot say. The material of which the wasp's nest is constructed, and the fashion of its cells, have been often described in books, and on these I need not comment, but proceed to a few facts less generally known.

Mr. Holland, who watched carefully the proceedings of these insects in the spring of 1865, observes that they are careful to select wood of a soft fibrous texture. On a suitable tree queen wasps may be seen settling in small parties during the first warm days of spring. With their jaws, which are of great power, they tear off fragments, which are thoroughly moistened, and then rolled into balls. They invariably worked backwards. Another thing is curious—namely, that they bring their materials to the spot where they are about to work, and usually pile them up in a little heap, waiting until a certain quantity has been accumulated. Great care is taken by the wasps, in the successive enlargements which are needed from time to time, that no earth shall be left in an insecure position, and the walls are made of considerable thickness. Though the cells are hexagonal, like those of the bee, they are placed in a reverse position, with the open ends downwards, and not horizontally. An egg is laid in each, but not at the bottom of the cell; it is situated at about one-third of the distance from the base to the top. Now here is a strange problem. The newly-hatched larva, which has no feet, and has not the agility which some apodous larvæ possess, does contrive somehow or other to reach the bottom. "How?" asks Mr. Murray, in one of his contributions to the "Annals of Natural History." "It cannot fall out of the egg-shell to reach it at one stroke, for the cell is mouth down and the bottom is at the top; it cannot fall up; it has, therefore, to work upwards. It is said by some the larva throws itself into a loop, and catching hold of the walls of the cell with its teeth (jaws?), then releasing the tail and throwing another loop, fastening its tail again as a sucker, and releasing its head, and so on, by a succession of sommersaults; but this to me seems impossible." However, the larva does get to the bottom; as to the question of its escape from the egg-shell, it appears that the egg has no shell, or a mere membrane, which is absorbed by the young larva. In this position the nurse wasps supply it with food, vegetable or animal, duly comminuted to suit the digestive organs of its immature condition. When full grown the grub or larva of the wasp is plump, rather unpleasant-looking, the head being black, and the interior exhibiting itself partially through the transparent skin of the back. Having finished eating it closes the opening of its cell by means of a silken pad, and is torpid until it emerges from the pupa stage a fully formed male or female wasp, to take its share in the duties of the community, which are really observed with commendable faithfulness and regularity.

A friend was the other day adverting to the intense satisfaction he had derived from reading an account of a parasite which haunts the flea, and whose history verified the poetic statement upon the subject, which he had always hitherto felt rather incredulous about. It was such a comfort, he observed, to believe that when a flea was nipping your leg it was exceedingly probable that his leg, or some other portion of his exterior, was also being operated upon! Now those who are enemies to the wasp will rejoice in the fact that it has a parasite, which rejoices in the name of Rhipophorus paradoxus, and, it is presumed, helps to keep the species from multiplying more rapidly. The conjectured history of this parasite is singular. Mr. F. Smith, our great hymenopterist, has devoted much attention to it, and from the observations communicated to him by a friend, he maintains that the eggs are deposited by the fly in the larva-cells of the wasp, and the larva feeds upon, or, in fact, in most cases kills the nearly adult larva of the wasp. I say in most cases, because Mr. Smith thinks that sometimes this parasite does only partial injury to the wasp grub, which becomes a pupa, though stunted. On the other hand, Mr. Murray believes that the supposed parasite only feeds upon the provision which is bestowed upon the young wasps by their foster-parents. It is seemingly a weak point in Mr. Smith's theory that he regards the young parasitic larva as the successful foe of the adult wasp larva, and it is certainly singular that it should be able to seize and devour one so much superior to itself. "Who shall decide when doctors disagree?"



Cucullia Verbasci.

In some seasons, as shown by Professor Westwood, a disease like that which occurs in apiaries, and which is called foul brood, destroys a large number of the young wasps ere they have completed their transformations. Toads, as is proved, devour bees without hesitation, yet it is thought they reject wasps; still the matter is dubious. McIntosh recommends the destruction of all nests in the radius of a mile from gardens where wasps are troublesome. The position of the nests must be ascertained by day with caution; and at dusk you sally forth, a deadly purpose in your heart, and with an uneasy expression of face, you fire a squib of gunpowder in the holes, or thrust therein a pad of wool well moistened with turpentine. Others recommend gas tar as efficacious. It is of great utility to secure in spring the mothers of the coming race. This may be done by a forcep net. Some authors assert that Hoya carnosa placed in the vicinity of fruit will draw all the wasps away from it; and as a more easily available expedient slices of boiled carrot have been suggested. I have not seen these tested.

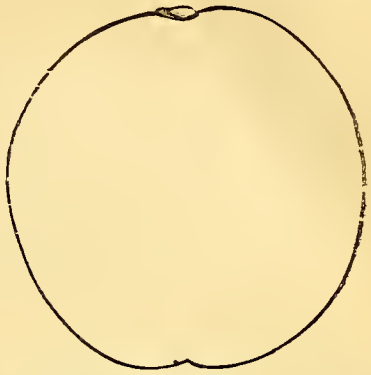
Our figure exhibits an individual of the Lepidopterous order —namely, the Mullein Shark (Cucullia Verbasci), the gaily coloured caterpillars of which feed in small parties on the Mullein, and occasionally on some species of Scrophularia. We show this, however, only for the sake of its relative the Aster Shark (C. Asteris), which, though generally a rare insect,

is at times found attacking China Asters. In and near woods the caterpillar of this moth is mostly found on the Golden Rod, and it is often sought for by entomologists at Darenth Wood in Kent, and West Wickham Wood in Surrey. Some years ago several of these caterpillars were discovered and brought to a friend of mine from a nursery at Norwood, the proprietor being annoyed at the new blight which was assailing his choice flowers. This caterpillar, which is elegantly marked with longitudinal lines, feeds through August and September, and, entering the earth, appears as a moth in June. It is hardly a species likely to become common enough to do injury.—J. R. S. C.

THE SULTAN PLUM.

This is a seedling raised by Messrs. Rivers from the Belle de Septembre Plum in 1864. It bids fair to be a valuable culinary Plum, as it is large, and excellent when cooked. Its

productiveness is something astonishing, as every stem is covered with fruit, and it forms a compact and most fruitful pyramid. Its fruit is of a deep purple, shaded with bright red. The tree sent to us was no more than 2 feet high, and two years old. It had on it six Plums, each the size of a large



Orleans, 6 inches in circumference, and, like it, its season is August. Its dwarf, pyramidal habit enables it to be planted in rows 6 feet apart, and 4 feet apart in the rows.

RENDLE'S PLANT PROTECTORS.

I am a perfect novice in gardening, live within four miles of London, have a small garden, and have no instruction nor advice except from your columns. From your recommendation I went in for ground vineries, and succeeded very well.

A few months since you published a letter giving a decided preference to Rendle's earthenware protectors over the older sorts, and, wishing to increase my stock, I took the writer's advice. I have been in trouble with my new frame ever since I have had it. I fancy the brick sides with glass top only cause the plants to draw. The wind blows the grooved bricks down, and plays havoc with the glass. I follow suit in trying to get at the plants. If I want to move my protector I find it rather a tedious job, and my wife wo'n't help me—she always takes one end of the wooden frames—and in fact I am bothered; but looking at the long string of testimonials, and large orders after trial from noblemen's gardeners, I think my misfortunes must be the result of my own ignorance and not understanding directions for fixing. Imagine my surprise, then, on finding that Mr. Rivers (advertised as a special admirer of the bricks) had to support his trial brick ground vinery with an unsightly wooden frame "to keep it from blowing down!" says his man. I hesitate no longer, but write to ask you to get one of those head gardeners who have hundreds of feet of the brick protectors (*vide* testimonials) to give me, and no doubt many others, some instructions how he guards against the effects of wind, &c. Of course, I do not suppose that a gardener plants Vines under these frames. If the maker of the wooden frames had called them Cauliflower, early Pea, or salad-protectors, or Strawberry-forwarders he would have had his testimonials and orders for hundreds of feet; perhaps he has, though he has not advertised them. Do, Messrs. Editors, give me and my class—viz., office until 6 P.M., and garden 100 feet by 20—a small space in "Doings for the Week" to ourselves, and let the writer—one of these great guns, of course—tell me in his first article how to make my brick protector as handy and little liable to damage as my wooden ground vineries.

By the way, am I conceited or is it true that my Grapes are larger, my Rivers's ground vineries (Rivett's improved), better made and better-looking than Mr. Rivers's own? But, then, his double-worked Maréchal Niel Roses in pots—have you seen them? A good many people have not, or not one would be left at Sawbridgeworth. I am tired of writing, you must be of reading; so—Au revoir.

WORK FOR THE WEEK.

KITCHEN GARDEN.

While the dry weather continues hoe every part of the garden thoroughly, as the seeds that were ripened in summer (where weeds were allowed to perfect seed and to shed them), have now vegetated and may be destroyed effectually, which is better than allowing them to stand over till spring among other crops. When a kitchen garden is at this season well stocked with autumn, winter, and spring crops, all neatly arranged and

well cultivated, and the walks, &c., in good order, I think the present not the least interesting period of the year in this useful department of gardening. Where the stems of *Asparagus* have become brown they may be cleared away, and the beds may be hoed, raked, and have their surface stirred to admit air into the soil as much as possible without disturbing the roots. Prepare ground on a south border or other favourable aspect for planting *Cauliflower* plants under hand-lights; a quantity may be pricked out in cold frames to receive protection from severe frost in winter. Let no favourable opportunity of earthing-up and otherwise attending to Celery pass by, but on no account let it be earthed-up so as in any way to bury the heart of the plant. It is much safer for the present to err on the other side. Prepare ground for plantations of Brown Cos and Hardy Green *Lettuce*, a double row of which may be planted at the foot of the south-east or west walls; the plants may be 4 inches apart in the row, and should they all stand over the winter, which is seldom the case, every alternate one can be removed to form other plantations.

FRUIT GARDEN.

Apples and Pears that have been gathered within the last fortnight should now be looked over carefully, when it will be found that those that were bruised or injured have begun to decay, and unless removed will infect others. Filberts are now ripe in most places and should be gathered. They are kept in good condition in a moderate-sized hamper packed firm; in this way they do not suffer from excess of moisture, and the kernels keep plump and sweet till May or June. The removal and transplanting of evergreens may be done as soon as rain occurs, with more chances of success than at any other period. The natural warmth of the soil placed about the roots, and the close damp weather generally prevailing in the autumn months, are the principal causes operating to insure success. Add to this a tendency well known to those who have planted largely at all seasons, in plants to form roots more readily after the season of active growth and during the ripening of the wood than at any other. Whether planting is done in masses or singly, the ground should be well trenched and drained before attempting to put a plant in. For single plants, if they are meant to thrive, a mere hole just sufficient to hold the roots is not sufficient, but the ground for some space round should be well worked-up to facilitate the progress of the future roots, as well as the escape of water. As each tree or shrub is planted secure it from the action of high winds. Mulch the surface to prevent evaporation from the soil, and besides occasional waterings at the roots when the earth becomes dry, and then only, sprinkle the tops well each evening, wetting the bark and foliage completely. This will be a much safer plan to promote their growth than pouring water on the roots of a plant when the soil around them is already in the shape of mud. Cuttings of Laurels, Privets, Yews, and various other evergreens may be now put in, and the layering of others which do not strike readily from cuttings should be proceeded with.

GREENHOUSE AND CONSERVATORY.

The conservatory will still be kept gay by fresh introductions of plants in bloom, and the removal of such as begin to decay. It will, however, be desirable not to overcrowd the house at this season of the year, as the permanent inmates will require to have all the light and air possible to effect the ripening of their wood. The climbing plants in this and other houses should likewise have a weekly regulation, shortening-back the shoots going out of bloom, and training the remainder in a suitable manner to cause a free natural growth. Climbing plants in pots, as Kennedyas, Hardenbergias, &c., should likewise be neatly tied to their trellises and exposed to a good share of light. The borders in the conservatory will require less water, and this should be still further reduced as the days shorten, making a difference, however, with strong-rooting plants, which will require larger quantities than others. The buds of Camellias where too thick should be thinned-out according to the strength of the plant; water plants which have not been recently potted with clear soot water, to help them to perfect good-sized blooms. A batch of Roses having had a short rest may now be placed in a light pit, for after removal to the plant houses or drawing-rooms they will be useful when the out-door ones are over. For a number which are useful I recommend the following varieties as blooming very late—namely, Devoniensis, Elise Sauvage, Goubault, and Smith's Yellow among the Teas. Most of the Perpetuals and Bourbons should likewise be grown, Géant des Batailles particularly so; and the dwarf miniature Roses are pretty objects for the drawing-room when grown in pots. A portion of the stock of Chrysanthemums should be placed under glass to forward them; thin out the bloom buds, and water the plants with liquid manure. In arranging Pelargoniums for the winter, allow them the lightest and warmest end of the house, unless there is a separate house for them, when the Fancies should have the best end. Keep them close to the glass, and do not allow them to touch each other. Those cut back late may yet be shaken from their old soil and repotted, placing them, however, in a slight bottom heat afterwards to facilitate their quick rooting; cuttings struck should be potted at once, if not done previously. Let the greatest cleanliness be carried out in every house; the pots should be frequently washed on the outside, and moss prevented from growing on the surface soil. Make it a rule to clean out each house after the morning's watering, that it may get dry early in the forenoon. Specimen plants should be frequently turned round to prevent their becoming one-sided. Any plants which have become crowded in the branches should be liberally thinned; no good can be expected from spray enclosed like a besom. Wherever insects appear, let the plants be thoroughly cleansed before going to their permanent stations, rubbing them well with the brush, and using a weak solution of soft soap in water in which a liberal sprinkling of sulphur has been blended. Any of the Chinese or Indian Azaleas which have not yet perfected their flower buds should be kept on a warm light shelf for awhile. The same may be said of Camellias which flowered late in the spring. Those required to blossom shortly should be kept in a warm situation, and receive liquid manure occasionally.

FLOWER FORCING.

Those who intend to provide a rich display very early in the spring should now be in the market and select plants proper for the purpose, and of a superior character as to the amount of flower buds and the form of the plant. These things, of course, involve some little expense, but such is amply repaid where a proper forcing structure is provided. It cannot be expected that gardeners as they are ordinarily situated can provide all the plants necessary for this purpose so well as the nurseryman. As one division of good forcers, I would recommend the ordinary American shrubs, many of which, although too large for the drawing-room stand, are admirably adapted for the vestibule or balcony, or for setting in conspicuous places in the conservatory or mixed greenhouse. Of such are the various Rhododendrons, Azaleas of the nudiflora class, with various hybrids, the Rhodora canadensis, Ledum latifolium and thymifolium, Kalmia latifolia, angustifolia, and glauca, Andromeda pulverulenta, the Daphne, especially Cneorum and even the old Polygala Chamæbuxus. These, with more of the same tribe, although not of very recent introduction, will be found to add greatly to the spring display, as also to the diffusion of a most gratifying fragrance. Such should be obtained forthwith, potted in smallish pots, and plunged in the warmest corner of the garden, from whence they may be successively introduced to the forcing house from the middle of November until February. Such, if gradually cooled down when out of blossom, may be turned out into a reserve garden of bog earth in April, and will frequently force very well the next season.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

When time could be given, trenching up Pea and Onion ground, in order to put in good breadths of Lettuces and Cabbages, was the principal work of routine. Part of the ground most likely to be devoted to Carrots, and similar crops, will be enriched with a quantity of good stuff from the rubbish-heap, mellow and rather fresh, turned down to the bottom of the trench. A little lime will make such soil all sweet, and even if we use it all the winter as ridges for crops that will come off early in spring, it will still serve with deep digging for Carrots in April. We would rather leave such ground open all the winter with sprinklings of lime and a little salt, even adding a sprinkling of gas tar from a rough brush—one of the best things in moderation, and in winter, for setting many intruders on Carrots, &c., on their travels, but when we cannot do the very best, we must often do the next best in our power.

FRUIT DEPARTMENT.

See previous notices as to collecting soils and composts, where fresh planting, and especially station-planting, is contemplated.

Strawberry plants in pots at all crowded should be placed

further apart, and water should he given with more care. The sun during the next three weeks will do much to perfect the fruit buds, and on this success will greatly depend. Some of our readers can never have their plants strong enough to suit them, but it is easy to have very strong and yet unmatured growth. We would sooner have plants somewhat weaker, but with the buds well ripened and matured. The same rule will also hold good as respects fruit trees in general; the ripening of the fruit buds ought to be of more importance than any mere growth, and, therefore, all mere growth that can be removed to give more sun and air to buds, will be of importance.

See what was said about clearing plants out of late vineries, and keeping them dry.

ORNAMENTAL DEPARTMENT.

Calceolarias were shaken by the deluge of rain a fortnight back, and are not such dense masses of colour, otherwise the beds, as a whole, never were more brilliant. The dryness began to tell on some rows of Ageratum, and even on beds of Coleus, and we were forced to water them and some rich beds of variegated Geraniums. We had our beds very early and strong this season, an advantage when the family stays in the country for the whole season; but later beds would look fresher and require less picking late in autumn. We were obliged to pick Ageratums closely. The dense lines showed the ripened seed-heads, but when removed there was plenty of the light blue left. To have the beds fine early and late, much picking must be resorted to.

Cuttings.—We have put in a good proportion of our cuttings for next season all right, and for economical purposes the bulk of them are inserted at once in shallow boxes. We went over our beds several times, so that no opening or break should be made in the beds. We know some of our friends who manage very cleverly in this respect, and take their cuttings, when they have no resident family, a month or six weeks before they are likely to be present; and in that case cuttings can be taken more freely without the contour of the beds suffering at all when the family become resident. Much care must be exercised when you have nothing but the beds to depend on for cuttings, and a family resident that looks on them every day. In such a case we would never be satisfied until we had what we have not had yet—a reserve garden whence cut flowers and cuttings should be taken. Of course there are men who can take cuttings even from beds, so as to leave little or no trace of the knife behind them; and there are, too, many others who, if they get hold of a cutting, throw all considerations of taste and the appearance of the bed to the winds. When a gardener in a large place must chiefly depend on local labourers, in such cases a reserve garden will he seen to be more a matter of importance. To secure bedding plants in the highest style of floral art, nothing should be taken from the beds, until the period of natural decay, but faded blooms and leaves.

We must refer to back numbers for what is needed for pot plants, &c., just to reiterate two ideas that have been mentioned, but not sufficiently ventilated. First, in saving the contour and outline of flower beds by taking short, stubby cuttings from the base of the plants, you will get nice healthy plants, hut they will bloom freely later than those plants raised from cuttings more exposed to sun and air.

Secondly, In looking at the brilliancy of flower beds in the open air now, in comparison of which the finest greenhouses and conservatories look poor in comparison, who is there that will give us from half an acre to an acre of ground covered with glass, and heated so that such striking masses of bloom should be continuous, instead of a few months' duration?—R. F.

TO CORRESPONDENTS.

Books (*Pomologist*).—The "Fruit Mannal;" a new edition is in preparation. The second edition of the "Rose Garden," price 6s. 6*d*. The price of the "Rose Annual" for 1858-59, 1859-60, is 5*s*.; for 1860-61, and 1861-62, 4*s*. You may obtain both from the author, Waltham Cross. In a like manner you may obtain Mr. Cranston's book from King's Acre Nurseries, Hereford. The Rev. S. Reynolds Hole's book is published by Blackwoods. (*A. H. A.*) Henfrey's Introductory Course of Botany by Dr. Masters, is the best book yon can next atndy.

Verbenas (*O. Orpet*).—Their colours are good, especially the purple, but the form is defective. It is impossible to give an opinion on the value of Verbenas for bedding without seeing the plants.

Phloxes (*A Constant Subscriber*).—We cannot recommend tradesmen. Any of the principal florists who advertise in our columns could supply nperior varieties.

Photograph (*Novus Homo*).—Write to Mr. Barron, Roya Horticultural Society, Chiswick, W.

Auriculas (*J. Martin*).—They will not do in a greenhouse; better have a common garden frame, and place the pots on coal ashes.

Grapes Shrivelling (*W. D.*).—We do not think that yon have overcropped your Vines, and unless the Grapes are what gardeners call "shanked"—that is, the stalks of the berries decayed before the Grapes are ripe, which of course cuts off the supply of nourishment to the berries and causes them to shrivel—the cause must be an insufficient supply of water at the roots. *A Reader* has a house of mixed Vines, and the berries of Madresfield Court are shrivelling when the others are all right. We would in this instance look for the evil at the roots. The Vine when growing requires a large quantity of water, and until the Grapes are ripe should not be allowed to become dry at the roots.

Cutting down Black Prince Vine (*T. H.*).—The best Grape Vine to grow in an early house for market purposes is Black Hamburgh. Train up a shoot from each of your Black Prince Vines, and when yon start your vinery introduce in pots two plants of Black Hamburgh which have been cut over some time previously. You should allow two shoots to grow from each Vine, and when the young rods are about 5 feet long inarch them, making the connection about 2 feet from the surface of the ground. The second shoot on the Hamburgh Vine will do to obtain some fruit from in the pot the following season. Inarching Vines is a more certain method than grafting them. The edible kinds of Gourds are useful for making pies when Apples are scarce; slice them up, and use Apples and Gourd in equal portions.

Grapes Mildewed (*R. B.*).—The Vines in both your houses have been attacked by mildew; it attacks both the leaves and fruit, causing the berries to crack, and prevents them from swelling to the usual size. Sulphur is the only preventive or remedy. On the first appearance of this pest throw flowers of sulphur over the leaves and berries, where affected, with a sulphur-distributor.

Royal Ascot Vine (*Reader*).—Royal Ascot is a good Grape. It is well adapted for pot culture and for planting in the vinery. It is inperior to Black Prince and Trentham Black. It will not supersede the Black Hamburgh for general cultivation, nor is it as a Grape equal to Black Alicante, bnt it ripens earlier and does not require so much heat as that variety.

Fungus on Celery Leaves (*W. H; Dota*).—The fungus is Trichobasis heraclei, the brand state of Puccinia; Darluca filum is also present. At this stage we know of no remedy.

Liliums (*J. Stuart*).—All Lilium lancifolium.

Grapes Shanking (*J. H.*).—Your signature was not clear, so your query was answered August 10th, page 109 to "T. H."

Planting a Vase with Bulbs (*A. W. B.*).—For such a vase, the planting would depend on the time you want it to be gay. To have it a perfect blaze at one time, what would or could be better than so many bands of Crocus 9 inches apart, each band of a distinct colour, and contrasting with its neighbour, as white, purple, orange, blue, &c.?

Cost of Trenching Ground (*Rogator*).—For No. 1, or trenching two spits deep (20 inches) in good loamy soil, we have paid £10 per acre, or one halfpenny per square yard, and for No. 2, twice No. 1, or 1*d*. per sqnare yard, which, of course, includes the removal of the roots and levelling; but much depends on the ground and the value of labour in the locality where the work is to be done. The price we name is where good labourers have 3s. per day.

Watering Melons when Ripening (*A Foreman*).—It is not a good plan to water Melons when they are "just ripe," for it tends to gorge the fruit with sap, cracking often results, and the flavour is deteriorated. Nor would it be well to allow the fruit to remain on the plants after being quite ripe, even if it were practicable, as the fruit will part from the footstalk if allowed to remain until dead ripe. They should be cut before that time.

Coprosma Baueriana variegata Propagation (*J. T.*).—Take cuttings of the current year's shoots when half ripe, insert them in sandy loam, peat, and silver sand, place them in a good bottom heat of 75°, and keep them close and moist. The soil should be kept moist but not very wet. They will root well in from three to six weeks, and should be potted off singly, and returned to a hotbed for a few days. When established they should be well hardened off. The best time to put in the cuttings is early in August.

Tulips for Simultaneous Flowering (*A. A.*).—Imperator rubrorum and Yellow Rose will not suit, as the latter is a late-blooming kind, but yon may have Yellow Tourneaol in place of Yellow Rose. Duke of York would not suit Yellow Rose, as the former flowers much earlier than the latter, but for Bleu Celeste Yellow Rose would suit. In the single varieties yon would be better suited, as more of them flower together than is the case with the double varieties. You might have Proserpine, dark rose, dwarf; Belle Alliance, scarlet, dwarf; Chrysolora, yellow, dwarf; Artus, scarlet; Keizer Kroon, crimson scarlet, margined with yellow; Monument, rosy cerise, flaked white; Couronne Pourpre, dark crimson; Bride of Haarlem, white, striped with crimson; Molière, purple, yellow base; Cramoisie superbe, rosy cerise; Royal Standard, white, feathered with rosy crimson; Yellow Prince, yellow; and Thomas Moore, orange, tall. Ne Plus Ultra and Sir Walter Scott Crocus are both lilac; there would be no contrast, though Ne Plus Ultra is a lilac purple. Lord Macaulay is a large dark purple, and would suit Sir Walter Scott. A dozen good and not expensive kinds of Gladiolus are Berenice, Endymion, Florian, Mars, Lælia, Le Titien, Janire, Jeanne d'Arc, Napoleon III., Raphael, Rembrandt, and Ninon de l'Enclos. Lachenalias will do well in a greenhouse, from which frost is excluded, on a shelf near the glass.

Echeveria secunda glauca and Sempervivum californicum Hardiness (*F. J.*).—The Echeveria is not hardy, and should be taken up, potted, and kept safe from frost. The Sempervivum is hardy in well-drained soils, and not very rich. If the soil is rich, and not dry, take up the plants, pot them, and winter them in a cold frame, keeping them dry.

Lapageria rosea Shoots going off (*J. R. W.*).—We should attribute the canse of the strong shoots from the base dying off when about 16 inches long to want of a good root action, in which case it will be necessary to look to the drainage, and give some fresh rough peat, removing as much of the old soil as practicable without interfering with the roots. Are you sure the shoots are not eaten off by slugs? We have a plant which has had all its shoots cut off in this way several times at the height you name. Snails, slugs, and woodlice are very fond of the young shoots of this plant. Examine the plant after dark with a lantern.

Soil for Pampas Grass (*A. B.*).—Take out the soil where yon intend to plant to a depth of 2 feet over a circle of twice that diameter. If there

is turf, place it at the bottom, and mix it with an equal quantity of leaf soil or old decayed manure, and then fill up the hole with two parts good loam (turfy if it is at command), one part leaf soil or old manure, and half a part of sand, raising it in the centre 1 foot above the surrounding level. Plant in March, water well in dry weather, and mulch with short manure in June and again in autumn, but at the latter season with more littery manure; let the dead grass remain throughout the winter, and remove it at the end of March or early in April.

Temperature of Stove (*J. L.*).—From this time and during winter the temperature should range from 60° to 65° at night, and from 70° to 75° by day, with a rise from sun heat to 80° or 85° up to November, afterwards to the middle of February let the temperature be from 55° to 60° at night and 65° to 70° by day, with a rise of from 10° to 15° from sun heat.

Removing Fruit Trees (*F. R.*).—You may safely remove at the close of this month the trees planted a twelvemonth last November, only take them up carefully, preserving all the fibres possible, and keep the roots from sun and air by covering them carefully with mats. Water after planting, shade from very bright sun, and sprinkle with water overhead morning and evening, but not if the weather be moist.

Araucaria not Thriving (*H. P.*).—We do not think the Araucaria will be of any more good. It has evidently been too deeply planted in the first instance, and the tree sought to recover itself by putting out roots near the surface—another evidence, if one were needed, that Conifers, of all trees, should never be deeply planted. Though we think your tree hopeless, we would, nevertheless, cut away the "ball root," and plant so that roots newly formed on the stem will not be covered with more than 6 inches of soil, and this we should do at once. Secure the tree well against winds.

Black Grapes not Colouring (*H. Temple*).—We think you may have too many Vines, but the chief mistake is too many bunches. We have in the case of two Hamburghs made the same mistake, and the berries are scarcely all through red, whilst those of Lady Downe's beside them are like ripe Sloes for colour.

Hedge for a Flower Garden (*A Lady*).—Holly, as you propose, would answer very well, and you may move them quite safely at from 3 to 4 feet high if they have been transplanted within two years. Their removal will, however, be costly, and if you purchase smaller plants, so long a time must elapse before they will answer for shelter, that we should plant some other evergreen. Common Yew answers perfectly, and can be safely removed when of considerable size, so that you may form a hedge at once. We prefer Yew to all other kinds of screens in trimmed grounds. Berberis Darwinii makes a first-rate evergreen screen, and grows much more rapidly than either Holly or Yew, and is a mass of golden flowers in spring. The quickest-formed fence we ever had was of American Arbor-Vitæ; it was made in a day by planting trees 6 feet high at about 18 inches apart. Any of the plants named would answer your purpose well, all being suitable for the boundary of a flower garden.

Solanum ciliatum Casting its Berries (*A. S. A.*).—We think it arises for want of a proper supply of water, or, in other words, the soil is too dry. Give water more copiously, and we think the berries will swell off.

Dwarf Standard Dessert Apples (*Elston*).—Six good kinds for dwarf standards are Early Red Margaret, Dutch Mignonne, King of the Pippins, Sykehouse Russet, Cox's Orange Pippin, and Pitmaston Nonpareil. Apricots and Nectarines would not succeed as dwarf standards in Northumberland, unless against a south wall. Plums would do, and of them we advise Golden Gage, Orleans, Kirke's, July Green Gage, Victoria, Belgian Purple, Prince Englebert, Jefferson, and Dismond.

House for Roses—Propagation House, &c. (*J. Ducker*).—We cannot undertake to give plans of proposed houses, but are always glad to give all the information we can, and criticise any submitted to us. Of the Rose house we may say that for so small a house we should not think of planting out the Roses, but would have them principally in pots; indeed all, except a climbing kind at every 4 feet. Instead of a span-roofed house we should have a half-span on one side facing the north, and the longer half of the span facing the south. The front, 7 feet high, should be formed of 3 feet of brickwork and 4 feet of glass, &c., and the whole of the front glass should open, and that at the back the whole length of the house. Along the front we would have a stage of laths 3 feet wide, level with the top of the brickwork, and, allowing 2 feet 6 inches, have a stepped stage to the back wall, but 3 feet flat next the wall. In front, beneath the stage, have a border in which to plant the climbing Roses. For the propagating house the walk would be best in the centre, with beds on each side, which should be chambered, and have two rows of 4-inch pipes beneath each. The bed may be covered with about 3 or 4 inches of plunging material. Two rows of 4-inch pipes would be required all round for top heat. Ventilation at the top would be sufficient. One fire would do for both houses if you employ a boiler and hot-water pipes; but if you have flues, which we do not consider suitable, you will need a fire for each house. The loam with a clay subsoil is the more suitable of the two kinds for Roses.

Caterpillars Infesting Cabbageworts (*Myton*).—There are plenty of things that will kill the caterpillars, but we cannot advise their application so near the season of use. We advise their being picked off by hand, also to dust with quicklime early in the morning or late at night.

Scarlet Runners not Podding (*A Constant Reader*).—We think the cause of the Scarlet Runners not podding is the dryness of the soil, the plants being against walls. Had good supplies of water been given two or three times a-week, with liquid manure occasionally, we think your crop would have been excellent.

Cutting Down Periwinkle (*J. L. P.*).—It will not do to cut down the Periwinkle at this season, especially as you wish to have the slope on which it is planted green all the winter. The best time to cut it down is in March, removing any irregular growth in August.

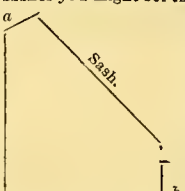
Green Gage Plum Tree Dying Suddenly (*A Beginner*).—The tree, with its inner bark reduced to a reddish powder, is attacked by Scolytus Pruni, and contains burrows of the larvæ and imagos. Though apparently in a healthy condition, it is to be suspected that the tree was not so in reality, later researches into the history of the Scolyti indicating that they locate themselves chiefly in trees which are either under some morbid influence, or have been partially destroyed by other insects. We recommend the removal of that particular tree. At this season of the year there is no reason to apprehend the evil would spread, since the beetles appear in June and July only to deposit eggs, and the larvæ have no power to migrate from tree to tree.

Spring Flower Gardening (*W. Hinds*).—We could not do better for you than recommend "Spring and Winter Flower Gardening," by Mr. Fleming, which you can have by post from our office for 2*s.* 7*½d.* Were we to enter fully into the affair it would require a treatise, and then we should break through one of our special rules, which prudence demands we should adhere to, and that is, to criticise proposed planting, but not to give the planting for a flower garden. It would be impossible to do this, as the applications would be endless. But, just as a hint, suppose you filled No. 1 with a centre and two bands of Hyacinths, say white, blue, and red, with an edging of Viola cornuta; then edge all the other beds next to it with Cerastium, and plant, according to your proposal, each bed with two colours of Tulips—the Van Thol would be pretty and cheap—but keeping the lighter colours to the centre, and the scarlet and crimson to the outside. Then the eight circles we would do in pairs of Crocus, edging yellow with purple, white with blue, and so on. The four large outside beds we would edge, two with Viola and two with Golden Feverfew, and these we would mix or cross, so as to make a difference. If you had Anemones they could come in well in two colours in these beds.

Joints of Hot-water Piping (*Jas. Luck*).—We have just done some thousands of feet of hot-water piping, and we have used rope yarn, or rather lint yarn, and red lead, and not one has failed. We like it best. Other plans have their advocates.

Hot-water Piping for Wintering-house (*An Old Subscriber*).—The house containing about 9500 cubic feet of air, 360 feet of 4-inch pipe, all flow *à la* Cannell, will keep the house quite safe. Say 45° to 50° in winter.

Protecting Peach Trees on a Wall (*J. P. F.*).—To make the most of a covering of glass for your wall you should enclose enough of space to enable you to walk inside and attend to the trees. If you had spare sashes you might set them against the trees, a foot or 18 inches distant.



We once used some old sashes, 6 feet long, for a wall of 8 feet like yours. We put posts 5 feet from the wall, and 8 inches above the ground On these we fixed a rail to support the ends of the sashes; a short rafter of 9 inches in length from beneath the coping supported the sloping rafter at the back. The sashes were fixed, and air given back and front by moveable boards, *a* and *b*, ventilators. If you have no sashes, the cheapest way would be to have such top and front ventilation, and make a roof fixed in the orchard-house style. We would have the width enclosed from 4 to 7 feet, as the space would be useful for many things. If of the latter width, you could take your glass right to the wall, and have about eight moveable lights at the apex, say 24 by 12 inches.

Double-spanned Greenhouse (*J. Hargate*).—The double span-roofed houses we have recommended for economy of space and construction, and we gave examples of them as existing at Messrs. Lane's, at Berkhampstead. The mode of top ventilation of a span-roofed house by means of a double ridge-board, with a swinging ventilator between, and a cap to cover all to keep out wet, we have also recommended, and we have given examples of successful practice. Your proposed plan of heating will answer, but if you want a high temperature in the one house you will want double your top-heat piping in winter. The return will answer for both top and bottom heat, and for returns we never trouble ourselves with stop-valves. Your main flow and return may be extended as you like, but they must be low enough, so that in all branching off from them the pipes shall rise, and these mains must be above the level of the boiler. Now, though your questions are too numerous for one time, we reply that we prefer the main flow and return to be 4 inches in diameter rather than 6; that the connections are generally in such cases 4 inches. We often have them 2 or even less. There will be no difficulty as to the return, but you may require to regulate or stop for a time the flow in the higher level until the water is going freely in the lower level. We have answered your fourth question already; there would not be enough piping for early work. There can be no question as to the return. The dipping we could not be sure about without observation or a sectional plan. No objection to the houses in pairs. We think the ventilation will be ample. The damping must be guarded against by professional care, air-giving, and judgment in watering. The glasses will be useful. You may then have bottom heat and a coolish atmosphere overhead. The boilers you speak of are first-rate; in fact, there are few bad boilers if well set and well managed. We have preferred the saddle-back because it is simple. Your mode of obtaining a moist bottom heat will do if you keep the rough material moist. Trough pipes are objectionable in chambers, unless you have some simple mode of filling them.

Stove in a Greenhouse (*F. T., Exon*).—We prefer a flat-headed iron stove to a round-headed one, and we would have a vessel made to stand on this top to hold water in preference to having the vessel cast with or joined to the stove. There will be plenty of vapour in the one case, and not so much heat as to boil the water. The vapour thrown off would not be injurious, but as the Grapes ripened you could easily put a slate or a piece of wood over the evaporating vessel. If the vessel is merely set on you may put some flowers of sulphur in the water, but not if the vessel is joined to the stove.

Names of Plants (*Nettley*).—We decidedly object to naming plants from imperfect material. Here you send mere tips of shoots. Happily all but one are recognisable at a glance. No. 2 is Lignstrum japonicum; 4, Chorozema varium; 5, Correa cardinalis; 6, Lantana Selloi (or Sellowii); 7, Poinsettia pulcherrima. You may have the "Cottage Gardeners' Dictionary" free by post from our office for 7*s.* 2*d.* (*F. J.*).—Clerodendron fœtidum of Bunge, from Northern China. (*R. B. L.*).—We have done our best to determine the fruit of the Cucurbit sent to us, and after having subjected it to the inspection of some of our most competent authorities, the conclusion deduced is that in all probability it is an example of Cucumis Anguria, a plant which was figured in the "Botanical Magazine" of last year (see tab. 5817), and known as that which yields a gherkin much used in West Indian pickles. It is the only Cucumis occurring in America, and it has been suggested that even there it may not be truly indigenous, but introduced by the Negroes from Tropical Africa. It is one of a difficult series, running from C. sativus on the one extreme, through C. metuliferus, C. pustulatus, C. arabicus, C. Figarei,

to the bitter and deleterious C. prophetarum, all charactorised by strong rugosities or prickles on the surface of their fruits. Should it be really the C. Anguria, then our warning as to the suspicious nature of the sap of these fruits will not apply in this instance. We should have been able to have spoken with far greater certainty had we been favoured with a leaf as well, which in C. Anguria is very deeply lobed. (*Lady Emily Turnour*).—Your plant is Eugenia Ugni, a kind of Myrtle, a native of Chili. The fruits are not only eatable, but are much esteemed by some. Two or three years ago a very fine specimen is said to have yielded "six quarts of delicious fruit." It grew in South Devon. (*Tamar Cottage*).—The climber is Lophospermum scandens, a native of Mexico, whilst the weed is the poisonous Enchanter's Nightshade, Circæa lutetiana. (*W. Nock*).—The common Agrimony, Agrimonia Eupatoria, and the Birdsfoot Trefoil, Lotus corniculatus, both common wildlings. (*C. J. Bromhead*).—Adiantum deltoideum of Swartz, a genuine West Indian species. (*Julia*).—Arabis albida, native of the Caucasus and Crimea, commonly used for spring bedding. (*Nemo*).—Cystopteris fragilis, the Brittle Fern, a British species, having a very wide geographical distribution. (*D.*).—1, Nephrodium decompositum, and 2, N. Thelypteris, both commonly known as Lastreas. The latter is also sometimes known as Aspidium Thelypteris, its English name being the Marsh Fern. (*A. E. F. C.*).—The name of your shrub is Leycesteria formosa, native of the Himalayas. Remove it at once, or within the next month. The dessert Pear we should recommend would be Louise Bonne of Jersey or Marie Louise. As to the pyramid, let it be lifted and root-pruned—that is to say, let all the very strong thick roots be shortened, so as to check the undue vigour you speak of. (*R. J. Gargrave*).—The Fungi sent are specimens of Sclerodermа vulgare, not edible. As you have the "Edible Funguses of Great Britain," the best book you can get, including the poisonous species, is "Mushrooms and Toadstools," with fifty-three coloured figures. Price 6s. Hardwicke, 192, Piccadilly, W.C.

POULTRY, BEE, AND PIGEON CHRONICLE.

BANTAMS versus GARDENS.

Like some of your correspondents, I, too, got an attack of "Bantam fever" on reading "Wiltshire Rector's" article in the Journal of June 1st. I "worked it out" by purchasing a cock and three hens, Black-breasted Reds. I have a small garden, my chief source of recreation. Confiding in the Rector's recommendations, I gave my Bantams the run of this. Now, either "Wiltshire Rector" or I have a new race of Bantams. His delight in slugs; mine refuse these, even when gathered for them. His do no harm; mine show a remarkable liking for young plants of cauliflowers and Brussels sprouts, and find evident pleasure in "burrowing," so to speak, among the roots of my miniature pear trees. To-day I expected a good harvest of seed from some fine French pansies, as I had remarked the seed vessels grow daily larger. To my surprise not a seed vessel was left. I concluded they had been eaten by the slugs that should have been devoured by the Bantams. While still searching, lest they might have fallen to the ground, one of the hens came in amid the pansies, and began to eat the young seed vessels. These I examined, and found the seed yet quite soft and almost transparent.

Now let me not be misunderstood. I do not write this to find fault with the good-natured Rector, for, fortunately, I can keep my Bantams elsewhere than in the garden; but I wish to warn those who may have no other place to keep them that they consider well before they risk spoiling their gardens. If my birds should be exceptions to the rule laid down by our Rector, and the beginning of a new race of Bantams (!), I intend to call them Come-outers!—H. C., *Galway*.

LIGHT BRAHMAS.

It appears to me that Light Brahmas are never to take a respectable position in poultry exhibitions. Here we are verging on the winter season of 1871, and with the exception of special prizes offered by the supporters of the variety, there is literally no chance for us, who admire the Lights, to carry off a single cup, or in many cases the first prize. The fact that the vast majority of committees give but one class for Brahmas is lamentable, and to hope to be first under such circumstances is to hope in vain; for upon reference to back numbers of the Journal I find that I am compelled to give up the voyage of discovery as a bad job. Still, however, the fact is thereby rendered apparent that out of the past thirteen exhibitions laying claim to some degree of importance, only two gave Light Brahmas separate classes, the whole of the remaining eleven first prizes and cups being carried off by the Dark variety. In the face of such a fact it is easily understood why there are so few exhibitors of Lights. For my own part I have been content to exhibit "few and far between." It is quite refreshing to examine such prize lists as Southampton and the Crystal Palace, and there is every reason to believe that such exhibitions of Light Brahmas as have never been seen will be displayed at these shows. Chepstow appears to have been the opening of their season; the thirty-three pens of chickens brought together were of the highest merit, the whole of the eighteen pens of pullets being highly commended. Ipswich, too, evidently believes in the preference exhibited by our judges, and for the cups has pitched Dark Brahmas against Cochins, and Light Brahmas against Dorkings. What will our fanciers say to this? Doubtless the awards will be anticipated. *En passant* I must say that the schedule of the Crystal Palace Committee is beyond all praise, but as much might have been expected from the high character of the committee and secretaries.

Now, I ask, why do our judges persist in discouraging Light Brahmas? The fact of their inferiority in size to their Dark brethren stands alone; but it is not "size" that wins, for I have invariably noticed Dark specimens winning which were both bad in shape and colour, whereas their Light opponents possessed these qualifications, although inferior in bulk. So far the chickens of the present season of both colours are pretty equal, but competition will doubtless make disparities. It has been noticed in a contemporary that not only have Darks won throughout the summer, but that the majority of first prizes have been won by one exhibitor. This redounds to his credit (if he bred the birds), but it is nevertheless discouraging. In conclusion I would beg of one of those gentlemen in whose hands are placed for award "the cups that cheer but not inebriate" to tell us what our favourites fall short in, and how we can match them upon even terms with Darks. If the answer is, "Increase the size," the matter is at an end, for it cannot be done, and any judge imposing this as a winning necessity must feel that he is acting partially, and I may almost say unjustly.—James Long.

CRYSTAL PALACE POULTRY SHOW.

"No more Crystal Palace for me. No, my pets, you sha'n't go there starving in the cold in the middle of November. Our losses last year were a White Fantail, a Golden Pheasant, and a pair of Jacobins." Such were my thoughts on going the rounds of my fowl houses, the postman having just given me the catalogue of the coming Show. There is something very curious about this Show. On referring to 1869 I find eight of those having the management took thirty-four prizes; and in 1870 I find seven of the managing parties took fifty prizes amongst them. Now the thought suggests itself to my mind, Would it not be more satisfactory if these parties refrained from showing at all, particularly as some amongst them are, I am informed, dealers in poultry, Pigeons, &c.? As I said before, it is very curious that a party being on the Committee should be so very fortunate as to show fourteen pens of birds, and except for two, get prizes for them all. My own case was very different. Feeling most anxious to give the Crystal Palace Show a lift, I sent sixteen lots, but never took a prize. I had the honour of seeing my name in print as taking first prize for a pair of Jacobins; this I was told was a mistake. It might have been, but one thing is quite certain, the birds never came into my possession again; they were stolen and another pair substituted for them, so this year I mean to keep my birds at home.—James Elgar, *Ormanthorpe Hall, Newark*.

CHEPSTOW POULTRY SHOW.

This was held on the 13th inst., in connection with a horticultural show, and the success was such that it is proposed to continue the Show annually. Light *Brahmas* were remarkably fine, and were exhibited by several well-known prizewinners. The *Pigeons* were very good.

Brahma Pootra (Light).—*Cockerels*.—Cup, Rev. J. D. Hoysted, Bradenstoke, Chippenham. 2, L. H. Ricketts, Banwell, Somerset. 3 and *hc*, J. Pares, Postford, Guildford. 4, T. A. Dean, Marden, Hereford. *vhc*, H. M. Maynard, Ryde, Isle of Wight. *Pullets*.—1, H. M. Maynard. 2, Rev. C. H. P. Abbott, Withington, Hereford. 3, J. Bloodworth, Cheltenham. Extra, H. M. Maynard; T. A. Dean. (Whole class highly commended.)

Brahma Pootra (Dark).—1, Lieut.-Col. Tickell, Cheltenham. 2, T. A. Dean. *Chickens*.—1, G. F. Parrott, Henbury, Bristol. 2, W. Sims, Stroud. *c*, D. Lane, Gloucester.

Cochin-China (Any variety).—1, T. A. Dean. 2, C. Bloodworth. *Chickens*.—1, C. Bloodworth. 2, J. Bloodworth. *hc*, J. Long, Plymouth; T. A. Dean.

Dorkings (Any variety).—*Chickens*.—1 and 2, J. McConnell, Ewens Harold, Hereford.

Game (Any variety).—*Chickens*.—1, T. Jones, Swansea. 2 and *hc*, H. T. Jarvis, Chepstow.

Hamburghs.—*Golden-pencilled and Spangled*.—1, C. Plimley, Wolverhampton. 2, F. Perrin, Ashley Vale, Bristol. *Silver-pencilled and Spangled*.—1, J. Carr, Hafod, Swansea (Spangled). 2, J. McConnell (Pencilled).

Spanish (Any variety).—1, C. Taylor, Gloucester. 2, J. McConnell. *c*, R. Barrett, Stroud.

Bantams.—1, G. Ashford, Newport. 2, T. Moore, Cardiff. 3, Lieut.-Col. Tickell. *hc*, F. A. C. Cooper, Ampney Crucis.

Any other Variety.—1, J. Hinton, Warminster (Silver Poland). 2, Rev. N. J. Ridley, Newbury (La Flèche). *hc*, L. Dean, St. Arvans, Chepstow (Light Brahma). *c*, A. G. Lawrence, Chepstow (Houdans).

Selling Class.—*Cock or Cockerel.*—1, T. Rogers, Walsall (Black Spanish). 2, R. Barrett, Strond (Black Spanish). *hc*, Lieut.-Col. Tickell (Houdans); T. A. Dean (Brahma Pootra); C. Bloodworth (Buff Cochin). *Hens or Pullets.*—1, J. S. Phillips, Newport, Mon (Game Duckwing). 2, L. Dean (Light Brahma). *hc*, C. Lynne, Chepstow (Dark Brahma); J. McConnell (Black Spanish); T. Rogers. *Miscellaneous.*—1, C. Price, Penterry, Chepstow (Ducks). 2, W. R. Holman, Bayahill, Cheltenham (Ducks).

PIGEONS.

Barbs.—1 and 2, H. Yardley, Birmingham. *c*, W. Cook, Swansea (2).
Carriers.—1 and 2, H. Yardley.
Fantails.—1 and 2, J. Walker, Newark. *vhc*, J. F. Loversidge, Newark. *c*, W. Crook; T. A. Dean.
Jacobins.—1, E. T. Dew, Weston-super-Mare. 2, H. Yardley. *c*, F. Waitt, King's Heath, Birmingham.
Nuns.—1, H. Yardley. 2, E. T. Dew. *c*, E. T. Dew; L. Dean.
Pouters.—1, W. Crook. 2, E. T. Dew. *c*, W. Crook; H. Yardley; E. T. Dew.
Tumblers (Any variety).—1 and 2, H. Yardley.
Any other Variety.—1, W. Crook (Yellow Magpies). 2, E. T. Dew. 3, H. Yardley. *c*, W. Crook (Ice Birds); J. H. Watkins.

Extra Stock.—*Poultry or Birds* (Any description).—1, L. Dean (Light Brahma). 2, C. Lynne (Dark Brahma). *hc*, T. A. Dean (5). *c*, L. Dean (Light Brahma) (2); J. Bloodworth (Black Bantam); L. H. Ricketa (Light Brahma) (2).
Prize for the greatest number of points in all classes, T. A. Dean.

Judges.—Mr. R. H. Nicholas, Newport; Mr. T. L. Brewer, Danny Craig, near Newport; Mr. T. Davies, Wellington Park, Redlands, Bristol. Dr. Cottle, of Cheltenham, judged the Pigeons.

MIDDLETON POULTRY AND PIGEON SHOW.

Middleton Show has long been noted for the general excellence of its poultry exhibitions, and this year's Show fully maintained the high character of previous meetings. It will, probably, be in the recollection of most of our readers that both the poultry and Pigeons are exhibited at Middleton in the open field, and in past years exceedingly wet weather has proved no common drawback to success. The Committee have, however, wisely resolved to provide for so serious a contingency on future occasions. A few new pens of novel construction were erected to test their sufficiency this year, and if they prove equal to the anticipated requirements the same plan will be adopted throughout the collection. The whole of the fronts of these new pens are of thin iron rods, exhibiting the birds to considerable advantage as compared to those show pens in ordinary use. The sides and backs are of plain woodwork; the roof slopes off to the back, and being covered with a waterproof sheeting, sudden rains are amply provided against; and, we must add, when not in use these pens are so constructed as to fold up into a space few would believe possible. Again, a shutter closing on hinges forms ample protection after nightfall. It hangs down below the pens during the show time, hiding entirely from view the travelling baskets, which, being placed beneath the pens, are quite preserved from heavy rains. No breakage of tails can occur in these pens, but there are two little improvements which at once suggest themselves to the mind of any practical observer, even at first sight. One is that the ironwork at the fronts should be somewhat closer for the 3 inches on each side of the pen to prevent the cocks from fighting; the other is of equal, if not greater importance, as the present construction of the doors rather aids than defeats the attempts at theft that unfortunately have of late been by far too general. The doors, as at present constructed, simply open sideways, the full height of the front, being fastened by an iron "nut" fixed inside on the bottom bar, the hinge being accomplished by the door turning on one of the bars that run from top to bottom. To this arrangement there are at least two evident objections: first, that the door opening entirely from top to bottom gives Game fowls, Hamburghs, and some of the most active poultry, abundant opportunity of escape whilst being penned, repacked, or inspected by the Judges, whilst theft would be more easily accomplished, if attempted, during the time of the Show being open to visitors. We suggest that if the doors slid up, with part of the top bar affixed, not only would the birds prove more difficult of access to the dishonestly disposed, but also the sudden rising of the top above the heads of bystanders would certainly be apt to attract attention, and thus, to a certain extent, obviate robbery.

About five hundred pens of really first-class chickens competed, and a more worthy display was never exhibited in this district. Although the *Game* fowls were quite equal to expectation, Brown Reds and Piles showed in best condition, the last-named variety taking the Game cup. The *Spanish* were uniformly good, but the *Brahmas* comprised show birds of the best individual excellence that have been seen for some years past at this season of the year. The cock shown by Lady Gwydyr was a very grand specimen, but looking in not quite so good show trim as when last exhibited, as continued exhibition inevitably tells hardly even on the best-constituntioned poultry. Mrs. Arkwright's Brahma pullets were also worthy of particular remark. *Cochins* were unusually good, and the *Hamburghs* equally so. Silver-pencilled (a rare occurrence) took the Hamburgh cup. The *Crève-Cœurs* were far the best of the French fowls, and the *Waterfowls* never mustered at Middleton more perfect as to general quality.

In *Pigeons*, Almonds were first-class, and though some of the Carriers sadly lacked condition, they were excellent birds, moulting time being the only cause of their shortcoming. Turbits and Fantails were really good, and the class for Dragoons was one equally good as to numbers and also quality. In Nuns, Mr. Yardley's pen, so much noticed of late in the discussion as to trimming, stood again first, whilst a pen of another exhibitor was disqualified for trimming by scissors. The Variety class was not so good as that of last year.

The weather on the whole was favourable, and we are told the Show was as usual a financial success.

The *Rabbits* were not so good as we are accustomed to see at this large Show; they were not so carefully penned. Half-bred short-eared specimens should not be mixed with Lops, and Lops with Angoras. Surely it cannot be that Middleton is losing its high character for Rabbits. I hope this friendly hint will be sufficient, and that a better arrangement will be made for the Rabbits, which now form at all shows no inconsiderable portion of the entries.

There were at Middleton forty-six entries—of Lops, eight; Angoras, eight; Himalayan, eight; Silver-Greys, four; Any other variety, seven; and in the Selling class, eleven. In some of the classes were good specimens. The Lop buck which carried off the first prize was well entitled to it; ears 21¾ by 5 inches; and the second prize was awarded to a Yellow and White under seven months old, which gives promise of a good Rabbit, and worthy of exhibition; ears 21¾ by 4¾ inches.

The Angoras, as a class, were not quite equal to others we have seen recently, either in size or fineness of wool, yet all seemed to have had that care bestowed upon them so essential to their showy appearance. The doe taking the first prize was justly placed on the list of honours. The second-prize buck was a well-formed young Rabbit, seven months old, and will, I doubt not, be found in an enviable position at future shows.

The Himalayans were rather small, yet one that stood at the top of the class was well marked, and had no very near approach in point of excellence. In this class some well-marked, but small, Rabbits were found, and the Judge was probably influenced in his opinion by size rather than other points fanciers like in this variety.

The first-prize Silver-Greys were fine specimens of what this variety should be, being large and well silvered; and the second prizetakers were by no means imperfect. I much prefer the general silvering of this variety to the darker and at times irregular patches of shade one used to see.

The Any other variety class contained the opposites in size. Mr. S. G. Hudson's Belgian Hare was a fine specimen, contrasting with this gentleman's Black and White Dutch as second prize. May I not ask if the latter variety should not have four white feet instead of two to be worthy of any honourable position?

The Selling class contained the usual miscellaneous collection, and the Yellow and White Lop doe of Mr. J. Boyle, and an Angora, were both worthy their position.

I regret to have to conclude my remarks respecting this Show by saying that some specimens had to be disqualified by reason of sundry tamperings, and I trust this is the last occasion I shall have to record such practices. I hope in future to have to record more numerous entries, and certainly would suggest that at this late season of the year the Rabbits should be under canvas, and that will not be more than requisite for their safety from cold, especially when coming from such a temperature as that of their hutches.—Charles Rayson.

Game (Black-breasted and other Reds).—*Chickens.*—1, C. Chaloner, Whitwell, Chesterfield. 2, T. Statter, jun., Whitefield. 3, E. Brough, Ballhaye Park, Leek. *Cockerel.*—Cup, A. Milnes, Rochdale. 2, E. Mann, Wallfield, Stand, Pilkington. *hc*, J. Fletcher, Stoneclough, Manchester; J. Spencer, Clayton, Bradford; E. Mann; E. Aykroyd, Eccleshill, Leeds. *c*, C. Chaloner.
Game (Any other variety).—*Chickens.*—1 and Cup, T. P. Lyon, Knotty Ash. 2, Barker & Charnock, Illingworth. 3, C. Chaloner. *hc*, S. Matthew. *c*, J. Fletcher. *Cockerel.*—1, J. Pickles, Banks, Mytholmroyd. 2, T. P. Lyon. 3, C. Chaloner. *Pullets.*—1 and Cup, W. H. L. Clare, Twycross, Atherstone. 2, C. Chaloner. 3, J. Fletcher. 4, T. P. Lyon.
Spanish.—*Chickens.*—1, J. Walker, Standiford, Wolverhampton. 2, Mrs. Allsopp, Hindlip Hall, Worcester. 3, Mrs. Hyde, Bedminster. *hc*, Clews and Adkins, Walsall. *c*, W. & F. Pickard, Thorner. *Cockerel.*—1 and Cup, Mrs. Allsopp. 2, C. W. Brierley, Middleton. *c*, H. Dale, Northallerton. *Pullets.*—1, J. Walker, Standiford, Wolverhampton. 2, H. Dale.
Dorkings.—*Chickens.*—1 and Cup, Mrs. Arkwright, Sutton Scarsdale, Chesterfield. 2, J. Martin, Claines, Worceater. 3, J. J. Waller, Kendal. *hc*, T. E. Kell, Wetherby; J. White, Warlaby, Northallerton; R. W. Richardson, Beverley. *Cockerel.*—1, J. Martin. 2, Mrs. Arkwright. *hc*, W. H. King, Rochdale. *Pullets.*—1, T. E. Kell. 2, Mrs. Arkwright. *c*, T. Statter, jun.; E. Leech, Rochdale; J. H. Wilson, St. Bees.
Brahma Pootra.—*Chickens.*—1, W. Hargreaves, Hullock Top, Bacup. 2, W. A. Taylor, Mancheater. 3, Horace Lingwood, Creeting, Needham Market. *hc*, T. F. Ansdell, Cowley Mount, St. Helens; Dr. Holmes, Whitecotes, Chesterfield; J. Ashworth, Rochdale; J. Long, Plymouth. *Cockerel.*—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, J. Ashworth, Rochdale. *hc*, Hon. Mrs. A. B. Hamilton, Woburn; T. F. Ansdell; J. Ashworth. *Pullets.*—1, Mrs. Arkwright. 2, Horace Lingwood. *hc*, Hon. Mrs. A. B. Hamilton (2); M. Leno, Markyate Street, Dunstable; Lady Gwydyr. *c*, W. Hargreavea; R. Hargreaves, Ridding Water, Delph; T. A. Dean, Moreton-on-Lugg; J. Ashworth; W. H. Butler.
Cochin-China (Buff and Cinnamon).—*Chickens.*—1, Cup, and 3, A. Taylor. 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, E. Leech. *Cockerel.*—1, Lady Gwydyr. 2, W. A. Taylor. *hc*, T. M. Derry, Gedney, Wisbeach. *Pullets.*—1, C. Sidgwick. 2, Mrs. Allsopp. *hc*, W. A. Taylor; J. Sichel, Timperley; J. Hey, Honley, Huddersfield.
Cochin-China (Any other variety).—*Chickens.*—1 and 2, C. Sidgwick. 3, Horace Lingwood. *c*, W. A. Taylor. *Cockerel.*—1, Horace Lingwood. 2, J. K. Fowler, Aylesbury. *c*, C. Sidgwick; E. Leech. *Pullets.*—1, C. Sidgwick. 2, W. A. Taylor.
Hamburghs (Gold-pencilled).—*Chickens.*—1, J. Wrigley, Tonge Hall, Middleton. 2, H. Beldon, Goitstock, Bingley. 3, Miss M. E. Wrigley, Tonge Hall, Middleton. *hc*, H. Pickles, jun., Earby, Skipton. *Cockerel.*—1, H. Pickles, jun. 2, J. Wrigley. *hc*, W. E. Walker, Heaton Park, Middleton; Miss Wrigley, Tonge Hall, Middleton; S. Smith, Northowram, Halifax. *Pullets.*—1, W. H. Tickner, Ipswich. 2, H. Pickles, jun. *hc*, J. Wrigley; J. Webster, Whitby.
Hamburghs (Silver-pencilled).—*Chickens.*—1 and Cup, H. M. Mann, Kendal. 2, H. Beldon. *Cockerel.*—1, H. Pickles, jun. 2, H. Beldon. *Pullets.*—1, H. Beldon. 2, W. M. Mann.
Hamburghs (Gold-spangled).—*Chickens.*—1, T. Scholes, Hollinwood, Manchester. 2, N. Marlor, Denton. 3, T. Boulton, Hanford, Stoke-on-Trent. *hc*, T. Scholes; J. Statter, New Brighton, Cheshire. *Cockerel.*—1, H. Pickles, jun. 2, J. Ogden, Chadderton, Manchester. *hc*, E. Brierley, Heywood; J. Buckley, Ashton-under-Lyne. *Pullets.*—1 and 2, J. Chadderton, Hollinwood, Manchester. *hc*, T. May, Wolverhampton.

HAMBURGHS (Silver-spangled).—*Chickens.*—1, H. Beldon. 2, H. Pickles, jun. 3, J. Fielding, Newchurch, Manchester. *hc*, Ashton & Booth, Broadbottom, Mottram. *Cockerel.*—1, H. Pickles, jun. 2, H. Beldon. *hc*, G. & J. Duckworth, Canal Mill, Church, Accrington; J. Fielding; Ashton & Booth. *Pullets.*—1, H. Pickles, jun. 2, Ashton & Booth. *hc*, Mrs. Allsopp; H. Beldon.

HAMBURGHS (Black).—*Chickens.*—1 and 2, C. Sidgwick. 3, J. Garside, Longlands, Slaithwaite. *hc*, T. Walker, jun., Denton. *Cockerel.*—1, W. A. Taylor. 2, C. Sidgwick. *hc*, E. Brierley. *Pullets.*—1, J. Holt, Middleton. 2, J. Garside. *hc*, D. Lord, Stacksteads, Mancheater; Stott & Booth, Huntley Brook, Bury.

FRENCH FOWLS.—*Chickens.*—1 and Cup, J. J. Malden, Biggleswade (Crève-Cœur). 2, J. K. Fowler. 3, W. Dring, Faversham. *hc*, R. B. Wood, Uttoxeter. *Cockerel.*—1, J. J. Malden (Crève-Cœur). 2, R. B. Wood. *hc*, Rev. C. B. Rowland, Lighthorne, Warwick; W. Dring; J. Sichel. *Pullets.*—1, J. J. Malden. 2, C. H. Smith, Radcliffe-on-Trent (Crève-Cœur). *hc*, G. W. Hibbert, Godley, Manchester; R. B. Wood; Rev. C. C. Ewbank, Langford Vicarage, Biggleswade (Crève-Cœur) (2); F. Bennett, Shiffnal.

ANY OTHER VARIETY.—1, H. Beldon. 2 and 3, P. Unsworth, Lowton, Newton-le-Willows. *hc*, R. Loft, Woodmansey, Beverley (Sultans). *Cockerel.*—1, H. Beldon. 2, W. Fearnley, Lowton, Newton-le-Willows. *Pullets.*—1, H. Beldon. 2, P. Unsworth.

GAME BANTAMS.—1 and Cup, T. Sharples, Forcat Bank, Rawtenstall. 2, J. Eaton, Farnsfield, Notts. 3, J. Oldfield, Shibden, Halifax. *hc*, G. Maples, jun., Wavertree, Liverpool; T. Sharples. *c*, C. Moore, Poulton-le-Fylde, Preston; G. Hall, Kendal; W. F. Entwisle, Westfield, Cleckheaton. *Cock or Cockerel.*—1, G. Maples, jun. 2, Bellingham & Gill, Burnley. 3, Ellis & Buckley, Accrington. *hc*, Ellis & Buckley; W. F. Eotwisle; T. Sharplea. *c*, J. Crosland, Sheffield; W. F. Entwisle; T. Sharplea; J. Oldfield; E. & J. T. Hudson, Ulverston; S. Stephens, jun., Ebley, Stroud.

BANTAMS (Any other variety).—1 and 3, M. Leno. 2, H. Beldon. *hc*, J. W. Morris, Rochdale; J. Walker, Halifax; S. & R. Aahton, Mottram, Manchester. *c*, J. Sichel (Pekin Bantams).

SELLING CLASS.—1, S. Lord, Healey Hall Bottoms, Rochdale. 2, Withheld. 3, J. Mills, Mount Ending, Healey, Rochdale (Brahma). *Cock or Cockerel.*—1, C. W. Brierley. 2, E. Leech. *c*, J. T. Travis, Rochdale. *Pullets.*—1, C. W. Brierley. 2, E. Ryder, Hyde. *c*, J. Horrocks, Tonge, Middleton; A. Bumford.

DUCKLINGS.—*Aylesbury.*—1, E. Leech. 2, J. K. Fowler. 3, J. Tinsley, Warrington. *Rouen.*—1, Cup, and 3, J. Scotson, Little Byrom, Lowton. 2, T. Wakefield, Golborne, Newton-le-Willows. *hc*, T. Wakefield; J. K. Fowler; E. Leech, Rochdale. *Any other variety.*—1, C. W. Brierley. 2, M. Leno (Mandarin). 3, H. B. Smith, Brooklands, Broughton (Fancy). *hc*, H. B. Smith (Fancy) (2); S. H. Stott, Fishergate, Preston.

GOSLINGS.—1, J. K. Fowler. 2, J. White, Whitby, Natherton, Wakefield. *hc*, E. Leech; J. H. Stott (Toulouse) (2).

TURKEYS.—1, E. Leech. 2, T. Statter, jun., Whitefield, Manchester.

PIGEONS.

TUMBLERS.—*Almond.*—2, J. M. Braid, Cambridge. 3, F. Moore, Barnley. *hc*, R. Fulton, Deptford (2). *Any other variety.*—1, B. Consterdine. 2 and 3, R. Fulton.

BALDS OR BEARDS.—1 and 2, W. Woodhouse, Lynn (Bearda). 3, B. Coneterdine. *c*, R. Fulton.

CARRIER.—*Cock.*—1 and *hc*, R. Fulton. 2, J. Stanley, Blackburn. 3, H. Yardley, Birmingham. *Hen.*—1 and 2, R. Fulton. 3, H. Yardley. *c*, T. Waddington, Feniscowles, Blackburn; J. Stanley, Blackburn.

POUTER.—*Cock.*—1 and 2, R. Fulton. *Hen.*—1 and 2, R. Fulton.

BARBS.—1 and 3, R. Fulton. 2, S. Holroyd, Leeds. *hc*, T. Waddiogton.

TUBBITS.—1, R. Fulton. 2, E. C. Stretch, Ormskirk. 3, B. Conaterdine. *c*, T. Waddington.

JACOBINS.—1, R. Fulton. 2, T. Waddington. 3, G. South, jun., London. *c*, T. Waddington; R. Fulton.

FANTAILS.—1, J. F. Loversidge, Newark-on-Trent. 2, R. Fulton. 3, J. Walker, Newark. *hc*, T. Waddington; A. M. Yette; J. F. Loveridge; J. Walker.

OWLS.—1, B. Consterdine. 2, R. Fulton. 3, H. Yardley. *hc*, A. Ashton, Middleton (2). *c*, J. Stanley; B. Consterdine.

NUNS.—1, H. Yardley. 2, F. Graham, Birkenhead. 3, Withheld.

DRAGOONS.—1, J. Holland, Manchester. 2, G. South, jun. 3, F. Graham. *hc*, J. Holland; F. Graham; W. H. Mitchell, Moseley, Birmingham. (Whole class commended).

TRUMPETERS.—1, O. Percival, Manchester. 2, R. Fulton. 3, H. B. Smith, Brooklands, Broughton, Preston.

ANY OTHER VARIETY.—1, R. Fulton. 2, H. Yardley. 3 and *c*, T. Waddington.

SELLING CLASS.—1, W. Nottage, Northampton. 2, O. Percival (Blue Owls).

RABBITS.

SPANISH.—1, J. Holt, Heywood. 2, T. C. Lord, Huddersfield. *hc*, J. Irving, Blackburn (2); J. Boyle, jun., Blackburn.

ANGORA.—1, A. H. Easten, Beverley Road, Hull. 2, W. Dixon. *hc*, J. Boyle, jun. *c*, S. Greenwood, Hebden Bridge; S. G. Hudson, Hull.

HIMALAYAN.—1, J. Boyle, jun. 2, C. W. H. Tomlinson, Newark-on-Trent. *hc*, J. Irving.

SILVER-GREY.—1 and 2, S. G. Hudson. *hc* and *c*, S. Greenwood.

ANY OTHER VARIETY.—1 and 2, S. G. Hudson (Belgian Hare). *hc* and *c*, J. Boyle, jun.

SELLING CLASS.—1, 2, and *hc*, J. Boyle, jun. *c*, A. H. Easten; J. Renshaw, jun., Gale, Littleborough, Manchester; S. G. Hudson (Angora); J. Baron, Castlemere, Rochdale; J. Kemp, Haslingden.

Messrs. Hewitt, Dixon, and Fielding judged the *Poultry*, and Mr. Tegetmeier the *Pigeons*.

I FORWARDED two pens of birds in good time, but have learned that at the judging my pens were empty, and on the Committee making inquiries through the kindness of a friend who knew that the birds had arrived, it was found that they had not been removed from the box, and, in fact, were very carefully placed amongst the empty packages. My cause of complaint is, that the Committee have taken my entry money and have prevented my birds, which have taken prizes wherever shown, from competing, and this without in any way offering to return the entry fees, or apologising for the neglect. My best Jacobin has returned home to-day unwell, and in the event of its death I shall most certainly hold the Committee responsible for the loss, and shall also expect them to return the entry money and carriage of the birds. —GEORGE ROPER, *Croydon*.

[If the Committee cannot satisfactorily account for your Pigeons not being exhibited, they ought at once to return the entrance money. —EDS.]

PARASITES ON CANARIES.

[THIS is in answer to a correspondent, "C. L."]

UNQUESTIONABLY parasites are a great nuisance, but I think we who breed largely and have a greater or less visitation according to circumstances, think less of them than those to whom they are a comparative novelty. I can understand how their appearance in a small aviary can be traced to the introduction of a bird infested with them; but their simultaneous appearance in all the cages in a large room containing, say, accommodation for fifty pairs, must be attributed to some other cause. That they are parasites and originally proceed from the bird there can be no doubt, but that the birds are infested with them at any time, night or day, to the extent many suppose I very much doubt. Indeed, it is impossible that a tithe of the pests found in any single compartment could find a resting place on the body of any one bird. If a cage in which they have taken-up their quarters be examined by candlelight, they will be seen taking their walks abroad on the top, back, sides, inside, outside, everywhere; and they will be seen running over the feathers of the bird with an extraordinary activity which they exhibit at no other time. But I think that few or none will be observed during the day, either on the cage or on the bird; while immediately under it in the lining of its nest, or at the back of it, there may be a colony—a living mass of the pests, all huddled together and waiting for nightfall before they issue from their place of concealment. This has always suggested to me a mode of attack which I find quite adequate to the occasion. I search for their head quarters in a crack, under a loose flake of whitewash, in a corner in any retired place, and with a pretty strong solution of glue or paste, made thin enough to work easily with a brush, I concrete the whole fraternity, grind them, crush them up, work them up into a paste with the thick whitewash on the cage. After a visit of investigation paid to each cage, a careful examination of the ends of the perches and the places where these rest on the front cross-bar, or where they are connected with the wires, a scrape of a knife in every crack, and a general war of extermination, I find only a few stragglers the next night. Those I do find I just bruise against the cage. Some will be again seen on the bird, and according to the number so must the next day's search be. Those left will be looking about for a hiding-place all next day, avoiding the spots visited by the paste-brush, and falling easy victims to a quick eye. If the outside cracks are tenanted—and that can soon be ascertained by the white dusty appearance at the edges—nothing is better than simply applying the catch-'em-alive principle, by giving the place a touch of varnish. Like slugs in a garden they are easily trapped. A piece of paper an inch square, attached by three edges to the ceiling of each cage will trap thousands. Any such place they will at once take possession of, and then a judicious squeeze settles the business. I have heard persons say they will stand anything, delight in boiling water, and are very salamanders. But it is all stuff. If your cages are small immerse them in the kitchen copper.

I do not know what to say about their getting into the woodwork of a room. You know that it is an awful question to ask, and enough to frighten half the intending breeders for next season. My experience on that head is just this—When I was foraging for furniture for my bird-room, and laying violent hands on whatever stray articles I could seize, I confiscated, among other things, an old chair with a broken back, albeit a comfortable chair in which I spent many a happy hour among my birds, till I found that some string with which I had reduced a compound fracture of the back was swarming with the parasites. How they got there I do not know, unless by the ordinary mode of locomotion, for the chair stood in a corner remote from any cage. Sometimes I used it to stand on when doing anything to the top of my stack of cages, and it may be that some of the little nuisances dropped on it, and at once established themselves, and set about fulfilling one of the laws of Nature in right earnest. But I do not think there is much danger of their getting into the woodwork of a room. I never heard of its occurring. I have found one on my shirt-sleeve, but that has only been after a brush with them, and only last week the white *piqué* told my wife she had got them! But it turned out to be only an active little nuisance of another kind.

I do not know much of the qualifications of the Chaffinch as a song bird. His capabilities are much vaunted in some works, but of his song, pure and simple, or cultivated, I have no knowledge.—W. A. BLAKSTON.

WHITBY CANARY SHOW.

[THE following were omitted in our last.]

OF Messrs. Smith & Preen's Golden-spangled Lizards, and Mr. Ritchie's (Darlington) Silvers, the Golden-spangled birds were remarkably fine specimens, well moulted, in very forward condition, and were such as anyone might be justly proud of, showing great

quality with excellent caps and spangles. Mr. Ritchie's Silver hen was one of those birds the like of which is not seen every day. She might have been better capped, and she would be none the worse if the larger spangles were more defined; but taking her all-in-all she is a bird to make one's mouth water. The mottle on the neck behind the cap is such as is not seen in one bird in a hundred. Smith & Preen were also very highly commended in the Silver class; and on again referring to my notes, I cannot say positively whether it was their bird or Mr. Ritchie's pen which was rather cloudy. If I have been putting the saddle on the wrong horse I must be excused.

In Greens, Mr. Lawson, Saltburn, won by condition. The second bird (J. Stevens), was backward.

The "Any other variety" was a splendid class. Mr. Bulmer's first was a high-class Variegated Yellow Belgian. Messrs. Burniston were second with a good Evenly-marked Yellow Yorkshire; Moore and Wynn third with a Variegated-crested Cinnamon; and Mr. Hawman extra third with an Evenly-marked Cross-bred.

Variegated Mules were few, and with the exception of the first Jonque (Stevens), poor. Dark Mules were backward. The district entries showed a marked improvement on last year.—W. A. Blakston.

NATIONAL PERISTERONIC SOCIETY.

The first Show for the season of this well-known Society took place on the 19th inst., at the Freemasons' Hall. It consisted entirely of young birds bred this season, and, if we mistake not, we saw several future prizewinners. Here they do not compete for prizes, but after being well scanned by the members from 8 to 11 P.M., return to the same or another cote, none the worse in beauty of plumage and condition. For these the birds of the members of this Society are justly celebrated. Amongst the gems we noticed some grand Black and Dun Carriers from Messrs. Hedley and Ord; good pens of Blues and Silver Carriers from Mr. B. Ford, of Weymouth; a pen of very good Yellow Dragoons and Jacobins from Mr. Betty; a pen of the best Barbs we have seen for some time; also various other breeds from different members.

THE SATINETTE.

We now turn our attention to this most beautiful variety of Pigeon, although in so doing we depart somewhat from our proposed course; but having received numerous inquiries for a description of the breed, we deem it advisable to give the information we have and publicity to our opinions.

Satinette is the name by which the breed is distinguished in England, that name being given to them on their first appearance at our public exhibitions, and by that name they will be best known, therefore we adopt the name, which seems to us not an inappropriate one; but they are not known by that name in the East, whence they came. The Satinette is of foreign origin, and has not only been cultivated and perfected abroad, but, being so highly prized and so much admired, has been kept almost exclusively by those fanciers whose diligence, care, and skill have been the means of raising such charming little pets; for their own special amusement it may have been, but it will, doubtless, result in eliciting the high praise of all true lovers of the beautiful. To the Mahommedan Pigeon-keepers the credit of producing this variety is due. They seem to have pursued their study of Pigeons at least with a refined taste for the beautiful, such as it would be well for us to endeavour to emulate. The Satinette may be said now to be a native of Smyrna, a seaport town of Natolia, in Asiatic Turkey, but we believe the breed was originally propagated further east by an aged follower of Mahomet, who, alone and unaided, with untiring zeal in his efforts to establish these beautiful spangled Pigeons, prosecuted his study of the "sacred Dove" until perfect specimens of the kind were abundant in his flock, some of which were, as an especial favour, presented (about twenty years ago) to our excellent member and fellow-fancier, H. P. Caridia, Esq. They were taken by him to Smyrna, where he raised, distributed, and left many of the breed, bringing with him to England (sixteen years ago) the first (about twelve pairs) of the kind that were introduced into this country.

Of the exploits of this breed of Pigeons as prizetakers many fanciers are aware, for to exhibit them was to win. Indeed, no judge with a proper appreciation of either form or feather could pass them by without awarding the badge of merit, for, as will be seen by the accompanying illustration, the Satinette is a paragon of beauty.

This exquisite little Pigeon will compare favourably with any known breed in form and feather, and what the Sebright Bantam is among poultry such is the Satinette among Pigeons. The Satinette is a great acquisition to our English stock, and appears to have been appreciated by English fanciers. Large sums of money have been expended in their purchase, and the highest premiums have been awarded to them at our exhibitions, though the competition in the "Any variety" class is generally strong. We know of one pair that have been competitors at most of our public shows, and have won upwards of £60 in prizes. The scarcity of these birds, their delicacy of colour and constitution, and high value, are the primary causes of their not appearing more frequently at our exhibitions. By the importations that have been received recently by us the breed may become more generally known ere long.

The points of the Satinette are as follows:—The head is round; the beak short, strong, and flesh-coloured; the eye is large and dark; the neck is gently tapered, and well arched; the breast prominent, and a large frill must be well defined from the neck to the breast; the body small and compact; the legs and feet well feathered, and entirely covered to the nails; the carriage of the bird must be erect, and in most points of form bearing resemblance to the Owl. The head, neck, breast, belly, thighs, and lower part of back pure white; on the sides of wings, primary coverts, and saddle of back is a ground tint of a light and delicate pinkish brown, deepening in tone towards the edges of each feather, and terminating in a fine black fringe upon all the smaller feathers on the sides and shoulders of wing; the coverts, however, are not fringed with black at the edges, but they, in company with all the feathers upon which the brownish colour is visible, are distinctively marked with black spear points. Thus there is a variety of graduated shades of rich brown upon every coloured feather, bordered by a fringe of black, such as may be seen in the Hamburgh fowls. The tail of the bird is of a slatey blue colour, with a broad band of black at its extremity; in the centre of this band, and upon each of the twelve feathers of which the tail is comprised, should be a distinct and well-defined white spot (see accompanying sketch of feather, drawn half real size).

This peculiar feather is dissimilar to any other variety, and forms one of the chief characteristics of the breed. Fanciers can easily imagine the extremely beautiful and novel appearance of a flight of these birds. Unfortunately, we Birmingham fanciers may possess the birds in all their native beauty, yet must admire them within their loft or through the wires of the aviary within which they are imprisoned, for were we to give them liberty the sight would assuredly astonish the "flying fraternity" of our Pigeon-keeping town, and might lead either to the Pigeons or the flying fraternity "going astray."

The Satinette is very active on the wing, and in its native clime is said to fly long and well, and in compact bodies; but, as we have said, it has not been our lot to see many on the wing, still we have seen them at large, a few of which have entire liberty always with us, and undoubtedly thrive better for it. Satinettes are a delicate variety; they are good breeders, but bad feeders. The use of foster-parents of stronger constitution for the rearing of their young is advantageous, as they are too apt to desert their young, or only half feed them. Some will rear and raise their young well, but, as a rule, they are not to be trusted.

Satinettes are very changeable in their plumage. When young, and before their first moult, they are of a sort of mahogany colour pencilled with black, and certainly not very attractive at that period of their existence, but on the appearance of the first new feathers we acquire an idea of what we may expect when the entire body has suffered a similar change; the contrast in the colours becomes much stronger and the markings more distinct, and what might be supposed to be an inferior bird before the moult often developes into a grand specimen.

It may here be observed that Satinettes, like all other Pigeons, do not breed all perfect and true; some are foul-feathered, some are clean-legged, some have poor frills, others have flat heads, but in all of them there is clearly traceable the one distinct and highly meritorious breed of Pigeon.

There is of the Satinette family a very beautiful sub-variety which they occasionally breed, and by some fanciers these offshoots may be preferred to the Satinettes themselves; they are called Brunettes. They have a light pinkish brown plumage,

with similar markings to the Satinette, but of a much lighter and more delicate colour, there being no black or bluish cast, such as is seen in the Satinette, but in general appearance they present a regularly dappled marble aspect. These birds show all the excellencies in form, carriage, &c., but the markings are not so strong and conspicuous. The Satinette proper has a plain head, but there are some of the variety that have crested heads, and they, too, are very attractive, and by many would be chosen in preference to the Satinette. Those peaked or crested are now all the fashion in Smyrna. They have, no doubt, been raised by judicious crosses between the Satinette and the Pencilled Turbit of the same country, which is scarcely less beautiful.

We could say much more in praise of the Satinette, but with a few words as to food we will now conclude. The climate of Turkey is excessively hot; in consequence the birds there feed on hemp seed alone, but fanciers of the breed in this country must not follow out that as a staple food. Occasionally hemp seed is useful and necessary, but to feed on that alone in this country will result inevitably in death. Vetches, small Indian corn, buckwheat, and old English wheat, with an occasional sprinkling of hemp seed, will be found to suit the constitution

of the Satinette very well. Care must, of course, be taken to prevent an over-gorge; never suffer food to remain unconsumed from one meal to another; keep your birds with a keen appetite, or the sudden change from greasy hemp to the more substantial grain may prove too much for their digestive powers; feed moderately; give clean water daily, and keep the birds warm and dry always. If these precautions are adopted we see no reason why the Satinette may not be in profusion amongst us.—Birmingham Columbarian Society.—*J. W. Ludlow, Secretary.*

LIGURIANS IN JERSEY—THE HONEY HARVEST.

I no not purpose now to give any account of what my stocks have done this season, but I wish to bring before the notice of your readers a somewhat curious circumstance in connection with my bees.

Out of four stocks of bees I have two pure Ligurians, and these are, as far as I know, the only stocks in the island. What was my astonishment, then, on going to drive a hive about a mile distant, to discover a number of Ligurians living peaceably with the blacks. I looked to see if any of the adjoining stocks were Ligurians, thinking I might possibly have lost a swarm without knowing it, for I was absent from home when my bees swarmed; but a close scrutiny proved that this was not the case.

A few days afterwards I went to drive another hive, distant just two miles in a bee line; again I was surprised to find a considerable number of Ligurians living in it in company with the black inhabitants. In this case also I looked to see if any of the adjoining stocks were Ligurians, but they evidently were not. Since this an apiarian friend went to drive a hive somewhere else, and found Ligurians in that also. It would seem as though all the black stocks within two miles of mine have Ligurian bees in them, all of which must evidently have deserted from my hives. All these hives were either in the midst of or near to the heather, but I am distant about a mile from it.

The honey harvest here has been decidedly good, better than for several years past, though up to the end of June the bees had made little or no honey. Yesterday I weighed a hive tenanted by a swarm of this year; it contained at least 45 lbs. of honey, and this is a fair sample of what strong stocks have done here this year. This is strange, as the honey harvest has been so bad elsewhere; but in the summer of 1868, so favourable in many places, stocks here grew lighter after the middle of June instead of getting heavier. The honey, however, owing perhaps to the wet season, seems much thinner than it was last year. Can any of your correspondents tell me if the neighbourhood of Bishop Auckland, Durham, is favourable for bee-keeping?—D. N., *Cantab.*

OUR LETTER BOX.

Market Drayton, Northallerton, and Stokesley Shows (*H. P. and others*).—As the Committees concluded they were not worth advertising, we do not consider them worth reporting.

Black Hamburghs at Bingley Show.—Mr. C. Sidgwick took both first and second prizes, we are informed.

Chickens Dying (*Inquirer*).—You do not give us data enough to frame an answer. You begin with a string of questions, so will we. How old are they? Where do they roost? Is the hen at liberty? Have they access to grass? At what hour are they fed in the morning? At what age are they attacked with the disorder? Have they a grass run? If they have not, what are the artificial appliances resorted to? While you await your answer, dose them plentifully with bread and ale, and let them be fed at daybreak.

Wheaten Bantams (*J. F. C.*).—They have lighter, that is, more golden hackles, and breasts the colour of a newly-gathered corn of wheat. The rest of the colour is that of a Black Red. The eyes of Game or Black Bantams being perfect in sight are not important. It is, however, imperative that all should be alike. A Black Bantam should be small in size, have a firm double comb, a purely white deaf ear, and blue legs; the tails should be scanty, and carried rather drooping than otherwise. The sickles cannot be too long.

Breeding Black Hamburghs (*Black Hamburgh*).—We know no breed of black fowls in which the cock is not subject to coloured feathers. They are generally red, and are to be found in Spanish, Polish, and all others. Black Cochins were discarded for this reason. Black Hamburghs are manufactured, and some of their component parts will creep out. We would not breed from a bird that had coloured feathers in his body, but we should not hesitate because of three or four in his hackle. We have no doubt you can select an exhibition pen. You must not be discouraged, but must recollect it takes some time to establish a breed.

Spanish Cock's Face (*M.*).—If your Spanish cock has not naturally a white face you cannot make it white. If a Spanish cock has not a white face at seven or eight months old he never will have one, and as an exhibition bird is worthless.

Black-breasted Red Bantam Cock (*Far West*).—The white down is not desirable, but it is not important. The brown feathers on the breast merely prove he is a Brown and not a Black Red. The drooping of the wings is a grave fault, and if you have other birds to choose from take one free from it, rather than breed from the bird you mention. The red feathers would disqualify in a class where the competition is confined to Black Reds.

Chickens Becoming Blind (*E. H., Reigate*).—Your chickens have the roup. It may have been caught from the mother, or it may arise from insufficient feeding or from a bad locality. Chickens at this time of year want much more attention than those that are hatched earlier. The nights are getting longer than the days, and every day the temperature is lower. Now, to be successful in chickens it is necessary they should be fed at daybreak always, at this time of year soon after half-past five. When there is a very heavy dew or white frost the chickens, after being fed, should be driven back into the rip with the hen—feed her also, that she may rest satisfied—and not allowed to run about till the sun is up and the grass is dry. Reflect for a moment. At 6 P.M. the chickens are at roost. If they are fed at what is called first thing in the morning, which is now about seven, they have been thirteen hours without food: there is neither growth, health, nor strength in that. If you have named all the food you give it is not enough. It would not be enough in May or June. At this time they must be fed as in January and February—chopped cooked meat, bread and ale, boiled egg chopped fine, grits, bread and milk, dough, and they should have beer to drink. As the atmosphere falls in temperature the food must be more generous. We doubt whether you will save any of the brood, but you must put them at once on bread and strong beer. If their house or the place in which the rip is put have a wooden, stone, or brick flooring, either will cause the complaint from which the chickens are suffering. If the hen is allowed to run about with the chickens, that may be the cause. At this season of the year it is better she should be shut up.

Weight of Buff Cochin Cockerel (*Lemon Buff*).—The cockerel, five months old, weighing over 8 lbs., is very heavy. One pound per month is good growth and weighing. Yours has made more than 1½ lb.

China Geese (*A. W.*).—It is a very common thing for people to praise things that are given to them. They would be ungrateful if they did not, and would forget the old adage, "not to look a gift horse in the mouth." If you want to test the value of birds, sell them. That was our experience of them. They made great weight, but not good meat. Our opinion is that the domestic Goose is the best table bird of the tribe, and that of these a real stubble-fed one is again the best. It is many years since we saw any Swan Geese, and we believe the true breed has disappeared. We have them in an old painting. They not only have long taper necks, but they have not the yellow knob. Goose eggs are excellent, but they require to be eaten fresh.

Plumage of Cinnamon Cochin Cockerel—Silver Buff (*A Constant Subscriber*).—There are two colours for Cinnamon Cochin cocks. One is all over the colour of a piece of wetted cinnamon; the other is a French white, with splashes of dark gamboge all over the pinmage, especially the hackle. The term Silver Buff is a mistake, it should be Silver Cinnamon. There is no such bird as a Silver Buff. The hen should have a French white body with light, nearly white, under feathers. The hackle should be a very dark yellow, like the colour of gamboge, before it is rubbed.

White-crested and Spangled Polands (*A. Wylie*).—Mr. Vivian, of Swansea, used to show them, and they were common in France as white "Padoues." We have seen many of them. They should be bearded, and should have neither wattles, horns, nor spikes. The same rules apply to Spangled Polands. All Polands are subject to what one of their great admirers, who objects to the term hump-backed, calls "curvature of the spine."

Consequences of Non-prepayment.—I request you to publish this further information respecting the man Ellison. I applied to the police concerning him, and their answer was that he is well known, and that his real name is Kilshaw, and that I must get a warrant. I have since received a letter addressed to a gentleman in Lancashire, from Eastham, Cheshire, and signed "R. Tomlinson." The letter is exactly the same as mine in writing and style, only in deeper mourning! The publication of my letter in your columns warned this gentleman in time.—Fred. Temple Hillyard, *Southam, Warwickshire*.

Crossing the Wood Pigeon with the Domestic (*Cressy*).—This has often been attempted, but never, so far as we know, with success. It is impossible to make the wild birds return for long to a Pigeon house. Mr. Brent had a hen Wood Pigeon which paired with a cock Dragoon, but they had no young.

Pigeon Trimming at Allerton (*Examiner and others*).—We cannot insert more on the subject.

Canaries Fighting (*J. H. B.*).—Nothing but separating them will put a stop to the planting, but you can try whether two or more of the most peaceably disposed will live together quietly.—W. A. B.

Rabbit with One Eye Blind (*Edith*).—The blindness of a Rabbit is often caused by exposure to cold air. The appearance presented by yours suggests bathing the eye with warm milk and water. Keep the Rabbit warm, the hutch clean and free from the smell of ammonia as much as possible. Should this fail, consult a veterinary surgeon. We do not think it infectious, yet for the sake of quiet it will be advisable to keep it alone for a while. Give carrots, turnips, oats (crushed), a little bran, no beans, but little green food, and that never wet.

Chameleons.—*A Constant Reader* wishes for information upon the feeding and keeping of chameleons in a fernery during winter.

Mr. Henry Lane died on the 16th inst., at the age of 45. He had only been ill a week of gastric fever. He was one of our earliest breeders of Spanish fowls.

REMARKS.

20th.—A dull, cloudy, and cold day, except for a short time in the after noon, but I suspect much finer in the country.

21st.—Fine all day, but rather chilly at night.

22nd.—A very fine day, but with quite an autumnal temperature.

23rd.—Fine morning, but getting gradually more and more cloudy till 3 30, when slight rain began to fall, and continued getting rather heavier till midnight, about which time it rained very heavily, nearly an inch having fallen between 9 P.M. on Saturday and 9 A.M. on Sunday, the greater portion having fallen between 12 and 2.

24th.—Rather dull morning, but quite bright and fine in the afternoon.

25th.—Fine in early morning, but began to rain soon after 3 P.M., and continued till midnight.

26th.—Fine in morning, but cloudy and cold after, and during the middle of the day very dark, but brighter towards evening; fine night, lunar halo at 10 P.M.—G. J. Symons.

COVENT GARDEN MARKET.—September 27.

Supplies have been moderate throughout the week, with a steady demand. Spanish and Jersey Grapes are coming to hand in considerable bulk, prices ranging from 9*d.* to 1*s.* 6*d.* per lb., but none have keeping qualities. Good hothouse Grapes, both Hamburghs and Muscats, are sufficient for the trade. The Potato trade is heavy at former prices, supplies being large both by rail and water.

From observations taken near London during forty-three years, the average day temperature of the week is 69.7°, and its night temperature 47.1°. The greatest heat was 80°, on the 5th, 1834; and the lowest cold 25°, on the 11th, 1860. The greatest fall of rain was 1.08 inch.

THE ROSE SEASON—ROSES.

THE first bloom of Roses this year and last was the finest floral sight that I ever saw. A few Roses at first bloomed abnormally. A line of twelve Duchesse de Caylus, for instance, had all green centres or hard blooms that did not expand. I have had only one tree, Céline Forestier, a lofty tree on the south frontage of my house, slightly affected with mildew; but many of the trees have suffered sadly from orange fungus; all, however, are now freshly foliaged, and many are blooming well. It broke out as soon as the foliage appeared in spring. It was so general that I did not, as I usually do, remove the affected foliage with a pair of scissors in order to burn it. To have done so would have injured the health of the trees more than the fungus did. Injured lungs are better than no lungs at all. As many spores must have dropped round the plants, and perhaps taken hold of the bark, I mean, after the season is over, to lime the ground, cut back the plants a little, remove useless shoots, and sponge the remainder of the plant with vitriol and water, about 2 ozs. of vitriol to 3 gallons of water, which is strong enough to burn the fungus without injuring the bark. It is troublesome work, but a rosarian will not mind that. A rosarian and a mere possessor of Roses are very different persons.

I sowed a great portion of my Rose ground in August with Early Stone Turnips, which I shall in due time chop up and dig in. I shall manure the trees with nitrophosphate, instead of with horse and pig dung. No manure is so favourable to fungoid diseases as raw horse dung. If applied it should lie on the surface of the ground all winter, or be scalded before application.

As the catalogues are long and would bewilder novices, I must ask the Editors to kindly publish the following selection from the autumnal families. I must omit some beautiful Roses as being bad growers, though they are marked in the catalogues "Vig."

Hybrid Perpetuals.—Abel Grand, Achille Gonod, Alfred Colomb, Anna Alexieff for poles or walls, Antoine Ducher, Baron Adolphe de Rothschild, *Baron Chaurand, Baronne Prévost, Black Prince, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Comtesse de Chabrillant, *Comtesse d'Oxford, Dr. Andry, Duc de Cazes, Duchesse de Caylus, Duchesse d'Orléans, Duke of Edinburgh, *Edward Morren, *Elie Morel, *Elisa Boëlle, *Empereur de Maroc, Felix Genero, Fisher Holmes, François Lacharme, Général Jacqueminot, Gloire de Ducher, a grand Rose; Gloire de Vitry, John Hopper, Jules Margottin, John Keynes, Lady Suffield, a beautiful Rose; La France for a conservatory (it soils in foul weather out of doors), La Ville de St. Denis, not yet beaten in its colour; Leopold Premier, Lord Clyde, Lord Macaulay. The following all have the prefix of Madame, I shall only put Madame to the first. Madame Alice Dureau, Boll, Boutin, C. Crapelet, Charles Verdier, *Chirard, Clémence Joigneaux, Emile Boyau, Fillion, Jacquier, Julie Daran, Knorr, La Baronne de Rothschild, Rivers, Victor Verdier, Vidot. Mdlle. Annie Wood and Mdlle. Marie Rady, *Marquise de Castellane, Maréchal Vaillant, Maurice Bernardin, Marguerite de St. Amand, *Perfection de Lyon, Pierre Nottiug, Prince Camille de Rohan, Prince de Portia, Princess Mary of Cambridge, Sénateur Vaisse, Sœur des Anges, Souvenir de Poiteau, Souvenir de Dr. Jamin, Souvenir de la Reine d'Angleterre, a splendid autumn Rose; Souvenir de W. Wood, Triomphe de Caen, a fine dark bedder; Triomphe de Paris, Victor Verdier, W. Griffiths, and Monsieur de Montigny, blooming finely now, and the healthiest of all the Hybrid Perpetuals. I have seventeen plants of it. It never suffers from white or orange fungus. Cranston only keeps it. It is one of the finest of all the large Roses.

Those marked with an asterisk (*) are splendid Roses of late introduction. They are of fine growth and foliage.

Bourbon Perpetuals.—Baron Gonella, Baronne de Maynard, Marguerite Bonnet.

Bourbons.—Acidalie, Souvenir de Malmaison; Sir J. Paxton for poles, it is a fine corymb Rose.

China.—Mrs. Bosanquet.

Macartney.—Maria Leonida. It is distinct and most beautiful. Its colour is fleshy white, with vermilion stamens. It is not a show Rose.

Noisettes.—Céline Forestier, *Rêve d'Or, new, distinct, and choice; Solfaterre, a wall; Triomphe de Rennes, Maréchal Niel.

Tea.—I do not recommend Tea Roses to beginners, except the two first-named; they are both very hardy. Gloire de Dijon, Sombreuil, Adam, Devoniensis A1, Madame Margottin, *Madame Trifle, Madame Willermoz, Souvenir d'Elise Vardon (first-rate), Souvenir d'un Ami. For conservatories: Elise Sauvage, Vicomtesse de Cazes, and Madame Bravy.

I conclude with a few observations. The reader cannot burn his fingers with any of the above Roses. I have put in none but hardy, free-growing, and free-blooming Roses. I regret to leave out three beauties as bad growers here—namely, Marie Baumann, Marquise de Mortemart, and Lacharme's Louis Van Houtte. Mr. Turner kindly gave me Granger's Louis Van Houtte; it is here still, and a good grower, and quite distinct; but as a flower it is not so good as the novelty. I saw a whole line of Lacharme's Rose at the Dorset Nurseries, Blandford. The rate of growth of the whole line was miserable. It had better be tried on its own roots; for I have known Roses grow well on their own roots that would not grow at all on alien stocks. Louis XIV. is an instance of it—a Rose that has never been approached in its colour. Charles Wood is like it, but it is not always a free-bloomer. I saw these in long lines at the Dorset Nurseries; the plants were very fine, the foliage and flowers excellent: Marquise de Castellane, Comtesse d'Oxford, Rêve d'Or, and Baron Chaurand. The first is a grand Rose, and the last is a great beauty—deep scarlet crimson, shaded with blackish maroon. The place to judge of new Roses is the nurseryman's garden. Till Roses are put on strong and suitable stocks we cannot judge of them. Roses also that will do wonders under glass are often worthless out of doors. I never pay any

attention to "certificates" till I know this point. Bacchus was a misery out of doors, but grown under glass it was of good size, full, round, and radiant with fine growth and broad healthy foliage.—W. F. Radclyffe.

SEDUM FABARIA AS A BEDDING PLANT.

It is a long time since I have had the opportunity of recommending a more useful plant for general purposes than Sedum Fabaria, known also to some as S. spectabile. It has a highly decorative effect in any place, but as a bedding plant it is singularly beautiful. My first idea of using it as a bedding plant was prompted by my seeing it last year employed by Mr. Robson, of Linton, as a vase plant, and as such it was very attractive. I forget whether or no he has used it as a bedding plant; if he has done so he will, perhaps, be able to state more accurately its qualities than I can do. This Sedum has never failed to attract the attention of the many visitors to these gardens, and when its good qualities become better known I venture to predict for it a bright future.

For those who may wish to try this plant for next season, and yet do not know how to obtain a stock of it (I allude to amateurs), I will just state that I purchased six plants last autumn, which I think is the best time to buy, and it being a hardy herbaceous plant, I kept them in a cold frame all the winter in pots. At the beginning of February numerous small shoots made their appearance; I then took the plants into the greenhouse, where they grew fast, and when the shoots were long enough to furnish cuttings with two joints, I propagated all I could get. These soon rooted in the house although only under a hand-light, and when long enough, each afforded a cutting. Thus I soon had as large a stock of plants as I required. All were potted off singly in 4-inch pots, as they became established they were turned into a cold frame, and before the end of March the most forward were standing out of doors without the slightest protection.

Any common soil does for this plant, and, being hardy, it may be planted in the beds as early as these can be prepared. The first year the plants may not exceed 1 foot in height, nor at any time does the plant, to my knowledge, greatly exceed 18 inches in height; but in the second year, through the stools increasing in size very much, I have seen two-year-old plants 2 feet or more in diameter, but no higher than I have stated, and every shoot produces a large and broad rosette of pink flowers.

No supports are needed for the shoots of Sedum Fabaria, and it has fine foliage; it has also a very compact form of growth, and is altogether a desirable plant for everyone who grows and loves flowers. If it has a fault for bedding purposes it is that of flowering late, September being its usual month—a very desirable time with most people; but even without its bloom its appearance is so distinct as to be as attractive in that way as many sorts of plants are even when in bloom, so that no disappointment can arise as regards the plant's growth.

When the plants die down in autumn they may be left in the bed, or taken up and stored away in dry soil in the same way as Dahlias. Like most of the genus it is an admirable rockwork plant. It is so employed at Battersea Park and other places, but I have not yet seen it bedded out. It is also a capital decorative plant for the greenhouse and conservatory. I have this season met with it used as such, and have heard it spoken highly of by everyone. Like most of the genus it thrives admirably in dry weather. I advise everyone who has room for a flower of any sort to grow this plant.—Thomas Record.

PREVENTING THE ONION GRUB.

When I entered upon my present charge, more than thirteen years ago, I was told that Onions could not be obtained by spring-sowing, as the Onion grub carried all off, and I very soon found this to be too true. I tried many things which I thought preventives, but did not succeed. At last I adopted the following system:—Early in the autumn I point-in good rotten turf; as soon as the ground is frozen sufficiently to carry the barrow, I stretch a line down each side of the bed and cover the whole of the bed with dung to the depth of 1½ inch. The dung used is from the old hotbeds. I prefer decayed cow dung, but this I cannot get, as it is all carted to the farm. The ground lies thus till the second week of March, when I usually sow, weather permitting. The rake is taken to break all lumps that may not have crumbled-down with the frost. I then tread the ground quite firm, sow upon the dung, and give a slight covering.

This method I have practised for the last eight years with the greatest success, as we are never without Onions all the year round. The varieties which I employ for spring sowing are—White Portugal, Brown Globe, James's Keeping, Bedfordshire Champion, and Nuneham Park. The last-named does not keep well, but produces fine bulbs. For the autumn sowing I use the above-named, also the Madeira and Giant Rocca. By sowing the White Portugal in August and plantint it out in March, it keeps longer than any other, the bulbs being ripened under a more powerful sun.

To those who are not troubled with the Onion grub this paper will be of no interest, but to some of your readers it may prove useful. To those who have not grown Veitch's Giant Autumn Cauliflower, I say, Try it, and you will find it everything that can be desired. It more resembles the Broccoli than the Cauliflower, in the grandeur and colour of the leaves, producing giant heads, close and firm as a board. I have exhibited it at three shows this autumn, and each time have carried off the palm.—A. S. O. H. C.

HYDROCHLORIC ACID NOT A SOLVENT OF SILICA.

Mr. James A. Whitney makes the assertion that hydrochloric acid is a solvent of silica. He states that hydrochloric acid is produced in the soil by the decomposition of salt, and that the acid so formed, "acting on the sand grains, dissolves the silica and insures the greater per-centage of this element, which analysis of the ash has shown to exist in the straw of the grain grown on salted, sandy land." Salt in the presence of iron is decomposed, chloride of iron formed, and the sodium liberated becomes caustic soda, which is a solvent of silica. It is the soda, not the salt, which does the work. Hydrochloric acid has no action on silica, but it has on silicates. The East India cane is not covered with silica, but with a silicate, and the action of hydrochloric acid, like all acids, is on the base.

"There is no acid, except fluoric, which can directly dissolve dry or calcined silica."—(*Ure.*)

"Native silica, whether crystalline or amorphous, is insoluble in all acids, except hydrofluoric."—(*Watt's Chemistry.*)

He states that, when salt is decomposed in the soil, the chlorine combines with hydrogen, forming muristic acid. When water is combined with chlorine in the dark, as under the surface of the soil, it will remain as chlorine and water; but in the presence of strong light, or at a very high heat—red heat—hydrochloric acid is formed. When hydrochloric acid comes in contact with a silicate of iron, the acid is itself decomposed, a chloride of iron is formed and the silica is set free. Hydrochloric acid, potash, and silica are easily made to combine; but pure hydrochloric acid and pure silica never. He states that hydrochloric acid is one of the most powerful solvents of silica known in chemistry. This is a gross mistake. Hydrofluoric acid and the alkali are the great solvents of silica.—Thomas Taylor, *Washington, D.C.*

RENDLE'S PATENT PORTABLE PLANT PROTECTORS.

I have noticed a letter in your publication of the 28th of September, signed "Au revoir," telling how unsuccessful he has been with the plant protectors introduced by me. I have been quite prepared to hear of some failures, because although the protectors are so simple, yet, like everything else, they require management and attention.

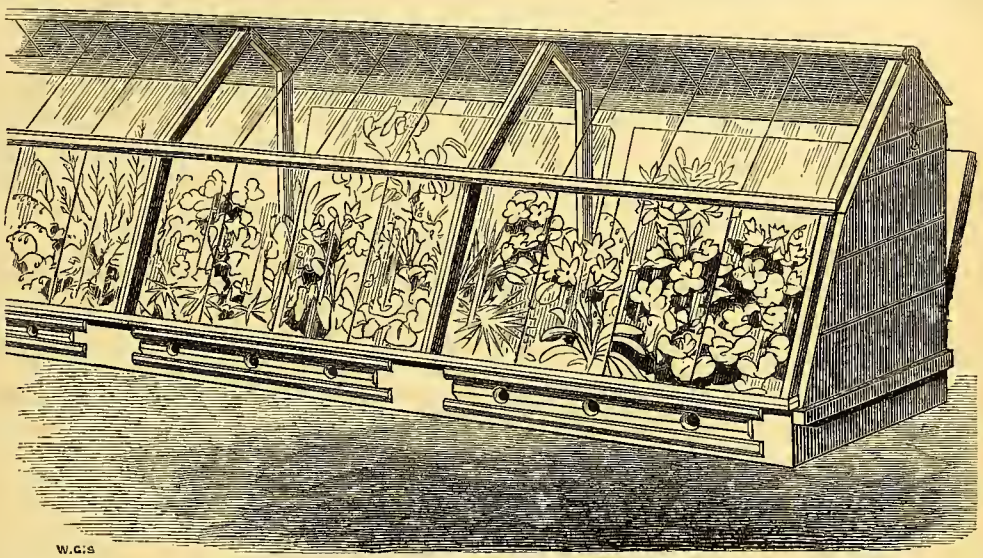
"Au revoir" will, I have no doubt, be surprised to hear that a most excellent gardener who worked them thoroughly all through the last severe winter, obtained three crops of Lettuces and Endive out of them. The first crop was ready by the middle of December, and as the plants were cleared away, they were replaced by others taken from store pans, and so a constant succession was kept up. Your readers will remember that we had a very severe winter, more than 25° of frost. In fact, the protectors have done more than I ever expected them to do. I never dreamt that they would be used for winter culture. I merely intended them in the first instance to protect the plants from the cold and frosty nights of spring. At the time these Endives were being supplied to the table they were worth 9*d.* each in London. Taking the Endive, therefore, at its market value, the protectors were paid for the first season.

I can show a letter from one of our most eminent horticulturists, who is at the head of a ducal establishment, in which he states that he had shown my little glass houses to one of our princes; and I can also show a letter ordering a large quantity of protectors to be sent to His Royal Highness after seeing their value.

In the spring of last year I had the honour of sending to Enville, the residence of the Earl of Stamford and Warrington, more than 500 feet of the protectors. They were used with great success all through the spring of 1870, and they answered so well that on the 28th of May I received a letter from Mr. Edward Bennett, the well-known gardener at Enville, who states that his lordship was so much pleased with the protectors that he wished to have 500 feet more. Mr. Bennett thoroughly worked them all through last winter, and had his Peas three weeks earlier than usual, and on the 23rd of August last he wrote to me, saying—"The more I see and have to do with your protectors the more I am convinced of their utility, and I strongly recommend them to everyone." Mr. D. T. Fish only last week wrote to me and said, that he had the protectors now in full swing for Lettuces, &c., and that they had proved most successful.

I could give dozens of similar examples of complete success.

"Au revoir" says "The protectors are liable to be blown down by the wind." This is from mismanagement and carelessness. The examples exhibited by me at the International Exhibition have been there since the 1st of May, and I do not think a brick has been displaced or a pane of glass broken. In the spring I saw several hundred feet at work at Belvoir Castle, and although they have been at work all through the winter, I did not see a single brick out of place. "Au revoir" refers to his wife; perhaps he has some children also, who have been "playing at houses," and other tricks, whilst he has been hard at work in the city.



W.G.S

Again, "Au revoir" says that the plants are liable to draw. Wrong again; mismanagement again. If the plants draw he does not give sufficient ventilation. He can open the bricks at pleasure, and leave large or small pigeon-holes as he likes. Both complaints are absurd and frivolous; but there are some people in the world who will find fault and grumble if they do not exactly understand what they are about.

I have never despised or found fault with the dear old wooden ground vinery; indeed, in some things I think it is most useful. There is quite room enough for all. My protectors will, I am sure, introduce a new system of gardening, and you will see that some of our foremost men are already finding it out. They are intended for large establishments for protecting our early and valuable vegetables from the cold and frost of winter and spring, and are not, perhaps, so useful in small suburban flower gardens such as that belonging to "Au revoir." If your correspondent wishes to make a choice present to his wife, let me recommend him to have one of the Rev. H. Bréhaut's "lawn conservatories," of which the accompanying is a representation. She will be able to lift it from one part of the garden to the other with ease.—W. Endcumbe Rendle, 3, *Westminster Chambers, S.W.*

THE FIRST CHIPPENHAM FLOWER SHOW.

I have often wondered, during my fifteen-years residence near Chippenham, that the town had no flower show, or, as those "high fallutin" writing gentlemen, the reporters of county papers, prefer to call it—"a floral fête." Trowbridge, by no means an inviting-looking town, with its blue-dyed filthy river, obnoxious to eye and nose, has long had its flourishing show, to which Chippenham people go by hundreds every year. Then, out-of-the-way Malmesbury (all towns are necessarily out of the way that are ten miles from a railway station—a great pity this in regard to Malmesbury, with its beautiful abbey ruins and market cross), yes, even out-of-the-way Malmesbury has also its prosperous show, and on its show-day this year lines of carriages made my village lane gay, almost noisy; while Chippenham, easy of access on all sides, with railways to London, Bath, Salisbury, Devizes, and Calne, with these lines branching out into others, is the very place for a flower show, to say nothing of a cluster of parks all round, where there must be gardens and gardeners. Then the place—"though I say it, who, perhaps, hadn't ought"—is very attractive in appearance, is it not? Let Charles Kingsley answer this question. In his "Madame How and Lady Why," in the chapter entitled "Homeward Bound," he says, "Now we shall run downhill for many a mile, down the back of the oolites, past pretty Chippenham, and Wootton Bassett, towards Swindon spire."

But, in spite of all these advantages, "pretty Chippenham" remained without a flower show, although it sends hosts of young people especially, generally in pairs (curious circumstance that!), to the Bath shows. It is, however, said that once in older days there was a flower show held at Chippenham; at least, when a couple of old inhabitants get together they are given to talk of the show in old Squire Neeld's time. But it was held—oh, the horrors!—in the Town Hall, and the ladies' skirts, although it was long before crinoline days, knocked over the flower-pots and damaged the flowers, and exhibitors said "they'd never send their plants any more." Then the hall was so hot that the stout perspired, and the fat were fagged out, and the thin fainted; and so it came to pass that a flower show at Chippenham became a memory—an unpleasant memory, and nothing more.

Thus it remained until late last June, when, asked by a few residents, the Mayor convened a meeting to establish a Horticultural and Cottage Garden Improvement Society. This meeting was very thinly attended; almost everybody had, it

seemed, something else to do that evening. There was, indeed, the Mayor—a mayor and a half of most mayors, a fine, tall, broad, rosy-cheeked, and kindly-minded west-countryman; but he complained of the fewness of those present, and said he was surprised that no more people came when the object of the meeting was so undeniably excellent. The tidings of the thinness of the meeting spread to a waggish friend of mine, who wrote, "Your flower show does not seem to flourish." But beginnings are seldom to be trusted. Thus, what a small beginning has many a wide rolling river; and what a bad beginning many people have who have a good ending, notably doctors. There are no men who more worthily, more quietly, and more thoroughly respectably discharge their professional duties, and fill their place in the world, than medical men—if anything, too quietly and too unostentatiously, letting those talking lawyers take a place above them. By the way, I am glad to read of another doctor made a baronet, for it is a profession not sufficiently honoured. But to return; how very badly the medical profession begins. Think of that queer, noisy, loudly-dressed genus—medical students. I have known them all my life, and a short time since saw a group inside the court of old Bartholemew's, tossing up their hats and cheering at their sucess at a recent examination. They were just what they always were, for the most part funnily dressed, funny fellows, some fops, some the reverse, all, or nearly all, decidedly queer dogs; and yet these will presently become quiet, orderly, do-their-duty, hard-working medical practitioners. I might notice other beginnings, but enough.

To go on with our Chippenham flower show. That very small beginning, that very sparsely-attended meeting, did a great deal. (N.B.—If you want work done, don't have many to do it; a small committee does most, and you know the proverb, "Many cooks," &c.) It was decided that there should be, come what might, a Chippenham Flower Show and Cottage Garden Improvement Society. Then it was also decided that it should include all the parishes in the Chippenham Union—that is, about thirty parishes. This was a wide decision, for if you want a horticultural society to prosper, and a cottagers' improvement society to do good extensively, let it embrace a district surrounding a town. Then there was a very excellent device hit upon. All the clergymen of the thirty parishes were elected Vice-Presidents; that secured the support, influence, and co-operation in each parish of its incumbent, and—— secured also thirty subscribers. Then this little meeting revealed to us an excellent Hon. Secretary, a stranger almost, but one who knew what to do and did it. Besides the clergy, all other men of position, lords, squires, and professional men were asked to become Vice-Presidents, and the member for the borough to become the President, and so by next meeting a nice £100 or more was subscribed. A good working Committee was appointed, business men being lovers of a garden, and the leading nurserymen. You want in such cases business heads to manage, as well as hearts that warm towards a garden.

I have entered somewhat minutely into details, and shall enter thus into further details, because I can well fancy that some who read this paper will be wishing in their neighbourhood to do next year as we have done, so I want this article to be such as can be referred and be a guide to such persons.

To return. One thing, we all at that little meeting promised to do—try to do all we could in every way to forward the object in view, to procure copies of rules for our guidance, &c. So "Wiltshire Rector" wrote to one of his "old Gooseberries." The Editors of this Journal gave themselves that name, and frequently refer to it, so evidently they like it. Well, one of the "old Gooseberries" answered, "We have first-rate rules for flower shows, and we lend them to ignorant parsons." "W. R." had a great wish to squeeze that "old Gooseberry" very hard for his sauciness, only he could not put out his arm quite a hundred miles; in fact, he wished to play "old Gooseberry" with him. However, some people's deeds are a great deal better than their words. So it was in this case; or, perhaps, it was the other old Gooseberry who caused those excellent rules to be published in the next week's Journal—viz., that for July 20th. This is a great boon, for there are those capital rules to be referred to at any time, and used by all needing their assistance. Armed with these rules I went to the next meeting, where, aided by them, we drew up rules locally suitable, for circumstances and localities differ somewhat. The "old Gooseberries" promised and sent a number of their useful manuals as additions to the cottagers' prizes. Specially did I plead for children's prizes—*e.g.*, for the best nosegay of wild flowers, for British field Ferns, &c.

I pleaded for children's prizes for this reason. There are just a few years in human life when a taste is created, or a bent is given—from about ten to fifteen. Before, children are too young, and then after fifteen life's duties and life's work lay their stern claim upon us all, when a taste can scarcely be given, but may be cultivated at spare hours and give great delight, a pleasure none can prize sufficiently highly. Thus a lad learns in those years to handle a cricket-bat, and gets to understand the game and plays a match or two, and the taste is set. But the boy grows, and that great youth-swallowing London receives him. He yearns at times for the country, specially on bright spring or summer mornings. He longs as a Swiss does for his mountains. He thinks of the downs or hedgerows where he shot rabbits, or it may be swampy places where he brought down a snipe or two. He cannot do as General Oglethorp, Dr. Johnson's friend did, shoot snipes in the Strand, but he can play cricket in Battersea Park. So eager-eyed and glad he rushes off on Saturday afternoons to his cricket match. But for that learning cricket between the ages of ten and fifteen he would have been, as so many are, a listless pipe-sucker, with no healthy hobby to cheer him. So of other tastes. A love of pets allowed in the boy hangs by the man, and he in many a happy hour blesses that taste early given and permitted. But chiefest of all, flowers. The boy or girl who at twelve years of age gets a prize will most likely be a lover and cultivator of flowers during life. So I was very anxious for children's prizes, and also that the children in all schools of the humbler class should be admitted to the show in the afternoon at a penny a-head.

Many committee meetings followed where real work was done. All arrangements having been made, not forgetting the eatables and drinkables (mark well this recommendation—have in addition a tea tent, it always tends to sobriety), then comes the great anxiety about the weather, for upon a fine day all depends. If Jupiter Pluvius (I wish that fellow were drowned and done for), should reign, then comes utter ruin to show and to pocket.

I must further remark that it is of the highest importance to choose a fit place for a show. A peer residing four miles off most kindly offered his park, but that was too far distant from the town. All committees of shows should regard the well-being of the tradesmen of a town, not only that of innkeepers, but of shopkeepers. I have a strong feeling that every class should live and let live. Tradesmen date from the time of Chaucer at least. No co-operative stores for me. I support the regular tradesmen and feel it a duty so to do. Thus, I think, not only should a flower show be held close to a town, but the tradesmen should not be asked to close their shops as early as the show opens, but at least two hours after. John wants a brooch for Mary, so the jeweller will have a turn. Jane will want new gloves, and the girls will before the day, or on the day, want, I know not what, for just let women get into a draper's shop and see how long they will stay! The bill may usually be measured by the length of the husband's or father's face when he looks over it. This last is but a joke, but seriously I say, help the tradesmen.

Fortunately, Chippenham has a park almost in the town; Chippenham lies on one side of the Avon, and Monkton Park on the other, the entrance being from the town. Added to its other advantages is this great one, that the resident always readily permits all meetings conducive to the welfare of the inhabitants of the town to be held in Monkton Park.

All ready, and all waiting for the weather. Monday, September 4th, was a wet day. Barometers were tapped very often in many houses, for Tuesday is to be the day of the Show. The wholly unweather-wise man who has no barometer anticipated rain, having very likely a meagrim about the moon; the half-wise man who has a barometer and does not understand it, going by the words and not the proportionate rise or fall, also prophesied rain; while the wholly weather-wise-man, who both had and understood his barometer, declared it would be fine on the morrow, and it was fine. A heavy, heavy mist hung over us in the early morning of Tuesday, as sleepy eyes saw, and then came a bright, bright forenoon; just a glorious sunshiny-day between two wet ones. The grass green as an emerald with late rain, and on the roads all dust laid thoroughly, and yet no dirt. I drove early into the town and saw that the inhabitants of the ancient borough (its charter dates from King John's day), were determined to do their utmost. Arches were being erected, flags large and small and tiny were drooping, flying, and fluttering according to their size. As usual, too many "Welcomes," and not enough variety. Still the good

people had evidently risen to the occasion. I purposely avoided going near the show until all was ready, so that I might not see any part until I saw all. A show rapidly got up, only thought of late in the season, takes everyone by surprise and unprepared. This, however, is no bad thing for once, as it reveals what is a neighbourhood's natural turn for horticulture when no inducement for cultivation by prizes exists.

Viewed in this light the Chippenham Show was excellent, as the gardeners' and cottagers' long tents showed. Much ingenuity was manifested in the class for floral devices. One of the best represented a lawn gay with beds, the colours well selected, and a miniature fountain playing in the centre. Another represented the borough arms. These things display ingenuity as well as a taste for flowers. Truth to say, it was a pleasant scene. Flowers, fruit, music, sunshine, the grass so vividly green, dappled here and there with shadows thrown on it by the fine Elms, while a silver thread of water glistened in the distance, for the Avon, the Bristol Avon, the very water there seen, soon to rush between the mighty rocks of St. Vincent, and beneath the great suspension bridge, runs along the edge of the park; while the old church tower sent forth its jocund peal of sounds to add to the charm. "But the people! Oh! the people!" how they poured in—and the money too. After six no more visitors were to be admitted, as at eight all was to be over, but they were not to be denied; and where will you find a committee that has the heart to refuse money? There were five thousand people all enjoying themselves rationally and purely. I liked much to see the school children troop in, especially the poor workhouse children—what a treat it was for them! Among the cottage prizetakers were two very noticeable. An old man of eighty got a prize for his Asters; he never exhibited before, nor at his age will probably again, but had, as I well know, kept a gay garden all his life. The other, a bright-eyed little boy, was first for the best nosegay of wild flowers. One going out of the world, the other coming in, yet each happy in his success—I scarce know which was the happier. I might notice other incidents did room permit. Suffice it to say the Show was a success florally and financially.

I noticed where a few improvements might be made, and I hope will be made next year. Thus—4*s*., 3*s*., and 2*s*. as prizes for cottagers, should be 5*s*., 4*s*., and 3*s*. A cottage exhibitor takes much trouble, and loses a day's work in bringing his property for exhibition, and in attending the show, to which, of course, he is admitted free. Now a day's wages are too valuable for him to lose, and he should have a chance of being more than reimbursed. Then, also, the neighbouring gentry should be asked to send in large plants in pots as ornaments to fill up the centre of the large stands. Then, too, some Rose-growers, notably one in Bath, will, if their expenses be paid, send in many stands of Roses, not for competition, but which, being grand specimens, will add much to the beauty of the exhibition.

The Show over, the band playing the crowd out just as daylight faded, I walked through the whole town from end to end. Great was the display of flags, arches, garlands, archways of evergreens, some in front of shops extended across the pavement, festoons, illuminated stars, Prince-of-Wales plumes, and the universal and very-varied-in-form Chinese lanterns. All these "house decorations" extended from end to end of the town, over a mile in length. I walked slowly through the crowd of five thousand people (they waiting for the fireworks to be let off after dark), I kept on the sharp look-out for everything to be approved or disapproved, and having watched all before the Show, in the Show, and afterwards in the town for twelve hours, I give the verdict—"A well-managed horticultural show, such as this was at Chippenham, gives a maximum of pleasure with a minimum of evil."—Wiltshire Rector.

Messrs. Sutton & Sons, of Reading have erected at the Crystal Palace a harvest trophy in the centre transept, affording one of the most complete displays of the produce of the earth ever exhibited. Neither trouble nor expense has been spared to make the collection worthy of the occasion. The trophy consists of two hundred varieties of Grasses, Mangold Wurzel of 20 lbs. each, Swedes of 16 lbs. each, Turnips, and other varieties of agricultural roots. Of Potatoes there are seventy-five varieties, as well as many other horticultural products. Of Apples and Pears Messrs. Sutton have seventy-five dishes of each, in addition to other fruits. The trophy is 50 feet in length, with a tower at each end 25 feet high, the whole surmounted with a magnificent Pampas Grass and sheaves of Wheat, Barley, Oats, &c.

POTATOES.

"K." is quite right about there being more than one kind of Potato sent out as the Early Rose. I imported last year from one of the best seedsmen in New York a few of the Bresee's King of the Earlies, and of the Early Rose. The latter sample was a round light red Potato, a heavy cropper, but fulfilling the description given of them by Mr. Rivers; so also was Bresee's King of the Earlies, though a heavy cropper, and very early. I tasted at a friend's house early last month a long, mealy, well-flavoured Kidney Potato, which he called Early Rose, and of which I saw some roots turned up in the garden, very productive, with fine tubers. Here clearly are two kinds of Early Rose, and there may be more. I should be much obliged if "K." would send me a few—say a score, of his Early Rose and Harrison's, and if he can add a few sets of Mona's Pride he will still further oblige.—Alex. Wallace, *Colchester*.

N.B.—I may add that I saw at the Horticultural Gardens a red Kidney Potato, called the Early Rose.

THE PLANTING-OUT AT THE CRYSTAL PALACE.

I am inclined to think that the Crystal Palace gardens do more to encourage a taste for gardening and a love of flowers among the lower classes than even the London parks, although the latter are so much more accessible. It is true that one can now see in every park in London flower beds laid out in the best of taste, and kept in the most perfect trim, but when all has been done that art can devise, it is clear that it is impossible to counteract the effects of the atmosphere. For a few days after the beds have been planted all look most bright and beautiful, but very soon London air and London smoke make the flowers fade, the bright-foliaged plants grow dirty, and the dark ones dingy, after which it is only a struggle to keep up appearances, and frequenters of the parks, who have no other standard to judge by, see but a faint reflection of the glories of a bright garden in a clear atmosphere. At Norwood, however, there are none of these drawbacks, and the tens of thousands who visit the Crystal Palace every summer and revel in the gardens, are able to see and appreciate what can be done by a combination of the greatest taste and skill, backed up by large resources.

Here, as everywhere else, the beds were planted very late in consequence of the very late, cold, wet season, and July was far advanced before all were filled. It was wonderful, however, to see how very speedily some of the beds put on a gay appearance. It was almost magical. I have always considered it most creditable to the Crystal Palace Company that it expends so much money in keeping the gardens in a high state of perfection. It was, I think, the first place of public amusement that aimed so high and accomplished so much in that way. It struck me, however, that in one most important respect there was a decided falling-off this year, and that is in the condition in which the turf is kept on the upper terrace. It has certainly required more watering and cutting, and in this one respect these gardens are decidedly inferior to the parks, where the grass round the beds is most beautifully kept, and presents a sight most grateful to the eye weary of bricks and mortar.

It would seem to have been the aim of the master mind who planned the planting-out to make as many different combinations as possible. This has its advantages, as it enables those who come to the gardens for hints which shall assist them in their plans for next year, to see not only what to adopt, but also what to avoid. There are in these gardens some of the most agreeable, and certainly some of the most repulsive combinations I ever saw, but the latter are very few in number.

The most successful bed in the whole garden is in one of the sharp corners near the rosery, and is filled with Duchess of Sutherland Geranium, edged with two rows of Iresine Lindeni and two rows of Golden Feverfew. This is a really splendid arrangement. Not far from it there is another really fine bed of Waltham Seedling Geranium edged with Christine. Another most successful bed is made up of Centaurea candidissima edged with Coleus and Golden Feverfew. On the opposite side of the rosery is a very effective bed of Amaranthus melancholicus ruber edged with Centaurea and Lobelia. The effect of the sunshine through the Amaranthus was particularly fine.

In the companion bed, which was intended to match it, the Amaranthus had entirely failed. It is apparently as precarious as it is beautiful.

The sloping bank round the rosery, always one of the great features of these gardens, is very effectively planted with Scarlet Geranium Christine, Golden Gem Geranium, Coleus, and Bijou. The design, which is very pretty, is, I am afraid, beyond my powers of description. The effect is somewhat marred by the Geraniums, which are introduced for their foliage only, being allowed to blossom. There are similar instances of neglect in other parts of the garden. I must not pass over the beds inside the rosery. Two of them, filled with Lucius Geranium, Beetroot, and Golden Feverfew, will bear comparison with any in the gardens. The dark polished leaves of the Beetroot have a splendid effect.

The line of beds running nearly the whole length of the upper terrace present the most startling appearance of any in the grounds. The oblong beds are filled with Waltham Seedling Geranium, Bijou, Coleus, and Golden Feverfew. The round beds are planted with Calceolarias, Christine and Madame Vaucher Geraniums, and Lobelias. I have never seen anything more rich and beautiful than these beds, looking at them from one end. The effect of the Coleus between Bijou Geranium and Golden Feverfew is very grand, but it is marred by Bijou being allowed to blossom.

The chain border, generally such a success, is this year a comparative failure—a result caused in some measure by the rather ragged and neglected condition of the turf, which requires a more liberal use of both watering-pot and mowing-machine. It is planted with Christine and Scarlet Geraniums, Marigold, and Alyssum. The beds are joined with links of Golden Feverfew. This is a very great mistake, for it is the very essence of a chain border that the outer edging should be carried unbroken round the whole design.

There are some very successful beds of Verbenas and Petunias—as good, indeed, as any I have seen, the former being unusually good. One bed of John Wilson, cerise, edged with White Perfection, is very handsome. The Lobelia does not appear to have been at all successful; it has grown but not flowered well. The blossom of Christine seems to have been very short-lived. The Coleus I have never seen richer in colour or more transparent, in spite of the early summer having been so very ungenial. The Geraniums Waltham Seedling, Duchess of Sutherland, and Lucius have made a great show, and are very extensively used in the gardens. The last-named looks best beside a dark-foliaged plant. How we ever got on without the Golden Feverfew I cannot think! It goes so well with everything, especially all dark-foliaged plants, and is so compact in its habit, and so true in its colour.

I have only mentioned a few of the arrangements which seemed to me most worthy of remark. There are many others which are very pretty, and some which could only be mentioned in order that they may be avoided. Of these latter I may point out the only two beds out of the four inside the rosery, which I have not alluded to. Taken altogether the Crystal Palace gardens quite come up to their usual standard, and some of the arrangements cannot, I think, be surpassed. The garden superintendent would confer a benefit on thousands of amateur gardeners if he would place in each bed tallies with the names of the plants. It may not have been the aim of the Crystal Palace Company, but it is none the less the case, that these gardens give their character not only to others in the neighbourhood, but also to many in distant parts of the country. I know one garden nearly two hundred miles from London where year after year the most effective arrangements of the previous year at the Crystal Palace have been adopted. It is very easy to make a mistake if one trusts too implicitly to the gardeners, for their pronunciation of names and their orthography are at times somewhat eccentric, to say the least.—W. H. B.

Crystallised Flowers.—Construct some baskets of fancy form with pliable copper wire, and wrap them with gauze. Into these tie to the bottom Violets, Ferns, Geranium leaves—in fact, any flowers except full-blown Roses—and sink them in a solution of alum of 1 lb. to a gallon of water, after the solution has cooled. The colours will then be preserved in their original beauty, and the crystallised alum will hold faster than when from a hot solution. When you have a light covering of crystals that completely covers the articles, remove the basket carefully, and allow it to drip for twelve hours. These baskets make a beautiful parlour ornament, and for a long time preserve the freshness of the flowers.—(*English Mechanic and World of Science.*)

ROYAL HORTICULTURAL SOCIETY.

October 4th.

On one of the finest of autumnal days was held the combined Fruit Show of the Royal Horticultural Society and the International Exhibition of 1871. The two were from their very nature combined, and the two were also to a very considerable extent intermixed. "It was a heavy day," said the Judges, and it was not till late in the day that they had completed their task. We cannot, therefore, give, as is our wont, a detailed list of the honours that were gained, as we make our report; we must refer for that to another column, for the exigencies of the press required all notes to be completed before even in other, and the most competent quarters, the decision had been arrived at. And who that had seen, as we saw, the long array of fruits from divers parts—who that had seen the multitudinous fruits (and these, too, of the finest quality) sent by Messrs. Baltet, of Troyes, could say that the Judges were slow in their work? They had work to do, they kept at it till late in the day, but they did it, and we only wish we could do ours as well. On all hands it was admitted, and we know it, that this Fruit Show, got up in so little time, has been the most successful ever held since the memorable one of 1862, and to that it would hardly yield, though not so extensive, and, owing to the season, not taking, as regards out-door fruit, such a high position in the size, and perhaps quality of the productions shown.

In Class 1, for the most complete collection of Apples, three fruits of each variety, there were numerous fine collections. Messrs. Lucombe, Pince, & Co., of Exeter, sent upwards of a hundred varieties. Among them were excellent specimens of the Gooseberry Apple, Kerry Pippin, King of the Pippins, Waterford Nonpareil, Hoary Morning, Dutch Mignonne. Harrow Pippin is a clean-looking handsome variety. Mr. Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, had a collection of 130 sorts, many of them, as usual with his exhibitions, highly coloured, but not nearly so large-sized as his fruit generally is—a circumstance, no doubt, due in his case, as in many others, to the season. Blenheim Pippin, Warner's King, Manks Codlin, Adams' Pearmain, Alexander were a few of the best represented. There were, besides, several seedling varieties. Messrs. Baltet frères, of Troyes, contributed a splendid collection of 150 kinds, including large and fine specimens of Rymer, Mère de Ménage, Reinette du Canada, Calville Saint-Sanveur, President Dufays Dumoncean, Golden Winter Pearmain, Rhode Island Greening, Wadhurst Pippin, Belle Dubois, &c. Of sorts remarkable for the beauty or depth of their colour, we noticed Fenouillet Gris, Archiduc Antoine, Belleflenr, Ramsdell's Sweet, Calville rouge d'hiver, Borsdorffer, Alexander, Apis petit, and Api noir. R. Webb, Esq., Culham House, Reading, had a fine collection of highly-coloured fruit.

Mr. W. Paul contributed a collection of 171 of the best varieties for kitchen and dessert. Of the former there were excellent examples of Tower of Glammis, Lord Derby, Calville Maliogre, Blenheim Pippin, Cellini, Dredge's Fame, Rhode Island Greening; of the latter the beautiful little Lady Apple, Fearns' Pippin, Fairy Pippin, Cornish Gilliflower, one of the ugliest and best of Apples, Margil, and many more.

From Mr. A. Moffat, gardener to H. Allsopp, Esq., Hindlip Hall, Worcester, came a very fine collection of fifty sorts, some grown on bush trees, others on horizontal cordons, and others again on pyramids and standards. From bush trees Lord Suffield, Winter Hawthornden, King of the Pippins, Blenheim Pippin, Bess Pool, Warner's King, and Ribston Pippin were very fine, so were Belle Josephine, Alexander, Dumelow's Seedling, Reinette du Canada, and Beauty of Kent from cordons. Mr. Chaff, gardener to A. Smee, Esq., sent a collection of 155 kinds. Nelson's Codlin, Lord Derby, Pott's Seedling, Lord Suffield, Striped Beefing, and Blenheim Pippin were represented by large and fine specimens, and among dessert kinds King of the Pippins, Ribston Pippin, Cox's Orange Pippin, &c., were very good. Mr. E. Spivey, Hallingbury Place, Bishop's Stortford, sent seventy-five varieties, and Mr. Carmichael, gardener to H.R.H. the Prince of Wales, Sandringham, contributed a fine collection of sixty-two kinds.

Class 2 was for the best collection of Dessert Apples. Mr. W. G. Pragnell, gardener to D. W. Digby, Esq., Castle Gardens, Sherborne, Dorset, sent fifty kinds, Mr. A. Moffat a small but good collection, and Mr. Chaff fifty varieties. In these were very good specimens of Pearson's Plate, Ribston Pippin, King of the Pippins, and Blenheim Pippin. Mr. Ford, Leonardslee, had forty-eight kinds, among which was First-class, a showy high-coloured sort; Wax Apple, a pretty little yellow kind, several seedlings, and good specimens of well-known varieties. Mr. Spivey sent a small collection; R. Webb, Esq., one of fifty; and Mr. Scott, Merriott Nurseries, 290 sorts.

In Class 3, for the best collection of Culinary Apples, Mr. Ford exhibited eighty kinds, of which Beauty of Kent, Blenheim Pippin, and Shepherd's Seedling were very good. Mr. Stephenson, gardener to T. C. Barker, Esq., Leigh Hill, Essex, had fine specimens of Alexander, Cox's Pomona, &c. Mr. Spivey, Mr. Chaff, Mr. Lydiard, Batheaston, Mr. Mitchell, and Mr. W. Thompson, Clements, Ilford, also sent good collections.

In Class 4, for the most complete collection of Pears, Mr. Gardiner, gardener to E. P. Shirley, Esq., Lower Eatington Park, Stratford-on-

Avon, had in his forty very fine fruit of Louise Bonne of Jersey, Beurré Magnifique, Easter Beurré, Gansel's Bergamot, Duchesse d'Angoulême, and Huyshe's Prince Consort, besides many others. From Mr. Carmichael came fifty varieties, including Beurré de Rance, Beurré Clairgeau, Duchesse d'Augoulême, Seckle, Beurré Diel, Knight's Monarch, the beautiful Forelle speckled like a trout, hence another name for it, the Trout Pear. Messrs. Lucombe, Pince, & Co., Exeter, sent sixty kinds, of which the most noticeable for size were Prince Albert, Huyshe's Bergamot, Huyshe's Victoria, Beurré Clairgeau, Délices d'Aremberg, and Beurré Diel. Messrs. Baltet frères, of Troyes, had a collection of upwards of three hundred kinds, and many of the specimens magnificent. Certainly this was the most complete collection we have ever seen. To enter into details would be almost a hopeless task. We can merely signalise a very few, as Duchesse d'Angoulême, British Queen, Beurré Clairgeau, Triomphe de Jodoigne, Lieutenant Poiteven, Colmar Van Mons, Beurré Bachelier, and Beurré Hardy. Mr. Spivey; Mr. Pragnell; R. Webb, Esq, Culham House, Reading; Mr. Wildsmith, gardener to Viscount Eversley, Heckfield; Mr. Stephenson, gardener to T. C. Barker, Esq.; and Mr. Lydiard, Bathealton, also sent collections.

The next Class, 5, was for collections of Dessert Pears. Here Messrs. Baltet, of Troyes, made a grand display, sending very fine specimens of Conseiller de la Cour, Doyenné du Comice, Duchesse d'Angoulême, Beurré Diel, Prince Impérial, Beurré Baltet père, and a multitude of other sorts. Mr. Moffat sent some very fine specimens of Glou Morçeau, Duchesse d'Angoulême, Beurré Hardy, in all forty-eight kinds; and among the other exhibitors were Mr. Stephenson, Mr. Chaff, Mr. W. Thompson, and G. F. Wilson, Esq. The last-named had magnificent fruits from trees which had been grown fifteen years in pots. The Chaumontel, Louise Bonne of Jersey, Triomphe de Jodoigne, Easter Beurré, Marie Louise, and Maréchal de la Cour were the finest specimens from pot culture, indeed from any culture, we have seen.

Class 6 was for Kitchen Pears, and here again Messrs. Baltet took the lead, although several others had good collections.

Of Grapes, such as those shown both for the International and Royal Horticultural Society's prizes, it is difficult to speak too highly. Mr. Meredith exhibited—that is a simple statement; we are accustomed to find Mr. Meredith first, and yet he was not so in this case—that is a good guarantee that the Show was of no mean order. Messrs. Lane, of Great Berkhampstead, sent one of the largest and most beautifully-ripened bunches of Muscat of Alexandria we have ever seen; it only wanted a fortnight longer to have been perfection. In addition to this they had a collection in which were magnificent bunches of Black Hamburgh, Golden Champion, Muscat of Alexandria, Alicante, and Black Muscat of Alexandria. Mr. Meredith sent very fine bunches of Black Hamburgh, Madresfield Court—this compact in bunch and great in berry—Child of Hale, Lady Downe's, Trebbiano, and Alicante, all of first-rate size and quality. In other exhibits we noticed from Mr. Clarke, gardener to J. C. Browne, Esq., Holmbush, Horsham, good specimens of Kempsey Alicante; from Mr. Bannerman, gardener to Lord Bagot, Blithefield, a splendid 6-lb. bunch of Gros Guillaume; from the same exhibitor Lady Downe's and Alicante; from Mr. Clarke, Lady Downe's; from Mr. Morris, gardener to H. T. Salmon, Esq., Gayton House, Northampton, splendid bunches of Mrs. Pince, rubbed in carriage; Black Hamburgh, and Black Prince.

Mr. Meredith, of Garston, sent a very good collection of White Grapes; Mr. Morris, another; and the latter and Mr. Meredith had fine single bunches of Trebbiano, by far surpassed by Messrs. Lane's splendid bunch of Muscat of Alexandria. Messrs. Lane had also a magnificent collection, including Black Hamburgh and Golden Champion, with grand berries. In their collection of Black Grapes Gros Guillaume, the Muscats, and Trebbiano were also exceedingly fine. From the Chiswick Gardens of the Royal Horticultural Society came a collection in which were some truly remarkable bunches of Gros Guillaume, Madresfield Court, Black Monukka, which is a seedless Grape, and others.

Messrs. Rivers & Son, Sawbridgeworth, sent a very large and interesting collection of Apples not for competition, likewise Messrs. Lee, of Hammersmith, Mr. Cadger, of Luton Hoo, and Messrs. Paul.

Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, exhibited a fine Smooth-leaved Cayenne Pine Apple of 9¾ lbs. from a plant nineteen months old, also two Queens, one of 4½, another of 4¼ lbs., from plants thirteen months old. Mr. Barnett, gardener to W. Terry, Esq., Peterborough House, Fulham, sent three fine Queens, weighing respectively 4 lbs. 6 ozs., 4 lbs. 11 ozs., and 5 lbs.; while Mr. Jones, gardener to Earl Vane, Wynyard Park, Stockton, had a splendid Queen, but over-ripe, of 5 lbs. 13 ozs. Mr. Tillery, gardener to the Duke of Portland, Welbeck Abbey, brought a collection of fruits, consisting of Peaches, Plums, Melons, &c.; Mr. Pragnell also had an excellent collection. Mr. Moffat exhibited three fine specimens of Golden Gem Melon, large and most tempting in appearance. Mr. Spivey also sent a collection. Some very fine fruit of Lord Palmerston and Walburton Admirable Peaches came from Mr. J. Saltford, Islington Gardens, Ruddington; from Mr. Golbourne, gardener to J. Blyth, Esq., Woolhampton, twelve very fine Salway Peaches; and from Mr. Turner, of Slough, Belle de Fontenay Raspberry, the fruit very large and fine, and freely produced, which this variety has not the reputation of doing.

Messrs. Carter & Co. offered prizes for collections of six varieties of American Potatoes. Mr. Frisby, gardener to H. Chaplin, Esq., Blankney Hall, Slenford, was first with King of the Earlies, Climax, Bresee's Prolific, Peach Blow, Early Rose, and Early Goodrich, Second came Mr. Garland, of Killerton, with Climax, King of Earlies, Early Rose, Early Goodrich, Bresee's Prolific, and Bresee's Peerless. All these were large, but had an air of coarseness. Mr. D. Lumsden, gardener to the Right Hon. R. C. Nisbet Hamilton, Bloxholm Hall, also exhibited large tubers of several of these varieties. Messrs. Lee, of Hammersmith, sent a very good collection. Messrs. Criscuolo, Kay, & Co., 57, Gracechurch Street, had fine specimens of Tripoli Onions.

Messrs. Wheeler, of Gloucester, sent splendid fruit of Brockworth Park Pear, which is large in size and excellent in flavour. Mr. Glover, Epping, had very good samples of Williams's Bon Chrêtien Pears, and excellent Apples.

Of Edible and Poisonous Fungi, which were one of the leading features of the Show, Messrs. Hoyle & Austin, Mr. English, of Epping, and Worthington G. Smith, Esq., sent collections. To these we may probably revert hereafter.

Fruit Committee.—George F. Wilson, Esq., in the chair. Mr. Turner, Royal Nurseries, Slough, sent examples of a Cucumber named Wizard, a handsome variety with a few black spines. Mr. Hepper, gardener, The Elms, Acton, sent very fine examples of Hepper's Giant Tomato. Mr. Wildsmith, gardener to Viscount Eversley, Heckfield Park, Winchfield, Hants, sent some very fine examples of Veitch's Autumn Giant Cauliflower. Mr. Evershed, Minsted Gardens, Godalming, sent a good collection of vegetables, consisting of Cauliflowers, Peas, Vegetable Marrows, &c. Mr. Gardiner, Eatington Park, Stratford-on-Avon, sent a collection of twenty-five varieties of Potatoes. Messrs. Carter & Co., High Holborn, sent a fine lot of Onions. The Committee considered the Naseby Mammoth and Nuneham Park to be very closely allied, and both to be good selections of the White Spanish; and the new White Intermediate and the Bedfordshire Champion to be identical, and much resembling the old Globe. Mr. Bland, gardener to Earl Kilmorey, Gordon House, Isleworth, sent a fine basket of Mushrooms. Messrs. Veitch & Sons sent a large and interesting collection of Beets, with examples baked and boiled, and growing—viz., Nutting's Dwarf Red, Dewar's Dwarf Red, Whyte's Black, Cattell's Crimson, Dell's Crimson, Pine Apple, Egyptian Turnip-rooted, also the Improved Silver or Sea-kale, and the Red Brazilian for decorative purposes. Messrs. Veitch also sent some very fine Endives—viz., Fraser's Improved Broadleaf, White Batavian, Digswell Prize, White Curled very fine, Green Curled, and Moss Curled. Mr. W. Taylor, 9, Southbrook Road, Lee, Kent, sent examples, accompanied with a long communication, of Chenopodium Quinox, which is good used as a Spinach.

Mr. Wells, Southend, sent some examples of Grapes grown in Wells's ground vinery. The varieties were Golden Champion, Black Hamburgh, Muscat of Alexandria, Muscat Hamburgh. They were not so good as in former years. Mr. Wildsmith, gardener to Lord Eversley, sent a large bunch of Black Hamburgh Grapes grown on an old Vine transplanted last season. Mr. Bannerman, gardener to Lord Bagot, Blithefield, Rugeley, sent a Grape stated to be a seedling, but which was considered to be the Mill Hill Hamburgh. Mr. Parsons, Ranelagh Nursery, Leamington, sent examples of the Ahercairney Grape, which is the true Alicante. Messrs. Lucombe, Pince, & Co., sent examples of a white seedling Grape, having large bunches and fair-sized oval berries with a nice sweet flavour. Mr. A. Ingram, Alnwick Castle Gardens, sent examples of a seedling Grape bearing strong resemblance to Mrs. Pince's Black Muscat, but which the Committee considered superior to that variety in flavour. Mr. Gardiner, gardener to Lady C. B. Percy, Guy's Cliffe, Warwick, sent examples of a seedling Grape which produces the bunches sometimes white, sometimes black, and sometimes variegated. It was considered the same as the Aleppo or Variegated Chasselas. Mr. Pearson, nurseryman, Chilwell, Nottingham, sent several seedling Grapes of great promise. One named Abram Bass, a large oval black berry like Alicante, with a strong Muscat flavour, was considered highly promising. Several others in the style of the Alicante were good. From the Society's Garden, Chiswick, came examples of Madresfield Court Black Muscat and Frankenthal grown in a cold house. The Madresfield Court was fine in appearance and superior in every respect to the Frankenthal, thus stamping its value and its capabilities for cultivation in cold houses.

Mr. G. Carnford, gardener to H. D. Streatfield, Esq., Cheddington, Edenbridge, Kent, sent some examples of Late Admirable Peaches. Mr. Poulton, gardener to C. S. Dickins, Esq., Coolhurst Park, Horsham, sent some fine examples of Walburton Admirable Peaches. Mr. J. Groom, gardener to Earl Stradbroke, Henham Hall, Wangford, Suffolk, sent some good Walburton and Late Admirable Peaches. Mr. W. Cox, the Gardens, Madresfield Court, Great Malvern, sent some fine examples of Rivers's Victoria Nectarine, a very fine variety, to which a special certificate was awarded.

Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet, Surrey, sent very large and fine examples of the Avocado Pear, or Persea gratissima. Mr. W. Paul, Waltham Cross, sent a Pear named Souvenir du Congrés, which was approved of by the Committee, but had past its best. G. F. Wilson, Esq., Heatherbank, Weybridge Heath, sent well-grown examples of Doyenné du Comice Pears.

Mr. Davie, Bridge Street, Peterborough, sent a very fine Apple, named Lord Huntley. Bass, Esq., Moat Bank, Burton-on-Trent, sent White Calville and Cox's Orange Pippin Apples, the latter being large and good specimens. Mr. Sage, Ashridge Court, Berkhampstead, sent a dish of Apples which proved to be the Early Julien. Mr. F. Dancer, Little Sutton, Chiswick, sent dishes of Belle de Septembre and Sandall's Plum, both very valuable late varieties for cooking purposes.

Mr. Beach, gardener to the Marquis of Northampton, sent some specimens of a species of Fungus, to which a special certificate was awarded.

Floral Committee.—W. Marshall, Esq., in the chair. The subjects for examination on this occasion were very few. Mr. Williams, of Holloway, had a first-class certificate for Macrozamia spiralis, an extremely graceful Palm. A first-class certificate was also awarded to Mr. Bull, of Chelsea, for Desmodium pendnliflorum, with drooping rose-purple flowers, a pretty climber. Urania amazonica, a plant with Banana-like foliage, also came from the same exhibitor. Mr. Green, gardener to W. Wilson Saunders, Esq., had a special certificate for a collection of Neottias and other terrestrial Orchids. Mr. Green had also a fine specimen of Miltonia Morelliana. Mr. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, sent Agave Gibsii, a striking kind. From Mr. Turner, Slough, came several of the Dahlias which he has before exhibited. Mr. Russell, Mayfield, Falkirk, had also a special certificate for a fine spike of Vanda cærnlea. Messrs. Veitch likewise had a special certificate for a collection chiefly consisting of fine specimen Orchids. Mr. Bull, Mr. Standish, and Messrs. E. G. Henderson contributed miscellaneous collections, the last-named showing a fine group of the Guernsey Lily.

CELERY CULTURE.

The dryness of the weather, notwithstanding a falling barometer, induced us to give before the late rains a soaking of sewage to the bed which we shall earth-up next, followed with a watering overhead with clear water from the rose of a pot. Since we last alluded to the subject, contrary to the orders of our conductors, but somewhat excusable under the circumstances, a number of inquiries have been privately made as to the economy of the Incomparable White Celery, and what might be the average girth and height of our plants. Well, with the exception of the necessity of bringing the plants a little forward, as putting out small plants late seems to be the chief cause why so many cannot get on with this kind, there can, as respects the ground occupied and the small earthing-up required, be no question as to the economy involved. Further than the wish that those with little ground to spare should obtain the greatest quantity and of good quality from little space, we have no object whatever in recommending this dwarf Celery, or any dwarf Celery, as the Sandringham or other sorts, only we have found out that a good many variously named Celeries turn out vastly alike when treated alike. Now, at the risk of being a little egotistical, which we would rather avoid at all times, we may mention that this Celery bed, watered as described, will be our third in rotation, and that as yet it is not so strong, because not quite so early planted, as the second bed earthed-up and now being used. These beds were 4 feet wide, with 4-feet ridges between. These ridges bore heavy crops of Peas in the centre, with Radishes, Spinach, and Lettuces along the sides. The beds each held three rows of the dwarf Celery, the rows a foot apart from centre to centre. Along the row the plants were about 9 inches from centre to centre—that is to say, the plants in the bed when planted would stand 12 by 9 inches, or a little closer in general. The plants in this bed had been all cleaned and tied some time ago, the tying done loosely; but now it is so firm that the heart is blanching, and putting your hand firmly round the head below the leaves, you cannot squeeze it more closely together. Round that firm head, below the leaves, a tape line drawn tightly averaged 14 inches in circumference, some plants more, some less. The height from the ground to the extremities of the leaves averaged about 16 or 17 inches. Now, such a circumference is nothing to the huge Celery we have grown; but from every one of these compact little plants it is most likely we shall be able to send a nice head fit to appear at any table, and from 12 to 15 inches in length, though we think a foot is generally as long as goes there after receiving its various trimmings. We have fair red Celery in beds close by, as we must study and provide for all tastes; but that red Celery, averaging double the height of this Incomparable White, would not measure so much in circumference as this dwarf white.

One more remark. Let those who delight in huge heads of Celery have them by all means; but we know there are many more concerned about the bulk of a first-rate material, that can be sent in for the table from a small space, than having a few wonderfully large heads. In many a farmer's garden we have seen more room taken up with a single row of inferior Celery, than would have sufficed for a bed of three or four rows of a first-rate dwarf sort.—R. F.

PRESTON HALL, NEAR MAIDSTONE.

The traveller by the North Kent Railway from London to Maidstone may notice, three or four miles before he reaches the latter town, an edifice on the left-hand side of the line. The glimpses thus obtained will enable him to perceive that it is a mansion of the highest class. It is Preston Hall, the seat of H. A. Brassey, Esq., M.P., and is beautifully placed in a park of considerable dimensions, well diversified by noble timber trees and an undulating surface. Finer specimens of many of our native trees it would be difficult to find; as examples, two Sweet Chestnuts near the mansion have each a circumference of 21 feet at about 5 feet from the ground, and their tops indicate the most luxuriant health. A group of Elms was pointed out to me as being still larger. Other species are equally well represented, and the position they occupy showed that good taste prevailed even in a long-bygone age. There were groups here and there on an elevated knoll, then again concealing the boundary or some other object not required to be seen, while the distant scenery was let in by ample glades judiciously left open, the view from the mansion being rich and varied. The view from the north front commands the greatest extent of park, and is especially well diversified. Adjoining the mansion is the terrace garden with its fountain and sculptured figures, as well as embroidered beds, the whole separated from the park by an ornamental stone balustrading. The ground here descends gently from the mansion to the lower part of the park, while at the bottom, at the distance of nearly a mile, runs the river Medway. The ground rising on the opposite side terminates in that ridge of chalk so often called "the Backbone of Kent." Seen from the same spot is the parish church of Aylesford, for its plain square tower peeps through between the trees, together with some parts of the village, the quaint and antique gables of many of the dwellings giving evidence of their origin at a period when there was no lack of timber. A little to the north of the village runs "the Pilgrims' Road," along which devotees to the cathedral city of Canterbury pursued their journeyings. More remarkable still, and I believe also within the same parish, is "Kits Coty House," a monument of an antiquity of great but unfixed date. Some antiquaries believe it was erected to denote the spot where Catigern, a British prince, fell in battle with the first inroad of Saxon invaders.

Turning to Preston Hall and entering the dressed grounds, one of the first objects we meet with is "the old garden," as it is called, for it must be observed the present mansion, erected some twenty-five years ago, is some little distance from where an old one stood, the latter being entirely removed, its walled garden alone being retained. Against one of the principal walls of this glass cases have been erected, not temporary, flimsy, but substantial things, which, I have every reason to believe, were more costly than a range of lean-to houses 15 feet wide would have been. Peach and other trees were bearing excellent crops in these glass cases, which are about 6 or 7 feet wide, the front lights being as high as the wall and all moveable; the top also is of glass and span-roofed, the whole presenting as much glass as is generally met with in lean-to houses 20 feet wide. A few Plum and Cherry trees are planted against the front glass, and in some of the cases there was a shelf for Strawberries—the whole in excellent condition, and at the time of my visit (the end of May) full of fruit, the latest batch of Strawberries, British Queen, being then in, and finer fruit could not well be, notwithstanding the long period of dull cold weather previous to that time.

The other portions of the garden were under crops of the usual kind, a border of fine Lily of the Valley being not the least interesting of its contents; but as there is a new kitchen garden and an extensive breadth of fruit plantation as well to look over, we will first take a peep into the latter, and a door from the old garden at once introduces us into what in Kent is called "a fruit plantation," but is often elsewhere named an orchard. In many respects it resembles hundreds of others in the neighbourhood, so I will add a few details of its character and management. First, then, I may say the site to the west of the mansion (having both the old and new kitchen garden

between it and the pleasure ground), slopes gently to the north, the soil slightly inclined to be gravelly, and in very dry seasons the adjoining husbandry crops suffer much from the lack of water. I believe, however, the subsoil was well broken up when it was planted upwards of twenty years since, but it is deficient of shelter on the west side, a wall of only moderate height on that side separating it from the high road; and I believe that now and then the high south-westers occasionally do here serious damage to the fruit. The trees in general are very healthy. This orchard is about five acres in extent, and the greater portion of it is planted with Apple, Plum, and Pear trees, 6-feet standards with heads which have been trained, or rather helped, to assume the ordiuary rounded form such trees usually take when unassisted; no serious cuttings, I believe, at any time having taken place. These trees are about 24 feet apart each way, and underneath them are either Filbert and Cob-nut trees, or Gooseberries and Currants, the latter 6 feet apart, and the Nuts double that distance.

The cultivation, under the care of Mr. Bradley, differs considerably from that adopted in most fruit plantations of a like kind. Excepting the hoe no other tool is used, and that but sparingly; for, as Mr. Fish has somewhere written a notice on a Vine border, "Sacred to the roots of the Grape Vine," so Mr. Bradley makes the whole of the ground occupied by his fruit trees sacred to their use, not infringing on their domain with the spade, fork, or other implement further than is necessary to destroy such weeds as find their way there. He is, nevertheless, alive to their wants in other matters, and gives them all kinds of aids in the way of manure. In fact, he makes this orchard a receptacle for all kinds of refuse that will decay within a period of two years; this is his rule, and it will be seen it includes a vast multitude of objects—whole barrow-loads of rubbish from the kitchen garden, short grass and other matters from the pleasure ground, and even the cuttings and trimmings of shrubs and other things, avoiding all thick and unruly branches that might be in the way. Now and then many pieces as thick as one's thumb, I see, find their way in amongst them, but in a cut-up condition, while occasionally as a treat a little rough dung is given to some tree overloaded with fruit, or which from some other cause is looking badly, and Mr. Bradley says it is wonderful the good it does.

Some will say the miscellaneous character of the covering on the ground may look badly, but such is not the case. The atmosphere quickly blanches all into one hue, and the appearance is on the whole as agreeable as if the ground were naked, while the condition of the trees proves that they relished the food thus provided for them. I believe other fruit-growers are falling into Mr. Bradley's views on the matter. I mentioned relative to some orchards at Brenchley in this county that Mr. Mainwairing, a gentleman there, who cultivates a great many acres of fruit for market purposes, pointed out one acre that he had only manured with cut-up Hop bines for several years, and it was looking well; and the example at Preston Hall in a season like this, when fruit crops are far from abundant, shows that the treatment their roots receive promotes their welfare. At the same time it is not saying too much to affirm that, if a more liberal allowance of manure could be given, the result would be still greater fruitfulness. Mr. Bradley has been obliged to limit the application of animal manure to weakly specimens.

I will now glance at the mode of pruning adopted here, which in the main differs not much from that usually followed in the orchards of the neighbourhood. The Apple, Pear, and Plum trees require but little knife work at the present stage of their growth beyond now and then shortening-in an unruly branch or shoot. The trees being mostly twenty years old, and being fruitful, are not prone to make more wood than is wanted to gradually increase their size, nevertheless they are all looked over every year, and the branches thinned, where required, in winter; but it is in the management of the Filbert and Cob-nut trees that Mr. Bradley's practice differs from that generally adopted in the neighbourhood.

He adopts the summer-pruning system, and follows it out throughout the season, commencing to pinch off the tips of every shoot early in summer as soon as it can be ascertained which are bearing fruit and which not. The latter have their tips nipped off with the finger and thumb, leaving from 6 inches to a foot to be cut off in winter. But this nipping-in process has to be several times repeated during the season, especially as regards the central shoots, which under ordinary circumstances run up into long tapering rods of from 4 to 6 feet or more in length, but are confined to the condition of a somewhat lengthened spur. Mr. Bradley also disapproves of the custom of laying bare the collar of the plant every autumn by scraping the soil from it in a basin form, as he thinks it encourages rather than prevents the formation of suckers.

The severe pruning the Cob and Filbert will endure is certainly greater than that inflicted on any other kind of fruit-bearing tree, unless it be the Grape Vine and Currant, but even these are not subjected to such incessant severe pinching as Mr. Bradley gives to his Filberts; yet the result in fruit-bearing is all that could be wished for, Mr. Bradley rarely failing to have a good crop, and this season he has one unusually good.

Before passing from the fruit-culture I must note that some trees of Ribston Pippin seemed as healthy-looking as those of the other varieties of Apple. Mr. Bradley explained this by saying that only a few years ago that kind was grafted upon a robust grower of less note. I forget which it was, but the result proves that, for a time at least, the tendency which the Ribston has to fall into an unhealthy state has been arrested.

I now come to the kitchen garden proper. The new garden was made at the time the mansion was built, and notwithstanding many good properties, it is on the whole the least important part in point of size, of this domain; indeed, the space available for vegetables is very small. In shape it is a parallelogram, with its longest sides running east and west, a fine range of lean-to houses occupies the whole of the north wall; while the south one, separated from the pleasure grounds by a neat Yew hedge enclosing the usual slip, is covered with glass walls also, but in this instance forming a similar glass case to that described in the old garden—viz., an upright glass front as high as the wall, with a span-roofed top, Peach and other trees being trained against the wall, while Cherries, Plums, and now and then Vines, are trained thinly against the front glass. A row of hot-water pipes also runs along this structure, sufficient to protect its contents from frost in winter and spring, the whole having a showy appearance; but I question much whether the same length of lean-to houses would not have been cheaper, and much more useful, the glass cases alluded to being not more than 6 or 7 feet wide, and requiring as much glass in their construction as would do for houses of nearly three times their width. The houses, however, occupying the north wall are all of ample width, and are mostly Grape and Peach houses; one of the latter, just ripening its fruit in the latter part of June, was all that could be wished for in regard to health and abundance of fruit. Another coming on was equally promising; while in the other vineries there were excellent Muscat Grapes, faultless in regard to setting, and although not ripe when I saw them, their healthy appearance indicated they would finish off their crop without that stumblingblock in the way of Grape-growing—shanking.

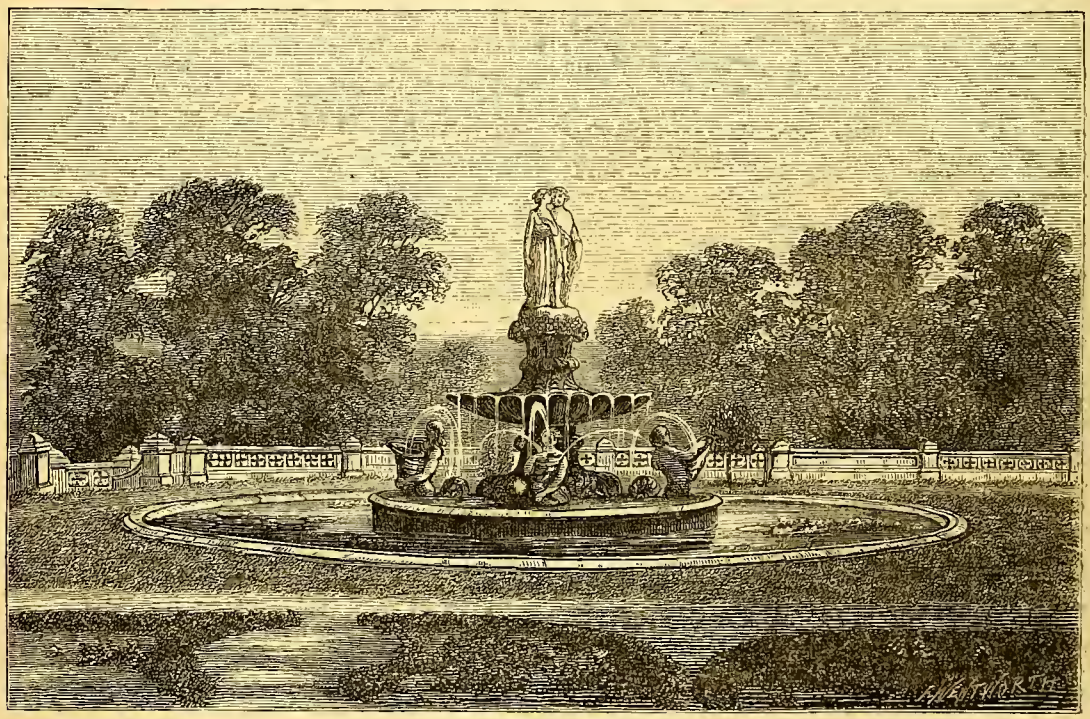
Mr. Bradley also pointed out one or two Vines of Golden Champion that looked remarkably well, but he had his doubts about the bunches finishing so, as he says they are so liable to cracking, and consequently decaying, in ripening. The Vine seemed to bear well, and the bunch and size of berry were remarkably good.

Most of the Vines were pruned on the spur-system, they were not at all crowded, and the house being 18 or 20 feet wide, afforded ample space for a good length of rod. The Black Hamburghs that were ripening off were remarkably fine, and the late kinds were also in a promising condition; that esteemed kind prevailing amongst the latter as well. These houses occupied the whole of the back wall, excepting a small space at each corner, and as each vinery was furnished with a large bed in the centre for such plants as now and then are necessarily placed there, as Capsicums, flowering plants, &c., the whole had a well-furnished appearance. A central opening into this fine range from the south is made available for introducing some Tea and Banksian Roses into the unheated porch forming the division which, I was told, were of great service in early spring.

This range did not constitute the only glass structure, for at the back of the wall against which the houses were placed, there were two houses having a north aspect, which were of great service in summer in retaining plants in bloom, when a more sunny exposure would have hastened them on. Fine specimen Azaleas and Cape Heaths were here; the former kept remarkably late, while the easy access to them and their convenient arrangement made them an agreeable appendage to the range. These north aspects, however, I ought to observe, maintain the same line as that of the sheds and other back buildings which occupy the north side of the wall; but the

space in front of these sheds is not by any means to be regarded as background and rubbish corners, for there are other glass structures equally attractive to company, consisting of lines of glazed pits heated and unheated, and a forcing pit in which Cucumbers are to be had almost every day in the year. This pit is span-roofed, and partly sunk in the ground—the entrance at one end—and consists of four compartments, both Melons and Cucumbers being grown. The pathway is down the centre, and there is a raised bed on each side suitably heated with hot water, and affording a good place for the plants, for it was about 3 feet or more wide. Other pipes by the sides of the pathway gave the necessary top heat, and excellent crops were the result. Both Melons and Cucumbers were trained against the glass, with the fruit hanging down, that of the former being supported in the usual way by small pieces of netting, and both exhibiting the most robust health. Behind this pit were two large span-roofed plant houses with glass all round; one of them was appropriated as a plant stove, the other as an intermediate house. The former was fitted with a tank and ample heating apparatus, and contained excellent specimens of the most popular plants usually met with in such places, some for flowering, others for their foliage. One plant which particularly attracted my attention might be said to combine the useful as well, for it had a very fine bunch or cluster of the fruit of Musa Cavendishii; the plant occupied a corner of the pit, and was by no means remarkable for size; on the contrary, I have seen many much larger, but the fruit-bunch was certainly a fine one for such a plant. The length of stalk having fruit upon it was 20 inches, the diameter of the cluster 18 inches, the length of the largest individual fruit 8 inches, the girth 6 inches, and the total number 162. When gathered in mid-June forty of them weighed 16 lbs. 5 ozs., or a trifle over 6½ ozs. each, and a few days afterwards fourteen more fruits were cut averaging over 6½ ozs. each; so that it is fair to expect the cluster altogether would exceed 60 lbs.

The fruit-room here is not the mere lean-to shed met with in many places, but a structure erected for the purpose, and, with the exception of one at Knowsley, about the best I ever met with. I forget the construction of the roof, but the house is placed under the shade of some large trees, and is partly sunk in the ground, two or three steps leading down to the door at one end, and as the ground is very dry this is not attended with any inconvenience. It is a span-roofed building, is ceiled part of the way up the rafter, there are ventilators in the centre, and windows at the north side and at each end, the door being at the west end. Tiers of shelves run along each side, and one tier in the centre, with ample pathways, and a fixed table at one end for displaying special fruits. Mr. Bradley would, I believe, like to have more ventilation in the room. He says the openings at top are hardly sufficient to carry off



Terrace Garden and Fountain.

all the vapour given off by such a mass of fruit when it is first put in, and no doubt he is right.

Retracing our steps to the north front of the mansion we have immediately beneath us the terrace flower garden as designed by Mr. Nesfield, with its ample fountains, displaying considerable artistic talent, and surrounded by a series of scroll beds of good size, and mostly edged with Box and gravel walks, to which access is gained by a flight of steps down the correctly-formed slopes and landings from the terrace. An open balustrading on the retaining wall separates this symmetrical garden from the park, and the same kind of fence returns round the east side also, where there is also another set of flower beds on the lower level of a different design; but I venture to think the space enclosed here, in proximity to the mansion, seems much too small and confined, while to the south or carriage front there is ample space.

The conservatory at the east side of the mansion is a polygon, not very large, and united to it by a corridor from the drawing-room. In the centre of this conservatory there is usually a group of large ornamental plants on a permanent bed, while a few also stand around, leaving ample pathway, edged with stone kerbing.

The broad terrace on the north side of the mansion extends westward in a direct line for some distance, after first descending a few steps to a lower level, terminated at its western extremity by a summer-house of artistic design. This fine walk is 14 feet wide, and at regular intervals standard Roses of uniform height and size are introduced on the broad turf margins, as are likewise Irish Yews carefully trained to one stem each, and a few flower beds.

The entrance to the garden is through ornamental iron gates partially gilded, while statuary adorns the sides of the wide steps leading to it, and it is here the fine Yew hedges enclosing the slip also terminate, a neat arch through the hedge giving access to the slip. Continuing my walk westward along this fine terrace path I found that it communicates with other walks of a subordinate character right and left. One to the right, a little beyond the western end of the kitchen garden, and at right angles to the main walk, is covered with an archwork of trailing Roses, Honeysuckles, Clematises, &c., but mostly

Roses, and, being of good length, forms an admirable retreat in hot weather.

The pleasure ground to the south side of this terrace walk rises gently, and is diversified by specimen Conifers and other trees, amongst which are very fine Taxodium sempervirens; also masses of shrubs. Walks of convenient width give access to it in suitable places, the area being large, and eventually the dressed ground merges into a wood at its south-western side, through which walks also ramify; but just at the extremity of the dressed ground in this direction, and where it is well enclosed with large trees, a fernery is formed. Amongst the other things which give it interest, the judicious laying-on of water is not omitted, and a grotto, on which the water trickles down, is supported by marble columns carved with Moorish characters, brought home by Mr. Betts from the north of Africa.

Following the walks leading through the wood from this spot I found in suitable places Rhododendrons and other shrubs had been extensively planted, with large patches of a much-neglected plant, St. John's Wort, and suddenly I reached an imposing building concealed amongst the green verdure, the racquet court, and then the entrance-lodge, having made a somewhat more than semicircular sweep to the south side of the mansion. Here is obtained one of the best views of the mansion. It is built of Kentish ragstone, with Bath stone dressings, and architecturally is highly enriched. The carriage road approaches it in a straight line and at right angles, and is broad and margined by a very spacious width of turf on each side, backed by rows of Cedrus Deodara, destined, I hope, to make a fine avenue, for already in size and healthiness they are equal to any of their age (twenty years I believe), and there are two rows on each side, the inner lines at least 100 if not 120 feet apart.

Arriving at the end of this drive, which terminates on a gentle eminence, I perceived that two more such straight lines also enter there at different angles. One of them I was told was nearly three miles long. The other, about three-fourths of a mile, pointed to an eminence having a conspicuous summer-house, and other attractions about it. This drive lay mostly through a piece of coppice of Chestnut and Oak, but ornamental Conifers had been planted at intervals along the line to give it a clothed appearance in winter, and Rhododendrons were more extensively planted in front, while the ground, descending first, afterwards rose more rapidly, giving the terminus an elevated appearance. The soil is different soil from that which I had been traversing, being in fact a dark-coloured sand. On this elevation, or mount, a commodious two-storied summer-house has been erected, with a thatched roof overhanging a gallery, from which a most charming view of the surrounding country is obtained.

Young Rhododendron plants are coming up in thousands from self-sown seeds, and some years ago I remember seeing some patches as thick as ever Groundsel is when in condition. Some Larch trees, planted many years since, were in a less satisfactory state, showing that the Scotch Fir is the most suitable for this site, but Ghent Azaleas could not have been better, neither could Kalmias, but Andromeda floribunda and others seemed not quite so robust, although good. All other plants of a similar kind are here well exemplified, excepting Heaths, which the presence of rabbits renders difficult to keep; but the sight of the gorgeous masses of bloom presented by the Rhododendron and Azalea can have but few parallels, and although I have described the space they occupy round here as pleasure ground, it is not so in the usual sense in which that phrase is used, for with the exception of the grass being mown on the paths intersecting it a few times a year, and the Thistles and Nettles removed, all other herbage is allowed to find a home, and after the blaze of bloom presented by the American plants is over, one scarcely less effective is offered by the Foxglove occupying every spare corner, and pushing its way up through the evergreens as well, while its lower extremities are hid from view by the less pretentious Brake, which, if unable to vie with it in colour, is immensely its superior in gracefulness, and continues its services to the end of the season.

By a shorter route I gained the highway, and with a hearty shake of the hand with my worthy friend, Mr. Bradley, of whose kindness I have had many proofs, and of whose abilities this fine place exhibits so many examples, I departed. My description falls short of the beauties of Preston Hall, therefore I say to others who have the opportunity, Go and see.—J. Robson.

Preston Hall.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Strict attention to the order and general propriety of the garden at this season will have its obvious advantages. *Cabbage* planting can be proceeded with. *Celery* will still want earthing-up as it advances, and *Endive* must be tied up to blanch. There should be two separate receptacle for garden

rubbish attached to every kitchen garden—I allude to this matter because the accumulation of weeds and decayed vegetable matter is considerable at this season—one to receive the matter convertible by gradual decomposition into manure, the other to contain every substance that can conveniently be burnt. A good reserve of burnt earth and wood ashes should belong to every garden; the latter may be very advantageously substituted for manure of a stronger character in rich soils which it is desirable to relieve. Vegetable gourmands pretend to discriminate between the Broccolis and Cabbages grown on poor soil and those cultivated in highly manured gardens around London. It is highly probable that the flavour of the Cabbage tribe may be heightened and not improved by rank soil, and no doubt manure is sometimes excessively and injudiciously employed in the cultivation of vegetables, as in most cases it is not the mere production of the object, but its attainment with every interest and peculiar advantage that is coveted; therefore, the judgment should be exercised in every case that involves a distribution of manure, and another attempt made towards a most desirable improvement in vegetable culture. Thin out young crops of *Spinach*, *Turnips*, &c., before they become weakly and drawn through standing too closely together. Stir the surface of the soil deeply among growing crops to admit air to the roots, and to keep down weeds. Let spare ground be manured and dug or trenched for another crop whenever time can be spared for that kind of work.

FRUIT GARDEN.

Look daily to the housing of tender kinds of Pears, gathering a few at a time, and preserving carefully names and dates. Let preparations be made for planting fruit trees at an early opportunity, avoiding deep and highly-manured borders, draining thoroughly for stagnant water, and planting high in proportion to the humidity of the situation.

FLOWER GARDEN.

Tender plants in borders must be covered when there is the slightest appearance of frost. As has been often recommended, give careful attention to young stock, and recollect that sturdy, well-rooted plants are much easier to winter than large plants with long-jointed soft wood. With good convenience late-rooted cuttings may still be potted-off, but unless they are very thick in the cutting-pots we would prefer wintering them in these to shifting at this season, for they occupy much less space in the cutting-pots, and having more space for their roots they are frequently more healthy, and require less attention in winter than those potted singly. Square pans 12 inches wide and 5 inches deep are very suitable for wintering Verbenas, Lobelias, and other plants which can be kept in a small state. One of these will hold some twenty good plants, and with care, to prevent their being injured by damp, they will winter quite as well treated in this way as if potted singly in 4-inch pots, and a vast quantity may be stored in a small space. Where subjects of this kind have to be wintered in cold frames or pits the plants should be potted singly, as they would be very liable to damp off, despite every care, if placed thickly together in pans and put where it may be impossible to give air for weeks together. I must, however, protest against the system of wintering bedding stock in such unsuitable places. This practice is generally adopted from some mistaken notion of economy; but if a fair calculation of the time required to attend to plants wintered in this way could be made, and all the losses taken into account, it would be found to greatly outbalance the trifling cost of putting up a proper heating apparatus, and furnishing a few bushels of coke or coal annually. Where alterations are projected or in hand these should be proceeded with, and where plantations are to form part of the demesne, and in conspicuous situations, trenching should always be resorted to. Gilpin had a very good plan of forming groups in parks; he first determined on the positions where two, three, or more, would be effective, and not far from each other, he planted these with trees of the desired kind, and of a permanent character, and then enclosed a rectangular figure around them, filling up all the intervals with trees of very rapid growth, with Gorse, Broom, &c., as nurses. Alterations carried out during the autumn are doubly important, both on account of the season for planting, turfing, and such operations, and also on account of the busy character of the spring months, which always bring sufficient claims on the most diligent, without the pressure of extras of any kind. The remodelling of parterres or the making of new ones may be carried on after the middle of the month, and where old ones are to be broken up the herbaceous tribes already existing should be numbered or named in due time in order to be able to ascertain the heights, colours, &c. Ornamental shrubs, whether evergreen or deciduous, may be removed with every chance of success after the second week; no hesitation need take place as to the kinds, provided the ground is properly prepared by trenching or otherwise, and thoroughly drained.

GREENHOUSE AND CONSERVATORY.

The Camellias which had been forced into growth in February and March will shortly be ready to open their buds. Let them be liberally supplied with clear and weak liquid manure; soot water and guano in a liquid state is advised; the latter in very small quantities. The application of liquid manure is frequently wrongly conducted. There is no such wholesale manuring in Nature as we see practised in an artificial way. The ammonia of the atmosphere is presented in very weak doses, but in a continuous way. May we not take Nature as a model? Some of the earliest Epacrises may be placed in a close part of the greenhouse, where they will soon open their blossoms, also Daphnes, and many other plants, provided their flower-buds are prominent. Aim at keeping the atmosphere of this house rather dry, using just enough of fire heat on damp, cold nights to allow of giving sufficient air to keep the atmosphere in motion, so as to prevent damp being injurious. In arranging the stock in its winter quarters in these structures beware of overcrowding, drawn stock is not endured in these days; it is far better to throw a portion entirely away than to spoil superior specimens. Much of second-rate character, which requires another season's growth, may be preserved in good dry pits, at least till the middle of December, when, if very hard weather occurs, they may have a chance of removal, perhaps, to some of the other structures until the end of January. It ought ever to be a maxim in regular plant houses that no two plants touch, still we must confess that many who would admit the propriety of the principle are frequently compelled to practise otherwise through want of sufficient accommodation. The ephemeral things introduced for decorative purposes must be removed as they exhibit signs of decay. Mildew is often engendered by such plants. With ordinary resources a good successional supply of Heliotropes, Fuchsias, Scarlet Geraniums, &c., may be managed. The Chinese Chrysanthemums will shortly give a feature to the general display; large plants may be taken up, potted, and kept in a close frame for a week or two, when they will flower equally well with others. Salvia azurea should also be taken up from the ground and potted, it will bloom until late in November if kept in the conservatory. Salvia splendens is also useful for the same purpose.

STOVE.

Twiners on the roofs of stoves should now be more than ever kept within bounds, cutting back all shoots that have done flowering, and tying the others so as to obstruct light as little as possible. Place specimens ripening their wood in the coolest part of the house, and water sparingly at the roots. Achimenes, Gloxinias, and Gesneras, that are properly ripened off may be stowed away in any dry place, where they will be secure from frost, but take care to place them where they will be free from damp, and they should not be exposed to a lower temperature than about 45° or 50°.—W. Keane.

DOINGS OF THE LAST WEEK.

"It never rains but it pours" has been well exemplified during the past week. For eight days we have scarcely had a dry hour until this Saturday afternoon, the 30th of September, when we saw the sun once more. On Friday night and Saturday morning we had downpours that turned most of our walks into miniature canals. Having previously picked over our flower beds, they stood four days and nights of almost constant rain with impunity, looking if anything more bright from the moisture. The rain of Thursday, and especially of Friday night and Saturday morning, accompanied as it was with a wind approaching to a gale, has given the masses of bloom a drowned appearance, from which, unless we have bright, dry weather in October, they will not recover. If, however, we have some dry, bright weather, there are sufficient fresh opening buds to continue the brightness a few weeks longer where there is strength and vigour in the plants. To-day we looked along lines of Madame Vaucher Geranium, from which, two or three days ago, we could have cut hundreds, if not even thousands, of fine pure heads of bloom almost without their being missed, and yet to-day, when we wanted them, we could not,

among the thousands of large corymbs of bloom, have gathered half a dozen that were perfect and would appear ornamental in glasses and vases.

This reminds us how useful for merely looking at, and for cutting purposes, it would be to have a garden on the grouping system under glass, however much smaller it should be. Protected from the heaviest of these rains and the keen winds, these beds of ours would have been as bright as they were eight or ten days ago. Had we to carry out such a design we would have all the sashes in the roof pivot-hung, so that the rain should be permitted to enter or be shut out at pleasure. We may here remark that to our knowledge gardeners are very often blamed most wrongfully for not having this and that done, when they are powerless, from want of means, to do what their own judgment shows them the importance of doing. After all, even now it is only in comparatively few places that gardeners have the opportunity to carry out their ideas of what they know to be right. In the majority of cases they must do what they can, and get as much as possible from the smallest possible outlay. The great standing grievance, and one that helps, too, to damp enthusiasm, is simply this—that people who generously spend a pound expect as great things as their neighbours have who spend from twenty to a hundred pounds on the same objects. In a glass-covered flower garden the masses of perfect bloom, being protected from the rain, would have been splendid for weeks, and if the plants were protected from frost by hot-water pipes they would be splendid throughout the winter months.

If masses of bloom are to be great objects we here foreshadow what may be effected in the future. With light hollow iron columns and fixed roofs, unless where necessarily moveable, there is a grand opening for genius and enthusiasm in this direction; and the effects would be far more startling, and at the same time more gratifying, than in wandering through mixed conservatories arranged upon the present system. There are few who have witnessed the glare of bedding plants, toned down by the subtropical fine foliage that Mr. Gibson has done so much to make fashionable, that did not regret that the interest and beauty were so short-lived. Who that has influence to bear will help to give a people's low-roofed conservatory in Hyde Park, and thus enable Mr. Gibson to show the thousands and millions what may be done with fine colours and fine foliage in the winter and spring, as well as in the summer and autumn months? We ourselves tried this subtropical attraction years before it came out so strongly at Battersea, and we would have continued, only the winds here tore our fine foliage to pieces. Few things would delight us more than to have the opportunity of seeing large conservatories in our public gardens and parks, where our fellow workers might see at all seasons the brightest of flowers and the most beautiful of foliage.

KITCHEN GARDEN.

The rains that for the present have made such wrecks in the flower garden saved all watering in this department, have done good to pastures and Turnips, and have only been a drawback where valuable corn still remains in the fields. With the exception of looking after fresh-planted Cabbages, Lettuces, &c., all work here has been at a standstill, chiefly on the principle that, owing to the ground and pathways being so wet, it was difficult to do work without making work. Slugs and snails were the chief enemies to be guarded against in the case of young plants, and dusting round, not on, them with powdered lime and soot, putting fresh Lettuce and Cabbage leaves on the ground, and examining them frequently, were the chief preventives employed, and hitherto with success, as few plants have been interfered with.

Even *Cabbages* after a heavy crop of Onions, say if planted in September, and intended to produce heavily in the season of 1872, and to April and May, 1873, are all the better of having some rather rank rough material turned into the bottom of the trench. Ground that has been fairly treated for Onions ought to be in the best possible condition for Cabbages when well dug, pulverised, rolled, and planted, and for early produce the plants do as well as in the trenched-up ground; but for long continuous bearing on the old stools, we have always found the trenched-up part, with rough manure at the bottom, produced the longest.

Generally we treat a piece on each plan. The Cabbage thus left long on the ground is generally such a robber, that Celery, for which a good quantity of manure has been added, is one of its best successors. On removing such long-standing plantations of Cabbages in May, we have not only found the whole ground interlaced with roots, but they were found in great fleshy bundles at the bottom of the trenches, where the rather rough dressing had long become decayed and sweet before the roots of the Cabbages had gone deep enough to reach it.

We have as yet only planted out part of our Cabbages, and we shall follow in a week or two with the whole, as we did not sow so early this season, for the disaster of last winter in killing the most of our fine strong plants has impressed us with the importance of its being better to be a week or two later than to have a promising crop destroyed. We surmounted the disaster pretty well, and had Cabbages not so much later than usual, but at the additional trouble and labour of sowing in heat, pricking out under glass, and getting nice stubby plants, that lifted with balls, to grow with great rapidity in the prepared soil. We would, however, rather avoid all such additional labour, and one means of doing so is to sow a fortnight later, and plant out younger though stubby plants.

When the ground cannot at once be prepared, it is well to prick out the plants 3 or 4 inches apart, that they may be more stubby before being planted. This will be an improvement, whether the plants be put in with a dibber or a trowel. Many cottagers would save themselves much trouble and anxiety by resorting to this pricking-out process. When they plant out poor, puny, drawn-up plants from a thick seed-bed, the plants are at once subjected to many casualties from which they would be comparatively free if they had been more sturdy from exposure, though not higher when planted out.

Another means of securing sturdy growth in the autumn, and the first part of the winter, is to plant in ground comparatively poor and firm on the surface. The latter can be secured by rolling when dry before planting, as anything like caking can be prevented by a scuffle with the Dutch hoe afterwards. Sometimes when the Onion ground has been rather too rich we have drawn drills, and placed some light soil mixed with lime rubbish along the rows, which encouraged abundant and free rooting of the Cabbage plants, but which kept the plant on the whole stubby and healthy in winter, and more able to encounter frost and sunshine, and all variations of weather. When the warm days of spring had come, the descending roots getting into richer soil, gave succulence and richness to the leaves and the tender hearts. We have always been rather shy of planting early, except a small piece to come in first. Last winter ought to act as a warning. Few Cabbages at all forward escaped in this locality, and the loss to the cottage gardener who could not force on young plants was truly great, as fine, crisp, solid Cabbages are regular fill-dishes for a family.

Caterpillars on Vegetables.—With the exception of a bed of Savoys that were pricked out for future transplanting, which had little left on them but the main stems and midriba of the leaves, we have suffered little or nothing from caterpillars, though they have been very destructive in the neighbourhood, and especially in the case of Savoys and Brussels Sprouts. We believe that our freedom from these pests is partly owing to the comparatively limited number of white butterflies that made their appearance, and to the zest with which they were hunted down by a young lady and gentleman some seven and five years of age, using neat branches of spruce and small hooped bags of Nottingham netting fastened to a stick. We have endless inquiries on this subject.

The first is, How best to keep away or destroy the caterpillars before they do the damage. The catching the butterfly before it deposits its myriads of eggs is the best preventive. When we had little boys in the garden we used to give them some hours of this work in the brightest hours when the butterflies appeared. When the caterpillars are established on the under sides of the leaves, dusting the plants on the under side with powdered quicklime by itself or mixed with a little soot, soon settles them. A more cleanly mode, and economical as respects the lime, is to put a shovelful of such quicklime in a barrel of water, stir it well, and when settled and clear syringe repeatedly the under sides of the leaves. The acridity of the lime water soon settles all that it touches. Cottagers, who could not get lime readily, might use soot in fine powder or mixed up with water like the lime, but in four or five times the quantity, applying it, like the lime water, when comparatively clear. It is difficult to get such water as clear as brandy unless you can add a little quicklime to it. Then the liquid is better for the purpose than when only one of the materials is used.

The second question is, What to do with such riddled plants, even after they are strong and have taken firm hold. Some, even at this late season, have cleared out the plants, and put in

fresh, however small. We would not advise this in the case of strong plants of Savoys and Brussels Sprouts, though they may not have a sound leaf left on them. We would wash them with the syringe as stated above, and with the help at the roots of such rains as we have had, we feel very confident we should obtain many gatherings of nice small heads or shoots from the stems, ten times more in quantity than we could expect from young plants turned out at the end of September. In all such cases we should, then, advise the leaving of the strong stems, though the leaves are mostly eaten and gone, but to make doubly sure the ground might be forked over, and young plants dibbled in between. The old stems, if sound and fresh, will, however, be the plants to depend on for large heads.

Cauliflowers.—As soon as the ground shall have become a little drier we shall plant out what we intend for hand-lights, will most likely pot some, and prick-out where a little protection can be given, as with all our after-care the earliest Cauliflower is generally the best. For late-heading Cauliflower the rains have been very favourable. Young Cauliflowers intended for the first crop next year can hardly be too young now. They are less liable to button than older plants.

Celery.—Fortunately we have plenty earthed-up to go on with, as we should not like to earth-up in such weather. Most likely after so much rain we shall use sifted furnace ashes round the plants to keep worms and slugs from the stems. We have had sent us some leaves of Celery much infested with the Celery grub, which, secure between the two skins, eats up the juicier substance between them. There is no remedy now but taking off all such leaves, and burning or otherwise destroying them before the grubs eat their way out to go to the earth, and pass through their chrysalis state. The most simple and effective preventive we have found is very slightly dusting the plants several times with dry snot after the end of June. The scent seems to deter the fly from depositing its eggs, and where there are no eggs there will be no grubs. At any rate we have not been troubled since we used that simple precaution.

FRUIT GARDEN.

The winds have blown down some of the best fruit, and the most forward will need gathering as soon as dryness sets in. Our crops of Apples and Pears are very fair, but in general a small crop, especially of Apples, is the rule in this neighbourhood. As an evidence, a gentleman, who has a large garden which he cultivates for profit, told us he had a wonderful crop of Apples last year, and could make but very little of them. This season he did not think he had a tenth part of the crop of last year, and yet he received from a dealer just five times as much money for them. In some places, as at Luton Hoo, Pears are far beyond an average crop. The difference as to the yield of fruit at two places is in some seasons astonishing, though there may be no great distance between the places, and the treatment given very much alike.

Filberts and Nuts which are ripe should be gathered so as to be safe from their many admirers, four-footed and two-footed. When dried pretty well we never found them keep better than when packed pretty tightly in 10-inch pots, the pots set closely in a place of an equal rather low temperature, with a sod of turf reversed placed over the pot, and merely a double layer of paper beneath it. Of course, mice and rats must be looked after, or they would soon empty the pots as effectually as squirrels would do. This idea was first suggested to us by finding nuts with the outside covering even fresh in the underground storehouse of a squirrel in the month of March.

We thought that after such deluges of rain our fruit would be free from wasps and insects, but we found some hard Seckle Pears to-day pretty well filled with wasps; but we must say, in all honesty, that they seemed to have taken possession after mice and rats had nibbled a way for them. The wet, too, we find has cracked a number of fine Plums before they are ripe.

For general details we must refer to previous numbers, merely stating that late Peaches in the orchard house are now very useful, that late vineries wanted more air and more heat in these wet days, and that to neutralise the deluges of rain we put some 6 inches of dry litter over the outside borders. We would have used sashes or other modes of throwing-off water if we could.

ORNAMENTAL DEPARTMENT.

We have alluded to the effects of the rain; one simple fact is worth noting. If flower beds are kept picked—that is, all dead and decaying blooms removed, a moderate rain does them little injury. If faded flowers are washed over fresh ones, the appearance is greatly marred. We expected rain, and turned all available labour to pick the beds on a dry afternoon. As stated, the beds, say of Geraniums, so thick with fine masses of bloom that you could scarcely find room for a finger between them, stood the rain of four days and four nights with impunity; so that if no rain and winds had succeeded, the beds and borders would have suffered but little. This favourable result so far was to a great extent owing, in our opinion, to the previous removal of all faded blooms.

We need say nothing of lawns. Nothing could be better for them; and as to walks, we shall pass a roller over them as soon as the weather is dry enough. The chief work has been repotting Pelargoniums that had broken after being pruned, potting Lycopods and Ferns, taking Salvias, Heliotropes, &c., under shelter, putting-in cuttings under glass, cleaning, surface-stirring, and giving abundance of air to the cuttings struck and striking. As we must keep our cuttings in little room without potting, this last matter of air-giving is of importance for keeping them stubby and healthy in winter. We also took under glass Scarlet Geraniums that had been repotted—at least part of them—for late autumn and winter blooming. Most of our cuttings have been protected from the rain, but the sashes have been raised back and front to allow the air freely to pass. We would house Azaleas and Camellias now if we could, but we must look after them and wait a little longer. If we had intended doing much in the way of forcing Lilacs, Rhododendrons, and hardy Azaleas, we would have had them potted by the middle of October, and if the pots had a little bottom heat all the better. We have thus forced Roses well in winter that were taken out of the ground and potted in October. The great point is to be obtain fresh roots before you start the buds.—R. F.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Rose Catalogue*, 1871-72.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Bulbs and Flower Roots, Stove and Greenhouse Plants, &c.*

Richard Daan, 8, Denmark Villas, Ealing.—*Catalogue of Hyacinths and other Bulbs, Hardy Bedding Plants, &c.*

Butler & McCulloch, Covent Garden Market, London, W.C.—*Catalogue of Dutch and Cape Bulbs, &c.*

William Thomson, Tweed Vineyard, Clovenfords by Galashiels.—*Catalogue of Vines and Pines.*

Barnard, Bishop, & Barnards, Norwich.—*Catalogue of Garden Requisites.*

Child & Co., 49, Darley Street, Bradford, and Bradford Nurseries, Shipley.—*Catalogue of Dutch Bulbs, &c.*

Georgs Yates, Underbank, and Royal Oak Mills, Stockport.—*Catalogue of Flower Roots.*

D. Danvessa, Avenue Dauphine, Orléans.—*Catalogue of Fruit and Ornamental Trees and Shrubs, &c.*

Haupt-Catalog der Königlich Prinzlich Niederländischen Baumschulen, Muskau (Park-Inspector, E. Petzold).—Catalogue of Fruit and Ornamental Trees and Shrubs.

David G. McKay, Market Hill, Sudbury, Suffolk.—*Descriptive Catalogue of Dutch Flower Roots, Roses, Fruit Trees, Ornamental Trees and Shrubs, &c.*

TO CORRESPONDENTS.

Books (*Delta, Scarborough*).—For exotic Ferns, Hooker's "Icones Filicum;" for English Ferns, Moore's "Nature-printed Ferns." They have coloured plates.

Offensively-smelling Fungus (*W. Simons*).—It is Phallus impudicus, long known and common.

Botanic Garden (*J. Smith*).—Many gardens are termed "Botanic," which have no just pretension to the name. If it is really intended to make the garden illustrative of the science of botany, a portion of the garden should have plants in it arranged according to the Natural System, and all have labels with the names written upon these. Even in all other parts of the garden each plant or group of the same plant should be similarly labelled. As to the ornamental parts, that must be left to the judgment of the managers.

Who is a Practical Gardener? (*Rose*).—A man who understands gardening, and can cultivate the plants grown in a garden, and perform the operations there required is a practical gardener, though he never was apprenticed to one of the trade.

Outgoing and Incoming Tenant (*Inquirer*).—The incoming tenant need not pay you for the trees you have planted, and if you injure or remove them the landlord could recover their value from you.

Beurré Bollwiller Pear (*G. A. T.*).—This is stated to be one of the last late Pears, succeeding the Easter Beurré, carrying on the succession several weeks later, and being of as good quality at the beginning of May as it was in March. It requires to be grown on the Pear stock. We cannot say whether it is to be depended upon in the midland counties. Bergamotte Esperen forms a more healthy and fruitful pyramid.

Peat (*S. E. C.*).—Any of the dealers who advertise in our columns would readily supply you, at your railway station. If you want but a small quantity you might obtain it from a neighbouring nurseryman.

Bicolor Geranium (*Bicolor*; *J. E. S. S.*).—It is utterly impossible to judge from the leaves sent. Send a plant to the Floral Committee, Royal Horticultural Society. Habit is of much importance in judging the value of a Bicolor, so that it would be misleading to give an opinion on a leaf.

Rooted Cuttings (*E. M., Dublin*).—Probably Mr. Poulton, Fountain Nursery, Angel Road, Edmonton, Middlesex.

Ringed Spots on Strawberry Leaves (*J. P.*).—A species of Septoria does appear sometimes on these bleached spots, but most commonly, as in this instance, there is no fungus. It is an open question whether these bleached spots are caused by fungi; we rather doubt it. They do little damage to the plants, as the season of growth is nearly closed.

Stove for Greenhouse (*H. B.*).—If one of Shrewsbury's gas-heated apparatus is not enough, why not have two, one at each end of the greenhouse? If you tell Mr. Shrawsbury the size of your house he will inform you what you need. (*A Reader*).—We do not know what reply you refer to. Tell us the volume and page.

List of Fruit Trees (*Five-years Subscriber*).—*Apricots:* Shipley's, Royal, Moorpark, and Peach. *Nectarines:* Hunt's Tawny, Downton, Elruge, Violette Hâtive, Pine Apple, and Victoria. *Peaches:* Early York, Early Grosse Mignonne, Royal George, Alexandra Noblesse, Bellegarde, Grosse Mignonne, Violette Hâtive, Princess of Wales, Walburton Admirable, Lord Palmerston, Lady Palmerston, and Salway. A north wall is a very unfavourable position for Pear and Plum trees, unless you are in a dry and early part of the country; it would be better to plant the north wall with Morello Cherries and Red Currants. You might try of *Pears*, Doyenné d'Eté, Jargonelle, Williams's Bon Chrêtien, Louise Bonne of Jersey, and Maria Louise; of *Plums*, Rivers's Early Prolific, Victoria, Kirke's, and Jefferson.

Wellingtonia gigantea (*A. Kerr*).—It has produced cones in many places. The intention at page 221 was to inquire whether it has produced pollen and fertile seeds in England. We have heard that home-grown seeds have been known to show symptoms of germination, but that they never produced seedling plants.

Various (*An Amateur*).—*Asparagus seed* is fit to gather when the berries are red. We simply strip them from the stalks and store them in shallow boxes, using dry sand for packing, and keeping them in a dry cool place until spring. We sow early in April. The remains of a turf stack will answer for *packing Geraniums* to be wintered in a spare room. We should add one-third of loam and sharp sand. In packing Geraniums in boxes, to be wintered in a cellar, use dry soil or sand, and remove all the leaves. They should not be watered, but ought to be looked over occasionally, and any parts which have damped-off or decayed should be cut away. Frost must be excluded. It depends in a great measure on the condition of the manure, and the time of year at which it is applied; but some of the fertilising properties will be washed down to the roots with the first rains or waterings.

Seedling Passiflora cærulea Treatment (*Beginner*).—Winter them in a greenhouse or other structure where protection can be given from frost, and in March shift those you intend for the greenhouse into 9-inch pots, draining well and using a compost of two parts turfy loam, one part leaf soil, and one part sandy peat. When they have filled the pots with roots plant them out in a border if you already have or can form one in the greenhouse, and they will grow more in one season than in three years in a pot. If inconvenient to plant out, shift them into 15-inch pots when the 9-inch pots are full of roots. The plants you purpose planting out may be turned out in April against a south wall, where they will succeed in all but cold northerly exposures. For the first winter or two afford protection from severe frost by a covering of mats, which should be removed whenever the weather is mild.

Seedling Cyclamen Treatment (*D. M.*).—Continue in the warm house plants from seed sown in March, having corms the size of peas, and two or three leaves, until the seedlings are coming into flower. We have some plants from seed sown in April that have been in frames all the summer and are now showing flower. Could you not give them bottom heat?

Storing Seed Potatoes (*A. E. F. C.*).—"Pieing" is not so good as placing the Potatoes on the floor of a granary thinly, and allowing all the air and light you can. In frosty weather it will be necessary to cover them with straw to keep them from frost, or if you cannot keep frost from them in the granary, they may be "pied" after they have been some time on the granary floor. The kinds you name are good—viz., Skerry Blues and Sutton's Red-skinned Flourball, fine for winter use, and not nearly so liable to disease as many other kinds. This season with us three-fourths of the tubers of Early Oxford and Early Perfection are diseased; one-half of those of the Early Rose, one-fourth of Lapstone and Early Red Kidney; but Ashleaf, Myatt's Prolific, Mona's Pride, Victoria, Red-skinned Flourball, and some seedling varieties are sound.

Exposing Protected Apple Trees (*An Amateur*).—When the fruit is gathered the glass protector would be best removed, as there is nothing equal to winter exposure for destroying insect pests, and inducing a complete state of rest. In planting cordon Apple trees to grow under glass, it will be well if each group be of one kind, as then the uniformity of growth and ripening will not be interfered with, as it might be were several kinds planted in a group. It is not, however, imperative. The principle that regulates glass is simply that thin glass is more liable to breakage and does not keep heat in nearly so well as thick glass. Plate glass—that is, polished plate, is not suitable to horticultural purposes, being too bright, so that plants have their foliage scorched in bright weather. Rough plate, however, is good, probably the best of all. 26-oz. and 32-oz. glass is not superior to 21-oz., only glass of these weights retains heat better, and is not so liable to breakage. We use 26-oz. for fruit houses.

Lilium eximium not Flowering (*A Constant Subscriber*).—We presume your plants are in pots, in which we find they do little good, making little beyond offsets. We should plant them out at once in rich light soil, adding freely leaf soil and sandy peat, and sand if the soil is at all heavy. Cover the bulbs about 1½ inch deep, and with a like thickness of partially decayed hotbed dung. They should have an open sunny exposure. They ought to flower in August.

Transplanting Large Birch Trees (*W.*).—You may remove the trees, 12 to 20 feet in height, if they have not been grown very closely together and can be moved with good fibrous roots, which are essential to success. Move them this autumn as soon as the leaves have fallen, and when planted secure them against winds

Potting Skimmia japonica (*H. A.*).—You may now take up the plant, of which the berries are changing colour, taking care not to cut off too many of the roots, otherwise the berries will fall. It is one of a few plants which are very ornamental for window decoration in winter.

Climbers, Ferns, &c., for a Small Conservatory (*Flora*).—Of climbing plants for the roof, Passiflora Comte Nesselrode, P. Countess Guiglini, Mandevilla suaveolens, and Tacsonia Van-Volxemi. These are free-growers and should be planted in a border. Other climbers are—Sollya linearis, Rhynchospermum-jasminoides, Lapageria rosea, Kennedya inophylla floribunda, K. Marryattæ, K. bimaculata variegata, Jasminum gracile, Hoya carnosa, Habrothamnus fasciculatus, and Hibbertia volubilis. Flowering plants are—Acaciae armata, platyptera, oleifolia elegans, pulchella, and longiflora magnifica; Acrophyllum venosum, Aphelexis macrantha purpurea, A. Woodsii; Beaufortia splendens, Blandfordia Cunninghami, Boronia Drummondi, Cassia corymbosa, Chorozema cordatum splendens, Coronilla glauca, Correa Brilliant, Crowea saligna major, Cypripedium insigne, Cytisus racemosus, Daphne indica rubra, Dracophyllum gracile, Eriostemon intermedium, Eutaxia floribunda, Genetyllis fuchsioides, Indigofera decora, Kalosanthes Lonie Napoleon Buonaparte, K. miniata grandiflora, Imantophyllum miniatum, Libonia floribunda, Lasiandra macrantha floribunda, Monochætum ensiferum, Narium rubrum plenum, Phœnocoma prolifera Barnesii, Pimelea spectablis rosea, Plumbago capensis, Polygala Dalmaisiana, P. acuminata, Rhododendron jasminiflorum, R. javanicum, R. Princess Royal, Sedum Sieboldi variegatum, Statice brassicæfolia, S. profusa, Vallota purpurea, and Witsenia corymbosa. Besides these you will, of course, have Camellias, Azaleas, Primulas, tree Carnations, Cinerarias, Calceolarias, Pelargoniums, Fuchsias, Cyclamens, bulbs, &c. For the back wall to plant along with Camellias, Citrus nobilis will suit. After the bud of a Rose has taken, the shoot on which it is budded should not be cut off close to the bud until the following February or March.

Various (*R. F.*).—In frosty weather you can command a temperature of from 50° to 55°; but to do that in very severe weather the water will require to be heated to upwards of 200°, or nearly boiling. Good Scarlet Geraniums for bedding are Bayard, Blackband, Blazer, Cramoisie Supérieure, Crimson Perfection, Little Excellent, Queen of Nosegays, Sunlight, and Waltham Seedling. The best plan to secure a stock is to grow the plants in pots, take off the cuttings as you can secure them, strike them in heat, potting and growing them on. In this way you will have cuttings from both old and young plants. Good pink or rose kinds are Christine Noseggay, Arthur Pearson, Amy Hogg, Pink Stella, and Queen of Roses. Whites are—The Bride and White Perfection; Alexandra is a good Geranium, also Waltham Bride. Silver-edged are—Prince Silverwings, Picturata, Snowflake, Bright Star, and Bijou. There is much similarity between many of the Tricolor Pelargoniums, but Sophia Dumaresque and Lady Cullum are, as you say the journals describe, "very distinct," and we add "good." It is when they are of specimen size that their markings are most fully developed. In a young state they are much alike. For bedding purposes we have no experience of the Geranium you name. It is well to propagate Carnations, Pinks, and Hollyhocks every year, but it is not necessary to prevent degeneration, which does not occur. Hollyhocks are propagated by cuttings, the short stubby shoots at the base of the plant being taken off closely, potted in sandy soil, and placed in a gentle hotbed. A young Carnation plant with one stem will put out side shoots in due time, but if it grows very tall take out the centre at 6 inches.

Vines and Gooseberry Bushes.—(*J. L.*).—A strong one-year-old cane will be better than an old unfruitful rod. The young cane will be sure to show for fruit, and larger bunches will be obtained from it. The old rod will also bear fruit next year, if the lateral shoots are strong and well-ripened. Is there not room in your house for both? An ordinary vinery attached to a house like yours should have space for more than one rod. If you have no plants underneath the Vines in summer, the rods may be trained to the roof at 2 feet 9 inches apart; if there are plants in the house they should not be closer than 6 feet. Gooseberry bushes may be trained as standards. It is not necessary to strike the cuttings in pots. Now is the best time to put them in; take off the strongest young shoots with a heel attached, and pick out all the buds except three or four at the point of the shoot. Plant the cuttings firmly in ordinary garden mould. When the cuttings begin to shoot in spring, place a stick to each plant, and train only one shoot up to the required height, pinching out all side shoots.

Red Spider on Vines (*West Cumberland*).—Now that the Grapes are ripe shut up the house closely, and having made the hot-water pipes as hot as you can, coat them with sulphur brought to the consistency of thin paint with a solution of 3 ozs. of soft soap to the gallon, going over the pipes two or three times. In addition to this you may go over the leaves and brush off the insects, destroying their webs with a dust brush. Beyond this we do not know what you can do, for to introduce water would be fatal to the keeping of the Grapes.

Vines not Thriving (*Henri*).—Unless the wireworm has eaten the roots we cannot conceive how the Vines did not grow, if you did not starve them for want of water. Some time ago we stated how we were called upon to see some Vines that would not grow, planted inside too; the top soil seemed all right, but the roots were as dry as if planted over an oven. We would prune back the 6-feet Vine to 3 feet or so, and nip out the buds not wanted. We would leave the other weak ones as long as you could, provided you had a fair bud at the point. Whenever the buds swelled we would rub off, not cut, all except the best and most promising ones. We would examine the soil as to moisture. Trap by every means the wireworm, and sprinkle a little tar where there is no chance of the roots penetrating. Place a half-barrowload of horse droppings over the roots of each Vine, then some dry litter, and adopt some mode for throwing off snow and cold rains, and next spring we hope the Vines will push strongly. Until then we would not think of destroying and replanting.

Forcing Lifted Vines (*H. L. Cuzner*).—You will not succeed with forcing Vines in November that you intend to lift and replant now. As you have cropped the borders and mean to force, your best plan would be to remove as much of the effete soil from the surface as you could do without much injury to the roots, not minding if you exposed a few fibres; then cover with a couple of inches of fibrous loam mixed with lime rubbish, then with from 2 or 4 inches of similar material enriched with superphosphate, and a good sprinkling of bones. Cover with some litter manure for a foot in depth at once, so as to keep the heat in the ground, and about the middle of November add as much more as would

give a temperature of from 60° to 65°, and 70° on the surface of the border, which will encourage fresh rooting upwards. If taking-up is resolved upon, we have frequently described the process.

Vines Planting (*Gas-meter Maker*).—As the Vine has been planted two years, instead of taking it up we would fork carefully round it, and, if the roots are now spreading, leave well alone and top-dress with dissolved bones and horse droppings. If you resolve to relift, you cannot do it too soon. Be careful of every fibre, replant in fresh soil, water at about 70°, cover the soil over with litter to keep out cold, and if with anything to keep out cold rains all the better, so that the roots may be excited into activity before the top breaks. Use the fresh loam by all means, but do not raise it 8 inches above the present soil and roots. You may get new roots in the fresh soil, but you will injure the old roots. We lately saw a fine Oak tree killed because the stem and old soil were covered with a foot of refuse earth. Your Vines ought to do in the north of London in the open air, but of course a glass covering, temporary, or orchard-house fashion, would be in favour of the Vines and fruit.

Strawberry Plants for Forcing (*A. B.*).—We presume the Strawberry plants are now in pots, and the sooner you can place them in the conservatory, or anywhere else to save them from this drenching as well as frost, the better. They will be quite safe if the temperature be a little above freezing, and will want little attention, except seeing that they do not become over-dried until you wish to start them for forcing. It would be of no advantage keeping them at all warm in winter until you wished to start them fairly, and then they must be brought on gradually and have no checks. Perhaps we do not quite see the drift of your question. For early forcing, say commencing in November or December, the plants ought to be well established in their fruiting pots, the outsides and insides of the balls being a complete mass and network of fine roots.

Beds on Grass (*Sunny*).—Provided you have enough of room on each side of the walk and to spare for a croquet ground, we would put a series of small beds along the sides of the wide walk, and also of that in front of the windows. Nothing, on the whole, would look better or be more simple than parallelograms and circles; the first with the ends curved to suit the circles; the parallelogram 8 feet by 4, and the circles 4 feet in diameter; 4 feet from the walk, if so much can be spared, and 4 feet between the beds, to be filled with bulbs and spring flowers, and Geraniums in summer.

Manure for Meadow on Clayey Soil (*X. Y. Z.*).—If you can manage to collect a quantity of parings from the hedgesides or ditches, mix it with about one-sixth of its bulk of quicklime, let the heap lie a month or two, and then turn it; you will have a better manure than any of the artificial kinds, as the most of them seem better adapted to crops under tillage than to permanent grass; we have, nevertheless, seen excellent hay crops after a dressing of nitrate of soda, or of bone dust, both on heavy soil, but we prefer the action of lime, and have a partiality to bulk, which cannot be had in the artificial manures. If you cannot obtain parings of ditches, perhaps roadside scrapings can be had; these will be better still if at all sandy, and may be applied without the lime; but if you use the latter, take care the earthy materials are not too wet, otherwise the mass will become like mortar instead of the useful friable compost so much needed, and which you may apply at the rate of thirty one-horse loads to the acre if you have plenty of it, or twenty loads if it is scarce.

Rose Leaves Injured (*Edgeworth, W. F.*).—The leaves you enclose seem to be injured by smoke from chemical works; it is, however, difficult to say without knowing the position in which they were grown, and if there is no chimney near to hurt the leaves, they may suffer from the roots being too dry. We have seen leaves injured just in the same way in the neighbourhood of Birmingham and other smoky towns.

Rue Leaf (*J. E.*).—The following is "the full botanical description" which you ask for:—Leaves glaucous, pulpy, dotted, divided like the umbellate plants, doubly pinnate, or more properly what Linnæus calls superdecompound. Leaflets obovate, sessile, the lower ones smallest, the end one commonly trifid, with the middle lobe much larger than the rest.

Supply of Vegetables (*Bush*).—No one could value the supply unless he knew the amount and quality. In "The Estable Fuoguses," published at our office, there are coloured engravings and full descriptions of them. We could not epitomise them.

Iresine Lindeni from Seed (*An Amateur*).—It can no doubt be raised from seed, but we are not aware that the seeds are in commerce. It strikes so freely from cuttings that no one need be long in raising up a stock. By "Lobelia" we presume you mean Verbena venosa, plants of which raised from seed sown at the end of February in a hotbed of 75°, and forwarded in heat, will make good stocks by the end of May, and will bloom finely the first season, in fact better than older plants. The Geraniums which you hope to winter in a spare room we would continue in the Melon frame until November, keeping them rather dry, and admitting air abundantly. It may be necessary, if frosty nights occur, to throw mats over the lights.

Storing Filberts—Tritoma Flowering Late (*A Subscriber*).—They keep best in jars between layers of sand, and placed in a cellar. The cause of the Tritoma flowering late is no doubt the cold summer The plants being healthy we would not lift them, but would mulch round them with partially decayed leaves. They would probably flower earlier if lifted, and the best time to do that is as soon as the flowering is over. The plants will, however, be weakened by the lifting.

Trees for Exposed Mound (*J. B.*).—For the soil you name and an exposed situation we should confine ourselves to evergreens, and should plant them at 4 feet apart, using equal proportions of Austrian Pine, Corsican Pine, and Scotch Fir. The first-named is the hardiest of all, and makes the best shelter, and unless the mound be extensive we should plant it alone. If you wish for deciduous trees you may plant at 20 feet apart Sycamore and Norway Maple, filling up at 4 feet apart with the evergreen trees named.

Cucumber House Construction (*A Beginner*).—We should contrive for a walk at the back, raising the present wall to 7 feet, and making a front wall of about 3 feet 6 inches high. You will not need front lights, but we would have the front part of the roof of lights 7 feet long, and a short roof to the back of 3 or 4 feet, which will need to be regulated according as you cover the wall or not. If the wall be covered it should be "splayed" at top to the width of the wall plate. The back part should be fixed, and the top 18 inches of the 7-feet roof should have framed and glazed sashes, so as to open the entire length of the house from half an inch to a foot or more. The front part of the roof should be at an angle of 45°. The flue we should run along the front of the house, returning it along the centre of the bed which we should form for the soil, and back along the side of the walk. You will in that way have two pipes for top heat and one for bottom heat. It would be well if the covers of the flue were hollow, so as to retain water. The flues need not be raised more than half a brick from the floor, and may be about 12 inches deep and 9 inches wide inside, but they may be less. The bed we should have 4 feet wide, and enclosed with 4½-inch walls, but from 6 to 9 inches higher than the flue, which we would cover over; or we would form a bottom to the border of flags or slates, and thus have a chamber beneath the bed. You will need to carry the 4½-inch walls 18 inches above the flags, and on these you must place about 6 inches of stones for drainage, and then you will have left about a foot space for soil. You may have the furnace in front, and it should be so sunk that its top may be level with the bottom of the flue; you may then carry the flue through the house on the level, or with a very slight rise to the chimney.

Small Forcing House (*A Young Gardener*).—We have no objection to the depth of the chamber, 18 inches; we should like it better than if deeper. We do not quite understand the mode of heating; for bottom heat you have a pipe through each tank, which raises the temperature of the water to 130°; that would make two pipes, and yet you say you have four pipes for bottom heat. So we presume that one pipe on each side is in the tank, and the other in the chamber. By either or both modes, for such a narrow border, you will have enough of bottom heat, but for a house 9 feet wide we do not think that two pipes for top heat will be enough for Cucumbers in winter. We would rather have four. If you allow the holes in the slate to remain you should have 6 inches of open rubble over them, covered with washed fine gravel and sand below the turf and soil for Cucumbers, Vines, &c. If you stop up the holes the rubble will be equally required, and the vents you propose for letting up vapour would also do for pouring water down among the rubble. The vapour that rises from water in a tank at 130° will not injure if it rises at a distance of 15 inches or so from the foliage. It will also be modified by passing through the rubble. We would not like the roots of any plants to reach the heated slate. Cucumbers should not be overwatered in winter, or have too much hot vapour. The plants in pots will do best plunged if the bottom heat is not above 80°. From 60° to 65° is a good winter top temperature, with a gradual rise from sunshine. The Sooly-Qua Cucumber appears to be a Luffa; we should not like to eat it, though it is used in China.

Heating by Gas (*South Norwood*).—No injury occurs to plants in a house heated by gas if there be a tube to carry off the fumes into the open air. "In-door Gardening" will suit you; it can be had free by post from our office if twenty postage stamps are sent with your address.

Heating Greenhouse and Vinery (*J. H. Jones*).—We are sorry that your gas stove did not give you sufficient heat last winter. The great advantage of such stoves is the ease with which they are managed. But for this, heating a stove with gas we consider in general more costly, and far from being so effective as an iron stove with firebrick in the fireplace, and burning good coke. You would no doubt get more heat from the gas stove if you had a small boiler over it in the concave or saddle-back shape, as described in page 38 of the manual of "Greenhouses for the Many," to which you refer. We, too, would prefer 2-inch to 3-inch pipes. A small cistern set higher than the flow pipe, and communicating with it by a 1-inch pipe, the return pipe being near the bottom of the boiler, will supply the deficiency of getting the water in to which you refer, or a raised open pipe on the highest point of the flow pipe would answer as well. You will also succeed by placing in the furnace of the shed behind a piece or coil of pipe as you propose, taking the extreme end out into the open air. You will succeed still better by having a coil or band in the furnace as a boiler, and the pipes filled with water, with an opening at the highest point in the house for supplying with water. But to avoid all these complications we would sink the furnace in the potting shed some 15 or 18 inches, and then take a flow and return flue beneath your present pathway and up your present chimney. As you have the furnace there you will succeed better and with less trouble than with all these complications of gas, hot air, and hot water. Of course the three quarts of water in the boiler in "Greenhouses for the Many" refer to the boiler alone, and not to what is in the pipes. A case is shown round the boiler, so that the gas heats on all sides, otherwise we prefer that the gas heat should go right up the middle and round the sides, as in the conical system, or underneath and round as in the saddle-back system.

Heating a House 20 Feet by 10 Feet (*Grosmont*).—Would not the chimney stack that passes through the greenhouse give you enough of heat to keep out frost? In some such cases, where the fireplace is near the chimney, a metal plate, say 20 by 30 inches, let in securely, instead of brick, has given out enough of heat, along with the more moderate heat from the chimney above, to keep the enclosed space temperate in winter. There are two objections to heating the house with hot water from the dining-room fireplace; the first arising from the floor of the greenhouse being 15 inches below the level of the fireplace in the dining-room, instead of above it. With an open boiler at the back of the fireplace the flow pipe might go on a level, say 2 or 3 inches from the top of the boiler, and return to the bottom, but the flow pipe must not fall from the boiler, and therefore the pipes would require to be high in the house. With a fixed-top boiler, and the pipes still higher, the circulation would be more rapid. One-inch strong gas pipes would connect the boiler with the pipes in the house, and some 60 feet of 3-inch piping would be necessary. The second objection is that in severe weather in winter you would have to keep a fire close to the boiler at night, so as to prevent the water getting cool. All things considered, an iron stove about 14 inches square, the furnace part lined with firebrick, and set beside the chimney stack inside, with the smoke funnel into the chimney well up, and a vessel for water on the top, would be the simplest mode for obtaining security.

Wire-trellising Wire in Front of Fruit-tree Walls (*I. Y.*).—There can be no question that such wire-trellising, or rather straight wire line, as manufactured by Messrs. Barnard & Bishop, has a great advantage in every way over the old and too general practice of fastening the shoots of the trees with shreds and nails. The driving-in and pulling-out of nails soon disfigure the finest new wall. Every hole made and left open becomes a harbour for insects, every piece of shred left is the

very best breeding place for insect eggs, and it is chiefly because the proprietors of gardens cannot see how cheaply a nice new wall can be covered with strained wire from 6 to 9 inches apart that the old system is persevered in. Had we our way, on building a new wall, we would wet the surface well, that it might take a thin layer of Portland cement, which would leave the surface smooth and of a light colour, and on that we would have wires strained for tying the shoots and making them secure. For this purpose galvanised wire is the best, when looked at economically, as lasting longest and needing no painting, except at the ends, which should be daubed up, and any bits where the stretching causes the galvanising to crack. For want of this precaution we have known baskets, &c., made of galvanised wire very soon rust and decay. All such things should first be made and then dipped in the galvanising-tank. It is of importance, therefore, to secure every exposed end of galvanised wire on a trellis, so that the rust or oxidation shall not travel inwards from the exposed points. For trellises for espaliers, cordons, supporting Raspberries in rows, nothing will be found so economical in the end as iron supports and strained wires. When placed against walls the matter of distance is important. For most things, 1½ inch from the wall may be considered a good medium. If much closer the tying cannot be so easily done, and if farther from the wall the draught of air behind does much to do away with the advantages of the wall as a protection. When we have had some very old decayed walls, and could not obtain wire, we have used a rough concrete to fill up the holes and the worst inequalities, and then studded the wall with metal nails 9 inches apart, and tied to these nails. The nails were previously heated, steeped then in oil, and dried before being used. This mode of treatment greatly assisted in keeping them from rusting.

NAMES OF FRUITS.—(*G. C.*).—It is Hoary Morning, but the specimens are small. Perhaps you have too large a crop on the trees. (*F. M.*).—The Pear is Beurré de Capiaumont. The Apples must be local varieties. (*J. E. Ross*).—The Pears are, 1, Belle de Noël; 2, Nouveau Poiteau. The Plum is Lawson's Golden Gage. (*C. R. Limpfield*).—*Apples:* 1, Wormsley Pippin. *Pears:* 1, Ne Plus Meurie; 2, Williams's Boo Chrêtien; 3, Marie Louise; 4, Colmar; 5, Van Mons Léon le Clerc; 6, Autumn Colmar. *Plums:* 2, Late Orleans; 3, Jefferson; 4, a wilding, common in gardens in Surrey and Sussex.

POULTRY, BEE, AND PIGEON CHRONICLE.

TAILS.

THE transition seems easy from heads to tails. We always associate the latter with the memory of Lord Monboddo, and cannot help thinking of a Wiltshire shepherd, whom we once fraternised with for some hours on the downs, when the day was hot and we were lazy. We asked him why shepherds' dogs had such stumps of tails. He said he could not tell. "He knew it was so; but whether they were cut off, or 'drew in,' he did not know, he thought the latter."

Many will recollect the sensation created by the first Cochins "Have you seen these new fowls?" "Yes." "Well, describe them." "They have no tails." "They must be very ugly." Long discussions ensued. The first theory was that the tails had been pulled out, but time showed they did not grow, and it was accepted that the birds had no tails. Some said it was an improvement, others that they were the ugliest creatures ever seen. The public attention was, however, called to them, and the correspondence was large on "caudal appendages," as they were termed. It was not without its difficulties. It was found then, as it is now, that the older the birds get the more tail they have, and that it also becomes white with age. Nevertheless, the tail is entirely unlike the tail of any of our European poultry. It is more like a bunch of feathers, like those of the Ostrich. As soon as the style of it was settled, then the debate arose as to its colour. Black and white feathers were tabooed in the Buff breed, and were admissible only in the Grouse and Partridge. This led to malpractices; the feathers that offended were ruthlessly removed, whether they sinned in colour or size. Judges were expected to examine every tail and count the feathers. It seems also a sort of red-letter day for judges when they can disqualify a pen, and post a placard stating the grounds for doing so. At this time the ordeal a Cochin cock had to undergo was terrible, and all about its tail. At length it was nearly settled that the tail should be as small as possible; that there should be nothing approaching to sickle feathers; that such feathers as were permitted should be as nearly as might be the colour of the plumage. We believe that remains to this day.

Next came a feud second only to the Montagues and Capulets, Guelphs and Ghibellines. Fortunately the war was only a wordy one. Should Spangled Hamburghs have cock or hen tails? Several of the best breeders and judges we had declared for hen tails, but the majority went against them, and they have now disappeared. There is little doubt they were very numerous formerly in parts of Yorkshire. The writer of this article once procured a very small Golden-spangled Hamburgh cock perfectly hen-tailed, and it was of much service to Sir John Sebright in breeding his Bantams. The opponents of the hen tails called them "half-bred-looking creatures." Their advocates had long lists of mains that had been fought and won by the "henny-tailed" against the sickles. Then one day it was put forth as an imperative rule and undoubted truth, that no true Dorking could have any white in his tail. That was an evident mistake and was short-lived. Nevertheless, it did its work, the sickle feathers of Dorking cocks were constantly, accidentally, broken off. Sometimes they were coloured, at others they were mended. This has disappeared. The Game cock had too much tail, he frequently carried it over his back, hence the term "squirrel-tailed." The tails of Silver-spangled Hamburghs were cloudy, and the fiat went forth that they must be purely white, with a black moon at the end. The Sebright Bantam must not have even the suspicion of a sickle, and the feathers must be clear save lacing, and a spot at the extremity of each. The Spangled Poland must also have clear sickles, mooned. In the Golden and Silver Hamburghs (Pencilled), the cocks' tails must be bronzed or silvered on each edge of the principal feathers, the hens' tails must be pencilled to the tip.

Spanish and the French breeds are exempt from the requirements of judges and exhibitors so far as their tails are concerned. We shall have to do with them when we come to colour. Arrived at the tail of our argument, we are almost afraid in these Darwinian days of throwing down the apple of discord when we say, All the requirements we have named have been met, the objections have disappeared, and as soon as the laws of the judges were laid down there was no difficulty and little delay in producing birds that came up to the quality, and answered the requirements. Degeneracy in a tail-less breed shows itself by the faulty specimens increasing that ornament in every brood. In all manufactured breeds the chickens constantly go back to the component parts, and in cases where they are bred without fresh blood they return to it entirely. Thus a degenerate Sebright Bantam loses the hen tail, and has a full complement of long sickle feathers.

THE CRYSTAL PALACE POULTRY SHOW.

WE hardly know if the proper course would not be to place Mr. Elgar's letter in our solicitor's hands in lieu of offering a reply, as little doubt of its object can exist in the mind of anyone—viz., to prejudice the ensuing Show at the Crystal Palace, or why would Mr. Elgar have allowed ten months to have elapsed without bringing his charges before the public? But as possibly, if unanswered, his letter might influence some few who are unacquainted with the Committee, the Judges, and the management of our previous shows, we beg you will insert the following contradiction, the truth of which can be ascertained from our catalogues.

Mr. Elgar states, "It is very curious that a party being on the Committee should be so very fortunate as to show fourteen pens of birds and, except for two, get prizes for them all." This is more than curious, it is untrue. The most approximate case that can be found with the most fortunate Committeeman, is but four prizes with fourteen entries. Mr. Elgar's other statement with regard to the total prizes will be found upon the same authority to be equally untrue. With reference to Mr. Elgar's general statements about sending birds to the Palace in the middle of November in the cold, can Mr. Elgar point out a more suitable place than the nave of the Crystal Palace, with its regulated temperature? or can his fertile imagination conceive one? With regard to the White Fantail and the pair of Jacobins which are so ostentatiously paraded, "will you be surprised to find" that Mr. Elgar was not an exhibitor in either class, but that all his "pets" were consigned to the Selling class, the value of each pen being restricted to £2? and your readers may, perhaps, come to a better conclusion of their true value from the fact that the Judges never so much as commended them, and even at this price not one of them found a purchaser. It is, therefore, highly improbable that anyone would seek to make the exchange Mr. Elgar implies. Referring to the Pheasant, this Mr. Elgar informed us had died in transit under exceptional circumstances; he might further have had the fairness to have admitted that we paid him what he himself demanded and called the "marketable value."

Lastly, no mistake was made by us, and no authority exists for Mr. Elgar's assertion that he won a prize, for which we refer him to the Judges; and as Mr. Elgar's further remarks are chiefly an impeachment of those gentlemen, while stating our own belief in their integrity, an opinion which every exhibitor will endorse, we leave it to them to vindicate their own

cause should they see fit to notice an attack so manifestly libellous.—Chas. Howard and William J. Nichols, *Secs.*, 2, *Exeter Hall, Strand.*

[We have other letters in reply to Mr. Elgar, but those from the Committee alone can be inserted.—Eds.]

ENCOURAGEMENT TO MALAYS.

I believe that most poultry fanciers, although they may not perhaps admire, would nevertheless regret, the departure of Malays from the grand exhibitions, especially as there seemed last year some prospect of their looking up in the world. For many years Birmingham had offered them prizes, assisted, it is true, by subscriptions from breeders. Last year I collected some portion of this amount, and at the same time I pressed on the Committee the desirability of dividing the prizes more evenly—viz., into three prizes, £2, £1, and 10*s.*, instead of £3 and 10*s.* I may state that this more impartial division was in favour with the wishes of many of the contributors, and, therefore, I think, should have been complied with. The Committee, however, declined, considering it would be an insult to the breed to offer less than £3 for the first prize. I therefore reclined this year to collect any extra money, and I see by the prize list that nobody else has taken the matter in hand. The Committee, however, have decided to equalise the two prizes, and they have done this by making the first prize £2, and the second 10*s.*!! This is an encouragement with a vengeance, and apparently a change of idea as to what should be the value of a first prize for such a breed as the Malay.

Now, let us turn for a moment to the catalogues of 1869 and 1870. From those catalogues I obtain the following table:—

1869.

Breed.	No. of Entries.	Amount produced at 7*s.* 6*d.*	Prizes offered.
White-crested Black Polands	15	£5 12 6	£8
La Flèche	9	3 7 6	£8
Malay	18	6 15 0	£14

A glance at these figures will prove that the Malay was not the worst payer to the Association; and if we reflect that probably £3 10*s.* or more was collected by Malay breeders, the Malay not only distances the La Flèche, but treads closely on the Polands. Accordingly, in 1870 the Committee reduced the prizes to the La Flèche, and again the Malay breeders assisted the Committee by a collection. The last year then tabulated gives the following results:—

Breed.	No. of Entries.	Amount produced at 8*s.*	Prizes offered.
White-crested Black Polands	15	£6 0 0	£8
La Flèche	8	3 4 0	£6
Malay	27	10 16 0	£14

Now, in this table, the La Flèche have still further gone back, the Polands remain just where they were, but the Malays have half as many again on the list, and are by far the best payers; indeed, I believe they more than paid the Committee, if we deduct the added money. This, an outside observer would have supposed a reason for encouragement, and the encouragement takes the peculiar form of lessening the prizes to the Malay, whilst they are retained at the very same amount for the other two breeds. There are other breeds that are still offered the same prizes in 1871, though last year they were worse payers than the Malay—adult White Geese, for instance, and the Silver-laced Bantams. These, however, are not reduced at all, probably because it is not "sauce for the Goose;" but I should be very glad to understand the reasons that have guided the Committee. I know not what other breeders may decide, but unless this be altered my indignation, if not cooled down before, will decide me to keep my birds at home.—Joseph Hinton, *Warminster.*

GRIEVANCE OF DORKING PULLETS AT THE BIRMINGHAM SHOW.

I and my sister have been striving the whole of this somewhat changeable summer to put on our very best looks, and we were highly elated a short time ago, to hear you say that the Committee of the Birmingham Show had increased the value of some of the silver cups to ten guineas, and we jumped (in the dark) to the conclusion that this certainly must be an age of progress. I must, however, confess that I feel considerably hurt on looking over the prize list, to find that we have not been treated with the same amount of consideration or courtesy by the Committee as in former years. We are deprived of our five-guinea cup, and the most we can hope to win is £3 for first prize. Our big brother yonder has the chance of winning a ten-guinea cup, which, if he should win, would make him more domineering and unbearable than ever. Perhaps it may not be decorous for me to express an opinion in such matters, but it certainly appears more difficult and more deserving of honour to be able to show two good birds of my sex, and comply with that awful fourth regulation, which reads so formidable in italics, than to show one bird only.

Now, can you kindly inform us what we have done to deserve this treatment? Is it because we have not appeared in sufficient numbers to satisfy the Committee? I should have been glad to have had the opportunity of winning a cup at Birmingham, but we must now, I presume, "rest and be thankful," and obtain as much consolation as possible from the assurance of our elders, that "disappointments are good for young people."—Dorking Pullet.

POUTERS IN 1871.

One of the best indications of the increasing popularity of Pouters may be found in the more worthy position assigned to them in recent schedules. Continued advancement, however, depends more and more upon that trenchant comparison of specimens only possible in exhibitions of metropolitan, or rather of national character. Attention, therefore, may fairly be directed to the competitions organised by London and Edinburgh, for both of these shows are very available for the critical purpose in view, regard being had to the convenience of *locale*, the quality of the birds, the style and tastefulness of exhibition, and the general carefulness of management.

Following a noble lead, Edinburgh has put forth for its second exhibition a schedule of great strength, its classification continuing the liberal policy of the Glasgow fanciers, and beginning indeed where they left off; while in the matters of lower fees and increased prize money a determination is shown to outbid former Scotch successes, great though they have been.

London, with the Crystal Palace for head-quarters, and with all the eagerness of a recent convert, seeks to repeat and even to amplify its late experiment with the Pouter varieties. Its unfortunate selection of date last year told greatly to the disadvantage of the classes in question, and prevented many an excellent Scotch specimen from appearing. Bot, notwithstanding, a quite unexpected display resulted, contributed to mainly by English breeders, with just enough birds from Scottish and Irish friends to make every true fancier hope for more representative gatherings on future occasions. Such occasions now present themselves, for this year there is nothing to prevent the Pouters of Scotland coming to London, or those of England returning the compliment at Edinburgh. Thus, by marshalling under one roof all the strains from every locality, may be secured such opportunities for critical comparison and interchange as have never occurred before, and which remain as the best means of improvement to the breed if duly utilised.

The schedule of London lacks no inducement; it is compact, yet ample, providing for every bird of whatever age, colour, or marking; and of the prizes it may fairly be said that Pouters have never before been so worthily furnished. To the sum of £40, contributed by the Committee, have been added the following donations:—The National Peristeronic Society, a five-guinea cup; the North British Columbarian Society, ditto; Mr. Volckman, a three-guinea cup, for classes in which he will not compete; Messrs. Ure, Wallace, Huie, Gresham, Heaton, and Fulton, each two guineas; Messrs. Percivall, Esden, and Taylor, each half a guinea, and Mr. Rose one guinea, swelling the total to nearly £70, and providing five silver cups as special prizes, for which all the classes but two have chances in competition. Surely the appearance of Scotland in force at the Crystal Palace next November is foreshadowed by the interest already taken in the London Show. At any rate, London so accepts the graceful courtesies of the North British Columbarian Society and the northern fanciers named, and no time has been lost in announcing that a Scotch Pouter Judge will be appointed to co-operate with the English Judges should the number of Scotch entries warrant the arrangement. Under all the circumstances, therefore, the absence of Scotch birds would give rise to no little of wonder and disappointment. But, of course, they will be present, and equally, of course, English friends will help to garnish the Edinburgh Show, not only with their Pouters, but with such other varieties as may be scheduled.

It would be ungracious to omit Ireland from these remarks. It is known that the Pouter fancy steadily progresses there, and although Mr. Montgomery, one of its chief representatives,

has announced that his Pouters will this year be kept at home, it is hoped that the "sister isle" will none the less contribute many a specimen for comparison with the English and Scotch birds.—W. V.

HUNTINGDONSHIRE POULTRY SHOW.

This was held at St. Ives, on September 27th. The following is the prize list:—

Dorkings.—1 and 2, — Wood, Clapton. *Hens.*—Prize, E. Southwood, Fakenham. *Chickens.*—1 and 2, — Wood. *Pullets.*—Prize, — Wood. *Cock.*—Prize, — Wood. *Cockerel.*—Prize, — Wood.

Spanish.—1, S. Deacon, Polebrook Hall. 2, H. Yardley, Birmingham. *Hens.*—Prize, G. S. Hall, Ely. *Chickens.*—Prize, H. Yardley. *Cock.*—Prize, H. Yardley.

Game.—1, S. Deacon. 2, S. Matthew, Stowmarket. *Cock.*—Prize, S. Deacon.

Game Bantams (Black-breasted or other Reds).—1, H. Yardley. 2, J. Goodliffe, Conington.

Mixen Breed.—1, — Longland, Grendon. 2, W. Cutlack, jun., Littleport.

Cochin-China.—1, H. H. Bletsoe, Barnwell, Oundle. 2, J. Taylor, Sutton, Isle of Ely. *Chickens.*—Prize, H. H. Bletsoe.

Hamburghs (Any variety).—1, H. Yardley. 2, J. Goodliffa (Silver-pencilled).

Polish.—1, Rev. W. Thornhill, Offord D'Arcay. 2, H. Yardley.

Turkeys.—1, G. S. Hall, Ely. 2, Rev. N. J. Ridley, Newbury. *Poults.*—1, G. R. Pearson, Witham Common. 2, Mrs. W. Willson, Feustanton.

Pigeons (Collection of not less than three varieties).—1 and 2, H. Yardley.

Prize.—Cup for the greatest number of Prizes, R. Wood, Clapton.

Judges.—Mr. F. Rooper, Huntingdon, Mr. John Linton, Buckden Wood, and Mr. R. Margetts, Huntingdon.

WEST HARTLEPOOL CANARY SHOW.

I may as well deliver myself of it at once and be done with it. The bird *is* ticked. My first duty when judging at Hartlepool was to disqualify No. 21 (J. W. Frankland), in the Clear Yellow class. It was *the* bird and *is* ticked, most unmistakeably ticked in front and round the top of the left eye. But no blame to Mr. Frankland. He claimed the bird at Whitby upon my *ipse dixit* that it was not ticked. I make no excuse and I offer no comment. *Humanum est errare.*

I have pleasure in reporting the first Canary Show held at West Hartlepool, both because it was the first, and because it was in all respects such a signal success, reflecting much credit on the ability and indomitable energy of the Secretary, Mr. Thos. W. Abbott, who, without even having time to advertise, managed, by dint of much tact and prompt action, to present West Hartlepool with a Show of unusual excellence. The Exhibition was supplemented by the attraction of a brass band contest, but I was told that the Canary Show was the attraction, and certainly I never saw so many people at a show before. Calculating the number in a crowd is some people's forte, I cannot do it, but I am within bounds when I say that the visitors might have been numbered by the thousand, and the contents of the Chinese bowls at the money-taker's box seemed to promise a balance which will next year make West Hartlepool Show second to none in the amount of its prizes.

I need give no special review of the birds, as the greater part of them were noticed by me in my Whitby notes; besides, I am afraid of breaking out in a fresh place about the ticked Jonque! But I must just refer to another gem of a Silver Lizard, which Mr. Ritchie, of Darlington, brought out. The Whitby hen was there too, but it had to stand below this new beauty, also a hen.

As will be seen by the note at the foot of the award of prizes, there was a stoat to nail up, a most flagrant case of tailoring. Mr. John Robson, of Bedlington Iron Works, exhibited two Goldfinch Mules, really magnificent birds if they had been what they were represented to be. But they were not, and that makes all the difference, and it becomes absurd to compare them at all with other well-known Mules of proved integrity. I had seen both these delinquents before more than once, and am not sure that on one occasion the Jonque did not slip me, though I exposed them both at last Newcastle Show, where the manipulation was not quite so cleverly performed as on this occasion, and it was to these same birds that my remarks in the report of that Show referred. The Committee in that instance took no action in the matter, but Mr. Abbott requested me to make a note of the tailoring at Hartlepool.

A great feature of the Show was the collection of stuffed birds. The idea originated with the Honorary Secretary, who is himself learned in ornithology, and a clever taxidermist. The display made in this department was something striking, and the specimens exhibited were for the most part rare and well preserved. The first-prize "collection of stuffed birds," shown by Capt. Farrar, was very superior as regards rarity of specimens and excellency of mounting, points insisted on in the schedule, the latter condition especially being of primary importance, for no amount of red sealing-wax can atone for want of easy, life-like posing, though in this respect all the specimens were highly meritorious, and selection became almost an invidious task. Capt. Farrar's collection contained the very rare Purple Heron, splendidly mounted; Spoonbill, Honey Buzzard, Kite, Osprey, Merlin, Goshawk, Peregrine, Sparrow Hawk, and others of the family Accipitres. The second-prize collection of Mr. C. Smyth was elaborate, and contained some rare specimens, but, unfortunately, the mounting was inferior, excepting a large Bustard, a grand fellow, and a good specimen of the Sand Grouse. A case of Owls, many of them rare, were lost for want of being naturally set. Mr. Brown's collection of British birds contained some remarkably well-mounted examples, notably a case of Waxwings, which were shot at Darlington. A "single case" of magnificent Himalayan Pheasants, exhibited by Capt. Farrar, was great. Mr. John Gent was first in the "collection of foreign stuffed birds," with large and fine groups, but, unfortunately, I have not the names. Last, but not the least feature of the Exhibition, was the first-prize "single case" of Mr. Wm. Farrar's, which contained a pair of the almost extinct bird the Ruff. This case was, without exception, the gem of the Show, and such a pair is seldom seen. One bird was a clean White, and the other a pure Cinnamon.

This department in a bird show must of necessity be somewhat local in its character, as it would be unsafe to trust the large cases with their glass fronts to the tender mercies of the railway. But, where such specimens are known to abound, there can be no doubt the owners would be happy to enter into friendly rivalry, and as little doubt that the exhibition of rare or curious specimens of the taxidermist's skill is as instructive as interesting. And why not give prizes for collections of birds' eggs and nests? I know I am treading on some people's corns. But I am not advocating wholesale robbery, or anything which would lead to it. Confined within proper limits birds'-nesting is a healthy study, mentally, morally, and physically, and destroys the jacket and trowsers also to a great extent.—W. A. Blakston.

Belgians.—*Clear or Ticked Yellow.*—1 and 3, W. Bulmer, Stockton-on-Tees. *Clear or Ticked Buff.*—1 and 2, W. Bulmer. 3 and *hc*, R. Robinson, Middlesborough.

Judge.—Mr. W. A. Blakston, Sunderland.

SUPPORT FOR FRAMES DURING OPERATIONS.

I have found the following apparatus invented by an apiarian here exceedingly useful.

Take two pieces of half-inch wood 4 inches wide and about 1 inch longer than a Woodbury hive measured outside. In the centre of the two boards there is a pivot to enable them to work freely one on the other. To prevent their being wood-bound pennies are half sunk in both boards through which the pivot passes. Two uprights of half-inch wood, 3 inches wide, about 8½ inches high, and 14 inches apart, are fastened to the uppermost of the two boards, with groove to form a rest for the ends of a frame; each has a brass plate about one-tenth of an inch in thickness screwed to the top.

The use of the apparatus is to receive a frame when extracted from a Woodbury hive. If it is desired to find the queen, the frames have simply to be lifted out one after the other and placed in the apparatus; and when one side of a frame has been thus inspected it is turned round by means of the revolving pivot, and the reverse side brought into view. I will not dilate upon its advantages, especially to those apiarians who have no one to assist them in manipulations. By using it anyone can operate much more easily, as the use of both hands is obtained—an obvious assistance when the object is to look for royal cells, or anything else requiring careful inspection. Two bars and frames can be placed side by side on the rest if necessary, and the shape of the piece of brass at the top will prevent either being pushed off. The apparatus when in use is rested across one end of the hive after the top has been removed, a small block underneath the two ends of the lower board preventing its shifting while in use.—D. D. B.

[We can well imagine that the contrivance as described may be of use to some operators, but to ourselves and many others

it would be greatly in the way. We should strongly object to the position it is intended to occupy when in use. Over the open hive under inspection is the last place we should choose. A moveable stand which could be put up close to, or at any distance from, the stock under manipulation, such as a tripod, would be preferable. To any apiarian accustomed to manipulation with frames, the two hands of the operator are all that he requires; and to insure gentleness of treatment, with accuracy and dispatch, he cannot too soon endeavour to acquire such knack and facility of handling to enable him to do everything not only without other assistance, but with as few extraneous appendages as possible.—Eds.]

LIGURIANS IN JERSEY.

In reply to your correspondent "D. N., *Cantab*," I may say that there is nothing strange in his finding Ligurian-marked bees in common stocks kept within a distance of one or two miles from an apiary having one or more pure Ligurian colonies. The circumstance is not, however, due, as he supposes, to the desertion of his own bees, but to the fact that the young queens of these outlying hives have met with drones from his Italian stocks.

The late Mr. Woodbury, not very long after his introduction of Ligurian bees into Exeter, was surprised to find, on driving a cottager's hive located at least two miles and a half from his apiary, that the majority of the bees were well striped. The queen, however, was a common black one. Being desirous of seeing what might come of it, he asked me to put her at the head of one of my colonies. I did so, and had the queen for some yeare. The majority of her brood came out more or less well-coloured and ringed, but many were quite undistinguishable from the common brown bees. The drones, however, were perfectly unaltered in colour or markings from those of any other black queen. This last was one of the facts Mr. Woodbury was desirous of establishing, and he justly thought that this was a good opportunity for doing so.—S. B. Fox.

OUR LETTER BOX.

Houdan Hen Sitting Persistently (*M. M.*).—We are always glad to hear of such amiable deviations from certain natural rules. We have known them to take place with Spanish and Hamburghs; we will now add Houdan to the list of those that sometimes enjoy a luxury denied, as a rule, to their fellows in breed.

Poland Fowl's Crop, Water in (*W. C. D.*).—Hold the fowl up by his legs till the crop is entirely emptied. Feed him frequently and very little at a time. Ground oats slaked with strong beer, and in almost liquid state. If he will not eat, pour down a tablespoonful every three hours. He must never have enough at a time to make the crop hang down. He may have some water twice per day, but only be allowed to sip at it twice each time.

Plumage of Grey Dorking (*A. C.*).—There is no rule for the colour of a Grey Dorking. Any is admissible save black or white. We believe the breeding of Grey Dorkings is more satisfactory than the Silver-Greys. There were many birds in the Silver-Grey classes last year that were disqualified for defects of feather, that would have been successful in general competition. You may show them with confidence, the principal point being weight, and of course freedom from defects of shape.

Turkeys not Thriving (*W. L.*).—We believe the brick floor has something to do with your losses. Nothing can be worse. It is worse for Turkeys than fowls. Cover the floor of your house with road grit or gravel, or dry earth at least 6 inches deep. Feed the sickly birds freely on bread and strong ale. We cannot help attributing part of your failure to feeding on bad wheat. We have to write every week that the best food is the cheapest. Verily, those who christened bad and damaged corn "chicken's meat," have a great deal to answer for. If we understand you aright, the Turkeys play an important part at Christmas. In order to leave no stone unturned to ensure their value, you feed them on worthless food, and you arrive at this result, that birds large enough now to weigh 15 lbs., weigh nothing, being but skin and bone. In most counties Turkeys make 10*d.* per lb. Say in your locality they make 8*d.* You have sighty Turkeys should weigh 1200 lbs., value £41 6*s.* 8*d.* You have economised £5 by buying bad instead of good food, and you have eighty Turkeys, 700 lbs., value "nil." Your economy will have cost you at present, at least £30. It is probably not too late to mend it. Have some ground oats with a small quantity, say a tenth, of pea and beanmeal mixed with milk three or four times per day, and feed them with it. As soon as they begin to rally let a trough of the same food be put in their house, and leave the door open that they may go to it when they like, but there must not be enough to turn sour, and the trough should be well washed out every day. We believe in camphor, but you may try strong beer, and put wormwood in their water. If they have a grass run, well and good; but if they have not, they should have large sods of growing grass cut every day with plenty of mould on them, and thrown into them. They will eat it all. Lettuces are good for them, and all green food.

Pigeon Portraits (*A. M.*).—In addition to those you name, Nos. 548, 464, 471, 473, 483, and 500.

Feeding Bees to Obtain Honey (*E. M. L.*).—It would be absurd and valueless to feed your stock for the purpose of taking off honey. If the hive with empty combs has a strong population, it would be advisable to supply it with sufficient food to bring up its weight, exclusive of hive, to at least 15 lbs. before the end of October. If you require honey, and are prepared to sacrifice a strong and prosperous colony, you can drive out the bees of the old stock, and unite them to the swarm, feeding liberally, as in the first case. We should, however, recommend you to keep both your stocks if sufficiently populous, and if you are willing to afford the necessary outlay for sugar. We should also advise you to get "Bee-keeping for the Many," which can be obtained from our office for five stamps, and which will give you the information you require on driving bees, as well as on various other matters.

Removing Bees (*Alpha*).—Do not attempt to remove your hive or hives 30 yards, or 300 yards, unless you are prepared to sacrifice many hundreds of valuable lives. You must either take them to a distance of about two miles, where they must remain a sufficient length of time to cause them to forget the bearings of their old locality, and then bring them back to their permanent stand, or you may move them gradually, at the rate of about 1 foot at a time after every fine day in the direction of the place you wish them to occupy. The autumn and the spring of the year are the worst periods for shifting stocks short distances, as the bees are more liable to become chilled while puzzling to discover their entrances.

REMARKS.

27th.—Dull day, warmer but frequent showers, wet evening and night. Great depression of barometer, which fell during the night to 28.88 (reduced).

28th.—Barometer rising rapidly; fine morning, but showers in the middle of the day, fine evening.

29th.—Dull morning, cold and very rainy all day, but fine at night.

30th.—Heavy rain during the past night, fine day, but wet again in evening.

Oct. 1st.—Fine morning, but rain soon after noon, followed by still heavier, with thunder, lightning, and hail between 1 and 2 P.M.; showery afternoon and evening, but fine night. [evening.

2nd.—A fine day though occasionally cloudy, only one shower till the

3rd.—In early part a bracing October day, partially overcast after 3 P.M.

The rainfall of the past week has reached the unusual total of 2.84 ins., which following a week with 1.99 in., makes 4.83 inches in a fortnight, a quantity in this part of England extremely rare.—G. J. Symons.

COVENT GARDEN MARKET.—October 4.

The supply of wall fruit is beginning to fall off, and prices have improved.

POULTRY MARKET.—October 4.

Another Michaelmas has passed away, Queen Bess's day is less observed every year, and fewer Geese come to market. Those that were good this year sold well, but many that were thin and badly fed and killed will make a poor return. The real market for Geese now is at Christmas.

From observations taken near London during forty-three years, the average day temperature of the week is 59 6°, and its night temperature 40.8°. The greatest heat was 80°, on the 14th, 1861; and the lowest cold 24°, on the 15th, 1860. The greatest fall of rain was 1.04 inch.

BEDDING PLANTS IN 1871.—No. 1.

HAVING been asked by several of my gardening friends to send a record of my experience with bedding plants this season, and especially with Geraniums, I send a few notes which I think may be of general interest to your readers.

I have had on trial this year about a hundred varieties of the flowering section of bedding Geraniums, and, including Bronzes, Tricolors, and Variegated varieties, nearly 150 kinds. This includes the older and well-established sorts, about which it is not necessary to make many observations.

I preface the remarks by what many, I am afraid, will think an oft-told tale—the method of treatment I adopt during the winter and spring months, as I attribute my success in a great measure, especially with many of the more dwarf and tender sorts, to the treatment they receive preparatory to planting-out. The great bulk of my plants were taken off as cuttings at the time of lifting the plants from the garden at the end of October. A few of those kinds I was short of were struck previously, so as to be able to take a second batch of cuttings after potting-off, but nine out of ten were not taken off till after the middle of October; they were then put, six into a 4-inch pot, on stages in a span-roofed house, with a row of hot-water pipes immediately under them. The pipes kept up a circulation of warm dry air among the pots. The cuttings were carefully watered, never allowing the cutting pot to be too dry nor too wet, and by the 1st of January they were all struck, and ready to be potted-off, the tops having all been previously pinched while growing in the cutting pots.

We began potting-off in the last week of December, and had all the young plants put into 4-inch pots; we finished potting by the end of the first week of January. They were all kept on shelves and stages as near the lights as possible in double-span houses, kept by means of hot water at an average temperature of from 45° to 50°, with a fall at night to about 38°—occasionally, in one of the houses, on very cold nights, to a lower temperature; but my object is to keep them constantly growing, never to allow them to be checked by want of water, nor too much cold and damp. With plenty of light the growth is never long and spindly, and as they are all on stages and shelves where they are easily reached, any strong shoot is pinched so as to make it branch.

By the middle of April nearly all the plants are in bloom, and are not stopped any more, but are then put out under low frames with moveable panes of glass, the frames being supported on bricks with ventilation left between them. The frames are those I have previously described in the pages of this Journal, and are about 3 feet wide and 10 feet long, double-span, 12 inches high in the centre and 3½ at the sides, and made to hold loose pieces of 21-oz. glass 20 by 16 inches, the lower part of the pane being fastened by a moveable wire pin. These panes can be moved about by two men with all the glass in them, and can be put up on loose bricks or on fixed brick walls in less than an hour. Such frames do not give the trouble or entail the breakages of glass which your correspondent "Au revoir" complains of in your last week's number.

I began to bed-out on the 15th of May, and though we three times had the thermometer below freezing point in the last week in May and the first week of June, I could not see that any of the plants suffered from it. My experience leads me to conclude that plants suffer more from hot sun and cold winds than from frost, and that the best method of hardening-off plants is to inure them to direct sun and plenty of ventilation, and this I endeavour to do by never allowing any of my Geraniums to be shaded. There is an immense difference in the texture of the leaf between plants grown in light double-span houses close to the glass and those out of ordinary greenhouses, and I remember being much struck when, this spring, at bedding-out time, being short of two or three plants of Dr. Hogg to fill up a bed, we took some out of a greenhouse next to my house. All the leaves flagged, and the plants looked quite different to the others in the bed for more than a fortnight, and yet the greenhouse is a very light one, with glass down to the ground on three sides of it, but as it has a western aspect the plants were not inured to direct sun.

I have been thus particular in describing the treatment I adopt, as it may account for many Geraniums doing well with me which do not succeed elsewhere.

My soil is a good garden loam, but I always manure even for Geraniums, as I much dislike the system of starving plants into bloom, and by selecting sorts that bloom freely under good treatment you can insure your garden looking gay both in dry and wet seasons. Another thing I would mention, I never use broken pots or any hard materials as drainage, but riddled cinders from one-half to three-quarter-inch deep at the bottom of each 4-inch pot, and the plants, consequently, never have their roots disturbed at planting-out time, as the roots completely encircle the drainage, and the balls turn out of the pots whole. These cinders I find nearly as good as charcoal, and a barrowload of them is quickly prepared by riddling the ashes out of the house through a half-inch riddle to get rid of the fine dust, and then riddling again through a three-quarter-inch riddle, which leaves the larger and coarser pieces fit for the heating fires.

A great many of my plants are in good bloom when I put them out, and I do not find these plants in less bloom at the end of September than those turned out of cutting pots and store-boxes, and which do not begin to make a respectable show till the end of July. One good plant well treated is, in my opinion, worth six badly treated, and I will guarantee to make a better display with a thousand good plants in sufficient variety that have been properly prepared than six thousand wintered close together in boxes, and turned out in spring about the same size as when taken off the plants in autumn. I have seen a great many mistakes made by the use of quantity instead of quality. I do not, of course, mean to say that all gardeners

have the convenience for wintering Geraniums in the way I recommend, but I do strongly object to the cold and damp treatment of Geraniums being still advocated as the best, and it is altogether a fallacy to suppose that a plant is made tender by being kept warm and in a growing condition during winter, or that it is hardened and its constitution made stronger by being kept cold; on the contrary, I think that the reverse is generally the case. Plenty of light and air, with a sufficiency of water at the roots in accordance with the amount of evaporation, is the great secret, if it can be called a secret, of success. Nothing, of course, can be more enfeebling than forcing plants in winter in close, shaded houses where all the growth is necessarily lank and succulent; but this is a far different thing to what I am speaking of, and the cost of double-span houses with fixed rafters about 10 feet wide each is comparatively small; and if the Editors would like it, I will send drawings and details of a house only 30 feet by 10, which will hold about three thousand bedding plants in 4-inch pots, the glass put in without putty or laps, and plenty of ventilation secured without any hinged windows. [By all means do.—Eds.] All gardeners who have seen it have taken a great fancy to it.

I have allowed these prefatory notes to be too long to say anything with regard to the Geraniums themselves this time, but will do so in my next, and must apologise to many of your readers if I have only repeated what they have often heard before.—C. P. Peach.

THE BEST ROSE IN THE ROOM.

In two Rose Associations, to which I have the honour of belonging, a somewhat new form of competition has lately been started, by offering a prize for the best Rose in the show. It may be interesting to some of your readers to hear the result, and to know the names of the successful Roses. At first it was considered to be hardly fair that Tea Roses should be pitted against Hybrid Perpetuals, and perhaps scarcely possible to compare the two; however, that is now done, and in one instance at least a Tea Rose was the winner. The extra work given to the Judges is very considerable, and necessitates most exact knowledge of a Rose's "points" and special excellencies: perhaps such a prize is only possible among a small number of competitors; with us, at any rate, the thing has been a great success. The adjudging was entered upon as a labour of love, while the interest excited was very considerable. It is a prize that has the advantage of being, not unfrequently, taken by a Rose out of a box which had previously been unsuccessful, thus helping to spread the awards over a somewhat wider area. This is especially desirable where the rule prevails, as among us, that no competitor shall take more than three prizes at the same show. It is evident that a correctly-kept list of such prize Roses would furnish the names of a series, which, as they say, "no gentleman's family should be without."

All Rose growers must have remarked how, in certain seasons, some Roses seem to do so much better than in others. "Every dog has its day," perhaps every Dog Rose; certainly it is the case in the upper ten thousand. This is strikingly brought out in awarding the prize to "the best Rose in the Show." Sometimes a new Rose will carry all before it, as Maréchal Niel, and La France, which I have known take two prizes, one as "the best single bloom," and another as incomparably the finest flower exhibited; at other times old friends most securely hold their own, and Charles Lefebvre defies all comers.

To begin with, there is, this year, the Rose that challenged all England, which it would have been unpardonable if florists had not thus recorded in their catalogues.

"R. H. S. Great Show at Nottingham.
June 27.—Premier Rose Duke of Edinburgh."

Looking back over the annals of our county Association, I find, and very naturally, Charles Lefebvre standing at the head of the catalogue. On that occasion, in 1869, Madame Margottin was his companion as queen of the Tea Roses. At another show in the same year Alfred Colomb came to the front. In 1870, a Rose that is somewhat uncertain, Pierre Notting, was conqueror in the contest; in the present year, most unexpectedly, Prince Camille de Rohan; and the prize bloom, it may be remarked, had been grown on a Rose on its own roots beneath a south-west-aspect wall. Marie Baumann at a larger show, and much more naturally, was quite unapproachable. At a show in the autumn of the present year a comparatively unknown Rose gained all our suffrages—Monsieur Woolfield, who, both for shape and colour pre-eminent, appeared on this occasion, to have surprised even himself. He would probably, by that appearance, have won his way into more than one garden.

Thus my catalogue ends, but if this kind of prize or inquiry has been known in other counties besides that in which I write, and which some of your readers will probably recognise, now that I have set the ball rolling, let others state their experience and the champion Roses.—A. C.

POTATOES.

The soil of your correspondent "K." (see page 235) must be unearthly, and I should think lunar volcanic, or it would not play such pranks with Potatoes. The bare idea of his rejecting the Ashleafs is enough to make one think this, for after many, many years of experiment, I can safely say that for spring, summer, and early autumn eating there is no sort to approach the four or five sorts of Ashleafs, including the Gloucester Kidney. Their flavour is beyond approach, and after them, not the deluge, but the old true Lapstone—not purple, mind—and any gentleman of good taste would be satisfied. As to the Early Rose, and, indeed, all the Yankee sorts, they are, as compared with the above, nasty; I can say nothing with less meaning. They have been introduced by advertisers, and should be avoided.

My soil is not from the moon, and is not at all unearthly, but is a dry, sandy, calcareous loam, which never fails in giving us good Potatoes of English sorts. I received my seed of Early Rose and Goodrich from Mr. Barron of the Royal Horticultural Society's gardens, at Chiswick, and also from Boston, U.S. "K." has most likely been cultivating some English sort instead of that horrible misnamed Early Rose, a "*lucus a non lucendo*," and has thus been deceived, for, depend upon it, no American sort equals or approaches to equality our favourite English kinds, which it seems the French, with their peculiar horticultural conceit, have recently found out, and which the Americans, if their perverse climate will allow them to grow Ashleafs, will also find. As to the exhibition of fifty kinds of Potatoes, why not make it one hundred? I could select ten sorts from one bin. Out of the fifty let the exhibitors select five for the table of a gentleman, and two or three more productive sorts for cottagers, and say two for cattle, such a sort as the Mormons seem to eat, and which is now imported by some Mormon-lover. Surely the exhibiting of large numbers of Potatoes is a vanity.—Solanum.

A GARDENER'S HOLIDAY.—No. 1.

There is much of historical interest in the neighbourhood of Kelso, and the town is beautifully situated at the meeting of the Teviot and Tweed. Standing on the well-built bridge which crosses the Tweed, at one end we see the old Abbey built by King David I. (whom one of his successors designated "A sair saunt for a crown"), one of the most striking ruins of its kind in Scotland. Looking up the river on the left-hand side one sees the ruin of old Roxburghe Castle, the scene of many a fierce contest between the English and Scotch. James II. (of Scotland) was killed by the bursting of one of his own cannon when directing the siege of this Castle; the spot is still pointed out. There is much more to be seen here of great interest to the antiquary.

There is also at Kelso one of the best-arranged nurseries in the south of Scotland, that of Messrs. Stuart & Mein. The old nursery on the Coldstream road had to be given up to the authorities, and has now been converted into a cemetery. New grounds have, however, been taken at Croft House; these are in two divisions. One part has been planted with trees and shrubs, which were removed from the old grounds, and are now in sturdy and luxuriant health; the other division contains an extensive range of new hothouses, and is also devoted to growing annuals, bedding plants, Gladioli, &c. The houses are all of the span-roofed description. The propagating house and show house are each 60 feet long by 15 feet wide; in the centre of the propagating house is a glass-covered pit, and stages are fixed all round the sides and near the glass to receive the plants. The show house has a centre stage and staging round the sides, and is well adapted for growing plants as well as for showing them off to the best advantage. The whole range of glass houses is heated by one of Shanks's combined tubular and saddle boilers, and this Mr. Manson, the manager, assured me did its work in the most satisfactory manner. It may be as well to notice, in passing, that where a large extent of glass surface is heated on the one-boiler system, it is a mistake to

depend only on one boiler: there ought always to be two fixed, so that if one should fail the other may do the work while a new one is being put in or the other repaired.

There is a very interesting trial border plantsd with bedding and other plants. I noted the following—Ageratum Chater's Imperial Dwarf is a very fine variety either for beds or lines in ribbon borders; it grows only from 9 inches to a foot in height and flowers profusely. It is rather more difficult to preserve through the winter than the old variety. Viola Yellow Perfection.—This is also dwarf and free-flowering, and is well adapted for small beds and edgings. I also noticed a well-filled bed of Calceolaria Sultan, a sub-shrubby variety with large flowers of a rich crimson maroon colour; it is exceedingly effective as a bedding plant in the north, but I find it will not succeed in the neighbourhood of London. There were also in this border two beautiful beds of a fine strain of Phlox Drummondi, the different colours blending together; pink-striped and rose-coloured flowers shading to deep purple made a bed not easily matched in chaste beauty.

It is in this part of the nursery that the Gladioli are grown for exhibition. They are planted on a narrow border sheltered on the north side by a low wall; the tallest spikes would grow as high as this wall. The border was sloping to the south, so that the sun would act upon it as much as possible. Then as to soil: this is a very light loam resting on gravel. It is naturally poor, but no doubt trenching and manuring are resorted to in order to improve it. A large number of roots is not grown, but I noticed very few failures, notwithstanding the unprecedentedly unfavourable season. I believe it is intended to grow Gladioli to a much larger extent, in order to compete with the more extensive growers in the south. I have nowhere else seen such a healthy robust growth as in the plants here; and Mr. Manson, Messrs. Stuart & Mein's manager, makes no secret of his success, nor does he use any patent manure to attain such splendid results. Nearly the same varieties as we cultivate in the south are grown here. I saw some of the present year's new varieties which I had not seen previously, and I must say that 75 per cent. of M. Souchet's new ones were not worth sending out. Some of the high-priced ones, such as Phèdre, have no constitution, and many of the others have badly formed flowers as well as indifferent spikes. It would be wrong, however, to condemn them too hastily, as this has been a very bad season for them, and some of them are first-class flowers. The best, I think, is Horace Vernet, a very brilliant purplish red flower, stained white. Phidias is a fine flower of a new shade of colour, violet purple lined with white. Talisman has well-shaped flowers, violet, stained white; the spike is rather short. Sir J. Franklin, very long spike, the flowers rather thinly placed; the upper petals rose, lower petals largely marked with white. Edith Dombrain I have seen very fine. With me the spikes were short; the flowers are well shaped, ground white, feathered with carmine purple. Nestor is the best yellow; its growth is robust, and it has a very long spike of deep yellow flowers of large size, the lower petals slightly stained with red. These are the best of this season's flowers as far as I have seen, but we are all anxiously awaiting the report of "D., *Deal*," not only on this season's flowers, but also of those for next year. No one has better opportunities or is better qualified to judge than he is. In the stand of thirty spikes of fifteen varieties which Mr. Manson was arranging for Edinburgh, and which was awarded the first prize, I noted as the best—Shakspeare, Orphée, Rosa Bonheur, Princess Mary of Cambridge, Newton, Horace Vernet, Adolphe Brongniart, Michel Ange, Adanson, Thomas Methven, and Diomède.

In the private garden attached to Mr. Mein's residence was a long row of Parsons's New White Mignonette. The growth was more robust, perhaps, but in other respects it is not different from the ordinary variety. I also noticed another row of a new bedding Dahlia. It had, I was informed, been raised in the neighbourhood of Kelso. It grows from a foot to 18 inches in height, and does not require sticks to support the shoots. It is a most profuse bloomer; the flowers are bright scarlet, and as well-shaped as some of the show flowers. It is a decided acquisition as a ribbon-border plant. It has been named Sunrise.

From Kelso a pleasant walk down the banks of the Tweed for the distance of a mile brings you to Hendersyde Park. The mansion is beautifully situated, and commands a fine view of the river. This place now belongs to G. W. Griffiths, Esq. The gardener, Mr. Smail, I have long known as one of the most successful exhibitors in this neighbourhood. He is now an ardent cultivator of the Gladiolus, but the number of losses in his beds was very considerable. The soil is much the same as that at Kelso, so that in this case something else was the cause of failure. I would attribute it to the garden being very much surrounded by trees, so that the beds were shaded by them; the plants, although strong and healthy, were drawn. The Hollyhock has also been taken in hand by Mr. Smail. Two seedlings raised by him were in flower at the time of my visit. They have been sent out, I believe, by Messrs. Stuart & Mein. One named Mrs. Atkinson is a buff-coloured flower, and the finest of its colour I have yet seen. The other, William Mein, rosy crimson, is a well-shaped flower of great merit. There is some good gardening to be seen at Hendersyde Park; there is much of general interest in its extensive woods, and Mr. Smail, like all true gardeners, makes no secret about the culture of his favourite flowers.—J. Douglas.

THE BLACK PRINCE STRAWBERRY.

We gathered the first dish of this variety on the 24th of May, and a very heavy crop in the first week of June. After gathering the crop, not wanting the runners, we kept them and any old withered leaves cut off, and the beds well cleared of weeds. On the 9th of September we gathered a dish of perfectly ripe fruit off the same plants, and we picked several dishes since that date. There are at the present time (October 2nd), a good many ripe fruit remaining. The plants have been in their present position for three or four years. I attribute the second bearing and ripening to the earliness of the first crop, and to our immunity from spring frosts, which are so destructive to the Strawberry crop in many places more inland. In a direct line we are only three or four miles from the sea. It would be interesting to know if there are many cases of this kind in the dull sunless season that we have just passed.—E. H. Cooke, *The Gardens, Peniarth, South Wales.*

SELECT ROSES.

Your correspondent "P.," gives a list what he considers to be the best twelve Hybrid Perpetual Roses, with a view of eliciting from other growers their opinion, and if my experience is worth anything to growers in the northern counties of England, I give it with pleasure.

Taking "P.'s" list of twelve I quite agree with him that Marie Baumann, Baroness Rothschild, La France, Charles Lefebvre, Marquise de Castellane, Monsieur Noman, and Edward Morren are among twelve of the best Roses grown. I very much question if Louis Van Houtte will prove a superior Rose to Xavier Olibo, much in the same line of colour. Marie Baumann, described by "P." as a good grower, is only moderate here, and it is difficult to get good blooms from cut-back plants, but from maiden plants it is magnificent, and on going through a plantation of about thirty thousand plants, comprising all the best varieties grown, I thought it the finest of all. In place of the others mentioned—viz., Comtesse d'Oxford, Mdlle. Eugénie Verdier, Madame Vidot, and Comtesse de Chabrillant, I should prefer Alfred Colomb, one of the very grandest Roses raised; Madame Victor Verdier, which has been magnificent this year; Pierre Notting, the finest of the very dark varieties; and Marquise de Mortemart, the best of the very light varieties; but like Marie Baumann and some others of weak growth, it ought to be budded annually to have it in perfection. Closely following these are John Hopper, Dr. Andry, Comtesse de Chabrillant, Abel Grand, and Emilie Hausburg. The following are also first-rate and ought to be in every collection—viz., Duke of Edinburgh, Duc de Wellington, Baron Haussmann, Nardy Frères, Elie Morel, Duc de Rohan, Sénateur Vaisse, Maurice Bernardin, and Leopold Hausburg, the last named of weedy growth, but of excellent form and indispensable to exhibitors. Madame Vidot, which "P." places high in his list, is a beautiful Rose when caught good, which is very rarely the case, and I think Marquise de Mortemart, of similar colour, will be more suitable to the generality of growers.

Of Roses of recent introduction, first, I will take Comtesse d'Oxford and Mdlle. Eugénie Verdier, which are both highly praised by "P." The first is good, but nothing remarkable, whilst Mdlle. Eugénie Verdier is a coarse variety without any refinement whatever, my plant not having produced a single good bloom, and from about two or three dozen I saw growing near here during the past summer, I could not find a single bloom fit to put into a stand. It is, however, a good garden Rose, being very free-blooming, and pretty in colour. Of others not mentioned above, I think Dupuy-Jamain, Ferdinand

de Lesseps, and Perfection de Lyon will prove good, the last named a difficult opener. Paul Neron, of immense size, is coarse, but may prove good. Madame Liabaud is choice in colour but small.

In the lists of Teas given by your correspondents, I do not find Homère. I saw three trusses exhibited in one collection during the past summer most lovely in colour, being beautifully edged with pink like a Picotee, and of good size and shape. Will some one who has grown it kindly say if it succeeds well in the open air, and if it is as hardy as Souvenir d'un Ami, Madame Willermoz, and Madame Bravy, all of which have been beautiful with me during the past summer?

I never saw Roses so free from mildew as they are this season; even at this late period there are scarcely any traces of it, the stronger-growing kinds having sent up fine strong stems from 4 to 6 feet high. In pruning I always cut all the old wood out, and shorten the new well in. Nearly all my plants are grown on the Manetti stock, which I consider to be the best form of Rose-growing, especially in light soils, such as my own.—J. B., *Darlington.*

SUPERIOR MELONS.

Your correspondent, "Owen Thomas" (No. 547, page 215) in his list of superior Melons, may with every confidence add another first-class fruit to his number—namely, Golden Gem, raised by Mr. Cox, of Madresfield Court, and from its superior quality, handsome appearance, and good bearing, he will soon find it to be second to none. I quite agree with him that Golden Queen is a first-rate variety, but I have never been fortunate enough to grow it to anything like the weight which Mr. Thomas mentions—namely, 4 lbs. to 5 lbs. each, nor do I know anyone else who has done so. I received my seed direct from the Messrs. Stuart & Mein, of Kelso, in the spring of 1869. I have never allowed more than from two to four fruit to swell on a plant, but could not exceed 2½ lbs., nor could my friends, but all pronounce it a first-class Melon. I confine my list to three varieties—viz., for first use Malvern Hall; for general crop, Golden Gem and Golden Queen.—S. Taylor, *Sion Hill, Kidderminster.*

POTATOES—EARTHING *versus* NON-EARTHING—ESTIMATE OF VARIETIES.

A short time ago the subject of Earthing *versus* Non-earthing Potatoes was discussed in these pages, and, by what I could gather, the majority were for non-earthing. There was, it cannot be denied, some well-seasoned remarks thrown out, and much I fancy that most of us are well acquainted with. Well, the Editors said, Give us something more than "I think." At the time I read the discussion the men were earthing-up Potatoes. I had four short rows left unearthed, and the four next rows were left earthed-up until this week. We then took them up and found the unearthed wanting, when brought to the test of being weighed, by 11 lbs. in the four rows, say about 12½ square yards. I think that at a rough calculation it makes just 2 tons difference per acre, there being 56 lbs. in the earthed-up portion, and 45 lbs. in the unearthed rows.

I have been a long time convinced that earthing-up Potatoes is the right plan, and that, too, in all classes of soil. The same subject was much discussed four or five years ago. In the following year I left a quarter unearthed; I then considered, when they were taken up, that a third were lost. I can go back sixteen or eighteen years when the good old rough Reds and Blues were grown, and remember distinctly when there were a few rows left unearthed, that few Potatoes could be found in them.

I am for shallow planting with plenty of room between the plants, and plenty of earth placed around them, and that, too, as early as possible, say when about 4 inches high. Undoubtedly the damage in earthing-up is when they are too high. The advanced say, Plant deep in shallow ground. I say, Plant moderately shallow with plenty of room between, and earth-up with a good broad ridge not less than 15 or 16 inches through, and 4 or 5 inches deep.

In wet clayey land plant them on the surface and ridge them up when planted. Much of this will be worked down in cleaning, but must be renewed afterwards. I may here state, that this has been a rather wet summer, but it is no criterion with respect to the comparative merits of earthing and non-earthing; for two years ago, when I had the quarter mentioned above not earthed, it was a very dry summer.

I am sorry to endorse what has been said with regard to the closeness of the Early Rose Potato this season. We find the same remark stands for all sorts—in fact, we have scarcely any really good, still I am glad to bear testimony that the Early Rose has been less affected with the disease than any kind we have had this year. We have taken up a sack of it this week, and not half-a-peck was rotten; and as to the crop, I had a trial of ten sorts, and in the amount of produce the Early Rose far exceeded any of the rest, being triple that of some. I find on distributing some of them and the Red-skinned Flourball amongst the cottagers, that the Early Rose was generally small, so that it is evident it likes rich ground. The Red-skinned Flourball turned out a good cropper and produced very large tubers, so that it carried all before it at our Cottagers' Show—an infant of two-years growth, but doing extremely well. This Potato is an excellent late sort, and will, I hope, take the place of the degenerated White Rock, which is generally grown here. It can hardly be designated a garden variety, as the haulms grow so long. Mine this year grew from 3 to 4 feet long. The sets should be planted in good ground at least 3 feet apart. Of its quality I cannot speak, as it is evident the tubers should be kept until after Christmas before being used. Quality, however, is little thought of here with the mass of people, as they boil all their "Tattoes" in their "coul" (broth), and as you are doubtless aware, Leeks constitute the first and largest part of it. I would certainly prefer the Irish style of having good, rich, mealy Potatoes mashed with butter or new milk.

Has it been generally noticed that coloured Potatoes, especially blue or purple sorts, do much better than white in dark-coloured soil, notably bog soil, while Potatoes generally there grown taste earthy and are more liable to disease, and Kidneys, generally speaking, are oftener found black at the end?—J. T., *Maesgwynne, Whitland, South Wales.*

THE FOREST TREES OF HINDOSTAN.

(*Continued from page* 160.)

Of Magnoliaceæ we have more than twenty fine species in the Indian empire, most of them with flowers diffusing an overpowering perfume to a great distance, and even producing sickness and other severe affections in nervous individuals. Some of the Michelias are grand trees, seen about temples and places of pilgrimage, their golden hue and indescribable fragrance having long ago placed them among the sacred symbols of the Hindoo religion, and gradually led to a wide distribution of this choice class in cultivated groves and reserved lands. Others furnish the famous timber rarely met with in Christendom, there being no outlet from the remote woods and mountain forests where these trees flourish. A backwoods predecessor of mine, however, brought down to civilisation by boat a few planks, which were worked up into a dining table of wondrous beauty. The breadth of each piece was at least 4 feet, the grain was most curiously wavy and striped, the mixed hues of brown, black, red, and yellow, giving the well-polished surface the similitude of a tiger or zebra skin. As a piece of house furniture it was worthy of a palace. Of Anonaceæ, though we have something like one hundred in this tropical order, not one supplies any wood worth cutting, though as an avenue tree and useful to shade the traveller, Guatteria longifolia (or Mast tree, so named from its tapering, lofty growth) is here mentioned. This tree is very roughly handled by hurricanes, while its substance is so soft and corky as to preclude its "wrecks" from furnishing even fuel.

In Dilleniaceæ, another very tropical order, our virgin forests of the north-east are very abundant; more than nine genera exist within Indian limits. The wanderer in the swampy watershed of the Burrampooter valley will pass many days in the shade of Dillenia speciosa, which there attains a gigantic growth its admirers at Kew know not. The flower is truly barbaric and oriental, coarse and beautiful, the bright green, sharply-serrated foliage in full keeping, and lastly the abundant juicy fruits, yield a favourite repast to the pachydermata and larger fauna of the forest, and are not unacceptable to the various tribes of *homo* as an acid adjunct to their fish curry. The timber of some kinds is hard, and of such girth as to furnish canoes, while the leaves yield admirable material for the substratum of thatched roofs, besides being used by primitive artisans in the manner of "Dutch rushes" for polishing wood. Were there not so many finer and handsomer timber-producing trees in the same locality, Dillenia wood might have entered the market, as it is close-grained, and has been tried in gun-stocks with good repute.

Alangiaceæ:—This small order of Indo-Chinese character furnishes hard and handsome woods, not yet introduced into the European catalogue, though the four species are exceedingly plentiful in the remote regions of our north-east frontier.

Rhizophoraceæ, or Mangrove tribe, are tropical trees of the deadly salt swamps or muddy lagoons of the inland forests. A pleasant sight to a naturalist are those vast aquatic forests, casting their dusky shade in the mirror of water, and he must oft enter their leafy labyrinths in a light canoe paddled by some savage ally, should he wish to become familiar with the fish eagle, otter, alligator, and many "uncouth fishes," sole tenants of the fever-haunted waste. Two good kinds of hard durable wood are produced by this order, but hitherto only useful to the shipwrecked sailor from their isolated locale.

Of Myrtaceæ, India can boast one hundred and odd forms, chiefly fruit-bearing trees of lesser growth than could be termed forest timber, and indeed chiefly the denizens of enclosures and groves. However, Psidium or Guava does grow actually wild in the Coffee tract well known as the Wynaad jungle, Southern India (perhaps introduced). The trees in that locality extend for a great distance, and on one occasion of a general famine proved the value of their existence by saving an immense population from starvation, as the fruit contains a large per-centage of sugar and mucilage, and is noted to be in its most perfect condition and abundance during the rainless and blighted periods of the above terrible visitations, and Government long ago rendered punishable any injury to the food-yielding tract above mentioned. Guava wood, though rarely met with in the market, is a most desirable article, close-grained, tough, light, and applicable to all the purposes of British Beech, but it is never of any size. Some I felled in improving a neglected garden was perhaps 18 inches circumference, and rarely straight for more than 2 feet. It is most pleasant to turn in the lathe, makes prime tool handles and agricultural implements, also gunstocks of light and durable quality. I have occasionally purchased billets of the Indian gardeners, who sell them as firewood when clearing old enclosed lands.

Of this large order the Eugenias are handsome orchard trees, the purple mouth-staining Plums so astringently acid as to require salt in qualifying them for the human palate; indeed, the amount of tannic acid in every leaf and pore of these elegant trees renders it of some importance in native estimation, the bark yielding brown red dyes, and the timber imperishable beams and posts for bridges and well foundations, being hard, heavy, and incorruptible by reason of its great store of astringent saps. For shade and ornament unsurpassed, as they attain considerable dimensions, and have mostly showy, Myrtle-like blossoms, conspicuous in the waxy green, closely-set foliage. This wood is not in the market, being too heavy and coarse for export. I have used it for various out-door work, as well-gear for irrigation, gates, posts, &c. Sonneratia (in Myrtaceæ) is remarkable as furnishing a firewood replete with an aromatic resin, or oil, which long rendered it the only effective substitute for coal in the steamers on the river Indus, along the banks of which it grows abundantly.

Ternstromiaceæ, or Theads, another of the Indo-Chinese form of most interesting properties, but only one, a very rare and local tree, Thea assamica of the uninhabited tracts (about 27—28° north latitude on the Little Burrampooter and its tributaries), can be said to supply wood for constructive uses. The ultra savages on whose lone hunting grounds there exists a belt of these quaint unmatched Tea trees, some six miles long by a few hundred yards wide, jealously watch this spot, and explorers for the ruins of classic Sisopulnugger, hunters of ivory, retributive expeditions against those wild men and Tea-seed collectors, can all give a lively account of the "skedaddle" produced by a shower of swift and silent arrows, all heavily envenomed with aconite, shot from the leafy ambuscades of the "cropped hair" Mishmees, as those uncivil nomads style themselves, in distinction from their "unshorn" neighbours. This wood is known to the native backwoods man of that ilk as Boga Kat, or white wood, and is applied when obtainable to the ignoble purposes of walking staffs and sling yokes, being light and flexible.

Aceraceæ, or Sycamores.—There are several species in the Himalayas, but I have never met with any person, native or English, who had used the wood, for the trees generally grow on lofty heights, many days' journey removed from human dwellings, and being surrounded by so many other kinds of useful woods have escaped the axe *in toto*.

Sapindaceæ, or Soap-berry trees.—Only two or three of this very numerous Eastern order supply timber, which is hard, white, close-grained, and useful, but being surpassed by so many other woods within easier access is rarely cut down, and I have never worked it myself.

Æsculaceæ, or Horse Chestnuts.—The remote regions of the Upper Himalayas contain two or three species of Pavia, but I never saw a tree felled. They are valued for their bitter, farinaceous nuts by the mountaineers in famines, though quite as nauseous as our European congener.

Sterculiaceæ.—It is somewhat strange that of the many giants of the forest in the one hundred and odd species composing this very sylvan order, not one should supply any timber of utility in industrial art, being usually spongy and of pulpy consistence, while the bark of many is so tough, wiry, and pliable that cordage is manufactured, and even the lassos used by elephant-catchers are prepared of this substance. Foresters use the bark of Sterculia urens for their drag ropes, Tea planters as cables to ship their loads and fasten their rafts, builders to lift their timber into place, and aboriginal man for snare loops to entangle the wild buffalo, &c. The Tree cotton is the product of Gossampinus, a noble ornament of the woodlands. It is as soft and silky as swan's down, but cannot be used for the loom, only stubbings, &c.—Eos.—(*English Mechanic and World of Science.*

GROUND VINERIES.

And so, Monsieur "Au revoir," you have cut your fingers *à la* Rendle! If you had the original protector and used it for Vines, you would do so and not reap much satisfaction. The truth is that Mr. Rendle has an imagination at tropical heat, as shown by his very pretty book with its plates and impossible troughs, for growing Grapes in, and making our wine from English-grown Grapes. Poor Messrs. Gilbey! how they must have shaken in their shoes to contemplate the bare possibility of not importing any more wine! If the book had this effect it had no other, for no one seemed to patronise the invention, and these semicircular troughs with a groove for glass all went out of mind, and the book too, for I cannot find my copy; still the idea was new and attractive.

There is just a word or two to say about the protectors. Those sent out originally by Mr. Rendle were really interesting, and as protectors for lettuces and other garden crops were most useful, and when slightly improved were all that our clever gardener Mr. Ingram reported them to be. Here permit me to assert that Mr. Rivers never allowed his name to be used; he carefully avoided writing a sentence that could be used by an advertiser, but it seems, according to "Au revoir," to have been so used, just as it is made a handle to the Royal Ashleaf Kidney Potato, which requires no handle. Well, I must say that the grooved bricks, and their lasting qualities, and the facility of moving the ucture, seemed to me most agreeable, and so I tried them with Vines, which grew well and ripened their fruit almost as well as those in common ground vineries; but the sliding of the glass in the grooved bricks was to me intolerable, as the pinching of the Vines required them to be moved so frequently that cut fingers and friar's balsam were in the ascendant. Well, about this time I received from Mr. Rivett one of his improved ground vineries with one side moving on hinges. The wind had knocked over more than once the Rendle protectors, much to my disgust; and so I went over to Rivett, for, like Macedon and Monmouth, they both begin with R.

As far as I can judge Mr. Rendle has improved his protectors, so that cut fingers are not so much in the market, and if so improved they will be most useful for many garden crops, but not equal for Vines, or Peaches, or Pears, as are those of Mr. Rivett, which I pronounce to be the most convenient structures for small or even large gardens ever invented. The hinged side to the ground vinery is a capital idea. Mr. Rivett had it, I think, from Mr. Rivers, but I am not sure. The lifting this up, pinching the Vine, the cordon Peach tree, or gathering Strawberries and Peaches, is a real luxury; and then in winter the salads are always so comeatable, that although I should in large gardens or even in market gardens, employ the brick structures because they are cheap, and if built low will not be affected by the wind, for the amateur Rivett's improved ground vinery is all in all. The uses of this structure are not yet half understood, for, besides winter and spring salads, bedding plants may be kept under them with the usual air in mild weather, and in a sharp frost "sealed"—*i. e.*, covered with a thick coat of straw. If this is of sufficient thickness no frost will or can enter.

There are some new inventions by the Rev. T. Bréhaut and

patented by Mr. Rendle. Now I know that Mr. Rivers wrote to Mr. Bréhaut to express his approbation of all protective inventions, but he has not sanctioned the mention of his name in advertisements. Allow me to advise "Au revoir," and all owners of small gardens to adopt only Rivett's improved ground vinery or others of the same make, for there is no patent for hinges. These, placed on a few bricks, as mentioned in the "Miniature Fruit Garden," pp. 141 to 153, will be found among the most useful and economical of all garden structures. If more luxury is required the protectors of Mr. Bréhaut can be employed; they seem very good and useful, judging from the descriptions.

I do not quite understand "Au revoir" when he says, "If the maker of the wooden frames had called them Cauliflower-protectors," &c., "he would have had orders," &c. Does he mean the improved ground vineries? or does he allude to Rendle's protector supported by a wooden frame to prevent its being blown down, as mine has been till supported with slips of deal, which, if for Vines, those first invented require to be? and if made of sufficient height Vines grow well and ripen their fruit; but I confess to highly preferring Rivett's improved, which grows Vines so well and all other trees requiring protection.

The Vines of Mr. Rivers have hitherto been remarkable for ripening their fruit every season, but this year the fruit is not ripe, nor likely to ripen without a hot sun in October. I have to-day (October 2nd) had the pleasure of looking into the ground vineries of Mr. Rivers, so allow me to report faithfully. The first I looked into was one of Rendle's protectors, the original sort. This is 20 inches high in the back wall, to the N.W., and 14 inches high to the S.E. The front wall has pigeon-holes. In this was a healthy Vine, or the half of a Vine, 14 feet being perfectly healthy and full of fine bunches of fruit unripe of the early variety so much like Buckland Sweetwater—General della Marmora. The remaining 14 feet of this Vine were enclosed in a ground vinery 3 feet in diameter at base, of the usual kind, on bricks. In the 14 feet of Rendle's are sixty bunches fine; in the 14 feet of the same Vine under the common ground vinery—the base of the Vine—are twenty-five bunches. The top end enclosed in Rendle's in 1870 ripened some thirty bunches in spite of cut fingers. This is a triumph.

The next ground vinery on bricks has the Black Hamburgh trained under it full of fruit unripe. The next to this is a marvel, requiring eight 7-feet lengths to cover it; this is the Trentham Black, fruit unripe. This portion of the ground vineries is too narrow—only 30 inches at its base, but the Vines are full of health and the crop large. This long Vine is a charming sight. I learn that Mr. Rivers, observing towards the end of July the backwardness of the fruit, would not have them thinned, so that possibly—barely so—they might if thinned have been riper than they now are.

I hope this plain and truthful statement will satisfy "Au revoir." I have only to tell him and his friends that for their small gardens no protector is equal to the Rivett's improved with a hinge. It should be 3 feet 6 inches in diameter at its base, placed on brick, and then Vines, Peaches, Pears, all trained along the centre to a wire; and bedding plants, and salads, and early Peas, &c., may be grown in them to their heart's content. For larger cultivators the cheaper brick protectors of Rendle may be used.—An Old Lover of Protectors.

ROSES WITH IVY.

One of your correspondents has inquired if Roses and Ivy will do together, and has been answered by "Hortator." I have two high walls, one facing south, the other west; both are completely covered with Ivy and Roses. The way mine are grown is this. The Ivy and Roses were planted together. The Ivy will cling to the wall, and the Roses are trained to a wooden trellis, which should be at least 4 inches from the wall, otherwise the Ivy will choke the Roses. The varieties which I find do the best are Gloire de Dijon, Céline Forestier, and Maréchal Niel grafted on Gloire de Dijon. The contrast when the Roses are in bloom is grand. I have also trained on the same walls a white-corollaed Fuchsia, Madame Cornelissen, and at the present time the walls are the admiration of all who see them. Here the Fuchsias want no protection in winter, and I am in hopes of getting them to the top of the wall in a year or two. The upright pieces of the trellis are half-inch square and 9 inches apart.—J. T. Dawson, *Gardener to W. H. Smithard, Esq., Summerville, Guernsey.*

[The chief difficulty is not in keeping the stems of the Roses and Ivy apart, but in keeping the roots of the latter from robbing the Roses of sufficient nourishment.—Eds.]

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 20.

The Hop is a plant which belongs rather to the farming than to the gardening interest, though not unfrequently cultivated as an ornament in gardens, and used to conceal an unsightly paling by its graceful festoons, or to impart a pleasant greenness to the trelliswork of an alcove or summer-house. I presume that all the readers of this Journal are cognisant of the fact that this year has been a most unfavourable one. It is well known to the growers, and to the purchasers of the product of our Hop plantations, that no one year is exactly alike any other year, a constant succession of changes being occasioned by the seemingly peculiar liability of this plant to be affected by atmospheric phenomena, by the attacks of insect enemies, by parasitic vegetation, and by maladies not easily definable in addition to these. Just as some persons have remarked to me, that when they feel particularly comfortable they are sure that some trouble is approaching, so is it with the cultivator of Hops; in a good year he rejoices with trembling, since he may pay for it in two or three subsequent bad ones. On the other hand, in a very unfavourable year he has this consolation, that the next is nearly certain to be different, and most probably decidedly better.

Now 1870 was a decent average year, but 1871 is exceedingly below the mark, both in England and abroad. In a letter addressed to one of our daily journals, a Kentish Hop-grower makes the following dismal statement:—"The plant has this year, from its earliest shoot in the spring up to the time of picking, suffered from a succession of attacks as numerous and almost as fatal as the ten plagues of Egypt. I may enumerate wireworm and flea by millions, spiders, red and black fly, sometimes three deep, lying on the leaves, followed by innumerable lice, which destroy the vitality of the vine, and turn it black; mould, white and red, which eats away the Hop and destroys the sample; and to complete the calamitous list of foes, we generally have one or two terrific sou'-westers, which rend and shiver the Hops, so that some grounds in exposed positions look as if our gallant cavalry from Aldershot had charged the enemy through the plantations. I ought in fairness to add that we have two friends who occasionally come to our rescue and destroy the vermin, and I therefore mention with grateful respect our nursery friend, the lady-bird, and a sable insect called the "negur.'"

I do not profess to be any authority in Arachnids, but yet I demur to the wholesale condemnation of spiders. The true spiders are, I believe, staunch in their adherence to animal food, and decidedly reject vegetable aliment. Young spiders and small mites are often mistaken for each other, though there is a remarkable structural difference between them, one which, nevertheless, no one but a naturalist could be supposed to be cognisant of. Spiders are furnished with eyes, while mites are unprovided with organs of sight as far as we can tell. One of the mites, which is almost exactly like a small spider at a first glance, is that called Trombidium holosericum, and it also spins a delicate web for the protection of its young, rather than for the capture of prey. This is said sometimes to be sufficiently common on plants to impede their growth; whether or not it occurs on the Hop I cannot say. The harvest bug (Leptura autumnalis), which is abundant in June, does doubtless occasion some injury to the Hop at times, though a more usual visitant to the kitchen garden. This species can only be detected by close watching, from its minute size. Some species of the genus Acarus may also occasionally visit the Hop plantations.

It is no wonder that this writer, not, of course, an entomologist, though a shrewd observer of Nature, failed to trace the connection between the "fly" and the lice, they being, as is evident, aphides in different stages of growth. What he alludes to under the name of the "negur" is not quite clear; the larvæ of the lady-bird or lady-birds, for there is a plurality of species here, are called "niggers" in some places, and the name may also have been, for aught I know, applied to some of the larvæ belonging to the genus Syrphus, truculent individuals, indeed—wolves among the aphid sheep. Some newspaper editors have, it seems, been sending commissioners into the Hop districts to make their investigations and report thereupon, a proceeding a little in the manner of the proverbial individual who doubly secured his stable door when his steed had been

spirited away? As an independent and non-commissioned observer, I venture to give an opinion regarding a few of the prominent insect enemies which have made the Hop their prey this season, though I make no positive assertions with regard to the state of matters in the midland districts, though, presumably, what applies to the south would not be inapplicable to these. It is easy to catalogue a host of insects found on or near Hop plantations, and yet far from easy to apportion to each its due share of blame. I feel convinced that the principal transgressors have been the aphides, *alias* flies, *alias* lice, belonging to more than one species, though the "speciality" of the Hop, Aphis Humuli, ranks first; for certain species of plants have their particular enemies of the aphis genus, though some of these flies appear to be migrate without much discrimination. Indeed, Dr. Plimley, of Maidstone, has propounded a singular theory with regard to the habits of the Hop aphis. The hosts which cover the vines in May have been produced, he asserts, from flies which have been fed up on the Sloe. The autumn generation of this aphis, he thinks, deposit their eggs in this plant, and their progeny, when matured in the spring, take flight and settle in the Hop plantations. If this be really the case, it would, perhaps, be advisable to take measures for the extirpation of the Sloe or Blackthorn where it is growing wild in the hedges in those districts; but, for my own part, I am at present dubious as to this supposed fact.

The fly, we say, from its rapid reproduction, and the difficulty of dealing with it effectively, has always been an object of the special dislike of the Hop-growers, yet many years ago the veteran Kirby ventured to hint that they were somewhat to blame, and might thank themselves for much of the trouble and loss it caused them. He says, "Led by their old prejudices of the fly being produced by cold winds, &c., they do nothing towards its destruction, though, if aware of the way in which it is generated, and that by killing each female as it appears early in the spring, they would prevent the birth, not of thousands, but of millions of aphides. The aphides being soft are killed with the slightest pressure, so that it is merely necessary to rub an infested leaf between the thumb and fingers, with a force quite insufficient to injure its texture, to destroy every aphis upon it; and from experiments which I myself made in the Hop grounds of Worcestershire, when at Malvern in 1838, I am persuaded that every leaf of each plant might be thus cleared of the female aphides first attacking it in spring by women or children mounted on step-ladders for the purpose in ten minutes or less, so that six plants being cleared per hour by one person, sixty might be cleared per day.

I do not enter into any discussion as to this plan, but make the quotation chiefly because there is, after all, something more in the cultivator's idea about the "cold winds," whatever there may be in the "&c.," than Kirby thought, though it need furnish no excuse for slackening exertions. Aphides do not benefit primarily by these winds blowing mostly from north or east; nor, again, do they suffer from them, as numerous other species of insects certainly must. Then how is it that they increase so rapidly at such times? I am persuaded that it is because those species which should prey upon them are diminished in numbers, or rendered very inactive, by the ungenial influences of the season. Of the commoner species of the genus Coccinella (the well-known lady-bird) there were much fewer than usual in many places. Others, also, such as the Syrphi, and the beautiful fly designated Chrysopa perla, which are undoubtedly useful in reducing the number of aphides by means of their ravenous larvæ, did not work with their wonted diligence at this task, being backward in their appearance. There is a dipterous insect that in some years destroys many aphides, depositing eggs which produce a parasitic larva; this was, I suspect, also lacking in vigour. And, moreover, it must be borne in mind that aphides, though callous to many atmospheric influences, are now and then severe sufferers by heavy rains in spring and early summer. I have seen many of them lying drowned about their food-plants at such times, and it so happened that at one or two periods this year, when the aphides were multiplying rapidly, we had a spell of dry weather.

Rennie, many years ago, drew attention to the circumstance that about midsummer, or not very long afterwards, the plants are gradually freed of their tormentors; and a recent author observes that the first indication of the approach of a favourable change is the clustering of the aphides at the extremities of the leaves and twigs, while the lower leaves generally become almost clear of them. At this time, too, they cease to a great extent to suck the juices of the plant. Then do they migrate? No; modern entomologists of eminence think not, and regard as erroneous the assumptions made by White, of Selborne, and others on this point. Occasionally aphides will suddenly appear upon the Hop plants late in the season and invade the flowers themselves. Under these circumstances it sometimes happens that weakly plants are so severely injured as to die off in the autumn.

The small beetle called the "Hop flea," the Haltica concinna of most writers, does much harm in the spring; in fact, it infests the plants every spring in greater or less quantity, and last season it was the pioneer of the insect host, attacking the Hop at a very early stage in its growth. It has been supposed to be most injurious in years when the nights are cold and the days hot and dry, but this seems conjectural only. There is much more probability in the opinion of those who trace a connection between this insect and the manure applied to the hills, and hence they recommend that the soil should be turned up between the rows; and Loudon says that if good stable dung be used, and not littery dung, this insect is less troublesome, and the health of the plants is improved. "Prevention is better than cure," no doubt, but where these beetles have not been prevented from putting in an appearance they must be swept off the plants or picked off. The application of lime, under certain precautions, has been of much service, or the fleas may be brushed through a tin funnel into a wine bottle, out of which they cannot leap; also it is suggested that they may be captured by holding a large inverted bowl coated within with gas tar just above the plant, to which the insects are to be persuaded to leap up—a modification, in fact, of the "ketch 'em alive, oh!" plan, so pleasantly successful with flies. I doubt whether the plan of covering the young plant with fine earth at the time it is exposed to most danger is of marked utility, though some have spoken in its favour.

The wireworm I am not now about to touch upon, as I am not able to throw any new light upon the history of the species attacking the roots of the Hop. No doubt under this name are comprehended the larvæ of several beetles, and centipedes also, creatures of a very different nature. Modern researches into the history of centipedes show that they resort to plants and fruit chiefly for the sake of the insects upon them, yet when young they are vegetable-feeders, taking to stronger aliment as they grow older.

Many lepidopterous larvæ resort to the Hop. Hepialus Humuli feeds upon the roots of the Hop, also upon the Burdock and Nettle. The larva lives through the winter, but makes a nest for itself, remaining then in a state of torpidity. That this species is materially injurious to the Hop has never been proved. I have observed that in various localities I visit about London this moth, popularly called the Ghost, is much scarcer than formerly. Dr. Withering recommended covering the roots with stones as a preventive. Much more frequently observed is the gay caterpillar of the Pale Tussock (Orgyia pudibunda), which, though occurring often on the Hop, is a very promiscuous feeder. A friend reports to me that in some Hop gardens this year he saw quantities of the "Hop dogs," as these caterpillars are familiarly called. The yellow pencils of hair with which it is adorned, and the slashes of deep black across the light-green ground colour, render it conspicuous enough, and it is accused of doing much more harm than is really the case. The worst enemies of the Hop are not such insects as these, which merely devour the leaves, but those which, like the aphis, drain the plant of its vital juices, or strike, like the wireworm, at the seat of life below.—J. R. S. C.

PROPAGATION OF ECHEVERIA METALLICA BY CUTTINGS.

This striking plant is so useful in flower gardening for various purposes, that there are few places now where more or less of it is not seen. Strictly speaking, it belongs to the class of fine or characteristic-leaved plants. Its leaves are more valuable for ornament than its flowers; and to permit it to flower is equivalent to wasting its beauty, for the foliage quickly falls off in vigour and hue as the flower stem elongates, and the whole plant becomes ungainly, and unfit for any ornamental position. Large plants on one stem, with finely-developed leaves, are beautiful objects in vases so placed as to be a little under the eye; and in higher positions they are striking in appearance when contrasted side by side with softer and more

graceful objects. They are like bold castings in bronze, in their rigid symmetry and metallic hue. They are invaluable subjects wherever beds have to be filled that are overrun with roots of trees and shrubs, and probably overhung also by their arms. I know no plant that delights more than this in such circumstances. It picks up materials for luxuriant growth where the soil is almost dust dry to the depth of a foot or more; and its leaves acquire the deepest bronze and the finest form and size where the roots appear to have the least encouragement. This in my opinion constitutes its chief value for open-air gardening. It is hopeless to attempt flowering plants in such circumstances, and yet it frequently happens that beds have to be filled in which flowering plants cannot be expected to succeed.

This and other succulent subjects should be employed in cases of this kind. The ground may be carpeted with the beautiful little annuals, Sedum cæruleum, S. dasyphyllum, and others easy to obtain and easy to keep, of similar dwarf close habit; and the Echeveria, if planted at free distances over the surface which these will form, will have a pleasing and interesting effect, a combination of soft colouring and striking form. I have observed, as doubtless many have, that the plants vary in character considerably from seed. They vary in the size and shape of the leaves, some being narrower, some broader, some crisped or wavy, and others quite smooth on the margin; and the depth of metallic tinge varies as much as anything. Whatever value these qualities may have, it can only be secured and perpetuated by means of cuttings. This mode of propagation is not often resorted to.

It appears to be almost the uniform practice of all to rear what stock is wanted from seed. It is much less troublesome to increase it by means of cuttings—no kind of plant is more easily struck. The treatment is simple, and the necessary appliances are common to the worst-appointed gardens. Leaves make the best cuttings—those formed of flowering shoots are apt to spindle too much, and be leggy. The leaves of flower shoots just begun to push are the best; they are quite large enough, and can generally be got in sufficient quantity without injury to the stock plants. The leaves should be pulled, not cut off, and no trimming of the base will be found either necessary or desirable. If any cut or wound is made on the leaf in any way, it had better be laid aside to dry for some time before being put in the soil—a few hours will do. Any good sandy soil will do for striking them in—they will root in anything. A cold frame to which air is continually admitted is the best place to strike them in, and they may be put in either pots or boxes; they receive less check, however, in being potted on from the former if they are small thumbs or 60's. Whether pots or boxes be used, it will be best to plunge them so as to do away with the necessity of watering till the roots are struck, after which they may be given water sparingly as they require. Much water and a close atmosphere are conditions to be avoided by all means.—W. S.—(*The Gardener.*)

NOTES AND GLEANINGS.

Distribution of Plants.—We are requested to announce that the First Commissioner of Her Majesty's Works and Public Buildings intends to distribute this autumn among the working classes and the poor inhabitants of London, the surplus bedding-out plants in Battersea, Hyde, the Regent's, and Victoria Parks, and in the Royal Gardens, Kew. If the Clergy, School Committees, and others interested will make application to the Superintendents of the parks nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, in the cases of persons residing in that neighbourhood, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

—— Continuous-blooming Apple Trees.—Late in January I planted several Apple trees in my garden, one of which is quite a horticultural curiosity, for it has on it no less than four distinct crops of Apples. The tree bloomed at the usual time in spring, and it has continued to bloom up to the present date (October 9th), each time setting its fruit. In my neighbourhood there are several Denby's Seedling Plum trees with their second crop of fruit, but I never heard of a continuous-bearing Apple tree. Perhaps some one will kindly oblige me with the reason of this curious phenomenon.—T. J. Harrison, *Farndon, Chester.*

—— Mr. Frederick Waterer.—It is seldom that it happens that a man is admired and esteemed by everyone with whom he comes in contact, yet few persons could be found to deny that such were their feelings towards Frederick Waterer. He was the eldest son of Mr. John Waterer, who laboured with such assiduity and to such good purpose for so many years at the American Nursery at Bagshot. Here are grown those splendid Rhododendrons which excite so much admiration at the annual shows of the Royal Botanic Society, the result, in a great measure, of Frederick Waterer's skill. On the death of his father three years ago, Frederick, together with his brothers Michael and John, were left in possession of the business. Michael, however, withdrew, and thus the subject of our memoir was left co-partner with his younger brother John. He had been warned by his medical adviser that it was necessary for him to exercise great caution, as it was probable that his death might happen suddenly. On Tuesday, October 3rd, he retired to rest in his accustomed health, and in the morning of October 4th he was found dead. He was only forty-nine.

PLANTS SUITABLE FOR TABLE DECORATION.

Those who have never seen a dinner-table adorned with Crotons, Coleuses, and Caladium argyrites, can scarcely form a right idea of their exceeding loveliness, while those who have seen them will look upon them as old friends not to be discarded. Whether all be seen on the table at one time or in company with other plants, or each variety separately, with epergnes and such-like things, they cannot but give satisfaction to the beholder. Moreover, they have this to recommend them—they are easy to grow, and their colour is never better than when they are fairly established in small pots, and they will remain in good condition a long time without shifting into larger pots.

All the Crotons may be made useful for the dinner-table, but those best adapted for that purpose are C. variegatum, C. variegatum longifolium, and C. angustifolium, especially the two last. I always make it a rule to strike a few of each kind every year; November is the month I choose. Having prepared a few pots of peat, loam, and silver sand in equal parts, with bell-glasses to cover with, I take off the cuttings with a stem 4 inches long, and insert them about 2 inches deep. Here they may remain three or four weeks, after which time the glasses may be taken off and the pots allowed to remain as they are until about the middle of February, when they will be in good condition for potting-off singly in clean dry 3-inch pots, using a mixture of two parts loam, one part peat, and one part rotted dung, with a good sprinkling of silver sand. In about six weeks or two months they will require shifting into pots a size larger, using the same soil as before.

I have generally found Crotons to make nice-shaped plants without any pinching whatever. C. variegatum forms a pyramid, but if they should not break and grow into the desired shape, the top must be pinched off when about 9 inches high; they will then send out branches near the bottom. Much better plants, and a much brighter colour, are got by striking in the autumn instead of in spring. When the plants have grown too large for the table, or require larger pots, their beauty in the stove or conservatory will repay for all the care that has been taken of them. It will be found that the Croton delights in a good turfy loam.

Coleus Verschaffelti.—This is a most useful plant for the dinner-table, and has much to recommend it; first, it is very easy to cultivate where a stove or warm frame is at hand; secondly, it may be had at any time of the year by a little forethought in striking; and, thirdly, its beauty is improved by candle-light rather than otherwise. One way of growing this Coleus is to pinch it at every joint (or nearly so), but I have generally found it ready enough to break out into the pyramidal shape without any pinching whatever. This shape I consider looks best on the table, and the leaves are a much larger size than when pinching is resorted to. Where plants are required for the table at all times of the year, it is a good plan to strike a few cuttings very often, say every two months; they will strike standing about in the stove or in a dung-frame. As soon as they are rooted, pot off into small pots; and as soon as the pots are nearly full of roots, shift them to the size pot you use on the table—4-inch pots are large enough; keep them near the glass, and never shade after they are rooted, or they will not be so dark in colour as when fully exposed to the sun. Loam, leaf mould, and dung in equal parts, with a sprinkling of silver sand, is a good mixture for them; and when their work on the table is

done, if shifted to larger pots they will soon make very large plants. I have tried about a dozen of newer varieties with the same result, but like the Verschaffelti best.

Caladium argyrites.—This is a very useful plant for the dinner-table, and one that gives very little trouble where there is a stove. About the beginning of March I generally look over the bulbs, which are then at rest, turn them out of their pots, and repot them in the following soil—turfy loam, leaf mould, and very old cow dung in equal parts, with a sprinkling of silver sand. I have generally found the Caladium to last longer in a growing state, and also to make much larger leaves, if the bulbs are put into small pots first and then shifted to larger ones as soon as they have filled their pots with roots. The size of the pots we use on the table here are 4½-inch—accordingly the bulbs are put first into 3-inch pots, and when full of roots shifted into 4½-inch pots. When potting, it is a good plan to put a large bulb in the centre of a pot, with three or four smaller ones round it; this will bring the tallest and best leaves in the centre of the plant. As the plants are not required here till late in the summer, I only give enough water after potting to settle the soil about the bulbs; they are then put on a shelf in the stove until they start into growth, when water is given whenever it is required, until their beauty is past, when they may be returned to the shelf to gradually dry off.—W. Nokes.—(*The Gardener.*)

SUITORS FOR LEGISLATIVE PROTECTION.

In the last session of Parliament an Act was passed for the protection of sea birds, and efforts are being made, wisely made, for a similar shield being fixed before some of our land birds.

We are true, and ever shall be true, to our motto, "For Gardening and Gardeners," and we, therefore, for we know they trust us, have no hesitation in pleading strenuously for mercy to be shown to the small birds that frequent our gardens. Nay, we will plead even for one large bird too. We were staying with a friend, and whilst at the breakfast-table he exclaimed, "There are the rooks on the lawn again!" He hurried out of the room, fired at them, and killed one. "You are much in the wrong to kill those birds." "Go and see what holes they make in the grass." "Cut open the crop of your victim and see what it contains." It was done, and there were in that crop nothing but the grubs—larvæ—of the cockchafer (Melolontha vulgaris). The lawn was disfigured by brown patches, and those patches were caused by the grubs eating the roots of the grass. Whether our friend is still a corvicide we are not aware; he will read this, and may, perhaps, confess.

We are indebted to the Society for the Suppression of Cruelty to Animals for the engraving we append, and we would ask every gardener to attend to a few facts we now record. No plea do we offer for the bullfinch—he is put in the lowest corner—he is a marauder, and injures fruit tree buds, not for the sake of the caterpillars within them, but because the embryo buds are pleasing to his palate; yet he need not be destroyed, he is beautiful, and so very rare, and so very timid, that he may be scared away; a blank cartridge discharged will drive him away to far-off quiet hedgerows, not to return for weeks.

"Do not shoot the tomtits, Harry, they only pick the buds to get at the grubs in them." "Better leave the grubs alone—one enemy is better than two." "True, but the grub would become a perfect insect, and the parent of hundreds of other grubs to attack the buds next year."

We have watched the labours during their nesting time of every species of bird pourtrayed in the annexed drawing, and we record this as a fact—an unrefutable fact to which there is no exception—each parent bird brought daily to its nestlings hundreds of insects either in their perfect or larva state.

In Macgillivray's "British Birds" is this confirmatory statement:—

"At the distance of 9 feet from a thrush's nest, which was built in an old wall, I erected a hut with some branches of Spruce and Scotch Fir, and took possession of it on the morning of Thursday, the 8th of June, 1837, at a quarter past 1 o'clock, for the purpose of making observations on the habits of these birds. At half-past 2 o'clock they commenced feeding their brood. From that time until 4 o'clock they fed them fourteen times. From 4 to half-past 5 o'clock they fed them twenty-two times. As one of the young birds was dressing its feathers it lost its balance and fell on the ground. No sooner did the old ones perceive it than they set up the most doleful lamentations. I replaced it in the nest. Having seen me return to my retreat they would not feed their young until I came out. I accordingly went home for my boy, who, after I had gone in again, carefully concealed the entrance. His departure attracted their notice, for, after having followed him a considerable distance they returned, and, without suspicion, commenced their labour. From half-past 5 until 7 o'clock they fed them twenty-four times. From 7 to 8 o'clock they fed them sixteen times, and from 8 to 9 o'clock eleven times. From 10 to 11 o'clock they fed them ten times, and from 1 to 2 o'clock eleven times. From 2 to 3 o'clock they fed them eight times, and from 3 to 4 o'clock six times. From 7 to 8 o'clock they fed them thirteen times, and from 8 to half-past 9 o'clock thirteen times. They now ceased from their labours for this day, after having fed their brood 206 times."

"On Saturday morning, the 10th of June, 1837, at half-past 2 o'clock, I went into a house made of the branches of trees to watch the blackbirds while they were feeding their brood. It was within 9 feet of their nest, which was built in the hole of an old wall. At a quarter-past 3 o'clock in the morning they began to feed their young, which were four in number. From that time until 4 o'clock the male fed them only once, and sang almost incessantly, while the female fed them six times. From 4 to 5 o'clock the male fed them six and the female three times; from 5 to 6 o'clock the male fed them four, and the female five times; from 6 to 7 o'clock the male fed them three, and the female five times; and from 7 to 8 o'clock the male fed them three times. For the last four hours he sang most delightfully, except when he was feeding his tender offspring. As he had induced one of them to fly out after him, I was under the necessity of fixing it into its nest, and this caused some interruption to their feeding. From 8 to 9 o'clock the male fed them six, and the female seven times; and from 9 to 10 o'clock the male fed them four, and the female three times. From 10 to 11 o'clock the male fed them three, and the female two times; from 11 to 12 o'clock the male fed them two, and the female three times; from 12 to 1 o'clock the male fed them two, and the female four times; and from 1 to 2 o'clock the male fed them twice, and the female thrice. From 2 to 3 o'clock the female fed them twice; and from 3 to 4 o'clock the male fed them three, and the female four times. From 4 to 5 o'clock the male fed them three, and the female four times; from 5 to 6 o'clock the female fed them only twice; and from 6 to 7 o'clock she fed them three times. In the evening the male was so much engaged in singing that he left the charge of his family almost entirely to his tender-hearted spouse. From 7 to 8 o'clock the male fed them only once, and the female six times; and from 8 to twenty minutes past 9 o'clock, when they ceased from their mutual labours, the male fed them once, and the female seven times. When I left my retreat to my more comfortable abode the male was pouring forth his most charming melody. Thus, in the course of a single day, the male fed the young forty-four, and the female sixty-nine times."

"On Tuesday morning, the 4th of July, 1837, at a quarter past 2 o'clock, I went to observe the titmice feeding their brood. At half-past 3 o'clock in the morning the birds began to feed their young, which were six in number. From that time until 4 o'clock they fed them twelve times, and from 4 to 5 o'clock twenty-five times. From 5 to 6 o'clock they fed them forty times, which was astonishing, as during the whole of this hour they flew to a plantation at the distance of more than 150 yards from their nest. From 6 to 7 o'clock they fed them twenty-nine times; during a part of this hour they flew in every minute. From 7 to 8 o'clock they fed them twenty times; during this hour it rained very heavily. From 8 to 9 o'clock they fed them thirty-six times, and from 9 to 10 o'clock forty-six times; during a part of this last hour they fed them twelve times in five minutes. From 10 to 11 o'clock they fed them thirty-seven times, and from 11 to 12 o'clock thirty-nine times, and from 12 to 1 o'clock twenty-four times. From 1 to 2 o'clock they fed them twenty-three times, and from 2 to 3 o'clock thirty-four times, and from 3 to 4 o'clock eighteen times. From 4 to 5 o'clock they fed them twenty-nine times, and from 5 to 6 o'clock twenty-five times, and from 6 to 7 o'clock twenty times, and from 7 to half-past 8 o'clock twenty-five times. They now stopped, after having been almost incessantly engaged for nearly seventeen hours in their labours of love, and after having fed their young 475 times. They appeared to feed them solely with caterpillars. Sometimes they brought in a single large one, and at other times two or three small ones. It is therefore impossible to say how many had been carried in by them during the day."

Another good authority, the Rev. F. O. Morris, in "The Gamekeeper's Museum," says, "It is only during a portion, and not a large portion, of the year that the birds can find any fruit to

destroy; but they must live all the year round, and therefore of necessity eat fruit at a less rate than grubs. But the strongest evidence in the case is to be drawn from the actual experience of our French neighbours. In France the exterminators have really had their way. Partly for the sake of protecting their crops, and partly for the pleasure of eating their victims, the small farmers on the other side of the Channel have long waged war against small birds, and the minute subdivision of property has probably aided them in doing so with effect. The result is that you may travel for leagues in France without hearing a chirp or seeing the flutter of a feather along the hedge. But that result has been attended with an incident by no means satisfactory. What our naturalists have predicted as a possible contingency in England has actually occurred in France. Relieved from their feathered enemies, the grubs and insects have multiplied to such a degree as to be alarmingly numerous and

destructive. A Commission has been appointed to sit upon the subject, and its report was decidedly against the extermination of birds." A similar report has been made by the Belgian Secretary for the Home Department.

We could dwell upon each of the small birds which frequent our gardens, and show from our own observations and those of published authorities that this testimony of Macgillivray, one of the most careful observers of our native ornithology, is not only true of the Goffinch, but of all the others:—"The young are fed on insects of various kinds, which also form a principal part of the food of the old birds during the summer." We say, then, to all gardeners, Scare the birds, do not kill them. Keeping an old woman daily in a kitchen garden during the seed and fruit season, will cost little and be the most conservative practice. Even cherish the small birds, and then you will not incur the anathema such as is uttered by the yellowhammers when deprived of their eggs or young. "They continue some days about the place, chanting at intervals their dolorous ditty, which,

although unaltered in its notes, must doubtless be meant as an expression of their grief. In some parts of Scotland it is interpreted as signifying "Deil, deil, deil take ye"—that is, the cruel nesters."

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to plant out strong plants for *Coleworts*, and successions of the best plants sown in the season for standing as spring *Cabbage*. Prick out a quantity on sloping banks, &c., for a reserve for making up deficiencies which may be caused through the winter, and for planting successions in the spring. Continue to prick out *Cauliflowers* as they become fit to handle, and see that enough of all previously recommended vegetables is provided. Take favourable opportunities at all times of earthing-up *Celery*. See that it is quite dry, and the earth applied in a healthy pulverised state. Should Celery become affected with the fly dredge it with soot and charcoal dust. *Endive* should be blanched in succession, and continue to plant it on banks. Take up *Carrots* and store them in sand. See that the *Onions* already stored are in good condition. Those who have not already potted strong plants of *Parsley* in order to secure a reserve in rough weather, should lose no time now in performing it.

FRUIT GARDEN.

Continue to collect and store away the late varieties of Pears and Apples carefully, and see that those already stored are in good condition. Walnuts which have been collected and have sweated should now be placed in unglazed earthen pans which are quite dry; cover them with a piece of canvas or thick brown paper, and about 1 inch of dry sand over it, then store them in a moderately dry place, and as required for use in succession; they should be placed for eight or ten days previously in a damper place, which will freshen them and cause the inner skin to peel off easily. This is the best and easiest method of keeping Walnuts, Filberts, and other nuts. See that the potted Strawberries are secure from wet. Run a soft broom over the Peach and Nectarine trees with great care, to take off just the very ripest of the leaves. Pruning may be commenced amongst Pears and Apples. Shreds should be prepared on wet days, as well as labels for naming fruit trees. See that the old wall nails are cleaned and prepared in readiness for use. Use every possible means to well ripen the wood of Peach and Nectarine trees, and where the walls are flued a little fire heat should be applied until the leaves begin to fall freely. If the trees are too much crowded with young wood every shoot that will not be wanted at nailing time should be cut out, so as to expose those left to all the light possible. Attend to former directions as regards root-pruning, and where it is required let it be done at once. Root-pruning, however, is not of much service where the roots cannot strike down into the subsoil, and where this is the case it will be better to lift over-luxuriant trees and concrete the bottom of the border, as cutting the horizontal roots, although it may check the gross habit for a season, would not induce a fruitful habit.

FLOWER GARDEN.

Where evergreens are to be removed let it be done as soon as circumstances will admit, for the most favourable season for this sort of work will soon be past. The scarcer varieties of variegated Geraniums should not be risked in beds too long; they had better be taken up and potted immediately the weather becomes at all threatening. After potting it will be a good plan to place them on a gentle bottom heat in a pit or house, where the atmosphere can be kept sufficiently dry to prevent the foliage being injured. So circumstanced they will soon become established, when they may be stored away for the winter in a cool dry house, where they will be out of the reach of frost. Keep grass short and frequently rolled, so as in some measure to prevent the growth of moss, and keep the surface firm and smooth. Also roll gravel walks frequently in damp weather, so as to render them smooth and comfortable to walk on. Lose no time in planting offset Tulips, and any of the main bulbs which do not appear to be in a healthy state. Attend to the proper arrangement of the bulbs, and improve the collection by the introduction of new varieties as much as possible. Some do not like the trouble of growing breeder or self Tulips. Now, this appears a most interesting department of the fancy, for by this means the amateur becomes possessed of the finest strains or breaks possible. The same breeder may become rectified, still it does not follow that it will be good, and yet in the hands of another person a similar one may produce a magnificent and first-rate flower. Give Carnation layers in frames plenty of air, and those which were not rooted sufficiently early in the season should now be removed and treated in a similar manner to the first crop. Pansies, if of too long and straggling habit should have the tops removed, and Pinks should be occasionally examined and fastened.

GREENHOUSE AND CONSERVATORY.

The plants in these structures will as yet require a rather liberal watering, and this should be performed early in the morning, when needful. Winter-flowering plants which have thoroughly ripened their wood may have occasional applications of weak and clear manure water. A free ventilation must be permitted, leaving a little all night. Let Cyclamens, Lachenalias, Oxalis, Centradenias, and such little winter favourites be kept on a warm front or end shelf, totally unshaded. Roses in pots intended for flowering through the next two months should be allowed a very light situation, where there is a constant circulation of air. These are best at present, and, indeed, most of the winter, without fire heat, at least while the weather is mild, shutting up much solar heat early in the afternoon, and raising much moisture in the air by sprinkling all surfaces, &c. This valuable family is not yet sufficiently appreciated for winter purposes; they deserve a span-roofed house to themselves, and I have little doubt the time is not distant when such will be provided for them. What they want is a permanent bottom heat of 65° or 70°, or about 5° in advance of the atmospheric temperature. Thus situated, very little forcing would be required for heating the atmosphere. A night covering on the roof would generally suffice. Early Chrysanthemums will now be in a forward state, and such as show their buds prominently should be placed under glass. If it is desirable to have them in bloom as soon as possible, they may now safely be placed where a little artificial warmth can be afforded them; take care, however, that they are placed near the glass, well supplied with manure water, and air given them freely, as anything in the shape of close confinement would soon ruin them. Indeed, the whole stock of these should now be placed where it can be covered at night in case of frost, for although they will bear more of that than most things, it is not good policy to leave them to the mercy of the weather much after this season, unless in favoured localities. It is better, however, to place them in skeleton frames, or in a sheltered situation where they can be covered in case of need, than to huddle them too thickly together under glass, or to put them, as is sometimes done, under the shade of Vines. See that tree Violets are perfectly free from their enemy the red spider, for if the foliage is allowed to get disfigured at this season, the plants will long remain unsightly afterwards. See that the Epacrises and other winter-blooming plants are placed in a light part of the greenhouse where they will be fully exposed to the sun, so as to get the wood well ripened, and to ensure their blooming freely. Examine Heaths or anything else subject to mildew frequently, and apply sulphur immediately the pest can be perceived. Water must be very carefully applied at this season, especially in the case of large specimens, for there is much more danger in overwatering now than when the weather is warmer and the plants more active; therefore, look over the plants frequently, and never water until it is absolutely necessary.

STOVE.

A temperature of 65° to 70° by day, and 60° by night, will suffice, still using a somewhat moist atmosphere in the afternoon and during the night, with a free circulation of air, keeping also a quiet ventilation all night. As some of the Orchids become ripe, such as the Catasetum family, the Cycnoches, Lycastes, &c., they may be removed to a drier and somewhat cooler atmosphere. Pursue a kindly course of treatment with the Euphorbias, Gesneras, and similar subjects for winter-flowering, these will soon be of great service. The Phajus grandiflorus with the Neottia speciosa will soon begin to blossom, also the Cypripedium insigne and venustum. Let them have plenty of heat and moisture.—W. KEANE.

DOINGS OF THE LAST WEEK.

A FINE open week with sunny days, terminating, however, with heavy rains on the 7th inst. The sun made such a change in the flower beds, that we had them all picked over, taking away barrowloads of washed and spent blooms. Numbers of blooms began to show fresh and well, and but for the rains of to-day we calculated that by Monday we should have had something like a second summer display. However, on the

whole, the season has been far beyond the average for all departments of gardening.

KITCHEN GARDEN.

Glass Protections.—We planted out more Cabbages, and but for the rains rendering the ground clayey we should have had our most forward Cauliflowers planted out under old hand-glasses. Having these we use them, though battered and broken at the sides, and we hardly think them worth mending, except as regards the tops, which we keep whole; but we almost despair of keeping the sides right, there seems to be such an attraction between them and the points of forks and the points of the shoes of the men. We should greatly prefer stout wooden boxes, tarred at bottom or set on narrow slips of slate or tiles—boxes say 7 inches deep and from 18 to 24 inches square, with a moveable glass top. We have little difficulty in keeping the tops whole, but so much do the sides of metal hand-lights suffer with us, that some time ago in bad weather we removed the broken squares at the sides and replaced them with squares of old zinc which had been removed from a building. Among all the new inventions we should be satisfied with the box of wood and the top of glass. That top might be a little span, or it might be a single square of glass of the requisite size in a frame. The little box might be lower on the south side, so as to resemble a miniature garden frame; but where simplicity and economy are to be combined, we should make the box square all round, say 7 inches deep, and then by raising one side, say with a couple of bricks, we could give the fall any way we chose. For such work out of doors, for propagating in-doors, for retaining greater heat among small plants and cuttings in houses, where it might be necessary to have the atmosphere of the house drier and colder, we know of no plan more simple than such wooden boxes from 18 to 24 inches square, with a moveable glass top laid over them. In the case of tender cuttings under glass in a pit or house, if there should be any danger from damp from the condensed moisture on the under side of the glass, one need have no trouble with wiping and drying; all that will be required will be to lift the glass top and put the upper dry side undermost.

Neatness.—It is necessary to keep this in view, more especially at the present season. All decaying vegetables and masses of weeds are peculiarly depressing to the spirits at this season of the year. Amongst cottagers a little slovenliness is excusable during the harvest months, when generally all hands, large and small, are busily engaged. But when they are past the desire to have everything neat and clean, and all decaying matter and weeds placed where they shall contribute to future fertility instead of malaria, should be practically developed. How often have we noticed cottage gardens, and all about and outside the cottage, as neat as neat could be in April, May, and June, and onwards, and yet presenting a most dreary aspect in the months of September and October; rotting Cabbage leaves, weltering Potato tops, and decaying Bean stalks and Pea haulm tainting the air; whilst grass and rank weeds made almost impassable the pathway up to the house door, that was so clean and neat in May. No doubt the waning year has a great effect upon us all, but such results should be guarded against. We had intended long before now to have said something of the specialities of the

Woburn Cottagers' Horticultural Show the finest we ever saw, and the interest may be judged from the fact that there were above 1300 entries for competition, besides what was kindly sent for observation. We may be permitted here just to mention one of the peculiarities of this well-managed Cottagers' Society, and that is not merely the rewards given for the best-cultivated gardens and allotments, and the giving these awards to different districts in rotation; but the most excellent plan adopted by the Judges of going several times during the season, and, we believe, without notice, to examine and note down the peculiarities of culture and management of each competitor. We do not know when the year of competition commences, but as the show is generally held about July, it would be well that the year of competition should begin in the autumn months. We feel confident that such visits then would tend to do away with the autumnal slovenliness observable not only in cottage gardens, but also, we fear, not at all rare in many of our gardens where a regular gardener is kept.

Onions and Rotation of Crops.—Even in the wet week we could not find time to string or house our Onions, but we placed them all under the protection of lights, &c., before the wet weather set in. There is no better mode of keeping them than stringing them according to their sizes, and not making the strings too long. Provided the Onions are kept dry, as against the walls of an open shed, we have never seen them injured by frost. When thus hung up in the dry we would remove nothing from them, not a bit of the loose covering of the bulb; that is easily done before taking them to the kitchen. Many cottagers might keep their Onions much longer and sounder than they do if they could only be convinced that they would be perfectly safe, though very cool, if dry. This is so far important, as a sound Onion is often a great help to the labourer who must partake of his cold dinner in the open field.

Our Onions have been very fair, but not so large as we expected. Owing to the changes of the weather they stood still, and the tops of the flags were discoloured too early. Still we have a fine crop of good-sized bulbs, and in excellent condition. Lately we saw a fine quarter of equal-sized Onions at Luton Hoo. They were not like imported Onions, but throughout the large quarter the bulbs would average from 12 to 13 inches in circumference. We notice this chiefly from the fact that, so far as we recollect, this was the second if not third year for Onions on the same spot; and if we are not mistaken, Mr. Cadger told us that one of his old masters had grown Onions on the same ground for a number of years, and that the last year's crop was always the best—that is, superior to that which preceded it. This of course is contrary to the generally received ideas of the rotation of crops, but we have met with many instances in our own practice where the succession for two or three years of the same crop was attended with an advantage rather than a disadvantage. We think the rotation system is of most importance where there is a scarcity of garden ground, and more especially as it is only in the case of a few crops that we can be satisfied with one crop in the year; still it would be of importance to know well-authenticated cases where the same ground produced similar annual crops year after year without showing the least deterioration in their quality or quantity.

It is a singular fact, but no less a fact, that some of the oldest and most experienced are those who are the least stereotyped in their ideas as to rotation of cropping. We have vividly in our recollection just now a border in a kitchen garden which for from twenty to thirty years, and under the management of some six or seven successive gardeners, has been always planted with Brussels Sprouts, the young crop being soon planted after the other is done with. The present gardener told us he had the border well trenched and manured, and the crop was, if anything, better, though we believe it was always a most serviceable border. He also stated, what we knew to be a fact, that as it had borne Brussels Sprouts so well for so many years, he thought he might as well continue the practice, as the border was so situated that he could hardly use it for anything but such winter and spring vegetables.

FRUIT GARDEN.

We must refer to what has been lately said of gathering fruit, &c., and especially the earlier kinds, before fully ripe, so as to escape many enemies. The drenching weather interfered with the flavour of Peaches, &c., and it was a great annoyance to find a hole picked in a fine Peach or Pear, so that it could not be sent to table, and could only be cooked. Where other protective means cannot be tried much may be done by gathering before the fruit is fully ripe, and giving it a little help artificially. For instance, from one espalier tree well loaded we have still some dozens of the Williams's Bon Chrêtien Pear as hard as fresh-lifted Potatoes; but from that tree we have sent in dishes from the first week in September by selecting the forwardest, time after time, and giving them a little artificial heat. The fruit, so treated will not keep long, and therefore only as many should be made ready at a time as will meet the demand. We often treat Marie Louise and other fine Pears in the same way, and late Peaches in a cold wet season may thus be earlier sent in good condition to table; and while rather hard insects, &c., trouble them less.

ORNAMENTAL DEPARTMENT.

We have already alluded to the flower garden. With a week of fine weather there would still be a fine second summer show. It is well to pick away all dead blooms to keep ourselves from melancholy musings. Notwithstanding the greater exposure to the wind, plants in vases have suffered less from the wet than those on the ground. A late show of flowers will depend entirely on warmth and the coaxing rays of a bright sun. There are myriads of trusses and blooms just waiting for such an enticement to display their colours.

We have rarely had all the Scarlet section of *Geraniums* better than this season, and we have fallen back on a number

of old kinds, as Punch, Tom Thumb, Stella, Cybister, Rubens, Trentham Rose, &c., as suiting our purpose on the whole better than newer kinds. We have tried numerous rose pinks, and in a shady place Helen Lindsay is magnificent, and Forget-me-not and others are good; but for all places and situations we find nothing to equal the old Christine. For a light graceful pink with white and green variegated foliage, we have found nothing to surpass Silver Nosegay. Most of the weaker-growing kinds we were obliged to water in order that they should be kept on, and not suffer so much if a heavy rain came. Watering, however, is a matter of importance to us and to be indulged-in but rarely. Those who come from parks and places where a shower bath can be given to the beds every alternate evening, cannot believe that these massive plants, lately so full of bloom, must pretty well look after themselves. Necessity in the first place brought us to the conclusion that as it is not all gold that glitters, so abundance of water and the using it in abundance are not always an unmixed advantage.

A little matter is here worth noting. It is a very different thing to keep a regular good supply of good things every day for a resident family, and to have a flower garden gay with bedding plants as early as possible, and to satisfy the wishes of another family that is hardly ever at home until August and September. Much smaller plants and much less care will be required in the latter case, and yet the result will, for the time prepared for, be as good if not even better. As respects the flower garden, we have in our mind's eye places that were full and brilliant in July, or even the end of June, and other places very meagre then—plants few and far between; but the latter were quite as good as, and perhaps fresher-looking than the earlier ones, in the month of September, when they were most needed. There could be no comparison in the labour involved in the two different cases, but for the proprietors who did not see their gardens until the first days of September the less-labour system would be quite as telling. That system would not do for a resident establishment, and yet this simple fact is apt to be forgotten when the *£ s. d.* question comes to be taken into consideration. The whole question of a constant display in the flower garden, from nice variegated and evergreen shrubs in winter to early-blooming and nice-foliaged subjects in spring, to masses of bedding plants and subtropical plants in summer, is on the whole now less than hitherto a matter of peculiar skill than that of money, means, and labour. We do not require to tell our readers how it rejoices us to know what an impetus has been given to the love of the beautiful by the ornamental gardening that has been done at the Crystal Palace, at Kensington, at Victoria, Battersea, and Hyde Parks, Kew Gardens, &c.; still, with every desire to honour the talented superintendents and their desire to accomplish the greatest results with the smallest outlay, we are not the less convinced that it would be to the benefit of many a country gentleman, and to the advantage of many a gardener, if the results in these public places were not only commented on, but the expenditure involved were also taken into consideration.

Our general work with cuttings, potting, &c., has been much as detailed in previous weeks, and we must for the present conclude with alluding to two matters.

First, the white-leaved *Centaurea candidissima*. There is no difficulty in keeping the old plants by taking them up and repotting them, but they like plenty of room. Side shoots will strike freely in the spring in heat. Good-sized shoots in summer will do well if taken off in August. We have rooted them successfully by taking them off in September, and as we are doing now in October. For this purpose so late, we like, however, to cut off nice pieces, with stems not less in thickness than a good-sized quill, dress them neatly, leaving the foliage mostly untouched, and insert them in pans close to the sides of a small 60-sized pot, with a bit of slate down the middle and a little twig in the centre to tie the largish leaves to. But for room one cutting at the side of a small pot would be best. We use the slate to keep the roots distinct, as they are so brittle. We place these pots in a cold frame or pit for a fortnight or three weeks, keeping them a little damp, but not wet, until the base of the cutting begins to swell. Then we plunge the pots in a mild bottom heat, and as soon as the roots form we harden-off. If put in heat at once there is a great risk of damping. When cuttings are inserted in July and August the cool process will do all through. The above mode is best now and at the end of September. The other matter has reference to the

Coleus.—Let us here remark that in the case of many who have tried the only Coleus we have found worth room out of doors, the C. Verschaffelti, and without success, it has been greatly owing to two causes—poverty of soil, and dearth of water. Perhaps there are, properly speaking, three points instead of two essential to success:—First, strong plants to be turned out in fine weather in June; second, a fair top-dressing of rotten dung, as that from a decayed Mushroom bed, one of the causes of the success in the fine bed at Woburn; and thirdly, never to allow the beds to become dry. Our beds are very fair, full, and on the whole well coloured, but they would have been better if we had given them, or could have given them, more water in hot weather. Once established, like the Golden Pyrethrum, the Coleus thrives and looks best in a season diversified with sunshine and showers.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Early Rose Potato.—We have had so many letters wishing to purchase this variety from "K.," that if he has any to sell, and will send us his address for publication, we think that he will soon have disposed of his surplus.

Books (*Thistle*).—The "Fern Manual" gives full directions for the culture of Ferns. The "Cottage Gardeners' Dictionary" is practical. Keane's "In-door Gardening" would aid you in managing your greenhouse.

Supplying this Journal (*Cannazaro*).—Your newsman has his London parcel on Saturday. If you had the Journal direct from our office it would be posted on Thursday morning.

Gathering Pears (*C. J; E. T.*).—All Pears are fit for gathering as soon as, by lifting the fruit upwards, the stalk parts readily from the spray.

Variegated-leaved Violet (*W. Bill*).—It is one of those sports so frequently met with, and probably would return to the normal green colour in another soil and season. For use, if permanent, it would not equal the Golden Pyrethrum.

Bush Pear Trees (*Amateur*).—If your Louise Bonne Pear trees planted in 1869, lifted and planted in 1870, show signs of canker, then the soil must be unsuitable, or perhaps not properly drained. Fruit trees will not succeed in a cold wet subsoil. The Louise Bonne does better trained as a pyramid than as a bush, and the Quince is an excellent stock for it, producing larger fruit than from the Pear stock. In planting Pear trees grafted on the Quince, the stock should be quite covered up to the junction of the graft. The swelling at the junction to which you allude is not uncommon when the Quince is used as a stock. Drain your ground if it requires it, and trench 2 feet deep if the subsoil will admit of it, as in your case the evil seems to lie at the root, although, as the trees do well as pyramids with you, the mode of training may have some effect.

Planting a Peach House (*A Recent Subscriber*).—Three dwarf-trained and two standard trees will be sufficient for the back wall of a house 40 feet long. We do not think a line of espaliers near the front wall, planted with trees trained on the French system, is the best way to utilise your space. It would be much better to fix a wire trellis at the distance of a foot from the front sashes, and also wire the roof by straining wires horizontally at the distance of a foot from the glass; the wires should be strained tightly. The trees should not be trained quite up to the apex of the roof, as they would exclude the light from the trees planted against the back wall. You will require the same number and class of trees for the front as for the back; plant them a foot from the front wall. For the front we would select Peaches, Early York, Noblesse, and Grosse Mignonne; Nectarines, Violette Hâtive and Pine Apple. For the back wall we would have Peaches, Bellegarde, Desse Tardive, and Salway; Nectarinee, Elruge and Victoria.

Vallota purpurea Treatment (*A Constant Subscriber*).—The foliage of the plants would not become long if they were in a light airy position in a greenhouse from which frost is excluded. Place them nearer the glass, and so that they may receive light equally on all sides. The leaves should never be cut down, it being an evergreen, but those turning yellow should be removed. Keep it dry in winter, but not so much so as to cause the leaves to flag, and in spring, and when growing and flowering, water freely. It is one of the finest of greenhouse flowering bulbs, and ought to be in every garden.

Bellis aucubæfolia Losing Variegation (*Idem*).—It is usual for plants of this, in a season like the present, to become green from the cold and continued wet. If the soil had not been so rich, the plants would probably not have become green. Mix sand or grit with the soil as you propose, affording a slightly shaded position in summer. We cannot account for double white and red Daisies becoming single.

Iresine Lindeni and Alternanthera Propagation (*M. W.*)—Both are propagated by cuttings, which may be struck at all seasons, but best in August and September, and in March; place them in a bottom heat of 70° to 75°, keep them close, moist, and shaded, and they will strike as freely as Verbenas. The galvanised iron wire and fittings about which you inquire are good.

Various (*J. W. L.*).—It will not do to cut back the old Vine shoots to within two or three leaves of their base, but you may remove any laterals, indeed clear them all off, so as to admit more light and air to the shoots, and so ensure their better ripening. Prune when the leaves have fallen. For the red spider you cannot do better than syringe the Vines with a

solution of 2 ozs. of soft soap to the gallon, and when you prune them strip off all the loose bark and dress the canes with a solution of 3 ozs. of soft soap in a gallon of tobacco water, brought to the consistency of paint with flowers of sulphur. The Azaleas and Camellias with bad drainage should have this put in order at once, and if necessary you may repot them, but be very careful of the roots. Do not repot the Heaths having good drainage until early in March. We think the Strawberry plantation must be old, and placing road scrapings between the rows we do not think advisable We would cut away a part of the old leaves, and mulch between the rows with manure, and we should make a new plantation, and remove the old after next year's fruiting. Good kinds are President, Dr. Hogg, Rivers's Eliza, and Frogmore Late Pine. In digging the ground we would add nothing to it for Strawberries but manure, and that not very near the surface. For other crops you may add, for loosening the soil, coal ashes, which are preferable to road scrapings unless very gritty.

Propagating Heaths and Epacrises (*Brunswick*).—The cuttings should be taken from the points of the shoots when they become rather firm at the base, but before they are ripe. If they can be handled easily they are sufficiently firm. The time for taking the cuttings depends considerably on the kinds. When the plants have made fresh growth that can be handled easily, that is the proper time. The cutting-pots should be half filled with drainage, on that place the rough portions of sandy peat, filling to within half an inch of the rim with the finer particles, and then half an inch of silver sand, pressing firm and giving water, which should pass through the pots. Let the pots stand at least twelve hours, then press again, and put in the cuttings so that they may just clear each other. Set the pots on a shelf or bed in a cool stove or vinery at work, and cover with a close-fitting frame or bell-glasses. They must be kept close, just moist, and shaded from strong light. They will root surely in about six weeks, and should be gradually hardened off and potted singly, keeping them close for a short time afterwards, then they may be hardened off. Cuttings 1½ to 2 inches long are proper, inserting them about an inch in the soil. Epacrises are propagated in the same way, taking cuttings of the young shoots about 2 inches in length.

Mangold and Swede Turnips for Seed (*W. B. B.*).—Select the best-shaped and heaviest for seed, pulling them up, and storing them in sand in a shed and covering them with straw in severe weather, so as to save them from frost. Plant as soon after February as the ground is in good working order. Remove none of the roots except the tap roots of the Swedes. Plant in rows 3 feet apart, and 18 inches asunder in the rows.

Propagating Evergreens (*W. H. S. D.*).—Common Laurel, Portugal Laurel, and Aucubas should be inserted in the open ground in rows about ½ foot apart, and about 3 inches apart in the row, taking the cuttings with a short heel of about an inch of the last year's wood. Insert two-thirds of their length in the soil, and make it firm about them. The earlier they are put in the better, and it is desirable to cover the Aucubas with a frame and lights, admitting air in mild weather. The Hollies and Conifers should be covered with glass, the former under a wall or fence, and the others are best in a cold house covered with hand-glasses or frames. They ought not to be removed until the following autumn. For covering the trellis on the north side of the house Virginian Creeper (Ampelopsis hederacea) would suit; but if you want an evergreen we know of nothing so good as Ivy, the Irish and Rægner's being good. We have, however the Traveller's Joy (Clematis Vitalba) against a wall with a north aspect and it makes shoots several yards long in a season, and is now in fine flower.

Ivy for a Wall (*F. J.*).—The cuttings you intend putting in at 18 inches apart should be of the young growths, and may be from 18 inches to 2 feet long. Insert them half that length in the soil. It is not a bad plan, but it is preferable to put in the cuttings in a shady border, and transplant a year afterwards, when you can select equal-sized plants. With cuttings put in where they are to remain there is very often great irregularity of growth.

Covering for Frames (*Idem*).—We do not see the objection to straw mats, which, neatly made, are anything but unsightly. Next to straw, bast mats answer, but they are as unsightly as straw, and are not so effective. Frigi domo is also good. The covering to keep out frost will require to be about six thicknesses, and should be as dry as you can have it.

Stove and Greenhouse (*D.*).—To keep up stove heat in the first small division, you will need about 60 feet of 4-inch piping. In the larger division, to maintain a fair greenhouse temperature, you will require 50 feet. We are supposing that the pipes are above ground.

Coleus Seedling (*J. R. J.*).—The leaves are very richly coloured, mottled crimson, neatly edged with green, and stout.

International Fruit Show (*T. J.*).—There were a few omissions in our report of this Show; for instance, the beautifully ripened Coe's Golden Drop Plums, of which Mr. Record, gardener to the Marquis of Salisbury, at Hatfield, sent a basketful; Mr. Webb's collection of Filberts and Cob Nuts; the fine specimens of Cox's Golden Gem Melons from Mr. Moffat; Mr. Jack's Peaches; Messrs. Lucombe, Pince, & Co.'s Guavas; and Mr. W. Paul's beautiful group of Tea Roses. All these were noted at the time, but want of time and space prevented their being noticed. There is a limit even to the powers of the printing machine.

Pyrus Japonica (*E. T.*).—The fruit is of no use as an article of food. Your other question you will find answered in a reply to another correspondent.

Preserving Bedding Plants (*P. P. R.*).—Of Calceolarias we should take cuttings and insert them in a cold frame about 1½ inch apart, putting in the frame about 3 inches of good sandy soil, and about an inch of sand. Give air whenever the weather is mild, and when frosty protect with mats and straw, not removing the protection in severe periods until a general thaw. Gnaphalium lanatum you may winter by taking up the plants, and keeping them rather dry in a greenhouse, and the same of the Heliotrope and Verbenas. Of the latter we presume you have cuttings which were struck in August in a cold close frame. If not, you may still put in cuttings, but they will require to have a hotbed of 70°. Heliotrope cuttings may also still be put in; give them bottom heat. The old plants if wintered safely will give you cuttings which in March will strike freely in a hotbed. Golden Feather Pyrethrum is quite hardy. You may leave it where it is, placing a little leaf soil about the plants, or take it up, pot it, and winter it in the coolest part of the greenhouse, or in a frame. Iresine Herbstii take up, and pot in sandy soil, placing it in the warmest part of the greenhouse, giving no more water than sufficient to keep the plants fresh.

Cuttings of Gloire de Dijon Rose (*Julia*).—Pot them in now on an east or west border, under a wall or fence, and cover them with a hand-glass or frame, employing it only in case of heavy rains or frost. In mild weather give abundance of air The cuttings will be rooted by April, and may then be taken up carefully, potted, and placed in a frame, keeping them close and shaded from bright sun until they are growing freely; then harden them off.

Worms in Pots (*Idem*).—Place in a watering-pot 1 lb. of fresh lime, and pour over it three gallons of water, stir well up, and let the mixture stand forty-eight hours; then, after closing the holes in the pots, deluge the soil with the clear lime water. Let the soil remain so for six hours, afterwards liberate the drainage, and the worms will either come out of the pots or be destroyed. Clay or cork answers for stopping up the holes.

Dielytra and Datura Culture (*A. D.*).—Dielytra spectabilis may be treated as a hardy herbaceous plant, which it is, and it is one of the most beautiful for April or May. A plant from 3 to 4 feet in height, and from 5 to 6 feet in diameter, is very ornamental, but it rarely finds a place in spring flower gardening, though its foliage may render it conspicuous. All it requires is a good, rich, sandy loam, adding leaf soil or well-decayed manure liberally, giving a mulching of leaf soil or manure in autumn. It is also an ornament to the greenhouse or conservatory, and may be had in flower from January to April by gentle forcing. The plants for this purpose should be taken up now, and placed in pots which will hold the roots without cramping whilst they admit of a moderate quantity of soil all round. We use good turfy loam and one part of leaf soil, affording good drainage. Water moderately, and place in a cold pit or frame, drafting the plants into the forcing-house as required; or the plants may be taken to the greenhouse in January and have a light airy position after they begin to grow; and if the shoots have a tendency to draw, turn the plants round occasionally, so as to have them evenly balanced. Do not overwater, but let the soil become dry, then give a good supply before the foliage flags. After flowering place them out of doors in a sheltered position, and water throughout the summer as required, repotting in autumn, and placing in a frame. In case of a frame not being convenient the plants may have a sheltered situation, and the pots plunged to the rim in coal ashes, removing them to the greenhouse in January. *Datura cornigera* requires a compost of fibrous loam two parts, one part leaf soil or well-rotted manure, and good drainage. If the loam is not sandy add sand liberally. The plant ought now to be kept rather dry, lessening the supply of water gradually, and keeping them dry in winter. At the close of February or beginning of March prune them in rather closely, and water them sparingly until the shoots are a few inches long, then repot, removing any old soil that can be taken from the ball readily with a pointed piece of wood, and giving a moderate shift. Keep the plants rather close and moist for a few days, and water them sparingly until the potting is recovered, and then water plentifully, syringing morning and evening so as to ward off red spider. It ought to flower from July. It should have a light and airy position.

Painting Hot-water Pipes (*Idem*).—We have ours painted thinly with lamp black and linseed oil. We heat the pipes as hot as possible, and then paint well. We give an extra amount of air, and keep up the heat of the pipes until the paint is dry. We never experience any smell when the pipes are dry. During many years' practice we have not experienced any prejudicial effects from the painting.

Heating a Greenhouse (*Subscriber*).—An Arnott's stove would be too powerful for so small a house (14 feet by 13 feet). A gas stove, or Shrewsbury's gas-heated water apparatus, would be sufficient and more manageable.

Ammonia for Destroying Mealy Bug (*T. O. X.*).—The carbonate of ammonia sprinkled on sawdust or fibre will answer, but it is so very volatile that except in very small quantity there is great danger of scorching the foliage of the plants. It would be well to place the ammonia in saucers, filling-up with water. An ounce would be a sufficient quantity for a house 30 feet long by 20 feet wide. If it affect the eyes and nose much, give air, or the result will be scorched leaves. You would see what was stated by us at page 199 respecting the ammoniacal liquor of the gasworks placed in saucers.

Cedrus Deodara Pruning (*Idem*).—Now is a good time to prune this beautiful Conifer, and it is advisable to shorten branches that have grown irregularly, retaining, however, a well-disposed shoot for continuation. Victoria and Rivers's Early Prolific Plums succeed either as pyramids or standards. For orchards they are best grown as standards. In gardens pyramids only are suitable.

Greenhouse Vines (*Anxious Inquirer*).—Black Hamburgh and Royal Muscadine. Any of the principal nurserymen who advertise in our columns can supply superior specimens of the flowers you name.

Soda to Sewage (*J. B. G.*).—The quantity of soda you mention will have no injurious effect upon the sewage of the stable, &c.

Compost for Vine Border (*J. G. K.*).—We have to apologise for this being overlooked. Do not by any means use decaying animal matter in the composition of your Vine border; it would kill the roots as they came in contact with it, and the border would in time become a pasty mass; even in small quantities we would not use it. The best material for a Vine border is turfy loam, with a small portion of crushed bones; mortar rubbish and charcoal may be added if they can be obtained. For top-dressing, also, use turfy loam two parts, half-decayed cow and horse manure in equal proportions one part, and add an 8-inch potful of pulverised bones to each barrowload.

Salt as a Manure (*E. F.*).—See No. 547, page 218. You will there find a long article on the subject.

Vines with Begonias (*G. S.*).—According to your statement we would cut away the old stems of the Vines at once, in order to concentrate as much as possible in the shoots intended for next year's fruiting. So long as the leaves on these shoots remain greenish—that is, not yellowish, the heat of 60° to suit the Begonias now will do the Vines no harm, but as soon as the leaves fall, and the Vines take their period of rest, it will be well that the temperature from fire heat should not exceed 45°. When it is desirable that such a house should be kept warm all the winter, it is also desirable that the Vines should be kept cool by being placed along the front, and secluded by any of various modes from the heat of the house. We would water the Vines in the rows inside now

if very dry. If the soil is at all moist we would not water until three weeks or so before we wished to force them, and then we would use water at about 70°, and if moderately rich all the better. In fine, without any alterations you may do all you wish, only for two or three months in winter it will be best that the fire heat should not much exceed 45°. You may have 10° or more rise from sun heat.

Ground Vinery (*R. H.*).—If your ground vinery is a lean-to, let the glass face the south; if span-roofed, let the two sides face east and west, so as to get the morning and the afternoon sun. In the first place we would rather prefer the west end for planting, unless it were convenient to plant on the south side. On the second supposition we would plant in the south end.

Glazing a Vinery (*F. Duke*).—As you must have your glass only 6 inches wide, we would advise you to have each square of that width from 15 to 18 inches in length, according to the number of squares necessary to go from top to bottom without cutting. We would advise good thirds of 21-oz. glass, though fourths turn out well generally, if free from spots. At that length of squares we would give a lap of three-sixteenths of an inch—that is, between one-eighth and one-quarter of an inch, but all alike, and that you must allow for in ordering your glass. If the roof is steep one-eighth of an inch will be ample; if flat a little more will be desirable. Any of those firms that advertise in our pages would supply the glass cut to order, and when the glass is all to be of the same width and length, that is by far the most profitable and economical way of getting the glass of the right size. We are answering on the supposition that you are going to glaze with putty in the old-fashioned way, and if so, you cannot do the work too soon.

Hot Water not Circulating (*Chesham*).—If the water will not circulate in the apparatus heated by gas it is not, as you think, because the supply cistern goes at once into the flow-pipe. We have worked many kinds of apparatus where that was the arrangement. On the whole, if the cistern is higher than the highest pipe to be heated, we prefer the supply to enter the return-pipe, or to go into the bottom of the boiler at once; but still the other mode will not stop the circulation. There must be something else the matter. If the pipes are all right, you may have missed some air-vent, and accumulated air between two bodies of water will render circulation as impossible as if you had tight-fitting blocks of wood.

Butterflies and Moths (*A Young Entomologist*).—Of very popular books on these insects, the shilling volumes by Rev. J. G. Wood on "Common Moths," and Mr. Colman on "British Butterflies," serve as slight introductions in their study. These are published by Routledge. Of comprehensive works the three best are Stainton's "Manual of British Butterflies and Moths," Van Voorst, and Newman's "British Butterflies and British Moths" (Devonshire Street, Bishopsgate). Mr. Newman does not take the Micro-Lepidoptera.

Insects (*G. P. B.*).—Your Scotch Firs are infested by the common beetle, Hylurgus piniperda. All the infested shoots should be picked off and burnt as soon as ever their drooping condition indicates the presence of the insect in the centre of the shoot.—I. O. W.

Names of Fruits (*H. H.*).—1, St. Hurbain d'Hiver; 2, Rousselet de la Cour; 3, Tardif de Mons; 4, Forelle; 5, Fondante d'Automne; 6, Enfant Prodigne; 7, Beurré Bosc; 9, Beurré Luizet. (*R. B. L.*).—1, London Pippin; 2, Morris's Russet Nonpareil; 3, Ord's Apple; 4, Boston Russet.

Names of Plants (*Seybor*).—The berries and spray you enclosed are those of the Cratægus punctata, Dotted-fruited Thorn.

POULTRY, BEE, AND PIGEON CHRONICLE.

LEGS.

Heads, tails, now legs. Yes, fowls have legs. Any leg will do to walk with, and, barring accidents, it will satisfy its owner; but something more is required by those who look for perfection. Even human beings are careful about their legs. The high and mighty among us, the arbiters of fashion, have caused modes to vary, to hide either the want of a charm or the existence of a defect. Knee breeches and silk stockings were sad trials to a man whose leg resembled a mop-handle, or who was bow-legged, or who was more or less knock-kneed: hence trousers.

No such arrangement is, however, possible for fowls; and even as we said about heads, so we say of legs, that the varieties are as numerous and as remarkable among birds as among human beings, and that they are not wanting in affinity to them. As we sit and write we can see an overgrown Cochin cockerel, who seems endeavouring to emulate the ostrich and birds of that tribe in the length of his legs. They are long, ungainly, and so weak as to be almost useless, yet they were made to walk with, and he cannot walk without them. We have made him walk, and will attempt to describe it. His body is large and tolerably heavy, so much so that he is constrained from very weakness to pass most of his time on his knees, and to rest in that position. If food and water were brought to him we believe he would adopt it, that his legs would become stiff in that position, and that his motion would hereafter be partly a flapping like a wild Duck, with body injured, and both legs broken, and partly a jump like the kangaroo. (Query, Would it inaugurate a new breed?) We will, however, describe the walk such as it was. Compelled to rise it would have sighed if it had been possible for fowls to do so. It seemed impossible to lift up one leg while the weight was equally distributed on both; it therefore contrived by a sort of jerk to cast the weight on one, and taking advantage of its momentary freedom, the other was thrown forward, and the foot came with a pat on the ground. This continued with both feet alternately, made up its walking. It lasted as long as it was driven, but relieved from the *force majeure* it returned to its kneeling posture.

The same weakness may sometimes be seen in Dorkings. As in the other we have described, it is the result of overgrowth. The Dorking, however, being intended for the table at an early age, it is not so important. The only result will probably be, that, like the best-tempered and kindliest of the ship's crew wrecked formerly on the coast of New Zealand, he will be eaten first. But this is not the only fault in the Dorking's legs. He must have five toes, and these should be accurately developed; but sometimes the double toe grows into one with two nails; sometimes it seems to be attached to the bone of the leg, and to grow halfway up the leg before it can detach itself, making an appearance of two legs. Sometimes there are six claws instead of five; and sometimes the extra claws project so far and get so out of place, that the claw of one leg scratches the other leg each time the bird moves them. But the cocks of this and other breeds must have spurs, and these, again, are recalcitrant. Instead of growing inside the leg, an ornament and defence, they grow outside, and are an eyesore.

The legs of White Cochins, so beautifully yellow when they are young, become a dingy white as they get older.

Of the Game we will only remark that they sometimes sin, inasmuch as they have a duck instead of a flat foot—*i.e.*, the hinder toe, instead of being on the ground, is so high up that it only touches it with the nail.

The Cochins and Brahmas come deficient in feathering. Dorkings, Crêve-Cœurs, and Houdans have stubs all down the outside of their legs. Hamburghs appear with five claws, Dorkings with four, so that at times the breeder of all these wishes that nether garments, shoes, and stockings were admissible at shows. For ordinary purposes none of these things matter; but where in fowls, as in human beings, perfection is sought for, the search is a difficult one. The legs of Dorkings should be taper for their size, more so in the hen than the cock. The fifth claw should grow upwards; it should be well developed, but not sufficiently so to be a deformity or to interfere with walking. They should be white.

Hamburghs and Polish should have taper blue legs. Brahmas, Cochins, Game, and Malay should have stouter legs, giving the assurance of plenty of bone. Spanish have the longest legs, they must be blue. Houdans should have five claws, and short stout legs of mixed black and white colour. Crêve-Cœurs should have stout blue legs.

The only real disease to which legs are subject is the gout. It is said the Duke of Wellington was once asked whether he ever knew a private soldier gouty; the answer was, "No, but he had known an old fat sergeant suffer from it." So in fowls. The energetic, scratching, hard-living cottager's or small farmer's fowl, that chases the children and jumps at their bread and butter, never has the gout; but the florid and ofttimes overfed Dorking, that once stood first at Birmingham and has been pampered ever since, is often a sufferer from it.

FRENCH FOWLS AT THE CRYSTAL PALACE SHOW.

I am sorry to say it, but I cannot help thinking breeders of French fowls are not fairly used by the Committee of the above-named Show. Why should we be asked to pay an entrance-fee of 7*s.* 6*d.* for a first prize of £2, with the chance of winning a three-guinea cup; whilst most of the other breeds are offered a first prize of £3, and in many classes valuable cups? I would also like to know when the birds will be returned from the Show; as last year, although the Show closed on Saturday, some of my birds did not reach me until the Wednesday following.—Robert B. Wood, *Woodland Hall, Uttoxeter.*

The Southampton Poultry Show.—Allow me to state the result of the subscriptions which have been raised to give two silver cups, value five guineas each, to the best two pens of Light Brahmas at this Exhibition:—Mrs. T. Turner, £1 1*s.*; Mrs. A. Williamson, £1 1*s.*; Rev. N. J. Ridley, 10*s.*; Mr. J. Pares, 10*s.* 6*d.*; Mr. J. Rodbard, 10*s.* 6*d.*; Mr. H. Dowsett, £1 1*s.*; Mr. J. Storer, £1 1*s.*; Mr. J. Long, 10*s.* 6*d.*; Mr. F. Crook, 10*s.* 6*d.*; Mr. H. M. Maynard, £2 2*s.*; the Committee,

£1 1s.—Total, £10 10s. I hope when the breeders of Light Brahmas know that these cups are to be given that we may expect a very good collection of birds.—H. M. Maynard.

HANDICAPPING EXHIBITORS.

I was pleased to see the remarks of Mr. Kell on this subject, which I happen to know has of late been freely talked of as well as written about, and I was especially pleased at his caution against amateurs attempting too many breeds. A further reason against this, which he does not state, is that one breed, in a measure, spoils the eye for others of a different character, so that even a judge will not arbitrate so correctly or with so much ease in certain classes, after just judging other classes, as he can do when he comes to them with eye and mind fresh and unbiassed. But I now desire only to call attention to the fundamental error which lies at the root of all these discussions. I have done so before; but convinced as I am that the very best interests of the fancy are involved, it can hardly be done too often as occasion arises.

The error, of course, is the assumption that an equal *distribution of prizes* is the object to be attained. This being assumed, the analogy between handicapping a horse and doing the same for an exhibitor is obvious; it is done to give the inferior a "fairer chance" of winning, and if winning, only, be the end in view, no doubt the arguments are sound. But it is to this notion, I believe, every vice and fraud in the fancy, without exception, owes its origin. It leads to the disgraceful system of betting, to which Mr. Hewitt drew attention some time ago, and which is still going on; it leads to the most shameful and shameless borrowing of birds, and it leads above all to that system of fraud in plucking and other "preparation," which many of us feel keenly are a disgrace to us all. If encouraged, such a notion always must and will lead to these things.

But I confess I cling yet to the belief that shows are established, and that many honourable amateurs still breed and show their fowls for other objects, and chiefly for these two:—1, The real improvement of poultry in either beauty or value; and 2, the greater diffusion of a love and taste for, and success in, poultry-keeping. I believe the judges also so regard it. I cannot believe that Mr. Hewitt would care to devote the greater part of his time to judging shows if he only considered his awards in the light of paying money and deciding bets. He must believe that his work is of a higher character, and that in doing it he is of some real use to his generation. And if this be granted, it is impossible to resist the conclusion that the objects named can be secured in no other way than that in any given class the best birds win. Suppose that by any system of handicapping, the Judge I have named, or Mr. Teebay, or any other acknowledged as an authority, finds himself compelled to award the first prize to a pen which he knows is only fourth or sixth in order of merit, because its owner is a beginner!—I will not stay to inquire whether any judges worth having would consent to act under such restrictions—but suppose he did, what would be the results? The first would be that, as no one could know exactly how much the winner owed to handicapping, or if he owed anything at all, except from his own knowledge of fowls, every ignorant breeder or visitor to the show would believe those birds to be bad which were really the only perfect specimens, and be led to seek an entirely wrong standard for his own, by which the breed would rapidly become deteriorated. That this is no imaginary danger is proved by the effects which can always be observed by a keen eye to follow even one great error in judging at any important show. The second result would be, that the winner would be contented with his inferior birds, and would go on breeding them; whilst, if a real amateur, he would by the present system be spurred on either to purchase, or, better still, to breed superior stock. And as no real fancier can ever be long satisfied without really good birds, he must as the truth dawns upon him become discouraged. And so in both ways evil is done.

I would say, further, that any such system is needless. The great breeders who have been so complained of, win, not because it is a matter of money to them, for with several of them it is not; not because they have command of money, for some of them are men of small means; but simply because they study their fowls. And I say deliberately, that every one who will do this—who keeps fowls because he loves them, and will care for them, and watch them, and learn to understand them for himself, can attain success; and what is more, will find readily fanciers who will find a real pleasure in and help him to it. How much I owe myself to some two or three who were Brahma breeders before me I could not express in a written paper. But those of us who breed good birds do not produce them on the "any price" system. We do not go to a show to claim the first-prize cock, whatever he is, and then buy the first-prize pullets to mate with him. All three birds may be rightly judged, and be the very best of their sort, and yet will rather more likely than not breed mere trash. We look our birds over with loving care; we observe them day after day, gradually discovering faults even our eyes did not at first observe; and every one of these, and every individual peculiarity, is carefully weighed and allowed for before the partners for them are finally decided on. Often first conclusions are discarded; some hidden point strikes the attention, and demands another mate than that originally intended. Hours and hours are spent on this question of mating, but it is time well employed. And that is how real breeders win, or breed and sell birds which win in other names. That is how anyone may win his share who will take the pains and time to do it.

I confess I would not, if I could, have this altered; and I certainly speak with disinterested motives, for no one shows more rarely than I do, though I often supply birds to those who do. I would not have winning "made easy." There is something to me desirable in having a superiority which money cannot buy; and if I envy anybody, it is the feeling of the poor working man who has beaten in fair and severe competition the rich rival who has bought the best pen his money could procure. I have often seen this done, it is often done even now, and the man has a right to be proud who does it. It is hard work I grant; but it is just the fact that it *is* hard work which makes the satisfaction of it.

I would, however, always seek to avoid extremes, and there is one point that the discussion has, I think, shown to be desirable—that of having in smaller shows really local classes. These would meet all desirable objects without the objections I have mentioned. There would be no false pretences. The beginner would simply learn, if he won, that he had the best in his neighbourhood, and might thereby be encouraged to attempt having the best in the kingdom. But I speak, and the distinction is very important, of local *classes*, not local *cups*. Local cups only, in general classes, are open to all the objections of handicapping; but local classes can deceive no one, and will accomplish all the good desired. If the first-prize pen in the local class, as occasionally happens, really beats that in the open class, there are several easy ways of giving the due distinction.

As to buying, it can never be stopped, nor is it to be wished that it should. There is, however, one comfort—great buyers never learn to breed. I could name at least three prominent winners lately who have never yet bred a good bird for themselves, and while they buy in this reckless style never will. What pleasure there can be in it passes my comprehension; it is mere pride, not in the least real "poultry fancy." But, nevertheless, the high prices these people pay are one great support of those who are fanciers, and I do not see why anyone should complain.—L. Wright.

I was very glad to see that somebody was fighting against "handicapping," and I quite agree with Mr. Kell, and second his suggestions, and I also think with him with regard to the remedies and objections he throws out; but I must confess that I do not like to see a man "walk off" with all the prizes offered in one class, and this is often done. I suggest that exhibitors should only be allowed to show one pen in each class. I think this might be arranged to the advantage both of exhibitors and committees. I fancy that Mr. Kell and others will agree with me here, at least I hope so.—One Variety.

WHEATEN BANTAMS—GAME BANTAMS.

In "Our Letter Box," in your number of September 28th, I observe amongst answers to correspondents that the Wheaten Bantam is not clearly described. Will you allow me to remark that the bird you describe is a cross between a Wheaten and a Partridge Bantam? I have several of the pure Wheaten breed, and also many like your description.

The Wheaten hen should have a clear golden hackle, a light wheat-coloured breast, belly, and thigh, a clear buff body and wing, black tail, with the outer tail-coverts slightly marked or laced with buff. Many of the Wheaten hens have two shades of buff in the wings, the lighter shade edging each feather. The legs should be light willow or yellow, and the eyes clear

bright red. This is the Wheaten which breeds the richest-coloured Black-breasted Red cocks. There are Wheatens having white necks, and in every other respect answering the above description. These are exceedingly rare, but most useful for breeding Duckwing cocks.

The class for Wheaten hens, made by the Crystal Palace Committee at my suggestion, is for genuine Wheatens, and not the half-bred birds.

The answer to "Far West" in the Journal for September 28th is rather apt to mislead. Many of the best-coloured Black Red cockerels, when they moult the second or third time, grow some red feathers in the breast, either black feathers laced with red, or red with black spangles. These could not, however, be shown as Brown Reds, but are only faulty Black Reds, the main differences between the two colours being—

	Black Red Cock.	*Brown Red Cock.*
Head and face	Red	Dark purple.
Eye	Vermilion red	Darkest brown.
Hackle	Clear orange red, free from black	Orange, striped with black underneath.
Back and wing bow	Rich red	Orange.
Wing bar	Steel blue	Dark green.
Greater wing coverts	Clear bay	Black.
Breasts and thighs	Blue-black	Dark brown, with a light brown shaft and margin to each feather.
Legs and feet	Willow	Dark bronze, willow, or black.

The above is the standard of birds for exhibition.—W. F. E.

[We thank "W. F. E." very much for his elaborate description of certain breeds of Game. Our own long experience of Game has taught us there are numerous varieties, many being peculiar to certain localities, and the result of crosses. We never think of or treat of Game without thinking of the chameleon in our school days—

"'Sirs,' cries the umpire, 'cease your pother,
The creature's neither one nor t'other.
You all are right, and all are wrong,
Nor wonder if you find that none
Prefers your eyesight to his own.'"

Certain birds are made for exhibition—"manufac" as we read in Smollett. Provided the actual bird is really fit to take a prize, his origin is not important. Thus, a bird with more or less of red in his breast is either Brown-breasted or is descended from Black Reds that have had a cross of Brown. It is known to many of the most successful Brown Red exhibitors how most of their birds were made. It is also known they are now far superior to the Black Reds, but they have been made so by a judicious mixture of breeds. In the original days of showing there was but one class—"Black-breasted and other Reds," now they are divided. The bird of which we spoke is not a Black Red because he has brown feathers, *ergo* he must show in the Brown Reds. If, as our intelligent correspondent says, the bird does not belong to them, he cannot be shown at all. If, again, at the second or third moult it is common for many of the best Black Reds to throw red feathers in the breast, the birds will be only in the condition of the Silver-Grey Dorkings. Nineteen cocks out of twenty, after their first moult, throw white in the breast or tail. No longer Silver-Greys, they sink or rise, as the opinion may be, into the general class. "W. F. E." describes the Wheaten of a certain tinge as breeding the richest-coloured Black-breasted Red cocks, and others with white necks, as most useful for breeding Duckwings. These very facts argue for considerable latitude in treating of them. We differ positively on one point only. "W. F. E." says the legs must be willow; we believe the colours of the legs in a Game fowl of these breeds are no more important than would be the colour of a man's hair if he were competing with others for height.—Eds.]

COCKS SURELY MIGHT SIT IF WOMEN MIGHT VOTE.

Being an uncommon case, I think it might interest some of your readers to learn that there is here an old cock Turkey which is unfortunately afflicted with a "strong weakness"—if I may use an Hibernian phrase—to sit upon any sitting hens' nests that he may happen to find in the shrubberies or outhouses. It was no longer ago than yesterday that I caught him in the act of ejecting a Dorking hen from her nest at the foot of an elm tree, and forthwith enthroning himself, much to the poor hen's disgust and consternation, as well as danger to the newly-hatched chicks. Although chased away, he shortly returned, and after vainly trying to shift the hen, ceremoniously sat upon her back, where he continued his "peckings" at her head; after which it was deemed expedient to remove her from his importunities.

Apparently this propensity is inherent in him, as about three years ago he sat upon, for about a fortnight, a "set" of Duck's eggs; but finding, I presume, that "nil" resulted from his self-imposed undertaking, he consigned it to the care of the legitimate owner—a Dorking hen—who eventually was rewarded with a fair brood of ducklings.

As a supplement to the above I may state that I have heard of a Cochin cock hatching and rearing a brood of chickens.—William Gardiner, *Lower Eatington Park, Stratford-on-Avon.*

PRODUCTIVE GOLDEN-PENCILLED HAMBURGHS.

Up to the 7th of August I had eleven Golden-pencilled Hamburgh hens and one cock. On that date one hen died, reducing my number to ten. I commenced keeping my list on the 1st of March, and it is as follows:—

March	214
April	201
May	204
June	187
July	169
August	165
Total	1140

These fowls were kept in a run about 9 yards square, and fed on kitchen refuse and barleymeal, with corn in the evening. I should feel obliged if any of your readers would let me know if this is fair laying. — Joseph Napier, *Bradford Peverell, Dorchester.*

PRIZE FOR COCKERELS AND PULLETS AT THE CRYSTAL PALACE SHOW.

Could it not be arranged that those exhibitors who may intend to exhibit cockerels and pullets at this Show and also at Birmingham, should be allowed to pay an extra fee, say 10s., so as to make an extra prize for the best cockerel and pair of pullets? It should be quite optional, and would no doubt cause additional interest in the competition; and the honour of winning such a prize would be duly valued by every exhibitor who might be fortunate enough to possess good birds of both sexes. This would not involve the Committee in any risk in a pecuniary point of view; and if the question could be entertained the Committee might, after the entries had closed, send a post-card to all exhibitors who had made entries in both classes, inquiring whether they were willing to compete for the extra prize, and if so, requesting them to forward the fee by a certain date. I merely offer this as a suggestion, thinking it might be an interesting feature in the Show, and should be glad if it could be found practicable in this or any other way.—W. F.

ELLESMERE POULTRY AND PIGEON SHOW.

The Oswestry Agricultural Society has now for some years been noted for the excellence of that portion of the Show devoted to poultry, and of late years, without exception, the arrangements have been of so perfect a character as to leave no cause for complaint, for there has been a first-rate show-tent, also constant attendance on the wants of both visitors and poultry. Unfortunately, however, for the interests of this year's Show, a sudden gale not only prostrated the tent at the last moment, but tore it to shreds from end to end. After this mishap the Market Hall was immediately called into requisition, as the only place available for the protection of the birds. So far it was a capital makeshift, as the building afforded effective protection from the continuous downpour of rain, but with the exception of the few pens opposite the entrance, almost every pen was veiled in darkness, and not a few so much so that it was difficult for visitors to discriminate whether the pens were occupied or empty. Under these disadvantages the only resource of the Judge was to have almost every bird taken out of its pen whilst judging, and brought forward into the light of the doorway, the cock being first handled, and then the hen—in fact, the Judge's conclusions were made almost entirely by pursuing this plan.

The Exhibition certainly contained an unusually large number of the best specimens. *Game*, particularly the Brown Reds, were remarkably perfect. Grey and also White *Dorkings* were such as can rarely be seen. Some of the most noted prizetakers in the kingdom were to be found among the *Cochins*, but their beauties were marred by a light that even rendered doubtful the variety shown, much more a favourable inspection of their excellence. Some good pens of both Dark and Light *Brahmas* were entered; and the *Hamburghs* were so good that Oswestry could never boast the like of them before at any of its meetings. The French fowls were a superb collection; but the Game *Bantams* were not nearly so good as those shown in bygone

years in this neighbourhood. There was a fine and extensive entry of *Ducks;* and the entries for *Turkeys* and *Geese*, though so much fewer than heretofore, were a leading feature in the Show. The sweepstakes for *Pigeons* were well contested, and brought forward a few very rare varieties.

GAME.—*Black-breasted Red.*—1, P. A. Beck, Gnllafield, Welshpool. 2, H. M Julian, Hull. *hc*, P. O. Gill, Trewarn, Oswestry; Rev. P. G. Bentley, Felton Grange, Shrewsbury; W. C. Phillips, Worcester. *Brown-breasted Red.*—1, T. Burgess, Burleydam, Whitchurch. 2, Rev. P. G. Bentley. *hc*, T. Burgess; G. F. Ward, Wrenbury, Nantwich; T. Dyson, Clay Pits, Halifax: E. Winwood, Worcester; W. Adams, Ipswich. *c*, J. Chester, Nantwich. *Duckwing Greys and Whites or Piles.*—1, W. Dunning, Newport, Salop. 2, Barker & Charnock, Illingworth, Halifax. *hc*, J. Mitchell, Moseley, Birmingham.

DORKINGS.—1, J. Martin, Claines, Worcester. 2, A. Darby, Bridgnorth. *hc*, Miss Davies, Chester; E. Williams, Henllys, Berriew, Montgomeryshire.

COCHIN-CHINA.—*Brown or Partridge.*—1 and 2, C. Sidgwick, Ryddlesden Hall. *Buff or White.*—1, Mrs. Allsopp, Worcester. 2, H. Yardley, Birmingham. *hc*, C. Sidgwick; A. Darby; H. Tomlinson, Birmingham.

SPANISH.—1, Mrs. Allsopp. 2, Boulton & Glidden, Bristol. *hc*, Clewes and Atkins, Walsall; J. F. Sillitoe, Wolverhampton; J. Walker, Wolverhampton.

BRAHMA POOTRA.—*Dark.*—1, R. B. Wood, Uttoxeter. 2 and *c*, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. *Light.*—1 and *c*, T. A. Dean, Marden, Hereford. 2, J. Parez, Postford, Guildford. *hc*, R. B. Wood.

HAMBURGHS.—*Silver or Gold-pencilled.*—1, Ashton & Booth, Broadbottom, Mottram, Mancheater. 2, T. Bolton, Hanford, Stoke-on-Trent. *hc*, W. Speakman, Nantwich; J. Platt, Deane, Bolton, Lancashire. *Silver or Gold-spangled.*—1, Mrs. Allsopp. 2, Ashton & Booth. *hc*, C. Plimley, Wolverhampton; S. and R. Ashton, Mottram, Manchester; T. Bolton, Hanford, Stoke-on-Trent.

CRÈVE-CŒUR.—1, E. Pritchard, Wolverhampton. 2, J. K. Fowler, Aylesbnry. *hc*, J. J. Malden, Biggleswade.

HOUDANS.—1, R. B. Wood. 2, Hill & Co., Roundhill, Brighton. *hc*, E. Williams.

ANY OTHER VARIETY.—1, C. Sidgwick (Black Hamburgha). 2, Rev. A. Brooke, The Rectory, Shrawardine (Silver-spangled Polands). *c*, H. Yardley (Black Cochins).

GAME BANTAMS.—1, C. Ashworth, Halifax. 2, Ashley & Maitland, Red Hill, Worcester. *hc*, W. Griffiths, Nantwich; Ashley & Maitland; Bellingham and Gill, Burnley; A. H. Jnhb, Halifax.

BANTAMS.—1, S. & R. Ashton (White Bantams). 2, T. Bolton, Hanford, Stoke-on-Trent (Light Japanese).

MALAY.—*Cockerel.*—1, J. S. Rnoth, Chesterfield. 2, Rev. A. G. Brooke.

TURKEYS.—*Poults.*—1, E. Shaw, Oswestry. 2, no competition.

GOSLINGS.—1, S. H. Stott, Preston. 2, E. Shaw.

DUCKLINGS.—*Aylesbury.*—1 and 2, J. K. Fowler. *hc*, S. H. Stott. *Rouen.*—1, Miss Davies, Chester. 2, S H. Stott. *hc*, J. K. Fowler. *c*, E. Shaw.

EXTRA STOCK.

SELLING CLASS.—1, J. Crntchloe, Oswestry (Game). 2, H. Yardley, Birmingham (Buff Cochins). *c*, E. Shaw (Black Spanish); H. A. Dean (Silver-spangled Hamburgha).

GAME.—*Black-breasted.*—*Chickens.*—1, G. Cottle, Weatfelton. 2, Rev. P. G. Bentley, Shrewsbury. *hc*, P. A. Beck. *Any Colour.*—*Pullets* (Local).—1, C. Wedge, Oswestry. 2, Rev. P. G. Bentley. *hc*, Rev. P. G. Bentley; G. Cottle. *c*, J. Crntchloe; E. Shaw. *Amateurs' Prize* (Local).—*Cock.*—1, P. O. Gill, Trawern, Oswestry. 2, J. Crntchlne.

DORKINGS (Local).—1 and 2, E. Shaw.

SWEEPSTAKES.—*Pigeons.*—1, A. Hulme, Bettisfield (White Turbits). 2, Rev. A. G. Brooke, Shrawardine (Black Priests). *hc*, T. Jones, Oswestry (Barbs). A. Hulme (Black Magpies); Rev. A. G. Brooke (Creascents). *c*, E. Griffiths, Knockin (Antwerps).

Mr. Edward Hewitt, of Sparkbrook, Birmingham, was the Judge.

TONBRIDGE WELLS POULTRY SHOW.

THIS Show was held on the 6th inst., and was as perfect as any small show could be. The *Spanish* headed the list; the first-prize pullets were very good. *Dorkings*, Grey and Cuckoo, were well represented. In *Brahmas*, Mr. Dring was first with one of the most splendid cockerels ever seen, and in fine condition as regards plumage, carriage, and colour; a prosperous career seems cnt out for him if he remain as he is. The *Hamburghs* were good though few; in the Golden-pencilled variety one exhibitor swept the board. The *French* Fowls were a good class, pen 64 looked very promising. In the Variety Class the first prize went to White Cochins. *Ducks*, *Turkeys*, and *Geese* were all good, and there was a lovely pen of Turbit *Pigeons*, which were highly commended. Mr. Hedley judged.

SPANISH.—*Chickens.*—1, H. Brown, Putney Heath. 2, J. Francia, Hilden borough, Tonbridge. *hc*, E. J. W. Stratford, Addington Park, Maidstone.

DORKING.—*Chickens.*—1, G. W. Greenhill, Ashford. 2, R. Cheeaman, Weatwell, Ashford. 3, A. Arnold, Lamberhnrst. *hc*, E. J. W. Stratford; E. Williams, Henllya. *c*, G. Field, Aahurst; A. Arnold.

BRAHMA.—*Chickens.*—1, W. Dring, Faveraham (Dark). 2, E. J. W. Stratford. *hc*, M. Leno, Markyate Street. Dunstable (Light); Rev. J. G. B. Knight, Wrotham (Dark). *c*, H. Mitchell, Sydenham.

HAMBURGHS.—*Golden-spangled.*—*Chickens.*—1, W. Taylor, Maidatone. *Golden-pencilled.*—*Chickens*—1, *hc*, and *c*, R. S. S. Woodgate, Pembnry, Tonbridge Wells. *Silver-pencilled.*—*Chickens.*—1, B. Shelley, Maresfield Park, Uckfield. *Silver-spangled.*—*Chickens.*—1, A. J. B. Beresford Hope, M.P., Bedgebnry.

GAME DUCKWING.—*Chickens.*—1, W. Foster, Deal. *c*, J. Jeken, Eltham. *Any other Variety.*—1, J. Jeken. *hc*, W. Forster; T. G. Ledger, Folkestone.

FRENCH.—*Chickens.*—1, J. J. Malden, Biggleswade (Crêve-Cœur). 2, E. Williams (Crêve-Cœurs). *hc*, W. Dring (Houdans and Crêve-Cœurs).

ANY OTHER VARIETY.—*Chickens.*—1, R. S. S. Woodgate (White Cochins). 2, E. J. N. Hawker, Wycliffe, Tonbridge Wells (Silkies). *hc*, R. S. S. Woodgate (White Cochins); J. Wilde, Uckfield.

BANTAMS.—1 and *hc*, M. Leno, Dunstable (Silver-laced). 2, S. Samways, Southampton (Black). *c*, F. G. Phillips, Hastinga.

ANY BREED.—1, A. J. B. Beresford Hope, M.P. (White Malay). 2, W. Dring (Crêve-Cœurs). *hc*, R. S. S. Woodgate (Silkies); E. J. N. Hawker.

TURKEYS.—1, Earl of Abergavenny. 2, A. J. B. Beresford Hope, M.P.

GEESE.—1, Mrs. Lee, Penshurst. 2, A. J. B. Beresford Hope, M.P. *hc*, G. Pack, Tndelay; S. Green, Edenbridge; Earl of Abergavenny.

DUCKS.—*Aylesbury.*—1, G. W. Greenhill, Ashford. 2, Mrs. Lee. *Rouen.*—1, W. Jacobs, Shepherdswell. 2 and *hc*, A. Patchett, Hadlow Down. *Any other Breed.*—1, Mrs. Lea. 2, M. Leno. *hc*, G. S. Sainsbury, Devizes.

PIGEONS (Beat collection of not less than three kinds).—1, H. Yardley, Birmingham. 2, G. Ware, Frant. *hc*, G. Ware; O. E. Cresawell, Bagshot (Turbits).

BARE CUPS AT THE CRYSTAL PALACE SHOW.—I shall be greatly obliged by your stating that for the pieces of plate offered by me at the Crystal Palace Pigeon Show, neither my sister nor I have any intention of competing.—MATTHEW HEDLEY, *Claremont, Redhill, Surrey.*

FARNWORTH AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE seventh annual Exhibition of this Society was held at Farnworth, near Warrington, on the 5th inst., and attracted a larger attendance than any of the preceding Shows of the Society, while the entries were in excess of former years. In poultry the *Game* class was not so numerous as usual, and the same remark applies to *Cochins*, but *Hamburghs* surpassed anything yet seen at Farnworth. The competition was very close in Game *Bantams*, which was an excellent class. The Rouen and Aylesbury *Ducks* were really interesting, and there was a rare species of "Whistling" Duck which attracted a good deal of notice. *Geese* were remarkable for size, weight, and feather. Indeed, the poultry show, considering the lateness of the season, was one of the best features of this year's Exhibition.

GAME.—*Black-breasted Red.*—*Chickens.*—1, C. Chaloner, Whitwell. 2, J. Goodwin, Liverpool. *Brown-breasted Red.*—*Chickens.*—1, C. W. Brierley, Middleton. 2, J. Wood, Wigan. *Any other Variety.*—*Chickens.*—1, R. Halsall, Halewood. 2, J. Goodwin. *Any Colour.*—*Cock.*—1, J. Wood. 2, C. Chaloner, DORKING.—*Chickens.*—1, Miss Davies, Chester. 2, T. E. Kell, Wetherby.

SPANISH.—*Chickens.*—1, C. W. Brierley, Middleton. 2, J. Walker, Standeford.

COCHINS.—*Cinnamon or Buff.*—*Chickens.*—1 and 2, A. Darby, Bridgenorth. *Partridge-feather, or Any other Variety.*—*Chickens.*—1, C. Sidgwick, Keighley. 2, G. Gaskell, Southport.

HAMBURGHS.—*Golden-pencilled.*—*Chickens.*—1 and 2, H. Pickles, jun., Earby. *Golden-spangled.*—*Chickens.*—1, T. Walker, jun., Denton. 2, J. Statter, New Brighton. *Silver-pencilled.*—*Chickens.*—1, H. Pickles, jun. 2, W. M. Mann, Kendle. *Silver-spangled.*—1, H. Pickles, jun. 2, Ashton & Booth, Broadbottom.

POLAND (Any variety).—1 and 2, P. Unsworth, Lowton.

BRAHMA POOTRA.—*Chickens.*—1, Dr. Holmes, Chesterfield. 2, L. Mill, Liverpool.

GAME BANTAMS.—*Chickens.*—1, G. Maples, jun., Wavertree. 2, T. Sharples, Forest Bank. *Cock.*—1, T. Sharples. 2, G. Maples, jun.

BANTAMS (Any breed).—*Chickens.*—1, S. & R. Ashton, Mottram. 2, M. Leno, Dunstable.

ANY DISTINCT VARIETY.—*Chickens.*—1, J. Railton, Manchester. 2, T. Walker, jun., Denton.

ANY COLOUR OR BREED.—*Chickens.*—1, P. Unsworth, Lowton. 2, J. Mansell, Longton.

DUCKS.—*Rouen.*—1 and 2, A. Haslam, Hindley. *Aylesbury.*—1, J. K. Fowler, Aylesbury. 2, E. Leech, Rochdale. *Any other Variety.*—1, C. W. Brierley, Middleton. 2, R. Gladstone, jun., Court-Hey, Liverpool.

GEESE.—1, E. Leech, Rochdale. 2, S. H. Stott, Preston.

TURKEYS.—1 and 2, E. Leech.

The Judges were Mr. Richard Taehay, Folwood, Preston; and Mr. Joseph Hindson, Barton House, Everton.

LONG SUTTON POULTRY SHOW.

THIS was held on the 4th and 5th inst., in a field adjoining the railway station, and the poultry were exhibited in comfortable wooden sheds. Although the Farnworth Exhibition interfered to some extent with the number of entries, these were excellent in all the sections.

Dorkings were good in both classes, although some of the birds were in moult. In *Cochin* cocks the first was a good chicken, but the second rather too large in tail. The cup for cocks of the large varieties was won by the Cochin above-named. The cup for hens went to a nice pair of Buff pullets shown by the same exhibitor. Of *Brahma* hens, the first were birds of this year, and the second old birds. *Spanish* were a failure as regards numbers, as were the Golden-spangled *Hamburghs*, but the quality was all that could be desired. In the rest of the Hamburgh classes Mr. Beldon won all the first prizes and several of the second, also the cup for the best pen with Golden-pencilled, which pen contained a pullet of rare excellence. In *French* fowls both prizes went to Crêve-Cœurs, such as left nothing to be desired. In Red *Game* fowl Brown Red chickens won the first and cup, and Black Red the second; and in the next class Mr. Matthew showed an excellent pair of Duckwings, the only fault being the coarseness of tail in the cock bird. *Bantams* mustered well, the cup for Game being won by excellent Black Reds, the pullet in this pen being very true to colour. Of Brown Reds there were many good birds, but no good pairs. In the Variety class capital Piles stood first and Duckwings second. In Black and White, the first-named colour carried off the laurels. The class was unusually good, the first-prize and cup pen winning by earlobe and condition only over the second-prize pen, the cock in which carried the best colour we have yet seen produced. In the Variety class Silver-laced of the most perfect ground colour, combined with perfect lacing and clear tails, were first, and Golden-laced second. The cup would, undoubtedly, have gone to this pen, only the pullet seemed somewhat out of sorts. In the class for Any other variety of poultry Silver Polands won the cup, and Sultans were second. In Ornamental birds a cage of foreign birds stood first, with Golden Pheasants second.

The cup for *Turkeys* or *Aquatic Birds* was given to a large and perfect pen of Aylesbury Ducks; and in other varieties, Carolinas were first and Black East Indian second.

There were two Selling classes for poultry, in the first of which the prizes were awarded to Rouen Ducks, Spanish, and Dark Brahmas respectively, the cup going to the former pen; and in the second Selling class the first were Crêve-Cœurs, the second Black Bantams, and the third Golden-pencilled Hamburghs.

In *Rabbits* the cup was awarded to a young Sooty Fawn Lop buck, which was about perfect in all points, and the second in that class to a Fawn and White, the measurements of the ears of the first being

22½ inches by 4¾, and of the second 20½ and 4½ inches. In does, the first was a handsome Grey, with ears 23 by 4½ inches, and the second (22 by 4½) was a Fawn. For Any other pure breeed of hucks, an excellent young Silver-Grey was first and an older Rabbit second, and both were well silvered and uniform in colour. The first-prize doe was a perfect Himalayan, and the second an equally good Silver-Grey, which proved to be from the same yard as the first-prize buck. In the class for the heaviest Rabbit the first was 16 lbs. 13 ozs., and the second 15 lbs. 2 ozs. in weight.

Unfortunately, some of the pens, both of poultry and Rabbits, were too late, and others were empty, no doubt in consequence of the regulation that the specimens must be in the Show ground by noon on the Tuesday, which rule, we understand, is to be altered next year.

The *Pigeon* section was an excellent show of itself, and for the time of year the birds were in good feather. Carriers were a nice display, the style and quality of some of the adult birds being a great treat to the true fancier of this variety. The cup for this section was carried off by a capital Black hen. Young Carriers were also very good, the prizewinners being Blacks, and we noticed also a Blue cock of most promising qualities. In Antwerps the first were good Blue Chequers, and the second Duns; and in Pouter cocks Blue was first and White second, and in hens Yellow was first and Blue second. In Almond Tumblers the contest was very keen, and the cup for Shortfaces was awarded to them; in the next class Black Mottles were first and Blue Beards second. In Jacobins the first were Reds, which placed all others a long way in the background, but we preferred Mr. Fulton's Reds to the second-prize Yellows. The Fantails did not show well, perhaps owing to the coldness of the weather. The first-prize Turbits were Blacks, and the second Silvers; the class was of moderate quality. There were two classes for Barbs, one for adult and the other for birds of 1871. Miss Hedley carried off both the first prizes and the cup for the section with the old pair, which are doubtless at the summit of the fancy. The first prize for Dragoons went to Yellows and the second to Blues, both pairs being old birds. In the Variety class was a pair of the most perfect Black Trumpeters that we have seen this season; second came Blue Runts.

The point cup for poultry was won by Mr. Beldon, that for Pigeons by Mr. Fulton, that for the local classes by Mr. Clarke.

(*From a Correspondent.*)

The Pigeon department of the Long Sutton Show is looked to by many exhibitors with great interest, as giving a foreshadowing of their prospects of success in the great tournaments at the Crystal Palace (the entries for which, by-the-by, close on Monday next), and Birmingham Shows. At Long Sutton, as in previous seasons, if I mistake not I have this year seen many birds that will come to the front at the above Shows. I must refer your readers to the prize list for the names of the successful exhibitors, who sent, judging from the general quality of the birds, only the cream of their lofts; and those exhibitors who were beaten were not disgraced. The young Carrries were very good; the old ones not in that plumage which I could wish. A hen of excellent quality took the cup. In Pouters Messrs. Horner and Fulton divided the honours. In Almonds and Tumblers of any other variety the cup went to the former, and the first honours in the latter variety to Black Mottles. The remaining cup for the best pair of either Jacobins, Fantails, Owls, Turbits, Dragoons, Barbs, or any other distinct variety, went to Miss Hedley for a pair that well deserved the Judges' choice, she also winning the first prize for the best pair bred in 1871.

A word of praise is due to the management of this Society for the care taken of the birds whilst in their possession, though, I presume, on account of the difficulty of getting to Long Sutton exhibitors must take time by the forelock next year, otherwise they will, as this year, have their pets returned "too late for competition."

Dorkings.—*Cock.*—1, J. White, Warlaby, Northallerton. 2, G. Clarke, Long Sutton. *Hens or Pullets.*—1, E. W. Southwood, Fakenham. 2, W. H. Robson, North Reston, Louth. *hc*, G. Clarke.

Cochin-China.—*Cock.* — Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, R. Dawson, Beverley. *hc*, C. Sidgwick, Ryddlesden Hall, Keighley; T. M. Derry; J. Bloodworth, Cheltenham. *Hens or Pullets.*—Cup, Lady Gwydyr. 2, Henry Lingwood, Barking, Needham Market. *hc*, C. Sidgwick; F. Wilton, Gloucester; A. Darby, Bridgenorth.

Brahma.—*Cock.*—1, H. Beldon, Goitstock, Bingley. 2, Lady Gwydyr. *hc*, J. K. Fowler, Aylesbury. *Hens or Pullets.*—1, Lady Gwydyr. 2, T. F. Ansdell, St. Helen's. *hc*, W. Manafield, Cambridge; E. F. Maples, Spalding. *c*, Rev. N. J. Ridley, Newbury.

Spanish.—*Cock.*—1, H. Brown, Putney Heath. 2, H. Beldon. *Hens or Pullets.*—1, W. Woodhouse, Lynn. 2, H. Brown. *hc*, J. K. Fowler.

Hamburghs.—*Gold-spangled.*—1, H. Beldon. *Silver-spangled.*—1, H. Beldon. 2, J. B. Bly, Lowestoft. *hc*, S. S. Mossop; G. Speedy, Whitby. *Gold-pencilled.*—Cup and 2, H. Beldon. *hc*, A. Cole, Long Sutton. *Silver-pencilled.*—1 and 2, H. Beldon. *hc*, N. H. Scott, Sunderland.

French Fowls (Any variety).—1, Mrs. J. Cross (Crêve-Cœur). 2, J. K. Fowler. *hc*, G. W. Hibbert, Godley, Manchester (Houdan); W. Dring, Faversham (Crêve-Cœur); Rev. A. Brooke.

Game.—*Black-breasted or other Reds.*—Cup, E. Aykroyd, Eccleshill. 2, H. E. Martin. *hc*, S. Matthew, Stowmarket; J. Preston, Allerton, Bradford. *Any other Variety.*—1, S. Matthew (Duckwing).

Game Bantams.—*Black-breasted Reds.*—Cup, Bellingham & Gill, Burnley. 2, W. F. Entwisle, Westfield, Cleckheaton. *hc*, J. Oldfield, Shibden, Halifax; W. F. Entwisle; Bellingham & Gill; W. Adams, St. Clements, Ipswich. *c*, G. Daft, jun., Halloughton, Southwell, Notts (2); T. C. & E. Newbitt, Epworth. *Brown-breasted Reds.*—1, J. Oldfield. 2, T. Barker, Hill End, Burnley. *hc*, G. Hall, Kendal. *Any other Variety.*—1, W. F. Entwisle (Pile). 2, T. C. & E. Newbitt. *hc*, W. F. Entwisle (Duckwing); T. C. & E. Newbitt.

Bantams.—*Black or White.*—Cup, G. Clarke. 2, S. S. Mossop, Long Sutton. *hc*, J. Walker, Newark; R. Fulton; G. Clarke; S. & R. Ashton (2). *Any other Variety.*—1, Mrs. J. M. Procter, Hull. 2, F. Wilton, Gloucester (Gold Sebright). *hc*, J. R. Jessop, Hull (Sebrights); H. Beldon (Pekin); T. J. Miller, Fakenham (White Booted); T. Waddington, Feniscowles, Blackburn.

Any other Variety.—Cup, H. Beldon. 2, W. H. Tomlinson (Sultans). *hc*, C. Sidgwick (Black Hamburghs); W. K. Patrick, West Winch, Lynn (Polands) (2); T. Waddington (Polands) (2).

Ornamental Birds.—1, S. S. Mossop. 2, J. K. Fowler. *hc*, J. K. Fowler; G. Clarke (2).

Turkeys.—1, G. R. Pearson. 2, Mrs. E. Harris. *hc*, M. Kew, Market Overton. *c*, T. M. Derry, Gedney.

Ducks.—*Rouen.*—1, W. H. Robson, North Reston, Louth. 2 and *c*, J. K. Fowler. *hc*, W. H. Robson; S. S. Mossop. *Aylesbury.*—Cup and 2, J. K. Fowler. *hc*, W. Stonehouse. *Any other Variety.*—1, W. Binns (Carolina). 2, S. Burn, Whitby (Black East Indian). *hc*, J. Dring; J. K. Fowler; H. B. Smith (Carolina).

Geese.—1 and 2, J. K. Fowler. *c*, T. M. Derry.

Selling Classes (No. 1).—Cup, S. S. Mossop. 2, Burch & Boulter, Sheffield (Spanish). 3, W. H. Bell, Westfield, Burnley (Dark Brahma). *hc*, E. Redman Northowram, Halifax (Black Red Game); J. K. Fowler. (No 2).—1, Mrs. J. Cross, Appleby Vicarage, Brigg (French). 2, G. Clarke (Black Bantam). 3, A. Cole. *hc*, J. K. Fowler; G. Morling, Lynn (Duckwing Bantams).

PIGEONS.

Carriers.—*Black.—Cock.*—1 and *hc* (2), R. Fulton, Deptford. 2, E. Horner, Harewood. *c*, T. Waddington, Feniscowles, Blackburn. *Hen.*—Cup, R. Fulton. 2 and *hc*, E. Horner. *c*, T. Waddington. *Any other colour.—Cock.*—1, H. Yardley, Birmingham. 2, R. Fulton (Dun). *hc*, R. Fulton; E. Horner. *Hen.*—1 and 2, R. Fulton (Dun). *Any variety, bred in* 1871.—1 and 2, E. Horner. *hc*, A. Cole, Long Sutton (2); J. G. Dunn, Newcastle (Dun and Black); R. Fulton (Black and Blue); W. Campey, Beverley (Dun); E. Horner.

Antwerps.—1, H. Yardley. 2, C. F. Copeman. *c*, J. W. Collinson, Halifax; H. Yardley.

Pouters.—*Cock.*—1, 2, and *c*, R. Fulton. *hc*, E. Horner (2). *Hen.*—1, E. Horner. 2, R. Fulton. *c*, R. Fulton (2); E. Horner (2); G. Sturgess (2).

Tumblers.—*Almond.*—Cup, J. Ford, Monkwell Street, Loodon. 2, E. Horner. *hc*, J. Ford; R. Fulton (2). *c*, T. Waddington. *Any other Colour*,—1, J. Ford. 2, W. Woodhouse. *hc*, R. Fulton.

Jacobins.—1 and 2, E. Horner. *hc*, R. G. Sanders; E. Horner.

Fantails.—1 and 2, J. Walker, Newark. *hc*, J. F. Loversidge; W. H. Tomlinson. *c*, R. Fulton; E. Horner.

Owls.—1, T. Waddington. 2, P. H. Jones, Fulham. *hc*, R. Falton (2).

Turbits.—1, G. Roper, Croydon. 2, R. Fulton. *hc*, R. Fulton; E. Horner. *c*, G. H. Gregory, Taunton.

Barbs.—Cup, Miss Hedley, Claremont, Redhill. 2, R. Fulton. *hc*, E. Horner (2). *Young.*—1, Miss Hedley. 2, P. H. Jones. *hc*, G. H. Gregory; Miss Hedley.

Dragoons.—1, F. Graham, Birkenhead. 2, T. Waddington. *hc*, F. Graham; E. Horner. *c*, A. W. Wren, Lowestoft.

Any other Distinct Variety.—1 and 2, P. H. Jones. *hc*, T. C. Benson (Damascenes); G. H. Gregory (Magpies); E. Horner; T. Waddington (Pigmy Pouters). *c*, R. Fulton.

Selling Class.—1, S. Warrell, Spalding (Dun Carriers). 2, R. G. Sanders (Red Jacobin). *vhc*, E. Horner. *hc*, S. Warrell (Black Barbs). *c*, H. N. Harvey, Spalding (Yellow Turbits).

Rabbits.—*Lop-eared.—Buck.*—Cup, J. G. Quick. 2, Robinson & Lewin. *hc*, C. Lea, Nottingham; J. G. Quick; H. Cawood, Thorne; W. H. Tomlinson. *Doe.*—1, J. Bacon, Nottingham. 2, H. Cawood. *vhc*, Robinson & Lewin. *hc*, J. Bacon; J. F. Farrow; J. Irving, Blackburn. *c*, A. H. Easten, Hull. *Any other Breed.—Buck.*—1, J. R. Jessop, Hull (Silver-Grey). 2, S. G. Hudson (Silver-Grey). *hc*, A. Easten (Angora). *Doe.*—1, W. H. Tomlinson (Himalayan). 2, J. R. Jessop (Silver-Grey). *hc*, S. G. Hudson (Silver-Grey). *Heaviest.*—1, W. Arkwright, Sutton Scarsdale. 2, W. Jibb, Long Sutton. *hc*, J. Bacon; T. Mumby, Long Sutton; A. Langley, Downham Market.

Local Prizes.—1, G. Clarke (Dorking cock). 2, T. M. Derry (Buff Cochin cock). 3, A. Cole (Cochin pullets). 1, S. S. Mossop (Silver-spangled Hamburghs). 2 and 3, A. Cole (Gold-pencilled Hamburghs). 1 and 3, G. Clarke (Black Bantams). 2, S. S. Mossop (Black Bantams). 1, Mrs. E. Harris (Turkeys). 2, S. S. Mossop (Rouen Ducks). 3, T. M. Derry (Cambridge Turkeys). 1, 2, and 3, A. Cole (Black Carriers).

The *poultry* classes from 1 to 18 were judged by Mr. Teebay, and those from 19 to 30, also the *Rabbits*, by Mr. Hutton; the *Pigeons* by Messrs. Esquilant and Massey.

HINGES TO BAR-AND-FRAME HIVES.

As I am neither a bee-hive maker, nor seller, nor able to control the "protean" forms of the bar-and-frame hive, I cannot answer for even the Major Munn's bar-and-frame hive of Mr. Pettitt. Thus much, however, I can state—I have used no other hives from 1838 except my square hive and the triangular bar-and-frame which I patented in Paris in 1843, because I was precluded doing so in England, from its having been made, used, and exhibited from the year 1834 in some form or other. On the well-known principle of a "hive within a hive," each comb is fixed separately in each frame, and they either draw out or lift out, for daily examination, from a strongly-made outer box.

In 1851 I exhibited the so-called triangular bar frames, lifting into a quadrant glass-eided frame, to enable timid persons and ladies to examine each separate comb, and to remove or replace each frame.

In 1859 I presented to the Secretary of the Apiarian Society a cheap bar-and-frame hive, made with a wooden top bar and zinc slides and sides, with a pin through, to slide each frame upon, to remove wet comb, or examine each hourly if necessary, as has been already etated.

By-the-by, I am reminded that I have the fellow hive in use, not altered by Mr. Pettitt or by me one iota, except it has actually a swarm of bees working on the top of these "bar frames," which will remain for this winter and spring, and which I believe Mr. Pettitt has not seen. But who will introduce this principle of the bar and frames, suspended within a box, forming a complete apiary in itself without the bee-houses, bee-sheds, or bee-box covers now used with the modern hives—remains still to be seen. It must be admitted the Americans seem to have the best chance, seeing the energy with which they contend even for the shape of a hive, and the protean

forms of the same principle may be seen in any advertising American paper. I hope, therefore, Mr. H. A. King will be able to establish his right, and for all American bee-keepers, to make the moveable comb hives, as the Americans call the same principles as the bar-and-frame, in any form, shape, or size they may elect.—W. Augustus Munn.

BEES AND MICE.

I heard the other day of a lady who had a fine box of honey devoured by mice (so it was stated), and the question was put to me how such attacks could be prevented. The hives so plundered were of straw. Never having had experience either of this trouble or of any remedy, I could only suggest what I thought would be likely to answer; but if any of your readers have suffered in the same manner, and know of a remedy, they will doubtless do a service to others who may be in the same predicament. I advised the nailing of pieces of zinc or galvanised iron around the legs of the bee-house, or pedestal on which the hives were placed, in such a manner that when the mice crept up they might find a check in the overhanging metal, much in the same way as rats are prevented from getting into corn-ricks. Of course bees in hives of wood are exempt from this injury.—B. & W.

Hampshire Ornithological Society's Show.—This must be well supported by exhibitors, for the prizes are liberal, and, in addition, there are eleven cups, varying in value from ten to three guineas. The South-Western Railway will reconvey without charge all unsold pens. We are pleased to see that it is proposed to present a testimonial to the Secretary, Mr. Philip Warren. His courtesy and indefatigable exertions for the Society entitle him to this.

OUR LETTER BOX.

Crystal Palace Poultry Show (*J. Elgar*).—We cannot insert any more communications. The reply to your letter by the Secretaries we consider satisfactory, and your rejoinder only weakens your first statement.

Middleton Poultry Show.—Mr. A. H. Easten, 19, Wellington Terrace, Beverley Road, Hull, informs us that he was the winner of the first prize at Middleton for Lop-eared Rabbits, and not Mr. J. Holt.

Poultry Feeding (*J. H.*).—We agree with hardly any of your advisers. Fowls do not like oats. They will only eat them when driven to do so by hunger, and oats can only be profitably given when they are ground. We advise you to give barleymeal or ground oats slaked with water in the morning, some whole corn at midday, and meal again in the evening. The feed at midday may be varied, if you have table or kitchen scraps to substitute for the whole corn.

Dorking Cockerel (*J. Clack*).—It is not a common thing for fowls to be troubled as your Dorking cock is. If it should continue, you must shut the bird up for a night to insure his being in a fasting state, and give him two tablespoonsful of port wine. The weights of your birds are very satisfactory, and far above the average. We are disposed to think your feeding better calculated to produce weight than to make strength. With the advantages of perfect liberty, and unlimited grass run, the food given should be of the highest quality. Potatoes are very bad for poultry, they induce liver disease, and make fat *but not flesh*. Two meals per diem should be slaked oatmeal or barleymeal; the midday repast barley, maize, or scraps. The colour you mention in the plumage of the cock is not of the slightest importance in general competition.

Poultry Run (*J. E.*).—The run you mention is quite large enough, and we have no doubt you will find the partition sufficient if you make the wire incline inwards. Fowls will not then attempt to fly over.

Over-stimulated Chickens (*B. T. B.*).—We believe you made the mistake in giving bread and ale only. It is a medicine, and should be given accordingly. We rear many hundreds of chickens, and never give them any drink in winter but ale. The hen should be confined under the rip, but the chickens should be allowed to run in and out between the bars as they like after sunrise. Stimulating food is the safeguard from illness in bad weather, but it must be given with other things of a nourishing nature. It merely gives the system a fillip, and supplies an ephemeral strength to the patient while the disorder is treated.

Chinese Geese (*A. W.*).—The Geese you praise would not be profitable, as in such cases they have to encounter a market, and would not find a ready sale; nor do we believe they would sell at all, till all the common breeds had found purchasers. We know they are hardy, having bred them ourselves. We have hatched and reared them in mid-winter. We did not wish you to understand we thought they were given to you, but we said the praise of those to whom you gave them was not a fair criterion of value.

Mandarin Geese (*T. A. B.*).—We have never heard of Mandarin Geese. There is a White Chinese Goose that answers the description you give. It is too much the fashion to give imaginary names, and many are misled by the practice.

Dubbing Game Cocks (*A. H.*).—The best instrument for dubbing a Game cock is a pair of scissors. Those we employ are very like those used for clipping horses. There is a certain risk in dubbing a bird two years old, but it is very small. If the operation is well performed and the wound heals kindly it will not interfere with his chance of success. It has even one advantage—the comb will not grow after the operation. In dubbing we always cut from back to front, keeping as close to the skull as may be without laying it bare. You speak of the comb, but gills and deaf-ear must be cut equally clean.

Poultry Management (*Devon*).—The experience of half a century has convinced us that good corn, either whole or ground, and slaked with milk or water as may be most convenient, and the scraps and waste of a house, coupled with a sufficient grass run, are all that is required for poultry. All who keep poultry should follow nature as closely as possible, and rear their stock as Pheasants and Partridges feed, and as the hens of these birds rear their broods. This is the most natural, most economical, and most successful plan.

Doe Producing a Single Young One (*A Reader*).—Your doe is probably too fat, or if she is old she may only produce one or two young ones at a litter. At times, if frightened, as by say a mouse running across the hutch, or any other disturbing cause, she may have destroyed some of them. This some does are in the habit of doing. She should always have a clean hutch a few days before littering, with plenty of hay for her nest, and a little water or milk and water; for during the time of littering intense thirst is experienced, and to appease it, if no fluid is provided, the doe resorts to cannabalism in some instances.

Tick Beans for Pigeons (*H. S. S.*).—Any dealer in bird seeds could supply you.

Preserving Quinces (*J. F.*).—Of course you are familiar with their use along with Apples in pies and tarts. They may also be made into a marmalade, jelly, compôte, or syrup, and are used in various other ways. We give two modes of preparation. To make quince marmalade, gather the fruit when fully ripe, and of a fine yellow; pare, quarter, and core it; put the quinces into a saucepan with a little water, and set them on the fire until they are quite soft; then take them out, and lay them on a sieve to drain; rub them through, and weigh the pulp; boil an equal quantity of sugar to *petite casse*, then add the pulp, and stir them together over the fire until it will fall from the spoon like a jelly. The marmalade is then fit to be put into pots, and when cold cover them closely. To make compôte, take six quinces, cut them in halves, and core them; scald and pare them neatly. Put some clear syrup into a preserving-pan, with the juice of a lemon; when hot add the quinces, and give them a boil together; drain the fruit, arrange it in the compotier, leave the syrup to thicken a little, and pour it over the quinces.

Butter Produced Slowly (*A Subscriber*).—Let the cream become sour before putting it into the churn, and the butter will form more readily. Churn in a warmer room.

REMARKS.

4th.—Beautiful morning and fine day.

5th.—Very fine till 2.45, then a very heavy shower, and lighter rain after.

6th.—Cloudy morning, shower about noon, then fine.

7th.—Very frequent showers, and very dull the whole day.

8th.—Fine all day, particularly bright in the middle, but misty in the evening.

9th.—Autumn fog in the morning, but very fine in the afterpart of the day.

10th.—Fog in morning, fine day but rather cold, fine starlight night.

A fine autumnal week; the decline of temperature steadily continues, and there have been two slight frosts on grass.—G. J. Symons.

COVENT GARDEN MARKET.—October 11.

A fair amount of business for the season is being done.

From observations taken near London during forty-three years, the average day temperature of the week is 58.0°, and its night temperature 40.1°. The greatest heat was 69°, on the 22nd, 1863; and the lowest cold 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

GOSSIP ABOUT TEA ROSES.

YOU were good enough to allow me to say a few words about the best Hybrid Perpetual Roses a week or two ago, will you now give me space for a word or two respecting the Teas and Noisettes? Possibly I may be able to give my amateur friends "a wrinkle" or two.

I suppose there can be no two opinions about the beauty and value of Tea Roses—I include Noisettes in the Teas—but I doubt whether they are as extensively grown as they might and ought to be. When I first began Rose-growing I had an idea that Teas were exceedingly tender, and wanted a great deal of extra care and attention. Acting under this belief, and on the advice of a very experienced rosarian, I had two very expensive borders made for these Roses. The ground was excavated to a depth of 2 feet or more, and the bottom of the bed being filled with brickbats and other rough material, the bed was made with turf cut up roughly, and mixed with broken bones and stable dung. In these beds I planted my Tea Roses, some being on the Briar and others on the Manetti. The plants did pretty well, but not so well as I expected and had hoped; I therefore determined to bud them on Briars just like the Hybrid Perpetuals. These—I mean the Briars—I may state in parenthesis I always plant in trenches, into which I put a mixture (half and half) of good rich pig dung and stiff yellow clay, well incorporated with the bottom spit of the trench. This I find incomparably better than all dung, and no one who has not seen it would believe how the Briar will root into this mixture. The result of this budding was that the next year I had remarkably fine plants of Tea Roses without any extra trouble—much better, in fact, than those about which I had taken such pains.

I should add that I always protect my Teas a little in the winter, even the dormant buds, by placing a little bracken or common fern round the head, and tying it with a bit of tarred string.

As to the best kinds, I suppose almost everybody will admit that nothing can on the whole touch Maréchal Niel; for size, colour, and free growth, it is certainly unapproached. It is, however, it must be admitted, rather tender, and the first buds are very apt to be spoilt by spring frosts. I had a magnificent display of this Rose in 1870 on a west wall, but this year the buds, from the continued rains and cold weather, for the most part decayed without opening. It is singular that M. E. Verdier who introduced this fine Rose should have done so in such an equivocal way; for it could well have afforded to have been brought forward on its own merits.

I think the next best Tea is Madame Falcot; it is hardy, a capital Rose to flower, a very good grower, and very beautiful in colour. I have lately had the most lovely blooms of it. I think, too, it will make a valuable seed parent, though I fear we shall not often ripen its seeds here. I last year got nearly a pint of heps, and had a corresponding number of good plants, and apparently ripe seeds, but, I am sorry to say, only three came up. The seedlings have all bloomed—one was single, another so double that I do not think it will open when it is propagated, and the third was about as full as the parent. If we could get this colour on Maréchal Niel, it would be a grand addition to the Teas; and why should we not?

I think Devoniensis should come next in the list, for it is good in every way—large, a good grower, constant, and exceedingly beautiful in its delicate shadings of yellow, white, and pinky white. Moreover (although the very "thickness of its petals," as a critic some time since said, forbids the idea of its being raised in England), it is, I believe, unquestionably an English Rose, and, like John Hopper among the Hybrid Perpetuals, can hold its own in any company.

Climbing Devoniensis I do not like. It grows well enough I admit, but I have always found it very tender; all my plants, notwithstanding protection, being invariably so crippled by the winter as to be useless for flowering the following year. This is the only Tea Rose that I grow which has been so much injured by cold and wet.

I hardly know which Tea Roses to name as the next best; possibly Souvenir d'Elise, Madame Margottin, Madame Willermoz, Rubens, Niphetos, Souvenir d'un Ami, and Céline Forestier, and in the order named. There are other good Tea Roses, such as Adam, Triomphe de Rennes, Adrienne Christophle, Jaune de Smith, L'Enfant Trouvé, Moiret, and President, but some of them are inconstant, some shy bloomers, and some difficult to grow.

Triomphe de Rennes, for instance, I never could grow at all until lately. I tried it in every way I could think of, but it invariably, as soon as the foliage had fully expanded, cast it, so that the branches were always bare, except the 5 or 6 inches at the upper end. I at last tried it in large pots (12 and 14-inch) on the Briar, and nothing can do better than these plants.

Adrienne Christophle is a great favourite of mine, it is so striking and novel in colour, but I must acknowledge that it is very uncertain.

Smith's Yellow is another capricious Rose. In situations which it likes nothing can do better, but like *the* yellow Rose, for one place in which it will do, there are a hundred where it will not open at all. The only plant that I know of upon which the flowers almost always open well, and usually do not show a green eye, is one I bought of Mr. Cant some twenty-five years ago, and planted on the north front of a house in Suffolk in a cold clay soil. There is a building running at right angles with the west end of this house which prevents this plant from ever getting a gleam of sunshine, and yet, singular to say, it annually produces and opens fairly the most beautiful blooms. This is one of those anomalies in Rose-growing which no one can understand.

L'Enfant Trouvé by some, I believe, thought to be identical with Madame William, is in the catalogues marked as dwarf, but that is because the proper stock is not used for it. The way to grow this fine Rose—for it is a most beautiful and distinct variety—is to bud it on the common Banksian. On this it grows very freely indeed, and flowers

profusely. I have had wood of one year's growth on this stock as thick as my little finger, and 3 feet long; and further, I have several plants on a west wall which, without any protection whatever, have for years gone through the winter perfectly unscathed!

As to the newer Teas I can say very little, not having grown them. I saw, however, in Mr. William Paul's ground this summer the following varieties, which I marked as very fine, and to be obtained by me this autumn—viz., Belle Lyonnaise, Madame Levet, Marie Sisley, and Victor Pulliat. I forgot, though, that I have flowered here Madame H. Jamain; it is a good new Rose.

I observe that Mr. Radclyffe speaks of Marie Baumann and Louis XIV. as bad growers. This is quite contrary to my experience. The latter I do not grow now because it was so very inconstant, not one bloom in fifty coming in good form, but it grew very strongly indeed with me on Mr. Radclyffe's favourite stock the Manetti. I had plants on this 6 feet high and 3 feet through. As to Marie Baumann, I will send Mr. Radclyffe two or three shoots of this year's growth from Briar plants; they will speak for themselves. By-the-by, Mademoiselle Bonnaire does very well on the Manetti.—P., *Essex*.

GREENHOUSE PLANTS.—No. 7.

BULBOUS AND TUBEROUS-ROOTED PLANTS.

These as a rule require light airy positions, and they should be kept near the glass not only when growing, but when growth is complete. The more nearly the foliage approaches to 16 inches from the glass the more stiff and developed will be the growth, the more complete its maturation, and the greater the prospect of a strong good bloom.

Vallota purpurea, or Scarborough Lily, is, without exception, the most useful of all greenhouse bulbous plants. It succeeds admirably as a window plant, and is not subject to injury when used for house decoration. It is too well known to require any description, but I may say that the foliage is bright deep green, and the flowers brilliant scarlet. It is very free-flowering, and increases readily by offsets.

Single bulbs of Vallota purpurea may be grown in pots 5, 6, or 7 inches in diameter, and such are, perhaps, the most suitable for window or house decoration; or they may be grown in large pots, presenting a mass of foliage and in September a magnificent display of flowers. The common practice is to remove the offsets; but I consider this a mistake, for they contribute to the display of foliage, and in no way interfere with the flowering bulb or bulbs. I invariably allow all the offsets to remain, and they attain a flowering state as soon as, or sooner than if they were taken off and placed separately in small pots. When increase is wanted divide the plant into two or more parts, each with a bulb large enough to flower, placing them in pots that will hold the roots without cramping.

Repotting may be done in March, but it is well not to let it be too frequent nor to give large shifts, for this and all bulbs do best with the roots always touching the sides of the pot, or when under rather than over potted. I have not had them repotted for three years, and they do even better in that way than when potted many times in a year. Bulbs do not like their roots interfered with, more especially this and all that are evergreen. Once a-year is quite often enough to repot, and as long as the drainage remains good they will not sustain any injury if not potted for two or three years. Of course there are exceptions, but the only one that I have found is in the case of plants in a bad state of health, and this is mostly a result of overpotting, when there is a mass of soil and few roots.

In repotting pick out all the soil that you can, remove the drainage carefully, and drain the pots efficiently. Let the pots be large enough to hold the roots and admit of soil being worked in amongst them and all round. This is quite sufficient for all plants, large or small. The bulbs should be potted so that they may be about half covered with soil. I have tried them covered up to the neck, entirely under the soil, and also nearly clear of the soil, and could not see any difference in the growth or flowering. About half an inch should be left below the rim of the pot for watering, and the compost should be moderately dry, so that the soil can be made firm. A compost of two parts good hazel or yellow turfy loam, one part sandy peat, and one part leaf soil or well-rotted manure will grow the Vallota well, adding sand if the soil be deficient of it.

Water moderately after potting, give plenty of water when the plants are growing freely, and continue this up to August; then give no more than enough to keep the foliage fresh until the flower-scapes appear, afterwards water copiously until the flowering is past, then reduce the amount and keep the plants dry over the winter, but do not permit the foliage to become shrivelled. The cause of an enfeebled growth is very often free and needless winter watering.

If large plants are wanted (and for conservatories and large houses they are more effective than smaller plants), all that is required is to give a moderate shift every spring, not removing any of the offsets, but letting all grow together, and in the course of a few years we have a pot full of flowering bulbs.

The plant is all but, if not quite, hardy, but it is one of those few late summer-flowering plants which must ever continue indispensable for greenhouse-furnishing. Those wishing to try it as a hardy plant may do so in a warm border, affording it a moderately rich loamy soil, with a little peat and leaf soil, and planting so that the bulb may be covered over about an inch deep, and in autumn it should have a top-dressing of partially-decayed leaves. It is essential that the border be well drained, and copious waterings given in dry weather, so as to secure a good growth. So much water does the plant require, that it may be set in the basin of a fountain, where it luxuriates in a hot summer. I know of nothing that would give so gorgeous a mass as a bed of this in full flower out of doors in September.

Imantophyllum miniatum.—This yields to no greenhouse plant for effect and beauty early in winter and in spring. The leaves are long, more erect than those of Vallota, and about 2 inches broad. The flower-stem rises from a foot to 15 inches high, supporting an umbel of twelve flowers or more, the blossom having a footstalk about 3 inches long; a separate blossom when fully expanded is from 3 to 4 inches across. The flowers are deep salmon-coloured, with the lower portion of the petals of a yellow tinge.

Imantophyllum cyrthanthiflorum is very similar to the preceding in its general habit and style of growth, the flowers being rather paler in colour, but instead of being erect they are pendulous. It is a hybrid.

The Imantophyllums are closely allied to Clivia, and require nearly the same treatment; I shall, therefore, take them together.

Clivia nobilis has long bright deep leaves, and flowers borne on an erect flower-stem. They are long, tubular, red, with a considerable amount of yellow, and are numerously produced.

Imantophyllums and Clivia nobilis cannot be grown well in a cool greenhouse; they require, in fact, a warm greenhouse, or a winter temperature of 45° from fire heat, and in summer 65° to 80°. They should have the compost named for Vallota, and should not be overpotted, the main points being to secure a pot full of roots, along with good growth, encouraged by preserving a moist atmosphere, and giving an abundant supply of moisture when growing. When growth is complete keep the plants dry, exposing them fully to air and light. The plants will then live and flower in a temperature considerably lower than if the growth were imperfectly ripened. When growing they can hardly have too much water if the drainage is good, and the soil and roots are in a healthy state. Syringings overhead are also beneficial, but when the growth is complete diminish the supply of water, and place the plants where they can have unobstructed light. Throughout the winter they should not have more water than is sufficient to keep the foliage plump. When the flower-scapes appear the supply of water should be more liberal, and continued until the flowering is over, when, if the season be early in winter, the watering may be again diminished, for with so low a temperature as 45° any growth made is poor, and it is well to reserve all the energies of the plant for a vigorous growth with the return of genial weather, or to secure as much as possible a season of uninterrupted growth, and another of rest.

I have seen the Imantophyllum in beautiful flower in an orchard house in April, the plant having been placed in a warm pit in summer to make growth, and I have no doubt that it could be made to flower late in autumn by keeping it dry for a few weeks prior to placing it in a temperature of from 45° to 50°. The Clivia flowers with me sometimes in December, and at other times in April or May. The reason of this difference in time I do not know.

Sprekelia formosissima, or Jacobæa Lily.—This has narrow Amaryllis-like leaves; flowers rich crimson, on stems about a foot high. It is an old favourite, and without forcing, or in the greenhouse, it flowers about June, earlier or later according to temperature. With forcing it may be had in flower from February. It has one great defect—namely, that of flowering

either before the leaves are produced or when there are but few of these. Like many others, the beauty of the specimen is greater when there is a mass of bulbs in a pot, half a dozen or more not being too many for a 6-inch pot. They succeed admirably in a compost of fibrous loam two parts and one part of leaf soil, and should be covered to the neck. Drain the pots well, and place them near the glass. From the end of September to April keep the plants dry on a shelf, in April gradually moisten the soil, having previously examined the drainage and put it in order, also removing the surface soil and giving a top-dressing of fresh. When the flower-scapes appear water copiously, and after fresh foliage is made give very liberal supplies up to September; then place the plants on a shelf near the glass, and lessen the supply of water, but not so as to cause the foliage to become limp, and after September keep them dry.

If the plants are required to flower, say, in April or earlier, they may have the drainage put in order, removing any old soil that comes away freely, and be top-dressed, placed in a bottom heat of from 70° to 75°, and a top heat of from 55° to 60°, and they will start into flower. Just before the blooms expand the pots should be gradually withdrawn from the hotbed before removal to the greenhouse or sitting-room.

Avoid too large pots and potting over-frequently. After the removal of the old soil the pot should just hold the roots without cramping, while allowing of a little soil all round. No harm will result from the bulbs being left in the pots until the latter split; on the contrary, the plants are never so healthy nor so free-flowering as when they are in this state. If they should be enfeebled in growth repot them in a smaller-sized pot.—G. Abbey.

OLLA PODRIDA.

The Spanish dish of this name contains many ingredients, and so this short paper of mine must be a veritable hodge-podge. Into it first we will throw what is a very good thing in itself, but I should say a very bad thing when we get too much of it, and that is the Potato. Might not one write a pretty smart article on the Potato humbug? I am far from disparaging any attempt to give us new and good varieties; but when one enthusiast vows he has grafted the Jerusalem Artichoke on the Potato, or *vice versâ*, and obtained hybrids, and others tell me that the American varieties are beauties, why, then I do say, "Hold, avast!" By-the-by, I see one correspondent doubts whether Mr. Rivers and I had the true Early Rose. I *know* I had, for it came to me from Messrs. Carter and Co., and was sent to me on purpose to try as seed imported direct from the raiser. The first season I thought it tolerable, last season worthless, and this season worse even than that. I have seen, grown, and tasted all these Yankee gentlemen, and there is not one of them fit for any human being; they are good croppers, capital for pigs, but not for me. Here let me say that I received last autumn, from a correspondent in the north of Scotland, half a dozen round Potatoes for trial. I planted them, and they are the very best round Potato I know, evidently a Regent, but an uncommonly good one. If this meet his eye perhaps he will kindly renew the correspondence. I received also the other day from Mr. Whitbourne, of Loxford Hall, some magnificent tubers of Dalmahoy. He questions if the Lapstone is as good. I think it is better; but they were certainly splendid tubers, of fine flavour and mealy.

And now we come to Onions, dear to the Spaniard, dear to the English workmen, and without which even a Soyer or a Francatelli would find himself nonplussed. There were some very fine ones shown the other day at Kensington, notably the Intermediate and Nuneham Park exhibited by Messrs. Carter & Co. I confess these have more interest to me than the Tripoli varieties. Few will care for these large summer Onions. What we want are good keeping varieties; and as I do not much believe in seedling varieties of Onions, the object is to get good selected strains and improve them, and whatever does this is adding to our vegetable wealth.

Rendle's Plant-protectors seem to be very indigestible to some people, and to "Au revoir" especially. May I say to him that indigestion often proceeds from bad cooking? and so, perhaps, they have not agreed with him because he has not used them aright. All I can say is, I have used them this summer for various things, and have found them most useful. I had Strawberries under them a full fortnight before those in the open ground were ripe. I used them for ridge Cucumbers, and am now again using them for winter salading. That there will be breakages sometimes I know, but the idea of having wooden frames to support them is rather too absurd.

I have received several communications on the subject of new Gladiolus, and hope in a week or two to send forward a paper that shall be an answer to these questions, and which will be quite in time for orders. I am glad to see that this beautiful but most disappointing autumn flower is coming more and more into favour. The disease has again bothered me this year, and yet, like the Potato disease, I see no remedy for it.

We must have a perfume for our olla podrida, and what better than the Rose? I am surprised that "P., *Essex*," should have so misunderstood me about recommending Prince Léon. I know it to be a bad grower, and think I said so, but I said it was a Rose one ought not to discard; it was not, certainly, a Rose I would recommend in a select collection. I think it both pretty in colour and nice in shape when "well done." Let me say I dissent from his list. Marie Baumann I certainly never have seen as a good grower; if so with "P." he is fortunate. Then I should be loth to put Countess of Oxford in the best twelve before better known. Edward Morren is fine when good, but it is very apt to come with a bad centre. And what about John Hopper? Louis Van Houtte, too, requires proving as to its growing powers; and Madame Vidot is also a shy grower with me. In fact I should give a different list. Might it not be advantageous if a dozen of the best Rose-growers—I do not mean prizetakers, but well-known growers—were to give us a list in your pages of the best twelve, and then we might see which really the choicest were? Will Messrs. Radclyffe, Peach, Hole, Paul, Turner, &c., kindly do this? I think the result would be interesting and valuable.

And so my hodge-podge is finished. I have given it flavour, colour, and perfume, and hope it may nourish in some little way my gardening brethren.—D., *Deal*.

ONION CROP DESTROYED.

I have lost the whole of two large beds of spring-sown Onions by what I believe to be the Onion grub, and, as I have suffered similarly in both wet and dry seasons for the past five years, I should be extremely obliged for any information that would be likely to enable me to avoid this in future. I notice in last week's Journal a letter on this subject; but as I tried the same plan, or nearly so, this season as there particularised, I really have no confidence in it in my case, even if carried out to the very letter. I have also tried dressings at intervals of lime, soot, wood ashes, guano dry and liquid, sewage water, and soap-suds without the slightest good effect. I have also carted soil from a distance, and tried the plan of sowing one bed with manure on the surface, another having manure dug in, and a third without any manure; but the results have been nearly equal as far as avoiding the grub is concerned.

Can you give me any information respecting this grub, its appearance, &c., as in my case it is more like a maggot, and is generally to be found in the very centre of the decayed Onion?—H. Howard.

[We insert this letter without any reply, because we wish some of our correspondents who either are successful Onion growers, or who have suffered from the grub and found a remedy, to send to us the results of their experience. The following description of the grub and fly is given in the "Cottage Gardeners' Dictionary." "In light soils, especially, the Onion is liable to suffer from the grub or larva of Anthomyia ceparum (Scatophaga ceparum of some writers). The gardener who sees his young Onions, when about the thickness of a straw, turning yellow, and the leaves sunk down upon the ground, may at once know that they are the victims of this insect. Even when of larger growth the Onion is still liable to suffer from its attacks, and even up to the time of the bulb's full growth. If the outer coats of a young Onion thus destroyed are stripped off, the grub is at once detected; but if the Onion is older the grubs are often numerous. In both cases they will be found feeding on the very heart of the Onion. The grub varies from about a quarter to half an inch long, is fleshy, shining, whitish, cylindrical, tapering from the head to the tail, and divided into twelve segments. The pores through which it breathes are yellow, and in the first segment. In about three weeks from the time of being hatched it changes into a chestnut-coloured oval puparium, or case, within which is the real pupa. From this, in about a fortnight, the perfect fly comes forth. The female is entirely of a pale ashy colour, covered with black bristles. The male has a black line down the middle of the abdomen. The antennæ and legs are black; the wings are transparent, almost colourless, but iridescent pink and green. The female inserts her eggs within the leaf-sheaths of the

Onion, close to the ground. She continues to lay her eggs from May to September, producing several broods during that period. The latest brood remains in the pupa state through the winter, so that all old-decaying store Onions should be burnt up as spring advances."]

EARLY ROSE POTATO.

I am surprised that "K." (page 235), intends to discard all the varieties named in his list except Early Rose and Harrison's. Of the latter I know nothing, as I have never seen it. As to the Early Rose I am of the same opinion as Mr. Rivers—that it is worthless. Besides being watery when cooked, it has a dirty pink colour half way through, which in my opinion is a very great objection. I must allow that soil, climate, &c., make a great difference in the same variety of Potato. As "K." says, there may be more than one Potato under the name of the Early Rose; the variety which we have is very prolific, and has roundish medium-sized tubers, and rather short haulm. It is very liable to disease, as this season we had about 30 per cent. bad. I think "K." cannot have the same variety as we have, or he would soon discard it and retain some of the others named in list.

I cannot think how "K." can discard Royal Ashleaf, as I think it one of the best second early Kidney Potatoes grown. We here plant the Early May for the first crop out of doors and for forcing. It was quite as early, both in pits and on the border, as the Early Rose, and far before it in point of flavour, &c.—J. W. Sedgley.

ROSES AND IVY ON TRELLIS.

I have a wire trellis 5 feet high facing north-west and south-east. On the north-west side I purpose planting Irish Ivy, and on the south-west Roses. The soil is sandy. Can you tell me what Roses (Perpetuals) would be best in this situation, at what distance from the trellis and from each other they should be planted, and whether they would require any special treatment? The Roses I am thinking of are Baronne Prevost, Général Jacqueminot, Gloire de Dijon, Jules Margottin, Lord Raglan, Paul Verdier, Sir Joseph Paxton, and Solfaterre.—Y. L.

[We should advise planting the Roses at least 2 feet 6 inches from the wire trellis, as in light soil the roots of the Irish Ivy you propose to plant on the north-west side of the trellis will soon spread to the opposite side and injure the Roses. Irish Ivy forms very dense surface roots and is a gross feeder; and we should advise you every year to cut the roots on the south-west side about a foot from the trellis, and encourage the growth of the roots to the north. Have the Roses on the Manetti stock, and choose Général Jacqueminot, Gloire de Dijon, John Hopper, Charles Lefebvre, Madame Clémence Joigneaux, Boule de Neige, Climbing Devoniensis, and Céline Forestier. You do not say the length of the trellis; plant 3 feet apart, and if you want more than those named choose any others from the list you sent except Solfaterre, which is too tender.]

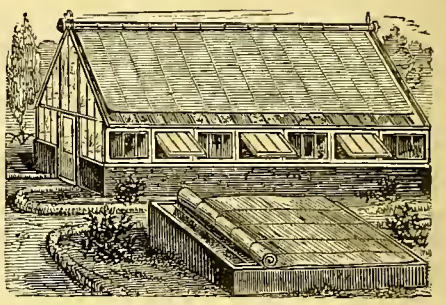
DAHLIA GLABRATA.

There is a small unpretending flower to which I would draw the attention of your readers. I call it "the lady's flower," as I have never known a lady who seeing it did not admire it. It is a small single Dahlia called Dahlia glabrata; a florist proper would, doubtless, despise it, but few, I think, who could see it, as I now see it before me in a vase with Roses, Mignonette, &c., as companions, but would be charmed with its elegant simplicity. In size it varies from that of a florin to a five-shilling piece, according to the vigour of the plant. Its colour usually varies from shades of light purple to violet, sometimes almost white. It is easily raised from seed sown in spring, and will flower the same autumn. I have never noticed the seed in any other catalogue than that of Mr. W. Thompson, of Ipswich. Like its more pretentious kindred, the double Dahlia, it requires protection in winter. I am sure your feminine readers will thank me for drawing attention to it, when they have once seen it in bloom.—Hortator.

The Horse Chestnuts in the Champs Elysées, Paris, are many of them (about one in ten I should imagine), in full bloom, with young leaves, several having on their branches at one time the old withered leaves, fruit, young leaves, and flowers. I noticed two pink-flowered trees among them (Pavia). The leaves are not so large now as they are when the spring flowers come, and the flower spikes are as a rule shorter and more compact than the spring ones, and the flowers themselves smaller. I conclude that this is what should have been next year's crop forced out before its time.—E. L. J.

SHADING AND PROTECTING.

We have received from Messrs. Dick Radclyffe & Co., of Holborn, samples of bags to protect bunches of Grapes and other fruits from the attacks of insects. They are made of a coarse gauze material dipped in boiled linseed oil, or some such substance, to render them durable, and from which circumstance they are called "medicated." Also samples of



greenhouse shading, such as is generally seen on the Continent, and especially in Germany, for shading windows of dwelling-houses in summer. We shall be glad to see this elegant material introduced to this country, if it can be supplied at such a price as to induce gardeners to cover a large extent of glass with it. No better summer shading can be found.

PLANT PROTECTORS.

I did not mean to enter upon the Rendle brick-protector controversy again, but I may be able to elucidate the difficulty which "An Old Lover of Protectors" says he is under when "Au revoir" alludes to the maker of wooden frames. I may be mistaken, but I think "Au revoir" refers to some wooden frames with moveable glass, which I described in the pages of the Journal nearly two years ago, and which awoke the vials of Mr. Rendle's wrath against me, as he thought I was a rival maker going to undersell him, or to infringe his patent, and he threatened me with proceedings in Chancery, &c., though how common deal frames with grooves for the glass had anything to do with loose brick protectors I could not well see. But on referring to Mr. Rendle's specifications on applying for a patent, I found he had tried to make it embrace as wide a scope as possible.

I do not remember to have seen Mr. Rendle's plant protectors anywhere in the Horticultural Gardens except in one of the corridors, where they are put up on a level floor under cover. I do not see that Mr. Rendle need take much credit for the glass not being displaced or broken there, as they cannot be injured by wind, and unless persons wilfully kicked against them they could not easily be knocked over. Mr. Rendle politely calls "Au revoir" clumsy and incompetent because he cannot see the merit of them; many other very practical gardeners have tried them, and have endorsed my opinion concerning them, and I have never seen any reason to alter it, that they are not so efficacious or so convenient as wood, nor are they, taking the area covered, any cheaper than old Cucumber frames. Mr. Rendle seems to have also come to the conclusion that wood is superior, as from the drawings I presume Mr. Bréhaut's lawn conservatory is of wood. What there is in it sufficiently novel or meritorious to deserve a patent I cannot myself see; perhaps the patent is a *nom de guerre*, intended to frighten away imitators, as the patent laws want great revision if any mere modification of wood and glass for horticultural purposes can be patented. I agree with "An Old Lover of Protectors," there is nothing like hinged lights for ground vineries or anything of a permanent character; and at Nottingham, Mr. Foster's (of Beeston) moveable frames—like those he has put up for Mr. Pearson at Chilwell—were an agreeable contrast to the loose bricks over the way. The first lot of brick protectors put up at Chiswick by Mr. Rendle's own man were nearly all blown down and the glass broken within two days,

and when I saw them two months afterwards were in a dilapidated condition. It may be a satisfaction to "Au revoir" to find others agree with him.—C. P. Peach.

HORTICULTURAL PARIS IN 1871.—No. 3.

BOURG-LA-REINE.

I have ever made it a point in visiting Paris to pay a visit to this little suburb. I do not know anyone that I enjoy a Rose chat more with than my good old friend Margottin. Rough diamond though he be, he knows, I fancy, as much (or more) of the Rose as anyone of my acquaintance; and although I would not take him exactly as a judge, yet he has such an amount of Rose lore that he can always bring together information such as a lover of the flower desires. But my visit this year was not for this purpose. I knew Bourg-la-Reine had suffered much from the war, Sceaux and Vitry more so; and although I was prevented from visiting the latter places, I was up with the lark to get to the former, and reached my old friend's quarters at a little after seven in the morning.

Since my last visit great changes had taken place. He had intended to have retired and to have put his amiable son Jules into his place, had built in his garden a neat house whence he could issue forth to superintend and advise; but the war came, that hateful, horrid war, which has brought such misery on many a French home, and many a German one too, and I had to hear a mournful tale of suffering.

Bourg-la-Reine was occupied by the Prussians early in the siege, and many of the inhabitants left, amongst them the Margottins, and their home was taken possession of by the Bavarians, and a mournful tale he had to tell of their doings. They had battered down his walls, had made a place for the passage of artillery and cavalry through his Rose quarters; and where one was in the habit formerly of seeing quantities of lovely Roses or beds of seedlings, there were now only Cabbages and Kidney Beans. These things were, perhaps, matters of military necessity, but their conduct in the house was unpardonable. Every piece of woodwork was torn to pieces and burnt; wooden chimney-pieces, frames of looking-glasses, chairs, even staircases were torn up and destroyed; filth of all kinds was allowed to accumulate, and this although there were heaps of faggots in the garden. It is such things as these that have exasperated the French; that have made such men as Margottin declare that they must dream of nothing but vengeance; that if it were needful he would be quite ready to shoulder his musket and march against the Germans. While talking over these things they said "That, bad as our treatment was, it was nothing to that which Jamain has experienced." Jamain is as well known to all fruit-lovers as Margottin is to Rose-growers, and I know few men in his line of life for whom I have a more thorough respect; and much as I thought of him before, the quiet and dignified way in which he spoke of his terrible losses, and the firm resolve which he evinced to make the best of things, greatly advanced him in my estimation. It was only last year that he took me all over his model garden, showed me his beautifully trained Pear trees, pointed out with pride the success of his treatment, and expatiated on the comfort he hoped to have in his new house. And now Marius sitting in the ruins of Carthage formed no inapt idea of our poor friend sitting in his desolate and half-destroyed house. The Prussians had occupied his place too, had destroyed all his beautiful Pear trees, had used the iron trellises on which they were trained for gabions, had cut up the trees for the same purpose, run trenches through his fruit quarters, made embrasures in his walls, and hacked his standard trees to pieces. But this did not fill up the measure of his sufferings. When the Commune took possession of Paris the Government troops occupied the Prussian positions at Bourg-la-Reine, and poor Jamain's house stood directly in front of the insurgent position of La Haute Bruyère, the shells from which pounded his house, and had it not been that a good portion of it was made of iron it would have been completely destroyed.

The men of whom I have thus written are men of somewhat extensive commerce and considerable means; they have not probably felt the pressure of their untoward circumstances as some might have done, but the small growers of Villejuif, Vitry, and other places have been utterly ruined, unless they can obtain some compensation from the Government, which seems more and more unlikely. The French themselves have done much to destroy the sympathy that was being excited for them, and the immense subscriptions to the new loans have made it questionable whether a great deal of our charity was not misapplied; but it is a good side on which to err, and I am sure it has excited in the minds of French horticulturists a deep feeling of gratitude towards their brethren in this country, who were so ready to help them in the hour of need.—D., *Deal*.

WELLINGTONIA GIGANTEA.

The account of the big tree, which we copy from J. Otis Williams's compilation of "Mammoth trees," first made its appearance in the *Sonora Herald*, and thence spread with wondrous rapidity, like our snow storms, from south-west to north-east, till it flooded the Atlantic seaboard. Crossing thence to England, in July, 1853, it appeared in the London *Athenæum* and the *Gardeners' Chronicle*; and in December of that year Dr. Lindley contributed to the last-named paper a scientific description of what he assumed to be a new genus, and proceeded to christen it the Wellingtonia, with the specific name of gigantea. The California Academy had already noticed it in their proceedings, and in America it had already been called the Washingtonia gigantea. Thus there was every prospect of a free fight between England and America in behalf of their respective heroes. At any rate, it was a very pretty quarrel as it stood. A compromise was effected through French mediation.

Endlicher had, in 1847, described the enormous Redwood, and had given it the name of Sequoia sempervirens, in honour of the distinguished Cherokee Sequoyah (better known as George Guess), the inventor of an alphabet of his native tongue, consisting of eighty-six characters, each representing a syllable, which still exists, not only as a curiosity of literature, but as a text-book for those who wish to make use of the Cherokee as a written language.

At a meeting of the Société Botanique de France held on June 28th, 1854, M. Decaisne demonstrated that the big tree of California and the Redwood belonged to the same genus, and proceeded to christen the former Sequoia gigantea, with the approbation of the Society; and the same year Dr. Torrey, of New York, and Professor Gray, of Cambridge, endorsed this nomenclature. Thus this aboriginal tree will be handed down to posterity with a purely American cognomen, and science exhibits herself as overriding all national pride and personal jealousy, as the tree in question overtops the Oaks and Sugar Pines that dwindle around its base. The interest excited by this discovery elicited scores of scientific notices in different languages. Seeds were sent to the Atlantic States and Europe, and found to germinate readily, and there are probably hundreds of thousands of these seedlings now in existence. Some are in the market, entitled "gardeners' varieties." They flourish with peculiar luxuriance in Great Britain, and grow with extraordinary rapidity. Numerous examples are cited where they have grown over 2 feet per year, and have produced cones when four or five years old.

But while the Sequoia gigantea has obtained a world-wide reputation, its near relative, the Redwood (Sequoia sempervirens) appears to Professor J. D. Whitney, the learned and indefatigable State geologist of California, to be even more attractive; and his description of it in his delightful "Guide-Book to the Yo-Semite Valley," is so charming that I cannot resist the temptation of making a pretty liberal quotation from it. After speaking of the Sequoia gigantea, and mentioning that its range is limited to the sierras, he proceeds:—

"Closely allied to it is the Sequoia sempervirens, or Redwood, which seems to be strictly a coast-range or seaboard tree, something resembling one class of our northern Cedars. Some of them are enormous, 50 feet in circumference, and 275 feet high. Mr. Asburner heard of a Redwood stump, seven miles from Eureka, 38 feet in diameter, in which thirty-three pack mules were corralled at one time; and various others are mentioned equally miraculous in their proportions." During the stormy winter of 1861-2, immense numbers of Redwood logs were carried out to sea along the northern coast of California. They were so abundant as to be dangerous to ships 150 miles from the coast. Numbers of them were piled up near Crescent City. Professor Brewer measured ten varying from 120 to 210 feet long. One of 200 feet was 10 feet in diameter at the base, and one of 210 feet was 3 feet in diameter at its little end. Accurate measurements are wanting, but there are many from 250 to 300 feet high.

"Thus we see," continues Professor Whitney, "that the Redwood falls in size but very little below the big tree, and it is not impossible that some of the former may yet be found as large as any of the latter. In general effect, the forests of

Redwood surpass even the groves of big trees. The Redwood forms frequently almost the entire forest, while the big tree nowhere occurs except when scattered among the other trees, and never in clusters or groups isolated from other species. Let one imagine an entire forest, extending as far as the eye can reach, of trees from 8 to 12 feet in diameter, and from 200 to 300 feet high, thickly grouped, their trunks marvellously straight, not branching till they reach 100 to 150 feet from the ground, and then forming a dense canopy which shuts out the view of the sky; the contrast of the bright cinnamon-coloured trunk with the sombre, deep, but yet brilliant green of the foliage; the utter silence of the forest, where often no sound can be heard except the low thunder of the breaking surf of the distant ocean—let one picture to himself a scene like this, and he may perhaps receive a faint impression of the majestic splendour of the Redwood forests of California."

Since the discovery of the Calaveras grove of big trees by Mr. Dowd, eight or nine more distinct groves have been found, all in California, and between 36° and 38½° of north latitude. They are all also between 5000 and 7000 feet above the level of the sea. But although some of the others are perhaps quite as remarkable, that of the Calaveras is the most celebrated. It was the first discovered, and has the advantage of being accessible on wheels, and possessing a good hotel. This grove is 3200 feet long and 700 feet wide, lying between two slopes, intersected by a brook running north-east and south-west. It contains about one hundred trees of large size, and a considerable number of smaller ones. Some have fallen since the discovery; one has been felled, and one has been killed by having the bark stripped to the height of 150 feet for exhibition in the Crystal Palace at Sydenham. These last two mentioned were perhaps the finest in the grove. Of thirty-one trees, measured by the party under Professor Whitney, the tallest measured 325 feet, and the shortest 231 feet. The greatest circumference at 6 feet from the ground was 61 feet, the least 27 feet. Hutchings, from actual measurement, states that there are ten trees of 30 feet and upwards in diameter, and more than seventy ranging from 15 to 30 feet. Sperry and Perry speak of several trees in the Calaveras grove nearly 100 feet in circumference.

At the Mariposa grove (which contains 365 trees) of forty-six living trees measured, the tallest was 272 feet in height, and the shortest 186, while the greatest circumference at the ground was 92 feet 7 inches, and the least was 27 feet, while the Grizzled Giant has a circumference at the ground of 93 feet 7 inches.

One of the most remarkable trees in the Calaveras grove lies prostrate and half buried in the soil, fitly named the "Father of the Forest," for the description of which I am mainly indebted to the very clever and interesting work of Mr. J. M. Hutchings, of Yo-Semite, called "Scenes of Wonder and Curiosity in California," which, in a very chatty and interesting way, takes the traveller without fatigue through the land of marvels. This tree measures in circumference, at the roots, 112 feet, and 200 feet to the first branch. Entering by an aperture on one side, and turning at a right angle, a horseman can ride a distance of 80 feet and emerge from a similar opening on the opposite side; 300 feet from its base, where it was broken off in its fall, it is 18 feet in diameter; and, judging from the trees shattered where it fell, it must have measured, at least, 435 feet in height. How many centuries it lived and flourished in its grandeur, the children of what now extinct races played beneath its shade, how many centuries it has lain there in its last sleep, amid the undisturbed solitude of the wilderness, are questions almost too vast for even imagination to attempt to answer.

A few weeks since, says the *Mariposa Gazette*, there was a crash in the Mariposa Big Tree grove, which was plainly heard at Clark & Moore's, five miles distant. On visiting the grove it was found that another big tree named "Andy Johnson" had fallen. It had been noticed for two years to be leaning more and more to the south, or south-east, but it had preserved a certain show of stability, and its present humiliating condition of prostration and ruin was not anticipated. It fell in the direction it had been leaning, and the whole upper portion of the trunk from a diameter of 8 feet to the top is broken and tossed about like the wreck of a mighty ship broken upon a surf. The wood, at the fractures, does not appear to be actually decayed, but very brittle in appearance.

Still more wonderful is the South grove, eight miles from Calaveras, by far the largest and finest grove of Sequoias yet discovered in California. In the scenes of "Wonder and Curiosity in California," already referred to, it is stated that "it contains 1380 trees, many of them of magnificent proportions. I have measured ten trees that were 21 feet larger in circumference than any others in either of the groves. Through the prostrate trunk of one tree, resembling an immense tube, we could have driven one of the heaviest Concord stages, crowded with passengers, a distance of 200 feet. In this grove is another tree, still standing but burnt out, in which twenty horses have been coralled at a time."

Professor Whitney concludes his report by saying:—"From what has been stated, the reader will readily gather that the 'big tree' is not that wonderfully exceptional thing which popular writers have almost always described it as being. It is not so restricted in its range as some other Coniferæ of California; it occurs in great abundance, of all ages and sizes, and there is no reason to suppose that it is now dying out any more than the Redwood.

"The age of the big tree is not so great as that assigned by the highest authorities to some of the English Yews, neither is its height as great by far as that of the Australian species, the Eucalyptus amygdalina, many of which, on the authority of Dr. Müller, the eminent government botanist, have been found to measure over 400 feet." "On the whole, it may be stated that there is no known tree which approaches the Sequoia in grandeur, thickness and height being both taken into consideration, unless it be the Eucalyptus. The largest Australian tree yet reported is said to be 81 feet in circumference at 4 feet from the ground; this is nearly, but not quite, as large as some of the largest big trees of California."—(*Boston Cultivator.*)

MR. ROBERT T. PINCE.

Mr. Robert Taylor Pince, the well-known and highly esteemed proprietor of the Exeter Nurseries, died at an early hour on the morning of the 9th inst., aged 67. The deceased gentleman had been an invalid for more than two years, and succumbed at last to an attack of hereditary gout. He was the son of Captain Pince, R.N., a gallant officer, who distinguished himself greatly by his indomitable pluck and bravery in the French War. Mr. Pince was originally intended for the law, and was articled to an attorney at Liverpool. But in his case love, which "rules the camp," ruled, or rather overruled the law. During a visit to Devonshire he met the fair niece of the late Mr. Lucombe, the proprietor of the Exeter Nursery, and in due time married her. The young lady is said to have had an invincible dislike to the legal profession, and Mr. Pince in consequence resigned his prospects of distinction in that quarter, and joined his uncle in the pursuit of horticulture and floriculture. He followed his new vocation with all the energy and enthusiasm peculiar to his nature, and soon became an accomplished botanist. He positively loved his flowers and plants, and nothing gave him greater pleasure than to accompany an appreciative visitor in a tour of his gardens, and greenhouses, and hothouses, and expatiate to him upon the beauties and characteristics of his choice collections. He imported fine exotics from South America, and added materially to the variety of the Exeter Nursery's collections by judiciously hybridising well-known species.

When in the prime of life he took pride and pleasure in competing with provincial and metropolitan nurserymen for horticultural and floricultural prizes, and was remarkably successful. The Camellias, Rhododendrons, and Orchids of his firm obtained celebrity under his supervision. The Camellia house in his grounds at Alphington is, perhaps, unrivalled in the kingdom. It is 200 feet long, and the plants in it have been cultivated to the dimensions of trees, producing myriads of blooms, thousands of which find their way annually into London drawing-rooms.

During the latter half of his career Mr. Pince devoted his attention to landscape gardening, and in this branch of his pursuit attained high excellence, and was also eminently successful. He has left the mark of his superior taste and skill upon many a park and garden in fair Devon. His last work, we believe, of this description was the laying-out of the grounds at Marley. His labours were not confined to his own special pursuits. In the course of his life he endeavoured to do all the good he could for the community. He was for many years chairman of the St. Thomas Local Board, and to the energy which he brought to bear upon the management of the sanitary affairs of that district may be attributed much of the success that has attended the Board's operations. Difficulties were to him only objects to be surmounted; and his perseverance and resolution were but intensified by obstacles and resistance.

He originated the system for St. Thomas by which the sewage of the district is deodorised and converted into a profitable manure, thus avoiding the cost of a law-suit threatened by the Railway Company, and the construction of a sewer to Starcross. His plan of deodorisation by means of carbolic acid, adopted at St. Thomas, was also adopted by his advice at Bombay, and from the authorities there he received a cordial vote of thanks for his council and guidance. It is principally due to his exertions that St. Thomas now enjoys the advantage of an independent and continuous water supply. When he retired from the St. Thomas Local Board, a year or two ago, he retired with the regret of all the members, and of the parish generally, but also with their hearty thanks for his valuable services. Hundreds can bear testimony to his generosity of disposition, and his numerous acts of kindness. It will be long indeed before his name is forgotten in St. Thomas, and it will never be mentioned without the respect due to a man who did his duty in his day and generation. The deceased gentleman's wife died about ten years ago, and he never fairly recovered from the shock and sorrow occasioned by her death. During his long illness his nephew and heir, Dr. William Robert Woodman, has been in constant attendance upon him, and has endeavoured to relieve him as much as possible from the cares necessarily incidental to the management of such a large business as that of the Exeter Nurseries.—(*Exeter and Plymouth Gazette.*)

POTATOES.

We have but very few really good Potatoes from forty varieties grown here on a good Potato soil.

I purpose to plant next season about 25 acres of Dalmahoys and Paterson's Victoria, two of the best round sorts for market on any soil.

In the forty varieties I had three American sorts, great croppers, but worthless except for pigs, and Bovinia is the same.

Of kidneys, all the Ashleafs are fine in flavour, including the Lapstone and Webb's Seedling; but they do not crop like the two round Potatoes above named.

Of earthing-up Potatoes, if all your gardener readers had time and inclination to give their experience, ninety out of every hundred would say, "By all means earth-up your Potatoes, both for produce and for earliness."

The Potato disease here is about equal in all the varieties, except the Dalmahoys. They are the most free from the plague. All others are about one-third diseased. The crop is large. Discard all recommendations of a large number of sorts for cultivation. Let those who really wish to benefit their neighbours name a few of their best; only a few sorts are wanted—not a host.—F. L., *Bailiff, Knowsley Cottage Farm, Prescot.*

HATFIELD HOUSE,

THE SEAT OF THE MARQUIS OF SALISBURY.

If it be a rule of nomenclature, "Once a palace always a palace," then this mansion should retain that title. From being desmesne of the Saxon Kings, Heathfield, for that is the true name of the place, passed by grant to the Abbey of Ely, and then to the bishopric of that name. Some bishop, now unknown, built there his palace, which was rebuilt on a larger and better style by Bishop Morton, in 1478. When it reverted to the crown we know not, but it was the residence of Prince Edward in the lifetime of his father, Henry VIII., and when he succeeded to the throne he conveyed it to his sister, Princess, eventually Queen, Elizabeth. During her sister Mary's reign she was resident here, under the kindly custodianship of Sir Thomas Pope. In 1607 James I. exchanged it for Theobalds with Sir Robert Cecil, created Earl of Salisbury, who laid the foundation in 1608, and in 1611 completed Hatfield House as it now remains.

James I. coveted Theobalds because it was more convenient for indulgence in "kingly sports," but Sir Robert Cecil evidently parted with it reluctantly, and writing in 1607 to Sir Thomas Lake, he tells that he had been to take a last look at Theobalds before it passed into the King's possession. He also tells that he purposed to enlarge Hatfield Park, and several noblemen had been there with him to decide where the future mansion should be placed. A silver thread of ability and aptness for business has ever characterised the Cecils, and in Sir Robert that thread was a stout one. It is very apparent in the details he required to be furnished from time to time of expenses to be incurred and of the progress of the work done. With judicious forecast he began early to arrange and plant the gardens, and we will just touch upon a few relative letters yet preserved. In October, 1609, Lady Tresham wrote to Sir Robert, then Earl of Salisbury, thanking him for his aid against her "vehement adversary John Lambe," and begging him to accept "half a hundred of fruit trees to plant at Hatfield."

Another letter in 1610 asks for instructions relative to the gardener's work to be done there. A third letter in 1611 contains estimates for bringing water in earthen pipes "from the springs to the dell;" and in November of that year fruit trees were sent to the Earl by the French Queen, but he observes "the Apples and Pears are inferior to the English, the Poire Chretienne excepted."

Hatfield House is at an easy distance from London—easy even in the old coaching times, and still more so now when one of the principal railways of the kingdom passes close to it, and has its first important station at the neighbouring picturesque village of Hatfield, nestling as it were in a valley under the shadow of the noble residence of the Cecils.

As we pass through this village we cannot but compare it with the more recent villas and other dwellings which we have passed on our journey from the great metropolis, for while in these red bricks and blue slates are the prominent features, both these have been held in supreme contempt by the architects of such villages as Hatfield—there most, if not all, of the buildings are square or oblong, and their relation one to another is totally disregarded. The lath and plaster gable end of one dwelling advances some distance more to the front than the broad side of another, which is, perhaps, weatherboarded, while another is a mixture of brickwork and flints, the latter concealed in some cases behind a thick coating of colouring matter. Plain flat tiles form the principal roofing of the whole. But what constitute the principal distinction between old country villages like Hatfield and the modern suburbs of a large city like London are the shade-giving trees, which in so many cases throw a shield over the whole, as well as adorn by their verdure.

Another feature usually met with in such villages is the venerable church and its surroundings. Some of these are worshipped by antiquarians, while over others they lament the changes undergone. In the church important alterations and restorations are being made through the liberality of the noble owner of Hatfield House, whose taste and judgment are both too good to leave any doubt of the issue—namely, that it will be embellished in a way becoming the parish church of a rural district; for though but some sixteen or seventeen miles from London, it is only by the occasional sound of passing trains (for they are but little seen from the mansion and grounds) that we are reminded we are near a busy thoroughfare.

The village occupies a valley, through which the Great North road used to run, and its hostelries, once so much needed, are now reduced in number, and the village has settled into one of those quiet country house-clusters which form so pleasing a feature in our land; but there is one connection which it has kept up, and that is its relationship to the great house on the hill—Hatfield House and Hatfield village still occupy the same relative position they did two hundred years ago, when royalty was no unusual visitor; and not many years ago Her Majesty was entertained here with becoming magnificence by the father of its present noble proprietor.

On leaving the railway station, which is close to the village, we descend a little into it, and then commence to rise, passing on our right the church, which forms a sort of connecting link between the village and the mansion, and our first entrance within the precincts of the latter is through a doorway adjoining to, and, we believe, also forming a part of, a mansion that stood here before the present noble structure was erected. A large portion of this building is still standing, and appropriated to some other purpose, but its peculiar features are retained as far as possible. How far back its history dates we are unable to say, but most likely it extends to the period of the wars of the Roses or even further back, as part of the modern building dates from the time of Henry VIII. This memento of a past age is but a short distance from the north front of the present structure, and has been recently carefully and judiciously restored.

The mansion of Hatfield occupies the northern end of a ridge of slight yet sufficient elevation, the ground falling gently away from it on all sides, excepting to the south. The building is regarded as one of the best examples of the Tudor style of architecture, of which Cobham Hall, in Kent, and Ingestrie Hall, in Staffordshire, are also examples. A portion of he

house is of stone, the remainder of brick with stone dressings, the window mullions being in all cases of stone. The north and south fronts present a façade of upwards of 200 feet, the other two sides being a little less. The building is also lofty; the two northern angles are surmounted by domed turrets, which give a commanding appearance.

The principal carriage entrance used to be on the south side, where a spacious courtyard of some 220 feet square, all gravelled (more than an acre), would seem to afford space for all comers, while suitable gates gave access to this enclosure, and the two corners furthest from the mansion were each surmounted by a sort of bastion, in connection with a subterranean passage. Beyond this court is one of the finest avenues to be met with, not of old, but healthy, middle-aged Lime trees. It consists of two rows of trees on each side, the distance between the inner rows being 250 feet. The ample space here shown is further enhanced by the conformation of the ground, which starting on a level from the house at length gradually rises to the south so as to present to view the grandeur of the whole, the glades of grass on each side being ample. The entire avenue, about a mile long, is seen from the court above described. The effect is noble, the wide and well-kept carriage road of course adding its share to the whole. The south court has lately been altered, not shorn of any of its importance, on the contrary beautified; for it has been found that these railway times have changed many things, and amongst others visitors from a distance invariably travel by rail, and the north front being more convenient of access by rail than the south front, for the latter such a spacious area of gravel is no longer required; the space has therefore been cut up into panels of turf, one panel on each side of the carriage road that passes through the centre, and each edged with a stone kerb, while on each of these, panel beds for flowers are also formed—large, bold, well-proportioned beds with plenty of grass space between them. The beds of Calceolarias exceeded in health and vigour anything of the kind I had seen for many years, and justly excited the surprise of two friends by whom I was accompanied, and who were well versed in the cultivation of this uncertain yet indispensable member of the great bedding-out family; and the surprise may be still more increased when it is known that these Calceolaria plants were the same as those which Mr. Record described in the pages of this Journal as having been wintered out of doors without any further protection than the snow which encased them in the dead months of winter. The variety is, I think, Aurantia, a more robust grower than Aurea floribunda, and I believe also older. It was impossible for anything to exhibit a more perfect state of health—not a dead leaf, and no prospect of any lack of flowers during the season, and, be it remembered, it was the middle of September when I saw them. I must say I was surprised at their being so healthy, for although we have never here (Linton Park), had occasion to complain of Calceolaria disease, it is a long time since we had nearly so good a bloom in September, and in many places that I have visited this season they had completely gone off—not merely ceased flowering, but absolutely were dying from some malady which everyone wanted a cure for. If I were to venture a reason for Mr. Record's plants doing so well, I should say that the fresh soil of the newly-made beds had some influence, at the same time the extremely hardy way in which the plants were reared no doubt caused them to flourish better in their improved position. I can only say I have not seen the same robust healthy growth and flowering of the Calceolaria in September for twenty years or more, and I hope if Mr. Record can enlighten us more as to the way to obtain a similar result he will do so.

The other plants occupying the beds were also good, and consisted of the most popular kinds of Geraniums, as Waltham Seedling and

Hatfield House—South Front.

Stella amongst the scarlets, Christine and Wiltshire Lass amongst the pinks; and that perhaps best of all flowering kinds, and one for which I believe the gardening world is indebted to poor Beaton, Indian Yellow, also had a place. Other kinds there were also, as well as some other bedding plants, but Mr. Record very wisely does not attempt to spoil a good effect by that heterogeneous diversity which is often met with elsewhere, for the kinds of plants employed were but few, and no one who saw the effect could wish their number increased.

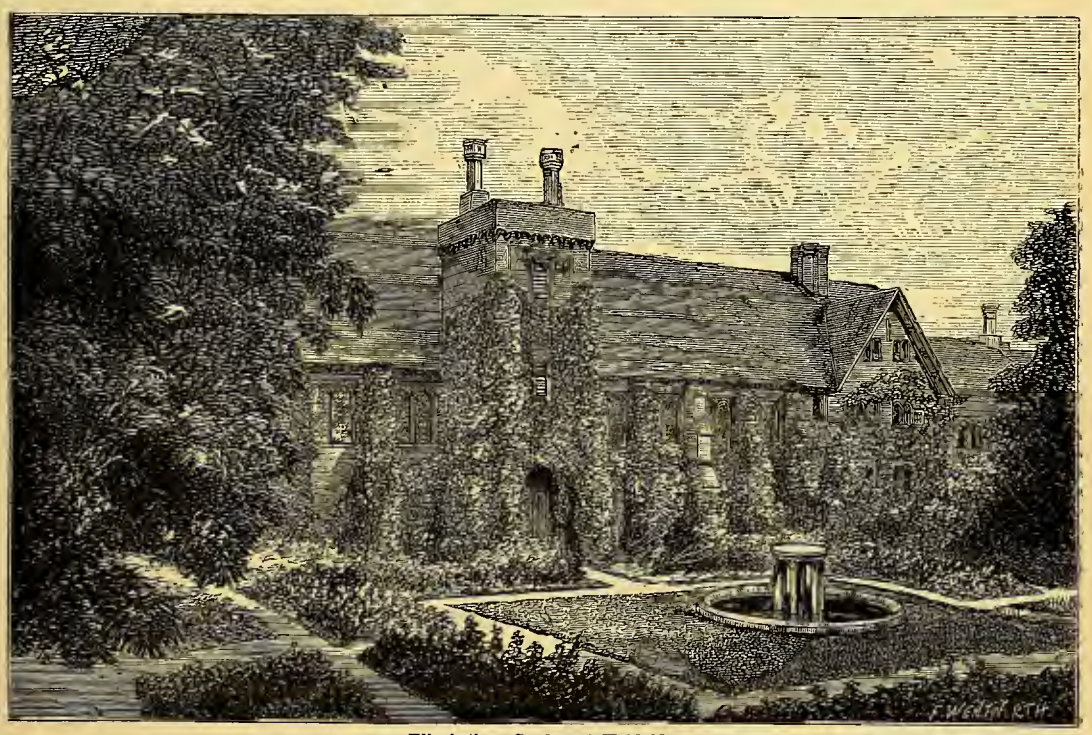
Having described the south court as having been recently converted into a garden, I will next proceed to one of the oldest flower gardens in the country, that still retains its original features, and this carries us back to the time of Queen Elizabeth, or rather to the time of her predecessor, for Elizabeth was a state prisoner at Hatfield for some years during Mary's reign. The garden now about to be described was in existence at that time, and the design of its flower beds, as well as other objects about it, cannot well be improved upon at the present day. This garden is situated on the west of the mansion, but not immediately connected with it, as some of the offices intervene. In form it is a square of about 200 feet to the side, and is therefore about an acre in extent. A circular basin of water is in the centre, and between the centre and each of the four corners is a Mulberry tree. The four Mulberry trees are reported to have been planted by Queen Elizabeth. They are alive yet, but, of course, present an aged appearance, yet, like other old Mulberry trees, they bear well, and, as I proved on my visit, produce good fruit. Some intersecting circles form the principal flower beds, which are also enlivened by turf and well-proportioned gravel walks. One of the most remarkable features is a colonnade of Lime trees all round, outside of which is a wall some 8 feet high. The Lime trees have been planted in pairs, and trained and cut so that no part of them is more than 10 or 12 feet high, forming, in fact, a continuous arcade on all four sides, while the inner or garden side is trained so as to represent twenty arches on a side, there being that number of trees employed. These trees have evidently been planted since the garden was made, very likely to replace others that might have been there before. The whole, taken in conjunction with the geometric figures of the flower beds and other

surroundings, is highly characteristic, and cannot fail to interest all who look upon such a thing. Into the planting of the beds it is needless to enter, as this is a transitory affair compared with the antiquity of the garden; but I should certainly like Mr. Record to give us a plan of this garden at some fitting opportunity, as it could not fail to be highly interesting to all, more especially to those who think that beauty of design only dates its origin from the latter half of the nineteenth century.

On the northern side of the above garden, through the Lime arcade, but at a lower level, is what is called the Palace Garden, so named from its being the spot on which Hatfield Palace once stood. The size and form of the old building, with its entrance door, shape and number of square towers, is distinctly shown by a narrow wall of stone put there for the purpose. A part of the building on the western side, with two of its towers, still remains. The interior formed one large room or hall, was the banquetting-hall of the palace, and was used by Queen Elizabeth when at Hatfield. The garden is enclosed by the boundary wall of the building above described, and was formerly used as a nursery for odd plants, but Mr. Record has lately turfed the ground over, and laid out a neat design of small beds, in which flowers of all sorts are to be grown for cuttings and other purposes instead of mutilating the beds in the best gardens.

Retracing our steps, and going towards the western side of the Elizabethan garden, and also at a lower level, reached by handsome flights of steps, we come upon a large and beautiful Rose garden, half an acre in extent; it is oblong in shape, and is cut in two by a walk across the centre. Each division has a large circular wire trellis on which to train Roses. The design is very neat; the beds are cut out of the turf, and contain some hundreds of the choicest Hybrid Perpetual and other Roses. By the sides of the walks standard Roses of equal height are planted, giving the whole a most inviting appearance. This garden also joins the arboretum, a space of several acres, in which are growing some fine specimens of Purple Beech, Cedar of Lebanon, Acacias, and that noble-looking tree Ailanthus glandulosa, besides many choice trees and shrubs of lower growth. The whole of the western side of the Rose garden and part of the arboretum it bounded by a long and wide terrace walk, which leads in a straight line to the conservatory, and gives a very suitable finish to this part of the grounds.

Retracing our steps we now come round to the eastern side of the mansion, and find there a broad gravelled terrace, bounded by a balustrading resting on a retaining wall, which forms the boundary of the promenade, and from which the flower garden in the basement below can be seen to the best possible advantage, for, let it be observed, here most things are planted in lines at right angles. The two gardens I have described on the south and western sides are each upwards of 200 feet square; this on the eastern side is of about the same size, and is reached by a broad flight of steps from the upper terrace. It consists of a series of figures in the usual formal Italian style, and each bed at the time of my visit was a picture of floral beauty, the only drawback being some edgings of Lobelia that were past their best. These beds, let it be observed, were not crowded, abundance of space was accorded them, and the mixture of turf and gravel walks presented a pleasing appearance, which was further enlivened by the bright colours of the occupants of the beds. Beyond this garden, and in a line with it, but on a lower level (for the ground declined in this direction), was another square of about the same size as the flower garden described. This is the croquet ground, most likely originally intended as a bowling-green, and which, like the garden above, was level and enclosed with a fancy balustrading, and reached by flights of steps. Beyond this croquet ground was one of those antique adjuncts to some of the noblest residences of the kingdom, the maze. The



Elizabethan Garden at Hatfield.

ground occupied by this has not been so completely levelled as the parts already noticed, but declines gently to the east, while the maze is composed of Yew hedges in a high state of preservation and keeping. Although I did not examine the extent closely, I should think it greater than that of the flower gardens. In form, I may remark, it was, like them, a square or oblong, the hedges were disposed in straight lines, and I believe with as much ingenuity and intricacy as in most devices of the kind.

Passing from the maze on the right and turning to the left hand we come upon a Rose walk or arcade, for the Roses are trained in a manner very similar to the Limes in the Elizabethan garden, over a trellis of ironwork, and comprise most of the best sorts of climbing Roses. When in bloom they are a magnificent sight. Passing along this walk, which is about 200 feet in length, and turning to the right hand, we see in course of formation a large lake of about 4 acres or more in extent; it is intended for a boating and skating pond. It is most delightfully situated in the valley eastward of the mansion below the maze. I believe there had previously been something of the kind, but it was situated outside of the garden proper and much less extensive, but the present lake is taken into the gardens, and it is intended to keep it as ornamental water. The ground has a pretty and natural elevation on every side. Already there is a walk running round the whole, and a good deal of planting has also been done, including lots of Gold and Silver Hollies, scarlet Oaks, Acacias, purple Sycamores, Yews, the Purple Beech, variegated Acer, purple, yellow, and plain Willows, Aucubas, choice and common Rhododendrons, Box trees, and many other ornamental things. These were all supplied by Mr. W. Paul, of the Waltham Cross Nurseries, and a very fine lot of shrubs they are. A work of such magnitude, and the arrangement of the groups of shrubs, so far as the work has been done—for there is yet much to be done—naturally requires time to bring out its beauties, but so far as it has gone it strikes the visitor with the belief that it is the most desirable and important improvement in this fine place; and when all is completed that is contemplated a separate description of this fine feature should be given in detail, as the arrangement of the shrubs has been anything but an easy matter

for Mr. Record, who must have devoted considerable time in working it out.

We next come to the northern side of the mansion, which has recently been altered and made into the most commodious carriage entrance, and to make it in keeping with the other sides of the house a large court has been enclosed and gravelled. An open-work balustrade, corresponding in design with that on the south side, has been erected around the northern court, which now embraces a space of 220 feet on the side, or upwards of an acre, entirely gravelled and ready for any purpose that may be wanted, and Mr. Record says it is not too large for special occasions when a number of carriages are assembled here. This, like the southern front, opens upon a straight avenue of trees, but in this instance they are much closer together, and seem not to have been used as a carriage drive as the others have been; in fact, the principal carriage drive curves round to the left after leaving this court, and a new road to the railway station is being made.

Before leaving this part of the grounds we must glance round and see how profusely the park is studded with handsome timber trees in this direction, for apart from the avenue alluded to—and all avenues at Hatfield are composed of four rows of trees—there are abundance of trees of all ages and sizes scattered over the park, not indiscriminately, but with taste and judgment, leaving large open glades here and there, groups arranged to conceal objects in the distance which it is not desirable to show, but at the same time leaving vistas in their proper places.

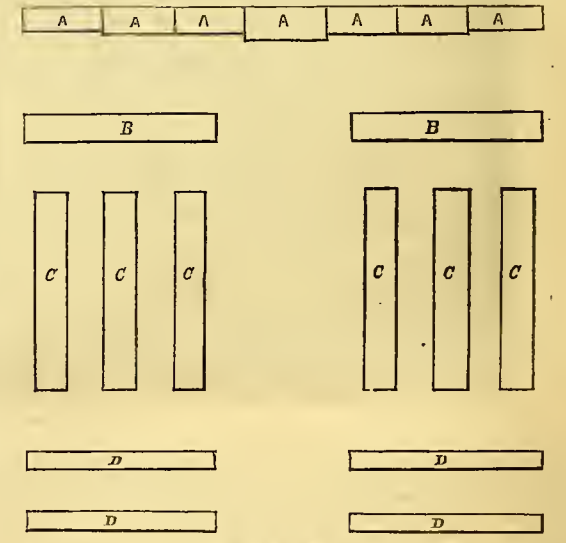
The park is very large, exceeding, I believe, two thousand acres, and much diversified. Some part of it is covered with Fern, in which not only a bullock but a man on horseback is said to have found concealment. Other portions possess a rich, grassy sward, while the whole is so undulating as to do away with that feeling of monotony which a too frequent repetition produces. The age of the trees is also a remarkable feature, and as an instance of this, I may mention an Oak situated but a short distance from the north entrance having a girth of 32 feet 5 inches at 5 feet from the ground. This relic of a bygone age is only a shell, but a mode has been adopted of prolonging its existence which I do not remember having seen before. The interior of the tree, which is hollow, has been filled-in with the ordinary gravelly soil of the district so as to form a compact mass. How far this may be conducive to the welfare of the tree time only can tell; but so venerable an object deserves the greatest care that can be bestowed upon it. I need hardly add that its top showed the usual symptoms of extreme age, portions being dead, and the spread of its branches not at all large. Let us, however, hope its life may be prolonged for many years. It would be satisfactory to know how many such trees exist in the land. Some years ago I myself measured one in a hedgerow in Buckinghamshire upwards of 26 feet in girth, and quite healthy. Still more recently I came across one in Staffordshire 31 feet and upwards in circumference. The most historical Oak, the one under which the Princess Elizabeth was reclining when a messenger came to hail her Queen of England, is no longer in existence, having fallen some forty years ago. Its shell is, however, preserved, but its size is not important.

A striking feature in this place is the inconvenient distance of the kitchen garden from the house which has been long felt, so that a new one is in course of formation which will be described in due time. The old kitchen garden, which was called "the Vineyard," was at the extreme north side of the park, upwards of a mile from the mansion. A path through the park led to it, and the entrance was through a sort of ornamental cottage; the side next the park was by no means remarkable, but the other side was extremely so. The cottage alluded to stood on the edge of a rather steep bank facing the north, at the bottom of which was a broad piece of water, formed by damming-up the river Lea, but its clear and bright appearance as well as the concealment of the weir head kept up the idea that it was an important river. On the other side of this river was the kitchen graden, an enclosure of between four and five acres, having a sort of ornamental tower at the centre of the top immediately facing the cottage. We entered and were surprised at the manner in which the sloping bank from the cottage to the water was disposed of, which was by Yew hedges all pointing in fan-shaped fashion to the cottage, the centre opening of course being the widest, and pointing directly over the water to the ornamental tower at the top of the kitchen garden. A broad walk through the latter gave an uninterrupted view to the object alluded to, while all the side openings, after pointing to the water, also had their course to some important centre in the garden or beyond it, while the age and good keeping of this singular feature carried the beholder back to a period when gardening as a profession must have been little known compared with what it is now; and yet how perseveringly and consistently have these fine features been attended to by the many generations of proprietors of Hatfield! Why it should be called the Vineyard is not so easy to understand, unless, as is not at all unlikely, Vines for wine-making were cultivated in the kitchen garden.

Returning to the neighbourhood of the mansion, and pursuing a south-west course, we emerge in the pinetum proper, and guided by Mr. Record, we find ourselves in a large sheltered spot, where some of the most valuable Conifers introduced to this country some fifty years ago have been planted, and many have attained the proportions of our native trees. Picea Pinsapo was especially fine, as is also P. cephalonica, while Cryptomeria japonica, Taxodium sempervirens, and sundry Pines, were well represented, Pinus excelsa being especially good. Neither were Araucarias wanting in size, while rising specimens of the more recently-introduced Conifers bid fair to equal others of like kinds elsewhere.

Diverging from this we come upon the conservatory, a new building, not lofty, but well adapted for the purpose it is intended for. This structure is 200 feet long by 24 feet wide, span-roofed, and with an ornamental pathway of good width up the middle, the roof being well clothed with creepers, and the sides with such permanent plants as Camellias and Orange trees, and amongst others I noticed one of the best Luculias I had seen for many a day. Fuchsias and other plants standing between gave a good display for the time being. In another part of the grounds I noticed abundance of plants being prepared for the autumn and winter decoration of the house. It ought also to be mentioned that connected with one end of this conservatory, but at right angles to it, so as not to compete with it in point of interest, was a plant stove, also well stocked with the plants mostly wanted at the time the family are here. Only those who are in the habit of supplying a family of rank with plants for the various purposes of table and room decoration, know how much this part of a gardener's duty has increased during the last few years, and how much with it the demand for cut flowers.

As the kitchen garden recently formed is in the direction of the conservatory, we ought to describe it here, but as the graperies and forcing houses intervene between the old kitchen garden and it, my remarks upon them should naturally precede any I have to make upon the other. They were not at the old garden as might be supposed, but were in a sort of yard to the north-west of the mansion, adjoining some farm buildings and other offices. They consisted of some vineries that had done good service in their time, of pits, and of smaller houses for forcing pot Vines, Cucumbers, and Strawberries. I believe that in years gone by there have been obtained from these pits and houses good Grapes from pot Vines. Those I saw this year were excellent. But as a new kitchen garden has been determined on, and as ranges of horticultural structures on a much larger scale are in course of formation, these houses and pits are to be done away with. At the time of my visit, however, they were fully employed, or rather the plants standing about showed that they had been so; and apart from the long array of Vines in pots, and the thousands of Strawberry plants to be taken in, plants for the decoration of the conservatory were being prepared by the hundred, Chinese Primulas, Cinerarias, Poinsettias, and what I was very pleased to see as an old and deserving favourite, a large batch of Calla æthiopica, a plant which far exceeds the bulk of the Caladiums in beauty of form. Cyclamens, Cupheas, Libonias, and other winter-flowering plants, were also being prepared. All of these were in the best possible condition, showing that Mr.



KITCHEN GARDEN.

PLAN OF HOUSES.

A, A, &c. Seven Grape houses forming a range of lean-to houses 270 feet long by the respective widths of 18, 16, and 14 feet. The centre house is the highest, and forms a conspicuous object from the central walk through the kitchen garden.

B, B, Two span-roofed forcing houses each 100 feet long by 14 feet wide. These may be used for Pines, Melons, &c.

C, C, Six span-roofed houses, each 100 feet long by 16 feet wide; the two outer ones being for Peach houses, the use of the others not yet determined upon, but they will be employed for growing plants for the present.

D, D, Cold pits each 100 feet long, and their number may, perhaps, be increased, and possibly some of them will be heated.

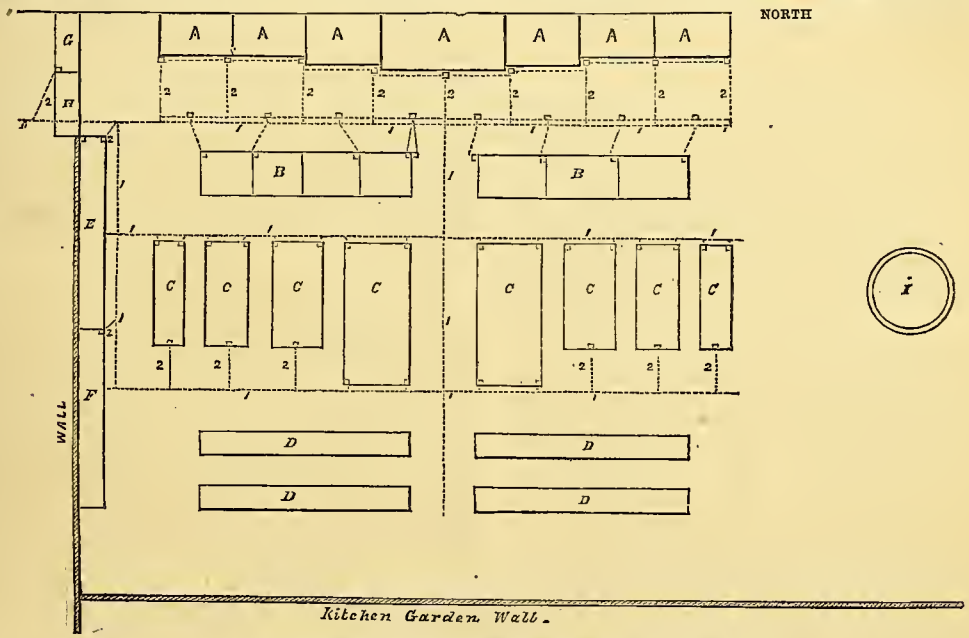
Record, notwithstanding the many duties such extensive alterations as he is making necessarily entail, nevertheless takes care to see into the details which play an important part in the embellishment of the place.

Taking our way in the direction of the new garden, myself and friends first came to the newly-erected Grape houses, and the neighbouring forcing houses, pits, and other structures.

The new kitchen garden is formed at a convenient distance to the south-west of the mansion, the path leading to it passing the conservatory above alluded to, which is included within the boundary of the park proper. The kitchen garden is outside, there not being enough space inside near the mansion that could be spared; being outside, it loses the benefit of the shelter which the fine belt of trees by the park boundary affords in that direction, but there was no alternative. A space of 8 or 10 acres cannot always be afforded at one place, and it is not unlikely that as great an extent will be wanted by the time this garden shall have been finished; for the area enclosed by the garden walls already built is 6¾ acres, exclusive of the space occupied by the forcing houses, &c., besides which there will probably be the slips, for few gardens are without these, and in many their extent far exceeds that of the interior. Much, however, is as yet incomplete, although the works are being carried on by a numerous staff of men. The kitchen garden as walled-in forms an oblong, or nearly so; for necessity has compelled a little divergence from the proper angle at the south-west corner, the south wall being shorter than the north one, and the other two walls longer than either. It is, I believe, intended at some time to run another wall across the garden east and west, so as to afford more south wall to the tender fruits; but as it is the north wall is of a good length, being 564 feet long, and 12 feet high; the other walls are of the same height, and all protected by a coping projecting about 3 inches over each side. Trees had been planted against part of the walls last spring, and in most cases promised well. All the ground was cropped or had been so, and healthy fine-looking vegetables met the eye in every direction. A broad walk from side to side crossed the centre of the garden pointing to the central vinery in the ranges of glass at the back; wide open-work gates were being put up in the centre of the north wall, while other walks, also of considerable width, were being carried round at a proper border distance from the outer walls.

In the forcing department, behind there was still much to do. Mechanics of various kinds were busily employed, and gangs of labourers and garden men were engaged in the earthworks, and that very important operation—making Vine borders. Turfy sods, from 4 to 6 inches thick, were being wheeled in upon a well-prepared foundation of drainage, and some of the Vines had only been planted a few days, yet were looking well. I believe Mr. Record intends one if not two of the vineries to be planted with Muscats, and one or two with Lady Downe's and other late Grapes, but the precise position of each I did not exactly note down.

The heating apparatus was ample, there being three or four boilers, but all united or so arranged that if one should fail the others could work without it. They were all saddle boilers on an improved plan,



PLAN OF HOUSES AS RE-ARRANGED, SHOWING THE DRAINAGE.

A, A, Seven vineries forming a range of lean-to houses 264 feet long, by the respective widths of 18, 16, and 14 feet. The centre house is the highest.

B, B, Two half-span or hip-roofed houses, each 100 feet long by 18 feet wide, divided into four and three compartments respectively. These will be supplied with bottom heat as well as top heat, and will be used for forcing Pines, Melons, Cucumbers, Dwarf Kidney Beans, &c.

C, C, Eight span-roofed houses, the largest two 70 feet long by 20 feet in width; the next size 50 feet long by 16 feet wide, all of which will be used for plant-growing and forcing. The next sized houses, 50 feet long by 14 feet wide, will most likely be Peach houses; and of the two outer houses, 50 feet long by 12 feet in width, one is for a Strawberry house, and the use of the other is not yet determined on.

D, D, Are bedding-plant pits; the two lengths nearest the span-roofed houses will be heated, and the rest are intended to be cold pits.

E, Will be a lean-to propagating house.

F, A house to be used for store plants and bulbs in a dormant state.

G, Boiler house, in which four boilers will probably be placed. The object in having them all together is, that the boilers may be connected one with the other, so that if any boiler should fail to supply the necessary heat required at particular times, or should be under repair, there may be a boiler to supply its place.

H, Is the fuel shed.

I, Water tank, 40 feet across, and 5 feet deep. This tank is kept supplied with water from a large pond situated some distance off in the park. From the tank the water will run into every house in the plan, and all of them are fitted-up with a tank above the hot-water pipes, so that the water may be heated to the temperature of the house.

The kitchen garden is also well supplied with water from the same lake and by the same means, and from a similar tank the water is conveyed all round the garden.

The dotted lines are intended to show the system of drainage adopted for the whole block of buildings. Figs. 1, 1, &c., is the main drain, and is laid with 12-inch glazed socket-pipes; and figs. 2, 2, &c., are the branches connected with the main drain to take the water from the bottoms of the Vine borders and the interior of hothouses.

and were placed at the north-west corner where the ground is low. I believe these boilers are calculated to heat the whole of the structures shown in the diagram, and being placed out of sight, the forcing pits and houses will be open to the inspection of company without anything offensive intruding itself. Probably other houses will ultimately be added to those already in course of erection, as the plan has been arranged with that view; but even as it is the important additions made by the present proprietor of Hatfield will no doubt rank amongst the most useful it has ever had, and near the mansion the changes that have been made by him have been in strict harmony with the character of the building.

I have only to add that the whole place was in excellent keeping, that there were proofs at every step of the future being thought of as well as the present; and finally, the belief of myself and all who accompanied me was that in Mr. Record the Marquis had found a gardener worthy of his place.—J. ROBSON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

TAKE advantage of favourable mornings for wheeling out old hotbed and other manures on spare ground, and getting the ground well trenched and roughly ridged to receive the bene-

ficial influence of the atmosphere. Cut off the *Asparagus* stems as soon as sufficiently decayed; clear the beds of all refuse, cast off right and left with a fork portions of the earth that covers the crowns of the plants, and apply a good dressing of manure; then return the earth over the manure. Those beds which have been attended to in the growing season by applications of liquid manure, will require nothing more than a thorough cleaning and forking carefully over, leaving the surface rough. Cape *Broccoli* and *Cauliflowers* now forming their heads should be well protected from frost by covering them with a few of the under leaves, or by breaking down the heart leaves on the head while forming. Continue to make sloping banks for planting *Endive*, *Lettuce*, *Cauliflowers*, and *Cabbage* plants, and keep the ground among those already planted out hoed and surface-stirred. Cabbage quarters should be searched for grubs and slugs, and any blanks that occur should be made good immediately. Those who grow tall varieties of *Brussels Sprouts* should take off a few of the lower leaves as they become ripe to encourage the sprouts. A good system to blanch Endive throughout the winter is to place 3 or 4 inches of sand on the floor of the fruit-room, vegetable-shed, or cellar, and take up a quantity of plants with balls of earth about once a-week in succession, and place them in the sand, where they will blanch beautifully without further trouble. See that the Winter *Spinach* is thoroughly thinned and aired, well hoed in favourable weather, and in every way encouraged.

FRUIT GARDEN.

The principal operations in this department are the gathering of the fruit as it becomes in proper condition, making preparations for filling-up blank spaces, and trenching new ground for orchards and fruit plantations. They should be well prepared to insure success. Planting may now be carried on with success; mulch and stake safely without delay. Continue to keep the runners removed from the Strawberries, and those that have been some time potted for forcing should now be placed in a comfortable situation to insure their not being too much soddened with wet. Strong pricked-out plants may still be potted with success if placed on a kindly bottom heat.

FLOWER GARDEN.

Except where alterations are in hand the principal work in this department for the present will be mowing and cleaning-up, and if anything like neatness is to be maintained, sweeping-up leaves will require daily attention; also let gravel walks be thoroughly cleared of weeds and moss. Roll them frequently when wet to keep the surface hard and smooth. Continue to afford young stock in pits and frames the most careful attention, and endeavour to have it well rooted and strong without keeping it so close and warm as to render it soft and liable to die-off on the first approach of wintery weather, as is the case with stock propagated in heat late in autumn, and then stored in cold pits for the winter. Therefore, admit air freely to all plants that are sufficiently rooted to bear it without flagging. Newly-potted-off plants should, however, be placed on a gentle bottom heat, which will impart a little warmth to the soil and encourage the formation of roots, but sufficient air should be given to prevent anything like weakly growth. Some spare beds should now be in readiness for the reception of Hyacinths and Tulips. These have a pleasing and interesting effect at an early period of the year when all is cold and seemingly lifeless, and when there is scarcely anything for the eye to rest upon but bare fields and leafless trees. Crown Imperials, hardy Liliums, bulbous Irises, Narcissus, and other bulbs should now be planted in the borders. Soils which have been used in the forcing department should be brought into the compost-yard and mixed up with decayed matter from the waste heap. This mixture forms an excellent manure for flower beds. Prepare composts for Roses by frequent turnings, at the same time adding rich materials; and if a quantity of wood can be procured, also trimmings from hedges and refuse from the shrubberies; these, formed into a heap and charred, will prove a valuable addition to stiff clayey soils.

GREENHOUSE AND CONSERVATORY.

A sufficient quantity of good friable turfy loam for next year's operations should now be procured and stacked up in rows, and thatched with fern or straw to throw off rain, likewise peat and sand, both valuable adjuncts in propagating. Summer-flowering twiners, which usually become unsightly at this season, should be cut back rather freely, as also any others that will bear this treatment. Shade can now well be dispensed with, therefore not a spray which can be spared should be left to obstruct the light. Acacias and other winter-flowering plants having been subjected to a period of comparatively dry treatment to secure their blooming profusely, should now be rather liberally supplied with water at their roots in order to bring them into flower during the dull season, when they will be much more esteemed than in spring, when flowers are becoming plentiful. Manure water, if it can be used, should be given frequently to Chrysanthemums. Give air freely on favourable opportunities, avoiding cold draughts against plants that have been brought from a warm house, and guard against damp by using gentle fires with a little top air on wet days. Let pot specimens in bloom be frequently re-arranged, so as to make the most of them, for the finest specimens become too familiar to be interesting when allowed to remain too long in one place. Be careful not to overwater plants brought from the stove, and also to use the water in a tepid state, as watering tender plants with cold water after this season, injures the young shoots, shortens the duration of the blossoms, and often ruins the plant. Use weak manure water for Salvia splendens, so as to preserve the plants in a vigorous state and keep them blooming as long as possible. Give attention to securing a plentiful succession of plants for maintaining the gaiety of the house as long as possible.

STOVE.

Hardwooded shrubs, such as Ixoras, that have not made their wood after flowering should be encouraged with a warm moist temperature, syringing them lightly overhead, and shutting up the house early in the afternoon. Give any growing plants that require it more pot room as soon as convenient, in order to have them well rooted in the fresh soil before winter. Keep a sharp look-out for insects, especially thrips, which are often troublesome at this time on such plants as are growing in a close warm house. Either fumigate or remove the affected plants, and thoroughly clean them immediately this pest is perceived, for if left to its own way with tender-growing foliaged plants it soon disfigures the finest specimens.

PITS AND FRAMES.

Premising that all tender plants are safely housed, and anxiety with regard to their safety in a great measure diminished, proceed with arranging them, and remove into any spare cold pits the stock of Pentstemons, Antirrhinums, Linums, Phloxes, Intermediate and other Stocks, and all herbaceous annual plants that require a little protection. The pots should be plunged in sand or coal ashes; plunging is not only a protection, but saves much labour in watering during the spring months. When all the plants are arranged in this department there should be a thorough cleaning; all litter, rubbish, and everything offensive to the eye should be removed. If the footpaths between the ranges of pits be in bad trim, a layer of gravel or coal ashes will add much to the neatness and to the comfort of visitors. Measures should be taken to destroy the field mice, which in hard winters work such havoc amongst plants in turf pits. Baits made of cheese, bread, or bacon do not take with these destructive little animals, but a brick trap baited with an acorn or chestnut they cannot resist.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Protectors.—Writing hastily as we do, we find that in alluding to battered and broken hand-lights, with the exception of stating how we filled the broken sides with zinc instead of glass (the zinc being clipped to the requisite size with scissors made on purpose almost as easily as you would clip paper with common scissors), we forgot to mention that with other glasses we used the frames as they were, and instead of glazing, merely set thin pieces of slates or thin boards against the sides where they were broken. We could not do without such rough mending, not so much on account of protection as for keeping all such intruders as mice and rats out of the lights at night. To exclude them still more, we frequently run a light line of tar round at a few inches from the bottom of each glass. Thus temporarily securing the sides of our hand-lights, we like to have the tops well glazed, and generally manage all such matters in wet and stormy days, when the men could do little or no work out of doors, with benefit to themselves or their employers. We find that Cauliflowers and Lettuces do, on the whole, as well under these glasses with opaque sides as they do when all the sides are of glass and in the best order. We are delighted to see that some of our neighbours have dozens of hand-lights, beautifully perfect, and well painted every year. At present we are satisfied with having the tops perfect,

chiefly to keep out intruders, as before now on mild nights, merely from leaving air on, we have had numbers of pretty Cauliflower plants cut down by grass mice and rats. Kill and trap as you may, there will never be an end to such work so long as game are encouraged and fed close to the garden.

One reason of our endeavouring to have the tops of our hand-lights sound is the use we put them to, when not wanted as protectors out of doors, for all propagating purposes during the season. Then, instead of using the bottoms of the glasses, it is often more handy to set the tops on bricks or a rim of wood. We think, however, most of our readers will now be convinced how much more economical it would be to use a square or two squares of glass in a frame instead of the double-hipped roof of the hand-light. The cutting of the glass to meet all the angles and triangles of the tops of the hand-lights is of importance at the present day, on account of the time it takes; but when glass was expensive, the working-up of all the little pieces became a matter of economy. It is altogether different now, for generally large squares in moderation are cheaper than small ones covering a similar space.

We think it important to make these remarks, as we have had several inquiries since last week respecting simple glass protectors. We still hold that a wooden frame with a glass top is the simplest if not the best, and of such we wish we could greatly increase our little stock. Although not at liberty to mention names, we may state that one friend who never tried for early Cauliflowers formerly, had some last season so early as to surprise all his neighbours. These were obtained from a protector formed of four pieces of wood nailed together with eight nails, and enclosing a space 20 inches square, a little elevated on the north side. The top was covered with one square of glass, from 21 to 26 ozs. to the foot, without a frame of any kind, resting on the boards. He was so satisfied with what he could produce in the way of early Cauliflowers, that we believe he has made a number of such boxes since, and had the glass square secured in a wooden frame 2 inches wide.

For mere protection we have long satisfied ourselves that a 1-inch board is nearly as good as a 4½-inch brick wall, and 2 inches as good as a 9-inch wall. Where the object is to obtain as much acceleration as possible from summer heat, brick will be superior to wood, as the heat which is absorbed during the day will be given out at night. Much the same result may be obtained even from single wooden structures by shutting up early. We have seen beautiful Cucumbers at the end of May and June from seeds sown in a shoemaker's workshop in February. They were kept near the stove until the seedlings were above ground, placed near the window during the day in a small glass case containing a tin that could be filled with hot water, and left nearer the stove at night until the plants were ready to go to a frame or pit, when they would pay well for all the care involved.

With all the advantages of hot-water heating there is still this disadvantage, that it has greatly lessened the requisite attention bestowed on everything when there were no such advantages. In conversation with several great gardeners lately they all seemed to agree in this—that it was diminishing the attention exercised by the young gardeners of the day in too many instances, because so much could be done by the simple turning of a valve, and most probably the valve would remain fixed when it ought to be open. After all it is attention to these little matters that makes up the elements of success. The youth who has a mind above giving attention to trifles ought never to think of being a gardener. We were once acquainted with a clever youth, who knew something of almost every "ology," sadly put out because he was taken to task for such a simple thing as not giving air early enough to a Peach house. That want of air, however, made almost every Peach drop before stoning time. Successful gardening results not so much from great scientific and intellectual attainments—though these are desirable when attended with a humble teachable spirit—as from a simple but careful attention to little things. It is the latter qualification that has enabled some comparatively unlettered gardeners, and even cottager and amateur gardeners, to achieve such wonderful results. Get, then, most certainly the best possible means if you can, but never despise the simplest modes or the most economical makeshifts if you cannot readily get what you consider the best; and for encouragement let us say that some of the largest establishments are often those where the most must be made of the simplest and most economical arrangements. By economical we mean for the time only, as there are reasons why a small yearly expense should be incurred rather than that ten or twenty times the amount should be spent at once, though this might be the most economical in the end.

In the fine dry weather of the week, with the exception of hoeing and slightly forking the surface of the ground among young Cabbages and Lettuces, thus admitting air and deterring slugs, we have done little in the kitchen garden. We have planted, however, more Cauliflower, pricked out a lot of young Onions to stand the winter and come in early, and earthed-up Celery, using thin boards and pieces of spouting to place some ashes round the outside of each plant. As to the Cauliflower, a little drift sand on the surface of the soil prevents the plants from damping, and the rougher the sand the less likely are snails and slugs to go over it.

Lettuces on Banks.—These did so well with us last winter, when so many under the protection of frames and at the bases of walls stood very badly, that on a piece of ground from which the summer crops have been taken we have thrown up three wide ridges, and planted them with Lettuces. These ridges run north and south, their sides, therefore, sloping to the east and the west respectively. The bases of the ridges are marked-out 6 feet wide, the apex of each ridge is therefore also 6 feet from its neighbour. This distance secures two things—the apex of each ridge is well raised above the ground level, and the gutter or furrow between two ridges is considerably below the regular ground level. To the comparative dryness of the plants in winter we attribute their greater safety as compared with those planted on the level ground. On each of these ridges we have five rows of plants, two on each sloping side and one along the apex. The ground was well pulverised, and then gently beaten with the back of a spade before planting. The rows are a foot apart, and the plants 6 inches from each other in the row, as the plants, though stubby, are small, and if they stand well, they can be thinned-out to a foot apart in the spring, when the thinnings will come in for succession. With a little mulching in spring we found the plants on the ridges arrived at great perfection with little or no watering. The greater depth of good soil made up for their greater exposure, and the gentle forking over the surface before mulching enabled the spring rains to percolate freely. A crisp early Lettuce being so much enjoyed by many who have only a small rather open garden, must form our excuse for mentioning these details, as we believe that on them the success will chiefly depend. This double-sided ridge will often be more suitable than a bank sloping to the south, as the greater the heat at one time the more risk from frost at another. Such improvised banks are suitable for any soil, but most useful when the soil is rather heavy. When the Lettuces are gone the banks can be levelled as before; but if we had plenty of ground we should not object to such banks as the above, and also others running east and west for a continuance. In the latter case we should have them of double the width at the base, and the south slope we would make larger than the north slope. In such cases we have found the south side most useful for early Cauliflowers, Potatoes, &c., whilst the north side was valuable for summer Lettuces, and late Strawberries. A great deal may be done even in small gardens by making, as it were, so many climates for ourselves.

Onions.—After the ground was well dug and firmed by rolling the surface in this fine weather, the Onions were fastened by the roots, without burying the stem at all, a secret for obtaining fine bulbs instead of thick long necks. We often do this in the early spring, but we get them rather larger when they are planted in autumn for the roots to get firm hold before winter.

Celery we earthed-up, some wholly, especially the dwarf, but the tall red only partially, to enable the heart to rise well. At this season it is well to take advantage of the dry weather for this purpose, as the dews of night will partly supply the waste by evaporation during the day. There will also be little or no danger of bolting, or of seed-stems appearing in consequence of dryness at the roots.

FRUIT DEPARTMENT.

We have not been able to remove a second sprouting of little shoots from bush and pyramidal trees as we wished, since the more air and sunlight there is admitted, the better is it for the buds to be left. The weather was so tempting that we gathered the most of our hardy fruit, though from present arrangements we have been obliged to store it away temporarily, as we feared that after a week of frosty mornings there might come close, damp weather when the moon appears in the evening instead of in the morning. The careful handling of all the keeping fruit is of much importance. One singular fact has happened

as respects some of the latest Pears. Though hard as flints, a great many dropped lately quite prematurely, and if you touched them they seemed to have no hold of their footstalks. We attribute the fact to a chill which they received during the continued cold rains. We should be glad to know if such premature dropping has happened elsewhere. This has taken place more with late Pears than with Apples, and has chiefly been confined to the latest kinds that keep well on to spring. The fruit seem perfectly sound.

Strawberry Plants.—The dry weather made us water the pots, contrary to our wishes; but they were becoming too dry, almost so much as to impoverish the bud. Too great dryness is not desirable even in winter. Cleared the plants of weeds and small runners that made their appearance. The sooner such plants can be brought under shelter the better, but we can rarely accomplish such work early. Even when the plants have been placed in earth-pits and protected by old sashes, we often lose many of them by the incursions of mice and rats, which eat the buds they would not touch when exposed. When frost is apprehended, however, we like to have some bundles of straw or litter to throw over the plants, of which a small quantity will be sufficient. Such protection will not keep out much wet, in which case the pots may be laid on their sides. A cool, dry place, however, under glass, is the best of all places for them, as when they are somewhat dry a sharp frost will not injure the roots much.

Planting.—As soon as the leaves begin to fade, though still retaining a good amount of green, is the best time for replanting and fresh planting. For the modes of doing so we must refer back to previous notices and volumes. For dwarf fruit trees in the open air the simplest mode is station-planting on little raised mounds, and encouraging the roots to keep near the surface by surface-mulching. Such a mode will involve the least trouble as regards replanting, root-pruning, or shoot-and-branch-pruning. Get a good crop from a tree almost as large as you want it, and under the above treatment you will have enough of strength for fertile buds, without any great need of the knife either above or below ground.

ORNAMENTAL DEPARTMENT.

With a sharp frost every morning, and bright sun every day, the air was so dry that nothing has suffered out of doors, except the Coleus, which is considerably injured. Even Heliotropes up to the 14th have been little injured. With the change of the moon we expect that we shall have less frost in the morning for some time to come, and if so, but for falling leaves the flower garden will be interesting a little while longer, as it has even now a good deal of bright bloom.

Leaves driving over a lawn tell us, however, what is coming; and however beautiful the colour of these leaves while on the trees, they sadly spoil the beauty of a smooth green lawn. When only few in number, it is the most expeditious plan to pick them up by the hand and place them in an apron or basket. Some hundreds of leaves scattered over a lawn may thus be quickly removed, when the attempt to sweep them would require much time and labour. When the grass needs mowing, and the leaves are on it, the mowing machine will take them out of sight. There could be no better autumn weather for using the machine all over, as the grass will grow slowly after such frosty mornings. Of course, when, by-and-by, fallen leaves are thick, the rake and the broom must be used, but when there are only a few, hand-picking will be the most efficient plan.

Cuttings for Flower Garden.—Our earliest-struck have had plenty of air during the day. Our latest that were put in cool places under glass, in order to give them a better chance, have had a little air at night, and scarcely any during the day. We want the sun with its heat to incite fresh growth and rooting. There is little chance of drawing cuttings by mere sun heat, and very little air will prevent any accumulation of moist vapour. Much may be done by thus economising sun heat, but it cannot be done when air is given as a mere matter of course, and the cuttings of a week ago or of yesterday and those inserted a month or six weeks since are treated alike as to air-giving. Rather than give fresh cuttings much air or shading, we would rather slightly sprinkle or bedew them with water once or twice during the hottest part of a sunny day, and thus lessen evaporation, whilst giving them the greatest amount of light they could bear. It would be well if the simple principle were acted upon—that every bit of shading not absolutely wanted impedes and hinders the rooting process. How often does shading, applied when really necessary, remain on for hours when it is doing injury. All needless shading, it should be remembered, only tends to deprive a plant of its vigour.

Calceolaria Cuttings.—The inquiries about these remind us that the time for putting them in is approaching. We never saw the plants better supplied with young shoots suitable for the purpose. We generally put them in about the end of the month in a cold pit, as frequently mentioned. We have no place to spare for them as yet, but if we have no severe frost, a few days later or earlier will make little difference. We find, however, that the cuttings give least trouble, and on the whole do rather better, when they keep plump and root but little until the days lengthen.

Where much is done with bulbs in the flower garden, and it is desirable to keep the bedding plants as long as possible, it is a good plan to set the bulbs on a bed of rough loam and leaf mould, cover them over, lift, and plant them with balls. Fine, strong, early growth is thus secured.

Besides routine, cleaning and watering, and getting plants in pots at all tender under, or ready to go under, protection, there has been much potting of Primulas, Cinerarias, and top-dressing Poinsettias, Euphorbias, Cypripediums, &c., for winter blooming. Rivina humilis is now lovely with its long racemes of scarlet berries, and from these berries young plants may be had in myriads.—R. F.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Hardy Trees and Shrubs, &c.*

Jean Verschaffelt, Faubourg de Brnxelles, 134, Ghent, Belgium.—*Catalogue des Plantes—Prix-courant pour l'Automne*, 1871, *et Printemps et Eté*, 1872.

Godwin & Sons, Ashbourne, Derbyshire, and Angel Road, Edmonton, London.—*Abridged Catalogue of the Best Roses*, 1871-72.

Stuart & Mein, Kelso.—*List of Select Gladioli.*

W. Chater, Saffron Walden.—*Catalogue of Hollyhocks and Roses.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

NOTICE.—We have declined receiving three packages of fruits, &c., sent us to be named, as they were not carriage paid.

ASPARAGUS SPINACH (*W.*).—It is all that Spinach can be expected to be, but the flavour hardly justifies the name.

"BRITISH WILD FLOWERS" (*A. L.*).—Of the sixth volume, twenty numbers have been issued, and six numbers of the seventh.

FLOWERING SHRUBS (*M. E. K.*).—We know of no work devoted to them exclusively. Glenny's "Handbook of the Flower Garden and Greenhouse" includes them, and so does the "Cottage Gardeners' Dictionary." Each is cheap.

PRUNING GOOSEBERRIES (*J. B. D.*).—Your Gooseberry plants are probably two years old, in which case you ought to thin out the young shoots if they are crowded, cutting the others back to half their length. The bushes will require to be pruned once a-year in winter, merely thinning out all superfluous shoots, and cutting an inch or two from the points of those which remain. Always study to obtain a compact, well-proportioned bush, and avoid crowding in the centre.

VINES (*James Dickenson*).—Add Black Damascus and Trebbiano to your list. The Muscats you mention are distinct.

OVERCROPPING VINES (*An Anxious Learner*).—Your young Vines have done remarkably well; and the reason that the Grapes have not coloured this year is that you have overcropped the Vines. You should only have taken two or three bunches from each rod the first year of their fruiting, and from 8 to 12 lbs. of Grapes the following season. As the young wood is strong and well ripened the Vines are all right, but you must be content with a very light crop from them next year.

SURFACE-DRESSING INSIDE VINE BORDERS (*H. W. C.*).—The best time to surface-dress Vine borders is immediately after the Vines are pruned, and the glass and woodwork of the house have received a thorough washing. As you used fresh horse droppings, no doubt it was Mushroom spawn that appeared in your borders. It would not injure the Vines, but it exhausts the compost, and we should prefer the border to be free from it. We surface-dress our Vine borders with the following compost annually, after removing 3 or 4 inches of the old material from the surface:—Equal quantities of fresh cow and stable manure, as free from straw as possible, are thrown together in a heap: it will soon heat violently, but we turn it over daily until it is pretty well decayed; it is then mixed with an equal quantity of turfy loam, when it is ready for use.

BLACK MUSCAT GRAPES CRACKED (*R. S.*).—Some varieties of Grapes are more liable to crack than others, and various causes may be assigned for their doing so. As your Grapes are well coloured and have a fine bloom on the berries, mildew would not be the cause. We think in your case the cause is too much moisture in the atmosphere of the house. Be careful when watering the plants not to spill any water; and in damp weather you should make up a fire in the forenoon when the ventilators

are open, allowing it to go out after midday. Always water the plants in the morning. For a good late Grape, later than those you have, we recommend Madresfield Court Black. For very late use, in February or March, Lady Downe's is the best.

Vines for a Cool Vinery (*C. R.*).—There is no black Grape that can be recommended to ripen in your house before Black Hamburgh. You may try the Muscat Hamburgh, and it cannot be too well known that Madresfield Court Black Muscat, though a late Grape, ripens well in a cool house. Of White Grapes to ripen before Buckland Sweetwater there is White Frontignan and Royal Muscadine. The latter, though not a showy Grape, is still a good hardy sort for a cool house.

Potato (*W. J., Shepherdswell*).—We cannot be certain of the name of the Potato you sent, but think it is Douglas's Irish Kidney. Do you not think it very hollow in the eye and wasteful in dressing? As you require a change of seed we would recommend you to change the sort at the same time.

Trellis for Peach House (*W. C.*).—The best material for your trellis is iron wire trained horizontally across the rafters, and fixed 9 inches apart and 12 inches from the glass. In your lean-to house, with trees trained to the back wall, you ought not to trellis the house more than half the distance up the rafters, leaving the upper portion of the roof clear to allow the sunlight to reach the trees on the back wall.

Roses (*G.*).—Yes, we think Bessie Johnson promises to be a late as well as an early bloomer. We know that flowers were upon it on the 10th inst. at Mr. Curtis's, the South Devon Rosery, Torquay, who, you will remember, raised it.

Clay Soil and Lime (*X. Y. Z.*).—The mixture would be a good top-dressing for light land; and the clay, after being burnt and mixed with lime, would be equally good for heavy land.

Errata.—In the description of Preston Hall, page 260, third line from the beginning, read "right-hand side" instead of left; and at page 262, and tenth line from the top of second column, read "upwards of 70 lbs." instead of 60, the bunch of fruit having considerably exceeded that weight. At the bottom of first column, page 273, read "frame" for 'pane.

Cherries for a North Wall (*A. F. B.*).—Morello is the only one worth growing on a north wall. For a west wall you can have Green Gage Plum and the Purple Gage.

Fruit-growing for Profit (*J. H. C.*).—From the little information in your note, we warn you not to invest your money as you suggest. We shall publish soon some notes on market gardening.

Planting Flower Beds (*Amateur, Cork*).—We have no doubt that the bed would look well. We have no faith in Myosotis sylvatica for the corresponding bed, but would recommend the common M. palustris, only it requires moisture, which can be had by mulching. M. azorica also would do, only both must have the seeds picked off. The other year we noticed a beautiful border of M. palustris at Ashridge Park in August; we noticed, however, that it was well watered. Mr. Fleming used it largely, and with fine effect, at Trentham. With some attention the Forget-me-not will last quite as long as Viola cornuta, and the latter will stand longer if fresh planted every year. To continue regular and well it should likewise have the seeds removed. If your fancy stones are of a dark colour, or if you make them black with a coat of tar, or, if the smell be unpleasant, with lampblack and oil, then you could not have a more beautiful ring inside of them than Cerastium tomentosum. If the stones are of a light whitish colour, then Oxalis corniculata rubra with its dark foliage would look well, with the Pyrethrum inside.

Frame for Bedding Plants (*I. H. M.*).—We would recommend you to have the floor of the pit or frame for preserving plants through the winter a little above rather than under the ground level. We would have no fermenting material beneath; it will cause more harm in winter by sending up damp than it will benefit the plants by the heat. You cannot have anything better for setting your plants on than dry ashes, and kept as dry as possible by taking your plants out as you water them, and letting them drain before you return them. They will be a little safer as respects the roots if plunged to the surface in cocoa-nut fibre. All the hardier bedding plants may be so kept, and there is no better plan for Calceolarias. A little house that you could go into, with a small flue or a hot-water pipe, would in the end be more serviceable and economical, as mats for covering are becoming dearer every year, and one mat will not be sufficient in severe weather without litter over the mat.

Heating an Aviary (*A Subscriber*).—We are not quite sure if you wish to heat A and C, as well as the glass-covered part B. A small conical boiler with the fire inside, with indiarubber fastenings for the pipes, would suit you, as you wish all to be moveable. In all such boilers exposed and set aboveground there is a loss of heat, unless there is a non-conducting covering placed over them, and then the pipes must be higher in the house. If against B, you could place a small furnace and one of Rivers's small flat boilers over it, you could heat all the places comfortably. For economy we would place a brick Arnott's stove in B, and if fed from the outside all the better; if birds are there, place a wire guard round A. If you want heat in A and C, then have an 18-inch opening at the apex of the C roof, and one close to the floor of each department, and the circulation will be ample, though it would be difficult to heat the wire-covered place. This would be the simplest plan. An iron stove may be used instead of brick, but the brick would be the most kindly; and the bricks could be taken down, though not so easily as the iron stove. An iron stove 15 inches square, with a fireplace of 9 inches in the centre, and height of 24 to 30 inches would be ample. It would be best square, so that the flat top might have a vessel of water placed upon it.

Heating Small Greenhouse (*H. G., Chichester*).—Use Shrewsbury's gas apparatus. If you write to the maker and tell him the size of the house, &c., he will inform you of the size and price of the apparatus. (*J. Tart*).—Use Shrewsbury's gas-heating apparatus.

Heating Workshop (*An Old Subscriber, Camden Road*).—Being nearly 20 feet square, one large Shrewsbury's gas-heated apparatus would suffice. Tell the maker the size of the workshop.

Slow-combustion Stove (*Amicus*).—We cannot give you any further details of the stove you inquire about. A good Geranium of the Jean Sisley shade of colour in the list we gave last week, is Blazer—the finest of the bright scarlets.

Rats Barking Fruit Trees (*F. H.*).—If you do not wish to destroy the rats, which we presume are water rats, you may dress the stems with paraffin oil, or you may wrap the stems with a hayband, and coat it all over with coal tar. The rats will not touch the trees, as in doing so they must get the tar on their coats, which they keep most scrupulously clean. If they are ordinary rats poison them by all means.

Liliums (*O. P.*).—The Liliums you name will in a greenhouse start into growth in December, or between that and March, according to the temperature. If the pots are protected from frost it is sufficient.

Gloxinia, Amaryllis, and Vallota purpusea (*Bulb Amateur*).—Gloxinias to flower in July should be potted in February and forwarded in a stove, or a pit with a stove temperature. Those for August should be potted in March, and those for September in April. The Amaryllis you must retard by keeping them dry in a cool stove until six weeks before you wish them to flower, and then give a brisk bottom heat to start them. Vallota purpurea will ordinarily flower in a greenhouse in September, but may be had in flower earlier by placing it in a gentle hotbed. The plants ought to be in pots when you get them, and if not, should be potted as soon as received. Pot the Liliums now, winter them in a cold pit or cool house, and protect them from frost. Grow them in a greenhouse for July, in a cold pit for August, and out of doors for September flowering. Twelve Liliums are not too many to make a good 11-inch pot. Of Vallota we have a score or more flowering bulbs in a like size of pot. Amaryllis and Gloxinia should be single bulbs.

Pruning Newly-planted Fruit Trees (*F. R.*).—We advise you to prune them at once, and mulch the ground round them with the stable dung you speak of, but we should prefer its being rather littery.

Viola cornuta and alba Dividing (*A Constant Subscriber*).—The best time is now for securing to each division a fair amount of roots. For late summer flowering March is preferable. It is better for a head gardener to enter a new situation in autumn than in spring. We cannot name the twelve best Lilies for greenhouse decoration in the spring. Liliums are summer and autumn flowering.

Preserving Geraniums (*A. B.*).—Without a greenhouse, and being ignorant of the convenience you have, we cannot say how you are to proceed in order to have strong plants in the spring. Either you will need to keep them in a room, dry and safe from frost, or packed in dry sand in a cellar, all the leaves being picked off. Keep them there safe from frost until March, then pot and place them in a frame over a gentle hotbed.

Pansies (*R. T. W.*).—They are common, and only suited for borders.

Peaches for Cool House (*F. C., Maidstone*).—Dr. Hogg, Early Grosse Mignonne, Royal George, Bellegarde, and Walburton Admirable.

Cocoa-nut Fibre Refuse (*Mrs. S.*).—Apply to Messrs. Barsham & Co., Kingston, Surrey.

Flower Garden Plans (*I. I.*).—Tastes differ too much for us ever to furnish a plan. For five postage stamps you can have "Flower Gardening for the Many" free by post from our office. It contains plans from which you can select.

Pandanus elegantissimus, Maranta Veitchii, and Terminalia elegans (*A Many-years Subscriber*).—The Pandanus is propagated by offsets, also the Maranta Veitchii. They should be taken off with a fair amount of root, and placed in small pots filled with sandy compost. Put them in a warm close frame, keep them moist, and harden them off after they have begun to grow freely. Terminalia elegans is increased by cutting off the growing points, with the base of the cutting firm but not very hard; insert singly in a small pot placed in one of larger size, covering with a bell-glass, and placing it in a hotbed of from 75° to 85°. They are all stove plants, and require a compost of two parts loam, one part sandy peat, one part leaf soil, and half a part each lump charcoal and silver sand. Good drainage is necessary, with moderate pot-room. Water freely when growing, maintaining a moist atmosphere, and shading from bright sun. Temperature 60° to 65° in winter, 65° to 70° at night, 75° to 90° by day in summer. Remove all the Walnuts from the husks and store them in layers of dry sand, in a dry cellar.

Grafting Spruce with Picea nobilis, Pinsapo, &c. (*J. D.*).—We have no doubt of the possibility of the graft, but we question its utility, as you will be obliged to use the side branches or growing points of the side branches of the Piceas, and such never form anything but a branch-like tree. Place the stocks in a cold frame, cover them with another frame of larger dimensions, or a frame in a cold house will serve just as well. Graft from the end of August until the scions begin to grow. We consider late in summer the best time to graft. Whiten the glass with a size of skim milk and whiting. Bind with matting and cover with grafting wax. Leave the grafts in the frame until the union is complete and the scions are growing, then admit air and harden off. Lilacs and Syringas are propagated by layers and suckers. The former may be made, and the latter taken off and planted now or in spring before they begin to grow.

Hardiness of Cytisus (*Brisbane*).—You do not say what species it is, but we presume it is C. racemosus, or some of the evergreen kinds used for greenhouse decoration. If it is the kind named we think it likely to be hardy against a west wall. The pot should have enough soil placed against it to cover the rim, and then be mulched with litter. In severe periods protect with mats, removing them whenever the weather is mild. We are not certain that it would survive severe weather with the protection named; and if you do not wish to risk losing the plant, we should not hesitate to cut away all the roots that are beyond the pot, and any irregularity of growth, and then remove it to the greenhouse. If you have duplicates we should test its hardiness, for we are convinced that many so-called greenhouse plants are hardy in well-drained soils.

Phloxes from Seed (*J. W.*).—We can only account for the seed not germinating by its being bad, which is often the case. Sow next March in good light loam, covering the seeds about a quarter of an inch with fine soil, water gently, place in a gentle hotbed, and keep just moist. Place the pots near the glass, and when the seedlings have a pair of rough leaves prick them off in pans at about an inch apart, return them to the hotbed, and when established harden them off and plant them out of doors. Try again, but with fresh seed. Old seed is useless. We do not credit the assertion you allude to. Supplying an article is essential to a seedsman's credit.

Names of Fruits (*Cacopomologist*).—*Apples:* 1, Trumpington; 2, Golden Winter Pearmain; 3, Marmalade Pippin; 6, Dutch Codlin; 7, Royal Russet; 8, Golden Russet; 9, Yorkshire Greening. *Pears:* 10, Napoléon; 11, Doyenné Gris; 13, Princess Charlotte. (*G. P. G.*).—

Pears: 1, Bois Napoléon; 2, Beurré Diel. *Apples:* Both numbers appear to be Lewis's Incomparable. (*E. B. B.*).—Your Apple is not Catshead, but a good specimen of Gloria Mundi. (*A. M., London*).—Lincolnshire Holland Pippin. (*Isca*).—1, Soldat Esperen; 2, Princess Charlotte; 3, Bellissime d'Hiver; 4, Dunmore. (*Mrs. Phelps*).—1, Reinette Blanche d'Espagne; 2, Margil; 3, Norfolk Colman. (*A. M.*).—1, Calebasse; 2, Duyeuné Gris; 3, Bergamotte Cadette; 4, Brown Beurré; 5, Dunmore; 6, Passe Colmar; 7, Lady's Finger. (*B. C. Gidley*).—Through the Pear being addressed to Dr. Hogg instead of to "The Editors," it was not unpacked during his absence, and was rotten on his return. (*Clay Bank*).—1, Tonneau; 2, Hampden's Bergamot. (*A. B.*).—Black Hamburgh. (*C. B.*).—4, Duchesse d'Angoulême, small specimen; 5, Jersey Gratioli; 6, Court of Wick; 7, Fondante des Charneuses; 8, Autumn Colmar; 11, Beurré Bosc; 14, Dumelow's Seedling; 15, Baddow Pippin; 16, Figue d'Alencon; 17, Vineuse; 18, Golden Winter Pearmain; 19, Reinette Grise. (*John Jeffries & Sons*).—No. 1, Mère de Ménage; 2, Duncan. (*James Dickson and Sons*).—Harvey's Wiltshire Defiance. (*W. W.*).—1, Thompson's; 2, Bergamotte Cadette; 3, Belle de Noël; 5, Beurré Diel; 6, Nouveau Poiteau; 7, Knight's Monarch; 8, Brown Beurré; 9, Nouveau Poiteau; 11, Louise de Prusse; 12, Beadnell's Seedling; 13, Winter Nelis; 15, Comte de Flandre; 17, Beurré Diel; 22, Comte de Paris; 25, Calebasse; 28, Conseiller de la Cour; 32, Winter Nelis; 34, Urbaniste; 43, Beurré des Charneuses; 45, Figue d'Alençon; 46, Jean de Witte; 47, Knight's Monarch; 48, Arbre Courbé. (*Fisherman*).—2, Sykehouse Russet; 3, Royal Russet; 4, Holland Pippin. (*A. M. R.*).—1, Cellini; 3, Winter Hawthornden; 4, Holland Pippin; 6, Dumelow's Seedling; 7, Hawthornden; 8, Augustus Pearmain. (*B. Godbold*).—1, Passe Colmar; 2, Susette de Bavay; 3, Fondante d'Automne; 4, Urbaniste; 5, Bellissime d'Hiver; 6, Duchesse d'Orleans. The Plum is McLaughlin.

NAMES OF PLANTS (*Aperio*).—Saxifraga pedatifida. It is not a British plant, and if you have found it in a wood it must have first escaped from some garden. As to the latter part of your inquiry, there are several other species of dactyloid Saxifrages, several of which are very closely allied. Examples are S. geranioides, ceratophylla, pedemontana, pentadactylis, capitata, adscendens, &c. (*J. C. C. S.*).—1, Lastrea Filix-mas (typical); 2, L. spinulosa; 9, L. dilatata; 4, L. remota; 6, L. Filix-mas, very young, certainly not L. Oreopteris as supposed, the character of venation separating it; 3, 5, and 7, Athyrium Filix-fœmina; the last very young, the first the most typical; 10, Very probably Lomaria alpina; 8, Too young to be identified; No. 4 is decidedly a good thing, being in a wild state excessively rare, and has only been recorded from one locality in England (Windermere). It has been found, however, in Germany and in the United States. (*O. P.*).—2, Meyenia Vogeliana; 3, Gesnera (or Isoloma) spicata; 4, Peperomia Saundersii, also known as P. argifolia var. argyrea; 5, Apparently Brugmansia suaveolens. No. 1 was not received. (*R. B. L.*).—Oxalis sensibilis, native of the United States. (*J. W. Abrahams*).—1, Ligustrum robustum, native of India, especially southern India and Ceylon; 2, No doubt it is Brugmansia suaveolens, or an ally, judging from the leaf alone. (*W. W., Putney*).—1, Adiantum cuneatum; 2, A. curvatum. (*Elizabeth M. Dance*).—Your Fern is Nephrolepis exaltata, a plant widely diffused in the tropics generally. Layer any of the "fibrous pieces" you speak of in small pots, attaching them there by a small hooked peg or a stone; allow them to root and get well started into growth before severing them from the parent plant. We cannot undertake to name florists' flowers, even if the specimens are in a good state, which yours were not. (*W. B.*).—Your flower is that of Anemone pavonina (Lois.), otherwise A. fulgens (Dec.), native of southern France and northern Italy. It was a somewhat unusual occurrence for such a plant to be blooming at this season of the year, we should suppose. It seems to have mistaken autumn weather for spring time, as your flower appears to be quite fresh. (*J. R. Neeve, Calne*).—1, Hypolepis anthriscifolia; 2, Lastrea dilatata; 3, Pellæa hastata; 4, Asplenium flaccidum; 5, Pteris serrulata var. cristata; 6, Adiantum hispidulum; 7, Lastrea Filix-mas; 8, Pteris cretica albo-lineata; 9, Not recognised. (*R. A. K.*).—Calceolaria chelidonioides, native of Peru and New Grenada.—H. B. K. (*W. B.*).—1, Asplenium flabellifolium; 2, Pteris biaurita; 3, Thunbergia grandiflora. (*J. Foster, Collumpton*).—We take your plant to be Cyrtanthera magnifica, more generally known as Justicia carnea (Hook.), an old-fashioned favourite in gardens, a native of Brazil. It is only the first part of "Paxton's Botanical Dictionary" which you see advertised for 2s., not the whole work. (*Connemara*).—Your shrub appears to be Calothamnus quadrifidus, a native of Australia, and frequent in greenhouses at home. Your account of a hedge of it sounds very strange to us; yet the twig sent is certainly as named, so far as we can tell. (*W. F. R.*).—From the imperfect specimen sent we can only say that we believe it to be the perennial Sunflower (Helianthus multiflorus plenus).

POULTRY, BEE, AND PIGEON CHRONICLE.

FEATHERS.

It is a remarkable fact, that although goldfinches and linnets produce their absolute fellows, and that there is no variety of colour, no cloudiness here, no mossing there, no deficiency, no excess, yet in breeding fowls the plumage is not so perfect. In wild birds, again, there is no throwing back. It may be they came originally from the same, but if so, Nature has forgotten it, for no trace of the beginning is ever visible.

All birds in a state of nature come perfect, so perfect that the most practised eye can detect no difference; yet we know that fowls can seldom be bred to an exhibition standard unless two yards are kept—one to breed cocks, the other hens. We speak of feather. We know that in Pencilled Hamburghs pencilled tails were called for in the hens and pullets, and they were accomplished, but at the same time clear hackles were wanted, and when the tails were pencilled so were the hackles. There is in Nature a sort of "compensation balance," or a vindication of herself. She will not allow us to improve her work, or to make serious inroads on that which she has made perfect. Where it is sought to increase size and weight, it has to be done according to rule. It has been attempted to increase the body, and to leave all other parts as they were. Thus in Dorkings 2 or 3 lbs. were to be added to the weight of the body, but it was ordered the legs should remain short. It could not be; the increase must take place everywhere, and must be spread over the whole frame. We have obtained the weight, but we have lost somewhat in symmetry, especially in shortness of legs.

If this be true of size, it is still more so in feather. Enthusiasts have tried to have one part of the body dark and another light in the same bird. It may not be. No greater exploit was ever performed in the way of feather than that of Sir J. Sebright, when he tasked himself to make or compose the Bantam that bears his name, and succeeded. He not only chose his colours, but he named the order of them; golden or silver feathers delicately edged with black. We have only to do with feathers, and therefore treat of no other point. It required delicate handling; the Black hen was wanted to restore and deepen lacing, and she did it, and then the bird was let alone for a year or two, and the lacing became perfect. The difficulty was to keep it so. It would only last a short time. Those who only know the Sebrights by seeing them in perfection have little idea what a poor shabby bird it becomes if left alone. All the lacing disappears, the round tail becomes a sickle, the comb is a single one, and the delicate correct lacing is a piece of patchwork of black and red, with here and there enough of spangling to justify its being called a spangled fowl.

As the beards of fowls are composed of feathers they come under our notice; Crève-Cœurs, Polands, Houdans, all require these appendages, yet they sometimes appear without them. It is disqualification in any competition. What's in a feather? Much. The finest Black Red Game cock that ever was seen is disqualified because two or three brown feathers are discovered on his breast. The Brown Red having a black breast is disqualified and disgraced by the fact of having one. Then more or less of brown feathers on the breast of a Grouse Cochin cock disqualify. The least mistake in the colour of a Silver-Grey Dorking, a black breast in a Golden-spangled Hamburgh cock, a clear hackle in a Silver pullet, mossiness in either, are all disqualifications, and will cost a prize, it may be a silver cup. In like manner, if Cochins or Brahmas lack the feathering on the legs they are hopelessly excluded from all chance of distinction. There are degrees in this tyrannical ruling. In the human being leaden combs, skilfully compounded washes, and the various appliances of an elaborate toilette may so increase and darken the down that it may do duty for moustache or beard; but in fowls, judges are pitiless, no apology will be admitted for a beard, and no excuse for deficient feathering.

Feathers, however, have their freaks. Instance, the Emu Cochine. Many of our readers will remember the beautiful bronze of Daphne and Apollo. The god is about to put his hand on her shoulder, but her prayer is heard, the bark is covering her body, and her fingers are becoming branches; so the Emu Cochine first had their tails and flight feathers changed into hair or silk, and then soon after all the feathers disappeared to make room for the same material. We had in the same hen and from the same parents perfect Emus and perfect Cochins. Another peculiarity in feather is, that all cocks of black plumage are prone to have coloured feathers in their hackles, saddles, and sometimes in their wings. This is true of Spanish, Polands, and was so constantly the case with Black Cochins it destroyed the breed. The hens were always black, but the cocks had white under-feathers, and these after the first moult mixed with the outer plumage to the great detriment of the breed. In many breeds where a white feather is a detriment it comes like grey hairs to men of a certain age, and allowance should be made for them in the yard. There is neither pity nor allowance at the exhibition.

WORKING-CLASS POULTRY PRIZES.

APPEALED to by Mr. L. Wright, I have given some thought to this subject. It seems to me that it is not a matter which needs to be met by a general subscription, but rather, like prizes for cottagers at horticultural shows, it is a subject to be considered by the committee of each town show; I say town show, because it is the townsman—artisan, mechanic, or other workman—that I have in view. Let, for instance, a dozen pens, or any number, taking whatever room can be spared, be marked "Working Men's Poultry." I would have no entrance fee at

all, but as there might be a glut of valueless birds sent, the committee should have power to admit to, say, their dozen pens, the best dozen birds (cock and hen), that were offered. The prizes should be money, not necessarily large sums, and in addition a framed and glazed card well got up with the exhibitor's name on, that of the show, and first, second, or third prize as it might be. I plead for the card framed, because I know such gives a man pleasure to hang up in his cottage, and the money could be put by the husband into the good wife's hand towards something most wanted. Perhaps there is a small doctor's bill, or the landlord frowns about that 10s. left of last quarter's rent. I am sure the thing could soon be done; let Bristol try, and may I be there to see the result.—WILTSHIRE RECTOR.

SILVER-BUFF COCHIN-CHINAS.

IN one of your replies to correspondents you write, evidently to some person desirous of learning into what varieties the Buff Cochin-China fowl sports, "There is no such thing as Silver-Buff." Now, I readily admit that the language of all fanciers is inaccurate; that in describing their pets they use phrases and compound words that Dr. Johnson would shudder at; but why "Silver-Buff" should be tabooed and "Silver-Cinnamon" be admitted it is difficult to see, and you allow Silver-Cinnamon! Both epithets, like "Silver-spangled Hamburgh," "Silver Sebright Bantams," "Silver varieties of Pigeons," are attempts to convey, what no human speech can fully express, an idea of one phase of natural beauty. To describe one shade of colouring, fanciers have borrowed a metaphor from gold; to describe another, from silver. In both cases the epithet gives but a shadow of the truth; but the fanciers, simple folk, are content, and intelligible to each other, and I do not see why they should not be. When you have once seen the ground colour termed "gold," you have no difficulty in understanding what a Golden variety is like, and so it is with "silver." When the compound "Silver-Cinnamon" has once been heard, and the feathering described by it seen, there is no difficulty in understanding what sub-variety of the Cinnamon-coloured Cochin is intended. Cinnamon-coloured is a metaphor which explains itself. Silver-Cinnamon was a good suggestion by some person, familiar with Gold and Silver Hamburghs or Bantams, who wanted to describe that sub-variety which always makes its appearance among Cinnamon birds—*i.e.*, where the neck, back, and tail are like the Cinnamon parents; but the breast, fluff, and legs are French white. Now, precisely the same variation occurs when we try to breed the different shades of Orange or Lemon-Buff. Pullets will appear which have the breast, legs, and fluff French white; whilst neck, back, and tail are of different shades of yellow. Silver-Cinnamons such pullets cannot be called, for there is not one feather on them which resembles the brown or chestnut-coloured bark of the cinnamon; why should the birds not be called Silver-Buff? They are entitled to the moiety Buff, because their hackles, saddles, and quills are of different shades of Buff. Why should the other moiety, Silver, be denied to them, when it is granted to their congeners who bear exactly the same relation in colour to their Cinnamon parents which these do to their Buff ancestors? Surely anyone who has ever seen a Birmingham Show knows that birds with whitish bodies and yellow necks do occur. Why should they not be called Silver-Buff?—SILVER-BUFF.

BANTAMS VERSUS GARDENS.

I AM afraid that "H. C., *Galway*," had not an attack of genuine Bantam fever, only what looked like it. Clearly he expected an alteration of nature, and that he should have a breed of fowls not granivorous chiefly and carnivorous partially, but the reverse. Now, I cannot warrant Bantams to devour heaps of slugs, but this I say, that under the limitations I mentioned in my article of June 1st, 1871, they do infinitely more good in a garden than harm; and add to this the pleasure of keeping them, and,—the eggs,—such eggs, too, so superexcellent.

Writing in this Journal as far back as December, 1862, I mentioned that I caught a brood of half-grown Blacks clearing a mignonette bed of caterpillars. I have also been followed all round the garden by a lot of chickens which eagerly devoured the green flies brushed off and shaken from my rose trees. Certainly, too, I know that by constantly having Bantams in a garden, it is kept wonderfully clear of all insect pests.

"H. C." not only writes from Ireland, but from western Galway; Ireland is called the Emerald Isle because of its greenness, and its landscapes are so green because of its humidity, and humidity breeds slugs in millions. A dry summer in England thins the slugs, a damp one increases them a thousandfold; but in Ireland, Galway lying to the Atlantic, no wonder there is an abundant crop of slugs there. St. Patrick charmed "the sarpints" from "ould Ireland," but he really should be woke up again to drive away the slugs from Galway. However, as the saint is not likely to be of any more use in this world, I will tell "H. C." how to clear his garden of slugs. Get a barrowful of cabbage leaves, lay them overnight singly near box edgings and wherever slugs delight to dwell. Go in the morning and gather up the leaves, and you will find slugs and snails under each leaf. Repeat this process—the same leaves will do—for a few nights, and "the take" of slugs will be great. Under the limitations I have made in my former article, and not kept in too great numbers, I am quite sure that Bantams do much more good than harm in a garden.

I have generally found that the people who have tried and then given up Bantams, have in their garden a nagging working man, who is always abusing the little things (the best Sebright I ever bred was killed by such a man), and then for the sake of peace master or mistress gets rid of the birds instead of the man. One such man caused a lady friend of mine to send away some high-class Tumbler Pigeons (*short*-beak Tumblers, mark you), because they opened and shelled his green peas; the real culprits were the jays, which he did not get up early enough to kill or drive away. These men have a born hatred to poultry. If "H. C." had a heap of dry earth in a warm corner his Bantams would not have burrowed as he describes.

"DEVON" inquires if Bantams can be kept profitably for laying. I answer, Certainly. Game Bantam pullets are as good as Hamburghs or Black-breasted Red Game pullets, which I have found equal to Hamburghs as winter layers. Game Bantams are certainly not delicate; but, perhaps, "DEVON" might prefer Blacks, which do not wander so far as Game. Bantams may be fed as other fowls, only they need much less. For more on feeding *vide* my article of July 6th. The warmer, in reason, they are kept, the better they lay in cold weather. WILTSHIRE RECTOR.

P.S.—Since writing the above I chanced to sit next to an Irishman at dinner. I surprised him by asking, "Is Galway famous for slugs?" After explaining myself, he said that being in the west there was probably an unusual supply of those slimy pests.—W. R.

FOUL BROOD.

THIS disease, of which so much has been written in this Journal, appears to be comparatively little known in England, although common enough in other countries. It seems to have spread largely in the United States of America, and to have found its way into Canada. I must happily profess myself to be totally unacquainted with it, nor do I know a single bee-keeper of my acquaintance out of Exeter who has had practical experience of the fell disease. It would not be uninteresting if we could obtain returns from different parts of England and Scotland, so as to ascertain whether this pest is on the increase. Who can tell how long it has been known in Britain? Did it come in with the Italian or Ligurian bees? for it seems to have been long known in Italy. Every reader of Virgil is acquainted with the minute account this poet gives of a disease which seems to have been not uncommon in his time. It has been supposed he was describing the dysentery which has long been known to be fatal to bees, but it may have been foul brood which he had in mind. Among remedies hyposulphite of soda appears to have been successfully used in Canada for the cure of the complaint, but for my own part I should be disposed to break up and burn every hive which I found affected.—B. & W.

BEE SUPERSTITIONS IN FRANCE.—In Brittany, if a person who keeps bees has his hives robbed, he gives them up immediately, because they never can succeed afterwards. This idea arises from an old Breton proverb, which says, being translated, "No luck after the robber." But why the whole weight of the proverb is made to fall on the bee hives, it might be difficult to determine. In other parts of France they tie a small piece of black stuff to the bee hives, in case of a death in the family;

and a piece of red on the occasion of a marriage—without which, it is believed, the bees would never thrive.

OUR LETTER BOX.

Books (*W. S.*).—Eaton's book is out of print.

Standard (*A Reader*).—Messrs. Groombridge & Sons.

Tunbridge Wells Poultry Show.—Mr. Samway's Bantams which obtained the second prize at the above Show were Black Red Game, not Black Bantams as stated.

Hackle of Light Brahmas (*M. D.*).—Perfectly white hackles would be a serious objection if brought into competition with pencilled ones.

Fowls Becoming Blind (*C. B.*).—Your fowls have the roup. Formerly it was considered very contagious. It is not so now; some will catch it, but all will not. Lime-white their houses, cleanse them scrupulously, wash their faces with cold water and vinegar, feed on bread and ale, and give Baily's pills.

Feeding Poultry (*A. S. L. M.*).—Your feeding is very bad. Alter it all. Give ground oats in the morning, whole corn, barley, or maize at midday, but no oats, and again in the evening ground oats slaked with water. If you have table and kitchen scraps, give them in lieu of the mid-day meal. If your neighbours fed as you did, we do not wonder they had the same illfortune. Have your fowls grass? Have they a supply of green food? If not, give it to them. Give them a huge sod, cut many inches deep; you will see them eat it all. It will be to them at first like the one day's fresh air and the one good dinner among trees to the 7240 children of St. Magnus Parvus, advertised in June and carried out in October—cannot have enough of it.

Crossing Brahmas and Dorkings (*A. F. B.*).—It is believed the produce takes more after the hen. The Dorking is the best table fowl, and the intent of the cross is to make a fowl for food. The Dorking should predominate; put them up then—Dorking pullets and Brahma cock. The first will give delicacy of flesh and flavour, the second hardness of constitution.

Feeding Brahmas (*W. H. D.*).—You will find the Brahmas hearty feeders, not so hearty as the Cochins, but they will make you a good return for the food they consume. Give them in the morning ground oats mixed with water, at mid-day house scraps of any kind, in the evening ground oats again. You say they have limited space, and you want eggs. Do not be persuaded to use stimulants. They do mischief and nothing else. Supply your birds with lots of road grit; give them large growing sods of grass, cut them with plenty of earth. Whatever you give, throw it down in lumps, and let the birds scatter it. While they are scratching and watching they find food that costs you little or nothing. If you begin to give stimulating food you will spoil the fowls, be they ever so good.

Legs of Japanese Bantams (*H.*).—The legs should be so short, and the wings should be carried so low down, that the former should be invisible. They should, nevertheless, not be booted.

Brahma Crooked-breasted (*J. R. L.*).—A crooked breast is only a positive disqualification in a Game cock; it is a disadvantage in any other. It is a disputed point whether the breast of a Brahma cock should be black or speckled. We lean in favour of the latter.

Colour of Crêve-Cœurs (*G. M.*).—The Crêve-Cœur is accepted in England as a black fowl, and we do not think the Cinder (?) Crêve-Cœur would have a chance against them. They must go to the "refuge for the destitute and friendless,"—the Any other variety class.

Fowls Turning Black and Dying (*A. D.*).—Your fowls get at something that is either poisonous or so injurious as to cause death. They have every appearance from your description of dying from the former cause. Remove some of them, and see if they suffer when they are elsewhere.

Aylesbury Ducks (*S. B. S.*).—There is no Grey Aylesbury Duck. The pure bird was always white. Grey Aylesbury is an invention.

Weight of Dorking Cockerel (*J. J. W.*).—The weight (9 lbs. at five months old), is enormous for a bird of that age, and far above anything we have ever seen in Silver-Greys. We should almost doubt his being Silver-Grey. Look closely. Is there no suspicion of white on any part of his breast; no white shade in his tail; no straw hackle? We advise you, if you have any doubt as to his colour, not to run the risk of his being disqualified as a bird of plumage, but, if all be well with him, to put him in general competition.

Worms in Fowls (*W. C. D.*).—We know no vermifuge so strong as camphor, and therefore advise you to administer it freely to such of your fowls as suffer like the deceased. Dose, two pieces the size of a garden pea. They must have access to some very improper food, as these worms can only be taken in the state of larvæ. What was the colour of them? It is evident they were not developed till they reached the gizzard.

Fantail Pigeons (*Fantail*).—Why at the Crystal Palace Show are prizes of £2, £1, and 10*s.* offered for all varieties except White Fantails? These have only 80*s.* as a first prize.

Accidents (*Ellen*).—We are very glad that you have asked the question, for there is a book—a waistcoat-pocket book, which every one should have—Smee's "Instructions for Prompt Treatment of Accidents."

Are these Bees Ligurian? (*H. B. C.*).—The bees sent are certainly not at all Ligurian, but that does not prove that your stock or queen is not of pure blood. It is the common practice of those apiarians who send out Ligurian stocks to make up their chief population by the aid of sealed brood comb, or of adult bees of the ordinary variety. As these die out their place will be filled by the pure progeny of the Italian mother. When the first batch of brood from the present queen takes wing from the hive, you will be able to ascertain whether your bees are pure bred or otherwise. As you do not say when you first received your stock, we cannot tell whether you ought to be able to see young bees this season, or if you will have to wait until spring. We do not know from whom you obtained your so-called Ligurian stock, but we believe that you may depend on obtaining a genuine article from Messrs. Neighbour.

Removing Bees to a Distance (*E. S. Tiddeman*).—We would advise you to defer moving your bees till after the first cold or frosty weather in November, except, perhaps, the one of which have the combs fallen on the bottom board; but we should try to move this bodily along with the others, board and post together. Bees, after some days' confinement in wet or frosty weather, are easily moved, and seem to make a fresh *reconnaissance* of their hives. We should place the bees (boards and hives) as they are on straw in a light spring cart, carefully stopping up the entrances, and walk them the whole six miles. The less jolting the better.

Grubs in Comb (*W. L.*).—The grubs you mention are probably those of the wax moth. We would examine the hive itself, driving the bees up among the combs with a little smoke. If the bees are few in number and the traces of wax moth considerable, we should advise you to destroy the hive, as you think of doing. But it may be the grubs have only found their way into the super. In this case we should certainly not destroy the hive, but content ourselves with clearing away the combs from the super. The wax moth is not likely to attack the neighbouring hives, unless they happen to be weak in bees; but we should take care to allow no empty combs to litter about to tempt them to breed and multiply.

REMARKS.

11th.—Cold, dull, uncomfortable day, though without rain.

12th.—Very fine in the early part of the day, and moderately so afterwards, but foggy at night.

13th.—First white frost seen here this season; hazy morning and evening, but fine between, and warmer.

14th.—White fog, clearing off by 11 A.M., and very fine after.

15th.—Foggy morning and evening, and rather so all day, though occasionally bright.

16th.—Rather foggy all day, with a little rain and great dampness.

17th.—Dull morning, very fine afterwards, and so warm as to be rather oppressive. Overcast at 10 P.M. Rain at midnight.

Although very little rain has fallen the week has been very damp, the air being saturated on three mornings (13th, 14th, and 15th), at 9 A.M. and at several other times. The uniformity in the maximum temperature of those days is also striking.—G. J. Symons.

COVENT GARDEN MARKET.—October 18.

This week we have again received heavy supplies of Apples and Pears both from France and the Channel Islands, notwithstanding which, home-grown fruit commands fair prices, and stands of good descriptions are easily cleared. Auction goods, also, have been freely offered, such as Nuts, Lemons, the Opuntia, and Almiera Grapes, the latter not being so good as they were last season. Agricultural reports state that Potatoes are much diseased in some parts; good qualities maintain prices.

POULTRY MARKET.—October 18.

No great change. Game is becoming plentiful, and has some little effect on poultry. If the weather become dry and colder, we may expect an improvement in prices.

From observations taken near London during forty-three years, the average day temperature of the week is 54.6°, and its night temperature 37.5°. The greatest heat was 67°, on the 31st, 1854; and the lowest cold 22°, on the 28th, 1836. The greatest fall of rain was 1.03 inch.

FORCING VEGETABLES.—No. 1.

THE POTATO.

WE are rapidly approaching the commencement of the forcing season, and perhaps it is unnecessary for me to remind all those who have any forcing to do that every preparation should be made without delay. The most successful are generally those who have well matured their plans, and who have everything in a fit state for use. In this and subsequent papers I purpose relating my experience in the forcing of such vegetables as are most in demand in the spring when other vegetables are not plentiful. I shall therefore begin with the Potato, because it is in general request, and is always looked for in its young state with more interest than any other vegetable.

The Potato is capable of being forced in a variety of ways; some prefer to force it in pots or boxes in a vinery or Peach house; others grow it successfully in pits or frames on hot dung beds; but whichever way be chosen, the selection of sound well-ripened tubers of a good sort is the most essential point I believe many sorts have been tried, some of them more on account of the size of their tubers than anything else; but to produce, regardless of the variety, the largest Potatoes within a given time ought not to be the aim of the Potato-forcer; he should strive by selection and cultural treatment to get in as short a time as possible a fair-sized well-proportioned Potato, somewhat dry and floury. For the attainment of this object there are not, in my opinion, for very early production, any better kinds than the old Ashleaf and Myatt's Prolific, as they are both short-topped sorts, and mature themselves early.

The next important point is the soil, not so much as regards its qualities and composition, as securing it early, and packing it under cover before the autumn rains come on. I remember that the very first day I entered a garden to work, my first task was collecting and storing soil for Potato-forcing. That was at Chilstone Park, in Kent, where the first crop was always planted in 12 or 14-inch pots in the following manner:—Every pot was well cleaned, a large piece of broken pot placed at the bottom, and the pot half-filled with leaves, not thoroughly decayed, but sufficiently so to form a rooting medium for the tubers, and to secure drainage. Some may say, "Why not place more drainage at the bottom of the pot, and leaf mould instead of decayed leaves?" This would certainly be easy to do, but the object is to allow the Potatoes every inch of rooting space, and if much space be taken up by the drainage there will not be enough for the number of tubers placed in the pot. Coarse gritty sand, or if such is not to be easily obtained, road-drift should be collected during the summer; and to this add an equal proportion of the soft sand of the locality, the colour not being a matter of importance. After mixing them together add a layer of the mixture 2 inches deep on the top of the leaves, and on this plant the tubers. I have found that three or even four of these in each pot are not too many. If there are three, place them in a triangle, and if four, in a square, as far apart as possible, with the tuber an inch or two clear of the side of the pot. Afterwards fill up each pot with the sand, and, without watering, place the pots side by side in some cool house or pit, where they will be secure from frost. If the Potatoes have sprouted before potting they will soon shoot up through the sand, and may then have abundance of light and air, regulated according to the weather. In a few days the pots may be taken to any moderately-heated structure, such as a vinery or Peach house, and watered as they require it. Should the roots appear above the soil, as is not unlikely if the house is kept moist, a top-dressing ought to be given, and as the haulm gains strength the plants will bear more heat; but great care should be taken not to force them too severely, which is easily done in the case of the Potato, and the crop will be ruined.

Another mode of pot-culture is preferred by some, and it has its advantages where space cannot be allowed at first for storing a number of large pots—it is that of potting the tubers singly in small pots, and afterwards transferring them to the large pots above alluded to. In this case there is the labour of two pottings instead of one, but I have been unable to discover that it is of any benefit to the crop, as some assert it is. On the other hand, when the Potatoes are to be forced on the planting-out system on dung beds, there is some advantage to be gained by placing the tubers in small pots, as above described, if the plants are kept in the pots long enough to form young Potatoes before transferring to the frames. The advantage in this case is that the tubers are fit for use as soon as those grown in pots, but the crop is no better. I have grown them in both ways at the same time, and with this result.

For the first crop I prefer pot-culture—firstly, because the tubers become fit for use early, and the pots can be transferred from one place to another as occasion requires; and, secondly, the ripening process, so necessary to a forced Potato, is more thoroughly under control. This ripening-off should commence when the tubers have completed their growth by our giving gradually more air, keeping a drier atmosphere, and by degrees withholding water. If only part of the crop be required at first, a few of the most forward pots can be selected for ripening, and the yield from pot-culture is generally satisfactory. If sand be used, as recommended, the Potatoes will turn out clear-skinned and good in colour. The middle of December is a good time to start the first crop, and every succeeding crop should be planted according to the demand for the preceding one.

If Potatoes are grown in dung beds, a bottom heat of 60° is very suitable; and while the bed is being prepared, I like to start the tubers in a gentle heat by placing single layers of them in boxes, and covering them with about an inch of soil; their eyes then break regularly, and roots are produced thickly, so close to the Potatoes that when planted out these can be taken up with a trowel and transferred to the frame without a check. It is not advisable to use a great depth of soil in the frame at first, I would rather add soil to the surface as the plants require it, using always an open gritty soil pressed moderately firm. A foot between

the rows, and about 8 inches apart in the row, are safe distances at which to plant. Water sparingly at all times, particularly on the finishing-off of the crop, otherwise, instead of having a firm-fleshed Potato of good flavour, you will have a soft and soapy one without flavour.—Thomas Record.

OPINIONS ABOUT ROSES.

It is always interesting to compare opinions with regard to Roses; and for the sake of inducing others to give their experiences of this year some correspondents have already done so, as the Rev. W. F. Radclyffe; "P., *Essex*;" Mr. A. H. Kent, and others, and I now offer a few more remarks. It is in my opinion very difficult to name the best twelve Roses, as in naming only twelve it would be necessary, I think, to give the best in each shade of colour. I will endeavour to do so, beginning with the dark Roses, and shading to the light. 1, Xavier Olibo; 2, Pierre Notting; 3, Charles Lefebvre; 4, Alfred Colomb; 5, Marie Baumann; 6, John Hopper; 7, Cécile de Chabrillant; 8, La France; 9, Baroness Rothschild; 10, Madame Vidot; 11, Gloire de Dijon; 12, Maréchal Niel.

Of these Xavier Olibo is hardly free enough in growth, but it is decidedly the finest as yet in its shade of colour. Pierre Notting requires protection from direct sun, as it burns. Charles Lefebvre still keeps its position as one of the hardiest and most useful Roses grown. Alfred Colomb, omitted in "P.'s" list, is, taking it all and all, the best Rose; and the next is Marie Baumann, running it a very close race, and drawing very near it in point of colour, only a shade lighter; its fault is that the flower-stem is too weak, and the bloom generally hangs its head; with me it makes plenty of growth. John Hopper is too well known to need any remark, except that many persons might not think its shape good enough for the first twelve. It has been everywhere good this year, and is more constant than any other variety. I especially remember a bloom shown by Mr. Mitchell, at Manchester, which not only was splendid in point of colour, but was not to be beaten in shape. Comtesse de Chabrillant still holds its own. La France is the most perpetual bloomer of any Rose yet introduced, not even excepting Gloire de Dijon, and I cannot understand why Mr. Radclyffe should consign it to the conservatory, as I will undertake, given six or twelve plants of any variety, oftener to pick good Roses for the table from La France than from any other Rose. It has some of the blood of the old China Monthly, as may be seen by noticing the manner in which the young wood pushes from growing shoots. Baroness Rothschild is the most beautiful Rose of its colour, and is quite unequalled both in size, form, and smoothness of petal. It has one great advantage—it rarely has more than one bud on a stem. Madame Vidot I should not have put into the list except for the sake of the colour, as there is no pure white good enough to name among the first twelve. Baronne de Maynard and Boule de Neige, though good Roses, cannot take rank among those I have named. Madame Vidot is most beautiful, but, alas! difficult to grow. When caught in perfection, as Capt. Cuttle would say, make a note of it. Gloire de Dijon I am still faithful to, and though rarely shown to perfection in stands of cut Roses during summer, it is a fine spring and autumn Rose, and an undeniable grower, certainly the best climber to cover a house with either a S.E., or S. to W. aspect. My No. 12, Maréchal Niel, is in favourable situations magnificent, and certainly the finest yellow Rose ever yet introduced.

I agree with Mr. Radclyffe, that Louis Van Houtte (Lacharme) is likely to be too weak a grower, besides which the flower is too small. I am in hopes that Marquise de Mortemart will succeed when established on the Manetti, as it will then get on to its own roots as well.

This summer has added still further to my faith in the Manetti stock for the permanent Rose garden. Many of my plants were cut down to the snow line, and more than half injured, but all have made shoots from beneath the soil, and nearly all have made from 4 to 6 feet of strong young wood from the base. Some that I cut down to only two eyes have pushed from below the ground, and have made as good plants as any. On a strong Rose soil, and for exhibition purposes, I do not deny that the Dog Rose is the best stock, but the Dog Roses (Briars) on which the nurserymen bud, are very unequal in point of merit, for besides the number of different kinds of Dog Roses which may be used as stocks, they are cut out of the hedgerows by the dozen or hundred with very little care, and the roots are often sadly damaged to begin with. Some, too, are old, others young, and nearly all contain a plentiful store of young root-suckers laid up in the hard knob root. With Manetti stocks it is different; they are all raised by cuttings under the care of the nurseryman, generally have much the same treatment, and have plenty of fibrous roots. They never throw up root-suckers, but only push shoots from dormant eyes at the base; if these eyes are properly cut out at planting time there will be no more shoots from the Manetti to trouble the Rose-grower. I have not had to cut away more than half a dozen Manetti shoots from six hundred plants this year, whereas a few dwarf standards on which I have some Bourbons, have furnished on an average from five to seven suckers each, to be pulled or cut out, but which can never be permanently got rid of without lifting and replanting, even if then.

Besides the twelve Roses I have named, I should add Abel Grand, Adolphe Brongniart, Antoine Ducher, Berthe Baron (rather too like Abel Grand), Boule de Neige, Centifolia rosea, Countess of Oxford—an undeniably good new Rose, which I should put among the first twelve if I had not confined myself as to colour—Devienne Lamy, Dr. Andry, Duc de Cazes, Duc de Rohan, occasionally splendid; Duke of Wellington, nearly fit for the first twelve; Duke of Edinburgh, very fine in point of colour, but nearly always quartered, and soon gone by; Dupuy-Jamain, very promising, very free-blooming, and of a pure bright colour like old Madame C. Crapelet, but not quite full enough; Edward Morren, a good Rose, but I have not yet seen its claim to the first prize at the Exposition Universelle at Paris, and I do not understand its being named as one of the first twelve; Elie Morel; Emilie Hausburg, an undoubtedly good Rose, very fine form; Fisher Holmes; François Lacharme; Henri Ledechaux, an exquisitely coloured Rose, giving me the impression it is a seedling of Jules Margottin crossed with Victor Verdier; Horace Vernet; La Brillante; La Duchesse de Morny, which runs a near race for the first twelve, a very soft pleasing cerise colour, with fine depth of petal, and good shape; Lady Suffield, La Ville de St. Denis, Lord Macaulay, Madame Boutin; Madame Caillat, a very fine Rose, and as yet distinct; Madame Clémence Joigneaux, glorious foliage; Madame Creyton, Madame Knerr, Madame Liabaud, Madame Thérèse Levet, Madame Victor Verdier, Mdlle. Eugénie Verdier, Mdlle. Marie Rady, Marguerite de St. Amand, Marquise de Mortemart, Marquise de Castellane, Madame Noman, Monsieur Paul Neron, Monsieur Woolfield, Nardy Frères, Paul Verdier, Prince de Portia, Princess Mary of Cambridge, Sénateur Vaisse, Vicomte Vigier, Victor Verdier, Victor le Bihan, Virginal. Bourbons—Baron Gonella, Louise Margottin, and Souvenir de Malmaison. Noisettes—Céline Forestier, Climbing Devoniensis, and Triomphe de Rennes. With Teas I have not much experience, and will leave them to your other correspondents who have lately given us some interesting and able remarks on them.—C. P. Peach.

P.S.—Since writing the above notes on Roses I have read the remarks of "J. B., *Darlington*," and "A. C." "J. B.'s" experience in the north of England very nearly corresponds with mine; the only difference is, I retain Cécile de Chabrillant and Madame Vidot instead of Madame Victor Verdier and Marquise de Mortemart. Madame Victor Verdier is undoubtedly good, but not sufficiently distinct, and Alfred Colomb is far superior in the same shade of colour. Marquise de Mortemart will not, I think, prove any stronger in constitution than Madame Vidot, and it is certainly not so finely shaped, as it opens much too flat. I am in hope that "J. B." has underrated Countess of Oxford, as a stand of twenty-four blooms put up by Messrs. Paul & Son at Manchester were nearly as fine as any twenty-four I have ever seen, except twenty-four of Baroness Rothschild and the same number of Madame Furtado. I am afraid Homère will be too delicate for the north of England. I add these few lines to what I have already said, as I have rarely read any notes on Roses that I could more thoroughly endorse.

As to "A. C.'s" remarks on the premier Rose at Nottingham, I may say, as one of the Judges, we were not at liberty to choose from all the stands in the tent, as is generally the case, and as in my opinion ought to be done whenever a prize is offered for the premier bloom at a show; and in this case there were several blooms of La France much finer than the Duke of Edinburgh shown by Messrs. Paul & Son. We had, however, to select from single specimens staged by growers for the purpose of competing for the prize, and the competition was very close indeed, Duke of Edinburgh winning on account of its fresh colour. Marquise de Mortemart would have beaten it if it had not been too flat, and President (Tea) ran a very near race. The Duke, shown at Nottingham, though very fine, was certainly by no means perfect in shape. It is a very good-con-

stitutioned Rose, and stands cold weather in the spring better than most Hybrid Perpetuals. Thyra Hammerick has always disappointed me. I have only had one good bloom of it this year, and not one from Souvenir de Poiteau, which is always rough, and I do not remember having seen a good bloom of it staged this year.—C. P. P.

POTATOES—EARTHING BETTER THAN NOT EARTHING.

I SAID I would send you the result of some experiments on this subject. I can answer for the correctness of them, for I saw the Potatoes weighed; 5 yards of each kind were taken up and weighed.

	Earthed.	Not Earthed.
Paterson's Victoria	18 lbs.	16 lbs.
Dalmaboy	16 lbs.	14 lbs.
Lapstones	16 lbs.	13 lbs.
Whitebread	18 lbs.	17 lbs.
Rocks	16 lbs.	11 lbs.

This is conclusive. There can be no question with me henceforth but that in a rich light soil like ours, in a moist summer like the past, earthing increases the crop. But it has advantages besides. The Potatoes earthed-up are certainly rather larger, and have less small ones among them. There are no green ones—a slight advantage. In lifting, the gain is very considerable. Where they have been grown on the flat the soil has set hard, and is more difficult to pierce. Then the fork has to be thrust downwards instead of through looser soil horizontally, which anyone looking on may see makes a great deal of difference in the labour. Then, on the flat, the digger, late in the season, when the haulm is dead, finds some difficulty in making out the row, and a few tubers are injured by the fork. Lastly, earthing-up, though much less laborious when carried out by a horse in the field than by one hand-hoeing, is quite as effective as two hand-hoeings in killing weeds. Those between the rows are effectually swept away, and those between the plants as effectually buried alive. This very great advantage alone would incline me to earth-up, even if it were proved to be slightly injurious to the crop. Facts have proved it to be beneficial.

The following rules, however, should be observed. Earthing should be done, if possible, after a shower—at any rate, not in very dry weather, that the roots may not be buried in a heap of dry dust. It should be done before the roots meet in the space between the rows, and the roots grow much faster than the tops; the ridge thrown up along the stems should not be pointed but flat on the top, that falling rain may not be shot off as by an umbrella, but soak in round the stem.

It still, however, remains to me as great a mystery as ever how it can benefit a plant to scrape the soil from its roots and expose them to the drought, and heap the soil round the stem of the plant, where roots do not find their way into it. I wish one of your scientific men would explain this.—WYESIDE.

SANTOLINA INCANA.

IT was some ten or twelve years ago that I first saw a dwarf grey-leaved plant so well managed as a bedding plant as to fairly approach perfection, and that was Cerastium tomentosum. It was planted in broad rings alternating with others of Lobelia speciosa around the Araucarias upon the upper terrace of the Crystal Palace, and I believe this arrangement was noticed in the Journal at the time. The exquisite neatness of the flower and the design, which has found a host of imitators since then, made as great an impression on others as it did upon me. The Cerastium has worthily been a very popular plant, holding the first place among dwarf grey-foliaged plants for many years, but at length it is doomed to an honourable retirement in the shrubbery or herbaceous border, where it ought always to find a place.

A plant now becoming even more popular than Cerastium is Santolina incana. This is one of those gems that have been used so extensively during the last few years in the flower-beds at Battersea Park. It has a dwarf, spreading, and very dense habit of growth, is of a beautiful clear bright shade of grey, and has foliage so minute and so serrated, that it is hardly possible to imagine anything in which grace and neatness are more exquisitely combined. It is, I believe, perfectly hardy, and, though such a dwarf plant, is quite free-growing enough to enable one to obtain a large stock of it from a few plants in a single season. I am glad of this, for from the high price at which it is still sold, 12s. a-dozen, I imagined that it must be a difficult subject to grow, or that its culture was not generally understood. That the latter is the case I am led to conclude from the fact that, after having had a dozen plants of it in my hands for half that number of months, I have found it is not at all a difficult plant to propagate, for cuttings of it strike root as freely out of doors in sandy soil without any protection as an ordinary bedding Geranium. There can be no reason, therefore, why this valuable plant should not speedily become as plentiful and cheap as the majority of other plants of its class. Some cuttings inserted in a border of the kitchen garden the last week in August, and suffered to remain fully exposed to all possible kinds of weather, have without one exception put forth roots, whilst others have grown equally well in a cool vinery. Thus, in addition to an elegant appearance, it possesses every other quality requisite in plants of this description.

With regard to its position in the flower garden, there is no necessity to say more than that its rigid firm growth gives it an additional advantage over Cerastium tomentosum, every branch as it points upwards rendering it a conspicuous object. Many of your readers have, doubtless, seen the skilful manner in which it has been introduced in some of those beautiful combinations of colour to be seen at Battersea Park. With masses of its grey are blended the bright crimson of Alternanthera amœna, and the cheerful yellow of the Golden Pyrethrum. These three plants may be strongly recommended, as much for the clear, distinct, and lasting colour of the foliage, as for their great utility either when employed as edgings to other plants, or when combined in those charming designs which carpet the beds, and which exhibit none of that glare so offensive in many floral displays. Very much can be done with them in the flower garden without the slightest fear of monotony. It is not often that a decided tone is imparted to a garden by its edging or border plants; but I may very safely venture to advise those seeking for novelty in their arrangements of colour for next season, to use these useful plants largely side by side, and with other suitable things, such as the true Trentham Blue Lobelia, Coleus, Iresine, Echeverias, Sempervivums, Polemonium, and Arabis lucida variegata. These few plants afford rich materials for planting entire beds, and for forming most beautiful ribbon lines, or embroidery round central masses of stronger-growing plants.

One word more respecting the Santolina. I do not suppose I have ascertained all its capabilities yet—the time has been too short for that, but I have seen enough of it to know that it is an exceedingly useful plant, amenable to the simplest method of culture, and, therefore, as valuable to the amateur as to the professional gardener.—EDWARD LUCKHURST.

RISING SUN DAHLIA.

MR. DOUGLAS, in writing of the Kelso Nurseries, mentions a fine scarlet bedding Dahlia. I can endorse all he says of it. It was not raised near Kelso, but in Northumberland, by Mr. Crossling, of Felton Park; he has a fine stock, one line of it being 128 yards long. Mr. Douglas reverses the name; it is Rising Sun, not Sunrise.—J. SMITH, *Croft House*.

AUTUMN STRAWBERRIES.

WE have received from Mr. George Lee, of Clevedon, near Bristol, about 1 lb. of Strawberries freshly gathered, of a size and quality equal to anything we tasted of the same class of fruit during the past summer. We have observed that this autumn some varieties of Strawberries have shown a free tendency to produce fruit, and in our own collections Vicomtesse Héricart de Thury has shown this peculiarity in a great degree. Mr. Lee appears to have observed this character in Strawberries during past seasons, and now he seems to rely so much on an autumn crop as to make it worth his while to give special attention to it. Mr. Lee, in a letter addressed to us, says—

"It may be interesting to some of your readers to hear that I get autumn Strawberries every season more or less, but some seasons a good crop. I am not quite sure about the date on which we gathered the first, but think about the end of August. For some weeks we have gathered about 10 lbs. per week, and when the autumns are free from frost we have fruit very late. Three years ago we gathered some during Christmas week. The kind was May Queen, which, if the plants are good and get a little rest in the summer, will generally produce a crop of fruit in the late summer and autumn. The best of all for autumn fruiting is one I had some years ago under the name of Patrick's Seedling; some of those I packed and posted for you are that variety. It is a very distinct variety, but is quite out of character as

compared with its summer appearance, not so dark, firmer, yet fine and of good flavour. The second best as a cropper is one which I had many years ago from Mr. Nicholson under the name of Sir Walter Scott, but this is pale and soft, yet large and a good cropper. The next best cropper is Swainstone's Seedling; this is very fine, rather pale, and rather soft, but of good flavour. From May Queen one may always obtain a crop; the berry is small and soft, but of good colour. From Black Prince, too, can be obtained, not a large crop, but berries of good colour and firm.—GEORGE LEE."

We hope to have the pleasure very shortly of receiving a paper from Mr. Lee on his mode of culture.

ORCHARD-HOUSE NOTES FOR 1871.

WE have just (October 9th) finished picking the last of the Peaches and choice Pears in the orchard house, and turned all the trees out of doors, where they are arranged close together. The pots stand on a hard gravel bottom, a handful of soot being scattered underneath each to prevent the ingress of worms. The pots are completely covered with cocoa-nut fibre refuse, which keeps the trees in good condition until the house is again ready for their reception in January.

An essential to success is repotting the trees, or top-dressing, early in September, or as soon afterwards as the fruit is gathered. I have found, after some years' experience, that those trees which are repotted in September always bear the best fruit the following season. I have therefore repotted nearly all our trees this season. Those potted in the early part of September had rooted into the fresh material, and were firmly established ten days after repotting. Pots of 15 inches in diameter are the largest size we use now, so that those trees which were growing in pots of this size have the roots sufficiently reduced to admit of an inch or more of fresh compost being rammed firmly between the ball and sides of the pot. Another advantage gained by repotting is that the drainage is renewed, as in many cases it becomes choked by worms working into the pot, and when this is the case I do not find the fruit of good flavour. It would be as well to state that in repotting in this manner trees which are in full leaf, care must be taken to prevent them from flagging, as not only would this occur, but the young wood would shrivel. To keep all right syringe the trees frequently, and keep the house rather close for a day or two.

It is unnecessary to enter into full cultural details at this time, as ample instructions have been given in recent numbers; but in passing I may remark on one very important matter connected with pot culture, and that is watering. The trees require abundant supplies of water, and especially after stoning has commenced. The uninitiated will be able to know this time by the stoppage of the swelling of the fruit (hitherto rapid), which takes place when the stones begin to form. Manure water should be given to the Peach and Nectarine trees with caution, and none before the fruit begins to stone. This year I have not used any, but relied entirely on surface-dressings given only twice—namely, about the end of June and in the middle of July, and there was no apparent difference either in the size or quality of the fruit, except some slight allowance that ought to be made for the unfavourable season.

It is equally important to pay attention to keeping the trees clean; do not allow insect pests of any description to harbour on them. Red spider is kept at a distance by syringing twice a-day in hot weather, and aphides of all sorts are destroyed by fumigation with tobacco. The aphis which attacks Peach trees is not easily destroyed. I fumigated our large orchard house six times one season before it was exterminated. I have noticed the insects drop from the trees and lie on the surface of the pots for three or four days, and yet show signs of vitality.

With regard to the best varieties to cultivate, of course a larger number of sorts may be grown in pots than when the trees are planted out. Beginning with the earliest Peaches, we have Early Beatrice, the earliest of all, followed closely by Early Rivers. This year their earliness was their only recommendation; the quality was very indifferent. If we could obtain a variety with fruit of large size and good quality, and ripening at the same time as Early Beatrice, it would be a great boon. We gathered Early Beatrice about the first week in July, and Early York three weeks later. The latter I think the hardiest and most useful early Peach we have; it is sure to carry a crop of good-sized well-flavoured fruit. Early Grosse Mignonne has very fine-flavoured fruit of large size, and was ripe the last week in July; the tree is rather tender. Rivers's Early York has not been so fine nor so early with me as the old sort. Ripening with Early York Peach was Hunt's Tawny Nectarine. This has two faults—the fruit is deficient of flavour, and the tree is more liable to mildew than any other I know. I would rather be without it in the orchard house, but we have not as yet another to replace it. As soon as mildew appears throw a cloud of flowers of sulphur amongst the trees with a distributor; this will effectually check its progress. When well grown this is a fair-sized good-looking fruit, and it hangs well on the tree after it is ripe. Rivers's Orange Nectarine has been particularly fine this year, and was the next to ripen after Hunt's Tawny.

After the foregoing the mid-season Peaches and Nectarines come in, and here there is no difficulty in making a selection. About the 10th of August we had ripe in abundance the following sorts of Nectarines, all first-rate—viz., Balgowan, Cricket, Downton, Elruge, Violette Hâtive, Pitmaston Orange, and, though somewhat later, but one of the very best, Pine Apple (Rivers). Of Peaches we had Royal George, Royal Charlotte, Alexandra Noblesse, a very large fine-flavoured kind, having a very pale skin with scarcely any flush of red; Grosse Mignonne, and Bellegarde, two of the best Peaches in cultivation. I have a number of new or little-known Peaches and Nectarines; some have not fruited yet, and respecting others which did fruit I can this year scarcely venture to give a decided opinion. Some are highly promising, others are of doubtful merit. Amongst midseason Peaches we can hardly look for any further improvement. Of Peaches and Nectarines ripening with Walburton Admirable some of the recently introduced varieties are decided acquisitions. Amongst those introduced from America I think Exquisite is one of the best yellow-fleshed Peaches we have when cultivated in the orchard house. I do not know whether it would be equally valuable as a wall-trained tree out of doors. Princess of Wales (Rivers) is a magnificent Peach when well grown, and is very distinct. Desse Tardive is another late variety which ought to be grown much more extensively than it is. I find it an excellent pot tree, setting fruit very freely when trained to a trellis under glass; the fruit is magnificent, 12 inches in circumference, from trees planted out.

For late Nectarines to succeed the Pine Apple there is that fine cross-bred variety Victoria; this will be a lasting memorial to Mr. Thomas Rivers of Sawbridgeworth. No collection should be without it. Prince of Wales I have never had finer than in the present season. The fruit was highly coloured outside, bright red at the stone, and measured just over 8 inches in circumference. This variety is liable to crack; to prevent its doing so, crop rather heavily, and do not give too much water when the fruit is swelling. These are our last Nectarines.

The Peaches continue longer. There are just three which I will name—Lord Palmerston, Lady Palmerston, and Salway. The only good one amongst the three this season has been Lady Palmerston; it ripened after Lord Palmerston and before Salway, and for a yellow-fleshed Peach it was of very good flavour. The fruit was only medium-sized, although it is generally large. Lord Palmerston, usually good, has shown too much of the Pavie blood to be agreeable, and the skin exhibited little colour, though fully exposed to what sun there was. As for Salway, the fruit is quite dry and unpleasant; but it is, as Mr. Rivers says, "sometimes good" even from pot trees, and it is to be had after the other two are over.

There are, no doubt, many of your readers and contributors who have also had experience with orchard-house fruit; if it differs from mine in any particular I should like to hear of it, especially in the case of the Early Beatrice and Early Rivers Peaches. One would like to know if Mr. Rivers still holds the same opinion of them.

I may say, in addition, that Pears and Plums have been fine this year. One Plum which I would particularly recommend is the Golden Esperen; it has fruit of delicious flavour and fine in appearance, though not of the largest size. Souvenir du Congrès and Madame Treyve will, I think, hold a high position amongst Pears. I had the former, which weighed half a pound each, from trees in pots under glass, and I weighed one fruit of the latter taken from a pot tree out of doors, and found its weight exactly 12 ozs. Souvenir du Congrès somewhat resembles Williams's Bon Chrêtien, but is rather later in ripening. The flavour of my specimens was past before I tried them; but some fruit sent on October 4th by Mr. William Paul, of Waltham Cross, to the Fruit Committee at South Kensington were of good flavour, although also a little past their best.—J. DOUGLAS.

THE PEACH CROP OF DELAWARE. — The *Wilmington Commercial* states that the railroad accounts, made up on the 14th

of September, show 2,656,673 baskets carried, and about a million were sent by water. The net prices returned to the grower are estimated at 35 cents per basket, so that the crop has brought into the peninsula this year over 1,225,000 dollars; and counting consumption at home, a fair statement would be very nearly a million and a half dollars.

PEAS FOR SUCCESSION.—No. 1.

"What varieties should I sow to obtain the longest succession of Peas, and when should I sow them?" These are questions which can only be satisfactorily answered by advising for both large and small gardens, for Peas differ considerably in height.

Peas for Large Gardens.—In these there is nothing to prevent tall as well as dwarf varieties being grown, for sticks may generally be procured with less difficulty and cost than in small gardens. In the latter, especially if near a town, Pea sticks are scarcely to be had for money—indeed, I have paid for sticks as much as the crop was worth; and in such cases it is desirable to dispense with sticks as much as possible by choosing kinds of Peas that will do with little or no support. I may remark that I do not believe in Peas that require no sticks. Those which I receive as growing only 1 foot high attain twice that height, and when unsupported produce one-half the crop which the same kinds do when staked. I may be told my ground is too rich. Nothing can be grown well without manure. Except for the early varieties—a few to come in early—the ground cannot be too rich. I manure heavily because I must crop heavily, and yet my soil shows no evidence of having had too much manure. Just pointing in a quantity of manure soon renders the surface soapy; and though everything sown or planted may be stimulated for a while, yet when the roots pass beyond that the time of trial begins; for dry hot weather sets in, growth comes to a standstill, and grubs innumerable, with mildew, make sad havoc of the crops. Manure heavily, dig deeply, and the crops will in general be satisfactory both in quantity and quality. The varieties of Peas are extremely numerous, and most of them have been useful in some soils and localities, or for some particular purpose. I therefore do not assert that those which I shall name are the best of all to equal them, but with me they have proved so.

Dillistone's Early, or Dickson's First and Best.—Height 3 feet. Sow from the 5th to the 10th of November on a warm south border; on the 10th of December also on a warm border; and again, if the ground is in good order, on the 15th of February; or, if the weather is very wet or frosty, on the 5th of March in an open situation. The Peas ought all to have a little soil drawn to them when 2 inches high, and be sticked. This applies to all Peas, but those on the south or warm borders should be sticked as soon as above-ground, putting in rather thickly the leafless spray of the Spruce Fir about a foot high, and staking fully afterwards. Also sow on the 5th and 15th July.

Laxton's Supreme.—6 feet. Sow March 5th, March 15th, and March 25th.

Eastes' Kentish Invicta.—4 feet. Sow March 5th and 15th, July 5th and 15th.

Champion of England.—6 feet. Sow March 15th and 25th, April 5th and 15th.

Fortyfold.—6 feet. Sow March 15th and 25th; April 5th, 15th, and 25th; May 5th.

Premier (Maclean's).—4 feet. Sow April 5th, 15th, and 25th; May 5th and 15th.

Veitch's Perfection.—3½ feet. Sow April 25th; May 5th, 15th, and 25th.

Hairs's Dwarf Green Mammoth.—3 feet. Sow May 15th and 25th; June 5th, 15th, and 25th.

Yorkshire Hero.—3 feet. Sow May 25th; June 5th, 15th, and 25th; and July 5th.

Ne Plus Ultra.—7 feet. Sow May 15th and 25th; June 5th, 15th, and 25th; and July 5th and 15th.

Under ordinary cultivation and in general seasons the Peas will be fit to gather the first week in June or earlier in the south; but I am in the north, and the beginning of June is about the time to expect to have Peas north of the Humber. There will be no break in the supply from early in June to early in October, and after that all depends on the weather. I have gathered a dish of Ne Plus Ultra on December 21st at a place nearly 500 feet above the sea level in Yorkshire. I have now (October 16th), Veitch's Perfection, Hairs's Dwarf Mammoth, and Yorkshire Hero with fine well-filled pods, and Ne Plus Ultra that shows blossoms as well as pods. They are in an open spot, where the east and west winds cannot cut nor knock them about, which is ruinous to Peas, especially late ones.

I think we shall have an acquisition in the Pea called Wonder of the World; it appears to stand autumn wet and cold well. It is evidently another Ne Plus Ultra.

The accompanying table will show at a glance the times of sowing:—

Variety.	Height.	Colour.	Nov.	Dec.	Feb.	March.	April.	May.	June.	July.
	ft.	*								
Dickson's First and Best	3	W.	5	10	15	5	....	....	....	5,
Eastes' Kentish Invicta	4	B.	..	..	..	5, 15	....	....	....	5, 15
Laxton's Supreme	6	G. M.	..	..	..	5, 15, 25	....	....	....	..
Champion of England	6	G.W.M	..	..	..	5, 15, 25	5, 15	....	....	..
Fortyfold	6	G.W.M	..	..	..	15, 25	5, 15, 25	5	....	..
Maclean's Premier	4	G.W.M	..	..	..	....	5, 15, 25	5, 15	....	..
Veitch's Perfection	3½	G.W.M	..	..	..	....	25	5, 15, 25	....	..
Dwarf Green Mammoth	3	G.W.M	..	..	..	....	....	15, 25	5, 15, 25	..
Yorkshire Hero (Dixon's)	3	G.W.M	..	..	..	....	....	25	5, 15, 25	5
Ne Plus Ultra	7	G.W.M	..	..	..	....	....	15, 25	5, 15, 25	5, 15

* White; B., Blue; G. M., Green Marrow; G. W. M., Green Wrinkled Marrow.

The above sowings would at first sight appear excessive, but the autumn and first spring sowing of Dickson's First and Best, Kentish Invicta, and Laxton's Supreme are quart sowings, all the others pints. So that we require of Dickson's First and Best, 4 qts.; Kentish Invicta, 2½ qts.; Laxton's Supreme, 2 qts.; Champion of England, 2 qts.; Fortyfold, 3 qts.; Premier, 2½ qts.; Perfection, 2 qts.; Dwarf Green Mammoth, 2½ qts.; Yorkshire Hero, 2½ qts.; and Ne Plus Ultra, 3½ qts., equal to 26½ qts., a sufficient seeding for a garden of two acres. A quart of early Peas will sow a row 36 yards, or 108 feet, and a quart of late or general crop 50 yards, or 150 feet. The distance between the rows is fully that which each variety attains in height.

It will be seen from the table that the aim is to make sure of a thorough first, midseason, and late supply, by frequent sowings, using also different varieties to insure a constant succession. My aim in growing Peas is to give enough to satisfy at first, and never to be without them. I remember a rather good tale of an Archbishop of York who was very partial to Orach. It happened that the gardener ran short of it, and the kitchen-server took in small dishes. His Grace ordered it twice a-day, and the kitchen-server was at his wits' end—there were only two small dishes left. He very properly consulted the head gardener, who directed him to send it all in at once—all he could find, and if the cook or anyone asked him if there was any more, to give them answer, "Cartloads." After the midday meal a messenger was dispatched to the gardener by his Grace to inquire if there were any more Orach, and got his answer, "Cartloads;" which, being told his Grace, he sent word to the cook, not until he again ordered to send in any more Orach. It is upwards of a century since this occurred, and it is true in principle to-day, and those just entering on the responsible charge of a garden will do well to "always make semblance of abundance of everything, and never ask a cook to be careful."—G. Abbey.

SEDUM FABARIA.

I am glad that Mr. Record has called attention to this plant, which deserves all he says in its favour, being, without exception, one of the best vase plants which I know, as hardy as the common Houseleek, and, like it, succeeding either with water or without it in the driest and hottest weather. We have some plants of it in vases not easy of access, and they have not been watered for many days, nay even for weeks together, and they did not appear to suffer in the least. The spreading uniform habit of the plant is all that can be desired in such places, it withstands wind and weather of all kinds, and although it flourishes in sunshine, it does well in the shade. Certainly its greatest defect is being late in flowering, but when once out, the flowers remain fresh a long time, both in beds and vases, for I have had it for some years in both, and I do not think I have ever lost a plant. A bed of it at the present time (October 13th) is about one of the best we have; it is an oval bed, 14 feet by 9, and was planted in the spring of 1869 (other plants were out many years before that), but those in the bed referred to grew up and flowered with as much regularity as could be desired. The bed is slightly raised in the centre; the flowers of the Sedum present the same outline, while the edging enhances the beauty of the whole. The edging is the dark ornamental Beet, which is employed in so

many places, and which I have grown more or less for some years; in this instance it comes in remarkably well, being just the proper height to meet the flower stems of the Sedum, while in point of colour, uniformity, and, above all, durability (for it lasts a great part of the winter), I almost think that it requires a champion as well as Sedum Fabaria.

I can fully confirm all Mr. Record states respecting the hardiness, easy culture, adaptability to all soils, and other qualities of this Sedum, the only drawback being that it is late in flowering; but the orderly appearance the plant presents before that time almost entitles it to be classed amongst those grown for foliage, while the promise of future bloom creates an interest well worth waiting a little time to realise. To those who want very large heads of bloom, I would recommend planting in spring young plants struck out of doors the preceding autumn, such as come up with only one or two stems to each. I will not say how large the corymbs may be, for I have seen so much of what I call injustice in measuring leaves and flowers that I will not pretend to say how large we had some of them a short time ago. In vases and beds I prefer the smaller heads which old plants throw up, more especially as they are much more numerous.—J. Robson.

TWELVE OF THE BEST ROSES.

I shall presume "D., *Deal*," means twelve Roses that answer to the following description—namely, that are best for exhibition and also for garden purposes, varied in colour, hardy, good growers, free and constant bloomers. The Roses are placed in alternations or shades of colours. Perfection de Lyon is the finest show Rose of them all. I had six plants each of Perfection de Lyon and Madame Chirard, and nine plants of Edward Morren to judge from. Edward Morren had no green eyes, but gave a splendid and abundant first and second series without one malformed bloom.

The following is my selection—Maréchal Niel (Pradel, jun., 1864), golden yellow; Pierre Notting (Portemer, 1863), deep crimson purple; Madame Chirard (1869), pale clear rose; Alfred Colomb (Lacharme, 1865), fiery red; Perfection de Lyon (Ducher, 1868), pure rose, with silvery lilac reverse of the petals; Madame Victor Verdier (Eugène Verdier, 1863), rich red; William Griffiths (Portemer, about 1854), salmon rose; Edward Morren (Granger, 1868), light silvery cerise; Marguerite de St. Amand (Sansal, 1864); Charles Lefebvre (Lacharme, 1861), rich dark shaded crimson; John Hopper (Ward. 1862), crimsonish centre, with paler edges; Maurice Bernardin (Granger or Levêque, 1861), vermilion. Mdlle. Marie Rady (Fontaine père, 1867), is a first-rate Rose, and I regret there is no room left for it in the twelve.—W. F. Radclyffe.

HOUSING CHRYSANTHEMUMS.

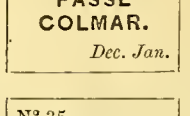
I always find my plants do better out of doors until the buds show colour than when I take them in before that time.

I do not house my plants before the 1st of November; I never find frost interferes or injures the buds before that time, as they do not bloom before the middle of November, even if put in a month earlier. Heavy rains and winds are more injurious than bright days and slight frost by night, as a little frost renders the plants hardy, and prevents drawing and the weakening of the buds.

Liquid manure I use very sparingly; I depend more on a good top-dressing composed of a mixture of soot and well-rotted manure, as it causes the foliage to be retained and at all times supplies nourishment to the plant.—P., *Rochelle, Cork.*

ADHESIVE FRUIT LABELS.

We have received from M. Edouard Pynaert, of Ghent, samples of his new adhesive fruit labels. It is impossible to speak too highly of this ingenious and very useful contrivance of Mr. Pynaert, by which fruit-growers, and especially fruit-exhibitors, are furnished with a means of labelling their fruit with a nomenclature at once correct and neat, which obviates the necessity of those large and clumsy cards we see so often accompanying specimens of fruits, and at the same time secures immunity from those stupid and sometimes laughable forms of nomenclature which are too common in our fruit exhibitions. If we were in a humorous mood we might make merry over some of the names that appeared at the late great fruit show at South Kensington. Such examples as Ballyband for Belle et Bonne, applied to the Apple of that name, are enough to make us long for a deliverance from such a system; and if fruit-exhibitors will adopt Mr. Pynaert's excellent tickets they will avoid the remarks which, though not uncalled for, are far from complimentary.



We give specimens of these adhesive tickets, and merely remark that they are on sheets, which are perforated like postage stamps, and the various tickets can easily be separated. Being gummed on the back they are always ready for use, and can be applied to the fruit with all the facility of postage labels. The cost of these tickets is small, only 2*s.* a-thousand for the general sheets, containing an assortment of names, and 2*s.* 6*d.* per thousand for special sheets containing a single variety. Orders for England accompanied by postage stamps will be sent free.

For labelling in the fruit-room, for sending in fruit for dessert, or for exhibition purposes, these simple and elegant tickets are a real boon. They were deservedly awarded a special certificate at the late International Fruit Show at South Kensington.

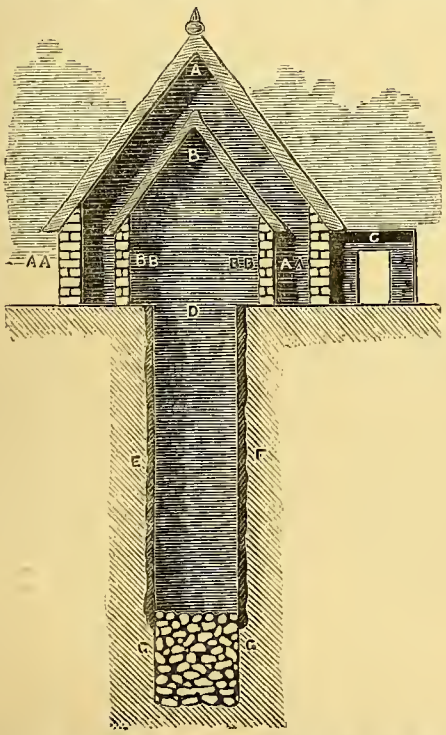
THE PRESERVATION OF ICE.

A prime necessary of life in the sultry and feverish East is congealed water, that most exhilarating and tonic of human beverages. In old times, the Anglo-Indian exile was solely dependent on the troublesome and expensive cooling preparations known as "freezing powders," of which saltpetre and sulphate of soda were the chief components, entailing the service of a special attendant called an abdar, or "water-cooler," with one or more assistants. This was generally the rule in the humid province of Bengal, and at the small out-stations throughout the country where ice could not be manufactured for want of frost, or funds. Now-a-days, our American cousins with special ships supply the seaboard, and our increasing network of railways carry up the superb blocks of Wenham Lake at a selling price of 3*d.* to 9*d.* per lb., more or less, according to the distance of transit. But there is a limit to all things, and ice will waste so much in travelling that it could not be sold at a remunerative rate, or meet with purchasers. Hence, machines on a large scale have been introduced into the more populous garrison towns, and do a large amount of business in the very hot months. Natives, especially those of rank, have taken to the luxury as a great improvement on their old lukewarm element; while in all the British hospitals Government sanction a certain outlay in this highly-valued therapeutic of Nature; undoubtedly it will save life in all those irritable and congested conditions of the brain and other organs, while as a styptic it is (next to electricity) unequalled. Could this great article of consumption be produced at a sufficiently low cost for issue as a daily ration to European soldiers, I have long ago been convinced that a large amount of mortality would be reduced.

As soon as we reach the N.W. provinces and the Punjaub we attain a climate with a winter and frosty nights in a long continuation, the soil and air as dry as any in the whole world. Here by the nocturnal radiations of heat we attain the most profitable results in congelation by the exposure of shallow saucers on plains strewed with straw. I remember one uncommonly sharp winter at Lahore more than twenty years ago, when our newly-built ice pits were crammed to the brim in ten or twelve days for the long hot season's supply of the unusually large garrison. Soon after sunset congelation began, and before sunrise a small army of coolies, man, woman, and child, were collecting and carrying off the glistening product, almost an inch thick—a most unusual circumstance, as the ice so made is seldom more than half an inch to a quarter of an inch in substance, and when thrown into the pits there consolidates into masses. The cold was such in that memorable season that dogs and mendicants were found dead on the exposed plains, and the troops, British and native, went out to exercise at midday, their fingers being too stiff to cap their fire-arms at an earlier hour, while officers and men off duty would be met in the sheepskin pelisses and camel-hair robes of far Afghanistan, with gloves and stockings of the latter dense material.

The so-called "ice-houses" of Northern India are more properly ice wells, and I will at once explain their very economical and efficient construction in these hot and dry climates, where, during most of the twelve months, the earth's surface is oven-

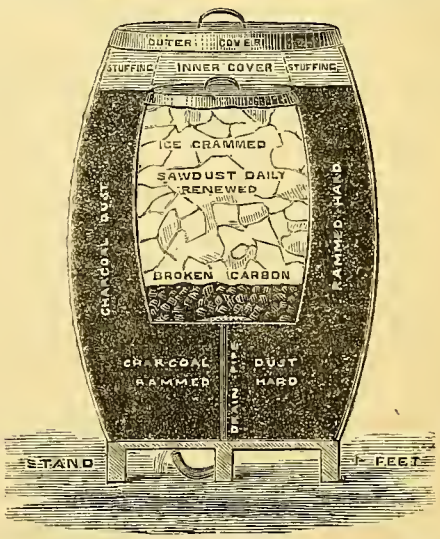
like in temperature, and rapidly falls to extreme cold as we descend, a natural result of which the northern races have long been cognisant, for in most cities there are "Tytchanas" or subterranean rooms, with stone benches, and even fountains therein, which are favourite retreats of the rich and idle during the excessive heat of the outer air. Perhaps in the very humid climate of Great Britain this oriental system of preserving the ice may not succeed, though it might be modified accordingly. A A, external walls about 5 feet high and 2 feet thick, of sun-dried clay brick. B B, internal walls of the same height, but only 1½ foot thick, of the same stuff. Both the above walls are circular, and when dry should be well plastered with any water-proof compo, to protect them in bad weather; I suggest bast mats as the best ones in England. Doors to enter each circular erection must be made, taking care that they are not opposite, so as to avoid direct entrance of the outer air. A, outer thatch, thick, and of reeds or rushes well packed. B, inner thatch of less thickness. C, porch built on to outer door, and having a closely-fitting door as first entrance. When taking out ice (always before sunrise) a person entering this outer door will shut it after him tightly, then enter the outer circular wall by its own door, fastening which he will open the inner door of central compartment; closing that also, he will then take off a thick felt cover from the mouth of the pit, and carry away the required ice in a double basket, covered with felt in each compartment, the blocks being separated by a stock of cold sawdust, stored between the walls. Beware of strong-scented woods when collecting the dust, as they will flavour



your ice. The well or pit must be in a dry, gravelly, or sandy, slightly-elevated situation, with a porous subsoil to the very bottom. The depth will depend on the quantity to be stored for the season; there is no advantage in a surplus. This pit is to be lined throughout with wicker-work (or matting in India) and spread with felt sheeting as thick as you can afford, as the best non-conductor in a large scale, E F. G G, the drainage chamber, which should be by choice in the most porous soil or stratum attainable, its object being, when filled with small charcoal, to act as a colander or strainer for the drippings of melted ice to pass away into the earth, without creating humidity, a state so destructive to all congelation and its preservation. The little entrance portico I should construct of Croggon's patent felt (being waterproof) nailed to a light framework of deal spars, well-pitched. The inner door should have a chain and padlock, and work so lightly on its hinges as to close on a latch by its own impetus.

I will now proceed to the construction of ice safes and small domestic receptacles for the daily supply. For the casual consumer, the invalid, or the midsummer picnic, I know of no plan so simple and effective as the following:—Have two good clean white blankets by you, the stouter the better, lift the lumps of ice, as large as you can get them, with a pair of wooden tongs into one blanket, and wrap it up into as small and uniformly tight a bundle as you can manage; put this in a light basket and wrap up the latter again in your other blanket, and keep in as dark and shady a spot as you can find. A bottle or two of previously cooled beer or soda water may be enclosed with your ice in the same blanket when packing. Every two hours in hot weather change your blankets, and try to keep your ice as dry as possible, therein consists the knack of preservation. Sawdust of hard woods is most useful as an auxiliary. The blankets will be none the worse for being used, if continually changed, as above. I tried a new discovery a few years ago, and it will give a valuable hint to nurses and others who have to economise their store of ice in a sick room or hospital. Dr. Schwarz published the fact that soft bird-feathers are the most effective of all non-conductors: he kept ice in a jug covered by a plate, some 6 lbs. weight, for eight days in an invalid's room during summer.

For many years I used the following inexpensive ice-box, constructed by my own hands, its principle taken from an American recipe book. The work is laborious and also dirty, unless feathers be used, which would cost something:—Get an eighteen-gallon cask, clean and new, if possible; get a smaller, of four gallons, or rather larger, according to your



probable requirements. On this scale I stored Wenham ice for forty-eight hours, 8 lbs. weight, after it reached me nearly two hundred miles by rail and boat, being in a joint club with others, and the total cargo being about 200 or 300 lbs. on every trip. We had to subscribe a small fund to purchase cases and country blankets, and advances to the American company in Calcutta. The blocks on arrival were all cut up and weighed out in allotments to the several subscribers. My share rarely exceeded £2 sterling *per mensem*, with a small dividend to receive when the cool season came round. The per-centage of loss by waste in transit was usually quite insignificant, unless detained by occasional mishaps.

The larger cask must be partially unhooped to admit the lesser, and a large quantity of clean and fresh charcoal dust must be previously collected. First a hole must be bored in the bottom for the outlet of drainage pipe, and then the cask fitted to stand on a strong frame on four feet, sufficiently high to contain the bend of the siphon when inserted into the pipe; both may be of lead tubing a quarter of an inch. Insert the length of pipe upright in the hole of large cask, and begin ramming well with a long heavy cylinder of wood close up to and around the pipe, till about an inch or two only remain above; you then put inside the smaller cask, which must have a hole at bottom to hold the pipe end. This being duly adjusted and quite straight, replace the top hoops of the large cask, and go on with the charcoal dust till you arrive close to the mouth of the small one, you will then put a curved piece of perforated zinc

over the pipe hole, and over that again firmly pack some animal carbon. You will now make two lids of the two cask-heads, nailing them on with leather bindings, and tack some extra stout felt, with a deep flounce of the same, all round. I covered all my outer cask with double felt, and then rendered the ice-safe fit for human eyes by a coat of cheap red cotton cloth. The last operation is to stuff all the space around the mouths of the inner and outer cask with felt clippings, covering them from view by a piece of cloth tacked on.— Eos. — (*English Mechanic and World of Science.*)

POSSINGWORTH.

The Seat of Louis Huth, Esq.

The elegant mansion of Possingworth stands upon one of those commanding eminences so frequent in the Weald of Sussex. The position is well chosen, overlooking a most magnificent landscape, which is expansive, but not flat or tame, as the lower part of it is beautifully undulating, sweeping downwards and outwards in the most picturesque manner, and rising again in the distance, till it meets the boundary line formed by the bold uplands of the South Downs. Midway in the field of view, and standing well back on either hand, are high turf-clad banks crested with trees, sloping downwards to a fine sheet of water, in a bold yet irregularly wavy outline, the beauty of which is much enhanced by the introduction of occasional admirably arranged groups of trees. Possingworth and its gardens are very beautiful, seeing it as I did in all the richness and beauty of one of those luxurious days when summer is gliding into autumn.

The house may be said to be quite enclosed by the dressed grounds. The carriage drive sweeping past the north front is so beautifully kept, as are the lawns through which it passes, that the eye is at once attracted by the exquisite neatness. A steep irregular bank springs from beside the drive to a considerable height upwards, its highest part having a dense mass of Firs growing there, sheltering the house, and, doubtless, forming an admirable background to it when viewed from the valley. On the west side the chief features are, a conservatory, whence a flight of steps leads on to a broad terrace walk with vases raised upon pedestals along its outer edge, and a lawn in fine order, level, and belted by a walk fringed on both sides with bright masses of flowers in beds; thus, while there was much of brightness here, an air of repose prevailed from the unbroken expanse of turf. This effect, and the way in which it was produced, impressed one as being worthy of attention, repose in gardenesque scenery being frequently difficult to attain satisfactorily.

The flower garden by the south front is also in connection with a terrace of handsome proportions. The flower-beds are few in number, simple in form, and of large size. They are upon turf, and are raised very high in the centre, forming a garden of a peculiarly massive and dignified character. They were well filled, the plants being beautifully graduated from the high centres downwards and outwards. Some of the beds were surrounded by a novel and pretty belt, consisting of two outer rows of dwarf Box edging planted closely side by side, and enclosing a compact band of Vinca major elegantissima, a foot wide, of a beautiful clear pale yellow, The Vinca was kept as dwarf as the Box, two more rows of which immediately succeeded on the inside, then came a band or path of gravel 2 feet wide, with another double line of Box enclosing the bed itself.

Apart from the principal flower garden were numerous well-filled beds, borders, and vases, all rich with summer's various charms. In one long border a collection of herbaceous plants is being gradually formed, this will in time be a very interesting and attractive feature. I would commend this plan to the notice of those who lament the sacrifice of many an old favourite to modern caprice.

A Rose garden of a somewhat quaint and formal aspect connects the flower garden with a shrubbery, to the east of which are the kitchen garden and the glass houses. The Rose garden consists of a series of long unbroken borders, not straight, but in the form of a gentle curve. They are upon sloping turf, in tiers one below the other; between every two borders, and running parallel with them, are low clipped Laurel hedges to shelter the Roses from the effects of high winds.

It was a treat to walk through the glass houses at Possingworth. No trash, no plants suffering from neglect, poor culture, or overcrowding meet the eye, but everything betokened the most painstaking care and skilful supervision. I was glad to see evidence on all sides of Mr. Reid's fondness for cone-shaped plants; to my mind no form is so symmetrical and elegant. The collection of Azaleas trained to this form, and clothed with foliage of a most healthy green, was a refreshing sight. A number of fine Allamandas were also so trained, and I noticed two fine specimens of the charming old favourite Rhyncospermum jasminoides laden with bloom for the second time this year, the plants having flowered freely in March. The plant houses and pits were well placed in a compact block, and the vineries and Peach houses ranged along south walls. These structures are well built, and had suitable fittings and excellent internal arrangements.

Of the Grapes which most attracted my attention were some deep-coloured bunches of Alicante, well shouldered and thoroughly finished, Bowood Muscat extremely fine, and Madresfield Court Muscat. Mr. Reid has this last fine kind grafted on a variety of stocks, planted in different houses. The bunches of it were of a useful medium size, and the berries were large, well-coloured, and altogether fully developed; but there was the cracking or bursting of many berries, a blemish which affected every bunch more or less. None of the various stocks upon which it was grafted seemed to have much influence in checking this serious evil. Of the plants of it which I saw bearing fruit, there were some upon their own roots, others were grafted upon Dutch Sweetwater, Royal Muscadine, and Frankenthal, upon which last there did not appear to be so many faulty berries, though they were not entirely absent. Every means had been unsuccessfully tried to prevent the cracking. It was not supposed to arise altogether from too much moisture in the borders. I particularly inquired about that. If there was a superabundance of sap it was checked by cutting a deep notch in the wood both immediately below and above the bunches. A few of them to which this treatment had been applied with severity bore tokens of suffering therefrom in the small size and pale colour of the fruit. Can a reason be given for this, or an effectual remedy be suggested? Remember, it is not to Vines in the hands of a novice that this has occurred, but to those under the care of an experienced, energetic, clever man, who has given the matter his most earnest attention, applying every remedy that he thought likely to succeed, but without avail. My own idea is that a border containing a larger quantity than is usual of crushed bones, broken bricks, and coarse gritty matter, and elevated well above the surface of the surrounding soil, would best suit a variety liable to be so affected.

In looking over new gardens like these, one is disposed to be more critical in the survey than when seeing old-established places; or rather, I should say, one is more keenly on the outlook for lessons of usefulness which may be applied to future practice. My visit was far from being a barren one in this respect, and while refraining from entering upon details which it would be wrong to make public without permission, I may safely venture to promise to keep no useful hint from the readers of "our Journal," but to introduce all such lessons in any future articles upon which they may bear.—Edward Luckhurst.

BULBS.

In the "Botanists' Repository" of Andrews, published about the beginning of the century, there are plates of a vast number of Cape bulbs, the names of which are not now to be found in nurserymen's catalogues, but which appear to be very desirable acquisitions. The greater number seem at that time to have been in the collection of Mr. Hibbert at Clapham, and nowhere else in this country. What has become of the Hibbertian collection? If it has been dispersed, has it fallen into any nurseryman's hands? Andrews figures a number of dwarf Gladioli that would be admirable for pot work, one of them a lovely blue. He also has plates of a number of tuberous-rooted Geraniums with yellow flowers; among these is one named radicans. Van Houtte has one in his catalogue under this name, but it is rosy pink, not yellow.—K. I. N.

RENDLE'S PLANT PROTECTORS.

I really must apologise for appearing again before your readers, but I cannot allow the remarks made by your correspondent, the Rev. C. P. Peach, to remain unchallenged. He says my protectors were fixed in the corridors of the International Exhibition. It is true a few of the specimens were fixed there, but I was allowed by the Royal Commissioners to erect large working protectors in the garden of the annexe.

There they were, and I am sorry your correspondent did not see them there, because then I am sure he would not have made the remarks he did. There they stood through many a gale and eddy-wind without a single brick being displaced or a pane of glass broken. One word more and I have done. He refers to the old-pattern bricks at Chiswick several years ago. I do not think he has seen the new "Belvoir Castle" or the "Enville" patterns; when he does so he will change his mind. He might as well say the locomotive steam engine is a failure because the original one on cog wheels broke down.—W. Edgcumbe Rendle.

[We think it needless to insert more upon this subject.—Eds.]

WOOLHOPE NATURALISTS' FIELD CLUB.

THE FORAY AMONG THE FUNGUSES.

The last field meeting of the year was held on October 10th. The attendance was numerous, the weather was beautiful, the scenery of the district selected for the hunt was very fine, and, above and beyond all for the object of the day's excursion, Funguses were abundant. The sun shone brilliantly as the visitors left the Dinmore station to wend their way up the hill to the tower on the top, but the admiration of the varied foliage tints was quickly exchanged for that of the forms and colouration of the Funguses. The scarlet tints of Hygrophorus coccineus, Peziza aurantia, and Agaricus (Amanita) muscarius; the amethyst and purple variety of A. laccatus; the large white Lactarius vellereus, the delicate Hygrophorus cossus, and Clavaria vermiculata; the yellow wax-like Hygrophorus ceraceus, and hundreds of others in shades of yellow, brown, and black, mixed by Nature's art, with many a varied grace of form and texture. Meantime the way led on, and whether it was the many attentions the Funguses had, or the old sad habit of keeping too long to the broad and easy path, the visitors found themselves on the turnpike-road to Leominster, without a sight of the tower. Away through the wood side tracks were taken, and the baskets were rapidly filled with the *spolia* of the day. In the hunt for the tower, which conceals itself wonderfully well in the woods of this wide-backed undulating hill, some found it and some didn't, and the President was amongst the unfortunate; and so it came to pass that the business of the Club was transacted under the Beech trees at the far side.

The delicate beautiful Fungus Agaricus mucidus, white and fragile, was here gathered from a decaying branch of the Beech tree above, and on its roots below Polyporus giganteus was beginning to grow. Here, too, soon was smelt out that curious, undesirable, beautiful, horrid, graceful, disgusting, interesting, stinking Fungus, Phallus impudicus, which is justly named "stink-horn."

The wood was now left for the more open ground of the hill, and on the remains of some charcoal-burning places the Funguses peculiar to such spots, Agaricus carbonarius, A. atratus, and Cantharellus radicosus were found.

The private bridge over the Lug was crossed, and following some little distance a tempting glade by the river's side the ascent of the hill was again made for the home journey, and the Fungus hunt was resumed all the more vigorously for the charming *hiatus* of the visit to the valley. The buff Hygrophorus pratensis, edible and good, with its odd little associate H. psittacinus, with several others, were gathered here. This last is said to be edible too, in spite of its greenish-yellow untempting aspect, and as the esculent Funguses have at length come uppermost, it may as well be said at once that many of them were found. A good dish of the Maned Agaric, Coprinus comatus, had already been secured as provision for the feast, and others had still to be gathered. A hunt was made for the "Vegetable Beefsteak," Fistulina hepatica, for it may almost be said of this, as Browning has lately said of the Pomegranate in the Island of Rhodes:—

> "Where'er the red bloom burns
> I' the dull dark verdure of the bounteous tree,
> Dethroning in the rosy isle the Rose,
> You shall find food, drink, odour, all at once."

But though some small specimens were found, they were too young to be fit for the table. The spiked Mushroom, Hydnum repandum, "Hydnum good as oysters," as Dr. Badham says, was found growing in several localities, and some fine specimens were gathered, but as this one had already been cooked at the dinners of the Club, the caterer passed them by for the Red Milk Agaric, Lactarius deliciosus, which is very plentiful this autumn in the situation it delights in, the drip of Scotch Firs. The Chantarelle, Cantharellus cibarius, was gathered, and very common it has been this year in almost every Oak wood of the county. This and Marasmius oreades, the Fairy-ring Agaric, or Champignon, have been extremely abundant all through the summer. If people did but know how strong and excellent is the catsup it makes they would not let it be thus wasted, though from its small size and rather dry nature it takes a deal of gathering to get a supply of this delicious condiment. Then there was Agaricus orcella, vegetable sweetbread, Boletus edulis, Russula heterophylla, Agaricus rubescens, Lepista nuda, and some others of which compassion for the compositor alone forbids the mention at this time. Edible Funguses often get into discredit from being eaten when unripe. There is a common saying about the Pear, that you should sit up all night to catch the minute it ripens; and if there is a basis of truth in the proverb with a fruit that takes so many months to reach perfection, one ought to be electrically sensitive to the exact moment of maturation of a Mushroom, which a few hours only will suffice to develope.

On the way through the woods many other Funguses were gathered; and by way of balancing the virtues of the edible kinds, it is well, perhaps, to mention that the virulently poisonous Lactarius torminosus or necator, "the slayer," as it is sometimes called, was very abundant, and a very beautiful Agaric it is with its rich orange zones and its woolly margin. The venomous-looking Lactarius turpis was frequently found, Agaricus fascicularis, A. sublateritius, and some others. One other Agaric only shall be named, and that because it is very rare and so very interesting. On a stump not far from the station Marasmius fœtidus, the little fœtid Marasmius, was growing plentifully. More Lactarii and Cortinarii were met with than could be named, for some were either new or in a peculiar form.

With well-laden baskets the Fungus-hunters reached the "Green Dragon," and all their fatigues were soon forgotten in close examination of the Funguses brought or sent for exhibition. Several of the scientific visitors who had come from long distances to be present at the foray had brought rare specimens with them. C. E. Broome, Esq., F.L.S., from the neighbourhood of Bath and Bristol, brought the small Truffle Genea hispidula from Hanham, near Bristol, Peronia punctata, Peziza rutilans and humosa, Polyporus scoticus, Agaricus squarrosus in its variety Mulleri, and many other sorts from Clifton and the Leigh Woods. The Rev. W. Houghton, F.L.S., &c., brought two specimens of Sparassis crispa, which is so excellent in flavour that it is a pity it is so rare; Agaricus clavipes, only of late added to the British Flora, and many others. W. Phillips, Esq., also brought from Shropshire Peziza onotica and cochleata; Agaricus (Clitocybe) cyathiformis, an unrecognised violet Cortinarius; (I.) Lycogala epidendron, &c. Charles Plowright, Esq., brought with him from Norfolk the rare Agaricus (Mycena) Iris, the curious and rare Cordiceps ophioglossoides growing parasitically on Elaphomyces muricatus, Boletus variegatus, and many others. The Rev. J. Jones Machen brought Craterellus crispus, &c. Miss Lewis, of Ludlow, sent Cantharellus tubæformis and many others. The remaining collections were from Herefordshire. A large hamper came from Whitfield of fine kinds in excellent order; a good collection was also sent by Mr. Miller from Eyewood, near Kington, containing the rare Hydnum zonatum, with two very grand specimens of Polyporus giganteus. Many members of the Club also did their duty scientifically, and the tables were well crowded with specimens. Time, unfortunately, did not admit of their being well arranged for study, but this want shall be supplied in some measure here. It will be an interesting feature if the Funguses gathered in Herefordshire for this meeting are put on record for the future. To prevent repetition, however, all those which have been already named in this account of the excursion will be omitted, and the names of the others well-recognised upon the table shall be strung together in the most concise manner and without comment. This arrangement will give readers in general the pleasant advantage of skipping them in a lump.

In the great order Agaricus the following species were present:—

(Amanita): phalloides, pantherinus, excelsus, vaginatus, and Ceciliæ.

(Lepiota): procerus, rachodes, excoriatus, Badhami, gracilentus, cristatus, and granulosus.

(Armillaria): melleus.

(Tricholoma): sejunctus, flavo-brunneus, albo-brunneus, rutilans, imbricatus, Columbetta, murinaceus, terreus, saponaceus, albus, personatus, nudus, grammopodius, humilis, and subpulverulentus.

(Clitocybe): nebularis, fumosus and its variety polius, odorus, cerussatus, dealbatus, infundibuliformis, geotrupus, and fragrans.

(Collybia): radicatus, maculatus, platyphyllus, fusipes, butyraceus, dryophilus, undatus, or vertirugis, tuberosus.

(Mycena): purus, polygrammus, alcalinus, epipterygius, pelliculosus, pterigenus, galopus, and tenuis.

(Pluteus): cervinus.

(Crepidotus): mollis.

(Entoloma): sinuatus, Bloxami, nidorosus, and rhodopolius.

(Clitopilus): prunulus and pupinalis.

(Nolanea): pascuus.

(Pholiota): spectabilis, mutabilis squarrosus, and radicosus.

(Hebeloma): lucifugus, longicaudus, fastibilis, and testaceus.

(Naucoria): cucumis, and furfuraceus.

(Psalliota): campestris, arvensis, æruginosus, squamosus, and semiglobatus.

(Hypholoma): lacrymabundus.

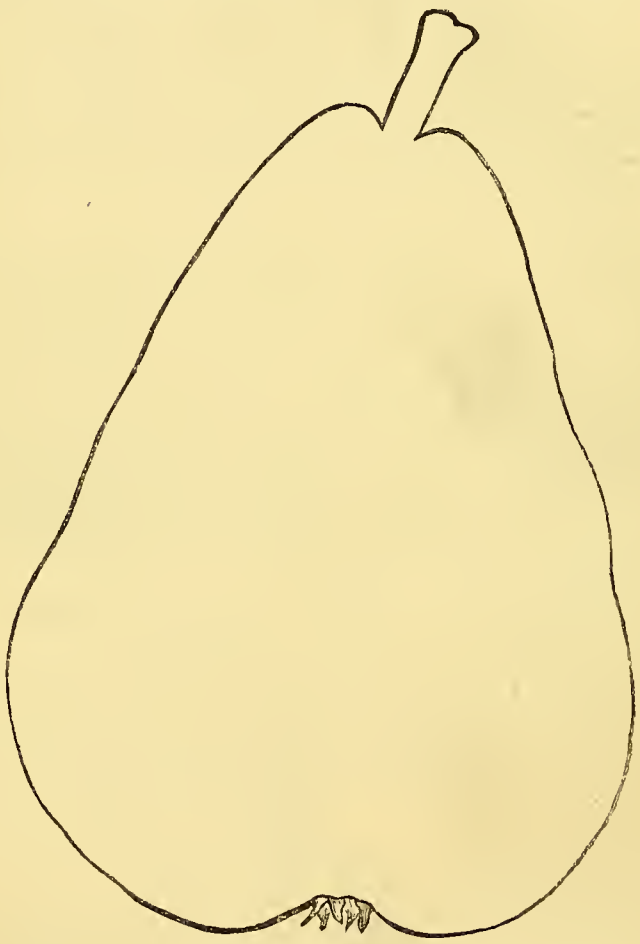
(Psilocybe): Fœnisecii, spadiceus, and semilanceolatus.

Coprinus atramentarius, picaceus, and niveus. Cortmarius callochrous, collinitus, fulgens, elatior, tabularis, diabolicus, cinnamomeus, caninus, and callisteus. Paxillus involutus, Gomphidius glutinosus, and viscidus. Hygrophorus olivaceo-albus, virginius, niveus, cerasinus, ovinus, Colemannianus, coccineus, puniceus, and lepurinus. Lactarius insulsus, blennius, chrysorrheus, pallidus, quietus, serifluus, subdulcis, glyciosmus, and fuliginosus. Russula nigricans, adusta, furcata, vesca, rubra, sardonia, virescens, emetica, ochroleuca, fragilis, and alutacea. Cantharellus aurantiacus and tubæformis. Marasmius urens, peronatus, and rotula. Lenzites

betulina. Boletus luteus, elegans, flavus, laricinus, granulatus, chrysenteron, luridus, scaber, versipellis, and badius. Polyporus perennis, squamosus, quercinus, lucidus, betulinus, fomentarius, cuticularis, versicolor, and igniarius. Trametes suaveolens. Dædalia quercina. Craterellus cornucopioides. Calocera cornea. Clavaria formosa, cristata, stricta, fumosa, and rugosa. Lycoperdon giganteum, cœlatum, saccatum, gemmatum, and pyriforme. Scleroderma vulgare. Cyathus striatus. Crucibulum vulgare. Helvella crispa. Leotia lubrica. Spathularia flavida. Thelephora laciniata. Peziza aurantia. Xylaria Hypoxylon, Merulius tremellosus, and Helotium virgultorum. Many others were also shown on the tables, which time did not admit of being properly named by the mycological authorities who were present.

OUR LARGEST AND FINEST SEPTEMBER PEAR.

I HAVE to-day (Sept. 25th) eaten one of the finest Pears of the month. It is large, and in colour much like the Brockworth Park. One figure in the "Dictionnaire de Pomologie" is like that given of this sort in the "Year-Book;" another in the same book differs from it widely. The French and English descriptions of it do not vary much. The former is "Peau jaune-citron, ponctuée, strié de roux, largement marbrée et tachée de même vers l'œil et le pédoncule;" the latter —"Skin smooth, pale yellow, slightly flushed and streaked with crimson on the exposed side."



Beurré de l'Assomption.

In France this sort ripens in August, here in September, and this year late. The habit of the tree is robust, much like Williams's Bon Chrêtien, of which I should think it a seedling, and it is marvellously fertile. There is none of the Williams's musk in its flavour, but a rich, pleasant, vinous, sugary taste. It seems as if this Pear is a twin of the Brockworth Park Pear, and if so, a very worthy sister or brother.

The Beurré de l'Assomption was raised at Nantes, and was introduced with another very large Pear raised at Lyons, called Souvenir du Congrès. This has much the habit of the former, and seems to be also a descendant of Williams's Bon Chrêtien, but it has hitherto proved coarse; it is, however, larger than Williams's, more robust in habit, and if it bear well it will prove a valuable market Pear.—T. R.

DESTROYING PHALLUS IMPUDICUS.

SOME of your readers may be glad to learn that we have succeeded at this place in gradually extirpating the miserably stinking Fungus (Phallus impudicus), with which we were a few years since much infested, by a steady perseverance in the following operation—viz., we dug up every Fungus as soon as it appeared, committing it to the fire, and spread over the place where it grew a handful of common salt. By the careful adherence to this mode of operation, in a copse of about a quarter of an acre the number of Fungi was reduced to one in the year 1869, to 0 in 1870, and to one in 1871.—C. W. JOHNSON, *Waldronhyrst, Croydon.*

FILMY FERNS.

WHAT are they? is a question not unfrequently put to us by correspondents and others. We purpose to-day furnishing a few particulars regarding their haunts and habits.

First, then, as to the name Filmy Ferns; it has been given to this most interesting division of the tribe by reason of the cobweb-like texture and transparency of the fronds of many of the species. In some this filmy, diaphanous character is so marked that the smallest print may be read through their fronds. This transparency is strikingly and pleasingly illustrated in that loveliest of Ferns, the New Zealand Todea superba, by quickly placing an envelope, or other piece of white paper, at the back of a frond, when the latter appears as though illuminated by a flash of light. Though the vast majority of species are to be found only in the lofty ranges of distant Chili and New Zealand, it is not necessary to travel outside our own country for examples of these delicate Ferns. In what is called, *par excellence*, the Irish or Killarney Fern, Trichomanes radicans, and the tiny Hymenophyllums, H. tunbridgense and H. Wilsoni, we have excellent illustrations of the two genera which take in nearly all the known species of Filmy Ferns. Now for a few words with regard to the haunts which they affect, and the conditions under which they are found growing.

The shady forest and the damp ravine in mountainous districts, where air and soil are saturated with moisture, are where the Filmy Fern grows and revels in luxuriance; consequently, in cultivation, a humid atmosphere is an essential element to their well-doing. They rather affect cold and temperate climes; and except in the case of a few West Indian species, artificial heat in their cultivation is not only not required, but must be sedulously avoided. Even natural atmospheric heat must be subdued by attention to aspect and other means of modification. Many of the species will bear with impunity the closest hug of the ice, but not one of them the slightest touch of the sunbeam; let it but play directly upon these delicate subjects, and they shrink from its influence, shrivel, and die. This, however, does not imply absolute darkness; too deep shade, even, suits only a few. They like light, but light subdued. The habit of most of them is to extend their creeping rhizomes over the rock or other surface to which they are attached. In growing species of this habit, care must be taken not to cover the delicate rhizomes with soil. The soil best suited to them

is a mixture of sandy peat, either alone or mixed with a small portion of loam and lumps of sandstone, such as the soft red granite of the Wicklow hills. Besides securing for them a humid atmosphere, it is essential that it be still, and currents of air carefully avoided. As to water, it should be quite pure, and free from lime—rain water is, of course, the best. As to the mode of watering, there must be no dashing or rough practice. When grown in Wardian cases, the practice of sprinkling overhead is very general; but whether in the Fern case, or the more extended field of the Filmy Fern house, the safer practice is, we fancy, to eschew hand or heavy watering, and let them draw their supply from the pure and compensating agency of alternate evaporation and condensation.—(*Irish Farmers' Gazette.*)

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 24.

DRAWING PLANS.

To transfer *fig.* 49 to the ground. Erect the rectangle A B C D, the sides being 55 feet and 82 feet respectively. Insert stakes at each point, and lay lines connecting them. Lay the diameter lines E F and G H. On each side of centre *z* (the point where the diameter lines cross each other), on diameter line E F, measure 18 feet 3 inches, and insert pegs as at centres *a* and *b*. From the peg at centre *a*, with a string 33 feet long, trace arc 1, as shown by radius *a* 1, terminating at points *g g*. From the peg at centre *b*, with the same radius, trace arc 2, as shown by radius *b* 2, also terminating at points *g g*, as shown by the dotted lines. From the peg at point *g*, with a string 11 feet 8 inches in length, trace arcs as shown at points *e*, H, *f*. Where the arcs cut arcs 1 and 2 insert pegs, as at points *e*, *f*. From the peg at point *g*, with a string 23 feet long, trace arcs as in *d*, *s*; insert a peg at each point. From the peg at centre *a*, with a string 29 feet long, trace arc 4, as shown by radius *a* 4; reduce the string 4 feet and trace arc 6; again reduce the string 4 feet and trace arc 9. From the peg at centre *b*, with the same lengths of string, trace arcs 5, 7, 10, corresponding with arcs 4, 6, 9. On each side of centre *z*, on diameter line G H, measure 10 feet, and insert a peg as at point *c*. From the peg at point *c*, with a string 11 feet 6 inches long, trace arc 3, connecting arcs 4 and 5; reduce the string 4 feet and trace arc 8, connecting arcs 6 and 7; again reduce the string 4 feet and trace arc *x*, connecting arcs 9 and 10. Trace the four small circles as shown; and with a radius of 5 feet trace the arcs that cut the ende of the beds. From the peg at centre *a*, with a string 13 feet 4 inches long, trace arc 11; reduce the string 1 foot and trace arc 12. From the peg at centre *d*, with a string 12 feet 4 inches long, trace arc 23; reduce the string 4 feet and trace arc 24. From the peg at centre *f*, with a string 12 feet 4 inches long, trace arc 21; reduce the string 1 foot and trace arc 22. From the peg at point *g*, with a string 11 feet 8 inches long, trace arc 19; reduce the string 4 feet and trace arc 20. Trace the corresponding arcs in the same manner. Find centres *h*, *i*, *k*, and *t*; insert a peg at each centre, and from their respective pegs trace arcs 25, 26, 27, 28; trace the other corner beds in the same manner. Divide the distance between points *i* and *k*, as shown by the dotted line, into two equal parts, and from the centre set off 2 feet on each side, lay lines from the points thus found to the angle of the figure, and lay out angles B, C, D in the same manner. Trace circles *u*, *v*, and *w*, also circles *t*, *r*, and *x*. Trace the corresponding side in the same manner. The width of the entrance walks, as shown in G H, is 4 feet. The lines and dotted parts represent Box; B, beds; W, walks; C, coloured material.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

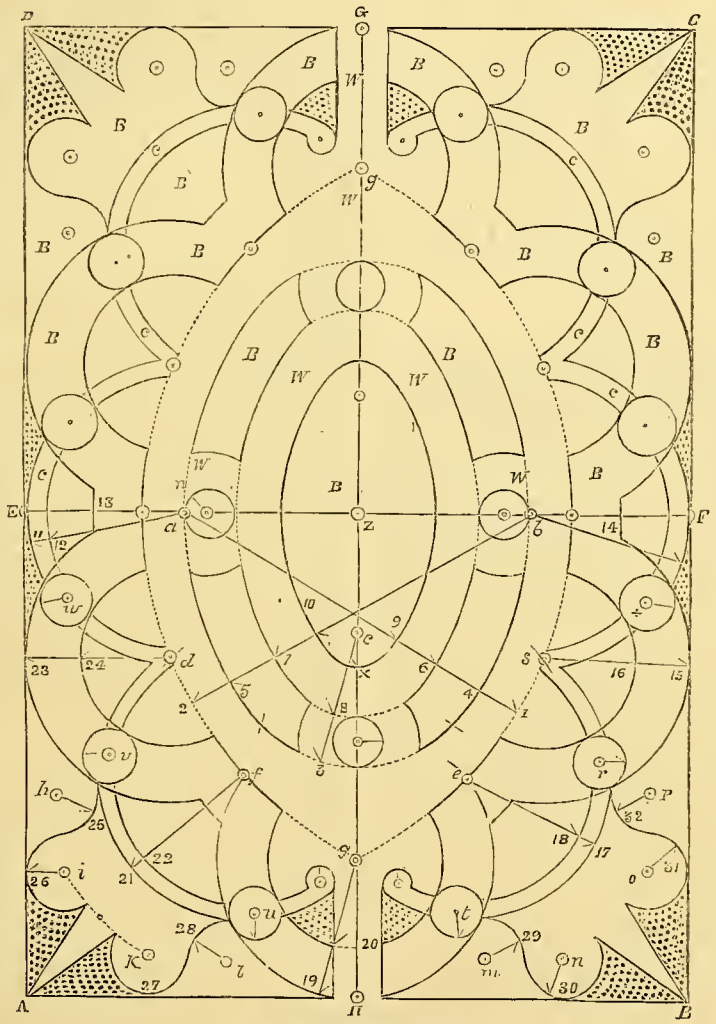


Fig. 49. Scale 16 feet to the inch.

THE AUSTRALIAN PEA, alias GROTTO'S MOSSY PEA.

Some sixteen or seventeen years ago a gentleman brought some Peas from Australia, which have since that time been cultivated in a few private gardens under the designation of the Australian Pea. Three or more years ago it got into the hands of Messrs. Kennedy & Co., seedsmen, Dumfries, and was last season distributed by them under the honest impression that it was a Pea new to this country. It was, however, confidently affirmed by the Messrs. Drummond, seedsmen, Stirling, to be none other than what they term Grotto's Mossy Pea, which had been grown in this country fifty years ago, but from some cause or another it had become scarce and little known by either seedsmen or gardeners. We have these two

Peas growing in the same row, and find them in every respect the same; and we observe that it has recently been shown in London under a third name, and there recognised as Grotto's. It is, however, a most valuable Pea for late supply, being an enormous cropper, medium-sized, and of a delicate green colour —points much appreciated by kitchen artists and those they have to cater for. Added to a delicious flavour, these qualities make it a very desirable Pea. We have frequently gathered it in fine condition at the very end of October. It has a thick mossy or succulent husk, and, in consequence, the Peas remain tender long after the appearance of the husk would indicate that they were too old. This Pea is well worthy of being, what may be called, reintroduced into all gardens where fine late Peas are an object, and where tall stakes are to be had. It grows 7 feet to 8 feet high. We think it best described by its original name—The Mossy (podded) Pea.—*(The Gardener.)*

MARKET GARDENING.

Fuller shows us the beginnings of market gardening two hundred years ago; he wrote in 1662. "Since gardening hath crept out of Holland to Sandwich in Kent, and thence into this county (Surrey) where, though they have given £6 an acre and upwards, they have made their rent, lived comfortably, and set many people on work." The extension of garden farming in Essex, with horse-tillage and steam cultivation, in one instance, has been rapid. A wealthy grower of vegetables is only lately deceased who was among the first to emigrate from the older site in Bedfordshire. He arrived in the new colony without capital, and without the skill to read or write a market tally, and lived to occupy a farm where more than 500 acres of vegetables were grown every year.

The Essex District extends from Stratford, bricks and mortar permitting, to West Ham, and thence through East Ham, to Barking, Rainham, Dagenham, Hornchurch, and Romford. The parishes of Aveley and Purfleet are at present, but may not long be, beyond the boundary of vegetable-growing. They are now famous for early Peas, and on June 19th this year large gangs of women were picking the first crop. At Rainham Strawberries were begun on the same day, and Potato-digging had commenced a few days earlier. The crops are all seven or eight days earlier than they would be under ordinary farming, without the warm coat of manure. The subsoil of the Thames Valley is a drift of sharp small flint, or gravel; it is generally covered with good light loam, which is in many cases several feet in depth, and is continually enriched by heavy dressings of dung.

This district takes most of the manure produced in the eastern part of London, and it supplies a large portion of the fresh, bulky vegetables consumed in the metropolis between spring and autumn. The whole of the produce is sent by road, and, except near a river wharf, or close to a station, the manure is brought by the waggons on their return from market. The outlay on the farms, as will presently be shown, generally exceeds £20 an acre, and requires such a return as is yielded only by garden crops and garden farming. The growth of corn has been almost abandoned.

In this district of large garden-farms the fields are seldom less than 10 acres in extent, and are generally from 20 to 40 acres.

In garden-farming there are no strict rules with regard to the succession of crops; the land is kept constantly under crop by sowing, or by replanting from seed-beds as fast as the fields are cleared. Cabbages may follow Cabbages; and the loading of the market waggon proceeds in one part of the field while the plough teams and planters are busily employed close by.

In the London district Potatoes are followed by a second crop. The earliest may be followed by Cabbages, the later by Savoys, and the latest by "Collards," for bunching during the winter months, when Cabbages are out of season. Cabbages should not be planted much later than the third week in June; they will then be sent to market in November. Savoys are next pricked out from the seed bed; and Collards, which are planted almost at any time when there is a piece of ground to spare, follow up to the end of August.

In dry seasons the transplanted crops require watering; and although irrigation generally is neglected, it is sometimes very beneficial to garden crops. A 50-acre gardener, who grows Celery, Cauliflowers, and other crops, showed me a little rivulet running through his ground. It costs him £60 a-year; but, "when other grounds are scorched," he said, "my garden is as green as a Leek! It will give some idea of speed in gardens if I mention that Cabbages planted in the second week in April afforded a first cutting this year on the 28th June. Another example of double crops is in the case of early Cabbages, which are sent to market in April and May. A month before cutting them, the land being in good tilth, holes are made in the rows with a spade, one hole between each two Cabbages; a boy follows and plants Potatoes, which are covered with the earth taken from the next row. This plan obviates the treading which occurs when the sets are planted between the rows.

Peculiar virtues have been attributed to the spade as an instrument of cultivation, but the secret of the great fertility which follows the spade lies in the heavy dressings usually applied to the gardens. As an example of this kind of cultivation, I visited a large garden of 40 or 50 acres, in the parish of Bermondsey, flourishing in the midst of smoke and vile smells. The larger part of the garden is planted with Radishes, Cauliflowers, and Celery, taken from the same ground every year; and the rotation is repeated every year, with the precaution of moving the site of the rows of Celery. These are planted 5 feet apart, with two rows of Cauliflowers between them. The ground is dug in the ordinary way, once a-year, in winter, as soon as the Celery is removed. One hundred tons of dung per acre are sometimes applied, at a cost of between £30 and £40. The Radishes are sown in March; the Cauliflowers, having been sown in October in frames, and protected from frost during the winter, are pricked out among the Radishes; and the Celery follows.

Eight acres of Rhubarb are cultivated with the five-tine steel fork. I was told, "the more manure the more Rhubarb." Asparagus is forced by frames and hot dung. Plants of three years' growth afford three weeks' cutting, and are then destroyed; and a less price than 7*s.* 6*d.* for a bundle of 105 does not pay the grower.

On the 11th of July a large bed was planted with "Collards" and Walcheren Broccoli in alternate rows, at 18 inches from row to row. The Broccoli will be sent to market in November. There is a large fenced plot for Cucumbers and Vegetable Marrows.

The very deep cultivation which is frequently heard of, and occasionally practised in agriculture with more or less profit, has not been found desirable in market gardens. The Cabbages, Greens, Cauliflowers, Broccoli, Onions, Potatoes, Cucumbers, &c., which fill the markets of London, are generally grown on a 7 or 8-inch furrow; and as a rule, only one furrow is turned for each crop. In the case of subsoiling for late Carrots and for Parsnips, the object appears to be to give mechanical assistance to the root, to enable it to run down long and tapering. One of the most eminent growers of Parsnips in the metropolitan district cultivates 9 or 10 inches deep by means of a common plough, followed by a subsoil plough. A 6 or 7-inch furrow is enough for two horses, and 3 or 4 inches are as far as the subsoiler reaches in a gravel loam with three horses.

Mr. W. W. Glenny has been good enough to permit me to give an account of his garden-farm at Barking. It consists of 150 acres of gravel loam, made rich and friable with manure, and kept in the highest state of cultivation. The farm is entirely in vegetables, with the exception of 18 acres of permanent pasture, and 16 of wheat, on the stiffest land, which is furthest from the railway station.

At the time of my visit the acreage of the farm was thus appropriated:—Potatoes, 34; permanent pasture, 18; spring-sown and Lisbon Onions, 15; Cabbage, 12; Red ditto, 2; seed-beds, 2; Carrots, 7; Parsnips, 9½; Dwarf Kidney Beans, 6; Scarlet Runners, 3; Vetches and green food for horses, 4; Parsley, 1½; Willow and Osier beds, 1½; Wheat, 13; Mangold, 1½; Peas, 8; Asparagus, 1; men's allotments, 1; Cucumbers and Vegetable Marrows, 2; seeds, 1; buildings, roads, brook, and small crops, such as Sage, &c., 11.

Twelve horses are kept to cultivate the farm, convey the produce a distance of eight miles to London, and to cart manure. The sums paid for dung, exclusive of cartage, during the past three years have been—£211 9*s.* 3*d.*, £271 16*s.* 7*d.*, and £278 15*s.* 2*d.* From 400 to 700 bushels of soot were also used in each year. About one-half of the dung is purchased at 3*s.* or 3*s* 6*d.* a-ton, and is drawn from London in the empty waggons; the remainder is bought at 5*s.* per ton, at the railway station or the quay. Some other manures, including the spent hops from an adjoining brewery, are also brought on this farm.

The live stock consists of a couple of milch cows, and forty or fifty pigs during the winter.

The labour bill, including beer, is £1500, or £10 an acre. At the time of my first visit (June 17th) the number of labourers employed, including ten women, a wheelwright, and a salesman, was thirty-five, and their wages amounted to £30 a-week. During the winter five women are employed preparing goods for market, bunching Leeks, pulling and bunching Greens, putting up Onions, &c.

The implements of the farm, besides carts and market waggons, consist of common ploughs, a double-breasted or ridging-plough, for moulding Potatoes, Beans, and Peas, and some hand-drills. A small patent tool, which resembles a Dutch hoe put on wheels, must be mentioned, because its use shows the mechanical effects of dung and good farming in making the surface friable. It is not uncommon for a man to push this little implement over two acres in a day, cutting up all the weeds between the wide rows of the garden crops.

A Willow-bed supplies bunching rods for tying the bunches of Onions, Greens, &c. The plants are set at 2 feet by 18 inches, and the bed lasts twelve years. Osiers of coarser habit are grown to make baskets for vegetables and fruit. I may note that the cost of the baskets (with a few sacks) used on the farm exceeds £50 a-year.

Parsnips are one of the main crops which are successfully grown on this farm. The chief points to observe in their cultivation are—1st, To sow on land that is least liable to wireworms and the small creatures—probably slugs—which are said to be invisible to the eye, and which soon make the Parsnips so, by eating the young plants as fast as they appear; the remedy for slugs is soot, and the prevention is, sowing on land that is not liable to be infested. 2nd, To take precautions against having forked Parsnips, and to grow them of a fine, tapering, marketable shape by breaking the land well up and applying the manure to the previous crop. It is not perfect management to sow after Corn, because the land is not then in sufficient heart and tillage; or after Clover and Grasses, on account of the danger of wireworms and canker; or after Potatoes, because Potato-ground ought to yield a crop of Greens after the Potatoes are off, instead of lying idle till Parsnips are sown. They generally follow late Cabbages or Savoys, which are cleared respectively in November and from Christmas till 1st of March. In either case, the field is not touched until immediately before sowing the Parsnips, and Mr. Glenny would prefer to plough, scarify, and sow on the same day, so that the seeds of the crop might start fairly with those of the small Nettle, Chickweed, Grass, and the Shepherd's-purse, which are favourite weeds in market gardens, frequently escaping the continual hoeing, and almost serving to establish in some quarters the theory of spontaneous generation. Supposing the clearings of the Savoys to have been bunched by the 1st of March, as in 1867 (14th of March in 1868, 20th of February in 1869), the land is ploughed with two horses and subsoiled with three horses, and is thus moved and stirred to a depth of about 9 inches. It is then drilled with a hand-drill as early in March as the state of the weather permits. Mr. Glenny objects to preparing the land in autumn, because it solidifies too much by the time the crop is sown. In garden-farming a stale furrow and a frosted surface are not entirely appreciated, since the made soil of a garden-farm is effectually pulverised by manure and surface tillage. Parsnips are sown 15 inches apart in the rows, and the plant is singled at 10 or 12 inches. The crop is hoed, singled, and kept clean for 45*s.* an acre. The hoeing this year had cost, up to 21st of June—First hoeing, 5*s.*; singling, 16*s.* 8*d.*; second hoeing, 6*s.* Frost does not injure Parsnips. The roots are raised and sent to market from the field, and are in season from November till the end of Lent, occupying the ground longer than any other crop.

Dwarf Kidney Beans often follow early Cabbages, without dung. The last of the three successive sowings is made about the 21st of June. This delicate plant is impatient of fresh manure, and requires the preparation of a perfect garden-tilth. Mr. Glenny always ploughs twice, and for this and similar crops the land should be lightly rolled, to level it and to retain moisture. Drills are formed at 2½ feet apart by means of a small hand-plough, or marker, drawn by a man and a boy; women follow, and drop a seed at every 9 inches, and the drill is then covered by a man with a hoe. The plants are carefully hoed. Dwarf Kidney Beans grow rapidly, and soon become what salesmen call "old Beans." In hot weather they should be gathered every other day, and they are cleared in about four pickings. The latest-sown Beans are cut down by the slightest frost.

Scarlet Runners are generally sown in the last week of April, after Greens. The land is ploughed twice, with an interval of two or three weeks. The rows should be 3 feet apart, and a seed is planted in every foot of the drill. Runners continue to bear until they are cut down by severe frost. When manured, they are liable to become too luxuriant in damp summers; they should, therefore, be planted on good land, without manure. It does not pay to support them on sticks, except when they are grown as a shelter for Cucumbers; and instead of giving them artificial support, an upstanding habit is induced by continually topping the vine from the period of its beginning to "run," about the middle of June.

Unless Dwarf Kidney Beans and Runners are gathered when very young, they should be sorted before sending them to market, in order that the broad ones may be picked out.

Cabbages.—A second crop in succession was planted this year, on June 21st, after ploughing in a second and heavy coat of dung with a 7-inch furrow. After rolling the land a line is used in setting the plants, which are put in with a short dibble, at a distance of 22 inches by 20 inches. In the case of "Collards," which are planted 12 or 14 inches each way, a light roll after the plough is followed by the "fiddle"—resembling a rake with four or five long teeth—dragged by a boy, to mark drills for the plants.

Red Cabbages for pickling are planted in October, a yard apart in each direction, and occasionally Collards are set previously between the rows in which the Cabbages will afterwards be planted. The catch crop is sent to market early in spring, before the ground is required by the main crop.—H. Evershed (in *Royal Agricultural Society's Journal.*)

(To be continued.)

MEALY BUG.

I have an early vinery which by some means became infested with mealy bug, and I have tried the following plan, but with what success I must leave the future to decide. As soon as the fruit was set I packed all the stems of the bunches with cotton wool, which in a great measure prevented the bug from travelling over it and lodging amongst the berries. The crop, which was excellent, averaged 30 lbs. to each Vine, and was borne on single rods spurred. The principal variety was Black Hamburgh. The bunches were all cut by the end of May. I then vigorously applied clear water with the syringe twice a-day, and at intervals of a week Gishurst compound at the rate of 4 ozs. to a gallon of water; and as soon as the Vines were stripped of their leaves I washed the stems with soft soap and warm water applied with a hard brush, then scraped every particle of old bark off, gave another scrubbing with the same, and lastly painted with Gishurst compound as directed for winter dressing. I painted all the wood—rafters and sashbars—with turpentine, and the back wall with hot lime. I pared 2 inches of soil off all the inside border, burying it in the kitchen garden, and I intend giving the Vines another dressing or two before they are started this winter. Should I be successful in stamping out this horrible pest I will not fail to let you know.—McGregor.

[Our correspondent wishes "Observer" would send more details. See our number published September 7th.—Eds.]

NOTES AND GLEANINGS.

Mr. George Mills, formerly gardener to Baroness de Rothschild at Gunnersbury Park, died on September 30th, at his residence, Uxbridge Road, Ealing, aged eighty-four years. After spending some time in the garden of Mr. Goldsmith at Roehampton, and Messrs. Lee & Kennedy's nurseries at Hammersmith, he went as gardener to Mrs. Hall Dare, of Cranbrook Park, Ilford, who, on her death, left him a pension of £30 per annum. He continued to fill the same post, along with that of bailiff, under her son, R. W. Hall Dare, Esq., M.P., remaining altogether twenty-two years at Cranbrook Park. In 1833 he became gardener at Gunnersbury, first to Mr. Copeland, and afterwards to Baroness de Rothschild. He retired in 1853, and after being engaged for some time in giving advice on laying-out gardens, he took to Rose-growing for market. He was celebrated as a successful cultivator of the Cucumber, Melon, and Pine Apple, and some very heavy specimens of the last-named fruit were grown by him. He published a treatise on the cultivation of the Cucumber and Melon, and another on that of the Pine Apple. The former, which we believe was revised by the late Mr. London, passed through three editions.

—— We have also to record the death of Mr. Jean Van Geert, the well-known and respected nurseryman of Ghent. He, too, had reached a ripe age, being in his 78th year at the time of his decease, which took place on October 14th.

—— Wellingtonia gigantea.—The *New York Times* states that a section cut from one of the original "big trees" of California is in New York on its way to a European Museum. Five men were employed twenty-five days in felling this huge tree; its height is 302 feet, and its largest diameter 32 feet. The specimen was cut at a distance of 20 feet from the base. The stump is covered in, and is now used as a ball-room! It has been ascertained from counting the annular rings that the tree is more than 2500 years old.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Persevere in hoeing, forking, and surface-stirring amongst progressing crops, particularly Coleworts, Cabbage, late Savoys, and Kale, as a considerable demand for vegetables of this description may be expected throughout this season, and more particularly in the forthcoming spring. The decayed *Asparagus* haulm should be cut on a fine day, and taken care of for thatching the Pea sticks, or tied in bundles to be placed as drainage under temporary structures for sheltering *Endive* and *Lettuce* in winter. In clearing the refuse from Asparagus plantations, and the decayed leaves from amongst the Broccoli, Kale, Savoys, &c., observe particularly if there are any fresh-used mouse-holes; if any should be discovered, at once pour some water hastily into the hole; this will start the inhabitants, which may then be destroyed. Collect some of the driest leaves for placing about the rootstocks of *Artichokes;* if leaves are not procurable, place dry litter or fern for their protection.

FRUIT GARDEN.

Look over all kinds of stored fruit occasionally, sort out the affected fruit, wipe others, where required, with a dry cloth, and where it is convenient, and where the plan is approved of, pack away in boxes, drawers, or casks some of the late table fruit in dry sand. Where there happens to be any quantity of spotted, rotten, or affected Apples and Pears, collect them together, pound them down, and press out the juice; barrel it, and see well to its fermentation by repeatedly racking it. A pleasant and wholesome beverage may be thus obtained for summer drinking. The out-door Vines should now be gone over, and all the lateral shoots that have been left on the strong shoots may be taken out, and two or three of the joints of all the young wood at once pruned off. This will greatly contribute to the ripening of the wood. Every means which will tend to encourage the ripening of the young wood should be adopted. Look over the trees in old orchards, and remove at once those that are considered worthless and worn-out. Prepare for making new plantations of Strawberries, Gooseberries, Currants, and Raspberries. A portion of the old plantation should be grubbed-up annually and renewed, if an abundance of fine fruit is expected to be obtained.

FLOWER GARDEN.

Preparations for severe weather should be completed as soon as possible. All tender stock intended for protection under glass must be at once placed in its winter quarters, plunging it as before observed in ashes or sawdust. A good supply of garden mats should be instantly provided, for although expensive they must be had, as it is folly to permit the ravages of the frost before they are procured. A good stock of new sawdust should be laid-by in a dry shed to put round the stems of tender Roses or half-hardy plants. This should always be obtained as new and fresh as possible. It should not, however, be applied to the plants for some time; when it is applied a dry period should, if possible, be chosen, as a casing of such material immediately after heavy rains would probably prove very prejudicial, for confined air or damp is a greater enemy than frost in many cases. Wooden shutters are very useful things, whether to lay on as a temporary framework to exclude wet and the keenest of the frost, or to cover pits and frames instead of mats. Old worn sashes which have been stripped of their glass may be brought into use by thatching them with a straw facing; temporary frames composed of rough slabs, may be readily got up to receive them, by any ordinary carpenter. Such will prove a relief to the regular frames, for in very many establishments there is no surplus of these, and most of them are wanted betimes to force Asparagus or Cucumbers, or for early Melons, &c., which purposes require that the frames should be at liberty by Christmas at the latest. Those who can spare time should wash all their pit and frame-glass before the dark weather sets in, as the disproportion of the light to the heat is the great bane of forcing in Britain during November and December. After the removal of summer-flowering plants, which takes place about this period, no time should be lost in having the beds freshened-up by a light digging, and fresh plants being put in so as to prevent the ground having a bare and dreary aspect throughout the winter. Nothing is better for this purpose than a supply of small neat plants of the different dwarf, hardy, evergreen shrubs. A sufficient number of these to fill a moderate-sized flower garden could be kept in pots and placed during summer in a reserve ground without much difficulty and trouble. Small plants of many of the variegated shrubs, together with others of a dark and light green tint, and the different modifications of conical and globular-formed heads and decumbent stems, would afford variety enough to render a flower garden very pleasing even in winter. All the offsets and small stock-roots of Tulips should be planted as early as convenient in the store beds. They may be planted in rows 6 or 8 inches apart, and the strongest 3 or 4 inches apart in the rows; the smaller ones may be put in closer. The principal blooming roots may be put in at the earliest opportunity; but if the present dry and favourable weather continue, no time should be lost in having them planted while the soil can be worked with facility. After wet the operation of planting will be far less satisfactorily performed. They may be planted 6 inches apart each way. On most soils the practice of placing a small portion of clean sand beneath each root, and a small cone of the same around and over it, is beneficial; it tends to keep the bulbs clean and healthy by preventing excess of moisture from accumulating in close contact with them. Other spring hardy bulbs, such as Hyacinths, Narcissus, Jonquils, Fritillarias, Crown Imperials, Lilies, Snowdrops, Crocus, Dog's-tooth Violets, &c., had better be planted as early as possible. The advantage of getting them fairly in the ground while it admits of being worked with such facility as at present, is too great to be overlooked. Pansies, as also plants of Polyanthuses, Auriculas, &c., whether kept in pots or frames, or planted in the open ground, should be carefully watched against the depredations of slugs, which soon make great havoc if neglected. When the frost has destroyed the flowers and foliage of Dahlias, the stems may be cut down within a foot of the ground, then lay a heap, 6 or 8 inches thick, of dry sawdust or some protective material close round the stem, extending about a foot each way. The roots had better not be taken up until the tubers have become more fully ripened.

GREENHOUSE AND CONSERVATORY.

These structures will now, of course, be arranged in a systematic way. The inmates, or at least some of them, begin to put on their winter attire. The numerous plants adapted for winter and spring-flowering will begin to afford much gratification, which will be enhanced by the desolate appearance outside. Scarlet Pelargoniums, Salvias, Camellias, Chrysanthemums, Cyclamens, and Perpetual Roses, will now require careful management, and most of them a liberal supply of water. Now that summer flowers are waning let a strict eye be kept on those which, though of no particular botanical interest, are of great importance as cheering the mind amidst the gloom of winter when all out of doors appears so desolate. Let all flowering plants, of whatever kind they are, be kept near the glass in the lightest situation to be found, and let those from warm climates enjoy bottom heat, if possible, until they commence flowering, when they will do tolerably well without. Of course, such plans cannot be carried out where Ericas, Pelargoniums, and hardwooded plants from temperate climates are preserved. I merely throw out the suggestion to those who have a number of structures.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The past week was almost as warm as the end of June. Flower beds in many cases assumed a bright appearance. Yellow Calceolarias were yellow again, and some of the Nosegay scarlet Geraniums were rather fine, but we fear that the threatened rain will deprive them of their beauty. As we wanted to empty a shallow pit of the little decayed dung at its bottom, in order to save two wheelings, we took it at once to part of our Asparagus ground. We cut down the Asparagus stems with an old scythe, knocked up the few weeds that appeared, raked the

ground roughly with a wooden rake, gave a sprinkling of salt, and then placed on the surface enough of the manure to form a covering fully 2 inches in thickness. This covering is chiefly put on in order to save the crowns and buds from severe frosts in winter and spring.

Cucumbers.—Those which were planted in pots sunk in a warm bed in a pit, have produced unusually well all the season. We meant to have replaced them before now, but they are still bearing so freely that we do not like to remove them just yet, and therefore have potted some strong plants in 10-inch pots, so that we may keep them in little space until we remove the others. It is likely enough that with a rich, light, top-dressing the plants would bear all the winter, but there is a little more risk with them than with younger plants. We lately took out a plant showing signs of distress; it had stood through the summer and winter of 1870. Once we had a plant in a wooden box in a Pine stove that stood and bore well for two winters and the greater part of three summers. Besides frequent pruning and cutting, and frequent rich top-dressings and manure waterings, the peculiar treatment it received was a sponging at times of the thick stem to remove greenish incrustations. The cracking of the stem longitudinally, and the consequent damping and decaying at the cracks, destroyed the plant at last. But for curiosity, we do not think there was any real advantage in keeping the plant so long; for even as respects room Cucumbers may be kept in little space in rather large pots until they are turned out into beds or fruiting pots, so as to show fruit at once.

We had this plant years before we were troubled with the disease, as whilst its attacks continued we could find no remedy, except frequent sowing and planting, for after the disease appeared we were perfectly helpless to save the plants. As we have frequently stated, we are ignorant now what brought it, and what took it away. We met with a fact lately in an establishment where Cucumbers were grown for market. In one house there was not a trace of disease. In another house the plants were killed; there was the breaking-out guttering on the fruit, and the unmistakeable brownish blotch on the foliage. The glass sashes of this house had been brought a good many miles from a place where they had been used for Cucumber-growing, and where the Cucumbers grown were diseased. The glass and woodwork had been thoroughly washed, but it would seem that somehow the taint had come with the sashes. Fresh painting might have obviated the evil. We can only say might, for in our own case we have washed glass, woodwork, and walls with water as hot as it could be applied. We have shut the place up, and fumigated it with burning sulphur. We lime-washed the walls with hot lime and sulphur, ran a paint-brush over all the woodwork, glass sashes included, and then, after a fine growth and gathering a few fine fruit, the disease would again show itself. The famed Cucumber-grower in the case referred to above may consider himself fortunate if the disease is confined to the one old house. We would rather grow anything else in it than Cucumbers.

Mushrooms.—We missed our old shed this summer, as whatever there might be in the park, there are reasons for our not taking any from thence. We have had a fair supply from the Mushroom house, but not the basketfuls of plump fleshy Mushrooms we used to have from the shed. We have covered a bed in the Mushroom house with a little litter. It has been spawned about three weeks, and we should like to see the Mushrooms in another three weeks, as the older beds will be getting thin by that time. This bed was in excellent order when spawned and earthed-up, and had just the desirable warmth to entice the spawn to run freely, but for a few days lately the heat seemed to decline too much, and hence the covering. Besides, this bed, being a shelf bed, we put the most of the material that will be need for another piece in the ground space for a bed underneath, and run mats round in the space between, so as to confine a little the heat of this fresh material to act on the bed. We can easily regulate this as well as the covering, when the bed shall have become healthily warm again. Too much heat would be injurious, and too little would not so much injure as delay the gathering of the crop. Having a hot-water pipe we could have turned heat on, but that would not have so well suited our purpose, as two other pieces are coming on, and both beds are yet too hot for spawning; one, though in otherwise excellent order, and firmly beaten, keeping its strong heat longer than we expected or wished, as we generally maintain a regular supply, not from large beds, but from small beds following each other. Had we applied the hot water, the house and this bed we are waiting to cool sufficiently would have been heated throughout, whilst all we wanted was to give a little extra heat to the first bed we have made this autumn, and this the dung beneath will do, whilst the mats round will prevent the steam affecting the Mushrooms now growing. When we get the desired heat in the bed, not more than the warmth of new milk, we shall remove the mats, and can easily keep down heat and steam by throwing some rough fibrous dry loam over the surface. This, mixed with the manure, will do for another piece of a bed, and we generally make those raised on shelf platforms before the beds on the ground. The material we have often alluded to; horse droppings, with about an equal portion of short litter, is the best, and this should be rather inclined to dryness than to wetness, especially at this season. As often stated, however, we have had fine beds formed chiefly of litter and tree leaves to give an enduring heat, and with from 3 inches of horse droppings on the surface. All these matters, however, have already been largely dwelt upon.

ORNAMENTAL DEPARTMENT.

Besides mowing, cleaning, and rolling, the chief work has been potting, shifting, making cuttings, washing glass, renewing glass where broken; also making arrangements for lifting some plants, for making Calceolaria cuttings in the manner often described for planting and potting Pinks, and for getting Chrysanthemums under cover.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

EPITAPH (*Stafford*).—Your loss we know is very severe, so we do not criticise your letter, but suggest that you should adopt this epitaph and ponder on its moral:—"A gardener wandering round the garden, one day asked, 'Who plucked that flower?' One of his fellow-labourers replied, 'It was The Master plucked it.' The gardener held his peace."

BOOK OF GARDEN PLANS (*A New Beginner*).—We know of none except our "Flower-Garden Plans," price 5*s.*

MR. RIVERS'S PORTRAIT (*Drummond Brothers*).—It was finished and suspended in the Council Room of the Royal Horticultural Society six months ago!

LEAVES OF SEEDLING FUCHSIA (*G. Rudd*).—They are very rich and unique—one crimson with a black centre, and the other yellow with a green centre and crimson nerves.

ECHEVERIA METALLICA (*Lower Norwood*).—We published the mode of propagation in page 279 of our number of the 12th inst.

STOVE (*L. B.*).—We cannot give an opinion of its merits, not knowing anyone who tried it.

PATENT GLASS ORCHARD (*F. R.*).—We know nothing of the structure.

PROBABLE PRICES OF FRUITS (*J. H. C.*).—So much depends upon season and quality, that it is impossible even to guess without the probability of misleading.

CANTUA BUXIFOLIA CULTURE (*W. D. A.*).—We fail to see in what respect you err in regard to your specimen of Cantua buxifolia. It is a plant usually regarded as of easy culture, requires to be grown in a greenhouse, has even been known to stand out the winter in Devonshire with but slight protection, and should be treated to a compost of light loam, fibry peat, and silver sand. As it is a native of the Peruvian Andes, at a pretty high or considerable elevation, it was expected on its introduction into this country to prove quite as hardy and as easily propagated as Fuchsias. Are you sure you do LOT keep it too hot? Your winter temperature may be as low as 45° without any detriment. As to bottom heat you cannot do better.

ROSE DIFFICULTIES (*E. E.*).—"I should like to know whether Roses on the Manetti stock, or those on the Briar, or those on their own roots are the best to grow in made soil?" No one can tell, unless knowing what the made soil is. If your soil is clayey, Briar Roses will do well in it. If it is of a light character, Manetti Roses will do best. If it is light and extra rich, Roses on their own roots will do well. I am often asked, "Which do you prefer, Roses on the Briar, on the Manetti, or on their own roots?" Well, as I am a very high cultivator, I should like all my Roses on their own roots. I buy them on the Manetti stock because they bloom at once, and get on their own roots within two years. They are then double-rooted. When they become strong on their own roots the Manetti roots will probably deteriorate. The roots of the worked Roses being on the surface, injure those of the Manetti stock which are beneath. If your soil is unsuitable to Roses, you must drain it, and mix plenty of decayed dung with it. If it is sandy and you cannot have clay, marl, or loam, procure chalk or lime. If your land is stiff, mix sand or ashes, and use unfermented manure. Half chalk and half clay is "white land;" it is the finest soil. There are only two patches of it in the county of Dorset. Broad Clover never fails on it, nor any other crop. Try and copy it. The trenching your land 3 feet deep and putting 6 inches of stones at the bottom is good management. If you can obtain some pasture clots, and chop them up, and mix them with the soil, they will do good. If you have cow dung mix it with the soil; it is excellent manure for Strawberries and Roses, and never injures anything. It is *the* manure for Dahlias and Hollyhocks. Buy the Roses next-named —Perfection de Lyon, Madame Chirard, E. Morren, Marquise de Castellane, Elisa Boëlle, Elie Morel, Baron Chaurand, Comtesse d'Oxford; and for your south frontage, Rêve d'Or, Noisette, distinct and of great beauty.—W. F. RADCLYFFE.

THIS YEAR'S PEARS.—"*T. G.*" asks, "Have any of your correspondents complained of their fruit, especially Pears, being this year deficient in flavour and in keeping quality? My Pears are exceedingly deficient in both flavour and keeping, or else my taste is much depraved. This is

quite possible, but will not explain why my Pears decay in less than half the ordinary time."

Budding Roses (*J. R. D.*).—Your Briar Roses having been budded where they are to grow permanently, I should not move any so budded to fill up vacancies or failures, but put in fresh Briars, and bud them next year. Never disestablish any Roses doing well. Stocks, either Briar or Manetti, established before budding, have a great advantage over removed Roses. This is one of the reasons of nurserymen's successes at Rose exhibitions. The first six Tea Roses you name are the best up to this time, and the first two are the best of all—Devoniensis, Souvenir d'Elise, Madame Willermoz, Souvenir d' un Ami, and Adam. The following are also good:—Hemer, Rubens, Sombreuil, and President; and for glass culture, Elise Sauvage, Vicomtesse de Cazes, and Madame Bravy. The following are the best of the new Tea Roses, so far as I have seen them—viz., Madame Margottin, Madame Trifle, and Marie Sisley. Marie Sisley is a perfect globe and full, and when it has a roseate hand round the edges of the petals it is a very superior Rose.—W. F. Radclyffe.

Rendle's Plant Protectors (*Jeune Jardinier*).—Nothing more can be said about them except as an advertisement.

Climbers for the South Front of a House (*Amateur*).—Bignonia radicans, Ceanothus grandiflorus, C. azureus, Escallonia macrantha, Magnolia grandiflora, Passiflora cærulea; Roses Cloth of Gold, Maréchal Niel, Sir Joseph Paxton; and Eccremocarpus scaber. Tecoma is the same as Bignonia radicans. Tecoma jasminoides will not succeed against a south wall. To the plants you name you may add Jasminum grandiflorum, Lardizabala biternata, Chimonanthus fragrans, Embothrium coccineum, and Garrya elliptica. The white Wistaria flowers as freely as the lilac one. Lamarque and Solfaterre are first-rate Roses for a wall, so is Climbing Devoniensis. Next to Passiflora cærulea, P. Comte Nesselrode is good, but we question its succeeding on a south wall. It is, however, worth a trial. All the Ipomœas are too tender, and the same remark holds good of Thunbergias. Tropœolum speciosum will succeed.

Planting out Belladonna Lilies (*J. B. B.*).—Plant them out as you propose on the warm border in front of the stove, and give a top-dressing of partially decayed leaves.

Stephanotis floribunda Fruiting (*G. B.*).—It is not unusual for this climber to fruit. Several instances have recently been noted in our pages, and ten years ago we saw plants raised from seeds ripened in this country.

Wistaria sinensis Cuttings (*Idem*).—Put in cuttings of the young shoots under a hand-light, when they are firm, in sandy soil, and keep them moist and shaded. Layers, however, are preferable; every joint of the ripened young shoots will make a plant. When rooted pot and grow them in a warm situation out of doors, encouraging a young shoot, and take off its point at 4 feet. Step the side shoots at three or four leaves as you would those of a pyramid Apple or Pear. The plant sometimes flowers in autumn—in fact, it generally produces some stray blossoms at that season, but the principal flowering takes place late in spring or early in summer.

Flower Garden Planting (*C. T. H., Dorset*).—Unless we edged the whole of the beds, we do not see how we could improve on your planting; but we think that 10 and 11 would be improved by Golden Pyrethrum instead of Cerastium, and then instead of Pyrethrum we would place Cerastium round 14, 15, 16, and 17. We feel sure the garden will look easy and very pretty.

Variegated Mangold Leaves (*J. L.*).—We would save the plant having the yellow and green variegated foliage, and try if the seedlings from it would come true, as then it might be useful in borders of fine-foliaged plants. It is possible that the seedlings may revert to their original green type, and it is also probable that the variegation will remain, just as in the case of Kales.

Gooseberries (*Quis*).—You cannot do better than apply to the nurseryman you name.

Gathering Pears (*Emma Pawle*).—The best time to gather your Winter Crassane Pears is when they will sever easily from the spur by merely lifting the fruit upwards without twisting or wrenching them off. The Winter Crassane ripens uncertainly, and rarely ripens at all. The best way to use them is to stew them.

Not Watering Vines (*A Novice*).—The Vines will not suffer, though the soil on the surface of the border may be dry for a couple of inches or so, as the roots are so far from the surface. You could not keep the Grapes well if the soil is watered now. We do not think that any mode of keeping Grapes quite equals leaving them on the Vine in a dry house, but the bunches keep very well with the shoot inserted in bottles of water, or even into Turnips or Beetroot. The important point is, that the place where they are put must be airy, dry, and free from frost. It is often advisable to make a compromise, and so treat Grapes after Christmas, as whilst they hang the house cannot be used for other purposes.

Erecting a Vinery, &c. (*W. Neck*).—As you have a wall at the north side, we would for early Grapes recommend a lean-to house. For earliness, too, we should prefer bringing the glass roof within 2 or 3 feet of the ground; but as you want to walk all round, you will require the front to be from 5½ to 6 feet in height, and about 4 feet of that to be glass. With Vines planted at the back and in front, a wooden or an open iron trellis would be best for walking on. The sparred shelf for plants might be 2½ feet from the ground in front, and the central stage 3 feet from the ground. A flat stage would do well, but you can have more plants if your stage has a centre and falls to the back and front. If you force early, the bedding plants will have to be removed soon after you begin to force. Such simple houses do most service when the Vines are assisted rather than forced. The depth of 2 feet will do for the Vine border, but as you plant inside, the drainage must be looked to before making the border. A fine will heat such a house, from 20 to 30 feet long, admirably. As to expense, we could not do better than refer you to our advertising columns, where you will see how much a cheap house will cost.

Greenhouse Shelves (*M. G.*).—The proposed alteration of shelves will not interfere with the bedding Geraniums, &c., further than from the lowering of the shelves they will be at a greater distance from the glass, and will, therefore, be more liable to draw. The ammonia from a Mushroom-bed beneath the stage will not injure the plants, nor will the steam arising from the forcing of Rhubarb and Sea-kale, provided the dung be sweet. The Mushroom-bed will give off some heat, and render less fire heat necessary. It is now too late to put in cuttings of Verbenas, except in a brisk heat. You may take up the old roots with balls, pot them, and winter them in the greenhouse. They will afford you a number of cuttings in spring, and these will strike freely in gentle heat, and make good plants by the end of May.

Evaporating-pans on Hot-water Pipes (*J. K.*).—The zinc pans will answer admirably for the purpose, and with care will last many years. In making the base semicircular to clasp the 4-inch iron pipe, there will be a depth of water at each side, and if there be from three-fourths to 1 inch in the centre, it will do for general purposes. Of course, if the depth over the centre is 2 inches it will take a longer time to evaporate the water. If the pans are made to fit the pipes tolerably well, there will be a considerable amount of evaporation by merely setting them on the hot-water pipes. The evaporation will be increased if along the sides, at bottom, and each end there is a coating of white or red lead not overthick. But if you want the greatest amount of evaporation from your pans, you must smear the rounded bottom well over with red lead or thick paint, and then squeeze it firmly down on the pipe when it is rather cool. In the first two cases the air, however small the quantity of it between the hot-water pipe and the trough, acts as a non-conductor. In the third case no air can be left. A clever mechanic would not believe that between the second and third mode there could be much difference, until he saw that the second method took double the time to evaporate a certain quantity of water that the third method did.

Tank-heated House (*An Old Subscriber*).—Will not 6½ feet to the ridge be rather low for a 15-feet-wide span-roofed house? With a 4-feet-wide tank in the centre you will either have little head room, or if the sides of the house are high enough for that, then the roof must be rather flat. With sufficient head room it would not matter if the sides were rather low, as we presume you intend to have a platform all round for plants. We have no objection to the tank-heating, but we do not perceive how a saving in expense is to be managed when good piping can be had for 9*d.* per foot; but that is a matter of opinion. Unless the tank is well made of wood, we do not think that either a cement or an iron tank would be so cheap as having iron pipes with rubble round them for affording bottom heat. The objection to wood is, that it gives out little or no heat from the sides, but only from the slates on the top. If a tank is formed of brick or iron, the sides will radiate heat. In such a case the sides might be 7 inches in height, though the water inside might be no higher than 3 inches, or at most 4 inches. You are quite correct in respect to the mode of connecting the tank with the boiler, but the tank must be level throughout. The tank will answer admirably, but our own opinion is, that pipes would be cheaper, packing round them rubble, and covering the top with fine-washed gravel, with holes or pipes inserted upright to pour water among the rubble when necessary. With the 3-inch pipes round the house besides, there would be no difficulty in keeping up in severe weather a temperature at least 10° higher than from 45° to 50° in winter. With these pipes your tank need not be more than 4½ inches deep. See what is said of having the sides deep. The water would circulate freely enough in both tanks and pipes if, as you propose, the pipes were on a lower level than the tank, but the pipes must be close all round, and at the highest point an air pipe must be inserted, which, if open at the top, must stand a foot higher than the level of the tank. You had better have an opening in the top of the tank, so that by means of a plug you may be able at times to regulate the flow, until the pipes on the lower level get their fair portion of the flow. Sometimes that may be necessary. A small saddle boiler or a small conical one will equally answer your purpose if it be properly set, well used, and a damper be regulated.

House for Plants (*J. P.*).—We have no doubt that the proposed plan will answer generally. Planting out or plunging pots as required will look neater than any stage. The plants will not get weak as in the establishment you refer to, nor will they be disinclined to bloom freely, as the light in your case will be unobstructed, and the glass will be so much nearer the plants. The small boiler inside the house will do, but it would be better if you could feed it from the outside. One pipe round the house, with such a surface of glass exposed, will scarcely keep the frost out in severe weather. We have no objection to the proposed mode of glazing, only we should like some soft non-conducting material between the glass and the iron clips.

Orchard-house Construction (*T. H. T.*).—With trees against the back wall it will be better to have no standards planted there, if the pathway should be a little nearer. You can then have the back wall in fruit to the bottom of the wall. The other arrangements as regards planting and pots will do. The ventilation will not be too much; it will be sufficient if you have a ventilator at each end, say a triangle from 24 to 30 inches wide at the base. It would be advisable to divide the house and heat one part, and for fruit in June it would be advisable to have a couple of pipes in the coldest portion. For your earliest end you may have White Frontignan, Black Hamburgh, Royal Muscadine, and even Muscat Vines. For the late house have Black Hamburgh, Trebbiano, West's St. Peter's, and, if heat is given, Lady Downe's. Of early Peaches have Early Gresse Mignonne, Noblesse, Ballegarde; of Nectarines, Elruge, Hardwicke Seedling, Rivers's Orange, Violette Hâtive, &c.

Nitro-phosphate, &c. (*E. F. W.*).—I get my nitro-phosphate from Mr. Blandford, of the Dorset Nurseries, Blandford. It is the same, I believe, as "blood manure." I use it for Peach and Nectarine trees, as well as Roses, when the trees are heavily cropped. "Steevie" takes up a double handful, drops it into my three-gallon watering-pot, gives it a good stir with a stick, and then pours over the "radius of the roots." One, two, or three gallons according to the requirements of the trees—Roses or wall trees—is poured on the roots. It is an excellent manure and innocuous. Apply it to the Rose trees in April, or at any time they require it. I am not a vinitor, but when Mr. Beck, Mr. Sturt's distinguished gardener, came to see the Roses and wall trees, I told him my two Black Hamburghs (fifty years old, planted outside), thanked "first-rate" every year. He said, "Pluck them up, plant new Vines inside, have an archway for the roots to run out into the outer soil, and then you will have some good Grapes."—W. F. Radclyffe.

Spiders (*A Lady in Cheshire*).—Many spiders live through the winter; in fact, some individuals lead us to the conclusion that their existence may last several years. Of those that hybernate, some continue in the net which they have constructed in the autumn, and others migrate from one spot to another in mild weather, making occasional nets to

secure chance flies, moths, &c. Some take long journeys from their nets, to which they return as winter retreats when the weather is severe. One has been noticed to be absent for several weeks, but it would turn up again, and the only way to explain this is to suppose that while on an excursion, through a change of temperature, it is rendered sluggish for a time, and cannot get home.

Insects (*Ignoramus*).—The white grubs, just like those found in Hazle-nuts, which have destroyed the roots of your Ficus elastica, are the larvæ of a brown beetle of the weevil family, belonging to the genus Otiorhynchus, which in the spring time feed on the young foliage after dark. The only plan to get rid of the grubs is to repot your plants, and burn the old soil.—I. O. W.

Names of Fruit (*J. B., Torquay*).—The Peach with the flesh like a highly-coloured Beetroot, is Sanguinole. (*X. Y.*).—Hunt's Deux Ans. (*Portland House*).—1, Beurré Amande; 5, Dunmore; 7, Beurré Clairgeau; 10, Beurré d'Aremberg; 11, Fondante d'Automne; 12, Beurré Defais; 14, Seckle; 16, Marie Louise; 17, Knight's Monarch; 18, Passe Colmar; 20 and 21, Urbaniste; 22, Bezi d'Esperen. Apple, Cellini. (*W. Miller*).—2, Kentish Codlin; 10, Court pendù-plat; 13, Golden Russet; 22, Coe's Golden Drop. (*R. Martin*).—1, Huyshe's Prince of Wales; 2, Belliesime d'Hiver; 3, Hampden's Bergamot; 4, Beurré Bosc; 6, Belle après Noël. (*Peter Tait*).—1, Margil; 3, Aromatic Russet; 4, Marsh Pippin; 5, Morris's Russet; 6, Herefordshire Pearmain. The Pear is King Edward's. (*W. and H. M. Goulding*).—1, Gendebien; 2, Triomphe de Jodoigne; 3, March Bergamot.

Names of Plants (*S. H.*).—Anemone vitifolia, native of the Himalaya. (*R. L. D.*).—A, Calceolaria chelidonioides, native of Peru and Chili. B, Epilobium montanum, a common wildling. C, Centranthus ruber, the Red Valerian. D, Anemone japonica. (*J. J. S.*)—The Finger-grass, Digitaria sanguinalis, otherwise Panicum sanguinale. (*W. D. A.*).—The Calceolaria is C. chelidonioides. The purple flower is Peristrophe speciosa, more generally known as Justicia speciosa. (*J. C.*).—1, Polypodium Schkuhrii, a variety of P. pectinatum; 2, Adiantum tenerum; 3, Asplenium (Darea) Bellangerii, *alias* Veitchianum. (*W. B.*).—The Anemone we received from you (flower only, not a scrap of other information), and which we named A. pavonina (A. fulgens), we now think may be A. japonica, of which we this week have received a similar specimen from another correspondent. Its blooming at this season in that case would be perfectly consistent. (*A. B.*).—You sent thirty-six specimens.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY EXPERIENCE PURCHASED.—No. 3.

My misfortunes since I commenced poultry-keeping have been so many and so various, I am inclined to believe that the happy people I read of weekly have all the pleasure and profit connected with it, and my unhappy self all the trouble and loss. But for the fact of so many ladies being prizewinners, I should imagine Fortune bestows her favours only on the sterner sex, and refuses the honours to her own.

Let me tell you how I once fondly imagined I could rear Black Spanish, and how I suffered for my presumption. I began by coveting my neighbour's birds of that noble breed, which was very wrong; then I got dissatisfied with my own six good motherly hens, because they were of that very useful but plebeian strain—barndoor. My neighbour did not wish to sell any of his poultry, and I thought I was doomed to the fate of Tantalus on a small scale; however, his gallantry ultimately overruled his selfishness, and he sent me two cockerels and a pullet, the only ones he could spare (they were hatched late, end of July), since I seemed anxious to possess the breed. Though grateful for the concession, I was rather astonished at the chickens, then about eight weeks old, for their first appearance was anything but prepossessing. All the little chickens I had ever seen were at that age comfortably clothed with feathers, but these were quite innocent of anything save a few patches of dirty grey down, and I thought that if "fine feathers do make fine birds," no feathers at all make very ugly ones. Still I hoped they would improve as they grew older, and inherit the grace and majesty of their parents. They grew older and rather bigger certainly, and looked like a kind of cross between a miniature Ostrich and the "Jackdaw of Rheims." The six highly respectable hens resented the presence of the immodest creatures in their run as a personal insult, and speedily ejected them in a most unceremonious manner, so they ran about outside in the garden, which was very bleak and exposed. As the weather for early autumn was very raw and cold, when the poor things saw a little sunshine in the next garden they very naturally flew over to bask in it. My friend next door, however, was very proud of his neat little garden, and he mildly suggested I should keep my chickens at home, a request so very reasonable that the few wing feathers of the "Spaniards" were at once clipped, which, as it was the only protection they had, it was refined cruelty.

The children had named them respectively "Jack," and "Jack's brother" and "sister," and the wretched trio would persist in standing shivering at the back door, till the children, brimming over with pity, let them in "just for one good warm," at the kitchen fire, but their kindness gave poor Jack a most distressing catarrh; something else covered their mouths and throats with what I believe is called canker; the cocks had their tall straight combs frostbitten, their faces became full of sores because I fed them on beefsteak and gave them too much. The six hens persistently refused to let them share their warmly-covered run, by giving them a practical and painful illustration of their fighting propensities, and we all eventually succumbed to this formidable army of misfortunes. One wretched morning in December, Jack and his brother and sister all went a long journey to the happy hunting grounds (return tickets not issued), and it is my firm belief that Fortune is not so blind as she pretends to be, but can just see sufficiently through her bandage to turn her wheel the wrong way when she sees me coming. Now, before I close my letter, if I have not "adorned a tale," let me try to "point a moral." Never attempt to rear birds of the Castilian breed until you know something of their habits and requirements.—J. K. L.

CURE OF ROUP.

When a bird is attacked with the characteristic cough of this malady, or has tenacious mucus about the beak with difficulty of breathing, I place it in a wicker coop in a quiet shed, and put before it a drinking fountain containing about a gill of water with which I have mixed one drop of tincture of aconite. In every instance during three years this treatment has had an effect almost marvellous, for, upon visiting the patient an hour or two afterwards, I have found that the symptoms have vanished. The attack for a day of two is liable to return, yet each time in a lighter form, but continuing the application has in no instance with us failed completely to remove the ailment in about forty-eight hours.

In case the disease should have made so much progress before it is observed that the sufferer is unable to drink, it will be necessary to give the dose. This is easily accomplished by pouring into the throat about a teaspoonful of the medicine as described. Such an instance occurred here during excessive wet weather, when I was absent from one of the houses two days. Upon going to see that all was kept in condition, I found a fine old fellow under one of the perches almost dead from very acute roup. I separated and dosed him immediately. He soon lost all the roupy symptoms, but continued extremely weak, and appeared to be fast sinking from atrophy. A medical friend suggested trying the homœopathic administration of arsenic. His advice was taken, with the best result. This very bird will, we hope, appear at the Crystal Palace Show.

The aconite dilution 3, may be purchased of any homœopathic chemist.—Mrs. Frank Cheshire.

OINTMENT FOR FOWLS' WOUNDS.

The following forms an ointment which I have tried with great success; it heals in a very short time the wounded heads of cocks after they have been fighting. Mix an ounce of oxide of zinc with 2 ozs. of hogs' lard; add, after mixing, a little olive oil, and apply with a feather once or twice a-day.—Digitalis.

Devizes Poultry Show.—As there appears to be some misunderstanding amongst exhibitors as to whether the Poultry and Pigeon Show to be held in Devizes in December is to be open to all, or confined to the county of Wilts, allow me space to say that competition is open to the whole kingdom, or I may say the whole world.—One of the Committee.

[We hope "the whole kingdom" will see this and patronise the Show, for the schedule of prizes is good.—Eds.]

Sale of Mr. James Watts's Poultry.—The poultry of Mr. James Watts, whose lease of Hazelwell Hall, King's Heath, has expired, was sold by auction by Messrs. Lythall & Clarke, on the 11th inst. The bidding was brisk, and high prices were realised. The following are some of the highest prices obtained:—A Dark Brahma cock, the winner of several prizes, £6 5s.; a pair of hens, £10; a pair of pullets, £5. Light Brahmas sold well, one pair of pullets fetching £4 5s., whilst single birds realised £1 15s., £1 6s., and £1. A clear Buff Cochin-China cock, winner of many prizes, fetched £5 5s., a hen £3 10s., and other birds £2 4s., £1 10s., and £1 5s. Silver-spangled Hamburghs and Spanish also fetched good prices. For dark Grey Dorkings £1 8s. and 15s. were given for single birds; Bantams (single) were sold for £2 2s., £1 16s., £1 10s,

and £1 4s. Pigeons also sold well, the highest prices being £4 10s. for a pair of Dentellettes, £2 15s. for a pair of Laced Turbits, £2 12s. for a pair of White African Owls, £1 18s. for a pair of Blue Antwerps, and £1 2s. for a pair of Blue Turbits. Mr. Watts is negociating for a new lease, and does not purpose abandoning poultry-breeding.

SPOILING THE GOOSE EGGS.

"My mother used to think" said Aunt Fanny to a group of youthful listeners, "that in order to have Geese eggs hatch, it was necessary to handle them with the greatest care, and that on no account must they be carried over a stream of running water. She had heard the saying from childhood, and I suppose never stopped to consider whether it was founded on reason or not. One spring, when I was about twelve years old and my brother Joe fourteen, mother resolved to set some Goose eggs. 'Fanny,' she said, 'is getting to be most a young woman, and it is time I was raising some feathers;' though, for the matter of that, she needn't have done it, for I've never needed but one bed so far," continued aunty, in a tone nowise regretful; then recovering the thread of her story, she proceeded.

"One Friday afternoon, at preparatory lecture, mother heard that Aunt Dilly Dunham had Geese eggs to spare; and moreover, that she would exchange them for hens' eggs, one for two. So early the next morning mother started Joe off to make an egg trade with Aunt Dilly. He had to go about a mile and a half on foot. It would never do to ride old Tip, she said, lest the jolting should addle the eggs; 'and mind you go cross-lots, through a corner of the woods, and keep this side of the creek, and then you will not have to cross the bridge near the house at all.' 'Mother, I don't believe it would hurt those eggs a particle if I should carry them over fifty bridges,' said Joe. 'It is well enough to be careful,' answered mother; 'it is getting late in the season, and I don't know where I could get any more if these should fail.' So Joe set off on his errand. He returned about noon, with nine Geese eggs which mother put in a hen's nest, in an old barrel turned down on its side, behind the smoke house. She charged us children to keep away from the nest entirely, but told us that in four weeks she hoped to have a nice flock of goslings. That night, when Joe and I were out in the back pasture after the cows, Joe said to me, 'Fan, mother will never get any goslings from those eggs if her notion is true, for I carried them over that bridge, and the high water was rushing through under there like everything.' 'Why, Joe, how could you disobey mother so?' said I, reproachfully. 'Because I wanted to know for myself whether that was a whim or not; and as for disobeying, I have not,' continued Joe, looking mighty innocent. 'Mother told me to go cross-lots, and I did; but she did not tell me to come back that way, so I came round the road.' 'But you knew what she meant,' said I; but he only laughed and bade me not to tell. The caution was needless, for Joe very well knew I'd never tell of anything that would get him into trouble.

"Now father did not wish to raise Geese (what man ever did?) he said they would spoil more hay and grain than their necks were worth, besides being the peskiest things to have around there ever was. Still he never opposed anything very much that mother wanted to do; but he thought if a little stirring would keep Geese eggs from hatching he would bestow a little attention on these. Accordingly when he and the hired man passed the barrel on their way to work, father would take hold and give the old hen and the eggs a good shaking, mother all the while being in blissful ignorance of these naughty experiments.

"But shaking and running water both proved harmless, for in good time up came the old hen with nine as promising goslings as ever were seen. Mother and I were delighted and stood feeding them, just as father, the hired man, and Joe came in to dinner. I saw a comical look pass between the two men, and I knew by the expression on Joe's face that the truth was coming out. 'Mother,' said he, 'those Geese eggs went twice over Mill creek the day I brought them home—once down by Aunt Dilly's, and then again over the main road.' 'Why Joe!' mother had only time to say, when the hired man spoke up, saying, 'and Mr. Gifford has given them a dozen good shakings in that barrel.'

"Mother looked a little as though she felt herself imposed upon, but she only said, as she went into the house, 'Joe, you are just like your father for all the world.' After that we raised our own Geese eggs, and if we ever wanted to set any, some of us would be sure to say, 'Now father, go and shake them.'"—(*Rural New Yorker.*)

ROSS POULTRY SHOW.

Few first attempts at the establishment of a poultry show have been more successful than that which resulted in the Exhibition at Ross, on the 24th inst., the general quality of the birds being good. As is usual at first shows, there were matters that might have been carried out more satisfactorily, particularly as regards the arrangement by which each exhibitor had to provide his own show pens. This oversight of the present year will be, we hear, remedied on future occasions. The tents were excellent, and admitted of no improvement.

In *Brahmas* all competed together, and they proved a good entry. Light-feathered being first, Dark ones second. In *Cochins*, Partridge-coloured were first, and Buffs second. Of Grey *Dorkings* there was one of the best entries, and, strange to say, of *Game* fowls one of the worst entries in the Show. The adult *Spanish*, as a rule, were not good, but a few good chickens were shown. Black Reds were in both cases the prizetakers in a general Bantam class. A better "Variety class" has rarely been exhibited; and the class for chickens of any variety was unexceptionably good. The *Water Fowls* and *Turkeys* were generally praiseworthy. Most of the *Pigeons* were meritorious, and added considerably to the interest of the meeting. The attention to the management of the birds, and the liberal feeding, were worthy of especial mention. Mr. Treasure, of Ross, exhibited a remarkably good pair of Dark Brahma chickens, but as the rule required two pullets and a cockerel, they could not take a place in the prize list. Very fine weather and a good attendance of visitors marked the Show.

Brahmas.—1, T. A. Dean, Marden. 2, J. H. Watkins, Byford, Hereford.
Cochins.—1, Rev. H. W. Tweed, Bridstow (Partridge). 2, C. Bloodworth, Cheltenham (Buffs). *hc*, W. Morris, Ross.
Dorkings.—1, E. Shaw, Oswestry. 2, J. McConnell, Ewais Harold.
Game.—1, E. Shaw (Brown Reds). 2, A. Armitage, Dadnor (Black Reds).
Hamburghs.—1 and 2, J. McConnell (Silver-spangled and Silver-pencilled). *hc*, C. Bloodworth.
Spanish.—1, R. H. Greaves, Trewaugh. 2, J. McConnell.
Bantams.—1, F. Wilson, Morpeth. 2, T. Roper, Ross. *hc*, T. Roper (2); J. Bloodworth; T. S. Barnett, Walford. *c*, H. Theyer, Walford Court.
Any other Variety (Including Cross-breed).—1, J. F. Mortimer, Rudhall (Crève-Cœur). 2, C. Bloodworth (Silver-spangled Polands). *hc*, J. McConnell (Silver Polands); H. Theyer. *c*, Sir J. R. Carnac, Bart., Wilton Hall (Blue Andalusians); E. Williams, Henllys (Houdans); A. Phillpotts, Trellersdee (Houdans). *Chickens.*—1, J. Bloodworth (White Cochins). 2 and 4, C. Bloodworth (Buff Cochins). 3, T. S. Barnett (Black Spanish). *hc*, J. Bloodworth (White Cochins); T. A. Dean (Light Brahmas) (2); A. Armitage; E. Shaw; E. Williams (Crève-Cœur). *c*, H. W. Barnett (Buff Cochins).
Ducks.—*Rouen or Aylesbury.*—1 and 2, F. Wilson. *hc*, Lt.-Col. W. S. Rooke, Biggleswear House, Rouen; E. Shaw, Oswestry. *c*, H. Theyer. *Any other Variety, including Cross-breeds.*—1, A. Armitage (Wild Ducks). 2, T. S. Barnett (Black East Indian). *hc*, F. J. Kearsey, Glewston (Cross-bred); L. C. Lawson (Brown Decoy).
Geese.—1, J. Loveridge, Daffalnke. 2, T. S. Barnett.
Turkeys.—1, E. Shaw (Cambridge). 2, A. Armitage. *hc*, K. M. Power.

PIGEONS.

Barbs.—1, H. Yardley, Birmingham. *hc*, J. H. Watkins, Byford, Hereford.
Carriers.—1, H. Yardley. *c*, H. Theyer, Walford Court.
Jacobins.—1, H. Yardley. *hc*, T. S. Barnett.
Nuns.—1, T. A. Dean, Marden.
Pouters.—1, H. Yardley. *c*, J. H. Watkins; H. Theyer.
Runts.—1, H. Yardley. *hc*, T. Donne, Ross.
Fantails.—1, H. Yardley. *c*, J. Watkins, Wisteston Court; T. S. Barnett.
Tumblers.—1, H. Yardley. *hc*, T. A. Dean.

Mr. E. Hewitt, of Birmingham, was the Judge.

SCARBOROUGH ORNITHOLOGICAL SOCIETY'S SHOW.

This took place on the 18th and 19th inst. The following is the prize-list:—

Norwich.—*Clear Yellow.*—1 and *hc*, Adams & Athersnch, Coventry. 2, Moore and Wynne, Northampton. *Clear Buff.*—1, Moore & Wynne. 2 and *hc*, Smith and Preen, Coventry.
Norwich.—*Clear Yellow and Buff.*—(Members only).—1, J. Dawes, Scarborough. 2, G. Clark, Scarborough. 3, M. King. *hc*, Waterson & Cross.
Norwich.—*Evenly-marked Yellow.*—1, Barwell & Golby, Northampton. 2 and *hc*, Adams & Athersnch. *Evenly-marked Buff.*—1, Adams & Athersnch. 2, Moore & Wynne. *hc*, G. Gayton, Northampton.
Norwich.—*Ticked and Unevenly-marked Yellow.*—1, Moore & Wynne. 2, Adams & Athersnch. *hc*, G. Gayton. *Ticked Buff.*—1, Barwell & Golby. 2, G. Mead, Scarborough. *hc*, Moore & Wynne.
Norwich (Crested).—1, R. Sutton, Norwich. 2 and *hc*, Moore & Wynne.
Belgian.—1, L. Belk. 2, J. N. Harrison, Belper. *hc*, Stephens & Lsek.
Yorkshire.—*Clear Yellow or Buff.*—1, T. Fawcett, jun., Baildon, Leeds. 2 and *hc*, J. Cooper, Middlesbrough. *Evenly-marked Yellow or Buff.*—1 and *hc*, Stephens & Leek. 2, L. Belk, Dewsbury.
Lizard.—*Golden-spangled.*—1, Smith & Preen, Coventry. 2 and *hc*, R. Ritchie, Darlington. *Silver-spangled.*—1, Smith & Preen. 2, R. Ritchie. *hc*, J. N. Harrison.
Cinnamon.—*Yellow or Buff.*—1, Barwell & Golby, Northampton. 2, E. Stansfield, Bradford. *hc*, T. Irons, Northampton.
Any other Variety.—1, T. Fawcett, jun, 2, M. Jackson, Scarborough. *hc* G. Clark, Scarborough.
Goldfinch Mule.—*Evenly-marked.*—1, Stephens & Leek. 2, E. Stansfield. *hc*, L. Belk. *Dark.*—1, Moore & Wynne. 2, E. Stansfield. *hc*, Stephens & Leek.

Green (Clear).—1, Stephens & Leeke. 2, W. Seargeant, Skelton. *hc*, J. Rowland.

Goldfinch Mule.—*Variegated.* — 1, W. & C. Burniston, Middlesbrough. 2, Stephens & Leeke. *hc*, J. Spence, New Hendon, Sunderland. *Dark.*—1, T. Tenniswood. 2, Moore & Wynne. *hc*, J. Munroe.

Goldfinch Moulted.—1, T. Tenniswood. 2, J. Munroe. *hc*, Stephens and Leeke.

Linnet Mule (Brown).—1, J. Spence. 2 and *hc*, Stephens & Leeke.

Linnet Moulted (Brown).—1, Fairclough & Howe, Middlesbrough. 2, J. Hardy, Skelton. *hc*, W. & C. Burniston.

Any other Variety.—*British Bird.*—1, J. Green. 2, —Bailey. *hc*, E. Graham, Middlesbrough. *Foreign Bird.*—1, J. Bell, North Ormesby. 2 and *hc*, G. Handsom, Middlesbrough.

INTRODUCTION OF YOUNG QUEENS TO COLONIES THAT ARE QUEENLESS.

Some ten years ago I was led to suspect that the ordinary statements of Huber and other eminent apiarians with regard to the antipathy of bees, under all circumstances, to change queens, was incorrect. Eminent writers have supposed that it would not be safe to introduce even a queen cell to a colony until twenty-four hours had elapsed after the old queen had been removed.

In experimenting with Italian bees, shortly after their introduction to this country, I soon ascertained that this was an entire mistake, and that queen cells could be safely introduced, under ordinary circumstances, immediately after the removal of the queen.* This led me to experiment further in the same direction. Supposing that perhaps the hatching of a young queen in the colony might reconcile them at once to her presence, I introduced to queenless colonies cells, the lids of which were being gnawed open by the young queen. In some instances these queens hatched in less than five minutes after the cells were inserted, and I found them to be unmolested, although the hive had been unqueened but a few moments before their introduction.

I now began to suspect that there might be something in the young queens themselves, either in their actions, or in their odour, or their voice, or want of voice, which made the bees indisposed to disturb them. Therefore, after unqueening the hive, I introduced just-hatched queens at once, and found them almost invariably well received. The bees would occasionally seem to manifest some surprise at their presence, and probably, if they could have spoken their feelings in words, would have said inquiringly—"Does your mother know you are out?"

If the queens were too young, they were sometimes dragged out of the hive, just as imperfect bees are removed by workers. I next discovered that in many instances these young queens could be put upon the very comb where the old mother was, and yet be undisturbed by the bees. In order to test this matter more thoroughly, after introducing a just-hatched queen and finding her well received, I would place upon the same comb an unfertile queen several days old. The bees would at once attack her furiously, confine, and speedily destroy her. It would seem, therefore, that under ordinary circumstances young queens which have not yet attained their proper colour, and perhaps the power of piping, may be introduced at once to queenless colonies. I have availed myself of this discovery largely in breeding Italian queens; it being a common practice with me as soon as the queen of a nucleus has laid a suitable number of eggs to test her purity, to cage her, and at once introduce a queen not more than five or six hours old. It may be that it would be safe to introduce queens even a day old, but my practice has been to select for this purpose such as had very recently hatched. When the young queen thus introduced becomes fertile, and has laid a proper number of eggs, I cage her in turn and introduce still another. And thus I am able, with one nucleus, to accomplish in queen-raising as much as is ordinarily done with two or three.

Occasionally I have known the workers to destroy these young queens, if not immediately, still within a few hours after their introduction. I do not, therefore, recommend the practice above described to those who have very few queens, nor would I risk a young queen which I value very highly. But, as under ordinary circumstances the breeder has often more queens than he knows what to do with, he can easily dispose of them in the way above described.

In order, at times, to secure a suitable number of queens for this purpose, I have been accustomed to condense into one colony a very large number of queen cells of about the same age, inspecting the colony about every hour in the day, and removing queens as fast as they hatched, and before they had an opportunity to destroy each other or the other queen cells. These same combs may be returned at night to their proper nuclei.

The expert will know how to avail himself of the plans which I have suggested, and how to modify them to suit his circumstances.—L. L. Langstroth (in *American Bee Journal.*)

* Instead of the circumlocution of saying "removing a queen from a hive, or giving a queen to a hive," I propose to use as more definite terms the words, "unqueening a hive," or "queening a hive."

TO GET HONEY FROM THE COMB.

As this is the time when bee-keepers are taking up weak stocks and taking off surplus boxes, it may be well to give a few hints how to clear honey.

It will be generally understood that virgin honey taken in surplus boxes is most marketable in that form, and is generally considered most palatable eaten in the comb. Still that portion of it which is uncapped is liable to sour and lose its flavour; hence such pieces of comb should have the honey extracted by the honey-extractor, or be broken up and the honey strained ont. It is also necessary to clear honey taken from weak stocks, or any old or queenless stocks that are taken up, as only small portions of the combs are pure enough for table use. In clearing honey, it is well to select all such pieces of comb as are free from brood, and clear it by itself, as the honey will be better than that contained in comb mixed with brood. The comb should then be placed in a cheese cloth and broken up, and the honey allowed to drain off. It is well to have a large dish or cullender, and lay the cloth into that. The dish can then be set over a crock or dish to receive the honey, and set away in the cellar, or some room away from the flies, and the honey allowed to drain off slowly, occasionally turning the comb with a spoon. The honey will be all the better for this slow clearing, as it will contain less small particles of comb and bee-bread. A large dish-pan, with holes punched in the bottom and a rim soldered on 1½ inch deep, is just the kind of cullender required, and is better for all culinary purposes than the old-style cullender. All the coarse and dirty comb, and comb containing brood, may be treated in the same way, though large patches of brood should be cut out and thrown away. After the honey has drained off, the comb may be placed in a tight dish and covered with water; let it stand and soak for a day; then strain the water off, and use it for making vinegar. The honey may be left to candy; or if put on the fire and brought to a scalding heat, and put into fruit jars and sealed, it will not candy, but keep for any length of time.—J. H. Thomas. —(*Canada Globe.*)

OUR LETTER BOX.

Cleaning Fowls for Exhibition (*R. H.*).—Take some warm water and common yellow soap, rub on a piece of flannel, and wipe the dirty feather downwards. After the dirt is removed wash freely with cold water, and dry either before a fire, or by means of a basket full of soft straw. In the winter we prefer the former; in the summer, when the sun is hot, we prefer the latter.

Lump on Brahma Cockerel's Breast (*Ignoramus*).—You do not state the age of the birds. Formations of a similar character are not uncommon along the breastbones of cocks, but we have never met with them so large as you describe. They generally present the appearance of a sac, containing a glutinous transparent fluid. If you have other fowls as good, but similarly visited, then we advise that these two be consigned to the kitchen and others kept. If you cannot do without these, remove the tumours by opening the skin and cutting them off. As a rule there is little or no circulation in them. When you have removed them from the bone sew up both skins separately, and rub the suture with soft

grease. If the fowls are three or four months old, as we suppose, you overfeed. Three times a-day is sufficient.

Scurf on Head of Spanish Cockerel (*E. W. S.*).—Rub the scurfy parts with compound sulphur ointment. You will also do well, while this appearance keeps on, to give occasional doses of castor oil—a tablespoonful twice per week. Lettuces are also very beneficial, especially those going to seed. Be careful not to injure the blood feathers. The injection of a little hot water will cleanse the ears; you may use a syringe for the operation. Your Hondans are suffering from cold. It is curable; the administration of some bread and ale twice per day, and allowing them to drink very little, having no water by them, but only being allowed to sip morning and evening.

Brown-red Game (*H.*).—The Brown Reds of late years have been superior in shape, and style, and feather to the Black Reds. It was very visible at all the large shows last year, and we shall not be surprised to see it again.

Japanese Bantams (*Amateur*).—They must have single combs and clean legs. The combs are very large. The legs are yellow, but they are so short, and the wings are carried so low, that they are not seen. Till lately there was but one breed. That had dark feathers in the tail and wing, and sometimes an odd spot or two about the body. There are now some recently-imported birds that are quite white. Your fowls with disordered eyes and sneezing are suffering from cold. Give them some bread and ale. See that their roosting house is free from draught.

Selecting a Brahma Cockerel (*W. H. H.*).—No. 1 cannot be entertained. A foot with four claws is inadmissible. No. 2 is the best, he has only a few red feathers, and they are not always hereditary. No. 3 will not do at all, his defect is always transmitted to posterity. Yours is not an *embarras de richesses*, but an *embarras de défauts*.

Points in Houdans (*F. P.*).—Houdans should have square bodies, top-knotted heads, ample beards, full breasts, short legs, five toes on each foot, black and white legs. The hens should be black and white without any other colour; the cocks may be permitted to have a few straw-coloured feathers in the hackle and saddle, but no red ones.

Light or Dark Game Fowls (*Black Red*).—We prefer the Light ones, if by such you mean those with the golden hackle. There is no latitude for the cocks, but there is some for the hens. The breed is constantly tampered with. The old cocker will tell you, "It is Squire Potter's strain, but I have mended it a bit, and it's many a day since we lost a main." The cocker looks only to the pit, and knows if he is successful it will be called his strain. Some prize Game breeders have gone so far as to have birds to suit the idiosyncracies of certain judges. The object of many of our large Game exhibitors is to breed a bird to win with, and they make him by a skilful combination. Hence the variety you have in your pens. All will do to exhibit, provided you match them well. You must not put a Dark and a Light bird in the same pen.

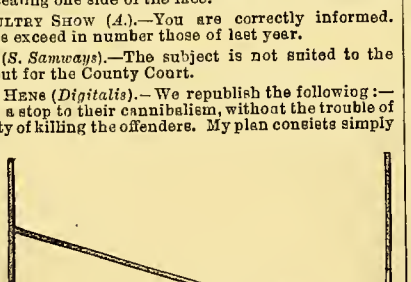
Laying Fowls (*J. A. H.*).—You would have to buy pullets because hens do not lay in the winter. A hundred pullets will cost, one with the other, 4*s.* 6*d.* each. Their cost to keep will depend much on the place where they are kept. If they have nothing but what is given they will cost £1 per week to feed. The number of eggs will depend on the breed of the laying hens. Hens will sit when they have done laying, although there may have been no cock with them. It is, of course, no use to allow them to sit on their own eggs.

Dorking Cockerel Weak-legged (*J. C.*).—Discontinue the Indian meal. Keep to oatmeal, whole barley, and table scraps. The weight is unusual for the age, and we should be disposed to think the bird had been putting on fat instead of making bone and muscle. Fattening food has a tendency to make the comb fall. A good upright comb is a certain sign of vigour, and vigour is very inimical to fattening. If you were to look in a coop of fowls put up to feed, you would see them all sitting in the way you mention, and their large, partly white and partly florid combs hanging down and concealing one side of the face.

Crystal Palace Poultry Show (*A.*).—You are correctly informed. We hear that the entries exceed in number those of last year.

Black-red Bantams (*S. Samways*).—The subject is not suited to the columns of a journal, but for the County Court.

Nests for Cannibal Hens (*Digitalis*).—We republish the following:—"I have completely put a stop to their cannibalism, without the trouble of watching or the necessity of killing the offenders. My plan consists simply in an improved nest or laying box (see accompanying section) with a false bottom, forming an inclined plane, down which the egg rolls, as soon as laid, into a receptacle beneath; and, of course, before the hen can have a chance of pecking, it, the egg is beyond her reach. Neither hay nor straw must be used in the nests,



but if the surfaces of the inclined planes are covered with smooth matting, a piece of old carpet, or sacking, every purpose will be answered. Another advantage of this laying box, is that where several hens use the same nest, the eggs are not soiled by their dirty feet in wet weather.—Typo."

Roup (*J. H.*).—You ask for "a cure for croup," but that is a disease attacking children. There is no certain cure for roup, it being a form of consumption in fowls. The following is an extract from the "Poultry-Keeper's Manual:"—"The symptoms are offensive discharge from the nostrils, froth in the corner of the eyes, and their lids swollen. This is contagious. Cause, exposure to excessive wet and cold. Remedy, wash the head daily, or twice daily, with tepid water. Sulphate of copper, one grain, daily, mixed in oatmeal mashed with ale, and plenty of green food. Separate the fowl from all others. If not better within a week kill the fowl." Mr. Baily also prepares pills for the roup. See a communication to-day on the efficacy of aconite.

Carrier with Cold in His Eyes (*C. H. C.*).—Add a little alum to the water you now use.

Runts at the Crystal Palace Show.—"*A. R. E.*" says, "A few exhibitors of Runts would be glad to be informed whether weight is to be the standard at the coming Show at the Crystal Palace, as at all other good shows, or feather, as at the last two shows held there."

Green Moss (*A Constant Subscriber*).—It is dyed after being thoroughly dried. Soaking first in a solution of indigo, then drying, and afterwards soaking in an infusion of quercitron bark, would probably cause the green colour.

Roots of Groundsel (*Oldaph*).—The soil remaining on the roots is not hurtful to Canaries.

REMARKS.

18th.—Fine in the morning, and continuing so all day; rather dull in the evening.

19th.—Rather dull and sunless; distant lightning between 7 and 8 P.M., with heavy rain, and rain also during the night.

20th.—Close, damp, uncomfortable day, with occasional showers.

21st.—Much colder; dull morning, rain at noon, and frequent showers after.

22nd.—Fine all day, rather foggy in the evening, but fine night.

23rd.—A much brighter day than any during this week.

24th.—Hazy morning and evening, but pleasant during the middle of the day.

The nights of Wednesday and Thursday (as indicated by the minima of the following days) were unusually warm, damp, and muggy, and the air throughout the week has been very damp, being perfectly saturated with vapour for many consecutive hours on several days. Much mist and fog. —G. J. Symons.

COVENT GARDEN MARKET.—October 25.

Business transactions, generally, have been of a favourable character during the week. Importations are not so heavy. Hothouse Grapes and Pines are sufficient for the demand, and some good late Peaches are still to be had, realising fair prices for the season. Cob Nuts and Filberts are plentiful. Large quantities of rough green vegetables, and good Broccoli, are offered in fine condition. Potatoes are much diseased, and there are considerable quantities in the market, which can only be cleared at a very low price.

From observations taken near London during forty-three years, the average day temperature of the week is 52.8°, and its night temperature 36.4°. The greatest heat was 63°, on the 5th and 6th, 1834; and the lowest cold 20°, on the 5th and 6th, 1868. The greatest fall of rain was 1.02 inch.

VINE-CULTURE UNDER GLASS.

THE subject of Vines and their culture has been repeatedly discussed in these columns by the ablest gardeners in Britain; all the phases of culture have been explained, the arrangement and composition of the borders have been treated of in the most lucid manner, and yet scarcely a week passes in which information is not asked for on some of the details of this important branch of gardening. I purpose, therefore, to offer a few cultural remarks, adding any recent information which I have obtained from my own practice, or seen in that of others.

Borders.—First in order is the border, and it is as well to state that no mysterious composition is required in its formation. It was only lately that a correspondent wished to know whether he could not utilise an old horse in the composition of his Vine border, and whether damaged cases of Australian meat could not be turned to profitable account for the same purpose. Masses of decaying animal or vegetable matter are worse than useless, and quantities of rich manure mixed with the loam do more harm than good in many cases. Nothing is more easy, if manure is required, than to apply it from the surface, and this after all is the natural way. It is a positive fact that the most magnificent Grapes are produced from Vines grown in borders entirely composed of turfy loam, without a particle of manure in any shape. I have a vivid recollection of a range of vineries where the borders were made of the top spit of a field that had been laid down in pasture for two or three years. This soil was dug up and thrown into the space that had been excavated to a distance of 6 feet on each side of the front wall, and the progress of the Vines was wonderful. On examining the border after the Vines had made one year's growth the whole of it was found to be permeated with masses of branching roots in the most healthy condition. The Vines were overcropped at first, and through some other mismanagement they failed, after thriving remarkably well for the first three or four years. Six feet more should have been added to the width of the borders both inside and outside after the third year, but this was not done; however, I saw enough of them to know that under proper management extraordinary results would have been obtained. In borders made with turfy loam it is interesting to watch the rapidity with which the roots spread along the surface after rich top-dressings have been applied.

I will now give another instance of a border made in a different way. In this case there was much preparation, and no expense was spared, the bottom being concreted, and crushed bones with manure added to the loam. The drainage, consisting of brickbats or similar material, was placed over the concrete. The Vines planted in this border grew remarkably well at first, but the Grapes which they produced never finished well, and shanking was common. There was one mistake made to which I wish to draw attention, and that was, although plenty of drainage was placed under the border, no outlet was made to carry away the superfluous water; but even after this was done, although there was an evident improvement, it was clear that a greater mistake had been made in adding too much manure in the first instance. The drainage admitted of an easy remedy, but it was not so easy to correct the other mistake. In many soils it is not necessary to place concrete at the bottom of a Vine border. In the dry gravel subsoil at Loxford Hall I do not find it necessary either to concrete or drain the borders. In a wet clay subsoil it would be necessary to do both.

Preparing and Planting.—Vines are very easily propagated from eyes, and when only a small number is required it is best to plant one eye only in the centre of a 3-inch pot. To obtain fine planting canes the pots should be placed in heat early in March; the temperature of the house should be 55° at night, and a genial bottom heat should be afforded. When the young plants have grown 6 inches high place them in 6-inch pots, using turfy loam enriched with some decayed manure, or, in preference, pulverised bones; plunge the pots again for a few days until the roots reach the sides, when the young Vines are better without bottom heat. As soon as they have tolerably well filled the pots with roots shift them again into 9 or 10-inch pots, and maintain a rather high temperature until the wood is well ripened, when they may be removed to a cool house. They should not be allowed to become dust dry at the roots during winter, as such a degree of dryness in the soil is injurious to them.

The best time to plant-out the Vines is in March, when the young shoots have grown 2 or 3 inches. The plants should be turned out of the pots, and the roots disentangled and spread out on a level surface, covering them with 6 inches of mould. It is not easy to give precise directions as to watering. If the plants as well as the border are in a moist condition I prefer not giving any water for a week after planting, but the house should be kept close, and a moist atmosphere maintained for a few days. I think it an evil to deluge either newly-planted or potted plants with water, as I have repeatedly noticed that they make fresh roots more freely when water is not applied for some time after planting. It is desirable to wait until the young rootlets are formed; the plant is then in a condition to take up water.

A vinery may also be planted with Vines struck from eyes the same season. The plants should be prepared in the way just stated, but the pots should be placed in heat as soon as convenient after the middle of January. The plants will be ready for potting into 9-inch pots by the first week of April, and will be ready for planting-out in the border early in May. Such Vines, if well managed, and if they experience no check, will grow to the top of a 20-feet rafter in the season in which they are planted. A few of them may be grown and fruited in pots, and will make canes of the strongest description. I use 13-inch and 15-inch pots for fruiting them in, draining well, and using sound turfy loam mixed with pulverised bones. This compost should be rammed in rather firmly, and the plants, when growing, should have plenty of light and air, especially when the wood begins to ripen. Such plants

will ripen a crop of fruit on the back wall of a newly-planted vinery or in other parts of the house, always bearing in mind that the fruit will not ripen well in a position where it is not exposed to the light and air. They have also a fine effect if grown as standards, with the head trained to a circular trellis, and the bunches allowed to hang down from the outer edge of the circle. The plants should be in such a position that the fruit may be just above the eye of a person looking at it.

After the young Vines are planted-out in the house, and have started into growth, a stick should be placed to each, as the young shoots are easily damaged, and I ought to state that it is better to train the shoots from the base of the plant, as such always grow strongest. A somewhat moist atmosphere should be maintained in the house; this is preferable to syringing the plants.

Those who intend planting a vinery, and who have not yet obtained the young Vines, should purchase them at once from a respectable nurseryman, and pay the highest price for them; a shilling or two saved in the price of a Vine must be considered a small matter in comparison with having a large number of failures from planting badly-grown canes. Those who rush to the cheapest market for their goods generally pay most in the end. When the plants are sent home they should be kept until planting time in a cool house where frost cannot injure them.

If the Vines are healthy and in good condition, all will start into rapid growth, when one shoot should be trained up at every 2 feet 9 inches, allowing 1 foot 6 inches at each end. There is much difference of opinion amongst practical men with respect to the best method of cutting the young rods at pruning time; some cut them back nearly to the bottom of the rafter, others go to the opposite extreme, and leave the young cane the whole length of the rafter. I prefer leaving from 6 to 9 feet from the bottom of the rafter, according to the strength of the canes. The weaker canes should be shortened most, and if any of them are unusually weak I should cut them close back to the bottom of the rafter; they would then break more strongly the following year. I should also take a crop of from two to three bunches from all canes that had grown to the top of the rafters. The second year each cane would carry about six bunches.

Varieties.—There is much difference of opinion regarding the best varieties to plant. To a certain extent the varieties are a matter of taste, and the Grape Vine is also much influenced by soil and situation. I have lately seen that very fine-flavoured Grape Chasselas Musqué in excellent condition, the bunches and berries very large for the variety, and beautifully ripened, and the same Vines do well every year; yet I have repeatedly seen this sort under apparently far more favourable circumstances, still it was not possible to get a presentable bunch from it. Again, there is Royal Ascot; how often has Mr. Standish shown it in splendid condition, the berries large and perfectly finished in every respect, and the flavour all that could be desired, yet many good Grape-growers fail to grow it creditably. It has done badly with me this year; most of the fruit cracked at the apex of the berries, and, as a consequence, decay soon set in. Mr. Pearson, of Chilwell, who is well known as one of our most successful Grape-growers, brought up a bunch of this, also in bad condition, to one of the meetings at South Kensington; so that we must likewise class this amongst uncertain Grapes. Take Golden Champion as one of the most recent introductions; it is a very champion amongst white Grapes when it can be obtained in good order. It has very much improved with me this year; the berries have not only finished off well, but they have also kept well, and I have bunches hanging now in good condition, although they were ripe in July. It has never grown very strongly with me, but always shows plenty of bunches; on the other hand, many good growers condemn it as utterly worthless, and most of them are agreed that it is an uncertain Grape. I have it grafted on the Black Hamburgh also on the Trentham Black. I will send you a few berries from each to say whether you think they are utterly worthless.

Our opinion is recorded in another column.—Eds.]

Many more Grapes could be mentioned as uncertain. I will name instead a few that will not cause disappointment. For general purposes, and the best of all Grapes, is the Black Hamburgh; every other must give place to this. Madresfield Court Black is said by some to surpass it; it is certainly a grand acquisition. This, with Lady Downe's, I would recommend for a cool house. As two white Grapes for a cool house I would choose White Frontignan and Buckland Sweetwater; the latter should be grafted on Black Hamburgh. Foster's White Seedling is by some thought a better Grape than Buckland Sweetwater, but it seldom acquires a golden colour, and has not such a fine appearance as the other. There are some very fine new white Grapes (that is, as far as one can judge from seeing a bunch and tasting the berries) being sent out by Messrs. Standish, of Ascot, and Mr. John Pearson, of Chilwell, Nottingham. All of them are early varieties, and adapted for cool houses. Ferdinand de Lesseps is the most distinct; it partakes of the blood of that highly-scented variety the Strawberry Grape, and is also perfumed; the berries are oval, of a rich golden colour, and delicious flavour. In Dr. Hogg, another variety raised by Mr. Pearson, and to be sent out by him, the bunch is long and tapering, the berries large, round, and of a rich Muscat or Frontignan flavour. The berries, Mr. Pearson says, are not liable to crack. In Mr. Standish's Ascot Citronelle we have another very early distinct Grape; the bunch and berries are medium-sized, with a very rich piquant flavour, partaking of the Frontignan. For the Muscat house I would plant Alicante and Muscat of Alexandria or Bowood Muscat.

I said nothing about Mrs. Pince's Black Muscat, which, with me, is an exceedingly fine variety, but it is uncertain, so many good growers having failed to produce good fruit from it. I have it grafted on Lady Downe's, but it does not colour so well on that variety as it does on its own roots. In the Muscat house on its own roots it has coloured pretty well, and carries a crop of fine bunches weighing from 2 to 3 lbs. each. One fault with Mrs. Pince is that the berries are apt to shrivel long before those of Lady Downe's or Alicante.—J. Douglas.

NEW ROSES FOR 1872.

The circumstances under which France was placed twelve months ago were undoubtedly the cause of the unusually small number of new Roses that were received from that country for the season 1870-71, the number being thirteen—three Remontant Hybrids and ten Tea-scented. Of these, six Tea-scented kinds were raised by Ducher, four Tea-scented and one Remontant by Levet, one Remontant by Guillot père, and the other by Schwartz. None of these are yet sufficiently well known to enable one to pronounce a decided judgment on their merits, and as yet but little notice has been taken of them in these pages. While the depression of French horticulture consequent upon the gigantic struggle brought to a close last spring, excited genuine sympathy among all classes here, in one department, at least, a negative kind of relief, so to speak, was felt by the Rose amateurs, and probably by the professional growers also, owing to the absence of the host of new Roses previously offered every year to delight and perplex, to interest and disappoint. Now the terrible storm has passed away, our sincerest wishes are that our French neighbours generally, and the horticultural portion of them in particular, may speedily recover their former vigour. A prominent sign of efforts being made to bring about returning prosperity is to be found in the announcement of new Roses for 1872 just received from Paris—their name is legion. To attempt at this early period to form any just estimate of what they are from the brief and somewhat formal descriptions attached to them would be but a waste of time and space. Any real improvement upon what we already possess we shall gladly accept; but it is too much to be feared the good is accompanied by so much that is worthless, that to pick it out from the multitude of subjects offered for choice must at best prove a perplexing and even wearisome task. To sum up, the announcements to the present time contain the names of fifteen Tea-scented Roses, one Remontant Moss, one Hybrid not Remontant, one Bourbon, and fifty Remontant Hybrids—in all sixty-eight. By placing before our Rose friends the list in its entirety, they will be able to analyse its contents and judge for themselves. The numerals prefixed are for convenience of reference.

TEA-SCENTED.

1. *Blanqui.*—Vigorous, very free-blooming. Flowers large, full, and symmetrical; pure white.

2. *Comte de Grivel.*—Vigorous and free-blooming. Flowers large, full, and well formed; straw yellow changing to white. Seedling from Canari.

3. *Comte Taverna.*—Very vigorous. Flowers large, very full, and well formed; yellow with brighter centre. Seedling from Louise de Savoie.

4. *Comtesse de Nadaillac.*—Vigorous and floriferous. Flowers large, full, and globular; bright vivid rose upon a copper apricot yellow ground.

5. *Henry Lecoq.*—Vigorous. Flowers medium, very full, with long swollen buds; deep rose.

6. *La Jonquille.*—Moderately vigorous. Flowers medium sized, not quite full; jonquil yellow, the most yellow variety of this section. Seedling from Lamarque.

7. *Le Nankin.*—Very vigorous. Flowers large, very full, and well formed; copper yellow with brighter centre.

8. *Louis Gigot.*—Very vigorous. Flowers very large, very full, well formed; pure white when first expanded, afterwards mottled white and rose. Very curious!

9. *Ma Capucine.*—Vigorous and free-blooming. Flowers medium-sized and semi-double; beautiful nasturtium (capucine) yellow, a new colour. Seedling from Ophirie.

10. *Madame Camille.*—Very vigorous and free-blooming. Flowers large, full, and well formed; soft aurora-like rose with whitish shading.

11. *Madame Céline Berthod.*—Vigorous and free-blooming. Flowers large, full, and well formed; sulphur yellow, very brilliant.

12. *Madame Jules Margottin.*—Vigorous and free-blooming. Flowers large, full, and well formed; beautiful soft rose with yellow *onglets*, deep red centre.

13. *Marie Van Houtte.*—Very vigorous. Flowers large, full, and well formed; yellowish white, striped and edged with bright rose.

14. *Perfection de Mont Plaisir.*—Vigorous, almost thornless, very floriferous. Flowers medium, full, and well formed; beautiful canary yellow.

15. *Souvenir de Paul Neron.*—Vigorous, very floriferous. Flowers large, full, well formed; salmon yellow edged with rose. Seedling from Ophirie.

REMONTANT MOSS ROSE.

16. *Madame Soupert.*—Very vigorous. Flowers medium, full, like a rosette; bright cerise or cherry red. Freely remontant and very mossy.

HYBRID ROSE NOT REMONTANT.

17. *Catherine Bonnard.*—Very vigorous. Flowers large, full, and well formed; beautiful dazzling rose carmine, very striking. Seedling from Madame Domage.

REMONTANT HYBRIDS.

18. *Abbé Bramerel.*—Vigorous. Flowers very large, full, and well formed; brilliant crimson red shaded with purplish brown, deep and velvety.

19. *André Dunant.*—Very vigorous. Flowers large, full, and well formed; very fresh soft rose, suffused silvery white. Seedling from Victor Verdier.

20. *Antonine Verdier.*—Very vigorous. Flowers large, full, and well formed; bright carmine rose. The flowers are almost always solitary; the buds are well formed, and will be sought after for bouquets.

21. *Auguste Rigotard.*—Vigorous. Flowers large, full, and well formed; cherry red suffused with white.

22. *Baron de Bonstetten.*—Very vigorous. Flowers very large and full; crimson red, blackish and velvety. Superior to M. Boncenne.

23. *Baronne Louise Uxkull.*—Vigorous and free-flowering. Flowers very large, full, and well formed; magnificent brilliant carmine rose; very fragrant.

24. *Baronne de Prailly.*—Very vigorous. Flowers very large and very full, globular; vivid red, shaded. Seedling from Victor Verdier.

25. *Bouquet Rose.*—Very vigorous, blooming in panicles. Flowers medium, full, and well formed; bright rose cerise.

26. *Coquette Normande.*—Vigorous. Flowers medium-sized, full, and globular, well formed; silvery and shaded vivid rose. Seedling from Jean Goujon.

27. *Docteur de Chalus.*—Vigorous. Flowers large, full, abundant, and well formed; reddish scarlet, centre velvety, reverse of petals rose pink.

28. *Docteur Lemée.*—Vigorous. Flowers large, full, and well formed; velvety purple shaded blackish.

29. *Etienne Levet.*—Vigorous, almost thornless, very free-blooming. Flowers large, full, and well formed; beautiful carmine red. Seedling from Victor Verdier.

30. *François Michelon.*—Vigorous and free-blooming. Flowers large and full, shape of the Cabbage or Provence Rose; beautiful deep rose, reverse of petals silvery. A seedling from Rose de la Reine.

31. *Jacques Plantier.*—Vigorous. Flowers large, full, and well formed, imbricated; flesh-coloured rose.

32. *Jeanne Gros.*—Vigorous. Flowers very large, full, and well formed; beautiful satin rose.

33. *Le Havre.*—Vigorous. Flowers large, full, and well formed; beautiful brilliant vermilion, finely coloured, very constant.

34. *L'Espérance.*—Vigorous. Large, full, and well formed; bright cerise carmine.

35. *Louis Charlin.*—Vigorous. Flowers very large and full; vivid rose with red centre.

36. *Louis Corble.*—Vigorous and free-blooming. Large, full, and well formed; beautiful cerise rose, shaded vivid carmine.

37. *Madame Bellon.*—Moderately vigorous. Flowers large, full, and lasting; beautiful soft rose.

38. *Madame Chaté.*—Vigorous. Flowers large, full, and well formed; "cerise métallique satiné de blanc."

39. *Madame Hippolyte Jamain.*—Very vigorous. Flowers very large and full, expanding well; white, slightly tinged with rose.

40. *Madame de Parrieu.*—Very vigorous. Flowers large, full, globular, well formed; beautiful vivid rose, shaded carmine. Seedling from Anna de Diesbach.

41. *Madame de Ridder.*—Very vigorous. Flowers large, full, and well formed; vivid amaranth red. Very floriferous.

42. *Madame de St. Puigent.*—Very vigorous and free-blooming. Flowers medium, full, and well formed; blood red flame colour with velvety slaty gloss. Seedling from Catherine Guillot.

43. *Madame George Schwartz.*—Very vigorous. Flowers large, full, and well formed; beautiful Hydrangea colour, changing to glittering rose.

44. *Madame Guillot de Montfavet.*—Vigorous. Flowers large, full, globular, and well formed; glittering white. Seedling from Duchess of Sutherland.

45. *Madame Lefebvre Bernard.*—Vigorous, almost thornless, very free blooming. Flowers very large, full, and imbricated; beautiful vivid rose marked with white. Seedling from Souvenir de la Reine d'Angleterre.

46. *Madame Livia Frege.*—Very vigorous. Flowers large, full, and well formed; soft rose, shaded violet, with silvery gloss. Seedling from Souvenir de la Reine d'Angleterre.

47. *Madame Renard.*—Very vigorous. Flowers large, full, and globular; brilliant salmon rose. Seedling from Jules Margottin.

48. *Mdlle. Marie Gonod.*—Very vigorous. Flowers large, full, and lasting; pure white. Seedling from Madame Laffay.

49. *Malfilâtre.*—Very vigorous. Flowers very large, full, globular, and rosette-shaped; deep red. Seedling from Jean Touvais.

50. *Marquise de Chambon.*—Vigorous. Flowers medium-sized, full, and well formed; beautiful salmon rose with deeper centre.

51. *Maxime de Larocheterie.*—Very vigorous. Flowers large and full; fine red and blackish purple, velvety, superb. Seedling from Léon des Combats.

52. *Monsieur Cordier.*—Very vigorous. Flowers very large and full; fine brilliant red. Seedling from Géant des Batailles.

53. *Œillet Fantaisie.*—Vigorous and free-blooming. Flowers medium-sized, full, and well formed; vivid rose purplish violet, each petal striped and marked with white like a Pink.

54. *Pierre Izambart.*—Very vigorous. Flowers large and full, with petals gracefully wrinkled; velvety crimson red, outside deep dull red. Seedling from Triomphe de l'Exposition.

55. *Prince Stirbey.*—Vigorous. Flowers large, full; bright flesh-coloured rose.

56. *Richard Wallace.*—Very vigorous. Flowers very large, full, and well formed; fine vivid rose, slightly tinged with white.

57. *Rosa Bonheur.*—Vigorous. Large, full, and well formed; beautiful vivid carmine rose.

58. *Sylvia.*—Vigorous. Large, full, and well formed; beautiful reddish purple with fiery lustre.

59. *Souvenir de Bellanger.*—Very vigorous. Flowers medium-sized, full; bright purple, outside vivid fiery red.

60. *Souvenir de Julie Gonod.*—Very vigorous. Flowers large, full, and well formed; very fine glossy satin rose.

61. *Souvenir de l'Exposition de Darmstadt.*—Very vigorous. Flowers large, full, and well formed; velvety and blackish, shaded with deep violet and blood red.

62. *Souvenir de Docteur Daviers.*—Very vigorous. Flowers medium-sized, full, and globular; deep velvety red.

63. *Souvenir de Général Douai.*—Vigorous. Flowers large, almost full, and globular; fine vivid rose.

64. *Thérésa.*—Vigorous. Large, full, and symmetrical; fine bright silvery rose.

65. *Vaucanson.*—Hybrid Noisette. Vigorous. Flowers medium-sized, full, and globular; vinous rose.

66. *Vicomte Douglas.*—Vigorous. Flowers medium-sized, full, and symmetrical; vivid red. Seedling from Duchess of Norfolk.

67. *Victor Verne.*—Very vigorous. Large, full, and symmetrical; bright currant red.

BOURBON ROSE.

68. *Amédée de Langlois.*—Vigorous. Flowers large, full, and lasting; fine deep reddish purple. Very free-blooming.

Under reserve I would suggest that Nos. 22 and 61 may prove worth a trial, both being of colours desirable as exhibition Roses. The long name of the latter might be abbreviated to the last word of it. I have rendered *se tenant bien* by "lasting," meaning the duration of the individual flower being longer than the usual average; it is often rendered "erect" in the Rose catalogues, which I think is not its signification.—A. H. Kent.

PROLONGING THE STRAWBERRY SEASON.

Anything which tends to instruct us as to the best mode of prolonging the Strawberry season is a boon to all interested in gardening matters. Even some of the old "blackbirds" among us will be very grateful to Mr. Lee for further information as to the system he pursues in order to secure a fair crop of well-developed Strawberries "every season." Here, in Herts, we have some Keens' Seedlings, forced early last spring, and turned out of pots in May, flowering and fruiting, some nice ripe Strawberries being gathered from time to time. But do not let us mislead the public; this is more to be attributed to

the mildness of the last few weeks than to anything new in Strawberry culture. However, let me ask, What is considered a fair length for the Strawberry season? How many months out of the twelve is it possible for gardeners, who force fruits of all kinds, or nearly so, to supply their employers daily with Strawberries? I may add that I succeeded in sending Strawberries (not including Alpines), five months out of the twelve for dessert this year, 1871.—An Old Blackbird, *Moor Park.*

PEAS FOR SUCCESSION.—No. 2.

Peas for Small Gardens.—By small gardens I do not mean those of very limited extent, but such as are of small area for the number and variety of vegetables which must be produced. In all gardens of less than half an acre I would not grow a Pea exceeding 4 feet in height; in those of a quarter of an acre or less, none that exceeded 3 feet; and under an eighth of an acre, none but the most dwarf. The tall varieties, if they do not shade more than the ground on which they grow, take up too much room, prevent a free circulation of air, and have a bad appearance in a space that must be devoted to dwarf subjects.

Dillistone's Early, or Dickson's First and Best.—3 feet. Sow November 10th and March 5th.

Little Gem.—2 feet. Sow November 10th on a warm or south border; March 5th and 20th; April 5th and 20th; May 5th and 20th; June 5th and 20th; July 5th and 15th.

Burbridge's Eclipse.—2½ to 3 feet. Sow March 5th and 20th; April 5th and 20th.

Princess Royal.—2½ to 3 feet. Sow March 5th and 20th; April 5th and 20th; May 5th.

Premier.—3½ feet. Sow April 20th; May 5th and 20th; June 5th and 20th.

Veitch's Perfection.—3 feet. Sow May 5th and 20th; June 5th and 20th.

Yorkshire Hero.—3 to 4 feet. Sow May 20th; June 5th and 20th; July 5th.

Dwarf Branching Waterloo.—3 feet. Sow June 5th and 20th; July 5th.

The two Peas most desirable in the above list are Little Gem and Dwarf Branching for a small garden. From sowings of Little Gem on November 10th, March 5th and 20th, April 5th and 20th, May 5th and 20th, June 5th and 20th, and July 5th; and of Dwarf Branching, commencing March 20th, and continued on the dates named for Little Gem, and made simultaneously up to July 5th, a good supply and succession of Peas may be calculated upon from the early part of June until production be stopped by cold weather. A pint of the two sorts named being put in at a time, ten sowings of Little Gem and eight of Dwarf Branching, or nine quarts will be required—a sufficient quantity for one-eighth of an acre. The quantity of seed may seem large, but as a rule, more, comparatively, is required for a small than a large garden.

The following table will show the times of sowing the above varieties:—

Sorts.	Colour.	Height.	Nov.	March.	April.	May.	June.	July.
	*	ft.						
Dillistone's Early, or Dickson's First and Best	w.	3	*10	*5	....	....	....	..
Princess Royal (Maclean)	w.m.	2½ to 3	..	*5, *20	*5, *20	*5	....	..
Little Gem (Maclean)	g.w.	2	*10	*5, *20	5, 20	5, 20	5, 20	*5, *15
Premier (Maclean)	g.w.	3½	..	....	*20	5, 20	*5, *20	..
Veitch's Perfection	g.w.	....	..	....	....	5, 20	5, 20	..
Yorkshire Hero (Dixon's)	g.w.	3 to 4	..	....	....	*20	5, 20	5
Dwarf Branching Waterloo	g.m.	3	..	....	....	....	*5, *20	*5
Burbridge's Eclipse	b.m.	2½ to 3	..	5, 20	*5, 20	....	....	..

* w., White; w.m., White Marrow; g.w., Green Wrinkled; b.m., Blue Marrow.

The sowings marked with an asterisk (*), will be ample for a garden of from half to three-quarters of an acre, and the whole for a garden of 1 to 1½ acre. The demand of one family for Peas may vary considerably from that of another, but I have found that a dish of Peas daily has been needed if it could be had, whilst with most it is a necessity. The varieties and sowings are calculated for affording the earliest, latest, and a constant succession, and I ought to say that the sowings for a small garden are proportionately more instead of less, as some might conclude, than for a large garden, which is owing to the sowing of dwarfer kinds; for though we may have more rows on a given space, and obtain as good a supply, yet for three rows of Little Gem at 1½ foot to 2 feet apart, we require three times the seed that we require for a row of Ne Plus Ultra at 7 feet.

Before sowing, all my Peas are red-leaded, making them wet with water, and then dusting with red lead, and stirring-up so as to redden them all over. If the ground be dry water the drills previous to sowing. Steeping Peas before sowing I do not practise. It is, perhaps, a good plan, but sowing in moist soil is better, and if "steeped" seed is sown in dry ground and no water is given, the vitality is impaired if not lost. With sowing on turves, and in pots in a frame, and afterwards planting out, I have had no success, and I do not advise the practice.

After the Peas come into flower they cannot have too much water, nor too frequent supplies of weak liquid manure if the weather is dry, and the soil cannot be too rich and too deep, nor can too much room be given.—G. Abbey.

BEDDING PLANTS IN 1871.—No. 2.

In continuing my remarks on Zonal Pelargoniums, I shall begin first with the crimson or dark scarlets. Of these the darkest I have yet tried is Crimson King (Henderson). It is of a beautiful colour, which affords a very good contrast to the foliage, but I am obliged to confess I am disappointed with it, as it has not proved a sufficiently free bloomer. I agree with Mr. Luckhurst, that in point of habit it is all that can be desired, the foliage covering the plants well, and the flower-stalks stiff and just above the foliage. I am in hopes it will bloom better from old plants.

Next in point of colour is Glory of Waltham (W. Paul). It has not proved so effective with me as I have seen it elsewhere. The leaves are plain, and I think it an advantage in all the crimson and scarlet sections to have little or no zone. I do not know whether there is any difference between Waltham Nosegay and Glory of Waltham; they have always seemed to me so nearly alike that I have not tried the two.

With regard to the next, Waltham Seedling (Beaton), I can only repeat what I have stated before, that it is one of the most valuable bedders we have, very free-blooming and constant, with very good flower-stalks, and it stands the wind and weather better than most Geraniums.

Bayard (Pearson), has again been very good, in size of truss superior to the latter, not so deep a crimson, but a brighter colour. It does not stand bad weather so well, as the footstalks of the trusses are longer, and the habit of the plant more straggling, but it is decidedly one of the most effective bedders we have.

R. K. Bowley (Downie, Laird, & Laing), which obtained a first-class certificate at Chiswick, grows with me too straggling. It is of much the same colour as Bayard, rather darker, and is not in my opinion nearly so good.

Vesta (Paul).—This is one of Mr. W. Paul's best; very free-blooming, with a dwarf habit. Very nearly the same colour as Glory of Waltham, and superior to it. It had a first-class certificate at Chiswick, and is quite worthy of the character given to it. I do not, however, think it has so good a truss, or carries the truss so well as Waltham Seedling.

Thomas Speed (Pearson), a dull crimson, has not come up to the expectations I had formed of it, as it has not bloomed with me this year nearly so well as last.

Bonfire (Paul)—This is very fine in point of colour, very bright crimson, with a good truss and habit. This is the first season I have tried it, and it seems to have a good constitution.

The next I name is a deep red, neither crimson nor scarlet—Duke of Devonshire (Pearson). With me this year it made one of the finest beds I ever saw. The size of the trusses is enormous, and they are very freely produced; its fault is that it has too long a flower-stalk.

Douglas Pearson, much the same in colour, though not so bright as Bayard, is, I think, a better bedder, because its habit is more compact, and the trusses stand up above the foliage better.

W. Thomson (Pearson) is also very good. I believe Mr. Pearson prefers it to Douglas Pearson, but with me the pips in the trusses are more crowded, and do not stand the weather so well.

Milton and Jupiter (Pearson), both shades of deep red, are not so good as Duke of Devonshire, Bayard, or Douglas Pearson, and not sufficiently distinct to make it worth while growing all of them.

All the above are in the crimson or dark scarlet section, and besides them I name some others of which I have not had quite enough to bed separately, as Sunshine (Laing), very pro-

mising, fine colour, and free-blooming; Star of Fire (Laing), a very bright dark scarlet of about the same colour as Bonfire, a very good truss, and dwarf habit, likely, I think, to be a great acquisition; and Rainbow (Paul), fine truss, rather too strong a habit, but it would be very good for large beds, and I can recommend it to those who prefer plain leaves. Another of Mr. Paul's, very distinct in colour, is Claude Lorraine, a magenta crimson; it has been highly spoken of by many, but I have not given it a sufficient trial yet. I must also say much the same of Robinson Crusoe, Chief Justice, Amethyst, Caractacus (all Paul's); they have all grown rather too much with me this year, to enable me to report properly about them.

I next take the scarlet section.

Lady Constance Grosvenor (Turner), is too well known to need any remark, it is decidedly one of the very best.

Cybister (Carter), I have decided to cast, as too straggling both in habit and petal.

Multiflora.—A good dwarf habit, and free-blooming.

Sobieski.—One of the very best; good truss, and carried well above the foliage, nice compact habit.

Rev. J. Woolley (Pearson).—Fine colour, and a very fine pot plant, but not quite free-blooming enough.

Vesuvius.—This disappointed me very much early in the season, but improved so greatly afterwards as to make me alter my opinion, and not cast it as I had at first intended. The trusses are not sufficiently large, and I do not like it so much as many others.

Much of the same colour are W. Underwood (Pearson), very good early in the season, but the habit is not sufficiently branching; Glorious, most uncertain, anything but glorious in bad weather; Roi d'Italie, flower-truss too small, with a bad constitution, only good for very fine seasons.

Grand Duke (Smith).—This is one of the very finest bedders; truss very large, habit good, free-blooming, and very constant. It is more of a light red than scarlet, and I can strongly recommend it to anyone; it is a strong grower, but not coarse.

Godfrey, much of the same shade of colour, is very good, but rather too long in the footstalk; it is, however, a very pleasing bright colour.

Kentish Hero I do not like either for its leaf or its flower, and I have decided to cast it.

Glow is a very good late-season variety, fine truss, and very circular flowers. I was disappointed with it early in the season, but it improved, as Vesuvius did, so much that I shall grow it again.

King of the Nosegays, light red, seems to have too delicate a constitution for bad weather.

Mrs. Laing is still a good variety, but well known.

I find that I have omitted among the dark crimsons two very promising varieties raised by Mr. Laing (Downie, Laird, and Laing)—viz., Moor of Venice and George Peabody; also a very good light scarlet, nearly the colour of Roi d'Italie, Phœbus, which I expect will turn out very well.

Lady Hawley (Downie & Co.), has grown too strongly with me this year, but is a fine pot plant.

I will take the cerise-coloured ones in my next communication, and will only add now some of the light crimson section which it is difficult to classify, as the well-known Lord Palmerston, which I still think one of the very best bedders, though it will not stand the treatment which Mr. A. H. Kent tested it with.

Le Grand is very uncertain, as a rule not free-blooming enough, very fine at times. An undoubtedly good pot plant.

Eclat (Smith), has a very large truss, but is too coarse except for large beds.

Masterpiece is all foliage and no flower.

David Garrick (Bell & Thorpe), is in the way of Eclat, but not so coarse, and a finer flower.

I conclude now by saying if anyone wishes to have my remarks on the warmer treatment of Geraniums in the winter confirmed, let him go to Mr. Pearson's, of Chilwell, during the winter, and, as I stated last year, many gardeners would do much better to use their late vineries for bedding plants rather than cold pits. If the temperature of the house is not kept above 45° it will not unduly excite the Vines, and very little fire heat will be needed.—C. P. Peach.

YORKSHIRE HERO POTATO.

That so many kinds of Potatoes should be named recently in the Journal as good, and no mention made of the best, is remarkable. I have this year grown in a light rich soil Rivers's Royal Ashleaf, Hogg's Coldstream, Lapstone, Daintree's Seedling, Wheeler's Milky White, Almond's First Early, and Yorkshire Hero, but the last-named is infinitely superior this year to any of the rest. In 1870 all were better than this year in flavour and mealiness, except Yorkshire Hero, which is as good this year as last.

I find Early Rose really an early Potato and a good cropper, all the tubers being ripe long before the disease came. I should say it is a good Potato to sell, as many retail buyers do not seem to know a good-flavoured Potato from a tasteless one.

I last year was imprudent enough to recommend good sorts of Potatoes to my friends, but, as so few can cook a Potato, my advice gratis met with the usual amount of appreciation. I have seen the attempt nearly succeed to spoil a Yorkshire Hero in the cooking, but it requires ingenuity.—Yam.

GOLDEN CHAMPION GRAPE.

We have received from Mr. Douglas, gardener to F. Whitbourne, Esq., of Loxford Hall, Essex, specimens of the Golden Champion Grape, with the following note in reference to a criticism on this Grape which recently appeared in the pages of a contemporary:—"The smaller specimens are from a Vine grafted on Black Hamburgh, and the others from one on Trentham Black. This Grape has done well with me in the present year, and both Mr. and Mrs. Whitbourne think highly of it, and have preferred it to Buckland Sweetwater." And well they might! The berries from the Vine grafted on Trentham Black were of a fine golden colour, clear, and without the slightest trace of spot, perfectly ripe, firm in flesh, excellent in flavour, and 1⅝ inch long by 1¼ inch broad. The Committee that would ignore such a Grape submitted to them would justly expose themselves to well-merited censure.

REVIEW OF THE VEGETABLE SEASON.

Although this, perhaps, has been one of the worst fruit seasons on record, we may deem ourselves fortunate in having a first-rate supply of all kinds of vegetables, and, with the exception of Potatoes, all of good quality.

To begin with the most important—namely, Peas. Laxton on the whole takes the lead with that excellent variety Alpha, which, sown successionally, is the best of Peas for all seasons; nevertheless, Carter's Imperial Wonder is certainly the most sugary of all Peas of my acquaintance. The following six varieties of Peas I consider the best—three early and three late—viz, Sutton's Ringleader [Dillistone's Early], Little Gem, and Laxton's Alpha for early kinds, or the latter for late; Carter's Imperial Wonder, Laxton's Quality, and Laxton's Supreme, a truly fine Pea for late crops and show purposes.

Among Potatoes I know of nothing like Early Coldstream, not one tuber having here been diseased, and it being fine both for use and for production, but selection is required in order to keep up a true stock. Royal Ashleaf and Myatt's are both good early varieties, and kidney-shaped Potatoes are preferred for the dining table. For a late-keeping variety Lapstone heads the list here. The American Potatoes have all been tried and all found wanting. Among new varieties Paterson's Bovinia is the most promising. Carter's Main Crop is perhaps the handsomest of all Potatoes, but lacks flavour; still, I shall try it again. The Marchioness of Lorne, another of Paterson's sent here for trial, is also particularly handsome, but I cannot afford to taste it this season.

Of Cauliflowers and Broccoli I find Walcheren the very best, giving us ample supplies from June to November, making three sowings—viz., in the second week of March, the second week of May for hand-lights, and the third week of August. We are now cutting heads of 3 inches in diameter, and others a foot across for secondary purposes, and of good quality. This is succeeded by Snow's, which keeps up a supply by protection with fern until February, when we have Sutton's White Sprouting and Osborn's Winter White, but for the latest of all nothing is so good nor so hardy as Eclipse (Cattell's).

Among Savoys I find nothing so valuable as Little Pixie. Planted out 16 inches plant from plant, the ground is literally covered with small but delicious heads of from 1½ to 2 lbs. each. I shall advise all my gardening friends to grow this Savoy largely.

The most useful vegetable just now is White or Sea-kale Beet grown in well-trenched rich ground. The leafstalks are nearly a quarter of an inch thick, and as white as snow. It is a great favourite with the cook.

For general purposes nothing surpasses Cole's Celeries, White and Red. Sandringham is also good, but in my opinion not equal to Cole's in quality.

Of Beans we have a capital variety in Carter's Champion, an extraordinary cropper of good quality.

Among the many varieties of Cabbages—the best of all green vegetables if ready in May—Barr's Little Pixie stands at the head. It is planted on a south border at 12 inches apart; all the plants are of one size.—R. Gilbert, *Burghley*.

ROYAL HORTICULTURAL SOCIETY.

November 1st.

For such an ungenial day, with the wind east and a slight dash of north in it, there was a fair show. Of the principal subjects for which prizes were offered in the floral and fruit departments—namely, Chrysanthemums and out-door Grapes, neither the number nor the quality of the exhibitions was up to the mark of past years—a circumstance entirely attributable to the lateness of the season. For Chrysanthemums the Show was quite a fortnight too early, while out-door Grapes, even near London, have, except under the most favourable circumstances, not ripened at all.

Of six large-flowering Chrysanthemums only two collections were shown—one from Mr. Goddard, gardener to F. C. Little, Esq., Cambridge Villa, Cambridge Park, Twickenham, and one from Mr. Rowe, gardener to Mrs. Lewis, Roehampton. The former were trained to single stems, branching into a narrow candelabrum-shaped head, but not hollow in the centre. Aurenm multiflornm, yellow; Princess Marie, lilac; and Mrs. G. Rundle, white, were very well bloomed; of the others James Salter and Duc de Conegliano are both very ornamental for conservatory decoration. Mr. Rowe's plants were the usual bush specimens, very healthy and well grown. Mrs. G. Rundle, Prince of Wales, and Gloria Mundi were very well bloomed. Mr. Rowe had the first prize, Mr. Goddard being second.

Of six Pompons, Mr. Rowe sent fine plants of White and Golden Cedo Nulli, and Salamon; the others were not fully out. Mr. Goddard sent plants trained on flat trellises, of which Madame Pépin, Lilac Cedo Nulli, and Aigle d'Or were in good bloom. Mr. Rowe was first, Mr. Goddard second.

The only stand of twenty-four cut blooms came from Mr. Rowe, gardener to Mrs. Lewis, Roehampton, and included very good blooms of Mrs. George Rundle, Prince Alfred, Lady Talfourd, Rev. J. Dix, Guernsey Nugget, Mr. Brunlees, and Bronze Jardin des Plantes. For these a first prize was given, and a like award was made to the same exhibitor for a stand of twelve, in which the varieties named were the best. Mr. Forsyth, of Stoke Newington, exhibited a stand not for competition.

Of decorative berried plants only two collections of nine were shown. That which took the first place came from Mr. George, gardener to Miss Nicholson, Putney Heath, and consisted of Solanum ciliatum, Cotoneaster microphylla, a green-leaved Aucuba with green fruit, an Orange, and a very good plant of Ardisia crenulata. Mr. Rowe, who was second, had nicely fruited plants of Ardisia crenulata, Cotoneaster, Skimmia japonica, yellow and red Capsicums, a Solanum, and two Aucubas.

Prizes were offered both by the Society and Messrs. Carter & Co. for the best collections of Potatoes. Mr. Dean, seedsman, Ealing, was first for the Society's prizes with a very clean well-grown collection of thirty-six kinds, among which were several of Mr. Fenn's seedlings, as Onwards, Rector of Woodstock, Woodstock Kidney, and Bountiful. Mr. Lumsden, gardener to the Right Hon. R. C. Nisbet Hamilton, Bloxholm Hall, Sleaford, was second with fifty-one dishes, among which there were many finely grown tubers. Mr. Garland, Killerton Gardens, and an exhibitor whose name did not appear, also sent collections.

For the prizes offered by Messrs. Carter & Co. several excellent collections were shown. The best came from Mr. D. Lumsden, Bloxholm Hall, and consisted of fifty-one dishes. The second prize went to Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, and comprised twenty-three dishes of large tubers. The best dish of Main Crop Potato, for which Messrs. Carter also offered a prize, came from Mr. Frisby, gardener to H. Chaplin, Esq., Blankney Hall, Sleaford.

For the best dishes of out-door Grapes grown against a wall without any protection, liberal prizes were offered by the Rev. George Kemp. Hitherto these prizes have been the means of bringing together a very interesting display; but this year, from the coldness of the summer and autumn, the number of exhibitors was very restricted, and but one kind was shown—Royal Muscadine, in every instance under the name of Sweetwater. Of this, well known as one of the best, if not the best, of out-door Grapes both for hardiness and flavour, Mr. Norris, Francis Court, Broadclyst, Exeter, had the largest and best-flavoured bunches. Second came Mr. Tranter, Upper Assenden, Henley-on-Thames. Mr. Hepper, gardener to C. C. Ledward, Esq., The Elms, Acton, also exhibited.

Of six dishes of dessert Pears there were numerous exhibitors, and some of the fruit were remarkably fine. The first prize went to Mr. Fowle, gardener to Sir H. St. John Mildmay, Bart., Dogmersfield, for Conseiller de la Cour and Benrré Clairgean, very fine, both from bush trees on the Quince stock; Hacon's Incomparable from a wall, Pitmaston Duchess and Flemish Beauty from a wall, and Duchesse d'Angouleme from a bush tree; all of these were large. The second prize went to Mr. Garland, Killerton, for extraordinarily large fruit of Gansel's, Benrré Bachelier, Maréchal de la Cour, Benrré Clairgean, Doyenné du Comice, and Van Mons Léon Leclerc. Third came Mr. J. Stephenson, gardener to F. C. Barker, Esq., Leigh Hill, Essex, with Grand Soleil, Urbaniste, Huyshe's Victoria, Benrré Diel, Glou Morçeau, and Marie Louise.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Mr. Johnstone, gardener to the Earl of Strathmore, Glamis Castle, Forfarshire, sent three handsome bunches of Muscat of Alexandria Grapes, weighing 10 lbs. 6 ozs. They were of beautiful colour, and were so much admired the Committee awarded a special certificate. Mr. Johnstone in his communication stated that he had two hundred bunches equally good. Mr. Johnstone also sent a bunch of a Grape called the Oakley Park, resembling the Morocco, but certainly different. It had a pleasant sweet flavour, and from the thickness of the skin and the firmness of the flesh, appeared as if it would be a useful late Grape. Mr. Wells, Southend, Essex, exhibited two baskets of Grapes grown in ground vineries; one of them, being the Muscat Hamburgh in excellent condition, large bunches, perfectly ripe, and of good flavour, received a special certificate. Rev. W. B. Caparn, Draycot, Weston-super-Mare, sent two bunches of Black Hamburgh Grapes, from Rendle's ground vinery, which were small and unripe. Mr. William Tubb, Regent's Park, sent some bunches of Syrian Grape.

Mr. H. Rose, gardener to Her Majesty, Frogmore, sent three splendid fruit of Smooth-leaved Cayenne Pines weighing 22½ lbs., cut from plants grown from rootless suckers planted September 20th, 1870. A special certificate was unanimously awarded to them. Mr. Sage, gardener to Earl Brownlow, Ashridge Park, exhibited a very large bunch of Musa Cavendishii, weighing 46 lbs., which was awarded a special certificate. Mr. Jacques, gardener to J. C. P. Cunliffe, Esq., Hooley House, Coulsdon, sent two good large fruits of Musa sapientum, from a bunch containing sixty-two fruits, averaging 1 lb. each, cut from a plant one year and four months old. They were awarded a special certificate.

Mr. Gardner, gardener to Col. Astley, Elsham Hall, near Brigg, sent fine specimens of Coe's Golden Drop, Coe's Late Red, excellent in flavour, and Guthrie's Late Green, very good; but of Coe's Golden Drop, though the fruit was beautiful, the flavour was past. Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, sent a dish of well-grown Reine Claude de Bavay, but the flavour was affected by the material used in packing. Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., sent a dish of St. Martin's Quetsche, a fine, late, yellow Plum of excellent flavour, also a collection of other fruits, consisting of eight species of Cratægus, two of Crabs, Winter Bonvie Pear, Red Currants, and Morello Cherries. The Committee awarded the collection a special certificate.

Mr. Essington, Ribbesford House, Bewdley, exhibited a dish of Autumn Josephine Pear, a seedling raised from Joséphine de Malines, but the fruit was past its best. Mr. Essington also sent another seedling, which the Committee requested might be sent again next season. Mr. W. Thompson, Clements, Ilford, sent dishes of Louise Bonne of Jersey, Benrré Ronge, and Doyenné du Comice. The latter was delicious. Mr. Powell, the Royal Gardens, Frogmore, sent fruit of a seedling Pear, called Premier, raised by himself. The fruit was from an open standard. The Committee desired to see it again. Mr. Penny, gardener to Sir C. D. Crosley, Sunningdale Park, sent a dish of well-kept Winter Greening Apple, misnamed Stunner Pippin. Mr. Jonathan Gavett, Daventry, sent a fine fruit of Gloria Mundi Apple, grown in California, and measuring 14½ inches in circumference. This fruit was taken from a tree three years old, bearing a crop equal to four or five barrels. The tree was sustained by irrigation during the dry season. The Committee awarded it a special certificate. Mr. C. Brown, gardener to D. P. Grenfell, Esq., Taplow, sent a collection of Apples grown on horizontal cordon trees, planted in November, 1869, but they were not remarkable for quality.

Mr. Chaff, gardener to Alfred Smee, Esq., F.R.S., Carshalton, exhibited a collection of twelve varieties of Apples, superior in quality and flavour, to which a special certificate was awarded. Mr. W. Earley sent a seedling Tomato, called Earley's Defiance, obtained as a cross between Red Italian and Orangefield, with the following communication—

"It would be a difficult task to exhibit upon your table all the merits of a first-class hybrid Tomato. As round Tomatoes possess more flesh and less seeds than ill-shapen ones, I claim roundness and exterior smoothness as an especial feature in this variety. It ripens earlier than Orangefield, and is so prolific that it carries efficiently five or six clusters of fruit upon each shoot; an example denuded of an earlier cluster or two I show you. So quickly does it form fruit and ripen them off, that it is injurious to the plants to pinch the shoots in, as is ordinarily practised. The examples exhibited are a part of the produce of a 9-inch pot, one of a row which stood across an open border, the single pot carrying and ripening 42 lbs. weight of fruit similar to those shown."

Mr. Charles Ross, The Gardens, Welford Park, Newbury, sent fruit of the "Sweet Pepper," a handsome red Capsicum without the biting flavour. Mr. Spary, Charley, near Lewes, sent specimens of a variegated Parsley; and Mr. Gilbert, the Gardens, Burghley House, Stamford, three Telegraph Cucumbers and three seedlings, but the Com-

mittee gave the preference to Telegraph. Mr. Cross, gardener to Sir H. Goldsmid, Bart., Rendcombe Park, Cirencester, sent specimens of Walcheren and Veitch's Autumn Giant Cauliflower.

Messrs. Carter & Co., exhibited a collection of twelve varieties of Onions, and sixty sorts of Potatoes, some Beet, Carrots, and Drumhead Cabbages, all of which were meritorious examples of their different kinds, and to which a special certificate was awarded. Mr. Lidgard, of Hammersmith, exhibited five varieties of Celery of large size and excellent quality, to which a special certificate was awarded.

Floral Committee.—W. Marshall, Esq., in the chair. The subjects on which the Committee had to decide were very limited in number, and those which merited special notice were but few. A special certificate was given to Messrs. Standish & Co., of Ascot, for a collection of Gladiolus, the result of hybridising Brenchleyensis and Gandavensis varieties, and probably others, with G. cruentus. The spikes were not so many-flowered as in the ordinary varieties, nor was the form so good, but the colours were very striking and novel, and the lateness of blooming remarkable. Whether the latter was a consequence of the corms being young, or the effect of hybridisation, we are unable to say; at all events there is every prospect that the varieties thus originated will give rise to fresh varieties in this beautiful flower, as well as a prolongation of its flowering period. Messrs. Standish & Co. also exhibited their late-flowering Lily of the Valley along with a pot of the ordinary kind. While the leaves of the former were all withered, those of the latter still preserved their freshness. Mr. Chaff, gardener to A. Smee, Esq., sent a specimen of Pteris scaberula, nearly 4 feet in diameter, in perfect health, and beautifully furnished. This had been grown in the hardy fernery in the open air since the 5th of last June. A special certificate was given. A like award was made to Messrs. E. G. Henderson & Son, Wellington Nurseries, St. John's Wood, for a charming collection of Sedums, Saxifrages, and other alpine plants in small pots. Sedum acre elegans, a neat little creamy green variety, received a first-class certificate. Messrs. Henderson also sent Bouvardia Davisoni, a white-flowered variety obtained between longiflora and Hogarth, and stated to be valuable for winter flowering; likewise Salvia angustifolia, not a new plant, but one of which the blue flowers might be a welcome addition in our greenhouses.

Mr. Green, gardener to W. Wilson Saunders, Esq., had first-class certificates for Billbergia chlorosticta, a new Brazilian species with brown leaves mottled with green, and Lomatophyllum Saundersii, with long, narrow, channelled, light green, rose-toothed leaves. Mr. Kemmery contributed a number of fine cut spikes of Cattleyas, a very large flower of Miltonia Morelliana, Odontoglossum Alexandræ, and other Orchids. From Messrs. E. G. Henderson came a curious black Fungus, Xylaxia polymorpha; and from Mr. Chapman, Gloucester, his Multum-in-parvo plant and flower protector, for placing round florists' flowers. These are perforated zinc openings in the sides of the boxes to admit air, and the whole can be readily taken to pieces.

THE ONION GRUB.

The destruction of the Onion crop by the maggot is a preventible disaster, but I believe not a curable one.

When the young plant attains to the production of two leaves, on a fine sunny day the Onion saw-fly deposits one or more eggs between the leaves. The grub is soon hatched, and finds its way down the stem to the root, which it destroys.

Now for the preventive. In the stage previously mentioned, if you go over the beds with a flour-dredger charged with flowers of sulphur, dredging the beds twice or thrice during three weeks, the saw-fly will not invade them. I have used this means for the last twenty years, and while my neighbours have suffered severely, my Onions have been exempt from this plague.—Joseph Burgess.

NAMES OF PLANTS.

As an example of the modification and perversion which names undergo as they are handed down from generation to generation, we may cite the familiar Sweet William of our gardens, a plant originally so called from the French *œillet*, a little eye, in allusion to its bright star-like flowers with their darker central spot of colour; the original meaning being lost and the pronunciation of the word slightly distorted, soon led to its being termed Willy, and thence the transition to Sweet William. In the same way the word Asparagus, originally derived from a Greek wood signifying to tear, many of the species being armed with sharp spines, being meaningless to the great majority of those who heard it, soon from the desire of the uneducated to modify an unknown word into one familiar to them, became the, in reality, much more meaningless word "Sparrow-grass;" while in conclusion, not to needlessly multiply examples, the plant we term Samphire was originally, from its love of the seashore, dedicated to St. Peter, the fisherman of Galilee, and is still known amongst the French as St. Pierre, and by the Italians as the Herba di San Pietro. As an example of the name of a plant becoming obscure from a custom connected with it becoming obsolete, I may just mention the Ground Ivy, which from its use at one time in brewing as a means of gilling, or as we should now term it fermenting, was known as Gill-run-by-ground, a name now meaningless. A few names arise from a certain sense of humour on the part of those who first started them: thus hemp, from its use in providing the halter, is in some old books called Gallows Grass, while others call it Neck Weed, and this grim humour changes into contempt in the names Dog's Violet, Dog's Mercury, and Dog's Orach, the prefix, as in the names Hog Fennel, Swine's Cress, and Horse Mint, implying worthlessness; even the beautiful wild Rose of our hedges shares this opprobrium, and that very widely, being not only Dog Rose in English, but the *Rose de chien* of the French, and the *hundrose* in Germany. —(*Marlborough College Magazine.*)

SUCCESSION POTATOES.

I am exceedingly obliged to you for naming the Potatoes for me. With regard to changing the sort, I am anxious not to do so, as it is a first-rate cropper on our soil, and of good quality for the table. I have tried several varieties, but not one will compare with this. If you could suggest a good variety I should be much obliged. I have lately tried the Red-skinned Flourball, but it is not fit for the table, although it crops well, the flavour being very rank and earthy. I always grow the old Ashleaf to commence with, followed up with the Fortyfold and the variety I forwarded to you [Douglas's Irish Kidney?] for winter and spring use. I do not care to have a number of varieties, but endeavour to grow the best individual variety that suits the seasons—viz., summer, autumn, and winter, the three sorts named above following in this order, and they certainly suit our soil better than any others I have tried.—W. J., *Shepherdswell.*

[To people of large income wine of foreign vintage and choice brand at a guinea a-bottle would not be an object of consideration, whilst to others a bottle of home-made wine at one-twentieth of the cost would prove both convenient and enjoyable. It is just so with Potatoes. A large landholder would probably be indifferent so long as he obtained quality, whether he grew an expensive sort or no—not so the possessor of a garden, or a mere quarter-of-an-acre man. Persons of the latter class are generally compelled to take into consideration both the quality and the economy of the form of a Potato.

Now the old Scotch Rock, and, say, Douglas's Irish Kidney, are first-rate sorts to eat, large and deep-eyed, the peeling which a cook-maid will cut off, diminishing the tubers into neat rhomboids of wasteful diameter; and if for the parlour table, she must still further destroy their outlines by deeply scooping out the eyes, so that they may not appear there when cooked. The old Cobbler's Lapstone Kidney, or Almond's Yorkshire Hero, or Paterson's Victoria, or Paterson's Alexandria, go one-third further with the same weight of crop. The kitchen-maid looks more kindly upon them, because she can peel them more quickly when pressed for time—and she generally is very much so at the Potato-peeling time of the day—and with no temptation to waste. The latter sorts are withal quite as good croppers and keepers, and better in flavour than "W. J.'s" Irish sort, and they are kinds which in his soil I would strongly recommend him to try. Paterson's Alexandria is a Potato of first-class quality, and I do not think it has been sufficiently recommended. It is, however, a tuber of colour, which is one reason, I suppose—for colour is not admired in the Potato markets as a rule. By all means keep to the Ashleafs and the old Fortyfolds; but even with these you should exchange your seed of them every two or three years for that from the county of Middlesex, or the farther north the better.—Robert Fenn.]

PORTRAITS OF PLANTS, FLOWERS, and FRUITS.

Bomarea chontalensis (Bomsres of Chontales Mountains). *Nat. ord.*, Amaryllideæ. *Linn.*, Hexandria Monogynia.—A native of Nicaragua, where it grows at a height of from 2000 to 2500 feet above the level of the sea. It is nearly allied to B. edulis, the tubers of which are eaten by the natives of St. Domingo in place of Potatoes. Its flowers are rose red, and it is a good stove climber.—(*Bot. Mag.*, *t.* 5927.)

Xiphion filifolium (Thread-like leaved Xiphion). *Nat. ord.*, Irideæ. *Linn.*, Triandria Monogynia.—Discovered by Boissier in the south of Spain. Flowers generally one on each plant, and of a violet purple colour.—(*Ibid.*, *t.* 5928.)

Epidendrum Pseudepidendrum (Epidendrum False-Epidendrum). *Nat. ord.*, Orchideæ. *Linn.*, Gynandria Monandria.—A parasitic plant, growing on a species of Ficus in the northern part of the Cordilleras of New Grenada. The sepals and petals are bright green, and the lip and upper parts of the column orange vermilion.—(*Ibid.*, *t.* 5929.)

Echidnopsis cereiformis (Cereus-like Echidnopsie). *Nat. ord.*, Asclepiadeæ. *Linn.*, Icosandria Monogynia.—Belongs to the tribe Stapelia, and is often known by the name Stapelia cylindrica. Its original home has never been discovered. Flourishes at Kew in a warm succulent house, and blooms from June to October. Flowers bright yellow, produced on cylindrical eight-grooved stems.—(*Ibid.*, *t.* 5930.)

Arisæma curvatum (Curved Arisæma). *Nat. ord.*, Aroideæ. *Linn.*, Monœcia Polyandria.—A common plant in the Himalayas and in some other parts of India. Its tuberous roots are employed like those of the Arum maculatum for food, but are previously deprived of their deleterious properties by washing. Spathe of a brownish purple colour outside, green inside; spadix long, tapering and curved; fruit a mass of fleshy red berries.—(*Ibid.*, *t.* 5931.)

Rose—*Princess Beatrice*.—"It is a full-sized, regularly-shaped, globular flower, perfectly double; the colour a deep but delicate shade of pink, with a clear blush margin; the petals are beautifully rounded, and of great substance, so that the durability of the flower is unexceptionably great. Flowers produced under glass in March last remained in condition a fortnight, and in the open ground in June and July they lasted twice the time of any other Rose.

"The flower in character and outline resembles Alfred Colomb, although differing widely in colour from that admirable variety. The growth is more like that of Victor Verdier, the vigorous shoots producing large, bright, handsome foliage. One great quality which must not be overlooked, is that it flowers as freely in September and October as in the summer months. It has received a first-class certificate from the Royal Horticultural Society."—(*Florist and Pomologist*, 3 s., iv., 217.)

SEASONABLE HINTS.

At no period of the year is there a greater temptation to relax one's efforts in the trim keeping of a garden than now, when the lengthening nights and the paling leaves denote the approach of winter. The season of growth is past, repose or decay takes the place of the vigour of vegetable life, and gusty autumnal winds scatter the falling leaves on all sides. The tendency of autumn is to impart an air of neglect, and more especially to those gardens where deciduous trees abound, so that unless great care is taken a dreary untidiness prevails, and all the pleasures of the garden seem to have departed with the bright days of summer. This is not right; autumn has its own peculiar attractions, and care should be taken that they do not lose any of their beauty or enjoyment through carelessness or neglect.

Amongst the more important work to be done now lawns especially require close attention. The excessive moisture, resulting from dewy nights, lies thickly on the turf, and wormcasts abound; the roller must, therefore, be set in constant use. In all gardens, besides the heavy iron roller, there should be a light roller, just heavy enough to pass briskly over a lawn to disperse dew and press down wormcasts, so that an active man can pass over a large area of turf in a short time. Lawns much seen can be rolled daily, after any stray leaves or other unsightly objects have been removed. The grass-edgings should also be constantly clipped, the walks well weeded, swept, raked and rolled, and flower borders kept neat and trim by removing all decaying leaves or plants as they occur. It is well to prolong the summer display in the flower beds as long as possible, but when "sere and yellow leaves" predominate, the beds should be cleared of their occupants, and the soil either turned up to the sweetening influence of winter, or planted with suitable winter plants.

I know it is a difficult matter to do all this as well and as promptly as one wishes; but apart from its being a matter of duty, it is worthy of our best efforts at a season of the year when the high keeping and exquisite neatness of a well-ordered garden are rendered all the more conspicuous and attractive by their contrast with the daily increasing wildness of Nature's garb. Nor do these remarks apply only to the flower garden and shrubbery, but they bear with equal force upon the kitchen garden and glass houses. Neatness should ever form a leading feature of kitchen-garden management. No spent crops or useless plants should disfigure the beds, or be suffered to needlessly exhaust the soil; the place for these is the rubbish-heap, where they may decay into manure, and the soil, instead of lying sodden and inert, is cast roughly up to become mellow and sweet by spring.

At the decline of the year it is very gratifying to look back upon a successful season, but its failures should be carefully remembered, and measures taken to guide our future efforts. A glance through the daily entries of the garden journal, which every gardener should keep, may now remind us of any blanks among the collection or selection of plants, fruit trees, or shrubs. It is well to do this annually, principally with the view of at once replacing a valuable variety of any species, and also because vacant places, wherever they occur, point to a scarcity of supply, besides implying carelessness and neglect.

All persons would like to attain perfection in what they do, many strive for it with more or less earnestness of purpose: hence the closer an object resulting from skill and application approaches perfection the more generally is it admired. It is by bringing such principles as these to bear upon every action of one's life that even a bed of Cabbage or Lettuce may be made to present so much excellence as to excite a feeling of admiration. Let it not be thought that this view of so simple a matter is at all overstrained. "Whatever is worth doing at all is worth doing well," is the maxim upon which my theme is founded, and it is the mainspring of all earnest efforts, however humble may be the object sought after. Autumn, then, is by no means a time of repose in gardens, much may be done now for another season; in reality the gardener's new year begins with the fall of the leaf—his measures now are productive of no immediate result, they are rather adopted and executed for the benefit of the crops of another season, and the glowing masses of floral beauty or the free succulent growth of vegetables of another summer will alike owe much of their excellence to the careful forethought of the cultivator at this period of the year.—Edward Luckhurst.

MARKET GARDENING.

(*Concluded from page* 323.)

The Bedfordshire District lies in Biggleswade, Sandy, and adjoining parishes. The soil is a sandy or gravelly loam, of excellent quality when not too light or thin, resting on sharp gravel, sand, or sandstone rock. The river Ivel, formerly navigable, runs through the district, joining the Ouse at Tempsford. Water is generally found at a depth of 16 feet. In order to shelter a level tract, rows of lofty Elms, trimmed into excessive ugliness, are allowed to disfigure the country in every direction. The same object might perhaps be attained, with agreement among proprietors, by the planting of fast-growing timber at salient points to break the currents of wind, and the neighbourhood might be ornamented as well as protected by such means without injury to the crops.

The crops grown include a considerable breadth of corn, Turnip, Kohl-Rabi, and Onion seeds, and a few Carrots and Parsnips. Scarcely any Peas are grown, and none of the "fancy crops," such as flowers and culinary herbs. The main crops are Potatoes and Onions, both for pickling and for "lofting"—*i.e.*, storing in airy lofts constructed for the purpose, with louvre boards for ventilation. A large portion of the produce is sent to the manufacturing districts. It is common to sell largely to the dealers or agents who visit Bedfordshire after the middle of June for the purpose of buying the growing crops of Potatoes, which are lifted and marketed under their direction during the following three months before the Scotch supply has commenced. This intervention of middlemen seems to be practically necessary, in order to regulate and distribute the daily supply of vegetables at the various distant markets.

The succession of crops is not regular. It is observed that Turnip seed is a good, and Potatoes a bad preparation for Wheat, and that Onions ought not to be taken from the same ground oftener than once in five years. A common rotation is:—1, Onions; 2, Turnip seed or Potatoes; 3, Wheat; followed by such crops as Onion seed (after Potatoes), Cucumbers, Carrots, or Parsnips. The most important crop is Onions, which receive enormous dressings of manure, and sometimes yield a handsome return. The method of cultivation is the same as at Barking—one ploughing, 6 inches in depth, and the manure harrowed in with the seed; 50 tons of dung per acre are sometimes applied, costing 8*s.* per ton at the railway, and 10*s.* when spread in the field. Small dressings of guano are

occasionally used, but in the case of Onions intended for "lofting," forcing manures must be applied cautiously, as they induce a luxuriant growth; and as bulbs which have been grown too rapidly do not keep satisfactorily, the grower loses the chance of selling his crop at £11 per ton in March! The cost of hoeing is £5 for the season.

Turnip seed or Potatoes follow Onions, with a dressing of guano for the former and of soot for the latter. Turnip seed is grown for seedsmen who supply the farmer with stock seed, which is drilled at 24 inches apart, or the plants are transplanted from a seed-bed in November. One ploughing suffices for this crop. The land is ploughed in autumn for Potatoes and again in spring, and the sets are planted with a dibble at the second ploughing. In the case of early Potatoes a wide furrow of 9 inches or 10 inches is given, and the sets are placed in alternate furrows. Late Potatoes are planted in every third furrow of 8 inches or 9 inches.

A few other particulars may be briefly noticed. Early Potatoes (which are not earthed), and Scarlet Runners are planted in alternate rows, the latter occupying the whole space between the rows (3 feet or 3½ feet) after the removal of the Potatoes. A large breadth of Cucumbers is grown. They are manured with perhaps 40 tons of dung per acre, planted thickly in rows, sheltered at 6-feet intervals by rows of Rye or Onion seed. Some growers sow many acres with this crop. Onion seed is also grown at 2-feet intervals, and is sometimes supported by stakes and string, but more generally by earthing-up.

General Remarks.—The preparation of the land for Onions indicates that they prefer a solid surface. In the Essex district a ploughing is given before Christmas, a large quantity of short dung is spread on the land during frost, and is well knocked with a fork; it is afterwards harrowed in with the seed. If dung be ploughed in, and especially if it be covered deeply, it is observed that the plant does not get hold of it until late in the season, and a rampant habit is induced at the end of June, when the Onion ought to be bulbing. The consequences of ploughing in dung would perhaps be less injurious on old garden ground, which is full of manure. Lisbon Onions for salade are sown in August or early in September.

Pickling Onions require the same cultivation and excessive manuring. They are sown very thickly, and are bleached by casting mould over them a short time before the crop is secured. The process of brining and skinning the crop for one large grower, employs about four hundred women working in sheds. Dung, which is usually placed in large heaps 5 feet high and frequently 10 yards wide, is turned twice for Onions.

Peas are not profitable in the field garden district. An occasional piece of early Peas is sown in November, to be followed by some such crop as Broccoli, which may be planted as soon as the Peas are off. After hoeing, the Peas are moulded up, and the haulm is laid to check over-luxuriance.

Broccoli and Cauliflowers are largely grown on the strong, deep fruit-bearing soil of Enfield, a spot which is famous for the tribe, and has given a name to one of the varieties of Cabbage. The cultivation of Cauliflowers and of Walcheren Broccoli has been noticed in connection with a garden in Bermondsey. The latter are usually planted after Potatoes or Cabbages at the end of June or early in July, and are cut from September to December. Market gardeners also provide a crop of Broccoli to cut early in spring, sowing the Sprouted, Winter White, and other kinds to plant early in September after Potatoes, &c. A heavy coat of dung is turned in with a deep furrow, on deep soil, by three horses, or dug in when the occupation is small. The earliest are sold in time to sow Carrots or Onions. Other varieties follow during the spring and summer.

Lettuce.—Without plenty of manure and garden cultivation Lettuces run to seed quickly. Hammersmith has given a name to one variety, and they are confined in great measure to neighbourhoods where the gardens are small. The Brown Cos is sown in November for early use; this and the White and better, but less hardy varieties, are sown in succession from February till June. The chief demand in London is at the end of May, and during June and July. Early sowings are made in seed-beds, later sowings may be made in drills without transplanting.

With respect to the weight of crops, which is the chief point of agricultural interest, garden crops are generally removed before they are mature, and they are planted thickly with that object. It is not the weight, but the number of bunches, that yields a large return. Prices vary so much that no precise estimates on the subject can be given, although one of my informants lent me his books containing exact accounts of monthly sales for several years. I can report a sale of early Potatoes (3 tons per acre) at £11 per ton, on a Saturday in the third week in June; on the Monday the price was £9 per ton, and it soon fell one-half. Cabbages when very plentiful are sometimes sold at 4*d.* a-dozen, they ought to fetch 9*d.*, and it is very satisfactory to the grower when they sell at 1*s.* a-dozen. Three hundred dozen bunches of Carrots per acre, including "chumps" or rough Carrots, sold to stable-keepers, are a very large crop; 2*s.* 6*d.* per dozen is a satisfactory price. This year Carrots are considered to sell well at 3*s.* A bunch contains from 50 Carrots, early in the season, to 25 when they are larger, 20 tons of Belgian Carrots, are considered a good crop; 40*s.* a ton is a common price at the stables in London. A crop of Parsnips generally weighs considerably more; the price of the finest roots varies from 1*s.* to 1*s.* 6*d.* per score of 22.

A good crop of "Collards" is 200 dozen bunches. It varies between 50 and 350 dozen, and the smaller crop may pay best, reducing the land but little, and selling perhaps at a high price, with comparatively small deductions for the cost of labour and marketing. One hundred and fifty bushels of Peas are a large crop, and £15 on the ground is a very great price, which is sometimes paid by dealers for a crop that would yield 8 quarters of threshed Peas; 2*s.* 6*d.* and 3*s.* per bushel are common prices in Covent Garden, up to 8*s.* for the first early Peas, or for "blues" when they come first to market, "whites" being then worth but little. A crop of Onions, I believe, weighs about half as much as a crop of Swedes in the Eastern Counties, where 20 tons of Swedes are a great crop, and from 10 to 15 tons are common crops; price from 5*s.* to 9*s.* per cwt. Prices are affected by a variety of circumstances which cannot be foreseen. A blight in the early Potatoes would raise the price of Carrots and other competitive vegetables. Cabbages were selling this year at 1*s.* a-dozen on June 14th, because there were few Peas or Potatoes in market. Each gardening district has its innings, which terminates suddenly; for example, any district which is earlier than another has possession of the market so long as the advantage lasts. During a fortnight last spring immense quantities of Cabbages were sent from Essex to the great manufacturing towns in the north.

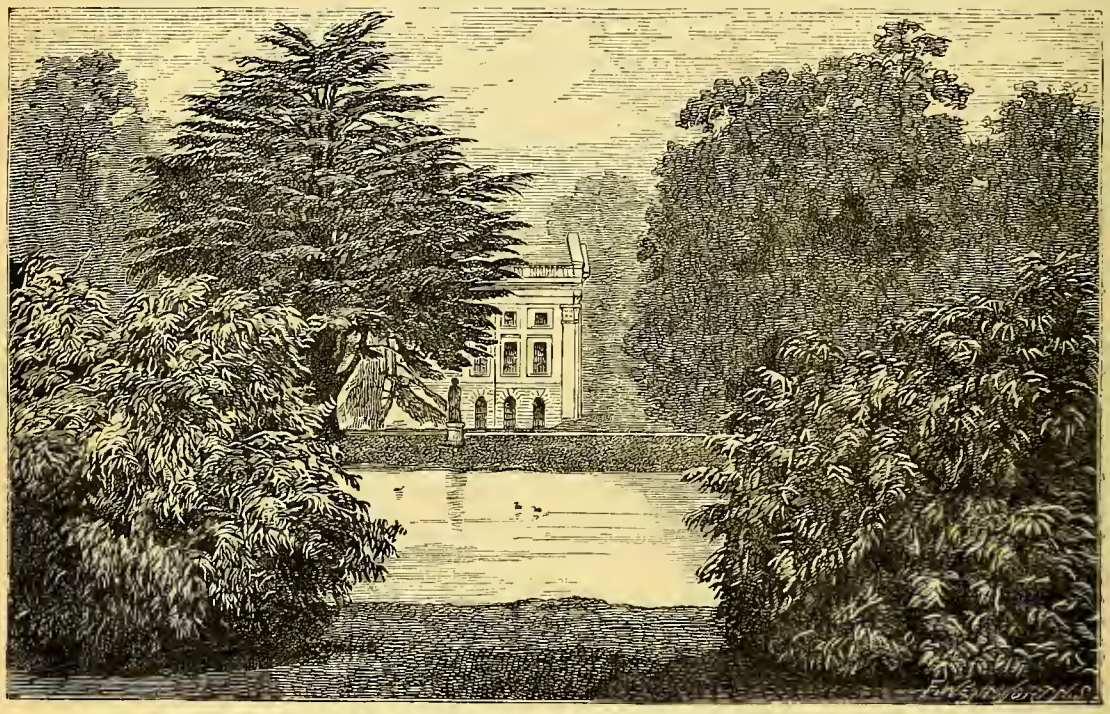
Lisbon sends the earliest Potatoes to London, the French coast and Scilly Islands follow, then Jersey, Guernsey, Cornwall, and Holland; and by the middle of June, these distant but early districts are driven out of the market, by the arrival of supplies from Essex, &c. Red Cabbages have been sold at 160*s.* per ton early in the season, and at 25*s.* per ton a fortnight afterwards; or at from 1*s.* to 4*s.* per dozen.—H. Evershed (in *Royal Agricultural Society's Journal.*)

MOOR PARK.

This residence of Lord Ebury is remarkable for its historical associations as well as for its sylvan beauty. It is situated near the southern extremity of the county of Herts, and adjoins the village of Rickmansworth, to which there is a branch from the main line of the North-Western Railway at Watford. The visitor, after alighting at the first-named village and crossing the river Colne, arrives in a very short time at one of the lowest points of the park. The first glance is sufficient to impress upon him the certainty that he is entering a domain to which the term Park has with all propriety been applied for many generations. In all directions he sees the beautiful sward studded with Oaks and other trees of all ages and conditions; some that might be almost contemporary with the Crusades, stunted and stag-headed, yet of immense girth, and each grand in all the characteristics of a weather-beaten and venerable tree; others not so old by a century or two, some of which might excite the cupidity of the timber merchant; and others still younger, promising to maintain that park-like character of the place for centuries to come. Nature has lent her aid towards perfecting all this; for instead of the simple level or uniform incline, here we have a succession of bold hills and valleys, all that the lover of park scenery could wish for without difficulty of access. These necessitate, however, a certain amount of curve in the carriage road to avoid inconvenient gradients, which is effected without rendering the road tortuous or unmeaning, and after a drive of nearly a mile, passing by on the way many noble trees close to the carriage road, the mansion is approached. It is a large and portly-looking stone building, the carriage front consisting of a portico of Corinthian columns, and presenting a front of some 180 feet or more, but owing to the character of the ground, the opposite side, which looks out upon an Italian garden, is one storey higher, the ground declining to that extent in the middle of the mansion. The site is

a little way up one of those valleys by which the whole of the park is divided, and this one opening to the north admits a fine view over the district, extending far in that direction, and which holds some other parks scarcely less important than the one in which we at present are. On the three other sides of the mansion the ground rises gently at first, and then more rapidly; in fact, the whole park, which consists of upwards of 600 acres, is a continued succession of hill and dale. Our legitimate endeavour must be to describe the dressed part of the grounds in detail, and first of all we may observe that these come properly under three divisions—the Italian garden adjoining the mansion; the upper pleasure ground, detached from the last and lying within a ring fence; and the kitchen garden proper, with its glazed structures, constituting the useful portion, which last-named is in another part of the park.

We shall commence with the Italian garden. This may be called the flower garden proper, and it adjoins the mansion on the opposite side of the carriage entrance. There seems to be some uncertainty as to the date of its formation, but it is said to be the work of one of the few lucky South Sea stockholders, who held this place in the early part of the last century, and did much to embellish it in various ways. The design of the beds is simple and good in its simplicity, the space allowed for paths is ample, and the beds are of proper size, contrasting favourably with some of the contracted beds of the present day, too often not larger than a pocket-handkerchief. The principal garden is in three compartments, with vases, sun dial, and fountains appropriately placed, and the whole surrounded by broad gravel walks. An ornamental balustrading serves to divide this from the park. The flower garden extends the whole length of the mansion for about 180 feet, and about the same in depth, but the dressed grounds stretch considerably further in a westerly direction, the front wall of the flower garden being carried on in a straight line some distance in that direction, and then returned at right angles. There is a terrace walk on the north-west side 20 feet wide, and not less than 600 feet.



Moor Park.

long, which is partly planted with choice Pinuses and other shrubs, and also contains that indispensable adjunct now-a-days—a croquet ground, with a summer-house and the other attendants of a mansion of pretension. The whole at the time of our visit was in the best possible order; the flower beds were gay with their various occupants, the turf was clean and trim, and the trees and shrubs were models of good culture. One of its compartments was enclosed with a fine hedge of Sweet Briar—a shrub not half so much employed as it ought to be.

The next important feature of the place is the old or upper pleasure ground. This detached portion of the grounds includes upwards of 25 acres, with a gameproof fence around, and occupies the summit and part of the sides of one of those eminences so numerous in the park. A straight walk, some 200 yards in length, leads to it from the house, and it is entered by flights of steps diverging right and left after the first landing, the whole presenting imposing specimens of masonry and sculpture, and among these a temple in imitation of the Acropolis of Athens.

The two walks that diverge at these steps take an easy and agreeable curve all round, but sufficiently far from the outer fence to prevent its being perceived, while other walks intersect in various places, the whole being in that easy natural style so truly English in all its parts. We ought in the first instance to have stated that the bordering to the fence on the inner side of this enclosure is mostly of hardy native trees, intermixed with shrubs of similar growth, while the interior is more open, having extensive glades of turf with broad masses of Rhododendrons, choice specimens of Pinuses, and plants of a like kind, but flower beds are very properly excluded. A fine piece of water was introduced here, a rustic summer-house there, while the temple mentioned looked well when viewed from the mansion and other parts.

The laying-out of this garden is due to one whom even every schoolboy who reads voyages and travels holds in honour—the much-respected Lord Anson, so celebrated for his voyage round the world and subsequent adventures. That he should devote himself to embellishing his country seat is as worthy of commendation, perhaps, as some of his other exploits, and that he should name the temple he there built "The Temple of the Winds," is not remarkable in one who had so often experienced their caprices.

The same noble proprietor was in other ways a great patron of gardening. Some think that it was he who introduced the Moor Park Apricot from eastern lands, and it is said the original tree lived on until 1840, when it died.

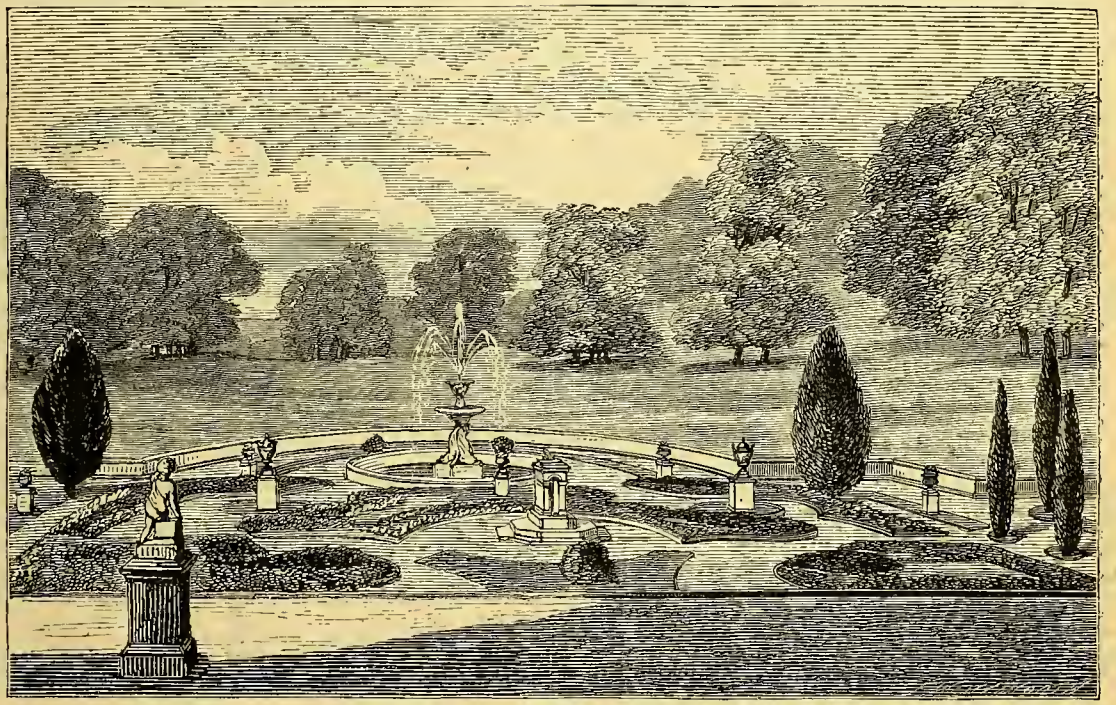
[The Moor Park Apricot is said by some to have been introduced by Lord Anson and planted at Moor Park. By others its introduction is ascribed to Sir Thomas More, who in the beginning of last century is also said to have planted it at Moor Park. A third account is that Sir John Temple introduced it. Which of these is correct it is impossible now to determine, but it was not till the close of the last century that this Apricot attained a general cultivation. It was not in the Brompton Park catalogue before 1784, when it is mentioned under the name of "Temple Apricot." In 1788 it is first called "Moor Park." In 1784 it was cultivated in that nursery to the extent of three rows, or about 300 plants; but in 1797 to the extent of thirty-five rows, or 3500 plants. The Moor Park is undoubtedly of French origin; it is either a seminal variety of the Abricot Pêche—not the Abricot Pêche of Duhamel, which is our White Masculine—but the Abricot Pêche of Bretonnerie and Roger Schabol, or is identical with it. Our own opinion is that it is identical with it. It is said to have originated in Piedmont as a seedling from the Alberge. It is not mentioned in the "Jardinier Français" of 1653, nor in any of the editions of De Quintinye. Switzer speaks of "a very large kind of Apricock that was cultivated at Woolhampton, Berkshire, as big as a Peach, and it is there called the French Apricock." This was in all proba-

ility the Moor Park, but neither Hitt nor Miller notice it in any editions of their works. The earliest record of it, except by Switzer, is to be met with in Roger Schabol.—Eds.]

At a short distance from the entrance is one of the most remarkable Spruce Firs I ever saw, and said to be one of the oldest in England. Mr. D. Cunningham, the able gardener at Moor Park, seems to think it might have been in existence at the time when the ill-fated Duke of Monmouth, to whom Moor Park belonged, met his tragic fate on Tower Hill. Tradition relates that at that time his widowed Duchess had all the Oaks in the park beheaded also, and had this tree been subjected to the same treatment as the Oaks, it is not unlikely that it would assume the form it now has, which is certainly a peculiar one. The bole of the tree, if it can be called one, is scarcely 3 feet high where it divides into three portions, each of them being a perfect tree of itself, uniformly clothed with branches, and towering up to a great height, symmetrically formed, with the branches interlacing where they meet. Two branches from them have touched the ground, taken root, and are rising up in rivalry of their parents. The whole group is most interesting, not the least remarkable feature being the formidable network the naked roots present on the surface. I had not the opportunity of measuring any of the specimens, but the main trunk must be upwards of 20 feet in circumference. The soil is dry and sandy, the Rhododendron seeming to grow freely in it, and there is every probability of its outliving many generations of the human race.

Near to it are two very fine Weymouth Pines, amongst the largest of their species. The roots of these trees also have raised themselves upon the surface, and present a huge network of serpent-like folds.

A little further on we found a fine Douglas Fir, and in another place a still finer Taxodium sempervirens, about 40 feet high. It is seldom we meet with this species in such good form. Picea Pinaspo was also good, though probably not so high as the Taxodium by 10 feet, yet a noble symmetrical tree. There was also an excellent Arancaria imbricata, which had evidently escaped the hard winter of 1866-67, for it was healthy and vigorous. Near to a piece of ornamental water was growing a fine specimen of the Golden Larch, well coloured, and contrasting favourably with the large masses of Rhodo-



Italian Garden at Moor Park.

dendrons not far from it, some of which almost touched the water. Libocedrus chilensis, a Conifer not by any means often met with in good condition, was here well represented everywhere. Cryptomeria japonica was also in good condition, being upwards of 25 feet high, and well furnished from the bottom upwards, with many other trees which I had not the opportunity of taking notice of. We must not forget the fine examples of the two most important of all Conifers, for they have been tried longest, and have stood the ordeal well, and they are the good old Scotch Fir and Cedar of Lebanon. Fine specimens of both graced the grounds in several places, and were probably amongst the first selection of trees planted there, while there seem to have followed others, including Cedrus Deodara and some more Conifers. It must not be supposed that they are crowded together in a confused manner; on the contrary, there is ample space for each, with large open glades of neatly-mown grass between, which in some places undulate irregularly, and at others are nearly level. The whole stands high, which no doubt accounts for the healthiness of the trees. The ground being dry enabled them to ripen their wood well in the autumn, and the outer belt of common trees gave that shelter to the inner ones so much wanted by trees and shrubs from other climates.

Having endeavoured to place before the reader a rough outline of the "Old Pleasure Ground," as it is termed, we will now diverge and make a few remarks on the horticultural show that was being held there at the time of my visit. It is called "The Rickmansworth Cottagers' Horticultural Exhibition," but the productions sent from the many gentlemen's gardens around formed by far the most attractive features of the Show, as well as occupied the greater space. It must not, however, be supposed that we disparage the cottagers' produce; on the contrary, much of it was as good in its way as could be desired, but such plants as Alocasias, Crotons, Allamandas, Caladiums, and Pines, Grapes, and Peaches, are not usually met with in cottagers' gardens, and they were present in great abundance. A large tent 150 feet long by 30 feet wide, with a stage in the centre and narrow shelf on each side, was filled with productions from gentlemen's gardens, and an excellent pair of pot Vines were formed into a pleasing-looking arch, spanning the centre stage at the entrance end. They were, we believe, Foster's Seedling, bearing a white Grape, and having a dozen good bunches evenly distributed over them. We believe they came from Mr. Brush, gardener to Sir H. Campbell, who exhibited other plants besides these; in fact, the exhibitors of plants and fruit were so numerous that we did not attempt to count them, but the gardeners of the Earls of Essex and Clarendon, Lords Ebury and Chesham, Sir H. H. Campbell, Bart., E. Majoribanks, D. Norton, R. Pryor, J. King, W. Jones Lloyd, W. H. Smith, D. Carnegie, and W. McMurray, Esqrs., were all contributors, as well as many others. There were other tents, in which bouquets, devices in flowers for the table, &c., were set forth, in most cases, I believe, the work of ladies; some were very neat, others novel, and one combined both these qualities. This was a design in imitation of a beam and scales, the beam and suspending strings of the scales being covered with moss and light creepers, while fruit occupied one scale and flowers the other. It is easy to guess which side went down, showing, as no doubt the designer intended it should, the superiority of fruit over flowers.

The cottagers' tent contained excellent examples of vegetables, but the competition in fruits was not so keen as it might have been, a matter which Lord Ebury in his address to the exhibitors alluded to. He addressed them on one of those sweet spots which seem almost to have been made for the purpose—a good-sized open space of close-shaven turf, surrounded by shrubs and trees, with a rustic summer-house at one side. His subject was Cottage Gardens and their Management, and the influence they have on the habits of all who

take an interest in them. His lordship spoke of the number of competitors in the present instance, there being upwards of 130, about the same as last year; also of the small quantity of fruit shown, and expressed his opinion that in all cases where a Plum or an Apricot could be planted with advantage against the walls of a cottage it ought to be done, as the return from such trees was often very considerable, and even said he would take care to have this done against such of his cottages as afforded space for them. After some further remarks of a like kind his lordship said he hoped the successful competitors would not regard their winnings as being of less value than on two former occasions, when they were handed to them by a Princess and a Prime Minister, and that a lady whom many of them knew had kindly consented to give the prizes. These consisted mostly of money, but one, a bible, given, we believe, by a lady in the neighbourhood, seemed very appropriate, as did some garden tools and other things.

The above digression on the subject of a horticultural show must not prevent us making mention of the kitchen garden and forcing houses. We are not sure whether the site is entirely a fresh one; be that as it may, the kitchen garden now is a short distance from the mansion, and concealed from it by the high growth between. It is, nevertheless, still in the park, and conveniently placed for shelter, quality of soil, and the other points that constitute a good garden. A hurried run through it enabled us to see that it was well cropped with vegetables, and the trees against the walls, and those grown as open standards, had a good crop of fruit on them for the season. The walls of the garden enclose upwards of four acres, and amongst other things we noticed some fine Keens' Seedling Strawberries, ripe and of fair size on August 16th. We had made up our mind to inquire for these, as in Mr. Cunningham's collection at the show there were dishes of these Strawberries and other fruits. Mr. Cunningham told us they were from some of those plants earliest forced, that were turned out as soon as the weather allowed, and which were then bearing well. He said he never was without Strawberries from the end of February up to that time. In the houses the earliest Peaches had been gathered in May, but there were later ones that were just then ripe, and more to follow, and the same might be said of Grapes. Some of these which had been planted about four years were just in their prime, and the whole betokened the best of management. The condition of the flower garden and old pleasure ground reflected the greatest credit on Mr. Cunningham, who in additiou to his many other duties, had much to do with the arrangement for the show. Lord Ebury considerately provided a dinner at the mansion for the gardeners who had brought plants to the show, where upwards of thirty sat down. Mr. Fleming, of Cliveden, was the Vice-Chairman; and Mr. Frost, from Dropmore, Mr. Wood, from Lord Ravensworth's, with others from a distance, were also present, making altogether an extraordinary meeting of the craft.

This notice of Moor Park would be incomplete without an outline of its history, for it is connected with many great events, and many great personages of bygone times.

Although never a Royal palace, it has on more than one occasion been the abode of one or more of our monarchs, and has changed owners as often, perhaps, as most large mansions. Nevertheless, with one exception, each of the many proprietors has done well by it. The fine timber trees that ornament the park have been allowed to stand, so that they now present the venerable aspect so much coveted. It has been the scene of events alluded to by Shakespeare, as well as furnished heroes and heroines for Sir Walter Scott and Bulwer-Lytton, so the ground can with all propriety be called classic; but our task is with dry facts, and to them we must adhere. The earliest record of the manor of "The More," tells of its being given to the Abbey of St. Alban's, by Offa, King of Mercia, more than eleven hundred years since, as an atonement for a cruel and treacherous murder he had committed, in putting to death the young sovereign of another state at the wedding feast of his own daughter. We then lose sight of Moor Park for several centuries, and it next appears leased from the Abbey at a penny a-year. But no residence of importance at Moor Park is noted till the beginning of that disastrous period of English history known as the "Wars of the Roses," when it became the property of Archbishop Nevill, a younger brother to the warlike and powerful Earls of Warwick and Montacute. The Archbishop appears to have been temporising and deceitful, actuated, perhaps, by anxiety to protect his great wealth. He it was who built the first mansion here, and history records that when Edward IV. was once his guest, an attendant whispered in the King's ear that some unfair play was meditated, and the King stole out of the house at night, and fled to Windsor. Soon after this the King himself, having given offence to the great Earl, was obliged to fly the kingdom, but returning soon after he fought the great and decisive battle of Barnet, in which the two Earls fell. The Archbishop soon after this was deposed from his high clerical position, and also from that of the Lord Chancellorship. The next occupant of Moor Park was one who had also fought at Barnet on the same side as the Nevills—the Earl of Oxford, who, after many changes of fortune, was eventually restored to his rights for the aid he rendered Henry VII. at Bosworth. He died in 1513, when Moor Park passed into the hands of another prelate and chancellor, one not more scrupulous than the former one, and whose end was somewhat of a like kind. Cardinal Wolsey who here, as at Hampton Court, lived most sumptuously, entertained Henry VIII. and his Queen, Catherine of Arragon, for a whole month, with all the pageantry which he knew so well how to display. Wolsey fell, and Moor Park then becoming Crown property, the Earl of Bedford was appointed ranger. The capricious Henry again paid the place a visit for three weeks, but this time accompanied by his fifth Queen, Catherine Howard. We next read of Queen Elizabeth granting the manor to another member of the Russell family for £120 a-year, and of an Earl and Countess of Bedford residing here at the time of the accession of James I. The Countess was an intimate friend of the Queen of that monarch, and one of the few who retired from Court at her death with an honourable reputation. This Earl is remembered as "the good Earl of Bedford," and he and the Countess must have been amongst the earliest patrons of gardening in this country, as Sir William Temple says, in 1655, that the garden at Moor Park, which the Countess laid out, exceeded in size and excellence all others he knew. It was sold about that time to the Earl of Pembroke, a literary nobleman, from whom it descended to another Earl of Pembroke, to whom the title of Montgomery was also added. Of him little is known, but history retains the tart reply of his wife some years after, made to a minister of Charles II., who wished to nominate a candidate for the borough of Appleby. "I have been bullied by an usurper and neglected by a Court, but I will not be dictated to by a subject. Your man sha'n't stand.—Anne of Dorset, Pembroke, and Montgomery."

Her husband alienated the house from the manor in 1632 to Rob. Cary, Earl of Monmouth, as "all that the great house or lodge lately built, wherein the Earl and Countess of Bedford lately dwelt; also all that new garden adjoining to the said house eastward, lately made by the said Earl of Pembroke; and that other garden with a bowling-green thereunto adjoining."

The next occupant of Moor Park was the Earl of Monmouth, either the descendant of the Sir Robert Carey who rode from London to Edinburgh in three days to announce the death of Queen Elizabeth to James I., or the veritable equestrian himself. He and his lady were entrusted with the bringing-up of the young prince, afterwards Charles I. The Earl of Monmouth died in 1639, when Moor Park passed into the hands of the Duke of Ormond, who sold it in 1660 to the unfortunate Duke of Monmouth, illegitimate son of Charles II. After his execution on Tower Hill his widowed duchess is popularly believed to have had all the trees in the park beheaded, but it is doubtful if they underwent any such operation, for certainly at the present time the old trees present the usual features.

Moor Park was again sold in 1720, and this time to a commoner—Mr. Styles, one of the few lucky speculators who gained wealth by the notorious South Sea scheme. He appears to have completely rebuilt the mansion, which formerly was a brick structure but is now encased with stone. An Italian architect was employed, and also artists to paint the ceilings, and it is said a sum of £150,000 was expended on the house and garden, a large sum at that day. Mr. Styles died in 1739, and the next possessor of Moor Park was Lord Anson, the circumnavigator, who, notwithstanding the many ups and downs he had encountered, appears to have been a man quite as well fitted to adorn a quiet country home as the turmoils of a naval life. Notwithstanding the many adventures at sea, narrow escapes, and almost miraculous successes, yet he had learned so little of worldly wisdom that it was jocularly said of him that "he had been round the world but had never been in it." He had, which was better, a fondness for gardening, and planned and executed the old pleasure ground as described, in which he was assisted by "Capability Brown." He also made the Temple of the Winds and the other features there, including the piece of ornamental water, a feat not accomplished without difficulty on a dry hill. It is said that during the time he held possession of Moor Park he spent the sum of £80,000 in embellishing it.

His successor sold it to Sir Laurence Dundas, who sumptuously entertained George IV. when Prince of Wales on several occasions. He is said to have removed to London some of the tapestry that decorated the rooms, but that loss was trifling when compared to that inflicted on Moor Park by its next occupant, a Mr. Rous, an East Indian merchant, who bought it of Sir L. Dundas. He was guilty of some most unpardonable sins against good taste in pulling down part of the mansion and spoiling it in other ways, but fortunately he spared the timber.

We next find it sold to a Mr. Williams, who, with his successor, held Moor Park the first twenty-five years of the present century, when a pressure on some bank with which he was connected induced him to sell it, and it was then bought by the father of its present noble proprietor, the first Marquis of Westminster. From him it passed to Lord Ebury, who, we hope, may long continue its possessor, as it well deserves to be presided over by one who can so thoroughly appreciate its beauties.—J. Robson.

NEW BOOK.

Culture of the Chrysanthemum as practised in the Temple Gardens, with a List of the Varieties. By J. Newton, *Gardener to the Honourable Society of the Middle Temple.*

This is a thoroughly practical little work, and our readers will find the results of the author's experience in its pages relative to soil, propagation, culture, insects, and varieties. We will not extract from those pages, but will select this introductory note.

"The red and white Roses, the badges of the houses of York and

Lancaster, are said to have had their origin in the Temple Garden, in the course of an animated conversation, approaching to a brawl, which took place on this spot between the Earls of Somerset, Suffolk, and Warwick; Richard Plantagenet, Vernon, and another lawyer. Plantagenet plucks a white Rose, and Somerset a red one, and Warwich thus prophesies:—

'This brawl to-day,
Grown to this faction, in the Temple Garden,
Shall send, between the red Rose and the white,
A thousand souls to death and deadly night.'
—*First Part of Henry VI.*, Act ii. Sc. 4.

"The Temple Garden was then famed for its Roses, as it is now for its Chrysanthemums. The old Sycamore tree, which died in 1847, supposed by some to have been planted by Sir Matthew Hale in 1659, and by others previous to the reign of Henry VIII., stands on the site of the old Thames wall, on which it originally grew. But by whomsoever planted, it was growing where it now stands in the reign of James II., and under its shade Dr. Johnson and Oliver Goldsmith frequently sat."

COLOUR AND ODOUR IN CONNECTION WITH FLOWERS AND THEIR FERTILISERS.

Professor Frederico Delpino, in his notes to a discourse of Dr. E. Müller's on "Fertilisation by Insects," translated in the *American Naturalist*, says:—The relations of colours and odours which occur between flowers and their fertilisers may to many appear a chimerical product of the imagination. But after a long series of observations I can assert that, however unexpected and surprising they may be, they are yet undeniable and real. It is believed by many that the æsthetic sense belongs only to the human race. Nothing is more erroneous. The sense of music alone, however much it has been perfected in birds through sexual selection, is beyond comparison more perfect in man. In the sense of taste and smell man is, by a singular coincidence, like bees and butterflies. Sweet things please our young not less than bees, and the ancient poets designated with the same word—nectar—the food of the gods and the honey of bees. By a no less singular coincidence the odours which allure bees and butterflies allure us too, and those which repel us repel bees. The graveolent flower of Rue, which is so excessively disagreeable to us, although visited by flies, repels bees and Lepidoptera, although it produces honey. As to the æsthetic sense of colours and form, then, if we speak the plain truth, man is inferior to many living things.

Passing in review the most beautiful forms, and those adorned with the most attractive colours, we have on one side flowers, and on the other their fertilisers—that is, birds, flies, humming-birds, Nectarinæ, Lepidoptera, Bombylii, Syrphidæ, and some Cetoniæ. The most beautiful forms and brilliant tints in the world are without question those of the humming-birds. They visit the most splendid and beautiful flowers on the earth; and the reason why the magnificent flowers of the tropical zone do not enter our climate, is certainly correlative to the causes which exclude from temperate and cold countries the humming-birds and gorgeous Lepidoptera which are peculiar to warm regions. But not all flowers are beautiful; there are some which have livid and repulsive colours. Nor do all flowers emit a pleasant odour, since some have a fetid smell, or one like that of decaying animal matter.

All the flowers which have this (those, *e g.*, of Arum Dracunculus, of the Stapeliæ, of some American Aristolochiæ, of the Rafflesiæ, Sapriæ, Brugmansiæ, Sapranthus, &c.), have without exception livid colours, and, like the skins of some serpents, are speckled with dark purple and yellowish black spots. Now all these flowers are fertilised exclusively by the flies which feed upon dead animals (Sarcophaga carnaria, Musca vomitoria, and the like). The flowers of the Ceropegiæ, one Aristolochia, Asarum, and Ambrosinia Bassii are fecundated exclusively by gnats (Phora, Ceratopogon, Cecydomia, Oscinis, &c.). All these have a generally livid tint, speckled or striped with dark purplish spots, and a putrid odour, for the most part like that of urine.

These few instances suffice to give an idea of the wonderful relations which occur between flowers and their fertilising agents with reference to colours and odours.—(*English Mechanic and World of Science.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

In this department proceed with such operations as draining where required, laying Box edgings, gravelling walks, and trenching and surface-stirring all spare ground. Stir the soil amongst *Cauliflower* plants under hand-glasses. Attend to the earthing of *Celery* when dry. Take advantage of the first dry weather for lifting *Beetroot*, *Carrots*, and *Parsnips*. Let them be taken up in the early part of the day, and spread on the surface of the ground till afternoon, when they may be removed to the storing room, and there spread out again till they are quite dry, after which they may be stored in dry sand. Remove the decaying leaves from *Broccoli*, *Brussels Sprouts*, and all other growing crops, carrying them at once to a piece of ground where they can be trenched into the soil, sprinkling them first with quicklime to destroy the snails and slugs with which they swarm at present, as well as to hasten decomposition. Constant attention will be necessary for some time to preserve plantations of *Lettuces* from slugs. Continue to keep every part of the garden as neat and orderly as the time of the year will allow.

FRUIT GARDEN.

Now that the summer work is fairly at an end, it is time to provide against an inordinate pressure in spring, for any arrears of autumn and winter work will prove a great hindrance at that busy period. Having in previous notices referred to planting and trenching, I will make a few practical remarks on pruning. The habits of fruit trees vary, more especially in regard to the manner of forming and exhibiting their buds; thus, there is no difficulty in distinguishing the fruit-bearing portions of the Apple, or of bush fruit in general, whilst in the Apricot and the Filbert at this period they are somewhat obscure. Even in Pears, more especially such as the Passe Colmar, the Seckle, the Marie Louise, and some others, it is difficult to prune with safety in the early part of winter. For these reasons, therefore, prune bush fruit the moment you can find time. Follow closely with the Cherries, Plums, and Apples, and towards Christmas lay by the knife until the early part of February, when the Filberts will be blossoming; then, after a slight thinning of the crowded and inside spray, male catkins may be brought, if requisite, and suspended among the branches. The Apricots will by that time give unequivocal signs by which to know the true blossom-buds; these, then, may immediately receive their pruning. The Peach and Nectarine will succeed the Apricot, and may be followed by the Pear, and, lastly, by the Fig. In pruning bush fruit, thin liberally. Let no two branches in the Black Currant and Gooseberry touch when finally thinned; they seldom require shortening, but an equal and judicious thinning is everything here. In pruning Apples the thinning of the branches or old wood should be the first step, but caution must be exercised. Mr. Knight, of Downton Castle, was greatly averse to cutting out large limbs unless a severe necessity existed. His authority is too great to be passed over easily, more especially as he lived most of his time in a cider district. In thinning the young wood of espaliers, remember that the first point is to secure a continuance of leading shoots to form a compact tree, and the second to secure a free admission of light to all parts of the tree. The same remarks will apply to the pruning of all the rough espalier or dwarf standards of the kitchen garden, be they of what kind they may. Raspberries may now be planted and pruned. Prepare ground for new plantations of Currants and Gooseberries. Cuttings of favourite sorts of Gooseberries may now be made and planted in beds manured with leaf mould and sand; the latter will aid their rooting, and the former will hasten their growth.

FLOWER GARDEN.

The Dahlias must be marked or numbered forthwith if not already done. The beds should now be looked carefully over, to see if there be any plants of choice character which cannot be suffered to become frosted; such may be taken up, potted, and removed to the frames. Delicate seedlings should have protection provided, and the choice and tender Roses may in the course of a week or two have a coating of cinders and ashes a couple of inches thick, among their stems. Let all bulb-planting be completed immediately. Evergreen and shrub-planting may now be performed with every prospect of success. Not a day should be lost, now that the weather has become more settled, in making up Pink beds; so much improvement has taken place of late years amongst these flowers that amateurs, unless they have added to their collections regularly, will find themselves apparently a century behindhand. Dahlias are still blooming in many places, but rather miserably; as soon as the tops are blackened with frost take them up, for they are apt to start at the crown, cut them off about a foot long, and place them in such a manner that the sap which exudes may not run into the hollow stems; should it do so, decay will probably be the consequence. Small pieces of zinc or lead attached to copper wire are best to mark them with, or the zinc

may be stamped with a number corresponding with the name in the book. Plant offsets of Tulips, arrange the best bed definitely previous to planting when the soil is sufficiently dry, the sooner the better. Take every opportunity of removing from the flower garden any remaining plants which it is desirable to keep for next season. Half-hardy plants and shrubs will likewise require some protection on frosty nights. Among the best protectors for this purpose are conical and pyramidal baskets made roughly with common Osiers; they admit air, but in severe frost should be thatched very slightly either with Fern, dry leaves, or the light spray from Yew or Spruce Fir. In this form they are not unsightly, and are cheaply made. As the beds are cleared proceed to fill them in one or other of the methods noticed in former calendars. If planted in the mixed style keep the shrubs in the centre of the beds, and the bulbs and low herbaceous plants to the sides and edges, where they will easily catch the eye, and prove more attractive. The bulbs, &c., should be correctly labelled, that they may not be disturbed in subsequent cleaning. To carry out this plan effectively a reserve garden is indispensable, so as to remove the plants to it in the spring, as well as for propagating and preparing them for winter.

GREENHOUSE AND CONSERVATORY.

The conservatory should be made as attractive as possible, as it will now become in some respects the only place where flowering plants can be inspected with comfort in unfavourable weather. Let the work of watering and changing the plants be done early in the day, that the effects of the watering and syringing may be removed, and an agreeable dryness pervade the house, before it is visited by the family. No pains must likewise be spared to keep the house gay by introducing plants in succession as they come into bloom, including a portion of the stove plants which have been grown expressly for this purpose. A little gentle forcing will bring the different varieties of Epiphyllum truncatum in bloom, and with the addition of Chrysanthemums, late Fuchsias, Pelargoniums, Pancratiums, Amaryllis, Mignonette, Neapolitan Violets, &c., a tolerably gay appearance may be maintained until the time when forced plants will be more generally available. Fires will be necessary, not so much for keeping up the temperature, unless during frost, as for the purpose of promoting a medium state of dryness in the internal air, so as to render the house enjoyable in all weathers. Some of the most useful plants for house decoration during winter and spring when subjected to gentle forcing are the different kinds of Rhododendrons, Azaleas, Kalmias, &c., usually termed American plants. As these have now perfected their buds, plants well furnished with buds can easily be selected for the purpose. Without naming each particular kind suitable, it may be remarked that many of the hybrid scarlet Rhododendrons, which owing to their earliness rarely bloom in perfection out of doors, are the best for early forcing, coming into bloom with but little trouble. After selecting the plants from the nursery have them potted in peat, in as small pots as the roots can be placed; they may then be watered and set in a pit or empty vinery to be brought forward as required, beginning with them very gently in a moist heat, and increasing the heat as they advance towards blooming.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cabbages.—As the heavy rains had beaten the ground we ran the points of a four-pronged fork between the rows, so as to leave the surface rough and open, choosing a dry day for the purpose. A fork or a Dutch hoe is the best tool for this work, as there is then no trampling on the ground after stirring it. After a damp night we scattered a light dusting of wood ashes, lime, and soot over the plants—just enough to prevent the snails and slugs from feeding on them, and not enough to impede the action of the leaves. The plants, though smaller than usual at this season, so as to be safe from frost, are healthy and growing well. Some grass mice nibbled a few, but several we caught, and round the quarter we beat a narrow space level and firm with the back of a spade, poured a cordon of tar over it, and that neither mice nor rats care to touch, so long as the tar remains moist enough to taint their fur. Notwithstanding the care in preparing the ground, we lost a few plants from grubs at the roots; and once there they can be destroyed in no other way than by examining the roots and catching and killing. We have, however, been troubled with very few this season. When slugs threatened to do damage we have several times run a cordon of lime and salt between the rows, but at a good distance from the young plants. The small quantity of salt under these circumstances did good as a manure, and if the weather was at all dry, it and the lime together prevented a snail passing. Next to picking up snails and slugs nothing annoys them so much as frequent surface-stirring. On the whole, we never saw less of slugs and snails than during this past season; and even caterpillars, that did great damage around us, troubled us but little. As soon as possible we shall prick-out a lot of small Cabbage plants in a bed, as when thus treated they make far better plants in every way in the spring than when left in the seed bed all the winter.

Cauliflowers.—Veitch's Late Cauliflower promises to be a very fine late kind, with leaves more upright than spreading. We shall have a quantity of rough hay and clean litter to put over the latest heads in case sharp frost should come on suddenly, but we hardly expect it just yet. This variety seems to be quite as hardy as the Walcheren. If we had a place which we could keep free from vermin and now cover with glass, we would take up a number of plants of this and other kinds with small heads at present, as when taken up with balls the heads would swell well, and be quite fresh when cut. Thus treated we have had nice Cauliflower throughout the winter, the plants being carefully protected from frost. When Cauliflower heads are nearly at their best at the end of October, we have kept them a long time by cutting them off close to the ground, removing the whole of the leaves, except two or three of the small ones over the head, and then packing the stems in rather damp earth or sand, with dry sand on the surface, in an airy shed where there was little light, and from which frost could be excluded. When such heads are placed for an hour in cold clean water they become quite firm and crisp. We have taken up and suspended the plants in sheds, planted them thickly in open sheds and in the open air, so that they could be easily covered when frost came; but of late years our great drawback has been keeping them from being spoiled by four-footed enemies. We have had scores of fine heads of Broccoli and Cauliflower thus cared for destroyed apparently only for mischief, as, on close examination, the left and cut-off parts would suit so well as to show that hardly anything had been eaten.

Young Cauliflower plants placed under hand-lights have not as yet been touched, partly owing to the surfacing of rough road drift sand, from which the finer particles had been excluded. It is very difficult for a mollusc to get over such material.

Lettuces and *Endive* planted on banks for spring supply have also had the surface of the soil between them gently broken, and this was more especially necessary as the surface had been beaten smooth at planting time, so that the small plants should be more secure. We have not noticed one plant that has given way. The rough surface will also keep off frost better than one which is smooth. This simple fact finds its way slowly among many of our readers. One of the things that convinced us many years ago was noticing that one round pit of Potatoes which we had helped to cover was frosted when opened after a severe winter, and another had the Potatoes sound, and this, too, we helped to cover. Both pits belonged to mechanics, and for the time very intelligent men. The Potatoes in each case were placed on a level surface, so as to form a cone, and were covered with straw. A space of 18 inches was then marked out round the heap, and beyond that a trench was dug all round, affording the earth to cover the heap, the soil being all over, except at the base, fully 15 inches thick. In one pit, as we put on each layer of soil we trod it rather firmly from the straw to the outside, and when finished we beat it firmly all over, so that the outside presented a smooth shining surface, to throw the rain off, as its owner said. The second pit was covered in the same way, but, except for the first layer or two, there was no treading, and when finished there was no patting of the outside. The rough exterior and the less solid soil arrested free radiation. We have often noticed since that in general, as respects a raised mound, a smooth surface absorbs more moisture than a rough more open one. We say in general, because in a regular downpour of rain the smooth surface will have the advantage, but it will be different during the drizzling rains that usually mark our winters. A few inches of rough litter on the outside of the first pit would have kept all safe. Pea and bean haulm, or a few tree leaves, are for this purpose very useful to cottagers who must keep their Potatoes out of doors.

Potatoes.—What few we have left from the garden have kept very well, and, so far as we can learn, those that followed the

advice given to cut down and remove the haulm as soon as affected, have suffered little in comparison with those who let matters take their chance. We noticed a quantity of Potatoes the other day that were raised from a field in the dry weather, and the bad ones that were seen were left. They looked then as housed a clean sample, but the other day they appeared as if they had come out of a mud hole; so many had become diseased and rotten as to make those look bad that remained sound. When such things are apprehended it is well to keep the Potatoes in thin layers, and, if much space cannot be given, to mix the layers liberally with dry earth and charcoal refuse. Though there has been a great outcry as to the extent of the disease, our conviction is that as yet it is rather made the most of; but as we are never sure in cold wet summers, and especially rich ground, it will be wise for all having but a small space of ground to plant chiefly early short-topped kinds. During the summer we heard glowing accounts of a magnificent new kind; the owner said the stems were then 4 feet in length. We have since been told that he has not had a sound Potato from the late giant-growing kind. The owner could not have appropriated above a few poles to Potatoes, and how much more prudent it would have been for him to have grown two or three rows of a good early kind instead of one row of this giant late one, all late kinds being more liable to disease than early ones.

Rhubarb, *Asparagus*, and *Sea-kale*.—Cleaned the most of these, and especially the latter, as the mice had begun on their crowns. We should have done something in regard to forcing some or all of these if we had had more tree leaves to afford a little heat. Besides these purposes we want slight hotbeds now for many purposes, and when we are short of material we must make the most of it.

FRUIT DEPARTMENT.

We mulched bush fruit trees, which have borne fairly, though not so well as last year. A heavy mulching given now generally disappears during the summer, but it encourage surface-rooting and an abundant production of fruit buds. Commenced pruning and cleaning in our early Peach house, which after this will be filled with boxes of bedding plants, at present under various kinds of protection. We have been obliged to keep plants in our earliest vineries, but hope to relieve them before long. The latest vinery we keep as dry as possible, with few plants in it. A little firing and air should be given during the day, and a little air all night. As yet we have had no damping, though the rain finds its way in at some places in the sides of the sashes. We cleared out a bed of ripening Melons, thinking they would complete their ripening as well in a warm place, and we thus set some lights at liberty. In the orchard house our last Peaches were used on October 24th, and there is nothing eatable in it, except a few Plums.

ORNAMENTAL DEPARTMENT.

With the exception of prominent places, we wait until the bulk of the leaves come down, unless we want them to help to give us some heat. We lately mentioned placing two cuttings of the white-leaved Centaurea in a small pot with a piece of slate between them, and setting them in a cold pit. These, after standing a fortnight, were plunged to the rim in a quickly-made hotbed, and in another fortnight or three weeks were well rooted, and will stand wherever they will not be too damp nor too cold. A later lot of cuttings, passing through the same cool process, were plunged in a similar bed the other day, and will, no doubt, strike as well. We have taken up a few fine bushy plants of Ageratums and Calceolarias, put them for early blooming in large pots, and plunged these in a mild bottom heat, whilst the tops are kept cool. Free flowering in winter and early in spring will depend on fresh active roots being quickly made after potting. The more tender variegated Geraniums, put in small pots separately, received similar treatment, as we wished to retain at least a portion of the foliage. The fresh roots soon reach the edges of the pots under these conditions. We have frequently told how to keep the various Scarlets in the smallest compass without any such help. Late cuttings have also been the better of such assistance, so that they may root before the days become shorter and darker. Verbenas we have not grown largely lately; we wish to grow them a little more, but the beds were so full of bloom buds that we could scarcely get what we considered fair cuttings early, and are putting in a number in small pots now, and these would do no good without a mild sweet heat beneath them. Of Calceolaria cuttings we have put in a fair portion in a cold pit in fresh soil, lightened with road drift, and covered with drift sand sifted fine. We place them 1 inch apart in rows 2 inches row from row, and even when put in so thickly they take up a large space. Potting, regulating, and general routine has been the same as in previous notices.—R. F.

TRADE CATALOGUES RECEIVED.

Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Descriptive Catalogue of Roses and Hollyhocks.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*G. B. C.*).—If you enclose five postage stamps with your address and order "Flower Gardening," you can have it free by post from our office, as you also can "Greenhouses," for seven stamps. Do not despise them because cheap. (*Ignoramus*).—We know of no books such as you name. There is no special art of procuring variegated plants known to the Chinese. Brent's little volume on "The Canary," contains drawings uncoloured of the varieties. You can have it post free from our office if you enclose nineteen postage stamps with your address. (*G. H. C.*).—"Wild Flowers" are published in shilling monthly parts containing eight coloured portraits of our native flowers. You can have a part free by post if you enclose 1*s.* 1*d.* with your address. (*Molestus*).—The "Cottage Gardeners' Dictionary" will suit you.

Market-Gardening (*E. H. G.*).—We regret that we cannot give you the information you seek. The notes were extracted from the last number of the Royal Agricultural Society's Journal. A letter directed to Mr. W. W. Glenny, Market Gardener, Barking, Essex, would reach him.

Twelve Dessert Apples (*An Amateur*).—The following will ripen in succession during the autumn and winter:—Blenheim Pippin, Court of Wick, Margil, Cockle Pippin, Nonpareil, Pitmaston Nonpareil, Sturmer Pippin, Wyken Pippin, Claygate Pearmain, Cornish Gilliflower, Court-Pendû-Plat, and Pine-Apple Russet.

Seedling Apple (*T. B. Mosley*).—Your seedling Apple from the Blenheim Pippin is good, but not so much so as many other varieties already in cultivation.

President Strawberry (*W. E.*).—It is an excellent variety for forcing or an early crop out of doors, and a good market kind.

Strawberry Black Bess (*J. T.*).—We never heard of a variety so named. As you speak so very highly of it, we will have it tasted if you send us a few plants.

Trees and Shrubs not Thriving (*J. W. M.*).—We think the cause of the plants not thriving is the bad preparation of the ground, and the dry character of the stony subsoil. We should have trenched the ground deeply, and have kept down all weeds for at least three years. In ground which is well prepared trees will make as much progress in three years as they would do in six years in that which is not in good order for planting. Clear the ground of the Couch Grass as you propose, and fill-up the blanks with Berberis Aquifolium, double-flowering Furze, oval-leaved Privet, tree Box, common Yew and Laurel, Snowberry, Weigela, Lilac, and Sweet Briar. The Rhododendrons will not thrive in such a soil, neither will the Birch and Poplar. Keep down all weeds for the next three years. If the situation be sheltered add Laurustinus (the black-leaved would be sure to thrive), and the Red-berried Elder.

Vegetables (*Amateur Gardener*).—Varieties of *Broccoli* to come into use in October and November are Early White Cape, Grange's Cauliflower, and Walcheren, sowing in the third week of May. Those to come in during February and March are Backhouse's Winter White Protecting, Veitch's Spring White, and Dilcock's Bride, sowing in the third week of April; these to come into use in May and June are Cattell's Eclipse, Emperor, and Lauder's Goshen Late White, sowing at the same time as the last. *Cauliflowers* for October and November are Walcheren, Stadtholder, and Veitch's Autumn Giant, sowing in the third week in May, but we do not know of any to come in in February and March. For May and June, Early London and Walcheren, sowing in the third week of August, and in October pricking out under hand-glasses or frames, and planting out in April. You say nothing of the supply for August and September, but we advise for this purpose an early sowing in March on a gentle hotbed, pricking-off when large enough, and hardening-off when ready. Sow out of doors early in April, and again at the close of the month; also from the 20th to the 24th of May, sow Dwarf Erfurt, Asiatic, and Stadtholder. For *Celery* to come in during October and November, sow Sandringham Dwarf White, and Ivery's Nonsuch in the first week of March; for February and March sow two weeks later, and for a later supply in the first week of April, employing the varieties above named. *Onions*, White Spanish, Reading, Brown Spanish, Deptford, Brown Globe, and James's Keeping; and for late keeping, Blood Red, sowing as early in March as the ground is in good working order; and sow Tripoli the second week in August, transplanting in spring. *Cabbages*.—Sow Atkins's Matchless, Cattell's Reliance, and Wheeler's Imperial in the first week of July; and in the first week of August, Battersea, Nonpareil Improved, Enfield Market, and Red Dutch. *Beet*.—Sow Dell's Crimson at the end of April. *Potatoes*.—Early, Myatt's Prolific; second early, Lapstone and Early Oxford; late, Victoria and Red-skinned Flourball, plant early in March, the end of March, and beginning of April. *Carrots*, for a small early crop on a warm border and light soil, sow at the end of March Early Short Horn; in the second week of April sow James's Intermediate Scarlet, Altringham, and Red Surrey, taking up early in November, and storing in sand in a cool shed. *Turnips*.—Sow Early Snowball and Six-weeks at the beginning of April, and every three weeks up to the first week of August, adding Orange Jelly after April. You will find Peas fully treated of in another page.—G. A.

Seedums cæruleum and dasyphyllum from Seed (*A Constant Subscriber*).—The former is an annual, but the latter is an herbaceous perennial. It would be best to sow both in spring as the season is so far advanced, using very sandy loam and lime rubbish, raising it well in the centre of the pots, and shading so as to lessen the necessity for very frequent waterings.

KEEPING GRAPES ON VINES (*F. F.*).—See page 326 To keep Grapes late on Vines, the house must be dry and secure from frost. If cut and kept with the ends of the shoots in roots, or bottles of water, with the hole of the bottle stuffed up, they must be kept in a dry cool place, but free from frost.

SOIL FOR VINES (*A Subscriber*).—The soil being full of wireworms we would have it sifted through a fine-meshed sieve, the rough remaining in the sieve burnt, and then remixed with that which had passed through the sieve. Salt added to the soil will not kill the wireworms.

ROOT-PRUNING (*J. M. K.*).—The tap-root of the Pear tree should be cut through.

CYCLAMEN TREATMENT (*L. B.*).—You do not say what kind it is. Place them in pots twice the diameter of the corms, draining the pots well, and using a compost of two parts turfy loam, one part leaf soil, and one part peat, with a free admixture of sharp sand and charcoal. Pot so that the corms may be just covered with soil. Place the pots in the sunniest window you have, and do not water more than to keep the soil moist, but when the leaves appear water more freely.

CYANOPHYLLUM MAGNIFICUM IN WINTER (*C. M.*).—Give it as little water as it is possible to do without allowing the leaves to flag or become limp, and maintain a moderate amount of moisture. It only loses the old leaves in winter. A temperature of from 55° to 60° at night, and 65° to 75° by day, is sufficient, affording moderate ventilation.

CUCUMBER AND MELON FOR EARLY AND LATE FORCING (*Idem*).—For early or late winter or summer crops we have found Cox's Volunteer Cucumber excellent, also Telegraph, and Masters's Prolific. If you want two, have the first and last, or if one, the first, but all are excellent. A good Melon for an early crop is Malvern Hall, and for a general crop Cox's Golden Gem and Heckfield Hybrid. This season, however, we cultivated many varieties, and Beechwood was the best.

LASIANDRA MACRANTHA CULTURE (*An Old Subscriber*).—This plant in a young state is not free-flowering, though of very free growth, but when 3 or 4 feet high it produces from the terminal shoots a profusion of fine saucer-shaped flowers, of a violet-blue colour. It requires to be grown in a warm greenhouse or cool stove, should have a light airy position, and ought never to be watered until the soil becomes dry; then before the eaves or growing shoots flag give a thorough supply. Pot it in March, and give another moderate shift in June, using a compost of two parts loam, with one-third of sandy peat, draining well. To form a well-furnished plant stop the shoots in March, or if needful, cut-in the plant, and again stop early in July. Libonia floribunda is not a stove but a greenhouse plant.

PLANTING FRUIT TREES ON MOUNDS (*A Cottage Gardener*).—The height of the mounds must be regulated by the state of the soil. In a very wet and heavy soil, with a subsoil of a similar character, mounds a yard high are not too much, whilst if the soil is not wet nor heavy, planting on the surface is sufficient, covering the roots with soil so as to raise a mound of about 12 or 15 inches. The mound should fall outwards three times the length of the height, so if the mound is 1 foot high it will run out at 3 feet all round. The junction of the stock and graft should not be covered with soil, but all below it. The roots should be covered 3 inches deep. Stable litter two weeks old will answer perfectly for mulching the trees. The spirit lamp will not do any harm in a frame if kept burning all night during frosty weather, but may be a means of safety from frost.

FERNS FOR CONSERVATORY RECESS (*Crypto*).—We presume the recess will have the same temperature as the conservatory, or be safe from frost. To have the water trickling over the stones is not desirable as regards culture, but to produce a cool, moist, and pretty effect, you may introduce water; but it must be conveyed in a cemented channel, so that it may not run over the soil on the ledges and crevices of the rockwork. You may have miniature waterfall streams, or dripping rocks, but the water should be kept clear of the soil for the plants, for few Ferns thrive with the soil sodden by constant stagnant moisture. The following will suit:—Acrophorus hispidus; Adiantum assimile, A. cuneatum, A. setulosum; Anemia flexuosa; Asplenium bulbiferum, A. flabellifolium, A. Veitchianum, A. monanthemum, A. fœniculaceum, A. dimorphum; Blechnum australe, Cheilanthes elegans, Davallia canariensis, D. dissecta; Doodia Dives, Doryopteris palmata, Lastrea glahella, Lomaria Herminieri, Nephrolepis tuberosa, Niphobolus rupestris, N. lingua corymbifera, Platycerium alcicorne, Platyloma rotundifolia, Pteris serrulata cristata, P. cretica albo-lineata; and of Lycopods, Salaginellas apoda, denticulata variegata, formosa, and Wildenovi.

AMARYLLIS CULTURE IN A COOL HOUSE (*Novice*).—We presume by a cool house you mean a cool stove. If so, place them on a shelf near the glass until February, giving no water; then repot, and place them in a hotbed or the warmest part of the stove, and water as the growth advances, giving abundant supplies of moisture whilst they are making fresh growth, and when this is complete keep them less moist and afford all the light you can command. If you place them in a hotbed remove them as soon as they have well started into growth, gradually withdrawing them from the hotbed so as not to cause a check. The principle on which you are to decide the character of the soil required for plants we cannot explain, but the "Cottage Gardeners' Dictionary" states the soil required for the plants enumerated.

VARIOUS (*R. G. I.*).—There is no objection to your heating the small stove and vinery with a flue for each, and a separate fireplace and furnace, provided the flues are sound, and the atmospheric moisture you want is obtained from the floor and from evaporating-basins placed on the flue, and not from sprinkling the flue itself. In the stove at any rate we would have 6 feet of the flue next the furnace brick-on-bed, instead of brick-on-edge, and strong tiles for covering, or oven bricks for that distance. The only objection against flues is allowing them to become foul from not cleaning them often enough, as they are then apt to take fire, or slight explosions will occur, which will be apt so to disturb the flue as to allow of the escape of dangerous gases into the house. For small places there is no cheaper mode of heating than by a good built flue. For an early vinery you would need as substantial a flue, but for a late one a flue brick-on-edge would do, say 2 feet from the furnace. For all small places hot water would be more expensive, but it would be safer and more cleanly, and one small boiler costing about 70s. would heat both houses. For the stove you would need about 90 feet of piping 4 inches in diameter, and you would need nearly as much for the Grapes, to come in, say, in August. If you wanted it much earlier, say May and June, you would need from 20 to 40 more feet of piping. A doorway from one house to another would be a great convenience and advantage, as you might often move plants from one place to the other without taking them out of doors. The border will be all right if there is a drain to take away what may collect beneath the rough rubble. The turf stacked-up will do, so will the turning, if you keep it dry, and so will the mode of filling the border, but filling half the border at first would be best. The woollen rags used should be chopped small, other rags and paper we would care nothing about. When thoroughly decomposed they are of little value, and before they are decomposed, like rank manure and carrion, they do more harm than good. A little fowls' manure with feathers may be used, but it is so strong that it is safest used moderately as a surface-dressing. As to proportions, to ten parts of your good pasture loam add two of old lime rubbish or plaster, one of charred wood, one of horse droppings sweet and dried, three hundredweight of broken bones that have been boiled, and one hundredweight of horn shavings if you can obtain them, with a moderate quantity, say one hundredweight, of chopped rags, as you seem to have them. These may be mixed and turned over before using them, but must not be sodden. If you wanted the Vines in the new house chiefly to be late kinds, we would recommend Trebbiano, Lady Downe's, and Kempsey's Alicante. If, however, you wish the house to alternate with the other, then we would choose similar sorts, as Hamburghs, Muscats, &c. You may treat the Vines as you say, using each vinery as a greenhouse every alternate year in winter, giving the other a complete rest; but in no vinery will any injury result from keeping plants in it after the Grapes are cut, if the temperature from artificial heat be not above 45°. For the Sweetwater, the Golden Champion we should think would do, but a Sweetwater ripened well is still a fine Grape. 21-oz., or fourths, will answer, but thirds will be better. If you bed on putty, you must also place putty above the glass. Beard's system requires no putty, and grooves do not require it. These have been described.

WINTERING GERANIUMS IN BOXES IN A CELLAR (*E. W.*).—It is suitable for those which have been planted out. When taken up they should be set for a few days in a shed, then stripped of all the leaves, sparing none, and afterwards placed in boxes, covering the roots well with dry sand. Do not cut the plants down but leave them entire, minus the leaves, and give no water from the present time up to March. They may be kept well in the dark dry cellar, if frost be excluded. In March take them from the cellar, pot them, and place them in a frame or hotbed, giving no water, but using moist soil. When they have made fresh roots and are growing freely, water copiously. They will be good for planting out in May.

ERECTING AN ORCHARD HOUSE (*Inquirer*).—If you had a wall we would say have a lean-to, as 60 feet by 16, would be a good house, divided in the middle so that you could have one compartment earlier than the other. Where there is no wall the span-roof with low walls at the sides, and a gable end to the north, would be the best. If, then, your house were 20 feet wide, you could have a 3-feet bed all round, a pathway 3 feet wide, and a bed of 8 feet in the centre.

WINTERING PLANTS IN A FRAME (*R V.*).—Mussett's portable hot-water apparatus would suit, with a tube to carry off the products of combustion, and so would Joyce's, or any other small stove, but not without a pipe going through the roof to carry off the smoke, however little. A pipe 2 inches in diameter would do. We have always considered that iron stoves should have their fire-box lined with fire-brick. If an iron stove ever becomes nearly red hot, all plants near it will suffer. Hence we should prefer a brick or cement stove, when it could be used. If the frame were near the house, two or three two-gallon bottles filled with hot water would do unless on the coldest nights. The difficulty in all such modes is, that in the case of frames you must lift a glass to get at a stove. In a small house with the same glass, you could open a little door and go in and light either a fire or lamp.

WATER RATS (*R. G.*).—We know of no mode of destroying them wholesale but by poison. Gas tar poured into their holes ejects them, but only causes them to change their residence.

PREPARING BONES FOR MANURE (*Hampshire Highlander*).—The least troublesome mode for you is to have the bones broken into small pieces by a hammer, and lay them in tiers, alternating with caustic potash in a sugar-hogshead. After a while they will be easily crumbled.

AMERICAN BLIGHT DESTROYING (*Gardener*.—Dress the trees now with paraffin oil, applying it with a brush to every part of the branches and shoots, and in summer syringe forcibly with water from an engine, and on its first re-appearance with a solution of 2 ozs. of soft soap, to a gallon of water.

MUSSEL SCALE ON APPLE TREES (*C.*).—Your Apple trees are infested by the mussel scale, an insect the presence of which always indicates want of vigour and health in the tree, caused by poverty of the soil or injury to the roots. The way to remedy this is to cut-in the branches, removing all those shoots that are affected, dress the whole tree with Gishurst compound, 4 ozs. dissolved in a gallon of water, and applied with a stout rough brush. Uncover the roots, and replace the soil taken out by good loam in which well-rotted stable manure has been incorporated, and with such treatment your trees will recover. The pyramidal trees you refer to had better be pruned judiciously, so as not to induce the production of too much wood, by merely removing those shoots that assume too great vigour.

NAMES OF FRUITS (*J. M. Dublin*).—Pitmaston Nonpareil. (*A. H. M., Cambridge*).—It is Baronne de Mello, one of the finest October and November Pears. (*J. Walsh*).—It is impossible to name Grapes from so small portions of a bunch. The white one is some of the forms of Chasselas Musqué. (*W. K., Angmering*).—Your Grape is Pinean Noir, or Black Burgundy. (*A. M. R.*).—No. 1, Beurré d'Aremberg; 2, Seckle; 3, Easter Beurré; 4, Beurré Clairgean; 5, Easter Beurré; 6, Seckle. (*A. S.*).—1, Monsiegneur Affre; 2, Van Mons Léon Leclerc.

NAMES OF PLANTS (*H. C. K.*).—Viburnum Opulus, the Gueldres Rose. Propagated by layers or cuttings in the autumn, in sandy soil, and a shady border, where they ought to remain two years unmoved. (*S. E. W.*). Salvia Horminum, very ornamental. Native of the south of Europe and the east, and especially frequent in Greece, Asia Minor, and Syria. (*W. H. M.*).—Either Lastrea dilatata (the Broad Fern), or its close ally, L. Fœniseccii, the Hay-scented Fern, probably the latter. (*Inquirer*).—Selaginella Kraussiana (S. hortensis of gardens), and Clitoria Ternatea, a common plant in Southern India. (*R. C., Buxted Park*).—The Honeysuckle is Lonicera chinensis. As to the Fern, you are quite wrong. It

is without doubt the Hay-scented Fern, Lastrea Fœnisecii, and in very good character. (*Linda*).—Cineraria maritima, otherwise Senecio Cineraria. Native of the shores of the Mediterranean. (*Tom Brown*).—Nephrodium molle and Adiantum tenerum.

POULTRY, BEE, AND PIGEON CHRONICLE.

LIGHT BRAHMAS.

But for a fortnight's absence from home I should have endeavoured earlier to make a few remarks upon the complaint of Mr. James Long—that Light Brahmas do not get their due from committees and judges. It is generally known that I have devoted much study and attention to Brahmas for many years, and my more personal friends also know that only my unfortunate "city" surrounndings tie me at present to the Dark variety. My preference would be for the Light, and if I ever have the pleasure of a country run I hope to keep them. Nevertheless, I cannot agree with Mr. Long's complaint; he puts the saddle on the wrong horse altogether, and the failure to win prizes and cups is not owing to any undue partiality of the judges for Dark birds, but because birds have not been shown good enough to win.

The simple fact is that Light Brahmas have lately very much deteriorated. I fear my plain statement will draw a hornet's nest about my ears, but I have studied the Brahma fowl long and closely, and make it advisedly. They have fallen off in colour, leg-feather, shape, and size. So far from judges being against them, I have heard the admittedly best judge we have, not in conversation with me, but independently, express his regret that such "miserable" Light Brahmas were shown; and on one occasion both he and his colleague observed that the hens were regularly "duck-shaped." Looking at the class, I saw at once how singularly appropriate the criticism was, the "Aylesbury" type of body being most conspicuous, and the exquisite neatness of the true Brahma shape completely gone. That there are exceptions I of course do not deny, and during the last twelve months several cocks especially have been shown of the true shape and colour, but mostly small in size. I may mention the two winning Birmingham cockerels of last year for instance, which were also good in leg-feather, for the purpose of rebutting Mr. Long's imputation that the judges go by size chiefly. It is rather singular, if his remarks are to be considered as shared by Light Brahma breeders generally, that while both these awards were evidently made in favour of colour and proportion as compared with mere size, I never heard any complaint made by those disappointed on the ground that the winning birds were so small! Further still, when at Plymouth I gave the cup (open there) to the Light birds in preference to the Dark, showing that Light can win sometimes. Mr. James Long, both verbally and in this Journal, was the first to complain, stating to me that the Darks (a very large but badly-shaped pen) ought to have won, and in these columns that the cup bird was far inferior to another, larger indeed in size, but much worse, both in true Brahma shape and colour.

It is not, then, that the judges have discouraged the Light Brahmas, but that the Light Brahmas have "discouraged" the judges. Let them be shown correct in shape, good in colour, and well feathered, even if not large, and they will win. Not many weeks ago I remember seeing it remarked in one of the reports that they had beaten the Darks in fair fight. But they can also be bred large, and whatever can make Mr. Long say as he does, that to increase the size "cannot be done," I am at a loss to conceive. Let Light breeders select their stock better, and keep their chickens at home to grow instead of sending them to the early shows, and they will soon improve. I do not know why it is, but while the best Dark Brahmas are usually kept back till matured, the Lights seem mostly to be early shown, and this I am sure is one cause of the deterioration, though want of knowledge in breeding and rearing does more. At all events, if there is any difference in the two breeds, I should say that decidedly the Light breed can be bred the larger. To my certain knowledge, there are several cocks now in the United States nearly 17 lbs. in weight; and one lately dead made a footprint 6¼ inches long. In hens 10 lbs. is a common weight there, and 12 lbs. not so very rare. In fact the best Light Brahmas now to be had must be sought in America, where they are both larger and better in quality than here; and there, if I sought a strain for myself, would I select my stock. It might be thought that the American climate is the cause of the difference, but if so the Darks also would be superior, whereas our Yankee friends' Dark birds cannot as yet compare with Light ones. We had even in England far larger Light birds a few years since than now, and they can be bred again to equal and even surpass their Dark rivals.

I lay stress on these things, because the *ad misericordiam* style of argument always injures a breed. A good fowl, as the Light Brahma is, if bred good enough, will command success, and the bare idea that petting or artificial "encouragement" is needed, is likely to stop all real effort in the right direction. Let our exhibiting friends leave off this and "get to work," and they will earn their just reward. The reference to prizes given "by supporters" is not just. If birds are not good enough to win on equal terms, which Light Brahmas lately have certainly not been, any extra "support" must of course, and rightly, come from private admirers; but the little real good, or rather the real harm, done by such artificial treatment, is seen by the small results produced by the "special" prizes thus given at Southampton and other places. They bring larger entries, but they do not bring pens to surpass, rarely indeed to equal the Darks. Perseverance in fair and honest competition can alone do this. I may here mention that by the liberality of a member of the Committee, the Lights will at Bristol have four cups (one to every class), against only two for the Darks. There surely is a fair chance for our friends, let us see what the result will be. I for one shall truly rejoice if my real favourites come fairly to the front in size and quality, but mere number of entries I care little for.

I would give some practical help where possible, and hence I remark on the general want of leg-feather in Light birds. Their breeders have not used equal judgment with the Dark fanciers in employing vulture hocks to restore it, which is very easily done with little bad result. There are various kinds of hocked cocks. There may be a moderate hock with very heavy leg-feather, and heavy hocks with only moderate feather. The latter class of bird has been often used by Light breeders, but is useless. But further, there may be heavy leg-feather, but it may spring perpendicularly, and hence not "tell" as it ought to do. Such a bird also will work little improvement in a badly-feathered strain. But select a few fine, long-backed, barely-feathered hens, and mate them with a cock very short and broad in the back, very high and broad in saddle, and with a good strong vulture hock, but with leg-feather under which stands well out in a horizontal direction. Cut his hocks neatly round with a pair of shears (not plucking them, as the feathers would soon grow again), and you will have at least three-fourths beautifully feathered birds, with just the hocks a good judge wishes to see. I say "Cut off the hocks" advisedly, having found it make a marked difference to the progeny; but I mean, of course, for breeding solely. Indeed, a cut hock is instantly detected by the most inexperienced judge, but I do not wish to be misunderstood as to the object of the proceeding.—L. Wright.

EXHIBITION GRIEVANCES.

I see in the Journal of the 26th ult. a short notice of the schedule of the Bristol Poultry and Pigeon Show, and the words, "As usual the prizes are very liberal;" but it seems that you have quite passed unnoticed the extreme liberality (on the part of those who intend to pay them) of the entrance fees. I had intended sending a pen or two, but as I find that I must first subscribe £1 to entitle me to the privilege of paying 6*s.* per pen in addition—*i.e.*, £1 6*s.* for one pen, or £1 12*s.* for two, and so on, I beg to decline; and I fancy that the competition for the liberal prizes will be confined to those who can enter twelve or thirteen pens, when the £1 subscription will be sufficiently distributed to bring the price of each entry down to the old amount—7*s.* 6*d.*, I think. There has lately been something said of the ability of large dealers and breeders to monopolise the prizes; if anything is calculated to encourage it it is such a rate of entry as this, where the exhibitors of two or three pens are utterly discouraged, and yet they are the real supporters of our shows.

I may mention at the present time another growing mistake, as I think, in the conduct of poultry shows—viz., the Secretary entering his own birds for exhibition and competition, the latter being the objectionable part. At a show to which I have for several years sent some pens, I was last year beaten by the Secretary, who carried off cup and second prizes, whilst my birds came next with a very high commendation. I do not question the fairness of the award, as I have sufficient confidence in the Judge, but in entering I had not counted on the Secretary as a competitor. This year I entered none, nor do I

intend doing so again, as it is evident that the fact of officials, who are present at the judging, being also exhibitors, must destroy confidence. I remember seeing after judging had commenced an exhibitor's bird taken by his owner from his travelling basket, where he had been overlooked by the officials, and penned, and immediately awarded first prize. Had the Secretary been an exhibitor in that class, what would have been said, or at least thought? I certainly think that a Secretary ought to abstain from exhibiting, nor even allow his son or daughter to enter his birds for his own particular show; and I think the majority of exhibitors will agree with me.—E. S. T.

POULTRY AND PIGEON CLUB.

The number of poultry and Pigeon shows which are now annually held, with the proposed new ones, the large amount of capital invested in birds, and the valuable prizes offered for competition, have created such an extended interest in poultry amongst all classes of society, that the time now seems to have arrived for the formation of a poultry and Pigeon club. Such a society seems to me to be very much needed. 1st, For starting new shows in fresh places, and co-operating and advising with existing committees. 2nd, To amalgamate many existing small local shows into one large influential show, and to arrange the dates of others, so as to prevent more than one being held on the same day as is now the case, often to the ruin of one, or possibly both. 3rd, To expose all shows started by unknown and irresponsible persons. 4th, It would be able to discuss and state the standard of excellence of many varieties in which it is now undecided and left for the decision of the judges, also to criticise the judges' awards.

Such an institution as the one proposed would be for the protection of exhibitors and breeders. As it is certain that next month there will be a great number of exhibitors and fanciers in London attending the Crystal Palace Show, it would be an excellent time to hold a meeting for the purpose of considering the subject, and for getting at the opinions of those who are likely to be interested in the formation of such a society. Could not some of our ardent fanciers be induced to take the initiative?—J.

IPSWICH POULTRY AND PIGEON SHOW.

This meeting, held on the 26th and 27th of October, was a marked success. The general excellence of the poultry was freely admitted, and we cannot but observe that the three Selling classes were very well filled with pens which would have taken a good position in the majority of prize lists, and remunerated any dealer for a visit to Ipswich to claim them. We regretted to find, as at last year's meeting, that a large number of pens arrived some hours after the Judge had commenced his duties, and, strange to say, in some cases portions consigned by the same owners, had been safely to hand on the previous day. It appears that although, to meet all possible contingencies, the Judges were delayed to 1 P.M., not less than thirty pens were then unoccupied. We may add that all the pens in the three very heavy Selling classes were filled, and we believe this was the first time a special Selling class has been appointed for Bantams.

The *Game* fowls were throughout a grand collection; and although Mr. Matthews, of Stowmarket, secured most of the premiums, he did so in a generally close competition. A rather unusual occurrence took place in this division of the Show, Mr. Matthews taking the silver cup for Game, all varieties or sexes being eligible, with a wonderfully well-shown Black Red *hen*. On the *Dorking* chickens it was evident that no common amount of attention had been bestowed, but there were a few cases of humped backs and other malformations that ought never to be admissible in a prize show pen. Although in former years Ipswich shows have been noted for the best of *Spanish* fowls, at the late meeting the collection of this variety was poor and meagre in the extreme. In the Variety class seldom has there been so close a run, a silver cup offered as first prize bringing together birds of the highest perfection. Silver-spangled *Polands*, and such a pen of *Malays* as are rarely to be seen at any show, were the prizetakers.

The *Ducks* exhibited, both Aylesbury and Rouens, proved a marvellously good class, Mr. Fowler, of Aylesbury, taking first and very highly commended, and Lady Gwydyr the second prize. The three pens, fortunately being side by side, proved a great attraction to all visitors.

Lady Gwydyr's success with both Buff *Cochins* and Dark *Brahmas* was well deserved, the birds being of first-rate quality and shown in admirable condition. Mr. Jeffries, the indefatigable Secretary, sent in several pens of very carefully selected Black Red Game *Bantams*, and maintained his reputation as a breeder of this popular variety.

The *Pigeons*, though not so numerous as in some previous years, were generally of very excellent character, more especially the Carriers, Fantails, and Variety class.

The Show was not only well supported by visitors, but we also hear is patronage has considerably increased.

Cochins.—1, Henry Lingwood, Needham Market. 2, J. Taylor, Sutton, Isle of Ely. *Chickens.*—1, 2, and Cup, Lady Gwydyr, Stoke Park, Ipswich. *vhc*, Henry Lingwood. *hc*, W. G. Ransom, Stowmarket; J. K. Fowler, Aylesbury. *c*, G. Lamb, Wolverhampton.

Brahma Pootra.—*Dark.—Chickens.*—1 and 2, Lady Gwydyr. *hc*, J. Hill, Brentwood; W. G. Ransom; J. K. Fowler. *Light.*—1, Withheld. 2, H. Dowsett, Pleshey, Chelmsford. *Chickens.*—1, M. Leno, Markyate Street. 2, H. Dowsett. *vhc*, Mrs. A. Williamson, Queenborough Hall, Leicester. *hc*, Dr. Campbell, Brentwood (2); W. T. Storer.

Dorkings.—1, J. Frost, Parham, Wickham Market. 2, Henry Lingwood. *Chickens*—1 and Cup, Henry Lingwood. 2, G. H. Greenhill, Ashford, Kent. *vhc*, J. O. Fison; O. E. Cresswell. *hc*, F. Parlett, Great Baddow; J. Drake, Ongar.

Game.—*Cockerel.*—1 and 2, S. Matthew, Stowmarket. *vhc*, H. E. Martin, Sculthorpe, Fakenham. *hc*, W. Kitson, Ipswich; W. Rayner, Ipswich. *c*, W. H. L. Clare, Twycross, Atherstone. *Hen or Pullet.*—1, Cup, and *vhc*, S. Matthew. 2, W. Rayner. *hc*, H. E. Martin.

Spanish.—*Chickens.*—1, J. F. Sillietoe. 2, Rev. T. P. Platten, Bildeston, Suffolk.

Hamburghs.—*Golden and Silver-pencilled.*—1 and *hc*, W. K. Tickner, Ipswich. 2, A. Cole, Long Sutton. *Golden and Silver-spangled.*—1 and Cup, T. Blakeman, Tettenhall, Wolverhampton. 2, J. B. Bly, Lowestoft. *vhc*, C. Plimley, Whitmore, Bearnes, Wolverhampton. *hc*, W. K. Tickner; Rev. F. Tearle; T. Dean, Keighley.

Bantams.—*Game.*—1, Cup, and 2, Miss E. H. Jeffries. *hc*, H. L. Cocksedge, Drinkstone House, Bury St. Edmonds; Hon. Mrs. Paget, Hoxne, Scole. *c*, T. Barker; W. Adams, St. Clements, Ipswich. *Any other Variety.*—1, M. Leno (Sebrights). 2, S. S. Mossop, Long Sutton. *hc*, Rev. F. Tearle (White and Black); T. J. Miller, jun. (White booted); J. Bloodworth, Cheltenham (White). *Selling Class.*—1, Cup, and 2, Miss E. H. Jeffries (Black Red). *hc*, T. Barker, Hill-End, Burnley (Game); J. Bloodworth (Black). *c*, Rev. T. C. Hose (Duckwing).

Crève Cœurs, Houdans, and La Flèche.—1 and Cup, J. K. Fowler. 2, W. Tippler (Houdans). *vhc*, J. J. Malden, Biggleswade (Crève-Cœurs); W. Dring, Faversham (Crève Cœur). *hc*, W. Burrows (La Flèche); C. H. Smith, Radcliffe-on-Trent (Crève-Cœurs). *c*, W. Burrows, Diss (Houdans).

Any other Variety.—1, H. Pickles, jun., Earby (Polands). *c*, Rev. N. J. Ridley, Newbury (Malay). *vhc*, W. Cutlack, jun., Littleport (Black Hamburghs); J. Berners, Woolverstone Park, Ipswich (Geese); W. Kensey, Gosbeck, Ipswich (Turkeys).

Ducks.—*Rouen and Aylesbury.*—1, J. K. Fowler. 2, Lady Gwydyr. *vhc*, H. B. Smith, Broughton, Preston; T. F. Upsher; J. K. Fowler. *c*, G. W. Greenhill, Ashford, Kent; J. Drake. *Any other Variety.*—1, S. & R. Ashton, Mottram. 2 and *vhc*, M. Leno (Whistling and Carolina). *hc*, H. B. Smith.

Selling Class.—1, W. Rayner, Ipswich (Brown Game). 2, H. Payne, Stowmarket (Buff Cochins). *vhc*, J. J. Malden, Biggleswade (Crève-Cœurs); W. Kitson, Ipswich (Black Red Game); Master W. M. Shaw, Rougham Rectory; T. Woollard; W. Rayner, Ipswich (Black Game); Miss E. J. N. Hawker (Silkies). *hc*, A. Cole, Long Sutton (Cochins); F. Parlett (Coloured Dorking); J. Dutton, Ipswich (Buff Cochin). *c*, Rev. W. F. Dixon, Oby Rectory, Norwich (White Cochin); H. Dowsett (Dorkings); Rev. F. Tearle, Gazeley Vicarage, Newmarket (Silver-spangled Hamburghs). *Cock, Cockerel, or Drake.*—1, Dr. Campbell (Light Brahma). 2, Master W. M. Shaw (Aylesbury). *hc*, J. J. Malden, Biggleswade (Crève-Cœur); A. Cole (Cochin); T. F. Upsher, Sutton, Ely (Rouen Drake); W. Rayner (Brown Red); H. Dowsett (Dorking). *c*, W. K. Tickner (Hamburgh); W. Tippler (Houdan); W. Speakman, Doddington Park, Nantwich (Hamburgh).

PIGEONS.

Carriers.—*Young.*—1 and 2, A. W. Wreo, Lowestoft. *vhc*, W. Lumb, Brotherod Hall, Rochdale. *hc*, H. Yardley, Birmingham. *c*, A. Cole.

Tumblers.—1, W. Lumb. 2, H Yardley.

Fantails.—1, J. Walker, Newark. 2, J. T. Cater. *vhc*, J. F. Loversidge, Newark; J. Walker. *hc*, J. F. Loversidge; O. E. Cresswell, Early Wood, Bagshot; H. Yardley.

Trumpeters.—1, C. Norman, Westerfield. 2, R. Elliott, Ipswich. *vhc*, H. Yardley.

Any other Variety.—1, H. Yardley. 2, W. Goddard, Stanhope St., London (Ice). *vhc*, Miss E. M. Buckel, Ipswich (Priests); O. E. Cresswell (Turbits). *hc*, W. Goddard (Blue Owls); H. Laver, Colchester (Runts); W. Lumb (Priests). *c*, F. Harwood, jun., Colchester (Antwerps); H. Laver (Pouters); F. Graham, Birkenhead (Nuns).

Selling Class.—1, C. Norman (Black Trumpeters). 2, W. Lumb (Turbits). *hc*, G. W. Bales, Ipswich (Pouters); T. Cater, Colchester (Yellow Magpies). *c*, F. Harwood, jun. (Pouters); G. W. Bales (Carriers).

CAGE BIRDS.

Canary.—*Clear*—1, T. Fenn, Ipswich. 2 J. Frost, Parham. *hc*, J. Frost; Cockle & Watson, Terrington, St. John's, Lynn. *c*, Cockle & Watson. *Mottled.*—1 and *hc*, Cockle & Watson. 2, T. Fenn. *Crested.*—1, Cockle & Watson. 2, J. Frost. *hc*, T. Fenn; Cockle & Watson.

Any other Variety.—1, Rev. T. C. Hose, Roydon Rectory, Diss (King Parrot). 2, G. W. Bales (Java Sparrows). *hc*, T. Fenn (Gold Lizard); Cockle & Watson (Lizard).

Selling Class.—1 and 2, T. Fenn (Norwich). *hc*, H. T. Frere, Burston Rectory, Diss (Lizard). *c*, Cockle & Watson.

The Judge was Mr. E. Hewitt, of Sparkbrook, near Birmingham.

DERBY BANTAM AND CANARY SHOW.

The fourteenth annual Exhibition of Canaries and other Cage Birds was held in the Lecture Hall, Wardwick, Derby, on the 28th and 30th of October. The following prizes were awarded:—

Bantams.—1 and Extra 1, J. Eaton, Farnsfield, Southwell. 2, F. Sale. *hc*, F. Sale; H. Shumach, Southwell; J. Eaton.

YOUNG BIRDS.

Belgian.—*Clear Yellow.*—1, J. Close, Derby. *Clear Buff.*—1, J. Close. *Marked Yellow*—1, H. Hutchinson, Derby. *Marked Buff.*—1, J. Close. *Variegated Yellow.*—1, John Clarke, Derby. *Variegated Buff.*—1, J. Close.

Norwich.—*Clear Yellow.*—1, R. Henson, Derby. 2, S. Burton, Derby. 3, J. Prosser. 4, John Clarke. 5, C. Wood, Derby. *hc*, E. Orme, Derby. *c*, A. Knight, Derby. *Clear Buff.*—1, R. Henson. 2, W. Sherwin, Derby. 3, J. G. Edge, Derby. 4, H. Johnson, Derby. 5, C. Wood. *hc*, S. Burton. *c*, J. Bennett, Derby.

Norwich.—*Marked Yellow.*—1, R. Henson. 2, J. Prosser, Derby. 3, H. Adams, Derby. 4, W. Sherwin. 5, John Clarke. *hc*, E. Orme. *c*, A. Ufton, Derby. *Marked Buff.*—1, E. Orme. 2, R. Henson. 3, H. Adams. 4, C. Merriu, Spondon. 5, C. Wood. *hc*, J. Bennett. *c*, J. G. Edge.

Norwich.—*Variegated Yellow.*—1, John Clarke. 2, E. Orme. 3, R. Henson. 4, J. Bennett. 5, James Clarke. *hc*, A. Knight. *c*, J. Marshall, Derby. *Variegated Buff.*—1, R. Henson. 2, S. Cholerton. 3, A. Ufton. 4, E. Orme. 5, W. Sherwin. *hc*, J. Marshall. *c*, A. Knight.

Norwich.—*Evenly-variegated Crested Buff.*—1, John Clarke. 2, H. Johnson. 3, J. G. Edge. *hc*, T. Clarke. *Any other Variety of Crested Yellow.*—1, W. Sherwin. 2, R. Henson. 3, H. Johnson. *hc*, S. Carrington, Chaddesden Siding. *c*, J. Prosser. *Any other Variety of Crested Buff.*—1, S. Burton. 2, J. Bryan. 3, H. Hutchinson. *hc*, A. Knight.

NORWICH (Green).—*Yellow.*—1, R. Henson. 2, J. Bennett. 3, C. Marson *Buff.*—1, E. Orme. 2, H. Hutchinson.

LIZARD.—*Golden-spangled.*—1, W. Sherwin. 2, A. Ufton. 3, S. Cholerton. *Silver-spangled.*—1, S. Bunting. 2, A. Ufton. 3, H. Macconnell, Derby. *hc*, W. Sherwin.

CINNAMON.—*Jonque.*—1, E. Coke. 2, S. Bunting. *Mealy.*—1, W. Sherwin. 2, S. Bunting. 3, H. Hutchinson. *Variegated or Marked Jonque.*—1, E. Coke. 2, H. Hutchinson. 3, S. Bunting. *c*, A. Knight. *Variegated or Marked Mealy.*—1, E. Coke. 2, S. Bunting. 3, A. Knight.

GOLDFINCH MULE.—*Jonque.*—1, J. Durance. *Mealy.*—1, W. Sherwin. *Dark Jonque.*—1, R. Nash. 2, H. Hutchinson. 3, W. Sherwin.

LINNET MULE.—1, S. Bunting. 2, H. Hutchinson. 3, S. Smith.

MULE (Any other variety).—1, J. Durance.

OPEN CLASSES.

NORWICH.—*Clear Yellow.*—1 and 2, E. Orme, Derby. *hc*, W. Walter, Winchester. *c*, J. Audley, Leicester. *Clear Buff.*—1, R. Hanson. 2, W. Walter. *hc*, J. Marshall. *c*, W. Meakin.

NORWICH.—*Marked Yellow.*—1, E. Orme. 2, G. Fisher. *hc*, Prosser & Wood. *c*, W. Walter. *Marked Buff.*—1, G. Fisher. 2, E. Orme. *hc*, D. Audley. *c*, W. Doyle.

NORWICH.—*Variegated Yellow.*—1, W. Jerram, Nottingham. 2, S. Tomes, Northampton. *c*, R. Whitaker, Darley. *Variegated Buff.*—1, W. Meakin. 2, W. Walter. *hc*, J. Stokes. *c*, W. Doyle, Nottingham.

NORWICH.—*Yellow Crested.*—1, T. Keys. 2, W. Sherwin. *hc*, Prosser and Wood. *c*, J. Mann, Burton-on-Trent. *Buff Crested.*—1, W. Meakin. 2 and *c*, J. Hurrell, Bishopwearmouth. *hc*, J. Bennett.

BELGIAN.—*Clear Yellow.*—1, J. N. Harrison, Belper. 2 and *hc*, J. Turner, Birmingham. *Clear Buff.*—1, T. Dove, Sutton-in-Ashfield. 2 and *hc*, J. Turner. *c*, J. Close.

BELGIAN.—*Marked or Variegated Yellow.*—1, J. Turner. 2, J. N. Harrison. *hc*, J. Close. *Marked or Variegated Buff.*—1, T. Dove. 2, J. Turner. *hc*, J. Close.

LIZARD.—*Silver-spangled.*—1, J. N. Harrison. 2, S. Bunting.

GOLDFINCH MULE.—*Jonque.*—1, S. Bunting. 2, E. Stansfield, Bradford. *hc*, J. N. Harrison. *Mealy.*—1, W. Smith, Birmingham. 2, A. Wortley. *hc*, E. Stanfield.

GOLDFINCH.—1, J. N. Harrison. 2, T. Keys. *hc*, S. Bunting.

LINNET.—1, J. N. Harrison. 2, S. Bunting. *hc*, T. Keys.

JUDGES.—*Canaries:* Mr. G. Moore, Northampton, Mr. E. Bemrose, Mr. G. Goodwin. *Bantams:* Mr. G. A. Crewe, Etwall.

MIDDLESBROUGH ORNITHOLOGICAL SHOW.

THIS took place on the 27th and 28th of October, the place of exhibition being the Town Hall, Middlesbrough.

BELGIAN.—*Clear Yellow.*—1, W. Bulmer, Stockton. 2, Stephens & Leeke, Middlesbrough. 3 and *hc*, R. Robinson, Middlesbrough. *c*, J. Calvert. *Clear Buff.*—1, R. Robinson. 2, W. Bulmer. 3, T. Fawcett, Baildon, Leeds. *hc*, W. Appleton, Marton. *c*, J. N. Harrison, Belper. *Ticked or Variegated.*—1 and 2, R. Robinson. 3 and *hc*, W. Needler. *c*, P. Rawnsley, Ledget Green, Bradford.

NORWICH.—*Clear Yellow.*—1 and 2, Adams & Athersuch, Spon End, Coventry. 3, J. Clemison, Darlington. *hc* and *c*, Moore & Wynne, Northampton. *Clear Buff.*—1, Wallace & Beloe, Bide Hill, Berwick-on-Tweed. 2, Moore & Wynne. 3 and *hc*, Adams & Athersuch. *c*, Smith & Preen, Coventry.

NORWICH.—*Evenly-marked Yellow.*—1 and 2, Adams & Athersuch. 3, Moore and Wynne. *hc*, R. Hawman, Middlesbrough. *c*, C. Greenwood, Scarborough. *Evenly-marked Buff.*—1 and 3, Adams & Athersuch. 2 and *c*, Wallace & Beloe. *hc*, W. & C. Burniston, Middlesbrough.

NORWICH.—*Ticked or Unevenly-marked Yellow.*—1, R. Simpson. 2, J. W. Frankland, Whitby. 3, Moore & Wynne. *hc*, Adams & Athersuch. *c*, Wallace and Beloe. *Ticked or Unevenly-marked Buff.*—1, Imhoff & Chapman, Coventry. 2, Adams & Athersuch. 3, J. Clemison. *hc* & *c*, Moore & Wynne.

NORWICH CREST.—1, M. King. 2, S. Tomes, Northampton. 3, Wallace and Beloe. *hc*, W. Bulmer. *c*, Moore & Wynne.

COPPY CREST.—1, Stephens & Leeke. 2 and 3, W. Cotton, Middlesbrough. *hc*, P. Rawnsley. *c*, L. Belk, Dewsbury.

LIZARD.—*Golden-spangled.*—1 and 2, Smith & Preen. 3, J. Taylor, Middlesbrough. *hc*, M. Holroyd, Great Horton. *c*, R. Ritchie. *Silver-spangled.*—1 and 2, Smith & Preen. 3, *hc*, and *c*, R. Ritchie, Darlington. *Gold or Silver-spangled, with Broken Cap.*—1, J. Calvert, Middlesbrough. 2, Fairclough & Howe, Middlesbrough. 3 and *c*, R. Ritchie. *hc*, M. Burton.

CINNAMON.—*Jonque.*—1, G. Gayton, Northampton. 2, Wallace & Beloe. 3, S. Tomes. *hc*, Moore & Wynne. *c*, J. N. Harrison. *Buff.*—1, R. Simpson, Whitby. 2, S. Tomes. 3, G. Cox, Northampton. *hc*, Moore & Wynne. *c*, Wallace and Beloe. *Buff or Yellow Variegated.*—1, T. Craggs, Stockton. 2, M. Holroyd, Stevens & Leeke *hc*, Moore & Wynne. *c*, L. Belk.

YORKSHIRE.—*Clear Yellow.*—1, T. Fawcett. 2, P. Rawnsley. 3, W. & C. Burniston, Middlesbrough. *hc*, J. Cooper, Middlesbrough. *c*, J. Rowland, Skelton. *Clear Buff.*—1, J. Baldwin. 2, J. Garbutt, Yarm. 3, J. Greenfield. *hc*, J. Cooper. *c*, T. Fawcett.

YORKSHIRE.—*Evenly-marked Yellow.*—1, R. Hawman. 2 and 3, Stevens and Leeke. *hc*, T. Tenniswood, Middlesbrough. *c*, P. Rawnsley. *Evenly-marked Buff.*—1, R. Hawman, Middlesbrough. 2 and *hc*, Stevens & Leeke. 3, L. Belk. *c*, R. Robinson. *Ticked or Unevenly-marked.*—1, L. Belk. 2 and 3, J. Garbutt. *hc*, J. Rowland. *c*, E. Graham, Middlesbrough.

GREEN.—*Clear.*—1, W. Sergeant, Skelton. 2 and 3, Stevens & Leeke. *hc*, W. Lawson, Skelton, Marske-by-the Sea. *c*, J. Rowland.

GOLDFINCH MULE.—*Evenly-marked.*—1, Stevens & Leeke. 2, L. Belk. 3, W. Needler, Hull. *hc*, J. Spence, New Hendon, Sunderland. *c*, P. Rawnsley. *Dark.*—1, Moore & Wynne. 2, T. Tenniswood. 3 and *hc*, Stevens & Leeke. *c*, J. Taylor.

LINNET MULE.—*Variegated.*—1, J. Spence. 2 and 3, Stevens & Leeke. *hc*, W. Chalk. *Dark.*—1, W. & C. Burniston. 2, W. Nichol. 3, J. Harris, *hc*, J. Clasby, South Stockton. *c*, J. Spence.

GOLDFINCH MOULTED.—1, J. N. Harrison. 2, T. Allenby, Crossgate, Durham. 3, T. Tenniswood. *hc*, J. Davenay, Walker Fonld, Knareshorough. *c*, Stevens and Leeke.

BROWN LINNET MOULTED.—1, W. Carrick, Middlesbrough. 2, W. Nichol, Middlesbrough. 3, R. Robinson. *hc*, T. Neilson, Stockton. *c*, J. N. Harrison.

ANY OTHER VARIETY OF BRITISH BIRD.—1, W. & C. Burniston. 2, R. Robinson. 3, E. Graham. *hc*, G. Cox, Northampton. *c*, G. Smith, Middlesbrough.

SELLING CLASS.—1, G. Garbutt, Broughton. 2, Wallace & Beloe. 3, W. & C. Burniston. *hc*, W. Hutton, Baildon, Leeds. *c*, Fairclough & Howe, Middlesbrough.

JUDGE.—Mr. T. Clark, Sunderland.

LARGE TURKEYS AND TURKEY BREEDING.

A PASSION for extra size is one of the weaknesses of the American mind. In the decisions given at our fairs, weight is not only an important item, but the one thing needful. In a scale of one hundred points weight would be the equivalent of fifty, in the minds of most judges. It is the big swine, the big pumpkin, and the largest fat ox that take the premium. Economy of fattening, or the process of production, is seldom inquired after.

The same bad taste is likely to affect the decisions in our poultry shows, unless the managers insist upon a more wholesome standard. A large, well-developed bird of maximum size is desirable; a monster is not, for any conceivable purpose, except to excite wonder and draw the crowd. We raise poultry chiefly for the table. What the producer wants in his stock is good quality of flesh, early maturity, and capacity to make the most flesh out of a given amount of food. A Turkey weighing 15 lbs. is just as good for the table as one weighing 30; and most housekeepers would prefer them under 12 lbs. In most markets the lighter weights would bring the higher price. It is only in the region of large hotels and boarding-houses that the very large birds bring an extra price. For what object, then, do we want large breeding birds, and how large do we want them? It takes about three years for a Turkey to attain his largest weight. If at twelve months a gobbler reach 30 lbs. live weight, at two years he would reach 35, and at three years 40, or a little more. But it is rare to get a male bird above 40 lbs., and then it is generally by some process of stuffing that destroys his stamina and ofttimes his life. This weight is excelled sometimes; but about the time one thinks he is almost sure of a forty-five pounder, the prodigy sickens and dies.

It may be assumed, then, that 40 lbs. is about the limit to which a vigorous Turkey cock may be safely carried, and from half to two-thirds of that weight is the last safe limit for the hens. With breeders of this size, and a little under, we should get large strong chicks, that will economise food, and mature earlier than the offspring of common-sized birds. No bird yields more quickly to treatment than the Turkey. The influence of a large-sized gobbler in a flock is immediately visible in the increased size of the chicks. The introduction of wild blood increases the hardiness of the young, a larger proportion of the eggs will hatch, and a much larger number of young will be likely to grow up. With a little painstaking it is quite easy to breed to any desired shade of plumage.—(*American Agriculturist.*)

CAMBRIDGE POULTRY SHOW.—This is well worthy of the attention of exhibitors, for besides the prizes there are twelve pieces of plate to be won, five of which are for Pigeons, and one for Rabbits. We regret that the Committee commit the error of having the Dorking prizes for "any variety." What chance have the White against the Coloured?

A GOSSIP ABOUT BEES IN NEW ZEALAND.

I FANCY I am beginning to advance a little in apiarian lore. For the last fourteen years I have never been without a good stock of bees, and I am happy to state that I keep gaining considerable knowledge about them from year to year by only paying them a very moderate amount of attention.

Bees here have few enemies, mice being those only of which I have any knowledge; nor have I ever discovered any disease amongst my stock, which consists generally of three swarms annually from each hive. I attribute this part of my success to allowing nature, with very little assistance from art, to have its own way. I also find that a free circulation of air all round each hive is as important for the sanitary condition of the bees as for that of the cottage here. Occasionally with me two casts will unite of their own accord when swarming. This occurred this season, and I have had to provide them a house in proportion.

When we harvest our honey annually we make several large casks of mead for use in-doors through the winter. Some of the beeswax has already been sent for disposal to England by one of our merchants. I find the best-provided stocks for the winter are the greatest robbers of their neighbours. When this happens I generally use a blockade all round the hive to prevent further depredations. The thieves then, finding they cannot obtain admission, cease in a few days to be troublesome, and leave the weaker swarm alone. Early and late seasons have a great deal to do with swarming here. Our bees have some very severe weather to contend with occasionally during the spring months, but they are never short of food all the winter if they dare leave the hive in the middle of the day to procure it—gorse hedges, broom, &c., in full flower for them to work at. I find the best way is, if practicable, wherever the swarm settles—for it is generally in a warm, sheltered, sunny place—to hive the bees on the spot, which invariably seems to suit them with me after the wedding trip or excursion is over. We hive our bees in boxes, which I place on the ground. If

put in a bee-house they would sometimes stand a good chance of being blown over, for I presume you have little idea in England what windy weather is like in this boisterous country.

I attribute my success to using large boxes for housing my bees. I consider giving the bees a large house to work in is doing them good service. I think bee-keepers at home cannot form any conception of the quantity of honey harvested in Canterbury alone annually. I notice that my bees work very little during the extremely hot weather which we experience, but remain outside their houses night and day by the thousand, fanning each other with their wings; at the same time, from the heat, the honey is running out of the comb like water. In hot weather I now take the precaution to shade them from the piercing rays of the sun with some spray. To finish my gossip about my management of bees, I usually place during the winter months a large board on the top of my bee-boxes quite flat. This board is much larger than the box, to prevent the dripping from our heavy rains, which occasionally last for three days at a time.

Can any of our learned bee-masters at home tell me when the queen bee deposits the first egg, and when she deposits the last egg? Anything I have written I do not think new. They are only notes of my fourteen-years experience with bees in Canterbury, New Zealand.—WILLIAM SWALE.

OUR LETTER BOX.

BRAHMA CHICKENS (*Medicus*).—The weight of your birds is good, and they will hold their own in competition. The twisted flight is a disqualification. It is useless to exhibit any bird having it. The white in the tail is quite immaterial. The vulture hock is a very serious fault. The brown on the wings may be passed over. If you have one cockerel—and you surely should have one out of six—without any twist in the flight, and without vulture hock, you may show him safely. Pullets seldom have twisted flights; they are subject to vulture hocks, but as you do not mention them we hope they will be exhibited satisfactorily. Their weights are good.

BANTAM COCKERELS DYING (*A Subscriber*).—There is something about the place that is injurious, if not poisonous, to the fowls. There is every appearance of poison. Tar water is often beneficial to fowls, but tar itself is very injurious, and has much the effect on the throat of a bird that a large dose of birdlime would on that of a human being. It prevents from swallowing, and the neck is kept stretched out to diminish, if possible, the discomfort of such a state of things. The reason why only one bird gets it is, there is only enough for one. We know no cure.

WHITE COCHINS VULTURE-HOCKED (*H. E. P.*).—Vulture hocks are so common among White Cochins, that if they were always a disqualification many classes would afford no competition. Where they are shown against birds free from this defect, those having it are disqualified. The committee of a show make the most advantageous terms they can for the carriage of birds to and fro. So far, however, from paying the expense of their going to and fro, it is always a stipulation that carriage shall in all cases be paid by the exhibitor. The only exception is where birds are sold; they are returned at the expense of the purchaser. There is no expense incurred by an exhibitor while his birds are at the show.

POULTRY FOOD (*W. C. D.*).—We advise you to give up the boiled potatoes, and to supply the liver sparingly. Give them plenty of green food.

BREEDING DUCKWING GAME (*R. P.*).—As a rule the manufacturers of Game fowls do not publish their prescriptions. In all poultry-making the manipulator is only guided by the fact that he must seek a bird possessing in excess that which his fowls lack. The commonest cross is with a Black Red to get brilliancy of colour. Your best plan will be to buy a sitting of eggs from some well-known prizetaker. Mr. Baily, of Mount Street, is a very large importer of Antwerps, we advise you to apply to him.

NON-CLOSING OF BEAK (*Brown Red*).—Wash the cockerel's mouth with alum and water. Remove any part of the excrescence that will come away with your nail, and then use caustic to it freely.

PREVENTING FLYING (*T. E. K.*).—Tie the flight feathers together with a piece of wire. As you may be in doubt as to what constitutes the flight, we will call it the first eight feathers of the wing.

GROUND OATS (*B. H.*).—By ground oats we mean the whole of the corn, husk and all, ground up so fine that it will mix like flour. We do not wonder your fowls did not like the ordinary ground oats; when mixed they have the appearance of chaff wetted up together. In Sussex, and in some parts of Surray, they have stones dressed on purpose, and the consequence is the whole of the corn is pulverised, and mixed into a rough dough; there is no occasion to sift anything. All animals like it—pigs, cows, horses, and poultry thrive upon it. It should not be mixed with barley or any other meal. It should be slaked with cold water. Fowls like whole Indian corn better than the meal made by grinding it. It is bad to make a pot-pourri of all your food, because you then tie your hands, and put a change of diet out of your power.

FOWLS SUDDENLY SNEEZING (*W. F.*).—Yours is not an uncommon case. Driving rain and cold winds often affect a whole yard. You need not be afraid of your dietary being too exciting. Bran and sharps are not high feeding, and may counteract the effect of the barley and Indian meal. You need not be uneasy about them. Let them have their liberty, and give them stale bread steeped in strong ale till the attack has passed. Discontinue the bran and sharps.

WARMING A PIGEON-LOFT (*Yorkshire*).—We do not approve of warming a loft by fires of any kind. Almond Tumblers, the most chilly of all Pigeons save African Owls, have lived and prospered in Canada. The damp may best be cured by good drainage; covering up damp only increases it. Secure a well-drained place, good walls, and well-fitting doors, you need fear nothing. It is not cold, but damp and draughts that injure Pigeons. The temperature you name is not a bad one.

RABBIT NETS (*W. Sheppard*).—We know of no makers, most countryman know how to make them. The dealers in birds, &c., in St. Martin's Lane, could probably supply you.

TORTOISE MANAGEMENT (*H. Nutt*).—They live upon lettuce leaves, sow-thistle and other succulent vegetable produce. If there is a heap of leaves in the garden your tortoise will bury itself in that heap; if not, bring it in-doors and place it in a cool cellar or cupboard, covered, but not wrapped up, by a piece of carpet. It will remain torpid until spring.

GRAPE JAM.—I think it is not generally known that excellent jam can be made from unripe grapes. At this time of year, vines in unfavourable positions are displaying numerous bunches of grapes that have no chance of ripening, and it is a pity to let them be wasted. The jam should be made like that from any other fruit. A pound of grapes to three-quarters of a pound of sugar. If well boiled the jam will become firm when cold, with a flavour very like guava jelly.—E. D.

REMARKS.

25th.—A very fine day; though rather foggy at night.

26th.—Very foggy all day; clearing off towards night.

27th.—Warmer and clearer, a tolerably fine day, but rather oppressive; and very slight rain occasionally; fine night.

28th.—Fair day, but only fitful sunshine, the air warm and much clearer than it has been lately.

29th.—A very beautiful day, warm, clear, and bright.

30th.—Fine till noon, then dull and slight rain soon after, and occasionally during the remainder of the day.

31st.—A very similar day, being fine in morning; and dull in the after part.

A damp autumnal week, with frequent mist and fog, but only a sprinkle of rain. A similar remark applies to the whole month of October, which has had less rain than usual, and yet has been one of the dampest for many years.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 1.

AMONG the general trade there has been a fair attendance during the past week, and prices remain much the same. Continental goods of first-class quality are barely sufficient for the demand, but last quotations have been the rule, and while the weather remains open we shall not expect much advance. Potato trade heavy, with large stocks.

POULTRY MARKET.—NOVEMBER 1.

THERE is a slight improvement in trade, and, if the weather were cooler, there would be in price. We may, however, look for it.

From observations taken near London during forty-three years, the average day temperature of the week is 49.8°, and its night temperature 34.2°. The greatest heat was 68°, on the 12th, 1841; and the lowest cold 18°, on the 15th, 1868. The greatest fall of rain was 1.24 inch.

THE GLADIOLUS IN 1871.

IT is said of the peculiar crop of this county (Kent) that it tries a farmer's patience more than any other, and that you can never calculate on your Hops until you have the money in your pocket. What Hops are to the Kentish farmer, the Gladiolus is to the gardener who cultivates it—the most uncertain, the most provoking of all his pets. Meeting my old friend and neighbour Mr E. Banks, of Sholden, the other day, I said, "Well, what about the Gladiolus this year?" His reply was, "I am almost sick and tired of them; again the disease has attacked mine, and I have lost very many of my best sorts, and yet I cannot give them up." My own experience is of the same character, and they really do try one's patience. Evidently, too, from Mr. Douglas's notes, he and others have experienced a like result, while my old friend Souchet affirms the same. The flower, therefore, must have powerful attractions if, in spite of all this uncertainty, it retains, as it does, its popularity.

The disease is a mysterious thing, and is, as far as I can judge, very analogous to that which attacks the Potato. It attacks the Gladiolus at particular stages of growth, and is independent of all kinds of soils and methods of culture. A plant will grow well all through the season, will throw up a good spike of bloom, and even after that will be struck with the disease. The foliage will turn yellow, and when the corm is taken up it is all over black spots, which speedily spread, until it all perishes by a species of dry rot. I had bulbs from which I cut blooms for the Metropolitan Floral Show on August 31st, and yet after that the bulbs perished. That cultivation has nothing to do with the disease I am sure from the fact that, in the same bed and of the same varieties, some have perished and others not; thus, I had five bulbs of Adolphe Brongniart (imported bulbs); of these four were sound, one horribly diseased. I had two bulbs of Horace Vernet, the same thing took place; but what is more singular still, I had bulbs from whence two shoots came, and of course two bulbs were formed; one of these was perfectly sound, the other gone. The idea entertained by some—amongst others, Mr. Douglas—that the best blooms were to be obtained from imported bulbs, I do not find to be borne out by fact. I had it tested this year, having planted of some varieties bulbs that I had grown myself, others that were imported, and, again, others that were grown from "spawn" by Mr. Banks, and I could not see that there was any noticeable difference in them. The theory that this disease is to be attributed to the high breeding of the varieties, or, rather, to the breeding in-and-in, will not, I think, hold good. I have had Brenchleyensis this year attacked by it, and such old flowers as Penelope, while Meyerbeer and Madame Furtado have been free. If it be a disease analogous to the Potato disease, we know that theory did not account for it; for the Potatoes raised from the seed of wild ones were affected by it, and the commonest and roughest varieties also suffered. I know of no remedy that can be suggested for the Gladiolus disease, and I fear that growers must be contented to take their chance. There are, however, I think, two things to be avoided in cultivation—not to allow any fresh manure to come into contact with the bulbs, and not to allow them to suffer from want of water, if the season be dry.

Complaint has been made as to the number of varieties sent out of late years by M. Souchet, and I think it is a pity that he should have deviated from his original plan of sending out six or eight each season, but it is to be remembered that he is honest in the matter; he has his three or four classes arranged according to price, and evidently leads growers to the inference that the best are to be found amongst the four or five high-priced ones. As I have before said, he does not trust to his own judgment in the matter: two or three of those best acquainted with the flower assist him in classifying and arranging the new varieties. Mr. Douglas says only about 25 per cent. are good. Well, that is about what he puts the high-priced at, though sometimes, indeed, it is different; for example, Nestor, which he places in the lowest class, will, I think, be grown extensively as the best yellow we have; while Pericles, one of the dearest of last year, I think, will not hold its position, and has not any claim to the place assigned to it. This excessive supply of new varieties of flowers is not confined to the Gladiolus or to France, as the catalogues testify. Much has been said about the English varieties of Gladiolus, but it is a noticeable fact, that, unless in the stands of the raisers, we never see any varieties but Souchet's; why I do not pretend to say, but the fact remains.

In answer to many inquiries as to the best varieties of last season, and the probabilities of the present, I am inclined to place at the head of last year Horace Vernet, flowers of brilliant colour and large size, with a good spike. Sir J. Franklin is a remarkable flower for its novelty of colour; the spike is hardly sufficiently long. Talisman is another novel flower, but I fear of delicate habit; and the same, from what I have experienced and heard from others, must be said of Phidias. Edith Dombrain I have seen very beautiful, although my own spikes of it were not large; it is one of those varieties that do not rapidly increase. Souchet told me it was raised ten years ago, but he had not been able to increase it sufficiently to put it in commerce until last season. Primatice comes next; while, I think, many will like Nestor. Van Spandouck, although brilliant in colour, is not a first-class flower. Amongst others are some which are exceedingly pretty and ornamental, and that years ago would have passed muster, but are not equal to one's idea of first-rate flowers. Of the flowers of 1869 Orphée is, I think, decidedly the best; Armide is fine; Delicatissima very pleasing in its novel shade of colour; Rosea Perfecta often very pretty and useful; and Rosa Bonheur very fine and vigorous. Robert Fortune is also very fine at times.

When I was at Fontainebleau at the end of August the greater portion of M. Souchet's flowers were out of bloom and, indeed, the great bulk of his collection is now grown at Montereau, the soil there being much more suitable for it

than that of Fontainebleau; consequently I did not see many of his new varieties. One I did see, which struck me as being very fine—Phœbus, very brilliant in colour, and with a fine spike. Beatrix will also, if I mistake not, be an addition to our white flowers, which La Candeur of 1869 certainly was not; while Madame Desportes, our very finest white, seems to be of a very delicate constitution. I have lost this season all I had of it, and Mr. Banks tells me he has great difficulty in keeping it.

As several have asked for my opinion of the older varieties, I here give the result of my observations, regarding them in the light of flowers that I should wish to set up in a stand, possessing most of the qualities required in exhibition flowers:

Adolphe Brongniart	Impératrice Eugénie	Maréchal Vaillant
Adanson	James Veitch	Marie Dumortier
Armide	Lacépède	Marie Stuart
Delicatissimum	Lady Franklin	Meyerbeer
Dr. Lindley	Legouvé	Michel Ange
Etendard	Le Titien	Molière
Eugène Scribe	Madame Desportes	Princess Marie de Cambridge
Eurydice	Madame Dombrain	Reine Victoria
Fulton	Madame Furtado	Sir William Hooker
Homère	Shakespeare	Virgile
Schiller	Ulysse	
Thomas Methven	Madame Vilmorin	

The judgment of French growers must differ from ours in some way, for I find amongst others Bernard de Jussieu described in the most glowing terms as a remarkable plant, and Semiramis declared to be without a rival. Now, neither of these is in my opinion a show flower; yet when I saw Semiramis first at Souchet's I thought it truly unrivalled, and never was I more disappointed than when it bloomed with me. All who have bloomed it seem to agree in their opinion of its demerits. The above is the result of my experience; and if there be anything which I have omitted that my correspondents have desired to know about, I shall be glad to supply the omission.—D., *Deal*.

FRUIT TREE PLANTING AND CULTURE.

If in the following notes a tendency to repeat former statements is observable in some instances, it is because experience has shown them to be sound, and that the principles they embody are highly important and very necessary to success in fruit-tree culture.

Too much stress can hardly be laid upon the importance of securing a thoroughly prepared station for a fruit tree before planting it, but first of all the necessary drainage of the land should be attended to. Nothing can be more annoying than to be unable to take advantage of a few days' favourable weather for planting, owing to many of the holes being full of water, which there is no prospect of getting rid of for some time to come. When it can be done, the stations should all be made before there is much danger of rain. The trees should be ordered early in October, so as to secure good plants, and be had from the nursery early in November. Never suffer the packages to remain a moment longer than is necessary in the hands of those to whom they are entrusted, during their transit from the nursery to the garden, but secure them as quickly as possible. Unpack, examine, and check off each tree, passing it on for planting or laying-in at once. Of course it is in every way more advantageous if the trees can be planted as they arrive from the nursery, but when this cannot be done the roots of the trees should be laid-in in soil temporarily, ready for planting upon the first favourable opportunity, which must be carefully watched for and taken advantage of. Mulching, staking, and naming should closely follow the planting, or, to be more correct, a label bearing the name should be found on the station when the tree is taken to be planted, for, to save time, the position of each tree should be decided upon before the planting begins. In addition to labelling the trees, a ground plan of the garden or orchard should be made, and the position of each fruit tree marked upon it with its name, as then no confusion can arise from the loss of labels.

Some time ago in a paper on this subject I strongly advocated the heading-back of young fruit trees at the time of planting. The soundness of my remarks was questioned by some at the time, but I am glad to say that a more extended practice and close observation since then, have confirmed the truth of what I then advanced. I know it requires some confidence and a thorough knowledge of fruit-tree culture to prompt one to cut a fine young tree of 5 or 6 feet in height, with a bushy head of stout vigorous wood, down to a mere bare stump at the time of planting, but I think the result need never be feared if the tree is healthy, planted in a thoroughly prepared station, and cared for as it ought to be. I have hitherto advocated the planting of "maiden" trees, but experience has taught me that it is far better to plant larger trees which have already undergone a year or two of training in a good nursery. When such trees are received from the nursery, each must be pruned as it may appear to require. No set rule can fairly be applied to a number of trees. Take, for instance, a number of such trees as a respectable nurseryman will send out as fine, vigorous, selected pyramids; the majority of them will be tolerably well furnished with shoots from the base upwards. The pruning of such trees consists simply in thinning and shortening the young wood. But there will also be some healthy enough and in full but misplaced vigour, that must at once be shorn of all their beauty by shortening the stems to about 18 inches from the base. Of a number of Apple, Pear, Plum, and Cherry trees, the stems of which were then nearly an inch in diameter, so pruned when planted last autumn, not one has failed to make a fine growth, averaging about eight fully-developed shoots a yard long upon each plant. One, a New Hawthornden Apple, has twelve stout shoots, each from 3 to 4 feet long. In doing this I consider I have laid the foundations of some handsome pyramids, for it is well known how highly important it is to secure and afterwards maintain an equal distribution of vigour in a fruit tree, and it is almost entirely owing to this principle not being fully recognised or practised, that they so frequently assume an appearance totally void of symmetry, and not nearly so productive as a well-trained handsome tree. I would not advocate symmetry at the expense of utility, nor need I do so, for the two things are so thoroughly compatible that they can invariably be united, whatever may be the variety so treated. It is well to allude to this, as I have noticed in several instances a tendency to carry the pinching and dwarfing of such trees to a hurtful excess. It is well ever to practise and advocate a vigorous use of the pruning knife, but such practice must always be tempered with judgment and prudence, and due care must be taken that the full free flow of sap is not interfered with.

Let it not be supposed by beginners that after a fruit tree is planted no further care is required. It must be closely watched as the buds swell in spring, especially in such a one as we experienced this year, when blight and caterpillars abounded. I have no faith in the sensational fruiting of newly-planted fruit trees; rather let us strive to promote the greatest possible vigour both in root and branch, taking care to guard every shoot from being broken by strong wind, and only checking the too-vigorous growth of the highest branches by pinching. Thus the first year is altogether devoted to establishing the tree in its permanent position; then in following seasons, as the tree gains size and strength, its fruiting properties may be suffered gradually to develope until it becomes one of the most useful and attractive objects in a garden.—Edward Luckhurst.

SEDUM FABARIA OR SPECTABILE.

I quite agree with all that Mr. Record has said (see page 254) concerning this Sedum as a bedding plant. When visiting the well-arranged flower garden at Hampton Court in September last, I was highly gratified to notice the pre-eminent position it occupies there, planted in masses, in the large, square, old Dutch style of beds, where it is seen to the greatest advantage—so much so, that those who may only have seen single plants can form but a remote idea of its true merits. Apart from the little skill required to grow it at any season of the year, and the small amount of labour involved in securing from it a beautiful display of autumn flowers, it offers the advantages of growing and blooming well under large spreading Yew trees, where we often see some of the choicest succulents dwindling. For such places nothing is more suitable than Sedum spectabile. Its glow of rosy purple flowers harmonises well with the dark Yews, and affords an amount of colour not to be obtained from other sources. Its lateness in flowering I consider no objection, as even when not in flower it has an excellent effect. Though there are many other Sedums of good quality, this may be considered the best for bedding where not classed with some of the stronger subjects. In my opinion it is too tall for its place on the rockwork at Battersea, for which some of the dwarfer species are better adapted. I believe Mr. Donald has bedded-out Sedum Fabaria at Hampton Court in former years with the same satisfactory results.—J. M.

Sedum Fabaria forms a good addition to our bedding plants here, and I consider it is a very useful and beautiful autumn-

flowering plant. It is perfectly hardy at this place, though we lift it in spring and divide it for redistribution in other mixtures. It would remain in one place for several years like any other herbaceous plant. It is essentially an amateurs' plant, and is well suited for those who have limited accommodation under glass for rearing the more tender flowers. Where bedding-out, as it is here, is looked upon more in autumn than summer, the value of this Sedum is even greater than elsewhere. I join Mr. Record and Mr. Robson in recommending such a good and useful plant to public notice.—H. Knight, *Floors Gardens.*

FORCING VEGETABLES.—No. 2.

THE KIDNEY BEAN.

This delicious vegetable may be very successfully forced in hothouses, and on hotbeds under pits and frames. In some large establishments the supply is kept up all the year round by following the out-door crops with those grown in pits and frames, and then by succeeding crops grown in pots and boxes, so that at Christmas and the New Year dishes of it can be placed upon the table. The Kidney Bean, however, is not so easily forced as the Potato, although a crop may be depended on when proper attention is paid to its culture. To keep a regular supply of several dishes a-week during winter, considerable space ought to be set apart for the culture of Kidney Beans, and if they can be allowed a house to themselves so much the better. When cultivated among other things, as very many gardeners are compelled to grow it, the Kidney Bean becomes an agent for the breeding of red spider, its greatest enemy, which attacks at once every other plant associated with it. Unwearied attention, therefore, must at all times be directed to check the appearance of that great pest; and, again, the treatment necessary for the successful culture of the Kidney Bean is not of such a kind that other plants may be submitted to it for any length of time without injury.

Taking first late forcing, which continues from September up to Christmas, beginning when it is no longer safe to plant them out-doors, the protection of a frame or pit with glass and without bottom heat will answer very well for the first two or three crops. In other respects the treatment given to these crops is so similar to that of those out-doors, that very little need be said about them, beyond reminding those who intend to cultivate the Kidney Bean at this season, that it enjoys a good, rich, open soil with plenty of drainage and moisture, requiring at the same time a l the heat the sun affords at this time of the year. For the crops planted in October, November, and onwards, bottom heat will be needed in some form or other, and I believe it has been a subject of discussion among gardeners whether it is better to provide that bottom heat by making-up a hotbed of manure and planting the Beans upon it, or by growing the plants in pots and placing them in some highly-heated structure, such as a Pine stove. For my own part I would give the preference to pot culture both for late-autumn and early-forced crops, but circumstances will often be found to limit the practice of one rule alone, and both have to be tried.

I think there is not a doubt that for a series of sowings the planting-out system would yield the most produce, and the Beans would be well grown out. Pot culture, I believe, is mostly practised in the winter months, being more convenient, since at that time of year, as light is deficient, they can be elevated, and if heat should decline the pots are moveable. The plants have a less vigorous growth, but the crop is often quite as heavy as when planted out. However, if grown on the planting-out system, I should advise a bottom heat of 60°, a top heat of from 70° to 80°, and a so.l made up of equal proportions of loam and manure, but not laid on the bed more than 9 inches deep. Instead of planting the Beans in the bed at first, they ought to be raised in pans or boxes and afterwards planted out; this checks a too-vigorous growth, and does not injure the crops, but I believe it promotes an earlier maturity. There is one advantage that a planted-out crop has over one grown in pots—it is not so liable to the attacks of red spider from having a more uninterrupted rooting space; but, when in bloom, the setting of the crop is a more difficult operation; it not being possible to give the Beans a free circulation of air, for, generally speaking, the places used for this sort of forcing are very small and are planted closely, the usual distance being 3 inches in the row, and 1 foot between each row. A circulation of air through the whole, therefore, is a thing to be accomplished if possible when the Beans are first planted out. No water should be given them at first, and not much at any time until they show signs of growing, otherwise whole rows of the plants will damp-off at the collar, but afterwards water of the same temperature as that of the house must be given in plenty, more especially after the crop is set; they should not then be allowed to become dry either at root or branch.

I believe autumn forcing of the Kidney Bean is not often practised, at any rate it is not thought so much of as early forcing by some. A dish of Beans for Christmas or New Year's-day is generally what gardeners are called upon to do, and to that I will direct my remarks. For Christmas the Beans should be planted six weeks before the time, or even more than that, for while approaching the shortest day everything grows very slowly. I cannot advise any better plan than that of planting the Beans in pans or boxes laid in so that they do not touch each other. When they are about 3 inches high, or just before they begin to make a shoot from the seed leaves, they should be transferred to the pots, using 12-sized pots, and putting five plants in a pot—that is, four round the sides and one in the centre. The same sort of soil should be used as for those planted out, only it should be warmed in the house before use, and in potting should not be pressed too firm, nor should the pots be filled full. My plan, and I have found it answer well, is to top-dress the Beans with rotten manure after they have been staked, which should be done as soon as they are started well in the pots. For this purpose I lay by all the worn-out birch brooms, and every twig of birch makes an excellent stake for each plant, doing without being tied if placed outside of the plant; and the only thing required to be attended to afterwards is plenty of light and heat—the same as for those planted out. They should be kept dry overhead when in bloom, but well syringed and watered at the roots, not allowing them to become too dry at any time during their growth. After the first crop is well established in pots the second crop should be sown; when the first crop is fit to gather the second should be just coming into bloom, and other crops should be coming on in proper succession.

The sorts often grown for forcing—all good in their way, such as Fulmer's Forcing and Newington Wonder—bear well, and are of a dwarf habit, but the pods are very small. I have tried most of those suitable for forcing, and have fixed upon the China or Robin's Egg as the best of all. It is certainly a better cropper than any other I know, and a very sure one, as it is not at all delicate in constitution.

With regard to the seed, I advise the use of that one year old in preference to that grown during the present year. The former is well matured and ripened by time, and, consequently, does not grow so vigorously, which makes it more suitable for pot culture, but the latter when sown in pans rots very much instead of coming up, and the plants I find also damp off after being potted much more than the others; this, I think, is purely from the want of age. For pot culture the plants should be placed as near the glass as possible, and in the hottest part of the house if grown among plants; and if grown in a structure by themselves, it is hardly possible to give them too much heat provided it is associated with plenty of moisture Thomas Record.

THE LAMB FERN.

The history of the Lamb Fern (Cibotium Barometz) is curious, as affording a striking instance of how our unquestioning forefathers accounted scarcely anything too marvellous for belief, provided it came to them from the ends of the earth, and of the way in which travellers' tales, in course of time, came to be proverbial for the unsubstantial nature of their foundations. In those days—two hundred years ago—something of a sensation was created in this country by the discoveries of certain travellers in Eastern Tartary. What they discovered was not a mare's nest, but whole flocks of sheep growing in the plains, rooted to the ground by their four legs, instead of roaming about at their own sweet will. So far they were vegetables, otherwise they were clothed with the finest Thibetan wool of a cream-white colour, and their mutton was made up of flesh and blood, and, we may suppose, of suet, like other civilised sheep. Like Sam Weller's vision, however, their range of pasture being limited, except in the case of some well-situated, long-necked individuals, the proportion of suet to skin and bone would of necessity be but small. So long as the herbage within their reach lasted they grew and fattened; when it was all done, they died and withered away. Then the Tartars gathered the wool, left the carcase for the wolves, sowed another

crop, and, no doubt, kept up a regular succession. Such was the system of Mongol sheep-farming two centuries ago. The little nucleus of truth around which all this nonsense clustered was simply this—like most of the Polypodiaceæ, C. Barometz, as an auxiliary means of propagating and spreading itself, sends out numerous rhizomes or creeping stems. These sometimes assume strange fantastic forms, among which may easily be traced those of sheep or lambs; no doubt that, in their native soil and climate, they will also attain to something of a sheep-like size, and their being covered with a thick coat of wool almost completes the resemblance. A good stretch of the imagination would do the rest, and invest them with legs, and horns, and everything else which a decent sheep requires. I have had a young plant of this Fern for some time, but nothing lamb-like has yet made its appearance. It has handsome bipinnated erect-growing fronds, and requires a stove temperature.—R. D. Taylor.

SELECT PEARS.

To the two excellent Pears which "T. R." brings to notice I beg to add another—namely, Fortunée Boisselot, also of Nantes origin. I have fruited it in a pot, and have some very fine fruit, quite as large as the contour of it in the "Dictionnaire de Pomologie." Being a late Pear—February in France, April here probably—it will prove of the three the most valuable. We had fruit of Souvenir du Congrès last year of above a pound weight each. Like one of its parents, Williams's Bon Chrêtien, it does not keep long, but it is nevertheless an acquisition to the September supply. I have not yet fruited the Beurré de l'Assomption, though we have it with several other new Pears, and hope it will prove a useful one. A French friend has written of it to me in high terms, also very highly of the Fortunée Boisselot as being a fine-flavoured Pear.—H. Knight, *Floors Gardens.*

ASPARAGUS CULTURE.

The Asparagus is a hardy plant, and yet when the buds at the base of the shoots are near the surface they sometimes suffer considerably from frost. This might have been one of the reasons of Asparagus being grown in beds, and of the regular manuring and earthing-up being performed before winter—a plan which was almost indispensable, when, instead of Asparagus all green, it was deemed essential to send to table 6 or more inches of stem blanched like Sea-kale, with from 1½ to 2 inches of green top on the surface. If I had plenty of ground I think I would again revert to the bed-system of culture. It has its advantages, for you can do the plants greater justice during the summer, and Asparagus may thus be grown in a quarter much in the same way as Onions or Parsnips. The spaces between the beds are also useful for such summer crops as Cauliflowers.

For various reasons, and more especially for making the most of a small extent of ground, I have for some time grown Asparagus in rows 2 feet apart. On first planting these rows the plants were placed on little elevated ridges, as the ground is rather stiff. In course of time, in consequence of the successive surfacings of rotten dung, the ridges are lost sight of, and the plants appear almost on a level. In this way I have had plenty of good shoots with but little trouble. All my experience points to the simple fact, that to encourage the growth of Asparagus, there is nothing like summer manuring and summer manure-watering.

Why do I mention this? Simply that many with small gardens, who have hitherto looked upon Asparagus as beyond their reach, may see that they could have good gatherings from rows that would singly take up little more space than a row of good Cabbages or a couple of rows of Carrots. Many a thriving tradesman is deterred from thinking of Asparagus on account of the deep trenching, the endless amount of manure, the necessary drainage, and the care required to manage even a small bed of Asparagus; but were the conviction spread, that with moderately loosened and enriched soil Asparagus would do remarkably well with a surface-mulching or manuring, its culture in small gardens would be increased twentyfold, and many an invalid would be refreshed by the dainty dish that at present is felt to be out of reach.

There is not the slightest necessity for trenching and putting in bones and other kinds of manure 3 feet deep. The Asparagus, on the whole, is more of a surface than a deep rooter. A depth of 2 feet, or 20 inches at least, of well-stirred soil would be helpful in the way of drainage; and if no more than 15 or 20 inches of good staple could be procured, then plant in beds, or in rows a little elevated, so as by degrees to increase the depth of the good soil. As a row might suit many of your readers having small gardens, I would advise them not to be too particular in digging down manure too far from the surface. Have some mellow, rotten dung mixed with the soil at from 6 to 9 inches from the surface; mark out the place for the row; spread the roots well out upon it, and be careful not to allow the fine fibres to become dry after taking up the plants for planting. After watering the roots raise about 5 inches of soil over them, sloping it both ways. Mulch with rotten dung; and mulch or give manure water in dry summer weather. As regards mulching in summer, the Asparagus may have anything from rotten dung to short grass; and plenty of house sewage, not too strong, should likewise be given. This, and not deep trenching and deep manuring, is the easiest plan of obtaining good-sized, crisp, sweet Asparagus. There are thousands of your readers who could give a little manure to a row of Asparagus in autumn, and more manure by a sprinkling of salt in summer, who never could take the trouble of making an Asparagus bed in the old-fashioned way.

With regard to the plants either for rows or beds, the easiest plan is to sow the seeds not too thickly, and thin the plants out to 6 inches apart. I have tried that plan, and very successfully, but under the best treatment a gathering can hardly be expected in less than three years from the time of sowing, and it would hardly be economical for those with but little ground to have it occupied all that time without obtaining remunerative produce. Besides, though I have tried with fair success sowing where the plants were to produce, I prefer transplanting plants from one to two years from the seed. In the latter way, by sowing rather thickly, a small space will hold a large number of plants, and then when we transplant fair returns are obtained in the second year, and the ground is, therefore, made the most of.

Transplanting may be performed every month from the present time to spring, but on the whole spring planting is preferable—just when the young shoots are from 1½ to 3 inches in length; but in either case the roots are carefully spread out, damped, covered, and then mulched. Only let the idea prevail that surface-mulching with rotten dung and a little salt in summer are of more importance than deep trenching, and many an artisan's and tradesman's table will be graced with Asparagus in its season.

As regards kinds, I may be wrong, but my opinion, based on practice, is that there is only one kind, I might almost say one variety of Asparagus, and that differences in appearance are less owing to seed or variety than to the mode of culture and variations of soil. Asparagus might be made passable in the stiffest hungriest soil, but that produced in a deep, rich, light loam could not easily be equalled. Hence in very stiff clayey loams burning a part of the clay, elevating the beds and rows, and lightening the soil with rotten leaf-mulching and lime rubbish, will be of great advantage.

Before cutting down a part of the Asparagus here, a quantity of seed was gathered, and then the tops were thrown into a heap to be burnt or charred. As showing the peculiarities of the season, many of the berries of the Asparagus were greenish-brown instead of ripe and bright red. I resorted to burning the tops rather unwillingly, as when cut before the feathery foliage falls, they make a good protection and light withal. The seed, however, which is left in such cases so drops, and grows afterwards, as often to render Asparagus a troublesome weed.

Forcing.—It is necessary to cut down early the Asparagus which is to be forced early, and if we had plenty of ground and little glass, I should like to have Asparagus from November until it came in from the open ground. For obtaining the earliest before Christmas, no mode is better than the old, though wasteful plan, of taking the roots up and packing them closely on a mild hotbed, with a covering of 2 or 3 inches of sandy loam and leaf mould. For such early forcing an old bed is often chosen. I much prefer, for all forcing, a piece from which the cutting in spring was early stopped, so that growth and ripening were early completed. With such materials, even for a fair-sized establishment, I have been satisfied with one or two lights of a frame at a time, generally using one at first, and in a fortnight or three weeks afterwards taking to the second. There is no better plan for obtaining early Asparagus in the late months of the year, nor, indeed, at any time, so far as the supply is concerned; but the waste of old, good plants

is something serious, and accounts for the high price that Asparagus must ever bring in the winter and early spring months. Hence the importance of having beds of Asparagus heated by hot water, or by fermenting material, where the plants remain without lifting or thus destroying them. Beds thus heated will yield well when forced every alternate year. It is to me always a matter of regret to see destroyed, by lifting and forcing in a frame, those fine roots, which, if left in the ground, would have done service for years, for they are of no further use after having been forced. I think heat beneath the roots adds to the vigour of the shoots, and plenty of light makes them nice and green and crisp, but any place where there is a heat of from 50° to 60° will bring Asparagus on well. I have even forced the shoots to push in a dark place, cut them when they were 6 or 7 inches long, then set their base in damp moss, and exposed them to light for several days under glass, but even then the heads were probably not quite so crisp as those grown in a slight hotbed and exposed to light as they grew.

For the sake of beginners, I may state that when the roots are thus taken to a hotbed the bottom heat should never be above from 75° to 80°; that if there is the least danger of the heat being more the roots should merely be left on the surface, and be slightly covered after watering, and then 2 or 3 inches more covering should be put on as the heat declines. The details of these matters are of primary importance to the inexperienced. For an early Asparagus bed, then, I seldom use a hotbed all of fresh materials, but select an old hotbed which has been used for Cucumbers or Melons. The soil is taken off, also the most decayed part of the dung; that which is not quite rotten is stirred, mixed with hot tree leaves or other fermenting material, and 2 inches or so of the rotten dung placed on the surface. On this are packed the numerous spreading roots, taking care not to let them get dry, putting in the first row as close as it is possible to do without the buds touching. A little leaf mould and sandy loam is scattered on the long roots, then the next row of roots is placed over them with the buds on a level with the first row. In this way a large number of roots can be packed in the space of a single light of 6 feet by 4. When all the roots are packed in, a sprinkling of light soil is thrown over them, and water is given at a temperature of about 65°, so that the fibres of the long roots may have no check. When sure that there is the proper heat, add a couple of inches or so of covering, for, where green shoots are preferred, covering for blanching is quite unnecessary.

Though the above is one of the simplest modes of forcing, yet, as already indicated, any mode will do where a little heat can be given. An old friend of mine was excessively fond of Asparagus, especially when it could not be obtained easily. He had a small greenhouse heated by a flue, and as the stokehole was small, it was always warmer than the greenhouse. He used wooden boxes a foot across and 10 inches deep. In these the roots of Asparagus were packed thickly as above, watered, and set near the stove in the stokehole, and the boxes covered lightly. When the Asparagus was about 4 inches long the covering was removed, and ere long the box was removed to the warmest part of the greenhouse, where the shoots soon became green enough for use. A few boxes kept up a good succession.

Some consider that Asparagus in the winter and early spring months cannot have too much air in order that it may be tender and healthful. Hence it is not uncommon to see the tender shoots exposed to a keen frosty north-easter after they have been forced into growth, instead of having just enough of air to keep them safe while surrounding them with a rather moist warm atmosphere. In the latter case the heads will be full, crisp, and sweet; in the former case they will be too much like so many hard-dried twigs, giving little pleasure to the eater, and doing as little credit to the grower and the cook.—R. Fish.

GRAPES RIPENING IN GROUND VINERIES.

I noticed a week or so ago that a correspondent, writing on ground vineries, stated he thought Grapes so grown would not ripen this year, and quoted those of Mr. Rivers, at Sawbridgeworth, as an instance. I think it well, therefore, to make known that I have thoroughly ripened the following—viz., Golden Champion, Early Golden Frontignan, Frankenthal, Morris's Hamburgh, Trentham Black, Foster's White Seedling, General Della Marmora, La Bruxelloise, the Muscat Hamburgh, and Fintindo. Many competent judges have tested the Grapes, and pronounced them excellent both in flavour and colour. Unfortunately I made a mistake in the day, and cut my last to show at the Royal Horticultural Society, for Wednesday, the 25th of October, instead of November 1st, as I ought to have done, otherwise I should have had the pleasure of exhibiting several varieties, all of which were grown under Rivett's ground vinery, old pattern, with the slight alteration of substituting iron hooks for putty. I should here mention that my Grapes are much later this year, and also that I for one am quite satisfied with the Grapes so grown, taking all things into consideration. In fact, some of mine have far surpassed others that I have seen, even this year, that have been grown in large houses.—Harrison Weir, *Weirleigh, Kent.*

POTATO CULTURE IN LINCOLNSHIRE.

Extensive tracts of land are devoted to Potato cultivation in this county, and the crop may therefore be considered a staple production. It affects the interests of many cultivators of the soil, and has a direct bearing on the food supply of large towns, which annually depend on extensive consignments from the Lincolnshire Potato fields, which are generally credited with furnishing produce of the best quality. At the first glance it may seem a little strange that not only the largest crops but the best samples of such crops are grown on the lowest land in the county, and this means the lowest land in the kingdom.

In the higher heath and cliff lands, which have generally a limestone base, the quality of the Potatoes cannot be surpassed, but on account of the shallowness of the soil the crop is not generally sufficiently productive to be cultivated specially and extensively. In the Fens the Potato is largely grown, and in dry seasons heavy crops are obtained, but at the best these are only of second-rate quality. The soil in the fen districts is a mass of black vegetable mould resting on clay; in wet weather it is pasty, and in dry weather it is blown about like clouds of soot. In such soil it is obvious that the appearance of the tubers will not be prepossessing, and owing to an almost total absence of calcareous matter, the quality is not of a high order. Still in favourable seasons it is fair, and as the crops are often large the Potato is extensively cultivated, simply because it pays as well as anything else. But it is on land lower than the fens where the largest breadths are planted and from which heavier crops are drawn, while the quality is fully equal if not superior to that of the best samples from the high lands in the kingdom. But how lower than the fens, which are only a few inches above the sea level? Well, hundreds of acres of the finest Potato land in the kingdom are really some 7 or 8 feet below the tidal level of the Trent, which flows through the Potato district. What a triumph of engineering skill is exhibited by the Isle of Axholme, the north-western division of the county! Once a morass, worthless except for fishing and fowling, and subject to the inundations of the Trent, Ouse, and Don; now the richest, most fertile, and productive land in the county, enjoying and meriting the name of the "garden of Lincolnshire." If ever merit and enterprise were acknowledged and rewarded it was when Charles I., 250 years ago, conferred the honour of knighthood on old Vermuden the Dutch drainer, who in about five years rescued above 180,000 acres of land, made it secure against tidal inroads, and laid the foundation of the complete system of draining and warping which has resulted in the present high state of fertility. Fifty thousand acres of this land belong to Lincolnshire, and that area is cropped almost exclusively with Potatoes, Wheat, and Flax. Far as the eye can reach, in a district level as the sea, beneath which it once lay, hardly anything can be seen but Potatoes with the alternate patches of corn. For miles it is the same—no variation, but one monotonous expanse of the Englishman's and Irishman's staff of life.

The long-continued adaptability of this warped land for Potato culture is probably owing to the large quantity of gypsum with which the isle abounds, supplying the two principal inorganic elements of which the tuber and haulm together are constituted—viz., lime and sulphuric acid. The gypsum also no doubt acts beneficially by its power of fixing ammonia and keeping it in store for the use of the crop. The land is highly manured, principally with night soil and town refuse; and it has long been the practice, when taking a boatload of Potatoes to the large towns, to load back with manure, a plan which is worthy of more general adoption. In addition to this practice artificial manures of all kinds are largely used, guano, however, greatly preponderating, as it has proved itself the most valuable for the purpose.

In planting, plenty of room is afforded, nearly 3 feet being allowed between the rows, and the sets are placed 14 or 15 inches apart. The rows are well earthed-up, a practice rendered especially necessary owing to the naturally cool moist soil of the district. Besides, earthing greatly facilitates the taking-up of the crops, which, being extensive, is a question of some moment. Earthing Potatoes, like other practices, must be modified by circumstances. It may be right in one place and wrong in another. In the district of which I am writing it is a necessity, while in the garden here it is a fallacy, the soil being light, deep, and dry. To plant shallow and earth-up high is doing the garden an injustice, as I can obtain far heavier crops by planting early and deep and earthing-up very lightly. General principles may be laid down, but to be successful the details must be carried out according to locality, soil, and circumstances.

To resume. The Potato crops in garden, heath, fen, and isle are poor. It is a question if there is much over half the quantity of good marketable tubers in the county that was last year produced. In the first place, the gross bulk of the crop is light; secondly, the disease is very extensive; and thirdly, the tubers, which are sound, are far below the usual standard in quality. This is directly traceable to an unpropitious season. When we find that in six months—April to September inclusive—nearly 16½ inches of rain have fallen, and the total yearly mean little exceeds 20 inches, we need not go further. The best part of the crops are the early garden varieties. Their principal growing month, May, was fine. Those who took their crop up before July 20th had a fair harvest. It was about this time the disease came and spread rapidly. My practice of taking up for seed while the tops are quite green and the skins slipping off by the touch has again stood me in good stead. Of those which I thus lifted not one tuber has become diseased, while of the few left for daily digging nearly half became bad. I have adopted this practice for fourteen years, and always with the same good result. The first period of disease, which was so disastrous to the earlies, left the late ones almost uninjured. The earlies were approaching maturity, and the foliage was unable to carry off the excessive moisture taken up by the roots, while the late kinds in vigorous growth were able successfully to elaborate the sap. I can account for their escape by no other theory. The 17th of August was a fatal day to the late crops. On that day an inch of rain fell in half an hour, and the germs of disease were established. The wet September completed their ruin. At the close of the month five days brought nearly 3 inches of rain, upwards of 1½ inch falling in one day. They could not stand this, and the Lincolnshire crop was lost.

As to kinds, Rocks and Regents are mainly relied on, with Paterson's Victoria close in their wake. This variety has come rapidly into favour, and last year bid fair to supplant its popular rivals. This year, however, it is very much diseased, and will in consequence lose prestige. It is in quality by far the best of the three, and this fact may redeem its character. Of course in a Potato country there are many fanciers, and nearly every sort home and foreign is tried and compared. The American kinds as a rule are found wanting in quality. Mr. Frisby, a first-rate grower, says Peach Blow is the best of the lot. My crop of Early Rose averaged 20 lbs. per square yard, with next to no disease. This is equivalent to nearly 7000 stones, or above 43 tons per acre. If its quality were but equal to its productiveness we should be under a debt of gratitude to brother Jonathan, but I for one cannot subscribe to a testimonial to him yet. Bovinia is by no means equal to our expectations. The Red-skinned Flourball is regarded with much favour, and bids fair to establish itself as a standard variety. It is a heavy cropper, very little diseased, and fair in quality. A kind called The Queen's is this year quite first-class. It is a good cropper, unsurpassed in quality, and not one tuber diseased. This and Flourball, growing amongst about twenty varieties, were remarkable for the strength of their constitution. When the tops of all the rest were blackened by disease the two kinds just referred to remained green and vigorous. The Queen's, I should say, is a strain of the Victoria, and a valuable one.

What I still find to be a desideratum is a heavy-cropping variety of first-rate quality, to come into use immediately after the Ashleafs, and carry us on to the late field varieties. I have tried many varieties to this end, and at present Ashtop Fluke comes the nearest to my requirements. This I intend to increase, and get rid of half a score others. As earlies for garden cultivation Rivers's Royal and Carter's Champion are both first-rate, the former being the best in a light soil, the latter in a strong one. But it is not of much use to enumerate varieties. Those which succeed in one place will not do so well in another. I have tried many kinds with the view of selecting the half-dozen best adapted to my particular soil, and have nearly attained my object. I recommend the plan to others as the most practical and useful.—J. W., *Lincoln.*

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 21.

Chilling were some of the nights of the last month, and these, together with occasional morning fogs, serve to remind us that we must prepare for winter. But the majority of the insect tribes need not the warnings of October, for they have already retired from view. Very few of those that hybernate in the larval or imago states linger on until now, but usually quit their food, or cease their flight ere September departs. Some tarry, however, and fly, in a very languid style, about the yet remaining garden flowers, or hover around the green Ivy blossoms, about which the bees, I perceive, are particularly busy. I behold them, and resolve forthwith that they shall not escape; they also shall appear in the dire catalogue, let the apiarians say what they will in their favour; for are not bees, at least in some seasons, amongst the predatory insects of our gardens?

A very large number of authors, writing for young and old, have agreed to give bees such excellent characters, that there is some danger of these "industrious insects" becoming a little vain, from the quantum of eulogy which they receive. Very diligent the workers undoubtedly are, yet the same thing might be said of many other species of the same class, whose merits scarcely anybody will take the trouble to inquire into. "Careful of their young, and almost affectionate towards them." Very likely, but so are a host of insect parents besides, who "do good by stealth, and blush to find it fame!" No; give bees—and I am in this connection speaking particularly of the social, not of the solitary species—their due eulogium; still it must be added that they can be cruel and quarrelsome, and also, upon occasion, turn robbers and thieves. As a rule, we have not much reason to complain of the injuries our fruit receives from these insects, but should their usual supplies of honey fail them, they will attack it quite as eagerly as any wasp or bluebottle can. Thus, in 1866, when in many places the season for honey-gathering was an unusually short one, it has been noted that the bees visited the fruit with eagerness, and did much more harm than the wasps. An observer, who watched them repeatedly while thus engaged, gave it as his opinion that they did not turn the sugar they thus obtained into honey, nor did they carry it to their homes; so that it would appear they sought the fruit from economical motives, that they might spare their store of honey. In Belgium, in the same year, it was reported that few wasps were seen, and the bees came in their stead. In the preceding year a West Sussex man noted, that though Plums and fruit generally were plentiful, July and August passed and scarcely a wasp was to be seen, but just as the wall fruit began to ripen it became the resort of troops of bees. The wall fruit failing them, they took to the Pears, and settled so often on the fallen ones that it was dangerous for children to go and pick them up; for the bees were noticed to be in a weakly and unhealthy condition, and, like human invalids, they became irritable and unpleasant in their tempers. Yet there were plenty of flowers that season, but the bees would not visit them; the conjectured reason being, that they contained little or no honey and pollen, with exceptions, of course. Going back a little further still, we find that a correspondent of a scientific journal states with regard to Scotland, during a season when the flowers had ripened with greater rapidity than usual, the bees were left suddenly destitute. "They, in consequence, attacked Plums and Apricots in such numbers that sometimes eighteen or twenty [?] bees would be found in one Plum. They effected their entrance by a small hole, only large enough to admit one at a time, and gradually cleared out the pulp until nothing was left but the skin. So artistically did they carry on their operations that, till examined, the Plum or Apricot with the bees within had all the appearance of sound and juicy fruit. On being shaken out the bees were helpless and feeble, and most of them probably died from the effects of their rich and unaccustomed food." This narrative may be slightly coloured, and the conclusion as to the decease of the depredators I certainly doubt, yet the facts are given *bonâ fide*, and corroborate other statements of a similar nature.

But there is another trick which bees put into practice at times, which leads the flower gardener to regard them with disfavour. When a bee comes to a flower, and finds that either from the length of the tube or from the closing of the lip it cannot obtain the honey, the bee goes off elsewhere. No, not always. It may do so, if it is in the prime of the flower season, but when honey is getting difficult to obtain the bee does not give it up. Instead of that, it ingeniously bores a hole in the right position to enable it to rifle the flower of its treasure. Several species of Fuchsia have been noticed as particularly the objects of attack. Some years ago nearly every blossom of Fuchsia elegans in some gardens exhibited these holes, which were a puzzle to the non-observant. Bees have also reached, in a similar way, the nectaries of the species of Delphinium, Aquilegia, &c.

Some of the wild solitary bees disfigure our garden shrubs, though they do them no positive injury. The most conspicuous offenders are those belonging to what are popularly called the Upholsterers, from the fact that their cells are very carefully and curiously lined, usually with leaves, occasionally with other materials. The Rose-leaf Cutter (Megachile centuncularis of Latreille) uses by preference the leaves of the Rose, Birch, and Mountain Ash, cutting out circular pieces with wonderful ingenuity. The nests contain a varying number of cells, and they are placed in a beaten path, or in the cavities of walls, sometimes in rotten wood. Other species frequent the Pear, the Elder, and various trees for the same purpose. On the banks of the Thames, near Kew, in 1865, I was surprised to find how extensively some bee of this division had been at work upon a long Privet hedge; in fact, I was led at first to suppose that some caterpillars had been devouring the leaves, until an examination of the character of the incisions proved that they had been made by bees. Some of the Upholsterer bees employ, instead of leaves, the petals of flowers. Anthocope Papaveris delights to deck her nest with the bright petals of the Corn Poppy.

There yet remain in the gardens, as well as in the fields and woods, a few external-feeding caterpillars, mostly, it may be assumed, of rather a melancholic turn; they almost seem to feel themselves out of place as they walk amongst the withered leaves and fading flowers, and prefer to retreat to the kitchen garden, where, even in autumn, there remains abundant provision for them. The juvenile caterpillars of the Angleshades Moth (Phlogophora meticulosa), are to be discovered now, and as the perfect insect, which appears in September and October, continues about for some time, we may possibly find both moth and caterpillar at once. The Angleshades Moth not unfrequently enters our rooms, being attracted thither by the lights. In its attitude of repose it has a peculiar appearance, the wings being folded and forming a roof, so that when resting upon the ground I have known the insect passed over even by an entomological eye, it having a resemblance to a bit of crumpled paper.

Phlogophora meticulosa.

The egg of the Angleshades is laid upon various plants. I have found it on the garden varieties of Chrysanthemum. By means of a moderate magnifying power, we perceive that it is channelled and dotted, the markings being regularly arranged, and giving to it, as Rennie observes, a likeness to a sea-egg in miniature. The caterpillar is a very general feeder; in the flower beds it attacks many species; besides the Chrysanthemum, it is partial to the Hollyhock and Primulaceous plants. In the winter it is more frequently found in the kitchen garden, feeding whenever the weather is tolerably mild upon the Cabbages and Lettuces; in fact, I do not believe it is ever entirely torpid. A dissection of this caterpillar shows that it has the vital organs well surrounded with fat, and its insensibility to cold may be thus explained. It is remarkably smooth and velvety, of an apple-green, occasionally brown, in both cases having indistinct whitish dots and white lines; the head is small, giving to it somewhat of a leech-like aspect. If alarmed the Angleshades caterpillar drops from its food, rolling itself into a ring more or less complete. It is rather inclined to shun the daylight, so that by examining different plants with a lantern after sunset these and other caterpillars will be discovered, the existence of which, it may be, the gardener had little idea of. He may have noticed the drooping leaves which they had nibbled during their night excursions, and removing these the next morning, has, perhaps, been inclined to think that "the slugs" had been the chief offenders.

These caterpillars attain their maturity in the month of April; eating pretty considerably of the early-spring growth, and then descending to the ground, they spin a cocoon of a slight texture on the surface. Many of the pupæ are fortunately killed by the spade. The first brood of the moth is on the wing in May and June, and there is generally, at least, a second brood of the caterpillars in the summer, producing the autumn moths. I have found the species commonly on the banks of the Thames, where the caterpillars feed on Groundsel and Docks.—J. R. S. C.

Megachile centuncularis.

d, Head of larva protruding from case *b*; *c*, narrow part of case formed of leaves.

APPLE AND PEAR TREE STOCKS.

Near Ilford there is one of the most beautiful orchards of pyramidal fruit trees one can wish to see. It is under the management of Mr. Green, a very intelligent student of nature, and a great lover of fruit culture, though not a gardener in the strict sense of the word. Amongst the many rows of very fine-shaped trees Mr. Green pointed out to me three or four of the following kinds—viz., Louise Bonne of Jersey and Beurré d'Amanlis Pears, and Sturmer Pippin Apple.

In growth these trees had apparently remained stationary for the last few years, the general stock so far exceeding them in height as to be about five times their size. These dwarfed specimens annually bore a crop of remarkably fine fruit, even in seasons when their more robust associates were barren. The cause is the stock, which is quite distinct from all surrounding ones, which foster stronger growths, and its distinctive marks are a very rough bark and a perfect freedom from suckers. As regards the Pears I would ask, Are seedling Quince stocks ever employed, or are the stocks invariably transplanted suckers? If seedling Quince stocks are occasionally

used, then there is an explanation of these rough-barked specimens. I state the facts to induce others to offer us an opinion upon the facts referred to.—W. E.

THE VICTORIA RASPBERRY.

Having paid a visit to a friend the other day, I was much astonished to see such a large crop of the finest Raspberries. To all who do not grow this noble autumn fruit I would say, Make a plantation at once. A piece of ground well trenched and manured, and planted with canes 3 feet apart each way, will make a good plantation.

My friend told me that he had gathered fruit from them three times a-week for tarts for the family. He has been able to gather fruit from them until the end of November in other years, and I have no doubt he will do the same again this year.

When other fruit for tarts is so scarce at this late time of the year, nothing is more acceptable than this fine fruit for a gentleman's table.—T. C. G.

BEDDING PLANTS IN 1871.—No. 3.

In continuing the list of the flowering section of Zonals, we come next to the cerise, and cerise shaded with violet or lilac.

The first I name, and the best, is Violet Hill (Henderson), which is still, in my opinion, the type of a bedding Geranium. I have, however, so often spoken in its praise that I need not add more at present. It is very dwarf in its habit and compact, and some persons have not succeeded with it from not giving it a sufficiently liberal treatment. The first bed in good bloom with me this year was planted with it, and never on any one day during the season could it be said that any other bed of Geraniums in the garden was superior to it.

Amy Hogg (Beaton), cerise, shaded with violet. This still keeps up its character as a free-flowering kind. The footstalk is rather too long, so that it does not stand wet very well.

Dr. Hogg (Beaton), cerise, with more violet than the last. This is a most striking kind in dull weather and in the autumn months. It does not seem to stand sun well, as on hot sunny days the petals shed very freely, and it is apt to run to seed. It is very free-blooming, but the habit is rather straggling. It would be very effective planted in a shady situation.

Duchess of Sutherland (Turner), rose cerise, is of a very pleasing but rather dull shade of colour; very free-flowering, but the flowers do not stand wet weather well.

Lady Kirkland (Laing).—This is one of the very best; large truss, and free-blooming. It has too long a footstalk, but is, in my opinion, decidedly an improvement on Duchess of Sutherland.

Arthur Pearson (Pearson).—Very like Amy Hogg, but a rounder flower and stiffer in the footstalk, and this year it was decidedly better than Amy Hogg.

Duchess (Beaton).—Too coarse and strong a habit. A good pot plant.

Charles Dickens (Bell & Thorpe).—Cerise, with a very glowing tint of violet in it; a very striking flower, with large truss and good habit. This is one of the most promising Geraniums sent out lately, and, I think, likely to become a popular favourite. It won the first prize at Kensington this year for a single hybrid Nosegay, and well deserved the award.

J. J. Lowe (Pearson), rose-coloured. A good pot plant, but not good as a bedder.

Lawrence Heywood.—This is something like Lady Kirkland, with a finer individual bloom, but not so large a truss, and with me it did not flower so freely. It is, however, an undeniably good pot plant.

Indian Yellow (Beaton).—This is a well-known free-flowering kind, of a peculiar shade of colour—cerise, with a shade of orange. There is no Geranium more constant in its blooming, and no garden should be without it.

Grace Holmes.—Somewhat more orange than the last; free-blooming, and of a dwarf habit, but the flowers are too similar in form to the old Spread Eagle.

Comet (W. Paul).—A strong-growing orange, with a large truss; very free-blooming in autumn in pots, and would be very good as a bedder in large beds.

Fame (W. Paul).—Something similar to the above, but I have not sufficiently proved it.

I next turn to the pink and lilac section. The first I shall name is Rose Rendatler. This still keeps up its high character with me. Large truss, free-blooming. A light rose pink, and a very telling colour, especially in dull days. Two opposite match beds in my garden this year were planted one with Rose Rendatler, and the other with Blue Bell, and it was curious to notice how much further Rose Rendatler could be seen than Blue Bell, and also how much better the effect was in combination with other colours.

Maid of Kent.—This is like Rose Rendatler in point of habit, but a deeper shade of pink and a finer colour, one that I can strongly recommend, and about which I can thoroughly endorse Mr. Luckhurst's opinion.

Blue Bell (W. Paul).—Bluish pink, a good pot plant, but not in my opinion a good bedder.

Countess of Rosslyn (Downie, Laird, & Laing).—Soft rosy pink, with dwarf habit; has been very good this year with me.

Christine Nosegay.—Soft pink, dwarf habit. This has not succeeded with me, and it was curious to remark, after the first severe morning frost, out of thirty different kinds in one bank this sort was killed, while very few of the others were injured.

Rose Perfection.—Light pink, pretty flower, but not free-blooming enough.

Ne Plus Ultra.—Like Rose Rendatler, a good pot plant, but not so good as Rose Rendatler for bedding purposes.

Beauty of Lee.—A good bright pink, not sufficiently proved by me.

Pink Queen (Downie, Laird, & Laing).—A very beautiful pink, especially in the autumn. It did not bloom freely early in the year, but I think it will succeed better another year, as I had continued to propagate from it too late in the spring.

Dante (W. Paul).—A good pink, not sufficiently proved with me.

Penelope (W. Paul).—Somewhat like the above, but a stronger grower.

Hydranges.—A beautiful flower, but not free-blooming enough out of doors; likely to be a good pot plant.

These are all the pinks which I have tried out of doors this year, as I have long since discarded Christine, as it always ran to seed, and had a very small inferior truss.

Of white kinds I think The Bride the best. I have also a very good dwarf white, sent me by Mr. Aldred. Madame Vaucher, White Tom Thumb, and White Perfection are to all intents identical—in fact, Madame Vaucher comes so truly from seed that it might almost be raised and sent out from seed as Madame Vaucher, and a great many white varieties sent out are nearly all the same.

I have omitted one or two among the scarlets and crimsons, notably Jean Sisley and Charlie Casbon. Jean Sisley has been very much puffed; it is a very fine round flower, and is a brilliant-coloured scarlet with a white eye, but I do not think it will make a good bedder, though it will certainly be a good pot plant. Charlie Casbon, a dwarf crimson, is in my mind much more promising; it is more free-blooming, larger, and looser in the truss, and stands weather better.

I will finish these remarks on bedding Geraniums with the Bronzes, Tricolors, and others; I will conclude now by saying that the pick of those I have named are Bayard, Waltham Seedling, Duke of Devonshire, Grand Duke, Lady Kirkland, Violet Hill, Rose Rendatler, Charles Dickens, Maid of Kent, Vesta, Lady Constance Grosvenor, and Sobieski.—C. P. Peach.

ALL THE GRAPES POSSIBLE.

I have a Black Hamburgh Grape Vine, which I intend shall bear in a 15-inch pot. It is about 10 feet long, and I wish it to bear all the Grapes that it will next year. Ought I to cut it back? If so, how far? I know that by letting it fruit so much I shall spoil it, but I do not mind that, as I only want it for one year.—A. H.

[In your case we would take a foot off the end of the Vine, top-dress the surface of the soil with rich material, place three or four sticks in the pot, and bend the cane or shoot round them. This will cause the buds to break more regularly, and you can thin out if you like; for if all the buds break, and they have been well ripened, more Grapes show than the pot Vine can bring to perfection with the best treatment.]

THE ONION GRUB.

My own practice, which has been successful, is to get some gas lime from the purifiers of the gasworks, thoroughly dry it, and sow a thin sprinkling over the Onion beds as soon as the young Onions make their appearance, and then give a second

dusting of the same sort when they have attained the thickness of a crow's quill. I found if I deferred the first dusting too long I did not save my crop.—T. G.

SEEDLING FUCHSIAS.

The two seedling Fuchsias of which I send blooms are extremely useful to us at this season. The drop is very large before it expands, and this renders them valuable for cut flowers in the same way as most of the Begonias are. I think it would be well if raisers of Fuchsias were to look more to the sepals in their improvements. The red Fuchsia has very dark leaves, and altogether it is a desirable plant even in foliage. I raised a large number last year, and the two sent were all that I thought worth keeping.—H. K.

[We much admire the red-sepalled variety, which must be very ornamental as a conservatory plant. The kind with pale sepals, though not a florist's flower, also appears to be very desirable for furnishing cut flowers and for vases.—Eds.]

STRAWBERRY WONDERFUL.

It may interest you to see different varieties of Strawberries bearing in the autumn. I have forwarded a small dish of Wonderful gathered this afternoon (Nov. 2nd), from a six-year-old bed in a very exposed situation, within half a mile of, and nearly on a level with, the highest land in the county. I think the merit of this variety is not so well understood as it deserves to be. With me it has been first-rate; for the last twelve years it has never failed to bear a good crop, except in 1867, when the frost killed nine-tenths of the blossom on the 21st and 22nd of May.

I have tried Wonderful in a rich heavy soil, and it will not do except in a very hot dry season, but on my light sandy soil it appears to be quite at home. It is of small growth, and is the heaviest cropper that I can find. When it first began to show signs of bearing in the autumn of 1862, just after we had finished gathering dry weather set in, and the plants all became as brown as they could be; they remained so for four weeks, then came rain, and they cheered up and soon began to blossom, which they did very freely. I quite expected it would injure them for the next year's crop, but it did not in the least, for that season we gathered 520 quarts from nine poles of ground. This quite established it in my estimation as worthy of cultivation, and it has never disappointed me.—Isaac Crick, *Haughton Park Gardens, Ampthill.*

[The Strawberries sent were of the first quality in size, colour, and flavour. This testimony to the merits of Wonderful in a light sandy soil, on the highest land in the county, where "it appears quite at home," is very valuable, and will be acceptable to those of our readers who have difficulty in getting a crop of Strawberries on such soils.—Eds.]

COVENT GARDEN SALESMEN.

Cornick v. Black.—This was an action brought at the Westminster County Court, on October 24th, by Samuel C. C. Cornick, market gardener, Mill Hill, Hendon, against John Black, fruit salesman at Covent Garden Market, to recover a sum of money he had kept back to his own use from the plaintiff out of sales of goods. The plaintiff first took some Grapes to the defendant as far back as April 23rd, 1869, and made an agreement for his fruit to be sold on commission at seven and a half per cent. The defendant was to return to the plaintiff the exact amount he made of every item, with the exception of deducting his commission. We cannot report the case fully, but the defendant consented to a verdict against him. It was proved that the defendant had not made true accounts, and a verdict was entered for plaintiff for 12s. 3*d.*, and 11s. costs, the plaintiff having to pay all his other expenses. The amount claimed was £12 15*s.*

MESSRS. CARTER & CO.'S POTATOES AT SOUTH KENSINGTON.—Nov. 1st.

There are some good people who have been clamorous for what they called in most euphonious langnage a Potato tournament. Well, they have had their wish, and in not as euphonious language I would say, "Much good may it do them." Potatoes were there of all shapes —kidney, round, pebble; of all colours—white, rosy, red, black; of all possible names—Premiers, Regents, Prizetakers, Champions, and I know not what; and yet who was one bit the wiser as to their quality or their productiveness—the two points which, above all others, Potato-growers and eaters want to know? And so it must be; for the task of tasting all these varieties is an idea from which even the most determined "tater-eater" might well recoil. As the names of the prizewinners have already been recorded, I shall say nothing with regard to their collections; but this I will say, That if any one of them can produce a better Potato for a gentleman's table than the Lapstone, I will eat a dish of it, peels and all.

But a most interesting collection for those who wished to know the appearance and names of the best (aye, and worst too) varieties grown, was that of Messrs. Carter, of Holborn, who had arranged very neatly in small mahogany trays a collection of nearly sixty varieties, and who had, moreover, given an impetus to Potato-growers by offering special prizes for collections of the "noble tuber." It may be interesting, then, to give the names of their exhibits in two tables, the Kidneys and the Rounds, afterwards giving such special notes as may seem necessary, in the former classing all Potatoes which are not round, and yet not true kidney-shaped, such as Paterson's Victoria, &c.

KIDNEY.	ROUND.
1. Gloucestershire Kidney.	29. Dunnett's Early Round.
2. Carter's Ashtop Fluke.	30. Fortyfold.
3. Norfolk Champion.	31. Miniature Dwarf.
4. Paterson's Victoria.	32. Scotch Regents.
5. Early Rose.	33. Climax
6. Wood's Seedling.	34. American Red.
7. Webb's Kidney.	35. Goldfinder.
8. Common Fluke.	36 Walker's Regent.
9. Early Giant Kings.	37. Sovereign of England.
10. Belgian Kidney.	38. Dalmahoys.
11. Myatt's Prolific.	39. Early Goodrich.
12. Belvoir Kidney.	40. Peerless.
13. Old Ashleaf.	41. The Queen.
14. Cornish Kidney.	*41. Scotch Dons.
15. King of the Potatoes.	42. Paterson's Regent.
16. Cook's Kidney.	43. Princess's Favourite.
17. Negro.	44. Striped Don.
18. King of the Earlies.	45. Early Shaw.
19. Milky White.	46. Regents.
20. Torquay Lapstone.	47. White Rock.
21. Jackson's Improved Ashleaf.	48. Carter's Champion.
22. American Flukes.	49. York Regent.
23. Cambridgeshire Kidney.	50. Red-skinned Flourball.
24. Pheasant-eye.	51. Carter's Main Crop.
25. Green's Late Kidney.	52. American White.
26. Prince Imperial.	53. Bovinia (cattle).
27. Rivers' Royal Ashleaf.	
28. Red Ashleaf.	
*28. Prince of Wales.	

Of many of these I have already expressed my opinion; there are a few more to be noted. Carter's Main Crop (51) is the handsomest red Potato I have ever seen; smooth as a cricket-ball, and without the least hollowness of eye—no waste whatever. As to its flavour I know nothing, but for appearance it is first-rate. The Princess's Favourite (No. 43) is a Danish tuber, a small round, and is so called because it is the favourite of our much-beloved Princess of Wales, who says that none of our English Potatoes are waxy enough for her. Prince Imperial (No. 26) is a long red kidney, imported from France, and said by many who have tried it to be very good. Striped Don (No. 44) is a curious-looking tuber, white, with red bands across it, but whether this in any way alters the character of the tuber I know not. The Regents were fine; and whether, after all, we have a better round Potato than a good Regent is questionable. As to Paterson's Victoria, I cannot alter my opinion of it. I dined the other day with a friend, an enthusiastic gardener, who pursues his hobby in the midst of great difficulties in London, and he had some of them, grown by a well-known lover and raiser of flowers, and cooked, not in my fashion, but peeled first, and there was still that twang about them I have always detected, as if partially frosted—an unpleasant sweetness. On the following day I dined at a restaurant, where we were served with Regents, and they were so good that I began to think I must withdraw what I had said about kidney Potatoes being the only fit ones to eat. The Dalmahoys are a kind of earlier Regent, and, as I have said, very good indeed. Carter's Ashtop Fluke (No. 2) is a handsome-looking Potato, and as I was looking at it a gardener said to me that he had grown it and found it to be both prolific and good. The Queen (41) is a seedling from Paterson's Victoria, somewhat more round than that variety, and said to be an improvement upon it. Miniature Dwarf (31) is stated to be a very excellent variety for forcing. Early Giant Kings (9) is a fine-looking kind, and stated to be a valuable variety.

We have now, I hope, had enough of Potato exhibitions. They have served the purpose of letting those who are interested see the many varieties. When anything better is produced, would it not be well to send it to the Fruit Committee (as has been done, I believe, before), and to let it be cooked? But I am myself sceptical of getting anything better than those varieties which we already possess. *Nous verrons.*—D., *Deal.*

THE GREAT VINERY AT CHISWICK.

Is there any gardener in the British Isles who has not heard something of Chiswick and its celebrated vinery? None, I think. Still it is only through the gardening periodicals that numbers of the reading public are made acquainted with places and things which are of interest, and I have therefore no doubt

that many gardeners will be interested in the accompanying sketches of the great vinery at Chiswick, and will be able to form some idea of what it is like without going to see it.

It was built in the year 1840 by Messrs. Bailey, of 272, Holborn, and is in form something like a boat bottom uppermost. The length is 200 feet, the breadth 25 feet, the height 30 feet. It is built of iron, having fifteen large iron girders on each side, fastened together at top with bolts and screws. Ventilation is secured by a continuous lantern at the top with 1-foot aperture, and fourteen double sets of shutters on each side.

This vinery, as it exists now, is merely a part of what was to have been an immense conservatory and winter garden, but the design, which was to be completed by degrees, was never carried out. We have consequently but one wing of a great building, of which the centre and the other wing are absent. The part that was finished was planted with a fine collection of trees and shrubs requiring protection and some warmth. These grew and flourished till the year 1857, when, many of them becoming too large for the place, a change was necessary; accordingly it was decided to convert the conservatory into a vinery, and this idea was ably carried out the following year by the then superintendent, Mr. McEwen. Almost every obtainable variety of Grape received a place, half the number altogether inside, and the other half outside. These all grew, flourished,

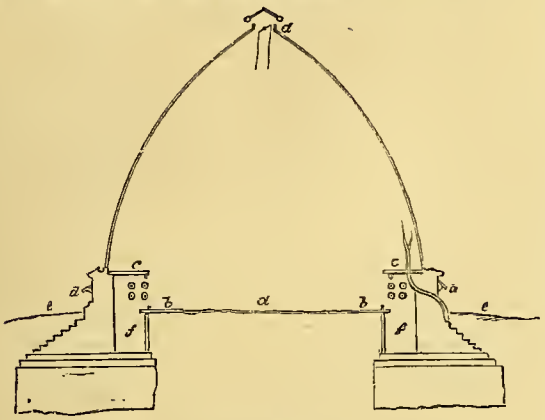
The large Vinery at Chiswick.

and proved a complete success. This state of things continued till a few years since, when, after several changes, Mr. Barron, the present able superintendent, took into consideration the great number of worthless varieties that were receiving the same care and attention as the rest and not affording good results. He gradually weeded out all the worthless kinds, and replaced them with branches from the really good varieties, thereby practising the extension system and short-spur system on the same Vine.

This was well, yet still there was something else. It was considered—not without cause—that the inside Vines did not succeed better than those planted outside—hardly so well, and at the same time involved a great amount of labour in watering, &c., which the outside Vines did not require. There was therefore something to be done. What was it? It was to abolish completely the inside border, Vines and all. This was done two years ago, and again recourse was had to the extension system to fill up vacancies. Any sorts which it was desirable to preserve were grafted on healthy shoots of good varieties, like Frankenthal, and the original stone path was uncovered all the way round and the centre nicely gravelled, at once giving a clean and finished appearance. This extension of branches required something more than the 6-feet border that had previously existed if it was to prove successful for any length of time. The border was therefore extended to more than double its original width with good substantial loam, &c.; and the path that was on a level with the top of the border was taken to the bottom beyond the 15-feet width, and thus all was compact. Nobly have the Vines repaid for the care and improvement. This year they have made splendid wood, some leaders

being upwards of 20 feet long and as thick as one's thumb; and the fruit has been, and is, very fine and of the first quality. No fire is used except in damp weather to prevent decay and a little while the bunches are colouring, but with plenty of air, and that is the reason why the Grapes are like Damsons.

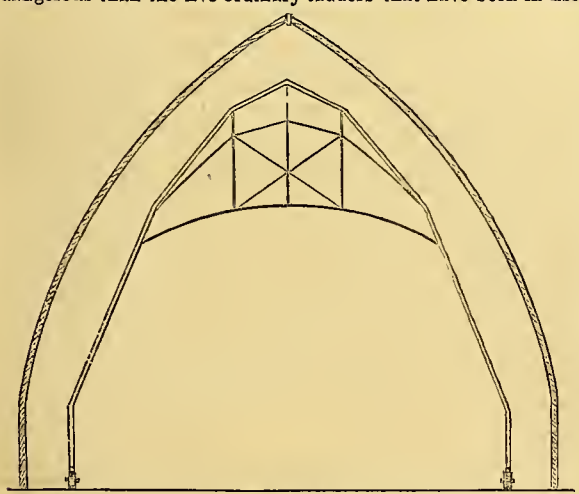
In winter the house is used for Camellias, Oranges, and other half-hardy trees and plants in pots and tubs, from which it is merely necessary to keep the frost, and this is easily done by means of two large boilers, which will efficiently heat the four rows of 4-inch piping carried down each side and one end. Directly under the pipes on each side are tanks running the whole length of the house; these receive all the water from the house. The accompanying sectional sketch will give a little idea of the form and arrangement inside.



Section of large Vinery.

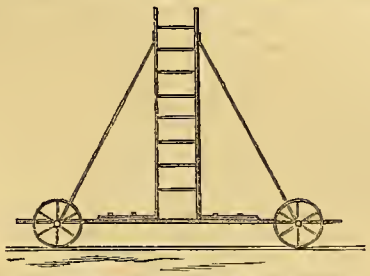
a, Gravel. *c*, *c*, Stone table. *e*, *e*, Vine border
b, *b*, Stone path. *d*, *d*, Ventilators. *f*, *f*, Tanks.

A want has long been felt for something easier and less dangerous than the five ordinary ladders that have been in use



Section of Ladder.—Height from gravel to platform 19 feet.

till the commencement of the present season. This want has



Base of Ladder.—Length 8 feet 6 inches.

at last been supplied by an elegant light wrought-iron ladder on wheels, in form like the house itself. A distance of 3 feet is allowed from it to the glass up the sides, gradually rounding off to 6 feet from the exact centre of the house, where it is furnished with a platform, giving ease and comfort in the working, and at the same time diminishing the labour nearly one-third. The wheels run against an iron ledge.

There are now eighty-three Vines in all growing in the outside borders, some of them with two, three, or more rods. The number of varieties has been reduced to twenty-six, some of which are grafted on the older plants. The varieties grown are Frankenthal, Black Hamburgh, Black Prince, Mill Hill Hamburgh, Dutch Hamburgh, Aramon, Muscat noir de Jura, West's St. Peter's, Muscat Hamburgh, Lady Downe's, Alicante, Black Tokay, Black Monukka, Espiran, Barbarossa or Gros Guillaume, Madresfield Court Muscat, Mrs. Pince's Muscat, Royal Ascot, Muscat of Alexandria, Chasselas de Fontainebleau, Golden Hamburgh, Chaouch, White Nice, Denbies Trebbiano, Buckland Sweetwater, and Raisin de Calabre.—W. S.

A GARDENER'S HOLIDAY.—No. 2.

On my way to the north I stayed for a day or two at Newcastle, and, of course, the first and most natural inquiry for a gardener to make was for the best gardens in the neighbourhood, but I found that gardening was not carried on with much spirit. There are two or three small places well kept, within a short distance of the town, and Sir W. Armstrong, whose private house is about two miles and a half from Newcastle, has had the grounds adjoining his residence at Jesmond laid out with much taste. There are here ranges of hothouses, numerous but very inconveniently placed, and likely to give the gardener a good deal of extra trouble in attending to them. The exotic fernery is of a somewhat original construction, but the roof is too low, so that some noble tree Ferns have not space enough to develope their fronds. The internal arrangement of this house consists of artificial rockwork, disposed in a very effective and natural manner. Of course, in a house of this description nearly all the plants are planted out; even a bell-glass is not admitted to protect such choice subjects as Todea pellucida and superba. The Killarney Fern was thriving in a shady position sheltered by projecting rockwork. Specimens of the best cultivated species were planted out in crevices and under projections of artificial rock; others were festooned overhead.

Crossing the public road from Jesmond, we come to Jesmond Dean. This also belongs to Sir W. Armstrong, and is open to the inhabitants of Newcastle. It is an extensive ravine through which a brook winds, on each side of which is a broad walk running along the base of the somewhat precipitous banks. It is very wild in places, and in keeping with the surroundings. Patches of native Heath and of American plants have been introduced; and in conspicuous positions, sheltered by surrounding rocks, some choice coniferous trees have been planted. It happened to be a wet day when I visited here, but under more favourable circumstances Jesmond and Jesmond Dean are well worthy of a visit.

From Newcastle it is half an hour by railway to Tynemouth, where there is nothing of interest to the practical gardener, For the botanist, however, there are specimens. A day spent in walking from Tynemouth to the Marsden rock and back, would be one never to be forgotten. Starting to walk from the mouth of the river on the south side, we come to extensive quarries whence the Tyne Commissioners are taking stone to build large piers on each side of the river. Near the edge of the quarries, and growing abundantly, is the Burnet Rose, Rosa spinosissima; farther along the coast and on the top of the rocks is to be found Genista tinctoria, Thalictrum majus, and a white variety of the common Bell-flower, Campanula rotundifolia alba, also the white and yellow Melilot, Spergularia marina, and abundant in moist shady positions is the common Scurvy Grass. Following the coast for three or four miles we come to Marsden rock, celebrated (when the coast guard were less effective than it is now), as being the best place on the coast for unloading brandy, tobacco, and other contraband goods, which were landed high and dry under a huge projecting rock. A circular hole yet remains, cut through at least 20 feet of solid rock, through which the packages were passed, as the readiest means of landing them on the top of the rocks. Here the botanist will find Betonica officinalis; the Black Horehound, Ballota nigra; also Euphorbia exigua, and Helminthia echioides. Other uncommon wild flowers are likewise to be found in the neighbourhood, such as the Salvia verbenacea, the wild Sage or Clary, and Diplotaxis tenuifolia, at Tynemouth Castle;

near Hartley, the rare Night-flowering Catchfly, Silene noctiflora, as well as Ranunculus arvensis. Between Sunderland and Marsden, on the roadside, is found the rather uncommon Sium nodiflorum and Inula dysenterica, the Fleabane, said to be a cure for dysentery. North from Tynemouth, and apparently indigenous, is the common Parsley, and the rare Bushy Red Mint, Mentha gentilis, at Monkseaton. Other rare native wild flowers which may be found at South Shields are Pyrethrum maritimum, Sea Feverfew, and Senebiera Coronopus, the common Wart-Cress. The district is rich in botanical specimens, and by visiting it at different seasons no doubt many more could be gathered.

The above notes and description are, perhaps, very uninteresting to many practical readers of this Journal. Young gardeners, in the majority of instances, do not study our native wild flowers; many of them think it beneath their notice, and of no practical benefit to do so. On the other hand, I think much good is to be derived from the study of botany, as exemplified in the collecting and naming of our native wild flowers. I have traversed hundreds of miles in search of specimens in my spare hours, mostly after six o'clock at night, and I can look back as I examine my dried specimens to many long and joyous rambles over hill and dale both in England and Scotland. Young gardeners would add very much to their useful stock of knowledge and improve their intellectual faculties if, instead of wasting their time in playing cards and dominoes, or in other and perhaps more questionable amusements, they would invest in Hooker's "Botany," or Withering's "British Plants," by Macgillivray, and begin to study the habits of the native wild flowers, which are "wasting their sweetness" in wild and luxuriant profusion around them. I could have spent my holiday at North Shields and Tynemouth, and gone home satisfied. I left reluctantly and went on to Kelso, about ninety miles further north, where I found the corn crops quite ten days in advance. I was very sorry both to see and hear of the alarming and wide-spread attack of the Potato crop, the disease in some cases being fatal to as much as 75 per cent. of the crop. There are some well-managed gardens in the neighbourhood of Kelso, and also the nurseries of Messrs. Stuart and Mein, where the best spikes of Gladioli that have ever been seen in Scotland are produced. At the time of my visit the stand which was awarded first prize at Edinburgh on the following day was being arranged.—J. Douglas.

PROTECTING THE BLOSSOMS OF FRUIT TREES.

During the severe frost last winter, I found considerable difficulty to fix upon some plan that would effectually serve for the above purpose. I had previously seen the efficacy of various kinds of covering; but of all those known to me, the best seemed to be one similar to that which I now mean to give a description of, and which may be designated the hay net.

I mentioned what I wanted to one of the most intelligent men employed in the garden, and he then told me that the wall trees here years ago used to be protected by a similar covering; and on inquiry I found that he knew how to proceed in the matter. Without any delay we made preparations for getting a lot of nets made, and the first thing that we required was a frame in which to make them. This we soon procured, which I can compare to an old-fashioned wooden bedstead without the cross-beams in the area. In addition it had a few wooden pins round it for holding the nets, as will be seen afterwards. The size of the frame was 11 feet long by 5 feet broad, and about 3 feet high, which was thought the most convenient. When the frame was procured, hay-ropes were made, for that material was ready at hand, and fixed upon it. We soon got a lot of nets made in one of the garden sheds, where the men were not exposed to the severe weather.

In getting the ropes laid upon the frame for making our nets, the first one was laid round the edge outside the pins for a margin; the next was placed diagonally, from one corner to the other; then others were laid in the same direction as the latter, at about 5 inches apart, till the space on both sides was filled up. Then, again, from the opposite angle was laid another diagonal, taken in and out between the others already fixed, after the fashion of wicker-work. A corresponding number of ropes were worked in on each side of the latter till the net was framed out. All the ends of these ropes were fixed to the margin in due course, and when a tie with tar cord was given at each crossing of the ropes, the net was ready for use.

We made as many nets in this way as protected about 150 yards of wall; and the rate we made them at was about one net per day for each man.

As the season advanced, and as soon as the first blossom began to expand, we put on our first set of nets. That was of course upon the Apricots; and in order to get them protected, the first part of our work was to place a lot of poles, and fix them, one every 5 feet, at an angle of about 65° to the wall; these were to answer the width of the nets, as will be understood, to keep them properly off the wall; behind, the poles were fixed; then we got on our nets, which we tied breadthwise to the topmost wire of the trellis, just under the coping. All that was now required was a wooden pin, put in to keep the two lower corners of the nets together, which were not kept in position by the poles, and the covering was complete.

We had all our Peaches and Apricots covered in this way, excepting one wall of the latter, and that we had protected by a double ply of herring nets and another of hexagon netting together. This we tried for comparison with the hay nets. What of the results of these two modes of covering? From the trees that were protected by the herring nets we have scarcely had a crop; whereas from those that were covered by the hay nets we have gathered an abundant crop; and we thinned as many fruit off them as would have made six good crops. These results speak for themselves, and show the superiority of the one mode of covering over the other.

On all favourable occasions, when we thought that we could render any assistance to the blossoms to insure their fertility, we lifted the nets up and doubled them back upon the top of the wall; and at all times when there might be some danger from frost they were let down again and pinned as before. These nets will be found to husband warmth considerably—at least they break the cold winds in a great degree—and they admit much more light than a person would at first imagine.

To conclude these notes, I can only say that I know of no better covering for wall trees—excepting glass—than the hay net; and I should advise all those who require to put up a temporary protection, and who have not already proved its efficacy, to give the plan a trial.—Robert Mackellar (in *The Gardener*).

MR. WILLIAM BAXTER.

On November 1st Mr. William Baxter, for upwards of thirty years Curator of the Botanic Garden, Oxford, died in the eighty-fourth year of his age. From the length of his years and his long retirement from active life, he was almost unknown to the present generation of horticulturists, but he was one who did good service in his day both to gardening and British botany. On the latter subject he published a large and useful work. He was appointed Curator of the Oxford Botanic Garden in 1813, from which office he retired twenty years ago in favour of his son, a worthy successor. During his curatorship, in conjunction with Dr. Daubeny many improvements were effected by him in the arrangement of the garden, and these have been added to by the present holder of the office. Indeed, the Baxters, father and son, are closely bound up with the history of the Oxford garden, the oldest botanic garden in the kingdom. (For a history of this see vol. xix., page 124.) It was in Cryptogamic botany that Mr. Baxter more particularly delighted, and his knowledge of Mosses and Fungi was very extensive. He was elected an Associate of the Linnean Society as long ago as 1817. Of his private character we need say nothing, for we wrote to Mr. Weaver, gardener to the Warden of Winchester College, and no better eulogium on Mr. Baxter will be recorded than is in this extract from Mr. Weaver's letter—

"I was with Mr. Baxter seven years. He was one of the most even-tempered of men, and ever ready to give information to anyone with great pleasure. He was the most modest and the most unassuming of men, and ever the same man. He was also one of the most abstemious of men. His garden assistants used to say that he never drank a gallon of stimulant liquor from one year's end to another, and was never known to go out into company, but was always at his books, specimens, and other duties of the garden. You could not ask him anything about the name of a Moss, Lichen, or anything in the way of vegetation but what he was ready and pleased to give the required information; indeed there was nothing that came amiss to him in the way of natural history generally. He was never known to take an idle walk, but was always on duty wherever he went in search of knowledge, whether to the fields, the woods, or to the different libraries. I wish I were able to give you a good history of my once good, kind master."

Royal Horticultural Society.—The following additional privilege is to be accorded in 1872, to the Fellows of this Society—viz., To receive gratis two non-transferable season

tickets for the International Exhibitions, admitting their owners at all times that the Exhibition is open to the public. Fellows taking advantage of their right to purchase two-guinea transferable tickets, are informed that each ticket purchased for £2 2*s*. carries with it a free ticket for the Exhibition, but that the name of the person nominated to have the use of such ticket must be given at the time of issue.

TEMPORARY HOTBEDS.

These are very useful for sheltering plants taken up from the flower garden, for striking late cuttings, and for forcing Asparagus, Rhubarb, and Sea-kale. It is expensive to make even a slight hotbed if long dung must be purchased, but where a little littery dung can be obtained, together with mowings from the lawn and fallen tree leaves, there is little difficulty in finding sufficient material. A mixture of grass, leaves, and litter will afford a good lasting heat, the grass contributing to the regular slow decomposition of the straw. When thrown together for a few days I often use the mixture at once, and just as often after it has had one turning; but in the case of all such temporary beds we want to get the heat under something, and not allow it to be spent in heating the general atmosphere. A bed of the above description, from 18 to 24 inches deep, would be apt to kill whatever was put on it if growing freely. For many purposes, therefore, I am quite satisfied if I can put from 15 to 24 inches of this hot rank mixture near the bottom of a bed, and above it from 6 to 12 inches of the half-rotten dung and leaves, similar to the above at first before being thoroughly sweetened. In this roots and pots can at once be set with safety, and the required amount of heat be obtained. After the first season, when one has an old bed to go to, there is no difficulty in following up this system. The safety consists in the surfacing with the half-decomposed material, which heats, and retains the heat given to it, whilst all unwholesome steam is absorbed by the under layers. For slight hotbeds, if the heat declines, you have only to take off the surface, stir up the fresh material, and add a little more (which will act like fresh fuel with a breeze), and cover again.

I have had to make hotbeds after turning and re-turning dung until it became sweet, but then it was much reduced in bulk. For many years I have wasted the fermenting heat but little, using it even with a fiery heat, and regulating the heat by a covering of partly decomposed sweet material from an old bed. A far more continuous heat is secured in this way than using material so turned and decomposed that it sinks so firmly together that air cannot enter to keep up the combustion; and in fact, if the air could enter there is nothing to waste—in other words to fire or give out heat. To make the most of the heat from fermenting animal and vegetable matter there must be a sufficient amount of moisture, and air, as well as warmth in the air, to support what we may call a slow regular combustion, or heat from decomposition. For example, a week or so ago the Cucumbers were taken out from four lights of framing over a hotbed made in February, and the plants turned out in March. The sides of the bed were well decayed, and perfectly suitable for top-dressing Strawberries, Asparagus, or flower beds. This portion and all the old surfacing were removed, but there was a fine cone in the centre still retaining heat, and eminently fitted for being mixed with fresh material, and surfacing beds to help on late cuttings.

This is only one instance of many in which it may be seen that such a rough way of making a bed is not only by far the most economical as regards material, but also the best mode for securing a lasting heat. When fermenting material was so turned and decomposed before being made into a bed, a bed, if made in February and taken out in October, if not lined would have had little heat left, and could have been cut out with a spade like so many slices of cheese. For an old bed a spade would have been almost useless for the centre, a fork was necessary to move it, and a goodly portion, therefore, after all these months, was in the best condition for use again.

When I used to see more of the doings of amateurs than I have seen lately, I was vexed at the sight of heaps of tan and fresh tree leaves sweetening until they were half rotten before being considered fit for a hotbed. When tan is brought from the yard fresh and wet, it is well to throw it in a heap in order that the superfluous moisture may drain away, and when it begins to heat well the sooner it is used the better. To allow it to heat until it become black is wasteful. I hardly know an instance of the most tender plant being injured by the fumes of hot tan, however fresh. Such care is even less necessary with tree leaves. When placed in a heap they soon heat if they are moist enough, and the vapour given off by tree leaves alone is harmless. Hence their usefulness for mild hotbeds when used by themselves, or as a surfacing from 9 to 12 inches thick over other fermenting materials, less safe and sweet in the vapours they emit.—R. Fish.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Make all possible speed while the weather continues favourable in cleaning and opening the surface of the soil. The atmosphere can then circulate in the soil, and keep it in a healthy condition for succeeding crops. This is also the best known means for the eradication of destructive insects and their larvæ. Watch for every favourable opportunity of hoeing, forking, and ridge-trenching, and do not allow weeds and vermin to rob you of your produce. It is not the quantity of manure that always produces the most abundant crops, but it is the judicious manner in which it is applied that will insure the greatest success. It is now time to lift all *Cauliflowers* showing heads, taking them up carefully with balls of earth and packing them closely by the heels in beds, and having some clean straw ready to cover them in case of frost. All the late Grange's and Snow's *Broccoli*, for the winter supply, may be treated in the same way. Spring Broccoli may be laid down in the rows where they have grown, and when planted in very wide rows they may be well earthed up to the leaves, when no danger need be feared from the most severe winters. As *Globe Artichokes* require protection in the winter months, clear away all the old stalks and dead leaves, and apply some rough litter around the roots. Sow *Peas* and Mazagan *Beans*, which succeed best on slightly raised ridges, the rows to be made on the side least exposed. As winter is at hand *Jerusalem Artichokes*, *Beet*, *Carrots*, *Scorzonera*, and *Salsafy*, ought to be stored in the vegetable shed on layers of clean sand. Cut the tops off neatly and closely, as their growing afterwards deteriorates the quality of the root. The forcing of *Sea-kale* and *Rhubarb* must now be attended to, and where there is a good stock of strong roots a supply of them will be easily kept up. Where there is room to spare in the Mushroom-house this forms a very suitable and convenient place for forcing them. The roots should be placed on a slight bed of warm dung, filling up the spaces between them with old tan, or the soil and manure mixed from an old Mushroom bed, giving a good watering to wash it in amongst the roots. The bottom heat should not be allowed to exceed 70°, as too much heat is not favourable to securing strong growth, and except for the first crop it may be dispensed with altogether. Take advantage of wet days for making fresh *Mushroom-beds*, and clearing out those that are spent; also, collect and prepare droppings for forming fresh beds, by spreading them in a shed, and turning them every day until they are sufficiently dried to prevent excessive fermentation after putting up. Plant *Shallots* on raised beds, and put plenty of charcoal or soot in the soil; they will escape the maggot better by early planting.

FRUIT GARDEN.

I would suggest the present as the most favourable time for lifting and root-pruning such fruit trees as are growing too luxuriantly to produce fruit; and as the autumn is the season generally fixed upon for making new borders or renovating old ones, I take the present opportunity of reminding those now about planting fruit trees of the danger everywhere apparent of making borders too deep as well as too rich. The border should not be deep—18 inches will be ample. The soil should be maiden loam of moderate consistency; no dung whatever should be used, and the roots should be prevented from passing below the border by a considerable depth of rubble or rough paving stones placed hollow. This border should dip from the wall so as to throw off surface rains, and expose it better to the sun. I would also make the border 4 feet in width at first, and extend it afterwards as required.

FLOWER GARDEN.

Choice plants in borders intended to be protected for the winter by slightly covering their roots, should be seen to at once. Moss, where it can be obtained in thick flakes, is by no means a bad protecting material; but unless it can be procured in pieces of considerable thickness, it is not so efficient or useful as spent tan, coal ashes, or half-decayed leaves. Also see to getting Fuchsias and such plants as are usually protected during the winter by covering secured against frost before it is

too late. Dry fern is an excellent material for covering the stems, &c., of plants that require a slight protection in winter, and is, doubtless, the least objectionable as regards colour of anything at command; but it is not easily procured in many neighbourhoods, and, probably, the best substitute is straw that has been exposed to the weather sufficiently long to darken its colour. Choice sorts of Hollyhocks, of which there is not a sufficient stock, should be taken up, potted, and placed under glass. These cannot with safety be trusted to the rigours of a severe winter, and plants taken up, potted now, and wintered in a cool house will be exceedingly useful for furnishing cuttings, and these, if obtained early in spring, will make excellent plants for next season. When alterations are in hand, push them forward with all possible dispatch while the weather continues favourable for out-door operations. Be very careful to secure plants against wind, especially large plants, which should never be left until they are properly staked or otherwise made fast, for when this is put off it frequently happens that the roots get injured through the tops being rocked about by the wind. Get any projected alterations among the shrubberies or herbaceous borders done in readiness for cleaning up as soon as the leaves are down; also let ground intended to be planted with Dahlias and Hollyhocks next season be deeply trenched and ridged up, so as to expose the soil as much as possible to the weather, putting in plenty of rotten manure, more especially where the Hollyhocks are to stand, for these require a deep rich soil. It should be our constant aim to make our gardens look as pretty and lively as possible, and this can be done with comparatively little trouble or expense, after the first outlay, by filling the beds at this season of the year with dwarf specimens of shrubs—that is, those beds which are not planted with bulbs or sown with hardy annuals. As many employers have an objection to see large masses of beds lying bare six or seven months out of the twelve, I think this objection could be easily removed by filling up the beds near the residence with Laurustinus, Aucuba japonica, green and variegated Holly, Arbutus, Berberis (evergreen), Rhododendron, and Box. Those at a greater distance might be filled with Portugal and common Laurel, Arbor-Vitæ, Phillyrea, &c., filling each bed with one distinct kind. In removing them from their winter to their summer quarters, plant them in prepared beds in the reserve garden, and by regularly pruning back the summer growth of some, and pinching off the ends of shoots of others, compact dwarf shrubs will be obtained, in readiness for another winter.

GREENHOUSE AND CONSERVATORY.

The summer-flowering twiners, which usually get unsightly at this season, should be cut back somewhat freely, as should any others that will bear that kind of treatment. The slight shade which they afford in the summer to plants underneath them, it need scarcely be stated, is not now required. Give air freely on all favourable occasions, but guard against damp by using gentle fires. Let pot specimens in bloom be frequently re-arranged, so as to make the most of them, for the finest plants become too familiar to be interesting when allowed to remain too long in one place.

COLD PITS.

If not already done, get straw shutters, or whatever else it may be intended to use for coverings for these, repaired and put in readiness for use without delay. Straw shutters if well made are somewhat expensive in the first instance, but they are considered by many to be the most efficient of any kind of covering in use, and, taking into consideration the time they last, they are perhaps as cheap as any. Expose the stock here freely to air on every favourable opportunity, so as to check growth and get the wood firm, in which state the plants will be less liable to suffer from the confinement which may soon be necessary than if kept close, with too much warmth and moisture. Very little water will be required at the roots, but look over the stock every few days. Withhold water until it is absolutely necessary, and then give a moderate soaking, the only safe method of watering at this season.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

We have placed Rhubarb and Sea-kale in the Mushroom house, where it will soon come on. Sea-kale out of doors we have cleaned, and covered the crowns to keep them from vermin; a little salt sprinkled round but not on the crowns, will keep slugs, &c., at bay. At this season and earlier we often place Sea-kale roots thickly in pots and boxes, instead of putting them at once in a dark place in the Mushroom house. By the former plan we can move the pots or boxes if they come in irregularly.

Globe Artichokes and Convolvulus.—Unfortunately the White Bindweed has somehow sprung up, and every small portion of root will grow if let alone. We have commenced forking over the ground carefully, and taking out every visible piece of the white roots before we dung the beds, preparatory to placing a little litter round the stools. This we think necessary to make all safe. They are hardy enough in common winters, but are likely to be killed in a very severe one, when the heads may be missed. As respects the Bindweed, frequent hoeing is necessary to eradicate it, but this must be done before the shoots are 2 inches long. By thus depriving the plant of its organs of respiration and elaboration the root ceases to exist. We found one of the best remedies for this was matting the ground above it. A piece of ground used in spring sent up shoots of the Bindweed by June, so we resolved to let it lie fallow for two or three months. By the middle of July the ground was covered with strong wreaths of the climber; then the short grass from the lawn was brought in every day and placed over the ground until it was 5 or 6 inches in thickness. No shoots ever came through it. The grass remained on the ground until November, and then on digging over not a live root was to be found. We fear the seeds often came from the rubbish heap used as manure. There are so many accounts of the difficulty of getting rid of it, that the above may be interesting.

We took up our younger Carrots, Beetroot, and Salsafy; the older Carrots were housed more than a month ago. It is a mistake to keep them in the ground until they begin to form fresh fibres, and also to let them remain too long when worms and other vermin disfigure them. We also took up some Turnips to prevent their growing larger and spongy. We likewise stirred the ground amongst all growing crops.

FRUIT DEPARTMENT.

Had our Raspberries cleaned and tied; the canes are strong, but not so well ripened as we wish to see them. Rough-pruned a number of bush trees, and went along the Strawberry rows, packing some of the dressing previously applied close to the plants and buds, and leaving a little ridge between. Even this slight elevation does much to protect them from the most cutting winds. Collected litter to throw over the pots of Strawberries out of doors if a sharp frosty night should come, as roots in pots are much more easily injured than those in the ground, or if the pots are plunged.

ORNAMENTAL DEPARTMENT.

No weather could be better for transplanting. Most plants are still fresh, and carry plenty of bloom in the flower garden. The Coleus ceased to be ornamental ten days ago; Iresine Lindeni has only begun to drop its leaves, and therefore for combination purposes, owing to its hardiness, it will suit better than the Coleus, and cost much less trouble, as it is of little use turning out small plants of Coleus. We shall take up a number of plants which we wish to keep before the frosty nights come, and these we shall be sure to have before long.

We generally pack a number of *Geraniums* and other plants thickly together in a heap, and then cover them at night with litter until we can find time to look them over. In answer to some inquiries, we may say that we depend chiefly for Scarlet Geraniums on small cuttings taken off in September, and kept thickly in boxes all the winter, but we generally take up a few of the strong old plants from the beds. These we usually treat in three ways. First we pot some of the best plants separately, using as small pots as the roots can be crammed into, take nothing off the plants but some of the larger leaves, water, and place the pots in a mild bottom heat, with the tops cool. These soon become well-established plants. Others we deprive of all the larger leaves and the rather soft points of the shoots, and pack the roots rather thickly in boxes. The third plan is to cut or snag-in the head all round 6 or 7 inches from the ground, so that the head may resemble a double deer's antlers in miniature—not a leaf is left. The cut ends are generally dipped in powdered lime, and then the roots are packed as firmly as they can be squeezed together in boxes or large pots, the snagged stems only being exposed. The plants are well watered, and when settled a surfacing of the driest earth is put on, and the plants will be safe all the winter wherever frost does not reach them. Light is of little importance until the heads begin to break in spring. This is by far the best plan for those who have little room and wish to make a flower

garden gay, as such plants generally flower well. A 12-inch pot will contain from twelve to eighteen large plants if they are pruned-in as above. Of course such storages will yield no gratification in winter. For these there must be little pruning, and a little help at the roots; even water at from 80° to 90° will help the free fresh rooting.

The chief work of the week has been looking after bulbs, potting, and fresh-surfacing plants; giving a little fresh rich dressing to Euphorbias, Justicias, Begonias, &c.; and dividing and potting Mosses and Ferns.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*J. C. K.*).—Thompson's "Gardener's Assistant," "Cottage Gardeners' Dictionary," Johnson's "Science and Practice of Gardening."

Horticultural Directory (*T. Clapham*).—There will be an edition of the "Horticultural Directory" for 1872.

Newton's "Chrysanthemum" (*J. W.*).—Messrs. Bradbury & Evans; price sixpence, we believe.

Various (*D. M.*).—We do not know anything about the dictionary you mention. Write to its publishers. "The Botanical Magazine" has such coloured plates and descriptions as you mention. The Blechnum brasiliense would suffer from want of heat, but we cannot be sure without knowing how you cultivate it.

Agaricus proceaus (*J. T. O.*).—Take up the spawn and place it in leaf mould.

Wheeled Hoe (*J. W. K.*).—We have no doubt this tool, described on page 323, is to be purchased. Why not write to Mr. W. W. Glenny, enclosing a directed stamped envelope for a reply?

Nurserymen Sending Trees not Ordered (*J. H. B.*).—We need not lash nurserymen who venture to do this, for the remedy is in the purchaser's own power. Send back the trees, and the nurseryman, having to pay the carriage, will not repeat the unwarrantable practice.

Fungus (*G. S.*).—Your Fungus is a common and delicious variety of Agaricus campestris. The true A. Georgei is a white-spored Agaric without a ring, which comes up only (about St. George's day) in the spring. The Horse Mushroom (Agaricus arvensis) is frequently referred to as A. Georgii. It is often difficult to distinguish it from the true Mushroom, and it is almost as good for the table.

Climbers not Thriving (*Novice*).—We think the most likely cause of the climbers not thriving against your house is the raised bank or terrace, which is undoubtedly dry, and may be rendered more so by a projecting roof, such as many houses have, and which is wholly unsuitable for climbers. If there is not a roof of this kind, we would take out the soil to a distance of a yard from the building and 2 feet deep, and fill up with rich loam, the top 2 or 3 inches from a pasture being preferred. This soil should be chopped up in rather small pieces, adding one-third of leaf soil or well-decayed manure, some lime rubbish, or one-sixth of sharp sand. Put in the soil rather firmly, and elevate it from 6 to 9 inches above the surrounding level. You will have a border a yard wide, which we would keep as a flower border for a time, and that will enable you to manure the climbers in autumn, to water them in summer, and when they are well established you can turf-up. Wistaria sinensis and Magnolia grandiflora ought to succeed on the south aspect; and if you have room add Jasminum grandiflorum, Ceanothus azureus, C. floribundus, Escallonia macrantha, and Garrya elliptica. On the east have Cydonia japonica, Jasminum nudiflorum, and Cotoneaster microphylla. Crataegus Pyracantha ought to thrive, and Virginian Creeper will be sure to succeed, but we should not like to plant it until we had given the others a good trial. The copse you are stubbing-up, and which you intend to sow down for pasture, should be well worked and cleaned, and do not sow until the beginning of April, when you may put in a light crop of Oats or Barley.

Growing Bulbs in Pots for Beds (*Violet*).—You may grow in pots all the bulbs and roots which you name—namely, Hyacinths, Tulips, Anemones, Ranunculus, Jonquils, Narcissus, and Crocuses, sinking the pots below the rims. There will be no necessity to pot the Hyacinths and Crocuses, and we should leave them and the Narcissus in the ground. When so treated they do better than in any other way. Take them up every second or third year, remove the offsets, and replant. Put three Ranunculuses in a 6-inch pot, one Anemone in a 4½-inch pot, and two Jonquils in a 4½-inch pot. You may sink the pots at the required place, and when the flowering is over, you can then remove them, and again plunge them in an open situation until the growth is complete. The Tulips may be potted singly in 4½-inch pots, and the pots plunged, taking up after flowering. The roots will come over the pot-rims, therefore the rims should be covered about an inch. You can put in the bedding plants between the rows of Hyacinths, &c.

Transparent Crab (*F. P.*).—The fruit makes an excellent Apple jam.

Dwarf and Runner Kidney Beans Forwarding in Heat (*F. R.*).—They may be sown rather thickly in boxes or pans, grown in a frame, hardened well off, and transplanted, after the weather has become warm, to a sheltered situation. Thus treated they will come in earlier than those sown in the open ground, but the produce is not so great. Peas for the first early crop may be treated in the same way, but it is well to sow them in pots or on narrow strips of reversed turf, and plant out with the ball or turf entire. Keep the plants from becoming drawn, and harden well off before planting out, affording a slight protection for a few days after planting out.

Walnut Tree not Thriving (*S. R.*).—We should allow the hayband to remain during the winter, and renew it in spring; if kept moist it would materially assist the flow of the sap. We would mix some old lime rubbish with the soil about the roots, and then give the top-dressing of manure as you propose, leaving it on throughout the summer.

Scorzonera and Sandringham Cabbage Management (*A Reader*).—Take up the roots now, cut off the tops half an inch above the crown, and store the roots in sand in a shed or cellar. They may be boiled like Parsnips, and, served with white sauce, are by many much esteemed. For next year's supply you must sow seeds about the middle of April. The tops of Sandringham Sprouting Cabbage should not be cut off until about February, and then they will produce a number of fine sprouts throughout the spring. You may cut the tops now, and the sprouts will come forward more quickly. The name of the flower is Colchicum autumnale.

Exterminating Thistles (*W. M.*).—Drain the land thoroughly not less than 3 feet 6 inches deep, and with a spud—one that drops in the hole some salt on its withdrawal—grub them up at the close of May or early in June, and again in August.

Plants for Trelliswork (*H. M. S.*).—There are very few evergreen climbers that are suitable for trellises in garden—indeed, there are none but the Ivies; Cotoneaster microphylla will, however, do. For the avenue, Poa nemoralis sempervirens and Festuca duriuscula are the most suitable. We could not say what, but consider most Mosses would grow well, there being stone and moisture. Mosses (with the exception of Selaginellae) are not included in the category of cultivated plants.

Hyacinths for Exhibition in March (*Old Subscriber*).—Pot them now in 6 inch pots, drain well, using a compost of two parts medium-textured loam, one part old cow dung or well-decayed manure, half a part of charcoal in pieces about the size of a pea, and half a part of silver sand. Place them in a cool house or cold frame, and if in a cool house they will do beneath the stage or shelves, just covered over with cocoa-nut refuse. Being in a moist state they will not require any water, but the soil must be kept moist. There they may remain a month, and should then be placed on a shelf near the glass, with a temperature of not more than 40° from fire heat, and this should be continued up to the close of January, when they should have 45° from fire heat, and with 5° more for a few weeks they will come in at the time required. Weak liquid manure may be given after the spike is clear of the leaves.

Wintering Geraniums (*Somerset*).—A two-light frame is not suitable, as, if frost be kept out, the plants suffer from damp The shelves over the dresser, we think, will be too warm, and warmth without light is ruinous. It is, however, far better than a cold frame. The late cuttings would have been better without the hothed. Harden and dry them off, and keep them safe from frost in the lightest place you have. Take up the old plants; do not cut them back, but remove most of the leaves, and keep them dry and safe from frost The stable loft is of no use unless you can keep frost from the plants, then it would answer very well for the old plants. You can pack them in boxes in dry soil, not water them until spring, potting and placing them in a hotbed about March.

Strawberries in Shallow Soil (*J. W. L.*).—Just loosen the soil between the rows, mulch at once with well-decayed manure, and cover with some of the littery portion. We would advise mulching the newly-planted Strawberries. It will keep the roots all right for the winter.

Tacsonia splendens and Brachysema Drummondi (*Idem*).—They have scarlet flowers. The Tacsonia flowers in summer, and the Brachysema from March to May. Keep the former dry in winter, and top-dress the whole of the border in February with rich compost. The plant will put out side shoots another season, and the Brachysema you may stop. The Habrothamnus elegans has deep rose or red flowers, produced in autumn and spring. Water freely in summer, and give liquid manure occasionally.

Plants for North Porch (*A Subscriber*).—The Escallonia requires a south aspect. We know of nothing that would answer but Cotoneaster microphylla or the Ivies; Rægner's is very suitable.

Removing Paint from Glass (*C. E. W. C.*).—It will peel off in time, or may be removed with cloths dipped in a hot solution of soft soap, 8 ozs. to the gallon, kept on until they are cool. Then clean the glass with spirits of turpentine and dry clothe. The paintere ought to have removed it after the rain.

Fruit Trees (*F. J.*).—It is easy to a practised eye to tell a Pear on the Quince from one on the Pear stock, and if you know one you will be able to tell the other easily, but we can only tell you that the bark of the Pear stock is much more smooth than that of the Quince, and the stock generally of an even thickness with the graft or scion, whilst of the Quince the bark is often rough or knotted, and the stock generally smaller than the scion. The best way to keep trees after they are received, if the weather is not frosty, is in the soil until they can be planted; but in frosty weather they are best left in the packages, covering them well with straw until the frost is past. To guard against damp your best plan is to give air whenever you safely can, tilting the lights so as to throw off the rain. We do not think there would be much use for the lime. In collecting leaves for leaf soil pile them in a heap, leave them for six months, then turn them over, and again in three months. They will decompose more quickly then if they were not turned. The top 2 or 3 inches of an old pasture where the soil is a good rich rather light loam, laid up grass side downwards for six months and then chopped up, adding a fourth of rotten manure, or a third of leaf soil, forms an excellent compost for bedding plants.

Stove (*Churchill*).—We think your large flue ought to be ample for all the heat you require; but if you want more heat at the coldest end, a stove of iron lined with fire-brick would suit your purpose, and an

Arnott's brick stove still better, but with such a flue round the house we should consider any stove quite unnecessary.

HEATING WITH HOT WATER (*A. B. C.*).—We should deceive you if we said you could heat your new house, which you say is 10 feet below the top of the boiler. If it had been all that higher, it would have been different. The same sort of boiler, or a conical or saddle-back, or even a flue, would do for the new orchard house, as you do not want much heat. We have no faith in the present boiler doing the work, owing to the level.

HEATING A GREENHOUSE (*G. A. H.*).—We can hardly see how a gas stove placed in your dwelling house, supplied with a boiler and pipes, should allow gas fumes to escape among your plants. These things, however, all require care and management. We have no faith in the close stoves you allude to, in whatever way the fuel is prepared. Amongst plants in large open halls the matter is quite different, but such a stove would do well enough if lined with fire-brick inside, and if even a 2-inch pipe were used to carry off the products of combustion through the roof. A small iron stove, say a foot or 15 inches square, lined with fire-brick at the fireplace, would be the simplest for such a house, but a little care is wanted to avoid dust inside the house, by damping the ashes before taking them out of the stove. If in such small houses a stove of this description could be placed close to a wall, or a brick stove 2 feet square and 30 inches high should be so placed as to be fed and attended to from the outside, all dust and smoke when lighting would be avoided. An evaporating-pan on the top would give moisture enough. For all such small houses nothing will equal a small stove for economy. We judge it will require about one-third of the fuel of a furnace and flue, and from one-sixth to one-eighth of what would be wanted by hot water.

GRAPES (*A. B.*).—Your Black Hamburghs are producing abortive berries, and this is, doubtless, caused by the roots being in a border which is "very damp, low, and cold." The only remedy is to drain the border, and renew the soil if it has become sodden. Vines will do with any quantity of water so long as it is not stagnant.

PRUNING PEACH TREES, &c. (*I. H. S.*).—All superfluous shoots should be removed from your Peach trees in summer, and the other young shoots which will carry the fruit next year should be trained in to the wall. This will expose the fruit to the influence of the sun, and it will not only be more highly coloured, but of better quality. It is not the black ant which is the cause of blight on your orchard-house trees, but the aphis, which is most effectually destroyed by fumigating with tobacco smoke. Washing the trees with a solution of Gishurst compound, 8 ozs. to the gallon, will also destroy them.

FRUIT TREES FOR A SOUTH WALL (*Glevum*).—We would not occupy a south wall with a Morello Cherry, as this tree succeeds well on a wall with a north aspect, or planted in the open ground as pyramids. Plant a Moorpark Apricot and a Marie Louise Pear. You can purchase standard-trained trees with clean stems of 6 feet in the nurseries; plant them at once.

PLANTING A VINERY (*A Subscriber*).—Plant Mill Hill Hamburgh by all means; it colours well, the berries are large, round, and equal in quality to Black Hamburgh. Inarch Golden Champion on Black Hamburgh. When well grown it is the best white Grape for a cool house. We would substitute Madresfield Court Black Muscat for Mrs. Pince.

LIST OF FRUIT TREES (*T.*).—A wall facing the east is not a good position for Peach and Nectarine trees. You do not say how many varieties you require. *Peaches.*—Early York, Royal George, Stirling Castle, and Violette Hâtive. *Nectarines.*—Rivers's Orange, Elruge, Violette Hâtive, and Pine Apple. *Pears.*—Jargonelle, Madame Treyve, Marie Louise, Beurré Hardy, Gansel's Bergamot, Beurré Bosc, Glou Morçeau, Easter Beurré, and Bergamotte Esperen. *Gooseberries.*—Golden Drop, Green Gage, Pitmaston Green Gage, Red Champagne or Ironmonger (of Scotland), Yellow Champagne, Whitesmith, Broom Girl, Crown Bob, and Warrington. *Currants.*—White Dutch, Knight's Early Red, Red Dutch, and Victoria. *Raspberries.*—Red Antwerp, Fastolf, and Yellow Antwerp.

INARCHING VINES (*B. W. Stannus*).—Black Alicante is a magnificent Grape. We would graft or inarch it on Canon Hall. Mrs. Pince's Black Muscat has not the Muscat flavour fully developed under all circumstances, though we have it very fine this year. It is a good Grape, but like your Canon Hall, uncertain.

PEACHES AND CAMELLIAS UNDER VINES (*A Young Essayist*).—We do not think Peach trees in pots will succeed in such a position. If you wish to give them a trial, get the trees as near the glass as possible, and train your Vine rods up at a distance of 5 feet apart. Camellias would do pretty well in the shade, but we think it would be more profitable as well as more satisfactory if you were to sacrifice the Peach trees.

UTILISING A LARGE HOUSE (*X. Y. Z.*).—For such a house so wide and lofty, and 320 feet long, we would advise heating—not a tenth, but a fifth, or a third, as the heated portion will be the most valuable. In this we would plant Vines, and have tables for plants and shelves for Strawberries or Dwarf Kidney Beans. Part next this, a cool house, we would plant with Vines of the hardier kinds, as Black Hamburgh and Royal Muscadine, and part with Peaches and Nectarines. The floor of these houses might be covered with vegetables in winter, as Cauliflowers, Endive, Lettuces, or great quantities of Violets, Wallflowers, and hardy Primroses if in demand. We think such a house would pay best if enough of iron piping were used to keep out frost in severe weather. For the part heated, for a 40-feet-wide house, 15 feet at the centre, and 8 feet at the sides, four pipes, as you propose, round two sides and one end, will answer if you do not commence forcing until towards February. The house may be filled with flowering plants all the winter, but until the extra heat is given to the Vines the temperature should not exceed 45° by fire heat.

SMALL GREENHOUSE (*E. C., Oakham*).—Under the circumstances a lean-to house would be the most economical, and with ventilators at the top of the back wall, all the roof might be fixed. A small saddle-back or conical boiler would answer, and the 4-inch pipes along the front and round each end would be sufficient. For such a house, 24 feet by 12, we would prefer a small flue beneath the pathway, and the top of the flue would form part of the pathway. With a half span or hip at the back, you would have a loftier house and more command of light, but you would need more heat. A couple of ventilators in the hip, with an opening at each end under the apex, would do. If you decide on a lean-to, and desire more height, you may raise the wall from 9 to 12 inches, and place 6-inch board ventilators most of the way. These, being on pivots, would be easily managed.

HEATING A VINERY AND GREENHOUSE (*T.*).—Your simplest plan would have been to have heated the two houses by a boiler placed behind where the two houses meet. By sinking the boiler sufficiently you could bring the flow and return pipe beneath the pathway, and then raise it in the house. A T-flow pipe would enable you to take a flow pipe into each house, joined then to the number of pipes you might think proper, by syphon joints. A socket valve on each of these flow pipes would enable you to regulate the heat in the vinery and the greenhouse at will, and to give heat to one and keep the heat from the other as desirable. In the position you propose for your boiler at the end of the range you must heat the vinery before you can heat the greenhouse at any time, and you must have the circulation complete in the vinery. Having secured that circulation you could take one pipe joined to a two-pipe syphon, with a valve to regulate the circulation, in the greenhouse. Were we obliged to have the boiler where you propose, we would have two flow pipes from the boiler, one in the usual way for the vinery, and the other a 1 or 2-inch strong pipe passing through the vinery, with a valve or tap, and joined to the flow pipes in the other house by cap joints. All the returns would join.

LILIUM AURATUM TREATMENT (*W. M.*).—As it is now in a resting state it should have no more water than will be sufficient to keep the soil moist, and if not already potted we should pot it at once. Turn the plant out of the pot, and remove as much soil as you can without injuring the roots. As the bulbs are small, 7-inch pots will be sufficiently large. Drain them well, and use a compost of two parts light turfy loam, one part sandy peat, and one part leaf soil or old cow dung, with a free admixture of sharp sand. Pot so that the crown of the bulb may be about an inch below the rim of the pot, and when the plant has made a shoot a few inches high top-dress with rich compost. Keep the plants safe from frost, and the soil only just moist, but when the plant is growing freely and flowering water copiously. It cannot have too light or airy a position.

VARIEGATED HOLLY (*E. Woollen*).—We have seen others with marbled leaves, but when propagated from and cultivated in other soils and seasons, the variegation gradually departed. If yours remains permanent it will be a desirable variety.

EMIGRATION (*A Gardener*).—We cannot venture to advise you. Some of our readers may be able to answer your query—"Which is the best part of Australia for a gardener to emigrate to?"

VEGETABLE MOULD FOR POTTING (*Groombridge*).—The mould from decomposed vegetable matter as Pea haulm, Cabbage stalks, &c., mixed with lime is good to mix with other materials as a compost for potting, but it must be thoroughly decomposed. We prefer leaf soil.

HARDINESS OF RICHARDIA (CALLA) ÆTHIOPICA, DICKSONIA, AND ALSOPHILA (*A Subscriber*).—The Richardia thrives in a tank in the greenhouse, but it should have abundance of light. Place some loam in the tank, and put a few stones over the roots. It does better with us as a pot plant, and without aquatic treatment. Dicksonia antarctica and squarrosa, and Alsophila australis, succeed in a house from which frost is excluded.

CACTUSES NOT FLOWERING (*J. F. B.*).—The cause of these not flowering is no doubt the want of light, and the distance from the glass. We would advise you to have them potted, and after being established a year we would turn them out of doors early in July in front of a south wall, and not house them until the close of September. Keep them dry during the winter, but not so much so as to cause the stems to shrivel. We think they will flower in the following April. For growing beneath Vines you might have Camellias, Azaleas, and variegated-leaved Begonias; indeed you might succeed with most greenhouse softwooded plants, placing them out of doors in summer.

NAMES OF FRUITS (*J. Taylor*).—1, Flower of Kent; 2, Cellini; 3, Barcelona Pearmain; 4, Red Wine; 5, Nonpareil; 7, Carel's Seedling; 10, Tower of Glamis; 11, Northern Greening; 12, Pearson's Plate; 13, Achan; 14, Dunmore. (*Mrs. Miller*).—The large Pear is Beurré Clairgeau, and the two smaller ones White Doyenné.

NAMES OF PLANTS (*C. F.*).—We succeed in identifying your leaves. No. 1 belongs to Baubinia purpurea, *L.*, a well-known and widely distributed plant in India; No. 2, a young spray of Eucalyptus obliqua, *L'Her.*, one of the Stringy-bark trees of Australian colonists, abundant in Victoria and Tasmania, but not, as you suppose, a native of New Zealand. (*Camjee*).—The Strawberry Spinach, Blitum virgatum, native of India, Persia, and the East. (*J. B.*).—Hibiscus rosa-sinensis, var. grandiflorus. (*Centurion*).—In all probability your plant is Calandrinia umbellata, but we are not absolutely certain. We have no doubt as to the genus, but your specimen is scarcely sufficient to make sure of the species. (*G. Davies*).—1, Nephrolepis exaltata; 2, Polypodium cambricum; 3, A variety of Polystichum aculeatum; 4, Adiantum hispidulum; 5, Selaginella Braunisna (S. pubescens of gardens); 6, Pteris crenata; 7, Microlepis novæ-zelandiæ. (*A. E. A.*).—Your Fern is quite correctly named Hypolepis repens. You certainly must afford it protection against cold, as it is a native of the tropics. (*G. McA.*).—Your Fern is, without a doubt, the Hymenophyllum tunbridgense. You appear to have thought it to be H. Wilsoni, otherwise H. unilaterale, which it is not; both are scarce, the latter the more so. (*M. H.*).—2, Salvia verticillata. The Stachye (No. 1) is Stachys recta, *L.*, native of central Europe. (*G. B.*).—1, Is Asclepias curassavica, *L.* Wild in the West Indies, but very generally cultivated as a garden plant all over the civilised world. Known in Jamaica as Wild Ipecacuanha, in other places as Swallow-wort. 2, Is Gomphocarpus fruticosus, *R. Br.*, from the Cape of Good Hope; also known as Asclepias fruticosa, or A. salicifolia. Both are among the oldest and best known of stove plants, but may be placed in a greenhouse when in bloom. (*T. B. W.*).—Your Ferns are—1, Pteris flabellata; 2, Nephrodium aparsum; 3, Onychium japonicum; 4, Litobrochia pedata; 5, Cheilanthes lendigera; 6, Polypodium vulgare. The Lycopods are—1, Selaginella Martensii; 2, S. Brauniana (S. pubescens); 3, S. Krausiana (S. borteneis). (*C. M. Major*).—Your Fern is Blechnum occidentale. As to Polypodium dilitatum of Lilbmann, it is a synonym of Nephrodium effusum. See Hooker "Synopsis Filicum," 287. (*W. B. B.*).—The Canary Grass, Phalaris canariensis, *L.* (*J. W. B.*).—Common Sparrey, Spergula arvensis. (*An Old Subscriber*).—The Spindle Tree, Euonymus europæus. (*O. W.*).—1, Cuphea platycentra; 2, Helichrysum bracteatum,

the common "Everlasting" of garden borders; 3, Senecio Cineraria, or Cineraria maritima; 4, Agathæa cœlestis. (*H. W. E.*).—Campanula Lœflingii, native of Spain.

POULTRY, BEE, AND PIGEON CHRONICLE.

LIGHT BRAHMAS.

As an enthusiastic admirer of this beautiful breed, I beg to be allowed one or two remarks on Mr. Wright's very interesting paper in last week's Journal. I am, comparatively, only a young beginner as a Light Brahma breeder, and write in the hope of gaining information. Having attended with tolerable regularity many of the leading shows, I certainly am somewhat surprised to find that Mr. Wright thinks that shape and colour can win against size. I am assuming that by "colour," is chiefly meant the clear black-striped neck and saddle hackle, as described in his book, "The Brahma Fowl."

Of late I have begun to think that his description in that book must be totally erroneous, for I have constantly seen prizes awarded to cocks without a vestige of marking on the saddle, and with a neck hackle that can only be appropriately described as "muddy." For example, at the late Cheltenham Show a pair of Light Brahma chickens, of almost perfect shape and markings according to Mr. Wright's standard, were merely commended, while the prizes went to birds with almost white hackles, but very superior in size. In fact, my experience so far shows that style and markings have no chance whatever against size. On what other grounds, I would ask, are three-fifths of all the Light Brahma prizes awarded to Mr. Pares's birds than their being of superior size? No one could maintain that they excel in style or colour. I quite agree with Mr. Wright that the case of the winning cockerels at Birmingham last year was an exception, but, unlike him, I have heard the award most bitterly complained of, on the ground that the prize birds were so small; and if my memory does not deceive me, your own reporter mentioned that in his opinion one at least of Mr. Pares's cockerels should have been in the first or second place. I think I am right in saying that the Birmingham first-prize cockerel was afterwards exhibited at Spalding, and merely commended in a small class, the prizes, as usual, going to size.

Now, are we to breed for striped hackle or for size? I, for one, should be glad to know. So far as my personal predilections go I entirely agree with Mr. Wright's standard of markings, and am disposed to think that many first-prize birds I have seen with nearly white hackles are as deserving of disqualification as if they had white legs, but evidently the Judges think differently.

Next, as to absolute size. I held my breath when I came to Mr. Wright's statement of cocks of 17 lbs., and hens of 12 lbs. We certainly are a long way behind our American brethren. Might I ask through your columns the purchaser of the American birds shown last year at Birmingham (which, I suppose, may be accepted as fair specimens, or they would hardly have been sent over, and which gained, I believe, the third prize), to let us know what their weight is now? I do trust that some of these American monsters may be about starting for the Crystal Palace or Birmingham Shows, and may I be there to see.—Outis.

ENTRANCE FEES.

The charge for entries ought to be no more than as follows:—5*s.* where there are £4, £2, and £1 prizes; 4*s.* where the prizes are £3, £1 10*s.*, and 10*s.*; 3*s.* where the prizes are £2, £1, and 10*s.*; and 2*s.* 6*d.* where the prizes are 30*s.* 15*s.*, and 10*s.* I cannot say anything against the Crystal Palace Show, as the Committee are giving so many cups—their entry fees are about right, had they no subscriptions.—John Cockroft.

DERBY CANARY SHOW.

The Show of October 28th and 30th was the largest ever yet held at Derby, and the birds, for quality and for beauty of plumage, could not well have been excelled. The Committee deserve great credit for the arrangements, every visitor being able to see well, and any bird which one wished to single out could be found at once.

In the classes for birds hatched this year, limited to members of the Society, there were 160 entries. As a class the Yellows were much better in colour than last year. In Buffs we did not notice any great change. The silver cup was won by Mr. R. Henson with fifteen points. Very seldom does one breeder exhibit so many good birds, taking out of six classes four first prizes, one second, and one third. No. 24 was the pet of the Show, and will, we are sure, before the season is over, win more laurels. Class 12 (Variegated Buff Norwich), was good throughout, the even marking showing much consideration and very careful breeding. There was a decided improvement both in the quantity and quality of the Crested birds as compared with former years. We were sorry to see that the Belgian and Lizard fancy does not seem to flourish in Derby.

Last year the Society decided on having classes open to all England, and from the success they then met with these prizes were again offered, and the result has far exceeded all expectations, 102 Norwich being entered, also several entries of Belgians, Mules, and Lizards; and the Committee intend still further to extend their sphere of operations in these classes.

Of Bantams there were twenty-nine entries; the prizewinners were perfect in every respect. We are of opinion that a poultry show might be successful in connection with this Society.

The weather was unfortunately very unfavourable, but we are informed the receipts were quite equal to expectation, and we hope another year this Society will receive more support at the hands of the fancy. We published last week the names of the Judges and the list of awards.

SOUTHAMPTON POULTRY, PIGEON, AND BIRD SHOW.

For eleven successive years this Show has held a very high position in public opinion, the Committee always paying the utmost attention to any suggestion likely to add to its attractions. At Southampton there are classes not only for exhibition poultry, but also for fowls ready dressed for table. Another prominent feature of this year's meeting has been the excellent collection of Canaries and other song birds combined with classes for foreign birds in great variety and of resplendent plumage. Consequently all visitors, whether strictly poultry-breeders or otherwise, could readily pass many hours in a pleasing and very instructive inspection. This year, by a greatly improved arrangement, the Exhibition was held in a central part of the town, and, had the weather been at all favourable, no doubt the receipts would have been proportionably increased. The large space available permitted of a far better display throughout than in former years, and in respect to the *Geese*, of which there was a truly magnificent collection, it is questionable whether they were not more comfortably situated than at their respective homesteads; certainly it has never been our lot to visit any show where the accommodation for these birds was at all comparable to that afforded at Southampton. The Auction Repository, in which the Show was held, has one other great advantage in nearly the whole of the roof being glass, so that the amount of light varies only to a trifling extent throughout. At a time like the present, when poultry shows are held in such rapid succession, and, in too many cases, in defiance of all risks, nearly simultaneously, a great deficiency in the number of entries generally ensues; nevertheless, at Southampton the entries were as numerous as in former years. *Spanish* were a very small class, as, unfortunately, seems to be the case at every show during this autumn, but the prize pens were much admired. Grey *Dorkings* were decidedly the strong feature of the Show, and here Mr. Martin, of Claines, secured the ten-guinea silver cup, the gift of Peter Merrick Hoare, Esq., M.P. for Southampton. It is worthy of note that both of Mr. Martin's pens were rosy-combed, of magnificent size, and in capital feather. It may not be amiss here to note that the truly objectionable feature of open wirework for the backs of the pens began to tell most unfavourably, for such were the massive proportions of the cup male bird, that at every movement the tail feathers were more or less rubbed to pieces by continued entanglement in the wirework behind, and not a few other large fowls were equally injured. The ten-guinea silver cup, given by Mrs. Merrick Hoare for the best pen of *Game* fowls, was secured by a grand pen of Brown Reds belonging to Mr. Julian, of Hull, and, strange to say, it was the only entry made by their owner against a very heavy competition. *Cochins* were mostly good, but, as a whole, they were scarcely in full condition. *Brahmas* were quite a feature of this exhibition, and Mrs. Williamson's Light-coloured chickens, if well cared for, are certain to find a position in many other prize lists. Of *French* fowls the display was excellent, and Game *Bantams* were also a very prominent class. In the Variety class for Bantams Silver-laced Sebrights stood first, and a very well-shown pen of Cuckoo Bantams second. Among the *Waterfowls*, a pen of Sebastopol Geese, several pens of Buenos Ayrean, Carolina, and Whistling Ducks were well worthy of notice.

Spanish.—1, H. Brown, Putney Heath. 2, Mrs. Allsopp, Hindlip Hall Worcester. *c*, J. F. Siletoe, Penfields, Wolverhampton.

Dorkings.—1 and Cup, J. Martin, Claines, Worcester. 2, J. Smith, Shilling lee Park, Petworth. *hc*, W. Peacocke, Efford, Lymington. *c*, H. Humphrey Attington, Pulborough; J. Chisman. *Chickens.*—1, J. Martin. 2, J Smith *hc*, Mrs. Hayne; Mrs. E. Wheatley, Blackmore Rectory, Ingatestone (2); Sir H. C. Paulet, Bart., Little Testwood, Totton; W. Trevitbick, Hayle, Cornwall; J. Smith; H. S. Fraser, Headley, Liphook (2). *c*, Sir H. C. Paulet, Bart.; J. Smith.

Cochins.—1, Cup, and *hc*, J. Sichel, Lark Hill, Timperley. 2, Mrs. Allsopp. *Chickens.*—1, Horace Lingwood. Creeting, Needham Market. 2, C. Bloodworth, Bayshill, Cheltenham. *hc*, W. Burch, Barnacle, Coventry; Horace Lingwood; J. K. Fowler, Aylesbury; A. C. Travers, Falmouth; J. Loog, Plymouth; R. S. S. Woodgate, Pembury, Tunbridge Wells; Mrs. H. Hozier, Alresford. *c*, F. W. Rust, Hastings; C. F. Wilson, Bartley Manor, Totton.

Brahmas.—*Dark.*—1, W. Dring, Faversham. 2 and *c*, Horace Lingwood. *hc*, H. P. Moor, Langley Lodge, Chipperham.

Brahmas.—*Light.*—Cup, Mrs. T. Turner, Avon, Ringwood. 2 and *hc*, J. Pares, Postford, Guildford. 3, H. M. Maynard. *Chickens.*—Cup and 2, Mrs. A. William,

son, Queeniborough Hall, Leicester. 3, Mrs. T. Turner. *hc*, H. M. Maynard, Holmewood, Ryde; Mrs. T. Turner; J. M. Rice, Bramber Rectory, Steyning; T. A. Dean, Marden, Hereford; J. Long, Plymouth; M. Leno, Markyate Street. *c*, C. F. Wilson; Mrs. Malcolm, Totton; J. R. Wright, Mayfield, Southampton; R. B. Wood, Uttoxeter; Dr. Campbell, Brentwood.

GAME.—*Black and other Reds.*—1 and Cup, H. M. Julian, Hull. 2, H. Gibson, Brockenhurst. *hc*, W. H. Stagg, Netheravon, Amesbury; H. Gibson. *Chickens.* —1, T. Burgess, Burleydam. 2, C. H. Ames. *hc*, S. Matthew, Stowmarket. *c*, C. W. M. Laxton, Nantwich.

GAME.—*Any other Variety.*—1, Mrs. S. Matthew. 2, J. Fletcher, Stoneclough, Manchester.

GAME.—*Cockerels.*—1 and Cup, T. Burgess. 2, H. E. Martin, Sculthorpe, Fakenham. *hc*, J. Jeken, Eltham; S. Matthew. *c*, A. Milnes, Rochdale. *Any other Variety.—Cockerels.*—1, Rev. F. Dutton, Windrush Vicarage, Burford. 2, S. Matthew.

HAMBURGHS.—*Silver and Gold-pencilled.*—1 and Cup, Ashton & Booth, Broadbottom, Mottram. Cup, F. Pittis, Newport, Isle of Wight. 2, N. Barter, Plymouth. *hc*, J. King, Oxford; H. Moore. *c*, H. H. Thompson, Coleshill, Farringdon. *Silver and Gold-spangled.*—1, N. Barter. 2, W. A. Tickner, Ipswich. *hc*, Mrs. Allsopp; Ashton & Booth; T. Blackman, Tottenhall, Wolverhampton; Mrs. J. Pattison, Dorchester.

POLANDS.—1, A. Cruttenden, Brighton. 2, G. W. Boothby, Louth. *hc*, C. Bloodworth.

FRENCH VARIETIES.—1, W. Dring, Faversham. 2, G. Mills, Woodville Hall, Dover. *hc*, J. Sichel; Rev. N. J. Ridley, Newbury. *c* J. K. Fowler.

HOUDANS.—*Chickens.*—Cup and 2, R. B. Wood. 3, W. Dring. *hc*, J. Sichel; W. Dring; R. B. Wood; W. Tippler, Duke's Roxwell, Chelmsford. *c*, Rev. G. B. Rowland, Pillerton Vicarage, Kineton.

ANY OTHER VARIETY.—1, J. Watts (Ptarmigan). 2, T. Moore, Fareham (Andalusians). *hc*, Rev. N. J. Ridley (Leghorns); T. Norwood, Churchfield, Salisbury (White Minorcas). *c*, T. M. Derry, Gedney (Black Hamburghs).

BANTAMS.—*Game.*—1, Cup, and 2, Ashley & Maitland, Worcester. *hc*, G. F. Ward, Wrenbury; C. Ashworth, Halifax; H. C. Rogers, Newport Pagnell; W. B. Jeffries, Ipswich; H. Gibson; W. Adams, Ipswich. *c*, C. Parsons, Dorchester; A. Dowdall, Southampton.

BANTAMS.—*Any other Variety.*—1, M. Leno (Silver-laced). 2, W. W. Boulton, Beverley (Cuckoo). *hc*, J. Watts, King's Heath, Birmingham (2); S. & R. Ashton, Mottram; E. Cambridge, Cotham, Bristol. *c*, J. Bloodworth.

DUCKS.—*White Aylesbury.*—1, G. W. Greenhill, Ashford. 2, J. K. Fowler. *hc*, G. Scutt, jun., Martinstown, Dorchester; W. Stephens, Highman Green, Gloucester; J. K. Fowler; A. Marvin. *c*, Miss F. A. C. Cresswell, Early Wood, Bagshot.

DUCKS.—*Rouen.*—1, G. Chase, Titchfield. 2, H. Dowsett, Pleshey, Chelmsford. *hc*, W. Birch; W. Stephens (2); Mrs. E. Wheatley, Blackmore Rectory, Ingatestone; S. H. Stott.

DUCKS.—*Any other Variety.*—1, F. Pittis, jun. (Buenos Ayrean). 2, M. Leno. *hc*, F. Pittis, jun.; S. & R. Ashton; Mrs. Hayne; G. S. Sainsbury, Devizes; J. J. Malden, Biggleswade; M. Leno.

GEESE.—1, J. K. Fowler (Grey). 2, Lady de Bathe, Chichester (Sebastopol). *hc*, Mrs. Ford, Shirley, Southampton (2); W. Trevithick; H. Yardley, Birmingham; Mrs. M. A. Charnbury, Bathampton. *c*, W. Stephens.

TURKEYS.—1, Mrs. J. Mayhew, Great Baddow. 2, G. R. Pearson, Witham Common, Grantham. *hc*, Rev N. J. Ridley; T. Bailey; Mrs. Clay, Fareham.

SELLING CLASS.—*Cock or Cockerel.*—1, H. P. Moore (Dark Brahmas). 2, A. C. Travers (Grey Dorkings). *hc*, H. M. Maynard; H. Humphrey, Attington, Pulborough; H. P. Moore; Rev. F. Cooper; B. F. Parrott, Henbury, Bristol (2). *c*, W. H. Stagg (2); J. Bloodworth; C. Bloodworth. *Hens or Pullets.*—1, H. D. Dent, Cosham (Buff Cochin). 2, J. Chisman (Light Brahmas) *hc*, H. Adney, Goodworth, Clatford; W. Walter, Winchester; Mrs. Malcolm; Lady Heathcote, Hursley Park, Winchester; Mrs. E. J. N. Hawker, Wycliffe, Tunbridge Wells. *c*, A. C. Travers; Lady de Bathe.

EXTRA CLASS.—*c*, H. C. Dear, North Stoneham, Southampton (2).

PHEASANTS.—1, Lady Heathcote.

ORNAMENTAL BIRDS.—1, Withheld. 2, G. W. Jones, Southampton.

PIGEONS.

POUTERS.—1, R. Fulton, Deptford. 2, E. T. Dew, Weston-super-Mare. *hc*, G. H. Gregory, Taunton; A. Heath, Calne. *c*, P. H. Jones, Fulham.

TUMBLERS.—1 and 2 J. Ford. *hc*, R. Fulton.

BARBS.—1, H. Yardley. 2, H. M. Maynard. *hc*, R. Fulton (2). *c*, E. S. C. Gibson.

JACOBINS.—1, G. Roper. 2, H. M. Maynard. *hc*, R. Fulton; H. M. Maynard; G. South, New Bond Street, London; H. Yardley; E. T. Dew.

FANTAILS.—1, Miss J. Millward, Newton St. Loe, Bristol. 2, H. Yardley. *hc*, A. A. Vander Meersch, Tooting; H. M. Maynard; J. Walker, Newark; H. Yardley. *c*, G. H. Gregory; H. M. Maynard.

OWLS.—1, R. Fulton. 2, H. Yardley.

TURBITS.—1, R. Fulton. 2, G. Roper, Croydon. *hc*, O. E. Cresswell, Early Wood, Bagshot; A. A. Vander Meersch; H. Yardley.

CARRIERS.—1, R. Fulton. 2, H. Yardley. *hc*, F. Morgan, Newport.

TRUMPETERS.—1, R. Fulton. 2, H. Yardley.

NUNS.—1, J. Watts. 2, E. T. Dew.

DRAGOONS.—1 and 2, W. Bishop, Dorchester. *hc*, G. H. Gregory; H. Allsopp; G. South. *c*, Master H. Jacoba, Sandown, Isle of Wight.

ANTWERPS.—1, H. Yardley. 2, H. R. Wright, Birmingham.

ANY OTHER VARIETY.—1, W. Bishop. 2, S. A. Wyllie, East Monlsey. *hc*, H. Yardley (2).

SELLING CLASS.—1, H. M. Maynard. 2, J. D. Blackman. *c*, F. Pittis, jun. (Magpies).

CANARIES.

NORWICH.—*Clear Yellow.*—1, Adams & Athersnch. 2, T. Mann, Camberwell. 3, J. Mortimer, West Smithfield, London. *vhc*, W. Walter, Winchester; Enoch and Chater, Hillfield, Coventry (2); T. Mann; Adams & Athersnch. *hc*, W. Walter; E. W. Lulham, Brighton. *c*, C. & D. Carver, Landport. *Clear Buff.*—1 and 2, Enoch & Chater. 3 and *c*, W. Walter. *vhc*, E. W. Lulham; Moore and Wynne. *hc*, Moore & Wynne; J. Mortimer; Smith & Preen, Coventry.

NORWICH.—*Marked or Variegated Yellow.*—1, Adams & Athersnch, Spon End, Coventry. 2, W. Barwell & Golby. *vhc*, T. Willsher; J. Mortimer; T. Mann. *hc*, W. Walter. *c*, E. W. Lulham. *Marked or Variegated Buff.*—1 and 2, Adams and Athersnch. 3, T. Mann. *vhc*, W. Walter; Barwell & Golby; E. W. Lulham. *hc*, J. Mortimer. *c*, Moore & Wynne (2).

NORWICH.—*Any other Variety.*—1, E. W. Lulham. 2, J. Mortimer. *vhc*, W. Walter; W. Barwell & Golby; Moore & Wynne. *hc*, Moore & Wynne. *c*, W. Walter; Moore & Wynne; J. Mortimer.

BELGIAN.—*Clear Yellow.*—1, O. Nicholson. 2, T. Moore. *vhc*, E. W. Lulham; T. Moore. *hc*, C. & D. Carver. *c*, W. Walter; O. Nicholson. *Clear Buff.*—1 and 2, O. Nicholson, Landport. *vhc*, C. & D. Carver; E. W. Lulham; J. W. Savage, Guildford; S. Spinke, Chippenham. *hc*, W. Walter; W. Andrews, Landport (2). *c*, W. Walter.

BELGIAN.—*Any other Variety.*—1, O. Nicholson. 2, T. Moore. *vhc*, O. Nicholson (2). *c*, C. & D. Carver; O. Nicholson; W. Stringer, Rowden, Chippenham.

LIZARD.—*Golden-spangled.*—1 and 2, Smith & Preen. *vhc*, W. C. Selkirk, Dover; O. Nicholson; T. W. W. Fairbrass, St. Dunstan's, Canterbury (2). *hc*, O. Nicholson. *Silver-spangled.*—1, Rev. V. Ward, Hythe. 2, O. Nicholson. *vhc*, W. C. Selkirk; Smith & Preen. *hc*, O. Nicholson; Rev. V. Ward. *c*, T. W. W. Fairbrass (2).

ANY OTHER VARIETY.—1, O. Nicholson. 2, R. Veitch, Northam, Southampton. 3, T. Mann (London Fancy Jonque). *vhc*, O. Nicholson; R. Veitch. *hc*, W. Barwell & Golby.

MULES (Any other variety).—1 and 2, Enoch & Chater. 3, J. Baxter, Newcastle-on-Tyne. *hc*, Enoch & Chater (2); E. W. Lulham; T. Willsher, Chichester.

BRITISH BIRDS.

BULLFINCH.—1, T. Willsher. *vhc* and *hc*, O. Nicholson.

GOLDFINCH.—1, T. Willsher.

LINNET.—1, — Wadham, Southampton.

SKYLARK.—1, O. Nicholson. *vhc*, D. Amor; H. B. Higgs, Southampton.

WOODLARK.—1, H. Janaway. *vhc*, O. Nicholson.

BLACKBIRD.—1, D. C. Amor.

SONG THRUSH.—1 S. Samways.

ANY OTHER VARIETY.—1, J. T. Turner, Avon, Ringwood (Raven). 2, R. Besseant, Southampton (Magpie). 3, T. Willsher (Yellowhammers).

FOREIGN BIRDS.

COCKATOO.—1, G. W. Jones, Nantwich. *vhc*, W. Walter.

PARROTS.—1, J. S. Harrison. *vhc*, Miss L. Standish, South Stoneham, Southampton; A. Van Santen, Southampton. *hc*, H. B. Higgs.

LOVE BIRDS.—1, W. Walter.

ANY OTHER VARIETY.—1 and *vhc*, W. Walter (Madagascar and Cockateels). 2, E. S. C. Gibson (Horned Owl). 3, J. T. Turner (Gigantic Kingfisher or Laughing Jackass).

JUDGES.—*Poultry:* Mr. Edward Hewitt, Birmingham; Rev. G. F. Hodgson. *Pigeons:* Mr. F. Esquilant, London. *Cage Birds:* Mr. A. Willmore, London.

NEWCASTLE-UPON-TYNE PIGEON AND CAGE BIRD SHOW.

THE Newcastle-on-Tyne Ornithological Society held their annual Exhibition of Pigeons and Canaries on November 2nd and 3rd, in the Corn Exchange, which is one of the finest buildings in the kingdom for the purpose, being very spacious and thoroughly lighted. The Show was highly successful, thanks to the good management of the Hon. Secs., Messrs. W. R. and H. O. Blenkinsop. The entries of Pigeons numbered 421 pens. We shall merely notice a few of the most striking pens, referring to the prize list for other particulars.

The *Carrier* classes contained some excellent birds, but were hardly up to last year's standard. Messrs. Stretch, Fulton, Waddington, and Massey exhibited the best birds.

The *Pouter* classes were well filled. The White cock from Mr. Skinner McGill stood first in his class, and but for being very dirty would probably have taken the principal special prize as well. Messrs. Fulton and Van Haansbergen showed good Blacks, which will make their mark in a better classification. Blacks had to compete with Blues, which was a great drawback, and we hope the Society will afford separate classes for each colour next year.

Short-faced *Almonds* comprised the best lot we have seen for a long time, every pen containing either one or two first-class birds, and the whole deservedly received high commendation. One pair were sold for £15, and these were not the prize birds. Several of the best birds were moulting, otherwise the awards might have been different.

Short-faced *Balds* or *Beards* were a wretchedly poor class as far as head and beak were concerned.

Amongst the *Tumblers* of any other variety were some very well-marked Mottles, which were the winners. Messrs. Blenkinsop's Kites were also very fine.

In *Barbs* the only pens worth notice were Mr. Fulton's pair of Reds and one pair of Blacks, and Mr. Van Haansbergen's two pens of Blacks. All these were superb, and, we doubt not, will be heard of again at the forthcoming shows.

Jacobins were a magnificent class. The first-prize Yellows well deserved their position. The second-prize pen of Reds were very good, but hard-pressed by several of the other competitors. We think Jacobins entitled to three classes. The class for Red or Yellow contained twenty-one pens, and the Any other colour class ten entries, thus paying better than any except the Sale and Turbit classes. In the other class for Jacobins of any other colour, Mr. Van Haansbergen swept the board, his two pairs of Whites being exquisite, and in our opinion equal to anything in the Jacobin classes.

White *Fantails* were a good class, Mr. Loversidge's pen *facile princeps*, and claimed at £10. We have seldom seen better, and of course they took the cup. Blue Fantails were all good. No other colour was shown.

In *Trumpeters* (Mottled), the first, second, and special prizes were excellent birds. In Any other colour excellent Whites were first. We thought Mr. Jones's highly commended pair equal to the second-prize pair. Several other good pens were shown.

Turbits numbered thirty-seven entries. Several good Shell-crested birds were shown, and we consider that the Society should allow one class to shell-crowned and two to point-headed birds. The first-prize Blues were sold for £4.

Magpies were good and plentiful.

Nuns were a good class, and not so much trimmed as formerly. The winning Yellows were very fine.

Some very pretty pens of foreign *Owls* were shown, both Whites and Blues. English Owls were a mixed lot. Many of the pens were passed on account of too close alliance to the foreigners. The first-prize Whites were excellent-headed birds, though we must say that colour does not please us in English Owls, the pretty Blues and Powder Blues being more to our liking.

Dragoons were very good. A pen of rather heavy Reds were very rich. Several pens of fine Yellows were also shown.

Common *Tumbler* classes contained very good Balds and Beards of all colours. A pair of Red Mottles were exceptionally fine. Some good Almonds were shown, but were not well matched.

The *Variety* class contained remarkably pretty birds.

The two Selling classes contained some birds which would have

stood well in the other classes. There was quite a rush to claim the prize pens; so great, indeed, that the Secretary had to take down the names of all the applicants and draw lots for each pen. For the winners in each class there were twenty-nine applicants. Several other pens were claimed.

CARRIER.—*Black.—Cock.*—1 and Cup, E. C. Stretch, Ormskirk. 2, R. Fulton, Deptford. *hc*, T. Waddington, Feniscowles, Blackburn. *hc*, R. Fulton. *Hen.* 1 and 2, R. Fulton. *hc*, T. Waddington. *Dun.—Cock.*—1 and Extra, R. Fulton. *Hen.*—1 and 2, R. Fulton.

POUTERS.—*Blue or Black.—Cock.*—1, 2, and Cup, R. Fulton. *hc*, W. B. Van Haansbergen, Newcastle-on-Tyne; T. Rule, Durham. *c*, Skinner McGill, Edinburgh; W. Rutherford, Edinburgh. *Hen.*—1 and 2, R. Fulton. *hc*, W. B. Van Haansbergen. *c*, R. Harrison, Darlington. *Red or Yellow.—Cock.*—1 and 2, R. Fulton. *hc*, F. Gresham, Sheffield *Hen.*—1 and 2, R. Fulton, *hc*, T. Waddington. *White.*—Cock.—1 and Extra, Skinner McGill. 2, R. Fulton. *hc*, W. Rutherford. *Hen.*—1, R. Fulton. 2, W. Moon, Edinburgh.

TUMBLERS.—(*Almond*).—*Short-faced.*—1 and Cup, R. Fulton. 2, J. Fielding, jun., Rochdale. (Whole Class Highly Commended). *Short-faced.*—1, J. W. Edge, Birmingham. 2, J. Fielding, jun. *Any other colour.*—1, J. Fielding, jun. 2, R. Fulton. *Common.*—1, J. G. Dunn. 2, R. Laws, St. Lawrence, Newcastle.

BARBS.—*Black.*—1, R. Fulton. 2 and *hc*, W. B. Van Haansbergen. *Any other Colour.*—1 and 2, R. Fulton. *hc*, W. Massey, Spalding.

OWLS.—*Forcign.*—1, J. Fielding, jun., 2, T. Waddington. *hc*, R. W. Richardson, Beverley; W. R. and H. O. Bleukinsop, Newcastle-on-Tyne. *English.*—1 and Cup, J. W. Edge. 2, J. Chadwick, Bolton. *hc*, A. Ashton, Middleton, Manchester; J. Chadwick; T. Waddington.

JACOBINS.—*Red or Yellow.*—1, J. Thompson, Bingley. 2, T. Rule. *hc*, R. Fulton (2); W. Massey; W. B. Van Haansbergen. *Any other Colour.*—1 and 2, W. B. Van Haansbergen. *hc*, J. Thompson; W. B. Van Haansbergen.

FANTAILS.—*White.*—1, Cup, and *hc*, J. F. Loversidge, Newark. 2, J. Walker, Newark. *Any other Colour.*—1, W. B. Van Haansbergen. 2, H. Yardley, Birmingham. *hc*, J. Chadwick; J. W. Edge.

TRUMPETERS.—*Mottled.*—1, 2, and Medal, W. B. Van Haansbergen. *hc*, T. Waddington. *Any other Colour.*—1, W. H. C. Oates, Besthorpe, Newark. 2, W. B. Van Haansbergen. *hc*, P. H. Jones.

TURBITS.—*Red or Yellow.*—1, T. Waddington. 2, G. Fletcher, Acomb Landing, York. *hc*, W. E. Easten, Hull; G. Fletcher; W. Roberts. *Blue.*—, R. Youll, East Bolden, Sunderland. 2, W. B. Van Haansbergen. *hc*, J. G. Dunn, Newcastle-on-Tyne; R Fulton; A. Brown, Durham.

MAGPIES.—1, R. Harrison, Darlington. 2, J. B. Bowden. *hc*, G. and W. Smith, Durham; P. H. Jones, Fulham.

NUNS.—1, W. B. Van Haansbergen. 2, R. W. Richardson, *hc*, W. E. Easten; T. C. Benson; J. B. Bowden; W. B. Van Haansbergen.

DRAGOONS.—1 and Cup, J. Holland, Manchester. 2, T. Waddington. *hc*, R. Fulton; F. Challoner, Benwell Grange, Newcastle; J. Holland, Manchester; T. Waddington.

ANTWERPS.—1, J. W. Collinson, Ward's Hall, Halifax. 2 and *hc*, J. Stanley, Salford.

BALDS OR BEARDS.—1, J. Percival, Peckham. 2, J. Miller, Newcastle-on-Tyne. *hc*, A. J. Sticks, Newcastle-on-Tyne; A. Jackson, Bolton. *Any other Colour.*—1, C. Anton, jun., York. 2, E. C. Stretch.

ANY OTHER VARIETY.—1, A. Crosbie, Melrose (Letz). 2, T. Waddington. *hc*, M. Ord, Ferryhill, Durham (Satinettes); T. Waddington; W. Lumb, Rochdale; R. Harrison.

SELLING CLASS.—*Pairs not to exceed* £2.—1, J. G. Orr, Beith, Ayrshire. 2, J. H. Watkins, Byford, Hereford. 3, M. Ord. *hc*, J. G. Orr; R. & J. Anderson, Newcastle-on-Tyne; W. H. C. Oates, Besthorp, Newark; T. Rule. *Pairs not to exceed* £1.—1, J. G. Orr. 2, A. Crosbie. 3, W. Bearpark.

CANARIES.

BELGIANS.—*Clear Yellow.*—1 and 2, J. Rutter, Sunderland. *Clear Buff.*—1 and Medal, J. Baxter, Newcastle. 2, J. Rutter. *Ticked or Variegated.*—1 and 2, J. Rutter. *Dun, or Dun Marked.*—1, W. Pearson. 2, J. Logan, New Backworth.

NORWICH.—*Clear Yellow.*—1, J. Cleminson, Darlington. 2, W. Watson, jun., Darlington. *Clear Buff.*—1, W. Watson, jun. 2 and *hc*, J. Cleminson. *c*, R. E. Triffitt, York. *Marked or Variegated.*—1, R. Hawman. 2, J. Baxter. *hc*, E. Mills, Sunderland. *c*, J. Robson, Gateshead. *Crested Yellow or Yellow Marked.*—1 and Medal, T. Irons, Northampton. 2, J. Cleminson. *hc*, T. Allenby, Durham. *Crested Buff or Buff Marked.*—1, J. Rutter, Sunderland. 2, J. Hurnell. *hc*, S. Tomes, Northampton. *c*, R. E. Triffitt; W. Watson, jun.

GLASGOW DONS.—*Clear Yellow.*—1, W. Clark, Newcastle-on-Tyne. 2, J. Kearr, New Backworth. *hc*, J. Soulsby, Chester-le-Street. *Buff.*—1 and Medal, J. Kearr. 2, W. Bone. *hc*, C. Lugton; J. Baxter. *Marked or Variegated.*—, J. Baxter. 2 and *hc*, J. Kearr.

LIZARDS.—*Golden-spangled.*—1, J. N. Harrison. 2, and *hc*, R. Ritchie, Darlington. *c*, R. Hawman, Middlesbrough-on-Tees. *Silver-spangled.*—1 and *hc*, R. Ritchie. 2, J. N. Harrison.

GOLDFINCH MULES.—*Yellow.*—1, J. Baxter. 2, J. Stevens, Middlesbrough. *hc*, S. Perkins, Gateshead. *Buff.*—1, 2, and Medal, J. Baxter, Newcastle-on-Tyne. *hc*, J. Spence, Hendon, Sunderland. *c*, E. Stansfield. *Dark.*—1, E. Stansfield. 2, T. Tennishood, North Acklam, Middlesbrough. *hc*, J. T. Harrison, Darlington. *c*, S. Tomes, Northampton; J. Stevens (2); T. Oxnet.

LINNET MULES.—1, J. Stevens. 2, J. Spence. *hc*, W. & C. Burniston, Middlesbrough; J. Stevens.

MULES (Any other variety).—1, E. Stansfield, Bradford. 2 and *hc*, J. Baxter.

CINNAMON.—*Jongue.*—1, S. Tomes. 2, E. Mills, Sunderland. *hc*, J. N. Harrison, Belper. *Buff.*—1, S. Tomes. 2, E. Mills. *c*, J. N. Harrison. *Marked or Variegated.*—1 and Medal, J. Spence. 2, R. Hawman. *hc*, J. Stevens.

GREEN.—1, J. King, Newcastle. 2, J. Stevens. *hc*, W. Pearson; J. Baxter.

ANY OTHER VARIETY.—1, W. & C. Burniston, Middlesbrough. 2, E. Stansfield. *hc*, J. Robson.

GOLDFINCH.—1, J. N. Harrison. 2, J. Baxter. *hc*, J. Stevens.

BROWN LINNET.—1, J. Baxter. 2, J. Wilson, Darlington. *hc*, W. & C. Barniston.

FOREIGN BIRDS.—1, J. Lamb, Newcastle-on-Tyne. 2, A. B. Brown, Newcastle-on-Tyne.

JUDGES.—*Pigeons:* Mr. T. J. Charlton, Bradford, and Mr. T. H. Ridpeth, Handforth. *Canaries:* Mr. T. Lowrey, Gateshead, and Mr. W. Robinson, Backworth.

SOUTH OF IRELAND POULTRY SHOW.—Our readers will see in an advertisement particulars of this, the "Cork" Show, the first established in Ireland. The prizes are good, and there are ten cups and medals in addition.

CRYSTAL PALACE POULTRY AND PIGEON SHOW.—We are glad to learn that there is a considerable increase in the number of entries this year. The poultry entries now reach 1463, being an increase of 224 over those of the last Show. The Pigeon entries number 894. No doubt there would have been many more entries had the Exhibition been held later in the season, when the old birds had recovered from their moult.

NATIONAL PERISTERONIC SOCIETY.

THE usual fortnightly meeting of the above Society was held at the Freemason's Tavern, on Tuesday, the 7th inst., and was attended by a large number of members and visitors. Some very good birds were shown, including remarkably fine Carriers by Mr. Ord and Mr. Feltham; a very pretty pen of Turbits by Messrs. South and Jones; Yellow Dragoons by Mr. Betty, which fully sustained that gentleman's reputation; and various other good and promising birds, old and young. The Society is in a very flourishing state; and for the convenience of members and friends visiting the Crystal Palace Show, it was resolved to have a special extra meeting on Tuesday, November 14th, at 8 P.M., when important and interesting matter will be introduced.

OUR LETTER BOX.

ROSS POULTRY SHOW.—Mr. F. Crotts informs us that he obtained the second prize for Bantams.

INQUIRY.—Mr. Alexander Johnston, Bathgate, N.B., has parted with Pigeons, value seven guineas, to Mr. R. T. Williamson, Wallasey, near Birkenhead, and as he can obtain no reply from him, he wishes to ascertain if any of our readers know anything of him.

DARK BRAHMAS (*C. McHardy*).—No one without seeing the birds could justly say to which pen the prize should have been awarded.

STANDARD (*W. G.*).—No authority. The time of opening the Crystal Palace Show is not yet advertised.

FOWLS TRESPASSING (*E. G.*).—You have no remedy but seeing the owner in the County Court. We recently saw that "*spring* chickens are those which will get over from their own side of a fence." We must quote on this subject from a very amusing book, "My Summer in a Garden:"—"I like neighbours, and I like chickens; but I do not think they ought to be united near a garden. Neighbours' hens in your garden are an annoyance. Even if they did not scratch up the corn, and peck the strawberries, and eat the tomatoes, it is not pleasant to see them straddling about in their jerkey, high-stepping, speculative manner, picking inquisitively here and there. It is of no use to tell the neighbour that his hens eat your tomatoes: it makes no impression on him, for the tomatoes are not his. The best way is to casually remark to him that he has a fine lot of chickens, pretty well grown, and that you like spring chickens broiled. He will take them away at once."

GAME COCK'S SPURS EXCESSIVE (*Digitalis*).—You may safely cut off the spurs of the bird, provided you do not cut to the quick and draw blood. It is injurious to do so. You cannot be mistaken about the Game cocks—a Black must have a black breast, a Brown has a brown breast. The hen of a Brown Red is nearly black, and has a bright golden hackle. The hen of the Black Red is brown with a yellow hackle. The snake head, as it is called, is the triumph of dubbing; everything in the way of flesh is removed, leaving only the skull and face covered with the red skin. The bird has no forehead, and the skull is level with the beak.

SILVER-SPANGLED HAMBURGH COCK (*J. P. F.*).—We gave these points only a few weeks back. They must have firmly-set combs, straight on the head, piked behind and turning upwards, full of points, rather large than small, but not overhanging the nostrils. Both sexes should have taper blue legs and a spangled breast. The wings should be barred and laced, the tails clear, with a distinct moon at the end of each feather. The hen must have a dark hackle, and her plumage should be accurately but plentifully spangled. There should be no mossing or indistinctness.

EXHIBITION GRIEVANCES.—"If '*E. S. J.*' were to change places with a secretary to a poultry exhibition only once, he would then understand the vast amount of anxiety, thought, and labour a secretary must go through before a show is brought to a close. He would never after be jealous if a secretary had the honour of taking a prize, or wish to exclude him, his son, or daughter from exhibiting.—HON. SEC."

POULTRY FEEDING (*P.*).—In very severe weather you may give your fowls some bread and ale, but they are not necessary under ordinary circumstances. When the ground is frozen as hard as a rock, and scratch is impossible, give them a little; when the surface of the earth is hidden by snow do the same. At other times good ground oats and whole barley are enough for them. (*Owl.*)—Always barley will not do. Vary it with some maize at midday. We do not much admire sharps. Give them the crumbs and cloth sweepings from the luncheon-table, also the kitchen scraps. The contents of the wash-tub will often mix well with barley-meal, and make good food for fowls. These are changes, and they are necessary. Fowls will starve to death on the best barley or any other food if they are confined to it.

WEIGHT OF LIGHT BRAHMAS AND COCHINS—DORKINGS (*E. S. P.*).—Your Brahmas and Cochins are not flagrantly wrong in anything. Their weight is good, but they should now begin to put it on faster. The description you give of your Dorkings is that of good Silver-Greys. They seem right in all particulars but one. It is a sad fault for the spur to be outside. It is a sign of bad constitution if these birds get long-legged; or of doubtful merit where the claws are badly developed. The leading characteristics of a breed should be strikingly carried out in every member of the family.

CRÊVE-CŒURS (*E. J. P.*)—You can get a Crêve-Cœur cock of any of the London dealers. Most of them keep them. Baily, in Mount Street, imports them largely.

EGGS MUSTY-TASTED (*J. R. W.*).—We frequently have such complaints as yours at this time of year, and especially where the birds run in shrubberies and pick up berries or search under leaves, and eat something that pervades the whole body. Nothing acquires taste more easily than an egg, and a fowl fed on garlic or shallot will impart the flavour of either to her eggs. It is difficult to advise you because you do not know

which are the offending birds, but we can give you comfort—it is only just now the eggs will have that taste. If you know the hen, then about two doses of castor oil, each about a table-spoonful, given at twenty-four hours' interval, will cure it.

Turkeys' Livers Disordered (*F. P.*).—The complaint is a disordered liver, the cure is not so easily given. Change of food, castor oil, and Baily's pills will do most good. Give no potato, no Indian corn. Put camphor, or wormwood, or both in the water they have to drink, and see that they roost in a place sheltered from the wind.

Duck's Legs Paralysed—Turkey Feeding (*R. C.*).—We fear your Duck is in bad case. The paralysis arises from internal disease or external injury. In either case we believe it to be incurable. It will be a kindness to kill it, as it will certainly die a lingering and painful death. Ducks are hardly more amenable to medical treatment than boas or cobras. We know a very intelligent man who fancied calomel was the right thing for poultry, and commenced his experiment on a Duck and a hen. He had a little leaning to homœopathy, and began with the smallest possible doses. He gradually increased the dose till the Duck took three table-spoonfuls, and the hen pecked it as fast as she could, and our experimentalist could not see any effect. Turkeys do well on ground oats, with a small quantity of beans and peas ground with them, and mixed with milk. They should be shut in a small place where they can roost comfortably, and should have their food in a trough, but only as much as they will eat at a meal. It should be fresh mixed morning and evening The very heaviest London Turkeys are crammed, but that is not necessary for ordinary purposes.

Removing a Tumour (*G. R. B.*).—You should have removed the tumour before it became so large as it is. It must be taken off at once. It will be a trifling operation if the tumour is not attached to the breastbone—so trifling, that when you open the skin the tumour will probably fall out. If it is attached to the bone it must be cut off with a very sharp knife or pair of scissors. There are two skins which will require to be sewn up separately, and each suture should be well rubbed over with grease. The bird will suffer very little. Your feeding is bad without being cheap. Light wheat is expensive food. Weight for weight, that which costs more costs less. Indian corn is a favourite food with fowls when whole; they will not eat it ground if they can help it. Boiled potatoes and boiled rice are worse. Hempseed is not good, being too heating. Feed on ground oats, whole Indian corn, and table scraps. We have no doubt the tumour or excrescence arises from weakness and insufficient food. It is possible that with feeding such as we prescribe he might weigh less, but he would look and show more. He would be as the trained 10-stone man is compared to the heavy, sleepy, spiritless man, who from sheer fat weighs 4 or 5 stone more. We know no one who can perform the operation for you.

Hastening a Pigeon's Moulting (*E. J. K.*).—Put your bird by itself in a clean pen in a warm place—for instance, a harness-room, or any south-fronted, warm, and dry building, and if it be cold, where there is a fire. Feed it on wheat and hempseed mixed. After this treatment be very careful that you send it to the show in a doubly-warm basket, one having canves or other material inside the wicker, or it would be sure to get cold.

Stocking Bar Hives (*Barton Joyce*).—The usual method adopted in shaking a swarm into bar or frame hives, is to hive the swarm first into a common straw hive. As soon as the bees are properly settled, or in the evening of the same day, they are knocked out on a cloth and the box set over them resting on two sticks. A better way is to remove the top board; see that the frames are all in place, and the bees furnished with bits of worker-comb for guide, then take the straw hive contsining the bees, and with a sharp concussion between the two hands dislodge the cluster so as to cause the bees to fall on the very top of the bars, repeating the blows until all are fallen. Some of the bees will pour out over the sides of the box, and many will go down between the bars at once. With a small sheet of zinc, or a spoon, shovel those bees that cluster out over the back on the top of the bars, and when the majority have gone down take the cover, and placing it on the extreme edge of the back of the hive, gradually press it on over the top, keeping it flat on the box. Those bees that are left outside will soon find their way in at the entrance. This is all best done as soon as the swarm has settled in the straw hive.

Saddle or Berkshire Hive.—"Can any of our readers give the weight of an empty saddle or Berkshire hive—that is, of the store-box minus the super?—J. H."

Feeding Bees (*Idem*).—If your hive is still so empty of honey, after all your feeding, that you cannot see any honey sealed-up or glistening in the open cells, you will have to feed probably all through the winter. But we would advise you to lose no time, and feed diligently every day that the weather is fine and still, and the bees abroad. Stop feeding when the weather is cold, and resume again on the return of mild open weather. Sugar-candy has been found a good food for bees, but it is usually made of loaf-sugar. We have no experience of the brown. We should thrust it in at the entrance rather than in the supers, taking care that it goes right into the hive below the combs.

Syrup for Bees and Barley Sugar (*E. S. H.*).—The syrup is best made of three parts of sugar to two parts of water by weight. Boil a few minutes; when cool it should be of the consistency of thin but not watery honey. Should it have been boiled too long and become too thick, a little water can be added to thin it. Recipe for barley sugar as food for bees:—Add to 3 lbs. of refined sugar a pint and a quarter of water, boil it quickly till it becomes very thick. Pour it on to a marble slab, or on to shallow dish slightly oiled or rubbed with butter; and when it begins to harden at the edges form it into sticks, lozenges, or balls, or any other shapes at pleasure.

Mange (*Blackpool*).—There are many varieties of skin disease to which dogs are liable. If it is that caused by an insect, then, as described by Mr. Meyrick, "the hair comes off in large patches, principally on the back and neck and round the eyes; in some cases the dog becomes almost bare. The skin is dry, hot, wrinkled, and scaly. The appetite generally continues good, but there is a great deal of thirst and some fever. The dog is continually scratching himself, and rubbing against the furniture if he is kept in the house. The old-fashioned sulphur treatment, if properly followed, is generally specific. Give small doses of sulphur (five grains) three times a-day, and rub into the skin equal parts of lard and sulphur. This operation should be performed before a fire to make the ointment flow, and the whole skin should be thoroughly saturated. Four or five applications, at intervals of three days, are usually enough to cure the disease. The skin should be well washed each time before the ointment is applied. In a very severe case the dog may be bled, and the ointment of iodide of mercury rubbed in, the dog's bowels being kept open, if necessary, with castor oil."

Grape Wine (*J. M. R.*).—We do not think it will ferment excessively if undisturbed and if you did not put yeast into the must. A little brandy added checks fermentation. We will give further information next week

REMARKS.

1st —A very lovely autumn day, clear and bright throughout.
2nd.—A cloudy but dry day.
3rd.—A very bright morning, cloudy at noon and so continued, but fair and pleasant.
4th.—Alternate sunshine and cloud with a little rain, but on the whole a pleasant day.
5th.—Very fine day though cold and wintry; stars bright at night.
6th.—Strong white frost; fine morning, but rather hazy after.
7th.—Foggy all day and occasionally dark, but clearer in the evening.

A dull November week with easterly wind, but damp atmosphere and falling barometer. Slight frost in the air only on one day, Monday the 6th. —G. J. Symons.

COVENT GARDEN MARKET.—November 8

Notwithstanding the fine weather of the past week, we are not able to report so firm a market. In rough produce trade has been heavy the last few days, and a considerable quantity has gone over from day to day. Importations have also been large. Good dessert Apples are scarce; Pears are sufficient for the trade, comprising Marie Louise, Glou Morçeau, Van Mons Léon Leclerc, Beurré Diel, and others. Dealers in Potatoes report that crops are heavy, and that a large proportion of them is, in some districts, affected with the blight.

POULTRY MARKET.—November 8.

We are tolerably well supplied. We have not a great demand, nor is there any glut. The prices are quite equal to those usually made at this time of year.

From observations taken near London during forty-three years, the average day emperature of the week is 58 8°, and its night temperature 41.4°. The greatest heat was 81°, on the 20th, 1866; and the loweet cold 18°, on the 19th, 1868. The greatest fall of rain was 0.80 inch.

SUCCESSIONS OF VEGETABLES.—No. 3.

HAVING been informed that my papers on Peas for succession were acceptable to a large number of the readers of this Journal, I have come to the conclusion that to make similar remarks on all the remaining kitchen garden crops would be serviceable. With this in view, I purpose to go through the whole list of vegetables, and Peas having headed the list, I will next turn my attention to Beans.

BROAD BEANS.

Early Mazagan.—Height 2½ feet. The hardiest and earliest. Sow November 5th to 10th, December 10th, and February 15th. All theee sowinge should he made on a warm border, one with a south aspect if possible, and in light soil. Draw the soil to the plants when they are fairly above ground. Sow also March 10th.

Early Longpod.—Height 3 feet. Larger and more productive than the preceding, but not so hardy, nor so early. Sow February 15th and March 10th.

Mackie's Monarch Longpod.—Height 3 feet. Fine both as regards prodnctiveness and quality. Sow March 10th and 25th, April 10th and 25th, May 10th and 25th, June 10th and 25th, and July 5th.

Broad Windsor.—Height 3 feet. Beans large, of good flavour. Productive. Sow March 10th and 25th, April 10th and 25th, May 10th and 25th, June 10th and 25th, and July 5th.

Green Longpod, or Genoa.—Height 3 feet. Productive, and said to be valued for its green colonr when cooked, but I have not known any great demand for these green Beans. Sow March 10th and 25th, April 10th and 25th, May 10th and 25th, June 10th and 25th.

Green Windsor.—Height 3 feet. Large and green. Sow March 10th and 25th, April 10th and 25th, May 10th and 25th, June 10th and 25th.

Here we have forty sowings of six varieties, sufficient seeding for a garden of four acres, a pint of each being sown at a time, except the first sowing of the kinds named for late autumn and first spring sowings, which should be quart sowings. For a garden of about two acres the first four kinds are recommended, the first sowings up to and inclusive of the first March sowing being of a quart each; afterwards sow pints. If green Beans are wanted, then one of those named may be sown instead of Monarch or Windsor, only the green sorts are not nearly so good. For a garden of three-quarters of an acre to an acre take the first-named three, and if a green one be required, sow the Green Longpod occasionally along with Monarch, sowing half the quantity of the latter variety.

For the first sowings light and moderately rich soil is most suitable, but for the March sowings and afterwards a good, rich, strong loam is best. The rows should be 2 feet apart, and the plants earthed-up when about 2 inches high. Cut off the tops just level with the bloom on the stems, for it ceases to be produced at a considerable distance from the top, and for the early crops cut over after a foot of flower-stem is secured.

Broad Beans north of the Hnmber come into use about the middle of June and continue until November.

For small gardens, or wherever space is a consideration, it may be advisable to sow the dwarf kinds.

Beck's Gem.—Height 1 foot. Dwarf and prolific. It is early, but not so early as the Mazagan, of which a few should be sown November 10th; it is the hardiest. Sow March 5th and 20th, April 5th and 20th, May 5th and 20th, June 5th and 20th.

Royal Dwarf.—Productive and dwarf. 1 foot. Sow November 10th, February 15th, March 5th and 20th, April 5th and 20th, May 5th and 20th, June 5th and 20th.

These may be sown in rows 1 foot apart, and a pint of one of the kinds sown at the times named will be sufficient for a garden of half an acre; I consider Beck's Gem the best, but half a pint of each may be sown. For a garden of one-eighth of an acre, half a pint of one of the kinds, sown at the times stated, will be ample. In the case of dwarf Beans, as in that of dwarf Peas, more seed is required than of the larger kinds. A quart of Beans will sow a row of 75 feet, or 25 yards.

DWARF KIDNEY BEANS.

Sir Joseph Paxton.—This is evidently an improved Early Forcing, Sion House, or Six Weeks, and with me best of all for early crops, whether forced or in the open ground. Height 1 foot to 15 inches. Sow April 15th on a warm border, May 1st and 15th, June 1st and 15th, and July 1st and 15th in a sheltered situation.

Dark Dun, or Liver-coloured.—1 foot 6 inches to 2 feet. Very prolific. Sow May 1st and 20th, June 10th and 25th, and July 10th, in a sheltered situation.

Negro Longpodded.—1½ to 2 feet. Very prolific. Sow May 1st and 20th, June 10th and 25th, and July 10th in a sheltered situation.

Half a pint of each sown at the times named is sufficient for a garden of two acres; whilst for one of an acre let the first two sowings and last be of Sir Joseph Paxton and Negro as specified, omitting Dark Dun. For half an acre let the first and last sowing be of Sir Joseph Paxton, and every alternate one of Negro, but also including the first.

The first and last sowings cannot have too warm a situation. Light soil is best for these; but rich deep loam is best for the successional sowings. The rows may be 2 feet apart, and the plants should be earthed-up when about 2 inches high. In dry weather they cannot have too much water, and liquid manure may be given between the rows; but the pods must be always gathered as they become fit for use. Half a pint of Kidney Beans will sow a row 25 yards long.

Dwarf Kidney Beans are in season from the early part of July to October or November, according to the time at which frost occurs.

TALL OR RUNNING KIDNEY BEANS.

Scarlet.—Very prolific, the best for general crop. Sow May 1st to 10th, and June 1st.

Carter's Champion.—A strong-growing variety of the Scarlet Runner, with much finer pods, very prolific. Sow May 1st and June 1st.

The Runner Beans succeed best in rich, deep, light soil, and should be sown in rows 6 feet apart, and the seeds about 4 inches apart. Good stakes should be driven into the ground at a foot apart, and so as to be not less than 6 feet above ground. To encourage early produce it is well to top the shoots at 1 foot, otherwise I do not advise stopping. Water abundantly in dry weather after the plants have come into flower, and liquid manure may advantageously be given once a-week.

One quart of each sort is sufficient for a garden of two acres, and half that quantity for one acre. Scarlet Runners

are in season from the early part of July until destroyed by frost.—G. Abbey.

SELECT ROSES.

One of our first Rose amateurs—not a grower for exhibition only, although the winner of many prizes—has asked me to send to the Journal a list of the best twelve Roses. I cannot but comply with this request. The task, however, would have been easier had the number been less restricted, or had the request been accompanied by a more distinct intimation as to the point of view from which the flower is regarded. It is well known that the best show Roses are not always the best for the garden or for purposes of general decoration, and the best for garden or house decoration are not always the best for exhibition. The grower who enjoys his Roses on the tree or when cut and placed evenly in vases, would not attain his end in the most complete manner by choosing the best show Roses. I shall therefore give my opinion of a separate dozen first-class flowers from each point of view; and as the growers for garden or house decoration are more numerous than the growers for exhibition, that list would seem fairly to claim the precedence.

Twelve First-class Roses for Garden or House Decoration.

Duke of Edinburgh.—Fine in colour.
Elizabeth Vigueron.—Blooms abundantly late.
Jules Margottin.—Very floriferous.
La France.—Free, fine, and very sweet.
Mdlle. Eugénie Verdier.—Fine, but sometimes rough.
Madame Alfred de Rougemont.—Good white.
Madame Victor Verdier.—Always good.
Monsieur Noman.—Good and distinct.
Princess Christian.—Very floriferous and fine.
Madame Falcot.—Free and fine.
Countess of Oxford.—Loses shape; a little early.
Gloire de Dijon.

Twelve First-class Roses for Exhibition.

Alfred Colomb.
Madame la Baronne de Rothschild.
Madame Vidot.—Uncertain, but often the best white Rose.
Marie Baumann.
Perfection de Lyon.—Uncertain, but grand when managed.
Charles Lefebvre.
Pierre Notting.—Uncertain, but grand when managed.
Louis Van Houtte.
Marquis de Castellane.
Devoniensis.
Maréchal Niel.
Souvenir d'Elise Vardon.

Now for a few general remarks. In the first place let me say that it is by painful effort I have excluded from the above lists so many good and valuable Roses. It is only in degree less painful than it would be to set down a list of one's twelve best friends, when there were scores or hundreds never encountered without feeling the pulse quicken and the heart grow lighter. Twelve Roses! when there are scores or hundreds which one cannot regard otherwise than with unqualified delight! Then one must have variety in colour. The white Roses are the weakest, but we must have some, and can only have the best. The crimson Roses are the strongest, and some of that colour omitted are better Roses than the white ones included; but we must not have too many of that colour. Further, certain varieties thrive better in one soil, in one climate, or under one system of management than in or under another. The seasons, too, influence Roses greatly. A flower that is fine in a cool cloudy summer is often of a lower quality in a warm sunny one, and *vice versâ*. With me Louis Van Houtte, although not a very strong grower, grows well enough and is a good hardy Rose, producing an abundance of fine flowers, but some of my friends tell me that with them it is weakly and unsatisfactory. Tastes also differ. I should place La France and Madame Falcot among the very best of garden Roses, but should hardly include them in a limited number of show Roses. My ideal of a show Rose is a smooth globular flower, full, of good substance, clear in colour, and of large size. La France loses its shape too soon to be a safe show flower. Edouard Morren is fine when caught, but uncertain. Mdlle. Eugénie Verdier is a good garden Rose. Prince Léon I have discarded altogether. Homère is one of the hardiest of Tea-scented Roses, growing and blooming freely. I received this Rose the first year from the raiser, and the second year I received the same Rose from France under the name of Socrates. There is confusion abroad with these two varieties; our Homère is often met with in France under the name of Socrates. I have a great love for Tea-scented Roses, but have not put more in my list because they are not hardy enough for out-of-door culture in all places. I believe, however, that some varieties of this group recently introduced will prove grand acquisitions both for general decoration and for exhibition; while clearer in colour and more constant in shape than Gloire de Dijon, they grow vigorously, and promise to be as hardy as that grand old Rose. —W. Paul, *Paul's Nurseries, Waltham Cross, N.*

A GRAPE VINE FOR TABLE DECORATION.

In order to provide a variety of dinner-table decorations one is compelled to exercise some judgment, and, therefore, must pass out of the beaten track in order to produce something pleasing, and if not altogether striking, it is the more appreciated. I will not trouble your readers with any lengthy preamble, because what I am about to describe is by no means novel, but has been practised for many years; so a review of the past is only to act as a "refresher." I shall, therefore, proceed to explain how a young healthy Vine loaded with fruit may be prepared so as to be suitable for the decoration of the dinner-table.

Select a fruitful Vine, from an eye the previous year, grown in a 12 or 14-inch pot in the ordinary way for forcing. Place the Vine in a late vinery where it will have plenty of light; draw the cane through the hole of a 7-inch pot, and allow the pot to rest on the surface of the soil in which the Vine is grown. Then fill the 7-inch pot with light, rich, and open soil, which will become filled with roots in the course of two or three months. The uppermost pot must be watered as occasion requires.

I have grown three Vines this year for the purpose described, each Vine carrying on an average eight bunches of fair size and quality. I used the first about the middle of September. When required for use a strong knife is thrust between the upper and lower pot, severing the Vine at its base. The 7-inch pot will then be found to be crammed with roots, which are quite sufficient, with frequent waterings (I set my pots in pans filled with water), to keep the Vine always fresh. A neat stake about 18 inches in length, or 2 feet if found more convenient, should now be inserted in the centre of the pot, and the Vine then carefully coiled round the stake, making it fast with neat ties of matting. A more pleasing object than such a Vine cannot well be imagined, its bunches of black fruit hanging gracefully down amidst a profusion of green foliage. I may add that I use only black Grapes, as they have, I think, a better appearance than light-coloured ones when placed on the table.—J. Gardner, *The Gardens, Elsham Hall.*

SANTOLINA INCANA.

I can endorse Mr. Luckhurst's remarks on this plant (see page 313), in respect to its being very easily grown and useful for bedding purposes. It is one of the many old subjects that have been brought into more general use during the last few years. We have used it for edging purposes for several seasons, and it has been admired by many persons. Its being quite hardy is a recommendation, as we have already quite enough of tender subjects to propagate.

I have found the best way of growing Santolina incana to be dibbling-in the cuttings about an inch apart in a Calceolaria frame during the first week of September. The Calceolariae are usually taken out in the second week of March and planted in Celery trenches.

The Santolina can be moved at the same time and planted in the position it is intended to occupy in the flower garden. It will bear cutting with the shears very well, and for edgings that have stood one year and are intended to remain, the best time to cut it back is March or early in April, and we cut it hard back with the best results. I am of opinion that in positions where it does not grow too high to interfere with the plants with which it is associated, it looks best not cut the first year—it has then an ease and gracefulness which we do not find in close, level lines. I have often compared it to a plantation of young Larch trees on a small scale.

I am surprised at the high price at which Mr. Luckhurst says it is selling—viz., 12*s.* per dozen, as it is one of the easiest plants I know to secure a stock of. A number of plants are growing here in a kitchen-garden border, struck in the autumn of 1869, and they are now nearly 2 feet high. I may add that the soil where they are growing is rather rich and

shaded, still the plants will grow freely enough in any ordinary soil.—H. J. C., *Hackwood Gardens, Basingstoke.*

GLADIOLUS CULTURE.

The subject of this article holds, and I think justly, the highest position amongst autumn flowers, for it has now been brought to a high state of perfection, and some of the varieties already sent out will not easily be surpassed. Of course I do not mean to say there is no room for improvement—there is; for instance, we have yellow flowers, but a clear yellow with the flower and spike of Madame Furtado is very desirable. What an acquisition would also be a variety with the colour of Lord Byron and the flowers and spike of Orphée; and so, too, would be flowers of other colours which we have not yet succeeded in obtaining.

Seedlings are easily raised, but it is not so easy to obtain a first-class variety with a good constitution and superior to those already in commerce. There have been a few good varieties raised in England, but the stock of them is very limited; indeed, I cannot name a single flower that has been sent out as yet in this country of any value to an exhibitor. The new varieties raised in France and grown by M. Souchet, can be obtained by the dozen from any seedsman in England, and it is on him that we must as yet depend for new varieties. If we do get a good many worthless sorts sent over every year, there are always a few really good flowers amongst them, and we must be content to weed out the bad ones as we do with the Roses. Some of the varieties have a decided tendency to degenerate in this country; others, again, seem to improve. I believe that in our anxiety to obtain the finest possible spikes we destroy the constitution of the plants by overfeeding. Under such circumstances many of the bulbs deteriorate, whereas if differently treated they maintain their position.

I can safely affirm that some of the French varieties have improved with me; of Madame Dombrain, for instance, I thought little the first year it was sent out, and this season, though an unfavourable one, it was finer than I ever had it before. Madame Desportes, sent out the same season, was magnificent, but I have not had a good spike of it since. Some varieties succeed better in unfavourable seasons than others, and I sometimes find that those varieties which flourish in a wet season will not do so in a dry, hot year; thus we must not be too hasty in discarding a variety that for the moment may be unpromising.

Another statement I ought to make is this, that many new sorts sent out at the highest price will not grow under any circumstances; they will sometimes grow in a promising manner at first, and ultimately go off in decline, dying-off while in apparently luxuriant health when the first flowers are on the point of opening. To be thus disappointed after months of unceasing care is most disheartening to the beginner, but the experienced cultivator makes up his mind to a certain number of losses annually.

I have had much success in the culture of the Gladiolus. I grow every good variety that is sent out, and a considerable number of bad ones, as well as hundreds of seedlings every year, and in my opinion no other autumn flower can be compared to this for grace and beauty. The Dahlia and Hollyhock are indispensable for the adornment of large gardens in autumn, but in small gardens they can seldom be introduced with advantage, and are of but little use for decorative purposes in-doors; but in no garden, however small, if the soil is suitable, can the Gladiolus be out of place, and few subjects are better adapted for being arranged in vases for the drawing-room, or for the dinner-table. During August and September this flower is produced in the greatest profusion, although by early and late planting a sufficient number of spikes may be obtained in July and October. The Gladiolus is admirably adapted for exhibition in autumn, and will be grown for this purpose as long as societies give sufficient encouragement; and what a striking contrast they form to the long formal lines and dumpy appearance of stands of Dahlias and cut blooms of Hollyhocks!

Whether Gladioluses are grown for exhibition or for general decorative purposes, the ground must be prepared for them by deep trenching and heavy manuring the previous autumn. No doubt a light sandy loam is that best adapted for the Gladiolus, and for such soil cow manure is the best; if it is a stiff loam, plenty of road-scrapings or sand may be incorporated with it, and stable manure should be used, but in every case the manure ought at least to be 6 inches beneath the surface. In fine weather during winter, and when the ground is dry, the surface may be lightly forked over. Choose a fine dry day about the middle of March to plant the first lot of bulbs to come in earliest. Do it thus:—Stretch a line across the border, and with a hoe draw four drills a foot apart; in these drills place the bulbs, also a foot apart, with a little sand over them, and then fill in the drills, so that there may be 2 inches of mould over the crown of the bulb. A space of 2 feet 6 inches should be allowed between the outside rows of each bed, to allow a man to get down with a water-pot without injuring the plants. The sticks should be put in at an early stage of growth, as, if this is delayed, not only does the plant incur the risk of being damaged by the wind, but the roots are injured by pushing the sticks into the ground. To prolong the blooming period, plant a few bulbs every fortnight until the first week in June.

As soon as dry weather sets in the watering-pot must be used, and to prevent evaporation mulch the beds with decayed frame manure. It is as well to state that when ground is highly manured there is always great danger of overwatering; even in very hot weather I seldom water the beds oftener than twice a-week, and then I do not use manure water.

The spikes should be fastened to the sticks as they appear, and this is nearly all the attention they require. Some growers shade the spikes to prolong the bloom, but the colours are brighter when the spike is freely exposed. If required for in-door decoration the spikes should be cut as soon as the first three flowers are expanded; the others will open in the water.

The best time to dig up the bulbs is towards the end of October, when a dry day should be chosen. Cut the stalks off as they are lifted, and place each sort with the label in an empty flower-pot; the small bulbs or spawn to be found at the base of the bulbs should be saved if an increase in the stock is desired. The pots must be placed in a dry airy position for a week or two, and if they are in the way, wrap each sort separately in a sheet of paper and pack all of them away in a box secure from frost.

The Gladiolus is also well adapted for pot culture, and fine spikes are obtained in this way. When thus grown the plants in flower may be removed to any desirable position, and are exceedingly effective in the greenhouse, in a conservatory among Ferns, or placed where the spikes rise above the foliage of plants not in flower. It is well to grow a few bulbs in pots to fill up blanks in the beds, say eight or ten to every hundred planted out. The best compost for the Gladiolus in pots is turfy loam of a light sandy nature three parts, one part rotted manure, and one of leaf mould, with a proportion of sand larger or smaller as the loam is light or heavy. Pot one bulb in the centre of a 6-inch pot, and when the plant has grown 6 inches, shift it again into an 8-inch pot. The pots should stand out of doors in an open position, but sheltered from cutting winds.

I append to this a list of the best sorts for exhibition. The best of the new ones for 1870-71 are Edith Dombrain, Horace Vernet, Nestor, Phidias, Sir J. Franklin, and Talisman. Of older sorts I recommend Armide, Adolphe Brongniart, Delicatissima, Etendard, Eugène Scribe, Fulton, Galilée, Homère, Horace, James Veitch, Lacépède, Madame Basseville, Madame Desportes, Madame Furtado, Maréchal Vaillant, Marie Dumortier, Mary Stuart, Meyerbeer, Legonvé, Ophir, Orphée, Princess Mary of Cambridge, Princess Clotilde, Madame Dombrain, Rosa Bonheur, Rosea perfecta, Rossini, Schiller, Shakespere, Sir W. Hooker, Ulysse, and Virgile.—J. Douglas.

THE CULTURE OF THE CYCLAMEN.

I obtained a packet of seed in February last, and sowed it in a shallow seed-pan, using sandy loam and a little well-decayed cow manure, with a covering of silver sand after sowing. I then placed the pan in a gentle bottom heat, and the young leaves soon made their appearance. As soon as the seedlings had made two leaves I potted them in thumb-pots and placed them near the glass, giving them very little water, but not allowing them to become dust dry. They soon filled the pots with roots. I then gave them a shift into 60-sized pots and let them remain till spring.

When the bedding plants were taken from the cold frames at the end of May I gave the young plants another shift, and let them remain in the cold frame all the summer months, keeping them well watered and slightly shaded in very hot weather. At the end of September I put them in 6-inch pots and placed them in a warm pit; very soon they began to show their flowers,

and now in nine months I have beautiful plants covered with flowers, the corms being nearly an inch in diameter. I have other plants which have been growing two years under cool treatment, and they are not nearly so good. From the packet of seed sown in spring I have several distinct varieties, and very sweet-scented.—Owen Orpet.

GREENHOUSE PLANTS.—No. 8.

Lachenalia.—A genus of beautiful small-growing plants, with rather long, narrow, fleshy, spotted leaves, and erect flower-stems about 6 inches long, bearing racemes of pretty pendant flowers from March to May.

Lachenalias are best grown on shelves near the glass, or in other light airy positions. Six-inch pots are quite large enough for a dozen bulbs, and for six or more a 4-inch pot, potting them so that the crowns may be just covered with soil. The pot should be well drained, and a compost of equal parts of light fibrous loam, sandy peat, and leaf soil, with a sixth part of silver sand, and the same proportion of charcoal, will grow them well. Commencing growth early in winter they should be potted then, or whenever they begin to push, and any desired increase may then be secured by dividing the bulbs or removing the offsets. Water as soon as they begin to grow, and continue to keep the soil moist until the leaves turn yellow, then discontinue watering until growth recommences.

The species are rather numerous, but a dozen of the best are—Lachenalia tricolor, red and yellow; L. fragrans, white and red; L. orchioides, green and white; L. pendula, red and greenish yellow; L. pallida, pale blue; L. quadricolor, scarlet and yellow; L. discolor, brown and orange; L. contaminata, pink; L. pustulata violacea, bluish purple; L. reflexa, pale pink; L. uniflora, white and blue; and L. rubida, red. When first potted the bulbs should be placed on and surrounded with silver sand.

Antholyza æthiopica maxima, a rather tall but pretty Iridaceous plant from the Cape of Good Hope, produces its showy orange scarlet flowers in a cool greenhouse from February to April. Surround the bulbs with sand, placing them about an inch deep, and plant half a dozen in a pot, allowing a distance equal to the diameter of the bulbs between every two, and also between them and the sides of the pot. Use the same compost as for Lachenalias. Water freely during the growing period, keep them dry when at rest, and pot when they begin to grow. After May the plants succeed in a warm situation out of doors, but must be placed under glass before frost.

Blandfordia Cunninghami.—This has rather long, linear, channelled leaves, and the flowers are of a deep red, with the ends of the petals yellow; they are produced in summer about July.

Blandfordia aurea.—Leaves narrow, linear, and channelled; flowers golden yellow, bell-shaped, and drooping, 1½ to 2 inches in length, and nearly as much in width, borne on a flower-stem 1 to 2 feet in height.

Both of the above are fine subjects for the greenhouse or conservatory, and succeed admirably in a compost of two parts of sandy peat, one part of light fibrous loam, and one part of leaf mould, the whole chopped up, but used in a rough state, adding one part of sand. Repot when the plants commence making fresh growth, watering freely until growth is completed, and the flowering past, then water less freely, but at no time must the soil be allowed to become very dry. The drainage must be good. Afford a light airy position, the nearer the glass the better, so long as the foliage does not touch it.

Bravoa geminiflora.—A small bulbous plant, with red flowers in July. Sow about half a dozen bulbs in a 6-inch pot, potting them in October, keeping them just moist over the winter. When they are growing water freely, lessening the supply after flowering, so that they may be rather dry up to October, then repot. Keep the plants near the light, and give abundance of air. The compost named for Lachenalias will suit these plants.

Chlidanthus fragrans.—A pretty bulbous plant, producing in June or July yellow, trumpet-shaped, fragrant flowers. It grows about a foot high. It should have a compost of two parts light fibrous loam, one part sandy peat, and one part leaf soil, with a free admixture of sand. Pot in March, removing all the soil, but not if it is filled with roots, and remove all the offsets, which it puts out very freely. The offsets may be potted and grown for future flowering. They will attain to a flowering state in one or two years. Water freely while the plant is growing, and in winter keep it dry.

Gastronema sanguineum.—A very pretty Amaryllidaceous plant, attaining a height of about 9 inches. Flowers bright scarlet, produced singly late in spring or early in summer. Let it have a pot twice the diameter of the bulb, potting so that the latter may be covered to the neck, which is rather long, surrounding it with sand. Keep it moderately watered for some time after repotting, which may be done in February; when the plant is growing freely water copiously, and when a good growth has been made give less water, but do not allow the leaves to flag. The plant should be kept near the glass in an airy position, and with little water until the return of growth early in spring. Soil, sandy loam, fibrous peat, and leaf mould in about equal proportions, with a sixth part of silver sand, and good drainage. *Gastronema sanguineum flammeum* is a fine variety, if variety it is, having generally double flower-scapes instead of single. The flowers are of a rosy carmine, but in some plants they are rosy pink. They appear during the early spring months simultaneously with the leaves, which are dark green. It is very pretty.

Albuca fastigiata elongata has long recurved leaves, tall flower-scapes 3 feet or more in height, bearing a raceme, about a foot in length, of white flowers tipped with green, which, from their long stalks and their waxy texture, are excellent for cutting. It flowers in June or July. Repot in March, removing the soil that comes away freely. Use in a rather rough state a compost of two parts sandy peat, and one part sandy loam, draining well. Water very freely whilst the plant is growing, and in winter keep it dry in a light airy position. A pot twice the diameter of the bulb is sufficient. Remove the offsets when repotting.

Anisanthus splendens.—Gladiolus-like foliage; flowers bright scarlet, in June or July; height about 2 feet. It requires the same treatment as Atholyza.

Arum crinitum.—Stem finely marbled; flowers pale flesh-coloured, broad, and of considerable length, produced in April or May. It is interesting and curious. Repot the plants early in spring, removing all the soil that comes away freely, and water moderately for a time, but freely when growing and flowering. The growth being complete water less freely, and in winter keep them merely moist, and no more. In hot weather they are the better of a slightly shaded position. Light sandy loam, with a little leaf soil, and good drainage, will grow them well.

Cyrtanthus obliquus.—Flowers deep golden yellow or orange, with green; very curious; fine evergreen foliage. The flowers are produced early in summer, generally in June. Soil hazel or yellow loam, fibrous, and used rather rough, adding a third of leaf soil or old cow dung. Give a pot twice the size of the bulb in width, and pot so that the bulb may be covered to the neck, affording good drainage. The best time to repot is after flowering or July, not removing more of the old soil than any loose parts, and not giving a large shift; pot firmly, and water freely while the plant is growing, but when the growth is complete place the plant near the glass, in the full sun, and give no more water than will preserve the leaves in a fresh state, for being an evergreen it must have water in winter, but the less, so long as the leaves do not shrivel, the better.

Cyrtanthus coccineus has scarlet flowers, C. McKenni has creamy white and slightly fragrant flowers, and is a newly-introduced variety.

Pancratium rotatum.—Fragrant flowers, white, borne on erect stout flower-scapes in clusters of sometimes a dozen. It has the outer segments of the flowers about 3 inches long, and a funnel-shaped crown not unlike a Daffodil or Eucharis. The period of flowering is generally July and August.

Pancratium speciosum.—This also has white flowers, which are sweet-scented, and appear from April to June or July. Soil and treatment the same as for Cyrtanthus.

Richardia (Calla) æthiopica.—An old and very common plant, being an herbaceous perennial, having fine Arum-like foliage, and creamy white spathes. It is an excellent window plant, and thrives amid the smoke and dust of large towns as well as in the purest air, and seems only to require abundance of water when growing, and sun to ripen the growth, or light with dryness will do. I have some fine masses of it producing magnificent flowers in spring and the early part of summer, and its foliage from September all through the winter resembles that of a fine green-leaved Caladium.

My mode of treatment is as follows:—After the flowering is past, and the foliage is dying down, water is less plentifully given, and in July the plants are turned out of the pots, the old soil removed, but the roots not much disturbed, and non-

of the offsets taken off unless increase be wanted, and then they are removed with good roots, and placed in pots that will hold them without cramping. The old plants are put into pots that will hold the ball, and allow of about 1 inch or 1½ inch of fresh soil all round, and it is put in firmly while rather dry. Good drainage is given, and the compost used is light turfy loam, with one part of leaf soil or old Mushroom-bed dung. The plants are set in a slightly shaded position, and have water rather sparingly, then they take their own time in starting into fresh growth, which will generally occur about the close of August. They are next brought to the front, have a light position, and by October they are in fine leaf, and the pots are full of fine white roots. Then if you desire to see this plant at its best, shift it into pots 4 inches wider, using the same soil as before, with plenty of sand. Water gently up to March, when, if the plants do not throw up for flowering, keep them dry—but not so dry as to cause the leaves to flag—for a month or six weeks; then water again. With me the result is in May, as fine a plant for foliage and flowers as ever graced a greenhouse or conservatory. Watering is continued until the flowering is over, and then it is lessened.

I do not believe in the plant being an aquatic in this country, though it will live in tanks out of doors in summer, or in a greenhouse all the year round; for aquatic treatment it should be taken back to the Nile, and there have the heat and dry air to which it is not exposed in our moister climate.—G. Abbey.

GOLDEN CHAMPION GRAPE.

I was pleased to see your defence of Golden Champion. I have had it splendid here. It was ripe in July, and when I knew the Prince of Wales was to be here, I kept it till then, the 19th October, and the Grapes were certainly the most magnificent I ever sent to an employer's table; they were like pigeons' eggs, and as yellow as Dr. Hogg saw them at Archerfield in 1865. The Grape was taken special notice of. The last bunches were sent in on November 1st, plump and fresh, while those of Buckland Sweetwater in the same house all turned bad—were rotten and fell from the stalks.—D. Thomson, *Drumlanrig Gardens.*

[The above-detailed, and other facts that have come to our knowledge respecting this Grape, are a sufficient reproof to those impetuous writers who either have not the skill to produce some varieties of fruit in their best state; or who do not give a thought that there are conditions of soil and situation which do not suit all varieties of fruits alike.—Eds.]

ROSES AND GERANIUMS.

Several other correspondents having sent you their experience with regard to bedding Geraniums and Roses, I also send you mine, and may remark that I have this year grown about eighty varieties of Geraniums, and the same number of Roses.

To begin with the former. If I were asked to select the best twelve Geraniums for making a display, I should name the following:—Foremost I must place Vesuvius, which has been with me a perfect mass of bloom all the season, and next I must select Indian Yellow, William Underwood, Rebecca, Scarlet Perfection (Sutton's), Waltham Seedling, Morning Star, and International; then I should conclude with four old and well-known varieties—viz., Tom Thumb, Stella, Trentham Scarlet and Christine.

In vases or pots the following twelve have done well with me:—Mrs. W. Paul, Acme, Lord Derby, Donald Beaton, Monsieur Martin, The Hon. Gathorne Hardy (an immense trusser), Kentish Fire, Chieftain, Monsieur Comner; and of the double varieties, Gloire de Nancy, Madame Lemoine, and Capitaine L'Hermite.

No two gardeners will give the same list of the best twenty Roses, as different kinds of soil cause them to grow so differently. Those that have done the best with me are Charles Lefebvre, Baroness Rothschild, Marguerite de St. Amand, Felix Genero, Maurice Bernardin, La France, Edward Morren, François Louvat, Boule de Neige, John Hopper, Fisher Holmes, Gloire du Ducher, William Griffiths, Mdlle. Marie Rady, Olivier Delhomme, Charles Lawson, Vicomtesse de Vesins, Lord Clyde, Professor Koch, and Monsieur Woolfield.

Maréchal Niel has not bloomed with me this year, being very much injured by the severe frosts last winter. My best four Roses this season have decidedly been Charles Lefebvre, La France, Maurice Bernardin, and Baroness Rothschild. —E. C., *Oakham.*

JARDIN D'ESSAI, ALGIERS.

In 1832 the then French Government conceived the idea of forming near the town of Algiers a botanical garden, in which all plants likely to be easily grown in Algeria, and which might be useful either for their ornamentation or for their economic value, should be kept for distribution or for sale. A portion of ground, about two miles from the town, situated between the sea and the public road, and occupying the place of an old hamma or marsh, was selected for this purpose. In 1867 the Emperor of the French conceded this establishment to the "Société Générale Algérienne," under whose auspices, but under the direct superintendence of M. Auguste Rivière, the gardens at present are.

In addition to the level swamp, the gardens now also occupy the slope of a low hill on the opposite side of the road. The level ground is laid out in alleys which open out into a circular boulevard which surrounds the whole garden. Carriages are admitted to the circular drive only, foot passengers to the cross walks. A stream of fresh water runs through the grounds, forming in one place a small lake.

One fresh from the botanical gardens of Europe is astonished at every step taken in the gardens by the wondrous vegetation which is shown by all the semi-tropical plants. Descending a few steps from the circular drive, a great Palm avenue is entered. This avenue was planted in 1847, and is formed of about eighty trees of the Date Palm, nearly as many of the Latania borbonica, and about 150 of the Dragon's-blood tree (Dracæna Draco). The avenue is about 10 yards wide, and between every two of the Date Palms there are two of the Dragon's-blood tree and one Latania. It terminates in a clump of Palm trees, which are planted almost to the border of the sea. When it is borne in mind that the Date Palms are from 20 to 50 feet high, the Latanias averaging about 12, and the Dracænas about 8 feet in height, the general effect of this splendid avenue may be imagined. All the trees were in December last in full flower or fruit, the golden trusses of the Date Palm contrasting well with the more brightly-coloured clusters of Latania berries. It would require more space than is at our disposal to describe the contents of all the various small avenues that branch off from the main one. The most remarkable smaller avenues are, perhaps, the one formed of Bamboo (Bambusa arundinaces), planted in 1863, and forming an immense mass of foliage, the stems supporting which are from 40 to 50 feet high, and that formed of about one hundred plants of Chamærops excelsa, each about 10 feet in height. But remarkable as are these charming sub-tropical alleys, the visitor is more than surprised when, on going towards the portion of the garden where the plants are grouped somewhat according to their natural orders, he finds specimens 15 feet high of Caryota urens and C. Cummingii, growing with vigour and covered with fruit; of Oreodoxa regia, from Cuba; several plants upwards of 25 feet in height; and a plant of Jubæa spectabilis, which is 12 feet high; and then just a few steps more and a parterre allotted to the natural family of the Musaceæ comes to view. As both the Plantain and Banana are grown in large quantities for their fruit in another portion of the grounds, the family is here chiefly represented by such genera as Strelitzia and Ravenalia. Magnificent specimens of the latter genus, with stems 9 to 10 feet high, exhibited great combs of flowers. We are not aware if the Traveller's Tree has flowered in Europe, and we were not prepared to find it in full flower in Algiers. It has not, however, matured its fruit in this garden. Near this grand parterre stood another with many fine specimens of Yucca, also a magnificent plot of Aralias—A. papyrifera, in full fruit and very handsome; the fine A. leptophylla and A. præmorsa, thickly covered with spines, and the very ornamental A. farinifera; and then one's attention is caught by a large tree (Carolinea macrocarps) from Brazil, with a couple of dozen of its fruit, each as big as a Cocoa-nut; by a small forest of Anona Cherimolia in full fruit, which is nearly as good as that of the closely related species which yields the Custard Apple. Near these is an immense tree some 30 feet in height, covered with fruit of the Avocado Pear (Persea gratissima); and at its feet is a quantity of the Guava tree (Psidium Cattleyanum) crowded with its perfectly ripe, large, pear-shaped, golden fruit. Growing up into the trees, and forming numerous and never-ending festoons, were some speci-

means of Cacti, chiefly species of Cereus. Some of these were of great size; and one specimen, which had completely strangled a Plantain tree some 25 feet, was said to have been covered in the autumn with 600 to 700 flowers. It must have been a sight worth a long pilgrimage to see.

Enough has been said to show what a surprising number of semi-tropical fruits luxuriate in the beds of this well-watered garden, and we might add many well-known vegetables to the list, as Sweet Batatas, Yam, Papaw. But all this while we have been writing of the great level portion of the garden. Outside of this, and on the other side of the roadway, there is a small hill, 200 or 300 feet in height, which slopes towards the garden and the sea, and is traversed by several ascending walks. This is the New Holland district of the garden, and certainly not the least interesting portion of it. In one section of it are different species of Acacia, many of them large trees, 20 to 25 feet in height. Of the Proteaceæ there were magnificent trees; of the genera Banksia, Hakea, and Grevillea, the collection of species was very large, all of them just bursting into masses of bloom. The most important of the trees growing in this corner of the hill was probably Eucalyptus globulus, of which some trees, now about 40 feet in height and over 4½ feet in circumference, were planted in 1862, and were then only a few inches high. Young well-established seedlings, of about 10 inches in height, are sold for 20s. a-hundred, and large numbers of them have been planted from time to time throughout Algeria by the French Government. This species grows in Algeria with most surprising rapidity, under very favourable circumstances, growing 18 to 19 inches in height each month. Its wood appears to be hard, close in the grain, and it is largely used in the construction of quays, bridges, and railways. This tree seems to do so well on the southern side of the Mediterranean that we think its culture ought to be successfully attempted in the south of Spain, in Sardinia, in Sicily, and the southern parts of Italy. In districts subject to heavy winds it requires for some years—owing to its rapid growth—some protection, but in places sufficiently warm for it, it ought to repay well for any little extra care it might be found to need.

Among the few species that we noticed that did not succeed in these gardens, we may mention the Cedrus Deodara; but Casuarina equisetifolia was flourishing, and one tree of Araucaria excelsa was about 60 feet in height, and measuring a little over 9 feet in circumference at its base.

The object of the Society in keeping up these gardens is, as we said, to introduce into Algeria all useful and ornamental plants likely to grow there. In addition they grow enormous quantities of young Palms and other ornamental plants for exportation to Europe, and some few plants interesting to the botanist for exchange with other establishments. In a place so favoured by Nature and so easily accessible to Europe, it would be, we venture to think, well worth the while of the director of these gardens to considerably enlarge the last portion of the Society's design. How many tropical plants are yet unknown to the large collectors of Europe, and what a vast percentage of deaths occur among the collections sent from the tropics at any season of the year to our shores! But with gardens like these at Algeria, situated on the sunny side of the Mediterranean, to act as a half-way house, the resources of the botanical gardens or establishments of the north would be indefinitely increased. Another purpose for which these gardens might be made most useful is for forming a collection of specimens of plants or fruits of economic interest. Many of the fruits, stems, &c., which ripen in these gardens as easily as Cherries or Potatoes with us, are not to be seen in some botanical collections, and are not, in Europe at least, to be purchased. How gladly would some botanist buy such as we here refer to if they were on sale, say at the depôt of the Algerian Society in Paris; and the expense of putting up such in salt and water would be a mere nothing. The same remarks would apply in many cases to portions of the roots of remarkable genera, and also to flowers. In calling attention to these gardens, we venture to suggest these hints to their well-known director, and also to that indefatigable botanist who, more than any other, now represents science in connection with the Algerian Society, Professor Durando of Algiers.—(*Nature.*)

POTATOES.

At page 335 are excellent notes on the vegetable crops of the past season, and amongst them some on Potatoes. Though agreeing generally with Mr. R. Gilbert in his estimate of the varieties named, I must be excused taking a very different view of Paterson's Bovinia. Mr. Gilbert says, "Of new varieties Paterson's Bovinia is the most promising." I am in hopes the last word is a misprint, and ought to have been unpromising, for with me it is a coarse grower, having most luxuriant haulm, and though planted a yard apart every way, had not half room enough; and all this waste of ground was incurred for the sake of two or three large ugly tubers, weighing, perhaps, several pounds each, which when cooked are like half-melted glue. I grew it as a curiosity for its great weight, and have had some immense tubers, but the weight is not equal from an equal space of ground to that produced by Red-skinned Flourball. Having satisfied my curiosity, I offered the tubers to our farm bailiff, thinking they might suit him for cattle or pigs, but he declined to have them, and pronounced them not fit for beasts. It is with me the ugliest, most useless, and worst-cropping of all Potatoes, and to a gardener worthless.

I have grown this year several American kinds, and find not one equal to our established varieties. Early Rose seems to be the best, and may be useful in a warm light soil and for frame culture, but in my cold soil and climate it is inferior and very much diseased.

Red-skinned Flourball is a strong grower, and requires much room; its tubers are too large, and may suit for market, but can never be of use to lovers of a good Potato until very late. Early Red Kidney has very large haulm, is a great cropper, more so than either Bovinia and Red-skinned Flourball, and in quality is quite equal to Red-skinned Flourball. It is, however, a late Potato, and has very large tubers as heavy as, if not heavier than, Red-skinned Flourball.

My latest conclusion as to the value of Potatoes is that the best are Veitch's Improved Ashleaf Kidney for first early crops and forcing, as it produces heavily and attains early maturity; Myatt's Prolific for early crops and forcing; Lapstone for a second early kind, and to continue until the late sorts come in; Early Oxford for a second early, and to come in until autumn; Paterson's Victoria for autumn, winter, and early spring use; and Red-skinned Flourball for late spring and early summer consumption. The above have with me this year been almost free from disease. The best Potato in cultivation for quality is the Lapstone, and it is second to none for amount of produce, taking the ground occupied into consideration. Like every other Potato, it does best in a light or well-pulverised soil. There are many forms of it; I have had several that are much inferior to the old or true sort.—G. Abbey.

GOOD AND BAD NEIGHBOURS.

The readers of this Journal must have all noticed the superior growth of certain plants when growing in the immediate neighbourhood of other plants. The farmer remarks how the wild Poppy haunts his Legumes—how the Cornflower only grows amongst his cereals. Other plants he notes are bad neighbours—such as the Brassica tribe in his arable land, the Acacia tree in his hedgerows. Now very recently the agriculturist has availed himself of one of these hints from Dame Nature to a very profitable extent in the growth of Swede Turnips, and, surely, there is something very valuable to be achieved in this way with other now only-languidly-growing crops, such as the Red Clover. Will you, then, allow me to ask the readers of the Journal to favour you with the result of their observations on good and bad neighbours in the tenants of the garden?

That much useful information may be in this way derived I have no doubt. I have seen in the garden several indications of the good effects of certain plants being placed in juxtaposition, and it is only within these few hours that I learn from a Scotch clergyman that in his garden at the Bridge of Allan, he can only secure good Carrots by growing them with Onions. He sows their seeds, it appears, together broadcast.

The fact that plants have their good and ill neighbours is not a modern discovery, for, as I have elsewhere remarked—

It was an early observation of the cultivators of the soil that there are good and bad neighbours even in the vegetable world. The Roman farmers noticed the vigour with which the Vine vegetated when planted near to the Elm. They were wont to call that tree the husband of the Vine, and it has been supposed that the Elm was, in fact, first introduced into England by the then masters of our island when they made their vineyards.

They were well aware that, although there is "a friendship" between some plants, there is "enmity" between others. Cato, one of the very early Roman authors, noticed that the Vine is at "enmity" with the Cabbage. And these facts were observed by more than one author of the sixteenth century. Thus, Conrad Heresbach, who

was born in 1508, remarks in his treatise on husbandry, "Because there is a natural friendship and love between certain trees, you must set them the nearer together, as the Vine and the Olive, the Pomegranate and the Myrtle; others," he continues, "have a natural hatred, as the Vine with the Filbert and the Bay."

Modern cultivators have noticed other facts of a similar kind, as how vigorously the plants of Wheat and Rye flourish amid the tares. These observations have, within the last year or two, led in a few places to some very practical and successful trials with our root crops. These experiments are hardly so well known to the cultivators of our islands as is desirable. They are not only valuable in themselves, but they appear to open a field of research, which in all probability will lead to other important results. I allude to the growth together in the same rows of the Swede Turnip and the Mangold. We are aware of the difficulty with which for some time back the Swede has been cultivated in many portions of our island, and this to such an extent that in considerable districts its cultivation has been abandoned. It is therefore most important that it has been found again to flourish on many soils when sown in conjunction with the Mangold, and this not in only the best Turnip soils but on the poor exhausted gravels of Bedfordshire—a county where the rainfall certainly does not aid the dryness of the soil, for the average annual fall of rain is there the least of all the English counties, being only about 20 inches—it was only about 15 inches in 1870. The mode of cultivation they adopt has been so well described to me by my friend Mr. John Porser, of Willington, near Bedford, that I need hardly attempt to give it in any other language. It was in a letter with which he favoured me in June of the present year that he observed, "I have grown now for six or seven years Mangolds and Swedes (not white Turnips) together, and with great success—not a failure have I yet known. Upon our hot gravelly soil we sow all upon the flat: it is far better than on the ridge. My plan is this: I drill early in April 4 lbs. of Mangolds per acre, and another drill follows running one hole only, which is about a pint of Swedes, in the same rows. When we set them out we leave as nearly as we can three, some only two, Mangolds to one Turnip. The Swedes grow very large, and very sound and healthy. Before we adopted this plan our land refused for years to grow a Turnip at all. We put them into pits or clamps by the second or third week in October, and they come out in the spring as sound and healthy as the Mangolds. Very many other farmers near here are doing the same, and with equal success. We certainly grow a greater weight per acre than we ever have done with Turnips only."

It being then established that the growth of certain plants is accelerated by having particular neighbours, we naturally inquire into the reason for this interesting fact. It is probable that it arises from some emanation either from the roots or the leaves of a plant which is grateful to its neighbour. It has been supposed by some Rose cultivators that its fragrance is increased by having a Leek or an Onion for its neighbour. Phillips, who died in 1708, in his "Cyder," alludes to this opinion.

"—— The Pœstan Rose unfolds
Her bud more lovely near the fœtid Leek
(Crest of stout Britons), and enhances thence
The price of her celestial scent."

—(*Farmers' Magazine*, vol. lxx., p. 172.)

To account, then, for these phenomena it has been supposed that plants excrete by their roots certain matters which are either nutritious or noxious to their neighbours. The experiments which have led to this conclusion are most of them collected by my brother, Mr. G. W. Johnson, in his work on "The Science and Practice of Gardening," page 49.—Cuthbert W. Johnson.

EDGINGS AND WALKS.

In the kitchen garden there is still the old-fashioned Box-edging to the principal walks. I do not consider it equal to an edging of slate, or even of well-laid tiles, though I prefer the slate as being more suitable in colour. Box-edging, if neatly kept, is very good, and, as a live edging, is superior to all others. I wanted to look over ours at the beginning of the summer, but owing to a pressure of work, clipping and making-up could not be attended to. I took up a bit of a cross walk not much traversed, lifted the Box, made the edgings all level and smooth, planted the piece afresh, and obtained more Box than was sufficient to fill up all vacancies.

The sweeping-up of the cuttings of Box left the walks a little more dingy than I like to see them, even in a kitchen garden. Most of the gravel here has enough of clay in it to make it bind well in summer, but as it is placed too shallow for frequent turning, its very smoothness in winter is apt to make it adhere to the feet in moist weather. A fresh appearance was given to the walks, and they were made pleasant to the feet for the winter, by a sprinkling of rather sharp red pit sand. I should be almost afraid to say how many yards I can make a small load of sand go over, but all looks fresh afterwards, and the main walks in a kitchen garden ought to be fresh in winter, whatever they may be at any other season.

A gardener from a great place said, "How clean and fresh your walks looks! But do you prefer or approve of cutting all your Box-edging at this season?" I answered, No; I should prefer to cut Box-edging early in summer or early in autumn, so that in the latter case the cut parts might push afresh and become green before the frost came.

The pleasure-ground walks I could not at the time make deeper, and it would be of little use to attempt to turn the most of those under my care, yet I have seldom met with walks more enjoyable from year's end to year's end. Those with grass verges are cut every year with an edging-iron, generally about May, so that the scissors may clip freely afterwards. All the cuttings are removed carefully and put in a heap to form a rich compost, the walks are then hard-brushed with a scrubby broom, a little salt put on, especially at the sides to keep worms away, and a slight covering of sand thrown over. Afterwards we seldom see a weed for the season, and the walks are comfortable and do not cling to the feet in wet or frosty weather. This treatment does not cost a tithe of what turning, levelling, and rolling would do. Of course even sanding must be thin, or it would soon puddle, but very little will suffice to give a fresh appearance and yet prevent such a result. No salt should be used now, except, perhaps, a very little at the sides, say for 3 or 4 inches, in order to keep worms under. I never like to use salt much after June, for if applied in autumn there is a danger of the walk being rendered damp for the winter.

I have seen walks made so deep that a yard of gravel would barely suffice for a half-yard run of a 7-feet walk. Some time ago I saw a place where from 24 to 30 inches of firm soil had been taken out in order to make a suitable approach to a mansion, all of which depth had to be filled with stones and gravel. In the majority of cases, where a firm bottom can be obtained a few inches from the surface, it is a perfect waste of labour and material to sink a great hole merely for the pleasure of filling it up with costly material. In such circumstances people forget that it is the firm earth beneath that carries the roadway, and that the dryness of the roadway on the surface is of far more importance than the depth of the material. I can recollect two instances in point. A roadway had to be formed through a park that had not been stirred for years, and through fields ploughed to the depth of but half a foot. The road was taken out 6 inches at the side, and much less in the centre, where the ground was hard; a layer of broken stones and flints was placed over in a somewhat semicircular form, and then a layer of gravel; this was rolled and the gravel raked in, as the wheels made a little depression. The road soon became firm on the surface, and stood much traffic uninjured; in fact, I have no hesitation in saying that it is much better for wheels than some other roads where fully four times the amount of material has been used.

The other case has reference to one of those damp, low places, where any quantity of stone or gravel disappeared, and then up would come the wet and mud to clog the wheels. The old level was disregarded, a lot of Black and White Thorn hedges were cut in the neighbourhood, and the cuttings brought and placed thickly in the spongy roadway. Clay, likewise, had to be removed for another purpose, and to get rid of it a layer of that clay, about 3 inches thick, was put over the thorns, trodden, and rolled, then a layer of stones, and lastly a layer of gravel, each from 4 to 6 inches deep. For more than fifteen years that roadway never required to be mended. Huge timber-gigs with heavy loads, drawn by four horses, passed over it, and the wheels scarcely left a track, the road being depressed as they passed, but afterwards returning to its original level. At eighteen years it was found that the thorn covered by the clay showed little signs of decay; and now the road, after having been made thirty years, is not quite so springy, but it has had nothing done to it, with the exception of a little rough gravel placed here and there in the wheel-ruts. In a place naturally damp, instead of sinking a walk I would at once raise it; and faggot wood, especially thorn, if kept from air, makes an excellent foundation. There can be no doubt that in the case referred to the clay preserved the thorns fresh for years by keeping them from the air.

Of all seasons of the year it is important that walks and roads on a gentleman's property should be clean and fresh in winter. Even tree-leaves lying about will not have the same melancholy effect if a good wide strip on each side of them is kept clean. The beauty of a walk will more particularly be found in its fitness for use without inconveniencing the feet. All drainage pools should be examined before winter,

as wherever water stands upon walks there will be an accumulation of slimy matter that will not only look unpleasant, but will cling to the feet. A walk may be overlooked in summer when it is so pleasant to traverse the soft dry velvet lawn, but a good walk for exercise is a comfort and luxury in winter.—R. Fish.

HARDY AND HALF-HARDY PLANTS FOR TABLE AND ROOM DECORATION.

Lily of the Valley (*Convallaria majalis*).—I know no more beautiful and fragrant hardy plant for blooming in-doors or for cut flowers than this. The handsome leaves of tenderest green, and the chaste sweet flowers arching elegantly on their stalks, present a union of charms rarely beheld in one plant—a fact which the flower-loving public appear duly to appreciate. For to say nothing of the estimation in which it is held for button-hole and other bouquets, and other purposes to which is is applied in the cut state, the thousands of pots forced annually in nursery and florists' gardens about towns, to sweeten and enliven sitting-rooms, sufficiently show the admiration bestowed upon it. A very large proportion of this supply is imported annually from Holland. The Dutch have sent us in the few bygone years sufficient to have stocked hundreds of acres to overflowing, but we are no richer in Lily of the Valley for it; imported stock is not even equal to the demand the present season, and the home-grown supply is not plentiful; nor is it so well favoured as the foreign. And what becomes of it all, the thousands of pots of home-grown and imported together, that find ready customers in winter and spring? In private gardens where much of it is forced, the gardener knows well the value of the old plants, and would as soon think of destroying anything else that is deemed worth keeping as of throwing them on the rubbish heap. A year's nursing and extra good cultivation will put forced Lily of the Valley in condition for forcing again; and no doubt nurserymen and florists would be glad to get back their old plants from their customers in such a state as that there would be a reasonable chance of recovering their lost stamina. As it is, however, they never return. They become the property of the police, falling into their hands by the way of the dust-bin and the agency of Polly the housemaid. This is a poor fate for a thing of beauty that is yet capable of being made beautiful as ever; for the same care and skill that developed its charms before are able to revive them again in due time.

Our present subject is one of perennial duration, and is, moreover, hardy and enduring to the utmost. It will even survive the dust-box, if quickly reclaimed while yet a little life remains; but it loves generous treatment, and well repays it. The imported Dutch clumps and crowns give flowers superior to our home-grown ones; it is even held to be a distinct variety, differing from ours in being more robust and luxuriant. It does not, however, retain this peculiarity, but quickly degenerates when subject to the conditions of our commonplace treatment. Any superiority it shows under forcing is due, I think, rather to the better climate and soil of Holland, and the special treatment given it by the Dutch. We should not expect many or fine Strawberries in winter and spring from plants lifted to force from the quarters a week or two before putting them into heat; and though Lily of the Valley is better adapted for forcing than the Strawberry, our expectations of the best results from it by ordinary efforts is only, therefore, a little less unreasonable. Forced as it usually is about private places, in clumps lifted from an old-established bed, the pots have as many crowns in them producing leaves only as there are crowns with flowers and leaves; and the abortive ones, besides leading to overcrowding, compete from first to last with those that flower for the food the pot contains, the contest being always more or less to the detriment of the latter.

There is no reason to doubt but that, if we adopted something like the Dutch plan of preparing our plants for forcing, the results would be quite as good in every way with our own as with their plants. We would require to break up our beds in the first instance, and carefully divide and select the crowns to such an extent as our demands suggested, and to plant them, the strongest and weakest by themselves apart, in rich well-trenched ground, 1½ inch asunder. The best time to do this is early in October, as it is also the best time for lifting and potting for forcing, but it will not yet be too late to do it when this comes to the hands of our readers, if the weather is open and mild. After planting—and in doing so the crowns ought to be almost buried—a mulching of old manure to the depth of 2 inches should be laid on the beds, and be beaten moderately firm with the spade, and blinded afterwards with a slight coating of soil. Anyone having old-established beds, and unwilling to break them up for this purpose, need not do so necessarily. The crowns in such a bed may be thinned out by means of a knife carefully inserted below the one to be removed, so as to sever it from the underground stem without injuring those that are to remain. Only the strongest in this case should be taken, and those that are left will benefit by their removal.

On this plan of treating Lily of the Valley, improved plants for forcing would not be our only gain; our stock would also greatly increase, and this, to the nurseryman and florist at least, is a very important point. It may be grown at home at half the cost of the imported roots, and everyone who indulges in the luxury of a pot in his room would ultimately share in the good of this economy. When lifting for forcing, or any other purpose, it is usual to discard all underground stems as useless. This is a mistake, for they may be made the means of largely increasing the stock in hand; every joint is prone to send up a crown when circumstances are favourable—that is, when there is room enough and pasturage sufficient for their development; and for the first two years it need not take up much room—a bushel of it may be put in a bed 4 feet by 6 feet. It is necessary in laying it in, to draw the soil off the bed wholly to the depth of a couple of inches, laying it on either side for handiness in putting it on again. The stems are laid on the bed thus prepared equally and evenly, and covered up with the soil, finishing off with a mulching in the same way as with the nursing bed for crowns, as described above.

Everyone that has to supply cut flowers or plants in flower for conservatory and room embellishment in winter, knows how to force Lily of the Valley; and our remarks on its treatment, to aid beginners, may be very brief. As early as the leaves are ripe the crowns should be lifted and potted, using rich sandy loam to pot them in. Put no manure in the soil; any enriching it may want is better applied in the liquid state after the plants are well started. Pot very firm; it is scarcely possible to make the soil too firm by pressure of the fingers merely, supposing it is in the proper state of dryness for potting. When finished, the tips of the crowns only should appear above the soil. They may then be watered, and put away in a cold frame till they are required for introducing into heat. It is always desirable to have the roots in action before the crowns begin to swell much. Mild bottom heat, applied in a cool atmosphere, secures this. I have started Lily of the Valley and other commonly-forced hardy subjects on the top of a heap of heating leaves in the open air in winter, giving them such top protection of straw or Spruce boughs as the weather rendered necessary, and was well pleased with the results. Plants so treated come away quickly and sturdily when they are brought into heat.

Our subject will not bear rapid or hard forcing; a temperature ranging from 50° to 60° suits best in early winter, but later on it will bear a few degrees higher. Keep it moderately moist till after the leaves and flowers burst the crowns, when the supplies of water must be gradually increased, and be alternated with applications of clear mild liquid manure. The syringe, if used at all, should be discontinued some time before the leaves and flower-spikes are half grown, especially if they are crowded in the pot; but it is preferable never to use it, taking the other ordinary means rather of keeping up atmospheric moisture instead. An over-moist atmosphere is favourable only to the production of fine flabby leaves and scanty weakly flowers that are liable to damp off on the occasion of the first check in temperature, and which under no circumstances continue to be long beautiful.

Hoteia japonica.—This gracefully pretty plant, so very liable to get injured by late frost in spring in most parts of Scotland and northern England, is a very good subject for room and table decoration. It may be very successfully forced, if not hurried too much or started too early. The present is a good time for lifting and potting it, but an early start is desirable, and I would advise lifting early in October, and the general treatment recommended for Lily of the Valley. The soil may be lighter, but equally firm potting is necessary; and manure of any kind, except liquid manure, is objectionable, causing, when applied to the majority of herbaceous plants that are forced, too much leaf growth, while the flowers are benefited little or nothing by the application. A little peat, however, is a very good addition to the compost for this plant. I would advise giving this a fortnight of bottom heat, either in the

open air or in a freely aired pit or frame, before putting it in a higher atmospheric temperature, such as that of a forcing-house or pit; and in other respects the treatment should be the same as for Lily of the Valley.—W. S. (in *Gardener*).

STOKE NEWINGTON CHRYSANTHEMUM SHOW,

The twenty-fifth annual Show of the Stoke Newington Chrysanthemum Society was held on the 14th and 15th inst.; and though not equal to several of its predecessors either in the number or the quality of the specimens and blooms exhibited, that circumstance appears to be solely due to the unfavourable season, and not to any falling-off in the interest taken in the flower.

Of pot plants there was but a small display; a few were very good, some were passable, and many indifferent as specimens. Most of them had the flowers but imperfectly expanded, and in another week or ten days will be seen to much greater advantage. The best three plants of the large-flowering kinds came from Mr. Howe, Shacklewell; the second best from Mr. Sharpe; the third best from Mr. James, of the Rochester Castle, a veteran grower. Among the varieties best represented were Dr. Sharpe, Gloria Mundi, Annie Salter, and Prince of Wales, the last full of bloom but not expanded.

For six Pompons Mr. Martin, gardener to F. Appleford, Esq., Woodbury Down, Stoke Newington, was first with good plants of Lilac and Golden Cedo Nulli and Andromeda. For three plants Mr. Martin was also first. Mr. James had a first prize for very good standards of the White, Lilac, and Golden Cedo Nulli, Bob, and others; Mr. Goodenough, Stamford Hill, being second.

Collections came from Messrs. James, Howe, and Goodenough, who had prizes in the order in which they are named. These comprised well-flowered plants of Gloria Mundi, Little Harry, John Salter, Prince of Wales, Mrs. Sharpe, and some Pompons.

Of cut blooms the show was likewise not very large, nor were the blooms so fine as in former years, still some of those exhibited were remarkably good. We will note the varieties which were best represented, not because of their extraordinary size, but because they were the best in a bad year, and were also the best in stands which we shall pass over. Mr. Rowe, of Roehampton, who was first for twenty-four cut blooms, had fine examples of Prince of Wales, Prince Alfred, Queen of England, Empress of India, Beauty, Mrs. George Rundle, Lady Slade, and John Salter—altogether a very even good stand. Mr. Berry, gardener to the Earl of Leven, Melville and Roehampton, was second with Miss Mary Morgan, Bronze Jardin des Plantes, and several of those already named. For twelve, Mr. Rowe and Mr. Berry were again first and second; Mr. Prickett, gardener to Mrs. Bowerbank, Stoke Newington, being third, and Mr. Drain, De Beauvoir Town, fourth. Among the blooms shown in these collections, Princess of Wales, from Mr. Rowe, was very fine, and the most notable of the others were Lady Slade, Mr. Brunlees, and Princess Teck, together with some kinds already named. The awards for sixes went to Messrs. Berry, Butcher, Rowe, and Holmes in the same order as their names occur. In the class not open to nurserymen and gardener, the principal prizetakers were Messrs. Sanderson, James, Yorley, Howe, and Slade.

Among other subjects exhibited there were several dishes of Apples from Mr. James; dishes and baskets of Apples and Pears from Mr. Smith, fruiterer, Stoke Newington; some Ferns; Palms and plants for table decoration from Mr. A. Forsyth, Stoke Newington; and a pretty Bouvardia called Queen of Roses from Messrs. E. G. Henderson, of St. John's Wood.

CORNICK VERSUS BLACK.

As I was reading the Journal on Friday last I was much surprised to see a very garbled account of a case in the Westminster County Court, headed "Cornick *v.* Black." I happened to be there on the 26th of September last, and heard the case opened; for knowing something of the parties, and being independent alike of each of them, I thought, Well, now, these market gardeners are a very ill-used set of men, to judge from their frequent appearance of late before the public, and here is one who has a veritable cause of complaint; but as the case proceeded it seemed to possess some very unusual features. The person who styled himself a market gardener in it was in the habit of sending, or taking himself, his goods to market, and had every opportunity of ascertaining their value before he parted with them to the salesman.

Somewhere in the latter part of April, 1869, he sent some things for which he received cash payment early in the May following, and continued sending, I think he said, to the end of the month, receiving cash for his consignments, without preferring any complaint against his salesmen; but the whole amount of the articles sent seemed to me a very limited affair. I purposely attended the day of the trial—viz., the 24th of October, and to my great surprise found that on two subsequent occasions when he went to the market he adopted a piece of very sharp practice, and took some one with him. After leaving his things with his salesmen, he so contrived that the person he brought with him should go and purchase some of the best of the things as a retail buyer. As soon as he ascertained the price given he concluded that would be his price, but finds out his mistake when the account sale is furnished; and because he was not allowed to make out the affair to comprise both wholesale and retail trading on his part, turned round and brought an action against the salesman for fraud. It also appeared in the course of evidence he had been actually paid over and above what his things realised, and therefore some extra profit, when it could fairly be made, was necessary to balance one transaction against another, and I was surprised the Judge did not notice this circumstance.—T. Taylor.

MORE ROSE GOSSIP.

If you and your readers are not tired, for this year, of Rose gossip, will you let one more humble enthusiast give his notions as to the best two dozen Roses in cultivation? The following well set up would, I think, be found hard to beat by Mr. Pochin or Mr. Baker:—Dr. Andry, Edouard Morren, Charles Lefebvre, Paul Neron, Comtesse d'Oxford, Duke of Edinburgh, La France, Exposition de Brie, Aurore Boréale, Baroness Rothschild, Fernando, Alfred Colomb, Marquise de Castellane, Sénateur Vaisse, Nardy Frères, Mdlle. Eugénie Verdier, Lady Suffield, Baron de Noirmont (B.), Marie Baumann, Louis Van Houtte, Maréchal Niel (N.), Annie Wood, John Hopper, and Sombreuil (T.).

The above I consider perfectly distinct in form and colour and vigorous hardy growers; the only kinds having any infirmities are La France, which remains too frequently in the bud, and Annie Wood shows a yellow eye, but is the most brilliant-coloured of Roses. Louis Van Houtte is, I am afraid, a feeble grower. Paul Neron is an improvement on Anna de Diesbach, almost if not identical in colour, but more double. I should have liked to have a Moss Rose in my twenty-four, but Lanei is the best, and rarely comes large enough for a show Rose among so limited a number.

If I may give an opinion as to the best new Rose I have seen this year, I select one I saw at Messrs. Paule', of Cheshunt, and which I was told was to be named Mr. Gladstone—a promising Rose in colour (dark) and habit of growth. Robert Marnock is large, but will look, I think, a plebeian beside Mr. Gladstone.—F. H. G., *Risendeniensis*.

P.S.—If anyone wishes for a very free-growing, free-blooming Hybrid Perpetual to cover a wall rapidly, I recommend him to try Fernando.

BUILDING A GREENHOUSE ON A SLOPING SURFACE.

I shall be obliged by your advice as to the best mode of heating a greenhouse which I am now building, first premising that, having rebuilt my dwelling-house, I found it necessary to pull down and remove to another site a range of old coach-houses and stabling, and so exposing to view, on approaching the house, a cowhouse, piggery, poultry-yard, &c. To conceal these was my chief object in erecting the greenhouse, which will face nearly due south.

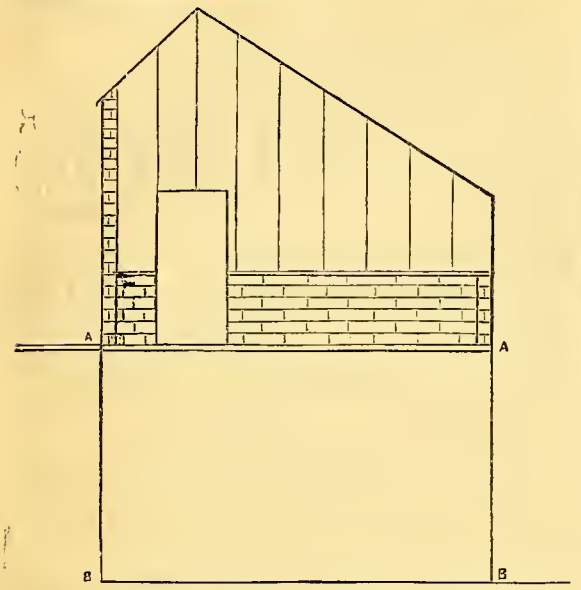
The position of the house and greenhouse is on ground sloping steeply from the south to the north, in length about 250 yards, and about halfway up; the slope upwards from the house being greater than that downwards to the carriage-entrance. In fact, the top of the garden is higher than the roof of the house, and are all eastward of, and nearly parallel to, the turnpike road, but considerably above it.

In pulling down the old stabling, &c., the site of which was originally excavated, we left the back wall standing to the height of about 10 feet, the level of the ground behind, forming a sort of dry area, the object being to hide the cowhouse, &c. We have built the greenhouse on four brick arches or vaults, communicating with each other by doorways. The vault furthest east has also a front doorway, this being the place where the heating apparatus is to be placed. The others are built up in front, and lighted with a piece of thick glass fixed, and ventilated with a terra-cotta air-brick, and small air-shafts in the back wall, rising to about 3 feet above the level of the ground behind. In these vaults I intend to store roots, &c. The intervals above in the roofs of the vaults are filled up with concrete, as also the floor level above to from 3 to 6 inches.

Of the greenhouse the back wall is carried up to the height of 10 feet above the ground level. There are four wooden ventilators in it at about 9 feet from the ground level. Its total length, inside measurement, will be 34 feet; its width, 14 feet; its height to the inside of the hipped roof, 14 feet. There will be a glass partition dividing it into two parts at about one-third of the distance from the east end. The roof is to be fixed. The glass, Hartley's rough, is borne on rafters 4½ inches by 2; that of the roof and sides, three-eighths of an inch thick; that in front, one-quarter of an inch thick. The rafters to be 1 foot

6 inches apart. The upper third part of three of the divisions of the roof to be made to open, sliding up and down. The front sashes to be hung on hinges, and to swing outwards.

The one-third partitioned-off at the east end is to be used more as a propagating house, the remaining two-thirds more as a general house, in which my wife will keep her plants; the gardener, probably, having but little voice in the matter, consequently but little responsibility.



A, A, Ground level at back. B, B, Ground level in front.
A, B, B, A, Side of vaults 10 feet high, 15 feet 6 inches wide outside, 14 feet wide inside.
End brickwork, 3 feet high; front sashes, 3 feet high; door 6½ feet high.

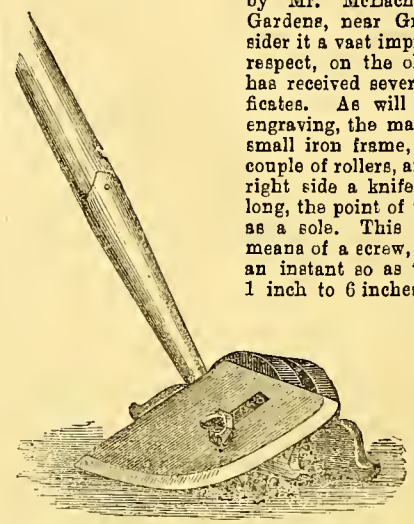
At the back of the eastern vault there has been carried up on arches a Pigeon house, rising some 25 feet from the back ground level; and through this Pigeon house the chimney-shaft from the vault below has been carried, leaving a place in which to carry up the chimney or pipes from the heating apparatus.—W. D. Paine, *Reigate*.

[As you wish to make the eastern division into a propagating house, you are quite right in the idea of having the heating apparatus there; and all things considered, a saddle boiler about 30 inches long would suit well, or a conical one of about the same dimensions. There is no other mode which would so easily enable you to have more heat in the propagating house with less or more in the main part of the building. In any spare part of this vault in winter you might grow Sea-kale and Rhubarb; and in the contiguous vault, merely by leaving the door open, you would have heat enough for Mushroom beds, whilst the other two vaults would come in for roots, blanched salads, &c.

The heating, too, would greatly depend on internal arrangements. For instance, to make the most of the internal arrangements as respects comfort and room, you might have a 3-feet bed in front of the propagating house, and a similar width of platform in the general house, a 3-feet path, and then a sloping stage of 8 feet for a base, which would take up the 14 feet in width. For easily getting at the plants a simpler arrangement would be to have a 2½-feet bed or platform all round, a 2½-feet pathway, and then a 4-feet platform or stage in the centre. To make the most of the propagating part you could have either the one bed in front, or in the latter case both back and front, heated by two hot-water pipes surrounded by rubble, with sand, ashes, or cocoa-nut refuse for plunging the cutting-pots in. One of these beds we would cover with small moveable sashes or squares of glass extending from the back to the front. The back border or platform would do for fresh-potted plants to be moved to the centre platform when becoming established. With two T-pipes you can have two flows and two returns to the boiler, one flow to go into the propagating house and one into the general house, the latter fitted with a throttle-valve, so that you could regulate or stop the circulation at pleasure, as it will often be necessary to have heat in the propagating house and to have none in the other house. Besides the hot-water pipes for bottom heat you would need two pipes all round in the propagating house for top heat, or three pipes round the front and two ends. Two pipes in front and at the ends of the other house would keep out frost. We think that with your ventilators in the back wall there is no occasion to have top lights to move. We should be perfectly satisfied with the wooden ventilators and the moveable lights in front.—Eds.]

McLACHLAN'S NEW PATENT VERGE-CUTTER.

Is it not surprising that so little that is new or improved has been added to garden implements? With the exception of the mowing machine, and, perhaps, Parkes's steel fork, garden implements remain very much as they were in the time of our great-grandfathers. We all the more heartily welcome this new edging-cutter, invented and patented by Mr. McLachlan, Dungourney Gardens, near Greenock, and consider it a vast improvement, in every respect, on the old edging-tool. It has received several first-class certificates. As will be seen from our engraving, the machine consists of a small iron frame, which is set on a couple of rollers, and has fixed at the right side a knife of about 6 inches long, the point of which is turned in as a sole. This blade is fixed by means of a screw, and can be set in an instant so as to cut verges from 1 inch to 6 inches deep, while the sole part of the knife detaches from the base the portion of edging detached from the side of the walk, thus doing with one action the work which requires an edging-tool and a Dutch hoe. This piece of simple mechanism is fitted to a wooden handle, 6 feet long, and the instrument is worked by the same sort of action required for Dutch hoeing. We have used this machine with our own hands, and find it very easily worked, and that it makes a very speedy and superior job.



Mr. McLachlan recently had a public trial of his invention, but the competitor with the old edging-tool soon gave up the contest. The testimony of the gardeners who saw the contest is as follows:—

"We, the undersigned, met for the purpose of proving Mr. McLachlan's edging-machine, and find that it is all that could be desired for the purpose, and a great improvement on the old system of edging. Mr. McLachlan, with the assistance of one man picking up the trimmings, cut with the sole-knife a verge 90 yards long in the short space of 7½ minutes."

[Signed by sixteen gardeners present at the trial.]

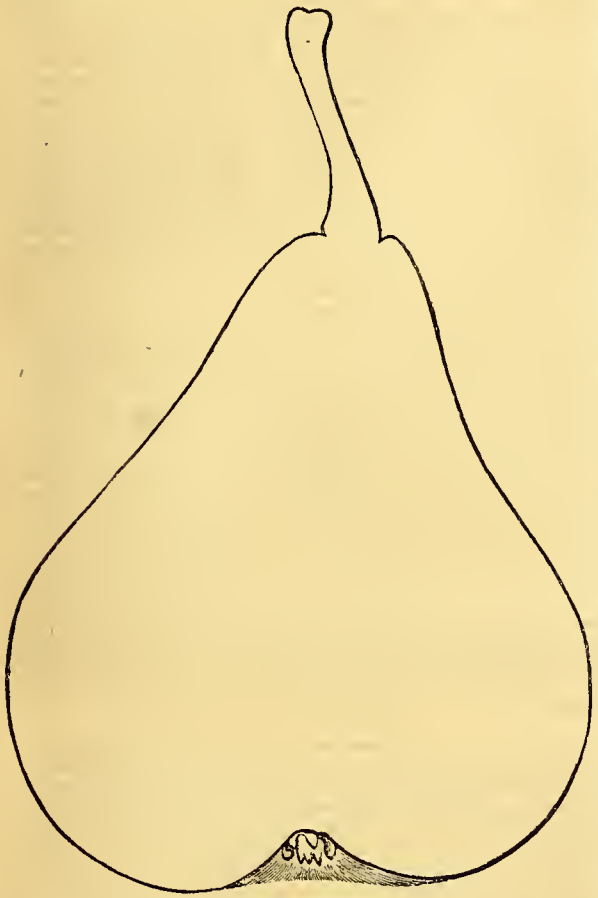
The work performed by the new machine was fully twice as much as was done by the old edging-tool, and a comparison of the work showed the great superiority of the work performed by the new one. The old tool either scatters that part detached from the edging over the walk, or requires a man or boy to follow with a Dutch hoe before it can be picked up; while that cut by the new one remains where it is cut, and can be gathered up without disturbing the walk.—(*The Gardener.*)

[We are glad to notice—and the more so because it has emanated from a gardener—a new form of an implement so much needed in modern gardens, and at the same time admitting of so much improvement. Gardeners, as Mr. McLachlan truly remarks, do not often try to improve their tools.—Eds.]

SINCLAIR PEAR.

It would be well if we could always know the exact spot where the various sorts of fruits will succeed best: and it is only by co-operation among fruit-growers and pomologists that we shall ever be able to arrive at so desirable a result. There are many fruits which when grown in the south are utterly worthless, and the same fruits grown in a northern latitude acquire all the excellence of some of the finest of the south.

On the other hand, certain fruits which are of the finest when grown in the north, are greatly inferior in the south. Where are there such Gooseberries, for instance, as are to be found north of the Tweed? Those of the southern part of the island bear no comparison with them. And where are there such Strawberries as are grown in England, far surpassing those of France? That excellent but very fleeting Pear Beurré Superfin, when grown in the North Riding of Yorkshire as our friend the Rev. W. Kingsley grows it, instead of ripening at the end of September, and decaying as fast as it ripens, as it does with us, is one of the finest December Pears at Thirsk, and, if we are not mistaken, Mr. Kingsley had kept it even till Christmas.



Sinclair Pear.

The Pear we figure to-day is one of those from which we learn the lesson, that what we often regard as an inferior fruit and unworthy of cultivation is in reality one of the greatest excellence. For this Pear we are indebted to the kindness of Sir Archibald Dunbar, of Duffus House, in whose garden, near Elgin, it was grown. Our figure gives an exact representation of the size and form of the fruit, and our reason for bringing it thus prominently before the notice of our readers is, that the large number of them who reside in the north and similar situations may know that in the Sinclair Pear they have one of the best October fruits this climate can produce.

The fruit is very handsome, with a smooth, clear, lemon-coloured skin, with a faint blush of red next the sun. The flesh is fine-grained, buttery and melting, very juicy and sweet, with a slight musky perfume.

This was raised by Dr. Van Mons, and was named in honour of Sir John Sinclair, Bart.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Wheeling out manures, composts, earths, mud, &c.; trenching, draining, making new walks, and repairing old ones, are amongst the principal operations at the present season in this department. Always make choice of suitable weather for performing each, with a view to cleanliness and good order. The *Asparagus* haulm may now be removed, cleaning the ground, and giving a good dressing of rotten manure. In the case of young plants which are only very lightly covered, the manure might be mixed with a quantity of leaf soil, and a good solid coat of this, 2 or 3 inches thick, applied. Take care to pot or lay in a sheltered situation a good store of Cape *Broccoli*, *Cauliflower*, and Grange's White Broccoli. The fine dry weather we have had of late has been particularly favourable for taking up *Beet*, *Carrots*, and *Parsnips*. The ground which they occupied should be trenched, and where the soil is clay or strong loam it should be ridged, that the frost and air may act on as large a surface of it as possible. *Celery* must be earthed-up carefully in suitable weather, and a supply of Endive must be blanched. *Jerusalem Artichokes* keep well in the ground, and can be taken up as required. To prevent the frost from injuring them the stalks may now be cut off within 5 or 6 inches of the surface, and laid between the rows, or a quantity of leaves or other vegetable refuse may be wheeled amongst them to cover the ground. The best plan, in respect to *Parsnips*, is to let them remain in the ground, and trench them out fresh as required for use; at this season of the year take care to have a good coating of manure or mulch spread over, so that in the event of frost it may always be easy to get at them. Proper sowings of *Peas* and *Beans* must be made immediately, but if this has been delayed the seed should be soaked in warm water for six hours to hasten the growth. Ground may now be prepared for new plantations of *Asparagus*, *Sea-kale*, and *Rhubarb*; and as these are permanent crops, every care ought to be bestowed on the thorough preparation of the soil. It ought to be in each case 3 feet deep, thoroughly trenched, manured, pulverised, and drained; where, too, the soil is exhausted it ought to be renewed with loam. Clear away dead leaves from old growing crops, and fill up blanks wherever they occur.

FRUIT GARDEN.

Continue to prepare for fruit-tree planting by draining, trenching, and pulverising the soil, and after planting tie them loosely and mulch in good time. Clear away all dead leaves from the wall trees, and remove the green fruit from the Fig. The established strong-growing fruit trees that are slow in producing fruit should be root-pruned. If the trees are planted too deeply, or the soil has been raised about them since planting, by all means fork the roots out carefully and plant again on the surface, spreading out the roots judiciously and mulching them. If trees to be operated upon are planted high and dry, fork about them at a reasonable distance, and prune back the main or strongest root. Raspberry plantations may be cleared of the dead canes and superfluous wood; the suckers should be taken off, and, where required, the strongest should be at once planted for succession. The most successful way of cultivating the Strawberry at this season is to add enough manure between the rows, which are, in general, nearly 3 feet apart, and to dig it in only a spade's width in the centre. It will, perhaps, be feared that the roots will be cut, as is really the case, but that is done intentionally, having been found by experience to be beneficial; its necessary tendency is to check overluxuriance in the leaf up to the period when the blossoms appear. By the time the fruit is swelling a new set of white roots will be found to have taken possession of the dug line, which, with the decomposed matter of the old Strawberry runners and a small amount of manure, contains everything necessary for the sustenance of the plant. At the end of February or the beginning of March the old leaves are entirely cut off, and a little soil is drawn to the crowns.

FLOWER GARDEN.

Those who propose making additions to their collections of Roses should do so at once, as there will be a better chance of obtaining good plants now than after the nursery stock has been repeatedly picked. The present season is also very favourable for planting all but tender sorts, which had better be kept under glass until next May; but these should be procured at once, and if they can be placed in a gentle heat throughout the winter, they will grow freely, and furnish cuttings which will root just as readily as a Verbena. In preparing ground for Roses, let it be trenched at least 2 feet deep, and very heavily dressed with manure mixed to the full depth of the soil. It is hardly possible to make the ground too rich for any kind of Roses, particularly the autumn-blooming kinds. Four or five inches of rotten farmyard dung will not be too much when the soil is naturally rather poor. Large-headed standards that have done blooming for the season should be cut back

somewhat freely to lessen the chances of their being injured by heavy gales of wind. Where walks are in good condition but weedy, recourse should be had to hand-weeding, for the use of the hoe and rake should be avoided at this season as much as possible. These tools do more harm than good by breaking up the surface, whilst the destruction of weeds is not secured. Those walks which are overrun with Starwort, Liverwort, and the various mosses, had better be dug over with the spade, thereby putting the whole out of sight, and presenting a new surface; this when rolled down smooth will have a neat appearance for some months.

GREENHOUSE AND CONSERVATORY.

Guard against damp by giving air freely when the state of the weather permits, and use fire heat only when it is indispensable, and then as sparingly as consistent with the safety of the plants. It will probably be necessary to force many plants gently to secure a succession of bloom for the conservatory, as few plants will make much progress at this season unless encouraged with more than an ordinary growing temperature. Where forcing must be resorted to, avoid subjecting the plants to a very high temperature, which is very injurious to many things, and causes the flowers to fall much sooner than if the heat were suited to the habit of the plants. Take advantage of unfavourable weather for out-door work to get the foliage of Camellias, Orange trees, &c., thoroughly cleaned, for this is very essential to their health. Look over the plants in the greenhouse frequently, and examine very closely those which are liable to suffer from mildew and damp, such as Leschenaultias and Boronias, for a short spell of neglect will sometimes result in the disfigurement of a promising plant. Boronias, Leschenaultias, Gompholobiums, &c., are very impatient of exposure to cold drying winds, and if they must be wintered in the same house with the hardier kinds of greenhouse plants, they should occupy a part of it where they will not be exposed to cold draughts, though air must be admitted by the top sashes freely on fine days. Young specimens of Azaleas which have been growing in heat had better be removed to a cool house for a few months. This will cause them to start more freely in spring. Keep Cinerarias and other softwooded plants clear of green fly, and endeavour to secure stocky specimens by affording them sufficient pot room, and admitting fresh air freely whenever the weather allows. Cinerarias are rather liable to be attacked by mildew at this season; if this enemy makes its appearance apply sulphur immediately.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Observation has led us to the conclusion, that in a growing bright moon we have the coldest air in the evening, and in a waning bright moon we have the greatest degree of cold in the morning. In a mild evening, therefore, after the new moon, with a thermometer about 40°, we would not be so particular in giving additional covering or firing to prepare for a frosty morning. On the other hand, with a waning moon, rising from midnight and onwards, and with signs of a falling thermometer before dark, we should like to be prepared for the very probable cold of the morning. In such cases, and, perhaps, in others, the greatest cold is often at sunrise or shortly after. We believe that if the direction of the wind, and the state of the atmosphere—cloudy or clear—and even the age of the moon were taken into consideration, some of the evils might be avoided that come from under and over protection and firing.

Cauliflower.—We have given no protection as yet to the young plants under hand-lights, as we rather like them to have a touch of frost. Fine plants coming in for use, we did not treat in any of the ways alluded to the other week, as we could not well place them under protection. Had we taken them up we could hardly have put them in more thickly than a piece of Veitch's that is coming in. Where the heads are still but half the size we wish them, we find that the lifting of the plants and laying them in, however carefully, has a slight tendency to affect the compactness of the head, and singularly enough plants thus treated have always been more attacked by rats and mice than those standing where they were planted. As we had some long litter to spare, and as the plants were thick, we heaped this up lightly between the rows a little above the flower centre, and then laying a nice Cauliflower leaf across, we put a little hay along the tops. The hay was some rough stuff with leaves and bits of sticks in it, a supply of which is useful on an emergency. By such means we have kept Cauliflowers, Walcheren Broccoli, and Snow's Broccoli, through most of the winter. Of course, the litter remains until the crop is cleared, which is done on a fine day, the rough hay being lifted off the plants and laid in little heaps for future use. When Cauliflower is planted rather thickly in beds, or on a narrow sloping bank, such covering should often be taken off and replaced, as it will ever be more effectual in proportion to its dryness. Had we at liberty a secure place under glass, such as the floor of an orchard house, we would have raised a lot carefully with balls, with the certainty that they would afterwards require less trouble. The above mode, however, has often answered even in rather sharp winters. The covering the ground and stems with litter in such a case, is of importance, as tending to keep the ground and the roots warm.

FRUIT GARDEN.

We could not move under protection our Strawberry plants in pots, but as they stood in beds we run some litter all round to protect the outside rows of pots, and then covered them over with dry litter. So long as the heat in the ground is prevented from escaping, a very little litter all over the top will prevent the soil being so frozen as to affect the roots. We have thus kept them all the winter, removing the litter from the top of the plants on fine days. They would be still safer from cold if plunged, but then to counterbalance this advantage they are apt to suffer from too much moisture. We would prefer having such pots, especially all those intended for early work, under glass, plunged or unplunged. The latter would not be necessary where there was no artificial heat, if a little covering over the top were given in the severest weather.

Grapes in the orchard house have neither been so good nor so well ripened as in previous years, owing to the coldness of the first part of the summer. In most cases much north of London, Grapes in unheated glass cases will depend much on the sun of the summer. Grapes in a wide late vinery, with two pipes in front, have hardly shown half a dozen of decaying berries. A little artificial heat is, therefore, an advantage where Vines are grown. The Messrs. Lane did wonders in their simple orchard house at Berkhampstead, but they did greater wonders when they took advantage of the hot-water pipes. In the Peach house we pruned, cleaned the front, and resurfaced, so as to get the floor and every available space covered with boxes of bedding plants. The first lot that we consider to be quite safe from damp and frost we will find room for elsewhere, when we give more heat to the Peaches to bring them on. This we do only because the room is valuable, as the end of this month, and the whole of the next is the most trying time to bedding plants in cold frames or pits, with the exception, perhaps, of Calceolarias, which do better without any artificial heat.

ORNAMENTAL DEPARTMENT.

When we wrote last week we could have gathered baskets of bloom from the flower beds; now little can be obtained except some Violets, Salvias, Lupines, Phloxes, and Chrysanthemums. The frost of the week has destroyed nearly everything aboveground. The Ageratums, that eight days ago were a mass of grey flowers, are now in a fit state for retirement. Our scarlet Geraniums, cuttings of the previous September and March, not only bloomed freely, but grew so strong and thick that, though the tops were injured, the plants were perfectly well lower down. We took up a number and put them under cover, in order to pack another lot away as referred to the other week. They will thus suit our purpose as well as those taken up early; and so long as the plants remain fresh and show a good deal of bloom, it seems undesirable to break the symmetry of the beds. A spring display is much more easily obtained than a summer display to be kept up into the winter. In consequence of this latter practice we have several times had the whole flower garden destroyed early in November; but once, by means of covering with mats, we had a beautiful show of Geraniums and Calceolarias on Christmas-day.

We went through the usual routine of potting, watering, and plunging fresh-potted, hardy plants in a mild hotbed to encourage fresh rooting. A few bulbs we wished to come in early were treated in the same manner, to attract the roots downwards whilst the top of the bulb was kept cool. Scarlet Geraniums in 6 or 8-inch pots that had been prevented blooming much in summer, and were put under glass some five weeks ago, promise to yield a fine crop of flowers when flowers of any kind are scarce. Primulas and Cinerarias also come in useful at this time. We have commenced securing all the most tender plants under glass, where a little heat can be given them until the days lengthen; in the meantime they are supplied with some rough protection.—R. F.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*Thornhill*).—Gordon's "Pinetum" and Supplement is the book you wish for.

Our Volumes (*T. R. Jones*).—They end the last Thursday in June and December, and an index is soon after published for each six-months volume.

Seedling Fuchsia (*R. H., Bournemouth*).—The Fuchsia, we think, has some merit, as far as we could judge from the bloom, which was very much withered. Why not send it to the Floral Committee of the Royal Horticultural Society?

Parsnips (*J. D.*).—We do not know the wholesale price, and we never recommend dealers. In Kelly's Directory is a list of Covent Garden salesmen.

Seedling Coleus (*G. E.*).—The leaves are rich-coloured and the beading of green good; but there are such legions of these varieties now—some very like yours—that we fear it would not be remunerative to expend money about it.

Stove Boiler (*J. P.*).—The 30-inch boiler will heat your house amply, but we have no faith in your doing so by having, according to your plan, your boiler above the ground, first raising your pipes, and then at once sinking them below the level of the bottom of the boiler. For an open-topped boiler the pipes may be level with, but not below, the part that comes directly from the boiler. To make your plan answer you would require to have air-pipes at all the bends, and then there would always be a risk. It is quite as natural for hot-water to rise as for hot air to do so. It is always unadvisable to take any hot-water pipe, even a return one, below the level of the bottom of the boiler. For such a house you would want four 4-inch pipes in the front of the house, besides a flow and return at each end, or three pipes all round except the back. Your sinking the boiler enough outside, or even inside to be fed from the outside, would save all difficulties; and then we would have a short chimney outside instead of taking an iron tube inside across the gable end of the house. That alone would most likely prove a fertile source of trouble as respects red spider.

Writing or Engraving on Glass (*A Young Gardener*).—The following, which we extract from "The Mechanics' Magazine," seems as if written by anticipation for you. "M. A. Wilbaux finds that words and designs may be printed on glass by the use of type made of any suitable elastic material. The printing ink contains, however, fluoride of calcium incorporated with it, and when the glass which has been thus printed on is submitted to the action of hot sulphuric acid, sulphate of lime is formed, and hydrofluoric acid set free, which immediately attacks the glass in the place of its birth. On subsequently washing off the ink stains, &c., the design is found to have been beautifully etched upon the plate."

Garden of Eden (*Querist*).—No certainty has been arrived at as to its locality, consequently it cannot be told whither Adam journeyed. Our correspondent adds—"An English writer says in his advice to young married women, 'that their mother Eve married a gardener.' It might be added that the gardener, in consequence of the match, lost his situation."

Evergreen Shrubs (*C. H. H.*).—You should have said how many kinds you need, for they are numerous. We will name about a dozen—Arbutus Unedo, Aucuba japonica, Berberis Aquifolium and Darwinii, Buddlea globosa, Laurel, Portugal Laurel, Cotoneaster, Cratægus Pyracantha, Escallonias, Kalmia latifolia, Laurustinus, and Rhododendrons.

Black Bess Strawberry.—We are informed that it is the same as Empress Eugénie.

Glass for Vinery (*J. S.*).—Had your house been for flowering plants, we would have said, Have ribbed shaded glass for the roof, and clear glass for the front. For Vines and fruit trees we would say, Decidedly use clear 21-oz. glass, or heavier if you do not mind the expense.

Window Plants (*G. C.*).—We do not think anything would suit your window better, after Chrysanthemums, than the yellow-flowered Cytisus racemosus, or for a dwarf, Cytisus Attleeanus. A compact plant in the centre, with blue and red Hyacinths on each side, would look very well. Coronilla glauca also blooms well in a window; the flowers are yellow. Early Cinerarias also do well if the leaves are frequently damped, and if merely kept from frost. Both the Cytisus and the Coronilla would require to be lifted from the window in severe frost. As a hardy plant, no fire being used, you might have a good-sized variegated Holly, an Aucuba, or even a Laurustinus that would bloom all the winter.

Orchard House, Position, &c. (*T. R. Jones*).—From the ground being occupied by tree roots which you cannot move, you may grow the fruit trees in pots, setting the latter on slates or tiles, otherwise the roots would be apt to interfere with the pots. Such a house, even though receiving little direct sun after two o'clock, but heated with hot water, would be better for Grapes in pots than a more exposed span-roofed house that had no heating, as in some seasons the Grapes do not ripen well when merely under glass, though much may be done with abundance of sunshine, and shutting the ventilators early. For Peaches, Nectarines, Cherries, Plums, &c., we should prefer the span-roofed house with the sides facing east and west, and the ends north and south, even with no heating; and if we placed Vines in pots there, we would make a division and have them by themselves, so that we could treat them a little differently as respects ventilation as soon as growth had fairly commenced. If you decide on having your new house in line with the present greenhouse, and if the pipes in the new house would run in the same line and level, you may easily continue your pipes in the orchard house, but the latter will not be quite so warm as the former. Again, though by having the circulation in the greenhouse complete, and the addition made by valves, you could then heat the greenhouse without heating the orchard house, you cannot heat the orchard house without first heating the greenhouse. Your case is similar to that alluded to in the second column, page 366, and all the difficulty would be avoided if your boiler had been placed between the two houses. It is always well to be able to heat each house separately. Thus you might wish to give more heat to the Vines when in bloom, and again to perfect the ripening, when heat would not be at all wanted in a common greenhouse. You might, it is true, neutralise the extra heat in either case by extra ventilation; but this involves extra expense for fuel. With your present arrangement, if we did not continue the heating in the orchard house, we would leave the greenhouse heating just as it is, only on the flow-pipe, as near the boiler as convenient, we would cut the pipe so as to fix a valve to open or shut at pleasure. On the top of the boiler we would fix another flow-pipe 1 inch in diameter, provide that too with a valve or stop-cock, take that small pipe through the greenhouse, and join it to the pipes in the orchard house by cap, blank socket, or blank spigot. You would thus have only the extra small pipe passing through the greenhouse, and with that exception you could heat each house separately. One thing, however, you must ever bear in mind—namely, never to put a fire on without opening the valve of one of the two flow-pipes, or you will have an explosion. If these matters should be deemed too troublesome, we would advise growing some pot Vines in your present greenhouse, and making your new house, where you say it will have all the sun possible, as that we think will be best for everything except the Vines.

Austrian Pine (*C. H.*).—The Austrian Pine requires to be protected from sheep until it is sufficiently grown to be out of their reach London dung can be procured from all the London railway stations, and on application to the master at any of the stations the information as to price and carriage can be obtained.

New Plum (*A Green Plum*).—We would recommend you in preference to grow the Transparent Gage. It is a fine fruit.

Pruning Pyramidal Fruit Trees (*W. Frodsham*).—If your pyramid fruit trees have made vigorous young shoots, we would shorten them to about two-thirds of their length, and if too thickly placed thin them out. Cut the shoot at an outside bud, so that the leading shoot which will grow from the top bud will take an outward direction. For pyramid trees summer pinching and pruning are best, as they induce fruitfulness. All the pruning that Gooseberry bushes require is to regulate the young shoots by thinning them out where crossing each other, and cutting the ends of those that remain.

Treatment of Dendrobium formosum (*C. M. M.*).—There can be no doubt that this plant is epiphytal, though it succeeds admirably as a pot plant like most others of the same genus. The pots are filled to two-thirds of their depth with crocks, over which should be placed a mixture of chopped sphagnum, fibrous peat, lumps of charcoal, and a little silver sand, with crocks, the whole compressed firmly and rising well above the rim. Let the roots of the plant alone be covered with the compost, when it is as much at home as if it were growing on the trunk of a tree. Being a native of Nepal and Moulmein it does not require a very high temperature, and will, indeed, grow in a warm vinery—an admirable place for a great number of Orchids. If the plant is in good health and in good growth, place it in a house with a temperature of 45° to 50°, and from now until March give only a sprinkling of water betimes to keep the pseudo-bulb from shrivelling up. In March you may put it in a vinery with a temperature of from 50° to 55°, increasing in a few weeks to 60° at night, and also sprinkle it overhead every morning for the first fortnight, when it will start into flower and afterwards into new growth. It should now be encouraged with moisture to make a good growth, and on that being completed and the bulbs being firm, keep it dry and moderately warm, but try to obtain a complete maturation by exposure to light and air. The flowers come from the base of the old leaves, and each pseudo-bulb will produce fresh leaves and a new pseudo-bulb from its base, or sometimes from other parts.

American Cranberry Culture (*F. B.*).—The treatment you describe yourself to have given your plants ought to have had a different result, but we fear you erred in the question of soil, and also with regard to the water in the ditches, which need not be very deep. Though peat is insisted on by some cultivators, it does well in a compost of equal parts turfy peat, leaf soil, and sandy fibrous loam. It may be planted in single rows in beds 4 feet in width, and the same distance apart, water being made to circulate a foot below the surface of the beds in a small ditch between. The position should be sontherly, and not shaded by overhanging trees, and a top-dressing of decayed leaves and sandy peat should be applied every November. Our correspondent wishes to know if any of our readers cultivate this plant, what is their estimate of it as a fruit-bearing bush, and what their mode of treatment.

Mediterranean Heath, Propagation (*A Subscriber*).—Take cuttings of the young shoots when their bases are rather firm, and stripping off the leaves from half the length of the cutting, and paring its base smooth, insert them round the sides of a pot clear of each other. The pot should be first filled half its depth with drainage and a little rough peat, and then to within three-quarters of an inch of the rim with very fine sandy peat, the whole being covered up to the rim with silver sand; water gently and press firm. After standing a few hours put in the cuttings, and place them in a cold house or pit covered with a hand or bell-glass. Keep close and moist, shading so as to lessen the necessity for watering, and when the cuttings have struck, as you may know by their growing, admit air gradually. Pot them off when well hardened, and keep them in a cool house or pit over the winter, planting out in the spring. They may also be wintered in the cutting-pots, and planted out in spring after being well hardened.

Vine Transplanting (*Amateur*).—Your Vine which has been growing out of doors for six or seven years should not be moved until March. In the meantime have the border well drained, taking out the soil if not of a light sandy nature, and placing over the drain rubble 9 inches to 1 foot deep, covering the whole with 2 feet 6 inches to 3 feet of turfy light loam, mixed with lime rubbish and a few half-inch bones. If the soil is light and sandy it will not be necessary to do more than drain the border; or if the ground is dry, not even the lime rubbish and bones will be required. The width of border you name will answer well for one Vine.

Coleuses Wintering (*Idem*).—They should be protected and have a temperature of from 45° to 50° by fire heat, being watered only when they become dry, and then moderately. They suffer most from damp and cold. Young plants winter more safely than old plants, and are better every way. We put in cuttings early in September, and have them now compact bushes in 4½-inch pots in a cool stove. They are extremely useful for decorative purposes, and endure a dry atmosphere very well.

Names of Fruits (*F. S. Milham*).—1, Beurré Clairgeau; 2, Northern Spy; 3, Birmingham Pippin; 4, English Codlin; 5, Scarlet Leadington. (*C. C. E.*).—Nonveau Poiteau. (*J. Green*).—Emile d'Heyst.

Names of Plants (*J. P.*).—Spindle Tree, Euonymus europæus. (*T. L. Mayo*).—1, Pteris serrulata; 2, Pellæa hastata; 3, Nephrolepis exaltata;

4, N. acuta; 5, Lomaria lanceolata; 6, Polypodium aureum; 7, Selaginella Martensii; 8, Pteris quadriaurita; 9, P. cretica albo-lineata; 10, Platyloma rotundifolia; 11, Asplenium flaccidum; 12, Polypodium vulgare; 13, Adiantum æthiopicum; 14, A. cuneatum; 15, Polypodium cambricum; 16, Begonia Dregii (B. parviflora); 17, B. insignis (B. incarnata); 18, B. coccinea. (*Goodness*).—Cosmos diveraifolius var. atro-sanguineus, native of Mexico. (*Mrs. B.*).—1, Polypodium aureum; 2, Asplenium nitidum. (*Rush*).—Cyclamen neapolitanicum, *Ten.*, native of Italy. (*C. M. Major*).—Your Orchid is Calanthe vestita var. rubro-ocnlata. Maxillaria aromatica, otherwise Lycaste aromatica, is about as distinct from this as any two plants need be. (*Donna Serafina*).—1, Polypodium aureum; 2, Cyrtomium falcatum; 3, Asplenium lucidum; 4, Pellæa adiantifolia; 5, Leycesteria formosa; 6, Solanum pyracanthos. Alternantheras require the temperature of a warm greenhouse during winter, should be potted in a light soil, and be kept moderately dry. Begonias require stove treatment, and to be supplied with no more water than is necessary; many kinds will, however, be in bloom this season. For general cultural directions on all sorts of plants we cannot do better than recommend the "Cottage Gardeners' Dictionary," in which brief instructions are given under every individual genus. Price 12s. 6*d*., to be obat our office. (*Curious*).—1, Selaginella Brauniana (S. pubescens); 2, Nerine pulchella; 3, Selaginella Martensii; 4, Corydalis lutea.

POULTRY, BEE, AND PIGEON CHRONICLE.

CRYSTAL PALACE POULTRY SHOW.

We expected a first-class show of poultry at the Crystal Palace; but we confess, remembering the earlier date fixed on this occasion, we were surprised at the magnitude and quality of the collection brought together. Nearly fifteen hundred pens of poultry and over nine hundred of Pigeons testify to the popularity of this new Show, and the confidence felt in its Committee of Management by the fancy at large; and such a number of entries is indeed treading very close on the heels of Birmingham.

Last year, as is well remembered, there were many faults to be found with the details of arrangement. On this occasion it gratifies us to be able to testify to the excellent manner in which the birds were shown. The open wire backs of the pens, which before worked so much evil, were now covered with calico; and the long rows of pens being placed in the nave, in full light, so long as daylight lasted the Judges had every facility for performing their really arduous duties. This leads us, in fact, to the greatest defect in the arrangements—the Judges' work was *too* arduous. They worked with a will, and without intermission; but we cannot consider three Judges sufficient for fifteen hundred pens of fowls, and the consequence was that many awards had to be made in failing light and under other disadvantages; and the whole with greater dispatch than is advisable, and at a Show of this class in particular.

DORKINGS.

Classes 1 to 3.—The cups for old birds were secured by the grand Rose-combs of Mr. Martin, who still keeps up the credit of the Holmesdale strain. The other prizes were only middling, and the Dorkings generally awakened in us very unfavourable anticipations, which we were pleased not to find realised by the rest of the Show. The cup cockerel was a very large and dark bird, with uncommonly good legs and feet. The next two prizes went also to birds dark in colour, and this is evidently preferred by the Judges, and should therefore be studied by Dorking-breeders. We should have been ourselves inclined to award the third prize to pen 24 or 25, both of which were very good. The winning pullets, too, were Dark, and in size far beyond the rest, which were most of them hardly ready to show by the middle of November. The second and third were well placed, but later on several of the highly commended pens will usurp their places.

4 to 8.—All the Silver-Grey hens in Class 4 were larger than usual. The cup pen were both birds genuine Dorkings, and the cock of a remarkably good colour; none of the others free from white on the breast. The first-prize cockerel was small, but very handsome; second much larger, but far from equal in colour and carriage. This breed is not progressing. Several of the pullets were not pure in colour, showing a nasty red tinge through the silver; but the first were very good. A special class for Cuckoo Dorkings brought a small but very good collection, and the cup pen was truly fine, but in both the others the cocks were too light in marking to match the hens. The Whites showed some improvement, in our judgment, both in colour and size; and several prize pens besides the winners were really good.

COCHINS.

9 to 12.—The old Buffs also were in pairs. First-prize a well-shaped deep-coloured cock with a medium-shade Buff hen, the cock having grand legs and feather, as, indeed, was the second-prize, the cock in which was lighter, being a gold tint; third-prize also a very dark, almost Cinnamon cock, very large and fine, but with a hen far too light to be a good match. But for this, second and third would probably have changed places. The cup cockerel was one of the finest birds we ever saw—certainly the best shown for four seasons, having finer development than of late in fluff and saddle, with a beautiful sound colour for breeding, and grandly-feathered legs. Second good in colour and fine, but far from equal to cup in shape. Third very large, and an even gold colour over the top; tail too long, but honestly left all in. The same exhibitor showed an unnoticed cockerel (pen 145), which when he has got some hackle on will probably be heard of. The pullets were much better and more numerous than last year, but still show much to desire as regards fluff and cushion before they are equal to the birds of years ago in these cardinal points of a Cochin. The cup pen had one grand bird, though with a bad comb; the other much smaller. Second fair in shape, a good match, and remarkably fine heads and combs. Mr. Taylor's third-prize birds were very similar, and the second and third prizes must have been hard to decide. The class for Silver Buffs contained only one entry of very poor quality, but the cup was awarded, we think, very injudiciously for the sake of "a discerning public."

13 to 15.—The cup pen of old Partridges contained a grand hen, but the cock hardly through the moult, which did not set him off well; he struck us as heavy and clumsy, but had beautiful legs and feet. Second a handsome but small hen, and cock a deal of brown in his thighs. It is quite plain that the Judges do not now consider this latter ought to disqualify a good bird, and the fact should be noted. Third a fine cock, but hen not in condition, otherwise we believe this pen would have been probably first. The best hen was in pen 177, but the cock was poor. The cup and second cockerels were as fine in plumage as could be wished, besides being of excellent shape; the metallic rich gloss they showed has been rare lately. Third was a mere raw chicken, though very promising. Many of the birds were far too poor in feather. First-prize pullets good, but not a match, and one had far too much tail. Second was a decided mistake, one bird being quite wanting in breast-pencilling, and we should ourselves have put the third-prize first, first-prize second, and given Mr. Tudman's 202 third. This class was not so good as some we have seen, and good matches were rare, which made placing the pens a doubtful matter. [We have since heard that none of Mr. Tudman's birds arrived in time.]

16 to 18.—All the prize old Whites were good Cochins in shape, and well feathered, but not one of the cocks was entirely free from yellow, which seems becoming more and more prevalent. The cockerels were better in colour, but still not that pure pearly white so desirable. First-prize an extra well-developed bird, good in nearly all points. Second and third rather narrower, and third rather poorly feathered. In pullets, the second-prize must assuredly have been cup but for a comparative want of feather, being best in shape, size, and colour; but all were good, and this was the best of the White classes.

BRAHMAS.

19 to 22.—The cup old Dark cock was a truly grand bird and well worth his place; colour, shape, feather, size—all good. The other two prizes were much criticised, and the third was in our opinion better than second, which we think might have made way for at least three others, being coarse in head, clumsy, and no saddle to speak of. The hens were remarkable for the three prize pens being every one first-class, while all the others were comparatively worthless. The cup for cockerels was rightly won by the Middleton cup bird, which has changed hands, and whose development is such as is rarely seen; but he was by no means in condition. Second was good in shape and feather, but hardly the bird we expected; and third had a slipped wing. This class rather disappointed us on the whole for one of forty entries. The pullets numbered forty-four, and was about the best on the whole which we remember for three seasons. Cup pen splendidly pencilled, both dark and yet clear, but narrow in shape. Second far better in shape, but not quite equal, though still first-rate in marking. Third very clearly and purely pencilled, but poorly feathered, and with same fault as the first. The pencilling in this class was the best seen for a long while, and we did not envy the Judges. We would only say that the cup should, we think, have gone to the hens, which were nearly perfect in shape as well as colour.

23 to 26.—Old Light cocks were very poor, nearly all being of a dirty straw colour. The best bird in all but size was the highly commended pen 368, which, if we mistake not, was winner last year, but was very small. The third-prize we did not like in any way. The cup for hens we were glad to see given to a decidedly hocked but heavy-feathered and beautifully coloured pair of very good shape and size. Second very large but bad colour, being a deep creamy tint. Third good colour and fair in shape, but very poor in feather. The cup cockerel a well-developed large bird, but with no rise in the saddle, which we think a great fault; hackle lightly but distinctly striped. Second good shape, size, and colour, and but for a slipped wing we would have selected him for the place of honour. This bird, however, showed strongly the tendency, now happily nearly stamped out of Darks, to grow white feathers in the tail. Third best in shape and colour of the class, but far too small. Pen 414 was a special example of the yellow tinge which is so offensive. Still this class showed some real advance on last year. The pullets also were better, the cup pen being a nice pair, really well feathered, and good clear colour, though the hackle should be darker. Second much the same. Third, on the contrary, good in hackle, but creamy. We are not sure we should not have selected for the cup one of the pens "left out in the cold;" and for the guidance of amateurs we would point to one of the birds in pen 463 as the best single neck and head in the class. The Light pullets numbered forty-seven pens, beating the Dark by three!

SPANISH.

27 to 30.—In the old cocks the cup and third were very good birds, but the second had one of the ugliest heads ever seen, and we have a strong suspicion the award was meant for 504 next door; but in any case we should have given either second or third to pen 508. The cup hens were very fine, but none of the rest were nearly in condition, and we would not speculate on their value. The cup cockerel had a

medium-sized face, but of super-excellent quality; the second also a fine specimen; the third had long lobes, but a rather poor face. The cup pullets were but middling, and decidedly inferior to the second-prize pair, which was the best in the class; third not nearly matured, and will be better in a month more. It will be seen that both cups for cocks were taken by a new Bristol exhibitor, thus filling the place of the departed Mr. Lane. This is as it should be, and we quote it as one of the many examples to meet the oft-repeated falsehood that practised exhibitors can "rig the market," and as showing that entire ontsiders have an equal chance with the Judges, if the birds are only good enongh to win.

FRENCH FOWLS.

31 to 34.—The cup Houdan cock was rather coarse, and with a small suspicion of Dorking cross, but good dark colour, and really an immense bird. Second and third about the average; third almost too dark perhaps. In hens Mr. Cooper was first again with a really fine pair, and second and third were not far off. It pleased us to see that English fanciers are getting the spangling of these fowls more regular in pattern, and that the splashed and patchy appearance is fast disappearing. In Any other French variety, the cup cock (Crêve-Cœur) was the best single French fowl in the Show; second and third also good Crêve-Cœurs, but a considerable distance behind the cup. In hens, first and third again were Crêve-Cœur, and rightly judged, the third will in a fortnight be far the better pair of the two. Second were La Flèche, and showing far more health and condition than usual, and with capital genuine French heads.

HAMBURGHS.

35 to 39.—In Gold-spangles the first-prize contained a first-rate cock with a hen in bad condition. The same remark, indeed, applies to all three, which were young cocks with old hens not fairly recovered moulting. In Silvers, the first-prize pen contained an unusually good hen, with a cock a little too dark and small. Second-prize a far better, all-but-perfect cock, but hen only middling, with spangles not large enough. Third not up to Mr. Beldon's usual style, the cock having rather a cobweb over his tail. The Gold-pencils secured the cup, the pullet being one of the very best ever exhibited, and the cockerel also of marked excellence. Second and third very fair average, and perhaps appeared worse than they were by contrast with the rare quality of the cup birds. In Silver-pencils Mr. Beldon was again to the front and far a-head, showing the only hen in the class with a properly pencilled tail. His second and the third only moderately good; but we noted the pencilling in the Silvers was recovering depth of colour, and were glad to see it. The Black Hamburghs were only moderate, and disappointed us.

GAME.

40 to 47.—Owing to the excellent light we never saw Game to better advantage than at this Show, and many who do not see it will lose a treat. The cup Black Red cock was rather too light in eye and hackle, but no doubt as good as in the class. Second a better colour, but not matured, and rather too leggy. Third rather short in the head for a Game fowl, but good. Still we were surprised not to see Mr. Douglas's bird, No. 687, "among the three;" he was certainly either second or third best of the lot. The first-prize hen left little to desire; second and third fair average prize birds, even for a Crystal Palace Show. The first-prize Brown Red cock was as good as could be, perfect shape and colour, and in fine condition. Second also good, but quite rough in comparison with either first or third, which last should have had second prize. Mr. Brierley took the cup for the fair sex with a very fine but also very old hen; second was a good pullet; third good, but not nearly fit to show, and when in good order will distance the lot. Duckwings were admitted by nearly all to be judged wrongly; the cup went to a fair cock in body, but wretchedly bad in colour, and with a forked tail, which looks decidedly novel in a Game fowl. The second was, perhaps, the best cock in the class, but even the winner's third might have displaced the cup with great advantage. In hens, the first was fine in shape, but not quite the thing in markings; second and third rather poor, and, perhaps, this was the weakest in quality of the Game classes. In the Any other variety classes the first and extra were taken by Mr. Brierley with one of the most perfect birds ever seen, and decidedly the best Game cock in the Exhibition. He was sound and excellent all over, but the marking especially was as if painted on "to order." This bird created quite an enthusiasm amongst the critics. Second and third need no remark, unless, perhaps, the third was too short in the hackle. In hens, the first-prize was a fine old yellow-legged Pile, the same exhibitor being also second with a good pullet; third only middling.

POLISH.

48 to 50.—The Gold-spangled class was remarkably well filled with good birds, but Mr. Beldon was not yet to be beaten, and took both cup and second with grand specimens of old birds. In Silvers also he came to the front in a good class, but still not equal to the Golds. The White-crested were few, but very good, and we were sorry not to see more of them.

MALAYS.

51.—These were few, but somewhat larger than usual, and most of them not quite moulted. Mr. Brooke's well-known pen were still the best.

ANY OTHER VARIETY.

52.—This class was unusually "varied," containing excellent examples of Sultans, Silkies, Cuckoo Cochins, Frizzles, Andalusians, Minorcas, and Leghorns. It was also remarkable for an interesting mule bird, bred between a Game cock and a Guinea-fowl, and shown with his "maternal parent." The appearance was remarkable, and both parents could be clearly traced, the Game blood "going to the head," and the Guinea fowl being predominant in the legs and body. We should like this bird to be persistently bred, with a view to see if the sterility in such cases is absolute. The question is interesting. Sultans took the cup, an extra first going to Mr. Wildey's Andalusians. Sultans again were third, while the only pair of Leghorns took second. We were glad to see the pretty Sultans again becoming so popular.

GAME BANTAMS.

53.—Failing light must make our remarks on these birds very few and very modest. The Judge himself had hardly fair play with them. The old Black Reds were poor, and we regret to see the class at all. GameBantams do not show well when old, they get stout and stocky in comparison. The cup cockerel was a gem and far ahead of the rest; second also good; but third too heavy to our taste—in shape we mean, not weight. The judging in pullets led to some remark; but there were many good birds, and there was room for any number of opinions on the subject. The Wheaten hens (a new class) as a rule were out of condition, and varied much in colour. Brown Red cockerels were few, but better in shape than the Blacks. Pen 980 we thought ought to have been in the list, but all the prize birds were good and very fairly placed so far as we could *see*. The Brown pullets showed marked improvement, colour and shape being now nearly perfect. In the next class all the prizes were taken by Duckwings, the Piles being poor. We can only say the cup bird was one of the best ever shown. The hens we were quite unable to pass an opinion upon.

We can offer no further remarks which would be of any use. The light was now gone, and without some power of passing a judgment no one has any right to profess to judge. We would only remark on the rare quality of the Selling classes, and in these we expect there will be fault found with the awards. We changed our own opinions every time we passed down them, and so might the Judges for all we know. As it was, extra prizes were given, so as to make eight prizes in each class. These classes have now become a feature in the Palace Show, and meet a real want, as proved by the amount of money that changes hands in them.

We were much pleased with this Show; and we would repeat that it only needs such a number of Judges as shall be able to arbitrate promptly, yet with deliberation, and we would add, proper comfort to themselves, to place it in the very first rank. Birmingham would do well to look to it, and will need all it can do to keep ahead. We confess we think the time this year rather too early. The chickens showed well, but the show of old birds was not what it would have been either in numbers or quality somewhat later.

Dorkings (Coloured).—1 and Cup, J. Martin. 2, Mrs. Arkwright, Sutton Scarsdale. 3, Henry Lingwood. *hc*, W. W. Ruttlidge, Shorthend, Kendal; J. Smith, Shillinglee Park, Petworth. *c*, T. Briden, Earby.

Dorkings (Coloured).—*Cockerels.*—Cup, J. Clark, Lochahers. 2, Viscount Turnour. 3, J. White, Warlaby, Northallarton. *hc*, W. S. Trevithick, Hayle, Cornwall; J. Webb, Romford.

Dorkings (Coloured). — *Pullets.*—1 and 3, Mrs. E. Wheatley. 2, J. Webb. *hc*, Mrs. E. Wheatley, Ingatestone (Dark); J. Clift, Dorking; J. Frost, Parham; J. Drake, Ongar; J. Glessall, Milnthorpe. *c*, Rev. E. Cadogan.

DUCKS (Any other variety and Ornamental Waterfowl).—1, S. Burn, Whitby. 2, M. Leno. 3, W. B. Smith. *hc*, C. W. Brierley; J. K. Fowler; E. C. Gibson; M. Leno (2); Rev. N. Serjeantson; H. B. Smith.

GEESE.—1, S. H. Stott, Preston. 2, J. K. Fowler. 3, W. Tippler.

TURKEYS.—1, F. Lythall, Banbury. 2, Mrs. J. Mayhew, Great Baddow. 3, J. Rodwell. *hc*, Rev. N. J. Ridley, Newbury; H. Cooper; Mrs. Dunn. c, W. Tippler.

PHEASANTS.—1, M. Leno. 2 and 3, J. K. Fowler.

PIGEONS.

POUTERS.—*Cocks.*—1 and Cup and 2, R. Fulton. 3, F. Gresham. *vhc*, J. Wallace, Glasgow. *hc*, R. Fulton; R. Marlin. (Black Pied).—1, F. Gresham. 2, R. Fulton. 3, J. Ure, Dundee. c, J. Wallace. (Red Pied).—1, F. Gresham. 2, R. Fulton. 3, A. Wright, Morningside, Edinburgh. *hc*, W. R. Rose; E. Horner, Harewood, Leeds. c, R. Fulton; R. Marlin. (Yellow Pied).—1 and 2, R. Fulton. 3, A. H. Stewart, West Bromwich. *hc*, W. Volckman. c, E. Horner; J. Ure. (White).—1 and Cup, F. Gresham. 2, A. H. Stewart. 3, M. Skinner, Fountainbridge, Edinburgh. *hc*, A. S. Thomas; R. Fulton; Mrs. Ladd, Calne (2). J. Wallace. Whole class commended. (Any Colour).—1, J. McGill, Elie, Fife. 2, F. W. Zurhorst, Dublin. 3, J. Morrison, Morningside, Edinburgh. *hc*, W. Volckman, Bishopsgate Street Within. (Blue or Black Pied).—1 and 2, F. Gresham. 3, W. B. Van Haansbergen, Newcastle-on-Tyne. (Red or Yellow Pied).—1 and Cup, H. T. Stewart. 2, R. Fulton. 3, P. H. Jones, Fulham.

POUTERS.—*Hens.*—(Blue Pied).—1 and Cup and 3, F. Gresham. 2, R. Fulton. (Black Pied).—1, A. H. Stewart. 2, W. B. Van Haansbergen. 3, E. Horner. (Red Pied).—1, J. Bawley, Bradford. 2, W. R. Rose, Kettering. 3, F. Gresham. (Yellow Pied).—1. R. Fulton. 2, E. Horner, Harewood. 3, N. Hill, Upper Norwood. Whole class highly commended. (White).—1, R. Fulton. 2, F. W. Zurhorst. 3, E. Horner. *vhc*, J. Wallace. (Blue or Black Pied)—1, J. Wallace. 2 and 3, W. Volckman. (Blue or Black Pied).—1, F. Gresham. 2 and 3, J. Wallace. (Red or Yellow Pied).—1 and Cup, R. Fulton. 2, W. R. Rose. 3 and c, A. H. Stewart.

CARRIERS (Black).—*Cocks.*—1 and 2, R. Fulton. 3, W. Woolley, Tarporley. *hc*, E. C. Stretch; F. T. Wiltshire, Lower Addiscombs, Surrey; R. Fulton. *Hens.*—1, 2, and 3, R. Fulton. *hc*, W. Woolley; R. Fulton.

CARRIERS (Dun).—*Cocks.*—1, E. Horner. 2, R. Fulton. 3, H. Yardley, Birmingham. *hc*, F. T. Wiltshire; R. Fulton. *Hens.*—1, F. T. Wiltshire. 2 and 3, J. C. Ord, Lupus Street, Pimlico. *hc*, J. Baker; H. M. Maynard; W. Massey.

CARRIERS (Any other colour).—1 and Cup, R. Fulton. 2, W. B. Tegetmeier, Finchley. 3, J. Watts. *hc*, G. Hodgkinson, Birmingham.

CARRIERS (Any other colour).—1, J. Watts. 2, R. Fulton. 3, W. Massey. *hc*, W. B. Ford, Weymouth, Dorset (2).

CARRIERS (Black).—1 and Cup and 2, F. T. Wiltshire. 3, — Hallam, Lozells, Birmingham. *hc*, R. Fulton; W. Massey; W. Siddons & Sons, Aston, Birmingham (2); W. Bammond, Ilford.

CARRIERS (Dun).—1 and 3, G. C. Holt, Greenbank, Lawton. 2, W. Siddons and Sons. *hc*, F. T. Wiltshire; W. Massey.

CARRIERS (Blue or Silver).—*Young Hens.*—1, R. Fulton. 2 and 3, G. Hodgkinson. *hc*, W. B. Tegetmeier; J. Watts.

TUMBLERS (Almond).—1 and Cup, J. Ford. 2 and 3, R. Fulton. *vhc*, E. Horner; J. M. Braid, Cambridge. *hc*, F. Moore. *Young.*—1 and Cup, F. Moore. 2, J. Ware, Dalston. 3, — Gilbert. c, F. Moore; J. M. Brsid; H. T. Davis, Lewisham Road; E. T. Dew, Weston-super-Mare.

TUMBLERS (Baldheads and Beards).—1 and 2, W. Woodhouse, Lynn. 3, G. Soutb, New Bond Street.

TUMBLERS (Any other variety Short-faced).—1, F. Moore. 2, J. Fielding, jun., Rochdale. 3, J. Ford. c, J. Watts.

BARBS (Black or Dun).—1 and Cup, R. Fulton. 2, Capt. H. Heaton, Manchester. 3, E. Horner. *vhc*, H. M. Maynard.

BARBS (Any other colour).—1 and 3, R. Fulton. 2, J. Firth, Dewsbury.

BARBS.—*Young.*—1 and Cup, 3, and *hc*, J. Firth. 2, F. Smith, Birmingham. *vhc*, Capt. H. Heaton (2); G. H. Gregory, Taunton.

BARBS.—1 and Cup, R. Fulton. 2, P. H. Jones. *vhc*, Capt. H. Heaton, Worsley, Manchester; R. Fulton. c, R. Fulton.

BARBS.—1 and Cup, T. Waddington. 2, Capt. H. Heaton. *vhc*, J. Lister, Keighley; R. Fulton.

JACOBINS (Red or Yellow).—1, Capt. H. Heaton. 2 and 3, R. Fulton. *hc*, Capt. H. Heaton; R. Fulton; E. Horner. c, E. Horner; W. Massey. Spalding.

JACOBINS (Any other colour).—1 and Cup, Capt. H. Heaton. 2, J. Thompson, Bingley. 3, J. B. Pinder. *hc*, S. A. Wyllie. c, J. B. Pinder, Harpurhey, Manchester; G. Roper, Croydon.

FANTAILS (White).—1, H. M. Maynard. 2, Rev. W. Serjeantson. 3, W. H. Tomlinson, Newark. *hc*, G. Ure; J. Sharpe, Johnstone. c, J. Baker, Spring Grove, Kew Bridge; J. F. Loveridge, Newark; Rev. W. Serjeantson. *Disqualified*, two cocks, 1938.

FANTAILS (Any other colour).—1, H. Yardley, Birmingham. 2, P. H. Jones. 3, A. H. Stewart. c, — Randall, Guildford.

NUNS.—1, W. Bearpark, Ainderby Street. 2, E. Horner. 3, R. W. Richardson. *hc*, W. Bankes; H. Yardley; F. Graham, Birkenhead.

TRUMPETERS (Black).—1, 2, 3, and Cup, J. Montgomery, Belfast.

TRUMPETERS (Any other colour).—1, W. B. Van Haansbergen. 2, E. Horner. 3, J. Firth, Webster Hill, Dewsbury. *hc*, E. Horner; J. Montgomery. c, W. H. C. Oates, Beathorpe, Newark.

OWLS (English).—1, P. H. Jones. 2, A. Mangnall, Broughton, Manchester. 3, J. Baker. *hc*, J. W. Edge, Birmingham; J. Kemp, Haslingden (2). c, A. Mangnall.

OWLS (Foreign).—1, E. Horner. 2, T. Waddington. 3, P. H. Jones. *hc*, J. Bowes, Herne Bay; R. Fulton.

TURBITS (Blue or Silver).—1, A. Mangnall. 2, E. T. Dew, Weston-super-Mare.

3, W. Goddard, Great Stanhope Street. *hc*, W. B. Van Haansbergen. *Disqualified.*—W. Bearpark, Stamped in flight.

TURBITS (Any other Colour).—1 and 3, G. Roper. 2, E. Horner. *hc*, A. A. Vander Meersch, Tooting; J. W. Edge.

MAGPIES.—1 and 3, E. Horner. 2, G. H. Gregory, Taunton.

DRAGOONS (Blue or Silver).—1 and Cup, W. R. Tegetmeier, Finchley. 2, W. Gibson. 3, F. Graham. *hc*, F. Graham (2); J. Holland, Cheetham Hill, Manchester.

DRAGOONS (Red or Yellow).—1 and 2, F. Graham. 3, G. South, New Bond Street, London. *hc*, S. C. Betty, Camden Town; W. Volckman.

DRAGOONS (White or any other colour).—1, J. Dunn, Newcastle. 2, J. C. Ord, Pimlico. 3, F. Graham. *hc*, H. T. Dwelly, Peckham.

ANTWERPS (Short-faced).—1, C. F. Copeman, Birmingham. 2, J. Coleman. 3, H. Yardley.

CUMULETS.—1, W. B. Tegetmeier. 2 and 3, A. Lubbock, Beckenham.

RUNTS.—1 and 3, S. A. Wyllie, East Moulsey. 2, T. D. Green, Saffron Walden.

PIGMY OR AUSTRIAN POUTERS.—1, — Kitchen, Blackburn. 2, P. H. Jones. 3, W. B. Tegetmeier.

ANY OTHER VARIETY.—1, T. Waddington. 2, J. Bowes, Herne Bay. 3, H. Draycott, Umberstone, Leicester. 4, A. H. Stuart. *hc*, T. Waddington; H. Yardley (2); W. Goddard.

SELLING CLASS.—1, J. Firth. 2, T. Adams. 3, J. Baker. *vhc*, J. Thompson. *hc*, H. Pratt; R. Fulton; J. Firth; A. H. Stuart; J. Thompson (2); W. B. Tegetmeier. *c*, R. W. Richardson; G. H. Gregory; E. Horner; P. H. Jones; W. B. Tegetmeier.

SELLING CLASS.—1, J. Ford. 2, J. Bowes. 3, E. Horner. 4, R. Fulton. *hc*, P. T'Anson, Grantham; Rev. A. G. Brooke, Shrewsbury.

COLLECTION OF FOUR PAIRS OF PIGEONS EXCLUSIVE OF CARRIERS AND POUTERS.—1, R. Fulton. 2, W. B. Van Haansbergen. 3, P. H. Jones.

PEN OF HOMING ANTWERPS.—1 and Cup, J. J. Sparrow, Berkley Square, Grosvenor Mews. 2, J. W. Collinson, Halifax. 3, J. J. Bradley, Birmingham. *hc*, W. B. Tegetmeier; B. Cracroft, Austin Friars; J. J. Sparrow; A. Webster, Kirkstall, Leeds; W. Lund, Shipley, Leeds; J. Edmonds, Clapham; J. Wright Rochdale, near Manchester; J. Deakin, Sheffield; J. A. James, Woolwich (2); A. Christy, Cudham. *c*, J. J. Sparrow (2); J. C. Ord.

JUDGES.—For *Poultry:* Mr. Edward Hewitt, Mr. Richard Teebay, and Mr. J. H. Smith. For *Pigeons:* Mr. E. L. Corker, Mr. Jones Percival, and Mr. T. H. Ridpeth.

BIRMINGHAM PHILOPERISTERON SOCIETY.

THE Committee of Management have just held their seventh annual Show, and it is most satisfactory to state that both as to the quality of the birds and the pecuniary success, this year's meeting has very far exceeded any yet held. Great interest is excited by the fact that the majority of the birds shown have been bred by members of the Society during the current year. Three hundred pens competed, most of them being far behind those generally met with at our public shows. Carriers throughout were superb, and some of the young ones especially so. In Pouters the display of white birds was magnificent, being such as is rarely equalled at any Pigeon show. The Fantails, Almonds, and Barbs were not less worthy of praise; the Owls, Turbits, and Jacobins were also much better than heretofore. Great, indeed, was the competition in the Antwerp and Dragoon classes, the general impression being, never were such well-filled classes of these breeds seen in Birmingham. The Variety class, too, contained so many new varieties, as to be quite a feature of the Show. Mr. Yardley sent in a very large cage of quite new breeds not for competition; they proved objects of great interest to visitors.

YOUNG BIRDS.

CARRIERS.—*Black.*—1, F. Smith, Selly Oak, Birmingham. 2, C. Mugg, Bromsgrove. 3 and 4, G. F. Whitehouse, King's Heath, Birmingham. *hc*, J. Coleman, West Bromwich; J. F. While, Birmingham; T. Robson, Penkridge. *Dun.*—1, G. F. Whitehouse. 2 and 3, J. F. While. *Any other Colour.*—1, J. Watts, Hazlewell Hall, King's Heath, Birmingham. 2, Withheld.

POUTERS.—1, 2, 3, and *hc*, G. Sturgess, Leicester.

FANTAILS.—1, G. While, Balsall Heath, Birmingham. 2, H. Adams. 3, F. H. Paget, Birstall, Leicester. *hc*, H. Adams, Beverley. *c*, J. W. Edge, Birmingham.

BARBS.—1, F. Smith. 2, H. O. Blenkinsop, Newcastle-on-Tyne. 3, H. Adams.

ALMONDS.—1, H. Adams. 2, No competition.

HALDS AND BEARDS.—1, J. W. Edge. 2, No competition.

SHORT-FACED (Any other variety).—1 and *c*, H. Adams (Red Mottle). 2, H. O. Blenkinsop (Almond Tumbler).

OWLS (English).—1, J. Watts. 2, G. F. Whitehouse. 3, J. W. Edge. 4, W. Bankes, Runcorn. *hc*, W. Bankes; W. T. Nicholds, Selly Park, Birmingham.

TURBITS.—1 and 6, T. Robson. 2 and 3, J. W. Edge. 4 and 5, W. Bankes. *hc*, F. H. Paget.

NUNS.—1 and 2, W. Bankes. 3, F. Graham, Birkenhead.

JACOBINS.—1 and 4, R. Saunders, Lever, Beverley. 2, H. O. Blenkinsop. 3, J. W. Edge. 6 and *hc*, H. Adams.

TRUMPETERS.—1, H. O. Blenkinsop. 2, T. Robson.

DRAGOONS.—*Blue.*—1, 4, 5, and Cup, W. T. Nicholds. 2 and 3, J. Coleman. 6 and 7, W. H. Mitchell. *hc*, F. Graham; W. H. Mitchell, Moseley, Birmingham; J. Watts; J. Coleman; W. T. Nicholds. *Yellow.*—1, F. Graham. 2, J. Watts. 3, W. H. Mitchell. *White.*—1 and 3, F. Graham. 2, H. Adams. *Any other Colour.*—1 and 4, J. Morris. 2, F. Graham. 3, J. Watts.

ANTWERPS.—*Dun.*—1 and Cup, C. Mugg. 2 and money prize, J. Coleman. 3 and 4, W. H. Mitchell. *hc*, W. H. Mitchell; F. Smith. *Dun Chequered.*—1, W. H. Mitchell. 2, J. Massey, Hunter's Lane, Birmingham. 3 and *hc*, C. Mugg. *Blue.*—1 and 2, W. H. Mitchell. 3, J. Coleman. *Blue Chequered.*—1, J. Massey. 2, W. H. Mitchell.

MAGPIES.—1, T. Robson. 2, J. Watts.

SWALLOWS.—1, J. Watts (Blue). 2, F. H. Paget (Yellow).

ANY OTHER VARIETY.—1 and 2, W. Bankes (Silverette and Satinette). 3, J. Watts (Dentillettes). *hc*, F. H. Paget (Yellow and Black Priests).

TUMBLERS (Muff-legged).—*Black Badges.*—1, F. Thomas. 2, G. While. *Blue Badges.*—1, J. W. Edge, Birmingham. 2, No competition. *Black Saddles.*—1, Withheld. 2, J. Morris. *Blue Saddles.*—1, J. W. Edge. 2, No competition. *Rosewings and Redbreasts.*—1 and 3, F. Thomas, Birmingham. 2, J. W. Edge. *Clear-legged.*—*Any other Variety.*—1, J. Watts. 2, No competition.

BIRDS OF ANY AGE.

CARRIER.—*Blacks.*—*Cocks.*—1 and 3, G. F. Whitehouse. 2, F. Smith. *hc*, J. F. While; J. Watts. *Hens.*—1, F. Smith. 2, Withheld. 3, G. F. Whitehouse.

CARRIER.—*Dun.*—*Cocks.*—1, J. Watts. 2, Withheld. *Hens.*—1, G. F. Whitehouse. 2, J. J. While. *hc*, J. Watts.

CARRIER.—*Any other Colour.*—1, J. Watts. 2, Withheld. *Hens.*—1 and Cup, J. Watts. 2, No competition.

POUTER.—*Cocks.*—1, 2, 3, and Cup, G. Sturgess (White). *Hens.*—1, 2, and 3, G. Sturgess.

FANTAILS.—1, J. W. Edge. 2, H. Adams.

BARBS.—1, J. Peace, Burton-on-Trent. 2, No competition.

ALMONDS.—1, H. Adams. 2, J. Peace. 3, J. Fielding, jun., Rochdale.

BALDS AND BEARDS.—1, J. W. Edge. 2, No competition.

SHORT-FACED (Any other variety).—1, J. Watts. 2, J. F. While (Kites).

OWLS.—*Foreign.*—1 and Cup, J. Fielding, jun. (Blue). 2, J. Watts (White). *hc*, G. F. Whitehouse (Blue). *English.*—1, J. W. Edge. 2, W. Bankes. 3, J. Watts. *hc*, G. F. Whitehouse.

TURBITS.—1, J. W. Edge. 2, W. Bankes. 3, T. Robson. *hc*, G. While; T. Robson.

NUNS.—1 and 2, W. Bankes.

JACOBINS.—1, R. Saunders. 2, T. Robson.

TRUMPETERS.—1 and Cup, and 2, T. Robson (White).

DRAGOONS.—*Blue.*—1, 2, and 3, W. H. Mitchell. *hc*, F. Graham; G. F. Whitehouse. *Yellow.*—1, W. H. Mitchell. 2 and 3, F. Graham. *White.*—1, H. Adams. 2, G. F. Whitehouse. 3, F. Graham. *Any other Colour.*—1, F. Graham. 2, No competition. (Single).—*Blue.*—1, J. Morris. 2, J. Watts. 3 and *hc*, W. H. Mitchell. *Any other Colour.*—1 and 2, W. H. Mitchell. 3, J. Morris. 4, H. Adams.

ANTWERPS.—*Blue.*—1 and 3, W. H. Mitchell. 2, J. Massey. *hc*, J. Watts. *Dun.*—1, J. Coleman. 2, C. Mugg. 3 and *c*, W. H. Mitchell. *Dun Chequered.*—1 and 2, J. Massey. 3, J. Coleman. *Single Cocks.*—1, J. Coleman. 2, J. Morris. 3, C. Mugg.

MAGPIES.—1, J. Watts. 2, T. Robson.

SWALLOWS.—1 and Cup, J. Watts (Blue). 2, F. H. Paget (Yellow).

ANY OTHER VARIETY OF FANCY.—1 and Cup and 2, W. Bankes (Satinettes and Sultanas). *hc*, J. W. Edge (Maned). *Single.*—1 and 4, H. Adams (Almond Tumbler and Red Mottled Short-faced). 2, J. Watts (Black Barb). 3, F. Smith (Black Barb). *hc*, J. Morris (Red Magpie); H. Adams (Almond Tumbler); W. Bankes (White Foreign Owl).

TUMBLERS (Muff-legged).—*Black Saddles.*—1, G. While. 2, No competition. *Blue Saddles.*—1 and 2, J. F. While. *Black Mottles.*—Prizes withheld. *Rosewings and Redbreasts.*—1, J. Watts. 2, Withheld. 3, J. W. Edge. *Any other Variety.*—1, J. W. Edge. 2, No competition. *Single Bird.*—1, J. Watts. 2, No competition. (Clear-legged).—*Balds and Beards.*—Prizes withheld. *Any other Variety.*—Prizes withheld.

The Judges of Antwerps were Mr. Edward Hewitt, of Sparkbrook, and Mr. Betts, of Summer Street, Edgbaston. The Judges for all the other fancy varieties were Mr. Hewitt and Mr. Yardley; and for the Flying Pigeons Mr. Maesy, of Hunter's Lane, all of Birmingham.

DARLINGTON ORNITHOLOGICAL SOCIETY'S SHOW.

A LIBERAL schedule of prizes, and the very indefatigable exertions of the Committee and Honorary Secretaries (Messrs. W. Hodgson and W. J. Steward), obtained 359 entries of birds, consisting of Canaries, Mules, and British and foreign birds. It was an excellent Exhibition. The Show was held in the very spacious and suitable hall of the Mechanics' Institute. There were about one hundred more entries than at the previous year's exhibition, and the birds generally were of first-class breed and quality. Yorkshire certainly is occupying a prominent position in the bird-exhibition world, but the Show at Darlington is one among several others which take a very high place annually in the county of Durham.

BELGIAN.—*Clear Yellow.*—1, J. Rutter, Bishopwearmouth. 2, W. Bulmer, Stockton. 3, R. Robinson, Middlesbrough. *hc*, J. S. Petch, Hull; R. Robinson. *c*, M. Holroyd, Great Horton. *Clear Buff.*—1 and 3, J. Rutter. 2, W. Bulmer. *hc*, R. Robinson (2); J. N. Harrison, Darlington. *c*, J. S. Petch. *Variegated Ticked or Unevenly-marked.*—1, 2, and *hc*, J. Rutter. 3, R. Robinson. *c*, R. Robinson; J. N. Harrison.

NORWICH.—*Clear Jonque.*—1 and 3, Adams & Athersuch, Coventry. 2, Moore and Wynne, Northampton. *hc*, Moore & Wynne; W. Watson, jun., Darlington; W. Hodgson, Darlington; Cox & Hillier, Northampton. *c*, Barwell & Golby, Northampton; J. Cleminson, Darlington; J. Rutter. *Disqualified*, Barwell and Golby. *Clear Buff.*—1 and 3, Moore & Wynne. 2, Smith & Preen. *hc*, Adams and Athersuch (2); J. H. Dosser, York; Wallace & Beloe, Berwick-on-Tweed. *c*, J. Devaney, Knaresbrough; G. Blackston, Whitby; Barwell & Golby; Moore and Wynne.

NORWICH.—*Evenly-marked Jonque.*—1 and 3, Adams & Athersuch. 2, Barwell and Golby. *hc*, Moore & Wynne; E. Mills, Sunderland; W. Hodgson. *c*, C. Greenwood, Scarborough; Adams & Athersuch. *Evenly-marked Buff.*—1, Adams and Athersuch. 2 and 3, Wallace & Beloe. *hc*, W. & C. Burniston; Layfield and Ellerton, Darlington; Moore & Wynne. *c*, Adams & Athersuch; J. Rutter.

NORWICH.—*Ticked or Unevenly-marked Jonque.*—1, Adams & Athersuch. 2, Barwell & Golby. 3, G. Gayton. *hc*, R. Simpson; Moore & Wynne (2). *c*, J. Cleminson. *Ticked or Unevenly-marked Buff.*—1, Adams & Athersuch. 2, Barwell & Golby. 3, Moore & Wynne. *hc*, J. Devaney. *c*, Moore & Wynne; W. Watson, jun.

NORWICH CREST.—1, J. Hurrell, Sunderland. 2, W. Watson, jun. 3, R. Hawman, Middlesbrough. *hc*, M. King, Scarborough; W. Bulmer; W. Robson, Durham; Wallace & Beloe; Moore & Wynne. *c*, Wallace & Beloe; Layfield and Ellerton; J. Rutter; Cox & Hillier.

CRESTED CANARY.—1, Stevens & Leek, Middlesbrough. 2, L. Belk, Dewsbury. 3, P. Rawnsley, Ledget Green, Bradford. *hc*, T. Fawcett, Baildon, Leeds. *c*, W. Park, Darlington.

LIZARD.—*Golden-spangled.*—1, J. Taylor, Middlesbrough. 2 and *hc*, R. Ritchie, Darlington. 3, J. N. Harrison, Belper. *Silver-spangled.*—1, J. N. Harrison. 2 and 3, R. Ritchie. *hc*, Smith & Preen, Coventry; R. Ritchie.

LIZARD WITH BROKEN CAP.—*Gold or Silver-spangled.*—1 and 3, Smith and Preen. 2, W. Watson, jun. *hc*, M. King; R. Ritchie (2); T. Fawcett. *c*, W. Robson; Stevens & Leeke.

CINNAMON.—*Jonque.*—1, Wallace & Beloe. 2 and 3, Barwell & Golby. *hc*, J. Devaney; J. Hurrell; Moore & Wynne; G. Gayton, Northampton; C. Gayton, Northampton. *c*, E. Stansfield, Bradford; Wallace & Beloe. *Buff.*—1, Barwell & Golby. 2, G. Gayton. 3, E. Mille. *hc*, Moore & Wynne; Cox & Hillier. *c*, W. Bulmer.

YORKSHIRE.—*Clear Yellow.*—1 and *hc*, J. Cooper, Middlesbrough. 2, J. Garbutt, Yarm. 3, P. Rawnsley. *Clear Buff.*—1, W. Thornton, Darlington. 2, T. Fawcett. 3 and *hc*, J. Cooper. *Disqualified*—T. Richardson, Guisborough; W. and C. Burniston.

YORKSHIRE.—*Evenly-marked Yellow.*—1, R. Hawman. 2 and 3, Stevens and Leeke. *hc*, T. Tenniswood. *c*, E. Stansfield. *Evenly-marked Buff.*—1, Stevens and Leeke. 2, T. Craggs. 3, P. Rawnsley. *hc*, L. Belk; T. Tenniswood. *c*, P. Rawnsley; Stevens & Leeke; R. Hawman.

ANY OTHER VARIETY OF CANARY.—1 and 2, Wallace & Beloe (Glasgow Don). 3, Moore & Wynne. *hc*, P. Rawnsley; T. Craggs.

SELLING CLASS.—1, G. Gayton. 2, W. Russell, Stapleton, Darlington. 3, J. N. Harrison. *hc*, W. Russell; H. Winter, Guisbrough; Fairclough & Howe, Middlesbrough; Wallace & Beloe; Layfield & Ellerton (Norwich); Stevens and Leeke; Barwell & Golby; R. Hawman; J. Cleminson (2). *c*, W. & C. Burniston (2); Wallace & Beloe (2); Layfield & Ellerton (Norwich); T. Allenby, Durham.

CAGE OF SIX CANARIES (Variety and Plumage).—1, Layfield & Ellerton. 2, J. Calvert, Bootham, York. 3, Stevens & Leek. *hc*, J. Gale, Darlington; Wallace and Beloe; R. Hawman; T. Allenby; J. Cleminson.

GOLDFINCH MULE.—*Evenly-marked.*—1, L. Belk. 2, Stevens & Leek. 3, Layfield & Ellerton. *hc* P. Rawnsley; Stevens Leek; Layfield & Ellerton. *c*, T.

Snaith. West Auckland (2): E. Stanafield (2). *Dark.*—1, Moore & Wynne-2 and 3, E. Stanafield. *hc*, T. Tenniswood; H. Winter; J. Taylor; Moore and Wynne; Stevens & Leeke. *c*, J. Goode; J. T. Harrison.

MULE (Any other Variety).—1, E. Stanafield (Bullfinch and Goldfinch). 2 and 3, Stevens & Leek. *hc*, T. Snaith (Linnet); J. T. Harrison (Greenfinch and Goldfinch). *c*, T. Snaith (Linnet); W. & C. Burniston (Linnet); Layfield and Ellerton (Siskin); W. J. Stewart, Darlington (Siskin).

CLEAR GREEN.—1, Stevens & Leek. 2, W. Robson. *hc*, Layfield & Ellerton.

GOLDFINCH.—1, T. Tenniswood. 2, J. N. Harrison. *hc*, Stevens & Leeke; J. Goode; T. Fawcett. *c*, J. Taylor; W. Robson.

JUDGE.—Mr. G. J. Barnesby, Derby.

RABBITS AT THE YORKSHIRE SOCIETY'S SHOW.

THE schedule issued this year is, perhaps, one of the most liberal and varied ever presented to exhibitors. The Lops are divided into six classes, and the other varieties into five, exclusive of the Selling class. All pens are for single Rabbits, which we much prefer. Two pieces of plate are given, one for the best Lop, the other for the best of any of the other six varieties which will be found there. The whole of the varieties of the Rabbits known in the county will be there, we doubt not, and each have a class and chance of a prize. The entry fee is moderate, and the prizes liberal. The Judges are well known for their knowledge of the varied points of excellence. The Committee are working hard to insure success. No entries can be made after the 16th inst.

ENTRANCE FEES.

As a member of a committee for the carrying out of a poultry show I cannot allow the letter of Mr. John Cockroft upon entry fees to pass without notice, otherwise exhibitors might conclude that the committees of many poultry shows were passing a nice balance into their own pockets, instead of which many of them find that there is not only plenty of hard work, but the balance is mostly on the wrong side. To give a rough idea of the working of a show, I consider the entry fees should pay the money prizes, the subscriptions pay for cups and hire of pens, and admissions pay the working expenses. To carry out the scale suggested by "J. C." every class must average from twenty-two to twenty-eight entries. Did he ever hear of such a show with only three prizes to a class? The entries at the Crystal Palace Show last year averaged about seventeen in a class, which I consider very good. "J. C." may consider that committeemen should be prepared to give £50 out of their own pockets for the benefit of the exhibitors. My advice to "J. C." is, "Make one of a committee to get up a show, let the entry fees and prizes be as you suggest—I promise to give all the support I can, and have no doubt the entries would be large—and when the accounts are all squared, let the readers of the Journal know on which side the balance is found."—L. WREN.

SUBSCRIBERS TOWARDS THE PIECE OF PLATE FOR BLACK EAST INDIAN DUCKS.—I have been getting up this for the Birmingham Show. The winner of the first prize will thus win a piece of plate value £4 4*s.*, and the Society's prize of £3. The contributors are—Mrs. Hayne, Dorchester, 10*s.* 6*d.*; Rev. Wm. Serjeantson, Shrewsbury, 10*s.* 6*d.*; Rev. John Richardson, Sandy, 10*s.* 6*d.*; W. E. George, Esq., Bristol, 10*s.* 6*d.*; G. S. Sainsbury, Esq., Devizes, 10*s.* 6*d.*; J. K. Fowler, Esq., Aylesbury, 10*s.* 6*d.*; Mr. Samuel Burn, Whitby, 10*s.* 6*d.*; Mr. F. Hall, Whitby, 5*s.*; F. E. Schofield, Esq., Morpeth, 5*s.* 6*d.*; total, £4 4*s.*—SAMUEL BURN, *Whitby.*

MAKING GRAPE WINE.

SIX days ago I expressed nine gallons of the juice from Black Hamburgh grapes for wine. It began to ferment almost immediately. The fermentation continues, and I cannot find the directions of your correspondent "UPWARDS AND ONWARDS" for checking it in case of going too far. I have put 10 lbs. of loaf sugar into the wine; the grapes were very sweet, and I thought sugar was hardly required. I have also put into it some vegetable charcoal, which a gentleman who makes cider informs me would be a valuable addition. Will you inform me in what numbers of the Journal I shall find the needful information?—J. M. R.

[Nos. 429 and 452, published in the year 1869, contain the information required.

The fermentation of your wine, however, was going on perfectly well without the addition of vegetable charcoal. It is curious to find how, in the many letters which I receive on this subject, the varying features of quackery will intrude. I described the plan of checking fermentation at a certain stage merely for the sake of economy; but "J. M. R." need not be frightened if fermentation goes on to the end unchecked, provided some of the best loaf sugar is given to bring the wine up to the general English palate of 10° before next May, or sooner if convenient, and in order to guard against acetous fermentation during summer. In fact, leaving economy out of consideration, further practice and observation have inclined me to allow my best juices to go through their fermentations without a check, which the saccharometer will reveal by floating at the index of 0°, and then to rack off and sweeten to taste as above. No sulphuring nor fining will then possibly be required, nor will the wines be subject to "cloud" from unfermented sugar, or be so liable to present us with "a last glass of thick" at the bottom of each bottle on consumption.

Unless "J. M. R.'s" Black Hamburghs were grown under glass and were perfectly ripe, I should consider 10 lbs. of sugar to nine gallons of juice a minimum quantity, notwithstanding his thinking the grapes were very sweet.

I begin my Muscadine vintage to-morrow (Nov. 8th), weather permitting. We have a capital yield, and the grapes are in good condition for making into wine. Our Esperione grapes are not good in colour, though sufficiently so for the fabrication of a pink champagne. These I shall let hang, except in case of frost, for a week or so longer, as they are firm, plump, and increasing in their colour. I shall allow them 3¾ lbs. of sugar per gallon of juice, and that is what I would advise for out-of-door black grapes this unfavourable ripening season; 3¼ lbs. of sugar will prove sufficient for the Royal Muscadines, the best of all out-of-door grapes at present for our uncertain English climate.—ROBERT FENN.]

FEEDING BEES.

IN "The English Mechanic and World of Science," there is a description with a diagram of an ingenious method of adapting the bottle-feeder to hives of straw. A gentleman, who signs himself "Joseph Gadsby," is the inventor. As he is not the patentee, but publishes his discovery *pro bono publico*, I cannot be at fault in extracting the following for the benefit of your readers. He says, "I have made both the round and square feeder [of the old type], and have thrown them aside as feeders . . . . . and have adapted the bottle with a small tin made in the shape of a funnel wrong side up, the hole where the spout would be placed made sufficiently large for the bottle neck to go in, and then a tube put in just to fit the neck of the bottle; and where the bottle neck reaches I fix a piece of perforated zinc to prevent the bees coming up. This I can fix on either wood boxes or straw hives. By the plan I have attempted to describe I can give them 4 lbs. in every twenty-four hours without any inconvenience."

Many of your readers who keep bees in hives of straw will be thankful for the hint given in the foregoing extract, as it is often found to be a great practical difficulty. Of course there must be a hole cut in the top of the straw hive, and the tin or zinc cap into which the bottle will go must be made sufficiently large to fit well over the top of the hive, and to support the bottle in an upright position. The whole can be covered over with a conical straw cap and hackle.—B.& W.

BEE HUNTING.

THE accompanying sketches, made during a recent jaunt in the Adirondack region, are illustrative of scenes that one may witness, if so disposed, while camping out in the "Wilderness."

"Max," said one of the ladies of the party to our guide, "there must be quantities of bees in the woods, for they hum

and buzz about that maple-sugar of ours until I am really afraid to go near it."

"Fog's right about, do they, Miss Mamie?" "Fogs" is a favourite phrase of Max's, and does duty in all sorts of ways. "Well, them's some of my molasses-makers," he continued; "if you like honey, I'll take up the hive to-morrow, and let you see how we 'line a bee tree.'"

"Bee-hunting," said Max, as we left the shanty the next morning for our hunt, "always reminds me of General Grant, for, like him, we fights it out on one line till we gets through."

"Smudging for Bees."

We soon reached our old clearing, when Max produced his little bee-box, from which he took some honeycomb, and put it in a little fire which I had quickly kindled on a convenient log.

"You see, girls," said he to the ladies, "the bees scents this from a mile or more away, and comes to see me when I call them so. Then I feeds the little chaps this way" said Max, as he placed some honey in the bottom of the bee-box. During the time that we waited for the arrival of Max's bees, the good fellow entertained us with stories of bear, panther, wolves, lynx, and all manner of things peculiar to the woods.

"Max! Max! here they come!" cried one of the girls, who, in listening to the stories, had not neglected to watch the bee-box.

"Know'd that some time ago," said Max; "only wanted to see whether they were going to get into the box without my help; but I guess they be. We'll watch 'em for a while, then put our mark on a few to see how far away they live."

The bees had by this time gotten well to work, seeing which, Max took some flour and dropped a little on the backs of two or three of the bees that were busy on the honey. By this time even the ladies had decided the line, for it was easy enough to watch the flight of the bee, from the time that it left the box, circled a few times, then directed its flight in a "bee-line" toward the hive. The marked bees soon returned and re-entered the open box.

"Ain't very far to that hive; warn't gone long, anyhow," quoth Max, as he gently shut the box lid and tapped on the box, to make the bees leave the honey in the bottom and rise to the top, so that he might shove in the little slide that divided the box in the centre, thus separating the bees from the honey. Picking up the box, Max started on the line, the party following after, each endeavouring to assist in locating the line. A quarter of a mile traversed in this way, we were halted by Max setting down the bee-box, drawing out the slide, and covering the box with his hat. (The box has a little glass window in the top.) Peeping in, and discovering that the bees were at work on the honey, he took away the hat and opened the box. In a short time we were again on the line, and in two more "tries" lined the honey-makers to their abode in the great trunk of an ancient birch tree.

"Working down the Bee Tree."

Max's axe now came into use, and as the tree came crashing down we dashed forward and stopped with moss the hole used by the bees as their entrance and exit. Rolls of thin birch bark were now lighted and held to the hole, from which the plug had been removed.

"Bees don't fight fire much before they gives up and takes the back track for the honey," said Max, when the bees had ceased the useless contest and he was engaged in chopping out the "big chips" that were to reveal the sweets. Soon we were removing the great combs of honey from the tree-trunk hive to the pails that we had brought with us.

On our way back to the shanty Max told how other bees, attracted by the honey, would come, and sometimes great battles would be fought; and the bees whose honey was lost, being weaker, would be defeated, and if their queen was killed would go off with the other bees and make sugar for them, thus starting another bee-tree for future capture.

Nearly 100 lbs. of honey was distributed from our bee-tree, besides the quantity that we consumed ourselves.—(*Harper's Weekly.*)

OUR LETTER BOX.

CAUTION.—"Committees and managers of forthcoming poultry and Pigeon shows should take care, for at the late Newcastle-on-Tyne Pigeon Show my first-prize White African Owl hen has had her frill pulled out by some malicious person, and she is quite unfitted for future exhibition. A liberal reward will be given to any person who may give information against the offender.—JOSHUA FIELDING JUN., *Park Terrace, Rochdale.*"

NORWICH SHOW (*A.*).—Thanks for the paper; when we have seen advertisements and prize lists we will give it such a notice as we think justified.

THE SOUTHAMPTON POULTRY SHOW.—In the "Other Variety" class, the second prize went to Mr. T. Moore, of Portsmouth, not Fareham.

GAME FOWLS' LEGS SCURFY (*J. W.*).—Your feeding is not good enough. Boiled potatoes and turnips are very bad food. The first are bad enough, the second are worse. The only thing in the whole bill of fare that can nourish your birds is the oatmeal. Depend upon it if you persevere in your present dietary, all your birds will suffer alike. Give ground oats, Indian corn, and table and kitchen scraps. Your birds must be too low in condition.

WHAT IS A PULLET? (*C. M. K.*).—Your question is somewhat difficult. Many declare all are pullets till the year in which they were hatched has passed away. We believe a pullet cesses to have any claim to that name after she has been broody.

BLACK BANTAMS (*G. F.*).—We have never had any trouble in breeding any Bantams, except the Sebrights. Blacks, Whites, Game want little care save that the hen should be put on a dry spot, that the little chickens may neither get draggled nor cramped. It is quite a different thing with the Sebrights. Many of their eggs are useless, and they are tender at first, but after they are a month old they do well. We have always found the earlobe to be hereditary. If you keep your Bantams dry, feed well, supply them with grass and fresh earth, they will do well. When one of the hens hatches, bring her out, put her under a rip in a dry sheltered place, and do not let her have her liberty. She will drag all her chickens to death if you do.

BROKEN SICKLE FEATHER (*H.*).—Leave the perfect feather as it is, and pull out the other, it will grow in two months; even if it be not as fine as the other it does not matter, provided the colour be right. Any deficiency of feathering, or any breaking of a sickle feather, is always viewed with suspicion in the breeds in which colour is the most important feature.

WORM IN HEN HOUSE (*Novice*).—We do not think the worm came from the hen, it has not the character it would have. If the foreign body in the cock's mouth is of a sort of cheesy nature, pull it off. If it is firmer, cut it off. If it is not developed, it can be easily removed with the thumb nail, and the best treatment then is camphor given frequently in pills the size of a garden pea. We never approve of putting fowls in an artificially-warmed place. If they have colds, give them some bread and ale twice per day. Let them have all the table scraps and odd pieces of meat, skin, and fat that are left at meal times. Heat should be communicated through food, and not by stoves or fireplaces.

GOLDEN-SPANGLED HAMBURGH FEATHERS (*G. C.*).—Nos. 3 and 4 are the best feathers, the moons or crescents are good upon them. The hackle feathers are good. The fault in them all is a deficiency of richness in the ground colour. They look a little washed out. We should advise you to introduce a rich-coloured dark cock into the yard next season.

POULTRY SNEEZING (*Blacks*).—There is little doubt your fowls are suffering from chill. It may be from the change in the weather, or from a brick, stone, or wooden floor. The incipient sneeze is a sure sign of "cold in the head." The quickest remedy to relieve the black comb is to administer two pills of camphor, each the size of a garden pea, and then to feed on some bread and ale. The black comb shows congestion, and when all other remedies fail it is sometimes necessary to bleed at the base of it. Poison would have the same effect on the comb, and so does indigestion. The latter is very rare among poultry. In the stage you mention it is not infectious. The Brahmas and Cochins are not subject to it. The Game are, and would most likely catch it. Use stimulants for present relief, then try to remove the cause.

LIGHT BRAHMAS (*R. G.*).—We cannot help thinking No. 1 has a crooked flight, else why should his feathers be folded high on his back? We do not mind the light saddle. We dread his wings, and we disapprove of his "coarse ugly head." We should be disposed to vote for No. 2 in spite of the light flight feathers, but we do not like a crooked breast. We do not think it hereditary, but it is the sign of a weak bird, and we should not, therefore, breed from him. If you are sure No. 1 has not twisted flights, then, taking his weight and good points into consideration, we should overlook the light saddle and the ugly head, and give him the preference. The single-combed bird will not do at all. He must be got rid of. As soon as the hen's crop dropped she should have been held up by the legs till her crop was emptied. She should have been very scantily supplied with water and have had less food; she would then have wasted. You were too ready with your knife. The operation should only be performed on a crop-bound bird. In that case the crop is as hard as a cricket-ball. All birds of the poultry tribe waste and fatten easily, and if you had fasted the hen a little she would have absorbed the fat that killed her. All the eastern breeds put on fat inside. There is nothing in your feeding that should cause excessive fat, unless the kitchen scraps were very good. Fat makes fat. We consider the fattening an accident, and believe she died from the operation. When you open another crop do not give bread and ale after the operation; thin gruel is all that is necessary for a day or two, given frequently in small quantities. We have never met with such fat about the crop except where fowls have been fed on meat.

GERMAN TOYS (*W. W.*).—The Germans are great Pigeon breeders, and are accustomed to put a number of pretty-feathered birds together, and if a pair alike in plumage are produced, they gave them a pretty name, and send them out into the world. Many such under various names which were seen at our shows a few years since, have quite disappeared. We know nothing of "German Hermits," and they are not mentioned in any Pigeon book extant.

ANTWERPS (*A. W.*).—Show Antwerps and working Antwerps differ. Our engraving was one of the former. These birds are bred carefully to colour and points. The working Antwerp is the one most likely you want, which is not so much a bird for the show-cage as for utility.

GOLDFINCH MULES BECOMING LIGHT (*M. G.*).—I apprehend from the query that it is a nest of dark self-coloured Mules, which will remain to all intents and purposes dark Mules, though the dull lustreless hue of the nest feathers will be exchanged for a brighter colour. Those birds which come under the class of Dark Jonques will be of a bright colour, while the Dark Mealies or Buffs will be of a dull leaden shade, the cocks in both classes having more or less of the Goldfinch "flourish" on the face, and the hens being minus that adornment, and clad in somewhat more sober garments. Dark Goldfinch Mules are sometimes extraordinary birds as regards colour, and very deservedly have a class to themselves in every schedule worth calling a schedule. If the Dublin Society issue a prize list sufficiently liberal no doubt our English fanciers will send birds—possibly accompany them, for there is no limit to the pluck of the fancy. But poor men, artisans, cannot afford the luxury of competing for honour; neither can poor men who are not artisans. I once was making active preparations for sending a collection across the Atlantic, but I found that a bronze medal would not pass current in the matter of freight. I am sorry to hear that all the Canaries in Ireland are bad. That can soon be remedied. I am now in communication with Australia respecting a consignment of high-class birds. If they can travel to the antipodes they can easily cross the Irish Sea.—W. A. BLAKSTON.

TREACLE FOR BEES (*J. Campbell*).—We have never fed with treacle, but see no reason why it should not do for bee food. We should dilute it with water if too thick, and perhaps boil it for a minute or two.

FEEDING COWS ON CABBAGES (*A Subscriber*).—They do not impart as turnipy flavour to the milk.

REMARKS.

8th.—Foggy and damp till noon, then fine and pleasant.

9th.—White frost; beautiful morning and fine day. Aurora at 10 30 P.M. and subsequently mostly white, but with red streamers.

10th.—A very fine day, though cold. Aurora again at night.

11th.—Frost, but fine morning; a very slight sprinkling of rain in afternoon, but fine evening. Encke's comet seen with a pocket telescope.

12th.—A very fine and bright day, though cold.

13th.—Rather hazy in the morning, fine at noon, but very cold. Evening very foggy.

14th.—Foggy early, a very fine bright day, but a wet evening, with blustering wind and rapid fall of barometer.

A very cold week, the mean temperature (36 3°) was nearly a degree below that of the month of January. Frost on every morning except Wednesday.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 15.

THE trade remains in much the same state as last week. Among fresh arrivals are some good Oranges, both the ordinary and the Tangerine variety, from the Azores; fine Pomegranates and Bananas from Teneriffe. Large quantities of fine French Pears have been submitted to auction during the week. The Potato trade is heavy, the best qualities only commanding fair prices.

From observations taken near London during forty-three years, the average day temperature of the week is 47.9°, and its night temperature 33.4°. The greatest heat was 62°, on the 25th, 1863; and the lowest cold 9°, on the 25th, 1858. The greatest fall of rain was 1.21 inch.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 1.

By Rev. William Lea, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

[We most emphatically ask for our readers' attention to the series of communications of which the following is the first; we ask for such an attention as will result in aiding to realise the writer's convictions—convictions the results of experience. We are emphatic in our advocacy, because our own observations and our own experience quite coincide with those of the writer. His position and known character are guarantees of his sincerity, truthfulness, and singleness of purpose, and that purpose is connected intimately with the internal peace and prosperity of our native islands. Political advocacy has no abiding place in our columns, but the *consequences* of the gradual annihilation of small farms have long rivetted our attention, and been a theme of regret. Most justly did the Patriarch deprecate as the worst of visitations the "washing away the things which grow out of the dust of the earth, and the destroying of the hope of man," and such a washing away and such a destroying of hope are results from the entire expunging of small farms. "I am emigrating because I cannot win from being a labourer here"—"I leave because the squire has added my bit of land to the Home farm"—were replies from two of the steadiest men in one parish. On a property with which we are acquainted there are three small holdings varying from twenty to forty acres each. These are models of good cultivation and domestic comfort. They serve as nurseries for a superior class of household servants and farm bailiffs, and as fast as these attain the necessary age they are eagerly sought after. If once the country is cleared of such tenancies as these, we shall lose a valuable element in our social scale.—Eds.]

THE very title of these papers may sound paradoxical. Political economists have long decided that small farms will not answer, and apparently they are right; for, as while small farms have disappeared from the midland counties years ago, there were in most parishes and properties several small takings of from five to ten or even twenty acres each—some of them were freeholds, others were rented—but in the present day few such are to be found. The freeholds have been bought up by the neighbouring proprietor, and, with his own small takings, added to the adjoining large farm, and in consequence a distinct class has disappeared from the social scale, a class which held an intermediate position between the labourer and the farmer: and the question I would ask my readers to consider is, Whether the country has not sustained a loss both socially and morally by the extinction of this particular class? and if so, whether it may not be to some extent restored?

In all our country districts we have now as a rule three distinct grades of society, separated from each other by sharp lines of demarcation—the landed proprietor, the large tenant farmer, and the labourer; and the objection to this state of things to my mind is this: the farmer may rise to be a landowner, but the labourer is stereotyped in his own present condition without any opportunity of rising in his own walk in life. It is different in every other occupation. The boy who goes into a shop or warehouse may look forward to be a master himself. The mason may become a builder, the carpenter an employer of labour, his children may in future rise to the highest offices of Church and State, for the Endowed Schools' Commission have now made a ladder of steps from the national school to the middle school, from the middle to the higher school, and from thence to the Universities, by which any boy, whom God has endowed with natural gifts and powers, may ascend. The agricultural labourer now stands alone in this respect, without any opportunity of rising in his own profession of cultivating the land. Suppose that by diligence and thrift he has been able to lay by money, it would be impossible for him to lay by enough to enter upon a farm of the extent of which farms are now. He might be able to take, to begin with, ten or twenty acres, and then by thrift to pass on to something more, and leave his son in a position to take something larger still; but, in the present day, there are no such small farms to be had. Hence there is nothing but emigration either to some town district or to some distant colony—emigration from the parish in which his fathers have tilled the land for generations—for the labourer, who has the will and the power to rise: and hence it is that our country parishes lose year by year the stoutest and thriftiest and most intelligent of their men, the very pith of their population. If it were on this ground only, if it were only to retain the best of the men in their native parishes, I think it would be the interest of all landed proprietors to keep a few small holdings on their properties to bridge over the gulf between the labourer and farmer, and to serve as inducements to such men to remain, in the hope of one day rising into the condition of farmers themselves.

But when I advocate small farms, I do not mean that all the country should be cut-up into little holdings as it is in some parts of France and Belgium. The line so often quoted on this subject—

"When every rood of land maintained its man"—

is a mere poetical figure of speech. All I recommend is that there should be a sufficient number of them to serve as stepping-stones for the best of the agricultural labourers, and as inducements to thrift and industry, which are sadly needed in these days of increasing pauperism, and decreasing self-respect and independence in the true sense of the word. If in every thousand acres, fifty or even twenty acres were let in small holdings it would probably meet the case; and as land will bring a higher rent in small quantities than in large, this would, to some extent,

compensate the landowner for the extra expenditure which would be required in buildings.

In addition to this, I think that the country in general has lost a great deal by the destruction of this class of small holders. People are always complaining about their servants; they say they are not what they used to be, they are so helpless that they have no idea of putting their hands to anything outside their common routine of work; and there is some truth in these and similar complaints, but I think that the explanation of the change is to be found in the fact that the class from which the most useful servants—aye, and our best soldiers—used to come has disappeared. If anyone will take the trouble to inquire into the parentage of those "treasures" whose loss he is now deploring, he will find that they were the children of small farmers or freeholders, who were brought up at home in habits of industry, hardiness, and thrift from the time they were able to walk, and taught to put their hands to anything that was required, and to turn everything to the best advantage. They lived hard too, and thought the now-despised "fat bacon" a luxury. But the children of the present class of agricultural labourers have none of these advantages of training—at any rate not in the same degree. There is no little farm to work on, with something to fill up every spare minute; no stock about the cottage to tend, no cow to milk, no chickens to feed, no grafting in the spring, no budding in the summer, no haymaking in the little croft, no binding-up after their father as he reaped the little patch of Wheat which was to keep them all the year round in sweet brown bread—only, perhaps, the pig to look to, if this savings' bank is not prohibited; and as for the children of the workers in towns, there is nothing to teach them habits of thrift or handiness, and consequently they have no idea of either. Whatever their wages are they spend them, and if they are out of work for a week they apply to the parish for relief. They have none of that real independence which makes it a point of honour not to be "beholden" to others for support; and I am afraid a man may travel some way without being told, as I was not long since, by an old woman of seventy-five—"I never had a farthing from the parish in any way in my life, and I would rather die than have it."

If I am right in the estimate I have formed of this class, their destruction has been a loss, not only to their own district, but to the country at large; and if so, it would be a great advantage if they could be reinstated. But how is this to be done? I am quite aware that small farms do not pay—*i.e.*, they will not enable the tenant to live, if they are farmed on the same system as large ones. If the man with five acres tries to grow the same crops as the man with five hundred, he must be beaten in the competition, and go to the wall. But a small farm managed on a different system will afford a very good living to its occupier. It must be planted with fruit, not with Wheat; with vegetables for man, and not with roots for cattle. I can speak to this point from my own experience (the results of which I am about to give) over a period of seven years; and though I have always sold my produce at something below the market price, I think the returns would show a very fair profit to an agricultural labourer, after paying a comparatively high rent. Of this, however, the reader must judge for himself, and to enable him to do so, I must, at the risk of appearing egotistical, give an account of my own experiment.

In 1864 I bought three acres of land, and having long had a hobby of my own in favour of small farms, I commenced to ride it at once, with a view of seeing how far such farms might be made to pay if planted with fruit. One portion I devoted to specimen trees of various kinds—Apples, Pears, Plums, Gooseberries—with a view of ascertaining the sorts which would make the best return if planted in quantities. On another portion I experimented with vegetables, and on a third portion I made a plantation of Gooseberries, Black Currants, and Plums, and sold the produce. It is of this third portion, as nearly as possible one acre in extent, that I purpose to give an account. I first cleaned and double-dug the land, made a broad walk up the middle, and then planted it with bushes 6 feet apart, in rows 6 feet from each other. Among these I planted Plums, some 24, others only 12 feet apart. My stock consisted of 800 Gooseberries, 320 Black Currants, and 110 Plums—1230 in all; the exact number to an acre, planting at 6 feet apart, is 1225. For the first three years I had room for three lines of Potatoes or other vegetables between the rows; then, as the bushes increased in size, for two, and in the last and seventh year for one line only. In three or four years more the bushes will have entirely covered the ground, and there will be no more room for vegetables, but by that time I expect that the trees alone will produce a very good return; but to enable my readers to judge what profit may be expected during the first seven years, I subjoin an account of the fruit sold from this acre of ground. The crop produced

	£	s.	d.		£	s.	d.
In 1865	1	18	6	In 1869	21	17	0
1866	3	6	6	1870	28	6	2
1867	10	15	8	1871	32	12	9
1868	10	16	9				

In addition to the fruit, this last year one line of Potatoes or Onions was planted between each row. The produce was thirteen bags of early Potatoes at 10*s.* per bag, and five pots of Onions at 4*s.* per pot of 90 lbs.—£7 10*s.* in all, which, with the fruit, gives a gross return of £40 2*s.* 9*d.* for the acre.

It may be interesting, perhaps, to go still further into detail, and to give the prices of each kind of fruit, and the amount for which the produce sold in each of the seven years, bearing in mind that the acre was planted with 800 Gooseberries, 320 Black Currants, and 110 Plums, and that a pot of Gooseberries is expected to weigh 90 lbs., a pot of Plums the same, and a pot of Black Currants 63 lbs., the pots—*i.e.*, the baskets in which they are packed—included. I should also mention that some sixty of the Black Currants when planted were large bushes.

1865.	£	s.	d.
The crop of Gooseberries, at 5*s.* 6*d.* per pot, produced	0	11	0
Black Currants, at 10*s.* „	1	7	6
Plums 0*s.* „	0	0	0
	£1	18	6

1866.	£	s.	d.

Black Currants, at 12*s.* 6*d.*	2	8	6
Plums	0	0	0
	£3	6	6

1867.	£	s.	d.
Gooseberries, at 7*s.* per pot	8	8	8
Black Currants, at 10*s.*	2	7	0
Plums	0	0	0
	£10	15	8

1868.	£	s.	d.
Gooseberries, at 5*s.* per pot	7	10	0
Black Currants, at 10*s.*	2	4	0
Plums, at 7*s.* 6*d.*	1	2	9
	£10	16	9

1869.	£	s.	d.
Gooseberries, at 6*s.* per pot	12	18	0
Black Currants, at 10*s.* 6*d.*	4	12	6
Plums, at 4*s.*	4	6	6
	£21	17	0

1870.	£	s.	d.
Gooseberries, at 8*s.* 4*d.* per pot	17	2	0
Black Currants, at 9*s.*	4	12	0
Plums, white, at 3*s.*; red, at 6*s.*	6	12	0
	£28	6	0

1871.	£	s.	d.
Gooseberries, at 10*s.* per pot	13	0	0
Black Currants, at 15*s.*	9	5	0
Plums, white, at 5*s.*; red, at 10*s.*	9	7	6
	£32	12	6

It will be seen from this account that the price of fruit varies according to the season. During the last seven years Gooseberries have been as high as 10*s.*, and as low as 5*s.* per pot; Black Currants have been as high as 15*s.*, and as low as 9*s.*; Plums in like manner have varied in the same proportion; but the price of Gooseberries depends upon another condition besides the quantity of the crop. The time at which the gathering begins is an important item. If the gathering does not begin till June, 6*s.* per pot will be as remunerative a price to the grower as 10*s.* would be if the gathering were commenced in the middle of May. But I will say nothing more of the Gooseberry now, as I shall devote the next paper to this most popular fruit.

The temperature is seldom known to be so low so early in the winter. The minimum of the thermometer here, taken at 9 A.M., as registered during the night for the last nine days, is

as follows. The thermometer is 4 feet from the ground. Snow fell heavily for a quarter of an hour on the 11th, between 1 and 2 P.M.

Nov.	Temp.	Nov.	Temp.	Nov.	Temp.
11th	24°	14th	28°	17th	26°
12th	22°	15th	40°	18th	18°
13th	22°	16th	30°	19th	26°

—H. Harris, *Naseby Woolleys, Northamptonshire.*

GOOD AND BAD NEIGHBOURS.

The question raised by your correspondent, Mr. C. W. Johnson, is one of great interest, and it may not be irrelevant to mention that in the course of some experiments on the influence of various manures on plants made for two years in succession in the gardens of the Royal Horticultural Society, presumptive evidence, at least, was obtained, showing that the Dutch Clover (Trifolium repens), and even more markedly the Anthoxanthum odoratum, do not thrive when grown by themselves, but require the association of other plants. To what cause this is to be attributed I can only guess—my suspicion being that the roots of these plants suffer from the undue evaporation from the surface soil, which is obviated to a great extent when other plants are grown with them. This would be an easy matter to decide by a simple experiment.

Mr. C. W. Johnson may perhaps be unaware of the circumstances which originated the experiments above referred to under the direction of the Scientific Committee. As they have a material bearing on the point raised by him, I may briefly mention that in consequence of the astonishing diversity in the number and the kinds of plants grown in different plots of pasture land in the park of Mr. J. B. Lawes, of Rothamsted, when treated with different manures, it was determined to grow certain plants, twelve in all, separately, and to treat them with various manures. In this manner it was hoped that some light might be thrown on the causes which lead to the predominance of one plant over another under certain conditions of manuring. In the unmanured pasture land at Rothamsted some fifty or sixty species of plants grow together in association, but by the application of certain manures the number of species is reduced, till at length in certain plots little else remains but the Dactylis glomerata. The manures might be positively injurious to some species, or, on the other hand, they might be inert so far as they were concerned, but specially favourable to some other more vigorous-growing plant which would get the upper hand.

The experiments at Chiswick, so far as they went and so far as they can be relied on, seem to show that the latter is the more probable supposition. In comparatively few cases did the manure, of whatever kind it might be, seem to act as a poison would do—though of course if the quantity employed were excessive it would act injuriously in any case. The predominance of one species over another seemed to the experimenters to be due, in the first instance, to the constitution and specially to the habit of the plant, and any manure which stimulated the general vigour of the plant intensified the peculiarities of habit of the plant operated on, and thus it may be conceived would give it an advantage over a plant of weaker constitution, and with a "habit" or organisation less adapted for getting on in the world.—Amicus occultus.

LAYING BROCCOLI, WITH CULTURAL NOTES.

The most important of vegetables for a spring supply is the Broccoli. It occupies the place of honour in spring as the Peas do in summer, and nothing can compensate for its absence; but whilst all admit its usefulness, few doubt its liability to succumb to the severity of the winter. In a word, it is one of the best as well as one of the most uncertain crops of the garden. To obviate this uncertainty is at present beyond the power of the gardener, and it can only be effected by introducing an altogether hardier class of varieties than we at present possess. Some sorts are put forward as having the necessary hardiness, but all I can say is, that I have never yet had the pleasure of getting hold of a variety possessing this all-important requirement. If ever one does come into my hands, and does prove its right to be called truly hardy, I will, if I can, sound its praise through all the land as one of the greatest boons to gardeners and the community generally.

There is no doubt that some sorts of Broccoli are more hardy than others, but I am nevertheless of the opinion that soil, position, and cultura treatment have a greater influence in determining their frost-resisting capabilities than any peculiar constitutional virtue. However hardy a Broccoli may be, it can still be made tender in the growing. In many instances this is unavoidable, but in some it is, to a certain degree, preventible. Low-lying districts subject to a heavy rainfall are naturally unsuited to the winter keeping of Broccoli, as in such places the plants are tender and succulent. In other localities the growth is slower and the plants are more woody, and consequently more hardy. I grow a few plants in an exposed open field on the farm, amongst the Cabbages raised for the cattle, and I cannot possibly grow plants in the garden at all equal to these in hardiness.

In growing Broccoli two points should be kept in mind—abundance of air, and not too rich feeding ground during the summer. The richer the ground the greater should be the distances between the plants, as in rich deep soils the orthodox 2 feet space is altogether useless; it should be at the least 3 feet, or even the plants may be 4 feet by 3. Better than enriching the ground is a limited use of manure, and if large heads are required, give instead heavy surface-dressings of rich stuff in spring, when the plants are safe from frost and are showing signs of growth. Spring-manuring is the most economical and far the best, since manure in summer goes to produce large leaves, whilst spring-manuring helps in producing large, close heads. In the latter case we have a sure and immediate return; in the former the result is uncertain, and the whole process dangerously open to failure.

And now a few remarks about protecting. Laying is the ordinary and the best mode. In advocating laying down the plants I am aware I am running counter to the opinions of many able gardeners, as frequent statements have appeared saying that the loss was greater amongst the plants laid down than amongst those left standing. Those who have thus decided will, of course, not be at the trouble of laying their plants for the future, but there are many, however, who have not decided, and to these I submit my opinion and experience on the question. In the first place, some plants are grown so tender that a severe winter will kill them, either standing up or lying down; and so fatal was last winter, that good heads of Broccoli brought extraordinary prices. Many, though laid, were killed, not, indeed, because they were laid, but in spite of it, and I believe that far more were destroyed because they were left standing. Extended observation and some hard practice have assured me that it is prudent to lay down a large proportion of Broccoli. But if the practice is sound, why a proportion—why not all? some will ask. Simply for the following reasons:—Laying down the plants has some disadvantages. These I am willing to acknowledge, and, acknowledging, to act accordingly. Plants left standing, if they escape the winter, are ready for cutting rather sooner, and form finer heads than those laid down. This advantage I turn to account in order to prolong the season. If it is a choice of large heads or none, leave the plants standing by all means; but if the main object is to have Broccoli with good heads to supply dishes, laying down the plants is, in my experience, the practice most to be relied on. I do not assert that laying down the plants will absolutely prevent loss, but it tends, when properly performed, towards lessening it very considerably. I can hardly remember the time when—in season—I had no Broccoli to cut. I admit that I have experienced scarcity, but this the cook never knew. Last spring, when heads were so scarce, I was fortunate in having a plentiful supply, but positively not one was cut from plants left standing. Careful summer culture—that is, not growing the plants too large and luxuriant, giving them abundance of room, and choosing the most exposed position—these, in conjunction with laying, are the best means of meeting the Broccoli season, and lessening the probability of loss and disappointment.

Laying should be done thoroughly or not at all. The most tender part of the plants is the neck. To cover with soil the hardier parts and leave the tender exposed is simply labour lost. How many thousands of plants are half laid and then killed, the system being blamed for the whole loss, and not the slightest acknowledgment or idea of error on the part of the operator thought of? In laying, two things must be avoided—the plants must not be laid too early nor too shallow. In the latter case the necks are exposed from the first; in the former they quickly grow upright, as if to invite the frost, and are quite as helpless to resist it as if left standing. They are as bare-necked and as tender as if they had not been laid down at all, as the leaves, which would otherwise have been firm and erect, are, by root-disturbance, flaccid, and fall away from the hearts or heads.

I have just laid down about thirty score of Broccoli. I chose the time because the weather was fine and dry. Had I been certain of the same weather ten days later, I should have preferred it. Some were carted from the open field, and some brought from other parts of the garden. A piece of ground intended for next year's Scarlet Runners and late Peas was manured as for winter-digging. On this the plants are laid as close as possible without absolutely overcrowding. In trenching-in the plants, the manure—old vegetable refuse—is put round the roots. They soon begin to grow, but not soon enough to lift up their heads before Christmas. The plants are kept out of the ground until they begin to wither a little, and are then laid-in almost over the hearts. The flaccid leaves of one plant overlap the other, and never again become upright. This affords great protection. The plants soon recover the check caused by late removal, in consequence of the fresh stuff put into the trenches assisting them to form nice heads instead of large leaves. It is important that the plants should be put in perfectly dry or they may rot. As it is, a few will no doubt perish from this cause, but it is better that a score or two should die from excess of moisture than that the whole crop should perish through excess of frost. This plan has enabled me to obtain a supply of Broccoli for many years past, and I do not suppose it will fail me in the ensuing spring, even if the winter should be, as the Rev. W. F. Radclyffe predicts, hyperborean. It is also advantageous in saving ground, as the plants go into much less than half the space they before occupied, and are cleared in time for the above-named crops, which are put in trenches after the manner of Celery. All this certainly does involve labour, and I myself have had to work hard at it. Rest, however, is all the sweeter when a man feels confident that his labour will bring him the reward he anticipates. This plan, be it remembered, will not give gigantic heads, but I care not for that; so long as I get plenty of serviceable plants I do all that is expected, and am satisfied.

I may state that I always sow a little salt amongst the plants once or twice in the growing season, having an idea that it assists them to resist frost. Should the winter prove severe, Broccoli will again be dear, as the plants are more succulent and tender than usual, owing to heavy rains. I advise laying even now. If the winter be mild, it will have some advantage by retarding a portion of the stock and prolonging the season of cutting.—J. W., *Lincoln.*

ALPINE PLANTS.

Lover of the Rose though I am, there was an account in the advertising columns of the Journal a few weeks since that I hailed with pleasure—one announcing the sale of the collection of Roses in pots belonging to Mr. Ware, of the Hale Farm Nurseries, as the houses in which they used to be grown were wanted for his increased stock of succulents and herbaceous plants. It was one of the surest indications of the rising tide that I had yet seen, if I except that when I was at Caunton at the time of the Nottingham show, our great Rose champion showed me the old Rose garden, which was going to be turned into an herbaceous garden for the especial delectation of "my lady," and as a *répertoire* from whence she might gather flowers for her rooms. Yes, a rising tide, which I believe all the Mrs. Partingtons will not be able to keep out with all their mops made of Calceolarias, Pelargoniums, and other bedding stuff. I do not advocate a complete exclusion of the present system, but a moderating of its extravagance. I deplore especially its influence on our cottage gardens, where in so many places bedding plants are taking the place of the old-fashioned flowers that had always something in them to gladden one's eyes; while their utter want of fragrance makes them a poor substitute for the sweet-smelling Stocks, Wallflowers, and Cloves which they have ousted.

It is now some time ago that I paid a visit to Mr. Ware's nurseries, and was then astonished at the vast number of herbaceous and alpine plants that he had in cultivation; but I have now before me his catalogue of ninety pages, and on an average about sixty species in a page, so if here is not variety enough where is it to be found? At the time of my visit the earlier spring flowers were making their appearance; and here is the great value of the alpine rock garden—flowers that are perfect gems, with colours of a brilliancy we rarely see in other flowers—(for what can vie with the glorious blue of Gentiana acaulis or Gentiana verna? or what pink more lovely than that of Silene acaulis?)—open their beauties for us in early spring time; and from the time that the Snowdrop and Siberian Squill are in bloom, all through the summer a succession of beauties is to be had, with Campanulas, Androsaces, Dianthus, &c.

I do not think that there is much difficulty in making an alpine garden anywhere. I am about as badly situated for it as most people, stone being so very scarce, and, in fact, I have been obliged to content myself with large flints obtained from the chalk formation. They are happily yellowish on the surface instead of white, and so even at first do not look very glaring, while in a little while I hope some of my pets will soon hide them from view. It must be remembered that the garden ought to face the full sun, and not be shaded by trees. I have made mine on the border of a shrubbery going up to my house; this is about 4 feet wide, and I have raised it somewhat, getting it out of the way of the roots of the trees, and taking care that none of them overshadow it. My plan was to arrange the stones (I wish I could call them rocks, but I cannot), on the border, which is made of the common soil of the garden; in this I planted such kinds as are not particular as to their soil—Sedums, Sempervivums, Campanulas, &c. When I came to plant those which are particular as to their food I made a good-sized hole in the spot required, took out the earth, and then filled it in with the compost required, being careful that even for small plants the hole should not be less than 1 foot or 18 inches deep. I had by me a supply of road grit, sand, peat, good loam, and leaf mould, and according to the requirements of each plant used them. "Dear me! what a trouble!" says some enthusiastic bedder-out; "why, I have nothing to do but dig over my beds in autumn, stir them up a little in spring, and they are ready." Exactly so; and is not this one reason why bedding-out is so much favoured? But to a man who has been growing Auriculas, Carnations, and other florists' flowers all his life such particularity is nothing. Care must be taken as to weeding, for some of the Alpines are so small in their growth that coarse weeds soon destroy them, and some of them also will require careful watering in summer.

As to choice of sorts, I believe the best plan for anyone would be to put himself in the hands of men who, like Messrs. Ware, of Tottenham, or Messrs. Backhouse, of York, have made these things a speciality, assured that he will meet with fair and liberal treatment, telling them the size of the rock garden, and asking them to give a list of plants and estimate for it; while those who have already formed one can cull at their will from such collections. I know this taste is inexplicable to some. My good brother-in-law, seeing me looking over the Alpines at Glasnevin, accosted me with a polite offer to lend me a magnifying-glass, as he could see nothing, yet to me they are a source of much pleasure, and I would commend them to all interested in gardening.—D., *Deal.*

MORE ROSE GOSSIP.

Marie Baumann was wretched with me all this summer; it had scarcely one good blossom, and now fully half the plant has died off. It has been growing in a large bed with the following Roses—Charles Lee, Madame Margottin, Vicomtesse de Vesins, Alba Rosea, Duke of Edinburgh, Louis Peyronny, La France, Sombreuil, Souvenir de Dr. Jamain, John Hopper, Anna de Diesbach, Madame Rothschild, Joséphine Beauharnais, Princess Mary of Cambridge, and Camille Bernardin. Some of these are delicate Roses, but, with the exception of Marie Baumann, all bloomed through the summer continually, and presented a beautiful combination of colour for a couple of years. Madame Margottin was very poor with me. Mr. Radclyffe lauded it so highly that I did not give it up. I had it potted last winter, kept in a cold frame, and planted out on the 15th of May, and it well repaid the trouble. Only two days ago I cut off the last of its grand flowers.

Could Marie Baumann be improved by the like treatment? I often ask myself. But then the growth is so different that I doubt the success of the experiment. Besides, I had it generally covered with glass during the spring months, and with no good result.

I have been much surprised that none of your correspondents has noticed Miss Ingram, which, though only a summer Rose, I think in shape and colour is unsurpassed. When fresh expanded this year in the beginning of July it was perfectly exquisite. The frost and rain in June spoiled many of the blossoms. For the time (about one month) which it lasts it is a great bloomer. Shall we ever see a white Rose on its model? We really want such.

Alfred Colomb I prize above all varieties of the bright-coloured section; I have never seen its superior. Charles Verdier

is also very beautiful, and Gloire de Ducher graud against a wall.

Suckers were so numerous this season that I much fear where there was neglect—and I have seen it—there will be large gaps in some gardens next year.

"J. B., *Darlington*," whose experience I endorse, inquires respecting the Tea Rose Homère. I saw it as a standard; it was beautiful. I budded it also on a standard and it is doing well; but I regret it was not grown as a dwarf, it being then more easily protected. Comte de Paris is also a handsome Tea.

If any who may read the foregoing remarks would say something from their own experience about Roses in a greenhouse without Vines they would much oblige—An Amateur, *South of Ireland*.

WINTER CUCUMBER CULTURE.

There is a growing demand for Cucumbers all the year round. From May to October there is little difficulty in providing a regular supply, but during the dead of the winter it causes no little trouble to those who are expected to have a Cucumber fit to cut every week. No doubt it is a matter of small moment to those who have a good house, plenty of pipes, and plenty of coal, but by others situated like myself, where the coal bill is not to exceed a certain figure, houses that are to be kept at a high temperature must be made the most of in order to save the fuel.

For several years I have tried planting out in the Cucumber house, training the vines on a trellis about 14 inches from the glass. This involved keeping another boiler at extra heat, as every house in that range except the Cucumber house only required the frost and damp to be kept out, and the result in the Cucumber house was anything but satisfactory. As the piping was rather short, it required heating up to a very high temperature, and we generally had so exhausted the plants that we planted again for spring and summer cutting. This made a break in the supply, however forward the plants which were to replace the old ones. Now, however, we use the Cucumber house for other things throughout the winter, and take advantage of the Pine-stove heat.

About the end of August we make up a bed in a pit, which keeps us going till October is out. In September we sow half a dozen seeds, principally of Telegraph. Mastere's Prolific does very fairly with me. Sometimes we strike cuttings for autumn or late spring production. I prefer them, as they fruit more speedily than plants from seed, and do not grow so rampant, but in the dead of winter striking them is too troublesome. For that time I use seedlings, as they grow more rapidly and sooner fill their pots with roots.

The best way to guard the seed from mice—and I think when so treated it also germinates better—is to fill the pot little more than half full of soil, and, after plunging it in bottom heat, to cover with a pane of glass; this allows the glass to remain till all danger is over as regards mice, which are very fond of pulling up the seeds even after they have vegetated.

When the plants show the rough leaf, I pot them singly in 3-inch pots, and when these are filled with roots, into 6-inch pots. I train the plants upright for about 3 feet, then stop them to cause laterals to form. These are stopped as soon as fruit is showing. When the fruit is set, the plants are shifted into 9-inch pots. The compost used is partially decayed turf, with a little old Mushroom-bed dung and leaf mould. I generally allow five fruit to a pot; sometimes the plants will show double that number, but I consider five quite enough. No shoots are allowed to grow. All the energy of the plant is concentrated on these fruit, and the plant after bearing is thrown away.

I make a sowing about once a-month up to January, when I sow and plant out in the Cucumber house.

I find that Cucumbers will do without bottom heat, but the fruit swells a little quicker with it.

When watering I use the water at 85° to 90°, and as soon as the pots are filled with roots I use manure water, varying it with guano sometimes.

The number of pots of fruiting plants varies with our requirements; sometimes, as at Christmas, we require more, but as a rule one pot lasts us a fortnight, and three pots of plants in a fruiting state keep us going. The chief advantage of this mode of growing them lies in the ability to grow the plants and shift them into any house having the required temperature—70° by night and 80° by day, varying according to the weather, as I think it is bad policy to keep up the same amount of heat in dull weather or severe frost as in mild sunny weather.

Whether the plants are trained upright or on trellises, I prefer them to be in pots for winter, from my experience. One great secret of success is never to let dry heat come in contact with the leaves, as they are soon attacked by insects. Give them a mild humid atmosphere, and, if possible, change the air in the house every day, for which purpose a very small opening is sufficient at this time of the year.—T. M.

CHRYSANTHEMUMS IN THE TEMPLE GARDENS.

These gardens keep up their reputation for their excellent show of this autumnal flower, of which Mr. Newton, Mr. Broome's successor in the Inner Temple, and Mr. Dale, of the Middle Temple, are both skilful cultivators. Mr. Dale, of course, has long been known, but Mr. Newton is a comparatively new recruit to the ranks of Chrysanthemum-growers, and it is very gratifying to find that, as in last year, so in this, he has been successful in producing a fine display notwithstanding an extremely unfavourable season. The large-flowering varieties, as of yore, are placed under a temporary protection of sashes and canvas walling in front of Crown Office Row, the run of border thus covered being 110 feet. Among them we noticed good examples of Prince Alfred, Guernsey Nugget, White Globe, Little Harry, Prince of Anemones, Gluck, and others, but in many cases the expansion of the blooms has been checked by the severe weather we are experiencing, and but for the occurrence of which the show would have been much finer. This points to the necessity of means for affording a little artificial heat, which we think might be secured at a trifling expense, and would be useful for other purposes as well. The beds of Pompons have also been in fine bloom, but have suffered much from the frost. We may add that next the river, on a portion of the ground reclaimed by the Thames embankment, there has been formed a noble walk of some 600 feet in length by 28 in breadth, along which have been planted fine, strong, young trees of the Occidental Plane. Other improvements are also in progress, which will alter still more for the better the appearance of the grounds.

In the Middle Temple Mr. Dale's exhibition, though not nearly so extensive, is, as usual, of high quality, though with him, as elsewhere, the effects of the season are evident. Among the varieties best represented are White Globe, Mrs. George Rundle, Prince Alfred, Venus, Lord Derby, Golden Beverley, Guernsey Nugget, Progne, Phidias, white and pink, pretty in colour; Prince of Anemones, and the fine-tasselled Japanese variety, James Salter. Mr. Dale has also good beds of Pompons, which, had it not been for the weather, would have formed gay masses for a long time.

ASPARAGUS CULTURE.

I entirely agree with Mr. Fish, "that to encourage the growth of Asparagus there is nothing like summer manuring, and summer manure watering." I have had stronger proofs than ever of this in the past season, and as it may tend to encourage many to cultivate this vegetable, I will describe my practice and its results.

I cultivate my Asparagus in single rows, and being obliged last spring to plant a quantity in poor soil, and with a limited supply of manure, I had a favourable opportunity for trying the effects of summer manuring. The soil was trenched 2 feet deep, the best soil kept uppermost, and a little manure mixed with it near the surface. The roots of the plants were then carefully spread out and covered about 4 inches deep with soil taken from between the rows. They started into growth well—for the plants were strong—and when the roots began to put forth spongioles, sheep-dung water of moderate strength was given them; and as the plants gained size and vigour a proportionate increase was made in the strength and quantity of the liquid, till in the hot days of summer it was given twice or three times a-week.

Under this treatment the plants continued to grow freely throughout the summer, sending up such a constant succession of stout young shoots that most of them have formed fine large stools or crowns. On the approach of autumn, finding the growth still active and young shoots still appearing, the liquid manure was gradually withheld in order that the entire growth might be matured before cold weather set in. It is well in such instances as this to afford the luxuriant growth some support, so that it may not be broken off by strong wind, which it frequently is when standing out fully exposed in single rows.

That the foregoing method is altogether superior to the wasteful one of heaping a quantity of solid manure over the roots just as growth has ceased, must be patent to all. By one system the health and requirements of the plants are watched and cared for throughout the season of growth; by the other, if it deserves to rank as a system at all, a thick costly layer of manure is spread over the roots at the very time that their power of absorbing food is reduced to a minimum. Doubtless, much of the rich components of the manure does eventually feed the roots, and is absorbed into the plant's system, but there must also be considerable waste. It is best, therefore, to apply such manure in the form of a mulching early in summer; the roots, being then in full activity, seize on the rich food with avidity. Moreover, it serves admirably to protect them from drought in summer or frost in winter. It is, however, only when Asparagus is grown in low-lying, badly-drained soil that protection is necessary in winter; when the soil is well-drained and thoroughly cultivated, there need be no fear that this vegetable will suffer in the slightest degree from the effects of frost. —Edward Luckhurst.

VEGETABLES FOR NEXT YEAR.

Remarks on the above subject are well timed, as the season is again coming round for procuring supplies of seeds for another year. I forward a few hints, hoping that other correspondents will do the same, so that we may all be able to procure any good novelty that we have not hitherto grown.

To begin with Peas, I think that most gardeners will agree with me that the past season has been a favourable one for that esteemed vegetable. For early crops we generally grow Dickson's First and Best [Dillistone's Early], and Taber's Perfection. This season we added Kentish Invicta, and it turned out exceedingly well, coming in a few days later than the former two, sown at the same time on the same border. We commenced to pick on May 31st. The next to follow was Essex Rival, a capital second early variety. This again was followed by Laxton's Supreme and Prolific; then by Advancer, Wonderful, and Premier. The above six sorts were sown at the same time, on a west border, and made an excellent succession. I do not intend again growing Laxton's two Peas for the parlour table, as I find they come in but very little earlier than Advancer. The latter has been considered much the best variety. Supreme is a great bearer and a fine Pea for exhibition, but by my employers is not considered of very good flavour. We picked daily supplies for weeks from the same sowing of Advancer, Wonderful, and Premier. They became fit for use in the order named. The first dish of Advancer was picked on the 20th of June. Premier proved with us the best Pea this season, taking it altogether. The last dish of it was picked on November 4th, and the quality would have been very good had it not been for the sharp frost we had here the night before—viz., 7° below freezing. They were in full flower yesterday (November 12th), when the haulm was pulled up. I may add that our soil here is a stiff calcareous loam, and has been used for kitchen garden crops upwards of 150 years.

We grow the old Walnut-leaved Kidney for our earliest crop of Potatoes, both in pits and out of doors. We have tried many varieties, but for early use and good flavour nothing is equal to it. Veitch's Improved Ashleaf comes in next, and is an excellent sort; it is the heaviest cropping Kidney Potato we have tried for early use. Dalmahoy, Paterson's Victoria, and York Regent are all good. For our latest crop we grow a variety called Smith's Seedling. This is a good cropper, well shapen, does not grow very large, and is good for table from the time it is dug up until early Potatoes come in again. I have not seen this variety anywhere until I came to this locality. It is a round Potato with a pink eye, though sometimes we come across a root with but a small spot of pink on each tuber. I will forward you a small dish of them for your opinion. I have tried the American varieties, but have not grown them in sufficient quantities yet to be able to say what they will be. Red-skinned Flourball we find an extraordinary cropper and good for baking. From a peck of seed planted this spring we dug up six bushels of Potatoes.

Our earliest Cauliflower is Early London, sown the first week in September, and wintered in a cold pit. I sow Walcheren at the same time for a succession. Erfurt Mammoth, sown in a frame in February, comes in next. I then sow the same variety again out of doors in March. Another sowing of Walcheren and Veitch's Autumn Giant in April, and again in the second week in May, will carry us on until nearly Christmas, and longer if carefully protected. I find Veitch's Autumn Giant a splendid variety; some say it is too large, but it is easy to cut the heads when small. We have had them since the second week in September, and have still a nice lot to come in. The seed was sown as stated above.

For early spring use we sow Snow's Winter White Broccoli the first week in April. Veitch's Spring White sown at the same time follows that useful old sort. Miller's Dwarf White is a good variety to stand the winter. Willcove Improved, Goshen Late White, and Cattell's Eclipse carry us on until the end of May or the first week of June. The last two varieties we always plant on a north border.

Of Savoys, we grow Early Dwarf Ulm and Dwarf Green Curled, planted immediately after the early Potatoes are dug.

Our earliest Cabbages are Veitch's Improved, Atkins's Matchless, and Wheeler's Imperial. The first named is the sweetest little Cabbage we know, and can be planted to advantage 15 inches apart each way.

Of Celery, we find Incomparable White and Hood's Dwarf Red good varieties. This season I have some of Williams's Red, but have not tried it yet. When growing in the row I cannot distinguish it from Hood's.

Our earliest Dwarf Kidney Beans are Newington Wonder and Fulmer's Forcing, followed by Negro Longpod through the season. We find all three good useful varieties.

We had a large bed of Onions this year. The varieties were White Spanish (seed saved from home-grown selected bulbs), Nuneham Park (evidently a good variety of the former), White Globe, Bedfordshire Champion (these again were very much alike), Danvers' Yellow, a good variety, and James's Keeping, for use late in the spring. I find nothing beats the Red Italian Tripoli for standing the winter.

Of Beets, we find Pine Apple Short Top and Dell's Crimson both good.

Dutch Forcing and Early Horn are good early Carrots, with Intermediate for late use.

For Kale to stand the winter, Veitch's Dwarf Green Curled is a first-rate variety.

Our Lettuce to stand the winter is a local variety, called Hampshire Brown Cos; it is an excellent sort; I have frequently cut them 2 lbs. each early in June. For summer use I find Paris White Cos and Hicks' Hardy White Cos both first-rate varieties. Stanstead Park is a good Cabbage Lettuce for early spring use.—H. J. C., *Hackwood Gardens, Basingstoke.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Meryta latifolia (Broad-leaved Meryta). *Nat. ord.*, Araliaceæ. *Linn.*, Pentandria Pentagynia. — A native of Norfolk Island. First discovered by F. Bauer. It has a slender tapering stem of from 50 to 60 feet in height, with a cluster of large leaves, each 3 feet long, at the apex, from the centre of which rises the inflorescence. This consists of hermaphrodite flowers, sessile, with imperfect anthers, crowded in clusters of six so as to form many compound yellow heads, which are seated on an erect green rachis.—(*Bot. Mag., t.* 5932.)

Diascia Barberæ (Diascia of Mrs. Barber).—Remarkable for its two spurs at the base of the flower, which are no doubt filled with nectar to attract insects for the purpose of effecting fertilisation. Named after Mrs. Barber, who sent over the seeds. Flowers rose-red, with a yellow spot, in the centre of which are two green dots, situated on the throat of the corolla; arranged in racemes of from 4 to 6 inches long.—(*Ibid., t.* 5933.)

Prunus cerasifera (Cherry-bearing Plum). *Nat. ord.*, Rosaceæ. *Linn.*, Icosandria Monogynia.—The "Cerisette" of the French and the "Kirschpflaume" of the Germans, known in this country as the Myrobalan Plum. The fruit is either solitary or in a small fascicle, has an acid taste and a firm flesh. Seldom produces fruit in England, as the flowers are generally nipped by the frost.—(*Ibid., t.* 5934.)

Plagianthus Lyalli (Lyall's Plagianthus). *Nat. ord.*, Malvaceæ. *Linn.*, Monadelphia Dodecandria.—A small tree which grows in the mountainous regions of New Zealand, and was discovered there by Dr. Lyall. It flowers in January, and is then a conspicuous feature round the forests, whilst in autumn it is not less so from the beautiful golden colour of the fading leaves. Flowers pure white with pink styles, and arranged in fascicles.—(*Ibid., t.* 5935.)

Megaclinium purpuratum (Purpled Megaclinium). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Discovered at the

month of the Nun River, in tropical Africa. Rachis, including the connate bracts, narrowing towards the scape, and acute at the end; colour a dirty yellow green, sprinkled with purple. Flowers a quarter of an inch long. Column short, wings triangular.—(*Ibid.*, *t.* 5936)

PYRUS MALUS FLORIBUNDA.—"A prominent position in the very front ranks of hardy ornamental deciduous trees must be allotted to this remarkably floriferous plant, which forms a small tree, producing long slender branches, which burst out in early spring (about the end of April) into leafy garlands of brilliantly-coloured flowers. From each of the numerous buds proceeds a short spur-like shoot of about an inch in length, bearing several of the small lanceolate, acutely-serrated leaves, and terminating in a kind of corymb of seven or eight lovely blossoms on slender peduncles, which thus convert the shoots into very brilliant floral wreaths, measuring from 4 to 6 inches through. The flower buds are ovate, about half an inch long, and of rich crimson, looking like clusters of small elongated Cherries. The calyx is narrow and acuminate, the segments woolly inside and smooth outside, while the small oblong ovary is pubescent. The blossoms are succeeded by small round fruits. When half expanded the flowers appear striped with white and carmine, the petals being imbricated, the inner part remaining white, while the outer exposed half becomes coloured. Fully expanded the flowers are white, the five petals being white inside, spreading, oblong, rounded at the apex, and distinctly clawed; in the centre is a tuft of numerous erect stamens, and five styles somewhat exceeding them in length. The gradation of colour, and the varying form presented by the buds and flowers, are very pleasing. Their profusion renders the plant exceedingly gay and ornamental, and, indeed, in the earlier stages of development, owing to the abundant but gracefully disposed trusses of highly-coloured buds, the appearance of the tree is truly gorgeous. Beautiful as are the Almond trees in the early spring, they are utterly eclipsed by this handsome Pyrus, which has not only a more elegant, but more brilliantly coloured inflorescence, with a setting of small green leaves.

"We cannot claim actual novelty for this plant, but it is comparatively new, and so little known, that we doubt not our readers generally will find in it a novel source of floral beauty. The figure was derived from specimens furnished by Mr. Waterer, of Knap Hill, and we have received others equally beautiful from Mr. W. Paul, of Waltham Cross, Mr. Cripps, of Tunbridge Wells, and the garden of the Royal Horticultural Society. This tree should be introduced everywhere, and planted freely."—(*Florist and Pomologist*, 3 s., iv., 241.)

CORNICK VERSUS BLACK.

SEEING in the Journal for November 16th that Mr. Taylor has made very severe remarks upon the case that was tried October 24th between myself and Mr. Black, I ask Mr. Taylor if he will be so kind as to prove that what he has said is true. He says the person I brought with me purchased some of the best of the things—Mr. Taylor is mistaken. My first witness purchased the whole lot; so there is no best or worst about that. In the next item, which was an account by itself, there were 3 lbs. 3 ozs. of Grapes. I told my witness to purchase the 2 lbs. 3 ozs. which were in a punnet by themselves, and then ask the price of the 1 lb., and if he could get the salesman to sell it for less than the rate the 2 lbs. 3 ozs. were sold at, to buy the 1 lb. also. The 2 lbs. 3 ozs. were sold for 20*s.*, and the salesman would not sell the 1 lb. under 10*s.*; so if there was any best or worst in this last, the best was left with the salesman. Mr. Taylor says it appeared I had been paid over and above what my things realised. Surely if such had been the case, with such able counsel as Mr. Black had in Mr. Moore, Q.C., the contest would not have been given up in my favour as soon as my last witness was sworn, and before he was examined.—S. C. C. CORNICK.

LILY OF THE VALLEY CULTURE.

WE have several times tried a few of the imported clumps, and with fair success, though we have had quite as good shows from our own home-grown roots. Both grow best with the pots in a very gentle heat and in a dark place, such as a Mushroom house. When the shoots rise, and the bloom-stalks show themselves, let them be exposed then to light by degrees, without giving them any sudden check. Of course this extra care is chiefly necessary for early returns. These imported clumps have, however, given us a lesson, and we cannot keep it to ourselves. Instead of allowing the plants to run into beds, we shall be deceived if these imported masses do not stand more thinly apart. Some that we turned out thinly in rows, in little bundles, showed very fair buds when we took them up. It is only lately that these chaste flowers became an object of interest, and that a succession had to be kept up for a considerable time. We had no great stock to go to, so when we wanted a number of good pots, we used to take up a part of a bed well matted with roots, tear it to pieces, pick it over, and after selecting the best-swelled prominent hard buds, we packed from six to nine of the roots in a 6-inch pot. What was left we used to plant again in the usual bed-fashion. Now we should be inclined to plant entirely in rows, and in little separate clumps in the rows. We last season took up a few as described, potted them, and when their flowering was over we put the pots in the orchard house, so that the leaves should experience no check. They were then turned out of the pots, the contents of each pot making two or three patches, and well mulched; when taken up they had buds almost as strong as imported roots. Meanwhile, those persons who have no such old beds or patches to fall back on, had better have at once a dozen or a score of patches from Holland. Bulb merchants make a point of importing these patches sufficiently large, with a mass of roots, to fill a 6 or 7-inch or even a larger pot. The patches will cost from 1*s.* to 1*s.* 6*d.* each, and whether obtained by the dozen or the hundred, we would advise the dark treatment with a mild heat at first. If the pots were partly plunged in a temperature of 70°, whilst that at the top close to the buds was merely from 55° to 60°, success would be more certain. We have found placing an empty reversed pot over that containing the roots an advantage. Towards spring all these precautions are of less moment. In the open air the plants thrive well in good sandy loam, and a mulching with rotten dung in summer will improve the size and maturity of the flowering buds. Good flower stems may be expected if the buds are firm and a quarter of an inch or more, in diameter. We lately saw a great number of plants which were expected to be useful for forcing. Hardly a bud shoot was larger than a good-sized stocking needle. Such plants would require two years' growth and great care to make them fit for forcing. Ladies who like to gather such beautiful flowers for themselves, should be merciful on the fine healthy leaves, for if these are taken at all freely the buds for next year will be inferior.—R. F.

GORHAMBURY.—No. 1.

THERE are few places of greater interest to the antiquary than St. Albans and its neighbourhood. Its venerable abbey, if not equal to some of our cathedrals in architectural beauty, has nevertheless peculiar features of its own. Bold, massive, and commanding in appearance, it is still more notable for the various materials of which it is composed. Stones from the walls of the ancient city of Verulam, mixed with Roman bricks from some neighbouring dwellings and Saxon masonry, form the heterogeneous matter used by the Normans in constructing this pile. Verulam seems to have been situated not more than the distance of a couple of stone throws from the abbey; and antiquarians have of late, by patient exploration, pretty clearly laid down the boundaries of this old settlement, though they cannot definitely say by whom it was destroyed. The crumbling remains of flints and mortar appear to indicate the period of its existence as being long anterior to the Roman invasion, while an adjacent church, that of St. Michael, is reported, and on very good grounds, to have been built on the site of another. Although an historical interest is attached to the neighbourhood of St. Albans, the town itself presents little that is remarkable excepting its agreeable position, which is somewhat elevated, the ground falling away gently on all sides, differing in this respect from those of most other towns in this district; Hertford, Ware, and Luton being all in valleys.

Our business, however, is not with St. Albans but with Gorhambury, a manor and park upwards of two miles to the west of that town. Alighting from the North-Western Railway, and taking the nearest footpath to Gorhambury, we pass the spot where stood Verulam, the ruins of which in few places are more than a yard in height. From this place there is also a good view of the noble abbey. We continue our way through the churchyard of St. Michael, and leaving the various legended Prae Wood on our left, we find ourselves confronted by the entrance lodge to Gorhambury, but the park itself is some distance beyond. The road is wide, and bounded by neatly clipped hedges, with arable land on each side; and passing along we at length reach another gate, which admits us to the park. Here a long stretch of carriage road winds through a park of unusual size, studded with numerous trees and flanked on at least two of its sides by an extensive wood. The mansion is at

first scarcely discernible, but as we journey on and pass the trees which shroud it from view, we become gradually more impressed with a sense of its importance, and cannot but admire the good taste which placed it there. The park has many groups of trees and some avenues of great length. The mansion, kitchen garden, and dressed grounds, which occupy an area of from fifty to sixty acres, are situated near the middle, being well sheltered with large trees profusely scattered around, and which give to the whole the appearance so characteristic of a country home.

The mansion of Gorhambury, the principal seat of Viscount Grimston, Earl of Verulam, is one of those Grecian structures which became fashionable about the end of the seventeenth and beginning of the following century. A row of Corinthian columns adorns its southern front, and on the opposite side broad flights of steps lead the visitor to the best suite of rooms in that direction, whilst at the same spot access is obtained to a lower floor. The offices are united at the north-west side, but the other sides are all included in the garden. The mansion, which is built of a local sandstone, carries the stamp of age upon it, and presents a noble appearance.

[Before proceeding with our notes on the various departments of the gardens we will record what we know of the early history of the place.

GORHAMBURY.

Robert de Gorham, Abbot of St. Albans, appropriated to himself part of the manor of Westwick, attached to the abbey, erected a mansion, and called it Gorhambury—that is, Gorham's Residence. His family were natives of Gorham, in Normandy. It was situated lower down the hill in front of the present mansion. Robert de Gorham died in 1166. Gorhambury then became the property of the abbey, and so remained until the abbey's dissolution in the time of Henry VIII. That monarch granted it to Sir Ralph Rowlatt, whose son conveyed it in 1543 to Sir Nicholas Bacon, and in that family it has since remained. A house was built by him. He commenced building in 1563, and finished in 1568. It cost him about £2000, but then, he adds, in a private memorandum, he did not reckon "any timber felled within the Lord Keeper's woods, neither is there valued any freestone from the abbey of St. Albans," for that was ruthlessly despoiled on the occasion.

Queen Elizabeth visited him there often, and when there in 1577, she told him, "Your house is too little for you." "Not so, Madam," was his reply, "but your Majesty has made me too great for my house."

The Queen was first at Gorhambury in 1570-1, but of that and some other visits we have seen no narrative; but it is certain she was well contented with her entertainment, for she was there again in 1573. So novel were such visits to Sir Nicholas, that previously to her first visit he wrote to Lord Burghley for advice how to entertain her; "for," he added, "in very deede no man is more rawe in suche a matter then myselfe." We have not Lord Burghley's reply. In 1577, as already noted, Her Majesty was again at Gorhambury, and we have an account of the cost of this visit to Sir Nicholas. The gross amount was £577 6*s.* 7½*d.*, but we will only particularise that "206 capons cost £16 5*s.* 4*d.*; pullets 21*s.*; chickens, 31 dozen and 8, £6 6*s.* 4*d.*; geese, 10 doz., £6 12*s.*; ducklings, 12 doz., £3 13*s.*; pigeons, 19 doz. and 7, 42*s.* 10*d.*; rabbits, 61 doz. and 9, £7 9*s.* 6*d.*; herbs, flowers, and Artichokes, £6 15*s.* 10*d.*"

The estate passed to the youngest son of Sir Nicholas, Francis, the celebrated "Lord Bacon," who found the difficulty and expense of bringing a sufficient supply of water to Gorhambury was so large, that he said, "If the water could not be brought to the house, he would bring the house to the water." He, therefore, built Verulam House at the end of the avenue facing the ponds at an expense of about £10,000. The estate at length vested in a female of the Bacon family, and she married a Grimston. The third Viscount Grimston commenced building the present mansion in 1776. The centre was from

FLOWER GARDEN AT GORHAMBURY.

the designs of Sir Robert Taylor, but he died before the whole was completed, and the wings were added in an inferior style.—Eds.]

The dressed grounds extend a considerable distance on both sides of the mansion, and are well furnished with trees and shrubs, while to the south there is an open expanse holding a geometrical group of flower beds. Beyond this an unusual feature in ornamental groundwork is met with, being an elevated terrace walk running parallel with the mansion at the distance of about 150 feet. It is raised about 3 feet above the level of the panel whereon are the flower beds, and which is the same as that of the walk at the base of the mansion. The proportions of this terrace are also imposing, being some 20 feet wide and 400 or 500 feet long. A ha-ha or retaining wall, with an ornamental iron fence upon it, forms the park boundary on that side, the interior having a grass slope of the ordinary angle. I suspect there are few who walk upon this fine terrace but remark how well everything looks from it, the beds of scarlet Geraniums showing to every advantage, and a peep into the park where Lady Verulam's Alderney cows are grazing is also obtained. Still, with all these advantages I am not sure that it is an improvement. It carries with it a feeling that it is too artificial, and on looking from the walk nearest to the mansion its appearance is not pleasing. Had the panel of the flower beds been sunk, and the walk close to the mansion made the same height as that of the terrace, it would have been different, but, as it is, it is rather intrusive than ornamental. Shrubs and other plants disguise it, excepting in front of the flower garden; it is only there that fault can be found with it, and I am not sure that many will do even that.—J. Robson.

NOTES AND GLEANINGS.

We understand that the Royal Horticultural Society's Provincial Show is to take place in 1872 at Birmingham, than which we think but few towns, if any, offer a better chance of success. Birmingham, next to London, is the most important railway centre in the country, easily accessible from all parts, and horticulture is well supported by the inhabitants of the town and surrounding district. The site of the exhibition we believe is to be the Lower Aston grounds. A local committee is being organised, of which Mr. A. Forrest, of Cherry Street, is the secretary *pro tem.*; and we doubt not that the Warwickshire men will make their show as great a success as that held at Nottingham this year.

—— Mr. Henry Willis, of Whidown, Broadclyst, Devonshire, dug up in his garden, a few days ago, under one stalk, the extraordinary number of one hundred Lapstone Kidney Potatoes, the produce of a single grain of seed taken from the Potato apple planted in the spring of the year.

—— In another column are noticed the Chrysanthemums in the Temple Gardens. Those of Mr. Forsyth, of the Brunswick Nursery, Stoke Newington, are now in perfection and are well worth inspection, and worthy of Mr. Forsyth's reputation as a grower of specimen blooms and plants. We purpose giving details next week, but those who wish to see the flowers at their best should not longer delay.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As severe weather may soon be expected, every means should be adopted to secure a continuance of autumn delicacies, such as choice Cauliflowers, salads, &c. All the *Broccoli* and Greens should now be looked over, and every dead leaf removed to the compost-yard. This, and a general clearing of decayed matters, together with the trenching and ridging of all vacant ground, will give the kitchen garden an air of cleanliness and system. Late-sown *Cabbages* in the seed-bed should have some old and dry soil from the shed sprinkled among their stems; this will prevent them from becoming crooked in consequence of snow or other causes. Some *Parsley* should have a protection which will exclude snow, and it is then picked with greater security. On dry well-drained ground on a south aspect a sowing of *Peas* may now be made. The double-blossomed Early Frame is the most profitable for this purpose. Prince Albert is ten days earlier, but is apt to suffer much from cold winds and wet, and does better when started in heat and transplanted in February. Where there are not pits adapted for forcing *Sea-kale* and *Rhubarb*, let a quantity of each be covered with pots or wooden boxes, or be hooped over with rods, and have fermenting material placed round them. Leaves are preferable to any other covering, and by placing over them some long stable dung they are prevented from being blown about the garden. It is beneficial to water the soil in which the plants to be forced are growing with water heated to 130°, covering the ground immediately with leaves.

FRUIT GARDEN.

Figs against walls will require some protecting material placed over them, more especially in the midland and northern counties. Some wall trees, as Pears, Plums, Cherries, &c., are often attacked by scale, in which case the trees should be well washed with a mixture of soft soap, tobacco water, and lime; half a pint of spirits of turpentine may be added to every four gallons of the mixture when they are much infested. The lime is added to give consistence to the mixture, and to show that no part of the trees is missed in dressing. Let this be applied during dry weather, if possible, that it may remain on for some time, and before the trees are nailed. Where orchard trees have been for some years left unpruned, the hand-saw will be required to thin out the larger branches. Keep the middle of the trees open to admit air, and to promote the formation of fruit buds on the interior of the branches. It is, however, a bad practice to leave any description of fruit tree to itself, as it would in all cases pay the cultivator to prune such once a-year at least. Do not let Pears become over-ripe before being used; also look over the whole stock as often as time can be spared, removing any fruit that exhibits symptoms of decay, and put them aside for immediate use. Any of the choice varieties of Pears that do not ripen properly in the fruit room should be removed to a warm dry room for a few days. This will be found to greatly improve them. Keep the fruit room as cool and dry as possible; if frost is excluded from it, it can scarcely be too cool where the object is to preserve the fruit plump and sound as long as possible.

FLOWER GARDEN.

Alterations, planting, &c., will be carried out this autumn with much comfort as far as the weather is concerned, and those who have employed additional labour to carry out this work will have little to regret in the spring. All tender or half-hardy shrubs should have some protection planned forthwith, and especially the tender kinds of Roses. Standards of the latter may have a bunch of dry moss, a wisp of hay or straw, or some dried fern bound round the head, and the whole well fastened to a stake. Those in beds are best secured with a coating of moss. Any porous material which will not retain water long, and, of course, prevent the air circulating, will no doubt answer. The ground should be coated over 4 inches thick at least. We are now approaching a season when little can be done with florists' flowers. Auriculas, Carnations, Pinks, and Pansies, are in their winter quarters, and Tulips ought to be safely deposited in their beds. Attention must be paid to the former; the labour, however, is by no means serious. Regular and careful watering, with an unbounded supply of air whenever the weather is tolerably mild, is the chief requisite, not forgetting to keep a sharp eye on snails and other noxious insects. The past season has not been remarkable for Tulips, as far as their exhibition is concerned. Every florist must bear in mind that now is the season to prepare composts, to secure turf and lay it in heaps, to collect leaves, and, in fact, to lay in a store of soils adapted to the different wants of his plants.

GREENHOUSE AND CONSERVATORY, FORCING HOUSES, AND PITS.

These structures will very soon require to be in full activity to supply the constant demand that will be made on them for plants in bloom. Care must, however, be taken before plants are removed to sitting-rooms, to gradually harden them for a day or two, either by placing them in the conservatory or intermediate house. In addition to keeping the conservatory gay with blooming plants, let the arrangement of the house be occasionally changed by grouping the plants somewhat differently, and adding a few striking specimens for effect. Pay attention to plants intended for successive blooming. Azaleas, Rhododendrons, Justicias, Luculias, Eranthemums, Cape Jasmines, Euphorbias, and Epiphyllums for forcing should be in readiness when wanted. Hyacinths and Narcissus should be protected by a frame. When they begin to grow remove the plunging material down to the surface of the pots to prevent their rooting upwards. With the assistance of a garden frame and some stable manure or tan to furnish a gentle heat, the Hyacinth may be flowered at Christmas, and with a good stock of bulbs the display may be kept up till April or May. For early flowering the bulbs should be planted at the beginning of September; those to flower in spring should be planted in October,

November, and December. The best pots are 5-inch (48's), for one bulb, and 6 or 7-inch (32's and 24's), for three bulbs. It may be well to add, that three bulbs grown together in one pot produce a much finer effect than single bulbs. If smaller pots than the above be used, greater care will be necessary in watering. The soil used for potting should be as rich as possible, such as one-half fresh loam cut from a pasture with the turf decayed in it, and well-decomposed cow or horse manure, with a small portion of clear sand well intermixed. If this cannot be obtained the lightest and richest soil at hand must be employed. Fill the pots lightly with the prepared compost and place the bulb on the surface, slightly pressing it into the soil. After giving the newly-planted bulbs a liberal watering, set the pots out of doors in a place where perfect drainage is secured, and cover them with about a foot of old tan, ashes, sawdust, leaf soil, or any other light material. After remaining here for a month or five weeks the bulbs will be sufficiently rooted to render it safe to remove them to a gentle bottom heat of about 55°, introducing the pots in numbers proportionate to the demand, at intervals of about a fortnight. Persons possessing no better accommodation for growing plants than a room window, will with ordinary management be able to grow and flower the Hyacinth as well, if not to have bloom as early, as those who can command a gentle bottom heat. A sitting-room window forms a suitable position for Hyacinths while in bloom, and their beauty will there be longer in fading than in most situations. In no instance should they be removed from a close atmosphere, or suddenly exposed in a sitting-room window until they have been previously hardened in a suitable temperature to withstand cold drying winds. The inexperienced should avoid subjecting the plants to sudden changes at any period of their growth. Where Achimenes and Gloxinias are required to bloom early, a few pots may soon be started by plunging them in a gentle bottom heat.—W. Keane.

DOINGS OF THE LAST WEEK.

Protection is now a matter of importance. A good portion of our bedding plants are in an earth pit under old sashes, and merely protected with litter, and as yet they are all safe, but as soon as we can find room we shall remove them to a place of greater safety for several months. In the kitchen garden we protected Cauliflowers, Lettuces, and Celery, as worth the labour bestowed, and, provided the weather is cold enough to prevent anything like growth, we do not at all care about uncovering every day. In cold weather the darkness will do little harm if there be no incitement to growth. We have often found that plants covered-up looked as well after a night of three weeks or a month in duration as they would have done after one natural night, but in all such cases there must be no growth. Young Cauliflowers under hand-lights, after having been slightly frosted, were covered up night and day for three weeks or more, and when the weather changed, and the uncovering took place after the ground was thawed, the plants were healthy and fresh. During that time there had been several hours of fine sunshine, but the air being frosty and keen, it was deemed better to let the plants remain as they were. The excitement from the sun heat, if the plants were exposed to it, would only make them more tender instead of more robust. This rule may be followed safely in cold weather with all comparatively hardy plants that have no artificial heat given to them until the sun's power has considerably increased.

In addition to placing some long stable litter lightly between the rows of Celery, leaving the centre highest, and the litter coming down over the sides, we have thrown some rough hay and litter over the beds, and sometimes in severe weather the litter has remained for three weeks or a month, with the exception of breaking and turning it. When uncovered on the change of the weather the Celery foliage looked almost as green as it did in October. In all such cases you must first get your plants cool before you cover them.

Where artificial heat is given either by means of a hotbed or hot-water pipes, so as to stimulate growth or elongation, continuous covering would be ruinous. In such cases all the light compatible with the necessary degree of heat must be given to keep the plant healthy. We regret that we cannot make this sufficiently clear to some. One gentleman who saw fit for use a bed of Lettuces and Endive that had been covered in severe weather, thought he might effect a great saving by thus treating a bed of early Cucumbers—judge with what result. We have frequently seen a bed of Cauliflowers and early Broccoli with heads not larger than walnuts, covered-up in severe weather for three weeks and then swelling the heads and doing well. Such heads covered-up in a temperature of from 45° to 50° would have become a mass of rottenness. The advisability of continued covering at this season in cold weather depends on the coolness of the plant protected, a coolness so great that there shall be no incentive to fresh growth or elongation. Let this be thoroughly understood, and in severe weather many an hour of covering and uncovering may be spared. In prolonged severe weather the little sun that appeared would be better kept out. Under hand-lights we have had Cauliflower plants in December and January in severe weather, part uncovered every day to get what little sun was to be had, and the other part shut out from light for fully three weeks, after being cooled or very slightly frosted, and almost uniformly the last referred to turned out the best—first in cutting, and first in luxuriance as the days lengthened. The coolness before covering is the secret.

Of course there are exceptions. We have referred to bedding plants still out of doors under old sashes. As we had not too much litter to spare, and as we did not like to risk freezing them a little if we could avoid it, we removed the covering on the sunny day of the 18th inst., so that the sun should warm the interior, covering up as soon as the sun left them. By shutting in the sun heat less covering would be necessary to keep out frost; but the plan must not be often repeated, or the plants would suffer.

We have alluded above to turning over the litter. This should be done frequently in severe weather, when the litter is scarce. For this object hay and fine straw are the best of all protection, as they are so easily moved; and as often as the surface is broken the frost must begin its work anew, as every turning breaks the line of radiation. In a severe morning we have frequently had the covering of our cold pits and frames shaken over at daybreak, and have thus prevented frost penetrating in the keenest hours of the twenty-four.

With abundance of hot water much of this care may cease to be necessary, but even then a little covering will greatly conduce to health and safety in many cases. For instance, in growing Cucumbers in winter there is no difficulty in obtaining enough of heat from hot water if the piping is sufficient, and just as little difficulty in obtaining by evaporating pans as much atmospheric moisture as will be necessary now—and that should be rather at its minimum at this dark season of the year—nevertheless, in all houses or pits which could be partially covered with a cloth or mats in severe weather at night, and say to 7 or 8 A.M., there will alike be an economy of fuel and better conditions for the health of the plants, if free radiation from the glass be arrested, and consequently a free condensation of moisture on the glass to drop all over the leaves of the plants just when it is least desirable. We know how much of this could be averted by having grooved sashbars; yet notwithstanding their importance, how seldom is it that even the first gardeners are able to introduce them into practice. Too many are glad to secure a covering of glass, though not done at all in the way their experience would suggest as the best.

Broccoli.—We shall take the first opportunity to lay down the general crop, and the more the plants are inclined, without injuring the roots, the better. For this purpose a little earth should be removed from one side of the plant, the stem bent down to the opening, and earth taken from the other side to place over the stem, thus also preparing for the next plant. The advantage of this treatment is, that the centre of the plant where the flower-head is produced, instead of being exposed to free radiation, is protected by the leaves of the plant overlapping it. As when a plant is frosted much depends on gradual thawing, it is best to turn the heads, when inclining them, to the north, and the next best is to turn them to the west instead of the east. When we have grown two rows of Broccoli between rows of Peas, instead of laying down the Broccoli we have dug a trench where the Peas stood and earthed-up the Broccoli like Celery; and, on the whole, in favourable winters these plants produced larger heads than those laid down, but in severe weather they would have scarcely escaped unless the centres had been protected.

Securing Plants from Frost.—There are endless inquiries, to which we must here only allude, as tending to the safety of plants where there is the most limited convenience. For window plants nothing is better than the window, after the room is heated to dispel the frost. When the room is dry from fires, a little sponging and sprinkling at midday will be of great assistance. In severe nights the plants will be safest in the

centre of the room. When the weather is very severe a clean cloth may be laid over them, and remain until the room is cleaned and dusted. In spare rooms, and in small frames and pits out of doors, which cannot be opened to use a small stove, large earthenware bottles will often be of great advantage, put in when filled with hot water. A good-sized argand gas-burner will keep two or three lights tolerably safe, but the light should rise into a large inverted funnel, with a small gas pipe from it to the open air. We have proved but too well that even an argand gas-burner, which consumes the gas the most perfectly of any, will soon make havoc among growing and flowering plants when there is no regular outlet from it. A large composite candle that needs no snuffing, a good paraffin lamp that would need no trimming for the night, would keep out frost with the help of a little covering on the glass, and the burning of either of these without an outlet is much less dangerous than gas burned in the same way.

In all small glass houses where you can enter by a door all these modes may be tried, but the simplest and best in default of a flue would be a small iron or brick stove, with a pipe going through the roof. In low pits little in this way can be done as respects stoves, but we can recollect hundreds of pits with front walls, say from 12 to 18 inches in height, and a back wall from 3½ to 5 feet in height, and say 30 feet in length; and were we asked the simplest and cheapest mode for merely keeping frost out, we would say, Make a brick stove in the centre close to the back wall, say 30 inches square, and from 36 to 42 inches in height, and make an opening in the back wall large enough to fix your furnace and ashpit doors, so as to do all the feeding there. It would be best to have the smoke pipe at the front or sides, and bring it out at the back wall; but if that were too much trouble, the pipe might rise at once from the top of the stove through an iron square in the roof. A 3-inch pipe would be ample, rising 2 or 3 feet above the wall. Nothing would be wanted but sending a 2½-inch pole through it about once a month. With such an upright pipe draught must be regulated from the ashpit door, and when the fire was fairly burning and the bricks were warm, something like a one-eighth-inch opening would sustain a long quiet combustion. For a nice little pit we know of no mode of keeping out frost that would be so cleanly, effectual, and economical. By using coke or the best cinders there would be little smoke.—R. F.

TRADE CATALOGUES RECEIVED.

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Forest Trees, Hardy Ornamental Trees and Shrubs.*

J. Harrison, Grange Nursery, Darlington, and Scorton Nursery, Catterick.—*Descriptive Catalogue of Roses and Hollyhocks.*

TO CORRESPONDENTS.

Books (*W. L.*).—You are quite right. The price of "Flower-Garden Plans" is 5s., and you can have it post free from our office for that sum and 2d. for postage. (*Idem*).—"Henfrey's Introductory Course of Botany," edited by Dr. Masters, is the best book you can have.

Pears for Cordons in North Lincolnshire (*Amateur*).—Citron des Carmes, Beurré d'Amanlis, Louise Bonne of Jersey, Jersey Gratioli, Thompson's, and Marie Louise.

Ferns for Cold Fernery (*M. B.*).—As your house is cold you may cultivate a great many of the better class of hardy Ferns, which are quite as beautiful as many of the tender exotic species. Adiantum Capillus-Veneris, A. pedatum; Asplenium Adiantum-nigrum, A. Trichomanes, and its variety cristatum, A. fontanum, A. marinum; Athyrium Filix-fœmina, vars. corymbiferum, depauperatum, Frizelliæ, multifidum, plumosum, and Victoriæ; Blechnum Spicant imbricatum, B. Spicant ramosum; Cystopteris fragilis dentata, Lastrea cristata, L. dilatata cristata, L. Filix-mas, vars. cristata, Bollandiæ, and polydactyla; L. opaca; Lomaria alpina, L. chilensis; Polypodium alpestre, P. Dryopteris, P. Phegopteris, P. vulgare cambricum, P. vulgare; Polystichum acrostichoides, P angulare plumosum, P. Lonchitis, P. proliferum, P. cristatum gracile; Pteris aquilina cristata; Scolopendrium vulgare, vars. corymbiferum, crispum majus, cristatum, ramo cristatum, fissum, submarginatum, Wardii, and ramosum majus; Struthiopteris germanica, and Woodwardia radicans. The following may be added, and they will succeed in all but the most severe winters, when it would be advantageous to use the lamp you allude to. Cyrtomium falcatum, Litobrochia vespertilionis, Lomaria magellanica, Niphobolus lingua, Onychium japonicum, Pteris serrulata, and its variety cristata, and P. scabernla. The only Lycopods are Selaginella denticulata and Wildenovii.

Conservatory Climbers (*A Devonian*).—You name some of the best climbers, but we give you our selection for the roof. Bignonia jasminoides and vars. alba magna and splendida; Lapageria rosea; Kennedya Marryattæ, rubicunda superba; Mandevilla suaveolens; Passifloras cærulea racemosa, Comte Nesselrode, Countess Ginglini, Impératrice Eugénie; Sollya heterophylla, Tacsonia manicata, T. mollissima, and T. Van-Volxemi. Pergularia odoratissima succeeds in a conservatory, but is slow in establishing itself, and should have the warmest part. We think you are in error as to Tacsonia Buchanani, but we do not see why it should not succeed in a conservatory as well as Bignonia Tweediana. Many so-called stove climbers succeed in a warm conservatory. Passiflora Decaisneana for instance, one of the finest of the Passifloras, is now with us in fine bloom in a night temperature of 50°, it is finely scented. Other fine climbers or twiners are Cobæa scandens variegata, Hibbertia volubilis, Hoya carnosa, Jasminum gracile, J. grandiflorum; Kennedyas bimaculata variegata, inophylla floribunda, coccinea major, and monophylla; Physianthus albicans; Rhynchospermum jasminoides, Sollya linearis, and Tropæolum Triomphe de Gand. For the pillars we would have the smaller-growing of the former-named climbers and shrubs, as follows:—Habrothamnus fascicularis, H. aurantiacus, H. elegans; Luculia gratissima, Mitraria coccinea, Metrosideros floribunda, Abutilons insigne, striatum, Thompsoni, venosum; Acacias oleifolia elegans, armata, juniperina, longifiora magnifica; Berberidopsis corallina, Brachysema acuminata, Chorozema cordatum splendens, Clianthus magnificus, Cytisus racemosus, C. fragrans, Desfontainia spinosa, Gompholobium herbigerum, Eugenia hybrida, Myrtles, Plumbago capensis, Swainsonia galegifolia, and Thibandia macrantha. Lantanas would do, but we should prefer Tea-scented Roses, Heliotropes, and Geraniums, as Clipper, &c.

Storing Dahlia Tubers (*B. B.*).—Take them up if you have not already done so, lay them in a dry shed a few days, then clear them of the soil, and store them in boxes in dry sand, just covering the tubers with sand. Put them in a cool cellar, or any place where they will be safe from frost, bringing them out in March, and placing them in a hotbed or house with gentle heat.

Planting Forest Trees near the Coast (*Inquirer*).—We consider from the middle of February to the end of March the best time to plant forest trees. Do not, however, defer planting until very late in the season, for we find it does not answer. Indeed, we advise as early in February as you can plant, and not after March. There is no book specially devoted to the storing of fruit, but it is treated of in most works on gardening, as the "Cottage Gardeners' Dictionary," &c.

Show Fruit for Dumfriesshire (*An Amateur*).—You had better grow these against a wall—Transparent Gage Plum, Cellini Apple, and Madame Treyve Pear.

Diseased Vine Leaves (*F. P.*).—We have carefully examined the eruption on the back of your Vine leaves, and think it is produced by atmospheric influences, as there is no trace of mildew or insects. The young wood of your Vines is not properly ripened, and it is too late to do any good now by maintaining a higher temperature; all that you can do is to remove the leaves as they become yellow. You should also see that the border in which the roots are is efficiently drained; an undrained cold Vine border is often the cause of a late, watery growth. If the border is in good order, and a higher temperature kept up in your house next year, the Vines will be all right. Should the same sort of eruption appear on the leaf send us one or two.

Pandanus elegantissimus Leaves Spotted (*A Subscriber*).—When the leaves of the Pandanus are old they are apt to be so spotted, but the spotting frequently takes place when the leaves are fresh, and from two opposite causes—too great cold and a moist atmosphere, the cold liquid remaining in drops on the hard leaf, and again when there is a strong heat, a bright sun, and small globules of water acting as a burning glass. We have also seen beautiful leaves scorched from bright sun acting on little spots in the glass. It is just possible this may be the case with your plant. On closely examining the glass, if you find any spots they must be daubed with a little paint.

Chrysanthemums (*W. Scott*).—Refer to page 365.

Bones for Vine Border (*Hamburgh*).—Bones from the butcher's and from the house broken small by a heavy hammer, which is easily done on a stone slab, will answer well as the half-inch bones of the merchant.

Gladiolus Culture (*Souter*).—You will have seen what we published last week.

Vinery Arrangements (*H. P.*).—It is advisable that Vine stems should be from 12 to 18 inches distant from hot-water pipes. The Vines along the roof should not be less than the above; of course they will be a number of feet as the stems ascend towards the apex. The distance of the pipes from the border, provided they clear it, is of less consequence—say 3 inches. We approve of the plan of carrying the pipes on an iron bar, carried from the front wall to pier A, only we would suggest a small pier in the middle of the space to prevent the bar giving at all. We would prefer the four pipes distributed as flows from A to B, with the return pipe at the back, instead of having the pipes more uniformly distributed over the whole width of the floor, as then there would not be the same convenience as respects pathways, &c. We think the ventilation may answer if you have openings at each end under the apex. On the whole, however, we would have preferred doubling the number of the top ventilators if they had only been half the depth of the present ones.

Verbenas Diseased (*A Perplexed One*).—There were signs of thrips and mildew on the plants, otherwise seemingly all right, and for these smoking and sulphur-sprinklings would be the best remedies; but there were besides little dark spots—a kind of leprosy, on the leaves, and for that we can give you no remedy. We are sorry to say we suffered much ourselves last season, the plants beginning to be affected at the points, and the malady finding its way downward until the plants were destroyed. Perhaps some of our readers can advise. Do not let the plants suffer from cold. A heat of 60°, with frequent syringing in addition to the sulphuring, may bring them round.

Heating an Orchard House (*T. H. S., Ilfracombe*).—We think your proposed heating will suit your purposes in such a house. There will always be differences of opinion about boilers. For a moderate-sized boiler, such as will suit you, we have found cast-iron the most lasting. When a large boiler is required, say 4 to 5 feet in length, we prefer rivetted wrought-iron, as we always think that when of that size it is more difficult to get the casting equal and uniform.

Pruning Peach, Nectarine, and Plum Trees (*H. L.*).—It requires considerable judgment to successfully operate on much-neglected trees of these kinds trained against a wall. All the shoots that come straight from the main branches, and the old exhausted branches of the Peaches and Nectarines, must be cut clean out, and vigorous shoots trained in in their place, or a fresh disposition of the main branches made, selecting those that have the most and best-situated side shoots. The main branches should be 1 foot to 15 inches apart, and the side shoots or shoots of the current year trained in at the same distance along them

and cut back to a wood bud or triple bud, which is two bloom buds with a wood bud between. We would now thin out and nail up the branches and shoots, but defer shortening the latter until the first mild weather after the middle of February. If the trees are much neglected and deficient in shoots, the old branches should be cut out and fresh shoots trained in their place. You will require to cut away all the foreright shoots of the Plum trees to the base, and the side shoots to within half an inch of their base. The spurs, which are the short stubby shoots with the buds close together, should be left entire, but if very long they may be cut partially away, and a portion allowed to remain near the main branches for extension; this portion must have one or more spurs with buds, or it will perish. The pruning, also, should be done now.

Applying Soot (*Weston*).—The soot you have used as a dressing of a quarter of an inch thick, will not do any harm, but, on the contrary, is a most excellent manure. We would not, however, apply it at this season of the year, but in trenching now throw up the soil as roughly as possible, and early in March apply the soot, taking care that it is dry, and then fork the ground over. Soot is a good manure, and a very useful preventive against grubs. Its principal fertilising constituent is ammonia, which, if the soot is applied now, must in a great measure be lost before the spring.

Manuring Ground in Winter (*M. G.*).—We advise the manuring of all ground before digging or trenching for the winter. The manure should be turned in deeply as soon as spread, and the ground thrown up roughly now, and forked over in spring during dry frosty weather, if possible. The ground intended for Carrots we would now manure and trench, and in March fork well over and pulverise. At the close of the same month make the ground quite black with soot, and then quite white with quicklime, point them in with a fork, and sow the seed early in April. We have known this ward off the attacks of the fly and its grub.

Cucumber Seed (*H. W.*).—Cox's Volunteer and Masters's Prolific may be had of the principal seedsmen who advertise in our columns.

Iris hispanica Culture (*Wrekin*).—They are very pretty flowering bulbous plants, and should be planted now in an open sunny situation out of doors, planting in good, rich, light soil, and covering about 2 inches deep with light sandy soil. They may be planted half a dozen together about 3 inches apart, putting in a peg to indicate the position. They are quite hardy, and will not require removal for several years.

Pyramidal Fuchsias (*Senex*).—We presume that you are supplied with fine young plants that were struck this summer, being now in 4½ or 6 inch pots, and from 15 to 18 inches high. They require to be kept in a light position, and to have a moderate supply of water—in fact, to be kept gently growing throughout the winter in a temperature of more than 40°. In February they should be repotted into the same size of pot, removing all the soil that comes away freely from amongst the roots, and placed in a light airy structure near the glass, with a temperature of 45° from fire heat. In the course of about three weeks shift into 7-inch pots, and when the roots reach the sides, and before they become much matted, transfer to 9-inch pots, and the final shift may be given to an 11-inch pot at the end of May or early in June. The drainage in all cases should be good, and the compost may consist of turfy loam two parts, one part leaf soil, half a part old cow dung or well-rotted manure, a quarter of a part lump charcoal, and the same proportion of silver sand, the loam chopped up but used rather rough. Pot firmly, and place a neat stake to the leading shoot, which need not be stopped until it show flower, then take out its point. Train in its place the fresh shoot which will result from the stopping; this will not require stopping unless it grow extremely tall, and then it should be stopped so as to produce side shoots for the furnishing of the upper part of the plant. These will also require stopping, so as to cause them to branch, and should be kept from flowering until a good and shapely plant is formed. As you succeed well with pyramid Apple and Pear trees, we do not see why you should not secure fine specimen Fuchsias. Give them abundance of air and light, watering only when dry, but before the leaves flag, and giving weak liquid manure after the pots are full of roots. Continue the stopping until six or seven weeks before you wish the plants to flower.

Plants for a Cool Stove (*Idem*).—We only name a dozen, as you wish for but few. Allamanda neriifolia, Burchellia capensis, Franciscea confertiflora variegata, Gardenia radicans major, Ixora acuminata, Lasiandra macrantha floribunda, Monochætum ensiferum, Pentas carnea, Rondeletia speciosa major, Poinsettia pulcherrima, Mediuilla magnifica, and Imantophyllum miniatum, all of easy culture and cheap.

Bone Dust for Lawn (*M. A.*).—There is no manure so good for lawns as bone dust, and you may apply it at the rate of sixteen bushels per acre in March. Between now and then we would have the weeds grubbed up, and the lawn well raked with an iron rake before sowing the bone dust, rolling well after the first rain subsequent to manuring.

Conservatory with Hothouse (*F. C. Taylor*).—As you seem to have so many doors, we presume your pipes are laid beneath them, or below the floor level, and if so, more piping will be required than if the pipes were all exposed. As to your not getting so much heat in your hothouse department as in the cool house, we notice that you have three pipes on two sides, or rather on one side and one end, whilst for such a house, 14 feet wide, you would require such an amount of piping all round, or at least in proportion. Then you have shut off the greater part of one end as a pit, and thus, so far as the heat of the house is concerned, you have lessened its power to heat the atmosphere fully one-third. We are sorry you have pulled your pit out because it did not heat, as that might arise from such causes as the complete exclusion from air, the too great thickness of a covering of stone, or too much cocoa-nut refuse. That substance, when dry, would be more inaccessible to heat and cold passing through it than a secure thick matting. The cool house with four pipes has, on the whole, as much power of heating. Besides, when two divisions are thus heated from a boiler separately, it often happens that the flow is more rapid into one than the other, and in that case the valve should be regulated so as to give the full flow first where the flow naturally is most sluggish. If there is the least difference in the level of the pipes, the water will go most readily into the highest pipe. The boiler is no doubt a good one. When the fire is banked up, the damper, too, should be judiciously used. We think, then, that the chief deficiency in the hothouse is the need of more piping.

Insect (*W. N.*).—The insect found on a rod in a vinery is the chrysalis of the common small white butterfly, which had, probably, fed in the caterpillar state on Nasturtium or Mignonette growing in the neighbourhood.—I. O. W.

Name of Fruit (*W. H. M.*).—The Stone Pippin.

Names of Plants (*W. H. C.*).—We cannot undertake to name varieties of the Chrysanthemum nor of any other florists' flowers. (*T. R. J.*).—It is the Spindle or Prickwood bush, Euonymus europæus. (*C. W. H. Tillett*).—Doubtless your plant will be Echeveria gibbiflora. It is the typical form of the plant, of which what is usually known in gardens as E. metallica is only a variety merely differing in colour, consequently by botanists called E. gibbiflora var. metallica. They are originally from Mexico. (*H. J.*).—Maxillaria picta, native of Brazil; 2, Schizostylis coccinea, from South Africa. (*C. M. Major*).—1, Pellæa hastata; 2, Adiantum trapeziforme; 3, Cyperus alternifolius. (*A. Y. Z.*).—Selaginella caulescens. Pot your Euonymus in poor soil—any inferior loam to which no manure has ever been added—and allow a good proportion of coarse brown sand. Cut away such green shoots or leaves as you can conveniently spare. (*E. H.*).—One of the monstrous forms of the Lady-Fern (Athyrium Filix-fœmina), and apparently the one figured in Lowe's "Native Ferns" (vol. ii., page 36), as var. cristum-coronatum. We do not identify your succulent from the material supplied, but take it to be a Sempervivum, allied to S. Paivæ and S. spathulifolium.

POULTRY, BEE, AND PIGEON CHRONICLE.

OVERWORKING THE JUDGES.

We have listened to the statements of some of the best and unexaggerating judges of our poultry shows, and have no escape from the conviction that at the most extensive of those shows there must be either more judges employed or more time allowed for judging. When we expressed this opinion to a secretary he replied, "This is a novel fancy; they need to be equal to the occasion." To this reply an unrefutable answer is in the following extract from a letter we have received from one of the ablest of those judges:—

"I need scarcely say that year by year the competition becomes more and more general, almost in every class. I mean, that whilst judging we now find, perhaps, fifteen good pens out of every score, whereas about a dozen years back, three or four pens only out of the same number were worthy of a second inspection. So much for the classes in general, and committees now appoint quite as large a number of pens to each judge in his division, as formerly made the aggregate of a whole customary show. It requires no logician to prove that the responsibilities of the judges must be fully thrice as heavy; and as, to save expenses, committees always at large shows give quite as much in each division as occupies the whole day in judging, the arbitrators at these very large meetings rarely see anything of those classes to which they are not specially appointed. Hence, for instance, at the Crystal Palace Show, except in a few cases during the judging, when requested by my fellow judges to 'just give them my opinion' on difficulties cropping up in their allotted tasks, I saw nothing at all of the birds out of my own classes; yet I worked hard at it incessantly, without having even time to eat anything from daybreak until nightfall. Mr. Teebay and myself were 'completely knocked up;' Mr. Teebay's own words were, 'that when we sat down we could hardly get up again.' Birmingham will be even worse rather than better."

The time has now arrived, therefore, when the labour of the judges must be diminished. If this is not done the trustworthy will shrink from the task, exhibitors will be dissatisfied by hasty decisions, and then the committees will have to smart for diminished receipts.

LIGHT BRAHMAS.

I was pleased to read the letter of "Outis" (see page 367), as real thought about matters of breeding and exhibiting is the right way to succeed in both; and, perhaps, I shall do best by replying in order to my unknown friend's remarks just as they occur, and as though I were in conversation with him.

By "colour" in Light Brahmas I mean both black in the proper feathers, as described both by me and "Outis," and also a pure pearly white colour over the body. Many birds lately have been shown quite yellow, with hardly any real white about them at all. But further, while I regard the black in the neck-hackle as very important, indeed essential to a really good bird, black in the saddle is far less so, and is so described by me. Many of the best birds have white saddles, and these are often, as I have said in the work referred to, to be even preferred, while at the same time I do think that a thinly-striped saddle, when to be had, greatly sets off a bird. But the pullets also are to be considered. Their hackles lately have been nearly as bad as the cocks, and the brilliant black

we used to see is replaced by the "muddy" hackle "Outis" correctly mourns over in the cocks.

So much for definitions. Regarding Cheltenham, I admit that the prizes went to birds superior in size but deficient in markings; but I was there myself, though only a short time, and I must say I saw no chickens there of "almost perfect shape and markings." The only pair decently marked were far too narrow in body. With regard to Mr. Pares again, I can remember one Bristol show at least (1869, I think), where he showed the only really black-necked hens or pullets (I forget which) in the class, though I do admit his birds are usually lighter than I like. With regard to my remarks on the Birmingham awards, very singularly I wrote the contrary. What I said was, as I distinctly remember, that (like "Outis") I "never heard the awards *more* complained of, and on the very ground that the winning birds were so small;" and my object was to show that the exhibitors themselves were so running after mere size, that when an award was made on other grounds they complained of it. Mr. Long had said judges would only look at size; I instanced Birmingham to the contrary, and remarked (as written) that when judges (quite rightly) decided by shape and colour, the other exhibitors complained. My object was to show that judges would give honours even to small birds if good in shape and colour, but that it was the exhibitors who were looking to mere size. What may have become of the first-prize bird at Spalding I do not know, but I do know that he won again at the very best shows after, which is more to the point, and again proves that judges will encourage good colour and form when they meet with it. Many things may hinder a bird winning at any particular show, and there might also be other reasons than mere size for thinking Mr. Pares's fourth-prize cockerel ought to have been higher. After all, these are individual differences of opinion. My simple object was to prove that perfection in form and colour did and would win against size, and that breeders, on the contrary, rather went for size. Yet I would not "disqualify" white-hackled birds. After all, a bird must be judged as a whole; that is the great secret of judging, and will explain many awards which puzzle those who can only look at one point at a time. In saying, however, that birds correct in colour and shape "would win," I meant, of course, against mere size, I did not mean against Darks. While the more perfect birds in Lights are small, if at the same time the Darks are both correct in points, and have the advantage of being large as well, the Darks not only will but ought to win. That seems to me just the position of the case at present. Leg feather is also to be considered. But I am quite sure that if such birds as the two first Birmingham cockerels be shown of 11 lbs. weight—*i.e.*, combining the "points" of those two Light birds with the size of the Darks, they will win their share of cups at any show where Messrs. Hewitt or Teebay are the judges. It cannot be said such is now the case, and I have only given a weight which is constantly attained at Birmingham by Dark cockerels. I speak without having asked the opinions of the gentlemen I have named, but I have done what is, perhaps, better—made an analysis of their judgments at several of the best shows for three years, in order to form a correct scale of Brahma "points," and I am convinced their judgments will bear me out whenever they get the birds to give them a chance.

There's the rub. Small size in a large breed, of course, is heavy odds against a bird, and is alone enough to justify Darks winning, which are both large and good. But regarding the weights I stated, the very hen from which the portrait is taken in the work "Outis" refers to, weighed close on 12 lbs.; and not so very long back, when the same controversy of Lights and Darks was carried on in this Journal, Mr. Crook himself stated that if there were any difference the Lights could be bred the largest! I am certain they can be bred at least as large, and I repeat my caution, that in my own belief they are sent to early shows more than the best Dark birds are, and that this has something to do with it. Whatever the American birds were, they were larger than nearly all the rest of the class at Birmingham, but Mr. Simpson himself told me they were only third-rate, as was proved by their price of, I think, six guineas. I have myself seen an English Light Brahma cock of 13½ lbs, and good birds can be bred large as well as bad. If I ever get a chance to try I will guarantee to breed 11 lbs. cockerels by the third year. Long-backed hens, as I said in my last, are the stuff to work upon to obtain size with very short deep-bodied cocks. When size is obtained then we adhere to proper shape, of course; but it is useless when a breed is "down," as I think this is, to attempt to get every point at once. That is a great mistake of many, even experienced breeders. It takes years to make a strain what it ought to be, though two seasons will make giant strides towards perfection in good hands.—L. Wright.

If it is absolutely necessary that Light Brahmas should attain the enormous size of the Dark variety to win, I, of course, agree with Mr. L. Wright; but my argument is to the effect that as they are and always have been, in this country at least, much inferior in frame, they cannot be made to attain the size of their more fortunate rivals. Light Brahma breeders have done their very best year by year, but once more we fail to see great size; whereas, if possible, the dark birds are larger than ever. Symmetry, pencilling, and feather we can obtain, although Mr. Wright appears to doubt the ability of our breeders to secure the latter.

It appears to me a simple fact, that one variety is naturally larger than the other, and in common I believe with every fancier of the variety, I think that where both compete, size, if it is size, should not absolutely turn the scale, as it invariably does, and must under such circumstances. With reference to shape, particularly that of the "duck-shaped hens," I believe that "doctors disagree." Possibly it was the same eminent judge mentioned by Mr. Wright, who spoke to me of "the duck-like bodies" of a pair of hens, whereas their owner, everywhere acknowledged to be a great judge of the variety himself, told me that they were the finest he ever possessed, and coming from the most successful yard in the country this should be worth something. Mr. Wright instances the two Birmingham cockerels as examples of "small" winners; the fact is, that they were fair in size and first-rate in shape, whereas there was not a really large bird in the class, and certai y none combining symmetry with even moderately large siz Again at Plymouth, as Mr. Wright has instanced it, he may be well pardoned for the award. "Little Sampson" undoubtedly took the fancy of his judge, and shape carried the day against rivals, be it remembered, 8 lbs. heavier. From that award I became prejudiced in favour of shape *versus* size; possibly, Mr. Wright will, therefore, extend me forgiveness for this change of opinion.

I have little faith in Mr. Wright's remarks, that if bred "correct in shape, good colour, and well-feathered," they will win, even if not large, and if the Light birds really were larger a few years ago, they were as easily beaten as now. I have a few early numbers of the Journal of 1868, in which I find forty competitions, and in which *thirty-nine* were won by Dark birds. This speaks well for the past.

Mr. Wright's special remarks upon the Southampton prizes to my mind are a great argument in my favour; he states that these special cups do real harm, and bring small results, and that the birds do not surpass, or rarely equal the Darks. I have every reason to believe that all Light Brahma breeders look forward to Southampton as a sort of "passage of arms," and devote all their energies to the production of a good pen or two for the trial. It is one of the stimulants of the year, and although it has been admitted for the past few years that the Light Brahmas have been the best classes in the show, the winning birds have, nevertheless, succumbed to Dark specimens when in open competition at larger exhibitions.

We shall all thank Mr. Wright for his parting advice. Breeding from cocks whose hocks have been cut off resuscitates the idea of producing black-crested Polande, for it is as feasible to breed them from a White Poland with a black nightcap tied over his crest as to suppose that the scissors can affect the hock of the Brahma chicken. I have tried the experiment, and the result was so encouraging that I would not advise its repetition.—James Long.

AMALGAMATION OF COLUMBARIAN SOCIETIES.

I believe it would be advancing the interest shown in keeping Pigeons, if there were an amalgamation of all columbarian societies for the purpose of holding a grand annual exhibition of young birds. The secretary of each society should see that none but young birds are shown by the members. Place of exhibition should be balloted for in rotation.—A Columbarian.

Bristol Prize List.—We are requested by the Secretary to state that the Malay hen class has through an oversight been printed "For the best pair of pullets or hens," which should have been, and is intended to stand as "For the best single

pullet or hen." Exhibitors are therefore requested to send one bird only to each pen of that class, the same as for the Game hen classes.

BIRMINGHAM CATTLE AND POULTRY SHOW.

The entries in all departments for this, the twenty-third annual Exhibition, are highly satisfactory, showing an increase throughout, and necessitating the erection of an additional gallery, upwards of 200 feet in length, to accommodate the various exhibits. What will many of our country friends think of the poultry department with its 2660 entries, some individual classes containing more pens than are to be found in the whole of many county and local shows?

Amongst other improvements in the arrangements and regulations we note the election of life members, who alone are entitled to free admission on Saturday, the day of judging, when the charge to the general public is 10*s*. Between 9000 and 10,000 tickets of admission have been sold.

The prize poultry will be, as usual, sold by auction on the Monday of the Show; and Wednesday and Thursday evenings, after five o'clock, are devoted to the working classes, the charge of admission being reduced to sixpence each.

BRISTOL POULTRY SHOW.

Your correspondent, "E. S. T.," page 347, is evidently one of those who look upon poultry shows merely as places to which they can send their birds with the hope of making a profit. Although I admit that it is pleasant to win prizes enough to pay the expenses connected with showing, and better still if there is a profit, yet this should not be the only consideration. The Bristol Poultry Society was established by a few amateurs from a pure love of poultry, with the hopes of increasing the number of those who keep and rear pure birds, and also to improve the general breed of poultry in the west and south of England. Five shows have now been held, and at most of these the committee have incurred considerable losses. As the committee have not the slightest intention of making a profit out of the exhibition, it seems hard that they should be expected to bear any losses, and they think that they should be supported by those most interested—namely, the exhibitors.

Acting upon the advice of several friends who take an active interest in the Show, we have this year determined that everyone who wishes to compete for the prizes should subscribe £1 to the funds of the Society, that the entrance fee should be reduced to 6*s*., and we feel sure that we shall be supported by all true amateurs. Our place of exhibition is the best in England, our prize list will compare to advantage with the best of other prize lists, and we endeavour, to the best of our ability, to provide for the well-being and safety of the valuable specimens committed to our care. I would add, that should there be any surplus after providing for all expenses, it will be applied to increase the prize list next year.—E. Cambridge.

A few nights since I had a leisure hour, and I thought I would avail myself of the opportunity of looking over the schedule of the Bristol Poultry Show. First, I looked over the prizes offered for the different varieties, and pronounced them to be as usual very liberal. I then ticked three or four classes in which I thought it likely I should be able to exhibit. After settling this part of the business I turned to the rules, but the first dozen words were too much for me; 20*s*. subscription, 6*s*. entrance fee for each pen of poultry exhibited—I was obliged to put on my considering-cap. I thought, What does this 20*s*. subscription mean? I could only make of it at last, that the Committee wish to shut out all the small exhibitors by imposing the 20*s*. subscription. I am only expressing my own feelings on the subject; what the feelings of my fellow (small) exhibitors are I know not. Had the Committee adopted the Birmingham system and charged 3*s*. per pen, I should not have been so much surprised. However, it is not my vocation to dictate to the Committee, so I will be content to be this year —A Non-Exhibitor.

I, like many others, as appears by letters already published, am very much surprised at the alteration in the Bristol entry fees: by which, instead of a uniform charge of 7*s*. 6*d*. per pen (a sum quite large enough for the premiums offered), the terms now are £1 subscription, and 6*s*. entrance fee, thus practically excluding all small exhibitors who can only raise one or two pens, without materially affecting those who can enter a large number.

Of course it rests with the managers of each show to fix any entrance fee they like, only they must bear in mind that if too large it prevents competition; but whatever they fix let it be a charge per pen, thus making all alike, and not the antiquated mode of beginning by a subscription. Of course I am aware that a large number of tickets are given for the subscription, but these are of no value to the majority of exhibitors.—Charles Sidgwick.

WRONG FOWLS RETURNED.

"Would you be surprised" to hear that some person or persons within a radius of seventy miles of London are good judges of Dorking pullets? I am not. I will explain. I sent two Silver-Grey Dorking pullets (my very best) and a cockerel, the former in an open cage, the latter in a covered hamper, to the Exhibition of poultry at the Crystal Palace on November 13th. With pardonable vanity I looked anxiously for my name among the lists of those highly commended, but as it was not there I concluded that there must have been better birds than mine there. So I was resigned, and looked forward with pleasure to welcome my poor pullets back from their tedious journey and confinement; but fancy my horror on being told, "If you please, ma'am, they've sent back other birds to yours," and on inspection this proved to be the case. The cockerel in a covered hamper was all right, but my beautiful pullets, my own rearing this spring, and as perfectly marked as, I imagined, birds could be, had been replaced by two large hens, certainly a year old, one double-combed, and as red as possible all over the wings, and white in large patches; the other single-combed, and very defective as to colour, besides having had her wings clipped in places where white must have existed. When or where this transfer was made is impossible for me to discover, but it is, to say the least, not encouraging to an amateur breeder to lose good birds fit for exhibition, and to get in exchange hens only fit for the table. I may mention I put a fancy price of £20 on them, meaning to keep them for breeding, knowing it would be very difficult to replace them. I shall feel obliged if you could kindly find room for this in your Journal, as I think perhaps some of your correspondents might suggest some safe way of sending birds to shows. I don't suppose I am the only person who has been victimised, but it is a great loss to me, as my stock is very small, and I have no birds to equal those stolen.—G. S. Pasley, *Moorhill, Fareham, Hants.*

[You are not solitary in your misfortune. We hear of a similar exchange at the Southampton Show. Where is the exchange effected?—Eds.]

CRYSTAL PALACE POULTRY SHOW.

This Show came to a very successful termination on Friday last The health of the birds during the time was uncommonly good; there was only one death amongst the whole number in the Palace; this was a Brown Red Game cock, which arrived ill, and the Committee did all they could for the bird, but it proved of no avail. A Dark Brahma hen arrived dead in the basket. These two were the only deaths we heard of.

The judging was on the whole very satisfactory, and there were but few complaints. The excellent light in which every bird was seen by the Judges no doubt enabled them to give a correct judgment of the birds' merits, although some of the Judges were much pressed for time.

The sales were unusually large, especially in the Selling class. In this nearly every bird of any merit changed owners. All the prize birds were put up to auction, numbers of them realising more than double their original prices; in one case a Brahma cockerel sold for more than five times the catalogue price, so keen was the competition. Many birds sold for very high prices; Mrs. Arkwright's Dark Brahma pullets were claimed for 30 guineas, Mr. Burgess's Brown Red cockerel for £20, Mr. Clark's Coloured Dorking pullet for £10, Mr. F. L. Turner's Dark Brahma cockerel for £10 10*s*., Miss Hales' Light Brahma pullets for £12, and Mr. Beldon's Golden-pencilled Hamburgh for £10 10*s*. The total amount of sales for poultry was £590 11*s*.; and for Pigeons, £104 2*s*., making £694 13*s*. in all, one of the largest sales ever made at any show.

We omitted to mention that Miss Frew won the cup for the best pair of Wheaten hens, Mr. Fulton the cup for Blue Carrier hens, Black Carrier cock, and the best collection of four pairs of Pigeons, exclusive of Carriers and Pouters; Mr. Graham the cup for Red or Yellow Dragoons, and Mr. Dunn for White Dragoons. The Any variety cup went to Mr. Waddington.

The Show was closed at 4 P.M. on Friday, and the packing of the birds was commenced immediately, and despatched as quickly as possible

until 11 P.M., when the railways refused to take any more birds that night. The rest were sent off early on Saturday morning, so that all had left the Palace before 9 A.M. except six pens of poultry.

JOHNSTONE POULTRY SHOW.

THE fourth Annual Show of poultry and Pigeons took place in the New Public Hall, Johnstone, on the 11th inst. There were upwards of 650 birds exhibited, many of them very superior specimens. The attendance of visitors was very large, more especially in the afternoon, when there was scarcely room to move about. In addition to the money prizes, there were a number of extra prizes, consisting of timepieces, &c. The Committee were indefatigable in their exertions to discharge their duties, and the Show was greatly indebted for its success to the Secretaries, Messrs. Wylie and Nelson.

SPANISH.—1, Miss Rae, Garngad Hill, Glasgow. 2, W. Barr, Avon Braes, Hamilton. 3, A. Glendinning, Strathblane. *hc*, A. Robertson, Kilmarnock; A. Glendinning. *c*, A. Robertson.

ANY OTHER VARIETY.—1 and Timepiece, G. White (Trumpeters). 2, J. Dunlop (Turbits). 3, H. Yardley. *hc*, J. Dunlop (Owls); J. Sharp.

SELLING CLASS (Not to exceed 30s. per pen).—1, J. Sharp. 2, E. Robinson (Pouters). 3 and *hc*, G. White. *c*, J. Galt, Kilbirnie. (Pen not to exceed 15s.).—1, J. Aitken, Johnstone (Fantails). 2, Mrs. R. Frew. 3, E. Robertson, Craigelven (Pouters). *hc*, W. Wilson, Johnston. *c*, J. Sharp.

JUDGES.—*Poultry:* Mr. John M'Innes, Paisley, and Mr. Alexander Paterson, Airdrie. *Pigeons:* Mr. James Huie, Glasgow, and Mr. Matthew Stewart, Glasgow.

PRESENTATION.—The friends of Mr. Harrison Weir will be pleased to hear that the Directors of the Crystal Palace Company have presented him with a handsome silver tankard, in recognition of his suggestion of a Cat Show, and also for his services. We are induced to mention this, as he is so well known to our readers as having endeavoured to uphold poultry and Pigeon shows by his pen, pencil, and as a judge and exhibitor from their commencement at Birmingham, and the poultry shows held at the Zoological Society's Garden, Regent's Park, up to the present time; and we might add that it is partly owing to his graphic delineations at the commencement of the movement that its success is due.

SCOTTISH METROPOLITAN POULTRY SHOW.—This is to be held in Christmas week. There are three liberal prizes in each class besides twenty-two silver cups. The only blots are that no prize is offered for White Dorkings, and all the Polands are in one class! No judge can award the prize satisfactorily in such a jumble of Golden, Silver, and Black varieties.

HATFIELD (DONCASTER) ORNITHOLOGICAL SOCIETY'S SHOW.

THE members of this Society held their third Exhibition on the 16th and 17th inst., in the district of Hatfield Chase, and it proved quite a success. The Show was a combination of birds, fowls, eggs, and butter, and horticultural produce. The quiet and retired town of Hatfield is situated near the Manchester, Sheffield, and Lincolnshire line of railway, six or seven miles from Doncaster, and the trains of the company conveyed a considerable number of visitors to the place.

The show of Canaries and other cage birds was held in the schoolroom, and a marquee was fitted up in proximity to it for the poultry. The entries were exceedingly good, both in number and quality. Great praise is due to the Committee for their exertions, and also to Mr. W. Travis, the painstaking Honorary Secretary, for the excellent manner in which all the arrrangements were conducted. The following are the awards:—

GAME.—*Any Variety.*—*Cock.*—1 and Extra 2, J. Hepworth. 2, R. Bentley. *hc*, Yatea & Lambert. *c*, G. Hinchcliffe. *Any Pure Breed except Game.*—1, W. Williamson. 2, J. Mowbray. *c*, A. Fosbrooke. *Farmyard Cross.*—1 and 2, H. Hepworth. *hc*, J. Baddiley.

BANTAMS.—1, J. Hepworth. 2, J. Mowbray. *hc*, Master W. Constable. *Cock.*—1, J. Mowbray. Extra 1, R. Bentley. 2 and *hc*, J. Hepworth. *Hens.*—1, A. Fosbrooke. 2, J. Hepworth. *hc*, R. Bentley.

DUCKS.—1, R. Parkin. 2, R. Bentley. *hc*, H. Bepworth. *c*, T. Cooper.

CANARIES.

BELGIAN.—*Clear or Ticked Yellow.*—1, R. Rawnsley, Bradford. 2, L. Belk, Dewsbury. *hc*, J. N. Harrison, Belper. *Clear or Ticked Buff.*—1, J. N. Harrison. 2, T. Fawcitt, Baildon, Leeds.

NORWICH.—*Clear Yellow.*—1, J. Mortimer. 2, G. & J. Mackley, Norwich. *hc*, Moore & Wynne, Northampton (2); G. & J. Mackley. *c*, J. Dawes, Scarborough. *Clear Buff.*—1 and 2, G. & J. Mackley. *hc*, Barwell & Golby, Northampton; Moore & Wynne. *c*, Moore & Wynne.

NORWICH.—*Evenly-marked Yellow.*—1, Barwell & Golby. 2, Moore & Wynne. *hc*, C. Greenwood. *Evenly-marked Buff.*—1, G. Medd, Scarborough. 2, Moore and Wynne. *hc*, G. & J. Mackley. *c*, Barwell & Golby.

NORWICH.—*Ticked or Unevenly-marked Yellow or Buff.*—1, J. Mortimer. 2, G. Gayton, Northampton. *hc*, G. & J. Mackley; G. Medd. *c*, Moore and Wynne; J. Mortimer.

YORKSHIRE.—*Clear Yellow.*—2, P. Rawnsley. *Marked.*—1, P. Rawnsley. 2, J. S. Clarke, Hatfield. Extra 2, Stephens & Leek, Middlesbrough. *hc*, R. Hawman, Middlesbrough.

CINNAMON.—*Clear Jonque.*—1, Barwell & Golby. 2, R. E. Tuffitt, York. *hc*, Moore & Wynne. *c*, E. Stansfield, Bradford. *Clear Buff.*—1, Barwell and Golby. 2, Moore & Wynne. *c*, E. Stansfield.

LIZARD.—*Golden-spangled.*—1, J. Taylor, Middlesbrough. 2, J. N. Harrison. *Silver-spangled.*—1, J. N. Harrison. 2, M. Holroyd.

CRESTED OR TURNCROWN.—1, Stephens & Leek. 2, J. Mortimer. *vhc*, G. and J. Mackley (2). *hc*, L. Belk; P. Rawnsley; M. King, Scarborough. *c*, Barwell and Golby.

ANY OTHER VARIETY.—1, L. Belk (Marked Cinnamon). 2, P. Rawnsley. *c*, Moore & Wynne.

GOLDFINCH MULE.—*Light.*—1, L. Belk. 2, P. Rawnsley. *hc*, Stephens and Leek. *c*, W. Chesney, Readneaa. *Dark*—1, E. Stansfield. 2, Stephens & Leek. *vhc*, Moore & Wynne. *hc*, J. Taylor; T. Fosbrooke.

GOLDFINCH.—1 and 2, J. N. Harrison. *hc*, J. J. S. Clarke. *c*, Stephens and Leek; T. Fawcitt; J. Taylor.

LINNET.—1, J. N. Harrison. 2, A. Fosbrooke, Hatfield. *vhc*, Miaa Machin, Hatfield; E. Holgate, Hatfield; J. N. Harrison. *hc*, C. & T. Purdy.

BRITISH BIRD (Any variety).—1, Miss B. Morris, Bearswood Green (Thrush). 2, R. E. Tuffitt (Bullfinch). *hc*, T. Fosbrooke (Bramble Finch); H. Weat, Darlington (Bullfinch). *c*, — Peakit, Hatfield (Chaffinch).

FOREIGN BIRD (Any variety).—1, 2, and *hc*, J. M. Kirk, Doncaster (Cardinal and Weaver Bird).

LOCAL CLASSES.

CANARY.—*Buff or Yellow.*—1, R. Harrop, Hatfield. 2, B. Hanson, Thorne. *hc*, A. Fosbrooke; J. J. S. Clarke. *Marked or Mule.*—1, A. Fosbrooke. 2, E. Catta, Thorne. *hc*, J. J. S. Clarke; J. Richardson, Hatfield. *c*, Master E. Shaw, Parka, Hatfield; G. Stones.

GOLDFINCH.—1, G. Battie, Hatfield. 2, J. Richardson.

LINNET.—1 and 2, E. Catta. *hc*, Master T. H. Woodall, Woodhouse. *c*, Yatee and Lambert; Miss A. Peakit, Hatfield.

JUDGES.—*Poultry:* Mr. F. Salee, Crowle. *Cage Birds:* Mr. G. J. Barnesby, Derby.

PIGEONS AT THE CRYSTAL PALACE SHOW.

(*From a Correspondent.*)

THE Show of Pigeons at the Crystal Palace was beyond all comparison the most superb ever brought together; in numbers the largest, in varieties the most representative, in quality attaining nearest to perfect standards, and with a remarkable immunity from commonplace specimens. The list of exhibitors would be warrant sufficient for such a summary where nearly every exhibitor of mark appeared, only to re-appear in the schedule of awards in company with several less known but rising competitors.

The judgment, however, is always matter of comment, and without overlooking the difficulties of a delicate and onerous office, we would venture a few criticisms by way of exception to some of the awards, meantime most heartily crediting the Judges—Messrs. Percivall, Ridpeth, and Corker—with the utmost painstaking and a general result alike creditable to themselves and satisfactory to the exhibitors. The presence of the public during the judgment is unquestionably a distraction; so great a show, therefore, the more demands that the labours of the Judges should be advanced in early morning before visitors become numerous, and while the daylight is at its best. Insufficiency of light can be the only excuse for the awards in the Yellow Dragoon class, the prize birds in every case being surpassed by unnoticed specimens of far richer colour. Superiority of colour must always determine the

awards in this class whenever—as in this case—there is anything like uniformity in structure and carriage between rival pens. Mr. Betty, the cup-winner of last year, may therefore still congratulate himself on the possession of the best birds, notwithstanding that they do not figure in the prize list.

The Barh judgment was another vexed question, bnt we incline decidedly to the opinions which would have placed Captain Heaton in the higher position, merited not only by intrinsic excellence, bnt also by the superior condition of his birds. Sufficient stress is too seldom laid upon sound condition as an essential of competition, and it is pitiable to notice in the old classes how rapidly the typical cnp-winner lapses into his usual cronching, degraded, and spiritless attitude, notwithstauding all the eye-dressiug, plumage-washing, and "making-up" to which he has been subjected for the occasion. Just as round after round the battered heroes of the "P.R." are brought up "smiling" through the delicate attentions of their seconders, so do these jaded birds appear at show after show with enongh of apparent vitality forced npon them to stand a transient ordeal with the Judges for the time beiug. A few (fortunately but a few) snch specimens appeared at the Palace.

That any inconsistencies should have occurred in the judgment of the Ponter department is the more to be regretted, seeing how recent efforts have strengthened this division, and made it a principal feature of the Show. In some cases refinement of type and character very properly ruled the decisions, while in others mere bulk turned the scale; and as a whole, perhaps, the birds of heavy build seemed the most favonred. If bnlkiness be elevated to a standard property, then Ponter-breeding will be degraded to the simple process of producing boorish ungainly birds. The Ponter proper, however, is a happy combination of artistic traits in the departments of structure, carriage, and plumage, in all of which elegance and refinement shonld reign snpreme. Had the Jndges followed out consistently in all the classes their appreciation of the symmetrical and the refined, a different but more eatisfactory distribution of some of the awards would have resulted. Mr. Volckman, the Superintendent of this division, withdrew entirely from competition in the young classes, presenting the cup for young cocks. He, however, showed a bird or two of this season's rearing in the old classes, and gained for them considerable credit from Ponter exhibitors. Had classes for yonng Whites been provided, both Mrs. Ladd and Mr. Heath would have stood well with their excellent birds, some of which made their mark notwithstauding competition with much older specimens. The Scotch division complained of the too early date of the Show and consequent disadvantage of the later moult in the north. None the less their birds were represented by owners of well-known names, and met with deserved admiration in many cases.

Despite our strictnres, probably no show as an entirety was ever so evenly jndged or presented so many features of interest; and we may fairly conclude, from the deserved snccess of this the third year, that the Great London Poultry and Pigeon Exhibition may be numbered amongst established institutions.

Fife and Kinross Exhibition.—There are three prizes in each of the classes—not large, bnt the entries are corresponding—three shillings per pen for poultry, half-a-crown for Pigeons, and one shilling for Canaries. In addition to the prizes there are eight two-guinea cups. We regret seeing the mistake continued of having only one class for Dorkings.

"B. & W.'s" APIARY IN 1871.

As the bee season is now fairly over for the year, it is a good time to take a review of its lessons. None of your readers have yet given us their experience, although some of them must have a good deal to tell. By way of provocative, therefore, I will make a few notes of my own.

The year began with very good promise, although some of my hives were only half filled with comb, and therefore not very rich in honey. Only one hive died in the previous winter, and that was found to have plenty of food both in open cells and sealed comb. It was a made-up hive, its occupants being the combined stock of two strong cottage hives that had been condemned to the brimstone pit. As is usual with bees saved late in the year when put into an empty hive and fed up artificially, these bees made but comparatively little comb—just enough for present purposes, preferring to extend the cells rather than waste food in the construction of unnecessary comb. In this respect there is a marked contrast between the summer and autumn habits of bees. In the early part of the year they will fill everything with comb, utterly reckless of the consumption of honey. This is no doubt accounted for in this way, that the exigencies of breeding and the instinct of increase are stronger at that time than the instinct of self-preservation. Be this as it may, they did very well till the long and intense cold and snow of January came; then I suppose they were frozen to death, not having sufficient protection among the combs. But there were also symptoms of dysentery. Could it be the food they ate? for they were not snowed up at any time. This was coarse brown sugar boiled to a syrup. And yet I have never fed my bees on anything else, and they have always done well, as did the others fed equally upon the same food. It must be said, however, that these had no other food but this sugar, while my other hives had some honey stored up, however small the quantity. All the other hives did well save one, which I think had no queen. After parting with some, I reserved eight for my summer stock. Of these, it is true, several were exceedingly poor in bees and honey when March came; but by dint of careful spring feeding they speedily recovered, all but the one spoken of; and some of the poorest, which I thought could hardly survive, have done as well as any of the others.

March was a very promising month, so warm and tranquil in comparison to other seasons at this time of year. April was much the same. I imagine that a fair quantity of honey was gathered by the bees, although I certainly did not observe any addition to their stores, as has been the case in some years within my experience. Still a good deal of comb was constructed in some hives. May was an active and pleasant month, but no great quantity of honey was stored, owing to the singular absence of blossom in all our orchards this year. This usually supplies us with our first grand honey season, often in large-enough quantity to carry our hives well over the following winter, besides giving a considerable surplus.

At the beginning of May my apiary stood as follows:—

BEE HOUSE.

OUR LETTER BOX.

Southampton Show (*An Exhibitor*).—Can you prove that the fowl were not changed while in the care of the railway people?

Andalusians not Spanish (*St. Edmunds*).—Andalusians are very like Spanish, only they differ in colour. They are an offshoot from them. They have much the same properties. Feather-eating is peculiar to no breed, but some seem to practise it more than others. There is no doubt it arises from lack of something the fowls require in the way of medicine or change—but it is peculiar to them, and it is also very capricious. We have kept Spanish for years. They are in confinement. Three years ago they were all naked, and we could find nothing to stop the feather-eating, although we tried everything we knew. Although still in the same place, we have never had it since. The French breeds sometimes take to it, bnt in our experience, they and the Spanish are the only culprits in this way. It is difficult to explain, like human beings who eat tripe, onions, and such like, while others do not think them edible. Your space is a large one, and hardly amounts to confinement. Has it grass? You ask our advice as to breed. We connsel either Cochins or Brahmas; we know no other that do so well or so profitably as they do in a small space, and they are content with it. We hate the idea of a fowl with its wing cut close, and if Spanish are allowed a liberty they will make use of it to the detriment of comfort, the complaining of neighbonrs, and the fiery anger of those who tend the garden. The house you speak of will make a very good fowl house, the main reqnirements are to be wind and waterproof, and to have an earthen floor. A window is desirable, but not essential. At small expense yon could have a pane of glass "let into" the door. Send for your jobbing man, and he will soon prove to you it would cost a "very little more" to have a regular window in the brickwork.

Poultry Yards (*J. E.*).—We like the arrangements of your yard; and the runs, 100 feet by 80 feet, will well accommodate the numbers you propose, especially as the runs are grass. We snppose when the hens bring out their chickens you intend them to be put nnder rips in the yards marked n. They will answer the purpose well while they are small. Your fowls' houses are large enough, but they must be sufficiently high for a tall man to walk easily. They should not be less than 7 feet high in the centre, and that will enable yon to ventilate far above the birds as they sit at roost. Do not let your perches be more than 2 feet from the ground, and place them so that there will be no draught from the door. We prefer 2 feet of brickwork between the runs; it needs only to be 4-inch work. It is more durable, and we think answers the purpose better than boards. Four feet on the top of 2 feet of brickwork will make 6 feet high. This we believe will keep the half-bred Dorkings and Brahmas in, bnt it will not either White Dorkings or Spanish. Either you must carry it up considerably higher, or you must have wire hurdles fastened to the top of the others and leaning over inwards all round. We are

sorry we cannot give you an idea of the cost. It should not be much For partitions of roosting houses we always have brickwork 3 feet or 42 inches high, and the rest wire netting stretched on a frame to fit the roof. We prefer the common-shaped roof to the plain pent you propose, and we cover with slates and Bridgewater tiles. We have found the latter cheap and durable. The houses A will do only for sitting hens; they are useless for chickens after the hen has left, and they will not do for cockerels. Chickens deserted by their mother are old enough and strong enough, unless she be a very bad mother, to forage for themselves. Both they and the young cockerels require all the food they can have, as they have to make growth, and the natural meal they often get by prowling about is essential to them. As a rule, by the time you have cockerels old enough to want a place to themselves you have few sitting hens or small chickens. Let the young cocks have one space B, the sitting hens another, or two, and the orphan chickens the remainder. Your plan shows you are capable of being your own architect; if, then, you have bricks, lime, and timber at hand, you may build them very cheaply.

Cockerel for Stock (*E. H. R.*).—The cock hatched in March or April of one year is fit to breed from any time in the following year. He is an adult bird. When the opportunity exists for choosing, such a bird should be put to run with hens, and an older bird with pullets. It is always considered advisable to reverse the ages of the parents in such manner, taking care on neither side to use worn-out birds. As to your second question, a pullet is called by that name during the year she was hatched. As soon as she has seen her first New Year's-day she is a hen according to time computation; but in reality the January pullet that has laid her eggs in June and July, hatched them in August, and reared her chickens, is as much a hen in October as she ever will be. She is, nevertheless, after having enjoyed the honours of maternity, competent to exhibit her mature charms as a "chicken" of 187— during the whole year. It would not be remarkable if a Cochin or Brahma pullet laid at six months, but Spanish are not so early. What was she crossed with? Chickens of the year change their feathers, but do not moult.

Malvern Poultry Show (*L. H. R.*).—You have no other course to pursue than to sue in the County Court. No committee should hold a poultry show unless they are prepared, under any circumstances, to pay the prizes they offer.

Chickens for Table (*F. C. H.*).—Have Brahma hens to consort with the Dorking cock.

American Hens at Birmingham.—"I am happy to be able to afford 'Outis' the information he seeks respecting the third-prize American hens at Birmingham. They were purchased by John Beach, Esq., of Standeford, Brewood, and are now in his possession. They weigh together 22¾ lbs. They have been mated during the last summer with the second-prize Birmingham cockerel belonging to me.—Wm. Thos. Storer, *Brewood.*"

Pigeon's Wing Disease (*J. Walton and Constant Reader*).—Draw out the flight feathers of the diseased wing, and by the time they have grown again your birds will most probably be quite well.

German Hermit Pigeons (*W. Watson*).—Look to each schedule of a show, that must be your guide. If there is a prize for "Any other variety" enter your birds in that, or "Any new variety;" but the former is most likely to be, and that will be, the place for your birds.

Canary Show-Cage (*R. J. H.*).—The most useful cage for all ordinary purposes, except showing off "position" birds, is the ordinary wooden show-cage. Different exhibitors affect different styles of cages, and anyone conversant with the matter can name, almost at a glance, the "school" to which any particular class of cage belongs. A whole chapter might be written about show cages, and perhaps at the proper time and in the proper place the chapter will appear. They are for the most part all constructed on the same principle—top (sloping to reflect the light), bottom, back, and sides of wood, with wire front. I will just give the dimensions of one before me, an old one of Mr. Walter's, of Winchester, who knows about as well as any exhibitor in England what is a telling cage in which to show a bird. It formed one of a large grateful which usually precedes him by goods train when he means business at any show; and the very look of its old familiar face brings him before me with his wit, his humour, his pathos, and his umbrella, as I last saw him caging-off and making ready to do battle for one of our cups. It was from this cage that a clear Jonque which had just received the finishing stroke to its toilet escaped, and got in behind the dirty kettle. But the chapter of stories will appear with the chapter on cages. On this occasion the dimensions of the cage must suffice. Material, common deal, five-sixteenths of an inch thick, and No. 16 wire. Height of front, 14 inches; height of back, 10½ inches; length, 13½ inches; width, 6½ inches. The top slopes from front to back. The top cross-piece in the front into which the wires are inserted is three-quarters of an inch deep, and the bottom piece 2 inches. The wires are half an inch from centre to centre, with a water-hole at either end. Seed is thrown into the cage bottom, which is raised to within half an inch of the edge of the front cross-piece, causing the cage not to look so deep, and giving more light. This second bottom is not a necessity, but Walter's cages have it; it is a fixed false bottom. The bottom front piece must be 2 inches deep to make the cage look well; but I suppose Mr. Walter thinks 2 inches interior depth will swallow up too much light. The back or the front can be made to screw on and off to allow of colouring the inside with a mixture of whitiog and size (milk or thin paste will do instead of size), with just enough of ultramarine blue and rose pink to give it a warm tint. Make the mixture about the consistency of cream, and lay it on smoothly. The wires can be tied by either one or two cross wires; if by one, let it be opposite the middle of the back, and on it the perch or perches must rest, giving a fair view of the bird. A door at the side, with a secure fastening, large enough to admit the hand, and a wire handle at the top, I think, complete the cage. Paint the wires black and the front of the cage either black or green. The rest may remain unpainted, for it is never seen.—W. A. Blakston.

Bees near London (*H. L.*).—We have no doubt that bees may be kept at Hampstead, and with proper care in supplying them with artificial food during and after poor seasons, they may occasionally yield a tolerable supply of honey. We cannot say that we think they would prove very remunerative, but sufficiently so to become a source of very great pleasure. The noted Wildman kept bees at the top of his house in Holborn, and many persons now have apiaries in the outskirts of the great city. There is no hive invented that will certainly prevent swarming, but a good frame hive approaches nearest to the desideratum so much required by some apiarians. By the use of these you can make what swarms you may require artificially, and be at the same time relieved from all anxiety respecting the issue of natural swarms.

Ants in Hives (*H. W. C.*).—To stop ants from getting into bee hives, scatter guano from time to time round the pedestals. Another remedy which has been found effectual is ammoniacal liquid from the gasworks sprinkled underneath, and applied with a brush to the hive stances. It has been recommended also to use petroleum of the strongest scent in the same manner. Try these one after the other till you succeed. Bear in mind, however, that ants are very quick-witted, and if there be but a leaf or twig from any tree or bush touching the hives, they will make a long circuit and think nothing of a distant pilgrimage to get at their favourite food.

Gold Fish (*Goddess*).—Let the water be clean from a pond, changed once a-week; a layer of small pebbles and sand at the bottom of the vase; feed with raw meat shredded fine.

REMARKS.

15th.—Very fine in early morning; sharp hail shower at 11.30 A.M.; afterwards fair, fine night.

16th.—Lovely morning and fine day, rather damp at night.

17th.—Hail and snow in the night and sharp frost; beautifully fine day; moon and stars very bright at night.

18th.—A very fine day; frosty morning and night, and not visibly thawing in the day.

19th.—Very cold and rather foggy all day, but especially so at night.

20th.—Strong white frost in morning; fine day, and warmer towards the evening.

21st.—Fine, bright, and frosty all day. Lunar halo from 6.30 P.M. to 8 P.M.

Another week of unusually cold weather for November, Sunday the 19th being one of the coldest days in November for many years past.—G. J. Symons.

COVENT GARDEN MARKET.—November 22.

We are without improvement from last week, and have nothing material to report as conveying any fresh information. Some heavy cargoes of foreign produce have changed hands at the auctions during the last few days.

POULTRY MARKET.—November 22.

We have still an average trade, and a good supply. Grouse remain very plentiful, and Pheasants are more so.

	s.	d.		s.	d.

From observations taken near London during forty-three years, the average day temperature of the week is 48.0°, and its night temperature 35.3°. The greatest heat was 62°, on the 1st, 1857; and the lowest cold 14°, on the 5th and 6th, 1844. The greatest fall of rain was 1.02 inch.

SMALL FARMS—HOW THEY CAN BE MADE TO ANSWER.—No. 2.

By Rev. William Lea, *Vicar of St. Peter's, Droitwich, and Hon. Canon of Worcester.*

GOOSEBERRIES.—As the Gooseberry produces a profitable return earlier than any other fruit, we will give it the place of honour, and begin with it. The Gooseberry is now extensively grown for market in the midland counties. A great portion of the crop is gathered green, and is sent off in "pots" by rail to the large towns of the north—Manchester, Glasgow, and Sunderland, as well as to the "Black Country." When I speak of green Gooseberries I do not mean those small buttons tasting of the wood, which may be seen early in the season in Covent Garden, but large, full-grown fruit gathered from the beginning to the end of June for the delectation of the *dura ilia* of colliers and miners; and they, too, have tastes of their own, which the fruit-farmer will do well to consider. It is of no use his sending Gooseberries to market when Cherries have once been seen. Cherries, too, have their season, and then give place to Plums; but from the time Gooseberries come in till Cherries appear there is a steady demand for them: after that time they are only in demand when ripe, which means when they are partially coloured. Hence it is a common practice to gather the greater portion of the crop when green, and leave only a small part of it to ripen. Some do not even do this, but gather the whole of the crop when green, as the blackbirds commence a raid upon it directly the fruit begins to colour, and also because the ripe fruit is apt to arrive at the end of a long journey in the condition of jam.

In making a plantation of Gooseberries the bushes should be planted 6 feet apart, and in rows 6 feet from each other. This will take 1225 bushes to an acre. The best soil for them is a light loam. There should not be too much moisture, otherwise the trees are soon covered with moss, and cease to flourish. Here I may mention the best cure for moss is to sprinkle the branches with soot. If, therefore, the subsoil should be of clay, the ground should be deeply and thoroughly drained before the bushes are planted. The safest plan for a beginner will be to commence with a variety of sorts, and when he has discovered which of them is most congenial to his soil, to propagate largely from it. This is easily done, as the Gooseberry grows readily from cuttings if taken when the leaf has fallen and the wood is sufficiently hardened. I see the usual way, as recommended in garden books, is to take out all the eyes but two or three of the top ones. This will produce a bush with a long single stem, which may do very well for a dressed garden where appearances are to be consulted, but not for a fruit farm; for if your single stem is broken by the weight of fruit or any accident, or decays in the course of nature, your bush is gone. Instead of this, put in your cuttings, whether of Gooseberries or Currants, without taking out any eyes; by this means you will get in a much shorter space of time a large wide-spreading bush, which will not be liable to any of the accidents above-named. The way to set about it is this—Dig a long trench, and slope the side to about an angle of 45°; put in your cuttings 6 inches apart, cover them with light well-pulverised soil, and then press it down upon them as hard as possible, and in the next summer you find few gaps in your line. In pruning, all that is required is to cut off the branches which touch the ground, to let light and air into the middle of the bush, and to shorten some of the too-rampant shoots. The object should be to produce the largest possible bush and the greatest quantity of fruit.

And now comes the question, What sorts are best for this purpose? and the only answer to be given is, that it depends to a certain extent upon the soil. The three qualifications for excellence in a farm Gooseberry are—1st, That it possess sufficient toughness of skin to enable it to carry well; 2nd, That it shall be a free cropper; and 3rd, That it shall be dark-coloured, as dark Gooseberries sell better than green or yellow ones when they are ripe. The Gooseberry which is named Crown Bob unites all these requisites, and I believe suits most soils. When I began I ordered a large number of this variety, but the nurseryman, not having sufficient stock, sent me 100 Whitesmith, which I find suit my purpose and soil even better than the Crown Bob. Whitesmith is earlier, which is important if the fruit is to be picked green, and never fails to produce a crop, and to grow into strong bushes in two or three years from the cutting. From my own experience I should put the Whitesmith first. The Red Warrington is also a good market sort; so, too, are the Green Overall and Lord Rancliffe, the last two when ripe are excellent for the table. But for this purpose nothing is really equal to the two well-known old small varieties, the Pitmaston Green Gage and the Rough Red. The best out of some thirty new varieties which I have grown are Hopley's Companion (red), Leader (yellow), and Pet (green).

And now for a few words on the Gooseberry-grower's enemies. Blackbirds and missel thrushes, of course, are destructive to this as to all other varieties of ripe fruit, but by picking your crop when green you avoid all annoyance from them. Not so with your insect foes. The red spider will sometimes infest the bushes in such quantities as to shrivel-up all the leaves before the fruit is gathered, and seemingly to prevent the possibility of any healthy shoots; but the most destructive of all enemies is an abominable green grub, about half an inch in length, with black lines round its body. It comes in such numbers as to strip a whole plantation of its leaves, and, as I now write, my acre of Gooseberries is most indecent to look upon; line after line of trees with naked shoots, and not an atom of green to cover them. My bushes have often been infested with these hateful grubs, but never to such an extent as in the present season of 1871, which seems to be pre-eminent for blight of every kind. They appeared first of all about the first week in May, and here and there a bush was stripped by them, but they did not make much way, and on examining the bushes I found the head and

skin of the grubs upon the shoots, but not a living one to be seen. Again, in a fortnight, they appeared a second time, and disappeared again in the same manner. It was evident that some bird preyed upon them, sucked their juices, and left the hull upon the bush. I watched carefully to see to what bird I was indebted for ridding me of this pest, and after some observation I came to the conclusion that the much-maligned cuckoo was my friend. When the grubs were about there were always two or three cuckoos in the plantation. I think, too, that the chaffinch and the whitethroat also assisted, and perhaps some other soft-billed birds. The sparrows, too, sometimes visited the bushes early in the season, but as soon as there was anything like Peas or grain to be had they turned to plunder. They probably did not fancy this disgusting grub, and only used it for feeding their young. The cuckoo, the chaffinch, and whitethroat, however, seem to eat it with an appetite.

I had long been aware that this grub was the offspring of a sawfly, but I never could see the fly itself till this year, when I caught it *flagrante delicto*. It was a bright hot day early in August, and as I walked up the farm I saw a cloud of clear-winged flies disporting themselves about the bushes. They dropped from time to time, and then rose again; and suspecting that they were the parents of the grub, and after no good, I went up and watched their proceedings. The females, about the size of common house flies, with flat yellow bodies, were on the lower branches of the bushes; the males, considerably smaller, with thin, black, ichneumon-shaped bodies and transparent wings, were hovering in hundreds above. A fortnight later there was no doubt about their business. On examining the bushes I found numberless leaves perforated with little pinholes, which had been nibbled by the grubs just hatched, and on others there were the eggs not yet hatched, laid in close order along the ribs on the under side of the leaves, and principally on the lower branches of the bushes. In this arrangement one could not help admiring the instinct of the fly; directly its young are hatched they begin to eat their way upwards till they reach the end of the shoot. In this case there was evidently no time to be lost. A number of children were straightway set to work to pick off the perforated leaves. They did pick them, and six large bucketsful were collected and burnt. I thought I had got the better of my enemies, but on going into the plantation about a week later I found every tree covered with grubs in almost incredible numbers. It was no longer a question of picking perforated leaves — on some bushes scarcely any leaves were left, nor was it a matter for children; it was a case in which women must be employed. So I set some women to work, some with quicklime, others with fresh-powdered hellebore, to dredge the trees; both these remedies are recommended, and I wished to see which was the more effectual. In another week's time I was able to see the result. The lime was utterly useless, but the hellebore had saved a certain portion of the leaves. At any rate I have ascertained thus much about this detestable grub of the sawfly, which I now put down for the benefit of Gooseberry-growers —if you wish to escape this pest, encourage small birds, and especially soft-billed birds, in your plantation—above all, do what you can to protect the cuckoo. If, notwithstanding the exertions of the birds, these grubs infest your bushes, as soon as you detect their presence by the perforated leaves, have them carefully hand-picked, and if this does not stop their ravages dredge them well with fresh hellebore powder, which I believe to be the only thing that has the slightest effect upon them.
